Working Draft, Standard for Programming Language C++

Note: this is an early draft. It’s known to be incomple and incorrekt, and it has lots of bad formatting.

1 Scope

This document specifies requirements for implementations of the C++ programming language. The first such requirement is that they implement the language, so this document also defines C++. Other requirements and relaxations of the first requirement appear at various places within this document.

C++ is a general purpose programming language based on the C programming language as described in ISO/IEC 9899:2011 Programming languages — C (hereinafter referred to as the C standard). C++ provides many facilities beyond those provided by C, including additional data types, classes, templates, exceptions, namespaces, operator overloading, function name overloading, references, free store management operators, and additional library facilities.
2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

1.3 ISO/IEC 2382 (all parts), *Information technology — Vocabulary*
1.4 ISO 8601:2004, *Data elements and interchange formats — Information interchange — Representation of dates and times*
1.5 ISO/IEC 9899:2011, *Programming languages — C*
1.6 ISO/IEC 9945:2003, *Information Technology — Portable Operating System Interface (POSIX)*
1.7 ISO/IEC 10646, *Information technology — Universal Coded Character Set (UCS)*
1.10 ISO 80000-2:2009, *Quantities and units — Part 2: Mathematical signs and symbols to be used in the natural sciences and technology*

The library described in Clause 7 of ISO/IEC 9899:2011 is hereinafter called the *C standard library*.¹

The operating system interface described in ISO/IEC 9945:2003 is hereinafter called *POSIX*. ²

The ECMAScript Language Specification described in Standard Ecma-262 is hereinafter called *ECMA-262*. ³

[Note: References to ISO/IEC 10646-1:1993 are used only to support deprecated features (D.14). — end note]

¹ With the qualifications noted in Clause 17 through Clause 32 and in C.6, the C standard library is a subset of the C++ standard library.
3 Terms and definitions

For the purposes of this document, the terms and definitions given in ISO/IEC 2382-1:1993, the terms, definitions, and symbols given in ISO 80000-2:2009, and the following apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

— ISO Online browsing platform: available at https://www.iso.org/obp

16.3 defines additional terms that are used only in Clause 16 through Clause 32 and Annex D.

Terms that are used only in a small portion of this document are defined where they are used and italicized where they are defined.

3.1 access
(execution-time action) read or modify the value of an object

3.2 argument
(function call expression) expression in the comma-separated list bounded by the parentheses (7.6.1.2)

3.3 argument
(function-like macro) sequence of preprocessing tokens in the comma-separated list bounded by the parentheses (15.5)

3.4 argument
(throw expression) operand of throw (7.6.18)

3.5 argument
(template instantiation) constant-expression, type-id, or id-expression in the comma-separated list bounded by the angle brackets (13.3)

3.6 block
wait for some condition (other than for the implementation to execute the execution steps of the thread of execution) to be satisfied before continuing execution past the blocking operation

3.7 conditionally-supported
program construct that an implementation is not required to support
[Note 1 to entry: Each implementation documents all conditionally-supported constructs that it does not support. — end note]

3.8 diagnostic message
message belonging to an implementation-defined subset of the implementation’s output messages

3.9 dynamic type
(glvalue) type of the most derived object (6.6.2) to which the glvalue refers
[Example: If a pointer (9.2.3.1) p whose static type is “pointer to class B” is pointing to an object of class D, derived from B (11.6), the dynamic type of the expression *p is “D”. References (9.2.3.2) are treated similarly. — end example]
3.10 [defns.dynamic.type.prvalue]
**dynamic type**
(prvalue) static type of the prvalue expression

3.11 [defns.ill.formed]
**ill-formed program**
program that is not well-formed (3.29)

3.12 [defns.impl.defined]
**implementation-defined behavior**
behavior, for a well-formed program construct and correct data, that depends on the implementation and that each implementation documents

3.13 [defns.impl.limits]
**implementation limits**
restrictions imposed upon programs by the implementation

3.14 [defns.locale.specific]
**locale-specific behavior**
behavior that depends on local conventions of nationality, culture, and language that each implementation documents

3.15 [defns.multibyte]
**multibyte character**
sequence of one or more bytes representing a member of the extended character set of either the source or the execution environment

[Note 1 to entry: The extended character set is a superset of the basic character set (5.3). — end note]

3.16 [defns.parameter]
**parameter**
(function or catch clause) object or reference declared as part of a function declaration or definition or in the catch clause of an exception handler that acquires a value on entry to the function or handler

3.17 [defns.parameter.macro]
**parameter**
(function-like macro) identifier from the comma-separated list bounded by the parentheses immediately following the macro name

3.18 [defns.parameter.templ]
**parameter**
(template) member of a template-parameter-list

3.19 [defns.signature]
**signature**
(function) name, parameter type list (9.2.3.5), enclosing namespace (if any), and trailing requires-clause (9.2) (if any)

[Note 1 to entry: Signatures are used as a basis for name mangling and linking. — end note]

3.20 [defns.signature.templ]
**signature**
(function template) name, parameter type list (9.2.3.5), enclosing namespace (if any), return type, template-head, and trailing requires-clause (9.2) (if any)

3.21 [defns.signature.spec]
**signature**
(function template specialization) signature of the template of which it is a specialization and its template arguments (whether explicitly specified or deduced)
3.22 [defns.signature.member]
signature
(class member function) name, parameter type list (9.2.3.5), class of which the function is a member, 
cv-qualifiers (if any), ref-qualifier (if any), and trailing requires-clause (9.2) (if any)

3.23 [defns.signature.member.templ]
signature
(class member function template) name, parameter type list (9.2.3.5), class of which the function is a member, 
cv-qualifiers (if any), ref-qualifier (if any), return type (if any), template-head, and trailing requires-clause (9.2) 
(if any)

3.24 [defns.signature.member.spec]
signature
(class member function template specialization) signature of the member function template of which it is a 
specialization and its template arguments (whether explicitly specified or deduced)

3.25 [defns.static.type]
static type
type of an expression (6.7) resulting from analysis of the program without considering execution semantics
[Note 1 to entry: The static type of an expression depends only on the form of the program in which the 
expression appears, and does not change while the program is executing. — end note]

3.26 [defns.unblock]
unblock
satisfy a condition that one or more blocked threads of execution are waiting for

3.27 [defns.undefined]
undefined behavior
behavior for which this document imposes no requirements
[Note 1 to entry: Undefined behavior may be expected when this document omits any explicit definition of 
behavior or when a program uses an erroneous construct or erroneous data. Permissible undefined behavior 
ranges from ignoring the situation completely with unpredictable results, to behaving during translation or 
program execution in a documented manner characteristic of the environment (with or without the issuance 
of a diagnostic message), to terminating a translation or execution (with the issuance of a diagnostic message). 
Many erroneous program constructs do not engender undefined behavior; they are required to be diagnosed. 
evaluation of a constant expression never exhibits behavior explicitly specified as undefined in Clause 4 
through Clause 15 of this document (7.7). — end note]

3.28 [defns.unspecified]
unspecified behavior
behavior, for a well-formed program construct and correct data, that depends on the implementation
[Note 1 to entry: The implementation is not required to document which behavior occurs. The range of 
possible behaviors is usually delineated by this document. — end note]

3.29 [defns.wellformed]
well-formed program
C++ program constructed according to the syntax rules, diagnosable semantic rules, and the one-definition 
rule (6.2)
4 General principles

4.1 Implementation compliance

1. The set of diagnosable rules consists of all syntactic and semantic rules in this document except for those rules containing an explicit notation that “no diagnostic is required” or which are described as resulting in “undefined behavior”.

2. Although this document states only requirements on C++ implementations, those requirements are often easier to understand if they are phrased as requirements on programs, parts of programs, or execution of programs. Such requirements have the following meaning:

   (2.1) If a program contains no violations of the rules in this document, a conforming implementation shall, within its resource limits, accept and correctly execute that program.

   (2.2) If a program contains a violation of any diagnosable rule or an occurrence of a construct described in this document as “conditionally-supported” when the implementation does not support that construct, a conforming implementation shall issue at least one diagnostic message.

   (2.3) If a program contains a violation of a rule for which no diagnostic is required, this document places no requirement on implementations with respect to that program.

[Note: During template argument deduction and substitution, certain constructs that in other contexts require a diagnostic are treated differently; see 13.9.2. — end note]

3. For classes and class templates, the library Clauses specify partial definitions. Private members (11.8) are not specified, but each implementation shall supply them to complete the definitions according to the description in the library Clauses.

4. For functions, function templates, objects, and values, the library Clauses specify declarations. Implementations shall supply definitions consistent with the descriptions in the library Clauses.

5. The names defined in the library have namespace scope (9.7). A C++ translation unit (5.2) obtains access to these names by including the appropriate standard library header (15.2).

6. The templates, classes, functions, and objects in the library have external linkage (6.5). The implementation provides definitions for standard library entities, as necessary, while combining translation units to form a complete C++ program (5.2).

7. Two kinds of implementations are defined: a hosted implementation and a freestanding implementation. For a hosted implementation, this document defines the set of available libraries. A freestanding implementation is one in which execution may take place without the benefit of an operating system, and has an implementation-defined set of libraries that includes certain language-support libraries (16.5.1.3).

8. A conforming implementation may have extensions (including additional library functions), provided they do not alter the behavior of any well-formed program. Implementations are required to diagnose programs that use such extensions that are ill-formed according to this document. Having done so, however, they can compile and execute such programs.

9. Each implementation shall include documentation that identifies all conditionally-supported constructs that it does not support and defines all locale-specific characteristics.

4.1.1 Abstract machine

1. The semantic descriptions in this document define a parameterized nondeterministic abstract machine. This document places no requirement on the structure of conforming implementations. In particular, they need not copy or emulate the structure of the abstract machine. Rather, conforming implementations are required to emulate (only) the observable behavior of the abstract machine as explained below.

2) “Correct execution” can include undefined behavior, depending on the data being processed; see Clause 3 and 6.8.1.

3) This documentation also defines implementation-defined behavior; see 6.8.1.

4) This provision is sometimes called the “as-if” rule, because an implementation is free to disregard any requirement of this document as long as the result is as if the requirement had been obeyed, as far as can be determined from the observable behavior of the program. For instance, an actual implementation need not evaluate part of an expression if it can deduce that its value is not used and that no side effects affecting the observable behavior of the program are produced.
Certain aspects and operations of the abstract machine are described in this document as implementation-defined (for example, `sizeof(int)`). These constitute the parameters of the abstract machine. Each implementation shall include documentation describing its characteristics and behavior in these respects. Certain other aspects and operations of the abstract machine are described in this document as unspecified (for example, order of evaluation of arguments in a function call (7.6.1.2)). Where possible, this document defines a set of allowable behaviors. These define the nondeterministic aspects of the abstract machine. An instance of the abstract machine can thus have more than one possible execution for a given program and a given input.

Certain other operations are described in this document as undefined (for example, the effect of attempting to modify a const object). [Note: This document imposes no requirements on the behavior of programs that contain undefined behavior. — end note]

A conforming implementation executing a well-formed program shall produce the same observable behavior as one of the possible executions of the corresponding instance of the abstract machine with the same program and the same input. However, if any such execution contains an undefined operation, this document places no requirement on the implementation executing that program with that input (not even with regard to operations preceding the first undefined operation).

The least requirements on a conforming implementation are:

(6.1) — Accesses through volatile glvalues are evaluated strictly according to the rules of the abstract machine.
(6.2) — At program termination, all data written into files shall be identical to one of the possible results that execution of the program according to the abstract semantics would have produced.
(6.3) — The input and output dynamics of interactive devices shall take place in such a fashion that prompting output is actually delivered before a program waits for input. What constitutes an interactive device is implementation-defined.

These collectively are referred to as the observable behavior of the program. [Note: More stringent correspondences between abstract and actual semantics may be defined by each implementation. — end note]

### 4.2 Structure of this document

Clause 5 through Clause 15 describe the C++ programming language. That description includes detailed syntactic specifications in a form described in 4.3. For convenience, Annex A repeats all such syntactic specifications.

Clause 17 through Clause 32 and Annex D (the library clauses) describe the C++ standard library. That description includes detailed descriptions of the entities and macros that constitute the library, in a form described in Clause 16.

Annex B recommends lower bounds on the capacity of conforming implementations.

Annex C summarizes the evolution of C++ since its first published description, and explains in detail the differences between C++ and C. Certain features of C++ exist solely for compatibility purposes; Annex D describes those features.

Throughout this document, each example is introduced by “[Example: ” and terminated by “ — end example]”. Each note is introduced by “[Note: ” and terminated by “ — end note]”. Examples and notes may be nested.

### 4.3 Syntax notation

In the syntax notation used in this document, syntactic categories are indicated by italic type, and literal words and characters in constant width type. Alternatives are listed on separate lines except in a few cases where a long set of alternatives is marked by the phrase “one of”. If the text of an alternative is too long to fit on a line, the text is continued on subsequent lines indented from the first one. An optional terminal or non-terminal symbol is indicated by the subscript “\_opt”, so

```
{ expression\_opt }
```

indicates an optional expression enclosed in braces.

---

5) This documentation also includes conditionally-supported constructs and locale-specific behavior. See 4.1.
Names for syntactic categories have generally been chosen according to the following rules:

(2.1) — X-name is a use of an identifier in a context that determines its meaning (e.g., class-name, typedef-name).

(2.2) — X-id is an identifier with no context-dependent meaning (e.g., qualified-id).

(2.3) — X-seq is one or more X’s without intervening delimiters (e.g., declaration-seq is a sequence of declarations).

(2.4) — X-list is one or more X’s separated by intervening commas (e.g., identifier-list is a sequence of identifiers separated by commas).

4.4 Acknowledgments

5 Lexical conventions

5.1 Separate translation

The text of the program is kept in units called source files in this document. A source file together with all the headers (16.5.1.2) and source files included (15.2) via the preprocessing directive #include, less any source lines skipped by any of the conditional inclusion (15.1) preprocessing directives, is called a translation unit. [Note: A C++ program need not all be translated at the same time. —end note]

2 [Note: Previously translated translation units and instantiation units can be preserved individually or in libraries. The separate translation units of a program communicate (6.5) by (for example) calls to functions whose identifiers have external or module linkage, manipulation of objects whose identifiers have external or module linkage, or manipulation of data files. Translation units can be separately translated and then later linked to produce an executable program (6.5). —end note]

5.2 Phases of translation

The precedence among the syntax rules of translation is specified by the following phases.

1. Physical source file characters are mapped, in an implementation-defined manner, to the basic source character set (introducing new-line characters for end-of-line indicators) if necessary. The set of physical source file characters accepted is implementation-defined. Any source file character not in the basic source character set (5.3) is replaced by the universal-character-name that designates that character. An implementation may use any internal encoding, so long as an actual extended character encountered in the source file, and the same extended character expressed in the source file as a universal-character-name (e.g., using the \uXXXX notation), are handled equivalently except where this replacement is reverted (5.4) in a raw string literal.

2. Each instance of a backslash character (\) immediately followed by a new-line character is deleted, splicing physical source lines to form logical source lines. Only the last backslash on any physical source line shall be eligible for being part of such a splice. Except for splices reverted in a raw string literal, if a splice results in a character sequence that matches the syntax of a universal-character-name, the behavior is undefined. A source file that is not empty and that does not end in a new-line character, or that ends in a new-line character immediately preceded by a backslash character before any such splicing takes place, shall be processed as if an additional new-line character were appended to the file.

3. The source file is decomposed into preprocessing tokens (5.4) and sequences of white-space characters (including comments). A source file shall not end in a partial preprocessing token or in a partial comment. Each comment is replaced by one space character. New-line characters are retained. Whether each nonempty sequence of white-space characters other than new-line is retained or replaced by one space character is unspecified. The process of dividing a source file’s characters into preprocessing tokens is context-dependent. [Example: See the handling of < within a #include preprocessing directive. —end example]

4. Preprocessing directives are executed, macro invocations are expanded, and _Pragma unary operator expressions are executed. If a character sequence that matches the syntax of a universal-character-name is produced by token concatenation (15.5.3), the behavior is undefined. A #include preprocessing directive causes the named header or source file to be processed from phase 1 through phase 4, recursively. All preprocessing directives are then deleted.

5. Each basic source character set member in a character literal or a string literal, as well as each escape sequence and universal-character-name in a character literal or a non-raw string literal, is converted to the corresponding member of the execution character set (5.13.3, 5.13.5); if there is no corresponding member, it is converted to an implementation-defined member other than the null (wide) character.  

---

6) Implementations must behave as if these separate phases occur, although in practice different phases might be folded together.

7) A partial preprocessing token would arise from a source file ending in the first portion of a multi-character token that requires a terminating sequence of characters, such as a header-name that is missing the closing " or >. A partial comment would arise from a source file ending with an unclosed /* comment.

8) An implementation need not convert all non-corresponding source characters to the same execution character.
6. Adjacent string literal tokens are concatenated.

7. White-space characters separating tokens are no longer significant. Each preprocessing token is converted into a token (5.6). The resulting tokens are syntactically and semantically analyzed and translated as a translation unit. [Note: The process of analyzing and translating the tokens may occasionally result in one token being replaced by a sequence of other tokens (13.2). — end note] It is implementation-defined whether the sources for module units and header units on which the current translation unit has an interface dependency (10.1, 10.3) are required to be available. [Note: Source files, translation units and translated translation units need not necessarily be stored as files, nor need there be any one-to-one correspondence between these entities and any external representation. The description is conceptual only, and does not specify any particular implementation. — end note]

8. Translated translation units and instantiation units are combined as follows: [Note: Some or all of these may be supplied from a library. — end note] Each translated translation unit is examined to produce a list of required instantiations. [Note: This may include instantiations which have been explicitly requested (13.8.2). — end note] The definitions of the required templates are located. It is implementation-defined whether the source of the translation units containing these definitions is required to be available. [Note: An implementation could encode sufficient information into the translated translation unit so as to ensure the source is not required here. — end note] All the required instantiations are performed to produce instantiation units. [Note: These are similar to translated translation units, but contain no references to uninstantiated templates and no template definitions. — end note] The program is ill-formed if any instantiation fails.

9. All external entity references are resolved. Library components are linked to satisfy external references to entities not defined in the current translation. All such translator output is collected into a program image which contains information needed for execution in its execution environment.

5.3 Character sets

The basic source character set consists of 96 characters: the space character, the control characters representing horizontal tab, vertical tab, form feed, and new-line, plus the following 91 graphical characters:9

```
 a b c d e f g h i j k l m n o p q r s t u v w x y z
 A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
 0 1 2 3 4 5 6 7 8 9
 _ { } [ ] # ( ) < > % : ; . ? * + - / ^ & |
```

The universal-character-name construct provides a way to name other characters.

```
hex-quad:
    hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit
universal-character-name:
    \u hex-quad
    \U hex-quad hex-quad
```

The character designated by the universal-character-name \U00NNNNNNN is that character that has U+NNNNNNN as a code point short identifier; the character designated by the universal-character-name \uNNNNN is that character that has U+NNNNN as a code point short identifier. If a universal-character-name does not correspond to a code point in ISO/IEC 10646 or if a universal-character-name corresponds to a surrogate code point, the program is ill-formed. Additionally, if a universal-character-name outside the c-char-sequence, s-char-sequence, or r-char-sequence of a character or string literal corresponds to a control character or to a character in the basic source character set, the program is ill-formed.10 [Note: ISO/IEC 10646 code points are within the range 0x0-0x10FFFF (inclusive). A surrogate code point is a value in the range 0xD800-0xDFFF (inclusive). A control character is a character whose code point is in either of the ranges 0x0-0x1F or 0x7F-0x9F (both inclusive). — end note]

The basic execution character set and the basic execution wide-character set shall each contain all the members of the basic source character set, plus control characters representing alert, backspace, and carriage return, plus a null character (respectively, null wide character), whose value is 0. For each basic execution character set, the glyphs for the members of the basic source character set are intended to identify characters from the subset of ISO/IEC 10646 which corresponds to the ASCII character set. However, because the mapping from source file characters to the source character set (described in translation phase 1) is specified as implementation-defined, an implementation is required to document how the basic source characters are represented in source files.

10] A sequence of characters resembling a universal-character-name in an r-char-sequence (5.13.5) does not form a universal-character-name.
character set, the values of the members shall be non-negative and distinct from one another. In both the source and execution basic character sets, the value of each character after 0 in the above list of decimal digits shall be one greater than the value of the previous. The execution character set and the execution wide-character set are implementation-defined supersets of the basic execution character set and the basic execution wide-character set, respectively. The values of the members of the execution character sets and the sets of additional members are locale-specific.

5.4 Preprocessing tokens

preprocessing-token:
header-name
identifier
pp-number
character-literal
user-defined-character-literal
string-literal
user-defined-string-literal
preprocessing-op-or-punc
each non-white-space character that cannot be one of the above

1 Each preprocessing token that is converted to a token (5.6) shall have the lexical form of a keyword, an identifier, a literal, an operator, or a punctuator.

2 A preprocessing token is the minimal lexical element of the language in translation phases 3 through 6. The categories of preprocessing token are: header names, identifiers, preprocessing numbers, character literals (including user-defined character literals), string literals (including user-defined string literals), preprocessing operators and punctuators, and single non-white-space characters that do not lexically match the other preprocessing token categories. If a ‘’ or a ‘” character matches the last category, the behavior is undefined. Preprocessing tokens can be separated by white space; this consists of comments (5.7), or white-space characters (space, horizontal tab, new-line, vertical tab, and form-feed), or both. As described in Clause 15, in certain circumstances during translation phase 4, white space (or the absence thereof) serves as more than preprocessing token separation. White space can appear within a preprocessing token only as part of a header name or between the quotation characters in a character literal or string literal.

3 If the input stream has been parsed into preprocessing tokens up to a given character:

   (3.1) — If the next character begins a sequence of characters that could be the prefix and initial double quote of a raw string literal, such as R", the next preprocessing token shall be a raw string literal. Between the initial and final double quote characters of the raw string, any transformations performed in phases 1 and 2 (universal-character-names and line splicing) are reverted; this reversion shall apply before any d-char, r-char, or delimiting parenthesis is identified. The raw string literal is defined as the shortest sequence of characters that matches the raw-string pattern

encoding-prefix_opt R raw-string

   (3.2) — Otherwise, if the next three characters are <:: and the subsequent character is neither : nor >, the < is treated as a preprocessing token by itself and not as the first character of the alternative token <:.

   (3.3) — Otherwise, the next preprocessing token is the longest sequence of characters that could constitute a preprocessing token, even if that would cause further lexical analysis to fail, except that a header-name (5.8) is only formed

(3.3.1) — within a #include directive (15.2),
(3.3.2) — within a has-include-expression, or
(3.3.3) — outside of any preprocessing directive, if applying phase 4 of translation to the sequence of preprocessing tokens produced thus far is valid and results in an import-seq (15.4).

[Example:]
#define R "x"
const char* s = R"y";  // ill-formed raw string, not "x" "y"
— end example

4 [Example: The program fragment 0xe+foo is parsed as a preprocessing number token (one that is not a valid floating or integer literal token), even though a parse as three preprocessing tokens 0xe, +, and foo might produce a valid expression (for example, if foo were a macro defined as 1). Similarly, the program fragment]
1E1 is parsed as a preprocessing number (one that is a valid floating literal token), whether or not E is a macro name. —end example

Example: The program fragment x+++++y is parsed as x ++ ++ + y, which, if x and y have integral types, violates a constraint on increment operators, even though the parse x ++ ++ y might yield a correct expression. —end example

5.5 Alternative tokens
Alternative token representations are provided for some operators and punctuators.\(^{11}\)

In all respects of the language, each alternative token behaves the same, respectively, as its primary token, except for its spelling.\(^{12}\) The set of alternative tokens is defined in Table 1.

Table 1: Alternative tokens

<table>
<thead>
<tr>
<th>Alternative</th>

<td>compl</td>
<td>-</td>
<td>not_eq</td>
<td>!=</td>
</tr>
<tr>
<td>%:%: ##</td>
<td>#</td>
<td>bitand</td>
<td>&amp;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5.6 Tokens

Token:
- identifier
- keyword
- literal
- operator
- punctuator

There are five kinds of tokens: identifiers, keywords, literals,\(^{13}\) operators, and other separators. Blanks, horizontal and vertical tabs, newlines, formfeeds, and comments (collectively, “white space”), as described below, are ignored except as they serve to separate tokens. [Note: Some white space is required to separate otherwise adjacent identifiers, keywords, numeric literals, and alternative tokens containing alphabetic characters. —end note]

5.7 Comments

The characters // start a comment, which terminates with the characters */. These comments do not nest. The characters /* start a comment, which terminates immediately before the next new-line character. If there is a form-feed or a vertical-tab character in such a comment, only white-space characters shall appear between it and the new-line that terminates the comment; no diagnostic is required. [Note: The comment characters //, /*, and */ have no special meaning within a // comment and are treated just like other comments. Similarly, the comment characters // and /* have no special meaning within a /* comment. —end note]

5.8 Header names

Header-name:
- `< h-char-sequence >`
- `* q-char-sequence *`

h-char-sequence:
- h-char
- h-char-sequence h-char

\(^{11}\) These include “digraphs” and additional reserved words. The term “digraph” (token consisting of two characters) is not perfectly descriptive, since one of the alternative preprocessing-tokens is %:%: and of course several primary tokens contain two characters. Nonetheless, those alternative tokens that aren’t lexical keywords are colloquially known as “digraphs”.

\(^{12}\) Thus the “stringized” values (15.5.2) of [ and <: will be different, maintaining the source spelling, but the tokens can otherwise be freely interchanged.

\(^{13}\) Literals include strings and character and numeric literals.
h-char:
    any member of the source character set except new-line and >

q-char-sequence:
    q-char
    q-char-sequence q-char

q-char:
    any member of the source character set except new-line and "

[1] [Note: Header name preprocessing tokens only appear within a #include preprocessing directive, a __has__include preprocessing expression, or after certain occurrences of an import token (see 5.4). — end note]
The sequences in both forms of header-names are mapped in an implementation-defined manner to headers or to external source file names as specified in 15.2.

2 The appearance of either of the characters ' or \ or of either of the character sequences /* or // in a q-char-sequence or an h-char-sequence is conditionally-supported with implementation-defined semantics, as is the appearance of the character " in an h-char-sequence. 14

5.9 Preprocessing numbers  [lex.ppnumber]

pp-number:
    digit
    . digit
    pp-number digit
    pp-number identifier-nondigit
    pp-number ' digit
    pp-number ' nondigit
    pp-number e sign
    pp-number E sign
    pp-number p sign
    pp-number P sign
    pp-number .

1 Preprocessing number tokens lexically include all integer literal tokens (5.13.2) and all floating literal tokens (5.13.4).

2 A preprocessing number does not have a type or a value; it acquires both after a successful conversion to an integer literal token or a floating literal token.

5.10 Identifiers  [lex.name]

identifier:
    identifier-nondigit
    identifier identifier-nondigit
    identifier digit

identifier-nondigit:
    nondigit
    universal-character-name

nondigit: one of
    a b c d e f g h i j k l m
    n o p q r s t u v w x y z
    A B C D E F G H I J K L M
    N O P Q R S T U V W X Y Z

digit: one of
    0 1 2 3 4 5 6 7 8 9

1 An identifier is an arbitrarily long sequence of letters and digits. Each universal-character-name in an identifier shall designate a character whose encoding in ISO/IEC 10646 falls into one of the ranges specified in Table 2. The initial element shall not be a universal-character-name designating a character whose encoding falls into one of the ranges specified in Table 3. Upper- and lower-case letters are different. All characters are significant. 15

14) Thus, a sequence of characters that resembles an escape sequence might result in an error, be interpreted as the character corresponding to the escape sequence, or have a completely different meaning, depending on the implementation.

15) On systems in which linkers cannot accept extended characters, an encoding of the universal-character-name may be used in forming valid external identifiers. For example, some otherwise unused character or sequence of characters may be used to encode the \u in a universal-character-name. Extended characters may produce a long external identifier, but C++ does not
The identifiers in Table 4 have a special meaning when appearing in a certain context. When referred to in the grammar, these identifiers are used explicitly rather than using the identifier grammar production. Unless otherwise specified, any ambiguity as to whether a given identifier has a special meaning is resolved to interpret the token as a regular identifier.

Table 4: Identifiers with special meaning

<table>
<thead>
<tr>
<th>audit</th>
<th>final</th>
<th>module</th>
</tr>
</thead>
<tbody>
<tr>
<td>axiom</td>
<td>import</td>
<td>override</td>
</tr>
</tbody>
</table>

In addition, some identifiers are reserved for use by C++ implementations and shall not be used otherwise; no diagnostic is required.

- Each identifier that contains a double underscore __ or begins with an underscore followed by an uppercase letter is reserved to the implementation for any use.
- Each identifier that begins with an underscore is reserved to the implementation for use as a name in the global namespace.

5.11 Keywords

The identifiers shown in Table 5 are reserved for use as keywords (that is, they are unconditionally treated as keywords in phase 7) except in an attribute-token (9.11.1):

<table>
<thead>
<tr>
<th>new</th>
<th>delete</th>
<th>?</th>
<th>::</th>
<th>. *</th>
<th>-&gt;</th>
<th>~</th>
</tr>
</thead>
</table>

Furthermore, the alternative representations shown in Table 6 for certain operators and punctuators (5.5) are reserved and shall not be used otherwise:

5.12 Operators and punctuators

The lexical representation of C++ programs includes a number of preprocessing tokens which are used in the syntax of the preprocessor or are converted into tokens for operators and punctuators:

- place a translation limit on significant characters for external identifiers. In C++, upper- and lower-case letters are considered different for all identifiers, including external identifiers.
Table 5: Keywords [tab:lex.key]

Each preprocessing-op-or-punc is converted to a single token in translation phase 7 (5.2).

5.13 Literals [lex.literal]

5.13.1 Kinds of literals [lex.literal.kinds]

There are several kinds of literals."\(^{16}\)

 literal:
- integer-literal
- character-literal
- floating-literal
- string-literal
- boolean-literal
- pointer-literal
- user-defined-literal

5.13.2 Integer literals [lex.icon]

 integer-literal:
- binary-literal integer-suffix\(_{opt}\)
- octal-literal integer-suffix\(_{opt}\)
- decimal-literal integer-suffix\(_{opt}\)
- hexadecimal-literal integer-suffix\(_{opt}\)

 binary-literal:
- 0b binary-digit
- 0B binary-digit
- binary-literal \(^{opt}\) binary-digit

 octal-literal:
- 0
- octal-literal \(^{opt}\) octal-digit

 decimal-literal:
- nonzero-digit
- decimal-literal \(^{opt}\) digit

\(^{16}\) The term “literal” generally designates, in this document, those tokens that are called “constants” in ISO C.
hexadecimal-literal:
  hexadecimal-prefix hexadecimal-digit-sequence

binary-digit: one of
  0 1

octal-digit: one of
  0 1 2 3 4 5 6 7

nonzero-digit: one of
  1 2 3 4 5 6 7 8 9

hexadecimal-prefix: one of
  0x 0X

hexadecimal-digit-sequence:
  hexadecimal-digit
  hexadecimal-digit-sequence ',opt hexadecimal-digit

hexadecimal-digit: one of
  0 1 2 3 4 5 6 7 8 9
  a b c d e f
  A B C D E F

integer-suffix:
  unsigned-suffix long-suffix',opt
  unsigned-suffix long-long-suffix',opt
  long-suffix unsigned-suffix',opt
  long-long-suffix unsigned-suffix',opt

unsigned-suffix: one of
  u U

long-suffix: one of
  l L

long-long-suffix: one of
  ll LL

1 An integer literal is a sequence of digits that has no period or exponent part, with optional separating single quotes that are ignored when determining its value. An integer literal may have a prefix that specifies its base and a suffix that specifies its type. The lexically first digit of the sequence of digits is the most significant. A binary integer literal (base two) begins with 0b or 0B and consists of a sequence of binary digits. An octal integer literal (base eight) begins with the digit 0 and consists of a sequence of octal digits. An decimal integer literal (base ten) begins with a digit other than 0 and consists of a sequence of decimal digits. A hexadecimal integer literal (base sixteen) begins with 0x or 0X and consists of a sequence of hexadecimal digits, which include the decimal digits and the letters a through f and A through F with decimal values ten through fifteen. [Example: The number twelve can be written 12, 014, 0XC, or 0b1100. The integer literals 1048576, 1'048'576, 0X100000, 0x10'0000, and 0'004'000'000 all have the same value. — end example]

2 The type of an integer literal is the first of the corresponding list in Table 7 in which its value can be represented.

<table>
<thead>
<tr>
<th>Suffix</th>

<td>unsigned long long int</td>
<td>unsigned long long int</td>
</tr>
</tbody>
</table>

3 If an integer literal cannot be represented by any type in its list and an extended integer type (6.7.1) can represent its value, it may have that extended integer type. If all of the types in the list for the integer literal are signed, the extended integer type shall be signed. If all of the types in the list for the integer literal are unsigned, the extended integer type shall be unsigned. If the list contains both signed and unsigned types, the extended integer type may be signed or unsigned. A program is ill-formed if one of its translation units contains an integer literal that cannot be represented by any of the allowed types.

5.13.3 Character literals [lex.ccon]

A character literal is one or more characters enclosed in single quotes, as in ‘x’, optionally preceded by u8, u, U, or L, as in u8’w’, u’x’, U’y’, or L’z’, respectively.

A character literal that does not begin with u8, u, U, or L is an ordinary character literal. An ordinary character literal that contains a single c-char representable in the execution character set has type char, with value equal to the numerical value of the encoding of the c-char in the execution character set. An ordinary character literal that contains more than one c-char is a multicharacter literal. A multicharacter literal, or an ordinary character literal containing a single c-char not representable in the execution character set, is conditionally-supported, has type int, and has an implementation-defined value.

A character literal that begins with u8, such as u8’w’, is a character literal of type char8_t, known as a UTF-8 character literal. The value of a UTF-8 character literal is equal to its ISO/IEC 10646 code point value, provided that the code point value can be encoded as a single UTF-8 code unit. [Note: That is, provided the code point value is in the range 0x0-0x7F (inclusive). — end note] If the value is not representable with a
single UTF-8 code unit, the program is ill-formed. A UTF-8 character literal containing multiple c-chars is ill-formed.

4 A character literal that begins with the letter u, such as u’x’, is a character literal of type char16_t, known as a UTF-16 character literal. The value of a UTF-16 character literal is equal to its ISO/IEC 10646 code point value, provided that the code point value is representable with a single 16-bit code unit. [Note: That is, provided the code point value is in the range 0x0-0xFFFF (inclusive). — end note] If the value is not representable with a single 16-bit code unit, the program is ill-formed. A UTF-16 character literal containing multiple c-chars is ill-formed.

5 A character literal that begins with the letter U, such as U’y’, is a character literal of type char32_t, known as a UTF-32 character literal. The value of a UTF-32 character literal containing a single c-char is equal to its ISO/IEC 10646 code point value. A UTF-32 character literal containing multiple c-chars is ill-formed.

6 A character literal that begins with the letter L, such as L’z’, is a wide-character literal. A wide-character literal has type wchar_t. The value of a wide-character literal containing a single c-char has value equal to the numerical value of the encoding of the c-char in the execution wide-character set, unless the c-char has no representation in the execution wide-character set, in which case the value is implementation-defined. [Note: The type wchar_t is able to represent all members of the execution wide-character set (see 6.7.1). — end note] The value of a wide-character literal containing multiple c-chars is implementation-defined.

7 Certain non-graphic characters, the single quote ’, the double quote “, the question mark ?, and the backslash \, can be represented according to Table 8. The double quote “ and the question mark ? can be represented as themselves or by the escape sequences \ and \? respectively, but the single quote ’ and the backslash \ shall be represented by the escape sequences \’ and \ respectively. Escape sequences in which the character following the backslash is not listed in Table 8 are conditionally-supported, with implementation-defined semantics. An escape sequence specifies a single character.

Table 8: Escape sequences [tab:lex.ccon.esc]

<table>
<thead>
<tr>
<th>escape sequence</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>new-line NL(LF)</td>
<td>\n</td>
</tr>
<tr>
<td>horizontal tab</td>
<td>HT \t</td>
</tr>
<tr>
<td>vertical tab</td>
<td>VT \v</td>
</tr>
<tr>
<td>backspace BS</td>
<td>\b</td>
</tr>
<tr>
<td>carriage return CR</td>
<td>\r</td>
</tr>
<tr>
<td>form feed FF</td>
<td>\f</td>
</tr>
<tr>
<td>alert BEL</td>
<td>\a</td>
</tr>
<tr>
<td>backlash \</td>
<td>\</td>
</tr>
<tr>
<td>question mark</td>
<td>?</td>
</tr>
<tr>
<td>single quote</td>
<td>\’</td>
</tr>
<tr>
<td>double quote</td>
<td>&quot;</td>
</tr>
<tr>
<td>octal number ooo</td>
<td>\ooo</td>
</tr>
<tr>
<td>hex number hhh</td>
<td>\xhhhh</td>
</tr>
</tbody>
</table>

8 The escape \ooo consists of the backslash followed by one, two, or three octal digits that are taken to specify the value of the desired character. The escape \xhhh consists of the backslash followed by x followed by one or more hexadecimal digits that are taken to specify the value of the desired character. There is no limit to the number of digits in a hexadecimal sequence. A sequence of octal or hexadecimal digits is terminated by the first character that is not an octal digit or a hexadecimal digit, respectively. The value of a character literal is implementation-defined if it falls outside of the implementation-defined range defined for char (for character literals with no prefix) or wchar_t (for character literals prefixed by L). [Note: If the value of a character literal prefixed by u, u8, or U is outside the range defined for its type, the program is ill-formed. — end note]

9 A universal-character-name is translated to the encoding, in the appropriate execution character set, of the character named. If there is no such encoding, the universal-character-name is translated to an implementation-defined encoding. [Note: In translation phase 1, a universal-character-name is introduced whenever an actual extended character is encountered in the source text. Therefore, all extended characters are described in

---

18) They are intended for character sets where a character does not fit into a single byte.
19) Using an escape sequence for a question mark is supported for compatibility with ISO C++ 2014 and ISO C.
terms of universal-character-names. However, the actual compiler implementation may use its own native character set, so long as the same results are obtained. — end note]

5.13.4 Floating literals

floating-literal:
  decimal-floating-literal
  hexadecimal-floating-literal

decimal-floating-literal:
  fractional-constant exponent-part_opt floating-suffix_opt
digit-sequence exponent-part floating-suffix_opt

hexadecimal-floating-literal:
  hexadecimal-prefix hexadecimal-fractional-constant binary-exponent-part floating-suffix_opt
  hexadecimal-prefix hexadecimal-digit-sequence binary-exponent-part floating-suffix_opt

fractional-constant:
  digit-sequence_opt . digit-sequence
digit-sequence .

hexadecimal-fractional-constant:
  hexadecimal-digit-sequence_opt . hexadecimal-digit-sequence
  hexadecimal-digit-sequence .

exponent-part:
  e sign_opt digit-sequence
  E sign_opt digit-sequence

binary-exponent-part:
  p sign_opt digit-sequence
  P sign_opt digit-sequence

sign: one of
  + -

digit-sequence:
  digit
digit-sequence opt digit

floating-suffix: one of
  f l F L

1 A floating literal consists of an optional prefix specifying a base, an integer part, a radix point, a fraction part, an e, E, p or P, an optionally signed integer exponent, and an optional type suffix. The integer and fraction parts both consist of a sequence of decimal (base ten) digits if there is no prefix, or hexadecimal (base sixteen) digits if the prefix is 0x or 0X. The floating literal is a decimal floating literal in the former case and a hexadecimal floating literal in the latter case. Optional separating single quotes in a digit-sequence or hexadecimal-digit-sequence are ignored when determining its value. [Example: The floating literals 1.602'176'565e-19 and 1.602176565e-19 have the same value. — end example] Either the integer part or the fraction part (not both) can be omitted. Either the radix point or the letter e or E and the exponent (not both) can be omitted from a decimal floating literal. The radix point (but not the exponent) can be omitted from a hexadecimal floating literal. The integer part, the optional radix point, and the optional fraction part, form the significand of the floating literal. In a decimal floating literal, the exponent, if present, indicates the power of 10 by which the significand is to be scaled. In a hexadecimal floating literal, the exponent indicates the power of 2 by which the significand is to be scaled. [Example: The floating literals 49.625 and 0xC.68p+2 have the same value. — end example] If the scaled value is in the range of representable values for its type, the result is the scaled value if representable, else the larger or smaller representable value nearest the scaled value, chosen in an implementation-defined manner. The type of a floating literal is double unless explicitly specified by a suffix. The suffixes f and F specify float, the suffixes l and L specify long double. If the scaled value is not in the range of representable values for its type, the program is ill-formed.

5.13.5 String literals

string-literal:
  encoding-prefix_opt " s-char-sequence_opt "
  encoding-prefix_opt R raw-string

§ 5.13.5 19
s-char-sequence:
  s-char
  s-char-sequence s-char

s-char:
  any member of the basic source character set except the double-quote
  escape-sequence
  universal-character-name

raw-string:
  " d-char-sequence_opt ( r-char-sequence_opt ) d-char-sequence_opt "

r-char-sequence:
  r-char
  r-char-sequence r-char

r-char:
  any member of the source character set, except a right parenthesis

  d-char-sequence ( which may be empty ) followed by
  the initial d-char-sequence ( which may be empty ) followed by a double quote ".

d-char-sequence:
  d-char
  d-char-sequence d-char

d-char:
  any member of the basic source character set except:
    space, the left parenthesis, the right parenthesis, the backslash
    escape-sequence
    universal-character-name

1 A string-literal is a sequence of characters (as defined in 5.13.3) surrounded by double quotes, optionally
  prefixed by R, u8, u8R, u, uR, U, UR, L, or LR, as in "...", R"(...)", u8"...", u8R"**(...)**", u"...", uR"*- (...)*- "", U"...", UR"zzz(...)zzz", L"...", or LR"(...)", respectively.

2 A string-literal that has an R in the prefix is a raw string literal. The d-char-sequence serves as a delimiter. The
  terminating d-char-sequence of a raw-string is the same sequence of characters as the initial d-char-sequence.
  A d-char-sequence shall consist of at most 16 characters.

3 [Note: The characters '(' and ')') are permitted in a raw-string. Thus, R"delimiter((a|b))delimiter" is
  equivalent to "(a|b)". —end note]

4 [Note: A source-file new-line in a raw string literal results in a new-line in the resulting execution string
  literal. Assuming no whitespace at the beginning of lines in the following example, the assert will succeed:

    const char* p = R"(a
    b
c)";
    assert(std::strcmp(p, "a\nb\nc") == 0);
  —end note]

5 [Example: The raw string

    R"a(
      )
    a"

  is equivalent to "\n)a\n". The raw string

    R"(x = "\"y\""

  is equivalent to "x = \"y\"\n\". —end example]

6 After translation phase 6, a string-literal that does not begin with an encoding-prefix is an ordinary string
  literal. An ordinary string literal has type "array of n const char" where n is the size of the string as defined
  below, has static storage duration (6.6.5), and is initialized with the given characters.

7 A string-literal that begins with u8, such as u8"asdf", is a UTF-8 string literal. A UTF-8 string literal has
  type “array of n const char8_t”, where n is the size of the string as defined below; each successive element
  of the object representation (6.7) has the value of the corresponding code unit of the UTF-8 encoding of the
  string.

8 Ordinary string literals and UTF-8 string literals are also referred to as narrow string literals.
A string-literal that begins with u, such as u"asdf", is a UTF-16 string literal. A UTF-16 string literal has type “array of n const char16_t”, where n is the size of the string as defined below; each successive element of the array has the value of the corresponding code unit of the UTF-16 encoding of the string. [Note: A single c-char may produce more than one char16_t character in the form of surrogate pairs. A surrogate pair is a representation for a single code point as a sequence of two 16-bit code units. — end note]

A string-literal that begins with U, such as U"asdf", is a UTF-32 string literal. A UTF-32 string literal has type “array of n const char32_t”, where n is the size of the string as defined below; each successive element of the array has the value of the corresponding code unit of the UTF-32 encoding of the string.

A string-literal that begins with L, such as L"asdf", is a wide string literal. A wide string literal has type “array of n const wchar_t", where n is the size of the string as defined below; it is initialized with the given characters.

In translation phase 6 (5.2), adjacent string-literals are concatenated. If both string-literals have the same encoding-prefix, the resulting concatenated string literal has that encoding-prefix. If one string-literal has no encoding-prefix, it is treated as a string-literal of the same encoding-prefix as the other operand. If a UTF-8 string literal token is adjacent to a wide string literal token, the program is ill-formed. Any other concatenations are conditionally-supported with implementation-defined behavior. [Note: This concatenation is an interpretation, not a conversion. Because the interpretation happens in translation phase 6 (after each character from a string literal has been translated into a value from the appropriate character set), a string-literal’s initial rawness has no effect on the interpretation or well-formedness of the concatenation. — end note] Table 9 has some examples of valid concatenations.

Table 9: String literal concatenations  
[tab:lex.string.concat]

<table>
<thead>
<tr>
<th>Source</th>
<th>Means</th>
</tr>
</thead>
<tbody>
<tr>
<td>u&quot;a&quot;</td>
<td>&quot;a&quot;</td>
</tr>
<tr>
<td>u&quot;b&quot;</td>
<td>&quot;b&quot;</td>
</tr>
<tr>
<td>u&quot;ab&quot;</td>
<td>&quot;ab&quot;</td>
</tr>
</tbody>
</table>

Characters in concatenated strings are kept distinct.

[Example:

"\xA" "B"

contains the two characters ‘\xA’ and ‘B’ after concatenation (and not the single hexadecimal character ‘\xAB’). — end example]

After any necessary concatenation, in translation phase 7 (5.2), ‘\0’ is appended to every string literal so that programs that scan a string can find its end.

Escape sequences and universal-character-names in non-raw string literals have the same meaning as in character literals (5.13.3), except that the single quote ‘ is representable either by itself or by the escape sequence \', and the double quote " shall be preceded by a \, and except that a universal-character-name in a UTF-16 string literal may yield a surrogate pair. In a narrow string literal, a universal-character-name may map to more than one char or char8_t element due to multibyte encoding. The size of a char32_t or wide string literal is the total number of escape sequences, universal-character-names, and other characters, plus one for the terminating U'\0' or L'\0'. The size of a UTF-16 string literal is the total number of escape sequences, universal-character-names, and other characters, plus one for each character requiring a surrogate pair, plus one for the terminating u'\0'. [Note: The size of a char16_t string literal is the number of code units, not the number of characters. — end note] Within char32_t and char16_t string literals, any universal-character-names shall be within the range 0x0 to 0x10FFFF. The size of a narrow string literal is the total number of escape sequences and other characters, plus at least one for the multibyte encoding of each universal-character-name, plus one for the terminating ‘\0’. Evaluating a string-literal results in a string literal object with static storage duration, initialized from the given characters as specified above. Whether all string literals are distinct (that is, are stored in nonoverlapping objects) and whether successive evaluations of a string-literal yield the same or a different object is unspecified. [Note: The effect of attempting to modify a string literal is undefined. — end note]
5.13.6 Boolean literals

boolean-literal:
  false
  true

1 The Boolean literals are the keywords false and true. Such literals are prvalues and have type bool.

5.13.7 Pointer literals

pointer-literal:
  nullptr

1 The pointer literal is the keyword nullptr. It is a prvalue of type std::nullptr_t. [Note: std::nullptr_t is a distinct type that is neither a pointer type nor a pointer-to-member type; rather, a prvalue of this type is a null pointer constant and can be converted to a null pointer value or null member pointer value. See 7.3.11 and 7.3.12. — end note]

5.13.8 User-defined literals

user-defined-literal:
  user-defined-integer-literal
  user-defined-floating-literal
  user-defined-string-literal
  user-defined-character-literal

user-defined-integer-literal:
  decimal-literal ud-suffix
  octal-literal ud-suffix
  hexadecimal-literal ud-suffix
  binary-literal ud-suffix

user-defined-floating-literal:
  fractional-constant exponent-part ud-suffix
  digit-sequence exponent-part ud-suffix
  hexadecimal-prefix hexadecimal-fractional-constant binary-exponent-part ud-suffix
  hexadecimal-prefix hexadecimal-digit-sequence binary-exponent-part ud-suffix

user-defined-string-literal:
  string-literal ud-suffix

user-defined-character-literal:
  character-literal ud-suffix

ud-suffix:
  identifier

1 If a token matches both user-defined-literal and another literal kind, it is treated as the latter. [Example: 123_km is a user-defined-literal, but 12LL is an integer-literal. — end example] The syntactic non-terminal preceding the ud-suffix in a user-defined-literal is taken to be the longest sequence of characters that could match that non-terminal.

2 A user-defined-literal is treated as a call to a literal operator or literal operator template (12.5.8). To determine the form of this call for a given user-defined-literal L with ud-suffix X, the literal-operator-id whose literal suffix identifier is X is looked up in the context of L using the rules for unqualified name lookup (6.4.1). Let S be the set of declarations found by this lookup. S shall not be empty.

3 If L is a user-defined-integer-literal, let n be the literal without its ud-suffix. If S contains a literal operator with parameter type unsigned long long, the literal L is treated as a call of the form

operator "" X(nULL)

Otherwise, S shall contain a raw literal operator or a numeric literal operator template (12.5.8) but not both. If S contains a raw literal operator, the literal L is treated as a call of the form

operator "" X("n")

Otherwise (S contains a numeric literal operator template), L is treated as a call of the form

operator "" X<"c1", 'c2', ..., 'ck'>()

where n is the source character sequence c1c2...ck. [Note: The sequence c1c2...ck can only contain characters from the basic source character set. — end note]
4 If \( L \) is a user-defined-floating-literal, let \( f \) be the literal without its ud-suffix. If \( S \) contains a literal operator with parameter type \texttt{long double}, the literal \( L \) is treated as a call of the form

\[
\texttt{operator "" X(fL)}
\]

Otherwise, \( S \) shall contain a raw literal operator or a numeric literal operator template (12.5.8) but not both. If \( S \) contains a raw literal operator, the literal \( L \) is treated as a call of the form

\[
\texttt{operator "" X("f")}
\]

Otherwise (\( S \) contains a numeric literal operator template), \( L \) is treated as a call of the form

\[
\texttt{operator "" X<'}c_1', 'c_2', \ldots 'c_k'>()}
\]

where \( f \) is the source character sequence \( c_1c_2\ldots c_k \). [Note: The sequence \( c_1c_2\ldots c_k \) can only contain characters from the basic source character set. — end note]

5 If \( L \) is a user-defined-string-literal, let \( str \) be the literal without its ud-suffix and let \( len \) be the number of code units in \( str \) (i.e., its length excluding the terminating null character). If \( S \) contains a literal operator template with a non-type template parameter for which \( str \) is a well-formed \texttt{template-argument}, the literal \( L \) is treated as a call of the form

\[
\texttt{operator "" X<str>()}
\]

Otherwise, the literal \( L \) is treated as a call of the form

\[
\texttt{operator "" X(str, len)}
\]

6 If \( L \) is a user-defined-character-literal, let \( ch \) be the literal without its ud-suffix. \( S \) shall contain a literal operator (12.5.8) whose only parameter has the type of \( ch \) and the literal \( L \) is treated as a call of the form

\[
\texttt{operator "" X(ch)}
\]

[Example:

\[
\begin{align*}
&\text{long double operator "" _w(long double);} \\
&\text{std::string operator "" _w(const char16_t*, std::size_t);} \\
&\text{unsigned operator "" _w(const char*);} \\
&\text{int main() \{} \\
&\quad 1.2_w; \quad // \text{calls operator "" _w(1.2L)} \\
&\quad u"one"_w; \quad // \text{calls operator "" _w(u"one", 3)} \\
&\quad 12_w; \quad // \text{calls operator "" _w("12")} \\
&\quad "two"_w; \quad // \text{error: no applicable literal operator}
&\text{\}}
\end{align*}
\]

—end example]

8 In translation phase 6 (5.2), adjacent string literals are concatenated and user-defined-string-literals are considered string literals for that purpose. During concatenation, ud-suffixes are removed and ignored and the concatenation process occurs as described in 5.13.5. At the end of phase 6, if a string literal is the result of a concatenation involving at least one user-defined-string-literal, all the participating user-defined-string-literals shall have the same ud-suffix and that suffix is applied to the result of the concatenation.

9 [Example:

\[
\begin{align*}
&\text{int main() \{} \\
&\quad L"A" "B" "C"_x; \quad // \text{OK: same as L"ABC"_x} \\
&\quad "P"_x "Q" "R"_y; \quad // \text{error: two different ud-suffixes}
&\text{\}}
\end{align*}
\]

—end example]
6 Basics

1 [Note: This Clause presents the basic concepts of the C++ language. It explains the difference between an object and a name and how they relate to the value categories for expressions. It introduces the concepts of a declaration and a definition and presents C++’s notion of type, scope, linkage, and storage duration. The mechanisms for starting and terminating a program are discussed. Finally, this Clause presents the fundamental types of the language and lists the ways of constructing compound types from these. — end note]

2 [Note: This Clause does not cover concepts that affect only a single part of the language. Such concepts are discussed in the relevant Clauses. — end note]

3 An entity is a value, object, reference, structured binding, function, enumerator, type, class member, bit-field, template, template specialization, namespace, or pack.

4 A name is a use of an identifier (5.10), operator-function-id (12.5), literal-operator-id (12.5.8), conversion-function-id (11.3.7.2), or template-id (13.2) that denotes an entity or label (8.6.5, 8.1).

5 Every name that denotes an entity is introduced by a declaration. Every name that denotes a label is introduced either by a goto statement (8.6.5) or a labeled-statement (8.1).

6 A variable is introduced by the declaration of a reference other than a non-static data member or of an object. The variable’s name, if any, denotes the reference or object.

7 A local entity is a variable with automatic storage duration (6.6.5.3), a structured binding (9.5) whose corresponding variable is such an entity, or the *this object (7.5.2).

8 Some names denote types or templates. In general, whenever a name is encountered it is necessary to determine whether that name denotes one of these entities before continuing to parse the program that contains it. The process that determines this is called name lookup (6.4).

9 Two names are the same if

- they are identifiers composed of the same character sequence, or
- they are operator-function-ids formed with the same operator, or
- they are conversion-function-ids formed with the same type, or
- they are template-ids that refer to the same class, function, or variable (13.5), or
- they are the names of literal operators (12.5.8) formed with the same literal suffix identifier.

10 A name used in more than one translation unit can potentially refer to the same entity in these translation units depending on the linkage (6.5) of the name specified in each translation unit.

6.1 Declarations and definitions

1 A declaration (Clause 9) may introduce one or more names into a translation unit or redeclare names introduced by previous declarations. If so, the declaration specifies the interpretation and semantic properties of these names. A declaration may also have effects including:

- a static assertion (Clause 9),
- controlling template instantiation (13.8.2),
- guiding template argument deduction for constructors (13.10),
- use of attributes (Clause 9), and
- nothing (in the case of an empty-declaration).

2 Each entity declared by a declaration is also defined by that declaration unless:

- it declares a function without specifying the function’s body (9.4),
- it contains the extern specifier (9.1.1) or a linkage-specification (9.10) and neither an initializer nor a function-body,

(20) Appearing inside the brace-enclosed declaration-seq in a linkage-specification does not affect whether a declaration is a definition.
© ISO/IEC

— it declares a non-inline static data member in a class definition (11.3, 11.3.8),
— it declares a static data member outside a class definition and the variable was defined within the class with the constexpr specifier (this usage is deprecated; see D.4),
— it is introduced by an elaborated-type-specifier (11.2),
— it is an opaque-enum-declaration (9.6),
— it is a template-parameter (13.1),
— it is a parameter-declaration (9.2.3.5) in a function declarator that is not the declarator of a function-definition,
— it is a typedef declaration (9.1.3),
— it is an alias-declaration (9.1.3),
— it is a using-declaration (9.8),
— it is a deduction-guide (13.10),
— it is a static_assert-declaration (Clause 9),
— it is an attribute-declaration (Clause 9),
— it is an empty-declaration (Clause 9),
— it is an using-directive (9.7.3),
— it is an explicit instantiation declaration (13.8.2), or
— it is an explicit specialization (13.8.3) whose declaration is not a definition.

A declaration is said to be a definition of each entity that it defines. [Example: All but one of the following are definitions:

```c++
int a; // defines a
extern const int c = 1; // defines c
int f(int x) { return x+a; } // defines f and defines x
struct S { int a; int b; }; // defines S, S::a, and S::b
struct X {
  int x; // defines X
  static int y; // declares static data member y
  X(): x(0) { } // defines a constructor of X
};
int X::y = 1; // defines X::y
eenum { up, down }; // defines up and down
namespace N { int d; } // defines N and N::d
namespace N1 = N; // defines N1
X anX; // defines anX
```}

whereas these are just declarations:

```c++
extern int a; // declares a
extern const int c; // declares c
int f(int); // declares f
struct S; // declares S
typedef int Int; // declares Int
extern X anotherX; // declares anotherX
using N::d; // declares d
```

— end example]  

3 [Note: In some circumstances, C++ implementations implicitly define the default constructor (11.3.4.1), copy constructor, move constructor (11.3.4.2), copy assignment operator, move assignment operator (11.3.5), or destructor (11.3.6) member functions. — end note] [Example: Given

```c++
#include <string>

struct C {
  std::string s; // std::string is the standard library class (Clause 21)
};
```
int main() {
    C a;
    C b = a;
    b = a;
}

the implementation will implicitly define functions to make the definition of C equivalent to

struct C {
    std::string s;
    C() : s() {} 
    C(const C& x) : s(x.s) {} 
    C(C&& x) : s(static_cast<std::string&&>(x.s)) {} 
    // : s(std::move(x.s)) {} 
    C& operator=(const C& x) { s = x.s; return *this; } 
    C& operator=(C&& x) { s = static_cast<std::string&&>(x.s); return *this; } 
    //{ s = std::move(x.s); return *this; }
    ~C() {} 
};

—end example

4 [Note: A class name can also be implicitly declared by an elaborated-type-specifier (9.1.7.3). — end note]

5 In the definition of an object, the type of that object shall not be an incomplete type (6.7), an abstract class type (11.6.3), or a (possibly multi-dimensional) array thereof.

6.2 One-definition rule [basic.def.odr]

1 A variable, function, class type, enumeration type, or template shall not be defined where a prior definition is necessarily reachable (10.6); no diagnostic is required if the prior declaration is in another translation unit.

2 An expression or conversion is potentially evaluated unless it is an unevaluated operand (7.2), a subexpression thereof, or a conversion in an initialization or conversion sequence in such a context. The set of potential results of an expression e is defined as follows:

   — If e is an id-expression (7.5.4), the set contains only e.
   — If e is a subscripting operation (7.6.1.1) with an array operand, the set contains the potential results of that operand.
   — If e is a class member access expression (7.6.1.4) of the form e1 . template opt e2 naming a non-static data member, the set contains the potential results of e1.
   — If e is a class member access expression naming a static data member, the set contains the id-expression designating the data member.
   — If e is a pointer-to-member expression (7.6.4) of the form e1 .* e2, the set contains the potential results of e1.
   — If e has the form (e1), the set contains the potential results of e1.
   — If e is a glvalue conditional expression (7.6.16), the set is the union of the sets of potential results of the second and third operands.
   — If e is a comma expression (7.6.20), the set contains the potential results of the right operand.
   — Otherwise, the set is empty.

[Note: This set is a (possibly-empty) set of id-expressions, each of which is either e or a subexpression of e. 
Example: In the following example, the set of potential results of the initializer of n contains the first S::x subexpression, but not the second S::x subexpression.

struct S { static const int x = 0; }; 
const int &f(const int &r);
int n = b ? (1, S::x) : f(S::x); // S::x is not odr-used here
   // S::x is odr-used here, so a definition is required

— end example] — end note]

3 A function is named by an expression or conversion as follows:

   — A function is named by an expression or conversion if it is the unique result of a name lookup or the selected member of a set of overloaded functions (6.4, 12.3, 12.4) in an overload resolution performed
as part of forming that expression or conversion, unless it is a pure virtual function and either the expression is not an \textit{id-expression} naming the function with an explicitly qualified name or the expression forms a pointer to member (7.6.2.1).  [Note: This covers taking the address of functions (7.3.3, 7.6.2.1), calls to named functions (7.6.1.2), operator overloading (Clause 12), user-defined conversions (11.3.7.2), allocation functions for \textit{new-expressions} (7.6.2.7), as well as non-default initialization (9.3). A constructor selected to copy or move an object of class type is considered to be named by an expression or conversion even if the call is actually elided by the implementation (11.9.5).  — end note]

(3.2) A deallocation function for a class is named by a \textit{new-expression} if it is the single matching deallocation function for the allocation function selected by overload resolution, as specified in 7.6.2.7.

(3.3) A deallocation function for a class is named by a \textit{delete-expression} if it is the selected usual deallocation function as specified in 7.6.2.8 and 11.11.

A variable \texttt{x} whose name appears as a potentially-evaluated expression \texttt{e} is \textit{odr-used} by \texttt{e} unless

(4.1) \texttt{x} is a reference that is usable in constant expressions (7.7), or

(4.2) \texttt{x} is a variable of non-reference type that is usable in constant expressions and has no mutable subobjects, and \texttt{e} is an element of the set of potential results of an expression of non-volatile-qualified non-class type to which the lvalue-to-rvalue conversion (7.3.1) is applied, or

(4.3) \texttt{x} is a variable of non-reference type, and \texttt{e} is an element of the set of potential results of a discarded-value expression (7.2) to which the lvalue-to-rvalue conversion is not applied.

A structured binding is odr-used if it appears as a potentially-evaluated expression.

\texttt{*this} is odr-used if \texttt{this} appears as a potentially-evaluated expression (including as the result of the implicit transformation in the body of a non-static member function (11.3.2)).

A virtual member function is odr-used if it is not pure. A function is odr-used if it is named by a potentially-evaluated expression or conversion. A non-placement allocation or deallocation function for a class is odr-used by the definition of a constructor of that class. A non-placement deallocation function for a class is odr-used by the definition of the destructor of that class, or by being selected by the lookup at the point of definition of a virtual destructor (11.3.6). 21

An assignment operator function in a class is odr-used by an implicitly-defined copy-assignment or move-assignment function for another class as specified in 11.3.5. A constructor for a class is odr-used as specified in 9.3. A destructor for a class is odr-used if it is potentially invoked (11.3.6).

A local entity (Clause 6) is \textit{odr-usable} in a declarative region (6.3.1) if:

(9.1) either the local entity is not \texttt{*this}, or an enclosing class or non-lambda function parameter scope exists and, if the innermost such scope is a function parameter scope, it corresponds to a non-static member function, and

(9.2) for each intervening declarative region (6.3.1) between the point at which the entity is introduced and the region (where \texttt{*this} is considered to be introduced within the innermost enclosing class or non-lambda function definition scope), either:

(9.2.1) the intervening declarative region is a block scope, or

(9.2.2) the intervening declarative region is the function parameter scope of a \textit{lambda-expression} that has a simple-capture naming the entity or has a capture-default, and the block scope of the \textit{lambda-expression} is also an intervening declarative region.

If a local entity is odr-used in a declarative region in which it is not odr-usable, the program is ill-formed.  [Example:

\begin{verbatim}
void f(int n) {
  [] { n = 1; };  // error: n is not odr-usable due to intervening lambda-expression
  struct A {
    void f() { n = 2; }  // error: n is not odr-usable due to intervening function definition scope
  };
  void g(int = n);  // error: n is not odr-usable due to intervening function parameter scope
  [=](int k = n) {};
  // error: n is not odr-usable due to being

21) An implementation is not required to call allocation and deallocation functions from constructors or destructors; however, this is a permissible implementation technique.

§ 6.2
Every program shall contain exactly one definition of every non-inline function or variable that is odr-used in that program outside of a discarded statement (8.4.1); no diagnostic required. The definition can appear explicitly in the program, it can be found in the standard or a user-defined library, or (when appropriate) it is implicitly defined (see 11.3.4.1, 11.3.4.2, 11.3.6, and 11.3.5). A definition of an inline function or variable shall be reachable in every translation unit in which it is odr-used outside of a discarded statement. [Example:

```c
auto f() {
    struct A {};
    return A();
}
```

decltype(f()) g();
auto x = g();

A program containing this translation unit is ill-formed because g is odr-used but not defined, and cannot be defined in any other translation unit because the local class A cannot be named outside this translation unit. —end example]

A definition of a class is required to be reachable in every context in which the class is used in a way that requires the class type to be complete. [Example: The following complete translation unit is well-formed, even though it never defines X:

```c
struct X;
struct X* x1; // declare X as a struct type
X* x2; // use X in pointer formation
```

—end example] [Note: The rules for declarations and expressions describe in which contexts complete class types are required. A class type T must be complete if:

1. an object of type T is defined (6.1), or
2. a non-static class data member of type T is declared (11.3), or
3. T is used as the allocated type or array element type in a new-expression (7.6.2.7), or
4. an lvalue-to-rvalue conversion is applied to a glvalue referring to an object of type T (7.3.1), or
5. an expression is converted (either implicitly or explicitly) to type T (7.3, 7.6.1.3, 7.6.1.6, 7.6.1.8, 7.6.3), or
6. an expression that is not a null pointer constant, and has type other than cv void*, is converted to the type pointer to T or reference to T using a standard conversion (7.3), a dynamic_cast (7.6.1.6) or a static_cast (7.6.1.8), or
7. a class member access operator is applied to an expression of type T (7.6.1.4), or
8. the typeid operator (7.6.1.7) or the sizeof operator (7.6.2.4) is applied to an operand of type T, or
9. a function with a return type or argument type of type T is defined (6.1) or called (7.6.1.2), or
10. a class with a base class of type T is defined (11.6), or
11. an lvalue of type T is assigned to (7.6.19), or
12. the type T is the subject of an alignof expression (7.6.2.5), or
13. an exception-declaration has type T, reference to T, or pointer to T (14.3).

—end note]

There can be more than one definition of a class type (Clause 11), enumeration type (9.6), inline function with external linkage (9.1.6), inline variable with external linkage (9.1.6), class template (Clause 13), non-static function template (13.6.6), concept (13.6.8), static data member of a class template (13.6.1.3), member function of a class template (13.6.1.1), or template specialization for which some template parameters are not specified (13.8, 13.6.5) in a program provided that no prior definition is necessarily reachable (10.6) at the point where a definition appears, and provided the definitions satisfy the following requirements. There shall not be more than one definition of an entity that is attached to a named module (10.1); no diagnostic is required unless a prior definition is reachable at a point where a later definition appears. Given such an entity named D defined in more than one translation unit, then

```c
// outside the block scope of the lambda-expression

[&] { [n]{ return n; }; };
// OK

—end example]
— each definition of \( D \) shall consist of the same sequence of tokens; and

— in each definition of \( D \), corresponding names, looked up according to 6.4, shall refer to an entity defined within the definition of \( D \), or shall refer to the same entity, after overload resolution (12.3) and after matching of partial template specialization (13.9.3), except that a name can refer to

  — a non-volatile const object with internal or no linkage if the object

  — has the same literal type in all definitions of \( D \),

  — is initialized with a constant expression (7.7),

  — is not odr-used in any definition of \( D \), and

  — has the same value in all definitions of \( D \),

or

— a reference with internal or no linkage initialized with a constant expression such that the reference refers to the same entity in all definitions of \( D \);

and

— in each definition of \( D \), corresponding entities shall have the same language linkage; and

— in each definition of \( D \), the overloaded operators referred to, the implicit calls to conversion functions, constructors, operator new functions and operator delete functions, shall refer to the same function, or to a function defined within the definition of \( D \); and

— in each definition of \( D \), a default argument used by an (implicit or explicit) function call is treated as if its token sequence were present in the definition of \( D \); that is, the default argument is subject to the requirements described in this paragraph (and, if the default argument has subexpressions with default arguments, this requirement applies recursively)\(^\text{22}\); and

— if \( D \) invokes a function with a precondition, or is a function that contains an assertion or has a contract condition (9.11.4), it is implementation-defined under which conditions all definitions of \( D \) shall be translated using the same build level and violation continuation mode; and

— if \( D \) is a class with an implicitly-declared constructor (11.3.4.1, 11.3.4.2), it is as if the constructor was implicitly defined in every translation unit where it is odr-used, and the implicit definition in every translation unit shall call the same constructor for a subobject of \( D \). [Example:

```c
// translation unit 1:
struct X {
    X(int, int);
    X(int, int, int);
};
X::X(int, int = 0) { }
class D {
    X x = 0;
};
D d1;       //X(int, int) called by D()

// translation unit 2:
struct X {
    X(int, int);
    X(int, int, int);
};
X::X(int, int = 0, int = 0) { }
class D {
    X x = 0;
};
D d2;       //X(int, int, int) called by D();
//D()'s implicit definition violates the ODR

-end example]

If \( D \) is a template and is defined in more than one translation unit, then the preceding requirements shall apply both to names from the template’s enclosing scope used in the template definition (13.7.3), and also to dependent names at the point of instantiation (13.7.2). If the definitions of \( D \) satisfy all these requirements,

\( 22) 9.2.3.6 \) describes how default argument names are looked up.

\[ \text{§ 6.2} \]
then the behavior is as if there were a single definition of \( D \). \[ \text{Note: The entity is still declared in multiple translation units, and 6.5 still applies to these declarations. In particular, lambda-expressions (7.5.5) appearing in the type of \( D \) may result in the different declarations having distinct types. — end note} \] If the definitions of \( D \) do not satisfy these requirements, then the behavior is undefined.

6.3 Scope

6.3.1 Declarative regions and scopes

Every name is introduced in some portion of program text called a declarative region, which is the largest part of the program in which that name is valid, that is, in which that name may be used as an unqualified name to refer to the same entity. In general, each particular name is valid only within some possibly contiguous portion of program text called its scope. To determine the scope of a declaration, it is sometimes convenient to refer to the potential scope of a declaration. The scope of a declaration is the same as its potential scope unless the potential scope contains another declaration of the same name. In that case, the potential scope of the declaration in the inner (contained) declarative region is excluded from the scope of the declaration in the outer (containing) declarative region.

Example: In

```c
int j = 24;
int main() {
    int i = j, j;
    j = 42;
}
```

the identifier \( j \) is declared twice as a name (and used twice). The declarative region of the first \( j \) includes the entire example. The potential scope of the first \( j \) begins immediately after that \( j \) and extends to the end of the program, but its (actual) scope excludes the text between the \( , \) and the \( } \). The declarative region of the second declaration of \( j \) (the \( j \) immediately before the semicolon) includes all the text between \{ and \}, but its potential scope excludes the declaration of \( i \). The scope of the second declaration of \( j \) is the same as its potential scope. — end example]

The names declared by a declaration are introduced into the scope in which the declaration occurs, except that the presence of a friend specifier (11.8.3), certain uses of the elaborated-type-specifier (9.1.7.3), and using-directives (9.7.3) alter this general behavior.

Given a set of declarations in a single declarative region, each of which specifies the same unqualified name,

1. they shall all refer to the same entity, or all refer to functions and function templates; or
2. exactly one declaration shall declare a class name or enumeration name that is not a typedef name and the other declarations shall all refer to the same variable, non-static data member, or enumerator, or all refer to functions and function templates; in this case the class name or enumeration name is hidden (6.3.10). \[ \text{Note: A structured binding (9.5), namespace name (9.7), or class template name (Clause 13) must be unique in its declarative region. — end note} \]

[Note: These restrictions apply to the declarative region into which a name is introduced, which is not necessarily the same as the region in which the declaration occurs. In particular, elaborated-type-specifiers (9.1.7.3) and friend declarations (11.8.3) may introduce a (possibly not visible) name into an enclosing namespace; these restrictions apply to that region. Local extern declarations (6.5) may introduce a name into the declarative region where the declaration appears and also introduce a (possibly not visible) name into an enclosing namespace; these restrictions apply to both regions. — end note]

For a given declarative region \( R \) and a point \( P \) outside \( R \), the set of intervening declarative regions between \( P \) and \( R \) comprises all declarative regions that are or enclose \( R \) and do not enclose \( P \).

[Note: The name lookup rules are summarized in 6.4. — end note]

6.3.2 Point of declaration

The point of declaration for a name is immediately after its complete declarator (9.2) and before its initializer (if any), except as noted below. \[ \text{Example:}

```c
unsigned char x = 12;
{ unsigned char x = x; }
```

Here the second \( x \) is initialized with its own (indeterminate) value. — end example]
2 [Note: A name from an outer scope remains visible up to the point of declaration of the name that hides it. 
Example:
const int i = 2;
{ int i[1]; }
declared a block-scope array of two integers. — end example] — end note]

3 The point of declaration for a class or class template first declared by a class-specifier is immediately after the identifier or simple-template-id (if any) in its class-head (Clause 11). The point of declaration for an enumeration is immediately after the identifier (if any) in either its enum-specifier (9.6) or its first opaque-enum-declaration (9.6), whichever comes first. The point of declaration of an alias or alias template immediately follows the defining-type-id to which the alias refers.

4 The point of declaration of a using-declarator that does not name a constructor is immediately after the using-declarator (9.8).

5 The point of declaration for an enumerator is immediately after its enumerator-definition. [Example:
const int x = 12;
{ enum { x = x }; }
Here, the enumerator x is initialized with the value of the constant x, namely 12. — end example]

6 After the point of declaration of a class member, the member name can be looked up in the scope of its class. [Note: This is true even if the class is an incomplete class. For example,
struct X {
    enum E { z = 16 }; 
    int b[X::z];     // OK
};
— end note]

7 The point of declaration of a class first declared in an elaborated-type-specifier is as follows:

(7.1) — for a declaration of the form
class-key attribute-specifier-seq opt identifier ;
the identifier is declared to be a class-name in the scope that contains the declaration, otherwise
(7.2) — for an elaborated-type-specifier of the form
class-key identifier
if the elaborated-type-specifier is used in the decl-specifier-seq or parameter-declaration-clause of a function defined in namespace scope, the identifier is declared as a class-name in the namespace that contains the declaration; otherwise, except as a friend declaration, the identifier is declared in the smallest namespace or block scope that contains the declaration. [Note: These rules also apply within templates. — end note] [Note: Other forms of elaborated-type-specifier do not declare a new name, and therefore must refer to an existing type-name. See 6.4.4 and 9.1.7.3. — end note]

8 The point of declaration for an injected-class-name (Clause 11) is immediately following the opening brace of the class definition.

9 The point of declaration for a function-local predefined variable (9.4.1) is immediately before the function-body of a function definition.

10 The point of declaration of a structured binding (9.5) is immediately after the identifier-list of the structured binding declaration.

11 The point of declaration for the variable or the structured bindings declared in the for-range-declaration of a range-based for statement (8.5.4) is immediately after the for-range-initializer.

12 The point of declaration for a template parameter is immediately after its complete template-parameter. [Example:
typedef unsigned char T;
template<class T
= T     // lookup finds the typedef name of unsigned char
, T     // lookup finds the template parameter
N = 0> struct A { };
— end example]
Note: Friend declarations refer to functions or classes that are members of the nearest enclosing namespace, but they do not introduce new names into that namespace (9.7.1.2). Function declarations at block scope and variable declarations with the `extern` specifier at block scope refer to declarations that are members of an enclosing namespace, but they do not introduce new names into that scope. — end note

6.3.3 Block scope

A name declared in a block (8.3) is local to that block; it has block scope. Its potential scope begins at its point of declaration (6.3.2) and ends at the end of its block. A variable declared at block scope is a local variable.

The name declared in an exception-declaration is local to the handler and shall not be redeclared in the outermost block of the handler.

Names declared in the `init-statement`, the `for-range-declaration`, and in the condition of `if`, `while`, `for`, and `switch` statements are local to the `if`, `while`, `for`, or `switch` statement (including the controlled statement), and shall not be redeclared in a subsequent condition of that statement nor in the outermost block (or, for the `if` statement, any of the outermost blocks) of the controlled statement. [Example:

```c
if (int x = f()) {
    int x; // ill-formed, redeclaration of x
}
else {
    int x; // ill-formed, redeclaration of x
}
— end example]

6.3.4 Function parameter scope

A function parameter (including one appearing in a lambda-declarator) or function-local predefined variable (9.4) has function parameter scope. The potential scope of a parameter or function-local predefined variable begins at its point of declaration. If the nearest enclosing function declarator is not the declarator of a function definition, the potential scope ends at the end of that function declarator. Otherwise, if the function has a function-try-block the potential scope ends at the end of the last associated handler. Otherwise the potential scope ends at the end of the outermost block of the function definition. A parameter name shall not be redeclared in the outermost block of the function definition nor in the outermost block of any handler associated with a function-try-block.

6.3.5 Function scope

Labels (8.1) have function scope and may be used anywhere in the function in which they are declared. Only labels have function scope.

6.3.6 Namespace scope

The declarative region of a `namespace-definition` is its `namespace-body`. Entities declared in a `namespace-body` are said to be members of the namespace, and names introduced by these declarations into the declarative region of the namespace are said to be member names of the namespace. A namespace member name has namespace scope. Its potential scope includes its namespace from the name’s point of declaration (6.3.2) onwards; and for each `using-directive` (9.7.3) that nominates the member’s namespace, the member’s potential scope includes that portion of the potential scope of the `using-directive` that follows the member’s point of declaration. [Example:

```c
namespace N {
    int i;
    int g(int a) { return a; }
    int j();
    void q();
}
namespace { int l=1; }
// the potential scope of l is from its point of declaration to the end of the translation unit
```
namespace N {
    int g(char a) { // overloads N::g(int)
        return l+a;  // l is from unnamed namespace
    }

    int i;       // error: duplicate definition
    int j();    // OK: duplicate function declaration

    int j() {    // OK: definition of N::j()
        return g(i); // calls N::g(int)
    }

    int q();    // error: different return type
}

— end example

2 If a translation unit Q is imported into a translation unit R (10.3), the potential scope of a name X declared with namespace scope in Q is extended to include the portion of the corresponding namespace scope in R following the first module-import-declaration or module-declaration in R that imports Q (directly or indirectly) if

(2.1) — X does not have internal linkage, and
(2.2) — X is declared after the module-declaration in Q (if any), and
(2.3) — either X is exported or Q and R are part of the same module.

[Note: A module-import-declaration imports both the named translation unit(s) and any modules named by exported module-import-declarations within them, recursively. [Example:

Translation unit #1:
    export module Q;
    export int sq(int i) { return i*i; }

Translation unit #2:
    export module R;
    export import Q;

Translation unit #3:
    import R;
    int main() { return sq(9); }  // OK: sq from module Q

— end example] — end note]

3 A namespace member can also be referred to after the :: scope resolution operator (7.5.4.2) applied to the name of its namespace or the name of a namespace which nominates the member’s namespace in a using-directive; see 6.4.3.2.

4 The outermost declarative region of a translation unit is also a namespace, called the global namespace. A name declared in the global namespace has global namespace scope (also called global scope). The potential scope of such a name begins at its point of declaration (6.3.2) and ends at the end of the translation unit that is its declarative region. A name with global namespace scope is said to be a global name.

6.3.7 Class scope [basic.scope.class]

1 The potential scope of a name declared in a class consists not only of the declarative region following the name’s point of declaration, but also of all complete-class contexts (11.3) of that class.

2 A name N used in a class S shall refer to the same declaration in its context and when re-evaluated in the completed scope of S. No diagnostic is required for a violation of this rule.

3 A name declared within a member function hides a declaration of the same name whose scope extends to or past the end of the member function’s class.

4 The potential scope of a declaration that extends to or past the end of a class definition also extends to the regions defined by its member definitions, even if the members are defined lexically outside the class (this includes static data member definitions, nested class definitions, and member function definitions, including the member function body and any portion of the declarator part of such definitions which follows the declarator-id, including a parameter-declaration-clause and any default arguments (9.2.3.6)).
typedef int c;
enum { i = 1 };

class X {
    char v[i]; // error: i refers to ::i but when reevaluated is X::i
    int f() { return sizeof(c); } // OK: X::c
    char c;
    enum { i = 2 };}
};
typedef char* T;
struct Y {
    T a; // error: T refers to ::T but when reevaluated is Y::T
    typedef long T;
    T b;
};
typedef int I;
class D {
    typedef I I; // error, even though no reordering involved
};

—end example

The name of a class member shall only be used as follows:

- in the scope of its class (as described above) or a class derived (11.6) from its class,
- after the . operator applied to an expression of the type of its class (7.6.1.4) or a class derived from its class,
- after the -> operator applied to a pointer to an object of its class (7.6.1.4) or a class derived from its class,
- after the :: scope resolution operator (7.5.4.2) applied to the name of its class or a class derived from its class.

6.3.8 Enumeration scope [basic.scope.enum]

The name of a scoped enumerator (9.6) has enumeration scope. Its potential scope begins at its point of declaration and terminates at the end of the enum-specifier.

6.3.9 Template parameter scope [basic.scope.temp]

The declarative region of the name of a template parameter of a template template-parameter is the smallest template-parameter-list in which the name was introduced.

The declarative region of the name of a template parameter of a template is the smallest template-declaration in which the name was introduced. Only template parameter names belong to this declarative region; any other kind of name introduced by the declaration of a template-declaration is instead introduced into the same declarative region where it would be introduced as a result of a non-template declaration of the same name. [Example:

```c
namespace N {
    template<class T> struct A { }; // #1
    template<class U> void f(U) { } // #2
    struct B {
        template<class V> friend int g(struct C*); // #3
    }
}
```

The declarative regions of T, U and V are the template-declarations on lines #1, #2, and #3, respectively. But the names A, f, g and C all belong to the same declarative region — namely, the namespace-body of N. (g is still considered to belong to this declarative region in spite of its being hidden during qualified and unqualified name lookup.) — end example]

The potential scope of a template parameter name begins at its point of declaration (6.3.2) and ends at the end of its declarative region. [Note: This implies that a template-parameter can be used in the
declaration of subsequent *template-parameters* and their default arguments but cannot be used in preceding *template-parameters* or their default arguments. For example,

```cpp
template<class T, T* p, class U = T> class X { /* ... */ }
template<class T> void f(T* p = new T);
```

This also implies that a *template-parameter* can be used in the specification of base classes. For example,

```cpp
template<class T> class X : public Array<T> { /* ... */ }
template<class T> class Y : public T { /* ... */ }
```

The use of a template parameter as a base class implies that a class used as a template argument must be defined and not just declared when the class template is instantiated. —end note

4 The declarative region of the name of a template parameter is nested within the immediately-enclosing declarative region. [Note: As a result, a *template-parameter* hides any entity with the same name in an enclosing scope (6.3.10).] [Example:

```cpp
typedef int N;
template<N X, typename N, template<N Y> class T> struct A;
```

Here, X is a non-type template parameter of type `int` and Y is a non-type template parameter of the same type as the second template parameter of A. —end example] —end note

5 [Note: Because the name of a template parameter cannot be redeclared within its potential scope (13.7.1), a template parameter’s scope is often its potential scope. However, it is still possible for a template parameter name to be hidden; see 13.7.1. —end note]

### 6.3.10 Name hiding

A declaration of a name in a nested declarative region hides a declaration of the same name in an enclosing declarative region; see 6.3.1 and 6.4.1.

2 If a class name (11.2) or enumeration name (9.6) and a variable, data member, function, or enumerator are declared in the same declarative region (in any order) with the same name (excluding declarations made visible via using-directives (6.4.1)), the class or enumeration name is hidden wherever the variable, data member, function, or enumerator name is visible.

3 In a member function definition, the declaration of a name at block scope hides the declaration of a member of the class with the same name; see 6.3.7. The declaration of a member in a derived class (11.6) hides the declaration of a member of a base class of the same name; see 11.7.

4 During the lookup of a name qualified by a namespace name, declarations that would otherwise be made visible by a using-directive can be hidden by declarations with the same name in the namespace containing the using-directive; see 6.4.3.2.

5 If a name is in scope and is not hidden it is said to be *visible*.

### 6.4 Name lookup

The name lookup rules apply uniformly to all names (including typedef-names (9.1.3), namespace-names (9.7), and class-names (11.2)) wherever the grammar allows such names in the context discussed by a particular rule. Name lookup associates the use of a name with a set of declarations (6.1) of that name. The declarations found by name lookup shall either all denote the same entity or shall all denote functions or function templates; in the latter case, the declarations are said to form a set of overloaded functions (12.1). Overload resolution (12.3) takes place after name lookup has succeeded. The access rules (11.8) are considered only once name lookup and function overload resolution (if applicable) have succeeded. Only after name lookup, function overload resolution (if applicable) and access checking have succeeded are the semantic properties introduced by the name’s declaration and its reachable (10.6) redeclarations used further in expression processing (Clause 7).

2 A name “looked up in the context of an expression” is looked up in the scope where the expression is found.

3 The injected-class-name of a class (Clause 11) is also considered to be a member of that class for the purposes of name hiding and lookup.

4 [Note: 6.5 discusses linkage issues. The notions of scope, point of declaration and name hiding are discussed in 6.3. —end note]
6.4.1 Unqualified name lookup  

In all the cases listed in 6.4.1, the scopes are searched for a declaration in the order listed in each of the respective categories; name lookup ends as soon as a declaration is found for the name. If no declaration is found, the program is ill-formed.

The declarations from the namespace nominated by a using-directive become visible in a namespace enclosing the using-directive; see 9.7.3. For the purpose of the unqualified name lookup rules described in 6.4.1, the declarations from the namespace nominated by the using-directive are considered members of that enclosing namespace.

The lookup for an unqualified name used as the postfix-expression of a function call is described in 6.4.2. [Note: For purposes of determining (during parsing) whether an expression is a postfix-expression for a function call, the usual name lookup rules apply. In some cases a name followed by < is treated as a template-name even though name lookup did not find a template-name (see 13.2). For example,

```cpp
int h;
void g();
namespace N {
   struct A {};
   template <class T> int f(T);
   template <class T> int g(T);
   template <class T> int h(T);
}
int x = f<N::A>(N::A()); // OK: lookup of f finds nothing, f treated as template name
int y = g<N::A>(N::A()); // OK: lookup of g finds a function, g treated as template name
int z = h<N::A>(N::A()); // error: h< does not begin a template-id
```

The rules in 6.4.2 have no effect on the syntactic interpretation of an expression. For example,

```cpp
typedef int f;
namespace N {
   struct A {
      friend void f(A &);
      operator int();
      void g(A a) {
         int i = f(a);
      }
   };
}
```

Because the expression is not a function call, the argument-dependent name lookup (6.4.2) does not apply and the friend function f is not found. —end note]

A name used in global scope, outside of any function, class or user-declared namespace, shall be declared before its use in global scope.

A name used in a user-declared namespace outside of the definition of any function or class shall be declared before its use in that namespace or before its use in a namespace enclosing its namespace.

In the definition of a function that is a member of namespace N, a name used after the function’s declarator-id shall be declared before its use in the block in which it is used or in one of its enclosing blocks (8.3) or shall be declared before its use in namespace N or, if N is a nested namespace, shall be declared before its use in one of N’s enclosing namespaces. [Example:

```cpp
namespace A {
   namespace N {
      void f();
   }
}
void A::N::f() {
   i = 5;
```}

23) This refers to unqualified names that occur, for instance, in a type or default argument in the parameter-declaration-clause or used in the function body.
A name used in the definition of a class \( X \) outside of a complete-class context (11.3) of \( X \) shall be declared in one of the following ways:

- before its use in class \( X \) or be a member of a base class of \( X \) (11.7), or
- if \( X \) is a nested class of class \( Y \) (11.3.10), before the definition of \( Y \) in \( Y \), or shall be a member of a base class of \( Y \) (this lookup applies in turn to \( Y \)'s enclosing classes, starting with the innermost enclosing class), 25 or
- if \( X \) is a local class (11.5) or is a nested class of a local class, before the definition of class \( X \) in a block enclosing the definition of class \( X \), or
- if \( X \) is a member of namespace \( N \), or is a nested class of a class that is a member of \( N \), or is a local class or a nested class within a local class of a function that is a member of \( N \), before the definition of class \( X \) in namespace \( N \) or in one of \( N \)'s enclosing namespaces.

**Example:**

```cpp
namespace M {
    class B {
    }
}
namespace N {
    class Y : public M::B {
        class X {
            int a[i];
        }
    }
}
```

// The following scopes are searched for a declaration of i:
// 1) scope of class N::Y::X, before the use of i
// 2) scope of class N::Y, before the definition of N::Y::X
// 3) scope of N::Y's base class M::B
// 4) scope of namespace N, before the definition of N::Y
// 5) global scope, before the definition of N

— end example [Note: When looking for a prior declaration of a class or function introduced by a friend declaration, scopes outside of the innermost enclosing namespace scope are not considered; see 9.7.1.2. — end note] [Note: 6.3.7 further describes the restrictions on the use of names in a class definition. 11.3.10 further describes the restrictions on the use of names in nested class definitions. 11.5 further describes the restrictions on the use of names in local class definitions. — end note]

For the members of a class \( X \), a name used in a complete-class context (11.3) of \( X \) or in the definition of a class member outside of the definition of \( X \), following the member's declarator-id 26, shall be declared in one of the following ways:

- before its use in the block in which it is used or in an enclosing block (8.3), or
- shall be a member of class \( X \) or be a member of a base class of \( X \) (11.7), or
- if \( X \) is a nested class of class \( Y \) (11.3.10), shall be a member of \( Y \), or shall be a member of a base class of \( Y \) (this lookup applies in turn to \( Y \)'s enclosing classes, starting with the innermost enclosing class), 27 or

---

24) This refers to unqualified names following the class name; such a name may be used in a base-specifier or in the member-specification of the class definition.

25) This lookup applies whether the definition of \( X \) is nested within \( Y \)'s definition or whether \( X \)'s definition appears in a namespace scope enclosing \( Y \)'s definition (11.3.10).

26) That is, an unqualified name that occurs, for instance, in a type in the parameter-declaration-clause or in the noexcept-specifier.

27) This lookup applies whether the member function is defined within the definition of class \( X \) or whether the member function is defined in a namespace scope enclosing \( X \)'s definition.
— if X is a local class (11.5) or is a nested class of a local class, before the definition of class X in a block enclosing the definition of class X, or

— if X is a member of namespace N, or is a nested class of a class that is a member of N, or is a local class or a nested class within a local class of a function that is a member of N, before the use of the name, in namespace N or in one of N’s enclosing namespaces.

[Example:
    
    class B { };  
    namespace M {
        namespace N {
            class X : public B {
                void f();
            };
        }
    }
    
    void M::N::X::f() {
        i = 16;
    }

    // The following scopes are searched for a declaration of i:
    // 1) outermost block scope of M::N::X::f, before the use of i
    // 2) scope of class M::N::X
    // 3) scope of M::N::X’s base class B
    // 4) scope of namespace M::N
    // 5) scope of namespace M
    // 6) global scope, before the definition of M::N::X::f
    
    — end example] [Note: 11.3.1 and 11.3.8 further describe the restrictions on the use of names in member function definitions. 11.3.10 further describes the restrictions on the use of names in the scope of nested classes. 11.5 further describes the restrictions on the use of names in local class definitions. — end note]

Name lookup for a name used in the definition of a friend function (11.8.3) defined inline in the class granting friendship shall proceed as described for lookup in member function definitions. If the friend function is not defined in the class granting friendship, name lookup in the friend function definition shall proceed as described for lookup in namespace member function definitions.

In a friend declaration naming a member function, a name used in the function declarator and not part of a template-argument in the declarator-id is first looked up in the scope of the member function’s class (11.7). If it is not found, or if the name is part of a template-argument in the declarator-id, the look up is as described for unqualified names in the definition of the class granting friendship. [Example:

    struct A {
        typedef int AT;
        void f1(AT);
        void f2(float);
        template <class T> void f3();
    };
    struct B {
        typedef char AT;
        typedef float BT;
        friend void A::f1(AT); // parameter type is A::AT
        friend void A::f2(BT); // parameter type is B::BT
        friend void A::f3<AT>(); // template argument is B::AT
    };
    
    — end example]

During the lookup for a name used as a default argument (9.2.3.6) in a function parameter-declaration-clause or used in the expression of a mem-initializer for a constructor (11.9.2), the function parameter names are visible and hide the names of entities declared in the block, class or namespace scopes containing the function declaration. [Note: 9.2.3.6 further describes the restrictions on the use of names in default arguments. 11.9.2 further describes the restrictions on the use of names in a ctor-initializer. — end note]

During the lookup of a name used in the constant-expression of an enumerator-definition, previously declared enumerators of the enumeration are visible and hide the names of entities declared in the block, class, or namespace scopes containing the enum-specifier.

§ 6.4.1
©ISO/IEC

A name used in the definition of a static data member of class X (11.3.8.2) (after the qualified-id of the static member) is looked up as if the name was used in a member function of X. [Note: 11.3.8.2 further describes the restrictions on the use of names in the definition of a static data member. — end note]

If a variable member of a namespace is defined outside of the scope of its namespace then any name that appears in the definition of the member (after the declarator-id) is looked up as if the definition of the member occurred in its namespace. [Example:

```cpp
namespace N {
    int i = 4;
    extern int j;
}

int i = 2;

int N::j = i;  // N::j == 4
```
— end example]

A name used in the handler for a function-try-block (Clause 14) is looked up as if the name was used in the outermost block of the function definition. In particular, the function parameter names shall not be redeclared in the exception-declaration nor in the outermost block of a handler for the function-try-block. Names declared in the outermost block of the function definition are not found when looked up in the scope of a handler for the function-try-block. [Note: But function parameter names are found. — end note]

[Note: The rules for name lookup in template definitions are described in 13.7. — end note]

### 6.4.2 Argument-dependent name lookup

When the postfix-expression in a function call (7.6.1.2) is an unqualified-id, other namespaces not considered during the usual unqualified lookup (6.4.1) may be searched, and in those namespaces, namespace-scoped friend function or function template declarations (11.8.3) not otherwise visible may be found. These modifications to the search depend on the types of the arguments (and for template template arguments, the namespace of the template argument). [Example:

```cpp
namespace N {
    struct S { }
    void f(S);
}

void g() {
    N::S s;
    f(s);       // OK: calls N::f
    (f)(s);     // error: N::f not considered; parentheses prevent argument-dependent lookup
}
```
— end example]

For each argument type T in the function call, there is a set of zero or more associated namespaces and a set of zero or more associated entities (other than namespaces) to be considered. The sets of namespaces and entities are determined entirely by the types of the function arguments (and the namespace of any template template argument). Typedef names and using-declarations used to specify the types do not contribute to this set. The sets of namespaces and entities are determined in the following way:

(2.1) If T is a fundamental type, its associated sets of namespaces and entities are both empty.

(2.2) If T is a class type (including unions), its associated entities are: the class itself; the class of which it is a member, if any; and its direct and indirect base classes. Its associated namespaces are the innermost enclosing namespaces of its associated entities. Furthermore, if T is a class template specialization, its associated namespaces and entities also include: the namespaces and entities associated with the types of the template arguments provided for template type parameters (excluding template template parameters); the templates used as template template arguments; the namespaces of which any template template arguments are members; and the classes of which any member templates used as template template arguments are members. [Note: Non-type template arguments do not contribute to the set of associated namespaces. — end note]

(2.3) If T is an enumeration type, its associated namespace is the innermost enclosing namespace of its declaration, and its associated entities are T and, if it is a class member, the member’s class.
If \( T \) is a pointer to \( U \) or an array of \( U \), its associated namespaces and entities are those associated with \( U \).

If \( T \) is a function type, its associated namespaces and entities are those associated with the function parameter types and those associated with the return type.

If \( T \) is a pointer to a member function of a class \( X \), its associated namespaces and entities are those associated with the function parameter types and return type, together with those associated with \( X \).

If \( T \) is a pointer to a data member of class \( X \), its associated namespaces and entities are those associated with the member type together with those associated with \( X \).

If an associated namespace is an inline namespace (9.7.1), its enclosing namespace is also included in the set.

If an associated namespace directly contains inline namespaces, those inline namespaces are also included in the set. In addition, if the argument is the name or address of a set of overloaded functions and/or function templates, its associated entities and namespaces are the union of those associated with each of the members of the set, i.e., the entities and namespaces associated with its parameter types and return type. Additionally, if the aforementioned set of overloaded functions is named with a template-id, its associated entities and namespaces also include those of its type template-arguments and its template template-arguments.

Let \( X \) be the lookup set produced by unqualified lookup (6.4.1) and let \( Y \) be the lookup set produced by argument dependent lookup (defined as follows). If \( X \) contains

1. a declaration of a class member, or
2. a block-scope function declaration that is not a using-declaration, or
3. a declaration that is neither a function nor a function template

then \( Y \) is empty. Otherwise \( Y \) is the set of declarations found in the namespaces associated with the argument types as described below. The set of declarations found by the lookup of the name is the union of \( X \) and \( Y \).

[Note: The namespaces and entities associated with the argument types can include namespaces and entities already considered by the ordinary unqualified lookup. — end note]

[Example:

```cpp
namespace NS {
    class T {
    public:
        void f(T);
        void g(T, int);
    }
}

NS::T parm;
void g(NS::T, float);
int main() {
    f(parm);    // OK: calls NS::f
    extern void g(NS::T, float);
    g(parm, 1);  // OK: calls g(NS::T, float)
}
```

— end example]

When considering an associated namespace \( N \), the lookup is the same as the lookup performed when \( N \) is used as a qualifier (6.4.3.2) except that:

1. Any using-directives in \( N \) are ignored.
2. All names except those of (possibly overloaded) functions and function templates are ignored.
3. Any namespace-scope friend functions or friend function templates (11.8.3) declared in classes with reachable definitions in the set of associated entities are visible within their respective namespaces even if they are not visible during an ordinary lookup (9.7.1.2).
4. Any declaration \( D \) in \( N \) that is in the interface of a named module \( M \) (10.2) is visible if there is an associated entity attached to \( M \) with the same innermost enclosing non-inline namespace as \( D \).
5. If the lookup is for a dependent name (13.7.2, 13.7.4.2), any declaration \( D \) in \( N \) is visible if \( D \) would be visible to qualified name lookup (6.4.3.2) at any point in the instantiation context (10.5) of the lookup, unless \( D \) is declared in another translation unit, attached to the global module, and is either discarded (10.4) or has internal linkage.

[Example:
Translation unit #1:
export module M;
namespace R {
    export struct X {};
    export void f(X);
}
namespace S {
    export void f(X, X);
}

Translation unit #2:
export module N;
import M;
export R::X make();
namespace R { static int g(X); }
template<typename T, typename U> void apply(T t, U u) {
    f(t, u);
    g(t);
}

Translation unit #3:
module Q;
import N;
namespace S {
    struct Z { template<typename T> operator T(); }
}

void test() {
    auto x = make(); // OK, decltype(x) is R::X in module M
    R::f(x); // ill-formed: R and R::f are not visible here
    f(x); // OK, calls R::f from interface of M
    f(x, S::Z()); // ill-formed: S::f in module M not considered
              // even though S is an associated namespace
    apply(x, S::Z()); // OK, S::f is visible in instantiation context, and
                      // R::g is visible even though it has internal linkage
}

—end example]

6.4.3 Qualified name lookup
[basic.lookup.qual]

1 The name of a class or namespace member or enumerator can be referred to after the :: scope resolution operator (7.5.4.2) applied to a nested-name-specifier that denotes its class, namespace, or enumeration. If a :: scope resolution operator in a nested-name-specifier is not preceded by a decltype-specifier, lookup of the name preceding that :: considers only namespaces, types, and templates whose specializations are types. If the name found does not designate a namespace or a class, enumeration, or dependent type, the program is ill-formed. [Example:

class A {
    public:
    static int n;
};
int main() {
    int A;
    A::n = 42; // OK
    A a; // ill-formed: A does not name a type
}

—end example]

2 [Note: Multiply qualified names, such as N1::N2::N3::n, can be used to refer to members of nested classes (11.3.10) or members of nested namespaces. —end note]

3 In a declaration in which the declarator-id is a qualified-id, names used before the qualified-id being declared are looked up in the defining namespace scope; names following the qualified-id are looked up in the scope of the member’s class or namespace. [Example:

class X { };
class C {
    class X { }
    static const int number = 50;
    static X arr[number];
};
X C::arr[number]; // ill-formed:
    // equivalent to ::X C::arr[C::number];
    // and not to ::X C::arr[C::number];

— end example]

4 A name prefixed by the unary scope operator :: (7.5.4.2) is looked up in global scope, in the translation unit
where it is used. The name shall be declared in global namespace scope or shall be a name whose declaration
is visible in global scope because of a using-directive (6.4.3.2). The use of :: allows a global name to be
referred to even if its identifier has been hidden (6.3.10).

5 A name prefixed by a nested-name-specifier that nominates an enumeration type shall represent an enumerator
of that enumeration.

6 In a qualified-id of the form:
    nested-name-specifier_opt type-name :: ~ type-name
the second type-name is looked up in the same scope as the first. [Example:

    struct C {
        typedef int I;
    }
    typedef int I1, I2;
    extern int* p;
    extern int* q;
    p->C::I::~I();  // I is looked up in the scope of C
    q->I1::~I2();  // I2 is looked up in the scope of the postfix-expression

    struct A {
        ~A();
    }
    typedef A AB;
    int main() {
        AB* p;
        p->AB::~AB();  // explicitly calls the destructor for A
    }
— end example] [Note: 6.4.5 describes how name lookup proceeds after the . and -> operators. — end note]

6.4.3.1 Class members [class.qual]

1 If the nested-name-specifier of a qualified-id nominates a class, the name specified after the nested-name-
specifier is looked up in the scope of the class (11.7), except for the cases listed below. The name shall
represent one or more members of that class or of one of its base classes (11.6). [Note: A class member can
be referred to using a qualified-id at any point in its potential scope (6.3.7). — end note] The exceptions to
the name lookup rule above are the following:

   (1.1) — the lookup for a destructor is as specified in 6.4.3;

   (1.2) — a conversion-type-id of a conversion-function-id is looked up in the same manner as a conversion-type-id
       in a class member access (see 6.4.5);

   (1.3) — the names in a template-argument of a template-id are looked up in the context in which the entire
       postfix-expression occurs.

   (1.4) — the lookup for a name specified in a using-declaration (9.8) also finds class or enumeration names
       hidden within the same scope (6.3.10).

2 In a lookup in which function names are not ignored28 and the nested-name-specifier nominates a class C:

   (2.1) — if the name specified after the nested-name-specifier, when looked up in C, is the injected-class-name of
       C (Clause 11), or

28) Lookups in which function names are ignored include names appearing in a nested-name-specifier, an elaborated-type-specifier,
or a base-specifier.
— in a using-declarator of a using-declaration (9.8) that is a member-declaration, if the name specified after the nested-name-specifier is the same as the identifier or the simple-template-id’s template-name in the last component of the nested-name-specifier, the name is instead considered to name the constructor of class C. [Note: For example, the constructor is not an acceptable lookup result in an elaborated-type-specifier so the constructor would not be used in place of the injected-class-name. — end note] Such a constructor name shall be used only in the declarator-id of a declaration that names a constructor or in a using-declaration. [Example:

```cpp
struct A { A(); }
struct B: public A { B(); }
A::A() { }
B::B() { }
B::A ba;       // object of type A
A::A a;       // error, A::A is not a type name
struct A::A a2; // object of type A
```

— end example]

3 A class member name hidden by a name in a nested declarative region or by the name of a derived class member can still be found if qualified by the name of its class followed by the :: operator.

### 6.4.3.2 Namespace members [namespace.qual]

1 If the nested-name-specifier of a qualified-id nominates a namespace (including the case where the nested-name-specifier is ::, i.e., nominating the global namespace), the name specified after the nested-name-specifier is looked up in the scope of the namespace. The names in a template-argument of a template-id are looked up in the context in which the entire postfix-expression occurs.

2 For a namespace X and name m, the namespace-qualified lookup set S(X, m) is defined as follows: Let S′(X, m) be the set of all declarations of m in X and the inline namespace set of X (9.7.1) whose potential scope (6.3.6) would include the namespace in which m is declared at the location of the nested-name-specifier. If S′(X, m) is not empty, S(X, m) is S′(X, m); otherwise, S(X, m) is the union of S(N, m) for all namespaces N nominated by using-directives in X and its inline namespace set.

3 Given X::m (where X is a user-declared namespace), or given ::m (where X is the global namespace), if S(X, m) is the empty set, the program is ill-formed. Otherwise, if S(X, m) has exactly one member, or if the context of the reference is a using-declaration (9.8), S(X, m) is the required set of declarations of m. Otherwise if the use of m is not one that allows a unique declaration to be chosen from S(X, m), the program is ill-formed. [Example:

```cpp
int x;
namespace Y {
    void f(float);
    void h(int);
}
	namespace Z {
    void h(double);
}
	namespace A {
    using namespace Y;
    void f(int);
    void g(int);
    int i;
}
	namespace B {
    using namespace Z;
    void f(char);
    int i;
}
```
namespace AB {
    using namespace A;
    using namespace B;
    void g();
}

void h() {
    AB::g(); // g is declared directly in AB, therefore S is {AB::g()} and AB::g() is chosen
    AB::f(1); // f is not declared directly in AB so the rules are applied recursively to A and B;
               // namespace Y is not searched and Y::f(float) is not considered;
               // S is {A::f(int), B::f(char)} and overload resolution chooses A::f(int)
    AB::f('c'); // as above but resolution chooses B::f(char)
    AB::x++; // x is not declared directly in AB, and is not declared in A or B, so the rules
               // are applied recursively to Y and Z, S is {} so the program is ill-formed
    AB::i++; // i is not declared directly in AB so the rules are applied recursively to A and B,
               // S is {A::i, B::i} so the use is ambiguous and the program is ill-formed
    AB::h(16.8); // h is not declared directly in AB and not declared directly in A or B so the rules
                  // are applied recursively to Y and Z, S is {Y::h(int), Z::h(double)} and
                  // overload resolution chooses Z::h(double)
}

— end example]}

4 [Note: The same declaration found more than once is not an ambiguity (because it is still a unique declaration). Example:

namespace A {
    int a;
}

namespace B {
    using namespace A;
}

namespace C {
    using namespace A;
}

namespace BC {
    using namespace B;
    using namespace C;
}

void f() {
    BC::a++; // OK: S is {A::a, A::a}
}

namespace D {
    using A::a;
}

namespace BD {
    using namespace B;
    using namespace D;
}
void g()
{
    BD::a++; // OK, S is {A::a, A::a}
}
—end example —end note

[Example: Because each referenced namespace is searched at most once, the following is well-defined:

namespace B {
    int b;
}

namespace A {
    using namespace B;
    int a;
}

namespace B {
    using namespace A;
}

void f()
{
    A::a++; // OK, a declared directly in A, S is {A::a}
    B::a++; // OK, both A and B searched (once), S is {A::a}
    A::b++; // OK, both A and B searched (once), S is {B::b}
    B::b++; // OK, b declared directly in B, S is {B::b}
}
—end example]

6 During the lookup of a qualified namespace member name, if the lookup finds more than one declaration of the member, and if one declaration introduces a class name or enumeration name and the other declarations introduce either the same variable, the same enumerator, or a set of functions, the non-type name hides the class or enumeration name if and only if the declarations are from the same namespace; otherwise (the declarations are from different namespaces), the program is ill-formed. [Example:

namespace A {
    struct x {}
    int x;
    int y;
}

namespace B {
    struct y {}
}

namespace C {
    using namespace A;
    using namespace B;
    int i = C::x; // OK, A::x (of type int)
    int j = C::y; // ambiguous, A::y or B::y
}
—end example]

7 In a declaration for a namespace member in which the declarator-id is a qualified-id, given that the qualified-id for the namespace member has the form

    nested-name-specifier unqualified-id

the unqualified-id shall name a member of the namespace designated by the nested-name-specifier or of an element of the inline namespace set (9.7.1) of that namespace. [Example:

namespace A {
    namespace B {
        void f1(int);
    }

§ 6.4.3.2
using namespace B;
}

void A::f1(int){ } // ill-formed, f1 is not a member of A

—end example] However, in such namespace member declarations, the \textit{nested-name-specifier} may rely on \textit{using-directives} to implicitly provide the initial part of the \textit{nested-name-specifier}. [Example:

namespace A {
    namespace B {
        void f1(int);
    }
}

namespace C {
    namespace D {
        void f1(int);
    }
}

using namespace A;
using namespace C::D;

void B::f1(int){ } // OK, defines A::B::f1(int)

—end example]

\section*{6.4.4 Elaborated type specifiers} [basic.lookup.elab]

1 An \textit{elaborated-type-specifier} (9.1.7.3) may be used to refer to a previously declared \textit{class-name} or \textit{enum-name} even though the name has been hidden by a non-type declaration (6.3.10).

2 If the \textit{elaborated-type-specifier} has no \textit{nested-name-specifier}, and unless the \textit{elaborated-type-specifier} appears in a declaration with the following form:

\begin{quote}
\begin{verbatim}
class-key attribute-specifier-seqopt identifier;
\end{verbatim}
\end{quote}

the \textit{identifier} is looked up according to 6.4.1 but ignoring any non-type names that have been declared. If the \textit{elaborated-type-specifier} is introduced by the \textit{enum} keyword and this lookup does not find a previously declared \textit{type-name}, the \textit{elaborated-type-specifier} is ill-formed. If the \textit{elaborated-type-specifier} is introduced by the \textit{class-key} and this lookup does not find a previously declared \textit{type-name}, or if the \textit{elaborated-type-specifier} appears in a declaration with the form:

\begin{quote}
\begin{verbatim}
class-key attribute-specifier-seqopt identifier;
\end{verbatim}
\end{quote}

the \textit{elaborated-type-specifier} is a declaration that introduces the \textit{class-name} as described in 6.3.2.

3 If the \textit{elaborated-type-specifier} has a \textit{nested-name-specifier}, qualified name lookup is performed, as described in 6.4.3, but ignoring any non-type names that have been declared. If the name lookup does not find a previously declared \textit{type-name}, the \textit{elaborated-type-specifier} is ill-formed.

4 [Example:

\begin{quote}
\begin{verbatim}
struct Node {
    struct Node* Next;
    struct Data* Data; // OK: Refers to injected-class-name Node
};

struct Data {
    struct Node* Node; // OK: Refers to Node at global scope
    friend struct ::Glob; // error: Glob is not declared, cannot introduce a qualified type (9.1.7.3)
    friend struct Glob; // OK: Refers to (as yet) undeclared Glob at global scope. /* ... */
};

struct Base {
    struct Data; // OK: Declares nested Data
    struct ::Data* thatData; // OK: Refers to ::Data
    struct Base::Data* thisData; // OK: Refers to nested Data
    friend class ::Data; // OK: global Data is a friend
    friend class Data; // OK: nested Data is a friend
\end{verbatim}
\end{quote}

\section*{§ 6.4.4}
struct Data; // OK: Redeclares Data at global scope
struct ::Data; // error: cannot introduce a qualified type (9.1.7.3)
struct Base::Data; // error: cannot introduce a qualified type (9.1.7.3)
struct Base::Datum; // error: Datum undefined
struct Base::Data* pBase; // OK: refers to nested Data

--- end example

### 6.4.5 Class member access

1. In a class member access expression (7.6.1.4), if the . or -> token is immediately followed by an `identifier` followed by a <, the identifier must be looked up to determine whether the < is the beginning of a template argument list (13.2) or a less-than operator. The identifier is first looked up in the class of the object expression (11.7). If the identifier is not found, it is then looked up in the context of the entire postfix-expression and shall name a class template.

2. If the id-expression in a class member access (7.6.1.4) is an unqualified-id, and the type of the object expression is of a class type C, the unqualified-id is looked up in the scope of class C (11.7).

3. If the unqualified-id is ~type-name, the type-name is looked up in the context of the entire postfix-expression. If the type T of the object expression is of a class type C, the type-name is also looked up in the scope of class C. At least one of the lookups shall find a name that refers to cv T. [Example:

```cpp
struct A { }

struct B {
    struct A {
        void f(A* a);
    }

    B::f(A* a) {
        a->~A(); // OK: lookup in *a finds the injected-class-name
    }
}
--- end example
```

4. If the id-expression in a class member access is a qualified-id of the form

```
class-name-or-namespace-name::...
```

the class-name-or-namespace-name following the . or -> operator is first looked up in the class of the object expression (11.7) and the name, if found, is used. Otherwise it is looked up in the context of the entire postfix-expression. [Note: See 6.4.3, which describes the lookup of a name before ::, which will only find a type or namespace name. — end note]

5. If the qualified-id has the form

```
::class-name-or-namespace-name::...
```

the class-name-or-namespace-name is looked up in global scope as a class-name or namespace-name.

6. If the nested-name-specifier contains a simple-template-id (13.2), the names in its template-arguments are looked up in the context in which the entire postfix-expression occurs.

7. If the id-expression is a conversion-function-id, its conversion-type-id is first looked up in the class of the object expression (11.7) and the name, if found, is used. Otherwise it is looked up in the context of the entire postfix-expression. In each of these lookups, only names that denote types or templates whose specializations are types are considered. [Example:

```cpp
struct A { }
namespace N {
    struct A {
        void g() {}
        template <class T> operator T();
    }
}
```
```c
int main() {
    N::A a;
    a.operator A(); // calls N::A::operator N::A
}
```

--- end example

### 6.4.6 Using-directives and namespace aliases [basic.lookup.udir]

In a `using-directive` or `namespace-alias-definition`, during the lookup for a `namespace-name` or for a name in a `nested-name-specifier` only namespace names are considered.

### 6.5 Program and linkage [basic.link]

A program consists of one or more translation units (Clause 5) linked together. A translation unit consists of a sequence of declarations.

```
translation-unit:
    top-level-declaration-seq_opt
    global-module-fragment_opt module-declaration top-level-declaration-seq_opt private-module-fragment_opt

private-module-fragment:
    module : private ; top-level-declaration-seq_opt

top-level-declaration-seq:
    top-level-declaration
    top-level-declaration-seq top-level-declaration

top-level-declaration:
    module-import-declaration
    declaration
```

2 A `private-module-fragment` shall appear only in a primary module interface unit (10.1). A module unit with a `private-module-fragment` shall be the only module unit of its module; no diagnostic is required.

3 A token sequence beginning with `export_opt module` or `export_opt import` and not immediately followed by `::` is never interpreted as the `declaration` of a `top-level-declaration`.

4 A name is said to have `linkage` when it might denote the same object, reference, function, type, template, namespace or value as a name introduced by a declaration in another scope:

   (4.1) When a name has `external linkage`, the entity it denotes can be referred to by names from scopes of other translation units or from other scopes of the same translation unit.

   (4.2) When a name has `module linkage`, the entity it denotes can be referred to by names from other scopes of the same module unit (10.1) or from scopes of other module units of that same module.

   (4.3) When a name has `internal linkage`, the entity it denotes can be referred to by names from other scopes in the same translation unit.

   (4.4) When a name has `no linkage`, the entity it denotes cannot be referred to by names from other scopes.

5 A name having namespace scope (6.3.6) has internal linkage if it is the name of

   (5.1) a variable, variable template, function, or function template that is explicitly declared `static`; or

   (5.2) a non-template variable of non-volatile const-qualified type, unless

      (5.2.1) it is explicitly declared `extern`, or

      (5.2.2) it is inline or exported, or

      (5.2.3) it was previously declared and the prior declaration did not have internal linkage; or

   (5.3) a data member of an anonymous union.

[Note: An instantiated variable template that has const-qualified type can have external or module linkage, even if not declared `extern`. — end note]

6 An unnamed namespace or a namespace declared directly or indirectly within an unnamed namespace has internal linkage. All other namespaces have external linkage. A name having namespace scope that has not been given internal linkage above and that is the name of

   (6.1) a variable; or

   (6.2) a function; or

§ 6.5
— a named class (Clause 11), or an unnamed class defined in a typedef declaration in which the class has the typedef name for linkage purposes (9.1.3); or

— a named enumeration (9.6), or an unnamed enumeration defined in a typedef declaration in which the enumeration has the typedef name for linkage purposes (9.1.3); or

— a template

has its linkage determined as follows:

— if the enclosing namespace has internal linkage, the name has internal linkage;

— otherwise, if the declaration of the name is attached to a named module (10.1) and is not exported (10.2), the name has module linkage;

— otherwise, the name has external linkage.

In addition, a member function, static data member, a named class or enumeration of class scope, or an unnamed class or enumeration defined in a class-scope typedef declaration such that the class or enumeration has the typedef name for linkage purposes (9.1.3), has the same linkage, if any, as the name of the class of which it is a member.

The name of a function declared in block scope and the name of a variable declared by a block scope extern declaration have linkage. If such a declaration is attached to a named module, the program is ill-formed. If there is a visible declaration of an entity with linkage, ignoring entities declared outside the innermost enclosing namespace scope, such that the block scope declaration would be a (possibly ill-formed) redeclaration if the two declarations appeared in the same declarative region, the block scope declaration declares that same entity and receives the linkage of the previous declaration. If there is more than one such matching entity, the program is ill-formed. Otherwise, if no matching entity is found, the block scope entity receives external linkage. If, within a translation unit, the same entity is declared with both internal and external linkage, the program is ill-formed. [Example:

```c
static void f();
extern "C" void h();
static int i = 0;
void g() {
  extern void f(); // internal linkage
  extern void h(); // C language linkage
  int i; // #2: i has no linkage
  { extern void f(); // internal linkage
    extern int i; // #3: external linkage, ill-formed
  }
}
```

Without the declaration at line #2, the declaration at line #3 would link with the declaration at line #1. Because the declaration with internal linkage is hidden, however, #3 is given external linkage, making the program ill-formed. —end example]

When a block scope declaration of an entity with linkage is not found to refer to some other declaration, then that entity is a member of the innermost enclosing namespace. However such a declaration does not introduce the member name in its namespace scope. [Example:

```c
namespace X {
  void p() {
    q(); // error: q not yet declared
    extern void q(); // q is a member of namespace X
  }

  void middle() {
    q(); // error: q not yet declared
  }

  void q() { /* ... */ } // definition of X::q

  void q() { /* ... */ } // some other, unrelated q
  #end example]

§ 6.5
Names not covered by these rules have no linkage. Moreover, except as noted, a name declared at block
scope (6.3.3) has no linkage.

Two names that are the same (Clause 6) and that are declared in different scopes shall denote the same
variable, function, type, template or namespace if

(11.1) — both names have external or module linkage and are declared in declarations attached to the same
module, or else both names have internal linkage and are declared in the same translation unit; and
(11.2) — both names refer to members of the same namespace or to members, not by inheritance, of the same
class; and
(11.3) — when both names denote functions, the parameter-type-lists of the functions (9.2.3.5) are identical; and
(11.4) — when both names denote function templates, the signatures (13.6.6.1) are the same.

If multiple declarations of the same name with external linkage would declare the same entity except
that they are attached to different modules, the program is ill-formed; no diagnostic is required. [Note:
using-declarations, typedef declarations, and alias-declarations do not declare entities, but merely introduce
synonyms. Similarly, using-directives do not declare entities. —end note]

If a declaration would redeclare a reachable declaration attached to a different module, the program is
ill-formed. [Example:

"decls.h":
int f();   // #1, attached to the global module
int g();   // #2, attached to the global module

Module interface of M:
module;
#include "decls.h"
export module M;
export using ::f;   // OK: does not declare an entity, exports #1
int g();   // error: matches #2, but attached to M
export int h();   // #3
export int k();   // #4

Other translation unit:
import M;
static int h();   // error: matches #3
int k();   // error: matches #4
— end example] As a consequence of these rules, all declarations of an entity are attached to the same module;
the entity is said to be attached to that module.

After all adjustments of types (during which typedefs (9.1.3) are replaced by their definitions), the types
specified by all declarations referring to a given variable or function shall be identical, except that declarations
for an array object can specify array types that differ by the presence or absence of a major array bound (9.2.3.4).
A violation of this rule on type identity does not require a diagnostic.

[Note: Linkage to non-C++ declarations can be achieved using a linkage-specification (9.10). —end note]

6.6 Memory and objects [basic.memobj]

6.6.1 Memory model [intro.memory]

The fundamental storage unit in the C++ memory model is the byte. A byte is at least large enough to contain
any member of the basic execution character set (5.3) and the eight-bit code units of the Unicode UTF-8
encoding form and is composed of a contiguous sequence of bits, the number of which is implementation-
defined. The least significant bit is called the low-order bit; the most significant bit is called the high-order
bit. The memory available to a C++ program consists of one or more sequences of contiguous bytes. Every
byte has a unique address.

[Note: The representation of types is described in 6.7. —end note]

A memory location is either an object of scalar type or a maximal sequence of adjacent bit-fields all having
nonzero width. [Note: Various features of the language, such as references and virtual functions, might involve
additional memory locations that are not accessible to programs but are managed by the implementation.

29) The number of bits in a byte is reported by the macro CHAR_BIT in the header <climits>.
Two or more threads of execution (6.8.2) can access separate memory locations without interfering with each other.

[Note: Thus a bit-field and an adjacent non-bit-field are in separate memory locations, and therefore can be concurrently updated by two threads of execution without interference. The same applies to two bit-fields, if one is declared inside a nested struct declaration and the other is not, or if the two are separated by a zero-length bit-field declaration, or if they are separated by a non-bit-field declaration. It is not safe to concurrently update two bit-fields in the same struct if all fields between them are also bit-fields of nonzero width. — end note]

Example: A class declared as

```cpp
struct {
    char a;
    int b:5,
    c:11,
    :0,
    d:8;
    struct {int ee:8;} e;
}
```

contains four separate memory locations: The member `a` and bit-fields `d` and `e.ee` are each separate memory locations, and can be modified concurrently without interfering with each other. The bit-fields `b` and `c` together constitute the fourth memory location. The bit-fields `b` and `c` cannot be concurrently modified, but `b` and `a`, for example, can be. — end example]

6.6.2 Object model

The constructs in a C++ program create, destroy, refer to, access, and manipulate objects. An object is created by a definition (6.1), by a new-expression (7.6.2.7), when implicitly changing the active member of a union (11.4), or when a temporary object is created (7.3.4, 6.6.7). An object occupies a region of storage in its period of construction (11.9.4), throughout its lifetime (6.6.3), and in its period of destruction (11.9.4). [Note: A function is not an object, regardless of whether or not it occupies storage in the way that objects do. — end note] The properties of an object are determined when the object is created. An object can have a name (Clause 6). An object has a storage duration (6.6.5) which influences its lifetime (6.6.3). An object has a type (6.7). Some objects are polymorphic (11.6.2); the implementation generates information associated with each such object that makes it possible to determine that object’s type during program execution. For other objects, the interpretation of the values found therein is determined by the type of the expressions (7.6) used to access them.

Objects can contain other objects, called subobjects. A subobject can be a member subobject (11.3), a base class subobject (11.6), or an array element. An object that is not a subobject of any other object is called a complete object. If an object is created in storage associated with a member subobject or array element `e` (which may or may not be within its lifetime), the created object is a subobject of `e`’s containing object if:

(2.1) — the lifetime of `e`’s containing object has begun and not ended, and
(2.2) — the storage for the new object exactly overlays the storage location associated with `e`, and
(2.3) — the new object is of the same type as `e` (ignoring cv-qualification).

[Note: If the subobject contains a reference member or a const subobject, the name of the original subobject cannot be used to access the new object (6.6.3). — end note] [Example:

```cpp
struct X { const int n; 

union U { X x; float f; 

void tong() {
    U u = {{ 1 }}; // OK, creates new subobject of u (11.4)
    X *p = new (&u.x) X {2}; // OK, creates new subobject of u
    assert(p->n == 2); // OK
    assert(*std::launder(&u.x.n) == 2); // OK
    assert(u.x.n == 2); // undefined behavior, u.x does not name new subobject
}
```

— end example]
3 If a complete object is created (7.6.2.7) in storage associated with another object e of type “array of N unsigned char” or of type “array of N std::byte” (17.2.1), that array provides storage for the created object if:

3.1 — the lifetime of e has begun and not ended, and
3.2 — the storage for the new object fits entirely within e, and
3.3 — there is no smaller array object that satisfies these constraints.

[Note: If that portion of the array previously provided storage for another object, the lifetime of that object ends because its storage was reused (6.6.3). — end note] [Example:

```
template<typename ...T>
struct AlignedUnion {
    alignas(T...) unsigned char data[max(sizeof(T)...)];
};

int f() {
    AlignedUnion<int, char> au;
    int *p = new (au.data) int; // OK, au.data provides storage
    char *c = new (au.data) char(); // OK, ends lifetime of *p
    char *d = new (au.data + 1) char();
    return *c + *d; // OK
}
```

**Example:**

```
struct A { unsigned char a[32]; };
struct B { unsigned char b[16]; };
A a;
B *b = new (a.a + 8) B; // a.a provides storage for *b
int *p = new (b->b + 4) int; // b->b provides storage for *p
// a.a does not provide storage for *p (directly),
// but *p is nested within a (see below)
```

— end example]

4 An object a is nested within another object b if:

4.1 — a is a subobject of b, or
4.2 — b provides storage for a, or
4.3 — there exists an object c where a is nested within c, and c is nested within b.

5 For every object x, there is some object called the complete object of x, determined as follows:

5.1 — If x is a complete object, then the complete object of x is itself.
5.2 — Otherwise, the complete object of x is the complete object of the (unique) object that contains x.

6 If a complete object, a data member (11.3), or an array element is of class type, its type is considered the most derived class, to distinguish it from the class type of any base class subobject; an object of a most derived class type or of a non-class type is called a most derived object.

7 A potentially-overlapping subobject is either:

7.1 — a base class subobject, or
7.2 — a non-static data member declared with the no_unique_address attribute (9.11.11).

8 An object has nonzero size if it

8.1 — is not a potentially-overlapping subobject, or
8.2 — is not of class type, or
8.3 — is of a class type with virtual member functions or virtual base classes, or
8.4 — has subobjects of nonzero size or bit-fields of nonzero length.

Otherwise, if the object is a base class subobject of a standard-layout class type with no non-static data members, it has zero size. Otherwise, the circumstances under which the object has zero size are implementation-defined. Unless it is a bit-field (11.3.9), an object with nonzero size shall occupy one or more bytes of storage, including every byte that is occupied in full or in part by any of its subobjects. An object of trivially copyable or standard-layout type (6.7) shall occupy contiguous bytes of storage.
Unless an object is a bit-field or a subobject of zero size, the address of that object is the address of the first byte it occupies. Two objects with overlapping lifetimes that are not bit-fields may have the same address if one is nested within the other, or if at least one is a subobject of zero size and they are of different types; otherwise, they have distinct addresses and occupy disjoint bytes of storage.  

Example:

```c
static const char test1 = 'x';
static const char test2 = 'x';
const bool b = &test1 != &test2;  // always true
```

The address of a non-bit-field subobject of zero size is the address of an unspecified byte of storage occupied by the complete object of that subobject.

Note: C++ provides a variety of fundamental types and several ways of composing new types from existing types (6.7).  

### 6.6.3 Object and reference lifetime

The lifetime of an object or reference is a runtime property of the object or reference. A variable is said to have vacuous initialization if it is default-initialized and, if it is of class type or a (possibly multi-dimensional) array thereof, that class type has a trivial default constructor. The lifetime of an object of type \( T \) begins when:

- \((1.1)\) storage with the proper alignment and size for type \( T \) is obtained, and
- \((1.2)\) its initialization (if any) is complete (including vacuous initialization) (9.3),

except that if the object is a union member or subobject thereof, its lifetime only begins if that union member is the initialized member in the union (9.3.1, 11.9.2), or as described in 11.4. The lifetime of an object \( o \) of type \( T \) ends when:

- \((1.3)\) if \( T \) is a non-class type, the object is destroyed, or
- \((1.4)\) if \( T \) is a class type, the destructor call starts, or
- \((1.5)\) the storage which the object occupies is released, or is reused by an object that is not nested within \( o \) (6.6.2).

The lifetime of a reference begins when its initialization is complete. The lifetime of a reference ends as if it were a scalar object requiring storage.

Note: 11.9.2 describes the lifetime of base and member subobjects.  

The properties ascribed to objects and references throughout this document apply for a given object or reference only during its lifetime. [Note: In particular, before the lifetime of an object starts and after its lifetime ends there are significant restrictions on the use of the object, as described below, in 11.9.2 and in 11.9.4. Also, the behavior of an object under construction and destruction might not be the same as the behavior of an object whose lifetime has started and not ended. 11.9.2 and 11.9.4 describe the behavior of objects during the construction and destruction phases.  

A program may end the lifetime of any object by reusing the storage which the object occupies or by explicitly calling the destructor for an object of a class type with a non-trivial destructor. For an object of a class type with a non-trivial destructor, the program is not required to call the destructor explicitly before the storage which the object occupies is reused or released; however, if there is no explicit call to the destructor or if a delete-expression (7.6.2.8) is not used to release the storage, the destructor shall not be implicitly called and any program that depends on the side effects produced by the destructor has undefined behavior.

Before the lifetime of an object has started but after the storage which the object will occupy has been allocated or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any pointer that represents the address of the storage location where the object will be or was located may be used but only in limited ways. For an object under construction or destruction, see 11.9.4. Otherwise, such a pointer refers to allocated storage (6.6.5.4.1), and using the pointer as if the pointer were of type void* is well-defined. Indirection through such a pointer is permitted but the resulting value may only be used in limited ways, as described below. The program has undefined behavior if:

- \((6.1)\) the object will be or was of a class type with a non-trivial destructor and the pointer is used as the operand of a delete-expression,

---

30) Under the “as-if” rule an implementation is allowed to store two objects at the same machine address or not store an object at all if the program cannot observe the difference (6.8.1).

31) For example, before the construction of a global object that is initialized via a user-provided constructor (11.9.4).
the pointer is used to access a non-static data member or call a non-static member function of the
object, or
— the pointer is implicitly converted (7.3.11) to a pointer to a virtual base class, or
— the pointer is used as the operand of a \texttt{static\_cast} (7.6.1.8), except when the conversion is to pointer
to \texttt{cv\ void}, or to pointer to \texttt{cv\ void} and subsequently to pointer to \texttt{cv\ char}, \texttt{cv\ unsigned\ char}, or
\texttt{cv\ std::byte} (17.2.1), or
— the pointer is used as the operand of a \texttt{dynamic\_cast} (7.6.1.6).

\textbf{Example:}

```cpp
#include <cstdlib>

struct B {
    virtual void f();
    void mutate();
    virtual ~B();
};

struct D1 : B { void f(); };
struct D2 : B { void f(); };

void B::mutate() {
    new (this) D2; // reuses storage — ends the lifetime of \*:this
    f(); // undefined behavior
    ... = this; // OK, \*:this points to valid memory
}

void g() {
    void* p = std::malloc(sizeof(D1) + sizeof(D2));
    B* pb = new (p) D1;
    pb->mutate();
    *pb; // OK: pb points to valid memory
    void* q = pb; // OK: pb points to valid memory
    pb->f(); // undefined behavior, lifetime of \*:pb has ended
}
```

Similarly, before the lifetime of an object has started but after the storage which the object will occupy has
been allocated or, after the lifetime of an object has ended and before the storage which the object occupied
is reused or released, any \texttt{glvalue} that refers to the original object may be used but only in limited ways.
For an object under construction or destruction, see 11.9.4. Otherwise, such a \texttt{glvalue} refers to allocated
storage (6.6.5.4.1), and using the properties of the \texttt{glvalue} that do not depend on its value is well-defined.
The program has undefined behavior if:

— the \texttt{glvalue} is used to access the object, or
— the \texttt{glvalue} is used to call a non-static member function of the object, or
— the \texttt{glvalue} is bound to a reference to a virtual base class (9.3.3), or
— the \texttt{glvalue} is used as the operand of a \texttt{dynamic\_cast} (7.6.1.6) or as the operand of \texttt{typeid}.

If, after the lifetime of an object has ended and before the storage which the object occupied is reused or
released, a new object is created at the storage location which the original object occupied, a pointer that
pointed to the original object, a reference that referred to the original object, or the name of the original
object will automatically refer to the new object and, once the lifetime of the new object has started, can be
used to manipulate the new object, if:

— the storage for the new object exactly overlays the storage location which the original object occupied, and
— the new object is of the same type as the original object (ignoring the top-level \texttt{cv}-qualifiers), and
— the type of the original object is not \texttt{const}-qualified, and, if a class type, does not contain any non-static
data member whose type is \texttt{const}-qualified or a reference type, and
— neither the original object nor the new object is a \texttt{potentially-overlapping\ subobject} (6.6.2).
Example:

```c
struct C {
    int i;
    void f();
    const C& operator=( const C& );
};

const C& C::operator=( const C& other) {
    if ( this != &other ) {
        this->~C(); // lifetime of *this ends
        new (this) C(other); // new object of type C created
        f(); // well-defined
    }
    return *this;
}
```

C c1;
C c2;
c1 = c2; // well-defined
c1.f(); // well-defined; c1 refers to a new object of type C

— end example

Note: If these conditions are not met, a pointer to the new object can be obtained from a pointer that represents the address of its storage by calling `std::laundry (17.6). — end note

If a program ends the lifetime of an object of type `T` with static (6.6.5.1), thread (6.6.5.2), or automatic (6.6.5.3) storage duration and if `T` has a non-trivial destructor, the program must ensure that an object of the original type occupies that same storage location when the implicit destructor call takes place; otherwise the behavior of the program is undefined. This is true even if the block is exited with an exception. Example:

```c
class T { }
struct B {
    ~B();
};

void h() {
    B b;
    new (&b) T;
} // undefined behavior at block exit

— end example
```

Creating a new object within the storage that a const complete object with static, thread, or automatic storage duration occupies, or within the storage that such a const object used to occupy before its lifetime ended, results in undefined behavior. Example:

```c
struct B {
    B();
    ~B();
};

const B b;

void h() {
    b.~B();
    new (const_cast<B*>(&b)) const B; // undefined behavior
}

— end example
```

In this subclause, “before” and “after” refer to the “happens before” relation (6.8.2). Note: Therefore, undefined behavior results if an object that is being constructed in one thread is referenced from another thread without adequate synchronization. — end note

32) That is, an object for which a destructor will be called implicitly—upon exit from the block for an object with automatic storage duration, upon exit from the thread for an object with thread storage duration, or upon exit from the program for an object with static storage duration.

§ 6.6.3
6.6.4 Indeterminate values

1 When storage for an object with automatic or dynamic storage duration is obtained, the object has an indeterminate value, and if no initialization is performed for the object, that object retains an indeterminate value until that value is replaced (7.6.19). [Note: Objects with static or thread storage duration are zero-initialized, see 6.8.3.2. — end note]

2 If an indeterminate value is produced by an evaluation, the behavior is undefined except in the following cases:

   (2.1) — If an indeterminate value of unsigned ordinary character type (6.7.1) or std::byte type (17.2.1) is produced by the evaluation of:
   
      (2.1.1) — the second or third operand of a conditional expression (7.6.16),
   
      (2.1.2) — the right operand of a comma expression (7.6.20),
   
      (2.1.3) — the operand of a cast or conversion (7.3.8, 7.6.1.3, 7.6.1.8, 7.6.3) to an unsigned ordinary character type or std::byte type (17.2.1), or
   
      (2.1.4) — a discarded-value expression (7.2.3),
   
      then the result of the operation is an indeterminate value.

   (2.2) — If an indeterminate value of unsigned ordinary character type or std::byte type is produced by the evaluation of the right operand of a simple assignment operator (7.6.19) whose first operand is an lvalue of unsigned ordinary character type or std::byte type, an indeterminate value replaces the value of the object referred to by the left operand.

   (2.3) — If an indeterminate value of unsigned ordinary character type is produced by the evaluation of the initialization expression when initializing an object of unsigned ordinary character type, that object is initialized to an indeterminate value.

   (2.4) — If an indeterminate value of unsigned ordinary character type or std::byte type is produced by the evaluation of the initialization expression when initializing an object of std::byte type, that object is initialized to an indeterminate value.

[Example:

```c
int f(bool b) {
    unsigned char c;
    unsigned char d = c;   // OK, d has an indeterminate value
    int e = d;              // undefined behavior
    return b ? d : 0;       // undefined behavior if b is true
}
```

— end example]

6.6.5 Storage duration

1 The storage duration is the property of an object that defines the minimum potential lifetime of the storage containing the object. The storage duration is determined by the construct used to create the object and is one of the following:

   (1.1) — static storage duration

   (1.2) — thread storage duration

   (1.3) — automatic storage duration

   (1.4) — dynamic storage duration

2 Static, thread, and automatic storage durations are associated with objects introduced by declarations (6.1) and implicitly created by the implementation (6.6.7). The dynamic storage duration is associated with objects created by a new-expression (7.6.2.7).

3 The storage duration categories apply to references as well.

4 When the end of the duration of a region of storage is reached, the values of all pointers representing the address of any part of that region of storage become invalid pointer values (6.7.2). Indirection through an invalid pointer value and passing an invalid pointer value to a deallocation function have undefined behavior. Any other use of an invalid pointer value has implementation-defined behavior.33

33 Some implementations might define that copying an invalid pointer value causes a system-generated runtime fault.
6.6.5.1 Static storage duration

All variables which do not have dynamic storage duration, do not have thread storage duration, and are not local have static storage duration. The storage for these entities shall last for the duration of the program (6.8.3.2, 6.8.3.4).

If a variable with static storage duration has initialization or a destructor with side effects, it shall not be eliminated even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in 11.9.5.

The keyword `static` can be used to declare a local variable with static storage duration. [Note: 8.7 describes the initialization of local static variables; 6.8.3.4 describes the destruction of local static variables. — end note]

The keyword `static` applied to a class data member in a class definition gives the data member static storage duration.

6.6.5.2 Thread storage duration

All variables declared with the `thread_local` keyword have thread storage duration. The storage for these entities shall last for the duration of the thread in which they are created. There is a distinct object or reference per thread, and use of the declared name refers to the entity associated with the current thread.

A variable with thread storage duration shall be initialized before its first odr-use (6.2) and, if constructed, shall be destroyed on thread exit.

6.6.5.3 Automatic storage duration

Block-scope variables not explicitly declared `static`, `thread_local`, or `extern` have automatic storage duration. The storage for these entities lasts until the block in which they are created exits.

[Note: These variables are initialized and destroyed as described in 8.7. — end note]

If a variable with automatic storage duration has initialization or a destructor with side effects, an implementation shall not destroy it before the end of its block nor eliminate it as an optimization, even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in 11.9.5.

6.6.5.4 Dynamic storage duration

Objects can be created dynamically during program execution (6.8.1), using `new-expressions` (7.6.2.7), and destroyed using `delete-expressions` (7.6.2.8). A C++ implementation provides access to, and management of, dynamic storage via the global allocation functions operator new and operator new[] and the global deallocation functions operator delete and operator delete[]. [Note: The non-allocating forms described in 17.6.2.3 do not perform allocation or deallocation. — end note]

The library provides default definitions for the global allocation and deallocation functions. Some global allocation and deallocation functions are replaceable (17.6.2). A C++ program shall provide at most one definition of a replaceable allocation or deallocation function. Any such function definition replaces the default version provided in the library (16.5.4.6). The following allocation and deallocation functions (17.6) are implicitly declared in global scope in each translation unit of a program.

```cpp
[[nodiscard]] void* operator new(std::size_t);
[[nodiscard]] void* operator new(std::size_t, std::align_val_t);

void operator delete(void*) noexcept;
void operator delete(void*, std::size_t) noexcept;
void operator delete(void*, std::align_val_t) noexcept;
void operator delete(void*, std::size_t, std::align_val_t) noexcept;

[[nodiscard]] void* operator new[](std::size_t);
[[nodiscard]] void* operator new[](std::size_t, std::align_val_t);

void operator delete[](void*) noexcept;
void operator delete[](void*, std::size_t) noexcept;
void operator delete[](void*, std::align_val_t) noexcept;
void operator delete[](void*, std::size_t, std::align_val_t) noexcept;
```

These implicit declarations introduce only the function names `operator new`, `operator new[]`, `operator delete`, and `operator delete[]`. [Note: The implicit declarations do not introduce the names `std`,
std::size_t, std::align_val_t, or any other names that the library uses to declare these names. Thus, a new-expression, delete-expression or function call that refers to one of these functions without including the header <new> is well-formed. However, referring to std or std::size_t or std::align_val_t is ill-formed unless the name has been declared by including the appropriate header. — end note] Allocation and/or deallocation functions may also be declared and defined for any class (11.11).

If the behavior of an allocation or deallocation function does not satisfy the semantic constraints specified in 6.6.5.4.1 and 6.6.5.4.2, the behavior is undefined.

### 6.6.5.4.1 Allocation functions [basic.stc.dynamic.allocation]

1 An allocation function shall be a class member function or a global function; a program is ill-formed if an allocation function is declared in a namespace scope other than global scope or declared static in global scope. The return type shall be void*. The first parameter shall have type std::size_t (17.2). The first parameter shall not have an associated default argument (9.2.3.6). The value of the first parameter is interpreted as the requested size of the allocation. An allocation function can be a function template. Such a template shall declare its return type and first parameter as specified above (that is, template parameter types shall not be used in the return type and first parameter type). Template allocation functions shall have two or more parameters.

2 An allocation function attempts to allocate the requested amount of storage. If it is successful, it returns the address of the start of a block of storage whose length in bytes is at least as large as the requested size. The order, contiguity, and initial value of storage allocated by successive calls to an allocation function are unspecified. For an allocation function other than a reserved placement allocation function (17.6.2.3), the pointer returned is suitably aligned so that it can be converted to a pointer to any suitable complete object type (17.6.2.1) and then used to access the object or array in the storage allocated (until the storage is explicitly deallocated by a call to a corresponding deallocation function). Even if the size of the space requested is zero, the request can fail. If the request succeeds, the value returned by a replaceable allocation function is a non-null pointer value (7.3.11) p1 different from any previously returned value p2 unless that value p1 was subsequently passed to a replaceable deallocation function. Furthermore, for the library allocation functions in 17.6.2.1 and 17.6.2.2, p0 represents the address of a block of storage disjoint from the storage for any other object accessible to the caller. The effect of indirecting through a pointer returned from a request for zero size is undefined. 

3 An allocation function that fails to allocate storage can invoke the currently installed new-handler function (17.6.3.3), if any. [Note: A program-supplied allocation function can obtain the address of the currently installed new_handler using the std::get_new_handler function (17.6.3.5). — end note] An allocation function that has a non-throwing exception specification (14.4) indicates failure by returning a null pointer value. Any other allocation function never returns a null pointer value and indicates failure only by throwing an exception (14.1) of a type that would match a handler (14.3) of type std::bad_alloc (17.6.3.1).

4 A global allocation function is only called as the result of a new expression (7.6.2.7), or called directly using the function call syntax (7.6.1.2), or called indirectly to allocate storage for a coroutine state (9.4.4), or called indirectly through calls to the functions in the C++ standard library. [Note: In particular, a global allocation function is not called to allocate storage for objects with static storage duration (6.6.5.1), for objects or references with thread storage duration (6.6.5.2), for objects of type std::type_info (7.6.1.7), or for an exception object (14.1). — end note]

### 6.6.5.4.2 Deallocation functions [basic.stc.dynamic.deallocation]

1 Deallocation functions shall be class member functions or global functions; a program is ill-formed if deallocation functions are declared in a namespace scope other than global scope or declared static in global scope.

2 A deallocation function is a destroying operator delete if it has at least two parameters and its second parameter is of type std::destroying_delete_t. A destroying operator delete shall be a class member function named operator delete. [Note: Array deletion cannot use a destroying operator delete. — end note]

3 Each deallocation function shall return void. If the function is a destroying operator delete declared in class type C, the type of its first parameter shall be C*; otherwise, the type of its first parameter shall be void*. A

---

34 The intent is to have operator new() implementable by calling std::malloc() or std::calloc(), so the rules are substantially the same. C++ differs from C in requiring a zero request to return a non-null pointer.
A deallocating function may have more than one parameter. A usual deallocating function is a deallocating function whose parameters after the first are

1. optionally, a parameter of type `std::destroying_delete_t`, then
2. optionally, a parameter of type `std::size_t`, then
3. optionally, a parameter of type `std::align_val_t`.

A destroying operator delete shall be a usual deallocating function. A deallocating function may be an instance of a function template. Neither the first parameter nor the return type shall depend on a template parameter. A deallocating function template shall have two or more function parameters. A template instance is never a usual deallocating function, regardless of its signature.

4. If a deallocating function terminates by throwing an exception, the behavior is undefined. The value of the first argument supplied to a deallocating function may be a null pointer value; if so, and if the deallocating function is one supplied in the standard library, the call has no effect.

5. If the argument given to a deallocating function in the standard library is a pointer that is not the null pointer value, the deallocating function shall deallocate the storage referenced by the pointer, ending the duration of the region of storage.

### 6.6.5.4.3 Safely-derived pointers

A traceable pointer object is

1. an object of an object pointer type (6.7.2), or
2. an object of an integral type that is at least as large as `std::intptr_t`, or
3. a sequence of elements in an array of narrow character type (6.7.1), where the size and alignment of the sequence match those of some object pointer type.

A pointer value is a safely-derived pointer to a dynamic object only if it has an object pointer type and it is one of the following:

1. the value returned by a call to the C++ standard library implementation of `::operator new(std::size_t)` or `::operator new(std::size_t, std::align_val_t)`;
2. the result of taking the address of an object (or one of its subobjects) designated by an lvalue resulting from indirection through a safely-derived pointer value;
3. the result of well-defined pointer arithmetic (7.6.6) using a safely-derived pointer value;
4. the result of a well-defined pointer conversion (7.3.11, 7.6.3) of a safely-derived pointer value;
5. the result of a reinterpret_cast of a safely-derived pointer value;
6. the result of a reinterpret_cast of an integer representation of a safely-derived pointer value;
7. the value of an object whose value was copied from a traceable pointer object, where at the time of the copy the source object contained a copy of a safely-derived pointer value.

An integer value is an integer representation of a safely-derived pointer only if its type is at least as large as `std::intptr_t` and it is one of the following:

1. the result of a reinterpret_cast of a safely-derived pointer value;
2. the result of a valid conversion of an integer representation of a safely-derived pointer value;
3. the value of an object whose value was copied from a traceable pointer object, where at the time of the copy the source object contained an integer representation of a safely-derived pointer value;
4. the result of an additive or bitwise operation, one of whose operands is an integer representation of a safely-derived pointer value, if that result converted by reinterpret_cast<void*>(P) would compare equal to a safely-derived pointer computable from reinterpret_cast<void*>(P).

An implementation may have relaxed pointer safety, in which case the validity of a pointer value does not depend on whether it is a safely-derived pointer value. Alternatively, an implementation may have strict

---

35) The global `operator delete(void*, std::size_t)` precludes use of an allocation function `void operator new(std::size_t, std::size_t)` as a placement allocation function (C.3.2).

36) This subclause does not impose restrictions on indirection through pointers to memory not allocated by `::operator new`. This maintains the ability of many C++ implementations to use binary libraries and components written in other languages. In particular, this applies to C binaries, because indirection through pointers to memory allocated by `std::malloc` is not restricted.
pointer safety, in which case a pointer value referring to an object with dynamic storage duration that is not a safely-derived pointer value is an invalid pointer value unless the referenced complete object has previously been declared reachable (20.10.5). [Note: The effect of using an invalid pointer value (including passing it to a deallocation function) is undefined, see 6.6.5. This is true even if the unsafely-derived pointer value might compare equal to some safely-derived pointer value. — end note] It is implementation-defined whether an implementation has relaxed or strict pointer safety.

6.6.5.5 Duration of subobjects [basic.stc.inherit]

The storage duration of subobjects and reference members is that of their complete object (6.6.2).

6.6.6 Alignment [basic.align]

Object types have alignment requirements (6.7.1, 6.7.2) which place restrictions on the addresses at which an object of that type may be allocated. An alignment is an implementation-defined integer value representing the number of bytes between successive addresses at which a given object can be allocated. An object type imposes an alignment requirement on every object of that type; stricter alignment can be requested using the alignment specifier (9.11.2).

A fundamental alignment is represented by an alignment less than or equal to the greatest alignment supported by the implementation in all contexts, which is equal to \texttt{alignof(std::max\_align\_t)} (17.2). The alignment required for a type might be different when it is used as the type of a complete object and when it is used as the type of a subobject. [Example:

```
struct B { long double d; }
struct D : virtual B { char c; }
```

When D is the type of a complete object, it will have a subobject of type B, so it must be aligned appropriately for a \texttt{long double}. If D appears as a subobject of another object that also has B as a virtual base class, the B subobject might be part of a different subobject, reducing the alignment requirements on the D subobject. — end example] The result of the \texttt{alignof} operator reflects the alignment requirement of the type in the complete-object case.

An extended alignment is represented by an alignment greater than \texttt{alignof(std::max\_align\_t)}. It is implementation-defined whether any extended alignments are supported and the contexts in which they are supported (9.11.2). A type having an extended alignment requirement is an over-aligned type. [Note: Every over-aligned type is or contains a class type to which extended alignment applies (possibly through a non-static data member). — end note] A new-extended alignment is represented by an alignment greater than \texttt{__STDCPP\_DEFAULT\_NEW\_ALIGNMENT__} (15.10).

Alignments are represented as values of the type \texttt{std::size\_t}. Valid alignments include only those values returned by an \texttt{alignof} expression for the fundamental types plus an additional implementation-defined set of values, which may be empty. Every alignment value shall be a non-negative integral power of two.

Alignments have an order from weaker to stronger or stricter alignments. Stricter alignments have larger alignment values. An address that satisfies an alignment requirement also satisfies any weaker valid alignment requirement.

The alignment requirement of a complete type can be queried using an \texttt{alignof} expression (7.6.2.5). Furthermore, the narrow character types (6.7.1) shall have the weakest alignment requirement. [Note: This enables the ordinary character types to be used as the underlying type for an aligned memory area (9.11.2). — end note]

Comparing alignments is meaningful and provides the obvious results:

(7.1) — Two alignments are equal when their numeric values are equal.

(7.2) — Two alignments are different when their numeric values are not equal.

(7.3) — When an alignment is larger than another it represents a stricter alignment.

[Note: The runtime pointer alignment function (20.10.6) can be used to obtain an aligned pointer within a buffer; the aligned-storage templates in the library (20.15.7.6) can be used to obtain aligned storage. — end note]

If a request for a specific extended alignment in a specific context is not supported by an implementation, the program is ill-formed.
6.6.7 Temporary objects

Temporary objects are created

1. when a prvalue is converted to an xvalue (7.3.4),
2. when needed by the implementation to pass or return an object of trivially-copyable type (see below), and
3. when throwing an exception (14.1). [Note: The lifetime of exception objects is described in 14.1. — end note]

Even when the creation of the temporary object is unevaluated (7.2), all the semantic restrictions shall be respected as if the temporary object had been created and later destroyed. [Note: This includes accessibility (11.8) and whether it is deleted, for the constructor selected and for the destructor. However, in the special case of the operand of a decltype-specifier (7.6.1.2), no temporary is introduced, so the foregoing does not apply to such a prvalue. — end note]

The materialization of a temporary object is generally delayed as long as possible in order to avoid creating unnecessary temporary objects. [Note: Temporary objects are materialized:

1. when binding a reference to a prvalue (9.3.3, 7.6.1.3, 7.6.1.6, 7.6.1.8, 7.6.1.10, 7.6.3),
2. when performing member access on a class prvalue (7.6.1.4, 7.6.4),
3. when performing an array-to-pointer conversion or subscripting on an array prvalue (7.3.2, 7.6.1.1),
4. when initializing an object of type std::initializer_list<T> from a braced-init-list (9.3.4),
5. for certain unevaluated operands (7.6.1.7, 7.6.2.4), and
6. when a prvalue that has type other than cv void appears as a discarded-value expression (7.2).
— end note]

Example: Consider the following code:

```cpp
class X {
public:
    X(int);
    X(const X&);
    X& operator=(const X&);
    ~X();
};
class Y {
public:
    Y(int);
    Y(Y&&);
    ~Y();
};

X f(X);
Y g(Y);

void h() {
    X a(1);
    X b = f(X(2));
    Y c = g(Y(3));
    a = f(a);
}
```

X(2) is constructed in the space used to hold f()’s argument and Y(3) is constructed in the space used to hold g()’s argument. Likewise, f()’s result is constructed directly in b and g()’s result is constructed directly in c. On the other hand, the expression a = f(a) requires a temporary for the result of f(a), which is materialized so that the reference parameter of A::operator=(const A&) can bind to it. — end example]

When an object of class type X is passed to or returned from a function, if each copy constructor, move constructor, and destructor of X is either trivial or deleted, and X has at least one non-deleted copy or move constructor, implementations are permitted to create a temporary object to hold the function parameter or result object. The temporary object is constructed from the function argument or return value, respectively, and the function’s parameter or return object is initialized as if by using the non-deleted trivial constructor to copy the temporary (even if that constructor is inaccessible or would not be selected by overload resolution
to perform a copy or move of the object). \([\text{Note: This latitude is granted to allow objects of class type to be passed to or returned from functions in registers. — end note]}\]

4 When an implementation introduces a temporary object of a class that has a non-trivial constructor (11.3.4.1, 11.3.4.2), it shall ensure that a constructor is called for the temporary object. Similarly, the destructor shall be called for a temporary with a non-trivial destructor (11.3.6). Temporary objects are destroyed as the last step in evaluating the full-expression (6.8.1) that (lexically) contains the point where they were created. This is true even if that evaluation ends in throwing an exception. The value computations and side effects of destroying a temporary object are associated only with the full-expression, not with any specific subexpression.

5 There are three contexts in which temporaries are destroyed at a different point than the end of the full-expression. The first context is when a default constructor is called to initialize an element of an array with no corresponding initializer (9.3). The second context is when a copy constructor is called to copy an element of an array while the entire array is copied (7.5.5.2, 11.3.4.2). In either case, if the constructor has one or more default arguments, the destruction of every temporary created in a default argument is sequenced before the construction of the next array element, if any.

6 The third context is when a reference is bound to a temporary object.\(^{37}\) The temporary object to which the reference is bound or the temporary object that is the complete object of a subobject to which the reference is bound persists for the lifetime of the reference if the glvalue to which the reference is bound was obtained through one of the following:

\((6.1)\) a temporary materialization conversion (7.3.4),
\((6.2)\) \((\text{expression})\), where \text{expression} is one of these expressions,
\((6.3)\) subscripting (7.6.1.1) of an array operand, where that operand is one of these expressions,
\((6.4)\) a class member access (7.6.1.4) using the . operator where the left operand is one of these expressions and the right operand designates a non-static data member of non-reference type,
\((6.5)\) a pointer-to-member operation (7.6.4) using the .* operator where the left operand is one of these expressions and the right operand is a pointer to data member of non-reference type,
\((6.6)\) a
\((6.6.1)\) \(\text{const\_cast}\) (7.6.1.10),
\((6.6.2)\) \(\text{static\_cast}\) (7.6.1.8),
\((6.6.3)\) \(\text{dynamic\_cast}\) (7.6.1.6), or
\((6.6.4)\) \(\text{reinterpret\_cast}\) (7.6.1.9)
converting, without a user-defined conversion, a glvalue operand that is one of these expressions to a glvalue that refers to the object designated by the operand, or to its complete object or a subobject thereof,
\((6.7)\) a conditional expression (7.6.16) that is a glvalue where the second or third operand is one of these expressions, or
\((6.8)\) a comma expression (7.6.20) that is a glvalue where the right operand is one of these expressions.

[Example:
\[
\begin{verbatim}
template<typename T> using id = T;

int i = 1;
int&& a = id<int[3]>(\{1, 2, 3\})[i]; // temporary array has same lifetime as a
const int& b = static_cast<const int&>(0); // temporary int has same lifetime as b
int&& c = cond ? id<int[3]>(\{1, 2, 3\})[i] : static_cast<int&&>(0);
// exactly one of the two temporaries is lifetime-extended
\end{verbatim}
\]—end example] [Note: An explicit type conversion (7.6.1.3, 7.6.3) is interpreted as a sequence of elementary casts, covered above. [Example:
\[
\begin{verbatim}
const int& x = (const int&)1; // temporary for value 1 has same lifetime as x
\end{verbatim}
\]—end example] [Note: If a temporary object has a reference member initialized by another temporary object, lifetime extension applies recursively to such a member’s initializer. [Example:
\[
\begin{verbatim}
\]
\]—end note]

\(^{37}\) The same rules apply to initialization of an \text{initializer\_list} object (9.3.4) with its underlying temporary array.
struct S {
    const int& m;
};
const S& s = S{1}; // both S and int temporaries have lifetime of s
— end example] — end note]

The exceptions to this lifetime rule are:

(6.9) — A temporary object bound to a reference parameter in a function call (7.6.1.2) persists until the
completion of the full-expression containing the call.

(6.10) — A temporary object bound to a reference element of an aggregate of class type initialized from a
parenthesized expression-list (9.3) persists until the completion of the full-expression containing the
expression-list.

(6.11) — The lifetime of a temporary bound to the returned value in a function return statement (8.6.3) is not
extended; the temporary is destroyed at the end of the full-expression in the return statement.

(6.12) — A temporary bound to a reference in a new-initializer (7.6.2.7) persists until the completion of the
full-expression containing the new-initializer. [Note: This may introduce a dangling reference. — end
note] [Example:

struct S { int mi; const std::pair<int,int>& mp; };  
S a { 1, {2,3} };  
S* p = new S{ 1, {2,3} }; // creates dangling reference
— end example]

7 The destruction of a temporary whose lifetime is not extended by being bound to a reference is sequenced
before the destruction of every temporary which is constructed earlier in the same full-expression. If the
lifetime of two or more temporaries to which references are bound ends at the same point, these temporaries
are destroyed at that point in the reverse order of the completion of their construction. In addition, the
destruction of temporaries bound to references shall take into account the ordering of destruction of objects
with static, thread, or automatic storage duration (6.6.5.1, 6.6.5.2, 6.6.5.3); that is, if obj1 is an object with
the same storage duration as the temporary and created before the temporary is created the temporary shall
be destroyed before obj1 is destroyed; if obj2 is an object with the same storage duration as the temporary
and created after the temporary is created the temporary shall be destroyed before obj2 is destroyed.

8 [Example:

struct S {  
    S();  
    S(int);  
    friend S operator+(const S&, const S&);  
    ~S();  
};  
S obj1;  
const S& cr = S(16)+S(23);  
S obj2;

The expression S(16) + S(23) creates three temporaries: a first temporary T1 to hold the result of the
expression S(16), a second temporary T2 to hold the result of the expression S(23), and a third temporary T3
to hold the result of the addition of these two expressions. The temporary T3 is then bound to the reference
cr. It is unspecified whether T1 or T2 is created first. On an implementation where T1 is created before
T2, T2 shall be destroyed before T1. The temporaries T1 and T2 are bound to the reference parameters of
operator+; these temporaries are destroyed at the end of the full-expression containing the call to operator+.
The temporary T3 bound to the reference cr is destroyed at the end of cr’s lifetime, that is, at the end of the
program. In addition, the order in which T3 is destroyed takes into account the destruction order of other
objects with static storage duration. That is, because obj1 is constructed before T3, and T3 is constructed
before obj2, obj2 shall be destroyed before T3, and T3 shall be destroyed before obj1. — end example]

6.7 Types [basic.types]

1 [Note: 6.7 and the subclauses thereof impose requirements on implementations regarding the representation
of types. There are two kinds of types: fundamental types and compound types. Types describe objects (6.6.2),
references (9.2.3.2), or functions (9.2.3.5). — end note]
For any object (other than a potentially-overlapping subobject) of trivially copyable type \( T \), whether or not the object holds a valid value of type \( T \), the underlying bytes (6.6.1) making up the object can be copied into an array of `char`, `unsigned char`, or `std::byte` (17.2.1). If the content of that array is copied back into the object, the object shall subsequently hold its original value. [Example:

```cpp
#define N sizeof(T)
char buf[N];
T obj; // obj initialized to its original value
std::memcpy(buf, &obj, N); // between these two calls to std::memcpy, obj might be modified
std::memcpy(&obj, buf, N); // at this point, each subobject of obj of scalar type holds its original value
— end example]
```

For any trivially copyable type \( T \), if two pointers to \( T \) point to distinct \( T \) objects \( \text{obj1} \) and \( \text{obj2} \), where neither \( \text{obj1} \) nor \( \text{obj2} \) is a potentially-overlapping subobject, if the underlying bytes (6.6.1) making up \( \text{obj1} \) are copied into \( \text{obj2} \), \( \text{obj2} \) shall subsequently hold the same value as \( \text{obj1} \). [Example:

```cpp
T* t1p;
T* t2p;
// provided that t2p points to an initialized object ...
std::memcpy(t1p, t2p, sizeof(T)); // at this point, every subobject of trivially copyable type in *t1p contains
// the same value as the corresponding subobject in *t2p
— end example]
```

The object representation of an object of type \( T \) is the sequence of \( N \) `unsigned char` objects taken up by the object of type \( T \), where \( N \) equals `sizeof(T)`. The value representation of an object of type \( T \) is the set of bits that participate in representing a value of type \( T \). Bits in the object representation that are not part of the value representation are padding bits. For trivially copyable types, the value representation is a set of bits in the object representation that determines a `value`, which is one discrete element of an implementation-defined set of values.  

A class that has been declared but not defined, an enumeration type in certain contexts (9.6), or an array of unknown bound or of incomplete element type, is an incompletely-defined object type. Incompletely-defined object types and \texttt{cv void} are incomplete types (6.7.1). Objects shall not be defined to have an incomplete type.

A class type (such as “\texttt{class X}”) might be incomplete at one point in a translation unit and complete later on; the type “\texttt{class X}” is the same type at both points. The declared type of an array object might be an array of incomplete class type and therefore incomplete; if the class type is completed later on in the translation unit, the array type becomes complete; the array type at those two points is the same type. The declared type of an array object might be an array of unknown bound and therefore be incomplete at one point in a translation unit and complete later on; the array types at those two points (“array of unknown bound of \( T \)” and “array of \( N \) \( T \)” are different types. The type of a pointer to an array of unknown bound, or of a type defined by a \texttt{typedef} declaration to be an array of unknown bound, cannot be completed. [Example:

```cpp
class X; // X is an incomplete type
extern X* xp; // xp is a pointer to an incomplete type
extern int arr[]; // the type of arr is incomplete
typedef int UNKA[]; // UNKA is an incomplete type
UNKA* arrp; // arrp is a pointer to an incomplete type
UNKA** arrpp;

void foo() {
  xp++; // ill-formed: X is incomplete
  arrp++; // ill-formed: incomplete type
  arrpp++; // OK: sizeof UNKA* is known
}

struct X { int i; }; // now X is a complete type
int arr[10]; // now the type of arr is complete
```

38) By using, for example, the library functions (16.5.1.2) \texttt{std::memcpy} or \texttt{std::memmove}.
39) By using, for example, the library functions (16.5.1.2) \texttt{std::memcpy} or \texttt{std::memmove}.
40) The intent is that the memory model of C++ is compatible with that of ISO/IEC 9899 Programming Language C.
41) The size and layout of an instance of an incompletely-defined object type is unknown.

§ 6.7
X x;
void bar() {
    xp = &x;  // OK; type is “pointer to X”
    arrp = &arr;  // ill-formed: different types
    xp++;  // OK: X is complete
    arrp++;  // ill-formed: UNK can’t be completed
}

—end example—

7 [Note: The rules for declarations and expressions describe in which contexts incomplete types are prohibited. —end note]

8 An object type is a (possibly cv-qualified) type that is not a function type, not a reference type, and not cv void.

9 Arithmetic types (6.7.1), enumeration types, pointer types, pointer-to-member types (6.7.2), std::nullptr_t, and cv-qualified (6.7.3) versions of these types are collectively called scalar types. Scalar types, trivially copyable class types (11.1), arrays of such types, and cv-qualified versions of these types are collectively called trivially copyable types. Scalar types, trivial class types (11.1), arrays of such types and cv-qualified versions of these types are collectively called trivial types. Scalar types, standard-layout class types (11.1), arrays of such types and cv-qualified versions of these types are collectively called standard-layout types.

10 A type is a literal type if it is:

    (10.1) possibly cv-qualified void; or
    (10.2) a scalar type; or
    (10.3) a reference type; or
    (10.4) an array of literal type; or
    (10.5) a possibly cv-qualified class type (Clause 11) that has all of the following properties:

        (10.5.1) it has a trivial destructor,
        (10.5.2) it is either a closure type (7.5.5.1), an aggregate type (9.3.1), or has at least one constexpr constructor or constructor template (possibly inherited (9.8) from a base class) that is not a copy or move constructor,
        (10.5.3) if it is a union, at least one of its non-static data members is of non-volatile literal type, and
        (10.5.4) if it is not a union, all of its non-static data members and base classes are of non-volatile literal types.

    [Note: A literal type is one for which it might be possible to create an object within a constant expression. It is not a guarantee that it is possible to create such an object, nor is it a guarantee that any object of that type will be usable in a constant expression. —end note]

11 Two types cv1 T1 and cv2 T2 are layout-compatible types if T1 and T2 are the same type, layout-compatible enumerations (9.6), or layout-compatible standard-layout class types (11.3).

### 6.7.1 Fundamental types

1 There are five standard signed integer types: “signed char”, “short int”, “int”, “long int”, and “long long int”. In this list, each type provides at least as much storage as those preceding it in the list. There may also be implementation-defined extended signed integer types. The standard and extended signed integer types are collectively called signed integer types. The range of representable values for a signed integer type is \(-2^{N-1}\) to \(2^{N-1} - 1\) (inclusive), where \(N\) is called the width of the type. [Note: Plain ints are intended to have the natural size suggested by the architecture of the execution environment; the other signed integer types are provided to meet special needs. —end note]

2 For each of the standard signed integer types, there exists a corresponding (but different) standard unsigned integer type: “unsigned char”, “unsigned short int”, “unsigned int”, “unsigned long int”, and “unsigned long long int”. Likewise, for each of the extended signed integer types, there exists a corresponding extended unsigned integer type. The standard and extended unsigned integer types are collectively called unsigned integer types. An unsigned integer type has the same width \(N\) as the corresponding signed integer type. The range of representable values for the unsigned type is 0 to \(2^N - 1\) (inclusive); arithmetic for the unsigned type is performed modulo \(2^N\). [Note: Unsigned arithmetic does not overflow. Overflow for signed arithmetic yields undefined behavior (7.1). —end note]
An unsigned integer type has the same object representation, value representation, and alignment requirements (6.6.6) as the corresponding signed integer type. For each value $x$ of a signed integer type, the value of the corresponding unsigned integer type congruent to $x$ modulo $2^N$ has the same value of corresponding bits in its value representation.\footnote{This is also known as two’s complement representation.} [Example: The value $-1$ of a signed integer type has the same representation as the largest value of the corresponding unsigned type. — end example]

### Table 10: Minimum width

<table>
<thead>
<tr>
<th>Type</th>
<th>Minimum width $N$</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed char</td>
<td>8</td>
</tr>
<tr>
<td>short</td>
<td>16</td>
</tr>
<tr>
<td>int</td>
<td>16</td>
</tr>
<tr>
<td>long</td>
<td>32</td>
</tr>
<tr>
<td>long long</td>
<td>64</td>
</tr>
</tbody>
</table>

The width of each signed integer type shall not be less than the values specified in Table 10. The value representation of a signed or unsigned integer type comprises $N$ bits, where $N$ is the respective width. Each set of values for any padding bits (6.7) in the object representation are alternative representations of the value specified by the value representation. [Note: Padding bits have unspecified value, but do not cause traps. See also ISO C 6.2.6.2. — end note] [Note: The signed and unsigned integer types satisfy the constraints given in ISO C 5.2.4.2.1. — end note] Except as specified above, the width of a signed or unsigned integer type is implementation-defined.

Each value $x$ of an unsigned integer type with width $N$ has a unique representation $x = x_02^0 + x_12^1 + \ldots + x_{N-1}2^{N-1}$, where each coefficient $x_i$ is either 0 or 1; this is called the base-2 representation of $x$. The base-2 representation of a value of signed integer type is the base-2 representation of the congruent value of the corresponding unsigned integer type. The standard signed integer types and standard unsigned integer types are collectively called the standard integer types, and the extended signed integer types and extended unsigned integer types are collectively called the extended integer types.

A fundamental type specified to have a signed or unsigned integer type as its underlying type has the same object representation, value representation, alignment requirements (6.6.6), and range of representable values as the underlying type. Further, each value has the same representation in both types.

Type char is a distinct type that has an implementation-defined choice of “signed char” or “unsigned char” as its underlying type. The values of type char can represent distinct codes for all members of the implementation’s basic character set. The three types char, signed char, and unsigned char are collectively called ordinary character types. The ordinary character types and char8_t are collectively called narrow character types. For narrow character types, each possible bit pattern of the object representation represents a distinct value. [Note: This requirement does not hold for other types. — end note] [Note: A bit-field of narrow character type whose width is larger than the width of that type has padding bits; see 6.7. — end note]

Type wchar_t is a distinct type that has an implementation-defined signed or unsigned integer type as its underlying type. The values of type wchar_t can represent distinct codes for all members of the largest extended character set specified among the supported locales (28.3.1).

Type char32_t denotes a distinct type whose underlying type is unsigned char. Types char16_t and char32_t denote distinct types whose underlying types are uint_least16_t and uint_least32_t, respectively, in <cstdint>.

Type bool is a distinct type that has the same object representation, value representation, and alignment requirements as an implementation-defined unsigned integer type. The values of type bool are true and false. [Note: There are no signed, unsigned, short, or long bool types or values. — end note]

Types bool, char, wchar_t, char8_t, char16_t, char32_t, and the signed and unsigned integer types are collectively called integral types. A synonym for integral type is integer type. [Note: Enumerations (9.6) are not integral; however, unscoped enumerations can be promoted to integral types as specified in 7.3.6. — end note]

There are three floating-point types: float, double, and long double. The type double provides at least as much precision as float, and the type long double provides at least as much precision as double. The
set of values of the type float is a subset of the set of values of the type double; the set of values of the type double is a subset of the set of values of the type long double. The value representation of floating-point types is implementation-defined. [Note: This document imposes no requirements on the accuracy of floating-point operations; see also 17.3. — end note] Integral and floating-point types are collectively called arithmetic types. Specializations of the standard library template std::numeric_limits (17.3) shall specify the maximum and minimum values of each arithmetic type for an implementation.

13 A type cv void is an incomplete type that cannot be completed; such a type has an empty set of values. It is used as the return type for functions that do not return a value. Any expression can be explicitly converted to type cv void (7.6.3). An expression of type cv void shall be used only as an expression statement (8.2), as an operand of a comma expression (7.6.20), as a second or third operand of ?: (7.6.16), as the operand of typeid, noexcept, or decltype, as the expression in a return statement (8.6.3) for a function with the return type cv void, or as the operand of an explicit conversion to type cv void.

14 A value of type std::nullptr_t is a null pointer constant (7.3.11). Such values participate in the pointer and the pointer-to-member conversions (7.3.11, 7.3.12). sizeof(std::nullptr_t) shall be equal to sizeof(void*).

15 The types described in this subclause are called fundamental types. [Note: Even if the implementation defines two or more fundamental types to have the same value representation, they are nevertheless different types. — end note]

6.7.2 Compound types

Compound types can be constructed in the following ways:

1 Compounds types can be constructed in the following ways:

(1.1) — arrays of objects of a given type, 9.2.3.4;
(1.2) — functions, which have parameters of given types and return void or references or objects of a given type, 9.2.3.5;
(1.3) — pointers to cv void or objects or functions (including static members of classes) of a given type, 9.2.3.1;
(1.4) — references to objects or functions of a given type, 9.2.3.2. There are two types of references:
(1.4.1) — lvalue reference
(1.4.2) — rvalue reference
(1.5) — classes containing a sequence of objects of various types (Clause 11), a set of types, enumerations and functions for manipulating these objects (11.3.1), and a set of restrictions on the access to these entities (11.8);
(1.6) — unions, which are classes capable of containing objects of different types at different times, 11.4;
(1.7) — enumerations, which comprise a set of named constant values. Each distinct enumeration constitutes a different enumerated type, 9.6;
(1.8) — pointers to non-static class members, which identify members of a given type within objects of a given class, 9.2.3.3. Pointers to data members and pointers to member functions are collectively called pointer-to-member types.

2 These methods of constructing types can be applied recursively; restrictions are mentioned in 9.2.3. Constructing a type such that the number of bytes in its object representation exceeds the maximum value representable in the type std::size_t (17.2) is ill-formed.

3 The type of a pointer to cv void or a pointer to an object type is called an object pointer type. [Note: A pointer to void does not have a pointer-to-object type, however, because void is not an object type. — end note] The type of a pointer that can designate a function is called a function pointer type. A pointer to objects of type T is referred to as a “pointer to T”. [Example: A pointer to an object of type int is referred to as “pointer to int” and a pointer to an object of class X is called a “pointer to X”. — end example] Except for pointers to static members, text referring to “pointers” does not apply to pointers to members. Pointers to incomplete types are allowed although there are restrictions on what can be done with them (6.6.6). Every value of pointer type is one of the following:

(3.1) — a pointer to an object or function (the pointer is said to point to the object or function), or
(3.2) — a pointer past the end of an object (7.6.6), or

43) Static class members are objects or functions, and pointers to them are ordinary pointers to objects or functions.
A value of a pointer type that is a pointer to or past the end of an object represents the address of the first byte in memory (6.6.1) occupied by the object\(^{44}\) or the first byte in memory after the end of the storage occupied by the object, respectively. [Note: A pointer past the end of an object (7.6.6) is not considered to point to an unrelated object of the object’s type that might be located at that address. A pointer value becomes invalid when the storage it denotes reaches the end of its storage duration; see 6.6.5. — end note] For purposes of pointer arithmetic (7.6.6) and comparison (7.6.9, 7.6.10), a pointer past the end of the last element of an array \(x\) of \(n\) elements is considered to be equivalent to a pointer to a hypothetical element \(x[n]\). The value representation of pointer types is implementation-defined. Pointers to layout-compatible types shall have the same value representation and alignment requirements (6.6.6). [Note: Pointers to over-aligned types (6.6.6) have no special representation, but their range of valid values is restricted by the extended alignment requirement. — end note]

Two objects \(a\) and \(b\) are pointer-interconvertible if:

- they are the same object, or
- one is a union object and the other is a non-static data member of that object (11.4), or
- one is a standard-layout class object and the other is the first non-static data member of that object, or, if the object has no non-static data members, any base class subobject of that object (11.3), or
- there exists an object \(c\) such that \(a\) and \(c\) are pointer-interconvertible, and \(c\) and \(b\) are pointer-interconvertible.

If two objects are pointer-interconvertible, then they have the same address, and it is possible to obtain a pointer to one from a pointer to the other via a reinterpret_cast (7.6.1.9). [Note: An array object and its first element are not pointer-interconvertible, even though they have the same address. — end note]

A pointer to cv-qualified (6.7.3) or cv-unqualified void can be used to point to objects of unknown type. Such a pointer shall be able to hold any object pointer. An object of type cv void* shall have the same representation and alignment requirements as cv char*.

### 6.7.3 CV-qualifiers

A type mentioned in 6.7.1 and 6.7.2 is a cv-unqualified type. Each type which is a cv-unqualified complete or incomplete object type or is void (6.7) has three corresponding cv-qualified versions of its type: a const-qualified version, a volatile-qualified version, and a const-volatile-qualified version. The type of an object (6.6.2) includes the cv-qualifiers specified in the decl-specifier-seq (9.1), declarator (9.2), type-id (9.2.1), or new-type-id (7.6.2.7) when the object is created.

- A const object is an object of type const T or a non-mutable subobject of a const object.
- A volatile object is an object of type volatile T or a subobject of a volatile object.
- A const volatile object is an object of type const volatile T, a non-mutable subobject of a const volatile object, a const subobject of a volatile object, or a non-mutable volatile subobject of a const object.

The cv-qualified or cv-unqualified versions of a type are distinct types; however, they shall have the same representation and alignment requirements (6.6.6).\(^{45}\)

A compound type (6.7.2) is not cv-qualified by the cv-qualifiers (if any) of the types from which it is compounded. Any cv-qualifiers applied to an array type affect the array element type (9.2.3.4).

See 9.2.3.5 and 11.3.2.1 regarding function types that have cv-qualifiers.

There is a partial ordering on cv-qualifiers, so that a type can be said to be more cv-qualified than another. Table 11 shows the relations that constitute this ordering.

In this document, the notation cv (or cv1, cv2, etc.), used in the description of types, represents an arbitrary set of cv-qualifiers, i.e., one of \{const\}, \{volatile\}, \{const, volatile\}, or the empty set. For a type cv T, the top-level cv-qualifiers of that type are those denoted by cv. [Example: The type corresponding to the type-id const int& has no top-level cv-qualifiers. The type corresponding to the type-id volatile int *

---

44) For an object that is not within its lifetime, this is the first byte in memory that it will occupy or used to occupy.

45) The same representation and alignment requirements are meant to imply interchangeability as arguments to functions, return values from functions, and non-static data members of unions.
Table 11: Relations on `const` and `volatile`  

<table>
<thead>
<tr>
<th>no cv-qualifier</th>
<th><code>const</code></th>
<th><code>volatile</code></th>
<th><code>const volatile</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>const</code></td>
<td><code>volatile</code></td>
<td><code>const volatile</code></td>
<td></td>
</tr>
<tr>
<td><code>volatile</code></td>
<td><code>const volatile</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

`const` has the top-level cv-qualifier `const`. For a class type `C`, the type corresponding to the `type-id void (C::* volatile)(int) const` has the top-level cv-qualifier `volatile`. — end example]

Cv-qualifiers applied to an array type attach to the underlying element type, so the notation “cv T”, where T is an array type, refers to an array whose elements are so-qualified. An array type whose elements are cv-qualified is also considered to have the same cv-qualifications as its elements. [Example:

typedef char CA[5];
typedef const char CC;
CC arr1[5] = { 0 };
const CA arr2 = { 0 };

The type of both `arr1` and `arr2` is “array of 5 `const char`”, and the array type is considered to be const-qualified. — end example]

6.7.4 Integer conversion rank

1 Every integer type has an integer conversion rank defined as follows:

(1.1) — No two signed integer types other than `char` and `signed char` (if `char` is signed) shall have the same rank, even if they have the same representation.

(1.2) — The rank of a signed integer type shall be greater than the rank of any signed integer type with a smaller size.

(1.3) — The rank of `long long int` shall be greater than the rank of `long int`, which shall be greater than the rank of `int`, which shall be greater than the rank of `short int`, which shall be greater than the rank of `signed char`.

(1.4) — The rank of any unsigned integer type shall equal the rank of the corresponding signed integer type.

(1.5) — The rank of any standard integer type shall be greater than the rank of any extended integer type with the same size.

(1.6) — The rank of `char` shall equal the rank of `signed char` and `unsigned char`.

(1.7) — The rank of `bool` shall be less than the rank of all other standard integer types.

(1.8) — The ranks of `char8_t`, `char16_t`, `char32_t`, and `wchar_t` shall equal the ranks of their underlying types (6.7.1).

(1.9) — The rank of any extended signed integer type relative to another extended signed integer type with the same size is implementation-defined, but still subject to the other rules for determining the integer conversion rank.

(1.10) — For all integer types T1, T2, and T3, if T1 has greater rank than T2 and T2 has greater rank than T3, then T1 shall have greater rank than T3.

[Note: The integer conversion rank is used in the definition of the integral promotions (7.3.6) and the usual arithmetic conversions (7.2). — end note]

6.8 Program execution

6.8.1 Sequential execution

1 An instance of each object with automatic storage duration (6.6.5.3) is associated with each entry into its block. Such an object exists and retains its last-stored value during the execution of the block and while the block is suspended (by a call of a function, suspension of a coroutine (7.6.2.3), or receipt of a signal).

2 A constituent expression is defined as follows:

(2.1) — The constituent expression of an expression is that expression.
The constituent expressions of a braced-init-list or of a (possibly parenthesized) expression-list are the constituent expressions of the elements of the respective list.

The constituent expressions of a brace-or-equal-initializer of the form = initializer-clause are the constituent expressions of the initializer-clause.

Example:
```c
struct A { int x; }
struct B { int y; struct A a; }
B b = { 5, { 1+1 } };  
```
The constituent expressions of the initializer used for the initialization of b are 5 and 1+1. — end example

The immediate subexpressions of an expression e are

- the constituent expressions of e’s operands (7.2),
- any function call that e implicitly invokes,
- if e is a lambda-expression (7.5.5), the initialization of the entities captured by copy and the constituent expressions of the initializer of the init-captures,
- if e is a function call (7.6.1.2) or implicitly invokes a function, the constituent expressions of each default argument (9.2.3.6) used in the call, or
- if e creates an aggregate object (9.3.1), the constituent expressions of each default member initializer (11.3) used in the initialization.

A subexpression of an expression e is an immediate subexpression of e or a subexpression of an immediate subexpression of e. [Note: Expressions appearing in the compound-statement of a lambda-expression are not subexpressions of the lambda-expression. — end note]

A full-expression is

- an unevaluated operand (7.2),
- a constant-expression (7.7),
- an immediate invocation (7.7),
- an init-declarator (9.2) or a mem-initializer (11.9.2), including the constituent expressions of the initializer,
- an invocation of a destructor generated at the end of the lifetime of an object other than a temporary object (6.6.7), or
- an expression that is not a subexpression of another expression and that is not otherwise part of a full-expression.

If a language construct is defined to produce an implicit call of a function, a use of the language construct is considered to be an expression for the purposes of this definition. Conversions applied to the result of an expression in order to satisfy the requirements of the language construct in which the expression appears are also considered to be part of the full-expression. For an initializer, performing the initialization of the entity (including evaluating default member initializers of an aggregate) is also considered part of the full-expression.

Example:
```c
struct S {
    S(int i): I(i) { }  // full-expression is initialization of I
    int& v() { return I; }
    ~S() noexcept(false) { }
private:
    int I;
};
S s1(1);  // full-expression comprises call of S::S(int)
void f() {
    S s2 = 2;  // full-expression comprises call of S::S(int)
    if (S(3).v())  // full-expression includes lvalue-to-rvalue and int to bool conversions,
        // performed before temporary is deleted at end of full-expression
        { }
    bool b = noexcept(S());  // exception specification of destructor of S considered for noexcept
}
// full-expression is destruction of s2 at end of block
} // end example

struct B {
    B(S = S(0));
};
B b[2] = { B(), B() }; // full-expression is the entire initialization
// including the destruction of temporaries

---

[Note: The evaluation of a full-expression can include the evaluation of subexpressions that are not lexically part of the full-expression. For example, subexpressions involved in evaluating default arguments (9.2.3.6) are considered to be created in the expression that calls the function, not the expression that defines the default argument. —end note]

---

Reading an object designated by a volatile glvalue (7.2.1), modifying an object, calling a library I/O function, or calling a function that does any of those operations are all side effects, which are changes in the state of the execution environment. Evaluation of an expression (or a subexpression) in general includes both value computations (including determining the identity of an object for glvalue evaluation and fetching a value previously assigned to an object for prvalue evaluation) and initiation of side effects. When a call to a library I/O function returns or an access through a volatile glvalue is evaluated the side effect is considered complete, even though some external actions implied by the call (such as the I/O itself) or by the volatile access may not have completed yet.

---

Sequenced before is an asymmetric, transitive, pair-wise relation between evaluations executed by a single thread (6.8.2), which induces a partial order among those evaluations. Given any two evaluations A and B, if A is sequenced before B (or, equivalently, B is sequenced after A), then the execution of A shall precede the execution of B. If A is not sequenced before B and B is not sequenced before A, then A and B are unsequenced. [Note: The execution of unsequenced evaluations can overlap. —end note] Evaluations A and B are indeterminately sequenced when either A is sequenced before B or B is sequenced before A, but it is unspecified which. [Note: Indeterminately sequenced evaluations cannot overlap, but either could be executed first. —end note] An expression X is said to be sequenced before an expression Y if every value computation and every side effect associated with the expression X is sequenced before every value computation and every side effect associated with the expression Y.

---

Every value computation and side effect associated with a full-expression is sequenced before every value computation and side effect associated with the next full-expression to be evaluated.46

---

Except where noted, evaluations of operands of individual operators and of subexpressions of individual expressions are unsequenced. [Note: In an expression that is evaluated more than once during the execution of a program, unsequenced and indeterminately sequenced evaluations of its subexpressions need not be performed consistently in different evaluations. —end note] The value computations of the operands of an operator are sequenced before the value computation of the result of the operator. If a side effect on a memory location (6.6.1) is unsequenced relative to either another side effect on the same memory location or a value computation using the value of any object in the same memory location, and they are not potentially concurrent (6.8.2), the behavior is undefined. [Note: The next subclause imposes similar, but more complex restrictions on potentially concurrent computations. —end note]

---

[Example:
void g(int i) {
    i = 7, i++, i++; // i becomes 9
    i = i++ + 1; // the value of i is incremented
    i = i++ + i; // the behavior is undefined
    i = i + 1; // the value of i is incremented
}
—end example]

---

When calling a function (whether or not the function is inline), every value computation and side effect associated with any argument expression, or with the postfix expression designating the called function, is sequenced before execution of every expression or statement in the body of the called function. For each function invocation F, for every evaluation A that occurs within F and every evaluation B that does not

---

46) As specified in 6.6.7, after a full-expression is evaluated, a sequence of zero or more invocations of destructor functions for temporary objects takes place, usually in reverse order of the construction of each temporary object.
occur within \( F \) but is evaluated on the same thread and as part of the same signal handler (if any), either \( A \) is sequenced before \( B \) or \( B \) is sequenced before \( A \). [Note: If \( A \) and \( B \) would not otherwise be sequenced then they are indeterminately sequenced. — end note] Several contexts in C++ cause evaluation of a function call, even though no corresponding function call syntax appears in the translation unit. [Example: Evaluation of a new-expression invokes one or more allocation and constructor functions; see 7.6.2.7. For another example, invocation of a conversion function (11.3.7.2) can arise in contexts in which no function call syntax appears. — end example] The sequencing constraints on the execution of the called function (as described above) are features of the function calls as evaluated, whatever the syntax of the expression that calls the function might be.

If a signal handler is executed as a result of a call to the `std::raise` function, then the execution of the handler is sequenced after the invocation of the `std::raise` function and before its return. [Note: When a signal is received for another reason, the execution of the signal handler is usually unsequenced with respect to the rest of the program. — end note]

6.8.2 Multi-threaded executions and data races

A thread of execution (also known as a thread) is a single flow of control within a program, including the initial invocation of a specific top-level function, and recursively including every function invocation subsequently executed by the thread. [Note: When one thread creates another, the initial call to the top-level function of the new thread is executed by the new thread, not by the creating thread. — end note] Every thread in a program can potentially access every object and function in a program. Every thread in a program can potentially access every object and function in a program. Under a hosted implementation, a C++ program can have more than one thread running concurrently. The execution of each thread proceeds as defined by the remainder of this document. The execution of the entire program consists of an execution of all of its threads. [Note: Usually the execution can be viewed as an interleaving of all its threads. However, some kinds of atomic operations, for example, allow executions inconsistent with a simple interleaving, as described below. — end note] Under a freestanding implementation, it is implementation-defined whether a program can have more than one thread of execution.

For a signal handler that is not executed as a result of a call to the `std::raise` function, it is unspecified which thread of execution contains the signal handler invocation.

6.8.2.1 Data races

The value of an object visible to a thread \( T \) at a particular point is the initial value of the object, a value assigned to the object by \( T \), or a value assigned to the object by another thread, according to the rules below. [Note: In some cases, there may instead be undefined behavior. Much of this subclause is motivated by the desire to support atomic operations with explicit and detailed visibility constraints. However, it also implicitly supports a simpler view for more restricted programs. — end note]

Two expression evaluations conflict if one of them modifies a memory location (6.6.1) and the other one reads or modifies the same memory location.

The library defines a number of atomic operations (Clause 31) and operations on mutexes (Clause 32) that are specially identified as synchronization operations. These operations play a special role in making assignments in one thread visible to another. A synchronization operation on one or more memory locations is either a consume operation, an acquire operation, a release operation, or both an acquire and release operation. A synchronization operation without an associated memory location is a fence and can be either an acquire fence, a release fence, or both an acquire and release fence. In addition, there are relaxed atomic operations, which are not synchronization operations, and atomic read-modify-write operations, which have special characteristics. [Note: For example, a call that acquires a mutex will perform an acquire operation on the locations comprising the mutex. Correspondingly, a call that releases the same mutex will perform a release operation on those same locations. Informally, performing a release operation on \( A \) forces prior side effects on other memory locations to become visible to other threads that later perform a consume or an acquire operation on \( A \). “Relaxed” atomic operations are not synchronization operations even though, like synchronization operations, they cannot contribute to data races. — end note]

All modifications to a particular atomic object \( M \) occur in some particular total order, called the modification order of \( M \). [Note: There is a separate order for each atomic object. There is no requirement that these can

---

47) In other words, function executions do not interleave with each other.

48) An object with automatic or thread storage duration (6.6.5) is associated with one specific thread, and can be accessed by a different thread only indirectly through a pointer or reference (6.7.2).
be combined into a single total order for all objects. In general this will be impossible since different threads may observe modifications to different objects in inconsistent orders. — end note]

5 A release sequence headed by a release operation $A$ on an atomic object $M$ is a maximal contiguous subsequence of side effects in the modification order of $M$, where the first operation is $A$, and every subsequent operation is an atomic read-modify-write operation.

6 Certain library calls synchronize with other library calls performed by another thread. For example, an atomic store-release synchronizes with a load-acquire that takes its value from the store (31.4). [Note: Except in the specified cases, reading a later value does not necessarily ensure visibility as described below. Such a requirement would sometimes interfere with efficient implementation. — end note] [Note: The specifications of the synchronization operations define when one reads the value written by another. For atomic objects, the definition is clear. All operations on a given mutex occur in a single total order. Each mutex acquisition “reads the value written” by the last mutex release. — end note]

7 An evaluation $A$ carries a dependency to an evaluation $B$ if

(7.1) — the value of $A$ is used as an operand of $B$, unless:

(7.1.1) — $B$ is an invocation of any specialization of std::kill_dependency (31.4), or

(7.1.2) — $A$ is the left operand of a built-in logical AND (&&; see 7.6.16) or logical OR (||; see 7.6.15) operator, or

(7.1.3) — $A$ is the left operand of a conditional (?) operator, or

(7.1.4) — $A$ is the left operand of the built-in comma (,) operator (7.6.20); or

(7.2) — $A$ writes a scalar object or bit-field $M$, $B$ reads the value written by $A$ from $M$, and $A$ is sequenced before $B$, or

(7.3) — for some evaluation $X$, $A$ carries a dependency to $X$, and $X$ carries a dependency to $B$.

[Note: “Carries a dependency to” is a subset of “is sequenced before”, and is similarly strictly intra-thread. — end note]

8 An evaluation $A$ is dependency-ordered before an evaluation $B$ if

(8.1) — $A$ performs a release operation on an atomic object $M$, and, in another thread, $B$ performs a consume operation on $M$ and reads a value written by any side effect in the release sequence headed by $A$, or

(8.2) — for some evaluation $X$, $A$ is dependency-ordered before $X$ and $X$ carries a dependency to $B$.

[Note: The relation “is dependency-ordered before” is analogous to “synchronizes with”, but uses release/consume in place of release/acquire. — end note]

9 An evaluation $A$ inter-thread happens before an evaluation $B$ if

(9.1) — $A$ synchronizes with $B$, or

(9.2) — $A$ is dependency-ordered before $B$, or

(9.3) — for some evaluation $X$

(9.3.1) — $A$ synchronizes with $X$ and $X$ is sequenced before $B$, or

(9.3.2) — $A$ is sequenced before $X$ and $X$ inter-thread happens before $B$, or

(9.3.3) — $A$ inter-thread happens before $X$ and $X$ inter-thread happens before $B$.

[Note: The “inter-thread happens before” relation describes arbitrary concatenations of “sequenced before”, “synchronizes with” and “dependency-ordered before” relationships, with two exceptions. The first exception is that a concatenation is not permitted to end with “dependency-ordered before” followed by “sequenced before”. The reason for this limitation is that a consume operation participating in a “dependency-ordered before” relationship provides ordering only with respect to operations to which this consume operation actually carries a dependency. The reason that this limitation applies only to the end of such a concatenation is that any subsequent release operation will provide the required ordering for a prior consume operation. The second exception is that a concatenation is not permitted to consist entirely of “sequenced before”. The reasons for this limitation are (1) to permit “inter-thread happens before” to be transitively closed and (2) the “happens before” relation, defined below, provides for relationships consisting entirely of “sequenced before”. — end note]

10 An evaluation $A$ happens before an evaluation $B$ (or, equivalently, $B$ happens after $A$) if:
There are evaluations

An evaluation \( A \) simply happens before an evaluation \( B \) if either

- \( A \) is sequenced before \( B \), or
- \( A \) inter-thread happens before \( B \).

The implementation shall ensure that no program execution demonstrates a cycle in the “happens before” relation. \( \text{[Note: This cycle would otherwise be possible only through the use of consume operations. \text{--- end note}]} \)

An evaluation \( A \) simply happens before an evaluation \( B \) if either

- \( A \) is sequenced before \( B \), or
- \( A \) synchronizes with \( B \), or
- \( A \) simply happens before \( X \) and \( X \) simply happens before \( B \).

\( \text{[Note: In the absence of consume operations, the happens before and simply happens before relations are identical. \text{--- end note}]} \)

An evaluation \( A \) strongly happens before an evaluation \( D \) if, either

- \( A \) is sequenced before \( D \), or
- \( A \) synchronizes with \( D \), and both \( A \) and \( D \) are sequentially consistent atomic operations (31.4), or
- there are evaluations \( B \) and \( C \) such that \( A \) is sequenced before \( B \), \( B \) simply happens before \( C \), and \( C \) is sequenced before \( D \), or
- there is an evaluation \( B \) such that \( A \) strongly happens before \( B \), and \( B \) strongly happens before \( D \).

\( \text{[Note: Informally, if } A \text{ strongly happens before } B \text{, then } A \text{ appears to be evaluated before } B \text{ in all contexts. Strongly happens before excludes consume operations. \text{--- end note}]} \)

A visible side effect \( A \) on a scalar object or bit-field \( M \) with respect to a value computation \( B \) of \( M \) satisfies the conditions:

- \( A \) happens before \( B \) and
- there is no other side effect \( X \) to \( M \) such that \( A \) happens before \( X \) and \( X \) happens before \( B \).

The value of a non-atomic scalar object or bit-field \( M \), as determined by evaluation \( B \), shall be the value stored by the visible side effect \( A \). \( \text{[Note: If there is ambiguity about which side effect to a non-atomic object or bit-field is visible, then the behavior is either unspecified or undefined. \text{--- end note}]} \)

The value of an atomic object \( M \), as determined by evaluation \( B \), shall be the value stored by some side effect \( A \) that modifies \( M \), where \( B \) does not happen before \( A \). \( \text{[Note: The set of such side effects is also restricted by the rest of the rules described here, and in particular, by the coherence requirements below. \text{--- end note}]} \)

If an operation \( A \) that modifies an atomic object \( M \) happens before an operation \( B \) that modifies \( M \), then \( A \) shall be earlier than \( B \) in the modification order of \( M \). \( \text{[Note: This requirement is known as write-write coherence. \text{--- end note}]} \)

If a value computation \( A \) of an atomic object \( M \) happens before a value computation \( B \) of \( M \), and \( A \) takes its value from a side effect \( X \) on \( M \), then the value computed by \( B \) shall either be the value stored by \( X \) or the value stored by a side effect \( Y \) on \( M \), where \( Y \) follows \( X \) in the modification order of \( M \). \( \text{[Note: This requirement is known as read-read coherence. \text{--- end note}]} \)

If a value computation \( A \) of an atomic object \( M \) happens before an operation \( B \) that modifies \( M \), then \( A \) shall take its value from a side effect \( X \) on \( M \), where \( X \) precedes \( B \) in the modification order of \( M \). \( \text{[Note: This requirement is known as read-write coherence. \text{--- end note}]} \)

If a side effect \( X \) on an atomic object \( M \) happens before a value computation \( B \) of \( M \), then the evaluation \( B \) shall take its value from \( X \) or from a side effect \( Y \) that follows \( X \) in the modification order of \( M \). \( \text{[Note: This requirement is known as write-read coherence. \text{--- end note}]} \)

\( \text{[Note: The four preceding coherence requirements effectively disallow compiler reordering of atomic operations to a single object, even if both operations are relaxed loads. This effectively makes the cache coherence guarantee provided by most hardware available to C++ atomic operations. \text{--- end note}]} \)

\( \text{[Note: The value observed by a load of an atomic depends on the “happens before” relation, which depends on the values observed by loads of atomics. The intended reading is that there must exist an association of \text{--- end note}]} \)

\( \text{§ 6.8.2.1} \)
atomic loads with modifications they observe that, together with suitably chosen modification orders and the “happens before” relation derived as described above, satisfy the resulting constraints as imposed here. —end note

21 Two actions are potentially concurrent if

(21.1) — they are performed by different threads, or

(21.2) — they are unsequenced, at least one is performed by a signal handler, and they are not both performed by the same signal handler invocation.

The execution of a program contains a data race if it contains two potentially concurrent conflicting actions, at least one of which is not atomic, and neither happens before the other, except for the special case for signal handlers described below. Any such data race results in undefined behavior. [Note: It can be shown that programs that correctly use mutexes and memory_order::seq_cst operations to prevent all data races and use no other synchronization operations behave as if the operations executed by their constituent threads were simply interleaved, with each value computation of an object being taken from the last side effect on that object in that interleaving. This is normally referred to as “sequential consistency”. However, this applies only to data-race-free programs, and data-race-free programs cannot observe most program transformations that do not change single-threaded program semantics. In fact, most single-threaded program transformations continue to be allowed, since any program that behaves differently as a result must perform an undefined operation. —end note]

22 Two accesses to the same object of type volatile std::sig_atomic_t do not result in a data race if both occur in the same thread, even if one or more occurs in a signal handler. For each signal handler invocation, evaluations performed by the thread invoking a signal handler can be divided into two groups A and B, such that no evaluations in B happen before evaluations in A, and the evaluations of such volatile std::sig_atomic_t objects take values as though all evaluations in A happened before the execution of the signal handler and the execution of the signal handler happened before all evaluations in B.

[Note: Compiler transformations that introduce assignments to a potentially shared memory location that would not be modified by the abstract machine are generally precluded by this document, since such an assignment might overwrite another assignment by a different thread in cases in which an abstract machine execution would not have encountered a data race. This includes implementations of data member assignment that overwrite adjacent members in separate memory locations. Reordering of atomic loads in cases in which the atomics in question may alias is also generally precluded, since this may violate the coherence rules. —end note]

23 [Note: Transformations that introduce a speculative read of a potentially shared memory location may not preserve the semantics of the C++ program as defined in this document, since they potentially introduce a data race. However, they are typically valid in the context of an optimizing compiler that targets a specific machine with well-defined semantics for data races. They would be invalid for a hypothetical machine that is not tolerant of races or provides hardware race detection. —end note]

6.8.2.2 Forward progress

1 The implementation may assume that any thread will eventually do one of the following:

(1.1) — terminate,

(1.2) — make a call to a library I/O function,

(1.3) — perform an access through a volatile glvalue, or

(1.4) — perform a synchronization operation or an atomic operation.

[Note: This is intended to allow compiler transformations such as removal of empty loops, even when termination cannot be proven. —end note]

2 Executions of atomic functions that are either defined to be lock-free (31.9) or indicated as lock-free (31.5) are lock-free executions.

(2.1) — If there is only one thread that is not blocked (3.6) in a standard library function, a lock-free execution in that thread shall complete. [Note: Concurrently executing threads may prevent progress of a lock-free execution. For example, this situation can occur with load-locked store-conditional implementations. This property is sometimes termed obstruction-free. —end note]

(2.2) — When one or more lock-free executions run concurrently, at least one should complete. [Note: It is difficult for some implementations to provide absolute guarantees to this effect, since repeated
and particularly inopportune interference from other threads may prevent forward progress, e.g., by repeatedly stealing a cache line for unrelated purposes between load-locked and store-conditional instructions. Implementations should ensure that such effects cannot indefinitely delay progress under expected operating conditions, and that such anomalies can therefore safely be ignored by programmers. Outside this document, this property is sometimes termed lock-free. —end note

During the execution of a thread of execution, each of the following is termed an execution step:

- termination of the thread of execution,
- performing an access through a volatile glvalue, or
- completion of a call to a library I/O function, a synchronization operation, or an atomic operation.

An invocation of a standard library function that blocks (3.6) is considered to continuously execute execution steps while waiting for the condition that it blocks on to be satisfied. [Example: A library I/O function that blocks until the I/O operation is complete can be considered to continuously check whether the operation is complete. Each such check might consist of one or more execution steps, for example using observable behavior of the abstract machine. —end example]

[Note: Because of this and the preceding requirement regarding what threads of execution have to perform eventually, it follows that no thread of execution can execute forever without an execution step occurring. —end note]

A thread of execution makes progress when an execution step occurs or a lock-free execution does not complete because there are other concurrent threads that are not blocked in a standard library function (see above).

For a thread of execution providing concurrent forward progress guarantees, the implementation ensures that the thread will eventually make progress for as long as it has not terminated. [Note: This is required regardless of whether or not other threads of executions (if any) have been or are making progress. To eventually fulfill this requirement means that this will happen in an unspecified but finite amount of time. —end note]

It is implementation-defined whether the implementation-created thread of execution that executes main (6.8.3.1) and the threads of execution created by std::thread (32.3.2) provide concurrent forward progress guarantees. [Note: General-purpose implementations should provide these guarantees. —end note]

For a thread of execution providing parallel forward progress guarantees, the implementation is not required to ensure that the thread will eventually make progress if it has not yet executed any execution step; once this thread has executed a step, it provides concurrent forward progress guarantees.

[Note: This does not specify a requirement for when to start this thread of execution, which will typically be specified by the entity that creates this thread of execution. For example, a thread of execution that provides concurrent forward progress guarantees and executes tasks from a set of tasks in an arbitrary order, one after the other, satisfies the requirements of parallel forward progress for these tasks. —end note]

For a thread of execution providing weakly parallel forward progress guarantees, the implementation does not ensure that the thread will eventually make progress.

[Note: Threads of execution providing weakly parallel forward progress guarantees cannot be expected to make progress regardless of whether other threads make progress or not; however, blocking with forward progress guarantee delegation, as defined below, can be used to ensure that such threads of execution make progress eventually. —end note]

Concurrent forward progress guarantees are stronger than parallel forward progress guarantees, which in turn are stronger than weakly parallel forward progress guarantees. [Note: For example, some kinds of synchronization between threads of execution may only make progress if the respective threads of execution provide parallel forward progress guarantees, but will fail to make progress under weakly parallel guarantees. —end note]

When a thread of execution P is specified to block with forward progress guarantee delegation on the completion of a set S of threads of execution, then throughout the whole time of P being blocked on S, the implementation shall ensure that the forward progress guarantees provided by at least one thread of execution in S is at least as strong as P’s forward progress guarantees. [Note: It is unspecified which thread or threads of execution in S are chosen and for which number of execution steps. The strengthening is not permanent and not necessarily in place for the rest of the lifetime of the affected thread of execution. As long as P is blocked, the implementation has to eventually select and potentially strengthen a thread of execution in S. —end note] Once a thread of execution in S terminates, it is removed from S. Once S is empty, P is unblocked.
A thread of execution $B$ thus can temporarily provide an effectively stronger forward progress guarantee for a certain amount of time, due to a second thread of execution $A$ being blocked on it with forward progress guarantee delegation. In turn, if $B$ then blocks with forward progress guarantee delegation on $C$, this may also temporarily provide a stronger forward progress guarantee to $C$.  \[\text{-- end note}\]

If all threads of execution in $S$ finish executing (e.g., they terminate and do not use blocking synchronization incorrectly), then $P$’s execution of the operation that blocks with forward progress guarantee delegation will not result in $P$’s progress guarantee being effectively weakened.  \[\text{-- end note}\]

This does not remove any constraints regarding blocking synchronization for threads of execution providing parallel or weakly parallel forward progress guarantees because the implementation is not required to strengthen a particular thread of execution whose too-weak progress guarantee is preventing overall progress.  \[\text{-- end note}\]

An implementation should ensure that the last value (in modification order) assigned by an atomic or synchronization operation will become visible to all other threads in a finite period of time.

### 6.8.3 Start and termination

#### 6.8.3.1 main function

A program shall contain a global function called `main` attached to the global module. Executing a program starts a main thread of execution (6.8.2, 32.3) in which the `main` function is invoked, and in which variables of static storage duration might be initialized (6.8.3.2) and destroyed (6.8.3.4). It is implementation-defined whether a program in a freestanding environment is required to define a `main` function.  \[\text{Note:} \quad \text{In a freestanding environment, start-up and termination is implementation-defined; start-up contains the execution of constructors for objects of namespace scope with static storage duration; termination contains the execution of destructors for objects with static storage duration.} \ [\text{-- end note}]\]

An implementation shall not predefine the `main` function. This function shall not be overloaded. Its type shall have C++ language linkage and it shall have a declared return type of type `int`, but otherwise its type is implementation-defined. An implementation shall allow both

- a function of () returning `int` and
- a function of `(int, pointer to pointer to char)` returning `int`

as the type of `main` (9.2.3.5). In the latter form, for purposes of exposition, the first function parameter is called `argv` and the second function parameter is called `argc`, where `argc` shall be the number of arguments passed to the program from the environment in which the program is run. If `argc` is nonzero these arguments shall be supplied in `argv[0]` through `argv[argc-1]` as pointers to the initial characters of null-terminated multibyte strings (`ntmbs`) (16.4.2.2.5.2) and `argv[0]` shall be the pointer to the initial character of a `ntmbs` that represents the name used to invoke the program or "". The value of `argc` shall be non-negative. The value of `argv[argc]` shall be 0.  \[\text{Note:} \quad \text{It is recommended that any further (optional) parameters be added after `argv`.} \ [\text{-- end note}]\]

The function `main` shall not be used within a program. The linkage (6.5) of `main` is implementation-defined. A program that defines `main` as deleted or that declares `main` to be `inline`, `static`, or `constexpr` is ill-formed. The function `main` shall not be a coroutine (9.4.4). The `main` function shall not be declared with a `linkage-specification` (9.10). A program that declares a variable `main` at global scope, or that declares a function `main` at global scope attached to a named module, or that declares the name `main` with C language linkage (in any namespace) is ill-formed. The name `main` is not otherwise reserved.  \[\text{Example:} \quad \text{Member functions, classes, and enumerations can be called `main`, as can entities in other namespaces.} \ [\text{-- end example}]\]

Terminating the program without leaving the current block (e.g., by calling the function `std::exit(int)` (17.5)) does not destroy any objects with automatic storage duration (11.3.6). If `std::exit` is called to end a program during the destruction of an object with static or thread storage duration, the program has undefined behavior.

A `return` statement (8.6.3) in `main` has the effect of leaving the main function (destroying any objects with automatic storage duration) and calling `std::exit` with the return value as the argument. If control flows off the end of the `compound-statement` of `main`, the effect is equivalent to a `return` with operand 0 (see also 14.3).
6.8.3.2 Static initialization

Variables with static storage duration are initialized as a consequence of program initiation. Variables with thread storage duration are initialized as a consequence of thread execution. Within each of these phases of initiation, initialization occurs as follows.

Constant initialization is performed if a variable or temporary object with static or thread storage duration is initialized by a constant initializer (7.7) for the entity. If constant initialization is not performed, a variable with static storage duration (6.6.5.1) or thread storage duration (6.6.5.2) is zero-initialized (9.3). Together, zero-initialization and constant initialization are called static initialization; all other initialization is dynamic initialization. All static initialization strongly happens before (6.8.2.1) any dynamic initialization. [Note: The dynamic initialization of non-local variables is described in 6.8.3.3; that of local static variables is described in 8.7. — end note]

An implementation is permitted to perform the initialization of a variable with static or thread storage duration as a static initialization even if such initialization is not required to be done statically, provided that

(3.1) the dynamic version of the initialization does not change the value of any other object of static or thread storage duration prior to its initialization, and

(3.2) the static version of the initialization produces the same value in the initialized variable as would be produced by the dynamic initialization if all variables not required to be initialized statically were initialized dynamically.

[Note: As a consequence, if the initialization of an object obj1 refers to an object obj2 of namespace scope potentially requiring dynamic initialization and defined later in the same translation unit, it is unspecified whether the value of obj2 used will be the value of the fully initialized obj2 (because obj2 was statically initialized) or will be the value of obj2 merely zero-initialized. For example,]

```cpp
inline double fd() { return 1.0; }
extern double d1;
double d2 = d1; // unspecified:
    // may be statically initialized to 0.0 or
    // dynamically initialized to 0.0 if d1 is
    // dynamically initialized, or 1.0 otherwise
double d1 = fd(); // may be initialized statically or dynamically to 1.0
```

6.8.3.3 Dynamic initialization of non-local variables

Dynamic initialization of a non-local variable with static storage duration is unordered if the variable is an implicitly or explicitly instantiated specialization, is partially-ordered if the variable is an inline variable that is not an implicitly or explicitly instantiated specialization, and otherwise is ordered. [Note: An explicitly specialized non-inline static data member or variable template specialization has ordered initialization. — end note]

Dynamic initialization of non-local variables V and W with static storage duration are ordered as follows:

(2.1) If V and W have ordered initialization and V is defined before W within a single translation unit, the initialization of V is sequenced before the initialization of W.

(2.2) If V has partially-ordered initialization, W does not have unordered initialization, and V is defined before W in every translation unit in which W is defined, then

(2.2.1) if the program starts a thread (6.8.2) other than the main thread (6.8.3.1), the initialization of V strongly happens before the initialization of W;

(2.2.2) otherwise, the initialization of V is sequenced before the initialization of W.

(2.3) Otherwise, if the program starts a thread other than the main thread before either V or W is initialized, it is unspecified in which threads the initializations of V and W occur; the initializations are unsequenced if they occur in the same thread.

(2.4) Otherwise, the initializations of V and W are indeterminately sequenced.

[Note: This definition permits initialization of a sequence of ordered variables concurrently with another sequence. — end note]

A non-initialization odr-use is an odr-use (6.2) not caused directly or indirectly by the initialization of a non-local static or thread storage duration variable.

§ 6.8.3.3 78
It is implementation-defined whether the dynamic initialization of a non-local non-inline variable with static storage duration is sequenced before the first statement of `main` or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of any non-inline function or non-inline variable defined in the same translation unit as the variable to be initialized. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs. [Note: Such points should be chosen in a way that allows the programmer to avoid deadlocks. — end note] [Example:

```c
// - File 1 -
#include "a.h"
#include "b.h"
B b;
A::A(){
  b.Use();
}

// - File 2 -
#include "a.h"
A a;

// - File 3 -
#include "a.h"
#include "b.h"
extern A a;
extern B b;

int main() {
  a.Use();
  b.Use();
}
```

It is implementation-defined whether either `a` or `b` is initialized before `main` is entered or whether the initializations are delayed until `a` is first odr-used in `main`. In particular, if `a` is initialized before `main` is entered, it is not guaranteed that `b` will be initialized before it is odr-used by the initialization of `a`, that is, before `A::A` is called. If, however, `a` is initialized at some point after the first statement of `main`, `b` will be initialized prior to its use in `A::A`. — end example]

It is implementation-defined whether the dynamic initialization of a non-local inline variable with static storage duration is sequenced before the first statement of `main` or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of that variable. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

It is implementation-defined whether the dynamic initialization of a non-local non-inline variable with thread storage duration is sequenced before the first statement of the initial function of a thread or is deferred. If it is deferred, the initialization associated with the entity for thread `t` is sequenced before the first non-initialization odr-use by `t` of any non-inline variable with thread storage duration defined in the same translation unit as the variable to be initialized. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

If the initialization of a non-local variable with static or thread storage duration exits via an exception, the function `std::terminate` is called (14.5.1).

### 6.8.3.4 Termination

1. Constructed objects (9.3) with static storage duration are destroyed and functions registered with `std::atexit` are called as part of a call to `std::exit` (17.5). The call to `std::exit` is sequenced before the destructions and the registered functions. [Note: Returning from `main` invokes `std::exit` (6.8.3.1). — end note]

2. Constructed objects with thread storage duration within a given thread are destroyed as a result of returning from the initial function of that thread and as a result of that thread calling `std::exit`. The destruction of all constructed objects with thread storage duration within that thread strongly happens before destroying any object with static storage duration.

3. If the completion of the constructor or dynamic initialization of an object with static storage duration strongly happens before that of another, the completion of the destructor of the second is sequenced before

---

49) A non-local variable with static storage duration having initialization with side effects is initialized in this case, even if it is not itself odr-used (6.2, 6.4.5.1).
the initiation of the destructor of the first. If the completion of the constructor or dynamic initialization of an
object with thread storage duration is sequenced before that of another, the completion of the destructor of
the second is sequenced before the initiation of the destructor of the first. If an object is initialized statically,
the object is destroyed in the same order as if the object was dynamically initialized. For an object of array
or class type, all subobjects of that object are destroyed before any block-scope object with static storage
duration initialized during the construction of the subobjects is destroyed. If the destruction of an object
with static or thread storage duration exits via an exception, the function `std::terminate` is called (14.5.1).

4 If a function contains a block-scope object of static or thread storage duration that has been destroyed and the
function is called during the destruction of an object with static or thread storage duration, the program has
undefined behavior if the flow of control passes through the definition of the previously destroyed block-scope
object. Likewise, the behavior is undefined if the block-scope object is used indirectly (i.e., through a pointer)
after its destruction.

5 If the completion of the initialization of an object with static storage duration strongly happens before a call
to `std::atexit` (see `<cstdlib>`, 17.5), the call to the function passed to `std::atexit` is sequenced before
the call to the destructor for the object. If a call to `std::atexit` strongly happens before the completion
of the initialization of an object with static storage duration, the call to the destructor for the object is sequenced
before the call to the function passed to `std::atexit`. If a call to `std::atexit` strongly happens before
another call to `std::atexit`, the call to the function passed to the second `std::atexit` call is sequenced
before the call to the function passed to the first `std::atexit` call.

6 If there is a use of a standard library object or function not permitted within signal handlers (17.13) that
does not happen before (6.8.2) completion of destruction of objects with static storage duration and execution
of `std::atexit` registered functions (17.5), the program has undefined behavior. [Note: If there is a use of
an object with static storage duration that does not happen before the object’s destruction, the program
has undefined behavior. Terminating every thread before a call to `std::exit` or the exit from `main` is
sufficient, but not necessary, to satisfy these requirements. These requirements permit thread managers as
static-storage-duration objects. — end note]

7 Calling the function `std::abort()` declared in `<cstdlib>` terminates the program without executing any
destructors and without calling the functions passed to `std::atexit()` or `std::at_quick_exit()`.

§ 6.8.3.4
7 Expressions

7.1 Preamble

1 [Note: Clause 7 defines the syntax, order of evaluation, and meaning of expressions. An expression is a sequence of operators and operands that specifies a computation. An expression can result in a value and can cause side effects. — end note]

2 [Note: Operators can be overloaded, that is, given meaning when applied to expressions of class type (Clause 11) or enumeration type (9.6). Uses of overloaded operators are transformed into function calls as described in 12.5. Overloaded operators obey the rules for syntax and evaluation order specified in 7.6, but the requirements of operand type and value category are replaced by the rules for function call. Relations between operators, such as ++a meaning a+=1, are not guaranteed for overloaded operators (12.5). — end note]

3 Subclause 7.6 defines the effects of operators when applied to types for which they have not been overloaded. Operator overloading shall not modify the rules for the built-in operators, that is, for operators applied to types for which they are defined by this Standard. However, these built-in operators participate in overload resolution, and as part of that process user-defined conversions will be considered where necessary to convert the operands to types appropriate for the built-in operator. If a built-in operator is selected, such conversions will be applied to the operands before the operation is considered further according to the rules in subclause 7.6; see 12.3.1.2, 12.6.

4 If during the evaluation of an expression, the result is not mathematically defined or not in the range of representable values for its type, the behavior is undefined. [Note: Treatment of division by zero, forming a remainder using a zero divisor, and all floating-point exceptions vary among machines, and is sometimes adjustable by a library function. — end note]

5 [Note: The implementation may regroup operators according to the usual mathematical rules only where the operators really are associative or commutative. For example, in the following fragment

```c
int a, b;
/* ... */
a = a + 32760 + b + 5;
```
the expression statement behaves exactly the same as

```c
a = ((a + 32760) + b) + 5;
```
due to the associativity and precedence of these operators. Thus, the result of the sum (a + 32760) is next added to b, and that result is then added to 5 which results in the value assigned to a. On a machine in which overflows produce an exception and in which the range of values representable by an int is [-32768, +32767], the implementation cannot rewrite this expression as

```c
a = ((a + b) + 32765);
```
since if the values for a and b were, respectively, -32754 and -15, the sum a + b would produce an exception while the original expression would not; nor can the expression be rewritten as either

```c
a = ((a + 32765) + b);
```
or

```c
a = (a + (b + 32765));
```
since the values for a and b might have been, respectively, 4 and -8 or -17 and 12. However on a machine in which overflows do not produce an exception and in which the results of overflows are reversible, the above expression statement can be rewritten by the implementation in any of the above ways because the same result will occur. — end note]

6 The values of the floating operands and the results of floating expressions may be represented in greater precision and range than that required by the type; the types are not changed thereby.  

---

50) The precedence of operators is not directly specified, but it can be derived from the syntax.
51) Overloaded operators are never assumed to be associative or commutative.
52) The cast and assignment operators must still perform their specific conversions as described in 7.6.3, 7.6.18 and 7.6.19.
7.2 Properties of expressions

7.2.1 Value category

Expressions are categorized according to the taxonomy in Figure 1.

![Expression category taxonomy](fig:basic.lval)

1 Every expression belongs to exactly one of the fundamental classifications in this taxonomy: lvalue, xvalue, or prvalue. This property of an expression is called its **value category**. [Note: The discussion of each built-in operator in 7.6 indicates the category of the value it yields and the value categories of the operands it expects. For example, the built-in assignment operators expect that the left operand is an lvalue and that the right operand is a prvalue and yield an lvalue as the result. User-defined operators are functions, and the categories of values they expect and yield are determined by their parameter and return types. — end note]

2 [Note: Historically, lvalues and rvalues were so-called because they could appear on the left- and right-hand side of an assignment (although this is no longer generally true); glvalues are “generalized” lvalues, prvalues are “pure” rvalues, and xvalues are “eXpiring” lvalues. Despite their names, these terms classify expressions, not values. — end note]

3 [Note: An expression is an xvalue if it is:

   (4.1) the result of calling a function, whether implicitly or explicitly, whose return type is a rvalue reference to object type (7.6.1.2),
   (4.2) a cast to a rvalue reference to object type (7.6.1.6, 7.6.1.8, 7.6.1.9, 7.6.1.10, 7.6.3),
   (4.3) a subscripting operation with an xvalue array operand (7.6.1.1),
   (4.4) a class member access expression designating a non-static data member of non-reference type in which the object expression is an xvalue (7.6.1.4), or
   (4.5) a .* pointer-to-member expression in which the first operand is an xvalue and the second operand is a pointer to data member (7.6.4).

In general, the effect of this rule is that named rvalue references are treated as lvalues and unnamed rvalue references to objects are treated as xvalues; rvalue references to functions are treated as lvalues whether named or not. — end note]

[Example:

```c
struct A {
    int m;
};
A&& operator+(A, A);
A&& f();
```]
A a;
A&& ar = static_cast&lt;A&amp;&amp;&gt;(a);
The expressions f().f().m, static_cast&lt;A&amp;&amp;&gt;(a), and a + a are xvalues. The expression ar is an lvalue.
— end example]

The result of a glvalue is the entity denoted by the expression. The result of a prvalue is the value that the expression stores into its context; a prvalue that has type cv void has no result. A prvalue whose result is the value V is sometimes said to have or name the value V. The result object of a prvalue is the object initialized by the prvalue; a non-discarded prvalue that is used to compute the value of an operand of a built-in operator or a prvalue that has type cv void has no result object. [Note: Except when the prvalue is the operand of a decltype-specifier, a prvalue of class or array type always has a result object. For a discarded prvalue that has type other than cv void, a temporary object is materialized; see 7.2.3. — end note]

Whenever a glvalue appears as an operand of an operator that expects a prvalue for that operand, the lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), or function-to-pointer (7.3.3) standard conversions are applied to convert the expression to a prvalue. [Note: An attempt to bind a rvalue reference to an lvalue is not such a context; see 9.3.3. — end note] [Note: Because cv-qualifiers are removed from the type of an expression of non-class type when the expression is converted to a prvalue, an lvalue of type const int can, for example, be used where a prvalue of type int is required. — end note] [Note: There are no prvalue bit-fields; if a bit-field is converted to a prvalue (7.3.1), a prvalue of the type of the bit-field is created, which might then be promoted (7.3.6). — end note]

Whenever a prvalue appears as an operand of an operator that expects a glvalue for that operand, the temporary materialization conversion (7.3.4) is applied to convert the expression to an xvalue.

The discussion of reference initialization in 9.3.3 and of temporaries in 6.6.7 indicates the behavior of lvalues and rvalues in other significant contexts.

Unless otherwise indicated (9.1.7.2), a prvalue shall always have complete type or the void type; if it has a class type or (possibly multi-dimensional) array of class type, that class shall not be an abstract class (11.6.3). A glvalue shall not have type cv void. [Note: A glvalue may have complete or incomplete non-type cv void type. Class and array prvalues can have cv-qualified types; other prvalues always have cv-unqualified types. See 7.2. — end note]

An lvalue is modifiable unless its type is const-qualified or is a function type. [Note: A program that attempts to modify an object through a nonmodifiable lvalue or through an rvalue is ill-formed (7.6.19, 7.6.1.5, 7.6.2.2). — end note]

If a program attempts to access the stored value of an object through a glvalue whose type is not similar (7.3.5) to one of the following types the behavior is undefined:

(11.1) — the dynamic type of the object,
(11.2) — a type that is the signed or unsigned type corresponding to the dynamic type of the object, or
(11.3) — a char, unsigned char, or std::byte type.

If a program invokes a defaulted copy/move constructor or copy/move assignment operator for a union of type U with a glvalue argument that does not denote an object of type cv U within its lifetime, the behavior is undefined. [Note: Unlike in C, C++ has no accesses of class type. — end note]

### 7.2.2 Type

If an expression initially has the type “reference to T” (9.2.3.2, 9.3.3), the type is adjusted to T prior to any further analysis. The expression designates the object or function denoted by the reference, and the expression is an lvalue or an xvalue, depending on the expression. [Note: Before the lifetime of the reference has started or after it has ended, the behavior is undefined (see 6.6.3). — end note]

If a prvalue initially has the type “cv T”, where T is a cv-unqualified non-class, non-array type, the type of the expression is adjusted to T prior to any further analysis.

The cv-combined type of two types T1 and T2 is a type T3 similar to T1 whose cv-qualification signature (7.3.5) is:

(3.1) — for every i > 0, cv\textsuperscript{i}T3 is the union of cv\textsuperscript{i}T1 and cv\textsuperscript{i}T2;
(3.2) — if the resulting cv\textsuperscript{i}T3 is different from cv\textsuperscript{i}T1 or cv\textsuperscript{i}T2, then const is added to every cv\textsuperscript{k}T3 for 0 < k < i.

53) The intent of this list is to specify those circumstances in which an object may or may not be aliased.
[Note: Given similar types $T_1$ and $T_2$, this construction ensures that both can be converted to $T_3$. — end note]

4 The composite pointer type of two operands $p_1$ and $p_2$ having types $T_1$ and $T_2$, respectively, where at least one is a pointer or pointer-to-member type or std::nullptr_t, is:

(4.1) if both $p_1$ and $p_2$ are null pointer constants, std::nullptr_t;
(4.2) if either $p_1$ or $p_2$ is a null pointer constant, $T_2$ or $T_1$, respectively;
(4.3) if $T_1$ or $T_2$ is “pointer to cv1 void” and the other type is “pointer to cv2 $T$”, where $T$ is an object type or void, “pointer to cv12 void”, where cv12 is the union of cv1 and cv2;
(4.4) if $T_1$ or $T_2$ is “pointer to noexcept function” and the other type is “pointer to function”, where the function types are otherwise the same, “pointer to function”;
(4.5) if $T_1$ is “pointer to cv1 $C_1$” and $T_2$ is “pointer to cv2 $C_2$”, where $C_1$ is reference-related to $C_2$ or $C_2$ is reference-related to $C_1$ (9.3.3), the cv-combined type of $T_1$ and $T_2$ or the cv-combined type of $T_2$ and $T_1$, respectively;
(4.6) if $T_1$ or $T_2$ is “pointer to member of $C_1$ of type function”, the other type is “pointer to member of $C_2$ of type noexcept function”, and $C_1$ is reference-related to $C_2$ or $C_2$ is reference-related to $C_1$ (9.3.3), where the function types are otherwise the same, “pointer to member of $C_2$ of type function” or “pointer to member of $C_1$ of type function”, respectively;
(4.7) if $T_1$ is “pointer to member of $C_1$ of type cv1 $U$” and $T_2$ is “pointer to member of $C_2$ of type cv2 $U$”, for some non-function type $U$, where $C_1$ is reference-related to $C_2$ or $C_2$ is reference-related to $C_1$ (9.3.3), the cv-combined type of $T_2$ and $T_1$ or the cv-combined type of $T_1$ and $T_2$, respectively;
(4.8) if $T_1$ and $T_2$ are similar types (7.3.5), the cv-combined type of $T_1$ and $T_2$;
(4.9) otherwise, a program that necessitates the determination of a composite pointer type is ill-formed.

[Example:

typedef void *p;
typedef const int *q;
typedef int **pi;
typedef const int **pci;

The composite pointer type of $p$ and $q$ is “pointer to const void”; the composite pointer type of $pi$ and $pci$ is “pointer to const pointer to const int”. — end example]

7.2.3  Context dependence

[expr.context]

1 In some contexts, unevaluated operands appear (7.5.7, 7.6.1.7, 7.6.2.4, 7.6.2.6, 9.1.7.2, Clause 13). An unevaluated operand is not evaluated. [Note: In an unevaluated operand, a non-static class member may be named (7.5.4) and naming of objects or functions does not, by itself, require that a definition be provided (6.2). An unevaluated operand is considered a full-expression (6.8.1). — end note]

2 In some contexts, an expression only appears for its side effects. Such an expression is called a discarded-value expression. The array-to-pointer (7.3.2) and function-to-pointer (7.3.3) standard conversions are not applied. The lvalue-to-rvalue conversion (7.3.1) is applied if and only if the expression is a glvalue of volatile-qualified type and it is one of the following:

(2.1) (expression), where expression is one of these expressions,
(2.2) id-expression (7.5.4),
(2.3) subscripting (7.6.1.1),
(2.4) class member access (7.6.1.4),
(2.5) indirection (7.6.2.1),
(2.6) pointer-to-member operation (7.6.4),
(2.7) conditional expression (7.6.16) where both the second and the third operands are one of these expressions, or
(2.8) comma expression (7.6.20) where the right operand is one of these expressions.

[Note: Using an overloaded operator causes a function call; the above covers only operators with built-in meaning. — end note] If the (possibly converted) expression is a prvalue, the temporary materialization
conversion (7.3.4) is applied. [Note: If the expression is an lvalue of class type, it must have a volatile copy
constructor to initialize the temporary object that is the result object of the lvalue-to-rvalue conversion.
— end note] The glvalue expression is evaluated and its value is discarded.

7.3 Standard conversions [conv]

1 Standard conversions are implicit conversions with built-in meaning. 7.3 enumerates the full set of such
conversions. A standard conversion sequence is a sequence of standard conversions in the following order:

   (1.1) — Zero or one conversion from the following set: lvalue-to-rvalue conversion, array-to-pointer conversion,
          and function-to-pointer conversion.

   (1.2) — Zero or one conversion from the following set: integral promotions, floating-point promotion, integral
          conversions, floating-point conversions, floating-integral conversions, pointer conversions, pointer-to-
          member conversions, and boolean conversions.

   (1.3) — Zero or one function pointer conversion.

   (1.4) — Zero or one qualification conversion.

   [Note: A standard conversion sequence can be empty, i.e., it can consist of no conversions. — end note]

A standard conversion sequence will be applied to an expression if necessary to convert it to a required
destination type.

2 [Note: Expressions with a given type will be implicitly converted to other types in several contexts:

   (2.1) — When used as operands of operators. The operator’s requirements for its operands dictate the destination
          type (7.6).

   (2.2) — When used in the condition of an if statement (8.4.1) or iteration statement (8.5). The destination
          type is bool.

   (2.3) — When used in the expression of a switch statement (8.4.2). The destination type is integral.

   (2.4) — When used as the source expression for an initialization (which includes use as an argument in a
          function call and use as the expression in a return statement). The type of the entity being initialized
          is (generally) the destination type. See 9.3, 9.3.3.

   — end note]

3 An expression e can be implicitly converted to a type T if and only if the declaration T t=e; is well-formed,
for some invented temporary variable t (9.3).

4 Certain language constructs require that an expression be converted to a Boolean value. An expression e
appearing in such a context is said to be contextually converted to bool and is well-formed if and only if the
declaration bool t(e); is well-formed, for some invented temporary variable t (9.3).

5 Certain language constructs require conversion to a value having one of a specified set of types appropriate to
the construct. An expression e of class type E appearing in such a context is said to be contextually implicitly
converted to a specified type T and is well-formed if and only if e can be implicitly converted to a type T
that is determined as follows: E is searched for non-explicit conversion functions whose return type is cv T or
reference to cv T such that T is allowed by the context. There shall be exactly one such T.

6 The effect of any implicit conversion is the same as performing the corresponding declaration and initialization
and then using the temporary variable as the result of the conversion. The result is an lvalue if T is an lvalue
reference type or an rvalue reference to function type (9.2.3.2), an xvalue if T is an rvalue reference to object
type, and a prvalue otherwise. The expression e is used as a glvalue if and only if the initialization uses it as
a glvalue.

7 [Note: For class types, user-defined conversions are considered as well; see 11.3.7. In general, an implicit
conversion sequence (12.3.3.1) consists of a standard conversion sequence followed by a user-defined conversion
followed by another standard conversion sequence. — end note]

8 [Note: There are some contexts where certain conversions are suppressed. For example, the lvalue-to-rvalue
conversion is not done on the operand of the unary & operator. Specific exceptions are given in the descriptions
of those operators and contexts. — end note]
7.3.1 Lvalue-to-rvalue conversion

A glvalue (7.2.1) of a non-function, non-array type T can be converted to a prvalue.\(^{54}\) If T is an incomplete type, a program that necessitates this conversion is ill-formed. If T is a non-class type, the type of the prvalue is the cv-unqualified version of T. Otherwise, the type of the prvalue is T.\(^{55}\)

When an lvalue-to-rvalue conversion is applied to an expression e, and either
\begin{itemize}
  \item e is not potentially evaluated, or
  \item the evaluation of e results in the evaluation of a member ex of the set of potential results of e, and ex names a variable x that is not odr-used by ex (6.2),
\end{itemize}
the value contained in the referenced object is not accessed. [Example:
\begin{verbatim}
struct S { int n; };
auto f() {
  S x { 1 };
  constexpr S y { 2 };
  return [&](bool b) { return (b ? y : x).n; };
}
auto g = f();
int m = g(false);  // undefined behavior due to access of x.n outside its lifetime
int n = g(true);  // OK, does not access y.n
\end{verbatim}—end example]

The result of the conversion is determined according to the following rules:
\begin{itemize}
  \item If T is cv std::nullptr_t, the result is a null pointer constant (7.3.11). [Note: Since the conversion does not access the object to which the glvalue refers, there is no side effect even if T is volatile-qualified (6.8.1), and the glvalue can refer to an inactive member of a union (11.4). — end note]
  \item Otherwise, if T has a class type, the conversion copy-initializes the result object from the glvalue.
  \item Otherwise, if the object to which the glvalue refers contains an invalid pointer value (6.6.5.4.2, 6.6.5.4.3), the behavior is implementation-defined.
  \item Otherwise, the value contained in the object indicated by the glvalue is the prvalue result.
\end{itemize}
[Note: See also 7.2.1. — end note]

7.3.2 Array-to-pointer conversion

An lvalue or rvalue of type “array of N T” or “array of unknown bound of T” can be converted to a prvalue of type “pointer to T”. The temporary materialization conversion (7.3.4) is applied. The result is a pointer to the first element of the array.

7.3.3 Function-to-pointer conversion

An lvalue of function type T can be converted to a prvalue of type “pointer to T”. The result is a pointer to the function.\(^{56}\)
[Note: See 12.4 for additional rules for the case where the function is overloaded. — end note]

7.3.4 Temporary materialization conversion

A prvalue of type T can be converted to an xvalue of type T. This conversion initializes a temporary object (6.6.7) of type T from the prvalue by evaluating the prvalue with the temporary object as its result object, and produces an xvalue denoting the temporary object. T shall be a complete type. [Note: If T is a class type (or array thereof), it must have an accessible and non-deleted destructor; see 11.3.6. — end note]
[Example:
\begin{verbatim}
struct X { int n; };
int k = X().n;  // OK, X() prvalue is converted to xvalue
\end{verbatim}—end example]

\(^{54}\) For historical reasons, this conversion is called the “lvalue-to-rvalue” conversion, even though that name does not accurately reflect the taxonomy of expressions described in 7.2.1.

\(^{55}\) In C++ class and array prvalues can have cv-qualified types. This differs from ISO C, in which non-lvalues never have cv-qualified types.

\(^{56}\) This conversion never applies to non-static member functions because an lvalue that refers to a non-static member function cannot be obtained.
7.3.5 Qualification conversions

1 A cv-decomposition of a type T is a sequence of cvi and Pi such that T is
```
"cv0 P0 cv1 P1 ... cvn-1 Pn-1 cvn, U" for n ≥ 0,
```
where each cvi is a set of cv-qualifiers (6.7.3), and each Pi is “pointer to” (9.2.3.1), “pointer to member of class Ci of type” (9.2.3.3), “array of Nj”, or “array of unknown bound of” (9.2.3.4). If Pi designates an array, the cv-qualifiers cvi+1 on the element type are also taken as the cv-qualifiers cvi of the array. [Example: The type denoted by the type-id const int ** has two cv-decompositions, taking U as “int” and as “pointer to const int”. —end example] The n-tuple of cv-qualifiers after the first one in the longest cv-decomposition of T, that is, cv1, cv2, ..., cvn, is called the cv-qualification signature of T.

2 Two types T1 and T2 are similar if they have cv-decompositions with the same n such that corresponding Pi components are the same and the types denoted by U are the same.

3 A prvalue of type T1 can be converted to type T2 if the following conditions are satisfied, where cvi denotes the cv-qualifiers in the cv-qualification signature of Tj.\[57\]

(3.1) — T1 and T2 are similar.

(3.2) — For every i > 0, if const is in cvi then const is in cvi2, and similarly for volatile.

(3.3) — If the cvi1 and cvi2 are different, then const is in every cvi2 for 0 < k < i.

[Note: If a program could assign a pointer of type T** to a pointer of type const T** (that is, if line #1 below were allowed), a program could inadvertently modify a const object (as it is done on line #2). For example,
```
int main() {
    const char c = 'c';
    char* pc;
    const char** pcc = &pc;   // #1: not allowed
    *pcc = &c;
    *pc = 'C';                   // #2: modifies a const object
}
```
—end note]

(3.4) [Note: A prvalue of type “pointer to cv1 T” can be converted to a prvalue of type “pointer to cv2 T” if “cv2 T” is more cv-qualified than “cv1 T”. A prvalue of type “pointer to member of X of type cv1 T” can be converted to a prvalue of type “pointer to member of X of type cv2 T” if “cv2 T” is more cv-qualified than “cv1 T”. —end note]

(3.5) [Note: Function types (including those used in pointer to member function types) are never cv-qualified (9.2.3.5). —end note]

7.3.6 Integral promotions

1 A prvalue of an integer type other than bool, char16_t, char32_t, or wchar_t whose integer conversion rank (6.7.4) is less than the rank of int can be converted to a prvalue of type int if int can represent all the values of the source type; otherwise, the source prvalue can be converted to a prvalue of type unsigned int.

2 A prvalue of type char16_t, char32_t, or wchar_t (6.7.1) can be converted to a prvalue of the first of the following types that can represent all the values of its underlying type: int, unsigned int, long int, unsigned long int, long long int, or unsigned long long int. If none of the types in that list can represent all the values of its underlying type, a prvalue of type char16_t, char32_t, or wchar_t can be converted to a prvalue of its underlying type.

3 A prvalue of an unscoped enumeration type whose underlying type is not fixed can be converted to a prvalue of the first of the following types that can represent all the values of the enumeration (9.6): int, unsigned int, long int, unsigned long int, long long int, or unsigned long long int. If none of the types in that list can represent all the values of the enumeration, a prvalue of an unscoped enumeration type can be converted to a prvalue of the extended integer type with lowest integer conversion rank (6.7.4) greater than the rank of long long in which all the values of the enumeration can be represented. If there are two such extended types, the signed one is chosen.

4 A prvalue of an unscoped enumeration type whose underlying type is fixed (9.6) can be converted to a prvalue of its underlying type. Moreover, if integral promotion can be applied to its underlying type, a prvalue of an

\[57\] These rules ensure that const-safety is preserved by the conversion.
unscoped enumeration type whose underlying type is fixed can also be converted to a prvalue of the promoted
underlying type.

5 A prvalue for an integral bit-field (11.3.9) can be converted to a prvalue of type int if int can represent all
the values of the bit-field; otherwise, it can be converted to unsigned int if unsigned int can represent all
the values of the bit-field. If the bit-field is larger yet, no integral promotion applies to it. If the bit-field has
an enumerated type, it is treated as any other value of that type for promotion purposes.

6 A prvalue of type bool can be converted to a prvalue of type int, with false becoming zero and true
becoming one.

7 These conversions are called integral promotions.

7.3.7 Floating-point promotion [conv.fpprom]
1 A prvalue of type float can be converted to a prvalue of type double. The value is unchanged.

2 This conversion is called floating-point promotion.

7.3.8 Integral conversions [conv.integral]
1 A prvalue of an integer type can be converted to a prvalue of another integer type. A prvalue of an unscoped
enumeration type can be converted to a prvalue of an integer type.

2 If the destination type is bool, see 7.3.14. If the source type is bool, the value false is converted to zero
and the value true is converted to one.

3 Otherwise, the result is the unique value of the destination type that is congruent to the source integer
modulo 2^N, where N is the width of the destination type.

4 The conversions allowed as integral promotions are excluded from the set of integral conversions.

7.3.9 Floating-point conversions [conv.double]
1 A prvalue of floating-point type can be converted to a prvalue of another floating-point type. If the
source value can be exactly represented in the destination type, the result of the conversion is that exact
representation. If the source value is between two adjacent destination values, the result of the conversion is
an implementation-defined choice of either of those values. Otherwise, the behavior is undefined.

2 The conversions allowed as floating-point promotions are excluded from the set of floating-point conversions.

7.3.10 Floating-integral conversions [conv.fpint]
1 A prvalue of a floating-point type can be converted to a prvalue of an integer type. The conversion truncates;
that is, the fractional part is discarded. The behavior is undefined if the truncated value cannot be represented
in the destination type. [Note: If the destination type is bool, see 7.3.14. — end note]

2 A prvalue of an integer type or of an unscoped enumeration type can be converted to a prvalue of a floating-
point type. The result is exact if possible. If the value being converted is in the range of values that can
be represented but the value cannot be represented exactly, it is an implementation-defined choice of either
the next lower or higher representable value. [Note: Loss of precision occurs if the integral value cannot be
represented exactly as a value of the floating-point type. — end note] If the value being converted is outside
the range of values that can be represented, the behavior is undefined. If the source type is bool, the value
false is converted to zero and the value true is converted to one.

7.3.11 Pointer conversions [conv.ptr]
1 A null pointer constant is an integer literal (5.13.2) with value zero or a prvalue of type std::nullptr_t. A
null pointer constant can be converted to a pointer type; the result is the null pointer value of that type (6.7.2)
and is distinguishable from every other value of object pointer or function pointer type. Such a conversion
is called a null pointer conversion. Two null pointer values of the same type shall compare equal. The
conversion of a null pointer constant to a pointer to cv-qualified type is a single conversion, and not the
sequence of a pointer conversion followed by a qualification conversion (7.3.5). A null pointer constant of
integral type can be converted to a prvalue of type std::nullptr_t. [Note: The resulting prvalue is not a
null pointer value. — end note]

2 A prvalue of type “pointer to cv T”, where T is an object type, can be converted to a prvalue of type “pointer
to cv void”. The pointer value (6.7.2) is unchanged by this conversion.
A prvalue of type “pointer to \( cv \) \( D \)”, where \( D \) is a complete class type, can be converted to a prvalue of type “pointer to \( cv \) \( B \)”, where \( B \) is a base class (11.6) of \( D \). If \( B \) is an inaccessible (11.8) or ambiguous (11.7) base class of \( D \), a program that necessitates this conversion is ill-formed. The result of the conversion is a pointer to the base class subobject of the derived class object. The null pointer value is converted to the null pointer value of the destination type.

7.3.12 Pointer-to-member conversions

1 A null pointer constant (7.3.11) can be converted to a pointer-to-member type; the result is the null member pointer value of that type and is distinguishable from any pointer to member not created from a null pointer constant. Such a conversion is called a null member pointer conversion. Two null member pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to member of cv-qualified type is a single conversion, and not the sequence of a pointer-to-member conversion followed by a qualification conversion (7.3.5).

2 A prvalue of type “pointer to member of \( B \) of type \( cv \) \( T \)”, where \( B \) is a class type, can be converted to a prvalue of type “pointer to member of \( D \) of type \( cv \) \( T \)”, where \( D \) is a complete class derived (11.6) from \( B \). If \( B \) is an inaccessible (11.8), ambiguous (11.7), or virtual (11.6.1) base class of \( D \), or a base class of a virtual base class of \( D \), a program that necessitates this conversion is ill-formed. The result of the conversion refers to the same member as the pointer to member before the conversion took place, but it refers to the base class member as if it were a member of the derived class. The result refers to the member in \( D \)’s instance of \( B \). Since the result has type “pointer to member of \( D \) of type \( cv \) \( T \)”, indirect through it with a \( D \) object is valid. The result is the same as if indirecting through the pointer to member of \( B \) with the \( B \) subobject of \( D \). The null member pointer value is converted to the null member pointer value of the destination type.\(^{58}\)

7.3.13 Function pointer conversions

1 A prvalue of type “pointer to \( noexcept \) function” can be converted to a prvalue of type “pointer to function”. The result is a pointer to the function. A prvalue of type “pointer to member of type \( noexcept \) function” can be converted to a prvalue of type “pointer to member of type function”. The result designates the member function.

[Example:

```cpp
void (*p)();
void (**pp)() noexcept = &p; // error: cannot convert to pointer to noexcept function

struct S { typedef void (*p)(); operator p(); };  
void (*q)() noexcept = S();       // error: cannot convert to pointer to noexcept function
— end example]
```

7.3.14 Boolean conversions

1 A prvalue of arithmetic, unscoped enumeration, pointer, or pointer-to-member type can be converted to a prvalue of type \( \text{bool} \). A zero value, null pointer value, or null member pointer value is converted to \( \text{false} \); any other value is converted to \( \text{true} \).

7.4 Usual arithmetic conversions

1 Many binary operators that expect operands of arithmetic or enumeration type cause conversions and yield result types in a similar way. The purpose is to yield a common type, which is also the type of the result. This pattern is called the usual arithmetic conversions, which are defined as follows:

\[ (1.1) \quad \text{If either operand is of scoped enumeration type (9.6), no conversions are performed; if the other operand does not have the same type, the expression is ill-formed.} \]
\[ (1.2) \quad \text{If either operand is of type long double, the other shall be converted to long double.} \]
\[ (1.3) \quad \text{Otherwise, if either operand is double, the other shall be converted to double.} \]
\[ (1.4) \quad \text{Otherwise, if either operand is float, the other shall be converted to float.} \]

\(^{58}\) The rule for conversion of pointers to members (from pointer to member of base to pointer to member of derived) appears inverted compared to the rule for pointers to objects (from pointer to derived to pointer to base) (7.3.11, 11.6). This inversion is necessary to ensure type safety. Note that a pointer to member is not an object pointer or a function pointer and the rules for conversions of such pointers do not apply to pointers to members. In particular, a pointer to member cannot be converted to a \( \text{void} \)\.*
Otherwise, the integral promotions (7.3.6) shall be performed on both operands. Then the following rules shall be applied to the promoted operands:

- If both operands have the same type, no further conversion is needed.
- Otherwise, if both operands have signed integer types or both have unsigned integer types, the operand with the type of lesser integer conversion rank shall be converted to the type of the operand with greater rank.
- Otherwise, if the operand that has unsigned integer type has rank greater than or equal to the rank of the type of the other operand, the operand with signed integer type shall be converted to the type of the operand with unsigned integer type.
- Otherwise, if the type of the operand with signed integer type can represent all of the values of the type of the operand with unsigned integer type, the operand with unsigned integer type shall be converted to the type of the operand with signed integer type.
- Otherwise, both operands shall be converted to the unsigned integer type corresponding to the type of the operand with signed integer type.

If one operand is of enumeration type and the other operand is of a different enumeration type or a floating-point type, this behavior is deprecated (D.1).

### 7.5 Primary expressions

**primary-expression:**

- literal
- this ( expression )
- id-expression
- lambda-expression
- fold-expression
- requires-expression

**7.5.1 Literals**

A literal is a primary expression. Its type depends on its form (5.13). A string literal is an lvalue; all other literals are prvalues.

**7.5.2 This**

The keyword this names a pointer to the object for which a non-static member function (11.3.2.1) is invoked or a non-static data member’s initializer (11.3) is evaluated.

If a declaration declares a member function or member function template of a class X, the expression this is a prvalue of type “pointer to cv-qualifier-seq X” between the optional cv-qualifier-seq and the end of the function-definition, member-declarator, or declarator. It shall not appear before the optional cv-qualifier-seq and it shall not appear within the declaration of a static member function (although its type and value category are defined within a static member function as they are within a non-static member function). [Note: This is because declaration matching does not occur until the complete declarator is known. — end note]

[Note: In a trailing-return-type, the class being defined is not required to be complete for purposes of class member access (7.6.1.4). Class members declared later are not visible. [Example:

```c
struct A {
  char g();
  template<class T> auto f(T t) -> decltype(t + g())
  { return t + g(); }
};
template auto A::f(int t) -> decltype(t + g());
```

Otherwise, if a member-declarator declares a non-static data member (11.3) of a class X, the expression this is a prvalue of type “pointer to X” within the optional default member initializer (11.3). It shall not appear elsewhere in the member-declarator.

The expression this shall not appear in any other context. [Example:

---

59) As a consequence, operands of type bool, char8_t, char16_t, char32_t, wchar_t, or an enumerated type are converted to some integral type.
class Outer {
  int a[sizeof(*this)];        // error: not inside a member function
  unsigned int sz = sizeof(*this);  // OK: in default member initializer

  void f() {
    int b[sizeof(*this)];        // OK

    struct Inner {
      int c[sizeof(*this)];       // error: not inside a member function of Inner
    }
  }
} — end example]

7.5.3 Parentheses [expr.prim.paren]

A parenthesized expression \((E)\) is a primary expression whose type, value, and value category are identical to those of \(E\). The parenthesized expression can be used in exactly the same contexts as those where \(E\) can be used, and with the same meaning, except as otherwise indicated.

7.5.4 Names [expr.prim.id]

An \(id\text{-}expression\) is a restricted form of a \(primary\text{-}expression\). [Note: An \(id\text{-}expression\) can appear after . and \(\rightarrow\) operators (7.6.1.4). — end note]

An \(id\text{-}expression\) that denotes a non-static data member or non-static member function of a class can only be used:

1. as part of a class member access (7.6.1.4) in which the object expression refers to the member’s class\(^*\) or a class derived from that class, or
2. to form a pointer to member (7.6.2.1), or
3. if that \(id\text{-}expression\) denotes a non-static data member and it appears in an unevaluated operand. [Example:
   
   struct S {
     int m;
   };
   int i = sizeof(S::m);        // OK
   int j = sizeof(S::m + 42);   // OK
   — end example]

An \(id\text{-}expression\) that denotes an immediate function (9.1.5) shall appear as a subexpression of an immediate invocation or in an immediate function context (7.7).

An \(id\text{-}expression\) that denotes the specialization of a concept (13.6.8) results in a prvalue of type \textbf{bool}. The expression is \textbf{true} if the concept’s normalized \textit{constraint-expression} (13.4.2) is satisfied (13.4.1) by the specified template arguments and \textbf{false} otherwise. [Example:

   template<typename T> concept C = true;
   static Assert(C<int>);  // OK
   — end example] [Note: A concept’s constraints are also considered when using a template name (13.2) and during overload resolution (Clause 12), and they are compared during the partial ordering of constraints (13.4.4). — end note]

A program that refers explicitly or implicitly to a function with a trailing \textit{requires-clause} whose \textit{constraint-expression} is not satisfied, other than to declare it, is ill-formed. [Example:

   void f(int) requires false;

\(^*\) This also applies when the object expression is an implicit \((*this)\) (11.3.2).
void g() {
    f(0);
    // error: cannot call f
    void (*p1)(int) = f;
    // error: cannot take the address of f
    decltype(f)* p2 = nullptr;  // error: the type decltype(f) is invalid
}  

In each case, the constraints of \texttt{f} are not satisfied. In the declaration of \texttt{p2}, those constraints are required to be satisfied even though \texttt{f} is an unevaluated operand (7.2). —end example

7.5.4.1 Unqualified names

unqualified-id:

identifier
operator-function-id
conversion-function-id
literal-operator-id
\texttt{\~}type-name
\texttt{\~}decltype-specifier

An \texttt{identifier} is only an id-expression if it has been suitably declared (Clause 9) or if it appears as part of a declarator-id (9.2). [Note: For operator-function-ids, see 12.5; for conversion-function-ids, see 11.3.7.2; for literal-operator-ids, see 12.5.8; for template-ids, see 13.2. A type-name or decltype-specifier prefixed by \texttt{\~}denotes the destructor of the type so named; see 7.5.4.3. Within the definition of a non-static member function, an identifier that names a non-static member is transformed to a class member access expression (11.3.2). —end note]

The result is the entity denoted by the identifier. If the entity is a local entity and naming it from outside of an unevaluated operand within the declarative region where the unqualified-id appears would result in some intervening \texttt{lambda-expression} capturing it by copy (7.5.5.2), the type of the expression is the type of a class member access expression (7.6.1.4) naming the non-static data member that would be declared for such a capture in the closure object of the innermost such intervening \texttt{lambda-expression}. [Note: If that \texttt{lambda-expression} is not declared \texttt{mutable}, the type of such an identifier will typically be \texttt{const} qualified. —end note] If the entity is a template parameter object for a template parameter of type \texttt{T} (13.1), the type of the expression is \texttt{const T}. Otherwise, the type of the expression is the type of the result. [Note: The type will be adjusted as described in 7.2.2 if it is cv-qualified or is a reference type. —end note] The expression is an lvalue if the entity is a function, variable, structured binding (9.5), data member, or template parameter object and a prvalue otherwise (7.2.1); it is a bit-field if the identifier designates a bit-field. [Example:

void f() {
    float x, &r = x;
    [=] {
        decltype(x) y1;  // \texttt{y1} has type \texttt{float}
        decltype((x)) y2 = y1;  // \texttt{y2} has type \texttt{float const\&} because this lambda
                                // is not \texttt{mutable} and \texttt{x} is an \texttt{lvalue}
        decltype(r) r1 = y1;  // \texttt{r1} has type \texttt{float\&}
        decltype((r)) r2 = y2;  // \texttt{r2} has type \texttt{float const\&}
    }
}  
—end example

7.5.4.2 Qualified names

qualified-id:

nested-name-specifier template_opt unqualified-id

nested-name-specifier:

::

    type-name ::
    namespace-name ::
    decltype-specifier ::
    nested-name-specifier identifier ::
    nested-name-specifier template_opt simple-template-id ::

The type denoted by a decltype-specifier in a nested-name-specifier shall be a class or enumeration type.
A nested-name-specifier that denotes a class, optionally followed by the keyword template (13.2), and then followed by the name of a member of either that class (11.3) or one of its base classes (11.6), is a qualified-id; 6.4.3.1 describes name lookup for class members that appear in qualified-ids. The result is the member. The type of the result is the type of the member. The result is an lvalue if the member is a static member function or a data member and a prvalue otherwise. [Note: A class member can be referred to using a qualified-id at any point in its potential scope (6.3.7). — end note] Where type-name ::~ type-name is used, the two type-names shall refer to the same type (ignoring cv-qualifications); this notation denotes the destructor of the type so named (7.5.4.3). The unqualified-id in a qualified-id shall not be of the form ~decltype-specifier.

The nested-name-specifier :: names the global namespace. A nested-name-specifier that names a namespace (9.7), optionally followed by the keyword template (13.2), and then followed by the name of a member of that namespace (or the name of a member of a namespace made visible by a using-directive), is a qualified-id; 6.4.3.2 describes name lookup for namespace members that appear in qualified-ids. The result is the member. The type of the result is the type of the member. The result is an lvalue if the member is a function, a variable, or a structured binding (9.5) and a prvalue otherwise.

A nested-name-specifier that denotes an enumeration (9.6), followed by the name of an enumerator of that enumeration, is a qualified-id that refers to the enumerator. The result is the enumerator. The type of the result is the type of the enumeration. The result is a prvalue.

In a qualified-id, if the unqualified-id is a conversion-function-id, its conversion-type-id is first looked up in the class denoted by the nested-name-specifier of the qualified-id and the name, if found, is used. Otherwise, it is looked up in the context in which the entire qualified-id occurs. In each of these lookups, only names that denote types or templates whose specializations are types are considered.

7.5.4.3 Destruction [expr.prim.id.dtor]

An id-expression that denotes the destructor of a type T names the destructor of T if T is a class type (11.3.6), otherwise the id-expression is said to name a pseudo-destructor.

If the id-expression names a pseudo-destructor, T shall be a scalar type and the id-expression shall appear as the right operand of a class member access (7.6.1.4) that forms the postfix-expression of a function call (7.6.1.2). [Note: Such a call has no effect. — end note]

[Example:
struct C { };
void f() {
    C * pc = new C;
    using C2 = C;
    pc->C::~C2(); // OK, destroys *pc
    C().C::~C(); // undefined behavior: temporary of type C destroyed twice
    using T = int;
    O.T::~T(); // OK, no effect
    O.T::~T(); // error: 0.T is a user-defined-floating-literal (5.13.8)
}
— end example]

7.5.5 Lambda expressions [expr.prim.lambda]

A lambda-expression provides a concise way to create a simple function object. [Example:
#include <algorithm>
#include <cmath>
void abssort(float* x, unsigned N) {
    std::sort(x, x + N, [](float a, float b) { return std::abs(a) < std::abs(b); });
}
A \textit{lambda-expression} is a prvalue whose result object is called the \textit{closure object}. [Note: A closure object behaves like a function object (20.14). — end note]

In the \textit{decl-specifier-seq} of the \textit{lambda-declarator}, each \textit{decl-specifier} shall be one of \texttt{mutable, constexpr, or constexpr}. [Note: The trailing \texttt{requires-clause} is described in 9.2. — end note]

If a \textit{lambda-expression} does not include a \textit{lambda-declarator}, it is as if the \textit{lambda-declarator} were \texttt{()}. The lambda return type is \texttt{auto}, which is replaced by the type specified by the trailing-return-type if provided and/or deduced from \texttt{return} statements as described in 9.1.7.5. [Example:

\begin{verbatim}
    auto x1 = [](int i) { return i; }; // OK: return type is int
    auto x2 = [](return { 1, 2 }); // error: deducing return type from braced-init-list
    int j;
    auto x3 = []()->auto&& { return j; }; // OK: return type is int&
\end{verbatim}
—end example]

A lambda is a \textit{generic lambda} if there is a \textit{decl-specifier} that is a \texttt{placeholder-type-specifier} in the \textit{decl-specifier-seq} of a \textit{parameter-declaration} of the \textit{lambda-expression}, or if the lambda has a \texttt{template-parameter-list}. [Example:

\begin{verbatim}
    int i = [](int i, auto a) { return i; }(3, 4); // OK: a generic lambda
    int j = []<class T>(T t, int i) { return i; }(3, 4); // OK: a generic lambda
\end{verbatim}
—end example]

The type of a \textit{lambda-expression} (which is also the type of the closure object) is a unique, unnamed non-union class type, called the \textit{closure type}, whose properties are described below.

The closure type is declared in the smallest block scope, class scope, or namespace scope that contains the corresponding \textit{lambda-expression}. [Note: This determines the set of namespaces and classes associated with the closure type (6.4.2). The parameter types of a \textit{lambda-declarator} do not affect these associated namespaces and classes. — end note] The closure type is not an aggregate type (9.3.1). An implementation may define the closure type differently from what is described below provided this does not alter the observable behavior of the program other than by changing:

(2.1) — the size and/or alignment of the closure type,
(2.2) — whether the closure type is trivially copyable (11.1), or
(2.3) — whether the closure type is a standard-layout class (11.1).

An implementation shall not add members of rvalue reference type to the closure type.

The closure type for a \textit{lambda-expression} has a public inline function call operator (for a non-generic lambda) or function call operator template (for a generic lambda) (12.5.4) whose parameters and return type are described by the \textit{lambda-expression}'s \texttt{parameter-declaration-clause} and \texttt{trailing-return-type} respectively, and whose \texttt{template-parameter-list} consists of the specified \texttt{template-parameter-list}, if any. The \texttt{requires-clause} of the function call operator template is the \texttt{requires-clause} immediately following \texttt{<template-parameter-list>}, if any. The trailing \texttt{requires-clause} of the function call operator or operator template is the \texttt{requires-clause} of the \textit{lambda-declarator}, if any. [Note: The function call operator for a generic lambda might be an abbreviated function template (9.2.3.5). — end note] [Example:

\begin{verbatim}
    auto glambda = [](auto a, auto&& b) { return a < b; };
    bool b = glambda(3, 3.14); // OK
    auto vglambda = [](auto printer) {
        return [=](auto&& ... ts) {
            // OK: ts is a function parameter pack
            printer(std::forward<decltype(ts)>(ts)...);
            return [=]() {
                printer(ts ...);
            };
    };
\end{verbatim}
—end example]
auto p = vglambda( [](auto v1, auto v2, auto v3) {
    std::cout << v1 << v2 << v3; 
};
auto q = p(1, 'a', 3.14); // OK: outputs 1a3.14
q(); // OK: outputs 1a3.14
— end example

4 The function call operator or operator template is declared const (11.3.2) if and only if the lambda-expression’s parameter-declaration-clause is not followed by mutable. It is neither virtual nor declared volatile. Any noexcept-specifier specified on a lambda-expression applies to the corresponding function call operator or operator template. An attribute-specifier-seq in a lambda-declarator appertains to the type of the corresponding function call operator or operator template. The function call operator or any given operator template specialization is a constexpr function if either the corresponding lambda-expression’s parameter-declaration-clause is followed by constexpr or consteval, or it satisfies the requirements for a constexpr function (9.1.5). It is an immediate function (9.1.5) if the corresponding lambda-expression’s parameter-declaration-clause is followed by constexpr or consteval. [Note: Names referenced in the lambda-declarator are looked up in the context in which the lambda-expression appears. — end note] [Example:

auto ID = [] (auto a) { return a; }; // OK
static_assert(ID(3) == 3);
struct NonLiteral {
    NonLiteral(int n) : n(n) { }
    int n;
};
static_assert(ID(NonLiteral{3}).n == 3); // ill-formed
— end example

5 [Example:

auto monoid = [] (auto v) { return [=] { return v; }; };
auto add = [] (auto m1) constexpr {
    auto ret = m1();
    return [=] (auto m2) mutable {
        auto m1val = m1();
        auto plus = [=] (auto m2val) mutable constexpr
            { return m1val += m2val; };
        ret = plus(m2());
        return monoid(ret);
    };
};
constexpr auto zero = monoid(0);
constexpr auto one = monoid(1);
static_assert(add(one)(zero)() == one()); // OK
// Since two below is not declared constexpr, an evaluation of its constexpr member function call operator
// cannot perform an lvalue-to-rvalue conversion on one of its subobjects (that represents its capture)
// in a constant expression.
auto two = monoid(2);
assert(two() == 2); // OK, not a constant expression.
static_assert(add(one)(one)() == two()); // ill-formed: two() is not a constant expression
static_assert(add(one)(one)() == monoid(2)()); // OK
— end example

6 [Note: The function call operator or operator template may be constrained (13.4.2) by a type-constraint (13.1), a requires-clause (Clause 13), or a trailing requires-clause (9.2).] [Example:

```cpp
template <typename T> concept C1 = /* ... */;
template <std::size_t N> concept C2 = /* ... */;
template <typename A, typename B> concept C3 = /* ... */;

auto f = []<typename T1, C1 T2> requires C2<sizeof(T1) + sizeof(T2)>
    (T1 a1, T1 b1, T2 a2, auto a3, auto a4) requires C3<decltype(a4), T2> {
    // T2 is constrained by a type-constraint.
    // T1 and T2 are constrained by a requires-clause, and
    // T2 and the type of a4 are constrained by a trailing requires-clause.
```
The closure type for a non-generic lambda-expression with no lambda-capture whose constraints (if any) are satisfied has a conversion function to pointer to function with C++ language linkage (9.10) having the same parameter and return types as the closure type’s function call operator. The conversion is to “pointer to noexcept function” if the function call operator has a non-throwing exception specification. The value returned by this conversion function is the address of a function \( F \) that, when invoked, has the same effect as invoking the closure type’s function call operator on a default-constructed instance of the closure type. \( F \) is a constexpr function if the function call operator is a constexpr function and is an immediate function if the function call operator is an immediate function.

For a generic lambda with no lambda-capture, the closure type has a conversion function template to pointer to function. The conversion function template has the same invented template parameter list, and the pointer to function has the same parameter types, as the function call operator template. The return type of the pointer to function shall behave as if it were a decltype-specifier denoting the return type of the corresponding function call operator template specialization.

\[ \text{Note: If the generic lambda has no trailing-return-type or the trailing-return-type contains a placeholder type, return type deduction of the corresponding function call operator template specialization has to be done. The corresponding specialization is that instantiation of the function call operator template with the same template arguments as those deduced for the conversion function template. Consider the following:} \]

\[
\begin{align*}
\text{auto glambda} & = \lambda (\text{auto a}) \{ \text{return a;} \}; \\
\text{int \(*fp\)(\text{int})} & = \text{glambda};
\end{align*}
\]

The behavior of the conversion function of \( \text{glambda} \) above is like that of the following conversion function:

\[
\begin{align*}
\text{struct Closure} & \{ \\
\text{template<\text{class T}> auto operator()(\text{T t}) \text{ const \{ /* ... */ \}}} & \\
\text{template<\text{class T}> static auto lambda_call_operator_invoker(\text{T a}) \{ \\
& // \text{forwards execution to operator()(a) and therefore has} \\
& // \text{the same return type deduced} \\
& /* ... */ \} \}} & \\
\text{template<\text{class T> using fp\_t} & = \\
& \text{decltype(lamba\_call\_operator\_invoker(declval\_T\_t()))} \ (*\_t)\_t; \\
\text{template<\text{class T> operator fp\_t\_t<\text{T}\_t>() \text{ const} \{ \\
& \text{return \&lambda\_call\_operator\_invoker; \}}} & \\
\};
\end{align*}
\]

\[\text{—end note}\]

\[\text{Example:}\]

\[
\begin{align*}
\text{void f1(\text{int \(*\)(int))}} & \{ \} \\
\text{void f2(char \(*\)(int))} & \{ \} \\
\text{void g(\text{int \(*\)(int))} & \{ \} \quad \text{// #1} \\
\text{void g(char \(*\)(char))} & \{ \} \quad \text{// #2} \\
\text{void h(\text{int \(*\)(int))} & \{ \} \quad \text{// #3} \\
\text{void h(char \(*\)(int))} & \{ \} \quad \text{// #4} \\
\text{auto glambda} & = \lambda (\text{auto a}) \{ \text{return a;} \}; \\
\text{f1(glambda);} & \quad \text{// OK} \\
\text{f2(glambda);} & \quad \text{// error: ID is not convertible} \\
\text{g(glambda);} & \quad \text{// error: ambiguous} \\
\text{h(glambda);} & \quad \text{// OK: calls #3 since it is convertible from ID} \\
\text{int\& \(*fp\)(\text{int\*)} = \lambda (\text{auto\& a}) \rightarrow \text{auto\& \{ \text{return \&a;} \};} \quad \text{// OK}
\end{align*}
\]

\[\text{—end example}\]

The value returned by any given specialization of this conversion function template is the address of a function \( F \) that, when invoked, has the same effect as invoking the generic lambda’s corresponding function call operator template specialization on a default-constructed instance of the closure type. \( F \) is a constexpr function if the corresponding specialization is a constexpr function and \( F \) is an immediate function if the
function call operator template specialization is an immediate function. [Note: This will result in the implicit instantiation of the generic lambda’s body. The instantiated generic lambda’s return type and parameter types shall match the return type and parameter types of the pointer to function. — end note] [Example:

```cpp
auto GL = [](auto a) { std::cout << a; return a; };
int (*GL_int)(int) = GL; // OK: through conversion function template
GL_int(3); // OK: same as GL(3)
```
—end example]

The conversion function or conversion function template is public, constexpr, non-virtual, non-explicit, const, and has a non-throwing exception specification (14.4). [Example:

```cpp
auto Fwd = [](int (*fp)(int), auto a) { return fp(a); };
auto C = []  (auto a) { return a; };

static_assert(Fwd(C, 3) == 3); // OK
// No specialization of the function call operator template can be constexpr (due to the local static).
auto NC = []  (auto a) { static int s; return a; };
static_assert(Fwd(NC, 3) == 3); // ill-formed
```
—end example]

11 The lambda-expression’s compound-statement yields the function-body (9.4) of the function call operator, but for purposes of name lookup (6.4), determining the type and value of this (11.3.2.1) and transforming id-expressions referring to non-static class members into class member access expressions using (*this) (11.3.2), the compound-statement is considered in the context of the lambda-expression. [Example:

```cpp
struct S1 {
    int x, y;
    int operator()(int);
    void f() {
        [=]()->int {
            return operator()(this->x + y);  // equivalent to S1::operator()(this->x + (*this).y)
            // this has type S1*
        }
    }
};
```
—end example] Further, a variable __func__ is implicitly defined at the beginning of the compound-statement of the lambda-expression, with semantics as described in 9.4.1.

12 The closure type associated with a lambda-expression has no default constructor if the lambda-expression has a lambda-capture and a defaulted default constructor otherwise. It has a defaulted copy constructor and a defaulted move constructor (11.3.4.2). It has a deleted copy assignment operator if the lambda-expression has a lambda-capture and defaulted copy and move assignment operators otherwise (11.3.5). [Note: These special member functions are implicitly defined as usual, and might therefore be defined as deleted. — end note]

13 The closure type associated with a lambda-expression has an implicitly-declared destructor (11.3.6).

14 A member of a closure type shall not be explicitly instantiated (13.8.2), explicitly specialized (13.8.3), or named in a friend declaration (11.8.3).

### 7.5.5.2 Captures

```cpp
lambda-capture:
capture-default
capture-list
capture-default , capture-list

capture-default:
&
=

capture-list:
capture
capture-list , capture
The body of a lambda-expression may refer to variables with automatic storage duration and the `*this` object (if any) of enclosing block scopes by capturing those entities, as described below.

If a lambda-capture includes a capture-default that is `&`, no identifier in a simple-capture of that lambda-capture shall be preceded by `&`. If a lambda-capture includes a capture-default that is `=`, each simple-capture of that lambda-capture shall be of the form `"& identifier"`, `"this"`, or `"* this"`. [Note: The form `[&,this]` is redundant but accepted for compatibility with ISO C++ 2014. — end note] Ignoring appearances in initializers of init-captures, an identifier or `this` shall not appear more than once in a lambda-capture. [Example:

```cpp
guyen S2 { void f(int i); }

void S2::f(int i) {
    [&, i]{ };  // OK
    [&, this, i]{ };  // OK, equivalent to [&, i]
    [&, &i]{};  // error: i preceded by & when & is the default
    [=, *this]{};  // OK
    [=, this]{};  // OK, equivalent to [=]
    [i, i]{};  // error: i repeated
    [this, *this]{};  // error: this appears twice
}
— end example]

A lambda-expression shall not have a capture-default or simple-capture in its lambda-introducer unless its innermost enclosing scope is a block scope (6.3.3) or it appears within a default member initializer and its innermost enclosing scope is the corresponding class scope (6.3.7).

The identifier in a simple-capture is looked up using the usual rules for unqualified name lookup (6.4.1); each such lookup shall find a local entity. The simple-captures `this` and `* this` denote the local entity `*this`. An entity that is designated by a simple-capture is said to be explicitly captured.

If an identifier in a simple-capture appears as the declarator-id of a parameter of the lambda-declarator’s parameter-declaration-clause, the program is ill-formed. [Example:

```cpp
void f() {
    int x = 0;
    auto g = [x](int x) { return 0; };  // error: parameter and simple-capture have the same name
}
— end example]

An init-capture behaves as if it declares and explicitly captures a variable of the form “auto init-capture;” whose declarative region is the lambda-expression’s compound-statement, except that:

(6.1) — if the capture is by copy (see below), the non-static data member declared for the capture and the variable are treated as two different ways of referring to the same object, which has the lifetime of the non-static data member, and no additional copy and destruction is performed, and

(6.2) — if the capture is by reference, the variable’s lifetime ends when the closure object’s lifetime ends.

[Note: This enables an init-capture like “x = std::move(x);” the second “x” must bind to a declaration in the surrounding context. — end note] [Example:

```cpp
int x = 4;
auto y = [&r = x, x = x+1]()->int {
    r += 2;
    return x+2;
}
```
© ISO/IEC 2023

For the purposes of lambda capture, an expression potentially references local entities as follows:

- An id-expression that names a local entity potentially references that entity; an id-expression that names one or more non-static class members and does not form a pointer to member (7.6.2.1) potentially references *this. [Note: This occurs even if overload resolution selects a static member function for the id-expression. — end note]

- A this expression potentially references *this.

- A lambda-expression potentially references the local entities named by its simple-captures.

If an expression potentially references a local entity within a declarative region in which it is odr-usable, and the expression would be potentially evaluated if the effect of any enclosing typeid expressions (7.6.1.7) were ignored, the entity is said to be implicitly captured by each intervening lambda-expression with an associated capture-default that does not explicitly capture it. The implicit capture of *this is deprecated when the capture-default is =; see D.2. [Example:

```cpp
void f(int, const int (&)[2] = {});  // #1
void f(const int&, const int (&)[1]);  // #2
void test() {
    const int x = 17;
    auto g = [=](auto a) {
        f(x);  // OK: calls #1, does not capture x
    };

    auto g1 = [=](auto a) {
        f(x);  // OK: calls #1, captures x
    };

    auto g2 = [=](auto a) {
        int selector[sizeof(a) == 1 ? 1 : 2]{};
        f(x, selector);  // OK: captures x, might call #1 or #2
    };

    auto g3 = [=](auto a) {
        typeid(a + x);  // captures x regardless of whether a + x is an unevaluated operand
    };
}
```

Within g1, an implementation might optimize away the capture of x as it is not odr-used. — end example]

[Note: The set of captured entities is determined syntactically, and entities might be implicitly captured even if the expression denoting a local entity is within a discarded statement (8.4.1). — end example]

- An entity is captured if it is captured explicitly or implicitly. An entity captured by a lambda-expression is odr-used (6.2) in the scope containing the lambda-expression. [Note: As a consequence, if a lambda-expression explicitly captures an entity that is not odr-usable, the program is ill-formed (6.2). — end note] [Example:

```cpp
template<bool B>
void f1(int n) {
    [=](auto a) {
        if constexpr (B && sizeof(a) > 4) {
            (void)n;  // captures n regardless of the value of B and sizeof(int)
        }
    }(0);
}
```

— end example] — end note]
auto m2 = [i] {
    int x[N][M];          // OK: N and M are not odr-used
    x[0][0] = i;           // OK: i is explicitly captured by m2 and implicitly captured by m1
};

struct s1 {
    int f;
    void work(int n) {
        int m = n*n;
        auto m3 = [this, m] {
            auto m4 = [&j] {
                // error: j not odr-usable due to intervening lambda m3
                int x = n;
                x += m;    // OK: m implicitly captured by m4 and explicitly captured by m3
                x += i;    // error: i is odr-used but not odr-usable
due to intervening function and class scopes
                x += f;    // OK: this captured implicitly by m4 and explicitly by m3
            };
        };
    }
};

struct s2 {
    double ohseven = .007;
    auto f() {
        return [this] { // OK
            return [*this] {
                return ohseven;
            }();
        };
    }
    auto g() {
        return [] { // error: *this not captured by outer lambda-expression
            return [*this] { }
        }();
    }
};

— end example

9 [Note: Because local entities are not odr-usable within a default argument (6.2), a lambda-expression appearing in a default argument cannot implicitly or explicitly capture any local entity. Such a lambda-expression can still have an init-capture if any full-expression in its initializer satisfies the constraints of an expression appearing in a default argument (9.2.3.6). — end note] [Example:

void f2() {
    int i = 1;
    void g1(int = ([i] { return i; })()); // ill-formed
    void g2(int = ([i] { return 0; })()); // ill-formed
    void g3(int = ([=] { return i; })()); // ill-formed
    void g4(int = ([=] { return 0; })()); // OK
    void g5(int = ([] { return sizeof i; })()); // OK
    void g6(int = ([x=1] { return x; })()); // OK
    void g7(int = ([x=1] { return x; })()); // ill-formed
}

— end example

10 An entity is captured by copy if

(10.1) — it is implicitly captured, the capture-default is =, and the captured entity is not *this, or

(10.2) — it is explicitly captured with a capture that is not of the form this, &identifier, or &identifier initializer.

For each entity captured by copy, an unnamed non-static data member is declared in the closure type. The declaration order of these members is unspecified. The type of such a data member is the referenced type if the entity is a reference to an object, an lvalue reference to the referenced function type if the entity
is a reference to a function, or the type of the corresponding captured entity otherwise. A member of an anonymous union shall not be captured by copy.

11 Every id-expression within the compound-statement of a lambda-expression that is an odr-use (6.2) of an entity captured by copy is transformed into an access to the corresponding unnamed data member of the closure type. [Note: An id-expression that is not an odr-use refers to the original entity, never to a member of the closure type. However, such an id-expression can still cause the implicit capture of the entity. — end note] If *this is captured by copy, each expression that odr-uses *this is transformed to instead refer to the corresponding unnamed data member of the closure type. [Example:

```c
void f(const int*);
void g() {
    const int N = 10;
    [=] {
        int arr[N];  // OK: not an odr-use, refers to automatic variable
        f(&N);      // OK: causes N to be captured; &N points to
                    // the corresponding member of the closure type
    };
}
— end example]
```

12 An entity is captured by reference if it is implicitly or explicitly captured but not captured by copy. It is unspecified whether additional unnamed non-static data members are declared in the closure type for entities captured by reference. If declared, such non-static data members shall be of literal type. [Example:

```c
// The inner closure type must be a literal type regardless of how reference captures are represented.
static_assert([](int n) { return [&n] { return ++n; }(); }()(3) == 4);
— end example] A bit-field or a member of an anonymous union shall not be captured by reference.

13 An id-expression within the compound-statement of a lambda-expression that is an odr-use of a reference captured by reference refers to the entity to which the captured reference is bound and not to the captured reference. [Note: The validity of such captures is determined by the lifetime of the object to which the reference refers, not by the lifetime of the reference itself. — end note] [Example:

```c
auto h(int &r) {
    return [&] {
        ++r;          // Valid after h returns if the lifetime of the
                       // object to which r is bound has not ended
    };
}
— end example]
```

14 If a lambda-expression m2 captures an entity and that entity is captured by an immediately enclosing lambda-expression m1, then m2’s capture is transformed as follows:

(14.1) — if m1 captures the entity by copy, m2 captures the corresponding non-static data member of m1’s closure type;

(14.2) — if m1 captures the entity by reference, m2 captures the same entity captured by m1.

[Example: The nested lambda-expressions and invocations below will output 123234.

```c
int a = 1, b = 1, c = 1;
auto m1 = [a, &b, &c]() mutable {
auto m2 = [a, b, &c]() mutable {
    std::cout << a << b << c;
    a = 4; b = 4; c = 4;
};
a = 3; b = 3; c = 3;
m2();
};
a = 2; b = 2; c = 2;
m1();
std::cout << a << b << c;
— end example]
```
When the lambda-expression is evaluated, the entities that are captured by copy are used to direct-initialize each corresponding non-static data member of the resulting closure object, and the non-static data members corresponding to the init-captures are initialized as indicated by the corresponding initializer (which may be copy- or direct-initialization). (For array members, the array elements are direct-initialized in increasing subscript order.) These initializations are performed in the (unspecified) order in which the non-static data members are declared. [Note: This ensures that the destructions will occur in the reverse order of the constructions. — end note]

A simple-capture followed by an ellipsis is a pack expansion (13.6.3). An init-capture preceded by an ellipsis is a pack expansion that introduces an init-capture pack (13.6.3) whose declarative region is the lambda-expression’s compound-statement. [Example:

```
template<class... Args>
void f(Args... args) {
    auto lm = [&ARGS... args... ] { return g(args...); };
    lm();

    auto lm2 = [...xs=std::move(args)] { return g(xs...); };
    lm2();
}
—end example]

7.5.6 Fold expressions

A fold expression performs a fold of a pack (13.6.3) over a binary operator.

fold-expression:

  ( cast-expression fold-operator ... )
  ( ... fold-operator cast-expression )
  ( cast-expression fold-operator ... fold-operator cast-expression )

fold-operator: one of

  + - * / % ^ & | << >>
  += -= == /= &= <<= >>= =
  != < > <= >= && || , .* ->*

An expression of the form (... op e) where op is a fold-operator is called a unary left fold. An expression of the form (e ... e) where op is a fold-operator is called a unary right fold. Unary left folds and unary right folds are collectively called unary folds. In a unary fold, the cast-expression shall contain an unexpanded pack (13.6.3).

An expression of the form (e1 op1 ... op2 e2) where op1 and op2 are fold-operators is called a binary fold. In a binary fold, op1 and op2 shall be the same fold-operator, and either e1 shall contain an unexpanded pack or e2 shall contain an unexpanded pack, but not both. If e2 contains an unexpanded pack, the expression is called a binary left fold. If e1 contains an unexpanded pack, the expression is called a binary right fold. [Example:

```
template<typename ...Args>
bool f(Args ...args) {
    return (true & & ... & & args); // OK
}

template<typename ...Args>
bool f(Args ...args) {
    return (args + ... + args); // error: both operands contain unexpanded packs
}
—end example]

7.5.7 Requires expressions

A requires-expression provides a concise way to express requirements on template arguments that can be checked by name lookup (6.4) or by checking properties of types and expressions.
requires-expression:
  requires requirement-parameter-list_opt requirement-body

requirement-parameter-list:
  ( parameter-declaration-clause_opt )

requirement-body:
  { requirement-seq }

requirement-seq:
  { requirement-seq requirement

requirement:
  simple-requirement
  type-requirement
  compound-requirement
  nested-requirement

2 A requires-expression is a prvalue of type bool whose value is described below. Expressions appearing within a requirement-body are unevaluated operands (7.2).

3 [Example: A common use of requires-expressions is to define requirements in concepts such as the one below:

template<typename T>
concept R = requires (T i) {
  typename T::type;
  {i} -> const typename T::type&;
};

A requires-expression can also be used in a requires-clause (Clause 13) as a way of writing ad hoc constraints on template arguments such as the one below:

template<typename T>
requires requires (T x) { x + x; }
T add(T a, T b) { return a + b; }

The first requires introduces the requires-clause, and the second introduces the requires-expression. — end example]

4 A requires-expression may introduce local parameters using a parameter-declaration-clause (9.2.3.5). A local parameter of a requires-expression shall not have a default argument. Each name introduced by a local parameter is in scope from the point of its declaration until the closing brace of the requirement-body. These parameters have no linkage, storage, or lifetime; they are only used as notation for the purpose of defining requirements. The parameter-declaration-clause of a requirement-parameter-list shall not terminate with an ellipsis. [Example:

template<typename T>
concept C = requires(T t, ...) {
  // error: terminates with an ellipsis
  t;
};

— end example]

5 The requirement-body contains a sequence of requirements. These requirements may refer to local parameters, template parameters, and any other declarations visible from the enclosing context.

6 The substitution of template arguments into a requires-expression may result in the formation of invalid types or expressions in its requirements or the violation of the semantic constraints of those requirements. In such cases, the requires-expression evaluates to false; it does not cause the program to be ill-formed. The substitution and semantic constraint checking proceeds in lexical order and stops when a condition that determines the result of the requires-expression is encountered. If substitution (if any) and semantic constraint checking succeed, the requires-expression evaluates to true. [Note: If a requires-expression contains invalid types or expressions in its requirements, and it does not appear within the declaration of a templated entity, then the program is ill-formed. — end note] If the substitution of template arguments into a requirement would always result in a substitution failure, the program is ill-formed; no diagnostic required. [Example:

template<typename T> concept C =
requires {
  new int[-(int)sizeof(T)]; // ill-formed, no diagnostic required
}
7.5.7.1 Simple requirements

A simple-requirement asserts the validity of an expression. [Note: The enclosing requires-expression will evaluate to false if substitution of template arguments into the expression fails. The expression is an unevaluated operand (7.2). — end note] [Example:

```cpp
template<typename T> concept C = 
requires (T a, T b) {
    a + b; //C<T> is true if a + b is a valid expression
};
```

— end example]

7.5.7.2 Type requirements

A type-requirement asserts the validity of a type. [Note: The enclosing requires-expression will evaluate to false if substitution of template arguments fails. — end note] [Example:

```cpp
template<typename T, typename T::type = 0> struct S;
template<typename T> using Ref = T&;
template<typename T> concept C = requires {
    typename T::inner; // required nested member name
    typename S<T>; // required class template specialization
    typename Ref<T>; // required alias template substitution, fails if T is void
};
```

— end example]

2 A type-requirement that names a class template specialization does not require that type to be complete (6.7).

7.5.7.3 Compound requirements

A compound-requirement asserts properties of the expression E. Substitution of template arguments (if any) and verification of semantic properties proceed in the following order:

1. Substitution of template arguments (if any) into the expression is performed.
2. If the noexcept specifier is present, E shall not be a potentially-throwing expression (14.4).
3. If the return-type-requirement is present, then:
   1.1 Substitute of template arguments (if any) into the return-type-requirement is performed.
   1.2 If the return-type-requirement is a trailing-return-type (9.2), E is implicitly convertible to the type named by the trailing-return-type. If conversion fails, the enclosing requires-expression is false.
   1.3 If the return-type-requirement is of the form -> type-constraint, then the contextually-determined type being constrained is decltype((E)). The immediately-declared constraint (Clause 13) of decltype(E)) shall be satisfied. [Example: Given concepts C and D,

```cpp
requires {
    { E1 } -> C;
    { E2 } -> D<A_1, ···, A_n>;
};
```

is equivalent to

```cpp
requires {
    E1; requires C< decltype(E1) >;
```

§ 7.5.7.3
E2; requires D< decltype((E2)), A1, ..., An>; 
};

(including in the case where n is zero). —end example]

2 [Example:

```cpp
template< typename T > concept C1 = requires(T x) {
    {x++};
};
```

The compound-requirement in C1 requires that x++ is a valid expression. It is equivalent to the simple-requirement x++;

```cpp
template< typename T > concept C2 = requires(T x) {
    {*x} -> typename T::inner;
};
```

The compound-requirement in C2 requires that *x is a valid expression, that typename T::inner is a valid type, and that *x is implicitly convertible to typename T::inner.

```cpp
template< typename T > concept C3 =
    requires(T x) {
    {g(x)} noexcept;
    };
```

The compound-requirement in C3 requires that g(x) is a valid expression and that g(x) is non-throwing. —end example]

7.5.7.4 Nested requirements

nested-requirement:

```cpp
requires constraint-expression ;
```

1 A nested-requirement can be used to specify additional constraints in terms of local parameters. The constraint-expression shall be satisfied (13.4.2) by the substituted template arguments, if any. Substitution of template arguments into a nested-requirement does not result in substitution into the constraint-expression other than as specified in 13.4.2. [Example:

```cpp
template< typename U > concept C = sizeof(U) == 1;
```

```cpp
template< typename T > concept D = requires (T t) {
    requires sizeof(a) == 4; // OK
    requires a == 0; // error: evaluation of a constraint variable
    };
```

D<T> is satisfied if sizeof(decltype (+t)) == 1 (13.4.1.2). —end example]

2 A local parameter shall only appear as an unevaluated operand (7.2) within the constraint-expression. [Example:

```cpp
template< typename T > concept C = requires (T a) {
    requires sizeof(a) == 4; // OK
    requires a == 0; // error: evaluation of a constraint variable
    }
```

—end example]

7.6 Compound expressions

7.6.1 Postfix expressions

1 Postfix expressions group left-to-right.
postfix-expression:
  primary-expression*postfix-expression [ expr-or-braced-init-list ]
  postfix-expression ( expression-list_opt )
  simple-type-specifier ( expression-list_opt )
  typename-specifier ( expression-list_opt )
  simple-type-specifier braced-init-list
  typename-specifier braced-init-list
  postfix-expression . template_opt id-expression
  postfix-expression -> template_opt id-expression
  postfix-expression ++
  postfix-expression --
dynamic_cast < type-id > ( expression )
static_cast < type-id > ( expression )
reinterpret_cast < type-id > ( expression )
typeid ( expression )
typeid ( type-id )

expression-list:
  initializer-list

2 [Note: The > token following the type-id in a dynamic_cast, static_cast, reinterpret_cast, or const_cast may be the product of replacing a >> token by two consecutive > tokens (13.2). — end note]

7.6.1.1 Subscripting [expr.sub]
1 A postfix expression followed by an expression in square brackets is a postfix expression. One of the expressions shall be a glvalue of type “array of T” or a prvalue of type “pointer to T” and the other shall be a prvalue of unscoped enumeration or integral type. The result is of type “T”. The type “T” shall be a completely-defined object type.61 The expression E1[E2] is identical (by definition) to *((E1)+(E2)), except that in the case of an array operand, the result is an lvalue if that operand is an lvalue and an xvalue otherwise. The expression E1 is sequenced before the expression E2.

2 [Note: Despite its asymmetric appearance, subscripting is a commutative operation except for sequencing. See 7.6.2 and 7.6.6 for details of * and + and 9.2.3.4 for details of array types. — end note]

3 A braced-init-list shall not be used with the built-in subscript operator.

7.6.1.2 Function call [expr.call]
1 A function call is a postfix expression followed by parentheses containing a possibly empty, comma-separated list of initializer-clause which constitute the arguments to the function. The postfix expression shall have function type or function pointer type. For a call to a non-member function or to a static member function, the postfix expression shall either be an lvalue that refers to a function (in which case the function-to-pointer standard conversion (7.3.3) is suppressed on the postfix expression), or have function pointer type.

2 For a call to a non-static member function, the postfix expression shall be an implicit (11.3.2, 11.3.8) or explicit class member access (7.6.1.4) whose id-expression is a function member name, or a pointer-to-member expression (7.6.4) selecting a function member; the call is as a member of the class object referred to by the object expression. In the case of an implicit class member access, the implied object is the one pointed to by this. [Note: A member function call of the form f() is interpreted as (*this).f() (see 11.3.2). — end note]

3 If a function or member function name is used, the appropriate function and the validity of the call are determined according to the rules in 12.3. If the selected function is non-virtual, or if the id-expression in the class member access expression is a qualified-id, that function is called. Otherwise, its final overrider (11.6.2) in the dynamic type of the object expression is called; such a call is referred to as a virtual function call. [Note: The dynamic type is the type of the object referred to by the current value of the object expression. 11.9.4 describes the behavior of virtual function calls when the object expression refers to an object under construction or destruction. — end note]

4 [Note: If a function or member function name is used, and name lookup (6.4) does not find a declaration of that name, the program is ill-formed. No function is implicitly declared by such a call. — end note]

61) This is true even if the subscript operator is used in the following common idiom: k[x][0].
If the postfix-expression names a destructor or pseudo-destructor (7.5.4.3), the type of the function call expression is void; otherwise, the type of the function call expression is the return type of the statically chosen function (i.e., ignoring the virtual keyword), even if the type of the function actually called is different. This return type shall be an object type, a reference type or cv void. If the postfix-expression names a pseudo-destructor, the function call has no effect.

Calling a function through an expression whose function type is different from the function type of the called function's definition results in undefined behavior.

When a function is called, each parameter (9.2.3.5) is initialized (9.3, 11.3.4.2) with its corresponding argument. If there is no corresponding argument, the default argument for the parameter is used; the program is ill-formed if one is not present. [Example:
```cpp
template<typename ...T> int f(int n = 0, T ...t);
int x = f<int>(); // error: no argument for second function parameter
```
—end example] If the function is a non-static member function, the this parameter of the function (11.3.2.1) is initialized with a pointer to the object of the call, converted as if by an explicit type conversion (7.6.3). [Note: There is no access or ambiguity checking on this conversion; the access checking and disambiguation are done as part of the (possibly implicit) class member access operator. See 11.7, 11.8.2, and 7.6.14. —end note] When a function is called, the type of any parameter shall not be a class type that is either incomplete or abstract. [Note: This still allows a parameter to be a pointer or reference to such a type. However, it prevents a passed-by-value parameter to have an incomplete or abstract class type. —end note] It is implementation-defined whether the lifetime of a parameter ends when the function in which it is defined returns or at the end of the enclosing full-expression. The initialization and destruction of each parameter occurs within the context of the calling function. [Example: The access of the constructor, conversion functions or destructor is checked at the point of call in the calling function. If a constructor or destructor for a function parameter throws an exception, the search for a handler starts in the scope of the calling function; in particular, if the function called has a function-try-block (Clause 14) with a handler that could handle the exception, this handler is not considered. —end example]

The postfix-expression is sequenced before each expression in the expression-list and any default argument. The initialization of a parameter, including every associated value computation and side effect, is indeterminately sequenced with respect to that of any other parameter. [Note: All side effects of argument evaluations are sequenced before the function is entered (see 6.8.1). —end note] [Example:
```cpp
void f() {
    std::string s = "but I have heard it works even if you don’t believe in it";
    s.replace(0, 4, """).replace(s.find("even"), 4, "only").replace(s.find(" don’t"), 6, "");
    assert(s == "I have heard it works only if you believe in it"); // OK
}
```
—end example] [Note: If an operator function is invoked using operator notation, argument evaluation is sequenced as specified for the built-in operator; see 12.3.1.2. —end note] [Example:
```cpp
struct S {
    S(int);
};
int operator<<(S, int);
int i, j;
int x = S(i=1) << (i=2);
int y = operator<<(S(j=1), j=2);
```
After performing the initializations, the value of i is 2 (see 7.6.7), but it is unspecified whether the value of j is 1 or 2. —end example]

The result of a function call is the result of the operand of the evaluated return statement (8.6.3) in the called function (if any), except in a virtual function call if the return type of the final overrider is different from the return type of the statically chosen function, the value returned from the final overrider is converted to the return type of the statically chosen function.

[Note: A function can change the values of its non-const parameters, but these changes cannot affect the values of the arguments except where a parameter is of a reference type (9.2.3.2); if the reference is to a const-qualified type, const_cast is required to be used to cast away the constness in order to modify the argument’s value. Where a parameter is of const reference type a temporary object is introduced if needed (9.1.7, 5.13, 5.13.5, 9.2.3.4, 6.6.7). In addition, it is possible to modify the values of non-constant objects through pointer parameters. —end note]
A function can be declared to accept fewer arguments (by declaring default arguments (9.2.3.6)) or more arguments (by using the ellipsis, ..., or a function parameter pack (9.2.3.5)) than the number of parameters in the function definition (9.4). [Note: This implies that, except where the ellipsis (...) or a function parameter pack is used, a parameter is available for each argument. —end note]

When there is no parameter for a given argument, the argument is passed in such a way that the receiving function can obtain the value of the argument by invoking va_arg (17.13). [Note: This paragraph does not apply to arguments passed to a function parameter pack. Function parameter packs are expanded during template instantiation (13.6.3), thus each such argument has a corresponding parameter when a function template specialization is actually called. —end note] The lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are performed on the argument expression. An argument that has type cv std::nullptr_t is converted to type void* (7.3.11). After these conversions, if the argument does not have arithmetic, enumeration, pointer, pointer-to-member, or class type, the program is ill-formed. Passing a potentially-evaluated argument of class type (Clause 11) having a non-trivial copy constructor, a non-trivial move constructor, or a non-trivial destructor, with no corresponding parameter, is conditionally-supported with implementation-defined semantics. If the argument has integral or enumeration type that is subject to the integral promotions (7.3.6), or a floating-point type that is subject to the floating-point promotion (7.3.7), the value of the argument is converted to the promoted type before the call. These promotions are referred to as the default argument promotions.

Recursive calls are permitted, except to the main function (6.8.3.1).

A function call is an lvalue if the result type is an lvalue reference type or an rvalue reference to function (6.8.3.1).

### 7.6.1.3 Explicit type conversion (functional notation) [expr.type.conv]

A simple-type-specifier (9.1.7.2) or typename-specifier (13.7) followed by a parenthesized optional expression-list or by a braced-init-list (the initializer) constructs a value of the specified type given the initializer. If the type is a placeholder for a deduced class type, it is replaced by the return type of the function selected by overload resolution for class template deduction (12.3.1.8) for the remainder of this subclause.

If the initializer is a parenthesized single expression, the type conversion expression is equivalent to the corresponding cast expression (7.6.3). Otherwise, if the type is cv void and the initializer is () or {} (after pack expansion, if any), the expression is a prvalue of the specified type that performs no initialization. Otherwise, the expression is a prvalue of the specified type whose result object is direct-initialized (9.3) with (after pack expansion, if any), the expression is a prvalue of the specified type that performs no initialization.

### 7.6.1.4 Class member access [expr.ref]

A postfix expression followed by a dot . or an arrow ->, optionally followed by the keyword template (13.2), and then followed by an id-expression, is a postfix expression. The postfix expression before the dot or arrow is evaluated, the result of that evaluation, together with the id-expression, determines the result of the entire postfix expression.

For the first option (dot) the first expression shall be a glvalue. For the second option (arrow) the first expression shall be a prvalue having pointer type. The expression E1->E2 is converted to the equivalent form (*(E1)).E2; the remainder of 7.6.1.4 will address only the first option (dot).

Abbreviating postfix-expression, id-expression as E1.E2, E1 is called the object expression. If the object expression is of scalar type, E2 shall name the pseudo-destructor of that same type (ignoring cv-qualifications) and E1.E2 is an lvalue of type “function of () returning void”. [Note: This value can only be used for a notional function call (7.5.4.3). —end note]

Otherwise, the object expression shall be of class type. The class type shall be complete unless the class member access appears in the definition of that class. [Note: If the class is incomplete, lookup in the complete class type is required to refer to the same declaration (6.3.7). —end note] The id-expression shall name a member of the class or of one of its base classes. [Note: Because the name of a class is inserted in its class scope (Clause 11), the name of a class is also considered a nested member of that class. —end note] [Note: 6.4.5 describes how names are looked up after the . and -> operators. —end note]

---

62) If the class member access expression is evaluated, the subexpression evaluation happens even if the result is unnecessary to determine the value of the entire postfix expression, for example if the id-expression denotes a static member.

63) Note that (*(E1)) is an lvalue.
If E2 is a bit-field, E1.E2 is a bit-field. The type and value category of E1.E2 are determined as follows. In the remainder of 7.6.1.4, eq represents either const or the absence of const and vq represents either volatile or the absence of volatile. cv represents an arbitrary set of cv-qualifiers, as defined in 6.7.3.

If E2 is declared to have type “reference to T”, then E1.E2 is an lvalue; the type of E1.E2 is T. Otherwise, one of the following rules applies.

(6.1) — If E2 is a static data member and the type of E2 is T, then E1.E2 is an lvalue; the expression designates the named member of the class. The type of E1.E2 is T.

(6.2) — If E2 is a non-static data member and the type of E1 is “cq1 vq1 X”, and the type of E2 is “cq2 vq2 T”, the expression designates the named member of the object designated by the first expression. If E1 is an lvalue, then E1.E2 is an lvalue; otherwise E1.E2 is an xvalue. Let the notation vq12 stand for the “union” of vq1 and vq2; that is, if vq1 or vq2 is volatile, then vq12 is volatile. Similarly, let the notation cq12 stand for the “union” of cq1 and cq2; that is, if cq1 or cq2 is const, then cq12 is const.

If E2 is declared to be a mutable member, then the type of E1.E2 is “vq12 T”. If E2 is not declared to be a mutable member, then the type of E1.E2 is “cq12 vq12 T”.

(6.3) — If E2 is a (possibly overloaded) member function, function overload resolution (12.3) is used to determine whether E1.E2 refers to a static or a non-static member function.

(6.3.1) — If it refers to a static member function and the type of E2 is “function of parameter-type-list returning T”, then E1.E2 is an lvalue; the expression designates the static member function. The type of E1.E2 is the same type as that of E2, namely “function of parameter-type-list returning T”.

(6.3.2) — Otherwise, if E1.E2 refers to a non-static member function and the type of E2 is “function of parameter-type-list cv ref-qualifier,opt returning T”, then E1.E2 is a prvalue. The expression designates a non-static member function. The expression can be used only as the left-hand operand of a member function call (11.3.1). [Note: Any redundant set of parentheses surrounding the expression is ignored (7.5.3). — end note] The type of E1.E2 is “function of parameter-type-list cv returning T”.

(6.4) — If E2 is a nested type, the expression E1.E2 is ill-formed.

(6.5) — If E2 is a member enumerator and the type of E2 is T, the expression E1.E2 is a prvalue. The type of E1.E2 is T.

If E2 is a non-static data member or a non-static member function, the program is ill-formed if the class of which E2 is directly a member is an ambiguous base (11.7) of the naming class (11.8.2) of E2. [Note: The program is also ill-formed if the naming class is an ambiguous base of the class type of the object expression; see 11.8.2. — end note]

7.6.1.5 Increment and decrement

The value of a postfix ++ expression is the value of its operand. [Note: The value obtained is a copy of the original value — end note] The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than cv bool, or a pointer to a complete object type. The value of the operand object is modified by adding 1 to it. The value computation of the ++ expression is sequenced before the modification of the operand object. With respect to an indeterminately-sequenced function call, the operation of postfix ++ is a single evaluation. [Note: Therefore, a function call shall not intervene between the lvalue-to-rvalue conversion and the side effect associated with any single postfix ++ operator. — end note] The result is a prvalue. The type of the result is the cv-unqualified version of the type of the operand. If the operand is a bit-field that cannot represent the incremented value, the resulting value of the bit-field is implementation-defined. See also 7.6.6 and 7.6.19.

The operand of postfix -- is decremented analogously to the postfix ++ operator. [Note: For prefix increment and decrement, see 7.6.2.2. — end note]

7.6.1.6 Dynamic cast

The result of the expression dynamic_cast<T>(v) is the result of converting the expression v to type T. T shall be a pointer or reference to a complete class type, or “pointer to cv void”. The dynamic_cast operator shall not cast away constness (7.6.1.10).

If T is a pointer type, v shall be a prvalue of a pointer to complete class type, and the result is a prvalue of type T. If T is an lvalue reference type, v shall be an lvalue of a complete class type, and the result is an lvalue of the type referred to by T. If T is an rvalue reference type, v shall be a glvalue having a complete class type, and the result is an xvalue of the type referred to by T.
If the type of \( v \) is the same as \( T \) (ignoring cv-qualifications), the result is \( v \) (converted if necessary).

If \( T \) is “pointer to cv1 B” and \( v \) has type “pointer to cv2 D” such that \( B \) is a base class of \( D \), the result is a pointer to the unique \( B \) subobject of the \( D \) object pointed to by \( v \), or a null pointer value if \( v \) is a null pointer value. Similarly, if \( T \) is “reference to cv1 B” and \( v \) has type cv2 D such that \( B \) is a base class of \( D \), the result is the unique \( B \) subobject of the \( D \) object referred to by \( v \).

In both the pointer and reference cases, the program is ill-formed if \( B \) is an inaccessible or ambiguous base class of \( D \). [Example:

```c
struct B { };  
struct D : B { };  
void foo(D* dp) {    
    B* bp = dynamic_cast<B*>(dp);  // equivalent to B* bp = dp;  
}  
@end example]
```

Otherwise, \( v \) shall be a pointer to or a glvalue of a polymorphic type (11.6.2).

If \( v \) is a null pointer value, the result is a null pointer value.

If \( T \) is “pointer to cv void”, then the result is a pointer to the most derived object pointed to by \( v \). Otherwise, a runtime check is applied to see if the object pointed or referred to by \( v \) can be converted to the type pointed or referred to by \( T \).

If \( C \) is the class type to which \( T \) points or refers, the runtime check logically executes as follows:

(8.1) — If, in the most derived object pointed (referred) to by \( v \), \( v \) points (refers) to a public base class subobject of \( C \) object, and if only one object of type \( C \) is derived from the subobject pointed (referred) to by \( v \) the result points (refers) to that \( C \) object.

(8.2) — Otherwise, if \( v \) points (refers) to a public base class subobject of the most derived object, and the type of the most derived object has a base class, of type \( C \), that is unambiguous and public, the result points (refers) to the \( C \) subobject of the most derived object.

(8.3) — Otherwise, the runtime check fails.

The value of a failed cast to pointer type is the null pointer value of the required result type. A failed cast to reference type throws an exception (14.1) of a type that would match a handler (14.3) of type `std::bad_cast` (17.7.3).

[Example:

```c
class A { virtual void f(); };  
class B { virtual void g(); };  
class D : public virtual A, private B { };  
void g() {    
    D d;    
    B* bp = (B*)&d;  // cast needed to break protection    
    A* ap = &d;  // public derivation, no cast needed    
    D& dr = dynamic_cast<D&*>(bp);  // fails    
    ap = dynamic_cast<A*>(bp);  // fails    
    bp = dynamic_cast<B*>(ap);  // fails    
    ap = dynamic_cast<A*>(&d);  // succeeds    
    bp = dynamic_cast<B*>(&d);  // ill-formed (not a runtime check)  
}  
```

```c
class E : public D, public B { };  
class F : public E, public D { };  
void h() {    
    F f;    
    A* ap = &f;  // succeeds: finds unique A    
    D* dp = dynamic_cast<D*>(ap);  // fails: yields null; \( f \) has two \( D \) subobjects    
    E* ep = (E*)ap;  // ill-formed: cast from virtual base    
    E* ep1 = dynamic_cast<E*>(ap);  // succeeds  
}  
@end example]

[Note: Subclause 11.9.4 describes the behavior of a `dynamic_cast` applied to an object under construction or destruction. —end note]

64) The most derived object (6.6.2) pointed or referred to by \( v \) can contain other \( B \) objects as base classes, but these are ignored.
7.6.1.7 Type identification

1 The result of a typeid expression is an lvalue of static type const std::type_info (17.7.2) and dynamic type const std::type_info or const name where name is an implementation-defined class publicly derived from std::type_info which preserves the behavior described in 17.7.2. The lifetime of the object referred to by the lvalue extends to the end of the program. Whether or not the destructor is called for the std::type_info object at the end of the program is unspecified.

2 When typeid is applied to a glvalue whose type is a polymorphic class type (11.6.2), the result refers to a std::type_info object representing the type of the most derived object (6.6.2) (that is, the dynamic type) to which the glvalue refers. If the glvalue is obtained by applying the unary * operator to a pointer and the pointer is a null pointer value (7.3.11), the typeid expression throws an exception (14.1) of a type that would match a handler of type std::bad_typeid exception (17.7.4).

3 When typeid is applied to an expression other than a glvalue of a polymorphic class type, the result refers to a std::type_info object representing the static type of the expression. Lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) conversions are not applied to the expression. If the expression is a prvalue, the temporary materialization conversion (7.3.4) is applied. The expression is an unevaluated operand (7.2).

4 When typeid is applied to a type-id, the result refers to a std::type_info object representing the type of the type-id. If the type of the type-id is a reference to a possibly cv-qualified type, the result of the typeid expression refers to a std::type_info object representing the cv-unqualified referenced type. If the type of the type-id is a class type or a reference to a class type, the class shall be completely-defined.

5 If the type of the expression or type-id is a cv-qualified type, the result of the typeid expression refers to a std::type_info object representing the cv-unqualified type. [Example:

```cpp
class D { /* ... */ };  
D d1;  
const D d2;

typeid(d1) == typeid(d2); // yields true  
typeid(D) == typeid(const D); // yields true  
typeid(D) == typeid(d2); // yields true  
typeid(D) == typeid(const D&); // yields true

—end example]
```

6 If the header `<typeinfo>` (17.7.2) is not included prior to a use of typeid, the program is ill-formed.

7 [Note: Subclause 11.9.4 describes the behavior of typeid applied to an object under construction or destruction. —end note]

7.6.1.8 Static cast

1 The result of the expression static_cast<T>(v) is the result of converting the expression v to type T. If T is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue. The static_cast operator shall not cast away constness (7.6.1.10).

2 An lvalue of type “cv1 B”, where B is a class type, can be cast to type “reference to cv2 D”, where D is a class derived (11.6) from B, if cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If B is a virtual base class of D or a base class of a virtual base class of D, or if no valid standard conversion from “pointer to D” to “pointer to B” exists (7.3.11), the program is ill-formed. An xvalue of type “cv1 B” can be cast to type “rvalue reference to cv2 D” with the same constraints as for an lvalue of type “cv1 B”. If the object of type “cv1 B” is actually a base class subobject of an object of type D, the result refers to the enclosing object of type D. Otherwise, the behavior is undefined. [Example:

```cpp
struct B { };  
struct D : public B { };  
D d;  
B &br = d;
```

---

65) The recommended name for such a class is extended_type_info.

66) If p is an expression of pointer type, then *p, *(p), *(p), (**p), *(*(p)), and so on all meet this requirement.
A prvalue of type "pointer to \texttt{11} \texttt{10}\) can be cast to type “rvalue reference to \texttt{cv2 T2}” if “\texttt{cv2 T2}” is reference-compatible with “\texttt{cv1 T1}” (9.3.3). If the value is not a bit-field, the result refers to the object or the specified base class subobject thereof; otherwise, the lvalue-to-rvalue conversion (7.3.1) is applied to the bit-field and the resulting prvalue is used as the expression of the \texttt{static_cast} for the remainder of this subclause. If \texttt{T2} is an inaccessible (11.8) or ambiguous (11.7) base class of \texttt{T1}, a program that necessitates such a cast is ill-formed.

A value of integral or enumeration type can be explicitly converted to a complete enumeration type. If the inverse of any standard conversion sequence (7.3) not containing an lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), function-to-pointer (7.3.3), null pointer (7.3.11), null member pointer (7.3.12), boolean (7.3.14), or function pointer (7.3.13) conversion, can be performed explicitly using \texttt{static_cast}. A program is ill-formed if it uses \texttt{static_cast} to perform the inverse of an ill-formed standard conversion sequence. [Example:

```cpp
static_cast<D&>(br); // produces lvalue denoting the original \texttt{D} object
```

— end example]}

An lvalue of type “\texttt{cv1 T1}” can be cast to type “rvalue reference to \texttt{cv2 T2}” if “\texttt{cv2 T2}” is reference-compatible with “\texttt{cv1 T1}” (9.3.3). If the value is not a bit-field, the result refers to the object or the specified base class subobject thereof; otherwise, the lvalue-to-rvalue conversion (7.3.1) is applied to the bit-field and the resulting prvalue is used as the expression of the \texttt{static_cast} for the remainder of this subclause. If \texttt{T2} is an inaccessible (11.8) or ambiguous (11.7) base class of \texttt{T1}, a program that necessitates such a cast is ill-formed.

A value of a scoped enumeration type (9.6) can be explicitly converted to an integral type; the result is the same as that of converting from the original value to the floating-point type.

Any expression \(e\) can be explicitly converted to a type \(T\) if there is an implicit conversion sequence (12.3.3.1) from \(e\) to \(T\), or if overload resolution for a direct-initialization (9.3) of an object or reference of type \(T\) from \(e\) would find at least one viable function (12.3.2). If \(T\) is a reference type, the effect is the same as performing the declaration and initialization

\[ T \ t(e); \]

for some invented temporary variable \(t\) (9.3) and then using the temporary variable as the result of the conversion. Otherwise, the result object is direct-initialized from \(e\). [Note: The conversion is ill-formed when attempting to convert an expression of class type to an inaccessible or ambiguous base class. — end note]

Otherwise, the \texttt{static_cast} shall perform one of the conversions listed below. No other conversion shall be performed explicitly using a \texttt{static_cast}.

Any expression can be explicitly converted to type \texttt{cv void}, in which case it becomes a discarded-value expression (7.2). [Note: However, if the value is in a temporary object (6.6.7), the destructor for that object is not executed until the usual time, and the value of the object is preserved for the purpose of executing the destructor. — end note]

The inverse of any standard conversion sequence (7.3) not containing an lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), function-to-pointer (7.3.3), null pointer (7.3.11), null member pointer (7.3.12), boolean (7.3.14), or function pointer (7.3.13) conversion, can be performed explicitly using \texttt{static_cast}. A program is ill-formed if it uses \texttt{static_cast} to perform the inverse of an ill-formed standard conversion sequence. [Example:

```cpp
struct B { };
struct D : private B { };
void f() {
    static_cast<D*>(B*0);
    static_cast<int B::*>(int D::*0); // error: B is a private base of D
}
```

— end example]

The lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) conversions are applied to the operand. Such a \texttt{static_cast} is subject to the restriction that the explicit conversion does not cast away constness (7.6.1.10), and the following additional rules for specific cases:

A value of a scoped enumeration type (9.6) can be explicitly converted to an integral type; the result is the same as that of converting to the enumeration’s underlying type and then to the destination type. A value of a scoped enumeration type can also be explicitly converted to a floating-point type; the result is the same as that of converting from the original value to the floating-point type.

A value of integral or enumeration type can be explicitly converted to a complete enumeration type. If the enumeration type has a fixed underlying type, the value is first converted to that type by integral conversion, if necessary, and then to the enumeration type. If the enumeration type does not have a fixed underlying type, the value is unchanged if the original value is within the range of the enumeration values (9.6), and otherwise, the behavior is undefined. A value of floating-point type can also be explicitly converted to an enumeration type. The resulting value is the same as converting the original value to the underlying type of the enumeration (7.3.10), and subsequently to the enumeration type.

A prvalue of type “\texttt{pointer to cv1 B}\)”, where \(B\) is a class type, can be converted to a prvalue of type “\texttt{pointer to cv2 D}\)”, where \(D\) is a complete class derived (11.6) from \(B\), if \texttt{cv2} is the same cv-qualification as, or greater cv-qualification than, \texttt{cv1}. If \(B\) is a virtual base class of \(D\) or a base class of a virtual base class of \(D\), or if no valid standard conversion from “\texttt{pointer to D}\) to “\texttt{pointer to B}\) exists (7.3.11), the program is ill-formed. The null pointer value (7.3.11) is converted to the null pointer value of the destination type. If the prvalue of type “\texttt{pointer to cv1 B}\) points to a \(B\) that is actually a subobject of an object of type \texttt{D}, the resulting pointer points to the enclosing object of type \texttt{D}. Otherwise, the behavior is undefined.

§ 7.6.1.8

112
A prvalue of type “pointer to member of D of type cv1 T” can be converted to a prvalue of type “pointer to member of B of type cv2 T”, where D is a complete class type and B is a base class (11.6) of D, if cv2 is the same cv-qualification as, or greater cv-qualification than, cv1.67 If no valid standard conversion from “pointer to member of B of type T” to “pointer to member of B of type T” exists (7.3.12), the program is ill-formed. The null member pointer value (7.3.12) is converted to the null member pointer value of the destination type. If class B contains the original member, or is a base or derived class of the class containing the original member, the resulting pointer to member points to the original member. Otherwise, the behavior is undefined. [Note: Although class B need not contain the original member, the dynamic type of the object with which indirection through the pointer to member is performed must contain the original member; see 7.6.4. — end note]

A prvalue of type “pointer to cv1 void” can be converted to a prvalue of type “pointer to cv2 T”, where T is an object type and cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If the original pointer value represents the address A of a byte in memory and A does not satisfy the alignment requirement of T, then the resulting pointer value is unspecified. Otherwise, if the original pointer value points to an object a, and there is an object b of type T (ignoring cv-qualification) that is pointer-interconvertible (6.7.2) with a, the result is a pointer to b. Otherwise, the pointer value is unchanged by the conversion. [Example:
```cpp
T* p1 = new T;
const T* p2 = static_cast<const T*>(static_cast<void*>(p1));
bool b = p1 == p2; // b will have the value true.
```
—end example]

### 7.6.1.9 Reinterpret cast

1 The result of the expression `reinterpret_cast<T>(v)` is the result of converting the expression v to type T. If T is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue and the lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are performed on the expression v. Conversions that can be performed explicitly using `reinterpret_cast` are listed below. No other conversion can be performed explicitly using `reinterpret_cast`.

2 The `reinterpret_cast` operator shall not cast away constness (7.6.1.10). An expression of integral, enumeration, pointer, or pointer-to-member type can be explicitly converted to its own type; such a cast yields the value of its operand.

3 [Note: The mapping performed by `reinterpret_cast` might, or might not, produce a representation different from the original value. — end note]

4 A pointer can be explicitly converted to any integral type large enough to hold all values of its type. The mapping function is implementation-defined. [Note: It is intended to be unsurprising to those who know the addressing structure of the underlying machine. — end note] A value of type `std::nullptr_t` can be converted to an integral type; the conversion has the same meaning and validity as a conversion of `(void*)0` to the integral type. [Note: A `reinterpret_cast` cannot be used to convert a value of any type to the type `std::nullptr_t`. — end note]

5 A value of integral type or enumeration type can be explicitly converted to a pointer. A pointer converted to an integer of sufficient size (if any such exists on the implementation) and back to the same pointer type will have its original value; mappings between pointers and integers are otherwise implementation-defined. [Note: Except as described in 6.6.5.4.3, the result of such a conversion will not be a safely-derived pointer value. — end note]

6 A function pointer can be explicitly converted to a function pointer of a different type. [Note: The effect of calling a function through a pointer to a function type (9.2.3.5) that is not the same as the type used in the definition of the function is undefined (7.6.1.2). — end note] Except that converting a prvalue of type “pointer to T1” to the type “pointer to T2” (where T1 and T2 are function types) and back to its original type yields the original pointer value, the result of such a pointer conversion is unspecified. [Note: See also 7.3.11 for more details of pointer conversions. — end note]

7 An object pointer can be explicitly converted to an object pointer of a different type.68 When a prvalue `v` of object pointer type is converted to the object pointer type “pointer to cv T”, the result is `static_cast<cv

---

67 Function types (including those used in pointer-to-member-function types) are never cv-qualified; see 9.2.3.5.
68 The types may have different cv-qualifiers, subject to the overall restriction that a `reinterpret_cast` cannot cast away constness.
Converting a prvalue of type “pointer to T1” to the type “pointer to T2” (where T1 and T2 are object types and where the alignment requirements of T2 are no stricter than those of T1) and back to its original type yields the original pointer value. — end note]

Converting a function pointer to an object pointer type or vice versa is conditionally-supported. The meaning of such a conversion is implementation-defined, except that if an implementation supports conversions in both directions, converting a prvalue of one type to the other type and back, possibly with different cv-qualification, shall yield the original pointer value.

The null pointer value (7.3.11) is converted to the null pointer value of the destination type. [Note: A null pointer constant of type std::nullptr_t cannot be converted to a pointer type, and a null pointer constant of integral type is not necessarily converted to a null pointer value. — end note]

A prvalue of type “pointer to member of X of type T1” can be explicitly converted to a prvalue of a different type “pointer to member of Y of type T2” if T1 and T2 are both function types or both object types. The null member pointer value (7.3.12) is converted to the null member pointer value of the destination type. The result of this conversion is unspecifed, except in the following cases:

1. converting a prvalue of type “pointer to member function” to a different pointer-to-member-function type and back to its original type yields the original pointer-to-member value.
2. converting a prvalue of type “pointer to data member of X of type T1” to the type “pointer to data member of Y of type T2” (where the alignment requirements of T2 are no stricter than those of T1) and back to its original type yields the original pointer-to-member value.

A glvalue of type T1, designating an object x, can be cast to the type “reference to T2” if an expression of type “pointer to T1” can be explicitly converted to the type “pointer to T2” using a reinterpret_cast. The result is that of reinterpret_cast<T2*>(p) where p is a pointer to x of type “pointer to T1”. No temporary is created, no copy is made, and no constructors (11.3.4) or conversion functions (11.3.7) are called.

7.6.1.10 Const cast [expr.const.cast]

The result of the expression const_cast<T>(v) is of type T. If T is an lvalue reference to object type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue and the lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are performed on the expression v. Conversions that can be performed explicitly using const_cast are listed below. No other conversion shall be performed explicitly using const_cast.

[Note: Subject to the restrictions in this subclause, an expression may be cast to its own type using a const_cast operator. — end note]

For two similar types T1 and T2 (7.3.5), a prvalue of type T1 may be explicitly converted to the type T2 using a const_cast. The result of a const_cast refers to the original entity. [Example:

```cpp
typedef int *A[3]; // array of 3 pointer to int
typedef const int *const CA[3]; // array of 3 const pointer to const int

CA &&r = A[{}]; // OK, reference binds to temporary array object after qualification conversion to type CA
A &&r1 = const_cast<A>(CA[{}]); // error: temporary array decayed to pointer
A &&r2 = const_cast<A&&>(CA[{}]); // OK
```

— end example]

For two object types T1 and T2, if a pointer to T1 can be explicitly converted to the type “pointer to T2” using a const_cast, then the following conversions can also be made:

1. an lvalue of type T1 can be explicitly converted to an lvalue of type T2 using the cast const_cast<T2&>;
2. a glvalue of type T1 can be explicitly converted to an xvalue of type T2 using the cast const_cast<T2&&>;
3. if T1 is a class type, a prvalue of type T1 can be explicitly converted to an xvalue of type T2 using the cast const_cast<T2&&>.

69) T1 and T2 may have different cv-qualifiers, subject to the overall restriction that a reinterpret_cast cannot cast away constness.

70) This is sometimes referred to as a type pun when the result refers to the same object as the source glvalue.

§ 7.6.1.10

114
The result of a reference \texttt{const\_cast} refers to the original object if the operand is a glvalue and to the result of applying the temporary materialization conversion (7.3.4) otherwise.

A null pointer value (7.3.11) is converted to the null pointer value of the destination type. The null member pointer value (7.3.12) is converted to the null member pointer value of the destination type.

[Note: Depending on the type of the object, a write operation through the pointer, lvalue or pointer to data member resulting from a \texttt{const\_cast} that casts away a const-qualifier may produce undefined behavior (9.1.7.1). — end note]

A conversion from a type \(T_1\) to a type \(T_2\) \textit{casts away constness} if \(T_1\) and \(T_2\) are different, there is a cv-decomposition (7.3.5) of \(T_1\) yielding \(n\) such that \(T_2\) has a cv-decomposition of the form

\[
\text{cv}_0^{n} P_0^n \text{cv}_1^{2} P_1^{2} \cdots \text{cv}_{n-1}^{2} P_{n-1}^{2} \text{cv}_n^2 v_2,
\]

and there is no qualification conversion that converts \(T_1\) to

\[
\text{cv}_0^{n} P_0^n \text{cv}_1^{2} P_1^{1} \cdots \text{cv}_{n-1}^{2} P_{n-1}^{1} \text{cv}_n^2 v_1.
\]

Casting from an lvalue of type \(T_1\) to an lvalue of type \(T_2\) using an lvalue reference cast or casting from an expression of type \(T_1\) to an xvalue of type \(T_2\) using an rvalue reference cast casts away constness if a cast from a prvalue of type “pointer to \(T_1\)” to the type “pointer to \(T_2\)” casts away constness.

[Note: Some conversions which involve only changes in cv-qualification cannot be done using \texttt{const\_cast}. For instance, conversions between pointers to functions are not covered because such conversions lead to values whose use causes undefined behavior. For the same reasons, conversions between pointers to member functions, and in particular, the conversion from a pointer to a const member function to a pointer to a non-const member function, are not covered. — end note]

### 7.6.2 Unary expressions

Expressions with unary operators group right-to-left.

\[
\text{unary-expression} : \text{postfix-expression} \\
\quad \text{unary-operator} \text{ cast-expression} \\
\quad ++ \text{ cast-expression} \\
\quad -- \text{ cast-expression} \\
\quad \text{await-expression} \\
\quad \text{sizeof } \text{unary-expression} \\
\quad \text{sizeof ( type-id )} \\
\quad \text{sizeof } \ldots ( \text{identifier } ) \\
\quad \text{alignof ( type-id )} \\
\quad \text{noexcept-expression} \\
\quad \text{new-expression} \\
\quad \text{delete-expression}
\]

\[
\text{unary-operator} : \text{one of } * \ & \ + \ - \ ! \ ~
\]

#### 7.6.2.1 Unary operators

The unary \* operator performs \textit{indirection}: the expression to which it is applied shall be a pointer to an object type, or a pointer to a function type and the result is an lvalue referring to the object or function to which the expression points. If the type of the expression is “pointer to \(T\)”, the type of the result is “\(T\)”. [Note: Indirection through a pointer to an incomplete type (other than \texttt{cv void}) is valid. The lvalue thus obtained can be used in limited ways (to initialize a reference, for example); this lvalue must not be converted to a prvalue, see 7.3.1. — end note]

The result of each of the following unary operators is a prvalue.

The result of the unary & operator is a pointer to its operand.

1. \texttt{&} — If the operand is a \texttt{qualified-id} naming a non-static or variant member \(m\) of some class \(C\) with type \(T\), the result has type “pointer to member of class \(C\) of type \(T\)" and is a prvalue designating \(C::m\).
2. \texttt{&} — Otherwise, if the operand is an lvalue of type \(T\), the resulting expression is a prvalue of type “pointer to \(T\)” whose result is a pointer to the designated object (6.6.1) or function. [Note: In particular, taking the address of a variable of type “\texttt{cv T}” yields a pointer of type “pointer to \texttt{cv T}”. — end note] For

---

\texttt{const\_cast} is not limited to conversions that cast away a const-qualifier.

---

\(71\)
purposes of pointer arithmetic (7.6.6) and comparison (7.6.9, 7.6.10), an object that is not an array element whose address is taken in this way is considered to belong to an array with one element of type T.

— Otherwise, the program is ill-formed.

[Example:
 struct A { int i; }
 struct B : A {}
 ...
 &B::i ...
 // has type int A::*
 int a;
 int* p1 = &a;
 int* p2 = p1 + 1; // defined behavior
 bool b = p2 > p1;
 // defined behavior, with value true
 — end example] [Note: A pointer to member formed from a mutable non-static data member (9.1.1) does not reflect the mutable specifier associated with the non-static data member. — end note]

A pointer to member is only formed when an explicit & is used and its operand is a qualified-id not enclosed in parentheses. [Note: That is, the expression &(qualified-id), where the qualified-id is enclosed in parentheses, does not form an expression of type “pointer to member”. Neither does qualified-id, because there is no implicit conversion from a qualified-id for a non-static member function to the type “pointer to member function” as there is from an lvalue of function type to the type “pointer to function” (7.3.3). Nor is &unqualified-id a pointer to member, even within the scope of the unqualified-id’s class. — end note]

If & is applied to an lvalue of incomplete class type and the complete type declares operator&(), it is unspecified whether the operator has the built-in meaning or the operator function is called. The operand of & shall not be a bit-field.

The address of an overloaded function (Clause 12) can be taken only in a context that uniquely determines which version of the overloaded function is referred to (see 12.4). [Note: Since the context might determine whether the operand is a static or non-static member function, the context can also affect whether the expression has type “pointer to function” or “pointer to member function”. — end note]

The operand of the unary + operator shall have arithmetic, unscoped enumeration, or pointer type and the result is the value of the argument. Integral promotion is performed on integral or enumeration operands. The type of the result is the type of the promoted operand.

The operand of the unary - operator shall have arithmetic or unscoped enumeration type and the result is the negation of its operand. Integral promotion is performed on integral or enumeration operands. The negative of an unsigned quantity is computed by subtracting its value from \(2^n\), where \(n\) is the number of bits in the promoted operand. The type of the result is the type of the promoted operand.

The operand of the logical negation operator ! is contextually converted to bool (7.3); its value is true if the converted operand is false and false otherwise. The type of the result is bool.

The operand of ~ shall have integral or unscoped enumeration type; the result is the ones’ complement of its operand. Integral promotions are performed. The type of the result is the type of the promoted operand. There is an ambiguity in the grammar when ~ is followed by a type-name or decltype-specifier. The ambiguity is resolved by treating ~ as the unary complement operator rather than as the start of an unqualified-id naming a destructor. [Note: Because the grammar does not permit an operator to follow the ., ->, or :: tokens, a ~ followed by a type-name or decltype-specifier in a member access expression or qualified-id is unambiguously parsed as a destructor name. — end note]

7.6.2.2 Increment and decrement [expr.pre.incr]

1 The operand of prefix ++ is modified by adding 1. The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than cv bool, or a pointer to a completely-defined object type. The result is the updated operand; it is an lvalue, and it is a bit-field if the operand is a bit-field. The expression ++x is equivalent to x+=1. [Note: See the discussions of addition (7.6.6) and assignment operators (7.6.19) for information on conversions. — end note]

2 The operand of prefix -- is modified by subtracting 1. The requirements on the operand of prefix -- and the properties of its result are otherwise the same as those of prefix ++. [Note: For postfix increment and decrement, see 7.6.1.5. — end note]
The `co_await` expression is used to suspend evaluation of a coroutine (9.4.4) while awaiting completion of the computation represented by the operand expression.

```
await-expression:
  co_await cast-expression
```

An `await-expression` shall appear only in a potentially-evaluated expression within the compound-statement of a function-body outside of a handler (Clause 14). In a declaration-statement or in the simple-declaration (if any) of a for-init-statement, an `await-expression` shall appear only in an initializer of that declaration-statement or simple-declaration. An `await-expression` shall not appear in a default argument (9.2.3.6). An `await-expression` shall not appear in the initializer of a block-scope variable with static or thread storage duration. A context within a function where an `await-expression` can appear is called a `suspension context` of the function.

Evaluation of an `await-expression` involves the following auxiliary types, expressions, and objects:

1. `p` is an lvalue naming the promise object (9.4.4) of the enclosing coroutine and `P` is the type of that object.
2. `a` is the `cast-expression` if the `await-expression` was implicitly produced by a `yield-expression` (7.6.17), an initial suspend point, or a final suspend point (9.4.4). Otherwise, the `unqualified-id await_transform` is looked up within the scope of `P` by class member access lookup (6.4.5), and if this lookup finds at least one declaration, then `a` is `p.await_transform(cast-expression)`; otherwise, `a` is the `cast-expression`.
3. `o` is determined by enumerating the applicable `operator co_await` functions for an argument `a` (12.3.1.2), and choosing the best one through overload resolution (12.3). If overload resolution is ambiguous, the program is ill-formed. If no viable functions are found, `o` is `a`. Otherwise, `o` is a call to the selected function with the argument `a`. If `o` would be a prvalue, the temporary materialization conversion (7.3.4) is applied.
4. `e` is an lvalue referring to the result of evaluating the (possibly-converted) `o` expression.
5. `h` is an object of type `std::coroutine_handle<P>` referring to the enclosing coroutine.
6. `await-ready` is the expression `e.await_ready()`, contextually converted to `bool`.
7. `await-suspend` is the expression `e.await_suspend(h)`, which shall be a prvalue of type `void, bool, or std::coroutine_handle<Z>` for some type `Z`.
8. `await-resume` is the expression `e.await_resume()`.

The `await-expression` has the same type and value category as the `await-resume` expression.

The `await-expression` evaluates the (possibly-converted) `o` expression and the `await-ready` expression, then:

1. If the result of `await-ready` is `false`, the coroutine is considered suspended. Then:
   1. If the type of `await-suspend` is `std::coroutine_handle<Z>`, `await-suspend.resume()` is evaluated. 
      [Note: This resumes the coroutine referred to by the result of `await-suspend`. Any number of coroutines may be successively resumed in this fashion, eventually returning control flow to the current coroutine caller or resumer (9.4.4). — end note]
   2. Otherwise, if the type of `await-suspend` is `bool`, `await-suspend` is evaluated, and the coroutine is resumed if the result is `false`.
   3. Otherwise, `await-suspend` is evaluated.

If the evaluation of `await-suspend` exits via an exception, the exception is caught, the coroutine is resumed, and the exception is immediately re-thrown (14.1). Otherwise, control flow returns to the current coroutine caller or resumer (9.4.4) without exiting any scopes (8.6).

2. If the result of `await-ready` is `true`, or when the coroutine is resumed, the `await-resume` expression is evaluated, and its result is the result of the `await-expression`.

[Example:
```
template <typename T>
struct my_future {
  // ... *
  bool await_ready();
  void await_suspend(std::coroutine_handle<>);
};
```]

T await_resume();
};

template <class Rep, class Period>
auto operator co_await(std::chrono::duration<Rep, Period> d) {
    struct awaiter {
        std::chrono::system_clock::duration duration;
        /* ... */
        awaiter(std::chrono::system_clock::duration d) : duration(d) {}
        bool await_ready() const { return duration.count() <= 0; }
        void await_resume() {}
        void await_suspend(std::coroutine_handle<> h) { /* ... */ }
    }
    return awaiter{d};
}

using namespace std::chrono;

my_future<int> h();

my_future<void> g() {
    std::cout << "just about go to sleep...\n";
    co_await 10ms;
    std::cout << "resumed\n";
    co_await h();
}

auto f(int x = co_await h()); // error: await-expression outside of function suspension context
int a[] = { co_await h() }; // error: await-expression outside of function suspension context
—end example

7.6.2.4 Sizeof [expr.sizeof]

1 The sizeof operator yields the number of bytes occupied by a non-potentially-overlapping object of the type of its operand. The operand is either an expression, which is an unevaluated operand (7.2), or a parenthesized type-id. The sizeof operator shall not be applied to an expression that has function or incomplete type, to the parenthesized name of such types, or to a glvalue that designates a bit-field. The result of sizeof applied to any of the narrow character types is 1. The result of sizeof applied to any other fundamental type (6.7.1) is implementation-defined. [Note: In particular, sizeof(bool), sizeof(char16_t), sizeof(char32_t), and sizeof(wchar_t) are implementation-defined. —end note] [Note: See 6.6.1 for the definition of byte and 6.7 for the definition of object representation. —end note]

2 When applied to a reference type, the result is the size of the referenced type. When applied to a class, the result is the number of bytes in an object of that class including any padding required for placing objects of that type in an array. The result of applying sizeof to a potentially-overlapping subobject is the size of the type, not the size of the subobject. When applied to an array, the result is the total number of bytes in the array. This implies that the size of an array of n elements is n times the size of an element.

3 The value-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are not applied to the operand of sizeof. If the operand is a prvalue, the temporary materialization conversion (7.3.4) is applied.

4 The identifier in a sizeof... expression shall name a pack. The sizeof... operator yields the number of elements in the pack (13.6.3). A sizeof... expression is a pack expansion (13.6.3). [Example:

    template<class... Types>
    struct count {
        static const std::size_t value = sizeof...(Types);
    };
    —end example]

72) sizeof(bool) is not required to be 1.
73) The actual size of a potentially-overlapping subobject may be less than the result of applying sizeof to the subobject, due to virtual base classes and less strict padding requirements on potentially-overlapping subobjects.

§ 7.6.2.4 118
The result of `sizeof` and `sizeof...` is a prvalue of type `std::size_t`. [Note: A `sizeof` expression is an integral constant expression (7.7). The type `std::size_t` is defined in the standard header `<cassert>` (17.2.1, 17.2.4). — end note]

### 7.6.2.5 Alignof

An `alignof` expression yields the alignment requirement of its operand type. The operand shall be a `type-id` representing a complete object type, or an array thereof, or a reference to one of those types.

The result is a prvalue of type `std::size_t`. [Note: An `alignof` expression is an integral constant expression (7.7). The type `std::size_t` is defined in the standard header `<cassert>` (17.2.1, 17.2.4). — end note]

When `alignof` is applied to a reference type, the result is the alignment of the referenced type. When `alignof` is applied to an array type, the result is the alignment of the element type.

### 7.6.2.6 noexcept operator

The `noexcept` operator determines whether the evaluation of its operand, which is an unevaluated operand (7.2), can throw an exception (14.1).

```plaintext
noexcept-expression:
  noexcept ( expression )
```

The result of the `noexcept` operator is a prvalue of type `bool`. [Note: A `noexcept-expression` is an integral constant expression (7.7). The type `std::size_t` is defined in the standard header `<cassert>` (17.2.1, 17.2.4). — end note]

The result of the `noexcept` operator is `true` unless the `expression` is potentially-throwing (14.4).

### 7.6.2.7 New

The `new-expression` attempts to create an object of the `type-id` (9.2.1) or `new-type-id` to which it is applied. The type of that object is the allocated type. This type shall be a complete object type, but not an abstract class type or array thereof (6.6.2, 6.7, 11.6.3). [Note: Because references are not objects, references cannot be created by `new-expression`. — end note]  [Note: The `type-id` may be a cv-qualified type, in which case the object created by the `new-expression` has a cv-qualified type. — end note]

```plaintext
new-expression:
  :: opt new new-placement opt new-type-id new-initializer opt
  :: opt new new-placement opt ( type-id ) new-initializer opt

new-placement:
  ( expression-list )

new-type-id:
  type-specifier-seq new-declarator opt

new-declarator:
  ptr-operator new-declarator opt
  noptr-new-declarator

noptr-new-declarator:
  [ expressionopt ] attribute-specifier-seqopt
  noptr-new-declarator [ constant-expression ] attribute-specifier-seqopt

new-initializer:
  ( expression-list opt )
  braced-init-list
```

If a placeholder type (9.1.7.5) appears in the `type-specifier-seq` of a `new-type-id` or `type-id` of a `new-expression`, the allocated type is deduced as follows: Let `init` be the `new-initializer`, if any, and `T` be the `new-type-id` or `type-id` of the `new-expression`, then the allocated type is the type deduced for the variable `x` in the invented declaration (9.1.7.5):

```plaintext
T x init ;
```

[Example:
```c
new auto(1); // allocated type is int
auto x = new auto('a'); // allocated type is char, x is of type char*
```]
template<class T> struct A { A(T, T); };  

    auto y = new A{1, 2}; // allocated type is A<int>

[3] The new-type-id in a new-expression is the longest possible sequence of new-declarators. [Note: This prevents ambiguities between the declarator operators &[], &*, and [] and their expression counterparts. — end note]  

[Example:  

    new int * i; // syntax error: parsed as (new int*) i, not as (new int)*i

The * is the pointer declarator and not the multiplication operator. — end example]

[4] [Note: Parentheses in a new-type-id of a new-expression can have surprising effects. [Example:  

    new int(*[10])(); // error

is ill-formed because the binding is

    (new int) (*[10])(); // error

Instead, the explicitly parenthesized version of the new operator can be used to create objects of compound types (6.7.2):  

    new (int (*[10])());

allocates an array of 10 pointers to functions (taking no argument and returning int). — end example]  

[5] Objects created by a new-expression have dynamic storage duration (6.6.5.4). [Note: The lifetime of such an object is not necessarily restricted to the scope in which it is created. — end note] When the allocated object is not an array, the result of the new-expression is a pointer to the object created.

[6] When the allocated object is an array (that is, the noptr-new-declarator syntax is used or the new-type-id or type-id denotes an array type), the new-expression yields a pointer to the initial element (if any) of the array. [Note: Both new int and new int[10] have type int* and the type of new int[i][10] is int (*)([10]) — end note] The attribute-specifier-seq in a noptr-new-declarator appertains to the associated array type.

[7] Every constant-expression in a noptr-new-declarator shall be a converted constant expression (7.7) of type std::size_t and its value shall be greater than zero. [Example: Given the definition int n = 42, new float[n][5] is well-formed (because n is the expression of a noptr-new-declarator), but new float[5][n] is ill-formed (because n is not a constant expression). — end example]

[8] If the type-id or new-type-id denotes an array type of unknown bound (9.2.3.4), the new-initializer shall not be omitted; the allocated object is an array with n elements, where n is determined from the number of initial elements supplied in the new-initializer (9.3.1, 9.3.2).

[9] If the expression in a noptr-new-declarator is present, it is implicitly converted to std::size_t. The expression is erroneous if:

9.1] — the expression is of non-class type and its value before converting to std::size_t is less than zero;

9.2] — the expression is of class type and its value before application of the second standard conversion (12.3.3.1.2) is less than zero;

9.3] — its value is such that the size of the allocated object would exceed the implementation-defined limit (Annex B); or

9.4] — the new-initializer is a braced-init-list and the number of array elements for which initializers are provided (including the terminating ‘\0’ in a string literal (5.13.5)) exceeds the number of elements to initialize.

If the expression is erroneous after converting to std::size_t:

9.5] — if the expression is a core constant expression, the program is ill-formed;

9.6] — otherwise, an allocation function is not called; instead

9.6.1] — if the allocation function that would have been called has a non-throwing exception specification (14.4), the value of the new-expression is the null pointer value of the required result type;

9.6.2] — otherwise, the new-expression terminates by throwing an exception of a type that would match a handler (14.3) of type std::bad_array_new_length (17.6.3.2).

74] If the conversion function returns a signed integer type, the second standard conversion converts to the unsigned type std::size_t and thus thwarts any attempt to detect a negative value afterwards.
When the value of the expression is zero, the allocation function is called to allocate an array with no elements.

10 A new-expression may obtain storage for the object by calling an allocation function (6.6.5.4.1). If the new-expression terminates by throwing an exception, it may release storage by calling a deallocation function (6.6.5.4.2). If the allocated type is a non-array type, the allocation function’s name is operator new and the deallocation function’s name is operator delete. If the allocated type is an array type, the allocation function’s name is operator new[] and the deallocation function’s name is operator delete[].

[Note: An implementation shall provide default definitions for the global allocation functions (6.6.5.4, 17.6.2.1, 17.6.2.2). A C++ program can provide alternative definitions of these functions (16.5.4.6) and/or class-specific versions (11.11). The set of allocation and deallocation functions that may be called by a new-expression may include functions that do not perform allocation or deallocation; for example, see 17.6.2.3. — end note]

11 If the new-expression begins with a unary :: operator, the allocation function’s name is looked up in the global scope. Otherwise, if the allocated type is a class type T or array thereof, the allocation function’s name is looked up in the scope of T. If this lookup fails to find the name, or if the allocated type is not a class type, the allocation function’s name is looked up in the global scope.

12 An implementation is allowed to omit a call to a replaceable global allocation function (17.6.2.1, 17.6.2.2). When it does so, the storage is instead provided by the implementation or provided by extending the allocation of another new-expression. The implementation may extend the allocation of a new-expression e1 to provide storage for a new-expression e2 if the following would be true were the allocation not extended:

(12.1) — the evaluation of e1 is sequenced before the evaluation of e2, and
(12.2) — e2 is evaluated whenever e1 obtains storage, and
(12.3) — both e1 and e2 invoke the same replaceable global allocation function, and
(12.4) — if the allocation function invoked by e1 and e2 is throwing, any exceptions thrown in the evaluation of either e1 or e2 would be first caught in the same handler, and
(12.5) — the pointer values produced by e1 and e2 are operands to evaluated delete-expressions, and
(12.6) — the evaluation of e2 is sequenced before the evaluation of the delete-expression whose operand is the pointer value produced by e1.

[Example:

```c++
void mergeable(int x) {
    // These allocations are safe for merging:
    std::unique_ptr<char[]> a{new (std::nothrow) char[8]};
    std::unique_ptr<char[]> b{new (std::nothrow) char[8]};
    std::unique_ptr<char[]> c{new (std::nothrow) char[x]};

    g(a.get(), b.get(), c.get());
}

void unmergeable(int x) {
    std::unique_ptr<char[]> a{new char[8]};
    try {
        // Merging this allocation would change its catch handler.
        std::unique_ptr<char[]> b{new char[x]};
    } catch (const std::bad_alloc& e) {
        std::cerr << "Allocation failed: " << e.what() << std::endl;
        throw;
    }
}

— end example]

13 When a new-expression calls an allocation function and that allocation has not been extended, the new-expression passes the amount of space requested to the allocation function as the first argument of type std::size_t. That argument shall be no less than the size of the object being created; it may be greater than the size of the object being created only if the object is an array. For arrays of char, unsigned char, and std::byte, the difference between the result of the new-expression and the address returned by the allocation function shall be an integral multiple of the strictest fundamental alignment requirement (6.6.6) of any object type whose size is no greater than the size of the array being created. [Note: Because allocation
functions are assumed to return pointers to storage that is appropriately aligned for objects of any type with fundamental alignment, this constraint on array allocation overhead permits the common idiom of allocating character arrays into which objects of other types will later be placed.  — end note]

When a new-expression calls an allocation function and that allocation has been extended, the size argument to the allocation call shall be no greater than the sum of the sizes for the omitted calls as specified above, plus the size for the extended call had it not been extended, plus any padding necessary to align the allocated objects within the allocated memory.

The new-placement syntax is used to supply additional arguments to an allocation function; such an expression is called a placement new-expression.

Overload resolution is performed on a function call created by assembling an argument list. The first argument is the amount of space requested, and has type std::size_t. If the type of the allocated object has new-extended alignment, the next argument is the type’s alignment, and has type std::align_val_t. If the new-placement syntax is used, the initializer-clauses in its expression-list are the succeeding arguments. If no matching function is found and the allocated object type has new-extended alignment, the alignment argument is removed from the argument list, and overload resolution is performed again.

[Example:

(17.1) — new T results in one of the following calls:

    operator new(sizeof(T))
    operator new(sizeof(T), std::align_val_t(alignof(T)))

(17.2) — new(2,f) T results in one of the following calls:

    operator new(sizeof(T), 2, f)
    operator new(sizeof(T), std::align_val_t(alignof(T)), 2, f)

(17.3) — new T[5] results in one of the following calls:

    operator new[](sizeof(T) * 5 + x)
    operator new[](sizeof(T) * 5 + x, std::align_val_t(alignof(T)))

(17.4) — new(2,f) T[5] results in one of the following calls:

    operator new[](sizeof(T) * 5 + x, 2, f)
    operator new[](sizeof(T) * 5 + x, std::align_val_t(alignof(T)), 2, f)

Here, each instance of x is a non-negative unspecified value representing array allocation overhead; the result of the new-expression will be offset by this amount from the value returned by operator new[]. This overhead may be applied in all array new-expressions, including those referencing the library function operator new[](std::size_t, void*) and other placement allocation functions. The amount of overhead may vary from one invocation of new to another. — end example]

[Note: Unless an allocation function has a non-throwing exception specification (14.4), it indicates failure to allocate storage by throwing a std::bad_alloc exception (6.6.5.4.1, Clause 14, 17.6.3.1); it returns a non-null pointer otherwise. If the allocation function has a non-throwing exception specification, it returns null to indicate failure to allocate storage and a non-null pointer otherwise. — end note] If the allocation function is a non-allocating form (17.6.2.3) that returns null, the behavior is undefined. Otherwise, if the allocation function returns null, initialization shall not be done, the deallocation function shall not be called, and the value of the new-expression shall be null.

[Note: When the allocation function returns a value other than null, it must be a pointer to a block of storage in which space for the object has been reserved. The block of storage is assumed to be appropriately aligned and of the requested size. The address of the created object will not necessarily be the same as that of the block if the object is an array. — end note]

A new-expression that creates an object of type T initializes that object as follows:

(20.1) — If the new-initializer is omitted, the object is default-initialized (9.3). [Note: If no initialization is performed, the object has an indeterminate value. — end note]

(20.2) — Otherwise, the new-initializer is interpreted according to the initialization rules of 9.3 for direct-initialization.

The invocation of the allocation function is sequenced before the evaluations of expressions in the new-initializer. Initialization of the allocated object is sequenced before the value computation of the new-expression.
If the `new-expression` creates an object or an array of objects of class type, access and ambiguity control are done for the allocation function, the deallocation function (11.11), and the constructor (11.3.4) selected for the initialization (if any). If the `new-expression` creates an array of objects of class type, the destructor is potentially invoked (11.3.6).

If any part of the object initialization described above terminates by throwing an exception and a suitable deallocation function can be found, the deallocation function is called to free the memory in which the object was being constructed, after which the exception continues to propagate in the context of the `new-expression`. If no unambiguous matching deallocation function can be found, propagating the exception does not cause the object’s memory to be freed. [Note: This is appropriate when the called allocation function does not allocate memory; otherwise, it is likely to result in a memory leak. — end note]

If the `new-expression` begins with a unary `::` operator, the deallocation function’s name is looked up in the global scope. Otherwise, if the allocated type is a class type `T` or an array thereof, the deallocation function’s name is looked up in the scope of `T`. If this lookup fails to find the name, or if the allocated type is not a class type or array thereof, the deallocation function’s name is looked up in the global scope.

A declaration of a placement deallocation function matches the declaration of a placement allocation function if it has the same number of parameters and, after parameter transformations (9.2.3.5), all parameter types except the first are identical. If the lookup finds a single matching deallocation function, that function will be called; otherwise, no deallocation function will be called. If the lookup finds a usual deallocation function with a parameter of type `std::size_t` (6.6.5.4.2) and that function, considered as a placement deallocation function, would have been selected as a match for the allocation function, the program is ill-formed. For a non-placement allocation function, the normal deallocation function lookup is used to find the matching deallocation function (7.6.2.8) [Example:

```cpp
struct S {
    // Placement allocation function:
    static void* operator new(std::size_t, std::size_t);

    // Usual (non-placement) deallocation function:
    static void operator delete(void*, std::size_t);
};

S* p = new (0) S; // ill-formed: non-placement deallocation function matches
                   // placement allocation function
                   // placement allocation function
```

— end example]

If a `new-expression` calls a deallocation function, it passes the value returned from the allocation function call as the first argument of type `void*`. If a placement deallocation function is called, it is passed the same additional arguments as were passed to the placement allocation function, that is, the same arguments as those specified with the `new-placement` syntax. If the implementation is allowed to introduce a temporary object or make a copy of any argument as part of the call to the allocation function, it is unspecified whether the same object is used in the call to both the allocation and deallocation functions.

### 7.6.2.8 Delete

The `delete-expression` operator destroys a most derived object (6.6.2) or array created by a `new-expression`.

```
delete-expression:
    ::opt delete cast-expression
    ::opt delete [ ] cast-expression
```

The first alternative is a `single-object delete expression`, and the second is an `array delete expression`. Whenever the `delete` keyword is immediately followed by empty square brackets, it shall be interpreted as the second alternative. The operand shall be of pointer to object type or of class type. If of class type, the operand is contextually implicitly converted (7.3) to a pointer to object type. The `delete-expression`’s result has type `void`.

If the operand has a class type, the operand is converted to a pointer type by calling the above-mentioned conversion function, and the converted operand is used in place of the original operand for the remainder of

---

75) This may include evaluating a `new-initializer` and/or calling a constructor.

76) A `lambda-expression` with a `lambda-introducer` that consists of empty square brackets can follow the `delete` keyword if the `lambda-expression` is enclosed in parentheses.

77) This implies that an object cannot be deleted using a pointer of type `void*` because `void` is not an object type.
In a single-object delete expression, the value of the operand of \texttt{delete} may be a null pointer value, a pointer to a non-array object created by a previous \texttt{new-expression}, or a pointer to a subobject (6.6.2) representing a base class of such an object (11.6). If not, the behavior is undefined. In an array delete expression, the value of the operand of \texttt{delete} may be a null pointer value or a pointer value that resulted from a previous array \texttt{new-expression}.\footnote{If not, the behavior is undefined. [Note: This means that the syntax of the delete-expression must match the type of the object allocated by \texttt{new}, not the syntax of the new-expression. — end note]} If not, the behavior is undefined. [Note: This means that the syntax of the delete-expression must match the type of the object allocated by \texttt{new}, not the syntax of the new-expression. — end note]

In a single-object delete expression, if the static type of the object to be deleted is different from its dynamic type and the selected deallocation function (see below) is not a destroying operator delete, the static type shall be a base class of the dynamic type of the object to be deleted and the static type shall have a virtual destructor or the behavior is undefined. In an array delete expression, if the dynamic type of the object to be deleted differs from its static type, the behavior is undefined.

The \texttt{cast-expression} in a delete-expression shall be evaluated exactly once.

If the object being deleted has incomplete class type at the point of deletion and the complete class has a non-trivial destructor or a deallocation function, the behavior is undefined.

If the value of the operand of the delete-expression is not a null pointer value and the selected deallocation function (see below) is not a destroying operator delete, the delete-expression will invoke the destructor (if any) for the object or the elements of the array being deleted. In the case of an array, the elements will be destroyed in order of decreasing address (that is, in reverse order of the completion of their constructor; see 11.9.2).

If the value of the operand of the delete-expression is not a null pointer value, then:

\begin{enumerate}
\item If the allocation call for the new-expression for the object to be deleted was not omitted and the allocation was not extended (7.6.2.7), the delete-expression shall call a deallocation function (6.6.5.4.2). The value returned from the allocation call of the new-expression shall be passed as the first argument to the deallocation function.
\item Otherwise, if the allocation was extended or was provided by extending the allocation of another new-expression, and the delete-expression for every other pointer value produced by a new-expression that had storage provided by the extended new-expression has been evaluated, the delete-expression shall call a deallocation function. The value returned from the allocation call of the extended new-expression shall be passed as the first argument to the deallocation function.
\item Otherwise, the delete-expression will not call a deallocation function.
\end{enumerate}

[Note: The deallocation function is called regardless of whether the destructor for the object or some element of the array throws an exception. — end note] If the value of the operand of the delete-expression is a null pointer value, it is unspecified whether a deallocation function will be called as described above.

An implementation provides default definitions of the global deallocation functions \texttt{operator delete} for non-arrays (17.6.2.1) and \texttt{operator delete} for arrays (17.6.2.2). A C++ program can provide alternative definitions of these functions (16.5.4.6), and/or class-specific versions (11.11). — end note]

When the keyword \texttt{delete} in a delete-expression is preceded by the unary :: operator, the deallocation function’s name is looked up in global scope. Otherwise, the lookup considers class-specific deallocation functions (11.11). If no class-specific deallocation function is found, the deallocation function’s name is looked up in global scope.

If deallocation function lookup finds more than one usual deallocation function, the function to be called is selected as follows:

\begin{enumerate}
\item If any of the deallocation functions is a destroying operator delete, all deallocation functions that are not destroying operator deletes are eliminated from further consideration.
\item If the type has new-extended alignment, a function with a parameter of type \texttt{std::align_val_t} is preferred; otherwise a function without such a parameter is preferred. If any preferred functions are found, all non-preferred functions are eliminated from further consideration.
\item If exactly one function remains, that function is selected and the selection process terminates.
\end{enumerate}

\footnote{For nonzero-length arrays, this is the same as a pointer to the first element of the array created by that new-expression. Zero-length arrays do not have a first element.}
If the deallocation functions have class scope, the one without a parameter of type `std::size_t` is selected.

If the type is complete and if, for an array delete expression only, the operand is a pointer to a class type with a non-trivial destructor or a (possibly multi-dimensional) array thereof, the function with a parameter of type `std::size_t` is selected.

Otherwise, it is unspecified whether a deallocation function with a parameter of type `std::size_t` is selected.

For a single-object delete expression, the deleted object is the object denoted by the operand if its static type does not have a virtual destructor, and its most-derived object otherwise. [Note: If the deallocation function is not a destroying operator delete and the deleted object is not the most derived object in the former case, the behavior is undefined, as stated above. — end note] For an array delete expression, the deleted object is the array object. When a delete-expression is executed, the selected deallocation function shall be called with the address of the deleted object in a single-object delete expression, or the address of the deleted object suitably adjusted for the array allocation overhead (7.6.2.7) in an array delete expression, as its first argument. [Note: Any cv-qualifiers in the type of the deleted object are ignored when forming this argument. — end note] If a destroying operator delete is used, an unspecified value is passed as the argument corresponding to the parameter of type `std::destroying_delete_t`. If a deallocation function with a parameter of type `std::align_val_t` is used, the alignment of the type of the deleted object is passed as the corresponding argument. If a deallocation function with a parameter of type `std::size_t` is used, the size of the deleted object in a single-object delete expression, or of the array plus allocation overhead in an array delete expression, is passed as the corresponding argument. [Note: If this results in a call to a replaceable deallocation function, and either the first argument was not the result of a prior call to a replaceable allocation function or the second or third argument was not the corresponding argument in said call, the behavior is undefined (17.6.2.1, 17.6.2.2). — end note]

Access and ambiguity control are done for both the deallocation function and the destructor (11.3.6, 11.11).

### 7.6.3 Explicit type conversion (cast notation) [expr.cast]

The result of the expression `(T) cast-expression` is of type `T`. The result is an lvalue if `T` is an lvalue reference type or an rvalue reference to function type and an xvalue if `T` is an rvalue reference to object type; otherwise the result is a prvalue. [Note: If `T` is a non-class type that is cv-qualified, the cv-qualifiers are discarded when determining the type of the resulting prvalue; see 7.2. — end note]

An explicit type conversion can be expressed using functional notation (7.6.1.3), a type conversion operator (`dynamic_cast`, `static_cast`, `reinterpret_cast`, `const_cast`), or the `cast` notation.

```
cast-expression:
  unary-expression
  ( type-id ) cast-expression
```

Any type conversion not mentioned below and not explicitly defined by the user (11.3.7) is ill-formed.

The conversions performed by

1. `const_cast`
2. `static_cast`
3. `static_cast` followed by a `const_cast`,
4. `reinterpret_cast`
5. `reinterpret_cast` followed by a `const_cast`,

can be performed using the cast notation of explicit type conversion. The same semantic restrictions and behaviors apply, with the exception that in performing a `static_cast` in the following situations the conversion is valid even if the base class is inaccessible:

1. A pointer to an object of derived class type or an lvalue or rvalue of derived class type may be explicitly converted to a pointer or reference to an unambiguous base class type, respectively;
2. A pointer to member of derived class type may be explicitly converted to a pointer to member of an unambiguous non-virtual base class type;
3. A pointer to an object of an unambiguous non-virtual base class type, a glvalue of an unambiguous non-virtual base class type, or a pointer to member of an unambiguous non-virtual base class type
may be explicitly converted to a pointer, a reference, or a pointer to member of a derived class type, respectively.

If a conversion can be interpreted in more than one of the ways listed above, the interpretation that appears first in the list is used, even if a cast resulting from that interpretation is ill-formed. If a conversion can be interpreted in more than one way as a static_cast followed by a const_cast, the conversion is ill-formed. [Example:

```c++
struct A { }
struct I1 : A { }
struct I2 : A { }
struct D : I1, I2 { }
A* foo( D* p ) {
    return (A*)( p );    // ill-formed static_cast interpretation
}
```
—end example]

5 The operand of a cast using the cast notation can be a prvalue of type “pointer to incomplete class type”. The destination type of a cast using the cast notation can be “pointer to incomplete class type”. If both the operand and destination types are class types and one or both are incomplete, it is unspecified whether the static_cast or the reinterpret_cast interpretation is used, even if there is an inheritance relationship between the two classes. [Note: For example, if the classes were defined later in the translation unit, a multi-pass compiler would be permitted to interpret a cast between pointers to the classes as if the class types were complete at the point of the cast. —end note]

7.6.4 Pointer-to-member operators

1 The pointer-to-member operators ->* and .* group left-to-right.

```
pm-expression:
cast-expression
pm-expression .* cast-expression
pm-expression ->* cast-expression
```

2 The binary operator .* binds its second operand, which shall be of type “pointer to member of T” to its first operand, which shall be a glvalue of class T or of a class of which T is an unambiguous and accessible base class. The result is an object or a function of the type specified by the second operand.

3 The binary operator ->* binds its second operand, which shall be of type “pointer to member of T” to its first operand, which shall be of type “pointer to U” where U is either T or a class of which T is an unambiguous and accessible base class. The expression E1->*E2 is converted into the equivalent form (*(E1)).*E2.

4 Abbreviating pm-expression.*cast-expression as E1.*E2, E1 is called the object expression. If the dynamic type of E1 does not contain the member to which E2 refers, the behavior is undefined. Otherwise, the expression E1 is sequenced before the expression E2.

5 The restrictions on cv-qualification, and the manner in which the cv-qualifiers of the operands are combined to produce the cv-qualifiers of the result, are the same as the rules for E1.E2 given in 7.6.1.4. [Note: It is not possible to use a pointer to member that refers to a mutable member to modify a const class object. For example,

```c++
struct S {
    S() : i(0) {}
    mutable int i;
};
void f()
{
    const S cs;
    int S::* pm = &S::i;    // pm refers to mutable member S::i
    cs.*pm = 88;            // ill-formed: cs is a const object
}
```
—end note]

6 If the result of .* or ->* is a function, then that result can be used only as the operand for the function call operator (). [Example:

```c++
(ptr_to_obj->*ptr_to_mfct)(10);
```
calls the member function denoted by \texttt{ptr\_to\_mfct} for the object pointed to by \texttt{ptr\_to\_obj}. — end example\[
\]

In a \texttt{\*} expression whose object expression is an rvalue, the program is ill-formed if the second operand is a pointer to function whose ref-qualifier is \&, unless its cv-qualifier-seq is \texttt{const}. In a \texttt{\*} expression whose object expression is an lvalue, the program is ill-formed if the second operand is a pointer to function whose ref-qualifier is \&\&. The result of a \texttt{\*} expression whose second operand is a pointer to a data member is an lvalue if the first operand is an lvalue and an xvalue otherwise. The result of a \texttt{\*} expression whose second operand is a pointer to a member function is a prvalue. If the second operand is the null member pointer value (7.3.12), the behavior is undefined.

7.6.5 Multiplicative operators \[expr.mul\]

1 The multiplicative operators \texttt{*}, \texttt{/}, and \texttt{\%} group left-to-right.

```
multiplicative-expression:
  pm-expression
  multiplicative-expression \texttt{*} pm-expression
  multiplicative-expression \texttt{/} pm-expression
  multiplicative-expression \texttt{\%} pm-expression
```

2 The operands of \texttt{*} and \texttt{/} shall have arithmetic or unscoped enumeration type; the operands of \texttt{\%} shall have integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed on the operands and determine the type of the result.

3 The binary \texttt{*} operator indicates multiplication.

4 The binary \texttt{/} operator yields the quotient, and the binary \texttt{\%} operator yields the remainder from the division of the first expression by the second. If the second operand of \texttt{/} or \texttt{\%} is zero the behavior is undefined. For integral operands the \texttt{/} operator yields the algebraic quotient with any fractional part discarded;\textsuperscript{79} if the quotient \texttt{a/b} is representable in the type of the result, \((a/b)*b + a\%b\) is equal to \texttt{a}; otherwise, the behavior of both \texttt{a/b} and \texttt{a\%b} is undefined.

7.6.6 Additive operators \[expr.add\]

1 The additive operators \texttt{+} and \texttt{-} group left-to-right. The usual arithmetic conversions (7.4) are performed for operands of arithmetic or enumeration type.

```
additive-expression:
  multiplicative-expression
  additive-expression \texttt{+} multiplicative-expression
  additive-expression \texttt{-} multiplicative-expression
```

For addition, either both operands shall have arithmetic or unscoped enumeration type, or one operand shall be a pointer to a completely-defined object type and the other shall have integral or unscoped enumeration type.

2 For subtraction, one of the following shall hold:

(2.1) — both operands have arithmetic or unscoped enumeration type; or

(2.2) — both operands are pointers to cv-qualified or cv-unqualified versions of the same completely-defined object type; or

(2.3) — the left operand is a pointer to a completely-defined object type and the right operand has integral or unscoped enumeration type.

3 The result of the binary \texttt{+} operator is the sum of the operands. The result of the binary \texttt{-} operator is the difference resulting from the subtraction of the second operand from the first.

4 When an expression \texttt{J} that has integral type is added to or subtracted from an expression \texttt{P} of pointer type, the result has the type of \texttt{P}.

(4.1) — If \texttt{P} evaluates to a null pointer value and \texttt{J} evaluates to 0, the result is a null pointer value.

(4.2) — Otherwise, if \texttt{P} points to an array element \textit{i} of an array object \textit{x} with \textit{n} elements (9.2.3.4), the expressions \texttt{P + J} and \texttt{J + P} (where \texttt{J} has the value \textit{j}) point to the (possibly-hypothetical) array

\texttt{x}[\textit{i} + \textit{j}] if \textit{i} + \textit{j} is in bounds, or

\texttt{x}[\textit{i} + \textit{j} % \textit{n}] if \textit{i} + \textit{j} is out of bounds.

\texttt{x}[\textit{i} + \textit{j} % \textit{n}] is the same as \texttt{x}[\textit{i} + \textit{j} % \textit{n}]

\texttt{\%} is often called truncation towards zero.

\textsuperscript{80} An object that is not an array element is considered to belong to a single-element array for this purpose; see 7.6.2.1. A pointer past the last element of an array \textit{x} of \textit{n} elements is considered to be equivalent to a pointer to a hypothetical array element \textit{n} for this purpose; see 6.7.2.
element \(i + j\) of \(x\) if \(0 \leq i + j \leq n\) and the expression \(P - J\) points to the (possibly-hypothetical) array element \(i - j\) of \(x\) if \(0 \leq i - j \leq n\).

(4.3) Otherwise, the behavior is undefined.

5 When two pointer expressions \(P\) and \(Q\) are subtracted, the type of the result is an implementation-defined signed integral type; this type shall be the same type that is defined as `std::ptrdiff_t` in the `<cstddef>` header (17.2).

(5.1) — If \(P\) and \(Q\) both evaluate to null pointer values, the result is 0.

(5.2) — Otherwise, if \(P\) and \(Q\) point to, respectively, array elements \(i\) and \(j\) of the same array object \(x\), the expression \(P - Q\) has the value \(i - j\).

(5.3) — Otherwise, the behavior is undefined. [Note: If the value \(i - j\) is not in the range of representable values of type `std::ptrdiff_t`, the behavior is undefined. — end note]

6 For addition or subtraction, if the expressions \(P\) or \(Q\) have type “pointer to cv T”, where \(T\) and the array element type are not similar (7.3.5), the behavior is undefined. [Note: In particular, a pointer to a base class cannot be used for pointer arithmetic when the array contains objects of a derived class type. — end note]

### 7.6.7 Shift operators

`<expr.shift>`

1 The shift operators `<<` and `>>` group left-to-right.

```
shift-expression:
  additive-expression
  shift-expression << additive-expression
  shift-expression >> additive-expression
```

The operands shall be of integral or unscoped enumeration type and integral promotions are performed. The type of the result is that of the promoted left operand. The behavior is undefined if the right operand is negative, or greater than or equal to the width of the promoted left operand.

2 The value of \(E1 << E2\) is the unique value congruent to \(E1 \times 2^{E2}\) modulo \(2^N\), where \(N\) is the width of the type of the result. [Note: \(E1\) is left-shifted \(E2\) bit positions; vacated bits are zero-filled. — end note]

3 The value of \(E1 >> E2\) is \(E1 / 2^{E2}\), rounded down. [Note: \(E1\) is right-shifted \(E2\) bit positions. Right-shift on signed integral types is an arithmetic right shift, which performs sign-extension. — end note]

4 The expression \(E1\) is sequenced before the expression \(E2\).

### 7.6.8 Three-way comparison operator

`<expr.spaceship>`

1 The three-way comparison operator groups left-to-right.

```
compare-expression:
  shift-expression
  compare-expression <= compare-expression
```

2 The expression \(p <= q\) is a prvalue indicating whether \(p\) is less than, equal to, greater than, or incomparable with \(q\).

3 If one of the operands is of type `bool` and the other is not, the program is ill-formed.

4 If both operands have arithmetic types, or one operand has integral type and the other operand has unscoped enumeration type, the usual arithmetic conversions (7.4) are applied to the operands. Then:

(4.1) — If a narrowing conversion (9.3.4) is required, other than from an integral type to a floating point type, the program is ill-formed.

(4.2) — Otherwise, if the operands have integral type, the result is of type `std::strong_ordering`. The result is `std::strong_ordering::equal` if both operands are arithmetically equal, `std::strong_ordering::less` if the first operand is arithmetically less than the second operand, and `std::strong_ordering::greater` otherwise.

(4.3) — Otherwise, the operands have floating-point type, and the result is of type `std::partial_ordering`. The expression \(a <= b\) yields `std::partial_ordering::less` if \(a\) is less than \(b\), `std::partial_ordering::greater` if \(a\) is greater than \(b\), `std::partial_ordering::equivalent` if \(a\) is equivalent to \(b\), and `std::partial_ordering::unordered` otherwise.

5 If both operands have the same enumeration type \(E\), the operator yields the result of converting the operands to the underlying type of \(E\) and applying `<=` to the converted operands.
If at least one of the operands is of pointer type, array-to-pointer conversions (7.3.2), pointer conversions (7.3.11), function pointer conversions (7.3.13), and qualification conversions (7.3.5) are performed on both operands to bring them to their composite pointer type (7.2.2). If at least one of the operands is of pointer-to-member type, pointer-to-member conversions (7.3.12) and qualification conversions (7.3.5) are performed on both operands to bring them to their composite pointer type (7.2.2). If both operands are null pointer constants, but not both of integer type, pointer conversions (7.3.11) are performed on both operands to bring them to their composite pointer type (7.2.2). In all cases, after the conversions, the operands shall have the same type. [Note: If both of the operands are arrays, array-to-pointer conversions (7.3.2) are not applied. — end note]

If the composite pointer type is a function pointer type, a pointer-to-member type, or `std::nullptr_t`, the result is of type `std::strong_equality`; the result is `std::strong_equality::equal` if the (possibly converted) operands compare equal (7.6.10) and `std::strong_equality::nonequal` if they compare unequal, otherwise the result of the operator is unspecified.

If the composite pointer type is an object pointer type, `p <=> q` is of type `std::strong_ordering`. If two pointer operands `p` and `q` compare equal (7.6.10), `p <=> q` yields `std::strong_ordering::equal`; if `p` and `q` compare unequal, `p <=> q` yields `std::strong_ordering::less` if `q` compares greater than `p` and `std::strong_ordering::greater` if `p` compares greater than `q` (7.6.9). Otherwise, the result is unspecified.

Otherwise, the program is ill-formed.

The five comparison category types (17.11.2) (the types `std::strong_ordering`, `std::strong_equality`, `std::weak_ordering`, `std::weak_equality`, and `std::partial_ordering`) are not predefined; if the header `<compare>` is not included prior to a use of such a class type – even an implicit use in which the type is not named (e.g., via the `auto` specifier (9.1.7.5) in a defaulted three-way comparison (11.10.3) or use of the built-in operator) – the program is ill-formed.

### 7.6.9 Relational operators

The relational operators group left-to-right. [Example: `a<b<c` means `(a<b)<c` and not `(a<b)&&(b<c)`.

The lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are performed on the operands. The comparison is deprecated if both operands were of array type prior to these conversions (D.3).

The converted operands shall have arithmetic, enumeration, or pointer type. The operators `<` (less than), `>` (greater than), `<=` (less than or equal to), and `>=` (greater than or equal to) all yield `false` or `true`. The type of the result is `bool`.

The usual arithmetic conversions (7.4) are performed on operands of arithmetic or enumeration type. If both operands are pointers, pointer conversions (7.3.11) and qualification conversions (7.3.5) are performed to bring them to their composite pointer type (7.2.2). After conversions, the operands shall have the same type.

The result of comparing unequal pointers to objects is defined in terms of a partial order consistent with the following rules:

- If two pointers point to different elements of the same array, or to subobjects thereof, the pointer to the element with the higher subscript is required to compare greater.

- If two pointers point to different non-static data members of the same object, or to subobjects of such members, recursively, the pointer to the later declared member is required to compare greater provided the two members have the same access control (11.8), neither member is a subobject of zero size, and their class is not a union.

- Otherwise, neither pointer is required to compare greater than the other.

---

81) An object that is not an array element is considered to belong to a single-element array for this purpose; see 7.6.2.1. A pointer past the last element of an array `x` of `n` elements is considered to be equivalent to a pointer to a hypothetical element `x[n]` for this purpose; see 6.7.2.
5 If two operands \( p \) and \( q \) compare equal (7.6.10), \( p \leq q \) and \( p \geq q \) both yield \textit{true} and \( p < q \) and \( p > q \) both yield \textit{false}. Otherwise, if a pointer \( p \) compares greater than a pointer \( q \), \( p > q \), \( q < p \), and \( q > p \) all yield \textit{true} and \( p \leq q \), \( p < q \), \( q \geq p \), and \( q > p \) all yield \textit{false}. Otherwise, the result of each of the operators is unspecified.

6 If both operands (after conversions) are of arithmetic or enumeration type, each of the operators shall yield \textit{true} if the specified relationship is true and \textit{false} if it is false.

### 7.6.10 Equality operators

**equality-expression:***

- relational-expression

**equality-expression == relational-expression**

**equality-expression != relational-expression**

1 The == (equal to) and the != (not equal to) operators group left-to-right. The lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are performed on the operands. The comparison is deprecated if both operands were of array type prior to these conversions (D.3).

2 The converted operands shall have arithmetic, enumeration, pointer, or pointer-to-member type, or type \texttt{std::nullptr_t}. The operators == and != both yield \textit{true} or \textit{false}, i.e., a result of type \texttt{bool}. In each case below, the operands shall have the same type after the specified conversions have been applied.

3 If at least one of the operands is a pointer, pointer conversions (7.3.11), function pointer conversions (7.3.13), and qualification conversions (7.3.5) are performed on both operands to bring them to their composite pointer type (7.2.2). Comparing pointers is defined as follows:

   - (3.1) If one pointer represents the address of a complete object, and another pointer represents the address one past the last element of a different complete object, the result of the comparison is unspecified.

   - (3.2) Otherwise, if the pointers are both null, both point to the same function, or both represent the same address (6.7.2), they compare equal.

   - (3.3) Otherwise, the pointers compare unequal.

4 If at least one of the operands is a pointer to member, pointer-to-member conversions (7.3.12), function pointer conversions (7.3.13), and qualification conversions (7.3.5) are performed on both operands to bring them to their composite pointer type (7.2.2). Comparing pointers to members is defined as follows:

   - (4.1) If two pointers to members are both the null member pointer value, they compare equal.

   - (4.2) If only one of two pointers to members is the null member pointer value, they compare unequal.

   - (4.3) If either is a pointer to a virtual member function, the result is unspecified.

   - (4.4) If one refers to a member of class \( C_1 \) and the other refers to a member of a different class \( C_2 \), where neither is a base class of the other, the result is unspecified. [Example:

```c
struct A {};
struct B : A { int x; };
struct C : A { int x; };

int A::*bx = (int(A::*))&B::x;
int A::*cx = (int(A::*))&C::x;

bool b1 = (bx == cx); // unspecified
```

   - end example]

   - (4.5) If both refer to (possibly different) members of the same union (11.4), they compare equal.

   - (4.6) Otherwise, two pointers to members compare equal if they would refer to the same member of the same most derived object (6.6.2) or the same subobject if indirection with a hypothetical object of the associated class type were performed, otherwise they compare unequal. [Example:

```c
struct B {
    int f();
};
struct L : B { };
struct R : B { };
struct D : L, R { };
```

---

82) An object that is not an array element is considered to belong to a single-element array for this purpose; see 7.6.2.1.
```cpp
int (B::*pb)() = &B::f;
int (L::*pl)() = pb;
int (R::*pr)() = pb;
int (D::*pdl)() = pl;
int (D::*pdr)() = pr;
bool x = (pdl == pdr);  // false
bool y = (pb == pl);   // true
```

--- end example

5. Two operands of type `std::nullptr_t` or one operand of type `std::nullptr_t` and the other a null pointer constant compare equal.

6. If two operands compare equal, the result is `true` for the `==` operator and `false` for the `!=` operator. If two operands compare unequal, the result is `false` for the `==` operator and `true` for the `!=` operator. Otherwise, the result of each of the operators is unspecified.

7. If both operands are of arithmetic or enumeration type, the usual arithmetic conversions (7.4) are performed on both operands; each of the operators shall yield `true` if the specified relationship is true and `false` if it is false.

### 7.6.11 Bitwise AND operator

#### [expr.bit.and]

The `&` operator groups left-to-right. The operands shall be of integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed. Given the coefficients $x_i$ and $y_i$ of the base-2 representation (6.7.1) of the converted operands $x$ and $y$, the coefficient $r_i$ of the base-2 representation of the result $r$ is 1 if both $x_i$ and $y_i$ are 1, and 0 otherwise. [Note: The result is the bitwise AND function of the operands. — end note]

### 7.6.12 Bitwise exclusive OR operator

#### [expr.xor]

The `^` operator groups left-to-right. The operands shall be of integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed. Given the coefficients $x_i$ and $y_i$ of the base-2 representation (6.7.1) of the converted operands $x$ and $y$, the coefficient $r_i$ of the base-2 representation of the result $r$ is 1 if either (but not both) of $x_i$ and $y_i$ are 1, and 0 otherwise. [Note: The result is the bitwise exclusive OR function of the operands. — end note]

### 7.6.13 Bitwise inclusive OR operator

#### [expr.or]

The `|` operator groups left-to-right. The operands shall be of integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed. Given the coefficients $x_i$ and $y_i$ of the base-2 representation (6.7.1) of the converted operands $x$ and $y$, the coefficient $r_i$ of the base-2 representation of the result $r$ is 1 if at least one of $x_i$ and $y_i$ are 1, and 0 otherwise. [Note: The result is the bitwise inclusive OR function of the operands. — end note]

### 7.6.14 Logical AND operator

#### [expr.log.and]

The `&&` operator groups left-to-right. The operands are both contextually converted to `bool` (7.3). The result is `true` if both operands are `true` and `false` otherwise. Unlike `&`, `&&` guarantees left-to-right evaluation: the second operand is not evaluated if the first operand is `false`.

The result is a `bool`. If the second expression is evaluated, every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second expression.
7.6.15  Logical OR operator

\[\text{logical-or-expression} : \text{logical-and-expression} \mid \text{logical-and-expression} \]

1. The | operator groups left-to-right. The operands are both contextually converted to \text{bool} (7.3). The result is \text{true} if either of its operands is \text{true}, and \text{false} otherwise. Unlike |, || guarantees left-to-right evaluation; moreover, the second operand is not evaluated if the first operand evaluates to \text{true}.

2. The result is a \text{bool}. If the second expression is evaluated, every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second expression.

7.6.16  Conditional operator

\[\text{conditional-expression} : \text{logical-or-expression} \mid \text{expression} : \text{assignment-expression} \]

1. Conditional expressions group right-to-left. The first expression is contextually converted to \text{bool} (7.3). It is evaluated and if it is \text{true}, the result of the conditional expression is the value of the second expression, otherwise that of the third expression. Only one of the second and third expressions is evaluated. Every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second or third expression.

2. If either the second or the third operand has type \text{void}, one of the following shall hold:

   (2.1) — The second or the third operand (but not both) is a (possibly parenthesized) \text{throw-expression} (7.6.18); the result is of the type and value category of the other. The \text{conditional-expression} is a bit-field if that operand is a bit-field.

   (2.2) — Both the second and the third operands have type \text{void}; the result is of type \text{void} and is a prvalue. \[\text{Note: This includes the case where both operands are \text{throw-expression}s. — end note}\]

3. Otherwise, if the second and third operand are glvalue bit-fields of the same value category and of types \text{cv}1 \text{T} and \text{cv}2 \text{T}, respectively, the operands are considered to be of type \text{cv}T for the remainder of this subclause, where \text{cv} is the union of \text{cv}1 and \text{cv}2.

4. Otherwise, if the second and third operand have different types and either has (possibly cv-qualified) class type, or if both are glvalues of the same value category and the same type except for cv-qualification, an attempt is made to form an implicit conversion sequence (12.3.3.1) from each of those operands to the type of the other. \[\text{Note: Properties such as access, whether an operand is a bit-field, or whether a conversion function is deleted are ignored for that determination. — end note}\] Attempts are made to form an implicit conversion sequence from an operand expression \text{E}1 of type \text{T}1 to a target type related to the type \text{T}2 of the operand expression \text{E}2 as follows:

   (4.1) — If \text{E}2 is an lvalue, the target type is “lvalue reference to \text{T}2”, subject to the constraint that in the conversion the reference must bind directly (9.3.3) to a glvalue.

   (4.2) — If \text{E}2 is an xvalue, the target type is “rvalue reference to \text{T}2”, subject to the constraint that the reference must bind directly.

   (4.3) — If \text{E}2 is a prvalue or if neither of the conversion sequences above can be formed and at least one of the operands has (possibly cv-qualified) class type:

      (4.3.1) — if \text{T}1 and \text{T}2 are the same class type (ignoring cv-qualification) and \text{T}2 is at least as cv-qualified as \text{T}1, the target type is \text{T}2.

      (4.3.2) — otherwise, if \text{T}2 is a base class of \text{T}1, the target type is \text{cv}1 \text{T}2, where \text{cv}1 denotes the cv-qualifiers of \text{T}1.

      (4.3.3) — otherwise, the target type is the type that \text{E}2 would have after applying the lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions.

Using this process, it is determined whether an implicit conversion sequence can be formed from the second operand to the target type determined for the third operand, and vice versa. If both sequences can be formed, or one can be formed but it is the ambiguous conversion sequence, the program is ill-formed. If no conversion sequence can be formed, the operands are left unchanged and further checking is performed as described below. Otherwise, if exactly one conversion sequence can be formed, that conversion is applied to
the chosen operand and the converted operand is used in place of the original operand for the remainder of this subclause. [Note: The conversion might be ill-formed even if an implicit conversion sequence could be formed. — end note]

5 If the second and third operands are glvalues of the same value category and have the same type, the result is of that type and value category and it is a bit-field if the second or the third operand is a bit-field, or if both are bit-fields.

6 Otherwise, the result is a prvalue. If the second and third operands do not have the same type, and either has (possibly cv-qualified) class type, overload resolution is used to determine the conversions (if any) to be applied to the operands (12.3.1.2, 12.6). If the overload resolution fails, the program is ill-formed. Otherwise, the conversions thus determined are applied, and the converted operands are used in place of the original operands for the remainder of this subclause.

7 Lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are performed on the second and third operands. After those conversions, one of the following shall hold:

1. The second and third operands have the same type; the result is of that type and the result object is initialized using the selected operand.
2. The second and third operands have arithmetic or enumeration type; the usual arithmetic conversions (7.4) are performed to bring them to a common type, and the result is of that type.
3. One or both of the second and third operands have pointer type; pointer conversions (7.3.11), function pointer conversions (7.3.13), and qualification conversions (7.3.5) are performed to bring them to their composite pointer type (7.2.2). The result is of the composite pointer type.
4. One or both of the second and third operands have pointer-to-member type; pointer to member conversions (7.3.12), function pointer conversions (7.3.13), and qualification conversions (7.3.5) are performed to bring them to their composite pointer type (7.2.2). The result is of the composite pointer type.
5. Both the second and third operands have type `std::nullptr_t` or one has that type and the other is a null pointer constant. The result is of type `std::nullptr_t`.

7.6.17 Yielding a value

§ 7.6.17 133
auto f(int x = co_yield 5); // error: yield-expression outside of function suspension context
int a[] = { co_yield 1 }; // error: yield-expression outside of function suspension context

int main() {
    auto r1 = g1();
    auto r2 = g2();
    assert(std::equal(r1.begin(), r1.end(), r2.begin(), r2.end()));
}
— end example

7.6.18 Throwing an exception

throw-expression:

    throw assignment-expressionopt

1 A throw-expression is of type void.

2 Evaluating a throw-expression with an operand throws an exception (14.1); the type of the exception object is determined by removing any top-level cv-qualifiers from the static type of the operand and adjusting the type from “array of T” or function type T to “pointer to T”.

3 A throw-expression with no operand rethrows the currently handled exception (14.3). The exception is reactivated with the existing exception object; no new exception object is created. The exception is no longer considered to be caught. [Example: Code that must be executed because of an exception, but cannot completely handle the exception itself, can be written like this:

    try {
        // ...
    } catch (...) {
        // catch all exceptions
        // respond (partially) to exception
        throw;
        // pass the exception to some other handler
    }
— end example]

4 If no exception is presently being handled, evaluating a throw-expression with no operand calls std::terminate() (14.5.1).

7.6.19 Assignment and compound assignment operators

assignment-expression:

    conditional-expression
    yield-expression
    throw-expression
    logical-or-expression assignment-operator initializer-clause

assignment-operator: one of

    = += -= *= /= %= += -= >>= <<= &= ^= |=

2 In simple assignment (=), the object referred to by the left operand is modified by replacing its value with the result of the right operand.

3 If the left operand is not of class type, the expression is implicitly converted (7.3) to the cv-unqualified type of the left operand.

4 If the left operand is of class type, the class shall be complete. Assignment to objects of a class is defined by the copy/move assignment operator (11.3.5, 12.5.3).

[Note: For class objects, assignment is not in general the same as initialization (9.3, 11.3.4.2, 11.3.5, 11.9). — end note]
When the left operand of an assignment operator is a bit-field that cannot represent the value of the expression, the resulting value of the bit-field is implementation-defined.

The behavior of an expression of the form \( E_1 \ op = E_2 \) is equivalent to \( E_1 = E_1 \ op \ E_2 \) except that \( E_1 \) is evaluated only once. In += and -=, \( E_1 \) shall either have arithmetic type or be a pointer to a possibly cv-qualified completely-defined object type. In all other cases, \( E_1 \) shall have arithmetic type.

If the value being stored in an object is read via another object that overlaps in any way the storage of the first object, then the overlap shall be exact and the two objects shall have the same type, otherwise the behavior is undefined. [Note: This restriction applies to the relationship between the left and right sides of the assignment operation; it is not a statement about how the target of the assignment may be aliased in general. See 7.2.1. — end note]

A braced-init-list may appear on the right-hand side of

\[ \text{(9.1)} \]
— an assignment to a scalar, in which case the initializer list shall have at most a single element. The meaning of \( x = \{v\} \), where \( T \) is the scalar type of the expression \( x \), is that of \( x = T\{v\} \). The meaning of \( x = \{} \) is \( x = T\{} \).

\[ \text{(9.2)} \]
— an assignment to an object of class type, in which case the initializer list is passed as the argument to the assignment operator function selected by overload resolution (12.5.3, 12.3).

\[ \text{Example:} \]
complex<double> z;
z = \{ 1.2 \}; // meaning z.operator\(=\)(\{1,2\})
z += \{ 1, 2 \}; // meaning z.operator\(+\)=(\{1,2\})
int a, b;
a = b = \{ 1 \}; // meaning a=b=1;
a = \{ 1 \} = b; // syntax error
— end example]

7.6.20 Comma operator [expr.comma]

The comma operator groups left-to-right.

\[ \text{expression:} \]
\[ \text{assignment-expression} \]
\[ \text{expression} \]
\[ \text{expression} \], \text{assignment-expression} \]

A pair of expressions separated by a comma is evaluated left-to-right; the left expression is a discarded-value expression (7.2). Every value computation and side effect associated with the left expression is sequenced before every value computation and side effect associated with the right expression. The type and value of the result are the type and value of the right operand; the result is of the same value category as its right operand, and is a bit-field if its right operand is a bit-field. If the right operand is a temporary expression (6.6.7), the result is a temporary expression.

In contexts where comma is given a special meaning, [Example: in lists of arguments to functions (7.6.1.2) and lists of initializers (9.3) — end example] the comma operator as described in this subclause can appear only in parentheses. [Example:

\[
\text{f(a, (t=3, t+2), c);} \\
\text{has three arguments, the second of which has the value 5. — end example}
\]

7.7 Constant expressions [expr.const]

Certain contexts require expressions that satisfy additional requirements as detailed in this subclause; other contexts have different semantics depending on whether or not an expression satisfies these requirements. Expressions that satisfy these requirements, assuming that copy elision (11.9.5) is not performed, are called constant expressions. [Note: Constant expressions can be evaluated during translation. — end note]

\[ \text{constant-expression:} \]
\[ \text{conditional-expression} \]

A constant initializer for a variable or temporary object \( o \) is an initializer for which interpreting its full-expression as a constant-expression results in a constant expression, except that if \( o \) is an object, such an initializer may also invoke constexpr constructors for \( o \) and its subobjects even if those objects are of non-literal class types. [Note: Such a class may have a non-trivial destructor. Within this evaluation, std::is_constant_evaluated() (20.15.10) returns true. — end note]
A variable is *usable in constant expressions* after its initializing declaration is encountered if it is a `constexpr` variable, or it is of reference type or of const-qualified integral or enumeration type, and its initializer is a constant initializer.

An expression \(e\) is a *core constant expression* unless the evaluation of \(e\), following the rules of the abstract machine (6.8.1), would evaluate one of the following expressions:

1. **this** (7.5.2), except in a `constexpr` function or a `constexpr` constructor that is being evaluated as part of \(e\);
2. an invocation of a function other than a `constexpr` constructor for a literal class, a `constexpr` function, or an implicit invocation of a trivial destructor (11.3.6) [Note: Overload resolution (12.3) is applied as usual — end note] ;
3. an invocation of an undefined `constexpr` function or an undefined `constexpr` constructor;
4. an invocation of an instantiated `constexpr` function or `constexpr` constructor that fails to satisfy the requirements for a `constexpr` function or `constexpr` constructor (9.1.5);
5. an expression that would exceed the implementation-defined limits (see Annex B);
6. an operation that would have undefined behavior as specified in Clause 4 through Clause 15 of this document [Note: including, for example, signed integer overflow (7.2), certain pointer arithmetic (7.6.6), division by zero (7.6.5), or certain shift operations (7.6.7) — end note] ;
7. an lvalue-to-rvalue conversion (7.3.1) unless it is applied to
   1. a non-volatile glvalue that refers to an object that is usable in constant expressions, or
   2. a non-volatile glvalue of literal type that refers to a non-volatile object whose lifetime began within the evaluation of \(e\);
8. an lvalue-to-rvalue conversion (7.3.1) that is applied to a glvalue that refers to a non-active member of a union or a subobject thereof;
9. an invocation of an implicitly-defined copy/move constructor or copy/move assignment operator for a union whose active member (if any) is mutable, unless the lifetime of the union object began within the evaluation of \(e\);
10. an *id-expression* that refers to a variable or data member of reference type unless the reference has a preceding initialization and either
   1. it is usable in constant expressions or
   2. its lifetime began within the evaluation of \(e\);
11. a checked contract (9.11.4) whose predicate evaluates to `false`;
12. in a *lambda-expression*, a reference to this or to a variable with automatic storage duration defined outside that *lambda-expression*, where the reference would be an odr-use (6.2, 7.5.5); [Example:
   ```cpp
   void g() {
     const int n = 0;
     [z] {
       constexpr int i = n; // OK, n is not odr-used here
       constexpr int j = *kn; // ill-formed, kn would be an odr-use of n
     }
   }
   ```
   — end example] [Note: If the odr-use occurs in an invocation of a function call operator of a closure type, it no longer refers to this or to an enclosing automatic variable due to the transformation (7.5.5.2) of the *id-expression* into an access of the corresponding data member. [Example:
   ```cpp
   auto monad = [] (auto v) { return [=] { return v; }; };
   auto bind = [] (auto m) {
     return [=] (auto fvm) { return fvm (m()); }; 
   };
   ```
   // OK to have captures to automatic objects created during constant expression evaluation.
   ```cpp
   static_assert (bind (monad (2)) (monad ()) == monad (2)());
   ```
   — end example] — end note]
13. a conversion from type `cv void*` to a pointer-to-object type;
An integral constant expression is an expression of integral or unscoped enumeration type, implicitly converted to a prvalue, where the converted expression is a core constant expression. [Note: Such expressions may be
used as bit-field lengths (11.3.9), as enumerator initializers if the underlying type is not fixed (9.6), and as
alignments (9.11.2). — end note]

6 If an expression of literal class type is used in a context where an integral constant expression is required,
then that expression is contextually implicitly converted (7.3) to an integral or unscoped enumeration type
and the selected conversion function shall be constexpr. [Example:

```cpp
struct A {
  constexpr A(int i) : val(i) { }
  constexpr operator int() const { return val; }
  constexpr operator long() const { return 42; }
private:
  int val;
};
template<int> struct X { }
constexpr A a = alignof(int);
alignas(a) int n; // error: ambiguous conversion
struct B { int n : a; }; // error: ambiguous conversion
```
— end example]

7 A converted constant expression of type \( T \) is an expression, implicitly converted to type \( T \), where the converted
expression is a constant expression and the implicit conversion sequence contains only

- user-defined conversions,
- lvalue-to-rvalue conversions (7.3.1),
- array-to-pointer conversions (7.3.2),
- function-to-pointer conversions (7.3.3),
- qualification conversions (7.3.5),
- integral promotions (7.3.6),
- integral conversions (7.3.8) other than narrowing conversions (9.3.4),
- null pointer conversions (7.3.11) from `std::nullptr_t`,
- null member pointer conversions (7.3.12) from `std::nullptr_t`, and
- function pointer conversions (7.3.13),

and where the reference binding (if any) binds directly. [Note: Such expressions may be used in `new`
expressions (7.6.2.7), as case expressions (8.4.2), as enumerator initializers if the underlying type is fixed (9.6),
as array bounds (9.2.3.4), and as non-type template arguments (13.3). — end note] A contextually
converted constant expression of type \( \text{bool} \) is an expression, contextually converted to \( \text{bool} \) (7.3), where the converted
expression is a constant expression and the conversion sequence contains only the conversions above.

8 A constant expression is either a glvalue core constant expression that refers to an entity that is a permitted
result of a constant expression (as defined below), or a prvalue core constant expression whose value satisfies
the following constraints:

- if the value is an object of class type, each non-static data member of reference type refers to an entity
  that is a permitted result of a constant expression,
- if the value is of pointer type, it contains the address of an object with static storage duration, the
  address past the end of such an object (7.6.6), the address of a non-immediate function, or a null
  pointer value,
- if the value is of pointer-to-member-function type, it does not designate an immediate function, and
- if the value is an object of class or array type, each subobject satisfies these constraints for the value.

An entity is a permitted result of a constant expression if it is an object with static storage duration that
either is not a temporary object or is a temporary object whose value satisfies the above constraints, or if it is
a non-immediate function. [Example:

```cpp
consteval int f() { return 42; }
consteval auto g() { return f(); }
consteval int h(int (*p)() = g()) { return p(); }
constexpr int r = h(); // OK
constexpr auto e = g(); // ill-formed: a pointer to an immediate function
```
© ISO/IEC N4820

// not a permitted result of a constant expression

9 [Note: Since this document imposes no restrictions on the accuracy of floating-point operations, it is unspecified whether the evaluation of a floating-point expression during translation yields the same result as the evaluation of the same expression (or the same operations on the same values) during program execution.]

[Example:

```cpp
bool f() {
    char array[1 + int(1 + 0.2 - 0.1 - 0.1)]; // Must be evaluated during translation
    int size = 1 + int(1 + 0.2 - 0.1 - 0.1); // May be evaluated at runtime
    return sizeof(array) == size;
}
```

It is unspecified whether the value of f() will be true or false. — end example] — end note]

10 An expression or conversion is in an immediate function context if it is potentially evaluated and its innermost non-block scope is a function parameter scope of an immediate function. An expression or conversion is an immediate invocation if it is an explicit or implicit invocation of an immediate function and is not in an immediate function context. An immediate invocation shall be a constant expression. [Note: An immediate invocation is evaluated even in an unevaluated operand. — end note]

11 An expression or conversion e is manifestly constant-evaluated if it is:

(11.1) — a constant-expression, or
(11.2) — the condition of a constexpr if statement (8.4.1), or
(11.3) — an immediate invocation, or
(11.4) — a constraint-expression (13.4.2) including one formed from the constraint-logical-or-expression of a requires-clause, or
(11.5) — the initializer of a variable that is usable in constant expressions or has constant initialization.

[Example:

```cpp
template<bool> struct X {};  // type X<true>
X<std::is_constant_evaluated()> x;
int y;
const int a = std::is_constant_evaluated() ? y : 1;  // dynamic initialization to 1
double z[a];  // ill-formed: a is not usable
const int b = std::is_constant_evaluated() ? 2 : y;  // static initialization to 2
int c = y + (std::is_constant_evaluated() ? 2 : y);  // dynamic initialization to y+y

const expr int f() {
    const int n = std::is_constant_evaluated() ? 13 : 17;  // n is 13
    int m = std::is_constant_evaluated() ? 13 : 17;  // m might be 13 or 17 (see below)
    char arr[n] = {};  // char[13]
    return m + sizeof(arr);
}
```

— end example]

12 An expression or conversion is potentially constant evaluated if it is:

(12.1) — a manifestly constant-evaluated expression,
(12.2) — a potentially-evaluated expression (6.2),
(12.3) — an immediate subexpression of a braced-init-list,
(12.4) — an expression of the form & cast-expression that occurs within a templated entity, or
(12.5) — a subexpression of one of the above that is not a subexpression of a nested unevaluated operand.

83) Nonetheless, implementations should provide consistent results, irrespective of whether the evaluation was performed during translation and/or during program execution.

84) Testing this condition may involve a trial evaluation of its initializer as described above.

85) Constant evaluation may be necessary to determine whether a narrowing conversion is performed (9.3.4).

86) Constant evaluation may be necessary to determine whether such an expression is value-dependent (13.7.2.3).
A function or variable is needed for constant evaluation if it is:

(12.6) — a constexpr function that is named by an expression (6.2) that is potentially constant evaluated, or
(12.7) — a variable whose name appears as a potentially constant evaluated expression that is either a constexpr variable or is of non-volatile const-qualified integral type or of reference type.

[Example:

```cpp
struct N {
  constexpr N() {}
  N(N const&) = delete;
};
template<typename T> constexpr void bad_assert_copyable() { T t; T t2 = t; }
using ineffective = decltype(bad_assert_copyable<N>());
  // bad_assert_copyable<N> is not needed for constant evaluation
  // (and thus not instantiated)
template<typename T> constexpr void assert_copyable() { T t; T t2 = t; }
using check = decltype(assert_copyable<N>());
  // error: assert_copyable<N> is instantiated (because it is needed for constant evaluation), but the attempt to copy t is ill-formed

— end example]
8 Statements

1 Except as indicated, statements are executed in sequence.

    statement:
      labeled-statement
      attribute-specifier-seqopt expression-statement
      attribute-specifier-seqopt compound-statement
      attribute-specifier-seqopt selection-statement
      attribute-specifier-seqopt iteration-statement
      attribute-specifier-seqopt jump-statement
      declaration-statement
      attribute-specifier-seqopt try-block

    init-statement:
      expression-statement
      simple-declaration

    condition:
      expression
      attribute-specifier-seqopt decl-specifier-seq declarator brace-or-equal-initializer

The optional attribute-specifier-seq appertains to the respective statement.

2 A substatement of a statement is one of the following:

   (2.1) for a labeled-statement, its contained statement,
   (2.2) for a compound-statement, any statement of its statement-seq,
   (2.3) for a selection-statement, any of its statements (but not its init-statement), or
   (2.4) for an iteration-statement, its contained statement (but not an init-statement).

   [Note: The compound-statement of a lambda-expression is not a substatement of the statement (if any) in which the lambda-expression lexically appears. — end note]

3 A statement S1 encloses a statement S2 if

   (3.1) S2 is a substatement of S1 (Clause 9),
   (3.2) S1 is a selection-statement or iteration-statement and S2 is the init-statement of S1,
   (3.3) S1 is a try-block and S2 is its compound-statement or any of the compound-statements of its handlers, or
   (3.4) S1 encloses a statement S3 and S3 encloses S2.

4 The rules for conditions apply both to selection-statements and to the for and while statements (8.5). A condition that is not an expression is a declaration (Clause 9). The declarator shall not specify a function or an array. The decl-specifier-seq shall not define a class or enumeration. If the auto type-specifier appears in the decl-specifier-seq, the type of the identifier being declared is deduced from the initializer as described in 9.1.7.5.

   [Note: A name introduced in a selection-statement or iteration-statement outside of any substatement is in scope from its point of declaration until the end of the statement’s substatements. Such a name cannot be redeclared in the outermost block of any of the substatements (6.3.3). — end note]

5 The value of a condition that is an initialized declaration in a statement other than a switch statement is the value of the declared variable contextually converted to bool (7.3). If that conversion is ill-formed, the program is ill-formed. The value of a condition that is an initialized declaration in a switch statement is the value of the declared variable if it has integral or enumeration type, or of that variable implicitly converted to integral or enumeration type otherwise. The value of a condition that is an expression is the value of the expression, contextually converted to bool for statements other than switch; if that conversion is ill-formed, the program is ill-formed. The value of the condition will be referred to as simply “the condition” where the usage is unambiguous.

6 The value of a condition that is an initialized declaration in a statement other than a switch statement is the value of the declared variable contextually converted to bool (7.3). If that conversion is ill-formed, the program is ill-formed. The value of a condition that is an initialized declaration in a switch statement is the value of the declared variable if it has integral or enumeration type, or of that variable implicitly converted to integral or enumeration type otherwise. The value of a condition that is an expression is the value of the expression, contextually converted to bool for statements other than switch; if that conversion is ill-formed, the program is ill-formed. The value of the condition will be referred to as simply “the condition” where the usage is unambiguous.

7 If a condition can be syntactically resolved as either an expression or the declaration of a block-scope name, it is interpreted as a declaration.
8 In the `decl-specifier-seq` of a `condition`, each `decl-specifier` shall be either a `type-specifier` or `constexpr`.

8.1 Labeled statement  
A statement can be labeled.

```
labeled-statement:
  attribute-specifier-seq_opt identifier : statement
  attribute-specifier-seq_opt case constant-expression : statement
  attribute-specifier-seq_opt default : statement
```

The optional `attribute-specifier-seq` appertains to the label. An `identifier label` declares the identifier. The only use of an identifier label is as the target of a `goto`. The scope of a label is the function in which it appears. Labels shall not be redeclared within a function. A label can be used in a `goto` statement before its declaration. Labels have their own name space and do not interfere with other identifiers. [Note: A label may have the same name as another declaration in the same scope or a `template-parameter` from an enclosing scope. Unqualified name lookup (6.4.1) ignores labels. — end note]

2 Case labels and default labels shall occur only in `switch` statements.

8.2 Expression statement  
Expression statements have the form

```
expression-statement:
  expression_opt ;
```

The expression is a discarded-value expression (7.2). All side effects from an expression statement are completed before the next statement is executed. An expression statement with the expression missing is called a `null statement`. [Note: Most statements are expression statements — usually assignments or function calls. A null statement is useful to carry a label just before the `}` of a compound statement and to supply a null body to an iteration statement such as a `while` statement (8.5.1). — end note]

8.3 Compound statement or block  
So that several statements can be used where one is expected, the compound statement (also, and equivalently, called "block") is provided.

```
compound-statement:
  { statement-seq_opt }

statement-seq:
  statement
  statement-seq statement
```

A compound statement defines a block scope (6.3). [Note: A declaration is a `statement` (8.7). — end note]

8.4 Selection statements  
Selection statements choose one of several flows of control.

```
selection-statement:
  if constexpr_opt ( init-statement_opt condition ) statement
  if constexpr_opt ( init-statement_opt condition ) statement else statement
  switch ( init-statement_opt condition ) statement
```

See 9.2.3 for the optional `attribute-specifier-seq` in a condition. [Note: An `init-statement` ends with a semicolon. — end note]

2 The substatement in a `selection-statement` (each substatement, in the `else` form of the `if` statement) implicitly defines a block scope (6.3). If the substatement in a `selection-statement` is a single statement and not a `compound-statement`, it is as if it was rewritten to be a `compound-statement` containing the original substatement. [Example:

```
if (x)
  int i;
```

can be equivalently rewritten as

```
if (x) {
  int i;
}
```

Thus after the `if` statement, `i` is no longer in scope. — end example]
8.4.1 The if statement

If the condition (8.4) yields true the first substatement is executed. If the else part of the selection statement is present and the condition yields false, the second substatement is executed. If the first substatement is reached via a label, the condition is not evaluated and the second substatement is not executed. In the second form of if statement (the one including else), if the first substatement is also an if statement then that inner if statement shall contain an else part.\(^\text{87}\)

If the if statement is of the form if constexpr, the value of the condition shall be a contextually converted constant expression of type bool (7.7); this form is called a constexpr if statement. If the value of the converted condition is false, the first substatement is a discarded statement, otherwise the second substatement, if present, is a discarded statement. During the instantiation of an enclosing templated entity (Clause 13), if the condition is not value-dependent after its instantiation, the discarded substatement (if any) is not instantiated. [Note: Odr-uses (6.2) in a discarded statement do not require an entity to be defined. —end note] A case or default label appearing within such an if statement shall be associated with a switch statement (8.4.2) within the same if statement. A label (8.1) declared in a substatement of a constexpr if statement shall only be referred to by a statement (8.6.5) in the same substatement. [Example:

```cpp
template<typename T, typename ... Rest> void g(T&& p, Rest&& ...rs) {
    // ... handle p
    if constexpr (sizeof...(rs) > 0)
        g(rs...); // never instantiated with an empty argument list
}

extern int x; // no definition of x required

int f() {
    if constexpr (true)
        return 0;
    else if (x)
        return x;
    else
        return -x;
}
```

—end example]

An if statement of the form

```
if constexpr\_opt ( init-statement condition ) statement
```

is equivalent to

```
{
    init-statement
    if constexpr\_opt ( condition ) statement
}
```

and an if statement of the form

```
if constexpr\_opt ( init-statement condition ) statement else statement
```

is equivalent to

```
{
    init-statement
    if constexpr\_opt ( condition ) statement else statement
}
```

except that names declared in the init-statement are in the same declarative region as those declared in the condition.

8.4.2 The switch statement

The switch statement causes control to be transferred to one of several statements depending on the value of a condition.

The condition shall be of integral type, enumeration type, or class type. If of class type, the condition is contextually implicitly converted (7.3) to an integral or enumeration type. If the (possibly converted) type

\(^{87}\) In other words, the else is associated with the nearest un-elsed if.

§ 8.4.2 143
is subject to integral promotions (7.3.6), the condition is converted to the promoted type. Any statement within the `switch` statement can be labeled with one or more case labels as follows:

```plaintext
case constant-expression :
```
where the `constant-expression` shall be a converted constant expression (7.7) of the adjusted type of the switch condition. No two of the case constants in the same switch shall have the same value after conversion.

3 There shall be at most one label of the form

```plaintext
default :
```
within a `switch` statement.

4 Switch statements can be nested; a `case` or `default` label is associated with the smallest switch enclosing it.

5 When the `switch` statement is executed, its condition is evaluated. If one of the case constants has the same value as the condition, control is passed to the statement following the matched case label. If no case constant matches the condition, and if there is a `default` label, control passes to the statement labeled by the default label. If no case matches and if there is no `default` then none of the statements in the switch is executed.

6 `case` and `default` labels in themselves do not alter the flow of control, which continues unimpeded across such labels. To exit from a switch, see `break`, 8.6.1. [Note: Usually, the substatement that is the subject of a switch is compound and `case` and `default` labels appear on the top-level statements contained within the (compound) substatement, but this is not required. Declarations can appear in the substatement of a `switch` statement. — end note]

7 A `switch` statement of the form

```plaintext
switch ( init-statement condition ) statement
```
is equivalent to

```plaintext
{
    init-statement
    switch ( condition ) statement
}
```
except that names declared in the `init-statement` are in the same declarative region as those declared in the `condition`.

### 8.5 Iteration statements

[stmt.iter]

1 Iteration statements specify looping.

```plaintext
iteration-statement:
    while ( condition ) statement
    do statement while ( expression ) ;
    for ( init-statement condition ; expressionopt ) statement
    for ( init-statementopt for-range-declaration : for-range-initializer ) statement

for-range-declaration:
    attribute-specifier-seqopt decl-specifier-seq declarator
    attribute-specifier-seqopt decl-specifier-seq ref-qualifieropt [ identifier-list ]

for-range-initializer:
    expr-or-braced-init-list
```

See 9.2.3 for the optional `attribute-specifier-seq` in a `for-range-declaration`. [Note: An `init-statement` ends with a semicolon. — end note]

2 The substatement in an `iteration-statement` implicitly defines a block scope (6.3) which is entered and exited each time through the loop. If the substatement in an `iteration-statement` is a single statement and not a `compound-statement`, it is as if it was rewritten to be a `compound-statement` containing the original statement. [Example:

```plaintext
while (--x >= 0)
    int i;
```
can be equivalently rewritten as

```plaintext
while (--x >= 0) {
    int i;
}
```
Thus after the while statement, i is no longer in scope. — end example]

3 If a name introduced in an init-statement or for-range-declaration is redeclared in the outermost block of the substatement, the program is ill-formed. [Example:

```cpp
void f() {
    for (int i = 0; i < 10; ++i)
        int i = 0;  // error: redeclaration
    for (int i : { 1, 2, 3 })
        int i = 1;  // error: redeclaration
}
— end example]

8.5.1 The while statement [stmt.while]

1 In the while statement the substatement is executed repeatedly until the value of the condition (8.4) becomes false. The test takes place before each execution of the substatement.

2 When the condition of a while statement is a declaration, the scope of the variable that is declared extends from its point of declaration (6.3.2) to the end of the while statement. A while statement is equivalent to

```cpp
label :
{
    if ( condition ) {
        statement
        goto label ;
    }
}
```

[Note: The variable created in the condition is destroyed and created with each iteration of the loop. [Example:

```cpp
struct A {
    int val;
    A(int i) : val(i) {}  
    ~A() {}  
    operator bool() { return val != 0; }
};
int i = 1;
while (A a = i) {
    // ...
    i = 0;
}
```

In the while-loop, the constructor and destructor are each called twice, once for the condition that succeeds and once for the condition that fails. — end example] — end note]

8.5.2 The do statement [stmt.do]

1 The expression is contextually converted to bool (7.3); if that conversion is ill-formed, the program is ill-formed.

2 In the do statement the substatement is executed repeatedly until the value of the expression becomes false. The test takes place after each execution of the statement.

8.5.3 The for statement [stmt.for]

1 The for statement

```cpp
for ( init-statement condition; expression ) statement
```

is equivalent to

```cpp
{
    init-statement
    while ( condition ) {
        statement
        expression ;
    }
}
```
for (int i = 0; i < 10; i++)
    a[i] = i;

int j = i; // j = 42
— end example]
8.6 Jump statements

Jump statements unconditionally transfer control.

\[\text{jump-statement:}\]
break ;
continue ;
return \(\text{expr-or-braced-init-list}_{\text{opt}}\);
coroutine-return-statement
goto identifier ;

On exit from a scope (however accomplished), objects with automatic storage duration (6.6.5.3) that have been constructed in that scope are destroyed in the reverse order of their construction. [Note: For temporaries, see 6.6.7. — end note] Transfer out of a loop, out of a block, or back past an initialized variable with automatic storage duration involves the destruction of objects with automatic storage duration that are in scope at the point transferred from but not at the point transferred to. (See 8.7 for transfers into blocks). [Note: However, the program can be terminated (by calling std::exit() or std::abort() (17.5), for example) without destroying objects with automatic storage duration. — end note] [Note: A suspension of a coroutine (7.6.2.3) is not considered to be an exit from a scope. — end note]

8.6.1 The break statement

The break statement shall occur only in an iteration-statement or a switch statement and causes termination of the smallest enclosing iteration-statement or switch statement; control passes to the statement following the terminated statement, if any.

8.6.2 The continue statement

The continue statement shall occur only in an iteration-statement and causes control to pass to the loop-continuation portion of the smallest enclosing iteration-statement, that is, to the end of the loop. More precisely, in each of the statements

```c
while (foo) {
    do {
        { // ...
        { // ...
        } contin: ;
        contin: ;
    } while (foo);
}
```

a continue not contained in an enclosed iteration statement is equivalent to goto contin.

8.6.3 The return statement

A function returns to its caller by the return statement.

The \(\text{expr-or-braced-init-list}\) of a return statement is called its operand. A return statement with no operand shall be used only in a function whose return type is cv void, a constructor (11.3.4), or a destructor (11.3.6). A return statement with an operand of type void shall be used only in a function whose return type is cv void. A return statement with any other operand shall be used only in a function whose return type is not cv void; the return statement initializes the glvalue result or prvalue result object of the (explicit or implicit) function call by copy-initialization (9.3) from the operand. [Note: A return statement can involve an invocation of a constructor to perform a copy or move of the operand if it is not a prvalue or if its type differs from the return type of the function. A copy operation associated with a return statement may be elided or converted to a move operation if an automatic storage duration variable is returned (11.9.5). — end note] [Example:

```c
std::pair<std::string,int> f(const char* p, int x) {
    return {p,x};
}
```

— end example] Flowing off the end of a constructor, a destructor, or a non-coroutine function with a cv void return type is equivalent to a return with no operand. Otherwise, flowing off the end of a function other than main (6.8.3.1) or a coroutine (9.4.4) results in undefined behavior.

The copy-initialization of the result of the call is sequenced before the destruction of temporaries at the end of the full-expression established by the operand of the return statement, which, in turn, is sequenced before the destruction of local variables (8.6) of the block enclosing the return statement.
8.6.4 The **co_return** statement

**coroutine-return-statement:**

```
co_return expr-or-braced-init-list_opt;
```

1. A coroutine returns to its caller or resumer (9.4.4) by the **co_return** statement or when suspended (7.6.2.3). A coroutine shall not return to its caller or resumer by a **return** statement (8.6.3).

2. The **expr-or-braced-init-list** of a **co_return** statement is called its operand. Let \( p \) be an lvalue naming the coroutine promise object (9.4.4). A **co_return** statement is equivalent to:

   ```
   { S; goto final-suspend; }
   ```

   where **final-suspend** is the exposition-only label defined in 9.4.4 and \( S \) is defined as follows:

   (2.1) \( S = p\.return_value(expr-or-braced-init-list) \), if the operand is a **braced-init-list** or an expression of non-void type;

   (2.2) \( S = \{ expression_opt; p\.return_void(); \} \), otherwise;

   \( S \) shall be a prvalue of type **void**.

3. If \( p\.return_void() \) is a valid expression, flowing off the end of a coroutine is equivalent to a **co_return** with no operand; otherwise flowing off the end of a coroutine results in undefined behavior.

8.6.5 The **goto** statement

1. The **goto** statement unconditionally transfers control to the statement labeled by the identifier. The identifier shall be a label (8.1) located in the current function.

8.7 Declaration statement

1. A declaration statement introduces one or more new identifiers into a block; it has the form

   ```
   declaration-statement:
   block-declaration
   ```

   If an identifier introduced by a declaration was previously declared in an outer block, the outer declaration is hidden for the remainder of the block, after which it resumes its force.

2. Variables with automatic storage duration (6.6.5.3) are initialized each time their **declaration-statement** is executed. Variables with automatic storage duration declared in the block are destroyed on exit from the block (8.6).

3. It is possible to transfer into a block, but not in a way that bypasses declarations with initialization (including ones in **conditions** and **init-statements**). A program that jumps\(^{88}\) from a point where a variable with automatic storage duration is not in scope to a point where it is in scope is ill-formed unless the variable has vacuous initialization (9.3). In such a case, the variables with vacuous initialization are constructed in the order of their declaration. [Example:

   ```
   void f() {
     // ...
     goto lx;       // ill-formed: jump into scope of a
     // ...
     ly:
     X a = 1;
     // ...
     lx:
     goto ly;      // OK, jump implies destructor call for a followed by
                   // construction again immediately following label ly
   }
   ```
   — end example]

4. Dynamic initialization of a block-scope variable with static storage duration (6.6.5.1) or thread storage duration (6.6.5.2) is performed the first time control passes through its declaration; such a variable is considered initialized upon the completion of its initialization. If the initialization exits by throwing an exception, the initialization is not complete, so it will be tried again the next time control enters the declaration. If control enters the declaration concurrently while the variable is being initialized, the concurrent execution

---

\(^{88}\) The transfer from the condition of a **switch** statement to a **case** label is considered a jump in this respect.
shall wait for completion of the initialization.\footnote{The implementation must not introduce any deadlock around execution of the initializer. Deadlocks might still be caused by the program logic; the implementation need only avoid deadlocks due to its own synchronization operations.} If control re-enters the declaration recursively while the variable is being initialized, the behavior is undefined. [Example:

```c
int foo(int i) {
    static int s = foo(2*i);  // recursive call - undefined
    return i+1;
}
— end example]
```

A block-scope object with static or thread storage duration will be destroyed if and only if it was constructed. [Note: 6.8.3.4 describes the order in which block-scope objects with static and thread storage duration are destroyed. — end note]

8.8 Ambiguity resolution [stmt.ambig]

There is an ambiguity in the grammar involving expression-statements and declarations: An expression-statement with a function-style explicit type conversion (7.6.1.3) as its leftmost subexpression can be indistinguishable from a declaration where the first declarator starts with a `. In those cases the statement is a declaration.

[Note: If the statement cannot syntactically be a declaration, there is no ambiguity, so this rule does not apply. The whole statement might need to be examined to determine whether this is the case. This resolves the meaning of many examples. [Example: Assuming `T` is a simple-type-specifier (9.1.7),

```c
T(a)->m = 7;  // expression-statement
T(a)++;         // expression-statement
T(a,5)<<c;      // expression-statement
T(*d)(int);     // declaration
T(e)[5];        // declaration
T(f) = { 1, 2 }; // declaration
T(*g)(double(3)); // declaration
```

In the last example above, `g`, which is a pointer to `T`, is initialized to `double(3)`. This is of course ill-formed for semantic reasons, but that does not affect the syntactic analysis. — end example]

The remaining cases are declarations. [Example:

```c
class T {
    // ...
    public:
    T();
    T(int);
    T(int, int);
};
T(a);                    // declaration
T(*b);                   // declaration
T(c)=7;                  // declaration
T(d),e,f=3;              // declaration
extern int h;            // declaration
T(g)(h,2);               // declaration
— end example] — end note]
```

The disambiguation is purely syntactic; that is, the meaning of the names occurring in such a statement, beyond whether they are type-names or not, is not generally used in or changed by the disambiguation. Class templates are instantiated as necessary to determine if a qualified name is a type-name. Disambiguation precedes parsing, and a statement disambiguated as a declaration may be an ill-formed declaration. If, during parsing, a name in a template parameter is bound differently than it would be bound during a trial parse, the program is ill-formed. No diagnostic is required. [Note: This can occur only when the name is declared earlier in the declaration. — end note] [Example:

```c
struct T1 {
    T1 operator()(int x) { return T1(x); }
    int operator=(int x) { return x; }
```
T1(int) { }
}

struct T2 { T2(int) { } };
int a, (*(*b)(T2))(int), c, d;

void f() {
   // disambiguation requires this to be parsed as a declaration:
   T1(a) = 3,
   T2(4),
   (**b(T2(c)))(int(d));
   // T2 will be declared as a variable of type T1, but this will not
   // allow the last part of the declaration to parse properly,
   // since it depends on T2 being a type-name
}

—end example]
9 Declarations

Declarations generally specify how names are to be interpreted. Declarations have the form

```
declaration-seq:
  declaration
  declaration-seq declaration

declaration:
  block-declaration
  nodeclspec-function-declaration
  function-definition
  template-declaration
  deduction-guide
  explicit-instantiation
  explicit-specialization
  export-declaration
  linkage-specification
  namespace-specification
  empty-declaration
  attribute-declaration

block-declaration:
  simple-declaration
  asm-definition
  namespace-alias-definition
  using-declaration
  using-directive
  static_assert-declaration
  alias-declaration
  opaque-enum-declaration

nodeclspec-function-declaration:
  attribute-specifier-seqopt declarator ;

alias-declaration:
  using identifier attribute-specifier-seqopt = defining-type-id ;

simple-declaration:
  decl-specifier-seq init-declarator-listopt ;
  attribute-specifier-seq decl-specifier-seq init-declarator-list ;
  attribute-specifier-seqopt decl-specifier-seq ref-qualifieropt [ identifier-list ] initializer ;

static_assert-declaration:
  static_assert ( constant-expression ) ;
  static_assert ( constant-expression , string-literal ) ;

empty-declaration:
  ;

attribute-declaration:
  attribute-specifier-seq ;
```

[Note: asm definitions are described in 9.9, and linkage specifications are described in 9.10; function definitions are described in 9.4 and template-declarations and deduction-guides are described in Clause 13; namespace definitions are described in 9.7.1, using-declarations are described in 9.8 and using-directives are described in 9.7.3. — end note]

A simple-declaration or nodeclspec-function-declaration of the form

```
attribute-specifier-seqopt decl-specifier-seqopt init-declarator-listopt ;
```

is divided into three parts. Attributes are described in 9.11. decl-specifiers, the principal components of a decl-specifier-seq, are described in 9.1. declarators, the components of an init-declarator-list, are described in 9.2. The attribute-specifier-seq appertains to each of the entities declared by the declarators of the init-declarator-list. [Note: In the declaration for an entity, attributes appertaining to that entity may appear at the start of the declaration and after the declarator-id for that declaration. — end note] [Example:
Except where otherwise specified, the meaning of an attribute-declaration is implementation-defined.

A declaration occurs in a scope (6.3); the scope rules are summarized in 6.4. A declaration that declares a function or defines a class, namespace, template, or function also has one or more scopes nested within it. These nested scopes, in turn, can have declarations nested within them. Unless otherwise stated, utterances in Clause 9 about components in, of, or contained by a declaration or subcomponent thereof refer only to those components of the declaration that are not nested within scopes nested within the declaration.

In a simple-declaration, the optional init-declarator-list can be omitted only when declaring a class (Clause 11) or enumeration (9.6), that is, when the decl-specifier-seq contains either a class-specifier, an elaborated-type-specifier with a class-key (11.2), or an enum-specifier. In these cases and whenever a class-specifier or enum-specifier is present in the decl-specifier-seq, the identifiers in these specifiers are among the names being declared by the declaration (as class-names, enum-names, or enumerators, depending on the syntax). In such cases, the decl-specifier-seq shall introduce one or more names into the program, or shall redeclare a name introduced by a previous declaration. [Example:

```c
enum { }; // ill-formed
typedef class { }; // ill-formed
```
—end example]

In a static_assert-declaration, the constant-expression shall be a contextually converted constant expression of type bool (7.7). If the value of the expression when so converted is true, the declaration has no effect. Otherwise, the program is ill-formed, and the resulting diagnostic message (4.1) shall include the text of the string-literal, if one is supplied, except that characters not in the basic source character set (5.3) are not required to appear in the diagnostic message. [Example:

```c
static_assert(sizeof(int) == sizeof(void*), "wrong pointer size");
```
—end example]

An empty-declaration has no effect.

A simple-declaration with an identifier-list is called a structured binding declaration (9.5). If the decl-specifier-seq contains any decl-specifier other than static, thread_local, auto (9.1.7.5), or cv-qualifiers, the program is ill-formed. The initializer shall be of the form “= assignment-expression”, of the form “{ assignment-expression }”, or of the form “( assignment-expression )”, where the assignment-expression is of array or non-union class type.

Each init-declarator in the init-declarator-list contains exactly one declarator-id, which is the name declared by that init-declarator and hence one of the names declared by the declaration. The defining-type-specifiers (9.1.7) in the decl-specifier-seq and the recursive declarator structure of the init-declarator describe a type (9.2.3), which is then associated with the name being declared by the init-declarator.

If the decl-specifier-seq contains the typedef specifier, the declaration is called a typedef declaration and the name of each init-declarator is declared to be a typedef-name, synonymous with its associated type (9.1.3). If the decl-specifier-seq contains no typedef specifier, the declaration is called a function declaration if the type associated with the name is a function type (9.2.3.5) and an object declaration otherwise.

Syntactic components beyond those found in the general form of declaration are added to a function declaration to make a function-definition. An object declaration, however, is also a definition unless it contains the extern specifier and has no initializer (6.1). An object definition causes storage of appropriate size and alignment to be reserved and any appropriate initialization (9.3) to be done.

A nodeclspec-function-declaration shall declare a constructor, destructor, or conversion function. [Note: A nodeclspec-function-declaration can only be used in a template-declaration (Clause 13), explicit-instantiation (13.8.2), or explicit-specialization (13.8.3). — end note]

### 9.1 Specifiers

The specifiers that can be used in a declaration are

```c
[[noreturn]] void f [[noreturn]] (); // OK
```

---

[1] The specifiers that can be used in a declaration are
The optional attribute-specifier-seq in a decl-specifier-seq appertains to the type determined by the preceding decl-specifiers (9.2.3). The attribute-specifier-seq affects the type only for the declaration it appears in, not other declarations involving the same type.

Each decl-specifier shall appear at most once in a complete decl-specifier-seq, except that long may appear twice. The constexpr and consteval decl-specifiers shall not both appear in a decl-specifier-seq.

If a type-name is encountered while parsing a decl-specifier-seq, it is interpreted as part of the decl-specifier-seq if and only if there is no previous defining-type-specifier other than a cv-qualifier in the decl-specifier-seq. The sequence shall be self-consistent as described below. [Example:

typedef char* Pc;
static Pc; // error: name missing
Here, the declaration static Pc is ill-formed because no name was specified for the static variable of type Pc. To get a variable called Pc, a type-specifier (other than const or volatile) has to be present to indicate that the typedef-name Pc is the name being (re)declared, rather than being part of the decl-specifier sequence. For another example,

void f(const Pc); // void f(char* const) (not const char*)
void g(const int Pc); // void g(const int)
—end example]

[Note: Since signed, unsigned, long, and short by default imply int, a type-name appearing after one of those specifiers is treated as the name being (re)declared. [Example:

void h(unsigned Pc); // void h(unsigned int)
void k(unsigned int Pc); // void k(unsigned int)
—end example] — end note]

9.1.1 Storage class specifiers

The storage class specifiers are

storage-class-specifier:
static
thread_local
extern
mutable

At most one storage-class-specifier shall appear in a given decl-specifier-seq, except that thread_local may appear with static or extern. If thread_local appears in any declaration of a variable it shall be present in all declarations of that entity. If a storage-class-specifier appears in a decl-specifier-seq, there can be no typedef specifier in the same decl-specifier-seq and the init-declarator-list or member-declarator-list of the declaration shall not be empty (except for an anonymous union declared in a named namespace or in the global namespace, which shall be declared static (11.4.1)). The storage-class-specifier applies to the name declared by each init-declarator in the list and not to any names declared by other specifiers. [Note: See 13.8.3 and 13.8.2 for restrictions in explicit specializations and explicit instantiations, respectively. — end note]

[Note: A variable declared without a storage-class-specifier at block scope or declared as a function parameter has automatic storage duration by default (6.6.5.3). — end note]

The thread_local specifier indicates that the named entity has thread storage duration (6.6.5.2). It shall be applied only to the declaration of a variable of namespace or block scope, to a structured binding
declaration (9.5), or to the declaration of a static data member. When `thread_local` is applied to a variable of block scope the `storage-class-specifier static` is implied if no other `storage-class-specifier` appears in the `decl-specifier-seq`.

4 The `static` specifier shall be applied only to the declaration of a variable or function, to a structured binding declaration (9.5), or to the declaration of an anonymous union (11.4.1). There can be no `static` function declarations within a block, nor any `static` function parameters. A `static` specifier used in the declaration of a variable declares the variable to have static storage duration (6.6.5.1), unless accompanied by the `thread_local` specifier, which declares the variable to have thread storage duration (6.6.5.2). A `static` specifier can be used in declarations of class members; 11.3.8 describes its effect. For the linkage of a name declared with a `static` specifier, see 6.5.

5 The `extern` specifier shall be applied only to the declaration of a variable or function. The `extern` specifier shall not be used in the declaration of a class member or function parameter. For the linkage of a name declared with an `extern` specifier, see 6.5. [Note: The `extern` keyword can also be used in `explicit-instantiations` and `linkage-specifications`, but it is not a `storage-class-specifier` in such contexts. —end note]

6 The linkages implied by successive declarations for a given entity shall agree. That is, within a given scope, each declaration declaring the same variable name or the same overloading of a function name shall imply the same linkage. Each function in a given set of overloaded functions can have a different linkage, however. [Example:

```c
static char* f(); // f() has internal linkage
char* f() { /* ... */ } // f() still has internal linkage

char* g(); // g() has external linkage
static char* g() { /* ... */ } // error: inconsistent linkage

void h();
inline void h(); // external linkage

inline void l();
void l(); // external linkage

inline void m();
extern void m(); // external linkage

static void n();
inline void n(); // internal linkage

static int a; // a has internal linkage
int a; // error: two definitions

static int b;
extern int b; // b still has internal linkage

int c;
static int c; // error: inconsistent linkage

extern int d;
static int d; // error: inconsistent linkage
```

—end example]

7 The name of a declared but undefined class can be used in an `extern` declaration. Such a declaration can only be used in ways that do not require a complete class type. [Example:

```c
struct S;
extern S a;
extern S f();
extern void g(S);

void h() {
    g(a); // error: S is incomplete
```
f();            // error: S is incomplete
)
—end example]

8 The mutable specifier shall appear only in the declaration of a non-static data member (11.3) whose type is neither const-qualified nor a reference type. [Example:

class X {
    mutable const int* p; // OK
    mutable int* const q; // ill-formed
};
—end example]

[Note: The mutable specifier on a class data member nullifies a const specifier applied to the containing class object and permits modification of the mutable class member even though the rest of the object is const (6.7.3, 9.1.7.1). — end note]

9.1.2 Function specifiers [dcl.fct.spec]

1 A function-specifier can be used only in a function declaration.

    function-specifier:
       virtual
       explicit-specifier

    explicit-specifier:
       explicit ( constant-expression )
       explicit

2 The virtual specifier shall be used only in the initial declaration of a non-static class member function; see 11.6.2.

3 An explicit-specifier shall be used only in the declaration of a constructor or conversion function within its class definition; see 11.3.7.1 and 11.3.7.2.

4 In an explicit-specifier, the constant-expression, if supplied, shall be a contextually converted constant expression of type bool (7.7). The explicit-specifier explicit without a constant-expression is equivalent to the explicit-specifier explicit(true). If the constant expression evaluates to true, the function is explicit. Otherwise, the function is not explicit. A ( token that follows explicit is parsed as part of the explicit-specifier.

9.1.3 The typedef specifier [dcl.typedef]

1 Declarations containing the decl-specifier typedef declare identifiers that can be used later for naming fundamental (6.7.1) or compound (6.7.2) types. The typedef specifier shall not be combined in a decl-specifier-seq with any other kind of specifier except a defining-type-specifier, and it shall not be used in the decl-specifier-seq of a parameter-declaration (9.2.3.5) nor in the decl-specifier-seq of a function-definition (9.4). If a typedef specifier appears in a declaration without a declarator, the program is ill-formed.

    typedef-name:
       identifier
       simple-template-id

A name declared with the typedef specifier becomes a typedef-name. A typedef-name names the type associated with the identifier (9.2) or simple-template-id (Clause 13); a typedef-name is thus a synonym for another type. A typedef-name does not introduce a new type the way a class declaration (11.2) or enum declaration (9.6) does. [Example: After

typedef int MILES, *KLICKSP;
the constructions

    MILES distance;
    extern KLICKSP metricp;

are all correct declarations; the type of distance is int and that of metricp is “pointer to int”. —end example]

2 A typedef-name can also be introduced by an alias-declaration. The identifier following the using keyword becomes a typedef-name and the optional attribute-specifier-seq following the identifier appertains to that

§ 9.1.3 155
typedef-name. Such a typedef-name has the same semantics as if it were introduced by the typedef specifier. In particular, it does not define a new type. [Example:

```c
using handler_t = void (*)(int);
extern handler_t ignore;
extern void (*)(ignore)(int);  // redefine ignore
using cell = pair<void*, cell*>;  // ill-formed
```
—end example] The defining-type-specifier-seq of the defining-type-id shall not define a class or enumeration if the alias-declaration is the declaration of a template-declaration.

In a given non-class scope, a typedef specifier can be used to redeclare the name of any type declared in that scope to refer to the type to which it already refers. [Example:

```c
typedef struct s { /* ... */ } s;
typedef int I;
typedef int I;
typedef I I;
```
—end example]

In a given class scope, a typedef specifier can be used to redeclare any class-name declared in that scope that is not also a typedef-name to refer to the type to which it already refers. [Example:

```c
struct S {
typedef struct A { } A;     // OK
typedef struct B B;          // OK
typedef A A;                 // error
};
```
—end example]

If a typedef specifier is used to redeclare in a given scope an entity that can be referenced using an elaborated-type-specifier, the entity can continue to be referenced by an elaborated-type-specifier or as an enumeration or class name in an enumeration or class definition respectively. [Example:

```c
struct S;
typedef struct S S;
int main() {
    struct S* p;       // OK
}
struct S { };        // OK
```
—end example]

In a given scope, a typedef specifier shall not be used to redeclare the name of any type declared in that scope to refer to a different type. [Example:

```c
class complex { /* ... */ };  
typedef int complex;          // error: redefinition
```
—end example]

Similarly, in a given scope, a class or enumeration shall not be declared with the same name as a typedef-name that is declared in that scope and refers to a type other than the class or enumeration itself. [Example:

```c
typedef int complex;
class complex { /* ... */ };  // error: redefinition
```
—end example]

A simple-template-id is only a typedef-name if its template-name names an alias template or a template template-parameter. [Note: A simple-template-id that names a class template specialization is a class-name (11.2). If a typedef-name is used to identify the subject of an elaborated-type-specifier (9.1.7.3), a class definition (Clause 11), a constructor declaration (11.3.4), or a destructor declaration (11.3.6), the program is ill-formed. — end note] [Example:

```c
struct S {
    S0;
    ~S0();
};
typedef struct S T;
```
If the typedef declaration defines an unnamed class (or enum), the first typedef-name declared by the declaration to be that class type (or enum type) is used to denote the class type (or enum type) for linkage purposes only (6.5). [Note: A typedef declaration involving a lambda-expression does not itself define the associated closure type, and so the closure type is not given a name for linkage purposes. — end note] [Example:

typedef struct { } *ps, S;  // S is the class name for linkage purposes
typedef decltype({}) C; // the closure type has no name for linkage purposes
— end example]

9.1.4 The friend specifier [dcl.friend]

The friend specifier is used to specify access to class members; see 11.8.3.

9.1.5 The constexpr and consteval specifiers [dcl.constexpr]

The constexpr specifier shall be applied only to the definition of a variable or variable template or the declaration of a function or function template. The constexpr specifier shall be applied only to the declaration of a function or function template. A function or static data member declared with the constexpr or consteval specifier is implicitly an inline function or variable (9.1.6). If any declaration of a function or function template has a constexpr or consteval specifier, then all its declarations shall contain the same specifier. [Note: An explicit specialization can differ from the template declaration with respect to the constexpr or consteval specifier. — end note] [Note: Function parameters cannot be declared constexpr. — end note] [Example:

cconstexpr void square(int &x); // OK: declaration
cconstexpr int bufsz = 1024; // OK: definition
cconstexpr struct pixel {
  int x;
  int y;
  constexpr pixel(int);
};
cconstexpr pixel::pixel(int a) : x(a), y(x) // error: pixel is a type
{ square(x); }
cconstexpr pixel small(2); // error: square not defined, so small(2)
  // not constant (7.7) so constexpr not satisfied

cconstexpr void square(int &x) { // OK: definition
  x *= x;
}
cconstexpr pixel large(4); // OK: square defined
int next(constexpr int x) { // error: not for parameters
  return x + 1;
}
cextern constexpr int memsz; // error: not a definition
— end example]

2 A constexpr or consteval specifier used in the declaration of a function that is not a constructor declares that function to be a constexpr function. Similarly, a constexpr or consteval specifier used in a constructor declaration declares that constructor to be a constexpr constructor. A function or constructor declared with the consteval specifier is called an immediate function. A destructor, an allocation function, or a deallocation function shall not be declared with the consteval specifier.

3 The definition of a constexpr function shall satisfy the following requirements:

(3.1) — its return type shall be a literal type;
(3.2) — each of its parameter types shall be a literal type;
(3.3) — it shall not be a coroutine (9.4.4);
its function-body shall not enclose (Clause 8)

— an asm-definition,
— a goto statement,
— an identifier label (8.1),
— a definition of a variable of non-literal type or of static or thread storage duration or for which no initialization is performed.

[Note: A function-body that is = delete or = default encloses none of the above. — end note]

Example:

```cpp
constexpr int square(int x) { return x * x; }       // OK
constexpr long long_max() { return 2147483647; }   // OK
constexpr int abs(int x) {
    if (x < 0)
        x = -x;
    return x;                                         // OK
}
constexpr int first(int n) {
    static int value = n;
    // error: variable has static storage duration
    return value;
}
constexpr int uninit() {
    int a;
    // error: variable is uninitialized
    return a;
}
constexpr int prev(int x) { return --x; }            // OK
constexpr int g(int x, int n) {                       // OK
    int r = 1;
    while (--n > 0) r *= x;
    return r;
}
```

— end example]
For a constexpr function or constexpr constructor that is neither defaulted nor a template, if no argument values exist such that an invocation of the function or constructor could be an evaluated subexpression of a core constant expression (7.7), or, for a constructor, a constant initializer for some object (6.8.3.2), the program is ill-formed, no diagnostic required. [Example:

```cpp
constexpr int f(bool b)  
{ return b ? throw 0 : 0; }  // OK

call f true); }  // ill-formed, no diagnostic required

struct B {
  constexpr B(int x) : i(0) {}  // x is unused
  int i;
};

int global;

struct D : B {
  constexpr D() : B(global) {}  // ill-formed, no diagnostic required
    // value-to-value conversion on non-constant global
};
—end example]

If the instantiated template specialization of a constexpr function template or member function of a class template would fail to satisfy the requirements for a constexpr function or constexpr constructor, that specialization is still a constexpr function or constexpr constructor, even though a call to such a function cannot appear in a constant expression. If no specialization of the template would satisfy the requirements for a constexpr function or constexpr constructor when considered as a non-template function or constructor, the template is ill-formed, no diagnostic required.

A call to a constexpr function produces the same result as a call to an equivalent non-constexpr function in all respects except that

(7.1) — a call to a constexpr function can appear in a constant expression (7.7) and

(7.2) — copy elision is not performed in a constant expression (11.9.5).

The `constexpr` and `consteval` specifiers have no effect on the type of a constexpr function or a constexpr constructor. [Example:

```cpp
constexpr int bar(int x, int y)  // OK
{ return x + y + x*y; }

// ...

int bar(int x, int y)  // error: redefinition of bar
{ return x * 2 + 3 * y; }
—end example]

A `constexpr` specifier used in an object declaration declares the object as const. Such an object shall have literal type and shall be initialized. In any `constexpr` variable declaration, the full-expression of the initialization shall be a constant expression (7.7). [Example:

```cpp
struct pixel {
  int x, y;
};

call pixel ur = { 1294, 1024 };  // OK

call pixel origin;  // error: initializer missing
—end example]

9.1.6 The inline specifier
[dcl.inline]

The `inline` specifier shall be applied only to the declaration of a variable or function.

A function declaration (9.2.3.5, 11.3.1, 11.8.3) with an `inline` specifier declares an inline function. The inline specifier indicates to the implementation that inline substitution of the function body at the point of call is to be preferred to the usual function call mechanism. An implementation is not required to perform this inline substitution at the point of call; however, even if this inline substitution is omitted, the other rules for inline functions specified in this subclause shall still be respected.
A variable declaration with an `inline` specifier declares an `inline` variable.

A function defined within a class definition is an inline function.

The `inline` specifier shall not appear on a block scope declaration. If the `inline` specifier is used in a friend function declaration, that declaration shall be a definition or the function shall have previously been declared inline.

If an inline function or variable is odr-used in a translation unit, a definition of it shall be reachable from the end of that translation unit, and it shall have exactly the same definition in every such translation unit (6.2). [Note: A call to the inline function or a use of the inline variable may be encountered before its definition appears in the translation unit. — end note] If a definition of a function or variable is reachable at the point of its first declaration as inline, the program is ill-formed. An inline function or variable with external or module linkage shall have the same address in all translation units. [Note: A `static` local variable in an inline function with external or module linkage always refers to the same object. A type defined within the body of an inline function with external or module linkage is the same type in every translation unit. — end note]

An exported inline function or variable shall be defined in the translation unit containing its exported declaration, outside the `private-module-fragment` (if any). [Note: There is no restriction on the linkage (or absence thereof) of entities that the function body of an exported inline function can reference. A constexpr function (9.1.5) is implicitly inline. — end note]

### 9.1.7 Type specifiers

The type-specifiers are

```plaintext
type-specifier:
  simple-type-specifier
  elaborated-type-specifier
  typename-specifier
  cv-qualifier

type-specifier-seq:
  type-specifier attribute-specifier-seq
  type-specifier-seq

defining-type-specifier:
  type-specifier
  class-specifier
  enum-specifier

defining-type-specifier-seq:
  defining-type-specifier attribute-specifier-seq
  defining-type-specifier-seq
```

The optional `attribute-specifier-seq` in a `type-specifier-seq` or a `defining-type-specifier-seq` appertains to the type denoted by the preceding `type-specifiers` or `defining-type-specifiers` (9.2.3). The `attribute-specifier-seq` affects the type only for the declaration it appears in, not other declarations involving the same type.

As a general rule, at most one `defining-type-specifier` is allowed in the complete `decl-specifier-seq` of a `declaration` or in a `defining-type-specifier-seq`, and at most one `type-specifier` is allowed in a `type-specifier-seq`. The only exceptions to this rule are the following:

- (2.1) — `const` can be combined with any type specifier except itself.
- (2.2) — `volatile` can be combined with any type specifier except itself.
- (2.3) — `signed` or `unsigned` can be combined with `char`, `long`, `short`, or `int`.
- (2.4) — `short` or `long` can be combined with `int`.
- (2.5) — `long` can be combined with `double`.
- (2.6) — `long` can be combined with `long`.

---

(90) The `inline` keyword has no effect on the linkage of a function.
Except in a declaration of a constructor, destructor, or conversion function, at least one defining-type-specifier
that is not a cv-qualifier shall appear in a complete type-specifier-seq or a complete decl-specifier-seq.¹¹

[Note: enum-specifiers, class-specifiers, and typename-specifiers are discussed in 9.6, Clause 11, and 13.7,
respectively. The remaining type-specifiers are discussed in the rest of this subclause. — end note]

9.1.7.1 The cv-qualifiers

There are two cv-qualifiers, const and volatile. Each cv-qualifier shall appear at most once in a cv-qualifier-
seq. If a cv-qualifier appears in a decl-specifier-seq, the init-declarator-list or member-declarator-list of the
declaration shall not be empty. [Note: 6.7.3 and 9.2.3.5 describe how cv-qualifiers affect object and function
types. — end note] Redundant cv-qualifications are ignored. [Note: For example, these could be introduced by
typedefs. — end note]

[Note: Declaring a variable const can affect its linkage (9.1.1) and its usability in constant expressions (7.7).
As described in 9.3, the definition of an object or subobject of const-qualified type must specify an initializer
or be subject to default-initialization. — end note]

A pointer or reference to a cv-qualified type need not actually point or refer to a cv-qualified object, but it
is treated as if it does; a const-qualified access path cannot be used to modify an object even if the object
referenced is a non-const object and can be modified through some other access path. [Note: Cv-qualifiers
are supported by the type system so that they cannot be subverted without casting (7.6.1.10). — end note]

Any attempt to modify (7.6.19, 7.6.1.5, 7.6.2.2) a const object (6.7.3) during its lifetime (6.6.3) results in
undefined behavior. [Example:

```cpp
const int ci = 3;          // cv-qualified (initialized as required)
int i = 2;                 // not cv-qualified
const int* cip;            // pointer to const int
*cip = &i;                 // OK: cv-qualified access path to unqualified

int* ip;
ip = const_cast<int*>(cip); // cast needed to convert const int* to int*

const int ciq = new const int (3); // initialized as required
int* iq = const_cast<int*>(ciq); // cast required
```

For another example,

```cpp
struct X {
    mutable int i;
    int j;
};
struct Y {
    X x;
    Y();
};

const Y y;
y.x.i++;             // well-formed: mutable member can be modified
y.x.j++;             // well-formed: const-qualified member modified
Y* p = const_cast<Y*>(&y); // cast away const-ness of y
p->x.i = 99;         // well-formed: mutable member can be modified
p->x.j = 99;         // undefined: modifies a const subobject
```

The semantics of an access through a volatile glvalue are implementation-defined. If an attempt is made to
access an object defined with a volatile-qualified type through the use of a non-volatile glvalue, the behavior
is undefined.

---

¹¹ There is no special provision for a decl-specifier-seq that lacks a type-specifier or that has a type-specifier that only specifies
cv-qualifiers. The “implicit int” rule of C is no longer supported.
[Note: volatile is a hint to the implementation to avoid aggressive optimization involving the object because the value of the object might be changed by means undetectable by an implementation. Furthermore, for some implementations, volatile might indicate that special hardware instructions are required to access the object. See 6.8.1 for detailed semantics. In general, the semantics of volatile are intended to be the same in C++ as they are in C. —end note]

9.1.7.2 Simple type specifiers

The simple type specifiers are

\[
\text{simple-type-specifier:}
\begin{align*}
\text{nested-name-specifier}_{\text{opt}} & \text{ type-name} \\
\text{nested-name-specifier} & \text{ template simple-template-id} \\
\text{decltype-specifier} & \\
\text{placeholder-type-specifier} & \\
\text{nested-name-specifier}_{\text{opt}} & \text{ template-name} \\
\text{char} & \\
\text{char8_t} & \\
\text{char16_t} & \\
\text{char32_t} & \\
\text{wchar_t} & \\
\text{bool} & \\
\text{short} & \\
\text{int} & \\
\text{long} & \\
\text{signed} & \\
\text{unsigned} & \\
\text{float} & \\
\text{double} & \\
\text{void}
\end{align*}
\]

type-name:

\[
\begin{align*}
\text{class-name} & \\
\text{enum-name} & \\
\text{typedef-name}
\end{align*}
\]

1 A placeholder-type-specifier is a placeholder for a type to be deduced (9.1.7.5). A type-specifier of the form \text{typename}_{\text{opt}} \text{ nested-name-specifier}_{\text{opt}} \text{ template-name} is a placeholder for a deduced class type (9.1.7.6). The template-name shall name a class template. [Note: An injected-class-name is never interpreted as a template-name in contexts where class template argument deduction would be performed (13.7.1). —end note] The other simple-type-specifiers specify either a previously-declared type, a type determined from an expression, or one of the fundamental types (6.7.1). Table 12 summarizes the valid combinations of simple-type-specifiers and the types they specify.

2 When multiple simple-type-specifiers are allowed, they can be freely intermixed with other decl-specifiers in any order. [Note: It is implementation-defined whether objects of char type are represented as signed or unsigned quantities. The signed specifier forces char objects to be signed; it is redundant in other contexts. —end note]

9.1.7.3 Elaborated type specifiers

\[
\text{elaborated-type-specifier:}
\begin{align*}
\text{class-key} & \text{ attribute-specifier-seq}_{\text{opt}} \text{ nested-name-specifier}_{\text{opt}} \text{ identifier} \\
\text{class-key} & \text{ simple-template-id} \\
\text{class-key} & \text{ nested-name-specifier} \text{ template}_{\text{opt}} \text{ simple-template-id} \\
\text{enum} & \text{ nested-name-specifier}_{\text{opt}} \text{ identifier}
\end{align*}
\]

1 An attribute-specifier-seq shall not appear in an elaborated-type-specifier unless the latter is the sole constituent of a declaration. If an elaborated-type-specifier is the sole constituent of a declaration, the declaration is ill-formed unless it is an explicit specialization (13.8.3), an explicit instantiation (13.8.2) or it has one of the following forms:

\[
\begin{align*}
\text{class-key} & \text{ attribute-specifier-seq}_{\text{opt}} \text{ identifier} ; \\
\text{friend} & \text{ class-key}_{\text{opt}} \text{ identifier} ; \\
\text{friend} & \text{ class-key}_{\text{opt}} \text{ simple-template-id} ; \\
\text{friend} & \text{ class-key} \text{ nested-name-specifier identifier} ; \\
\text{friend} & \text{ class-key} \text{ nested-name-specifier template}_{\text{opt}} \text{ simple-template-id} ;
\end{align*}
\]

</tbody>
</table>

In the first case, the *attribute-specifier-seq*, if any, appertains to the class being declared; the attributes in the *attribute-specifier-seq* are thereafter considered attributes of the class whenever it is named.

2 [Note: 6.4.4 describes how name lookup proceeds for the *identifier* in an *elaborated-type-specifier*. —end note] If the *identifier* or *simple-template-id* resolves to a *class-name* or *enum-name*, the *elaborated-type-specifier* introduces it into the declaration the same way a *simple-type-specifier* introduces its *type-name* (9.1.7.2). If the *identifier* or *simple-template-id* resolves to a *typedef-name* (9.1.3, 13.2), the *elaborated-type-specifier* is ill-formed. [Note: This implies that, within a class template with a template *type-parameter* T, the declaration

friend class T;

is ill-formed. However, the similar declaration friend T; is allowed (11.8.3). —end note]

3 The *class-key* or *enum* keyword present in the *elaborated-type-specifier* shall agree in kind with the declaration to which the name in the *elaborated-type-specifier* refers. This rule also applies to the form of *elaborated-type-specifier* that declares a *class-name* or friend class since it can be construed as referring to the definition of the

§ 9.1.7.3
class. Thus, in any **elaborated-type-specifier**, the **enum** keyword shall be used to refer to an enumeration (9.6), the **union** **class-key** shall be used to refer to a union (Clause 11), and either the **class** or **struct** **class-key** shall be used to refer to a class (Clause 11) declared using the **class** or **struct** **class-key**. [Example:

```cpp
class E { a, b };
enum E x = E::a;
struct S { } s;
class S* p = &s;
```
— end example]

9.1.7.4 Decltype specifiers

`decltype-specifier`:

```cpp
decltype ( expression )
```

1 For an expression `e`, the type denoted by `decltype(e)` is defined as follows:

(1.1) — if `e` is an unparenthesized **id-expression** naming a structured binding (9.5), `decltype(e)` is the referenced type as given in the specification of the structured binding declaration;

(1.2) — otherwise, if `e` is an unparenthesized **id-expression** naming a non-type **template-parameter** (13.1), `decltype(e)` is the type of the **template-parameter** after performing any necessary type deducation (9.1.7.5, 9.1.7.6);

(1.3) — otherwise, if `e` is an unparenthesized **id-expression** or an unparenthesized class member access (7.6.1.4), `decltype(e)` is the type of the entity named by `e`. If there is no such entity, or if `e` names a set of overloaded functions, the program is ill-formed;

(1.4) — otherwise, if `e` is an `xvalue`, `decltype(e)` is `T&&`, where `T` is the type of `e`;

(1.5) — otherwise, if `e` is an `lvalue`, `decltype(e)` is `T&`, where `T` is the type of `e`;

(1.6) — otherwise, `decltype(e)` is the type of `e`.

The operand of the `decltype` specifier is an unevaluated operand (7.2).

[Example:

```cpp
const int&& foo();
int i;
struct A { double x; };
const A* a = new A();
dcl.type.decltype

dcl.type: ( expression )
```

2 If the operand of a `decltype-specifier` is a `prvalue` and is not a (possibly parenthesized) immediate invocation (7.7), the temporary materialization conversion is not applied (7.3.4) and no result object is provided for the `prvalue`. The type of the `prvalue` may be incomplete or an abstract class type. [Note: As a result, storage is not allocated for the `prvalue` and it is not destroyed. Thus, a class type is not instantiated as a result of being the type of a function call in this context. In that sense, a `decltype-specifier` is analogous to a use of a typedef-name, so the usual reasons for requiring a complete type do not apply. In particular, it is not necessary to allocate storage for a temporary object or to enforce the semantic constraints associated with invoking the type’s destructor. — end note] [Note: Unlike the preceding rule, parentheses have no special meaning in this context. — end note] [Example:

```cpp
template<class T> struct A { ~A() = delete; };
template<class T> auto h() -> A<T>;
template<class T> auto i(T) // identity
   -> T;
template<class T> auto j(T) // #1
   -> decltype(i(h<T>())); // forces completion of A<T> and implicitly uses A<T>::~A()
```
template<class T> auto f(T)                 // #2
    -> void;
auto g() -> void {
    f(42); // OK: calls #2. (#1 is not a viable candidate: type deduction
             // fails (13.9.2) because A<int>::~A() is implicitly used in its
             // decltype-specifier)
}

template<class T> auto q(T)                 
    -> decltype((h<T>())); // does not force completion of A<T>::~A()
void r() {
    q(42); // error: deduction against q succeeds, so overload resolution selects
             // the specialization "q(T) -> decltype((h<T>())" with T=int;
             // the return type is A<int>, so a temporary is introduced and its
             // destructor is used, so the program is ill-formed
}

—end example]

9.1.7.5 Placeholder type specifiers

placeholder-type-specifier: type-constraint_{opt} auto
                              type-constraint_{opt} decltype ( auto )

1 A placeholder-type-specifier designates a placeholder type that will be replaced later by deduction from an
   initializer.

2 A placeholder-type-specifier of the form type-constraint_{opt} auto can be used in the decl-specifier-seq of a
   function declaration or lambda expression and signifies that the function is an
   abbreviated function template (9.2.3.5) or the lambda is a generic lambda (7.5.5).

3 The placeholder type can appear with a function declarator in the decl-specifier-seq, type-specifier-seq,
   conversion-function-id, or trailing-return-type, in any context where such a declarator is valid. If the function
   declarator includes a trailing-return-type (9.2.3.5), that trailing-return-type specifies the declared return type
   of the function. Otherwise, the function declarator shall declare a function. If the declared return type of the
   function contains a placeholder type, the return type of the function is deduced from non-discarded return
   statements, if any, in the body of the function (8.4.1).

4 The type of a variable declared using a placeholder type is deduced from its initializer. This use is allowed in
   an initializing declaration (9.3) of a variable. The placeholder type shall appear as one of the
   decl-specifiers in the decl-specifier-seq and the decl-specifier-seq shall be followed by one or more declarators,
   each of which shall be followed by a non-empty initializer. In an initializer of the form
   ( expression-list )
   the expression-list shall be a single assignment-expression. [Example:
   "auto x = 5;" // OK: x has type int
   "const auto *v = &x, u = 6;" // OK: v has type const int*, u has type const int
   "static auto y = 0.0;" // OK: y has type double
   "auto int x;" // error: auto is not a storage-class-specifier
   "auto f() -> int;" // OK: f returns int
   "auto g() { return 0.0; }" // OK: g returns double
   "auto h();" // OK: h’s return type will be deduced when it is defined
   —end example] The auto type-specifier can also be used to introduce a structured binding declaration (9.5).

5 A placeholder type can also be used in the type-specifier-seq in the new-type-id or type-id of a new-
   expression (7.6.2.7) and as a decl-specifier of the parameter-declaration’s decl-specifier-seq in a template-
   parameter (13.1).

6 A program that uses a placeholder type in a context not explicitly allowed in this subclause is ill-formed.

7 If the init-declarator-list contains more than one init-declarator, they shall all form declarations of variables.
   The type of each declared variable is determined by placeholder type deduction (9.1.7.5.1), and if the type
   that replaces the placeholder type is not the same in each deduction, the program is ill-formed.
If a function with a declared return type that contains a placeholder type has multiple non-discarded return statements, the return type is deduced for each such return statement. If the type deduced is not the same in each deduction, the program is ill-formed.

If a function with a declared return type that uses a placeholder type has no non-discarded return statements, the return type is deduced as though from a return statement with no operand at the closing brace of the function body.

An exported function with a declared return type that uses a placeholder type shall be defined in the translation unit containing its exported declaration, outside the private-module-fragment (if any).

If the name of an entity with an undeduced placeholder type appears in an expression, the program is ill-formed. Once a non-discarded return statement has been seen in a function, however, the return type deduced from that statement can be used in the rest of the function, including in other return statements.

Return type deduction for a templated entity that is a function or function template with a placeholder in its declared type occurs when the definition is instantiated even if the function body contains a return statement with a non-type-dependent operand.

Redeclarations or specializations of a function or function template with a declared return type that uses a placeholder type shall also use that placeholder, not a deduced type. Similarly, redeclarations or specializations of a function or function template with a declared return type that does not use a placeholder type shall not use a placeholder.
template<> auto g(double); // OK, forward declaration with unknown return type
template <class T> T g(T t) { return t; } // OK, not functionally equivalent to #1
template char g(char); // OK, now there is a matching template
template auto g(float); // still matches #1
void h() { return g(42); } // error, ambiguous

template <typename T> struct A { friend T frf(T); }; auto frf(int i) { return i; } // not a friend of A<int>

— end example

A function declared with a return type that uses a placeholder type shall not be virtual (11.6.2).

A function declared with a return type that uses a placeholder type shall not be a coroutine (9.4.4).

An explicit instantiation declaration (13.8.2) does not cause the instantiation of an entity declared using a placeholder type, but it also does not prevent that entity from being instantiated as needed to determine its type. [Example:

```
template <typename T> auto f(T t) { return t; }
extern template auto f(int); // does not instantiate f<int>
int (*p)(int) = f; // instantiates f<int> to determine its return type, but an explicit instantiation definition is still required somewhere in the program
```

— end example]

9.1.7.5.1 Placeholder type deduction [dcl.type.auto.deduct]

A placeholder type deduction is the process by which a type containing a placeholder type is replaced by a deduced type.

1 A type T containing a placeholder type, and a corresponding initializer e, are determined as follows:

(2.1) for a non-discarded return statement that occurs in a function declared with a return type that contains a placeholder type, T is the declared return type and e is the operand of the return statement. If the return statement has no operand, then e is void();

(2.2) for a variable declared with a type that contains a placeholder type, T is the declared type of the variable and e is the initializer. If the initialization is direct-list-initialization, the initializer shall be a braced-init-list containing only a single assignment-expression and e is the assignment-expression;

(2.3) for a non-type template parameter declared with a type that contains a placeholder type, T is the declared type of the non-type template parameter and e is the corresponding template argument.

In the case of a return statement with no operand or with an operand of type void, T shall be either type-constraint_opt decltype(auto) or cv type-constraint_opt auto.

2 If the deduction is for a return statement and e is a braced-init-list (9.3.4), the program is ill-formed.

3 If the placeholder-type-specifier is of the form type-constraint_opt auto, the deduced type T' replacing T is determined using the rules for template argument deduction. Obtain P from T by replacing the occurrences of type-constraint_opt auto either with a new invented type template parameter U or, if the initialization is copy-list-initialization, with std::initializer_list<U>. Deduce a value for U using the rules of template argument deduction from a function call (13.9.2.1), where P is a function template parameter type and the corresponding argument is e. If the deduction fails, the declaration is ill-formed. Otherwise, T' is obtained by substituting the deduced U into P. [Example:

```
auto x1 = { 1, 2 }; // decltype(x1) is std::initializer_list<int>
auto x2 = { 1, 2.0 }; // error: cannot deduce element type
auto x3( 1, 2 ); // error: not a single element
auto x4 = { 3 }; // decltype(x4) is std::initializer_list<int>
auto x5( 3 ); // decltype(x5) is int
```

— end example]

[Example:

```
const auto &i = expr;
```

§ 9.1.7.5.1 167
The type of \( i \) is the deduced type of the parameter \( u \) in the call \( f(expr) \) of the following invented function template:

```cpp
template <class U> void f(const U& u);
```

—end example

5 If the placeholder-type-specifier is of the form `decltype(auto)` \( T \) shall be the placeholder alone. The type deduced for \( T \) is determined as described in 9.1.7.2, as though \( e \) had been the operand of the `decltype`. [Example:

```cpp
int i;
int&& f();
auto x2a(i);  // decltype(x2a) is int
dec_type(auto) x2d(i);  // decltype(x2d) is int
auto x3a = i;  // decltype(x3a) is int
dec_type(auto) x3d = i;  // decltype(x3d) is int
auto x4a = (i);  // decltype(x4a) is int
dec_type(auto) x4d = (i);  // decltype(x4d) is int&
auto x5a = f();  // decltype(x5a) is int
dec_type(auto) x5d = f();  // decltype(x5d) is int&
auto x6a = { 1, 2 };  // decltype(x6a) is std::initializer_list<int>
dec_type(auto) x6d = { 1, 2 };  // error, \{ 1, 2 \} is not an expression
auto x7a = i;  // decltype(x7a) is int*
dec_type(auto) x7d = i;  // error, declared type is not plain decltype(auto)
```

—end example

6 For a placeholder-type-specifier with a `type-constraint`, if the type deduced for the placeholder does not satisfy its immediately-declared constraint (Clause 13), the program is ill-formed.

9.1.7.6 Deduced class template specialization types

If a placeholder for a deduced class type appears as a `decl-specifier` in the `decl-specifier-seq` of an initializing declaration (9.3) of a variable, the placeholder is replaced by the return type of the function selected by overload resolution for class template deduction (12.3.1.8). If the `decl-specifier-seq` is followed by an `init-declarator-list` or `member-declarator-list` containing more than one `declarator`, the type that replaces the placeholder shall be the same in each deduction.

A placeholder for a deduced class type can also be used in the `type-specifier-seq` in the `new-type-id` or `type-id` of a `new-expression` (7.6.2.7), as the `simple-type-specifier` in an explicit type conversion (functional notation) (7.6.1.3), or as the `type-specifier` in the `parameter-declaration` of a `template-parameter` (13.1). A placeholder for a deduced class type shall not appear in any other context.

[Example:

```cpp
template<class T> struct container {
    container(T t) {}
    template<class Iter> container(Iter beg, Iter end);
};
template<class Iter>
container(Iter b, Iter e) -> container<typename std::iterator_traits<Iter>::value_type>;
std::vector<double> v = { /* ... */};
container c(7);  // OK, deduces int for T
auto d = container(v.begin(), v.end());  // OK, deduces double for T
container e(5, 6);  // error, int is not an iterator
```

—end example

9.2 Declarators

A declarator declares a single variable, function, or type, within a declaration. The `init-declarator-list` appearing in a declaration is a comma-separated sequence of declarators, each of which can have an initializer.

`init-declarator-list`:

- `init-declarator`
- `init-declarator-list , init-declarator`
The three components of a simple-declaration are the attributes (9.11), the specifiers (decl-specifier-seq; 9.1) and the declarators (init-declarator-list). The specifiers indicate the type, storage class or other properties of the entities being declared. The declarators specify the names of these entities and (optionally) modify the type of the specifiers with operators such as * (pointer to) and () (function returning). Initial values can also be specified in a declarator; initializers are discussed in 9.3 and 11.9.

Each init-declarator in a declaration is analyzed separately as if it was in a declaration by itself. [Note: A declaration with several declarators is usually equivalent to the corresponding sequence of declarations each with a single declarator. That is]

\[
T D_1, D_2, \ldots D_n;
\]
is usually equivalent to

\[
T D_1; T D_2; \ldots T D_n;
\]

where T is a decl-specifier-seq and each Di is an init-declarator. One exception is when a name introduced by one of the declarators hides a type name used by the decl-specifiers, so that when the same decl-specifiers are used in a subsequent declaration, they do not have the same meaning, as in

\[
\text{struct } S \{ /* \ldots */ \};
S, S, T; \quad // \text{declare two instances of struct } S
\]

which is not equivalent to

\[
\text{struct } S \{ /* \ldots */ \};
S, T;
// error
\]

Another exception is when T is auto (9.1.7.5), for example:

\[
\text{auto } i = 1, j = 2.0; \quad // \text{error: deduced types for } i \text{ and } j \text{ do not match}
\]
as opposed to

\[
\text{auto } i = 1; \quad // OK: } i \text{ deduced to have type int}
\text{auto } j = 2.0; \quad // OK: } j \text{ deduced to have type double}
\]

—end note]

The optional requires-clause (Clause 13) in an init-declarator or member-declarator shall not be present when the declarator does not declare a function (9.2.3.5). When present after a declarator, the requires-clause is called the trailing requires-clause. The trailing requires-clause introduces the constraint-expression that results from interpreting its constraint-logical-or-expression as a constraint-expression. [Example:

\[
\text{void } f_1(\text{int } a) \text{ requires true}; \quad // \text{OK}
\text{auto } f_2(\text{int } a) \rightarrow \text{bool requires true}; \quad // \text{OK}
\text{auto } f_3(\text{int } a) \text{ requires true } \rightarrow \text{bool}; \quad // \text{error: requires-clause precedes trailing-return-type}
\text{void } (*pf)() \text{ requires true}; \quad // \text{error: constraint on a variable}
\text{void } g(\text{int } (*)() \text{ requires true}); \quad // \text{error: constraint on a parameter-declaration}
\]

\[
\text{auto } p = \text{new } \text{void(*)(char) requires true}; \quad // \text{error: not a function declaration}
\]

—end example]

Declarators have the syntax

\[
\text{declarator: }
\text{ptr-declarator}
\text{noptr-declarator parameters-and-qualifiers trailing-return-type}
\text{ptr-declarator: }
\text{noptr-declarator}
\text{ptr-operator ptr-declarator}
\text{noptr-declarator: }
\text{declarator-id attribute-specifier-seq}
\text{noptr-declarator parameters-and-qualifiers}
\text{noptr-declarator } [ \text{constant-expression} ] \text{ attribute-specifier-seq}
(\text{ptr-declarator})
\]

§ 9.2
parameters-and-qualifiers:
    ( parameter-declaration-clause ) cv-qualifier-seq_opt
    ref-qualifier_opt noexcept-specifier_opt attribute-specifier-seq_opt

trailing-return-type:
    -> type-id

ptr-operator:
    * attribute-specifier-seq_opt cv-qualifier-seq_opt
    & attribute-specifier-seq_opt
    && attribute-specifier-seq_opt
    nested-name-specifier * attribute-specifier-seq_opt cv-qualifier-seq_opt

cv-qualifier-seq:
    cv-qualifier cv-qualifier-seq_opt

cv-qualifier:
    const
    volatile

ref-qualifier:
    &
    &&

declarator-id:
    ... opt id-expression

9.2.1 Type names

To specify type conversions explicitly, and as an argument of sizeof, alignof, new, or typeid, the name of a type shall be specified. This can be done with a type-id, which is syntactically a declaration for a variable or function of that type that omits the name of the entity.

type-id:
    type-specifier-seq abstract-declarator_opt

defining-type-id:
    defining-type-specifier-seq abstract-declarator_opt

abstract-declarator:
    ptr-abstract-declarator
    noptr-abstract-declarator_opt parameters-and-qualifiers trailing-return-type
    abstract-pack-declarator

ptr-abstract-declarator:
    noptr-abstract-declarator
    ptr-operator ptr-abstract-declarator_opt

noptr-abstract-declarator:
    noptr-abstract-declarator
    ptr-operator ptr-abstract-declarator_opt parameters-and-qualifiers
    noptr-abstract-declarator_opt [ constant-expression_opt ] attribute-specifier-seq_opt
    ( ptr-abstract-declarator )

abstract-pack-declarator:
    noptr-abstract-pack-declarator
    ptr-operator abstract-pack-declarator

ptr-abstract-pack-declarator:
    noptr-abstract-pack-declarator parameters-and-qualifiers
    noptr-abstract-pack-declarator_opt [ constant-expression_opt ] attribute-specifier-seq_opt
    ...

It is possible to identify uniquely the location in the abstract-declarator where the identifier would appear if the construction were a declarator in a declaration. The named type is then the same as the type of the hypothetical identifier. [Example:

```c
int    // int i
int *   // int *pi
int *3  // int *p[3]
int (*)(3) // int (*)(3)[3]
int *()  // int *(p[3](3])
int (*)(double) // int (*)(p[3](double)
```
2 A type can also be named (often more easily) by using a typedef (9.1.3).

9.2.2 Ambiguity resolution

1 The ambiguity arising from the similarity between a function-style cast and a declaration mentioned in 8.8 can also occur in the context of a declaration. In that context, the choice is between a function declaration with a redundant set of parentheses around a parameter name and an object declaration with a function-style cast as the initializer. Just as for the ambiguities mentioned in 8.8, the resolution is to consider any construct that could possibly be a declaration a declaration. [Note: A declaration can be explicitly disambiguated by adding parentheses around the argument. The ambiguity can be avoided by use of copy-initialization or list-initialization syntax, or by use of a non-function-style cast. — end note] [Example:

```c
struct S {
    S(int); // function declaration  
    S x(int()); // function declaration  
    S y((int(a))); // object declaration 
    S y((int)a); // object declaration  
    S z = int(a); // object declaration 
}

void foo(double a) {
    S w(int(a)); // function declaration 
    S x(int()); // function declaration 
    S y((int(a))); // object declaration 
    S y((int)a); // object declaration 
    S z = int(a); // object declaration 
}

— end example]
```

2 An ambiguity can arise from the similarity between a function-style cast and a type-id. The resolution is that any construct that could possibly be a type-id in its syntactic context shall be considered a type-id. [Example:

```c
template <class T> struct X {};  
template <int N> struct Y {};  
X<int()> a; // type-id  
X<int()> b; // expression (ill-formed) 
Y<int()> c; // type-id (ill-formed)  
Y<int()> d; // expression 

void foo(signed char a) { 
    sizeof(int()); // type-id (ill-formed)  
    sizeof(int(a)); // expression 
    sizeof(int(unsigned(a))); // type-id (ill-formed) 
    (int())+1; // type-id (ill-formed)  
    (int(a))+1; // expression  
    (int(unsigned(a)))+1; // type-id (ill-formed) 
}

— end example]
```

3 Another ambiguity arises in a parameter-declaration-clause when a type-name is nested in parentheses. In this case, the choice is between the declaration of a parameter of type pointer to function and the declaration of a parameter with redundant parentheses around the declarator-id. The resolution is to consider the type-name as a simple-type-specifier rather than a declarator-id. [Example:

```c
class C { };  
void f(int(C)) { } // void f(int(*fp)(C c)) { } // not: void f(int C) { }

int g(C);  

void foo() { 
    f(1); // error: cannot convert 1 to function pointer 
    f(g); // OK 
}
```

§ 9.2.2
For another example,

```c
class C { }
void h(int *(C*[10]));  // void h(int *(fp)(C_parm[10]));
// not: void h(int *C[10]);
```

--- end example ---

### 9.2.3 Meaning of declarators

1. A declarator contains exactly one declarator-id; it names the identifier that is declared. An unqualified-id occurring in a declarator-id shall be a simple identifier except for the declaration of some special functions (11.3.4, 11.3.7, 11.3.6, 12.5) and for the declaration of template specializations or partial specializations (13.8). When the declarator-id is qualified, the declaration shall refer to a previously declared member of the class or namespace to which the qualifier refers (or, in the case of a namespace, of an element of the inline namespace set of that namespace (9.7.1)) or to a specialization thereof; the member shall not merely have been introduced by a using-declaration in the scope of the class or namespace nominated by the nested-name-specifier of the declarator-id. The nested-name-specifier of a qualified declarator-id shall not begin with a decltype-specifier.

   [Note: If the qualifier is the global scope resolution operator, the declarator-id refers to a name declared in the global namespace scope. — end note] The optional attribute-specifier-seq following a declarator-id appertains to the entity that is declared.

2. A static, thread_local, extern, mutable, friend, inline, virtual, constexpr, or typedef specifier or an explicit-specifier applies directly to each declarator-id in an init-declarator-list or member-declarator-list; the type specified for each declarator-id depends on both the decl-specifier-seq and its declarator.

3. Thus, a declaration of a particular identifier has the form

   \[ T \ D \]

   where \( T \) is of the form attribute-specifier-seq\(\text{opt}\) decl-specifier-seq and \( D \) is a declarator. Following is a recursive procedure for determining the type specified for the contained declarator-id by such a declaration.

4. First, the decl-specifier-seq determines a type. In a declaration

   \[ T \ D \]

   the decl-specifier-seq \( T \) determines the type \( T \). [Example: In the declaration

   ```c
   int unsigned i;
   ```

   the type specifiers `int unsigned` determine the type "unsigned int" (9.1.7.2). — end example]

5. In a declaration attribute-specifier-seq\(\text{opt}\) \( T \ D \) where \( D \) is an unadorned identifier the type of this identifier is "\( T \)".

6. In a declaration \( T \ D \) where \( D \) has the form

   ```c
   ( D1 )
   ```

   the type of the contained declarator-id is the same as that of the contained declarator-id in the declaration

   \[ T \ D1 \]

   Parentheses do not alter the type of the embedded declarator-id, but they can alter the binding of complex declarators.

### 9.2.3.1 Pointers

1. In a declaration \( T \ D \) where \( D \) has the form

   ```c
   * attribute-specifier-seq\(\text{opt}\) cv-qualifier-seq\(\text{opt}\) D1
   ```

   and the type of the identifier in the declaration \( T \ D1 \) is "derived-declarator-type-list \( T \)", then the type of the identifier of \( D \) is "derived-declarator-type-list cv-qualifier-seq pointer to \( T \)". The cv-qualifiers apply to the pointer and not to the object pointed to. Similarly, the optional attribute-specifier-seq (9.11.1) appertains to the pointer and not to the object pointed to.

   [Example: The declarations

   ```c
   const int ci = 10, *pc = &ci, *const cpc = pc, **ppc;
   int i, *p, *const cp = &i;
   ```

   declare \( ci \), a constant integer; \( pc \), a pointer to a constant integer; \( cpc \), a constant pointer to a constant integer; \( ppc \), a pointer to a pointer to a constant integer; \( i \), an integer; \( p \), a pointer to integer; and \( cp \), a
constant pointer to integer. The value of ci, cpc, and cp cannot be changed after initialization. The value of pc can be changed, and so can the object pointed to by cp. Examples of some correct operations are

```c
i = ci;
*cp = ci;
p++;
p = cpc;
p = p;
ppc = &pc;
```

Examples of ill-formed operations are

```c
ci = 1;       // error
ci++;         // error
*pc = 2;      // error
cp = &ci;     // error
cpc++;        // error
p = pc;       // error
ppc = &p;     // error
```

Each is unacceptable because it would either change the value of an object declared `const` or allow it to be changed through a cv-unqualified pointer later, for example:

```c
*ppc = &ci;   // OK, but would make p point to ci because of previous error
*p = 5;      // clobber ci
```

---

3 See also 7.6.19 and 9.3.

4 [Note: Forming a pointer to reference type is ill-formed; see 9.2.3.2. Forming a function pointer type is ill-formed if the function type has cv-qualifiers or a ref-qualifier; see 9.2.3.5. Since the address of a bit-field (11.3.9) cannot be taken, a pointer can never point to a bit-field. — end note]

9.2.3.2 References

1 In a declaration `T D` where `D` has either of the forms

```c
& attribute-specifier-seq opt D1
&& attribute-specifier-seq opt D1
```

and the type of the identifier in the declaration `T D1` is “derived-declarator-type-list `T`”, then the type of the identifier of `D` is “derived-declarator-type-list reference to `T`”. The optional attribute-specifier-seq appertains to the reference type. Cv-qualified references are ill-formed except when the cv-qualifiers are introduced through the use of a typedef-name (9.1.3, 13.1) or decltype-specifier (9.1.7.2), in which case the cv-qualifiers are ignored. [Example:

```c
typedef int& A;
const A aref = 3;       // ill-formed; lvalue reference to non-const initialized with rvalue
```

The type of aref is “lvalue reference to int”, not “lvalue reference to const int”. — end example] [Note: A reference can be thought of as a name of an object. — end note] A declarator that specifies the type “reference to cv void” is ill-formed.

2 A reference type that is declared using `&` is called an lvalue reference, and a reference type that is declared using `&&` is called an rvalue reference. Lvalue references and rvalue references are distinct types. Except where explicitly noted, they are semantically equivalent and commonly referred to as references.

3 [Example:

```c
void f(double& a) { a += 3.14; }
//...
double d = 0;
f(d);
```

declares `a` to be a reference parameter of `f` so the call `f(d)` will add 3.14 to `d`.

```c
int v[20];
//...
int& g(int i) { return v[i]; }
//...
g(3) = 7;
```
declares the function g() to return a reference to an integer so g(3)=7 will assign 7 to the fourth element of the array v. For another example,

```c
struct link {
    link* next;
};
link* first;
void h(link*& p) { // p is a reference to pointer
    p->next = first;
    first = p;
    p = 0;
}
void k() {
    link* q = new link;
    h(q);
}
```

declares p to be a reference to a pointer to link so h(q) will leave q with the value zero. See also 9.3.3. —end example

4 It is unspecified whether or not a reference requires storage (6.6.5).

5 There shall be no references to references, no arrays of references, and no pointers to references. The declaration of a reference shall contain an initializer (9.3.3) except when the declaration contains an explicit extern specifier (9.1.1), is a class member (11.3) declaration within a class definition, or is the declaration of a parameter or a return type (9.2.3.5); see 6.1. A reference shall be initialized to refer to a valid object or function. [Note: In particular, a null reference cannot exist in a well-defined program, because the only way to create such a reference would be to bind it to the “object” obtained by indirection through a null pointer, which causes undefined behavior. As described in 11.3.9, a reference cannot be bound directly to a bit-field. —end note]

6 If a typedef-name (9.1.3, 13.1) or a decltype-specifier (9.1.7.2) denotes a type TR that is a reference to a type T, an attempt to create the type “lvalue reference to cv TR” creates the type “lvalue reference to T”, while an attempt to create the type “rvalue reference to cv TR” creates the type TR. [Note: This rule is known as reference collapsing. —end note] [Example:

```c
int i;
typedef int& LRI;
typedef int&& RRI;
LRI& r1 = i; // r1 has the type int&
const LRI& r2 = i; // r2 has the type int&
const LRI& r3 = i; // r3 has the type int&
RRI& r4 = i; // r4 has the type int&
RRI& r5 = 5; // r5 has the type int&&
decltype(r2) & r6 = i; // r6 has the type int&
decltype(r2) && r7 = i; // r7 has the type int&
—end example]
```

7 [Note: Forming a reference to function type is ill-formed if the function type has cv-qualifiers or a ref-qualifier; see 9.2.3.5. —end note]

9.2.3.3 Pointers to members [dcl.mpnt]

1 In a declaration T D where D has the form

```c
nested-name-specifier * attribute-specifier-seqopt cv-qualifier-seqopt D1
```

and the nested-name-specifier denotes a class, and the type of the identifier in the declaration T D1 is “derived-declarator-type-list T”, then the type of the identifier of D is “derived-declarator-type-list cv-qualifier-seq pointer to member of class nested-name-specifier of type T”. The optional attribute-specifier-seq (9.11.1) appertains to the pointer-to-member.
Example:

```c
struct X {
    void f(int);
    int a;
};
struct Y;
int X::* pmi = &X::a;
void (X::* pmf)(int) = &X::f;
double X::* pmd;
char Y::* pmc;
```

declares `pmi`, `pmf`, `pmd` and `pmc` to be a pointer to a member of `X` of type `int`, a pointer to a member of `X` of type `void(int)`, a pointer to a member of `X` of type `double` and a pointer to a member of `Y` of type `char` respectively. The declaration of `pmd` is well-formed even though `X` has no members of type `double`. Similarly, the declaration of `pmc` is well-formed even though `Y` is an incomplete type. `pmi` and `pmf` can be used like this:

```c
X obj;
// ...
obj.*pmi = 7;  // assign 7 to an integer member of obj
(obj.*pmf)(7);  // call a function member of obj with the argument 7
```

--- end example ---

A pointer to member shall not point to a static member of a class (11.3.8), a member with reference type, or “cv void”.

[Note: See also 7.6.2 and 7.6.4. The type “pointer to member” is distinct from the type “pointer”, that is, a pointer to member is declared only by the pointer-to-member declarator syntax, and never by the pointer declarator syntax. There is no “reference-to-member” type in C++. — end note]

### 9.2.3.4 Arrays [dcl.array]

In a declaration `T D` where `D` has the form

```
D1 [ constant-expression_opt ] attribute-specifier-seq_opt
```

and the type of the contained declarator-id in the declaration `T D1` is “derived-declarator-type-list `T`”, the type of the declarator-id in `D` is “derived-declarator-type-list array of `N T`”. The constant-expression shall be a converted constant expression of type `std::size_t` (7.7). Its value `N` specifies the array bound, i.e., the number of elements in the array; `N` shall be greater than zero.

In a declaration `T D` where `D` has the form

```
D1 [ ] attribute-specifier-seq_opt
```

and the type of the contained declarator-id in the declaration `T D1` is “derived-declarator-type-list `T`”, the type of the declarator-id in `D` is “derived-declarator-type-list array of unknown bound of `T`”, except as specified below.

A type of the form “array of `N U`” or “array of unknown bound of `U`” is an array type. The optional attribute-specifier-seq appertains to the array type.

`U` is called the array element type; this type shall not be a placeholder type (9.1.7.5), a reference type, a function type, an array of unknown bound, or cv void. [Note: An array can be constructed from one of the fundamental types (except void), from a pointer, from a pointer to member, from a class, from an enumeration type, or from an array of known bound. — end note] [Example:

```c
float fa[17], *afp[17];
```

declares an array of `float` numbers and an array of pointers to `float` numbers. — end example]

Any type of the form “cv-qualified-seq array of `N U`” is adjusted to “array of `N cv-qualified-seq U`”, and similarly for “array of unknown bound of `U`”. [Example:

```c
typedef int A[5], AA[2][3];
typedef const A CA;  // type is “array of 5 const int”
typedef const AA CAA; // type is “array of 2 array of 3 const int”
```

— end example] [Note: An “array of `N cv-qualified-seq U`” has cv-qualified type; see 6.7.3. — end note]
An object of type “array of \( N \) \( U \)” contains a contiguously allocated non-empty set of \( N \) subobjects of type \( U \), known as the elements of the array, and numbered 0 to \( N-1 \).

In addition to declarations in which an incomplete object type is allowed, an array bound may be omitted in some cases in the declaration of a function parameter (9.2.3.5). An array bound may also be omitted when an object (but not a non-static data member) of array type is initialized and the declarator is followed by an initializer (9.3, 11.3, 7.6.1.3, 7.6.2.7). In these cases, the array bound is calculated from the number of initial elements (say, \( N \)) supplied (9.3.1), and the type of the array is “array of \( N \) \( U \)”.

Furthermore, if there is a preceding declaration of the entity in the same scope in which the bound was specified, an omitted array bound is taken to be the same as in that earlier declaration, and similarly for the definition of a static data member of a class. [Example:

```c
extern int x[10];
struct S {
    static int y[10];
};
int x[]; // OK: bound is 10
int S::*y[]; // OK: bound is 10
void f() {
    extern int x[];
    int i = sizeof(x); // error: incomplete object type
}
—end example]

Note: When several “array of” specifications are adjacent, a multidimensional array type is created; only the first of the constant expressions that specify the bounds of the arrays may be omitted. [Example:

```c
int x3d[3][5][7];
```

declares an array of three elements, each of which is an array of five elements, each of which is an array of seven integers. The overall array can be viewed as a three-dimensional array of integers, with rank \( 3 \times 5 \times 7 \). Any of the expressions \( x3d, x3d[i], x3d[i][j], x3d[i][j][k] \) can reasonably appear in an expression. The expression \( x3d[i] \) is equivalent to \( *(x3d + i) \); in that expression, \( x3d \) is subject to the array-to-pointer conversion (7.3.2) and is first converted to a pointer to a 2-dimensional array with rank \( 5 \times 7 \) that points to the first element of \( x3d \). Then \( i \) is added, which on typical implementations involves multiplying \( i \) by the length of the object to which the pointer points, which is \( \text{sizeof(int)} \times 5 \times 7 \). The result of the addition and indirectness is an lvalue denoting the \( i \)th array element of \( x3d \) (an array of five arrays of seven integers). If there is another subscript, the same argument applies again, so \( x3d[i][j] \) is an lvalue denoting the \( j \)th array element of the \( i \)th array element of \( x3d \) (an array of seven integers), and \( x3d[i][j][k] \) is an lvalue denoting the \( k \)th array element of the \( j \)th array element of the \( i \)th array element of \( x3d \) (an integer). —end example] The first subscript in the declaration helps determine the amount of storage consumed by an array but plays no other part in subscript calculations. —end note]

Note: Conversions affecting expressions of array type are described in 7.3.2. —end note]

Note: The subscript operator can be overloaded for a class (12.5.5). For the operator’s built-in meaning, see 7.6.1.1. —end note]

9.2.3.5 Functions [dcl.fct]

In a declaration \( T \ D \) where \( D \) has the form

```c
D1 ( parameter-declaration-clause ) cv-qualifier-seq_opt
    ref-qualifier_opt noexcept-specifier_opt attribute-specifier-seq_opt
```

and the type of the contained declarator-id in the declaration \( T \ D1 \) is “derived-declarator-type-list \( T \)”, the type of the declarator-id in \( D \) is “derived-declarator-type-list noexcept_opt function of (parameter-declaration-clause) cv-qualifier-seq_opt ref-qualifier_opt returning \( T \)”, where the optional noexcept is present if and only if the exception specification (14.4) is non-throwing. The optional attribute-specifier-seq appertains to the function type.

In a declaration \( T \ D \) where \( D \) has the form

```c
D1 ( parameter-declaration-clause ) cv-qualifier-seq_opt
    ref-qualifier_opt noexcept-specifier_opt attribute-specifier-seq_opt trailing-return-type
```
and the type of the contained declarator-id in the declaration T D1 is "derived-declarator-type-list T". T shall be
the single type-specifier auto. The type of the declarator-id in D is "derived-declarator-type-list noexcept_opt
function of (parameter-declaration-clause) cv-qualifier-seq_opt ref-qualifier_opt returning U", where U is the type
specified by the trailing-return-type, and where the optional noexcept is present if and only if the exception
specification is non-throwing. The optional attribute-specifier-seq appertains to the function type.

A type of either form is a function type.\(^2\)

\[
\begin{align*}
\text{parameter-declaration-clause:} & \\
& \text{parameter-declaration-list}_{\text{opt}} \ldots_{\text{opt}} \\
\text{parameter-declaration-list:} & \\
& \text{parameter-declaration} \\
& \text{parameter-declaration-list} , \text{parameter-declaration} \\
\text{parameter-declaration:} & \\
& \text{attribute-specifier-seq}_{\text{opt}} \text{ decl-specifier-seq declarator} \\
& \text{attribute-specifier-seq}_{\text{opt}} \text{ decl-specifier-seq declarator} \text{ = initializer-clause} \\
& \text{attribute-specifier-seq}_{\text{opt}} \text{ decl-specifier-seq abstract-declarator}_{\text{opt}} \\
& \text{attribute-specifier-seq}_{\text{opt}} \text{ decl-specifier-seq abstract-declarator}_{\text{opt}} \text{ = initializer-clause}
\end{align*}
\]

The optional attribute-specifier-seq in a parameter-declaration appertains to the parameter.

The parameter-declaration-clause determines the arguments that can be specified, and their processing, when
the function is called. [Note: The parameter-declaration-clause is used to convert the arguments specified on
the function call; see 7.6.1.2. — end note] If the parameter-declaration-clause is empty, the function takes
no arguments. A parameter list consisting of a single unnamed parameter of non-dependent type void is
equivalent to an empty parameter list. Except for this special case, a parameter shall not have type cv void.
If the parameter-declaration-clause terminates with an ellipsis or a function parameter pack (13.6.3), the
number of arguments shall be equal to or greater than the number of parameters that do not have a default
argument and are not function parameter packs. Where syntactically correct and where “…” is not part of
an abstract-declarator, “ , ...” is synonymous with “...”. [Example: The declaration
\[
\text{int printf(const char*, ...)};
\]
d Declares a function that can be called with varying numbers and types of arguments.
\[
\begin{align*}
\text{printf("hello world")}; \\
\text{printf("a=%d b=%d", a, b)};
\end{align*}
\]
However, the first argument must be of a type that can be converted to a const char*. — end example] [Note: The standard header <cstdio> contains a mechanism for accessing arguments passed using the
ellipsis (see 7.6.1.2 and 17.13). — end note]

The type of a function is determined using the following rules. The type of each parameter (including
function parameter packs) is determined from its own decl-specifier-seq and declarator. After determining
the type of each parameter, any parameter of type “array of T” or of function type T is adjusted to be
“pointer to T”. After producing the list of parameter types, any top-level cv-qualifiers modifying a parameter
type are deleted when forming the function type. The resulting list of transformed parameter types and
the presence or absence of the ellipsis or a function parameter pack is the function’s parameter-type-list.
[Note: This transformation does not affect the types of the parameters. For example, int(*)(const int*,
decltype(p)*) and int(*)(int, const int*) are identical types. — end note]

A function type with a cv-qualifier-seq or a ref-qualifier (including a type named by typedef-name (9.1.3,
13.1)) shall appear only as:

\[
\begin{align*}
(6.1) & \quad \text{the function type for a non-static member function,} \\
(6.2) & \quad \text{the function type to which a pointer to member refers,} \\
(6.3) & \quad \text{the top-level function type of a function typedef declaration or alias-declaration,} \\
(6.4) & \quad \text{the type-id in the default argument of a type-parameter (13.1), or} \\
(6.5) & \quad \text{the type-id of a template-argument for a type-parameter (13.3.1).}
\end{align*}
\]

[Example:
\[
\text{typedef int FIC(int) const;}
\]

\(^2\) As indicated by syntax, cv-qualifiers are a significant component in function return types.
The effect of a `cv-qualifier-seq` in a function declarator is not the same as adding `cv`-qualification on top of the function type. In the latter case, the `cv`-qualifiers are ignored. [Note: A function type that has a `cv-qualifier-seq` is not a `cv`-qualified type; there are no `cv`-qualified function types. — end note] [Example:
```c
typedef void F();
struct S {
    const F f;  // OK: equivalent to: void f();
};
```
—end example]

The return type, the parameter-type-list, the `ref-qualifier`, the `cv-qualifier-seq`, and the exception specification, but not the default arguments (9.2.3.6) or the trailing `requires-clause` (9.2), are part of the function type. [Note: Function types are checked during the assignments and initializations of pointers to functions, references to functions, and pointers to member functions. — end note]

[Example: The declaration
```c
int fseek(FILE*, long, int);
```
deares a function taking three arguments of the specified types, and returning `int` (9.1.7). —end example]

A single name can be used for several different functions in a single scope; this is function overloading (Clause 12). All declarations for a function shall have equivalent return types, parameter-type-lists, and `requires-clauses` (13.6.6.1).

Functions shall not have a return type of type array or function, although they may have a return type of type pointer or reference to such things. There shall be no arrays of functions, although there can be arrays of pointers to functions.

Types shall not be defined in return or parameter types.

A typedef of function type may be used to declare a function but shall not be used to define a function (9.4). [Example:
```c
typedef void F();
F fv;     // OK: equivalent to void fv();
F fv {}   // ill-formed
void fv() {} // OK: definition of fv
```
—end example]

An identifier can optionally be provided as a parameter name; if present in a function definition (9.4), it names a parameter. [Note: In particular, parameter names are also optional in function definitions and names used for a parameter in different declarations and the definition of a function need not be the same. If a parameter name is present in a function declaration that is not a definition, it cannot be used outside of its function declarator because that is the extent of its potential scope (6.3.4). — end note]

[Example: The declaration
```c
int i,
    *pi,
    f(),
    *fpi(int),
    (*pif)(const char*, const char*),
    (*fpif(int))(int);
```
declares an integer `i`, a pointer `pi` to an integer, a function `f` taking no arguments and returning an integer, a function `fpi` taking an integer argument and returning a pointer to an integer, a pointer `pif` to a function which takes two pointers to constant characters and returns an integer, a function `fpif` taking an integer argument and returning a pointer to a function that takes an integer argument and returns an integer. It is especially useful to compare `fpi` and `pif`. The binding of `*fpi(int)` is `*(fpi(int))`, so the declaration suggests, and the same construction in an expression requires, the calling of a function `fpi`, and then using indirection through the (pointer) result to yield an integer. In the declarator `(*pif)(const char*, const char*)`
char*), the extra parentheses are necessary to indicate that indirection through a pointer to a function yields a function, which is then called. —end example] [Note: Typedefs and trailing-return-types are sometimes convenient when the return type of a function is complex. For example, the function `fpif` above could have been declared

```c
typedef int IFUNC(int);
IFUNC* fpif(int);
```
or

```c
auto fpif(int)->int(*)(int);
```

A trailing-return-type is most useful for a type that would be more complicated to specify before the declarator-id:

```c
template <class T, class U> auto add(T t, U u) -> decltype((*(T*)0) + (*(U*)0)) add(T t, U u);
```
rather than

```c
template <class T, class U> decltype(t + u) add(T t, U u);
```

—end note

A non-template function is a function that is not a function template specialization. [Note: A function template is not a function. —end note]

An abbreviated function template is a function declaration whose parameter-type-list includes one or more placeholders (9.1.7.5). An abbreviated function template is equivalent to a function template (13.6.6.1) whose template-parameter-list includes one invented type template-parameter for each occurrence of a placeholder type in the decl-specifier-seq of a parameter-declaration in the function’s parameter-type-list, in order of appearance. For a placeholder-type-specifier of the form auto, the invented parameter is an unconstrained type-parameter. For a placeholder-type-specifier of the form type-constraint auto, the invented parameter is a type-parameter with that type-constraint. The invented type template-parameter is a template parameter pack if the corresponding parameter-declaration-clause declares a function parameter pack (9.2.3.5). If the placeholder contains `decltype(auto)`, the program is ill-formed. The adjusted function parameters of an abbreviated function template are derived from the parameter-declaration-clause by replacing each occurrence of a placeholder with the name of the corresponding invented template-parameter. [Example:

```c
 template<typename T> concept C1 = /* ... */;
 template<typename T> concept C2 = /* ... */;
 template<typename... Ts> concept C3 = /* ... */;

 void g1(const C1 auto*, C2 auto&);
 void g2(C1 auto&...);
 void g3(C3 auto...);
 void g4(C3 auto);
```

These declarations are functionally equivalent (but not equivalent) to the following declarations.

```c
 template<C1 T, C2 U> void g1(const T*, U&);
 template<C1... Ts> void g2(Ts&...);
 template<C3... Ts> void g3(Ts...);
 template<C3 T> void g4(T);
```

Abbreviated function templates can be specialized like all function templates.

```c
 template<> void g1<int>(const int*, const double&); // OK, specialization of g1<int, const double>
```

—end example]

An abbreviated function template can have a template-head. The invented template-parameters are appended to the template-parameter-list after the explicitly declared template-parameters. [Example:

```c
 template<typename T> concept C = /* ... */;

 template <typename T, C U>
 void g(T x, U y, C auto z);
```

This is functionally equivalent to each of the following two declarations.

```c
 template<typename T, C U, C W>
 void g(T x, U y, W z);
```
A function declaration at block scope shall not declare an abbreviated function template.

A \textit{declarator-id} or \textit{abstract-declarator} containing an ellipsis shall only be used in a \textit{parameter-declaration}. When it is part of a \textit{parameter-declaration-clause}, the \textit{parameter-declaration} declares a function parameter \((13.6.3)\). Otherwise, the \textit{parameter-declaration} is part of a \textit{template-parameter-list} and declares a template parameter pack; see \textit{13.1}. A function parameter pack is a pack expansion \((13.6.3)\). [Example:

\begin{verbatim}
    template<typename T, typename U, typename W>
    requires C<U> && C<W>
    void g(T x, U y, W z);
\end{verbatim}

—end example]

There is a syntactic ambiguity when an ellipsis occurs at the end of a \textit{parameter-declaration-clause} without a preceding comma. In this case, the ellipsis is parsed as part of the \textit{abstract-declarator} if the type of the parameter either names a template parameter pack that has not been expanded or contains \texttt{auto}; otherwise, it is parsed as part of the \textit{parameter-declaration-clause}.\footnote{93} \footnote{94}

\subsection*{9.2.3.6 Default arguments} [decl.fct.default]

If an \textit{initializer-clause} is specified in a \textit{parameter-declaration} this \textit{initializer-clause} is used as a default argument. [Note: Default arguments will be used in calls where trailing arguments are missing \((7.6.1.2)\). — end note]

[Example: The declaration

\begin{verbatim}
    void point(int = 3, int = 4);
\end{verbatim}

declares a function that can be called with zero, one, or two arguments of type \texttt{int}. It can be called in any of these ways:

\begin{verbatim}
    point(1,2); point(1); point();
\end{verbatim}

The last two calls are equivalent to \texttt{point(1,4)} and \texttt{point(3,4)}, respectively. — end example]

A default argument shall be specified only in the \textit{parameter-declaration-clause} of a function declaration or \textit{lambda-declarator} or in a \textit{template-parameter} \((13.1)\); in the latter case, the \textit{initializer-clause} shall be an \textit{assignment-expression}. A default argument shall not be specified for a template parameter pack or a function parameter pack. If it is specified in a \textit{parameter-declaration-clause}, it shall not occur within a \textit{declarator} or \textit{abstract-declarator} of a \textit{parameter-declaration}.\footnote{94}

For non-template functions, default arguments can be added in later declarations of a function in the same scope. Declarations in different scopes have completely distinct sets of default arguments. That is, declarations in inner scopes do not acquire default arguments from declarations in outer scopes, and vice versa. In a given function declaration, each parameter subsequent to a parameter with a default argument shall have a default argument supplied in this or a previous declaration, unless the parameter was expanded from a parameter pack, or shall be a function parameter pack. A default argument shall not be redefined by a later declaration (not even to the same value). [Example:

\begin{verbatim}
    void g(int = 0, ...);
        // OK, ellipsis is not a parameter so it can follow
    void f(int, int);
        // a parameter with a default argument
    void f(int, int = 7);
\end{verbatim}

\begin{footnotes}
\footnote{93} One can explicitly disambiguate the parse either by introducing a comma (so the ellipsis will be parsed as part of the \textit{parameter-declaration-clause}) or by introducing a name for the parameter (so the ellipsis will be parsed as part of the \textit{declarator-id}).

\footnote{94} This means that default arguments cannot appear, for example, in declarations of pointers to functions, references to functions, or typedef declarations.
\end{footnotes}
void h() {
  f(3);       // OK, calls f(3, 7)
  void f(int = 1, int);  // error: does not use default from surrounding scope
}

void m() {
  void f(int, int);       // has no defaults
  f(4);                   // error: wrong number of arguments
  void f(int, int = 5);   // OK
  f(4);                   // OK, calls f(4, 5);
  void f(int, int = 5);   // error: cannot redefine, even to same value
}

void n() {
  f(6);       // OK, calls f(6, 7)
}

template<class ... T> struct C {
  void f(int n = 0, T...);
};

C<int> c; // OK, instantiates declaration void C::f(int n = 0, int)
—end example

For a given inline function defined in different translation units, the accumulated sets of
default arguments at the end of the translation units shall be the same; see 6.2. If a friend declaration
specifies a default argument expression, that declaration shall be a definition and shall be the only declaration
of the function or function template in the translation unit.

The default argument has the same semantic constraints as the initializer in a declaration of a variable of the
parameter type, using the copy-initialization semantics (9.3). The names in the default argument are bound,
and the semantic constraints are checked, at the point where the default argument appears. Name lookup
and checking of semantic constraints for default arguments in function templates and in member functions of
class templates are performed as described in 13.8.1. [Example: In the following code, g will be called with
the value f(2):

```c
int a = 1;
int f(int);
int g(int x = f(a)); // default argument: f(::a)

void h() {
  a = 2;
  {
    int a = 3;
    g(); // g(f(::a))
  }
}
```
—end example] [Note: In member function declarations, names in default arguments are looked up as
described in 6.4.1. Access checking applies to names in default arguments as described in 11.8. —end note]

Except for member functions of class templates, the default arguments in a member function definition that
appears outside of the class definition are added to the set of default arguments provided by the member
function declaration in the class definition; the program is ill-formed if a default constructor (11.3.4.1), copy or
move constructor (11.3.4.2), or copy or move assignment operator (11.3.5) is so declared. Default arguments
for a member function of a class template shall be specified on the initial declaration of the member function
within the class template. [Example:

```c
class C {
  void f(int i = 3);
  void g(int i, int j = 99);
};

void C::f(int i = 3) {} // error: default argument already specified in class scope
void C::g(int i = 99, int j) {} // in this translation unit, C::g can be called with no argument
—end example]
```
[Note: A local variable cannot be odr-used (6.2) in a default argument. —end note] [Example:

```c
void f() {
  int i;
```
extern void g(int x = i);  // error
extern void h(int x = sizeof(i));  // OK
// ... }
—end example]

[Note: The keyword this may not appear in a default argument of a member function; see 7.5.2. [Example:

class A {
    void f(A* p = this) { }  // error
};
—end example] —end note]

9 A default argument is evaluated each time the function is called with no argument for the corresponding parameter. A parameter shall not appear as a potentially-evaluated expression in a default argument. Parameters of a function declared before a default argument are in scope and can hide namespace and class member names. [Example:

    int a;
    int f(int a, int b = a);  // error: parameter a used as default argument
typeint I;
    int g(float I, int b = I(2));  // error: parameter I found
    int h(int a, int b = sizeof(a));  // OK, unevaluated operand
—end example] A non-static member shall not appear in a default argument unless it appears as the id-expression of a class member access expression (7.6.1.4) or unless it is used to form a pointer to member (7.6.2.1). [Example: The declaration of X::mem2() in the following example is ill-formed because no object is supplied for the non-static member X::a used as an initializer.

    int b;
    class X {
        int a;
        int mem1(int i = a);  // error: non-static member a used as default argument
        int mem2(int i = b);  // OK; use X::b
        static int b;
    }; The declaration of X::mem2() is meaningful, however, since no object is needed to access the static member X::b. Classes, objects, and members are described in Clause 11. —end example] A default argument is not part of the type of a function. [Example:

    int f(int = 0);
    void h() {
        int j = f(1);
        int k = f();  // OK, means f(0)
    }
    int (*p1)(int) = &f;
    int (*p2)() = &f;  // error: type mismatch
—end example] When a declaration of a function is introduced by way of a using-declaration (9.8), any default argument information associated with the declaration is made known as well. If the function is redeclared thereafter in the namespace with additional default arguments, the additional arguments are also known at any point following the redeclaration where the using-declaration is in scope.

10 A virtual function call (11.6.2) uses the default arguments in the declaration of the virtual function determined by the static type of the pointer or reference denoting the object. An overriding function in a derived class does not acquire default arguments from the function it overrides. [Example:

    struct A {
        virtual void f(int a = 7);
    };  
    struct B : public A {
        void f(int a);
    };  
    void m() {
        B* pb = new B;
    }
A* pa = pb;
pa->f();       // OK, calls pa->B::f(?)
pb->f();       // error: wrong number of arguments for B::f()
}
—end example]

9.3 Initializers [dcl.init]

1 The process of initialization described in this subclause applies to all initializations regardless of syntactic context, including the initialization of a function parameter (7.6.1.2), the initialization of a return value (8.6.3), or when an initializer follows a declarator.

initializer:
  brace-or-equal-initializer
  ( expression-list )
brace-or-equal-initializer:
  = initializer-clause
  braced-init-list
initializer-clause:
  assignment-expression
  braced-init-list
braced-init-list:
  { initializer-list ,opt }
  { designated-initializer-list ,opt }
  { }
initializer-list:
  initializer-clause ...opt
  initializer-list , initializer-clause ...opt
designated-initializer-list:
  designated-initializer-clause
  designated-initializer-list , designated-initializer-clause
designated-initializer-clause:
  designator brace-or-equal-initializer
designator:
  . identifier
expr-or-braced-init-list:
  expression
  braced-init-list

[Note: The rules in this subclause apply even if the grammar permits only the brace-or-equal-initializer form of initializer in a given context. — end note]

2 Except for objects declared with the constexpr specifier, for which see 9.1.5, an initializer in the definition of a variable can consist of arbitrary expressions involving literals and previously declared variables and functions, regardless of the variable’s storage duration. [Example:

```c
int f(int);
int a = 2;
int b = f(a);
int c(b);
—end example]
```

3 [Note: Default arguments are more restricted; see 9.2.3.6. — end note]

4 [Note: The order of initialization of variables with static storage duration is described in 6.8.3 and 8.7. — end note]

5 A declaration of a block-scope variable with external or internal linkage that has an initializer is ill-formed.

6 To zero-initialize an object or reference of type T means:

(6.1) — if T is a scalar type (6.7), the object is initialized to the value obtained by converting the integer literal 0 (zero) to T.\(^\text{95}\)

\(^\text{95}\) As specified in 7.3.11, converting an integer literal whose value is 0 to a pointer type results in a null pointer value.
if $T$ is a (possibly cv-qualified) non-union class type, its padding bits (6.7) are initialized to zero bits and each non-static data member, each non-virtual base class subobject, and, if the object is not a base class subobject, each virtual base class subobject is zero-initialized;

(6.3) if $T$ is a (possibly cv-qualified) union type, its padding bits (6.7) are initialized to zero bits and the object’s first non-static named data member is zero-initialized;

(6.4) if $T$ is an array type, each element is zero-initialized;

(6.5) if $T$ is a reference type, no initialization is performed.

To default-initialize an object of type $T$ means:

(7.1) If $T$ is a (possibly cv-qualified) class type (Clause 11), constructors are considered. The applicable constructors are enumerated (12.3.1.3), and the best one for the initializer () is chosen through overload resolution (12.3). The constructor thus selected is called, with an empty argument list, to initialize the object.

(7.2) If $T$ is an array type, each element is default-initialized.

(7.3) Otherwise, no initialization is performed.

A class type $T$ is const-default-constructible if default-initialization of $T$ would invoke a user-provided constructor of $T$ (not inherited from a base class) or if

(7.4) each direct non-variant non-static data member $M$ of $T$ has a default member initializer or, if $M$ is of class type $X$ (or array thereof), $X$ is const-default-constructible,

(7.5) if $T$ is a union with at least one non-static data member, exactly one variant member has a default member initializer,

(7.6) if $T$ is not a union, for each anonymous union member with at least one non-static data member (if any), exactly one non-static data member has a default member initializer, and

(7.7) each potentially constructed base class of $T$ is const-default-constructible.

If a program calls for the default-initialization of an object of a const-qualified type $T$, $T$ shall be a const-default-constructible class type or array thereof.

To value-initialize an object of type $T$ means:

(8.1) if $T$ is a (possibly cv-qualified) class type (Clause 11) with either no default constructor (11.3.4.1) or a default constructor that is user-provided or deleted, then the object is default-initialized;

(8.2) if $T$ is a (possibly cv-qualified) class type without a user-provided or deleted default constructor, then the object is zero-initialized and the semantic constraints for default-initialization are checked, and if $T$ has a non-trivial default constructor, the object is default-initialized;

(8.3) if $T$ is an array type, then each element is value-initialized;

(8.4) otherwise, the object is zero-initialized.

A program that calls for default-initialization or value-initialization of an entity of reference type is ill-formed.

[Note: For every object of static storage duration, static initialization (6.8.3.2) is performed at program startup before any other initialization takes place. In some cases, additional initialization is done later.
—end note]

An object whose initializer is an empty set of parentheses, i.e., (), shall be value-initialized.

[Note: Since () is not permitted by the syntax for initializer,

```c
X a();
```

is not the declaration of an object of class $X$, but the declaration of a function taking no argument and returning an $X$. The form () is permitted in certain other initialization contexts (7.6.2.7, 7.6.1.3, 11.9.2).
—end note]

If no initializer is specified for an object, the object is default-initialized.

An initializer for a static member is in the scope of the member’s class. [Example:

```c
int a;

struct X {
    static int a;
```
static int b;
};

int X::a = 1;
int X::b = a;  // X::b = X::a

— end example

If the entity being initialized does not have class type, the expression-list in a parenthesized initializer shall be a single expression.

The initialization that occurs in the = form of a brace-or-equal-initializer or condition (8.4), as well as in argument passing, function return, throwing an exception (14.1), handling an exception (14.3), and aggregate member initialization (9.3.1), is called copy-initialization. [Note: Copy-initialization may invoke a move (11.3.4.2). — end note]

The initialization that occurs

(16.1) — for an initializer that is a parenthesized expression-list or a braced-init-list,

(16.2) — for a new-initializer (7.6.2.7),

(16.3) — in a static_cast expression (7.6.1.8),

(16.4) — in a functional notation type conversion (7.6.1.3), and

(16.5) — in the braced-init-list form of a condition

is called direct-initialization.

The semantics of initializers are as follows. The destination type is the type of the object or reference being initialized and the source type is the type of the initializer expression. If the initializer is not a single (possibly parenthesized) expression, the source type is not defined.

(17.1) — If the initializer is a (non-parenthesized) braced-init-list or is = braced-init-list, the object or reference is list-initialized (9.3.4).

(17.2) — If the destination type is a reference type, see 9.3.3.

(17.3) — If the destination type is an array of characters, an array of char8_t, an array of char16_t, an array of char32_t, or an array of wchar_t, and the initializer is a string literal, see 9.3.2.

(17.4) — If the initializer is (), the object is value-initialized.

(17.5) — Otherwise, if the destination type is an array, the object is initialized as follows. Let \( x_1, \ldots, x_k \) be the elements of the expression-list. If the destination type is an array of unknown bound, it is defined as having \( k \) elements. Let \( n \) denote the array size after this potential adjustment. If \( k \) is greater than \( n \), the program is ill-formed. Otherwise, the \( i \)th array element is copy-initialized with \( x_i \) for each \( 1 \leq i \leq k \), and value-initialized for each \( k < i \leq n \). For each \( 1 \leq i < j \leq n \), every value computation and side effect associated with the initialization of the \( i \)th element of the array is sequenced before those associated with the initialization of the \( j \)th element.

(17.6) — Otherwise, if the destination type is a (possibly cv-qualified) class type:

(17.6.1) — If the initializer expression is a prvalue and the cv-unqualified version of the source type is the same class as the class of the destination, the initializer expression is used to initialize the destination object. [Example: \( T x = T(T(T())); \) calls the \( T \) default constructor to initialize \( x \). — end example]

(17.6.2) — Otherwise, if the initialization is direct-initialization, or if it is copy-initialization where the cv-unqualified version of the source type is the same class as, or a derived class of, the class of the destination, constructors are considered. The applicable constructors are enumerated (12.3.1.3), and the best one is chosen through overload resolution (12.3). Then:

(17.6.2.1) — If overload resolution is successful, the selected constructor is called to initialize the object, with the initializer expression or expression-list as its argument(s).

(17.6.2.2) — Otherwise, if no constructor is viable, the destination type is a (possibly cv-qualified) aggregate class \( A \), and the initializer is a parenthesized expression-list, the object is initialized as follows. Let \( c_1, \ldots, c_n \) be the elements of the aggregate (9.3.1). Let \( x_1, \ldots, x_k \) be the elements of the expression-list. If \( k \) is greater than \( n \), the program is ill-formed. The element \( c_i \) is copy-initialized with \( x_i \) for \( 1 \leq i \leq k \). The remaining elements are initialized with their default
member initializers, if any, and otherwise are value-initialized. For each \(1 \leq i < j \leq n\), every value computation and side effect associated with the initialization of \(e_i\) is sequenced before those associated with the initialization of \(e_j\). [Note: By contrast with direct-list-initialization, narrowing conversions (9.3.4) are permitted, designators are not permitted, a temporary object bound to a reference does not have its lifetime extended (6.6.7), and there is no brace elision.  

Example:
```c++
struct A {
  int a;
  int&& r;
};

int f();
int n = 10;
A a1{1, f()};
// OK, lifetime is extended
A a2(1, f());
// well-formed, but dangling reference
A a3{1.0, 1};
// error: narrowing conversion
A a4(1.0, 1);
// well-formed, but dangling reference
A a5(1.0, std::move(n));
// OK
```
—end example]  —end note]

— Otherwise, the initialization is ill-formed.

— Otherwise (i.e., for the remaining copy-initialization cases), user-defined conversions that can convert from the source type to the destination type or (when a conversion function is used) to a derived class thereof are enumerated as described in 12.3.1.4, and the best one is chosen through overload resolution (12.3). If the conversion cannot be done or is ambiguous, the initialization is ill-formed. The function selected is called with the initializer expression as its argument; if the function is a constructor, the call is a prvalue of the cv-unqualified version of the destination type whose result object is initialized by the constructor. The call is used to direct-initialize, according to the rules above, the object that is the destination of the copy-initialization.

— Otherwise, if the source type is a (possibly cv-qualified) class type, conversion functions are considered. The applicable conversion functions are enumerated (12.3.1.5), and the best one is chosen through overload resolution (12.3). The user-defined conversion so selected is called to convert the initializer expression into the object being initialized. If the conversion cannot be done or is ambiguous, the initialization is ill-formed.

— Otherwise, if the initialization is direct-initialization, the source type is `std::nullptr_t`, and the destination type is `bool`, the initial value of the object being initialized is `false`.

— Otherwise, the initial value of the object being initialized is the (possibly converted) value of the initializer expression. A standard conversion sequence (7.3) will be used, if necessary, to convert the initializer expression to the cv-unqualified version of the destination type; no user-defined conversions are considered. If the conversion cannot be done, the initialization is ill-formed. When initializing a bit-field with a value that it cannot represent, the resulting value of the bit-field is implementation-defined. [Note: An expression of type “cv1 T” can initialize an object of type “cv2 T” independently of the cv-qualifiers cv1 and cv2.

```c++
int a;
const int b = a;
int c = b;
```
—end note]

18 An *initializer-clause* followed by an ellipsis is a pack expansion (13.6.3).

19 If the initializer is a parenthesized *expression-list*, the expressions are evaluated in the order specified for function calls (7.6.1.2).

20 The same *identifier* shall not appear in multiple *designators* of a *designated-initializer-list*.

21 An object whose initialization has completed is deemed to be constructed, even if the object is of non-class type or no constructor of the object’s class is invoked for the initialization. [Note: Such an object might have been value-initialized or initialized by aggregate initialization (9.3.1) or by an inherited constructor (11.9.3). — end note] Destroying an object of class type invokes the destructor of the class. Destroying a scalar type
has no effect other than ending the lifetime of the object (6.6.3). Destroying an array destroys each element in reverse subscript order.

22 A declaration that specifies the initialization of a variable, whether from an explicit initializer or by default-initialization, is called the initializing declaration of that variable. [Note: In most cases this is the defining declaration (6.1) of the variable, but the initializing declaration of a non-inline static data member (11.3.8.2) might be the declaration within the class definition and not the definition at namespace scope. — end note]

9.3.1 Aggregates

1 An aggregate is an array or a class (Clause 11) with

(1.1) no user-declared or inherited constructors (11.3.4),
(1.2) no private or protected direct non-static data members (11.8),
(1.3) no virtual functions (11.6.2), and
(1.4) no virtual, private, or protected base classes (11.6.1).

[Note: Aggregate initialization does not allow accessing protected and private base class’ members or constructors. — end note]

2 The elements of an aggregate are:

(2.1) for an array, the array elements in increasing subscript order, or
(2.2) for a class, the direct base classes in declaration order, followed by the direct non-static data members (11.3) that are not members of an anonymous union, in declaration order.

3 When an aggregate is initialized by an initializer list as specified in 9.3.4, the elements of the initializer list are taken as initializers for the elements of the aggregate. The explicitly initialized elements of the aggregate are determined as follows:

(3.1) If the initializer list is a designated-initializer-list, the aggregate shall be of class type, the identifier in each designator shall name a direct non-static data member of the class, and the explicitly initialized elements of the aggregate are the elements that are, or contain, those members.

(3.2) If the initializer list is an initializer-list, the explicitly initialized elements of the aggregate are the first \( n \) elements of the aggregate, where \( n \) is the number of elements in the initializer list.

(3.3) Otherwise, the initializer list must be \( {} \), and there are no explicitly initialized elements.

4 For each explicitly initialized element:

(4.1) If the element is an anonymous union object and the initializer list is a designated-initializer-list, the anonymous union object is initialized by the designated-initializer-list \( \{ \ D \} \), where \( D \) is the designated-initializer-clause naming a member of the anonymous union object. There shall be only one such designated-initializer-clause. [Example:

```c
struct C {
  union {
    int a;
    const char* p;
  };
  int x;
} c = { .a = 1, .x = 3 };
```

initializes \( c.a \) with 1 and \( c.x \) with 3. — end example]

(4.2) Otherwise, the element is copy-initialized from the corresponding initializer-clause or is initialized with the brace-or-equal-initializer of the corresponding designated-initializer-clause. If that initializer is of the form assignment-expression or = assignment-expression and a narrowing conversion (9.3.4) is required to convert the expression, the program is ill-formed. [Note: If an initializer is itself an initializer list, the element is list-initialized, which will result in a recursive application of the rules in this subclause if the element is an aggregate. — end note] [Example:

```c
struct A {
  int x;
  struct B {
    int i;
    int j;
  };
```
} b;
} a = { 1, { 2, 3 } };

initializes a.x with 1, a.b.i with 2, a.b.j with 3.

struct base1 { int b1, b2 = 42; };
struct base2 {
    base2() {
        b3 = 42;
    }
    int b3;
};
struct derived : base1, base2 {
    int d;
};

derived d1{{1, 2}, {}, 4};
derived d2{{}, {}, 4};

initializes d1.b1 with 1, d1.b2 with 2, d1.b3 with 42, d1.d with 4, and d2.b1 with 0, d2.b2 with 42, d2.b3 with 42, d2.d with 4. — end example]

5 For a non-union aggregate, each element that is not an explicitly initialized element is initialized as follows:

1. If the element has a default member initializer (11.3), the element is initialized from that initializer.
2. Otherwise, if the element is not a reference, the element is copy-initialized from an empty initializer list (9.3.4).
3. Otherwise, the program is ill-formed.

If the aggregate is a union and the initializer list is empty, then

4. if any variant member has a default member initializer, that member is initialized from its default member initializer;
5. otherwise, the first member of the union (if any) is copy-initialized from an empty initializer list.

[Example:
struct S { int a; const char* b; int c; int d = b[a]; };
S ss = { 1, "asdf" }; initializes ss.a with 1, ss.b with "asdf", ss.c with the value of an expression of the form int{} (that is, 0), and ss.d with the value of ss.b[ss.a] (that is, 's'), and in
struct X { int i, j, k = 42; };
X a[] = { 1, 2, 3, 4, 5, 6 }; X b[2] = { { 1, 2, 3 }, { 4, 5, 6 } }; a and b have the same value
struct A {
    string a;
    int b = 42;
    int c = -1;
};
A{.c=21} has the following steps:
1. Initialize a with {}
2. Initialize b with = 42
3. Initialize c with = 21
— end example]

6 The initializations of the elements of the aggregate are evaluated in the element order. That is, all value computations and side effects associated with a given element are sequenced before those of any element that follows it in order.

7 An aggregate that is a class can also be initialized with a single expression not enclosed in braces, as described in 9.3.
The destructor for each element of class type is potentially invoked (11.3.6) from the context where the aggregate initialization occurs.  

[Note: This provision ensures that destructors can be called for fully-constructed subobjects in case an exception is thrown (14.2). — end note]

An array of unknown bound initialized with a brace-enclosed *initializer-list* containing \( n \) *initializer-clauses* is defined as having \( n \) elements (9.2.3.4).  

[Example:

```c
int x[] = { 1, 3, 5 };
```

declares and initializes \( x \) as a one-dimensional array that has three elements since no size was specified and there are three initializers. — end example]

An array of unknown bound shall not be initialized with an empty *braced-init-list* `{}`.  

[Note: A default member initializer does not determine the bound for a member array of unknown bound. Since the default member initializer is ignored if a suitable *mem-initializer* is present (11.9.2), the default member initializer is not considered to initialize the array of unknown bound.  

[Example:

```c
struct S {
  int y[] = { 0 };
};
```

— end example] — end note]

An *initializer-list* is ill-formed if the number of *initializer-clauses* exceeds the number of elements of the aggregate.  

[Example:

```c
char cv[4] = { 'a', 's', 'd', 'f', 0 }; // error
```

is ill-formed. — end example]

If a member has a default member initializer and a potentially-evaluated subexpression thereof is an aggregate initialization that would use that default member initializer, the program is ill-formed.  

[Example:

```c
struct A;
extern A a;
struct A {
  const A& a1 { A(a,a) }; // OK
  const A& a2 { A{} }; // error
};
A a(a,a);
// OK

struct B {
  int n = B{}.n;
  // error
};
```

— end example]

If an aggregate class \( C \) contains a subaggregate element \( e \) with no elements, the *initializer-clause* for \( e \) shall not be omitted from an *initializer-list* for an object of type \( C \) unless the *initializer-clauses* for all elements of \( C \) following \( e \) are also omitted.  

[Example:

```c
struct S { } s;
struct A {
  S s1;
  int i1;
  S s2;
  int i2;
```}

96) The syntax provides for empty *braced-init-lists*, but nonetheless C++ does not have zero length arrays.
When initializing a multi-dimensional array, the *initializer-clauses* initialize the elements with the last (rightmost) index of the array varying the fastest (9.2.3.4). [Example:]

```c
int x[2][2] = { 3, 1, 4, 2 };
```

initializes `x[0][0]` to 3, `x[0][1]` to 1, `x[1][0]` to 4, and `x[1][1]` to 2. On the other hand,

```c
float y[4][3] = {
    { 1 },
    { 2 },
    { 3 },
    { 4 }
};
```

initializes the first column of `y` (regarded as a two-dimensional array) and leaves the rest zero. —end example

Braces can be elided in an *initializer-list* as follows. If the *initializer-list* begins with a left brace, then the succeeding comma-separated list of *initializer-clauses* initializes the elements of a subaggregate; it is erroneous for there to be more *initializer-clauses* than elements. If, however, the *initializer-list* for a subaggregate does not begin with a left brace, then only enough *initializer-clauses* from the list are taken to initialize the elements of the subaggregate; any remaining *initializer-clauses* are left to initialize the next element of the aggregate of which the current subaggregate is an element. [Example:]

```c
float y[4][3] = {
    { 1, 3, 5 },
    { 2, 4, 6 },
    { 3, 5, 7 },
};
```

is a completely-braced initialization: 1, 3, and 5 initialize the first row of the array `y[0]`, namely `y[0][0]`, `y[0][1]`, and `y[0][2]`. Likewise the next two lines initialize `y[1]` and `y[2]`. The initializer ends early and therefore `y[3]`’s elements are initialized as if explicitly initialized with an expression of the form `float()`, that is, are initialized with `0.0`. In the following example, braces in the *initializer-list* are elided; however the *initializer-list* has the same effect as the completely-braced *initializer-list* of the above example,

```c
float y[4][3] = {
    1, 3, 5, 2, 4, 6, 3, 5, 7
};
```

The initializer for `y` begins with a left brace, but the one for `y[0]` does not, therefore three elements from the list are used. Likewise the next three are taken successively for `y[1]` and `y[2]`. —end example

All implicit type conversions (7.3) are considered when initializing the element with an *assignment-expression*. If the *assignment-expression* can initialize an element, the element is initialized. Otherwise, if the element is itself a subaggregate, brace elision is assumed and the *assignment-expression* is considered for the initialization of the first element of the subaggregate. [Note: As specified above, brace elision cannot apply to subaggregates with no elements; an *initializer-clause* for the entire subobject is required. —end note]
Braces are elided around the initializer-clause for `b.a1.i`. `b.a1.i` is initialized with 4, `b.a2` is initialized with `a`, `b.z` is initialized with whatever `a.operator int()` returns.  

[Note: An aggregate array or an aggregate class may contain elements of a class type with a user-declared constructor (11.3.4). Initialization of these aggregate objects is described in 11.9.1. — end note]

[Note: Whether the initialization of aggregates with static storage duration is static or dynamic is specified in 6.8.3.2, 6.8.3.3, and 8.7. — end note]

When a union is initialized with an initializer list, there shall not be more than one explicitly initialized element.  

[Example:

```c
union u { int a; const char* b; };  
u a = { 1 };  
u b = a;  
u c = 1; // error  
u d = { 0, "asdf" }; // error  
u e = { "asdf" }; // error  
u f = {.b = "asdf" };  
u g = {.a = 1, .b = "asdf" }; // error
```

—end example

[Note: As described above, the braces around the initializer-clause for a union member can be omitted if the union is a member of another aggregate. — end note]

### 9.3.2 Character arrays

An array of ordinary character type (6.7.1), `char8_t` array, `char16_t` array, `char32_t` array, or `wchar_t` array can be initialized by an ordinary string literal, UTF-8 string literal, UTF-16 string literal, UTF-32 string literal, or wide string literal, respectively, or by an appropriately-typed string literal enclosed in braces (5.13.5). Successive characters of the value of the string literal initialize the elements of the array.  

[Example:

```c
char msg[] = "Syntax error on line %s\n";
```

shows a character array whose members are initialized with a string-literal. Note that because `\n` is a single character and because a trailing `\0` is appended, `sizeof(msg)` is 25. — end example]

There shall not be more initializers than there are array elements.  

[Example:

```c
char cv[4] = "asdf"; // error
```

is ill-formed since there is no space for the implied trailing `\0`. — end example]

If there are fewer initializers than there are array elements, each element not explicitly initialized shall be zero-initialized (9.3).

### 9.3.3 References

A variable whose declared type is “reference to type `T`” (9.2.3.2) shall be initialized.  

[Example:

```c
int g(int) noexcept;  
void f() {  
  int i;  
  int& r = i; // r refers to i  
  r = 1; // the value of i becomes 1  
  int* p = &r; // p points to i  
  int& rr = r; // rr refers to what r refers to, that is, to i  
  int (*rg)(int) = g; // rg refers to the function g  
  rg(i); // calls function g  
  int a[3];  
  int (*ra)[3] = a; // ra refers to the array a  
  ra[1] = i; // modifies a[1]
  }
```

—end example

A reference cannot be changed to refer to another object after initialization.  

[Note: Assignment to a reference assigns to the object referred to by the reference (7.6.19). — end note]  
Argument passing (7.6.1.2) and function value return (8.6.3) are initializations.
The initializer can be omitted for a reference only in a parameter declaration (9.2.3.5), in the declaration of a function return type, in the declaration of a class member within its class definition (11.3), and where the extern specifier is explicitly used. [Example:

```c
int& r1;  // error: initializer missing
extern int& r2;  // OK
```
—end example]

Given types “cv1 T1” and “cv2 T2”, “cv1 T1” is reference-related to “cv2 T2” if T1 is similar (7.3.5) to T2, or T1 is a base class of T2. “cv1 T1” is reference-compatible with “cv2 T2” if a prvalue of type “pointer to cv1 T1” can be converted to the type “pointer to cv1 T1” via a standard conversion sequence (7.3). In all cases where the reference-compatible relationship of two types is used to establish the validity of a reference binding and the standard conversion sequence would be ill-formed, a program that necessitates such a binding is ill-formed.

A reference to type “cv1 T1” is initialized by an expression of type “cv2 T2” as follows:

(5.1) — If the reference is an lvalue reference and the initializer expression

(5.1.1) — is an lvalue (but not a bit-field), and “cv1 T1” is reference-compatible with “cv2 T2”, or

(5.1.2) — has a class type (i.e., T2 is a class type), where T1 is not reference-related to T2, and can be converted to an lvalue of type “cv3 T3”, where “cv1 T1” is reference-compatible with “cv3 T3”97 (this conversion is selected by enumerating the applicable conversion functions (12.3.1.6) and choosing the best one through overload resolution (12.3)), then the reference is bound to the initializer expression lvalue in the first case and to the lvalue result of the conversion in the second case (or, in either case, to the appropriate base class subobject of the object). [Note: The usual lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are not needed, and therefore are suppressed, when such direct bindings to lvalues are done. — end note]

[Example:

```c
double d = 2.0;
double& rd = d;  // rd refers to d
const double& rcd = d;  // rcd refers to d

struct A { };  
struct B : A { operator int&(); } b;
A& ra = b;  // ra refers to A subobject in b
const A& rca = b;  // rca refers to A subobject in b
int& ir = B();  // ir refers to the result of B::operator int&
```
—end example]

(5.2) — Otherwise, if the reference is an lvalue reference to a type that is not const-qualified or is volatile-qualified, the program is ill-formed. [Example:

```c
double& rd2 = 2.0;  // error: not an lvalue and reference not const
int i = 2;
double& rd3 = i;  // error: type mismatch and reference not const
```
—end example]

(5.3) — Otherwise, if the initializer expression

(5.3.1) — is an rvalue (but not a bit-field) or function lvalue and “cv1 T1” is reference-compatible with “cv2 T2”, or

(5.3.2) — has a class type (i.e., T2 is a class type), where T1 is not reference-related to T2, and can be converted to an rvalue or function lvalue of type “cv3 T3”, where “cv1 T1” is reference-compatible with “cv3 T3” (see 12.3.1.6),

then the value of the initializer expression in the first case and the result of the conversion in the second case is called the converted initializer. If the converted initializer is a prvalue, its type T4 is adjusted to type “cv1 T4” (7.3.5) and the temporary materialization conversion (7.3.4) is applied. In any case, the reference is bound to the resulting glvalue (or to an appropriate base class subobject).

97) This requires a conversion function (11.3.7.2) returning a reference type.
Example:

```cpp
struct A {
};
struct B : A {
} b;
extern B f();
const & A rca2 = f(); // bound to the A subobject of the B rvalue.
& B rra = f(); // same as above
struct X {
  operator B();
  operator int&();
} x;
const & x = x; // bound to the A subobject of the result of the conversion
int i2 = 42;
int& rri = static_cast<int&>(i2); // bound directly to i2
B& rrb = x; // bound directly to the result of operator B
```

— end example]

5.4 — Otherwise:

5.4.1 — If T1 or T2 is a class type and T1 is not reference-related to T2, user-defined conversions are considered using the rules for copy-initialization of an object of type “cv1 T1” by user-defined conversion (9.3, 12.3.1.4, 12.3.1.5); the program is ill-formed if the corresponding non-reference copy-initialization would be ill-formed. The result of the call to the conversion function, as described for the non-reference copy-initialization, is then used to direct-initialize the reference. For this direct-initialization, user-defined conversions are not considered.

5.4.2 — Otherwise, the initializer expression is implicitly converted to a prvalue of type “cv1 T1”. The temporary materialization conversion is applied and the reference is bound to the result.

If T1 is reference-related to T2:

5.4.3 — cv1 shall be the same cv-qualification as, or greater cv-qualification than, cv2; and

5.4.4 — if the reference is an rvalue reference, the initializer expression shall not be an lvalue.

Example:

```cpp
struct Banana {
};
struct Enigma { operator const Banana(); };
struct Alaska { operator Banana&(); };
void enigmatic() {
  typedef const Banana ConstBanana;
  Banana &&banana1 = ConstBanana(); // ill-formed
  Banana &&banana2 = Enigma(); // ill-formed
  Banana &&banana3 = Alaska(); // ill-formed
}
const double& rcd2 = 2; // rcd2 refers to temporary with value 2.0
double& rrd = 2; // rrd refers to temporary with value 2.0
const volatile int cvi = 1;
const int& r2 = cvi; // error: cv-qualifier dropped
struct A { operator volatile int&(); } a;
const int& r3 = a; // error: cv-qualifier dropped // from result of conversion function
double d2 = 1.0;
double& rrd2 = d2; // error: initializer is lvalue of related type
struct X { operator int&(); };
int& rri2 = X(); // error: result of conversion function is lvalue of related type
int i3 = 2;
double& rrd3 = i3; // rrd3 refers to temporary with value 2.0
```

— end example]

In all cases except the last (i.e., implicitly converting the initializer expression to the referenced type), the reference is said to bind directly to the initializer expression.

6 [Note: 6.6.7 describes the lifetime of temporaries bound to references. — end note]
9.3.4 List-initialization

List-initialization is initialization of an object or reference from a braced-init-list. Such an initializer is called an initializer list, and the comma-separated initializer-clauses of the initializer-list or designated-initializer-clauses of the designated-initializer-list are called the elements of the initializer list. An initializer list may be empty. List-initialization can occur in direct-initialization or copy-initialization contexts; list-initialization in a direct-initialization context is called direct-list-initialization and list-initialization in a copy-initialization context is called copy-list-initialization. [Note: List-initialization can be used

(1.1) — as the initializer in a variable definition (9.3)
(1.2) — as the initializer in a new-expression (7.6.2.7)
(1.3) — in a return statement (8.6.3)
(1.4) — as a for-range-initializer (8.5)
(1.5) — as a function argument (7.6.1.2)
(1.6) — as a subscript (7.6.1.1)
(1.7) — as an argument to a constructor invocation (9.3, 7.6.1.3)
(1.8) — as an initializer for a non-static data member (11.3)
(1.9) — in a mem-initializer (11.9.2)
(1.10) — on the right-hand side of an assignment (7.6.19)

Example:

```cpp
int a = {1};
std::complex<double> z(1,2);
new std::vector<std::string> {"once", "upon", "a", "time"}; // 4 string elements
f({"Nicholas","Amemarie"}); // pass list of two elements
return { "Norah" };              // return list of one element
int* e {};
               // initialization to zero / null pointer
x = double{1};            // explicitly construct a double
std::map<std::string,int> anim = { {"bear",4}, {"cassowary",2}, {"tiger",7} };
```

—end example] — end note

2 A constructor is an initializer-list constructor if its first parameter is of type `std::initializer_list<E>` or reference to possibly cv-qualified `std::initializer_list<E>` for some type E, and either there are no other parameters or else all other parameters have default arguments (9.2.3.6). [Note: Initializer-list constructors are favored over other constructors in list-initialization (12.3.1.7). Passing an initializer list as the argument to the constructor template `template<class T> C(T)` of a class C does not create an initializer-list constructor, because an initializer list argument causes the corresponding parameter to be a non-deduced context (13.9.2.1). — end note] The template `std::initializer_list` is not predefined; if the header `<initializer_list>` is not included prior to a use of `std::initializer_list` — even an implicit use in which the type is not named (9.1.7.5) — the program is ill-formed.

3 List-initialization of an object or reference of type T is defined as follows:

(3.1) — If the braced-init-list contains a designated-initializer-list, T shall be an aggregate class. The ordered identifiers in the designators of the designated-initializer-list shall form a subsequence of the ordered identifiers in the direct non-static data members of T. Aggregate initialization is performed (9.3.1).

Example:

```cpp
struct A { int x; int y; int z; };
A a{y = 2, x = 1}; // error: designator order does not match declaration order
A b{z = 2};        // OK, b.y initialized to 0
```

— end example]

(3.2) — If T is an aggregate class and the initializer list has a single element of type cv U, where U is T or a class derived from T, the object is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization).

(3.3) — Otherwise, if T is a character array and the initializer list has a single element that is an appropriately-typed string literal (9.3.2), initialization is performed as described in that subclause.

(3.4) — Otherwise, if T is an aggregate, aggregate initialization is performed (9.3.1).
N4820

© ISO/IEC

[Example:
double ad[] = { 1, 2.0 };
int ai[] = { 1, 2.0 };

// OK
// error: narrowing

struct S2 {
int m1;
double m2, m3;
};
S2 s21 = { 1, 2, 3.0 };
S2 s22 { 1.0, 2, 3 };
S2 s23 { };

// OK
// error: narrowing
// OK: default to 0,0,0

— end example]
(3.5)

— Otherwise, if the initializer list has no elements and T is a class type with a default constructor, the
object is value-initialized.

(3.6)

— Otherwise, if T is a specialization of std::initializer_list<E>, the object is constructed as described
below.

(3.7)

— Otherwise, if T is a class type, constructors are considered. The applicable constructors are enumerated
and the best one is chosen through overload resolution (12.3, 12.3.1.7). If a narrowing conversion (see
below) is required to convert any of the arguments, the program is ill-formed.
[Example:
struct S {
S(std::initializer_list<double>);
S(std::initializer_list<int>);
S();
// ...
};
S s1 = { 1.0, 2.0, 3.0 };
S s2 = { 1, 2, 3 };
S s3 = { };

// #1
// #2
// #3
// invoke #1
// invoke #2
// invoke #3

— end example]
[Example:
struct Map {
Map(std::initializer_list<std::pair<std::string,int>>);
};
Map ship = {{"Sophie",14}, {"Surprise",28}};

— end example]
[Example:
struct S {
// no initializer-list constructors
S(int, double, double);
S();
// ...
};
S s1 = { 1, 2, 3.0 };
S s2 { 1.0, 2, 3 };
S s3 { };

// #1
// #2
// OK: invoke #1
// error: narrowing
// OK: invoke #2

— end example]
(3.8)

— Otherwise, if T is an enumeration with a fixed underlying type (9.6), the initializer-list has a single
element v, and the initialization is direct-list-initialization, the object is initialized with the value
T(v) (7.6.1.3); if a narrowing conversion is required to convert v to the underlying type of T, the
program is ill-formed. [Example:
enum
byte
byte
byte
byte

§ 9.3.4

byte : unsigned char { };
b { 42 };
c = { 42 };
d = byte{ 42 };
e { -1 };

//
//
//
//

OK
error
OK; same value as b
error

195


struct A { byte b; };  
A a1 = { { 42 } }; // error  
A a2 = { byte( 42 ) }; // OK  

void f(byte);  
f({ 42 }); // error  

enum class Handle : uint32_t { Invalid = 0 };  
Handle h { 42 }; // OK  

— end example]  

— Otherwise, if the initializer list has a single element of type \( E \) and either \( T \) is not a reference type or its referenced type is reference-related to \( E \), the object or reference is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization); if a narrowing conversion (see below) is required to convert the element to \( T \), the program is ill-formed.  

[Example:  
int x1 {2}; // OK  
int x2 {2.0}; // error: narrowing  
— end example]  

— Otherwise, if \( T \) is a reference type, a prvalue of the type referenced by \( T \) is generated. The prvalue initializes its result object by copy-list-initialization. The prvalue is then used to direct-initialize the reference. [Note: As usual, the binding will fail and the program is ill-formed if the reference type is an lvalue reference to a non-const type. — end note]  

[Example:  
struct S {  
S(std::initializer_list<double>); // #1  
S(const std::string&); // #2  
// ...  
};  
const S& r1 = { 1, 2, 3.0 }; // OK: invoke #1  
const S& r2 { "Spinach" }; // OK: invoke #2  
S& r3 = { 1, 2, 3 }; // error: initializer is not an value  
const int& i1 = { 1 }; // OK  
const int& i2 = { 1.1 }; // error: narrowing  
const int (&iar)[2] = { 1, 2 }; // OK: iar is bound to temporary array  
}

struct A { } a;  
struct B { explicit B(const A&); };  
const B &b2{a}; // error: cannot copy-list-initialize B temporary from A  
— end example]  

— Otherwise, if the initializer list has no elements, the object is value-initialized.  

[Example:  
int** pp {}; // initialized to null pointer  
— end example]  

— Otherwise, the program is ill-formed.  

[Example:  
struct A { int i; int j; };  
A a1 { 1, 2 }; // aggregate initialization  
A a2 { 1.2 }; // error: narrowing  
struct B {  
B(std::initializer_list<int>);  
};  
B b1 { 1, 2 }; // creates initializer_list<int> and calls constructor  
B b2 { 1, 2.0 }; // error: narrowing  
struct C {  
C(int i, double j);  
};

§ 9.3.4 196
Within the initializer-list of a braced-init-list, the initializer-clauses, including any that result from pack expansions (13.6.3), are evaluated in the order in which they appear. That is, every value computation and side effect associated with a given initializer-clause is sequenced before every value computation and side effect associated with any initializer-clause that follows it in the comma-separated list of the initializer-list. [Note: This evaluation ordering holds regardless of the semantics of the initialization; for example, it applies when the elements of the initializer-list are interpreted as arguments of a constructor call, even though ordinarily there are no sequencing constraints on the arguments of a call. — end note]

An object of type std::initializer_list<E> is constructed from an initializer list as if the implementation generated and materialized (7.3.4) a prvalue of type “array of \( N \) const E”, where \( N \) is the number of elements in the initializer list. Each element of that array is copy-initialized with the corresponding element of the initializer list, and the std::initializer_list<E> object is constructed to refer to that array. [Note: A constructor or conversion function selected for the copy shall be accessible (11.8) in the context of the initializer list. — end note] If a narrowing conversion is required to initialize any of the elements, the program is ill-formed. [Example:

```cpp
struct X {
    X(std::initializer_list<double> v);
};
X x{ 1, 2, 3 };
```

The initialization will be implemented in a way roughly equivalent to this:

```cpp
const double __a[3] = {double{1}, double{2}, double{3}};
X x(std::initializer_list<double>(__a, __a+3));
```

assuming that the implementation can construct an initializer_list object with a pair of pointers. — end example]

The array has the same lifetime as any other temporary object (6.6.7), except that initializing an initializer_list object from the array extends the lifetime of the array exactly like binding a reference to a temporary. [Example:

```cpp
typedef std::complex<double> cmplx;
std::vector<cmplx> v1 = { 1, 2, 3};

void f() {
    std::vector<cmplx> v2{ 1, 2, 3};
    std::initializer_list<int> i3 = { 1, 2, 3};
}

struct A {
    std::initializer_list<int> i4;
    A() : i4{ 1, 2, 3 } {} // ill-formed, would create a dangling reference
};
```

For v1 and v2, the initializer_list object is a parameter in a function call, so the array created for \{ 1, 2, 3 \} has full-expression lifetime. For i3, the initializer_list object is a variable, so the array persists for the lifetime of the variable. For i4, the initializer_list object is initialized in the constructor’s ctor-initializer as if by binding a temporary array to a reference member, so the program is ill-formed (11.9.2). — end example] [Note: The implementation is free to allocate the array in read-only memory if an explicit array with the same initializer could be so allocated. — end note]

A narrowing conversion is an implicit conversion

(7.1) — from a floating-point type to an integer type, or

(7.2) — from long double to double or float, or from double to float, except where the source is a constant expression and the actual value after conversion is within the range of values that can be represented (even if it cannot be represented exactly), or
(7.3) — from an integer type or unscoped enumeration type to a floating-point type, except where the source is a constant expression and the actual value after conversion will fit into the target type and will produce the original value when converted back to the original type, or

(7.4) — from an integer type or unscoped enumeration type to an integer type that cannot represent all the values of the original type, except where the source is a constant expression whose value after integral promotions will fit into the target type.

[Note: As indicated above, such conversions are not allowed at the top level in list-initializations. — end note]

[Example:

```c
int x = 999; // x is not a constant expression
const int y = 999;
const int z = 99;
char c1 = x; // OK, though it might narrow (in this case, it does narrow)
char c2(x); // error: might narrow
char c3(y); // error: narrows (assuming char is 8 bits)
char c4(z); // OK: no narrowing needed
unsigned char uc1 = {5}; // OK: no narrowing needed
unsigned char uc2 = {-1}; // error: narrows
unsigned int ui1 = {-1}; // error: narrows
signed int si1 = { (unsigned int)-1 }; // error: narrows
int ii = {2.0}; // error: narrows
float f1 { x }; // error: might narrow
float f2 { 7 }; // OK: 7 can be exactly represented as a float
int f(int);
int a[] = { 2, f(2), f(2.0) }; // OK: the double-to-int conversion is not at the top level
```

— end example]

9.4 Function definitions

9.4.1 In general

1 Function definitions have the form

```
function-definition:
  attribute-specifier-seqopt decl-specifier-seqopt declarator virt-specifier-seqopt function-body
attribute-specifier-seqopt decl-specifier-seqopt declarator requires-clause function-body
```

Any informal reference to the body of a function should be interpreted as a reference to the non-terminal `function-body`. The optional `attribute-specifier-seq` in a `function-definition` appertains to the function. A `virt-specifier-seq` can be part of a `function-definition` only if it is a `member-declaration` (11.3).

2 In a `function-definition`, either `void declarator`; or `declarator`; shall be a well-formed function declaration as described in 9.2.3.5. A function shall be defined only in namespace or class scope. The type of a parameter or the return type for a function definition shall not be an incomplete or abstract (possibly cv-qualified) class type in the context of the function definition unless the function is deleted (9.4.3).

3 [Example: A simple example of a complete function definition is

```c
int max(int a, int b, int c) {
  int m = (a > b) ? a : b;
  return (m > c) ? m : c;
}
```

Here `int` is the `decl-specifier-seq`; `max(int a, int b, int c)` is the `declarator`; `{ /* ... */ }` is the `function-body`. — end example]

4 A `ctor-initializer` is used only in a constructor; see 11.3.4 and 11.9.

5 [Note: A `cv-qualifier-seq` affects the type of `this` in the body of a member function; see 9.2.3.2. — end note]

6 [Note: Unused parameters need not be named. For example,
void print(int a, int) {
    std::printf("a = %d\n", a);
}

— end note]

7 In the function-body, a function-local predefined variable denotes a block-scope object of static storage duration that is implicitly defined (see 6.3.3).

8 The function-local predefined variable __func__ is defined as if a definition of the form

    static const char __func__[] = "function-name";

had been provided, where function-name is an implementation-defined string. It is unspecified whether such a variable has an address distinct from that of any other object in the program.98 [Example:

    struct S {
        S() : s(__func__) { } // OK
        const char* s;
    };
    void f(const char* s = __func__); // error: __func__ is undeclared

— end example]

9.4.2 Explicitly-defaulted functions [dcl.fct.def.default]
1 A function definition whose function-body is of the form = default ; is called an explicitly-defaulted definition. A function that is explicitly defaulted shall

(1.1) — be a special member function or a comparison operator (7.6.8, 7.6.9, 7.6.10), and
(1.2) — not have default arguments.

2 The type $T_1$ of an explicitly defaulted function $F$ is allowed to differ from the type $T_2$ it would have had if it were implicitly declared, as follows:

(2.1) — $T_1$ and $T_2$ may have differing ref-qualifiers;
(2.2) — $T_1$ and $T_2$ may have differing exception specifications; and
(2.3) — if $T_2$ has a parameter of type const $C$&, the corresponding parameter of $T_1$ may be of type $C$&.

If $T_1$ differs from $T_2$ in any other way, then:

(2.4) — if $F$ is an assignment operator, and the return type of $T_1$ differs from the return type of $T_2$ or $T_1$’s parameter type is not a reference, the program is ill-formed;
(2.5) — otherwise, if $F$ is explicitly defaulted on its first declaration, it is defined as deleted;
(2.6) — otherwise, the program is ill-formed.

3 An explicitly-defaulted function that is not defined as deleted may be declared constexpr or consteval only if it would have been implicitly declared as constexpr. If a function is explicitly defaulted on its first declaration, it is implicitly considered to be constexpr if the implicit declaration would be.

4 [Example:

    struct S {
        constexpr S() = default; // ill-formed: implicit S() is not constexpr
        S(int a = 0) = default; // ill-formed: default argument
        void operator=(const S&) = default; // ill-formed: non-matching return type
        ~S() noexcept(false) = default; // OK, despite mismatched exception specification
    private:
        int i;
        S(S&) = default; // OK: private copy constructor
    };
    S::S(S&) = default; // OK: defines copy constructor

    struct T {
        T();
        T(T&&) noexcept(false);
    };

98) Implementations are permitted to provide additional predefined variables with names that are reserved to the implementation (5.10). If a predefined variable is not odr-used (6.2), its string value need not be present in the program image.

§ 9.4.2 199
struct U {
    T t;
    U();
    U(U &&) noexcept = default;
};
U u1;
U u2 = static_cast<U&&>(u1); // OK, calls std::terminate if T::T(T&&) throws

Explicitly-defaulted functions and implicitly-declared functions are collectively called defaulted functions, and the implementation shall provide implicit definitions for them (11.3.4, 11.3.6, 11.3.4.2, 11.3.5), which might mean defining them as deleted. A function is user-provided if it is user-declared and not explicitly defaulted or deleted on its first declaration. A user-provided explicitly-defaulted function (i.e., explicitly defaulted after its first declaration) is defined at the point where it is explicitly defaulted; if such a function is implicitly defined as deleted, the program is ill-formed. [Note: Declaring a function as defaulted after its first declaration can provide efficient execution and concise definition while enabling a stable binary interface to an evolving code base. —end note]

[Example:]

struct trivial {
    trivial() = default;
    trivial(const trivial&) = default;
    trivial(trivial&&) = default;
    trivial& operator=(const trivial&) = default;
    trivial& operator=(trivial&&) = default;
    ~trivial() = default;
};

struct nontrivial1 {
    nontrivial1();
};
nontrivial1::nontrivial1() = default; // not first declaration

9.4.3 Deleted definitions [dcl.fct.def.delete]

1 A function definition whose function-body is of the form = delete ; is called a deleted definition. A function with a deleted definition is also called a deleted function.

2 A program that refers to a deleted function implicitly or explicitly, other than to declare it, is ill-formed. [Note: This includes calling the function implicitly or explicitly and forming a pointer or pointer-to-member to the function. It applies even for references in expressions that are not potentially-evaluated. If a function is overloaded, it is referenced only if the function is selected by overload resolution. The implicit odr-use (6.2) of a virtual function does not, by itself, constitute a reference. —end note]

3 [Example: One can prevent default initialization and initialization by non-doubles with

struct onlydouble {
    onlydouble() = delete;
    template<class T>
    onlydouble(T) = delete;
    onlydouble(double);
};

—end example]

[Example: One can prevent use of a class in certain new-expressions by using deleted definitions of a user-declared operator new for that class.

struct sometype {
    void* operator new(std::size_t) = delete;
    void* operator new[](std::size_t) = delete;
};
sometype* p = new sometype; // error, deleted class operator new
sometype* q = new sometype[3]; // error, deleted class operator new[]

§ 9.4.3
Example: One can make a class uncopyable, i.e., move-only, by using deleted definitions of the copy constructor and copy assignment operator, and then providing defaulted definitions of the move constructor and move assignment operator.

```cpp
struct moveonly {
    moveonly() = default;
    moveonly(const moveonly&) = delete;
    moveonly(moveonly&&) = default;
    moveonly& operator=(const moveonly&) = delete;
    moveonly& operator=(moveonly&&) = default;
    ~moveonly() = default;
};
moveonly* p;
movenoity q(*p); // error, deleted copy constructor
```

—end example

9.4.4 Coroutine definitions

A function is a coroutine if it contains a coroutine-return-statement (8.6.4), an await-expression (7.6.2.3), or a yield-expression (7.6.17). The parameter-declaration-clause of the coroutine shall not terminate with an ellipsis that is not part of a parameter-declaration.

Example:

```cpp
task<int> f();

task<void> g1() {
    int i = co_await f();
    std::cout << "f() => " << i << std::endl;
}

template <typename... Args>
task<void> g2(Args&&...) {
    int i = co_await f();
    std::cout << "f() => " << i << std::endl;
}

task<void> g3(int a, ...) {
    int i = co_await f();
    std::cout << "f() => " << i << std::endl;
}
```

—end example

The promise type of a coroutine is `std::coroutine_traits<R, P1, ..., Pn>::promise_type`, where `R` is the return type of the function, and `P1...Pn` are the sequence of types of the function parameters, preceded by the type of the implicit object parameter (12.3.1) if the coroutine is a non-static member function. The promise type shall be a class type.

In the following, `pi` is an lvalue of type `Pi`, where `pi` denotes `*this` and `pi+1` denotes the `ith` function parameter for a non-static member function, and `pi` denotes the `ith` function parameter otherwise.

A coroutine behaves as if its function-body were replaced by:
{  
    promise-type promise promise-constructor-arguments;
    co_await promise.initial_suspend();
    try {
        function-body  
    } catch(...) {
        promise.unhandled_exception();
    }
    final-suspend:
    co_await promise.final_suspend();
}

where

— the await-expression containing the call to initial_suspend is the initial suspend point, and
— the await-expression containing the call to final_suspend is the final suspend point, and
— promise-type denotes the promise type, and
— the object denoted by the exposition-only name promise is the promise object of the coroutine, and
— the label denoted by the name final-suspend is defined for exposition only (8.6.4), and
— promise-constructor-arguments is determined as follows: overload resolution is performed on a promise 
    constructor call created by assembling an argument list with lvalues p₁,...,pₙ. If a viable constructor is 
    found (12.3.2), then promise-constructor-arguments is (p₁,...,pₙ), otherwise promise-constructor- 
    arguments is empty.

6 The unqualified-ids return_void and return_value are looked up in the scope of the promise type. If both 
    are found, the program is ill-formed. [Note: If the unqualified-id return_void is found, flowing off the end 
    of a coroutine is equivalent to a co_return with no operand. Otherwise, flowing off the end of a coroutine 
    results in undefined behavior (8.6.4). — end note]

7 The expression promise.get_return_object() is used to initialize the glvalue result or prvalue result object 
    of a call to a coroutine. The call to get_return_object is sequenced before the call to initial_suspend 
    and is invoked at most once.

8 A suspended coroutine can be resumed to continue execution by invoking a resumption member function 
    (17.12.3.4) of a coroutine handle (17.12.3) that refers to the coroutine. The function that invoked a resumption 
    member function is called the resumer. Invoking a resumption member function for a coroutine that is not 
    suspended results in undefined behavior.

9 An implementation may need to allocate additional storage for a coroutine. This storage is known as the 
    coroutine state and is obtained by calling a non-array allocation function (6.6.5.4.1). The allocation function’s 
    name is looked up in the scope of the promise type. If this lookup fails, the allocation function’s name is 
    looked up in the global scope. If the lookup finds an allocation function in the scope of the promise type, 
    overload resolution is performed on a function call created by assembling an argument list. The first argument 
    is the amount of space requested, and has type std::size_t. The lvalues p₁,...,pₙ are the succeeding 
    arguments. If no viable function is found (12.3.2), overload resolution is performed again on a function call 
    created by passing just the amount of space required as an argument of type std::size_t.

10 The unqualified-id get_return_object_on_allocation_failure is looked up in the scope of the promise 
    type by class member access lookup (6.4.5). If any declarations are found, then the result of a call to an 
    allocation function used to obtain storage for the coroutine state is assumed to return nullptr if it fails to 
    obtain storage, and if a global allocation function is selected, the ::operator new(size_t, nothrow_t) form 
    is used. The allocation function used in this case shall have a non-throwing noexcept-specification. If 
    the allocation function returns nullptr, the coroutine returns control to the caller of the coroutine and the 
    return value is obtained by a call to T::get_return_object_on_allocation_failure(), where T is the 
    promise type.

[Example:
#include <iostream>
#include <coroutine>

// ::operator new(size_t, nothrow_t) will be used if allocation is needed
struct generator {
    struct promise_type;
}
using handle = std::coroutine_handle<promise_type>;
struct promise_type {
    int current_value;
    static auto get_return_object_on_allocation_failure() { return generator{nullptr}; }
    auto get_return_object() { return generator{handle::from_promise(*this)}; }
    auto initial_suspend() { return std::suspend_always{}; }
    auto final_suspend() { return std::suspend_always{}; }
    void unhandled_exception() { std::terminate(); }
    void return_void() {}
    auto yield_value(int value) {
        current_value = value;
        return std::suspend_always{};
    }
};
bool move_next() { return coro ? (coro.resume(), !coro.done()) : false; }
int current_value() { return coro.promise().current_value; }
generator(generator const&) = delete;
generator(generator && rhs) : coro(rhs.coro) { rhs.coro = nullptr; }
~generator() { if (coro) coro.destroy(); }
private:
generator(handle h) : coro(h) {}
handle coro;
};
generator f() { co_yield 1; co_yield 2; }
int main() {
    auto g = f();
    while (g.move_next()) std::cout << g.current_value() << std::endl;
}

The coroutine state is destroyed when control flows off the end of the coroutine or the destroy member function (17.12.3.4) of a coroutine handle (17.12.3) that refers to the coroutine is invoked. In the latter case objects with automatic storage duration that are in scope at the suspend point are destroyed in the reverse order of the construction. The storage for the coroutine state is released by calling a non-array deallocation function (6.6.5.4.2). If destroy is called for a coroutine that is not suspended, the program has undefined behavior.

The deallocation function’s name is looked up in the scope of the promise type. If this lookup fails, the deallocation function’s name is looked up in the global scope. If deallocation function lookup finds both a usual deallocation function with only a pointer parameter and a usual deallocation function with both a pointer parameter and a size parameter, then the selected deallocation function shall be the one with two parameters. Otherwise, the selected deallocation function shall be the function with one parameter. If no usual deallocation function is found, the program is ill-formed. The selected deallocation function shall be called with the address of the block of storage to be reclaimed as its first argument. If a deallocation function with a parameter of type std::size_t is used, the size of the block is passed as the corresponding argument.

When a coroutine is invoked, a copy is created for each coroutine parameter. Each such copy is an object with automatic storage duration that is direct-initialized from an lvalue referring to the corresponding parameter if the parameter is an lvalue reference, and from an xvalue referring to it otherwise. A reference to a parameter in the function-body of the coroutine and in the call to the coroutine promise constructor is replaced by a reference to its copy. The initialization and destruction of each parameter copy occurs in the context of the called coroutine. Initializations of parameter copies are sequenced before the call to the coroutine promise constructor and indeterminately sequenced with respect to each other. The lifetime of parameter copies ends immediately after the lifetime of the coroutine promise object ends. [Note: If a coroutine has a parameter passed by reference, resuming the coroutine after the lifetime of the entity referred to by that parameter has ended is likely to result in undefined behavior. — end note]

If the evaluation of the expression promise.unhandled_exception() exits via an exception, the coroutine is considered suspended at the final suspend point.

The expression co_await promise.final_suspend() shall not be potentially-throwing (14.4).
9.5 Structured binding declarations

A structured binding declaration introduces the identifiers \( v_0, v_1, v_2, \ldots \) of the identifier-list as names (6.3.1) of structured bindings. Let \( cv \) denote the \( cv\)-qualifiers in the decl-specifier-seq and \( S \) consist of the storage-class-specifiers of the decl-specifier-seq (if any). First, a variable with a unique name \( e \) is introduced. If the assignment-expression in the initializer has array type \( A \) and no ref-qualifier is present, \( e \) is defined by

```
attribute-specifier-seqopt S cv A e ;
```

and each element is copy-initialized or direct-initialized from the corresponding element of the assignment-expression as specified by the form of the initializer. Otherwise, \( e \) is defined as-if by

```
attribute-specifier-seqopt decl-specifier-seq ref-qualifieropt e initializer ;
```

where the declaration is never interpreted as a function declaration and the parts of the declaration other than the declarator-id are taken from the corresponding structured binding declaration. The type of the id-expression \( e \) is called \( E \). [Note: \( E \) is never a reference type (7.2). — end note]

If the initializer refers to one of the names introduced by the structured binding declaration, the program is ill-formed.

If \( E \) is an array type with element type \( T \), the number of elements in the identifier-list shall be equal to the number of elements of \( E \). Each \( v_i \) is the name of an lvalue that refers to the element \( i \) of the array and whose type is \( T \). [Note: The top-level cv-qualifiers of \( T \) are \( cv \). — end note] [Example:]

```
auto f() -> int(&)[2];
auto [ x, y ] = f();  // x and y refer to elements in a copy of the array return value
auto& [ xr, yr ] = f(); // xr and yr refer to elements in the array referred to by f’s return value
```

Otherwise, if the qualified-id \( \text{std} :: \text{tuple\_size}<E> \) names a complete class type with a member named value, the expression \( \text{std} :: \text{tuple\_size}<E>::\text{value} \) shall be a well-formed integral constant expression and the number of elements in the identifier-list shall be equal to the value of that expression. Let \( i \) be an index prvalue of type \( \text{std} :: \text{size\_t} \) corresponding to \( v_i \). The unqualified-id \( \text{get} \) is looked up in the scope of \( E \) by class member access lookup (6.4.5), and if that finds at least one declaration that is a function template whose first template parameter is a non-type parameter, the initializer is \( e.\text{get<i>}() \). Otherwise, the initializer is \( \text{get}<i>(e) \), where \( \text{get} \) is looked up in the associated namespaces (6.4.2). In either case, \( \text{get}<i> \) is interpreted as a template-id. [Note: Ordinary unqualified lookup (6.4.1) is not performed. — end note] In either case, \( e \) is an lvalue if the type of the entity \( e \) is an lvalue reference and an xvalue otherwise. Given the type \( T_i \) designated by \( \text{std} :: \text{tuple\_element}<i, E>::\text{type} \) and the type \( U \), designated by either \( T_i& \) or \( T_i&& \), where \( U \) is an lvalue reference if the initializer is an lvalue and an rvalue reference otherwise, variables are introduced with unique names \( r_i \), as follows:

```
S U, r_i = initializer ;
```

Each \( v_i \) is the name of an lvalue of type \( T_i \) that refers to the object bound to \( r_i \); the referenced type is \( T_i \).

Otherwise, all of \( E \)'s non-static data members shall be direct members of \( E \) or of the same base class of \( E \), well-formed when named as \( e.\text{name} \) in the context of the structured binding, \( E \) shall not have an anonymous union member, and the number of elements in the identifier-list shall be equal to the number of non-static data members of \( E \). Designating the non-static data members of \( E \) as \( m_0, m_1, m_2, \ldots \) (in declaration order), each \( v_i \) is the name of an lvalue that refers to the member \( m_i \) of \( e \) and whose type is \( cv T_i \), where \( T_i \) is the declared type of that member; the referenced type is \( cv T_i \). The lvalue is a bit-field if that member is a bit-field. [Example:]

```
struct S { int x1 : 2; volatile double y1;};
S f();
const auto [ x, y ] = f();
```

The type of the id-expression \( x \) is “\text{const} \text{int}”, the type of the id-expression \( y \) is “\text{const volatile double}”. — end example]

9.6 Enumeration declarations

An enumeration is a distinct type (6.7.2) with named constants. Its name becomes an enum-name within its scope.

```
enum-name:
  identifier
```

§ 9.6 204
enum-specifier:
  
enum-head { enumerator-listopt }
enum-head { enumerator-list , }

enum-head:
  
enum-key attribute-specifier-seqopt enum-head-nameopt enum-baseopt

enum-head-name:
  
nested-name-specifieropt identifier

opaque-enum-declaration:
  
enum-key attribute-specifier-seqopt enum-head-name enum-baseopt ;

enum-key:

enum
enum class
enum struct

enum-base:
  
: type-specifier-seq

enumerator-list:
  
enumerator-definition
enumerator-list , enumerator-definition

enumerator-definition:
  
enumerator
enumerator = constant-expression

enumerator:
  
identifier attribute-specifier-seqopt

The optional attribute-specifier-seq in the enum-head and the opaque-enum-declaration appertains to the enumeration; the attributes in that attribute-specifier-seq are thereafter considered attributes of the enumeration whenever it is named. A : following “enum nested-name-specifieropt identifier” within the decl-specifier-seq of a member-declaration is parsed as part of an enum-base. [Note: This resolves a potential ambiguity between the declaration of an enumeration with an enum-base and the declaration of an unnamed bit-field of enumeration type. ]

```c
struct S {
  enum E : int {};
  enum E : int {}; // error: redeclaration of enumeration
};
```

— end example] — end note] If the enum-head-name of an opaque-enum-declaration contains a nested-name-specifier, the declaration shall be an explicit specialization (13.8.3).

The enumeration type declared with an enum-key of only enum is an unscoped enumeration, and its enumerators are unscoped enumerators. The enum-keys enum class and enum struct are semantically equivalent: an enumeration type declared with one of these is a scoped enumeration, and its enumerators are scoped enumerators. The optional enum-head-name shall not be omitted in the declaration of a scoped enumeration. The type-specifier-seq of an enum-base shall name an integral type; any cv-qualification is ignored. An opaque-enum-declaration declaring an unscoped enumeration shall not omit the enum-base. The identifiers in an enumerator-list are declared as constants, and can appear wherever constants are required. An enumerator-definition with = gives the associated enumerator the value indicated by the constant-expression. If the first enumerator has no initializer, the value of the corresponding constant is zero. An enumerator-definition without an initializer gives the enumerator the value obtained by increasing the value of the previous enumerator by one. [Example:

```c
enum { a, b, c=0 };
enum { d, e, f=e+2 };
```

defines a, c, and d to be zero, b and e to be 1, and f to be 3. — end example] The optional attribute-specifier-seq in an enumerator appertains to that enumerator.

An opaque-enum-declaration is either a redeclaration of an enumeration in the current scope or a declaration of a new enumeration. [Note: An enumeration declared by an opaque-enum-declaration has a fixed underlying type and is a complete type. The list of enumerators can be provided in a later redeclaration with an enum-specifier. — end note] A scoped enumeration shall not be later redeclared as unscoped or with
a different underlying type. An unscoped enumeration shall not be later redeclared as scoped and each
redeclaration shall include an `enum-base` specifying the same underlying type as in the original declaration.

4 If an `enum-head-name` contains a `nested-name-specifier`, it shall not begin with a `decltype-specifier` and
the enclosing `enum-specifier` or `opaque-enum-declaration` shall refer to an enumeration that was previously
declared directly in the class or namespace to which the `nested-name-specifier` refers, or in an element of the
inline namespace set (9.7.1) of that namespace (i.e., neither inherited nor introduced by a `using-declaration`),
and the `enum-specifier` or `opaque-enum-declaration` shall appear in a namespace enclosing the previous
declaration.

5 Each enumeration defines a type that is different from all other types. Each enumeration also has an `underlying
type`. The underlying type can be explicitly specified using an `enum-base`. For a scoped enumeration type, the
underlying type is `int` if it is not explicitly specified. In both of these cases, the underlying type is said to be
`fixed`. Following the closing brace of an `enum-specifier`, each enumerator has the type of its enumeration. If
the underlying type is fixed, the type of each enumerator prior to the closing brace is the underlying type and
the `constant-expression` in the `enumerator-definition` shall be a converted constant expression of the
underlying type (7.7). If the underlying type is not fixed, the type of each enumerator prior to the closing
brace is determined as follows:

1. If an initializer is specified for an enumerator, the `constant-expression` shall be an integral constant
expression (7.7). If the expression has unscoped enumeration type, the enumerator has the underlying
type of that enumeration type, otherwise it has the same type as the expression.
2. If no initializer is specified for the first enumerator, its type is an unspecified signed integral type.
3. Otherwise the type of the enumerator is the same as that of the preceding enumerator unless the
incremented value is not representable in that type, in which case the type is an unspecified integral
type sufficient to contain the incremented value. If no such type exists, the program is ill-formed.

6 An enumeration whose underlying type is fixed is an incomplete type from its point of declaration (6.3.2)
to immediately after its `enum-base` (if any), at which point it becomes a complete type. An enumeration
whose underlying type is not fixed is not an incomplete type from its point of declaration to immediately after
the closing `}` of its `enum-specifier`, at which point it becomes a complete type.

7 For an enumeration whose underlying type is not fixed, the underlying type is an integral type that can
represent all the enumerator values defined in the enumeration. If no integral type can represent all the
enumerator values, the enumeration is ill-formed. It is implementation-defined which integral type is used
as the underlying type except that the underlying type shall not be larger than `int` unless the value of an
enumerator cannot fit in an `int` or `unsigned int`. If the `enumerator-list` is empty, the underlying type is as
if the enumeration had a single enumerator with value 0.

8 For an enumeration whose underlying type is fixed, the values of the enumeration are the values of the
underlying type. Otherwise, the values of the enumeration are the values representable by a hypothetical
integer type with minimal width \( M \) such that all enumerators can be represented. The width of the smallest
bit-field large enough to hold all the values of the enumeration type is \( M \). It is possible to define an
enumeration that has values not defined by any of its enumerators. If the `enumerator-list` is empty, the values
of the enumeration are as if the enumeration had a single enumerator with value 0.

9 Two enumeration types are `layout-compatible enumerations` if they have the same underlying type.

10 The value of an enumerator or an object of an unscoped enumeration type is converted to an integer by
integral promotion (7.3.6). [Example:

```c
enum color { red, yellow, green=20, blue };  
color col = red;  
color* cp = &col;  
if (*cp == blue) // ...
```

makes `color` a type describing various colors, and then declares `col` as an object of that type, and `cp` as a
pointer to an object of that type. The possible values of an object of type `color` are `red`, `yellow`, `green`,
`blue`; these values can be converted to the integral values 0, 1, 20, and 21. Since enumerations are distinct
types, objects of type `color` can be assigned only values of type `color`.

```c
color c = 1;  // error: type mismatch, no conversion from int to color
int i = yellow;  // OK: yellow converted to integral value 1, integral promotion
```

99) This set of values is used to define promotion and conversion semantics for the enumeration type. It does not preclude an
expression of enumeration type from having a value that falls outside this range.
Note that this implicit `enum` to `int` conversion is not provided for a scoped enumeration:

```cpp
enum class Col { red, yellow, green };  
int x = Col::red;  // error: no Col to int conversion
Col y = Col::red;  // error: no Col to bool conversion
```

—end example

Each `enum-name` and each unscoped `enumerator` is declared in the scope that immediately contains the `enum-specifier`. Each scoped `enumerator` is declared in the scope of the enumeration. These names obey the scope rules defined for all names in 6.3 and 6.4.([Example:]

```cpp
enum direction { left='l', right='r' };  
void g() {
    direction d;  // OK
    d = left;  // OK
    d = direction::right;  // OK
}

enum class altitude { high='h', low='l' };  
void h() {
    altitude a;  // OK
    a = high;  // error: high not in scope
    a = altitude::low;  // OK
}
```

—end example] An enumerator declared in class scope can be referred to using the class member access operators (`::`, `. (dot) and -> (arrow)`, see 7.6.1.4.([Example:]

```cpp
struct X {
    enum direction { left='l', right='r' };  
    int f(int i) { return i==left ? 0 : i==right ? 1 : 2; }
};

void g(X* p) {
    direction d;  // error: direction not in scope
    int i;
    i = p->f(left);  // error: left not in scope
    i = p->f(X::right);  // OK
    i = p->f(p->left);  // OK
    // ...
}
```

—end example]

### 9.7 Namespaces

[basic.namespace]  
A namespace is an optionally-named declarative region. The name of a namespace can be used to access entities declared in that namespace; that is, the members of the namespace. Unlike other declarative regions, the definition of a namespace can be split over several parts of one or more translation units.

[Note: A namespace name with external linkage is exported if any of its `namespace-definitions` is exported, or if it contains any `export-declarations (10.2)`. A namespace is never attached to a module, and never has module linkage even if it is not exported. — end note] [Example:

```cpp
export module M;
namespace N1 {}  // N1 is not exported
export namespace N2 {}  // N2 is exported
namespace N3 { export int n; }  // N3 is exported
```

—end example]

The outermost declarative region of a translation unit is a namespace; see 6.3.6.
9.7.1 Namespace definition

namespace-name:
    identifier
namespace-alias

namespace-definition:
    named-namespace-definition
    unnamed-namespace-definition
    nested-namespace-definition

named-namespace-definition:
    inline_opt namespace attribute-specifier-seq_opt identifier { namespace-body }

unnamed-namespace-definition:
    inline_opt namespace attribute-specifier-seq_opt { namespace-body }

nested-namespace-definition:
    namespace enclosing-namespace-specifier :: inline_opt identifier { namespace-body }

enclosing-namespace-specifier:
    identifier
    enclosing-namespace-specifier :: inline_opt identifier

namespace-body:
    declaration-seq_opt

1 Every namespace-definition shall appear at namespace scope (6.3.6).

2 In a named-namespace-definition, the identifier is the name of the namespace. If the identifier, when looked up (6.4.1), refers to a namespace-name (but not a namespace-alias) that was introduced in the namespace in which the named-namespace-definition appears or that was introduced in a member of the inline namespace set of that namespace, the namespace-definition extends the previously-declared namespace. Otherwise, the identifier is introduced as a namespace-name into the declarative region in which the named-namespace-definition appears.

3 Because a namespace-definition contains declarations in its namespace-body and a namespace-definition is itself a declaration, it follows that namespace-declarations can be nested. [Example:

```c
namespace Outer {
    int i;
    namespace Inner {
        void f() { i++; } // Outer::i
        int i;
        void g() { i++; } // Inner::i
    }
}
```
—end example]

4 The enclosing namespaces of a declaration are those namespaces in which the declaration lexically appears, except for a redeclaration of a namespace member outside its original namespace (e.g., a definition as specified in 9.7.1.2). Such a redeclaration has the same enclosing namespaces as the original declaration. [Example:

```c
namespace Q {
    namespace V {
        void f(); // enclosing namespaces are the global namespace, Q, and Q::V
        class C { void m(); };  
    }
    void V::f() { // enclosing namespaces are the global namespace, Q, and Q::V
        extern void h(); // ... so this declares Q::V::h
    }
    void V::C::m() { // enclosing namespaces are the global namespace, Q, and Q::V
    }
}
```
—end example]

5 If the optional initial inline keyword appears in a namespace-definition for a particular namespace, that namespace is declared to be an inline namespace. The inline keyword may be used on a namespace-definition that extends a namespace only if it was previously used on the namespace-definition that initially declared the namespace-name for that namespace.
6 The optional attribute-specifier-seq in a named-namespace-definition appertains to the namespace being defined or extended.

7 Members of an inline namespace can be used in most respects as though they were members of the enclosing namespace. Specifically, the inline namespace and its enclosing namespace are both added to the set of associated namespaces used in argument-dependent lookup (6.4.2) whenever one of them is, and a using-directive (9.7.3) that names the inline namespace is implicitly inserted into the enclosing namespace as for an unnamed namespace (9.7.1.1). Furthermore, each member of the inline namespace can subsequently be partially specialized (13.6.5), explicitly instantiated (13.8.2), or explicitly specialized (13.8.3) as though it were a member of the enclosing namespace. Finally, looking up a name in the enclosing namespace via explicit qualification (6.4.3.2) will include members of the inline namespace brought in by the using-directive even if there are declarations of that name in the enclosing namespace.

8 These properties are transitive: if a namespace N contains an inline namespace M, which in turn contains an inline namespace O, then the members of O can be used as though they were members of M or N. The inline namespace set of N is the transitive closure of all inline namespaces in N. The enclosing namespace set of O is the set of namespaces consisting of the innermost non-inline namespace enclosing an inline namespace O, together with any intervening inline namespaces.

9 A nested-namespace-definition with an enclosing-namespace-specifier E, identifier I and namespace-body B is equivalent to

namespace E {
  inline
  namespace I {
    B
  }
}

where the optional inline is present if and only if the identifier I is preceded by inline. [Example:

namespace A::inline B::C {
  int i;
}

The above has the same effect as:

namespace A {
  inline namespace B {
    namespace C {
      int i;
    }
  }
}

—end example]

9.7.1.1 Unnamed namespaces

An unnamed-namespace-definition behaves as if it were replaced by

inline_opt namespace unique { /* empty body */ }
using namespace unique ;
namespace unique { namespace-body }

where inline appears if and only if it appears in the unnamed-namespace-definition and all occurrences of unique in a translation unit are replaced by the same identifier, and this identifier differs from all other identifiers in the translation unit. The optional attribute-specifier-seq in the unnamed-namespace-definition appertains to unique. [Example:

namespace { int i; } // unique::i
void f() { i++; }    // unique::i++

namespace A {
  namespace {
    int i;            // A::unique::i
    int j;            // A::unique::j
  }
  void g() { i++; }  // A::unique::i++
}

using namespace A;
void h() {
  i++;               // error: unique::i or A::unique::i
  A::i++;            // A::unique::i

§ 9.7.1.1
9.7.1.2 Namespace member definitions [namespace.memdef]

A declaration in a namespace N (excluding declarations in nested scopes) whose *declarator-id* is an *unqualified-id* (9.2.3), whose *class-head-name* (Clause 11) or *enum-head-name* (9.6) is an *identifier*, or whose *elaborated-type-specifier* is of the form *class-key attribute-specifier-seq* opt *identifier* (9.1.7.3), or that is an *opaque-enum-declaration*, declares (or redeclares) its *unqualified-id* or *identifier* as a member of N. [Note: An explicit instantiation (13.8.2) or explicit specialization (13.8.3) of a template does not introduce a name and thus may be declared using an *unqualified-id* in a member of the enclosing namespace set, if the primary template is declared in an inline namespace. — end note] [Example:

```cpp
namespace X {
    void f() { /* ... */ } // OK: introduces X::f()
}
namespace M {
    void g(); // OK: introduces X::M::g()
    using M::g;
    void g(); // error: conflicts with X::M::g()
}
} // end example]
```

Members of a named namespace can also be defined outside that namespace by explicit qualification (6.4.3.2) of the name being defined, provided that the entity being defined was already declared in the namespace and the definition appears after the point of declaration in a namespace that encloses the declaration’s namespace. [Example:

```cpp
namespace Q {
    namespace V {
        void f();
    }
    void V::f() { /* ... */ } // OK
    void V::g() { /* ... */ } // error: g() is not yet a member of V
    namespace V {
        void g();
    }
}
namespace R {
    void Q::V::g() { /* ... */ } // error: R doesn’t enclose Q
}
} // end example]
```

If a friend declaration in a non-local class first declares a class, function, class template or function template the friend is a member of the innermost enclosing namespace. The friend declaration does not by itself make the name visible to unqualified lookup (6.4.1) or qualified lookup (6.4.3). [Note: The name of the friend will be visible in its namespace if a matching declaration is provided at namespace scope (either before or after the class definition granting friendship). — end note] If a friend function or function template is called, its name may be found by the name lookup that considers functions from namespaces and classes associated with the types of the function arguments (6.4.2). If the name in a friend declaration is neither qualified nor a *template-id* and the declaration is a function or an *elaborated-type-specifier*, the lookup to determine whether the entity has been previously declared shall not consider any scopes outside the innermost enclosing namespace. [Note: The other forms of friend declarations cannot declare a new member of the innermost enclosing namespace and thus follow the usual lookup rules. — end note] [Example:

```cpp
// Assume f and g have not yet been declared.
void h(int);
template <class T> void f2(T);
```
namespace A {
  class X {
    friend void f(X); // A::f(X) is a friend
    class Y {
      friend void g(); // A::g is a friend
      friend void h(int); // A::h is a friend
      // ::h not considered
      friend void f2<T>(int); // ::f2<T>(int) is a friend
    };
  };
  // A::f, A::g and A::h are not visible here
  X x;
  void g() { f(x); } // definition of A::g
  void f(X) { /* ... */ } // definition of A::f
  void h(int) { /* ... */ } // definition of A::h
  // A::f, A::g and A::h are visible here and known to be friends
};

using A::x;

void h() {
  A::f(x);
  A::X::f(x); // error: f is not a member of A::X
  A::X::Y::g(); // error: g is not a member of A::X::Y
}

—end example]

9.7.2 Namespace alias [namespace.alias]

1 A namespace-alias-definition declares an alternate name for a namespace according to the following grammar:

namespace-alias-definition:
  identifier

namespace-alias-definition:
  namespace identifier = qualified-name-specifier ;

qualified-name-specifier:
  nested-name-specifier opt namespace-name

2 The identifier in a namespace-alias-definition is a synonym for the name of the namespace denoted by the qualified-name-specifier and becomes a namespace-alias. [Note: When looking up a namespace-name in a namespace-alias-definition, only namespace names are considered, see 6.4.6. — end note]

3 In a declarative region, a namespace-alias-definition can be used to redefine a namespace-alias declared in that declarative region to refer only to the namespace to which it already refers. [Example: The following declarations are well-formed:

namespace Company_with_very_long_name { /* ... */ }
namespace CVVLN = Company_with_very_long_name;
namespace CVVLN = Company_with_very_long_name; // OK: duplicate
namespace CVVLN = CVVLN;

—end example]

9.7.3 Using directive [namespace.udir]

using-directive:
  attribute-specifier-seq opt using namespace nested-name-specifier opt namespace-name ;

1 A using-directive shall not appear in class scope, but may appear in namespace scope or in block scope. [Note: When looking up a namespace-name in a using-directive, only namespace names are considered, see 6.4.6. — end note] The optional attribute-specifier-seq appertains to the using-directive.

2 A using-directive specifies that the names in the nominated namespace can be used in the scope in which the using-directive appears after the using-directive. During unqualified name lookup (6.4.1), the names appear as if they were declared in the nearest enclosing namespace which contains both the using-directive and the
nominated namespace. \[Note: \text{In this context, “contains” means “contains directly or indirectly”.} \ — \text{end note}\]

3 A \textit{using-directive} does not add any members to the declarative region in which it appears. \[Example:

```cpp
namespace A {
    int i;
namespace B {
    namespace C {
        int i;
    }
    using namespace A::B::C;
    void f1() {
        i = 5;    \hspace{1em} \text{// OK, C::i visible in B and hides A::i}
    }
}
namespace D {
    using namespace B;
    using namespace C;
    void f2() {
        i = 5;    \hspace{1em} \text{// ambiguous, B::C::i or A::i?}
    }
}
void f3() {
    i = 5; \hspace{1em} \text{// uses A::i}
}
void f4() {
    i = 5; \hspace{1em} \text{// ill-formed; neither i is visible}
}
```

— end example]

4 For unqualified lookup (6.4.1), the \textit{using-directive} is transitive: if a scope contains a \textit{using-directive} that nominates a second namespace that itself contains \textit{using-directives}, the effect is as if the \textit{using-directives} from the second namespace also appeared in the first. \[Note: \text{For qualified lookup, see 6.4.3.2.} \ — \text{end note}\]

\[Example:

```cpp
namespace M {
    int i;
}
namespace N {
    int i;
    using namespace M;
}

void f() {
    using namespace N;
    i = 7; \hspace{1em} \text{// error: both M::i and N::i are visible}
}
```

For another example,

```cpp
namespace A {
    int i;
}
namespace B {
    int i;
    int j;
namespace C {
    namespace D {
        using namespace A;
        int j;
        int k;
        int a = i;    \hspace{1em} \text{// B::i hides A::i}
    }
```
using namespace D;
int k = 89;  // no problem yet
int l = k;   // ambiguous: C::k or D::k
int m = i;   // B::i hides A::i
int n = j;   // D::j hides B::j
}
}

—end example]

5 If a namespace is extended (9.7.1) after a using-directive for that namespace is given, the additional members of the extended namespace and the members of namespaces nominated by using-directives in the extending namespace-definition can be used after the extending namespace-definition.

6 [Note: If name lookup finds a declaration for a name in two different namespaces, and the declarations do not declare the same entity and do not declare functions or function templates, the use of the name is ill-formed (6.4). In particular, the name of a variable, function or enumerator does not hide the name of a class or enumeration declared in a different namespace. For example,

```c
namespace A {
  class X {);
  extern "C"  int g();
  extern "C++" int h();
}
namespace B {
  void X(int);
  extern "C"  int g();
  extern "C++" int h();
}
using namespace A;
using namespace B;

void f() {
  X(1);  // error: name X found in two namespaces
  g();   // OK: name g refers to the same entity
  h();   // OK: overload resolution selects A::h
}
—end note]

7 During overload resolution, all functions from the transitive search are considered for argument matching. The set of declarations found by the transitive search is unordered. [Note: In particular, the order in which namespaces were considered and the relationships among the namespaces implied by the using-directives do not cause preference to be given to any of the declarations found by the search. — end note] An ambiguity exists if the best match finds two functions with the same signature, even if one is in a namespace reachable through using-directives in the namespace of the other. 

101 [Example:

```c
namespace D {
  int d1;
  void f(char);
}
using namespace D;

int d1;          // OK: no conflict with D::d1

namespace E {
  int e;
  void f(int);
}

namespace D {    // namespace extension
  int d2;
  using namespace E;

101) During name lookup in a class hierarchy, some ambiguities may be resolved by considering whether one member hides the other along some paths (11.7). There is no such disambiguation when considering the set of names found as a result of following using-directives.
void f(int);
}

void f() {
  d1++;  // error: ambiguous ::d1 or D::d1?
  ::d1++;  // OK
  D::d1++;  // OK
  d2++;  // OK: D::d2
  e++;    // OK: E::e
  f(1);   // error: ambiguous: D::f(int) or E::f(int)?
  f('a');  // OK: D::f(char)
}

—end example]

9.8 The using declaration

using-declaration:
  using using-declarator-list ;

using-declarator-list:
  using-declarator ... opt
  using-declarator-list , using-declarator ... opt

using-declarator:
  typename_opt nested-name-specifier unqualified-id

1 Each using-declarator in a using-declaration\(^{102}\) introduces a set of declarations into the declarative region in which the using-declaration appears. The set of declarations introduced by the using-declarator is found by performing qualified name lookup (6.4.3, 11.7) for the name in the using-declarator, excluding functions that are hidden as described below. If the using-declarator does not name a constructor, the unqualified-id is declared in the declarative region in which the using-declaration appears as a synonym for each declaration introduced by the using-declarator. [Note: Only the specified name is so declared; specifying an enumeration name in a using-declaration does not declare its enumerators in the using-declaration’s declarative region. — end note] If the using-declarator names a constructor, it declares that the class inherits the set of constructor declarations introduced by the using-declarator from the nominated base class.

2 Every using-declaration is a declaration and a member-declaration and can therefore be used in a class definition. [Example:

```cpp
struct B {
  void f(char);
  void g(char);
  enum E { e };
  union { int x; };
};

struct D : B {
  using B::f;
  void f(int) { f('c'); }    // calls B::f(char)
  void g(int) { g('c'); }    // recursively calls D::g(int)
};
—end example]

3 In a using-declaration used as a member-declaration, each using-declarator’s nested-name-specifier shall name a base class of the class being defined. If a using-declarator names a constructor, its nested-name-specifier shall name a direct base class of the class being defined. [Example:

```cpp
template <typename... bases>
struct X : bases... {
  using bases::g...;
};
```

\(^{102}\) A using-declaration with more than one using-declarator is equivalent to a corresponding sequence of using-declarations with one using-declarator each.

§ 9.8
X<B, D> x; // OK: B::g and D::g introduced

— end example] [Example:

```cpp
class C {
  int g();
};
class D2 : public B {
  using B::f; // OK: B is a base of D2
  using B::e; // OK: e is an enumerator of base B
  using B::x; // OK: x is a union member of base B
  using C::g; // error: C isn't a base of D2
};
```— end example]

4 [Note: Since destructors do not have names, a using-declaration cannot refer to a destructor for a base class. Since specializations of member templates for conversion functions are not found by name lookup, they are not considered when a using-declaration specifies a conversion function (13.6.2). — end note] If a constructor or assignment operator brought from a base class into a derived class has the signature of a copy/move constructor or assignment operator for the derived class (11.3.4.2, 11.3.5), the using-declaration does not by itself suppress the implicit declaration of the derived class member; the member from the base class is hidden or overridden by the implicitly-declared copy/move constructor or assignment operator of the derived class, as described below.

5 A using-declaration shall not name a template-id. [Example:

```cpp
struct A {
  template <class T> void f(T);
  template <class T> struct X { };
};
struct B : A {
  using A::f<double>; // ill-formed
  using A::X<int>; // ill-formed
};
```— end example]

6 A using-declaration shall not name a namespace.

7 A using-declaration shall not name a scoped enumerator.

8 A using-declaration that names a class member shall be a member-declaration. [Example:

```cpp
struct X {
  int i;
  static int s;
};
void f() {
  using X::i; // error: X::i is a class member and this is not a member declaration.
  using X::s; // error: X::s is a class member and this is not a member declaration.
}
```— end example]

9 Members declared by a using-declaration can be referred to by explicit qualification just like other member names (6.4.3.2). [Example:

```cpp
void f();
namespace A {
  void g();
}
namespace X {
  using ::f; // global f
  using A::g; // A's g
}
```
A `using-declaration` is a declaration and can therefore be used repeatedly where (and only where) multiple declarations are allowed. [Example:

```cpp
namespace A {
  int i;
}

namespace A1 {
  using A::i, A::i; // OK: double declaration
}

struct B {
  int i;
};

struct X : B {
  using B::i, B::i; // error: double member declaration
};
```

—end example]

Note: For a `using-declaration` whose nested-name-specifier names a namespace, members added to the namespace after the `using-declaration` are not in the set of introduced declarations, so they are not considered when a use of the name is made. Thus, additional overloads added after the `using-declaration` are ignored, but default function arguments (9.2.3.6), default template arguments (13.1), and template specializations (13.6.5, 13.8.3) are considered. —end note] [Example:

```cpp
namespace A {
  void f(int);
}

using A::f; // f is a synonym for A::f; that is, for A::f(int).
namespace A {
  void f(char);
}

void foo() {
  f('a'); // calls f(int), even though f(char) exists.
}

void bar() {
  using A::f; // f is a synonym for A::f; that is, for A::f(int) and A::f(char).
  f('a'); // calls f(char)
}
```

—end example]

Note: Partial specializations of class templates are found by looking up the primary class template and then considering all partial specializations of that template. If a `using-declaration` names a class template, partial specializations introduced after the `using-declaration` are effectively visible because the primary template is visible (13.6.5). —end note]

Since a `using-declaration` is a declaration, the restrictions on declarations of the same name in the same declarative region (6.3) also apply to `using-declarations`. [Example:

```cpp
namespace A {
  int x;
}
```
namespace B {
    int i;
    struct g { };  // OK: hides struct g
    struct x { }
    void f(int);
    void f(double);
    void g(char);
}

void func() {
    int i;
    using B::i;   // error: i declared twice
    void f(char);
    using B::f;  // OK: each f is a function
    f(3.5);      // calls B::f(double)
    using B::g;
    g('a');      // calls B::g(char)
    struct g g1;  // g1 has class type B::g
    using B::x;
    using A::x;  // OK: hides struct B::x
    x = 99;      // assigns to A::x
    struct x x1;  // x1 has class type B::x
}

—end example

If a function declaration in namespace scope or block scope has the same name and the same parameter-
type-list (9.2.3.5) as a function introduced by a using-declaration, and the declarations do not declare the
same function, the program is ill-formed. If a function template declaration in namespace scope has the same
name, parameter-type-list, return type, and template parameter list as a function template introduced by a
using-declaration, the program is ill-formed. [Note: Two using-declarations may introduce functions with
the same name and the same parameter-type-list. If, for a call to an unqualified function name, function
overload resolution selects the functions introduced by such using-declarations, the function call is ill-formed.
[Example:

namespace B {
    void f(int);
    void f(double);
}
namespace C {
    void f(int);
    void f(double);
    void f(char);
}

void h() {
    using B::f;      // B::f(int) and B::f(double)
    using C::f;      // C::f(int), C::f(double), and C::f(char)
    f('h');         // calls C::f(char)
    f(1);           // error: ambiguous: B::f(int) or C::f(int)?
    void f(int);    // error: f(int) conflicts with C::f(int) and B::f(int)
}

—end example] — end note

When a using-declarator brings declarations from a base class into a derived class, member functions and
member function templates in the derived class override and/or hide member functions and member function
templates with the same name, parameter-type-list (9.2.3.5), cv-qualification, and ref-qualifier (if any) in
a base class (rather than conflicting). Such hidden or overridden declarations are excluded from the set of
declarations introduced by the using-declarator. [Example:

struct B {
    virtual void f(int);
    virtual void f(char);
    void g(int);
}

§ 9.8  217
void h(int);
);

struct D : B {
    using B::f;
    void f(int);  // OK: D::f(int) overrides B::f(int);

    using B::g;
    void g(char);  // OK

    using B::h;
    void h(int);  // OK: D::h(int) hides B::h(int)
};

void k(D* p) {
    p->f(1);  // calls D::f(int)
    p->f('a');  // calls B::f(char)
    p->g(1);  // calls B::g(int)
    p->g('a');  // calls D::g(char)
}

struct B1 {
    B1(int);
};

struct B2 {
    B2(int);
};

struct D1 : B1, B2 {
    using B1::B1;
    using B2::B2;
};

D1 d1(0);  // ill-formed: ambiguous

struct D2 : B1, B2 {
    using B1::B1;
    using B2::B2;
    D2(int);  // OK: D2::D2(int) hides B1::B1(int) and B2::B2(int)
};

D2 d2(0);  // calls D2::D2(int)

—end example

[Note: For the purpose of forming a set of candidates during overload resolution, the functions that are introduced by a using-declaration into a derived class are treated as though they were members of the derived class (11.7). In particular, the implicit object parameter is treated as if it were a reference to the derived class rather than to the base class (12.3.1). This has no effect on the type of the function, and in all other respects the function remains a member of the base class. — end note]

Constructors that are introduced by a using-declaration are treated as though they were constructors of the derived class when looking up the constructors of the derived class (6.4.3.1) or forming a set of overload candidates (12.3.1.3, 12.3.1.4, 12.3.1.7). [Note: If such a constructor is selected to perform the initialization of an object of class type, all subobjects other than the base class from which the constructor originated are implicitly initialized (11.9.3). A constructor of a derived class is sometimes preferred to a constructor of a base class if they would otherwise be ambiguous (12.3.3). — end note]

In a using-declarator that does not name a constructor, all members of the set of introduced declarations shall be accessible. In a using-declarator that names a constructor, no access check is performed. In particular, if a derived class uses a using-declarator to access a member of a base class, the member name shall be accessible. If the name is that of an overloaded member function, then all functions named shall be accessible. The base class members mentioned by a using-declarator shall be visible in the scope of at least one of the direct base classes of the class where the using-declarator is specified.

§ 9.8 218
[Note: Because a using-declarator designates a base class member (and not a member subobject or a member function of a base class subobject), a using-declarator cannot be used to resolve inherited member ambiguities.]

[Example:

```c
struct A { int x(); }
struct B : A { }
struct C : A {
   using A::x;
   int x(int);
};

struct D : B, C {
   using C::x;
   int x(double);
};
int f(D* d) {
   return d->x(); // error: overload resolution selects A::x, but A is an ambiguous base class
}
```
—end example] —end note]

19 A synonym created by a using-declaration has the usual accessibility for a member-declaration. A using-declarator that names a constructor does not create a synonym; instead, the additional constructors are accessible if they would be accessible when used to construct an object of the corresponding base class, and the accessibility of the using-declaration is ignored. [Example:

```c
class A {
private:
   void f(char);
public:
   void f(int);
protected:
   void g();
};

class B : public A {
   using A::f; // error: A::f(char) is inaccessible
   public:
      using A::g; // B::g is a public synonym for A::g
};
```
—end example]

—end example]

—end example]

20 If a using-declarator uses the keyword typename and specifies a dependent name (13.7.2), the name introduced by the using-declaration is treated as a typedef-name (9.1.3).

9.9 The asm declaration

An asm declaration has the form

```c
asm-definition:
   attribute-specifier-seqopt asm ( string-literal )
```

The asm declaration is conditionally-supported; its meaning is implementation-defined. The optional attribute-specifier-seq in an asm-definition appertains to the asm declaration. [Note: Typically it is used to pass information through the implementation to an assembler. —end note]

9.10 Linkage specifications

All function types, function names with external linkage, and variable names with external linkage have a language linkage. [Note: Some of the properties associated with an entity with language linkage are specific to each implementation and are not described here. For example, a particular language linkage may be associated with a particular form of representing names of objects and functions with external linkage, or with a particular calling convention, etc. —end note] The default language linkage of all function types, function names, and variable names is C++ language linkage. Two function types with different language linkages are distinct types even if they are otherwise identical.

Linkage (6.5) between C++ and non-C++ code fragments can be achieved using a linkage-specification:
The string-literal indicates the required language linkage. This document specifies the semantics for the string-literals "C" and "C++". Use of a string-literal other than "C" or "C++" is conditionally-supported, with implementation-defined semantics. [Note: Therefore, a linkage-specification with a string-literal that is unknown to the implementation requires a diagnostic. — end note] [Note: It is recommended that the spelling of the string-literal be taken from the document defining that language. For example, Ada (not ADA) and Fortran or FORTRAN, depending on the vintage. — end note]

Every implementation shall provide for linkage to functions written in the C programming language, "C", and linkage to C++ functions, "C++". [Example:

```c
complex sqrt(complex);  // C++ linkage by default
extern "C" {
    double sqrt(double);  // C linkage
}
```

— end example]

Linkage specifications nest. When linkage specifications nest, the innermost one determines the language linkage. A linkage specification does not establish a scope. A linkage-specification shall occur only in namespace scope (6.3). In a linkage-specification, the specified language linkage applies to the function types of all function declarators, function names with external linkage, and variable names with external linkage declared within the linkage-specification. [Example:

```c
extern "C" typedef void FUNC();
FUNC f2;  // the name f2 has C++ language linkage and the
         // function's type has C language linkage
extern "C" FUNC f3;  // the name of function f3 and the function's type have C language linkage
void (*pf2)(FUNC*);  // the name of the variable pf2 has C++ linkage and the type
                     // of pf2 is “pointer to C++ function that takes one parameter of type
                     // pointer to C function"
extern "C" {
    static void f4();  // the name of the function f4 has internal linkage (not C language linkage)
    // and the function's type has C language linkage.
}
extern "C" void f5() {
    extern void f4();  // OK: Name linkage (internal) and function type linkage (C language linkage)
    // obtained from previous declaration.
}
extern void f4();  // OK: Name linkage (internal) and function type linkage (C language linkage)
                   // obtained from previous declaration.
void f6() {
    extern void f4();  // OK: Name linkage (internal) and function type linkage (C language linkage)
    // obtained from previous declaration.
}
```

— end example] A C language linkage is ignored in determining the language linkage of the names of class members and the function type of class member functions. [Example:

```c
class C {
    void mf1(FUNC_c*);  // the name of the function mf1 and the member function's type have
                        // C++ language linkage; the parameter has type “pointer to C function”
    FUNC_c mf2;  // the name of the function mf2 and the member function's type have
```
5 If two declarations declare functions with the same name and parameter-type-list (9.2.3.5) to be members of the same namespace or declare objects with the same name to be members of the same namespace and the declarations give the names different language linkages, the program is ill-formed; no diagnostic is required if the declarations appear in different translation units. Except for functions with C++ linkage, a function declaration without a linkage specification shall not precede the first linkage specification for that function. A function can be declared without a linkage specification after an explicit linkage specification has been seen; the linkage explicitly specified in the earlier declaration is not affected by such a function declaration.

6 At most one function with a particular name can have C language linkage. Two declarations for a function with C language linkage with the same function name (ignoring the namespace names that qualify it) that appear in different namespace scopes refer to the same function. Two declarations for a variable with C language linkage with the same name (ignoring the namespace names that qualify it) that appear in different namespace scopes refer to the same variable. A variable with C language linkage shall not be declared with the same name as a function with C language linkage (ignoring the namespace names that qualify the respective names); no diagnostic is required if the declarations appear in different translation units. [Note: Only one definition for an entity with a given name with C language linkage may appear in the program (see 6.2); this implies that such an entity must not be defined in more than one namespace scope. — end note] [Example:

```cpp
int x;
namespace A {
    extern "C" int f();
    extern "C" int g() { return 1; }
    extern "C" int h();
    extern "C" int x(); // ill-formed: same name as global-space object x
}
namespace B {
    extern "C" int f(); // A::f and B::f refer to the same function
    extern "C" int g() { return 1; } // ill-formed, the function g with C language linkage has two definitions
}
int A::f() { return 98; } // definition for the function f with C language linkage
extern "C" int h() { return 97; } // definition for the function h with C language linkage
// A::h and ::h refer to the same function

— end example]

7 A declaration directly contained in a linkage-specification is treated as if it contains the extern specifier (9.1.1) for the purpose of determining the linkage of the declared name and whether it is a definition. Such a declaration shall not specify a storage class. [Example:

```cpp
extern "C" double f();
static double f(); // error
extern "C" int i; // declaration
```
extern "C" {
  int i;          // definition
}
extern "C" static void g();      // error

—end example

8 [Note: Because the language linkage is part of a function type, when indirectioning through a pointer to C function, the function to which the resulting value refers is considered a C function. —end note]

9 Linkage from C++ to objects defined in other languages and to objects defined in C++ from other languages is implementation-defined and language-dependent. Only where the object layout strategies of two language implementations are similar enough can such linkage be achieved.

9.11 Attributes [dcl.attr]

9.11.1 Attribute syntax and semantics [dcl.attr.grammar]

Attributes specify additional information for various source constructs such as types, variables, names, blocks, or translation units.

attribute-specifier-seq:
  attribute-specifier-seq_opt attribute-specifier

attribute-specifier:
  [ [ attribute-using-prefix_opt attribute-list ] ]
  contract-attribute-specifier
  alignment-specifier

alignment-specifier:
  alignas ( type-id ..._opt )
  alignas ( constant-expression ...opt )

attribute-using-prefix:
  using attribute-namespace :

attribute-list:
  attribute_opt
  attribute-list , attribute_opt
  attribute ...
  attribute-list , attribute ...

attribute:
  attribute-token attribute-argument-clause_opt

attribute-token:
  identifier
  attribute-scoped-token

attribute-scoped-token:
  attribute-namespace :: identifier

attribute-namespace:
  identifier

attribute-argument-clause:
  ( balanced-token-seq_opt )

balanced-token-seq:
  balanced-token
  balanced-token-seq balanced-token

balanced-token:
  ( balanced-token-seq_opt )
  { balanced-token-seq_opt }
  any token other than a parenthesis, a bracket, or a brace

2 If an attribute-specifier contains an attribute-using-prefix, the attribute-list following that attribute-using-prefix shall not contain an attribute-scoped-token and every attribute-token in that attribute-list is treated as if its identifier were prefixed with N::, where N is the attribute-namespace specified in the attribute-using-prefix. [Note: This rule imposes no constraints on how an attribute-using-prefix affects the tokens in an attribute-argument-clause. —end note] [Example:
void f() {}  // same as [[CC::opt(1), CC::debug]]
[[CC::opt(1)]] [[CC::debug]]  // same as [[CC::opt(1)]] [[CC::debug]]
void g() {}  // error: cannot combine using and scoped attribute token
[[CC::opt(1)]]

—end example

3 [Note: For each individual attribute, the form of the balanced-token-seq will be specified. —end note]

4 In an attribute-list, an ellipsis may appear only if that attribute’s specification permits it. An attribute followed by an ellipsis is a pack expansion (13.6.3). An attribute-specifier that contains no attributes has no effect. The order in which the attribute-tokens appear in an attribute-list is not significant. If a keyword (5.11) or an alternative token (5.5) that satisfies the syntactic requirements of an identifier (5.10) is contained in an attribute-token, it is considered an identifier. No name lookup (6.4) is performed on any of the identifiers contained in an attribute-token. The attribute-token determines additional requirements on the attribute-argument-clause (if any).

5 Each attribute-specifier-seq is said to appertain to some entity or statement, identified by the syntactic context where it appears (Clause 8, Clause 9, 9.2). If an attribute-specifier-seq that appertains to some entity or statement contains an attribute or alignment-specifier that is not allowed to apply to that entity or statement, the program is ill-formed. If an attribute-specifier-seq appertains to a friend declaration (11.8.3), that declaration shall be a definition. [Note: An attribute-specifier-seq cannot appertain to an explicit instantiation (13.8.2). —end note]

6 For an attribute-token (including an attribute-scoped-token) not specified in this document, the behavior is implementation-defined. Any attribute-token that is not recognized by the implementation is ignored. [Note: Each implementation should choose a distinctive name for the attribute-namespace in an attribute-scoped-token. —end note]

7 Two consecutive left square bracket tokens shall appear only when introducing an attribute-specifier or within the balanced-token-seq of an attribute-argument-clause. [Note: If two consecutive left square brackets appear where an attribute-specifier is not allowed, the program is ill-formed even if the brackets match an alternative grammar production. —end note] [Example:

```c
int p[10];
void f() {
    int x = 42, y[5];
    int(p[x] { return x; }();)
        // error: invalid attribute on a nested declarator-id and
        // not a function-style cast of an element of p.
    y[[] { return 2; }()] = 2;
    int i [[vendor::attr([])]];  // well-formed implementation-defined attribute.
}
```

—end example

9.11.2 Alignment specifier [dcl.align]

1 An alignment-specifier may be applied to a variable or to a class data member, but it shall not be applied to a bit-field, a function parameter, or an exception-declaration (14.3). An alignment-specifier may also be applied to the declaration of a class (in an elaborated-type-specifier (9.1.7.3) or class-head (Clause 11), respectively). An alignment-specifier with an ellipsis is a pack expansion (13.6.3).

2 When the alignment-specifier is of the form alignas(constant-expression):

\[(2.1)\] — the constant-expression shall be an integral constant expression

\[(2.2)\] — if the constant expression does not evaluate to an alignment value (6.6.6), or evaluates to an extended alignment and the implementation does not support that alignment in the context of the declaration, the program is ill-formed.

3 An alignment-specifier of the form alignas(type-id) has the same effect as alignas(alignof(type-id)) (7.6.2.5).

4 The alignment requirement of an entity is the strictest nonzero alignment specified by its alignment-specifiers, if any; otherwise, the alignment-specifiers have no effect.

§ 9.11.2 223
The combined effect of all alignment-specifiers in a declaration shall not specify an alignment that is less strict than the alignment that would be required for the entity being declared if all alignment-specifiers appertaining to that entity were omitted. [Example:

```c
struct alignas(8) S {};    
struct alignas(1) U {
    S s;                    
}; // error: U specifies an alignment that is less strict than if the alignas(1) were omitted.
```
—end example]

6 If the defining declaration of an entity has an alignment-specifier, any non-defining declaration of that entity shall either specify equivalent alignment or have no alignment-specifier. Conversely, if any declaration of an entity has an alignment-specifier, every defining declaration of that entity shall specify an equivalent alignment. No diagnostic is required if declarations of an entity have different alignment-specifiers in different translation units. [Example:

```c
// Translation unit #1:
struct S { int x; } s, *p = &s;

// Translation unit #2:
struct alignas(16) S; // error: definition of S lacks alignment, no diagnostic required
extern S* p;
```
—end example]

7 [Example: An aligned buffer with an alignment requirement of A and holding N elements of type T can be declared as:

```c
alignas(T) alignas(A) T buffer[N];
```
Specifying alignas(T) ensures that the final requested alignment will not be weaker than alignof(T), and therefore the program will not be ill-formed. —end example]

8 [Example:

```c
alignas(double) void f(); // error: alignment applied to function
alignas(double) unsigned char c[sizeof(double)]; // array of characters, suitably aligned for a double
extern unsigned char c[sizeof(double)]; // no alignas necessary
alignas(float)
extern unsigned char c[sizeof(double)]; // error: different alignment in declaration
```
—end example]

9.11.3 Carries dependency attribute [dcl.attr.depend]

1 The attribute-token carries_dependency specifies dependency propagation into and out of functions. It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute may be applied to the declarator-id of a parameter-declaration in a function declaration or lambda, in which case it specifies that the initialization of the parameter carries a dependency to (6.8.2) each lvalue-to-rvalue conversion (7.3.1) of that object. The attribute may also be applied to the declarator-id of a function declaration, in which case it specifies that the return value, if any, carries a dependency to the evaluation of the function call expression.

2 The first declaration of a function shall specify the carries_dependency attribute for its declarator-id if any declaration of the function specifies the carries_dependency attribute. Furthermore, the first declaration of a function shall specify the carries_dependency attribute for a parameter if any declaration of that function specifies the carries_dependency attribute for that parameter. If a function or one of its parameters is declared with the carries_dependency attribute in its first declaration in one translation unit and the same function or one of its parameters is declared without the carries_dependency attribute in its first declaration in another translation unit, the program is ill-formed, no diagnostic required.

3 [Note: The carries_dependency attribute does not change the meaning of the program, but may result in generation of more efficient code. —end note]

4 [Example:

```c
/* Translation unit A. */

struct foo { int* a; int* b;};
std::atomic<struct foo *> foo_head[10];
```
int foo_array[10][10];

[[carries_dependency]] struct foo* f(int i) {
    return foo_head[i].load(memory_order::consume);
}

int g(int* x, int* y [[carries_dependency]]) {
    return kill_dependency(foo_array[*x][*y]);
}

/* Translation unit B. */

[[carries_dependency]] struct foo* f(int i);
int g(int* x, int* y [[carries_dependency]]);

int c = 3;

void h(int i) {
    struct foo* p;
    p = f(i);
    do_something_with(g(&c, p->a));
    do_something_with(g(p->a, &c));
}

The carries_dependency attribute on function f means that the return value carries a dependency out of f, so that the implementation need not constrain ordering upon return from f. Implementations of f and its caller may choose to preserve dependencies instead of emitting hardware memory ordering instructions (a.k.a. fences). Function g’s second parameter has a carries_dependency attribute, but its first parameter does not. Therefore, function h’s first call to g carries a dependency into g, but its second call does not. The implementation might need to insert a fence prior to the second call to g. —end example]

9.11.4 Contract attributes

9.11.4.1 Syntax

Contract attributes are used to specify preconditions, postconditions, and assertions for functions.

contract-attribute-specifier:
    [[ expects contract-levelopt : conditional-expression ]]
    [[ ensures contract-levelopt identifieropt : conditional-expression ]]
    [[ assert contract-levelopt : conditional-expression ]]

contract-level:
    default
    audit
    axiom

An ambiguity between a contract-level and an identifier is resolved in favor of contract-level.

A contract-attribute-specifier using expects is a precondition. It expresses a function’s expectation on its arguments and/or the state of other objects using a predicate that is intended to hold upon entry into the function. The attribute may be applied to the function type of a function declaration.

A contract-attribute-specifier using ensures is a postcondition. It expresses a condition that a function should ensure for the return value and/or the state of objects using a predicate that is intended to hold upon exit from the function. The attribute may be applied to the function type of a function declaration. A postcondition may introduce an identifier to represent the glvalue result or the prvalue result object of the function. When the declared return type of a non-templated function contains a placeholder type, the optional identifier shall only be present in a definition. [Example:

```c
int f(char * c)
    [[ensures res: res > 0 && c != nullptr]];
```

```c
int g(double * p)
    [[ensures audit res: res != 0 && p != nullptr && p *= 0.0]];```
auto h(int x)
    [[ensures res: true]];  // error: cannot name the return value
—end example]

4 A **contract-attribute-specifier** using **assert** is an **assertion**. It expresses a condition that is intended to be satisfied where it appears in a function body. The attribute may be applied to a null statement (8.2). An assertion is checked by evaluating its predicate as part of the evaluation of the null statement it applies to.

5 Preconditions, postconditions, and assertions are collectively called **contracts**. The **conditional-expression** in a contract is contextually converted to **bool** (7.3); the converted expression is called the **predicate** of the contract. [Note: The predicate of a contract is potentially evaluated (6.2). — end note]

6 The only side effects of a predicate that are allowed in a **contract-attribute-specifier** are modifications of non-volatile objects whose lifetime began and ended within the evaluation of the predicate. An evaluation of a predicate that exits via an exception invokes the function **std::terminate** (14.5.1). The behavior of any other side effect is undefined. [Example:

```cpp
void push(int x, queue & q)
    [[expects: !q.full()]]
    [[ensures: !q.empty()]]
{
    /* ... */
    [[assert: q.is_valid()]];
    /* ... */
}

int min = -42;
constexpr int max = 42;

constexpr int g(int x)
    [[expects: min <= x]]  // error
    [[expects: x < max]]  // OK
{
    /* ... */
    [[assert: 2*x < max]];
    [[assert: ++min > 0]];  // undefined behavior
    /* ... */
}
—end example]

9.11.4.2 Contract conditions  [dcl.attr.contract.cond]

1 A **contract condition** is a precondition or a postcondition. The first declaration of a function shall specify all contract conditions (if any) of the function. Subsequent declarations shall either specify no contract conditions or the same list of contract conditions; no diagnostic is required if corresponding conditions will always evaluate to the same value. The list of contract conditions of a function shall be the same if the declarations of that function appear in different translation units; no diagnostic required. If a friend declaration is the first declaration of the function in a translation unit and has a contract condition, the declaration shall be a definition and shall be the only declaration of the function in the translation unit.

2 Two lists of contract conditions are the same if they consist of the same contract conditions in the same order. Two contract conditions are the same if their contract levels are the same and their predicates are the same. Two predicates contained in **contract-attribute-specifiers** are the same if they would satisfy the one-definition rule (6.2) were they to appear in function definitions, except for renaming of parameters, return value identifiers (if any), and template parameters.

3 [Note: A function pointer cannot include contract conditions. [Example:

```cpp
typedef int (*fpt)() [[ensures r: r != 0]];  // error: contract condition not on a function declaration

int g(int x)
    [[expects: x >= 0]]
    [[ensures r: r > x]]
{
    return x+1;
}
```

§ 9.11.4.2 226
4 The predicate of a contract condition has the same semantic restrictions as if it appeared as the first expression-statement in the body of the function it applies to, except that the return type of the function is known in a contract condition appertaining to its definition, even if the return type contains a placeholder type.

5 A precondition is checked by evaluating its predicate immediately before starting evaluation of the function body. [Note: The function body includes the function-try-block (Clause 14) and the ctor-initializer (11.9.2). —end note] A postcondition is checked by evaluating its predicate immediately before returning control to the caller of the function. [Note: The lifetime of local variables and temporaries has ended. Exiting via an exception or via longjmp (17.13.2) is not considered returning control to the caller of the function. —end note]

6 If a function has multiple preconditions, their evaluation (if any) will be performed in the order they appear lexically. If a function has multiple postconditions, their evaluation (if any) will be performed in the order they appear lexically. [Example:

```c
void f(int * p)
  [[expects: p != nullptr]]       // #1
  [[ensures: *p == 1]]           // #3
  [[expects: *p == 0]]           // #2
{
  *p = 1;
}
—end example]
```

7 If a postcondition odr-uses (6.2) a non-reference parameter in its predicate and the function body makes direct or indirect modifications of the value of that parameter, the behavior is undefined. [Example:

```c
int f(int x)
  [[ensures r: r == x]]
{
  return ++x;              // undefined behavior
}
```

7.11.4.3 Checking contracts [dcl.attr.contract.check]

1 If the contract-level of a contract-attribute-specifier is absent, it is assumed to be default. [Note: A default contract-level is expected to be used for those contracts where the cost of run-time checking is assumed to be small (or at least not expensive) compared to the cost of executing the function. An audit contract-level is expected to be used for those contracts where the cost of run-time checking is assumed to be large (or at least significant) compared to the cost of executing the function. An axiom contract-level is expected to be used for those contracts that are formal comments and are not evaluated at run-time. —end note]

2 [Note: Multiple contract conditions may be applied to a function type with the same or different contract-levels. [Example:

```c
int z;
```
bool is_prime(int k);

void f(int x)
  [[expects: x > 0]]
  [[expects audit: is_prime(x)]]
  [[ensures: z > 10]]
{
  /* ... */
}
—end example] — end note]

A translation may be performed with one of the following build levels: off, default, or audit. A translation with build level set to off performs no checking for any contract. A translation with build level set to default performs checking for default contracts. A translation with build level set to audit performs checking for default and audit contracts. If no build level is explicitly selected, the build level is default. The mechanism for selecting the build level is implementation-defined. The translation of a program consisting of translation units where the build level is not the same in all translation units is conditionally-supported. There should be no programmatic way of setting, modifying, or querying the build level of a translation unit.

During constant expression evaluation (7.7), only predicates of checked contracts are evaluated. In other contexts, it is unspecified whether the predicate for a contract that is not checked under the current build level is evaluated; if the predicate of such a contract would evaluate to false, the behavior is undefined.

The violation handler of a program is a function of type "noexcept opt function of (lvalue reference to const std::contract_violation) returning void". The violation handler is invoked when the predicate of a checked contract evaluates to false (called a contract violation). There should be no programmatic way of setting or modifying the violation handler. It is implementation-defined how the violation handler is established for a program and how the std::contract_violation (17.8.2) argument value is set, except as specified below. If a precondition is violated, the source location of the violation is implementation-defined. [Note: Implementations are encouraged but not required to report the caller site. — end note] If a postcondition is violated, the source location of the violation is the source location of the function definition. If an assertion is violated, the source location of the violation is the source location of the statement to which the assertion is applied.

If a violation handler exits by throwing an exception and a contract is violated on a call to a function with a non-throwing exception specification, then the behavior is as if the exception escaped the function body. [Note: The function std::terminate is invoked (14.5.1). — end note] [Example:

    void f(int x) noexcept [[expects: x > 0]]; 

    void g() {
    f(0);  // std::terminate() if violation handler throws
  } 

—end example]

A translation may be performed with one of the following violation continuation modes: off or on. A translation with violation continuation mode set to off terminates execution by invoking the function std::terminate (14.5.1) after completing the execution of the violation handler. A translation with a violation continuation mode set to on continues execution after completing the execution of the violation handler. If no continuation mode is explicitly selected, the default continuation mode is off. [Note: A continuation mode set to on provides the opportunity to install a logging handler to instrument a pre-existing code base and fix errors before enforcing checks. — end note] [Example:

    void f(int x) [[expects: x > 0]]; 

    void g() {
    f(0);  // std::terminate() after handler if continuation mode is off;
    // proceeds after handler if continuation mode is on
  } 

—end example]
9.11.5 Deprecated attribute

The attribute-token deprecated can be used to mark names and entities whose use is still allowed, but is discouraged for some reason. [Note: In particular, deprecated is appropriate for names and entities that are deemed obsolescent or unsafe. — end note] It shall appear at most once in each attribute-list. An attribute-argument-clause may be present and, if present, it shall have the form:

```
( string-literal )
```

[Note: The string-literal in the attribute-argument-clause could be used to explain the rationale for deprecation and/or to suggest a replacing entity. — end note]

The attribute may be applied to the declaration of a class, a typedef-name, a variable, a non-static data member, a function, a namespace, an enumeration, an enumerator, or a template specialization.

A name or entity declared without the deprecated attribute can later be redeclared with the attribute and vice-versa. [Note: Thus, an entity initially declared without the attribute can be marked as deprecated by a subsequent redeclaration. However, after an entity is marked as deprecated, later redeclarations do not un-deprecate the entity. — end note] Redeclarations using different forms of the attribute (with or without the attribute-argument-clause or with different attribute-argument-clauses) are allowed.

[Note: Implementations may use the deprecated attribute to produce a diagnostic message in case the program refers to a name or entity other than to declare it, after a declaration that specifies the attribute. The diagnostic message may include the text provided within the attribute-argument-clause of any deprecated attribute applied to the name or entity. — end note]

9.11.6 Fallthrough attribute

The attribute-token fallthrough may be applied to a null statement (8.2); such a statement is a fallthrough statement. The attribute-token fallthrough shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. A fallthrough statement may only appear within an enclosing switch statement (8.4.2). The next statement that would be executed after a fallthrough statement shall be a labeled statement whose label is a case label or default label for the same switch statement. The program is ill-formed if there is no such statement.

[Note: The use of a fallthrough statement is intended to suppress a warning that an implementation might otherwise issue for a case or default label that is reachable from another case or default label along some path of execution. Implementations should issue a warning if a fallthrough statement is not dynamically reachable. — end note]

[Example:

```c
void f(int n) {
  void g(), h(), i();
  switch (n) {
    case 1:
    case 2:
      g();
      // warning on fallthrough discouraged
    case 3:
      h();
      // implementation may warn on fallthrough
    case 4:
      i();
      // ill-formed
    [[fallthrough]];
  }
}
```

— end example]

9.11.7 Likelihood attributes

The attribute-tokens likely and unlikely may be applied to labels or statements. The attribute-tokens likely and unlikely shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute-token likely shall not appear in an attribute-specifier-seq that contains the attribute-token unlikely.

[Note: The use of the likely attribute is intended to allow implementations to optimize for the case where paths of execution including it are arbitrarily more likely than any alternative path of execution that does not include such an attribute on a statement or label. The use of the unlikely attribute is intended to allow
implementations to optimize for the case where paths of execution including it are arbitrarily more unlikely than any alternative path of execution that does not include such an attribute on a statement or label. A path of execution includes a label if and only if it contains a jump to that label. Excessive usage of either of these attributes is liable to result in performance degradation. — end note]

3 Example:

```c
void g(int);
int f(int n) {
    if (n > 5) [[unlikely]] { // n > 5 is considered to be arbitrarily unlikely
        g(0);
        return n * 2 + 1;
    }
    switch (n) {
        case 1:
            g(1);
            [[fallthrough]];
        [[likely]] case 2: // n == 2 is considered to be arbitrarily more
            g(2);
            // likely than any other value of n
            break;
    }
    return 3;
}
— end example
```

9.11.8 Maybe unused attribute [dcl.attr.unused]

1 The attribute-token `maybe_unused` indicates that a name or entity is possibly intentionally unused. It shall appear at most once in each `attribute-list` and no `attribute-argument-clause` shall be present.

2 The attribute may be applied to the declaration of a class, a `typedef-name`, a variable (including a structured binding declaration), a non-static data member, a function, an enumeration, or an enumerator.

3 For an entity marked `maybe_unused`, implementations should not emit a warning that the entity or its structured bindings (if any) are used or unused. For a structured binding declaration not marked `maybe_used`, implementations should not emit such a warning unless all of its structured bindings are unused.

4 A name or entity declared without the `maybe_unused` attribute can later be redeclared with the attribute and vice versa. An entity is considered marked after the first declaration that marks it.

5 Example:

```c
[[maybe_unused]] void f([[maybe_unused]] bool thing1,
    [[maybe_unused]] bool thing2) {
    [[maybe_unused]] bool b = thing1 && thing2;
    assert(b);
}
```

Implementations should not warn that `b` is unused, whether or not `NDEBUG` is defined. — end example]

9.11.9 Nodiscard attribute [dcl.attr.nodiscard]

1 The attribute-token `nodiscard` may be applied to the `declarator-id` in a function declaration or to the declaration of a class or enumeration. It shall appear at most once in each `attribute-list` and no `attribute-argument-clause` shall be present.

2 [Note: A nodiscard call is a function call expression that calls a function previously declared `nodiscard`, or whose return type is a possibly cv-qualified class or enumeration type marked `nodiscard`. Appearance of a nodiscard call as a potentially-evaluated discarded-value expression (7.2) is discouraged unless explicitly cast to `void`. Implementations should issue a warning in such cases. This is typically because discarding the return value of a nodiscard call has surprising consequences. — end note]

3 Example:

```c
struct [[nodiscard]] error_info { /* ... */
    error_info enable_missile_safety_mode();
    void launch_missiles();
```
```c
void test_missiles() {
    enable_missile_safety_mode(); // warning encouraged
    launch_missiles();
}
error_info &foo();
void f() { foo(); }        // warning not encouraged: not a nodiscard call, because neither
                           // the (reference) return type nor the function is declared nodiscard

— end example]  

9.11.10 Noreturn attribute [dcl.attr.noreturn]

1 The attribute-token noreturn specifies that a function does not return. It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute may be applied to the declarator-id in a function declaration. The first declaration of a function shall specify the noreturn attribute if any declaration of that function specifies the noreturn attribute. If a function is declared with the noreturn attribute in one translation unit and the same function is declared without the noreturn attribute in another translation unit, the program is ill-formed, no diagnostic required.

2 If a function f is called where f was previously declared with the noreturn attribute and f eventually returns, the behavior is undefined. [Note: The function may terminate by throwing an exception. — end note] [Note: Implementations should issue a warning if a function marked [[noreturn]] might return. — end note]

3 [Example:
   [[[ noreturn ]] void f() {
       throw "error";    // OK
   }

   [[[ noreturn ]] void q(int i) { // behavior is undefined if called with an argument <= 0
       if (i > 0)
           throw "positive";
   }
   — end example]

9.11.11 No unique address attribute [dcl.attr.nouniqueaddr]

1 The attribute-token no_unique_address specifies that a non-static data member is a potentially-overlapping subobject (6.6.2). It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute may appertain to a non-static data member other than a bit-field.

2 [Note: The non-static data member can share the address of another non-static data member or that of a base class, and any padding that would normally be inserted at the end of the object can be reused as storage for other members. — end note] [Example:
   template<typename Key, typename Value,
            typename Hash, typename Pred, typename Allocator>
   class hash_map {
       [[[no_unique_address]]] Hash hasher;
       [[[no_unique_address]]] Pred pred;
       [[[no_unique_address]]] Allocator alloc;
       Bucket *buckets;
       // ...
   public:
       // ...
   };

   Here, hasher, pred, and alloc could have the same address as buckets if their respective types are all empty. — end example]
10 Modules

10.1 Module units and purviews

module-declaration:
  export\opt module module-name module-partition\opt attribute-specifier-seq\opt ;
module-name:
  module-name-qualifier\opt identifier
module-partition:
  : module-name-qualifier\opt identifier
module-name-qualifier:
  identifier .
  module-name-qualifier identifier .

1 A module unit is a translation unit that contains a module-declaration. A named module is the collection of module units with the same module-name. The identifiers module and import shall not appear as identifiers in a module-name or module-partition. The optional attribute-specifier-seq appertains to the module-declaration.

2 A module interface unit is a module unit whose module-declaration contains the export keyword; any other module unit is a module implementation unit. A named module shall contain exactly one module interface unit with no module-partition, known as the primary module interface unit of the module; no diagnostic is required.

3 A module partition is a module unit whose module-declaration contains a module-partition. A named module shall not contain multiple module partitions with the same module-partition. All module partitions of a module that are module interface units shall be directly or indirectly exported by the primary module interface unit (10.3). No diagnostic is required for a violation of these rules. [Note: Module partitions can be imported only by other module units in the same module. The division of a module into module units is not visible outside the module. — end note]

4 [Example:

Translation unit #1:
  export module A;
  export import :Foo;
  export int baz();

Translation unit #2:
  export module A:Foo;
  import :Internals;
  export int foo() { return 2 * (bar() + 1); }

Translation unit #3:
  module A:Internals;
  int bar();

Translation unit #4:
  module A;
  import :Internals;
  int bar() { return baz() - 10; }
  int baz() { return 30; }

Module A contains four translation units:

(4.1) — a primary module interface unit,
(4.2) — a module partition A:Foo, which is a module interface unit forming part of the interface of module A,
(4.3) — a module partition A:Internals, which does not contribute to the external interface of module A, and
(4.4) — a module implementation unit providing a definition of bar and baz, which cannot be imported because it does not have a partition name.

§ 10.1
A module unit purview is the sequence of tokens starting at the module-declaration and extending to the end of the translation unit. The purview of a named module M is the set of module unit purviews of M’s module units.

The global module is the collection of all global-module-fragments and all translation units that are not module units. Declarations appearing in such a context are said to be in the purview of the global module. [Note: The global module has no name, no module interface unit, and is not introduced by any module-declaration. — end note]

A module is either a named module or the global module. A declaration is attached to a module as follows:

1. If the declaration
   - is a replaceable global allocation or deallocation function (17.6.2.1, 17.6.2.2), or
   - is a namespace-definition with external linkage, or
   - appears within a linkage-specification,
     it is attached to the global module.

2. Otherwise, the declaration is attached to the module in whose purview it appears.

A module-declaration that contains neither export nor a module-partition implicitly imports the primary module interface unit of the module as if by a module-import-declaration. [Example:

Translation unit #1:
module B:Y;
int y();

// does not implicitly import B

Translation unit #2:
export module B;
import :Y;
int n = y();

// OK, does not create interface dependency cycle

Translation unit #3:
module B:X1;
int &a = n;

// error: n not visible here

Translation unit #4:
module B:X2;
import B;
int &b = n;

// OK

Translation unit #5:
module B;
int &c = n;

// implicitly imports B

// OK

— end example]

10.2 Export declaration

export-declaration:
export declaration
export { declaration-seq_opt }

An export-declaration shall appear only at namespace scope and only in the purview of a module interface unit. An export-declaration shall not appear directly or indirectly within an unnamed namespace or a private-module-fragment. An export-declaration has the declarative effects of its declaration or its declaration-seq (if any). An export-declaration does not establish a scope and its declaration or declaration-seq shall not contain an export-declaration.

A declaration is exported if it is

1. a namespace-scope declaration declared within an export-declaration, or
2. a module-import-declaration declared with the export keyword (10.3), or
3. a namespace-definition that contains an exported declaration, or
4. a declaration within a header unit (10.3) that introduces at least one name.
The interface of a module \( M \) is the set of all exported declarations within its purview. [Example:

```c
export module M;
namespace A {
    export int f();  // exported
    int g();         // not exported
}
```

The interface of \( M \) comprises \( A \) and \( A::f \). — end example]

3 An exported declaration shall declare at least one name. If the declaration is not within a header unit, it shall not declare a name with internal linkage.

4 [Example:

Source file "a.h":
```c
export int x;
```

Translation unit #1:
```c
module;
#include "a.h"         // error: declaration of x is not in the purview of a module interface unit
export module M;
export namespace {}    // error: does not introduce any names
export namespace {
    int a1;
}
namespace {
    export int a2;   // error: export of name with internal linkage
}
export static int b;  // error: b explicitly declared static
export int f();       // OK
export namespace N { } // OK
export using namespace N;  // error: does not declare a name
```

— end example]

5 If the declaration is a using-declaration (9.8) and is not within a header unit, all entities to which all of the using-declarators ultimately refer (if any) shall have been introduced with a name having external linkage. [Example:

Source file "b.h":
```c
int f();
```

Importable header "c.h":
```c
int g();
```

Translation unit #1:
```c
export module X;
export int h();
```

Translation unit #2:
```c
module;
#include "b.h"
export module M;
import "c.h";
import X;
export using ::f, ::g, ::h;  // OK
struct S;
export using ::S;            // error: S has module linkage
namespace N {
    export int h();
    static int h(int);       // #1
}
export using N::*;           // error: #1 has internal linkage
```
A redeclaration of an exported declaration of an entity is implicitly exported. An exported redeclaration of a non-exported declaration of an entity is ill-formed. [Example:

```c
export module M;
struct S { int n; };
typedef S S;
export typedef S S;  // OK, does not redeclare an entity
export struct S;    // error: exported declaration follows non-exported declaration
```

— end example] [Example:

```c
export module M;
struct S { int n; };
struct Y { };
}
namespace {
    struct S { };
}
export void f();  // OK
export struct Y { };  // OK
export T id(T);  // OK
export struct A;  // & exported as incomplete

export void rootFinder(double a) {
    return [=](double x) { return (x + a/x)/2; };
}
export const int n = 5;  // OK, n has external linkage
```

Implementation unit of M:

```c
module M;
struct A {
    int value;
};
```

Main program:

```c
import M;
int main() {
    X::f();  // OK, X is exported and definition of X is reachable
    X::Y y;  // OK, X::Y is exported as a complete type
    auto f = rootFinder(2);  // OK
    return A{45}.value;  // error: & is incomplete
}
```

— end example] [Example:

```c
§ 10.2 235
```
Interface unit of M:

```cpp
export module M;
static int f();  // #1
export int f();  // error: #1 gives internal linkage
struct S;        // #2
export struct S;
namespace {
    namespace N {
        extern int x;  // #3
    }
}
export int N::x;  // error: #3 gives internal linkage
```

—end example —end note

9 [Note: Declarations in an exported namespace-definition or in an exported linkage-specification (9.10) are exported and subject to the rules of exported declarations. [Example:

```cpp
export module M;
export namespace N {
    int x;  // OK
    static_assert(1 == 1);  // error: does not declare a name
}
```

—end example —end note]

10.3 Import declaration [module.import]

module-import-declaration:

```cpp
export_opt import module-name attribute-specifier-seq_opt ;
export_opt import module-partition attribute-specifier-seq_opt ;
export_opt import header-name attribute-specifier-seq_opt ;
```

1 In a module unit, all module-import-declarations shall precede all other top-level-declarations in the top-level-declaration-seq of the translation-unit and of the private-module-fragment (if any). The optional attribute-specifier-seq appertains to the module-import-declaration.

2 A module-import-declaration imports a set of translation units determined as described below. [Note: Namespace-scope names exported by the imported translation units become visible (6.3.6) in the importing translation unit and declarations within the imported translation units become reachable (10.6) in the importing translation unit after the import declaration. —end note]

3 A module-import-declaration that specifies a module-name M imports all module interface units of M.

4 A module-import-declaration that specifies a module-partition shall only appear after the module-declaration in a module unit of some module M. Such a declaration imports the so-named module partition of M.

5 A module-import-declaration that specifies a header-name H imports a synthesized header unit, which is a translation unit formed by applying phases 1 to 7 of translation (5.2) to the source file or header nominated by H, which shall not contain a module-declaration. [Note: All declarations within a header unit are implicitly exported (10.2), and are attached to the global module (10.1). —end note] An importable header is a member of an implementation-defined set of headers. H shall identify an importable header. Two module-import-declarations import the same header unit if and only if their header-names identify the same header or source file (15.2). [Note: A module-import-declaration nominating a header-name is also recognized by the preprocessor, and results in macros defined at the end of phase 4 of translation of the header unit being made visible as described in 15.4. —end note] A declaration of a name with internal linkage is permitted within a header unit despite all declarations being implicitly exported (10.2). If such a declaration declares an entity that is odr-used outside the header unit, or by a template instantiation whose point of instantiation is outside the header unit, the program is ill-formed.

6 When a module-import-declaration imports a translation unit T, it also imports all translation units imported by exported module-import-declarations in T; such translation units are said to be exported by T. When a module-import-declaration in a module unit imports another module unit of the same module, it also imports all translation units imported by all module-import-declarations in that module unit. These rules may in turn lead to the importation of yet more translation units.

7 A module implementation unit shall not be exported. [Example:
Translation unit #1:
module M:Part;

Translation unit #2:
export module M;
export import :Part; // error: exported partition :Part is an implementation unit
— end example]  
8 A module implementation unit of a module M that is not a module partition shall not contain a module-import-declaration nominating M. [Example:
module M;
import M;  // error: cannot import M in its own unit
— end example]  
9 A translation unit has an interface dependency on a module unit U if it contains a module-declaration or module-import-declaration that imports U or if it has an interface dependency on a module unit that has an interface dependency on U. A translation unit shall not have an interface dependency on itself. [Example:
Interface unit of M1:
export module M1;
import M2;

Interface unit of M2:
export module M2;
import M3;

Interface unit of M3:
export module M3;
import M1;  // error: cyclic interface dependency M3 → M1 → M2 → M3
— end example]  

10.4 Global module fragment

global-module-fragment:
module ; top-level-declaration-seq_opt
1 [Note: Prior to phase 4 of translation, only preprocessing directives can appear in the top-level-declaration-seq (15.3). — end note]  
2 A global-module-fragment specifies the contents of the global module fragment for a module unit. The global module fragment can be used to provide declarations that are attached to the global module and usable within the module unit.

3 A declaration D is decl-reachable from a declaration S in the same translation unit if:
(3.1) — D does not declare a function or function template and S contains an id-expression, namespace-name, type-name, template-name, or concept-name naming D, or
(3.2) — D declares a function or function template that is named by an expression (6.2) appearing in S, or
(3.3) — S contains an expression E of the form
postfix-expression ( expression-list_opt )
whose postfix-expression denotes a dependent name, or for an operator expression whose operator denotes a dependent name, and D is found by name lookup for the corresponding name in an expression synthesized from E by replacing each type-dependent argument or operand with a value of a placeholder type with no associated namespaces or entities, or
(3.4) — S contains an expression that takes the address of an overloaded function (12.4) whose set of overloads contains D and for which the target type is dependent, or
(3.5) — there exists a declaration M that is not a namespace-definition for which M is decl-reachable from S and either
(3.5.1) — D is decl-reachable from M, or
(3.5.2) — D redeclares the entity declared by M or M redeclares the entity declared by D, and D is neither a friend declaration nor a block-scope declaration, or
— D declares a namespace N and M is a member of N, or
— one of M and D declares a class or class template C and the other declares a member or friend of C, or
— one of D and M declares an enumeration E and the other declares an enumerator of E, or
— D declares a function or variable and M is declared in D, or
— one of M and D declares a template and the other declares a partial or explicit specialization or an implicit or explicit instantiation of that template, or
— one of M and D declares a class or enumeration type and the other introduces a typedef name for linkage purposes for that type.

In this determination, it is unspecified
— whether a reference to an alias-declaration, typedef declaration, using-declaration, or namespace-alias-declaration is replaced by the declarations they name prior to this determination,
— whether a simple-template-id that does not denote a dependent type and whose template-name names an alias template is replaced by its denoted type prior to this determination,
— whether a decltype-specifier that does not denote a dependent type is replaced by its denoted type prior to this determination, and
— whether a non-value-dependent constant expression is replaced by the result of constant evaluation prior to this determination.

A declaration D in a global module fragment of a module unit is discarded if D is not decl-reachable from any top-level-declaration in the top-level-declaration-seq of the translation unit. [Note: A discarded declaration is neither reachable nor visible to name lookup outside the module unit, nor in template instantiations whose points of instantiation (13.7.4.1) are outside the module unit, even when the instantiation context (10.5) includes the module unit. — end note]

Example:

const int size = 2;
int ary1[size]; // unspecified whether size is decl-reachable from ary1
constexpr int identity(int x) { return x; }
int ary2[identity(2)]; // unspecified whether identity is decl-reachable from ary2

template<typename> struct S;
template<typename, int> struct S2;
constexpr int g(int);
template<typename T, int N>
S<S2<T, g(N)>> f(); // S, S2, g, and :: are decl-reachable from f

template<int N>
void h() noexcept(g(N) == N); // g and :: are decl-reachable from h

— end example]

Example:

Source file "foo.h":

namespace N {
    struct X {}; // unspecified whether size is decl-reachable from ary1
    int d();
    int e();
    inline int f(X, int = d()) { return e(); }
    int g(X);
    int h(X);
}

Module M interface:

module;
#include "foo.h"
export module M;

template<
typename T>
tf() {  
   N::X x;  // N::X, N, and :: are decl-reachable from use_f
   return f(x, 123);  // N::f is decl-reachable from use_f.
   // N::e is indirectly decl-reachable from use_f
   // because it is decl-reachable from N::f, and
   // N::d is decl-reachable from use_f
   // because it is decl-reachable from N::f
   // even though it is not used in this call
}

template<
typename T>
tg() {  
   N::X x;  // N::X, N, and :: are decl-reachable from use_f
   return g((T(), x));  // N::g is not decl-reachable from use_g
}

template<
typename T>
ht() {  
   N::X x;  // N::X, N, and :: are decl-reachable from use_h
   return h((T(), x));  // N::h is not decl-reachable from use_h, but
   // N::h is decl-reachable from use_h<int>
}

int k = use_h<int>();  // use_h<int> is decl-reachable from k, so
// N::h is decl-reachable from k

Module M implementation:

module M;

int a = use_f<int>();  // OK
int b = use_g<int>();  // error: no viable function for call to g;
// g is not decl-reachable from purview of
// module M’s interface, so is discarded
int c = use_h<int>();  // OK

— end example]

10.5 Instantiation context

The instantiation context is a set of points within the program that determines which names are visible to argument-dependent name lookup (6.4.2) and which declarations are reachable (10.6) in the context of a particular declaration or template instantiation.

During the implicit definition of a defaulted special member function (11.3.3), the instantiation context is the union of the instantiation context from the definition of the class and the instantiation context of the program construct that resulted in the implicit definition of the special member function.

During the implicit instantiation of a template whose point of instantiation is specified as that of an enclosing specialization (13.7.4.1), the instantiation context is the union of the instantiation context of the enclosing specialization and, if the template is defined in a module interface unit of a module M and the point of instantiation is not in a module interface unit of M, the point at the end of the top-level-declaration-seq of the primary module interface unit of M (prior to the private-module-fragment, if any).

During the implicit instantiation of a template that is implicitly instantiated because it is referenced from within the implicit definition of a defaulted special member function, the instantiation context is the instantiation context of the defaulted special member function.

During the instantiation of any other template specialization, the instantiation context comprises the point of instantiation of the template.

In any other case, the instantiation context at a point within the program comprises that point.

Example:

Translation unit #1:

export module stuff;

export template<
typename T, typename U> void foo(T, U u) { auto v = u; }
export template<
typename T, typename U> void bar(T, U u) { auto v = *u; }
Translation unit #2:
export module M1;
import "defn.h";  // provides struct X {};
import stuff;
export template<typename T> void f(T t) {
    X x;
    foo(t, x);
}

Translation unit #3:
export module M2;
import "decl.h";  // provides struct X; (not a definition)
import stuff;
export template<typename T> void g(T t) {
    X *x;
    bar(t, x);
}

Translation unit #4:
import M1;
import M2;
void test() {
    f(0);
    g(0);
}

The call to f(0) is valid; the instantiation context of foo<int, X> comprises

(7.1) — the point at the end of translation unit #1,
(7.2) — the point at the end of translation unit #2, and
(7.3) — the point of the call to f(0),
so the definition of X is reachable (10.6).

It is unspecified whether the call to g(0) is valid: the instantiation context of bar<int, X> comprises

(7.4) — the point at the end of translation unit #1,
(7.5) — the point at the end of translation unit #3, and
(7.6) — the point of the call to g(0),
so the definition of X is not necessarily reachable, as described in 10.6. — end example]

10.6 Reachability [module.reach]

1 A translation unit U is necessarily reachable from a point P if U is a module interface unit on which the translation unit containing P has an interface dependency, or the translation unit containing P imports U, in either case prior to P (10.3). [Note: While module interface units are reachable even when they are only transitively imported via a non-exported import declaration, namespace-scope names from such module interface units are not visible to name lookup (6.3.6). — end note]

2 All translation units that are necessarily reachable are reachable. It is unspecified whether additional translation units on which the point within the program has an interface dependency are considered reachable, and under what circumstances.  

3 A declaration D is reachable or necessarily reachable, respectively, if, for any point P in the instantiation context (10.5),

(3.1) — D appears prior to P in the same translation unit, or
(3.2) — D is not discarded (10.4), appears in a translation unit that is reachable or necessarily reachable from P, respectively, and either does not appear within a private-module-fragment or appears in a private-module-fragment of the module containing P.

104) Implementations are therefore not required to prevent the semantic effects of additional translation units involved in the compilation from being observed.

§ 10.6
The accumulated properties of all reachable declarations of an entity within a context determine the behavior of the entity within that context. [Note: These reachable semantic properties include type completeness, type definitions, initializers, default arguments of functions or template declarations, attributes, visibility of class or enumeration member names to ordinary lookup, etc. Since default arguments are evaluated in the context of the call expression, the reachable semantic properties of the corresponding parameter types apply in that context. [Example:

Translation unit #1:
export module M:A;
export struct B;

Translation unit #2:
module M:B;
struct B {
  operator int();
};

Translation unit #3:
module M:C;
import :A;
B b1; // error: no reachable definition of struct B

Translation unit #4:
export module M;
export import :A;
import :B;
B b2;
export void f(B b = B());

Translation unit #5:
module X;
import M;
B b3; // error: no reachable definition of struct B
void g() { f(); } // error: no reachable definition of struct B

—end example] — end note]

[Note: An entity can have reachable declarations even if it is not visible to name lookup. — end note] [Example:

export module A;
struct X {};
export using Y = X;

module B;
import A;
Y y; // OK, definition of X is reachable
X x; // ill-formed: X not visible to unqualified lookup

— end example]
11 Classes

A class is a type. Its name becomes a class-name [class] within its scope.

\[
\text{class-name:}
\begin{align*}
\text{identifier} \\
\text{simple-template-id}
\end{align*}
\]

A class-specifier or an elaborated-type-specifier (9.1.7.3) is used to make a class-name. An object of a class consists of a (possibly empty) sequence of members and base class objects.

\[
\text{class-specifier:}
\begin{align*}
\text{class-head \{} \text{member-specification} \text{opt} \text{\}}
\end{align*}
\]

A class declaration where the class-name in the class-head-name is a simple-template-id shall be an explicit specialization (13.8.3) or a partial specialization (13.6.5). A class-specifier whose class-head omits the class-head-name defines an unnamed class. [Note: An unnamed class thus can’t be final. —end note]

A class-name is inserted into the scope in which it is declared immediately after the class-name is seen. The class-name is also inserted into the scope of the class itself; this is known as the injected-class-name. For purposes of access checking, the injected-class-name is treated as if it were a public member name. A class-specifier is commonly referred to as a class definition. A class is considered defined after the closing brace of its class-specifier has been seen even though its member functions are in general not yet defined. The optional attribute-specifier-seq appertains to the class; the attributes in the attribute-specifier-seq are thereafter considered attributes of the class whenever it is named.

If a class-head-name contains a nested-name-specifier, the class-specifier shall refer to a class that was previously declared directly in the class or namespace to which the nested-name-specifier refers, or in an element of the inline namespace set (9.7.1) of that namespace (i.e., not merely inherited or introduced by a using-declaration), and the class-specifier shall appear in a namespace enclosing the previous declaration. In such cases, the nested-name-specifier of the class-head-name of the definition shall not begin with a decltype-specifier.

If a class is marked with the class-virt-specifier final and it appears as a class-or-decltype in a base-clause (11.6), the program is ill-formed. Whenever a class-key is followed by a class-head-name, the identifier final, and a colon or left brace, final is interpreted as a class-virt-specifier. [Example:

\[
\begin{align*}
\text{struct A;} \\
\text{struct A final \{}; \quad \text{// OK: definition of struct A,} \\
\text{\quad not value-initialization of variable final}
\end{align*}
\]

\[
\begin{align*}
\text{struct X \{} \\
\text{struct C \{} \text{constexpr operator int() \{} \text{return 5; \}} \text{\};} \\
\text{struct B final : C\{}; \quad \text{// OK: definition of nested class B,} \\
\text{\quad not declaration of a bit-field member final}
\end{align*}
\]

—end example]

[Note: Complete objects of class type have nonzero size. Base class subobjects and members declared with the no_unique_address attribute (9.11.11) are not so constrained. —end note]
11.1 Properties of classes

1 A trivially copyable class is a class:
   (1.1) where each copy constructor, move constructor, copy assignment operator, and move assignment operator (11.3.4.2, 11.3.5) is either deleted or trivial,
   (1.2) that has at least one non-deleted copy constructor, move constructor, copy assignment operator, or move assignment operator, and
   (1.3) that has a trivial, non-deleted destructor (11.3.6).

2 A trivial class is a class that is trivially copyable and has one or more default constructors (11.3.4.1), all of which are either trivial or deleted and at least one of which is not deleted. [Note: In particular, a trivially copyable or trivial class does not have virtual functions or virtual base classes. — end note]

3 A class $S$ is a standard-layout class if it:
   (3.1) has no non-static data members of type non-standard-layout class (or array of such types) or reference,
   (3.2) has no virtual functions (11.6.2) and no virtual base classes (11.6.1),
   (3.3) has the same access control (11.8) for all non-static data members,
   (3.4) has no non-standard-layout base classes,
   (3.5) has at most one base class subobject of any given type,
   (3.6) has all non-static data members and bit-fields in the class and its base classes first declared in the same class, and
   (3.7) has no element of the set $M(S)$ of types as a base class, where for any type $X$, $M(X)$ is defined as follows.\(^{105}\) [Note: $M(X)$ is the set of the types of all non-base-class subobjects that may be at a zero offset in $X$. — end note]
   (3.7.1) If $X$ is a non-union class type with no (possibly inherited (11.6)) non-static data members, the set $M(X)$ is empty.
   (3.7.2) If $X$ is a non-union class type with a non-static data member of type $X_0$ that is either of zero size or is the first non-static data member of $X$ (where said member may be an anonymous union), the set $M(X)$ consists of $X_0$ and the elements of $M(X_0)$.
   (3.7.3) If $X$ is a union type, the set $M(X)$ is the union of all $M(U_i)$ and the set containing all $U_i$, where each $U_i$ is the type of the $i$th non-static data member of $X$.
   (3.7.4) If $X$ is an array type with element type $X_e$, the set $M(X)$ consists of $X_e$ and the elements of $M(X_e)$.
   (3.7.5) If $X$ is a non-class, non-array type, the set $M(X)$ is empty.

4 [Example:

```c
struct B { int i; }; // standard-layout class
struct C : B { }; // standard-layout class
struct D : C { }; // standard-layout class
struct E : D { char : 4; }; // not a standard-layout class

struct Q {};
struct S : Q { }
struct T : Q { }
struct U : S, T { } // not a standard-layout class
```
— end example]

\(^{105}\) This ensures that two subobjects that have the same class type and that belong to the same most derived object are not allocated at the same address (7.6.10).
A standard-layout struct is a standard-layout class defined with the class-key struct or the class-key class. A standard-layout union is a standard-layout class defined with the class-key union.

[Note: Standard-layout classes are useful for communicating with code written in other programming languages. Their layout is specified in 11.3. — end note]

[Example:

```cpp
struct N {
    int i;
    int j;
    virtual ~N();
};

struct T {
    int i;
    private:
    int j;
};

struct SL {
    // standard-layout but not trivial
    int i;
    int j;
    ~SL();
};

struct POD {
    // both trivial and standard-layout
    int i;
    int j;
};
```

— end example]

11.2 Class names

A class definition introduces a new type. [Example:

```cpp
struct X { int a; };
struct Y { int a; };
X a1;
Y a2;
int a3;
```

declares three variables of three different types. This implies that

```cpp
a1 = a2; // error: Y assigned to X
a1 = a3; // error: int assigned to X
```

are type mismatches, and that

```cpp
int f(X);
int f(Y);
```

declare an overloaded (Clause 12) function f() and not simply a single function f() twice. For the same reason,

```cpp
struct S { int a; };
struct S { int a; }; // error, double definition
```

is ill-formed because it defines S twice. — end example]

A class declaration introduces the class name into the scope where it is declared and hides any class, variable, function, or other declaration of that name in an enclosing scope (6.3). If a class name is declared in a scope where a variable, function, or enumerator of the same name is also declared, then when both declarations are in scope, the class can be referred to only using an elaborated-type-specifier (6.4.4). [Example:

```cpp
struct stat {
    // ...
};

stat gstat; // use plain stat to define variable
```
int stat(struct stat*); // redeclare stat as function

void f() {
    struct stat* ps; // struct prefix needed to name struct stat
    stat(ps); // call stat()
}

— end example] A declaration consisting solely of class-key identifier; is either a redeclaration of the name in the current scope or a forward declaration of the identifier as a class name. It introduces the class name into the current scope. [Example:

    struct s { int a; };

    void g() {
        struct s; // hide global struct s with a block-scope declaration
        s* p; // refer to local struct s
        struct s { char* p; }; // define local struct s
        struct s; // redeclaration, has no effect
    }

— end example] [Note: Such declarations allow definition of classes that refer to each other. [Example:

class Vector;

class Matrix {
    // ...
    friend Vector operator*(const Matrix&, const Vector&);
};

class Vector {
    // ...
    friend Vector operator*(const Matrix&, const Vector&);
};

Declaration of friends is described in 11.8.3, operator functions in 12.5. — end example] — end note]

3 [Note: An elaborated-type-specifier (9.1.7.3) can also be used as a type-specifier as part of a declaration. It differs from a class declaration in that if a class of the elaborated name is in scope the elaborated name will refer to it. — end note] [Example:

    struct s { int a; };

    void g(int s) {
        struct s* p = new struct s; // global s
        p->a = s; // parameter s
    }

— end example]

4 [Note: The declaration of a class name takes effect immediately after the identifier is seen in the class definition or elaborated-type-specifier. For example,

    class A * A;

first specifies A to be the name of a class and then redefines it as the name of a pointer to an object of that class. This means that the elaborated form class A must be used to refer to the class. Such artistry with names can be confusing and is best avoided. — end note]

5 A simple-template-id is only a class-name if its template-name names a class template.

11.3 Class members [class.mem]

member-specification:
    member-declaration member-specification_opt
    access-specifier : member-specification_opt

§ 11.3 245
member-declaration:

  declarator brace-or-equal-initializer_opt
  identifier_opt attribute-specifier-seq_opt : constant-expression brace-or-equal-initializer_opt

virt-specifier-seq:
  virt-specifier
  virt-specifier-seq virt-specifier

virt-specifier:
  override
  final

pure-specifier:
  = 0

1 The **member-specification** in a class definition declares the full set of members of the class; no member can be added elsewhere. A **direct member** of a class \( X \) is a member of \( X \) that was first declared within the **member-specification** of \( X \), including anonymous union objects (11.4.1) and direct members thereof. Members of a class are data members, member functions (11.3.1), nested types, enumerators, and member templates (13.6.2) and specializations thereof. [Note: A specialization of a static data member template is a static data member. A specialization of a member function template is a member function. A specialization of a member class template is a nested class. — end note]

2 A **member-declaration** does not declare new members of the class if it is
   (2.1) — a friend declaration (11.8.3),
   (2.2) — a **static_assert-declaration**,
   (2.3) — a **using-declaration** (9.8), or
   (2.4) — an **empty-declaration**.

For any other **member-declaration**, each declared entity that is not an unnamed bit-field (11.3.9) is a member of the class, and each such **member-declaration** shall either declare at least one member name of the class or declare at least one unnamed bit-field.

3 A **data member** is a non-function member introduced by a **member-declarator**. A **member function** is a member that is a function. Nested types are classes (11.2, 11.3.10) and enumerations (9.6) declared in the class and arbitrary types declared as members by use of a typedef declaration (9.1.3) or **alias-declaration**. The enumerators of an unscoped enumeration (9.6) defined in the class are members of the class.

4 A data member or member function may be declared **static** in its **member-declaration**, in which case it is a **static member** (see 11.3.8) (a static data member (11.3.8.2) or static member function (11.3.8.1), respectively) of the class. Any other data member or member function is a **non-static member** (a non-static data member or non-static member function (11.3.2), respectively). [Note: A non-static data member of non-reference type is a member subobject of a class object (6.6.2). — end note]

5 A member shall not be declared twice in the **member-specification**, except that
   (5.1) — a nested class or member class template can be declared and then later defined, and
   (5.2) — an enumeration can be introduced with an **opaque-enum-declaration** and later redeclared with an **enum-specifier**.
[Note: A single name can denote several member functions provided their types are sufficiently different (Clause 12). — end note]

6 A complete-class context of a class is a

(6.1) function body (9.4.1),
(6.2) default argument (9.2.3.6),
(6.3) noexcept-specifier (14.4),
(6.4) contract condition (9.11.4), or
(6.5) default member initializer

within the member-specification of the class. [Note: A complete-class context of a nested class is also a complete-class context of any enclosing class, if the nested class is defined within the member-specification of the enclosing class. — end note]

7 A class is considered a completely-defined object type (6.7) (or complete type) at the closing } of the class-specifier. The class is regarded as complete within its complete-class contexts; otherwise it is regarded as incomplete within its own class member-specification.

8 In a member-declarator, an = immediately following the declarator is interpreted as introducing a pure-specifier if the declarator-id has function type, otherwise it is interpreted as introducing a brace-or-equal-initializer. [Example:

```c
struct S {
    using T = void();
    T * p = 0;    // OK: brace-or-equal-initializer
    virtual T f = 0; // OK: pure-specifier
};

— end example]
```

9 In a member-declarator for a bit-field, the constant-expression is parsed as the longest sequence of tokens that could syntactically form a constant-expression. [Example:

```c
int a;
const int b = 0;
struct S {
    int x1 : 8 = 42;    // OK, "= 42" is brace-or-equal-initializer
    int x2 : 8 { 42 };    // OK, "{ 42 }" is brace-or-equal-initializer
    int y1 : true ? 8 : a = 42; // OK, brace-or-equal-initializer is absent
    int y2 : true ? 8 : b = 42; // error: cannot assign to const int
    int y3 : (true ? 8 : b) = 42; // OK, "= 42" is brace-or-equal-initializer
    int z : 1 || new int { 0 }; // OK, brace-or-equal-initializer is absent
};

— end example]
```

10 A brace-or-equal-initializer shall appear only in the declaration of a data member. (For static data members, see 11.3.8.2; for non-static data members, see 11.9.2 and 9.3.1). A brace-or-equal-initializer for a non-static data member specifies a default member initializer for the member, and shall not directly or indirectly cause the implicit definition of a defaulted default constructor for the enclosing class or the exception specification of that constructor.

11 A member shall not be declared with the extern storage-class-specifier. Within a class definition, a member shall not be declared with the thread_local storage-class-specifier unless also declared static.

12 The decl-specifier-seq may be omitted in constructor, destructor, and conversion function declarations only; when declaring another kind of member the decl-specifier-seq shall contain a type-specifier that is not a cv-qualifier. The member-declarator-list can be omitted only after a class-specifier or an enum-specifier or in a friend declaration (11.8.3). A pure-specifier shall be used only in the declaration of a virtual function (11.6.2) that is not a friend declaration.

13 The optional attribute-specifier-seq in a member-declaration appertains to each of the entities declared by the member-declarators; it shall not appear if the optional member-declarator-list is omitted.

14 A virt-specifier-seq shall contain at most one of each virt-specifier. A virt-specifier-seq shall appear only in the first declaration of a virtual member function (11.6.2).
The type of a non-static data member shall not be an incomplete type (6.7), an abstract class type (11.6.3), or a (possibly multi-dimensional) array thereof. [Note: In particular, a class \( \text{C} \) cannot contain a non-static member of class \( \text{C} \), but it can contain a pointer or reference to an object of class \( \text{C} \). — end note]

[Note: See 7.5.4 for restrictions on the use of non-static data members and non-static member functions. — end note]

[Note: The type of a non-static member function is an ordinary function type, and the type of a non-static data member is an ordinary object type. There are no special member function types or data member types. — end note]

[Example: A simple example of a class definition is

\[
\text{struct tnode} \\
\text{\{ char tword[20];} \\
\text{\int count;} \\
\text{\tnode* left;} \\
\text{\tnode* right;} \\
\text{\}};
\]

which contains an array of twenty characters, an integer, and two pointers to objects of the same type. Once this definition has been given, the declaration

\[
\text{tnode s, *sp;} \\
\]

declares \( s \) to be a \( \text{tnode} \) and \( sp \) to be a pointer to a \( \text{tnode} \). With these declarations, \( sp->\text{count} \) refers to the \( \text{count} \) member of the object to which \( sp \) points; \( s.\text{left} \) refers to the \( \text{left} \) subtree pointer of the object \( s \); and \( s.\text{right}->\text{tword}[0] \) refers to the initial character of the \( \text{tword} \) member of the \( \text{right} \) subtree of \( s \). — end example]

Non-static data members of a (non-union) class with the same access control (11.8) are allocated so that later members have higher addresses within a class object. The order of allocation of non-static data members with different access control is unspecified (11.8). Implementation alignment requirements might cause two adjacent members not to be allocated immediately after each other; so might requirements for space for managing virtual functions (11.6.2) and virtual base classes (11.6.1).

If \( T \) is the name of a class, then each of the following shall have a name different from \( T \):

1. every static data member of class \( T \);
2. every member function of class \( T \) [Note: This restriction does not apply to constructors, which do not have names (11.3.4) — end note] ;
3. every member of class \( T \) that is itself a type;
4. every member template of class \( T \);
5. every enumerator of every member of class \( T \) that is an unscoped enumerated type; and
6. every member of every anonymous union that is a member of class \( T \).

In addition, if class \( T \) has a user-declared constructor (11.3.4), every non-static data member of class \( T \) shall have a name different from \( T \).

The common initial sequence of two standard-layout struct (11.1) types is the longest sequence of non-static data members and bit-fields in declaration order, starting with the first such entity in each of the structs, such that corresponding entities have layout-compatible types, either both entities are declared with the \texttt{no_unique_address} attribute (9.11.11) or neither is, and either both entities are bit-fields with the same width or neither is a bit-field. [Example:

\[
\text{struct A} \{ \text{int a; char b;} \}; \\
\text{struct B} \{ \text{const int b1; volatile char b2;} \}; \\
\text{struct C} \{ \text{int c; unsigned : 0; char b;} \}; \\
\text{struct D} \{ \text{int d; char b : 4;} \}; \\
\text{struct E} \{ \text{unsigned int e; char b;} \}; \\
\]

The common initial sequence of \( A \) and \( B \) comprises all members of either class. The common initial sequence of \( A \) and \( C \) and of \( A \) and \( D \) comprises the first member in each case. The common initial sequence of \( A \) and \( E \) is empty. — end example]

Two standard-layout struct (11.1) types are layout-compatible classes if their common initial sequence comprises all members and bit-fields of both classes (6.7).
Two standard-layout unions are layout-compatible if they have the same number of non-static data members and corresponding non-static data members (in any order) have layout-compatible types (6.7).

In a standard-layout union with an active member (11.4) of struct type T1, it is permitted to read a non-static data member m of another union member of struct type T2 provided m is part of the common initial sequence of T1 and T2; the behavior is as if the corresponding member of T1 were nominated. [Example:

```c
struct T1 { int a, b; }
struct T2 { int c; double d; }
union U { T1 t1; T2 t2; }
int f() {
    U u = { { 1, 2 } }; // active member is t1
    return u.t2.c; // OK, as if u.t1.a were nominated
}
```

—end example] [Note: Reading a volatile object through a glvalue of non-volatile type has undefined behavior (9.1.7.1). —end note]

If a standard-layout class object has any non-static data members, its address is the same as the address of its first non-static data member if that member is not a bit-field. Its address is also the same as the address of each of its base class subobjects. [Note: There might therefore be unnamed padding within a standard-layout struct object inserted by an implementation, but not at its beginning, as necessary to achieve appropriate alignment. —end note] [Note: The object and its first subobject are pointer-interconvertible (6.7.2, 7.6.1.8). —end note]

### 11.3.1 Member functions [class.mfct]

1. A member function may be defined (9.4) in its class definition, in which case it is an inline member function (9.1.6), or it may be defined outside of its class definition if it has already been declared but not defined in its class definition. A member function definition that appears outside of the class definition shall appear in a namespace scope enclosing the class definition. Except for member function definitions that appear outside of a class definition, and except for explicit specializations of member functions of class templates and member function templates (13.8) appearing outside of the class definition, a member function shall not be redeclared.

2. An inline member function (whether static or non-static) may also be defined outside of its class definition provided either its declaration in the class definition or its definition outside of the class definition declares the function as `inline` or `constexpr`. [Note: Member functions of a class have the linkage of the name of the class. See 6.5. —end note]

3. [Note: There can be at most one definition of a non-inline member function in a program. There may be more than one inline member function definition in a program. See 6.2 and 9.1.6. —end note]

4. If the definition of a member function is lexically outside its class definition, the member function name shall be qualified by its class name using the `::` operator. [Note: A name used in a member function definition (that is, in the parameter-declaration-clause including the default arguments (9.2.3.6) or in the member function body) is looked up as described in 6.4. —end note] [Example:

```c
struct X {
    typedef int T;
    static T count;
    void f(T);  
};
void X::f(T t = count) { }
```

The member function f of class X is defined in global scope; the notation X::f specifies that the function f is a member of class X and in the scope of class X. In the function definition, the parameter type T refers to the typedef member T declared in class X and the default argument count refers to the static data member count declared in class X. —end example]

5. [Note: A static local variable or local type in a member function always refers to the same entity, whether or not the member function is inline. —end note]

6. Previously declared member functions may be mentioned in friend declarations.

7. Member functions of a local class shall be defined inline in their class definition, if they are defined at all.
[Note: A member function can be declared (but not defined) using a typedef for a function type. The resulting member function has exactly the same type as it would have if the function declarator were provided explicitly, see 9.2.3.5. For example,

```c
typedef void fv();
typedef void fvc() const;
struct S {
    fv memfunc1;  // equivalent to: void memfunc1();
    void memfunc2();
    fvc memfunc3;  // equivalent to: void memfunc3() const;
};
fv S::* pmfv1 = &S::memfunc1;
fv S::* pmfv2 = &S::memfunc2;
fvc S::* pmfv3 = &S::memfunc3;
```

Also see 13.3. — end note]

11.3.2 Non-static member functions

A non-static member function may be called for an object of its class type, or for an object of a class derived (11.6) from its class type, using the class member access syntax (7.6.1.4, 12.3.1.1). A non-static member function may also be called directly using the function call syntax (7.6.1.2, 12.3.1.1) from within the body of a member function of its class or of a class derived from its class.

If a non-static member function of a class X is called for an object that is not of type X, or of a type derived from X, the behavior is undefined.

When an id-expression (7.5.4) that is not part of a class member access syntax (7.6.1.4) and not used to form a pointer to member (7.6.2.1) is used in a member of class X in a context where this can be used (7.5.2), if name lookup (6.4) resolves the name in the id-expression to a non-static non-type member of some class C, and if either the id-expression is potentially evaluated or C is X or a base class of X, the id-expression is transformed into a class member access expression (7.6.1.4) using (*this) (11.3.2.1) as the postfix-expression to the left of the . operator. [Note: If C is not X or a base class of X, the class member access expression is ill-formed. — end note] Similarly during name lookup, when an unqualified-id (7.5.4.1) used in the definition of a member function for class X resolves to a static member, an enumerator or a nested type of class X or of a base class of X, the unqualified-id is transformed into a qualified-id (7.5.4.2) in which the nested-name-specifier names the class of the member function. These transformations do not apply in the template definition context (13.7.2.1). [Example:

```c
struct tnode {
    char tword[20];
    int count;
    tnode* left;
    tnode* right;
    void set(const char*, tnode* l, tnode* r);
};

tnode::set(const char* w, tnode* l, tnode* r) {
    count = strlen(w)+1;
    if (sizeof(tword)<=count)
        perror("tnode string too long");
    strcpy(tword,w);
    left = l;
    right = r;
}

void f(tnode n1, tnode n2) {
    n1.set("abc",n2,0);
    n2.set("def",0,0);
}

In the body of the member function tnode::set, the member names tword, count, left, and right refer to members of the object for which the function is called. Thus, in the call n1.set("abc",&n2,0), tword refers
```
A non-static member function may be declared `const`, `volatile`, or `const volatile`. These `cv-qualifiers` affect the type of the `this` pointer (11.3.2.1). They also affect the function type (9.2.3.5) of the member function; a member function declared `const` is a `const member function`, a member function declared `volatile` is a `volatile member function` and a member function declared `const volatile` is a `const volatile member function`. [Example:

```c
struct X {
    void g() const;
    void h() const volatile;
};
```

`X::g` is a `const member function` and `X::h` is a `const volatile member function`. — end example]

A non-static member function may be declared with a `ref-qualifier` (9.2.3.5); see 12.3.1.

A non-static member function may be declared virtual (11.6.2) or pure virtual (11.6.3).

### 11.3.2.1 The this pointer

In the body of a non-static (11.3.1) member function, the keyword `this` is a prvalue whose value is a pointer to the object for which the function is called. The type of `this` in a member function of a class `X` is `X*`. If the member function is declared `const`, the type of `this` is `const X*`, if the member function is declared `volatile`, the type of `this` is `volatile X*`, and if the member function is declared `const volatile`, the type of `this` is `const volatile X*`. [Note: Thus in a `const member function`, the object for which the function is called is accessed through a `const` access path. — end note] [Example:

```c
struct s {
    int a;
    int f() const;
    void g() { return a++; } // error
};
```

The `a++` in the body of `s::h` is ill-formed because it tries to modify (a part of) the object for which `s::h()` is called. This is not allowed in a `const member function` because `this` is a pointer to `const`; that is, `*this` has `const` type. — end example]

Similarly, `volatile` semantics (9.1.7.1) apply in `volatile member functions` when accessing the object and its non-static data members.

A `cv-qualified member function` can be called on an object-expression (7.6.1.4) only if the object-expression is as `cv-qualified` or less-cv-qualified than the member function. [Example:

```c
void k(s& x, const s& y) {
    x.f();
    x.g();
    y.f();
    y.g();
    // error
}
```

The call `y.g()` is ill-formed because `y` is `const` and `s::g()` is a non-const member function, that is, `s::g()` is less-qualified than the object-expression `y`. — end example]

[Note: Constructors and destructors cannot be declared `const`, `volatile`, or `const volatile`. However, these functions can be invoked to create and destroy objects with `cv-qualified` types; see 11.3.4 and 11.3.6. — end note]

### 11.3.3 Special member functions

The default constructor (11.3.4.1), copy constructor, move constructor (11.3.4.2), copy assignment operator, move assignment operator (11.3.5), and destructor (11.3.6) are `special member functions`. [Note: The implementation will implicitly declare these member functions for some class types when the program does not explicitly declare them. The implementation will implicitly define them if they are odr-used (6.2) or

---

106) See, for example, `<cstring>` (21.5).
needed for constant evaluation (7.7). — end note] An implicitly-declared special member function is declared at the closing } of the class-specifier. Programs shall not define implicitly-declared special member functions.

2 Programs may explicitly refer to implicitly-declared special member functions. [Example: A program may explicitly call or form a pointer to member to an implicitly-declared special member function.

```
struct A { };
struct B : A {
    B& operator=(const B &);
    B& B::operator=(const B & s) {
        this->A::operator=(s);
        return *this;
    }
}
```

— end example]

3 [Note: The special member functions affect the way objects of class type are created, copied, moved, and destroyed, and how values can be converted to values of other types. Often such special member functions are called implicitly. — end note]

4 Special member functions obey the usual access rules (11.8). [Example: Declaring a constructor protected ensures that only derived classes and friends can create objects using it. — end example]

5 For a class, its non-static data members, its non-virtual direct base classes, and, if the class is not abstract (11.6.3), its virtual base classes are called its potentially constructed subobjects.

11.3.4 Constructors [class.ctor]

1 Constructors do not have names. In a declaration of a constructor, the declarator is a function declarator (9.2.3.5) of the form

```
ptr-declarator ( parameter-declaration-clause ) noexcept-specifier_opt attribute-specifier-seq_opt
```

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

1.1 — in a member-declaration that belongs to the member-specification of a class or class template but is not a friend declaration (11.8.3), the id-expression is the injected-class-name (Clause 11) of the immediately-enclosing entity or

1.2 — in a declaration at namespace scope or in a friend declaration, the id-expression is a qualified-id that names a constructor (6.4.3.1).

In a constructor declaration, each decl-specifier in the optional decl-specifier-seq shall be friend, inline, constexpr, or an explicit-specifier. [Example:

```
struct S {
    S(); // declares the constructor
};
S::S() { } // defines the constructor
```

— end example]

2 A constructor is used to initialize objects of its class type. Because constructors do not have names, they are never found during name lookup; however an explicit type conversion using the functional notation (7.6.1.3) will cause a constructor to be called to initialize an object. [Note: The syntax looks like an explicit call of the constructor. — end note] [Example:

```
complex zz = complex(1,2.3);
cprint( complex(7.8,1.2) );
```

— end example] [Note: For initialization of objects of class type see 11.9. — end note]

3 An object created in this way is unnamed. [Note: 6.6.7 describes the lifetime of temporary objects. — end note] [Note: Explicit constructor calls do not yield lvalues, see 7.2.1. — end note]

4 [Note: Some language constructs have special semantics when used during construction; see 11.9.2 and 11.9.4. — end note]
A constructor can be invoked for a \texttt{const}, \texttt{volatile} or \texttt{const volatile} object. \texttt{const} and \texttt{volatile} semantics (9.1.7.1) are not applied on an object under construction. They come into effect when the constructor for the most derived object (6.6.2) ends.

A \texttt{return} statement in the body of a constructor shall not specify a return value. The address of a constructor shall not be taken.

A constructor shall not be a coroutine.

### 11.3.4.1 Default constructors

A \textit{default constructor} for a class \texttt{X} is a constructor of class \texttt{X} for which each parameter that is not a function parameter pack has a default argument (including the case of a constructor with no parameters). If there is no user-declared constructor for class \texttt{X}, a non-explicit constructor having no parameters is implicitly declared as defaulted (9.4). An implicitly-declared default constructor is an inline public member of its class.

A defaulted default constructor for class \texttt{X} is defined as deleted if:

1. \texttt{X} is a union that has a variant member with a non-trivial default constructor and no variant member of \texttt{X} has a default member initializer,
2. \texttt{X} is a non-union class that has a variant member \texttt{M} with a non-trivial default constructor and no variant member of the anonymous union containing \texttt{M} has a default member initializer,
3. any non-static data member with no default member initializer (11.3) is of reference type,
4. any non-variant non-static data member of const-qualified type (or array thereof) with no \texttt{brace-or-equal-initializer} is not const-default-constructible (9.3).
5. \texttt{X} is a union and all of its variant members are of const-qualified type (or array thereof),
6. \texttt{X} is a non-union class and all members of any anonymous union member are of const-qualified type (or array thereof),
7. any potentially constructed subobject, except for a non-static data member with a \texttt{brace-or-equal-initializer}, has class type \texttt{M} (or array thereof) and either \texttt{M} has no default constructor or overload resolution (12.3) as applied to find \texttt{M}'s corresponding constructor results in an ambiguity or in a function that is deleted or inaccessible from the defaulted default constructor, or
8. any potentially constructed subobject has a type with a destructor that is deleted or inaccessible from the defaulted default constructor.

A default constructor is \textit{trivial} if it is not user-provided and if:

1. its class has no virtual functions (11.6.2) and no virtual base classes (11.6.1), and
2. no non-static data member of its class has a default member initializer (11.3), and
3. all the direct base classes of its class have trivial default constructors, and
4. for all the non-static data members of its class that are of class type (or array thereof), each such class has a trivial default constructor.

Otherwise, the default constructor is \textit{non-trivial}.

A default constructor that is defaulted and not defined as deleted is \textit{implicitly defined} when it is odr-used (6.2) to create an object of its class type (6.6.2), when it is needed for constant evaluation (7.7), or when it is explicitly defaulted after its first declaration. The implicitly-defined default constructor performs the set of initializations of the class that would be performed by a user-written default constructor for that class with no \texttt{ctor-initializer} (11.9.2) and an empty \texttt{compound-statement}. If that user-written default constructor would be ill-formed, the program is ill-formed. If that user-written default constructor would satisfy the requirements of a \texttt{constexpr} constructor (9.1.5), the implicitly-defined default constructor is \texttt{constexpr}. Before the defaulted default constructor for a class is implicitly defined, all the non-user-provided default constructors for its base classes and its non-static data members shall have been implicitly defined. \[Note: An implicitly-declared default constructor has an exception specification (14.4). An explicitly-defined definition might have an implicit exception specification, see 9.4. — end note\]

Default constructors are called implicitly to create class objects of static, thread, or automatic storage duration (6.6.5.1, 6.6.5.2, 6.6.5.3) defined without an initializer (9.3), are called to create class objects of dynamic storage duration (6.6.5.4) created by a \texttt{new-expression} in which the \texttt{new-initializer} is omitted (7.6.2.7), or are called when the explicit type conversion syntax (7.6.1.3) is used. A program is ill-formed if the default constructor for an object is implicitly used and the constructor is not accessible (11.8).

[Note: 11.9.2 describes the order in which constructors for base classes and non-static data members are called and describes how arguments can be specified for the calls to these constructors. — end note]

### 11.3.4.2 Copy/move constructors

1 A non-template constructor for class `X` is a copy constructor if its first parameter is of type `X&`, `const X&`, `volatile X&`, or `const volatile X&`, and either there are no other parameters or else all other parameters have default arguments (9.2.3.6). [Example: `X::X(const X&)` and `X::X(X&, int=1)` are copy constructors.

```cpp
struct X {
    X(int);
    X(const X&, int = 1);
};
X a(1);       // calls X(int);
X b(a, 0);    // calls X(const X&, int);
X c = b;      // calls X(const X&, int);
```

—end example

2 A non-template constructor for class `X` is a move constructor if its first parameter is of type `X&&`, `const X&&`, `volatile X&&`, or `const volatile X&&`, and either there are no other parameters or else all other parameters have default arguments (9.2.3.6). [Example: `Y::Y(Y&&)` is a move constructor.

```cpp
struct Y {
    Y(const Y&);
    Y(Y&&);
};
extern Y f(int);
Y d(f(1));     // calls Y(Y&&)
Y e = d;       // calls Y(const Y&)
```

—end example

3 [Note: All forms of copy/move constructor may be declared for a class. [Example:

```cpp
struct X {
    X(const X&);
    X(X&);       // OK
    X(X&&);      // OK, but possibly not sensible
};
```

—end example]

—end note

4 [Note: If a class `X` only has a copy constructor with a parameter of type `X&`, an initializer of type `const` or `volatile X` cannot initialize an object of type (possibly cv-qualified) `X`. [Example:

```cpp
struct X {
    X();       // default constructor
    X(X&);     // copy constructor with a non-const parameter
};
const X cx;
X x = cx;    // error: X::X(X&) cannot copy cx into x
```

—end example] —end note

5 A declaration of a constructor for a class `X` is ill-formed if its first parameter is of type (optionally cv-qualified) `X` and either there are no other parameters or else all other parameters have default arguments. A member function template is never instantiated to produce such a constructor signature. [Example:

```cpp
struct S {
    template<typename T> S(T);
    S();
};
S g;

void h() {
    S a(g); // does not instantiate the member template to produce S::S<S>(S);
    // uses the implicitly declared copy constructor
}
```
If the class definition does not explicitly declare a copy constructor, a non-explicit one is declared implicitly. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy constructor is defined as deleted; otherwise, it is defined as defaulted (9.4). The latter case is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor (D.5).

The implicitly-declared copy constructor for a class \( X \) will have the form
\[
X::X(const X&)\]
if each potentially constructed subobject of a class type \( M \) (or array thereof) has a copy constructor whose first parameter is of type \( const M & \) or \( const volatile M & \)\(^{107}\). Otherwise, the implicitly-declared copy constructor will have the form
\[
X::X(X&)\]

If the definition of a class \( X \) does not explicitly declare a move constructor, a non-explicit one will be implicitly declared as defaulted if and only if

- \( X \) does not have a user-declared copy constructor,
- \( X \) does not have a user-declared copy assignment operator,
- \( X \) does not have a user-declared move assignment operator, and
- \( X \) does not have a user-declared destructor.

[Note: When the move constructor is not implicitly declared or explicitly supplied, expressions that otherwise would have invoked the move constructor may instead invoke a copy constructor. — end note]

The implicitly-declared move constructor for class \( X \) will have the form
\[
X::X(X&&)\]

An implicitly-declared copy/move constructor is an inline public member of its class. A defaulted copy/move constructor for a class \( X \) is defined as deleted (9.4.3) if \( X \) has:

- a potentially constructed subobject type \( M \) (or array thereof) that cannot be copied/moved because overload resolution (12.3), as applied to find \( M \)’s corresponding constructor, results in an ambiguity or a function that is deleted or inaccessible from the defaulted constructor,
- a variant member whose corresponding constructor as selected by overload resolution is non-trivial,
- any potentially constructed subobject of a type with a destructor that is deleted or inaccessible from the defaulted constructor, or,
- for the copy constructor, a non-static data member of rvalue reference type.

A defaulted move constructor that is defined as deleted is ignored by overload resolution (12.3, 12.4). [Note: A deleted move constructor would otherwise interfere with initialization from an rvalue which can use the copy constructor instead. — end note]

A copy/move constructor for class \( X \) is trivial if it is not user-provided and if:

- class \( X \) has no virtual functions (11.6.2) and no virtual base classes (11.6.1), and
- the constructor selected to copy/move each direct base class subobject is trivial, and
- for each non-static data member of \( X \) that is of class type (or array thereof), the constructor selected to copy/move that member is trivial;

otherwise the copy/move constructor is non-trivial.

A copy/move constructor that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.2), when it is needed for constant evaluation (7.7), or when it is explicitly defaulted after its first declaration. [Note: The copy/move constructor is implicitly defined even if the implementation elided its odr-use (6.2, 6.6.7). — end note] If the implicitly-defined constructor would satisfy the requirements of a constexpr constructor (9.1.5), the implicitly-defined constructor is constexpr.

Before the defaulted copy/move constructor for a class is implicitly defined, all non-user-provided copy/move constructors for its potentially constructed subobjects shall have been implicitly defined. [Note: An implicitly-declared copy/move constructor has an implied exception specification (14.4). — end note]

---

\(^{107}\) This implies that the reference parameter of the implicitly-declared copy constructor cannot bind to a \textit{volatile} lvalue; see C.1.6.
The implicitly-defined copy/move constructor for a non-union class $X$ performs a memberwise copy/move of its bases and members. \[\text{Note: Default member initializers of non-static data members are ignored. See also the example in 11.9.2. — end note}\] The order of initialization is the same as the order of initialization of bases and members in a user-defined constructor (see 11.9.2). Let $x$ be either the parameter of the constructor or, for the move constructor, an xvalue referring to the parameter. Each base or non-static data member is copied/moved in the manner appropriate to its type:

- if the member is an array, each element is direct-initialized with the corresponding subobject of $x$;
- if a member $m$ has rvalue reference type $T&&$, it is direct-initialized with $\text{static\_cast}\langle T&&\rangle(x.m)$;
- otherwise, the base or member is direct-initialized with the corresponding base or member of $x$.

Virtual base class subobjects shall be initialized only once by the implicitly-defined copy/move constructor (see 11.9.2).

The implicitly-defined copy/move constructor for a union $X$ copies the object representation (6.7) of $X$.

### 11.3.5 Copy/move assignment operator

A user-declared copy assignment operator $X::\text{operator}=\text{is a non-static non-template member function of class } X$ with exactly one parameter of type $X, X&, \text{const } X&, \text{volatile } X&, \text{or } \text{const volatile } X&$. \[\text{Note: An overloaded assignment operator must be declared to have only one parameter; see 12.5.3. — end note}\]

\[\text{Note: More than one form of copy assignment operator may be declared for a class. — end note}\] \[\text{Note: If a class } X \text{ only has a copy assignment operator with a parameter of type } X&, \text{an expression of type } \text{const } X \text{ cannot be assigned to an object of type } X. \[\text{Example:}\]

```cpp
struct X {
    X();
    X& operator=(X&);
};
const X cx;
X x;
void f() {
    x = cx;  // error: X::operator=(X&) cannot assign cx into x
}
```

\[\text{— end example}\] — end note]

If the class definition does not explicitly declare a copy assignment operator, one is declared implicitly. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy assignment operator is defined as deleted; otherwise, it is defined as defaulted (9.4). The latter case is deprecated if the class has a user-declared copy constructor or a user-declared destructor (D.5). The implicitly-declared copy assignment operator for a class $X$ will have the form

$X& X::\text{operator}=(\text{const } X&)$

if

- each direct base class $B$ of $X$ has a copy assignment operator whose parameter is of type $\text{const } B&, \text{const volatile } B&, \text{or } B$, and
- for all the non-static data members of $X$ that are of a class type $M$ (or array thereof), each such class type has a copy assignment operator whose parameter is of type $\text{const } M&, \text{const volatile } M&, \text{or } M$.

Otherwise, the implicitly-declared copy assignment operator will have the form

$X& X::\text{operator}=(X&)$

A user-declared move assignment operator $X::\text{operator}=\text{is a non-static non-template member function of class } X$ with exactly one parameter of type $X&&, \text{const } X&&, \text{volatile } X&&, \text{or } \text{const volatile } X&&$. \[\text{Note: An overloaded assignment operator must be declared to have only one parameter; see 12.5.3. — end note}\]

\[\text{Note: More than one form of move assignment operator may be declared for a class. — end note}\]

---

108) Because a template assignment operator or an assignment operator taking an rvalue reference parameter is never a copy assignment operator, the presence of such an assignment operator does not suppress the implicit declaration of a copy assignment operator. Such assignment operators participate in overload resolution with other assignment operators, including copy assignment operators, and, if selected, will be used to assign an object.

109) This implies that the reference parameter of the implicitly-declared copy assignment operator cannot bind to a volatile lvalue; see C.1.6.
If the definition of a class \( X \) does not explicitly declare a move assignment operator, one will be implicitly declared as defaulted if and only if:

1. \( X \) does not have a user-declared copy constructor,
2. \( X \) does not have a user-declared move constructor,
3. \( X \) does not have a user-declared copy assignment operator, and
4. \( X \) does not have a user-declared destructor.

[Example: The class definition

```c
struct S {
    int a;
    S& operator=(const S&) = default;
};
```

will not have a default move assignment operator implicitly declared because the copy assignment operator has been user-declared. The move assignment operator may be explicitly defaulted.

```c
struct S {
    int a;
    S& operator=(const S&) = default;
    S& operator=(S&&) = default;
};
```

—end example]

The implicitly-declared move assignment operator for a class \( X \) will have the form

\[ X\& X::operator=(X&&); \]

The implicitly-declared copy/move assignment operator for class \( X \) has the return type \( X\& \); it returns the object for which the assignment operator is invoked, that is, the object assigned to. An implicitly-declared copy/move assignment operator is an inline public member of its class.

A defaulted copy/move assignment operator for class \( X \) is defined as deleted if \( X \) has:

1. a variant member with a non-trivial corresponding assignment operator and \( X \) is a union-like class, or
2. a non-static data member of \texttt{const} non-class type (or array thereof), or
3. a non-static data member of reference type, or
4. a direct non-static data member of class type \( M \) (or array thereof) or a direct base class \( M \) that cannot be copied/moved because overload resolution (12.3), as applied to find \( M \)'s corresponding assignment operator, results in an ambiguity or a function that is deleted or inaccessible from the defaulted assignment operator.

A defaulted move assignment operator that is defined as deleted is ignored by overload resolution (12.3, 12.4).

Because a copy/move assignment operator is implicitly declared for a class if not declared by the user, a base class copy/move assignment operator is always hidden by the corresponding assignment operator of a derived class (12.5.3). A \textit{using-declaration} (9.8) that brings in from a base class an assignment operator with a parameter type that could be that of a copy/move assignment operator for the derived class is not considered an explicit declaration of such an operator and does not suppress the implicit declaration of the derived class operator; the operator introduced by the \textit{using-declaration} is hidden by the implicitly-declared operator in the derived class.

A copy/move assignment operator for class \( X \) is trivial if it is not user-provided and if:

1. \( X \) has no virtual functions (11.6.2) and no virtual base classes (11.6.1), and
2. the assignment operator selected to copy/move each direct base class subobject is trivial, and
3. for each non-static data member of \( X \) that is of class type (or array thereof), the assignment operator selected to copy/move that member is trivial;

otherwise the copy/move assignment operator is \textit{non-trivial}.

A copy/move assignment operator for a class \( X \) that is defaulted and not defined as deleted is \textit{implicitly defined} when it is odr-used (6.2) (e.g., when it is selected by overload resolution to assign to an object of its class type), when it is needed for constant evaluation (7.7), or when it is explicitly defaulted after its first declaration. The implicitly-defined copy/move assignment operator is \texttt{constexpr} if

\[ \S\text{ 11.3.5} \]
X is a literal type, and
the assignment operator selected to copy/move each direct base class subobject is a constexpr function, and
for each non-static data member of X that is of class type (or array thereof), the assignment operator selected to copy/move that member is a constexpr function.

Before the defaulted copy/move assignment operator for a class is implicitly defined, all non-user-provided copy/move assignment operators for its direct base classes and its non-static data members shall have been implicitly defined. [Note: An implicitly-declared copy/move assignment operator has an implied exception specification (14.4). —end note]

The implicitly-defined copy/move assignment operator for a non-union class X performs memberwise copy/move assignment of its subobjects. The direct base classes of X are assigned first, in the order of their declaration in the base-specifier-list, and then the immediate non-static data members of X are assigned, in the order in which they were declared in the class definition. Let x be either the parameter of the function or, for the move operator, an xvalue referring to the parameter. Each subobject is assigned in the manner appropriate to its type:

- if the subobject is of class type, as if by a call to operator= with the subobject as the object expression and the corresponding subobject of x as a single function argument (as if by explicit qualification; that is, ignoring any possible virtual overriding functions in more derived classes);
- if the subobject is an array, each element is assigned, in the manner appropriate to the element type;
- if the subobject is of scalar type, the built-in assignment operator is used.

It is unspecified whether subobjects representing virtual base classes are assigned more than once by the implicitly-defined copy/move assignment operator. [Example:

```cpp
struct V {
};
struct A : virtual V {
};
struct B : virtual V {
};
struct C : B, A {
};
```

It is unspecified whether the virtual base class subobject V is assigned twice by the implicitly-defined copy/move assignment operator for C. —end example]

The implicitly-defined copy assignment operator for a union X copies the object representation (6.7) of X.

### 11.3.6 Destructors

In a declaration of a destructor, the declarator is a function declarator (9.2.3.5) of the form

\[ ptr-declarator \ ( parameter-declaration-clause ) \ \text{noexcept-specifier}\_opt \ \text{attribute-specifier-seq}\_opt \]

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

- in a member-declaration that belongs to the member-specification of a class or class template but is not a friend declaration (11.8.3), the id-expression is ~class-name and the class-name is the injected-class-name (Clause 11) of the immediately-enclosing entity or
- in a declaration at namespace scope or in a friend declaration, the id-expression is nested-name-specifier ~class-name and the class-name names the same class as the nested-name-specifier.

A destructor shall take no arguments (9.2.3.5). Each decl-specifier of the decl-specifier-seq of a destructor declaration (if any) shall be friend, inline, or virtual.

The address of a destructor shall not be taken. A destructor can be invoked for a const, volatile or const volatile object. const and volatile semantics (9.1.7.1) are not applied on an object under destruction. They stop being in effect when the destructor for the most derived object (6.6.2) starts.

[Note: A declaration of a destructor that does not have a noexcept-specifier has the same exception specification as if it had been implicitly declared (14.4). —end note]

If a class has no user-declared destructor, a destructor is implicitly declared as defaulted (9.4). An implicitly-declared destructor is an inline public member of its class.

A defaulted destructor for a class X is defined as deleted if:

- X is a union-like class that has a variant member with a non-trivial destructor,
any potentially constructed subobject has class type M (or array thereof) and M has a deleted destructor or a destructor that is inaccessible from the defaulted destructor,

or, for a virtual destructor, lookup of the non-array deallocation function results in an ambiguity or in a function that is deleted or inaccessible from the defaulted destructor.

A destructor is trivial if it is not user-provided and if:

- the destructor is not virtual,
- all of the direct base classes of its class have trivial destructors, and
- for all of the non-static data members of its class that are of class type (or array thereof), each such class has a trivial destructor.

Otherwise, the destructor is non-trivial.

A destructor that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.2) or when it is explicitly defaulted after its first declaration.

Before the defaulted destructor for a class is implicitly defined, all the non-user-provided destructors for its base classes and its non-static data members shall have been implicitly defined.

After executing the body of the destructor and destroying any automatic objects allocated within the body, a destructor for class X calls the destructors for X’s direct non-variant non-static data members, the destructors for X’s non-virtual direct base classes and, if X is the most derived class (11.9.2), its destructor calls the destructors for X’s virtual base classes. All destructors are called as if they were referenced with a qualified name, that is, ignoring any possible virtual overriding destructors in more derived classes. Bases and members are destroyed in the reverse order of the completion of their constructor (see 11.9.2). A return statement (8.6.3) in a destructor might not directly return to the caller; before transferring control to the caller, the destructors for the members and bases are called. Destructors for elements of an array are called in reverse order of their construction (see 11.9).

A destructor can be declared virtual (11.6.2) or pure virtual (11.6.3); if any objects of that class or any derived class are created in the program, the destructor shall be defined. If a class has a base class with a virtual destructor, its destructor (whether user- or implicitly-declared) is virtual.

[Note: Some language constructs have special semantics when used during destruction; see 11.9.4. — end note]

A destructor is invoked implicitly

- for a constructed object with static storage duration (6.6.5.1) at program termination (6.8.3.4),
- for a constructed object with thread storage duration (6.6.5.2) at thread exit,
- for a constructed object with automatic storage duration (6.6.5.3) when the block in which an object is created exits (8.7),
- for a constructed temporary object when its lifetime ends (7.3.4, 6.6.7).

In each case, the context of the invocation is the context of the construction of the object. A destructor may also be invoked implicitly through use of a delete-expression (7.6.2.8) for a constructed object allocated by a new-expression (7.6.2.7); the context of the invocation is the delete-expression. [Note: An array of class type contains several subobjects for each of which the destructor is invoked. — end note] A destructor can also be invoked explicitly. A destructor is potentially invoked if it is invoked or as specified in 7.6.2.7, 9.3.1, 11.9.2, and 14.1. A program is ill-formed if a destructor that is potentially invoked is deleted or not accessible from the context of the invocation.

At the point of definition of a virtual destructor (including an implicit definition (11.3.6)), the non-array deallocation function is determined as if for the expression delete this appearing in a non-virtual destructor of the destructor’s class (see 7.6.2.8). If the lookup fails or if the deallocation function has a deleted definition (9.4), the program is ill-formed. [Note: This assures that a deallocation function corresponding to the dynamic type of an object is available for the delete-expression (11.11). — end note]

In an explicit destructor call, the destructor is specified by a ~ followed by a type-name or decltype-specifier that denotes the destructor’s class type. The invocation of a destructor is subject to the usual rules for member functions (11.3.1); that is, if the object is not of the destructor’s class type and not of a class derived from the destructor’s class type (including when the destructor is invoked via a null pointer value), the program has undefined behavior. [Note: Invoking delete on a null pointer does not call the destructor; see 7.6.2.8. — end note] [Example: § 11.3.6]
struct B {
  virtual ~B() { }
};
struct D : B {
  ~D() { }
};
D d_object;
typedef B b_alias;
B* b_ptr = &d_object;

void f() {
  d_object.B::*B(); // calls B's destructor
  b_ptr->*B(); // calls B's destructor
  b_ptr->*b_alias::*B(); // calls B's destructor
  b_ptr->*b_alias::*b_alias(); // calls B's destructor
}

—end example—

Note: An explicit destructor call must always be written using a member access operator (7.6.1.4) or a qualified-id (7.5.4.2); in particular, the unary-expression ~X() in a member function is not an explicit destructor call (7.6.2.1). —end note

15 [Note: Explicit calls of destructors are rarely needed. One use of such calls is for objects placed at specific addresses using a placement new-expression. Such use of explicit placement and destruction of objects can be necessary to cope with dedicated hardware resources and for writing memory management facilities. For example,

void* operator new(std::size_t, void* p) { return p; }
struct X {
  X(int);
  ~X();
};
void f(X* p);

void g() {
  // rare, specialized use:
  char* buf = new char[sizeof(X)];
  X* p = new(buf) X(222); // use buf[] and initialize
  f(p);
  p->X::*X(); // cleanup
}
—end note—

16 Once a destructor is invoked for an object, the object no longer exists; the behavior is undefined if the destructor is invoked for an object whose lifetime has ended (6.6.3). [Example: If the destructor for an automatic object is explicitly invoked, and the block is subsequently left in a manner that would ordinarily invoke implicit destruction of the object, the behavior is undefined. —end example] —end note—

17 [Note: The notation for explicit call of a destructor can be used for any scalar type name (7.5.4.3). Allowing this makes it possible to write code without having to know if a destructor exists for a given type. For example:

typedef int I;
I* p;
p->I::*I();
—end note—

18 A destructor shall not be a coroutine.

11.3.7 Conversions

Type conversions of class objects can be specified by constructors and by conversion functions. These conversions are called user-defined conversions and are used for implicit type conversions (7.3), for initialization (9.3), and for explicit type conversions (7.6.3, 7.6.1.8).

User-defined conversions are applied only where they are unambiguous (11.7, 11.3.7.2). Conversions obey the access control rules (11.8). Access control is applied after ambiguity resolution (6.4).
[Note: See 12.3 for a discussion of the use of conversions in function calls as well as examples below. — end note]

4 At most one user-defined conversion (constructor or conversion function) is implicitly applied to a single value. [Example:

```cpp
struct X {
    operator int();
};

struct Y {
    operator X();
};

Y a;
int b = a; // error, a.operator X().operator int() not tried
int c = X(a); // OK: a.operator X().operator int()
```

—end example]

5 User-defined conversions are used implicitly only if they are unambiguous. A conversion function in a derived class does not hide a conversion function in a base class unless the two functions convert to the same type. Function overload resolution (12.3.3) selects the best conversion function to perform the conversion. [Example:

```cpp
struct X {
    operator int();
};

struct Y : X {
    operator char();
};

void f(Y & a) {
    if (a) {
        // ill-formed: X::operator int() or Y::operator char()
    }
}
```

—end example]

11.3.7.1 Conversion by constructor [class.convctor]

A constructor that is not explicit (9.1.2) specifies a conversion from the types of its parameters (if any) to the type of its class. Such a constructor is called a converting constructor. [Example:

```cpp
struct X {
    X(int);
    X(const char*, int = 0);
    X(int, int);
};

void f(X & arg) {
    X a = 1; // a = X(1)
    X b = "Jessie"; // b = X("Jessie", 0)
    a = 2; // a = X(2)
    f(3); // f(X(3))
    f({1, 2}); // f(X(1, 2))
}
```

—end example]

[Note: An explicit constructor constructs objects just like non-explicit constructors, but does so only where the direct-initialization syntax (9.3) or where casts (7.6.1.8, 7.6.3) are explicitly used; see also 12.3.1.4. A default constructor may be an explicit constructor; such a constructor will be used to perform default-initialization or value-initialization (9.3). [Example:

```cpp
struct Z {
    explicit Z();
    explicit Z(int);
```
explicit Z(int, int);

Z a;        // OK: default-initialization performed
Z b();     // OK: direct initialization syntax used
Z c = {};   // error: copy-list-initialization
Z a1 = 1;   // error: no implicit conversion
Z a3 = Z(1);  // OK: direct initialization syntax used
Z a2(1);   // OK: direct initialization syntax used
Z* p = new Z(1);  // OK: direct initialization syntax used
Z a4 = (Z)1;   // OK: explicit cast used
Z a5 = static_cast<Z>(1);  // OK: explicit cast used
Z a6 = { 3, 4 };  // error: no implicit initialization

—end example —end note

3 A non-explicit copy/move constructor (11.3.4.2) is a converting constructor. [Note: An implicitly-declared
copy/move constructor is not an explicit constructor; it may be called for implicit type conversions. —end
note]

11.3.7.2 Conversion functions

1 A member function of a class \( \text{X} \) having no parameters with a name of the form

\[
\text{operator conversion-type-id} \\
\text{conversion-type-id:} \\
\text{type-specifier-seq conversion-declarator}^{\text{opt}} \\
\text{conversion-declarator:} \\
\text{ptr-operator conversion-declarator}^{\text{opt}}
\]

specifies a conversion from \( \text{X} \) to the type specified by the \( \text{conversion-type-id} \). Such functions are called conversion functions. A decl-specifier in the decl-specifier-seq of a conversion function (if any) shall be neither a defining-type-specifier nor static. The type of the conversion function (9.2.3.5) is “function taking no parameter returning \text{conversion-type-id}”. A conversion function is never used to convert a (possibly cv-qualified) object to the (possibly cv-qualified) same object type (or a reference to it), to a (possibly cv-qualified) base class of that type (or a reference to it), or to (possibly cv-qualified) void.\(^{110}\) [Example:

```c
struct X {
    operator int();
    operator auto() -> short;  // error: trailing return type
};
```

void f(X a) {
    int i = int(a);
    i = (int)a;
    i = a;
}
In all three cases the value assigned will be converted by \( \text{X::operator int()} \). —end example]

2 A conversion function may be explicit (9.1.2), in which case it is only considered as a user-defined conversion
for direct-initialization (9.3). Otherwise, user-defined conversions are not restricted to use in assignments and
initializations. [Example:

```c
class Y { };
struct Z {
    explicit operator Y() const;
};
```

void h(Z z) {
    Y y1(z);    // OK: direct-initialization
    Y y2 = z;   // ill-formed: copy-initialization
```
Y y3 = (Y)z;  // OK: cast notation

void g(X a, X b) {
    int i = (a) ? 1+a : 0;
    int j = (a&&b) ? a+b : i;
    if (a) {
    }
}
— end example]

3 The conversion-type-id shall not represent a function type nor an array type. The conversion-type-id in a conversion-function-id is the longest sequence of tokens that could possibly form a conversion-type-id. [Note: This prevents ambiguities between the declarator operator * and its expression counterparts. [Example:

```cpp
&ac.operator int*i; // syntax error;
    // parsed as: k(ac.operator int *)i
    // not as: k(ac.operator int)*i
```

The * is the pointer declarator and not the multiplication operator. —end example] This rule also prevents ambiguities for attributes. [Example:

```cpp
operator int [(noreturn)] (); // error: noreturn attribute applied to a type
— end example] — end note]

4 Conversion functions are inherited.

5 Conversion functions can be virtual.

6 A conversion function template shall not have a deduced return type (9.1.7.5). [Example:

```cpp
struct S {
    operator auto() const { return 10; } // OK
    template<class T>
    operator auto() const { return 1.2; } // error: conversion function template
};
— end example]

11.3.8 Static members [class.static]

1 A static member s of class X may be referred to using the qualified-id expression X::s; it is not necessary to use the class member access syntax (7.6.1.4) to refer to a static member. A static member may be referred to using the class member access syntax, in which case the object expression is evaluated. [Example:

```cpp
struct S {
    static void reschedule();
};

void f() {
    process::reschedule(); // OK: no object necessary
    g().reschedule(); // g() is called
}
— end example]

2 A static member may be referred to directly in the scope of its class or in the scope of a class derived (11.6) from its class; in this case, the static member is referenced to as if a qualified-id expression was used, with the nested-name-specifier of the qualified-id naming the class scope from which the static member is referenced. [Example:

```cpp
int g();
struct X {
    static int g();
};
struct Y : X {
    static int i;
};
int Y::i = g(); // equivalent to Y::g();
```
If an unqualified-id (7.5.4.1) is used in the definition of a static member following the member’s declarator-id, and name lookup (6.4.1) finds that the unqualified-id refers to a static member, enumerator, or nested type of the member’s class (or of a base class of the member’s class), the unqualified-id is transformed into a qualified-id expression in which the nested-name-specifier names the class scope from which the member is referenced. [Note: See 7.5.4 for restrictions on the use of non-static data members and non-static member functions. —end note]

Static members obey the usual class member access rules (11.8). When used in the declaration of a class member, the static specifier shall only be used in the member declarations that appear within the member-specification of the class definition. [Note: It cannot be specified in member declarations that appear in namespace scope. —end note]

### 11.3.8.1 Static member functions

[class.static.mfct]

1 [Note: The rules described in 11.3.1 apply to static member functions. — end note]

2 [Note: A static member function does not have a this pointer (11.3.2.1). — end note] A static member function shall not be virtual. There shall not be a static and a non-static member function with the same name and the same parameter types (12.1). A static member function shall not be declared const, volatile, or const volatile.

### 11.3.8.2 Static data members

[class.static.data]

1 A static data member is not part of the subobjects of a class. If a static data member is declared thread-local there is one copy of the member per thread. If a static data member is not declared thread_local there is one copy of the data member that is shared by all the objects of the class.

2 The declaration of a non-inline static data member in its class definition is not a definition and may be of an incomplete type other than cv void. The definition for a static data member that is not defined inline in the class definition shall appear in a namespace scope enclosing the member’s class definition. In the definition at namespace scope, the name of the static data member shall be qualified by its class name using the :: operator. The initializer expression in the definition of a static data member is in the scope of its class (6.3.7). [Example:

```c
class process {
    static process* run_chain;
    static process* running;
};
```

```c
process* process::running = get_main();
process* process::run_chain = running;
```

The static data member run_chain of class process is defined in global scope; the notation process::run_chain specifies that the member run_chain is a member of class process and in the scope of class process. In the static data member definition, the initializer expression refers to the static data member running of class process. — end example]

[Note: Once the static data member has been defined, it exists even if no objects of its class have been created. [Example: In the example above, run_chain and running exist even if no objects of class process are created by the program. — end example] — end note]

3 If a non-volatile non-inline const static data member is of integral or enumeration type, its declaration in the class definition can specify a brace-or-equal-initializer in which every initializer-clause that is an assignment-expression is a constant expression (7.7). The member shall still be defined in a namespace scope if it is odr-used (6.2) in the program and the namespace scope definition shall not contain an initializer. An inline static data member may be defined in the class definition and may specify a brace-or-equal-initializer. If the member is declared with the constexpr specifier, it may be redeclared in namespace scope with no initializer (this usage is deprecated; see D.4). Declarations of other static data members shall not specify a brace-or-equal-initializer.

4 [Note: There shall be exactly one definition of a static data member that is odr-used (6.2) in a program; no diagnostic is required. — end note] Unnamed classes and classes contained directly or indirectly within unnamed classes shall not contain static data members.

5 [Note: Static data members of a class in namespace scope have the linkage of the name of the class (6.5). A local class cannot have static data members (11.5). — end note]
11.3.9 Bit-fields

A member-declarator of the form

\[
\text{identifier} \opt \text{attribute-specifier-seq} \opt : \text{constant-expression brace-or-equal-initializer} \opt
\]

specifies a bit-field. The optional attribute-specifier-seq appertains to the entity being declared. A bit-field shall not be a static member. A bit-field shall have integral or enumeration type; the bit-field semantic property is not part of the type of the class member. The constant-expression shall be an integral constant expression with a value greater than or equal to zero and is called the width of the bit-field. If the width of a bit-field is larger than the width of the bit-field’s type (or, in case of an enumeration type, of its underlying type), the extra bits are padding bits (6.7). Allocation of bit-fields within a class object is implementation-defined. Alignment of bit-fields is implementation-defined. Bit-fields are packed into some addressable allocation unit. [Note: Bit-fields straddle allocation units on some machines, not on others. —end note]

A declaration for a bit-field that omits the identifier declares an unnamed bit-field. Unnamed bit-fields are not members and cannot be initialized. An unnamed bit-field shall not be declared with a cv-qualified type. [Note: An unnamed bit-field is useful for padding to conform to externally-imposed layouts. —end note]

As a special case, an unnamed bit-field with a width of zero specifies alignment of the next bit-field at an allocation unit boundary. Only when declaring an unnamed bit-field may the width be zero.

The address-of operator & shall not be applied to a bit-field, so there are no pointers to bit-fields. A non-const reference shall not be bound to a bit-field (9.3.3). [Note: If the initializer for a reference of type const T& is an lvalue that refers to a bit-field, the reference is bound to a temporary initialized to hold the value of the bit-field; the reference is not bound to the bit-field directly. See 9.3.3. —end note]

If a value of integral type (other than bool) is stored into a bit-field of width \(N\) and the value would be representable in a hypothetical signed or unsigned integer type with width \(N\) and the same signedness as the bit-field’s type, the original value and the value of the bit-field compare equal. If the value true or false is stored into a bit-field of type bool of any size (including a one bit bit-field), the original bool value and the value of the bit-field compare equal. If a value of an enumeration type is stored into a bit-field of the same type and the width is large enough to hold all the values of that enumeration type (9.6), the original value and the value of the bit-field compare equal. [Example:

```c
enum BOOL { FALSE=0, TRUE=1 };  
struct A {  
BOOL b:1;  
};  
a A;  
void f() {  
a.b = TRUE;  
if (a.b == TRUE)  
// yields true  
    { /* ... */ }  
}  
```

—end example]

11.3.10 Nested class declarations

A class can be declared within another class. A class declared within another is called a nested class. The name of a nested class is local to its enclosing class. The nested class is in the scope of its enclosing class. [Note: See 7.5.4 for restrictions on the use of non-static data members and non-static member functions. —end note]

[Example:

```c
int x;  
int y;  
struct enclose {  
    int x;  
    static int s;  
}  
```
struct inner {
    void f(int i) {
        int a = sizeof(x); // OK: operand of sizeof is an unevaluated operand
        x = i; // error: assign to enclose::x
        s = i; // OK: assign to enclose::s
        ::x = i; // OK: assign to global x
        y = i; // OK: assign to global y
    }
    void g(enclose* p, int i) {
        p->x = i; // OK: assign to enclose::x
    }
};

inner* p = 0; // error: inner not in scope
—end example

Member functions and static data members of a nested class can be defined in a namespace scope enclosing the definition of their class. [Example:

```c
struct enclose {
    struct inner {
        static int x;
        void f(int i);
    };
};

int enclose::inner::x = 1;
void enclose::inner::f(int i) { /* ... */ }
—end example
```

If class X is defined in a namespace scope, a nested class Y may be declared in class X and later defined in the definition of class X or be later defined in a namespace scope enclosing the definition of class X. [Example:

```c
class E {
    class I1; // forward declaration of nested class
    class I2;
    class I1 { }; // definition of nested class
};

class E::I2 { }; // definition of nested class
—end example
```

Like a member function, a friend function (11.8.3) defined within a nested class is in the lexical scope of that class; it obeys the same rules for name binding as a static member function of that class (11.3.8), but it has no special access rights to members of an enclosing class.

11.3.11 Nested type names [class.nested.type]

Type names obey exactly the same scope rules as other names. In particular, type names defined within a class definition cannot be used outside their class without qualification. [Example:

```c
struct X {
    typedef int I;
    class Y { /* ... */ }; // error
    I a;
};

I b; // error
Y c; // error
X::Y d; // OK
X::I e; // OK
—end example
```
11.4 Unions [class.union]

1 In a union, a non-static data member is active if its name refers to an object whose lifetime has begun and has not ended (6.6.3). At most one of the non-static data members of an object of union type can be active at any time, that is, the value of at most one of the non-static data members can be stored in a union at any time. [Note: One special guarantee is made in order to simplify the use of unions: If a standard-layout union contains several standard-layout structs that share a common initial sequence (11.3), and if a non-static data member of an object of this standard-layout union type is active and is one of the standard-layout structs, it is permitted to inspect the common initial sequence of any of the standard-layout struct members; see 11.3. — end note]

2 The size of a union is sufficient to contain the largest of its non-static data members. Each non-static data member is allocated as if it were the sole member of a non-union class. [Note: A union object and its non-static data members are pointer-interconvertible (6.7.2, 7.6.1.8). As a consequence, all non-static data members of a union object have the same address. — end note]

3 A union can have member functions (including constructors and destructors), but it shall not have virtual (11.6.2) functions. A union shall not have base classes. A union shall not be used as a base class. If a union contains a non-static data member of reference type the program is ill-formed. [Note: Absent default member initializers (11.3), if any non-static data member of a union has a non-trivial default constructor (11.3.4.1), copy constructor, move constructor (11.3.4.2), copy assignment operator, move assignment operator (11.3.5), or destructor (11.3.6), the corresponding member function of the union must be user-provided or it will be implicitly deleted (9.4.3) for the union. — end note]

4 [Example: Consider the following union:

```cpp
union U {
    int i;
    float f;
    std::string s;
};
```

Since `std::string` (21.3) declares non-trivial versions of all of the special member functions, `U` will have an implicitly deleted default constructor, copy/move constructor, copy/move assignment operator, and destructor. To use `U`, some or all of these member functions must be user-provided. — end example]

5 When the left operand of an assignment operator involves a member access expression (7.6.1.4) that nominates a union member, it may begin the lifetime of that union member, as described below. For an expression E, define the set S(E) of subexpressions of E as follows:

(5.1) If E is of the form A.B, S(E) contains the elements of S(A), and also contains A.B if B names a union member of a non-class, non-array type, or of a class type with a trivial default constructor that is not deleted, or an array of such types.

(5.2) If E is of the form A[B] and is interpreted as a built-in array subscripting operator, S(E) is S(A) if A is of array type, S(B) if B is of array type, and empty otherwise.

(5.3) Otherwise, S(E) is empty.

In an assignment expression of the form E1 = E2 that uses either the built-in assignment operator (7.6.19) or a trivial assignment operator (11.3.5), for each element X of S(E1), if modification of X would have undefined behavior under 6.6.3, an object of the type of X is implicitly created in the nominated storage; no initialization is performed and the beginning of its lifetime is sequenced after the value computation of the left and right operands and before the assignment. [Note: This ends the lifetime of the previously-active member of the union, if any (6.6.3). — end note] [Example:

```cpp
union A { int x; int y[4]; };
struct B { A a; };
union C { B b; int k; };
int f() {
    C c; // does not start lifetime of any union member
    c.b.a.y[3] = 4; // OK: S(c.b.a.y[3]) contains c.b and c.b.a.y;
    // creates objects to hold union members c.b and c.b.a.y
    return c.b.a.y[3]; // OK: c.b.a.y refers to newly created object (see 6.6.3)
}

struct X { const int a; int b; };
union Y { X x; int k; };
```
void g() {
    Y y = { { 1, 2 } };  // OK, y.x is active union member (11.3)
    int n = y.x.a;
    y.k = 4;  // OK: ends lifetime of y.x, y.k is active member of union
    y.x.b = n;  // undefined behavior: y.x.b modified outside its lifetime,
                // S(y.x.b) is empty because X's default constructor is deleted,
                // so union member y.x's lifetime does not implicitly start
}
—end example

6 [Note: In general, one must use explicit destructor calls and placement new-expression to change the active member of a union. —end note] [Example: Consider an object u of a union type U having non-static data members m of type M and n of type N. If M has a non-trivial destructor and N has a non-trivial constructor (for instance, if they declare or inherit virtual functions), the active member of u can be safely switched from m to n using the destructor and placement new-expression as follows:
    u.m.&M();
    new (&u.n) N;
—end example]

11.4.1 Anonymous unions [class.union.anon]

1 A union of the form

        union { member-specification } ;

is called an anonymous union; it defines an unnamed type and an unnamed object of that type called an anonymous union object. Each member-declaration in the member-specification of an anonymous union shall either define a non-static data member or be a static_assert-declaration. [Note: Nested types, anonymous unions, and functions cannot be declared within an anonymous union. —end note] The names of the members of an anonymous union shall be distinct from the names of any other entity in the scope in which the anonymous union is declared. For the purpose of name lookup, after the anonymous union definition, the members of the anonymous union are considered to have been defined in the scope in which the anonymous union is declared. [Example:

        void f() {
            union { int a; const char* p; };  
            a = 1;
            p = "Jennifer";
        }

Here a and p are used like ordinary (non-member) variables, but since they are union members they have the same address. —end example]

2 Anonymous unions declared in a named namespace or in the global namespace shall be declared static. Anonymous unions declared at block scope shall be declared with any storage class allowed for a block-scope variable, or with no storage class. A storage class is not allowed in a declaration of an anonymous union in a class scope. An anonymous union shall not have private or protected members (11.8). An anonymous union shall not have member functions.

3 A union for which objects, pointers, or references are declared is not an anonymous union. [Example:

        void f() {
            union { int aa; char* p; } obj, *ptr = &obj;
            aa = 1;  // error
            ptr->aa = 1;  // OK
        }

The assignment to plain aa is ill-formed since the member name is not visible outside the union, and even if it were visible, it is not associated with any particular object. —end example] [Note: Initialization of unions with no user-declared constructors is described in 9.3.1. —end note]

4 A union-like class is a union or a class that has an anonymous union as a direct member. A union-like class X has a set of variant members. If X is a union, a non-static data member of X that is not an anonymous union is a variant member of X. In addition, a non-static data member of an anonymous union that is a member of X is also a variant member of X. At most one variant member of a union may have a default member initializer. [Example:
union U {
    int x = 0;
    union {
        int k;
    };
    union {
        int z;
        int y = 1;  // error: initialization for second variant member of U
    };
};

—end example

11.5 Local class declarations [class.local]

A class can be declared within a function definition; such a class is called a local class. The name of a local class is local to its enclosing scope. The local class is in the scope of the enclosing scope, and has the same access to names outside the function as does the enclosing function. [Note: A declaration in a local class cannot odr-use (6.2) a local entity from an enclosing scope. —end note] [Example:

```c
int x;
void f() {
    static int s;
    int x;
    const int N = 5;
    extern int q();
    int arr[2];
    auto [y, z] = arr;

    struct local {
        int g() { return x; }  // error: odr-use of non-odr-usable variable x
        int h() { return s; }   // OK
        int k() { return ::x; } // OK
        int l() { return q(); } // OK
        int m() { return N; }  // OK: not an odr-use
        int* n() { return &N; } // error: odr-use of non-odr-usable structured binding y
        int p() { return y; }  // error: odr-use of non-odr-usable variable y
    };
}

local* p = 0;  // error: local not in scope
—end example]

2 An enclosing function has no special access to members of the local class; it obeys the usual access rules (11.8). Member functions of a local class shall be defined within their class definition, if they are defined at all.

3 If class X is a local class a nested class Y may be declared in class X and later defined in the definition of class X or be later defined in the same scope as the definition of class X. A class nested within a local class is a local class.

4 A local class shall not have static data members.

11.6 Derived classes [class.derived]

A list of base classes can be specified in a class definition using the notation:

```
base-clause:
   : base-specifier-list

base-specifier-list:
   base-specifier ..opt
   base-specifier-list , base-specifier ..opt

base-specifier:
   attribute-specifier-seqopt class-or-decltype
   attribute-specifier-seqopt virtual access-specifieropt class-or-decltype
   attribute-specifier-seqopt access-specifier virtualopt class-or-decltype
```

§ 11.6 269
class-or-decltype:
  nested-name-specifier+, type-name
  nested-name-specifier template simple-template-id
decltype-specifier

access-specifier:
  private
  protected
  public

The optional attribute-specifier-seq appertains to the base-specifier.

2 A class-or-decltype shall denote a (possibly cv-qualified) class type that is not an incompletely defined class (11.3); any cv-qualifiers are ignored. The class denoted by the class-or-decltype of a base-specifier is called a direct base class for the class being defined. During the lookup for a base class name, non-type names are ignored (6.3.10). A class B is a base class of a class D if it is a direct base class of D or a direct base class of one of D’s base classes. A class is an indirect base class of another if it is a base class but not a direct base class. A class is said to be (directly or indirectly) derived from its (direct or indirect) base classes. [Note: See 11.8 for the meaning of access-specifier. — end note] Unless redeclared in the derived class, members of a base class are also considered to be members of the derived class. Members of a base class other than constructors are said to be inherited by the derived class. Constructors of a base class can also be inherited as described in 9.8. Inherited members can be referred to in expressions in the same manner as other members of the derived class, unless their names are hidden or ambiguous (11.7). [Note: The scope resolution operator :: (7.5.4.2) can be used to refer to a direct or indirect base member explicitly. This allows access to a name that has been redeclared in the derived class. A derived class can itself serve as a base class subject to access control; see 11.8.2. A pointer to a derived class can be implicitly converted to a pointer to an accessible unambiguous base class (7.3.11). An lvalue of a derived class type can be bound to a reference to an accessible unambiguous base class (9.3.3). — end note]

3 The base-specifier-list specifies the type of the base class subobjects contained in an object of the derived class type. [Example:

```c
struct Base {
  int a, b, c;
};

struct Derived : Base {
  int b;
};

struct Derived2 : Derived {
  int c;
};
```

Here, an object of class Derived2 will have a subobject of class Derived which in turn will have a subobject of class Base. — end example]

4 A base-specifier followed by an ellipsis is a pack expansion (13.6.3).

5 The order in which the base class subobjects are allocated in the most derived object (6.6.2) is unspecified. [Note: A derived class and its base class subobjects can be represented by a directed acyclic graph (DAG) where an arrow means “directly derived from”. An arrow need not have a physical representation in memory. A DAG of subobjects is often referred to as a “subobject lattice”.

```
Base
  \_ Derived1
  \_ Derived2
```

Figure 2: Directed acyclic graph [fig:class.dag]

— end note]
6 [Note: Initialization of objects representing base classes can be specified in constructors; see 11.9.2. — end note]

7 [Note: A base class subobject might have a layout (6.6.5) different from the layout of a most derived object of the same type. A base class subobject might have a polymorphic behavior (11.9.4) different from the polymorphic behavior of a most derived object of the same type. A base class subobject may be of zero size (Clause 11); however, two subobjects that have the same class type and that belong to the same most derived object must not be allocated at the same address (7.6.10). — end note]

11.6.1 Multiple base classes

A class can be derived from any number of base classes. [Note: The use of more than one direct base class is often called multiple inheritance. — end note] [Example:

class A { /* ... */};
class B { /* ... */};
class C { /* ... */};
class D : public A, public B, public C { /* ... */};
—end example]

2 [Note: The order of derivation is not significant except as specified by the semantics of initialization by constructor (11.9.2), cleanup (11.3.6), and storage layout (11.3, 11.8.1). — end note]

3 A class shall not be specified as a direct base class of a derived class more than once. [Note: A class can be an indirect base class more than once and can be a direct and an indirect base class. There are limited things that can be done with such a class. The non-static data members and member functions of the direct base class cannot be referred to in the scope of the derived class. However, the static members, enumerations and types can be unambiguously referred to. — end note] [Example:

class X { /* ... */};
class Y : public X, public X { /* ... */}; // ill-formed
class L { public: int next; /* ... */ };
class A : public L { /* ... */ };
class B : public L { /* ... */ };
class C : public A, public B { void f(); /* ... */ }; // well-formed
class D : public A, public L { void f(); /* ... */ }; // well-formed
—end example]

4 A base class specifier that does not contain the keyword virtual specifies a non-virtual base class. A base class specifier that contains the keyword virtual specifies a virtual base class. For each distinct occurrence of a non-virtual base class in the class lattice of the most derived class, the most derived object (6.6.2) shall contain a corresponding distinct base class subobject of that type. For each distinct base class that is specified virtual, the most derived object shall contain a single base class subobject of that type.

5 [Note: For an object of class type C, each distinct occurrence of a (non-virtual) base class L in the class lattice of C corresponds one-to-one with a distinct L subobject within the object of type C. Given the class C defined above, an object of class C will have two subobjects of class L as shown in Figure 3.

Figure 3: Non-virtual base

In such lattices, explicit qualification can be used to specify which subobject is meant. The body of function C::f could refer to the member next of each L subobject:

void C::f() { A::next = B::next; } // well-formed
Without the A:: or B:: qualifiers, the definition of C::f above would be ill-formed because of ambiguity (11.7). — end note]

[Note: In contrast, consider the case with a virtual base class:

```cpp
class V { /* ... */ }
class A : virtual public V { /* ... */ }
class B : virtual public V { /* ... */ }
class C : public A, public B { /* ... */ }
```

![Figure 4: Virtual base](fig:class.virt)

For an object c of class type C, a single subobject of type V is shared by every base class subobject of c that has a virtual base class of type V. Given the class C defined above, an object of class C will have one subobject of class V, as shown in Figure 4. — end note]

[Note: A class can have both virtual and non-virtual base classes of a given type.

```cpp
class B { /* ... */ }
class X : virtual public B { /* ... */ }
class Y : virtual public B { /* ... */ }
class Z : public B { /* ... */ }
class AA : public X, public Y, public Z { /* ... */ }
```

For an object of class AA, all virtual occurrences of base class B in the class lattice of AA correspond to a single B subobject within the object of type AA, and every other occurrence of a (non-virtual) base class B in the class lattice of AA corresponds one-to-one with a distinct B subobject within the object of type AA. Given the class AA defined above, class AA has two subobjects of class B: Z’s B and the virtual B shared by X and Y, as shown in Figure 5.

![Figure 5: Virtual and non-virtual base](fig:class.virtnonvirt)

— end note]

### 11.6.2 Virtual functions

A non-static member function is a virtual function if it is first declared with the keyword virtual or if it overrides a virtual member function declared in a base class (see below).\(^{111}\) [Note: Virtual functions support dynamic binding and object-oriented programming. — end note] A class that declares or inherits a virtual function is called a polymorphic class.\(^ {112}\)

If a virtual member function vf is declared in a class Base and in a class Derived, derived directly or indirectly from Base, a member function vf with the same name, parameter-type-list (9.2.3.5), cv-qualification, and

---

\(^{111}\) The use of the virtual specifier in the declaration of an overriding function is valid but redundant (has empty semantics).\(^ {112}\) If all virtual functions are immediate functions, the class is still polymorphic even though its internal representation might not otherwise require any additions for that polymorphic behavior.
ref-qualifier (or absence of same) as `Base::vf` is declared, then `Derived::vf overrides Base::vf`. For convenience we say that any virtual function overrides itself. A virtual member function `C::vf` of a class object `S` is a *final overrider* unless the most derived class (6.6.2) of which `S` is a base class subobject (if any) declares or inherits another member function that overrides `vf`. In a derived class, if a virtual member function of a base class subobject has more than one final overrider the program is ill-formed. [Example:

```cpp
struct A {
    virtual void f();
};
struct B : virtual A {
    virtual void f();
};
struct C : B, virtual A {
    using A::f;
};

void foo() {
    C c;
    c.f(); // calls B::f, the final overrider
    c.C::f(); // calls A::f because of the using-declaration
}
```
—end example]

[Example:

```cpp
struct A { virtual void f(); }
struct B : A { }
struct C : A { void f(); }
struct D : B, C { } // OK: A::f and C::f are the final overriders
    // for the B and C subobjects, respectively
```
—end example]

3 [Note: A virtual member function does not have to be visible to be overridden, for example,

```cpp
struct B {
    virtual void f();
};
struct D : B {
    void f(int);
};
struct D2 : D {
    void f();
};
```
the function `f(int)` in class `D` hides the virtual function `f()` in its base class `B; D::f(int)` is not a virtual function. However, `f()` declared in class `D2` has the same name and the same parameter list as `B::f()`, and therefore is a virtual function that overrides the function `B::f()` even though `B::f()` is not visible in class `D2`. —end note]

4 If a virtual function `f` in some class `B` is marked with the *virt-specifier* `final` and in a class `D` derived from `B` a function `D::f` overrides `B::f`, the program is ill-formed. [Example:

```cpp
struct B {
    virtual void f() const final;
};
struct D : B {
    void f() const;  // error: D::f attempts to override final B::f
};
```
—end example]

5 If a virtual function is marked with the *virt-specifier* `override` and does not override a member function of a base class, the program is ill-formed. [Example:

---

113) A function with the same name but a different parameter list (Clause 12) as a virtual function is not necessarily virtual and does not override. Access control (11.8) is not considered in determining overriding.
struct B {
    virtual void f(int);
};

struct D : B {
    virtual void f(long) override;  // error: wrong signature overriding B::f
    virtual void f(int) override;  // OK
};

— end example]

6 A virtual function shall not have a trailing requires-clause (9.2). [Example:
struct A {
    virtual void f() requires true;  // error: virtual function cannot be constrained (13.4.2)
};

— end example]

7 Even though destructors are not inherited, a destructor in a derived class overrides a base class destructor declared virtual; see 11.3.6 and 11.11.

8 The return type of an overriding function shall be either identical to the return type of the overridden function or covariant with the classes of the functions. If a function D::f overrides a function B::f, the return types of the functions are covariant if they satisfy the following criteria:

(8.1) — both are pointers to classes, both are lvalue references to classes, or both are rvalue references to classes

(8.2) — the class in the return type of B::f is the same class as the class in the return type of D::f, or is an unambiguous and accessible direct or indirect base class of the class in the return type of D::f

(8.3) — both pointers or references have the same cv-qualification and the class type in the return type of D::f has the same cv-qualification as or less cv-qualification than the class type in the return type of B::f.

9 If the class type in the covariant return type of D::f differs from that of B::f, the class type in the return type of D::f shall be complete at the point of declaration of D::f or shall be the class type D. When the overriding function is called as the final overrider of the overridden function, its result is converted to the type returned by the (statically chosen) overridden function (7.6.1.2). [Example:

    class B {
    class D : private B { friend class Derived; }
    struct Base {
        virtual void vf1();
        virtual void vf2();
        virtual void vf3();
        virtual B* vf4();
        virtual B* vf5();
        void f();
    };

    struct No_good : public Base {
        D* vf4();        // error: B (base class of D) inaccessible
    };

    class A;
    struct Derived : public Base {
        void vf1();      // virtual and overrides Base::vf1()
        void vf2(int);   // not virtual, hides Base::vf2()
        char vf3();      // error: invalid difference in return type only
        D* vf4();       // OK: returns pointer to derived class
        A* vf5();       // error: returns pointer to incomplete class
        void f();
    };

    void g() {
      Derived d;
    }

114) Multi-level pointers to classes or references to multi-level pointers to classes are not allowed.
Base* bp = &d; // standard conversion:
    Derived* to Base*
bp->vf1(); // calls Derived::vf1()
bp->vf2(); // calls Base::vf2()
bp->f(); // calls Base::f() (not virtual)
B* p = bp->vf4(); // calls Derived::vf4() and converts the
    // result to B*
Derived* dp = &d;
D* q = dp->vf4(); // calls Derived::vf4() and does not
    // convert the result to B*
dp->vf2(); // ill-formed: argument mismatch
}

—end example

[Note: The interpretation of the call of a virtual function depends on the type of the object for which it is called (the dynamic type), whereas the interpretation of a call of a non-virtual member function depends only on the type of the pointer or reference denoting that object (the static type) (7.6.1.2). — end note]

[Note: The virtual specifier implies membership, so a virtual function cannot be a non-member (9.1.2) function. Nor can a virtual function be a static member, since a virtual function call relies on a specific object for determining which function to invoke. A virtual function declared in one class can be declared a friend (11.8.3) in another class. — end note]

A virtual function declared in a class shall be defined, or declared pure (11.6.3) in that class, or both; no diagnostic is required (6.2).

[Example: Here are some uses of virtual functions with multiple base classes:

```cpp
struct A {
    virtual void f();
};

struct B1 : A {
    // note non-virtual derivation
    void f();
};

struct B2 : A {
    void f();
};

struct D : B1, B2 {
    // D has two separate A subobjects
};

void foo() {
    D d;
    // A* ap = &d; // would be ill-formed: ambiguous
    B1* b1p = &d;
    A* ap = b1p;
    D* dp = &d;
    ap->f(); // calls D::B1::f
    dp->f(); // ill-formed: ambiguous
}
```

In class D above there are two occurrences of class A and hence two occurrences of the virtual member function A::f. The final overrider of B1::A::f is B1::f and the final overrider of B2::A::f is B2::f. — end example]

[Example: The following example shows a function that does not have a unique final overrider:

```cpp
struct A {
    virtual void f();
};

struct VB1 : virtual A {
    // note virtual derivation
    void f();
};
```
struct VB2 : virtual A {
    void f();
};

struct Error : VB1, VB2 { // ill-formed
};

struct Okay : VB1, VB2 {
    void f();
};

Both VB1::f and VB2::f override A::f but there is no overrider of both of them in class Error. This example is therefore ill-formed. Class Okay is well-formed, however, because Okay::f is a final overrider. —end example

Example: The following example uses the well-formed classes from above.

struct VB1a : virtual A { // does not declare f
};

struct Da : VB1a, VB2 {
};

void foe() {
    VB1a* vb1ap = new Da;
    vb1ap->f(); // calls VB2::f
}

—end example

Explicit qualification with the scope operator (7.5.4.2) suppresses the virtual call mechanism. [Example:

class B { public: virtual void f();
};
class D : public B { public: void f();
};

void D::*f() { /* ... */ D::*f();
}

Here, the function call in D::*f really does call B::*f and not D::*f. —end example

A function with a deleted definition (9.4) shall not override a function that does not have a deleted definition. Likewise, a function that does not have a deleted definition shall not override a function with a deleted definition.

A constexpr virtual function shall not override a virtual function that is not constexpr. A constexpr virtual function shall not be overridden by a virtual function that is not constexpr.

If an overriding function specifies contract conditions (9.11.4), it shall specify the same list of contract conditions as its overridden functions; no diagnostic is required if corresponding conditions will always evaluate to the same value. Otherwise, it is considered to have the list of contract conditions from one of its overridden functions; the names in the contract conditions are bound, and the semantic constraints are checked, at the point where the contract conditions appear. Given a virtual function f with a contract condition that odr-uses *this (6.2), the class of which f is a direct member shall be be an unambiguous and accessible base class of any class in which f is overridden. If a function overrides more than one function, all of the overridden functions shall have the same list of contract conditions (9.11.4); no diagnostic is required if corresponding conditions will always evaluate to the same value. [Example:

struct A {
    virtual void g() [[expects: x == 0]];
    int x = 42;
};

int x = 42;
struct B {
    virtual void g() [[expects: x == 0]];
}

struct C : A, B { // error: preconditions of overridden functions are not the same
    virtual void g();
};
11.6.3 Abstract classes

[Note: The abstract class mechanism supports the notion of a general concept, such as a shape, of which only more concrete variants, such as circle and square, can actually be used. An abstract class can also be used to define an interface for which derived classes provide a variety of implementations. — end note]

A virtual function is specified as a pure virtual function by using a pure-specifier (11.3) in the function declaration in the class definition. [Note: Such a function might be inherited: see below. — end note] A class is an abstract class if it has at least one pure virtual function. [Note: An abstract class can be used only as a base class of some other class; no objects of an abstract class can be created except as subobjects of a class derived from it (6.1, 11.3). — end note] A pure virtual function need be defined only if called with, or as if with (11.3.6), the qualified-id syntax (7.5.4.2). [Example:

```c
class point { /* ... */
    point center;
public:
    point where() { return center; }
    void move(point p) { center=p; draw(); }
    virtual void rotate(int) = 0; // pure virtual
    virtual void draw() = 0; // pure virtual
};
```

— end example] [Note: A function declaration cannot provide both a pure-specifier and a definition — end note] [Example:]

```c
struct C {
    virtual void f() = 0 { }
};
```

— end example

[Note: An abstract class type cannot be used as a parameter or return type of a function being defined (9.2.3.5) or called (7.6.1.2), except as specified in 9.1.7.2. Further, an abstract class type cannot be used as the type of an explicit type conversion (7.6.1.8, 7.6.1.9, 7.6.1.10), because the resulting prvalue would be of abstract class type (7.2.1). However, pointers and references to abstract class types can appear in such contexts. — end note]

A class is abstract if it contains or inherits at least one pure virtual function for which the final override is pure virtual. [Example:]

```c
class ab_circle : public shape {
    int radius;
public:
    void rotate(int) {}
    // ab_circle::draw() is a pure virtual
};
```

Since shape::draw() is a pure virtual function ab_circle::draw() is a pure virtual by default. The alternative declaration,

```c
class circle : public shape {
    int radius;
public:
    void rotate(int) {
    void draw();
    // a definition is required somewhere
};
```

would make class circle non-abstract and a definition of circle::draw() must be provided. — end example

[Note: An abstract class can be derived from a class that is not abstract, and a pure virtual function may override a virtual function which is not pure. — end note]

Member functions can be called from a constructor (or destructor) of an abstract class; the effect of making a virtual call (11.6.2) to a pure virtual function directly or indirectly for the object being created (or destroyed) from such a constructor (or destructor) is undefined.
11.7 Member name lookup

Member name lookup determines the meaning of a name (id-expression) in a class scope (6.3.7). Name lookup can result in an ambiguity, in which case the program is ill-formed. For an unqualified-id, name lookup begins in the class scope of this; for a qualified-id, name lookup begins in the scope of the nested-name-specifier. Name lookup takes place before access control (6.4, 11.8).

The following steps define the result of name lookup for a member name \( f \) in a class scope \( C \).

1. If each of the subobject members of \( C \) is a base class subobject of at least one of the subobject members of \( f \), or if \( f \) is empty, \( S(f, C) \) is unchanged and the merge is complete. Conversely, if each of the subobject members of \( S(f, C) \) is a base class subobject of at least one of the subobject members of \( f \), or if \( f \) is empty, the new \( S(f, C) \) is a copy of \( S(f, B_i) \).

2. Otherwise, if the declaration sets of \( f \) and \( C \) differ, the merge is ambiguous: the new \( S(f, C) \) is a lookup set with an invalid declaration set and the union of the subobject sets. In subsequent merges, an invalid declaration set is considered different from any other.

3. Otherwise, the new \( S(f, C) \) is a lookup set with the shared set of declarations and the union of the subobject sets.

4. If \( C \) contains a declaration of the name \( f \), the declaration set contains every declaration of \( f \) declared in \( C \) that satisfies the requirements of the language construct in which the lookup occurs. [Note: Looking up a name in an elaborated-type-specifier (6.4.4) or base-specifier (11.6), for instance, ignores all non-type declarations, while looking up a name in a nested-name-specifier (6.4.3) ignores function, variable, and enumerator declarations. As another example, looking up a name in a using-declaration (9.8) includes the declaration of a class or enumeration that would ordinarily be hidden by another declaration of that name in the same scope. —end note] If the resulting declaration set is not empty, the subobject set contains \( C \) itself, and calculation is complete.

5. Otherwise (i.e., \( C \) does not contain a declaration of \( f \) or the resulting declaration set is empty), \( S(f, C) \) is initially empty. If \( C \) has base classes, calculate the lookup set for \( f \) in each direct base class subobject \( B_i \), and merge each such lookup set \( S(f, B_i) \) in turn into \( S(f, C) \).

6. The following steps define the result of merging lookup set \( S(f, B_i) \) into the intermediate \( S(f, C) \):

   - If each of the subobject members of \( S(f, B_i) \) is a base class subobject of at least one of the subobject members of \( f \), or if \( S(f, B_i) \) is empty, \( S(f, C) \) is unchanged and the merge is complete. Conversely, if each of the subobject members of \( S(f, C) \) is a base class subobject of at least one of the subobject members of \( f \), or if \( f \) is empty, the new \( S(f, C) \) is a copy of \( S(f, B_i) \).

7. The result of name lookup for \( f \) in \( C \) is the declaration set of \( S(f, C) \). If it is an invalid set, the program is ill-formed. [Example:

   ```c
   struct A { int x; }; // S(x,A) = { { A::x }, { A } }
   struct B { float x; }; // S(x,B) = { { B::x }, { B } }
   struct C: public A, public B { }; // S(x,C) = { invalid, { A in C, B in C } }
   struct D: public virtual C { }; // S(x,D) = S(x,C)
   struct E: public virtual C { char x; }; // S(x,E) = { { E::x }, { E } }
   struct F: public D, public E { }; // S(x,F) = S(x,E)
   int main() {
     F f;
     f.x = 0; // OK, lookup finds E::x
   }
   ```

   \( S(x, F) \) is unambiguous because the A and B base class subobjects of D are also base class subobjects of E, so \( S(x, D) \) is discarded in the first merge step. —end example]

8. If the name of an overloaded function is unambiguously found, overload resolution (12.3) also takes place before access control. Ambiguities can often be resolved by qualifying a name with its class name. [Example:
struct C : A, B {
    int f() { return A::f() + B::f(); }
};

—end example]

9 [Note: A static member, a nested type or an enumerator defined in a base class \( T \) can unambiguously be found even if an object has more than one base class subobject of type \( T \). Two base class subobjects share the non-static member subobjects of their common virtual base classes. — end note] [Example:

```cpp
struct V {
    int v;
};
struct A {
    int a;
    static int s;
    enum { e };  
};
struct B : A, virtual V {  
};
struct C : A, virtual V {  
};
struct D : B, C {  
};

void f(D* pd) {
    pd->v++;          // OK: only one \( v \) (virtual)
    pd->s++;          // OK: only one \( s \) (static)
    int i = pd->e;    // OK: only one \( e \) (enumerator)
    pd->a++;          // error, ambiguous: two \( a \)s in \( D \)
}
—end example]

10 [Note: When virtual base classes are used, a hidden declaration can be reached along a path through the subobject lattice that does not pass through the hiding declaration. This is not an ambiguity. The identical use with non-virtual base classes is an ambiguity; in that case there is no unique instance of the name that hides all the others. — end note] [Example:

```cpp
struct V { int f(); int x;  
};
struct W { int g(); int y;  
};
struct B : virtual V, W {  
    int f(); int x;  
    int g(); int y;  
};
struct C : virtual V, W {  
};
struct D : B, C { void glorp();  
};
```

![Figure 6: Name lookup](fig:class.lookup)

The names declared in \( V \) and the left-hand instance of \( W \) are hidden by those in \( B \), but the names declared in the right-hand instance of \( W \) are not hidden at all.

```cpp
void D::glorp() {
    x++;          // OK: \( B::x \) hides \( V::x \)
    f();          // OK: \( B::f() \) hides \( V::f() \)
    y++;          // error: \( B::y \) and \( C\)'s \( W::y \)
    g();          // error: \( B::g() \) and \( C\)'s \( W::g() \)
}
```

§ 11.7 279
11 An explicit or implicit conversion from a pointer to or an expression designating an object of a derived class
to a pointer or reference to one of its base classes shall unambiguously refer to a unique object representing
the base class. [Example:

```cpp
struct V { }
struct A { }
struct B : A, virtual V { }
struct C : A, virtual V { }
struct D : B, C { }

void g() {
    D d;
    B* pb = &d;
    A* pa = &d;  // error, ambiguous: C’s A or B’s A?
    V* pv = &d;  // OK: only one V subobject
}
```

—end example]

12 [Note: Even if the result of name lookup is unambiguous, use of a name found in multiple subobjects might
still be ambiguous (7.3.12, 7.6.1.4, 11.8.2). — end note] [Example:

```cpp
struct B1 {
    void f();
    static void f(int);
    int i;
};
struct B2 {
    void f(double);
};
struct I1: B1 { }
struct I2: B1 { }
struct D: I1, I2, B2 {
    using B1::f;
    using B2::f;
    void g() {
        f();  // Ambiguous conversion of this
        f(0);  // Unambiguous (static)
        f(0.0);  // Unambiguous (only one B2)
        int B1::* mpB1 = &D::i;
        // Unambiguous
        int D::* mpD = &D::i;  // Ambiguous conversion
    }
}
```

—end example]

11.8 Member access control [class.access]

1 A member of a class can be

(1.1) — private; that is, its name can be used only by members and friends of the class in which it is declared.

(1.2) — protected; that is, its name can be used only by members and friends of the class in which it is declared,
by classes derived from that class, and by their friends (see 11.8.4).

(1.3) — public; that is, its name can be used anywhere without access restriction.

2 A member of a class can also access all the names to which the class has access. A local class of a member
function may access the same names that the member function itself may access.\(^{115}\)

3 Members of a class defined with the keyword `class` are `private` by default. Members of a class defined with
the keywords `struct` or `union` are public by default. [Example:

```cpp
class X {
    int a;  // X::a is private by default
};
```

\(^{115}\) Access permissions are thus transitive and cumulative to nested and local classes.
struct S {
    int a;  // S::a is public by default
};
—end example]

4 Access control is applied uniformly to all names, whether the names are referred to from declarations or expressions. [Note: Access control applies to names nominated by friend declarations (11.8.3) and using-declarations (9.8). — end note] In the case of overloaded function names, access control is applied to the function selected by overload resolution. [Note: Because access control applies to names, if access control is applied to a typedef name, only the accessibility of the typedef name itself is considered. The accessibility of the entity referred to by the typedef is not considered. For example,

class A {
    class B {
    public:
        typedef B BB;
    }
};

void f() {
    A::BB x;  // OK, typedef name A::BB is public
    A::B y;  // access error, A::B is private
}
—end note]

[Note: Access to members and base classes is controlled, not their visibility (6.3.10). Names of members are still visible, and implicit conversions to base classes are still considered, when those members and base classes are inaccessible. — end note] The interpretation of a given construct is established without regard to access control. If the interpretation established makes use of inaccessible member names or base classes, the construct is ill-formed.

5 All access controls in 11.8 affect the ability to access a class member name from the declaration of a particular entity, including parts of the declaration preceding the name of the entity being declared and, if the entity is a class, the definitions of members of the class appearing outside the class's member-specification. [Note: This access also applies to implicit references to constructors, conversion functions, and destructors. — end note]

[Example:

class A {
    typedef int I;  // private member
    I f();
    friend I g(I);
    static I x;
    template<int> struct Q;
    template<int> friend struct R;
    protected:
        struct B {
        }
    ;

    A::I A::f() { return 0; }
    A::I g(A::I p = A::x);
    A::I g(A::I p) { return 0; }
    A::I A::x = 0;
    template<A::I> struct A::Q {
    }
    template<A::I> struct R {
    }

    struct D: A::B, A {
    }

    Here, all the uses of A::I are well-formed because A::f, A::x, and A::Q are members of class A and g and R are friends of class A. This implies, for example, that access checking on the first use of A::I must be deferred until it is determined that this use of A::I is as the return type of a member of class A. Similarly, the use of A::B as a base-specifier is well-formed because D is derived from A, so checking of base-specifiers must be deferred until the entire base-specifier-list has been seen. — end example]
The names in a default argument (9.2.3.6) are bound at the point of declaration, and access is checked at
that point rather than at any points of use of the default argument. Access checking for default arguments in
function templates and in member functions of class templates is performed as described in 13.8.1.

The names in a default template-argument (13.1) have their access checked in the context in which they
appear rather than at any points of use of the default template-argument. [Example:

```cpp
class B {
};
template <class T> class C {
protected:
  typedef T TT;
};
template <class U, class V = typename U::TT>
class D : public U {
  D <C<B> >* d; // access error, C::TT is protected
};
```
—end example]

### 11.8.1 Access specifiers

[access-specifier: member-specification_*opt*]

1 Member declarations can be labeled by an access-specifier (11.6):

```
access-specifier : member-specification_opt
```

An access-specifier specifies the access rules for members following it until the end of the class or until another
access-specifier is encountered. [Example:

```cpp
class X {
  int a; // X::a is private by default: class used
public:
  int b; // X::b is public
  int c; // X::c is public
};
```
—end example]

2 Any number of access specifiers is allowed and no particular order is required. [Example:

```cpp
struct S {
  int a; // S::a is public by default: struct used
protected:
  int b; // S::b is protected
private:
  int c; // S::c is private
public:
  int d; // S::d is public
};
```
—end example]

3 [Note: The effect of access control on the order of allocation of data members is described in 11.3. — end note]

4 When a member is redeclared within its class definition, the access specified at its redeclaration shall be the
same as at its initial declaration. [Example:

```cpp
struct S {
  class A;
  enum E : int;
private:
  class A { }; // error: cannot change access
  enum E: int { e0 }; // error: cannot change access
};
```
—end example]

5 [Note: In a derived class, the lookup of a base class name will find the injected-class-name instead of the
name of the base class in the scope in which it was declared. The injected-class-name might be less accessible
than the name of the base class in the scope in which it was declared. — end note]

§ 11.8.1
11.8.2 Accessibility of base classes and base class members

If a class is declared to be a base class (11.6) for another class using the `public` access specifier, the public members of the base class are accessible as public members of the derived class and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the `protected` access specifier, the public and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the `private` access specifier, the public and protected members of the base class are accessible as private members of the derived class.

In the absence of an `access-specifier` for a base class, `public` is assumed when the derived class is defined with the `class-key` `struct` and `private` is assumed when the class is defined with the `class-key` `class`. [Example:

```cpp
class B { /* ... */ };  // B private by default
class D1 : private B { /* ... */ };  // B is a private base of D1, D3, and D5, and a protected base of D7 and D8.
class D2 : public B { /* ... */ };  // B public by default
class D3 : B { /* ... */ };  // B is a public base of D2, D4, and D6, and D3, and D5, and D7 and D8.
class D4 : private B { /* ... */ };  // B is a private base of D2, D4, and D6, and D3, and D5, and a protected base of D7 and D8.
class D5 : private B { /* ... */ };  // B private by default
```]

[Note: A member of a private base class might be inaccessible as an inherited member name, but accessible directly. Because of the rules on pointer conversions (7.3.11) and explicit casts (7.6.3), a conversion from a pointer to a derived class to a pointer to an inaccessible base class might be ill-formed if an implicit conversion is used, but well-formed if an explicit cast is used. For example,

```cpp
class B {
  public:
    int mi;  // non-static member
    static int si;  // static member
  priv:
    // derived class
}
class D : private B {
};
class DD : public D {
  void f();
};

void DD::f() {
  mi = 3;  // error: mi is private in D
  si = 3;  // error: si is private in D
  ::B::b;
  b.mi = 3;  // OK (b.mi is different from this->mi)
  b.si = 3;  // OK (b.si is different from this->si)
  ::B::si = 3;  // OK
  ::B* bp1 = this;
  ::B* bp2 = (::B*)this;
  bp2->mi = 3;  // OK with cast
  bp2->si = 3;  // OK: access through a pointer to B.
}
```]

As specified previously in 11.8, private members of a base class remain inaccessible even to derived classes unless friend declarations within the base class definition are used to grant access explicitly.
A base class $B$ of $N$ is accessible at $R$, if

- an invented public member of $B$ would be a public member of $N$, or
- $R$ occurs in a member or friend of class $N$, and an invented public member of $B$ would be a private or protected member of $N$, or
- $R$ occurs in a member or friend of a class $P$ derived from $N$, and an invented public member of $B$ would be a private or protected member of $P$, or
- there exists a class $S$ such that $B$ is a base class of $S$ accessible at $R$ and $S$ is a base class of $N$ accessible at $R$.

Example:
```cpp
class B {
   public:
      int m;
};
class S: private B {
   friend class N;
};
class N: private S {
   void f() {
      B* p = this;
      // OK because class $S$ satisfies the fourth condition above: $B$ is a base class of $N$
      // accessible in $f()$ because $B$ is an accessible base class of $S$ and $S$ is an accessible
      // base class of $N$.
   }
};
```

- end example]

If a base class is accessible, one can implicitly convert a pointer to a derived class to a pointer to that base class (7.3.11, 7.3.12). [Note: It follows that members and friends of a class $X$ can implicitly convert an $X*$ to a pointer to a private or protected immediate base class of $X$. — end note] The access to a member is affected by the class in which the member is named. This naming class is the class in which the member name was looked up and found. [Note: This class can be explicit, e.g., when a qualified-id is used, or implicit, e.g., when a class member access operator (7.6.1.4) is used (including cases where an implicit “this->” is added). If both a class member access operator and a qualified-id are used to name the member (as in $p->T::m$), the class naming the member is the class denoted by the nested-name-specifier of the qualified-id (that is, $T$). — end note] A member $m$ is accessible at the point $R$ when named in class $N$ if

- $m$ as a member of $N$ is public, or
- $m$ as a member of $N$ is private, and $R$ occurs in a member or friend of class $N$, or
- $m$ as a member of $N$ is protected, and $R$ occurs in a member or friend of class $N$, or in a member of a class $P$ derived from $N$, where $m$ as a member of $P$ is public, private, or protected, or
- there exists a base class $B$ of $N$ that is accessible at $R$, and $m$ is accessible at $R$ when named in class $B$.

Example:
```cpp
class B;
class A {
   private:
      int i;
   friend void f(B*);
};
class B: public A { };
void f(B* p) {
   p->i = 1;  // OK: $B*$ can be implicitly converted to $A*$, and $f$ has access to $i$ in $A$
}
```

- end example]

If a class member access operator, including an implicit “this->”, is used to access a non-static data member or non-static member function, the reference is ill-formed if the left operand (considered as a pointer in the
“.” operator case) cannot be implicitly converted to a pointer to the naming class of the right operand. [Note: This requirement is in addition to the requirement that the member be accessible as named. —end note]

### 11.8.3 Friends

A friend of a class is a function or class that is given permission to use the private and protected member names from the class. A class specifies its friends, if any, by way of friend declarations. Such declarations give special access rights to the friends, but they do not make the nominated friends members of the befriending class. [Example: The following example illustrates the differences between members and friends:

```cpp
class X {
  int a;
  friend void friend_set(X*, int);
public:
  void member_set(int);
};
void friend_set(X* p, int i) { p->a = i; }
void X::member_set(int i) { a = i; }
void f() {
  X obj;
  friend_set(&obj,10);
  obj.member_set(10);
}
—end example]
```

Declaring a class to be a friend implies that the names of private and protected members from the class granting friendship can be accessed in the `base-specifiers` and member declarations of the befriended class. [Example:]

```cpp
class A {
  class B { };
  friend class X;
};
struct X : A::B {
  // OK: A::B accessible to friend
  A::B mx;
  // OK: A::B accessible to member of friend
  class Y {
    A::B my;
    // OK: A::B accessible to nested member of friend
  };
};
—end example]  [Example:]

class X {
  enum { a=100 };  // OK, Y is a friend of X
};
class Y {
  int v[X::a];  // error: X::a is private
};
—end example]
```

A class shall not be defined in a friend declaration. [Example:]

```cpp
class A {
  friend class B { };  // error: cannot define class in friend declaration
};
—end example]
```

A friend declaration that does not declare a function shall have one of the following forms:
friend elaborated-type-specifier;
friend simple-type-specifier;
friend typename-specifier;

[Note: A friend declaration may be the declaration in a template-declaration (Clause 13, 13.6.4). — end note]

If the type specifier in a friend declaration designates a (possibly cv-qualified) class type, that class is declared as a friend; otherwise, the friend declaration is ignored. [Example:

```cpp
class C;
typedef C Ct;

class X1 {
  friend C; // OK: class C is a friend
};

class X2 {
  friend Ct; // OK: class C is a friend
  friend D; // error: no type-name D in scope
  friend class D; // OK: elaborated-type-specifier declares new class
};
template <typename T> class R {
  friend T;
};

R<C> rc; // class C is a friend of R<C>
R<int> Ri; // OK: "friend int;" is ignored

—end example]

4 A function first declared in a friend declaration has the linkage of the namespace of which it is a member (6.5). Otherwise, the function retains its previous linkage (9.1.1).

5 When a friend declaration refers to an overloaded name or operator, only the function specified by the parameter types becomes a friend. A member function of a class X can be a friend of a class Y. [Example:

```cpp
class Y {
  friend char* X::foo(int);
  friend X::X(char); // constructors can be friends
  friend X::~X(); // destructors can be friends
};

—end example]

6 A function can be defined in a friend declaration of a class if and only if the class is a non-local class (11.5), the function name is unqualified, and the function has namespace scope. [Example:

```cpp
class M {
  friend void f() { } // definition of global f, a friend of M.
  // not the definition of a member function
};

—end example]

7 Such a function is implicitly an inline function (9.1.6). A friend function defined in a class is in the (lexical) scope of the class in which it is defined. A friend function defined outside the class is not (6.4.1).

8 No storage-class-specifier shall appear in the decl-specifier-seq of a friend declaration.

9 A name nominated by a friend declaration shall be accessible in the scope of the class containing the friend declaration. The meaning of the friend declaration is the same whether the friend declaration appears in the private, protected, or public (11.3) portion of the class member-specification.

10 Friendship is neither inherited nor transitive. [Example:

```cpp
class A {
  friend class B;
  int a;
};

—end example]
```cpp
class B {
friend class C;
};

class C {
  void f(A* p) {
    p->a++;
    // error: C is not a friend of A despite being a friend of a friend
  }
};

class D : public B {
  void f(A* p) {
    p->a++;
    // error: D is not a friend of A despite being derived from a friend
  }
};

— end example]  

If a friend declaration appears in a local class (11.5) and the name specified is an unqualified name, a prior declaration is looked up without considering scopes that are outside the innermost enclosing non-class scope. For a friend function declaration, if there is no prior declaration, the program is ill-formed. For a friend class declaration, if there is no prior declaration, the class that is specified belongs to the innermost enclosing non-class scope, but if it is subsequently referenced, its name is not found by name lookup until a matching declaration is provided in the innermost enclosing non-class scope. [Example:

class X;
void a();
void f() {
  class Y;
  extern void b();
  class A {
    friend class X;  // OK, but X is a local class, not ::X
    friend class Y;  // OK
    friend class Z;  // OK, introduces local class Z
    friend void a();  // error, ::a is not considered
    friend void b();  // OK
    friend void c();  // error
  };
  X* px;  // OK, but ::X is found
  Z* pz;  // error, no Z is found
}

— end example]  

## 11.8.4 Protected member access  [class.protected]

An additional access check beyond those described earlier in 11.8 is applied when a non-static data member or non-static member function is a protected member of its naming class (11.8.2). As described earlier, access to a protected member is granted because the reference occurs in a friend or member of some class C. If the access is to form a pointer to member (7.6.2.1), the nested-name-specifier shall denote C or a class derived from C. All other accesses involve a (possibly implicit) object expression (7.6.1.4). In this case, the class of the object expression shall be C or a class derived from C. [Example:

class B {
  protected:
    int i;
    static int j;
};

class D1 : public B {
};

class D2 : public B {
  friend void fr(B*,D1*,D2*);

117) This additional check does not apply to other members, e.g., static data members or enumerator member constants.

§ 11.8.4

287
```
void mem(B*, D1*);

void fr(B* pb, D1* p1, D2* p2) {
    pb->i = 1; // ill-formed
    p1->i = 2; // ill-formed
    p2->i = 3; // OK (access through a D2)
    p2->B::i = 4; // OK (access through B, even though naming class is B)
    int B::* pmi_B = &B::i; // ill-formed
    int B::* pmi_B2 = &D2::i; // OK (type of &D2::i is int B::*)
    B::j = 5; // ill-formed (not a friend of naming class B)
    D2::j = 6; // OK (because refers to static member)
}

void D2::mem(B* pb, D1* p1) {
    pb->i = 1; // ill-formed
    p1->i = 2; // ill-formed
    i = 3; // OK (access through this)
    B::i = 4; // OK (access through this, qualification ignored)
    int B::* pmi_B = &B::i; // ill-formed
    int B::* pmi_B2 = &D2::i; // OK
    j = 5; // OK (because j refers to static member)
    B::j = 6; // OK (because B::j refers to static member)
}

void g(B* pb, D1* p1, D2* p2) {
    pb->i = 1; // ill-formed
    p1->i = 2; // ill-formed
    p2->i = 3; // ill-formed
}

—end example]}

11.8.5 Access to virtual functions [class.access.virt]

The access rules (11.8) for a virtual function are determined by its declaration and are not affected by the rules for a function that later overrides it. [Example:

```cpp
class B {
    public:
        virtual int f();
};

class D : public B {
    private:
        int f();
};

void f() {
    D d;
    B* pb = &d;
    D* pd = &d;

    pb->f(); // OK: B::f() is public, D::f() is invoked
    pd->f(); // error: D::f() is private
}
—end example]
```

1 Access is checked at the call point using the type of the expression used to denote the object for which the member function is called (B* in the example above). The access of the member function in the class in which it was defined (D in the example above) is in general not known.

11.8.6 Multiple access [class.paths]

If a name can be reached by several paths through a multiple inheritance graph, the access is that of the path that gives most access. [Example:
class W { public: void f(); };  
class A : private virtual W { };  
class B : public virtual W { };  
class C : public A, public B {  
  void f() { W::f(); }  
  // OK  
};  

Since W::f() is available to C::f() along the public path through B, access is allowed. — end example]

11.8.7 Nested classes 

A nested class is a member and as such has the same access rights as any other member. The members of an enclosing class have no special access to members of a nested class; the usual access rules (11.8) shall be obeyed. [Example:

```c++
class E {
  int x;
  class B { };  
  class I {
    B b;  
    // OK: E::I can access E::B
    int y;
    void f(E* p, int i) {
      p->x = i;  
      // OK: E::I can access E::x
    }
  };
  int g(I* p) {
    return p->y;  
    // error: I::y is private
  }
};
```
— end example]

11.9 Initialization 

1 When no initializer is specified for an object of (possibly cv-qualified) class type (or array thereof), or the initializer has the form (), the object is initialized as specified in 9.3.

2 An object of class type (or array thereof) can be explicitly initialized; see 11.9.1 and 11.9.2.

3 When an array of class objects is initialized (either explicitly or implicitly) and the elements are initialized by constructor, the constructor shall be called for each element of the array, following the subscript order; see 9.2.3.4. [Note: Destructors for the array elements are called in reverse order of their construction. — end note]

11.9.1 Explicit initialization 

An object of class type can be initialized with a parenthesized expression-list, where the expression-list is construed as an argument list for a constructor that is called to initialize the object. Alternatively, a single assignment-expression can be specified as an initializer using the = form of initialization. Either direct-initialization semantics or copy-initialization semantics apply; see 9.3. [Example:

```c++
struct complex {
  complex();
  complex(double);
  complex(double,double);
};

complex sqrt(complex,complex);  

complex a(1);  
complex b = a;  
complex c = complex(1,2);  
complex d = sqrt(b,c);  
complex e;  
complex f = 3;  
complex g = { 1, 2 };  
```

§ 11.9.1
An object of class type can also be initialized by a \textit{braced-init-list}. List-initialization semantics apply; see 9.3 and 9.3.4. [\textit{Example}:
\begin{verbatim}
complex v[6] = { 1, complex(1,2), complex(), 2 };
\end{verbatim}
Here, \texttt{complex::complex(double)} is called for the initialization of \texttt{v[0]} and \texttt{v[3]}, \texttt{complex::complex(double, double)} is called for the initialization of \texttt{v[1]}, \texttt{complex::complex()} is called for the initialization \texttt{v[2]}, \texttt{v[4]}, and \texttt{v[5]}. For another example,
\begin{verbatim}
struct X {
  int i;
  float f;
  complex c;
} x = { 99, 88.8, 77.7 };
\end{verbatim}
Here, \texttt{x.i} is initialized with 99, \texttt{x.f} is initialized with 88.8, and \texttt{complex::complex(double)} is called for the initialization of \texttt{x.c}. —\textit{end example} [\textit{Note}: Braces can be elided in the \textit{initializer-list} for any aggregate, even if the aggregate has members of a class type with user-defined type conversions; see 9.3.1. —\textit{end note}]

[\textit{Note}: If \(T\) is a class type with no default constructor, any declaration of an object of type \(T\) (or array thereof) is ill-formed if no \texttt{initializer} is explicitly specified (see 11.9 and 9.3). —\textit{end note}]  

\section*{11.9.2 Initializing bases and members}  

\texttt{ctor-initializer}:
\begin{verbatim}
: mem-initializer-list
mem-initializer-list:
  mem-initializer ...opt
  mem-initializer-list , mem-initializer ...opt
mem-initializer:
  mem-initializer-id ( expression-list_opt )
  mem-initializer-id braced-init-list
mem-initializer-id:
  class-or-decltype
  identifier
\end{verbatim}

In a \texttt{mem-initializer-id} an initial unqualified \texttt{identifier} is looked up in the scope of the constructor's class and, if not found in that scope, it is looked up in the scope containing the constructor's definition. [\textit{Note}: If the constructor's class contains a member with the same name as a direct or virtual base class of the class, a \texttt{mem-initializer-id} naming the member or base class and composed of a single identifier refers to the class member. A \texttt{mem-initializer-id} for the hidden base class may be specified using a qualified name. —\textit{end note}]  

Unless the \texttt{mem-initializer-id} names the constructor's class, a non-static data member of the constructor's class, or a direct or virtual base of that class, the \texttt{mem-initializer} is ill-formed.

\begin{verbatim}
struct A { A(); }; typedef A global_A; struct B { }; struct C: public A, public B { C(); }; C::C(): global_A() { }      // mem-initializer for base A —end example
\end{verbatim}

[\textit{Example}:
\begin{verbatim}
struct A { A(); }; struct B: public virtual A { };
\end{verbatim}

If a \texttt{mem-initializer-id} is ambiguous because it designates both a direct non-virtual base class and an inherited virtual base class, the \texttt{mem-initializer} is ill-formed. [\textit{Example}:
\begin{verbatim}
struct A { A(); }; struct B: public virtual A { }
\end{verbatim}

\section*{§ 11.9.2}
A **ctor-initializer** may initialize a variant member of the constructor’s class. If a **ctor-initializer** specifies more than one **mem-initializer** for the same member or for the same base class, the **ctor-initializer** is ill-formed.

A **mem-initializer-list** can delegate to another constructor of the constructor’s class using any **class-or-decltype** that denotes the constructor’s class itself. If a **mem-initializer-id** designates the constructor’s class, it shall be the only **mem-initializer**; the constructor is a **delegating constructor**, and the constructor selected by the **mem-initializer** is the **target constructor**. The target constructor is selected by overload resolution. Once the target constructor returns, the body of the delegating constructor is executed. If a constructor delegates to itself directly or indirectly, the program is ill-formed, no diagnostic required.  

```cpp
struct C {
    C( int ) { }  // #1: non-delegating constructor
    C( int ) : C(42) { }  // #2: delegates to #1
    C( char c ) : C(42.0) { }  // #3: ill-formed due to recursion with #4
    C( double d ) : C('a') { }  // #4: ill-formed due to recursion with #3
};
```

The **expression-list** or **braced-init-list** in a **mem-initializer** is used to initialize the designated subobject (or, in the case of a delegating constructor, the complete class object) according to the initialization rules of 9.3 for direct-initialization. 

```cpp
struct B1 { B1(int); /* ... */ };
struct B2 { B2(int); /* ... */ };
struct D : B1, B2 {
    D(int);
    B1 b;
    const int c;
};
D::D(int a) : B2(a+1), B1(a+2), c(a+3), b(a+4) { /* ... */ }
D d(10);
```

A temporary expression bound to a reference member in a **mem-initializer** is ill-formed.  

```cpp
struct A {
    A() : v(42) { }  // error
    const int& v;
};
```

In a non-delegating constructor, if a given potentially constructed subobject is not designated by a **mem-initializer-id** (including the case where there is no **mem-initializer-list** because the constructor has no **ctor-initializer**), then

- if the entity is a non-static data member that has a default member initializer (11.3) and either
  - the constructor’s class is a union (11.4), and no other variant member of that union is designated by a **mem-initializer-id** or
  - the constructor’s class is not a union, and, if the entity is a member of an anonymous union, no other member of that union is designated by a **mem-initializer-id**, the entity is initialized from its default member initializer as specified in 9.3;
- otherwise, if the entity is an anonymous union or a variant member (11.4.1), no initialization is performed;
- otherwise, the entity is default-initialized (9.3).
[Note: An abstract class (11.6.3) is never a most derived class, thus its constructors never initialize virtual base classes, therefore the corresponding mem-initializers may be omitted. — end note] An attempt to initialize more than one non-static data member of a union renders the program ill-formed. [Note: After the call to a constructor for class X for an object with automatic or dynamic storage duration has completed, if the constructor was not invoked as part of value-initialization and a member of X is neither initialized nor given a value during execution of the compound-statement of the body of the constructor, the member has an indeterminate value. — end note]

```c
struct A {
    A();
};

struct B {
    B(int);
};

struct C {
    C() { } // initializes members as follows:
    A a; // OK: calls A::A()
    const B b; // error: B has no default constructor
    int i; // OK: i has indeterminate value
    int j = 5; // OK: j has the value 5
};
```

—end example]

10 If a given non-static data member has both a default member initializer and a mem-initializer, the initialization specified by the mem-initializer is performed, and the non-static data member’s default member initializer is ignored. [Example: Given

```c
struct A {
    int i = /* some integer expression with side effects */;
    A(int arg) : i(arg) { }
    // ...
};
```

the A(int) constructor will simply initialize i to the value of arg, and the side effects in i’s default member initializer will not take place. —end example]

11 A temporary expression bound to a reference member from a default member initializer is ill-formed. [Example:

```c
struct A {
    A() = default; // OK
    A(int v) : v(v) { } // OK
    const int& v = 42; // OK
};
A a1; // error: ill-formed binding of temporary to reference
A a2(1); // OK, unfortunately
```

—end example]

12 In a non-delegating constructor, the destructor for each potentially constructed subobject of class type is potentially invoked (11.3.6). [Note: This provision ensures that destructors can be called for fully-constructed subobjects in case an exception is thrown (14.2). —end note]

13 In a non-delegating constructor, initialization proceeds in the following order:

(13.1) — First, and only for the constructor of the most derived class (6.6.2), virtual base classes are initialized in the order they appear on a depth-first left-to-right traversal of the directed acyclic graph of base classes, where “left-to-right” is the order of appearance of the base classes in the derived class base-specifier-list.

(13.2) — Then, direct base classes are initialized in declaration order as they appear in the base-specifier-list (regardless of the order of the mem-initializers).

(13.3) — Then, non-static data members are initialized in the order they were declared in the class definition (again regardless of the order of the mem-initializers).

(13.4) — Finally, the compound-statement of the constructor body is executed.

§ 11.9.2 292
[Note: The declaration order is mandated to ensure that base and member subobjects are destroyed in the reverse order of initialization. — end note]

Example:

```cpp
struct V {
  V();
  V(int);
};

struct A : virtual V {
  A();
  A(int);
};

struct B : virtual V {
  B();
  B(int);
};

struct C : A, B, virtual V {
  C();
  C(int);
};

A::A(int i) : V(i) { /* ... */ }
B::B(int i) { /* ... */ }
C::C(int i) { /* ... */ }
V v(1); // use V(int)
A a(2); // use V(int)
B b(3); // use V()
C c(4); // use V()
```

—end example

Names in the expression-list or braced-init-list of a mem-initializer are evaluated in the scope of the constructor for which the mem-initializer is specified. [Example:

```cpp
class X {
  int a;
  int b;
  int i;
  int j;
  public:
    const int& r;
    X(int i): r(a), b(i), i(i), j(this->i) { }
};
```

initializes X::r to refer to X::a, initializes X::b with the value of the constructor parameter i, initializes X::i with the value of the constructor parameter i, and initializes X::j with the value of X::i; this takes place each time an object of class X is created. —end example] [Note: Because the mem-initializer are evaluated in the scope of the constructor, the this pointer can be used in the expression-list of a mem-initializer to refer to the object being initialized. —end note]

Member functions (including virtual member functions, 11.6.2) can be called for an object under construction. Similarly, an object under construction can be the operand of the typeid operator (7.6.1.7) or of a dynamic_cast (7.6.1.6). However, if these operations are performed in a ctor-initializer (or in a function called directly or indirectly from a ctor-initializer) before all the mem-initializers for base classes have completed, the program has undefined behavior. [Example:

```cpp
class A {
  public:
    A(int);
};
```

§ 11.9.2
class B : public A {
  int j;
public:
  int f();
  B() : A(f()),
         // undefined: calls member function but base A not yet initialized
       j(f()) { }    // well-defined: bases are all initialized
};

class C {
public:
  C(int);
};
class D : public B, C {
  int i;
public:
  D() : C(f()),
         // undefined: calls member function but base C not yet initialized
     i(f()) { }     // well-defined: bases are all initialized
};

—end example

17 [Note: 11.9.4 describes the result of virtual function calls, typeid and dynamic_casts during construction for the well-defined cases; that is, describes the polymorphic behavior of an object under construction. —end note]

18 A mem-initializer followed by an ellipsis is a pack expansion (13.6.3) that initializes the base classes specified by a pack expansion in the base-specifier-list for the class. [Example:

```cpp
template<class... Mixins>
class X : public Mixins... {
public:
  X(const Mixins&... mixins) : Mixins(mixins)... { }
};

—end example]

11.9.3 Initialization by inherited constructor [class.inhctor.init]

1 When a constructor for type B is invoked to initialize an object of a different type D (that is, when the constructor was inherited (9.8)), initialization proceeds as if a defaulted default constructor were used to initialize the D object and each base class subobject from which the constructor was inherited, except that the B subobject is initialized by the invocation of the inherited constructor. The complete initialization is considered to be a single function call; in particular, the initialization of the inherited constructor’s parameters is sequenced before the initialization of any part of the D object. [Example:

```cpp
struct B1 {
  B1(int, ...) { }
};

struct B2 {
  B2(double) { }
};

int get();

struct D1 : B1 {
  using B1::B1;      // inherits B1(int, ...)
  int x;
  int y = get();
};

void test() {
  D1 d(2, 3, 4);    // OK: B1 is initialized by calling B1(2, 3, 4),
```
// then d.x is default-initialized (no initialization is performed),
// then d.y is initialized by calling get()

D1 e;  // error: D1 has a deleted default constructor

}  

struct D2 : B2 {
  using B2::B2;
  B1 b;
};

D2 f(1.0);  // error: B1 has a deleted default constructor

struct W { W(int); };  
struct X : virtual W { using W::W; X() = delete; };  
struct Y : X { using X::X; };  
struct Z : Y, virtual W { using Y::Y; };  
Z z(0);  // OK: initialization of Y does not invoke default constructor of X

template<class T> struct Log : T {
  using T::T;  // inherits all constructors from class T
  ~Log() { std::clog << "Destroying wrapper" << std::endl; }
};

Class template Log wraps any class and forwards all of its constructors, while writing a message to the standard log whenever an object of class Log is destroyed. — end example

2 If the constructor was inherited from multiple base class subobjects of type B, the program is ill-formed. [Example:  
struct A { A(int); };  
struct B : A { using A::A; };  

struct C1 : B { using B::B; };  
struct C2 : B { using B::B; };  

struct D1 : C1, C2 {
  using C1::C1;
  using C2::C2;
};  

struct V1 : virtual B { using B::B; };  
struct V2 : virtual B { using B::B; };  

struct D2 : V1, V2 {
  using V1::V1;
  using V2::V2;
};  

D1 d1(0);  // ill-formed: ambiguous
D2 d2(0);  // OK: initializes virtual B base class, which initializes the A base class  
// then initializes the V1 and V2 base classes as if by a defaulted default constructor

struct M { M(); M(int); };  
struct N : M { using M::M; };  
struct O : M {};  
struct P : N, O { using N::N; using O::O; };  
P p(0);  // OK: use M(O) to initialize N’s base class,  
// use M(O) to initialize O’s base class

— end example

3 When an object is initialized by an inherited constructor, initialization of the object is complete when the initialization of all subobjects is complete.
11.9.4 Construction and destruction

For an object with a non-trivial constructor, referring to any non-static member or base class of the object before the constructor begins execution results in undefined behavior. For an object with a non-trivial destructor, referring to any non-static member or base class of the object after the destructor finishes execution results in undefined behavior. [Example:

```c
struct X { int i; };  
struct Y : X { Y(); }; // non-trivial  
struct A { int a; };  
struct B : public A { int j; Y y; }; // non-trivial

extern B bobj;
B* pb = &bobj; // OK  
int* p1 = &bobj.a; // undefined, refers to base class member  
int* p2 = &bobj.y.i; // undefined, refers to member's member

A* pa = &bobj; // undefined, upcast to a base class type  
B bobj; // definition of bobj

eextern X xobj;
int* p3 = &xobj.i; // OK, X is a trivial class  
X xobj;
```

For another example,

```c
struct W { int j; };  
struct X : public virtual W { };  
struct Y {  
    int* p;  
    X x;  
    Y() : p(&x.j) { // undefined, x is not yet constructed  
        }  
};

— end example]
```

During the construction of an object, if the value of the object or any of its subobjects is accessed through a glvalue that is not obtained, directly or indirectly, from the constructor’s this pointer, the value of the object or subobject thus obtained is unspecified. [Example:

```c
struct C;
void no_opt(C*);

struct C {  
    int c;  
    C() : c(0) { no_opt(this); }  
};

const C cobj;

void no_opt(C* cpctr) {  
    int i = cobj.c * 100; // value of cobj.c is unspecified  
    cpctr->c = 1;  
    cout << cobj.c * 100 << '\n'; // value of cobj.c is unspecified
}

eextern struct D d;
struct D {  
    D(int a) : a(a), b(d.a) {}  
    int a, b;  
};  
D d = D(1); // value of d.b is unspecified

— end example]
```
To explicitly or implicitly convert a pointer (a glvalue) referring to an object of class \(X\) to a pointer (reference) to a direct or indirect base class \(B\) of \(X\), the construction of \(X\) and the construction of all of its direct or indirect bases that directly or indirectly derive from \(B\) shall have started and the destruction of these classes shall not have completed, otherwise the conversion results in undefined behavior. To form a pointer to (or access the value of) a direct non-static member of an object \(\text{obj}\), the construction of \(\text{obj}\) shall have started and its destruction shall not have completed, otherwise the computation of the pointer value (or accessing the member value) results in undefined behavior. [Example:

\[
\begin{align*}
\text{struct A} & \{ \}; \\
\text{struct B} & : \text{virtual A} \{ \}; \\
\text{struct C} & : B \{ \}; \\
\text{struct D} & : \text{virtual A} \{ D(A*) \}; \\
\text{struct X} & \{ X(A*) \}; \\
\text{struct E} & : C, D, X \{ \\
E() & : D(\text{this}), \quad // \text{undefined: upcast from } E* \text{ to } A* \text{ might use path } E* \rightarrow D* \rightarrow A* \\
& \quad // \text{but } D \text{ is not constructed} \\
& \quad // \text{"D((C*)this)" would be defined: } E* \rightarrow C* \text{ is defined because } E() \text{ has started,} \\
& \quad // \text{and } C* \rightarrow A* \text{ is defined because } C \text{ is fully constructed} \\
X(\text{this}) & \{ \} \quad // \text{defined: upon construction of } X, C/B/D/A \text{ sublattice is fully constructed} \\
\}
\end{align*}
\]
—end example]

Member functions, including virtual functions (11.6.2), can be called during construction or destruction (11.9.2). When a virtual function is called directly or indirectly from a constructor or from a destructor, including during the construction or destruction of the class’s non-static data members, and the object to which the call applies is the object (call it \(x\)) under construction or destruction, the function called is the final overrider in the constructor’s or destructor’s class and not one overriding it in a more-derived class. If the virtual function call uses an explicit class member access (7.6.1.4) and the object expression refers to the complete object of \(x\) or one of that object’s base class subobjects but not \(x\) or one of its base class subobjects, the behavior is undefined. [Example:

\[
\begin{align*}
\text{struct V} & \{ \\
& \quad \text{virtual void } f(); \\
& \quad \text{virtual void } g(); \\
& \}; \\
\text{struct A} & : \text{virtual V} \{ \\
& \quad \text{virtual void } f(); \\
& \}; \\
\text{struct B} & : \text{virtual V} \{ \\
& \quad \text{virtual void } g(); \\
& \quad B(V*, A*); \\
& \}; \\
\text{struct D} & : A, B \{ \\
& \quad \text{virtual void } f(); \\
& \quad \text{virtual void } g(); \\
& \quad D() : B(A*\text{this}, \text{this}) \{ \} \\
& \}; \\
B::B(V* v, A* a) & \{ \\
& \quad f(); \quad // \text{calls } V::f, \text{ not } A::f \\
& \quad g(); \quad // \text{calls } B::g, \text{ not } D::g \\
& \quad v->g(); \quad // v \text{ is base of } B, \text{ the call is well-defined, calls } B::g \\
& \quad a->f(); \quad // \text{undefined behavior, } a\text{’s type not a base of } B \\
& \}
\end{align*}
\]
—end example]

The \texttt{typeid} operator (7.6.1.7) can be used during construction or destruction (11.9.2). When \texttt{typeid} is used in a constructor (including the \texttt{mem-initializer} or default member initializer (11.3) for a non-static
data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of \texttt{typeid} refers to the object under construction or destruction, \texttt{typeid} yields the \texttt{std::type_info} object representing the constructor or destructor’s class. If the operand of \texttt{typeid} refers to the object under construction or destruction and the static type of the operand is neither the constructor or destructor’s class nor one of its bases, the behavior is undefined.

\texttt{dynamic_cast} (7.6.1.6) can be used during construction or destruction (11.9.2). When a \texttt{dynamic_cast} is used in a constructor (including the \texttt{mem-initializer} or default member initializer for a non-static data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of the \texttt{dynamic_cast} refers to the object under construction or destruction, this object is considered to be a most derived object that has the type of the constructor or destructor’s class. If the operand of the \texttt{dynamic_cast} refers to the object under construction or destruction and the static type of the operand is not a pointer or object of the constructor or destructor’s own class or one of its bases, the \texttt{dynamic_cast} results in undefined behavior. [Example:

```cpp
struct V {
    virtual void f();
};
struct A : virtual V { }
struct B : virtual V {
    B(V*, A*);
};
struct D : A, B {
    D() : B((A*)this, this) { }
};
B::B(V* v, A* a) {
    typeid(*this);
    // type_info for B
    typeid(*v);
    // well-defined: *v has type V, a base of B yields type_info for B
    typeid(a);
    // undefined behavior: type A not a base of B
    dynamic_cast<B*>(v);
    // well-defined: v of type V*, V base of B results in B*
    dynamic_cast<B*>(a);
    // undefined behavior, a has type A*, A not a base of B
}
```

— end example]

11.9.5 Copy/move elision

When certain criteria are met, an implementation is allowed to omit the copy/move construction of a class object, even if the constructor selected for the copy/move operation and/or the destructor for the object have side effects. In such cases, the implementation treats the source and target of the omitted copy/move operation as simply two different ways of referring to the same object. If the first parameter of the selected constructor is an rvalue reference to the object’s type, the destruction of that object occurs when the target would have been destroyed; otherwise, the destruction occurs at the later of the times when the two objects would have been destroyed without the optimization.\footnote{Because only one object is destroyed instead of two, and one copy/move constructor is not executed, there is still one object destroyed for each one constructed.} This elision of copy/move operations, called \textit{copy elision}, is permitted in the following circumstances (which may be combined to eliminate multiple copies):

\begin{enumerate}
\item[(1.1)] in a \texttt{return} statement in a function with a class return type, when the \textit{expression} is the name of a non-volatile automatic object (other than a function parameter or a variable introduced by the \textit{exception-declaration} of a \textit{handler} (14.3)) with the same type (ignoring cv-qualification) as the function return type, the copy/move operation can be omitted by constructing the automatic object directly into the function call’s return object

\item[(1.2)] in a \texttt{throw-expression} (7.6.18), when the operand is the name of a non-volatile automatic object (other than a function or catch-clause parameter) whose scope does not extend beyond the end of the innermost enclosing \textit{try-block} (if there is one), the copy/move operation from the operand to the exception object (14.1) can be omitted by constructing the automatic object directly into the exception object
\end{enumerate}
— in a coroutine (9.4.4), a copy of a coroutine parameter can be omitted and references to that copy replaced with references to the corresponding parameter if the meaning of the program will be unchanged except for the execution of a constructor and destructor for the parameter copy object

— when the *exception-declaration* of an exception handler (Clause 14) declares an object of the same type (except for cv-qualification) as the exception object (14.1), the copy operation can be omitted by treating the *exception-declaration* as an alias for the exception object if the meaning of the program will be unchanged except for the execution of constructors and destructors for the object declared by the *exception-declaration*. [Note: There cannot be a move from the exception object because it is always an lvalue. — end note]

Copy elision is not permitted where an expression is evaluated in a context requiring a constant expression (7.7) and in constant initialization (6.8.3.2). [Note: Copy elision might be performed if the same expression is evaluated in another context. — end note]

2 *Example:*

```cpp
class Thing {
public:
  Thing();
  ~Thing();
  Thing(const Thing&);
};

Thing f() {
  Thing t;
  return t;
}

Thing t2 = f();

struct A {
  void *p;
  constexpr A(): p(this) {}‰
};

constexpr A g() {
  A a;
  return a;
}

constexpr A a; // well-formed, a.p points to a
constexpr A b = g(); // well-formed, b.p points to b

void h() {
  A c = g(); // well-formed, c.p may point to c or to an ephemeral temporary
}
```

Here the criteria for elision can eliminate the copying of the local automatic object `t` into the result object for the function call `f()`, which is the global object `t2`. Effectively, the construction of the local object `t` can be viewed as directly initializing the global object `t2`, and that object’s destruction will occur at program exit. Adding a move constructor to `Thing` has the same effect, but it is the move construction from the local automatic object to `t2` that is elided. — *end example*

3 In the following copy-initialization contexts, a move operation might be used instead of a copy operation:

— If the *expression* in a return or co_return statement (8.6.3) is a (possibly parenthesized) id-expression that names an object with automatic storage duration declared in the body or parameter-declaration-clause of the innermost enclosing function or lambda-expression, or

— if the operand of a throw-expression (7.6.18) is the name of a non-volatile automatic object (other than a function or catch-clause parameter) whose scope does not extend beyond the end of the innermost enclosing try-block (if there is one), overload resolution to select the constructor for the copy or the return_value overload to call is first performed as if the object were designated by an rvalue. If the first overload resolution fails or was not performed, or if the type of the first parameter of the selected constructor or the return_value overload is
not an rvalue reference to the object’s type (possibly cv-qualified), overload resolution is performed again, considering the object as an lvalue. [Note: This two-stage overload resolution must be performed regardless of whether copy elision will occur. It determines the constructor or the return_value overload to be called if elision is not performed, and the selected constructor or the return_value overload must be accessible even if the call is elided. — end note]

**Example:**
```cpp
class Thing {
public:
  Thing();
  ~Thing();
  Thing(Thing&&);
private:
  Thing(const Thing&);
};

Thing f(bool b) {
  Thing t;
  if (b)
    throw t;          // OK: Thing(Thing&&) used (or elided) to throw t
  return t;          // OK: Thing(Thing&&) used (or elided) to return t
}

Thing t2 = f(false); // OK: no extra copy/move performed, t2 constructed by call to f

struct Weird {
  Weird();
  Weird(Weird&);
};

Weird g() {
  Weird w;
  return w;           // OK: first overload resolution fails, second overload resolution selects Weird(Weird&)
}

— end example
```

### 11.10 Comparisons

#### 11.10.1 Defaulted comparison operator functions

A defaulted comparison operator function (7.6.8, 7.6.9, 7.6.10) for some class C shall be a non-template function declared in the **member-specification** of C that is

1. a non-static const member of C having one parameter of type const C&, or
2. a friend of C having two parameters of type const C&.

If the class definition does not explicitly declare an == operator function, but declares a defaulted three-way comparison operator function, an == operator function is declared implicitly with the same access as the three-way comparison operator function. The implicitly-declared == operator for a class X is an inline member and is defined as defaulted in the definition of X. If the three-way comparison operator function is declared as a non-static const member, the implicitly-declared == operator function is a member of the form

```cpp
bool X::operator==(const X&) const;
```

Otherwise, the implicitly-declared == operator function is of the form

```cpp
friend bool operator==(const X&, const X&);
```

[Note: Such a friend function is visible to argument-dependent lookup (6.4.2) only (9.7.1.2). — end note]

The operator is a **constexpr** function if its definition would satisfy the requirements for a **constexpr** function.

[Note: The == operator function is declared implicitly even if the defaulted three-way comparison operator function is defined as deleted. — end note]

A type C has **strong structural equality** if, given a glvalue x of type const C, either:

1. C is a non-class type and x <= x is a valid expression of type std::strong_ordering or std::strong_equality, or
Otherwise, if at least one overload resolution (12.3), as applied to
C

If any

A defaulted equality operator (7.6.10) function shall have a declared return type

The return value V of a defaulted == operator function with parameters x and y is determined by comparing corresponding elements x_i and y_i in the expanded lists of subobjects for x and y (in increasing index order) until the first index i where x_i == y_i yields a result value which, when contextually converted to bool, yields false. If no such index exists, V is true. Otherwise, V is false.

A defaulted != operator function for a class C with parameters x and y is defined as deleted if

— overload resolution (12.3), as applied to x == y (also considering synthesized candidates with reversed order of parameters (12.3.1.2)), results in an ambiguity or a function that is deleted or inaccessible from the operator function, or

— x == y cannot be contextually converted to bool.

Otherwise, the operator function yields (x == y) ? false : true.

[Example:

struct D {
    int i;
    friend bool operator==(const D& x, const D& y) = default;
    // OK, returns x.i == y.i
    bool operator!=(const D& z) const = default;  // OK, returns (*this == z) ? false : true
};
— end example]

11.10.2 Equality operators

A defaulted equality operator (7.6.10) function shall have a declared return type bool.

A defaulted == operator function for a class C is defined as deleted unless, for each x_i in the expanded list of subobjects for an object x of type C, x_i == x_i is a valid expression and contextually convertible to bool.

The return value V of a defaulted == operator function with parameters x and y is determined by comparing corresponding elements x_i and y_i in the expanded lists of subobjects for x and y (in increasing index order) until the first index i where x_i == y_i yields a result value which, when contextually converted to bool, yields false. If no such index exists, V is true. Otherwise, V is false.

A defaulted != operator function for a class C with parameters x and y is defined as deleted if

— overload resolution (12.3), as applied to x == y (also considering synthesized candidates with reversed order of parameters (12.3.1.2)), results in an ambiguity or a function that is deleted or inaccessible from the operator function, or

— x == y cannot be contextually converted to bool.

Otherwise, the operator function yields (x == y) ? false : true.

11.10.3 Three-way comparison

Given an expanded list of subobjects for an object x of type C, the type of the expression x_i <=> x_i is denoted by R_i. If the declared return type of a defaulted three-way comparison operator function is auto, then the return type is deduced as the common comparison type (see below) of R_0, R_1, ..., R_n-1. [Note: Otherwise, the program will be ill-formed if the expression x_i <=> x_i is not implicitly convertible to the declared return type for any i. — end note] If the return type is deduced as void, the operator function is defined as deleted.

The return value V of type R of the defaulted three-way comparison operator function with parameters x and y of the same type is determined by comparing corresponding elements x_i and y_i in the expanded lists of subobjects for x and y (in increasing index order) until the first index i where x_i <=> y_i yields a result value v, where v_i != 0, contextually converted to bool, yields true; V is v_i converted to R. If no such index exists, V is std::strong_ordering::equal converted to R.

The common comparison type U of a possibly-empty list of n types T_0, T_1, ..., T_n-1 is defined as follows:

— If any T_i is not a comparison category type (17.11.2), U is void.

— Otherwise, if at least one T_i is std::weak_equality, or at least one T_i is std::strong_equality and at least one T_j is std::partial_ordering or std::weak_equality, U is std::weak_equality (17.11.2.2).

— Otherwise, if at least one T_i is std::strong_equality, U is std::strong_equality (17.11.2.3).

— Otherwise, if at least one T_i is std::partial_ordering, U is std::partial_ordering (17.11.2.4).

— Otherwise, if at least one T_i is std::weak_ordering, U is std::weak_ordering (17.11.2.5).
— Otherwise, $U$ is `std::strong_ordering` (17.11.2.6). [Note: In particular, this is the result when $n$ is 0. —end note]

### 11.10.4 Relational operators

1. A defaulted relational (7.6.9) operator function for some operator $@$ shall have a declared return type `bool`.

2. The operator function with parameters $x$ and $y$ is defined as deleted if

   (2.1) overload resolution (12.3), as applied to $x \leftrightarrow y$ results in an ambiguity or a function that is deleted or inaccessible from the operator function, or

   (2.2) the operator $@$ cannot be applied to the return type of $x \leftrightarrow y$.

   Otherwise, the operator function yields $x \leftrightarrow y @ 0$.

3. [Example:

   ```cpp
   struct C {
       friend std::strong_equality operator<(const C&, const C&);
       bool operator<(const C&) const = default;  // OK, function is deleted
   };
   —end example]

### 11.11 Free store

1. Any allocation function for a class $T$ is a static member (even if not explicitly declared `static`).

2. [Example:

   ```cpp
   class Arena;
   struct B {
       void* operator new(std::size_t, Arena*);
   };
   struct D1 : B {
   };
   
   Arena* ap;
   void foo(int i) {
       new (ap) D1;  // calls B::operator new(std::size_t, Arena*)
       new D1[i];   // calls ::operator new[](...)
       new D1;      // ill-formed: ::operator new(std::size_t) hidden
   }
   —end example]

3. When an object is deleted with a `delete-expression` (7.6.2.8), a deallocation function (`operator delete()` for non-array objects or `operator delete[]()` for arrays) is (implicitly) called to reclaim the storage occupied by the object (6.6.5.4.2).

4. Class-specific deallocation function lookup is a part of general deallocation function lookup (7.6.2.8) and occurs as follows. If the `delete-expression` is used to deallocate a class object whose static type has a virtual destructor, the deallocation function is the one selected at the point of definition of the dynamic type’s virtual destructor (11.3.6).\(^\text{119}\) Otherwise, if the `delete-expression` is used to deallocate an object of class $T$ or array thereof, the deallocation function’s name is looked up in the scope of $T$. If this lookup fails to find the name, general deallocation function lookup (7.6.2.8) continues. If the result of the lookup is ambiguous or inaccessible, or if the lookup selects a placement deallocation function, the program is ill-formed.

5. Any deallocation function for a class $X$ is a static member (even if not explicitly declared `static`). [Example:

   ```cpp
   class X {
       void operator delete(void*);
       void operator delete[](void*, std::size_t);
   };
   
   class Y {
       void operator delete(void*, std::size_t);
   }
   ```

\(^\text{119}\) A similar provision is not needed for the array version of `operator delete` because 7.6.2.8 requires that in this situation, the static type of the object to be deleted be the same as its dynamic type.
Since member allocation and deallocation functions are static they cannot be virtual. [Note: However, when the cast-expression of a delete-expression refers to an object of class type, because the deallocation function actually called is looked up in the scope of the class that is the dynamic type of the object if the destructor is virtual, the effect is the same in that case. For example,

```cpp
struct B {
    virtual ~B();
    void operator delete(void*, std::size_t);
};

struct D : B {
    void operator delete(void*);
};

struct E : B {
    void log_deletion();
    void operator delete(E* p, std::destroying_delete_t) {
        p->log_deletion();
        ::operator delete(p);
    }
};

void f() {
    B* bp = new D;
    delete bp; // 1: uses D::operator delete(void*)
    bp = new E;
    delete bp; // 2: uses E::operator delete(E*, std::destroying_delete_t)
}
```

Here, storage for the object of class D is deallocated by D::operator delete(), and the object of class E is destroyed and its storage is deallocated by E::operator delete(), due to the virtual destructor. —end note] [Note: Virtual destructors have no effect on the deallocation function actually called when the cast-expression of a delete-expression refers to an array of objects of class type. For example,

```cpp
void f(int i) {
    D* dp = new D[i];
    delete [] dp; // uses D::operator delete[](void*, std::size_t)
    B* bp = new D[i];
    delete[] bp; // undefined behavior
}

—end note]

Access to the deallocation function is checked statically. Hence, even though a different one might actually be executed, the statically visible deallocation function is required to be accessible. [Example: For the call on line “// 1” above, if B::operator delete() had been private, the delete expression would have been ill-formed. —end example]

[Note: If a deallocation function has no explicit noexcept-specifier, it has a non-throwing exception specification (14.4). —end note]
12 Overloading

When two or more different declarations are specified for a single name in the same scope, that name is said to be overloaded, and the declarations are called overloaded declarations. Only function and function template declarations can be overloaded; variable and type declarations cannot be overloaded.

When a function name is used in a call, which function declaration is being referenced and the validity of the call are determined by comparing the types of the arguments at the point of use with the types of the parameters in the declarations that are visible at the point of use. This function selection process is called overload resolution and is defined in 12.3. [Example:

```cpp
double abs(double);
int abs(int);

abs(1);       // calls abs(int);
abs(1.0);     // calls abs(double);
```

— end example]

12.1 Overloadable declarations

Not all function declarations can be overloaded. Those that cannot be overloaded are specified here. A program is ill-formed if it contains two such non-overloadable declarations in the same scope. [Note: This restriction applies to explicit declarations in a scope, and between such declarations and declarations made through a using-declaration (9.8). It does not apply to sets of functions fabricated as a result of name lookup (e.g., because of using-directives) or overload resolution (e.g., for operator functions). — end note]

Certain function declarations cannot be overloaded:

(2.1) — Function declarations that differ only in the return type, the exception specification (14.4), or both cannot be overloaded.

(2.2) — Member function declarations with the same name and the same parameter-type-list (9.2.3.5) cannot be overloaded if any of them is a static member function declaration (11.3.8). Likewise, member function template declarations with the same name, the same parameter-type-list, and the same template parameter lists cannot be overloaded if any of them is a static member function template declaration. The types of the implicit object parameters constructed for the member functions for the purpose of overload resolution (12.3.1) are not considered when comparing parameter-type-lists for enforcement of this rule. In contrast, if there is no static member function declaration among a set of member function declarations with the same name and the same parameter-type-list, then these member function declarations can be overloaded if they differ in the type of their implicit object parameter. [Example:

```cpp
class X {
    static void f();    // dll-formed
    void f();           // dll-formed
    void f() const;     // dll-formed
    void f() const volatile; // dll-formed
    void g();           // OK: no static
    void g() const;     // OK: no static
    void g() const volatile; // OK: no static
};
```

— end example]

(2.3) — Member function declarations with the same name and the same parameter-type-list (9.2.3.5) as well as member function template declarations with the same name, the same parameter-type-list, and the same template parameter lists cannot be overloaded if any of them, but not all, have a ref-qualifier (9.2.3.5). [Example:

```cpp
class Y {
    void h() &;      // OK
    void h() const &; // OK
    void h() &&;     // OK, all declarations have a ref-qualifier
};
```
3 [Note: As specified in 9.2.3.5, function declarations that have equivalent parameter declarations and requires-clauses, if any (13.4.2), declare the same function and therefore cannot be overloaded:]

— Parameter declarations that differ only in the use of equivalent typedef “types” are equivalent. A typedef is not a separate type, but only a synonym for another type (9.1.3). [Example:

```c
typedef int Int;
void f(int i);
void f(Int i);     // OK: redeclaration of f(int)
void f(int i) { /* ... */ }
void f(Int i) { /* ... */ }  // error: redefinition of f(int)
— end example
```

Enumerations, on the other hand, are distinct types and can be used to distinguish overloaded function declarations. [Example:

```c
enum E { a };
void f(int i) { /* ... */ }
void f(E i) { /* ... */ }
— end example
```

— Parameter declarations that differ only in that one is a function type and the other is a pointer to the same function type are equivalent. That is, the function type is adjusted to become a pointer to function type (9.2.3.5). [Example:

```c
void h(int());
void h(int (*)());  // redeclaration of h(int())
void h(int x()) { }  // definition of h(int())
void h(int (*)(x)()) { }  // ill-formed: redefinition of h(int())
— end example
```

— Parameter declarations that differ only in that one is a function type and the other is a pointer to function type (9.2.3.5). [Example:

```c
typedef const int cInt;
int f (int);
int f (const int);  // redeclaration of f(int)
int f (int) { /* ... */ }  // definition of f(int)
int f (cInt) { /* ... */ }  // error: redefinition of f(int)
— end example
```
Only the \texttt{const} and \texttt{volatile} type-specifiers at the outermost level of the parameter type specification are ignored in this fashion; \texttt{const} and \texttt{volatile} type-specifiers buried within a parameter type specification are significant and can be used to distinguish overloaded function declarations.\footnote{When a parameter type includes a function type, such as in the case of a parameter type that is a pointer to function, the \texttt{const} and \texttt{volatile} type-specifiers at the outermost level of the parameter type specifications for the inner function type are also ignored.} In particular, for any type \(T\), “pointer to \(T\)”, “pointer to const \(T\)”, and “pointer to volatile \(T\)” are considered distinct parameter types, as are “reference to \(T\)”, “reference to const \(T\)”, and “reference to volatile \(T\)”.}

\begin{Verbatim}
(3.5) Two parameter declarations that differ only in their default arguments are equivalent. \[\text{Example:}\]
\begin{verbatim}
Consider the following:

void f (int i, int j);
void f (int i, int j = 99); // OK: redeclaration of f(int, int)
void f (int i = 88, int j); // OK: redeclaration of f(int, int)
void f (); // OK: overloaded declaration of f

void prog () {
    f (1, 2); // OK: call f(int, int)
    f (1); // OK: call f(int, int)
    f (); // error: f(int, int) or f()?
}
\end{verbatim}
\end{Verbatim}

\end{quote}

\subsection{Declaration matching \[over.dcl\]}

\begin{enumerate}
\item Two function declarations of the same name refer to the same function if they are in the same scope and have equivalent parameter declarations (12.1) and equivalent trailing \textit{requires-clauses}, if any (9.2). A function member of a derived class is \textit{not} in the same scope as a function member of the same name in a base class. \[\text{Example:}\]
\begin{verbatim}
struct B {
    int f(int);
};

struct D : B {
    int f(const char*);
};

Here \(D::f(const\ char*)\) hides \(B::f(int)\) rather than overloading it.

void h(D* pd) {
    pd->f(1); // error:
    // \(D::f(const\ char*)\) hides \(B::f(int)\)
    pd->B::f(1); // OK
    pd->f("Ben"); // OK, calls \(D::f\)
}
\end{verbatim}
\end{quote}

\item A locally declared function is not in the same scope as a function in a containing scope. \[\text{Example:}\]
\begin{verbatim}
void f(const char*);
void g() {
    extern void f(int);
    f("asdf"); // error: \(f(int)\) hides \(f(const\ char*)\)
    // so there is no \(f(const\ char*)\) in this scope
}
\end{verbatim}
\end{quote}

\begin{verbatim}
void caller () {
    extern void callee(int, int);
    {
        extern void callee(int); // hides callee(int, int)
        callee(88, 99); // error: only callee(int) in scope
    }
\end{verbatim}

\end{enumerate}
Different versions of an overloaded member function can be given different access rules. [Example:

```cpp
class buffer {
    private:
    char* p;
    int size;
    protected:
    buffer(int s, char* store) { size = s; p = store; }
    public:
    buffer(int s) { p = new char[size = s]; }
};
```

— end example]

12.3 Overload resolution

Overload resolution is a mechanism for selecting the best function to call given a list of expressions that are to be the arguments of the call and a set of candidate functions that can be called based on the context of the call. The selection criteria for the best function are the number of arguments, how well the arguments match the parameter-type-list of the candidate function, how well (for non-static member functions) the object matches the implicit object parameter, and certain other properties of the candidate function. [Note: The function selected by overload resolution is not guaranteed to be appropriate for the context. Other restrictions, such as the accessibility of the function, can make its use in the calling context ill-formed. — end note]

Overload resolution selects the function to call in seven distinct contexts within the language:

1. invocation of a function named in the function call syntax (12.3.1.1.1);
2. invocation of a function call operator, a pointer-to-function conversion function, a reference-to-pointer-to-function conversion function, or a reference-to-function conversion function on a class object named in the function call syntax (12.3.1.1.2);
3. invocation of the operator referenced in an expression (12.3.1.2);
4. invocation of a constructor for default- or direct-initialization (9.3) of a class object (12.3.1.3);
5. invocation of a user-defined conversion for copy-initialization (9.3) of a class object (12.3.1.4);
6. invocation of a conversion function for initialization of an object of a non-class type from an expression of class type (12.3.1.5); and
7. invocation of a conversion function for conversion in which a reference (9.3.3) will be directly bound (12.3.1.6).

Each of these contexts defines the set of candidate functions and the list of arguments in its own unique way. But, once the candidate functions and argument lists have been identified, the selection of the best function is the same in all cases:

1. First, a subset of the candidate functions (those that have the proper number of arguments and meet certain other conditions) is selected to form a set of viable functions (12.3.2).
2. Then the best viable function is selected based on the implicit conversion sequences (12.3.3.1) needed to match each argument to the corresponding parameter of each viable function.

If a best viable function exists and is unique, overload resolution succeeds and produces it as the result. Otherwise overload resolution fails and the invocation is ill-formed. When overload resolution succeeds, and the best viable function is not accessible (11.8) in the context in which it is used, the program is ill-formed.

12.3.1 Candidate functions and argument lists

The subclauses of 12.3.1 describe the set of candidate functions and the argument list submitted to overload resolution in each context in which overload resolution is used. The source transformations and constructions defined in these subclauses are only for the purpose of describing the overload resolution process. An implementation is not required to use such transformations and constructions.
The set of candidate functions can contain both member and non-member functions to be resolved against the same argument list. So that argument and parameter lists are comparable within this heterogeneous set, a member function is considered to have an extra first parameter, called the *implicit object parameter*, which represents the object for which the member function has been called. For the purposes of overload resolution, both static and non-static member functions have an implicit object parameter, but constructors do not.

Similarly, when appropriate, the context can construct an argument list that contains an *implied object argument* as the first argument in the list to denote the object to be operated on.

For non-static member functions, the type of the implicit object parameter is

(4.1) "Ivalue reference to cv X" for functions declared without a ref-qualifier or with the & ref-qualifier

(4.2) "Rvalue reference to cv X" for functions declared with the && ref-qualifier

where X is the class of which the function is a member and cv is the cv-qualification on the member function declaration. [Example: For a const member function of class X, the extra parameter is assumed to have type “reference to const X”. —end example] For conversion functions, the function is considered to be a member of the class of the implied object argument for the purpose of defining the type of the implicit object parameter. For non-conversion functions introduced by a using-declaration into a derived class, the function is considered to be a member of the derived class for the purpose of defining the type of the implicit object parameter. For static member functions, the implicit object parameter is considered to match any object (since if the function is selected, the object is discarded). [Note: No actual type is established for the implicit object parameter of a static member function, and no attempt will be made to determine a conversion sequence for that parameter (12.3.3). —end note]

During overload resolution, the implied object argument is indistinguishable from other arguments. The implicit object parameter, however, retains its identity since no user-defined conversions can be applied to achieve a type match with it. For non-static member functions declared without a ref-qualifier, an additional rule applies:

(5.1) even if the implicit object parameter is not const-qualified, an rvalue can be bound to the parameter as long as in all other respects the argument can be converted to the type of the implicit object parameter. [Note: The fact that such an argument is an rvalue does not affect the ranking of implicit conversion sequences (12.3.3.2). —end note]

Because other than in list-initialization only one user-defined conversion is allowed in an implicit conversion sequence, special rules apply when selecting the best user-defined conversion (12.3.3, 12.3.3.1). [Example:

```cpp
class T {
    public:
    T();
};

class C : T {
    public:
    C(int);
};
T a = 1; // ill-formed: T(C(1)) not tried

— end example]
```

In each case where a candidate is a function template, candidate function template specializations are generated using template argument deduction (13.9.3, 13.9.2). If a constructor template or conversion function template has an explicit-specifier whose constant-expression is value-dependent (13.7.2), template argument deduction is performed first and then, if the context requires a candidate that is not explicit and the generated specialization is explicit (9.1.2), it will be removed from the candidate set. Those candidates are then handled as candidate functions in the usual way. [Note: A given name can refer to one or more function templates and also to a set of overloaded non-template functions. In such a case, the candidate functions generated from each function template are combined with the set of non-template candidate functions.

A defaulted move special function (11.3.4.2, 11.3.5) that is defined as deleted is excluded from the set of candidate functions in all contexts. A constructor inherited from class type C (11.9.3) that has a first
parameter of type “reference to \( cv1 \ P \)” (including such a constructor instantiated from a template) is excluded from the set of candidate functions when constructing an object of type \( cv2 \ D \) if the argument list has exactly one argument and \( C \) is reference-related to \( P \) and \( P \) is reference-related to \( D \). [Example:

```cpp
struct A {
    A();
    A(A &&);         // #1
    template<typename T> A(T &&);  // #2
};
struct B : A {
    using A::A;
    B(const B &);
    // #3
    B(B &&) = default;    // #4, implicitly deleted
    struct X { X(X &&) = delete; } x;
};
extern B b1;
B b2 = static_cast<B&&>(b1); // calls #3: #1, #2, and #4 are not viable
struct C { operator B&&(); };  // calls #3
B b3 = C();
```
—end example]

12.3.1.1 Function call syntax [over.match.call]

1 In a function call (7.6.1.2)

```cpp
postfix-expression ( expression-list_opt )
```

if the `postfix-expression` denotes a set of overloaded functions and/or function templates, overload resolution is applied as specified in 12.3.1.1.1. If the `postfix-expression` denotes an object of class type, overload resolution is applied as specified in 12.3.1.1.2.

2 If the `postfix-expression` denotes the address of a set of overloaded functions and/or function templates, overload resolution is applied using that set as described above. If the function selected by overload resolution is a non-static member function, the program is ill-formed. [Note: The resolution of the address of an overload set in other contexts is described in 12.4. —end note]

12.3.1.1.1 Call to named function [over.call.func]

1 Of interest in 12.3.1.1.1 are only those function calls in which the `postfix-expression` ultimately contains a name that denotes one or more functions that might be called. Such a `postfix-expression`, perhaps nested arbitrarily deep in parentheses, has one of the following forms:

```cpp
postfix-expression:
    postfix-expression . id-expression
    postfix-expression -> id-expression
    primary-expression
```

These represent two syntactic subcategories of function calls: qualified function calls and unqualified function calls.

2 In qualified function calls, the name to be resolved is an `id-expression` and is preceded by an `->` or `. ` operator. Since the construct \( A->B \) is generally equivalent to \((\ast A).B\), the rest of Clause 12 assumes, without loss of generality, that all member function calls have been normalized to the form that uses an object and the `. ` operator. Furthermore, Clause 12 assumes that the `postfix-expression` that is the left operand of the `. ` operator has type “\( cv \) \( T \)” where \( T \) denotes a class. Under this assumption, the `id-expression` in the call is looked up as a member function of \( T \) following the rules for looking up names in classes (11.7). The function declarations found by that lookup constitute the set of candidate functions. The argument list is the `expression-list` in the call augmented by the addition of the left operand of the `. ` operator in the normalized member function call as the implied object argument (12.3.1).

3 In unqualified function calls, the name is not qualified by an `->` or `. ` operator and has the more general form of a `primary-expression`. The name is looked up in the context of the function call following the normal rules for name lookup in expressions (6.4). The function declarations found by that lookup constitute the set of candidate functions. Because of the rules for name lookup, the set of candidate functions consists

---

122) Note that \( cv \)-qualifiers on the type of objects are significant in overload resolution for both glvalue and class prvalue objects.
(1) entirely of non-member functions or (2) entirely of member functions of some class T. In case (1), the argument list is the same as the expression-list in the call. In case (2), the argument list is the expression-list in the call augmented by the addition of an implied object argument as in a qualified function call. If the keyword this (11.3.2.1) is in scope and refers to class T, or a derived class of T, then the implied object argument is (+this). If the keyword this is not in scope or refers to another class, then a contrived object of type T becomes the implied object argument. If the argument list is augmented by a contrived object and overload resolution selects one of the non-static member functions of T, the call is ill-formed.

12.3.1.1.2 Call to object of class type

If the postfix-expression E in the function call syntax evaluates to a class object of type "cv T", then the set of candidate functions includes at least the function call operators of T. The function call operators of T are obtained by ordinary lookup of the name operator() in the context of (E).operator().

In addition, for each non-explicit conversion function declared in T of the form

    operator conversion-type-id ( ) cv-qualifier-seq_opt ref-qualifier_opt noexcept-specifier_opt attribute-specifier-seq_opt ;

where the optional cv-qualifier-seq is the same cv-qualification as, or a greater cv-qualification than, cv, and where conversion-type-id denotes the type “pointer to function of (P1, ..., Pn) returning R”, or the type “reference to pointer to function of (P1, ..., Pn) returning R”, or the type “reference to function of (P1, ..., Pn) returning R”, a surrogate call function with the unique name call-function and having the form

    R call-function ( conversion-type-id F, P1 a1, ..., Pn an ) { return F (a1, ..., an); }

is also considered as a candidate function. Similarly, surrogate call functions are added to the set of candidate functions for each non-explicit conversion function declared in a base class of T provided the function is not hidden within T by another intervening declaration.

If such a surrogate call function is selected by overload resolution, the corresponding conversion function will be called to convert E to the appropriate function pointer or reference, and the function will then be invoked with the arguments of the call. If the conversion function cannot be called (e.g., because of an ambiguity), the program is ill-formed.

The argument list submitted to overload resolution consists of the argument expressions present in the function call syntax preceded by the implied object argument (E). [Note: When comparing the call against the function call operators, the implied object argument is compared against the implicit object parameter of the function call operator. When comparing the call against a surrogate call function, the implied object argument is compared against the first parameter of the surrogate call function. The conversion function from which the surrogate call function was derived will be used in the conversion sequence for that parameter since it converts the implied object argument to the appropriate function pointer or reference required by that first parameter. —end note] [Example:

```c
int f1(int);
int f2(float);
typedef int (*fp1)(int);
typedef int (*fp2)(float);
struct A {
    operator fp1() { return f1; }
    operator fp2() { return f2; }
} a;
int i = a(1); // calls f1 via pointer returned from conversion function
```

12.3.1.2 Operators in expressions

If no operand of an operator in an expression has a type that is a class or an enumeration, the operator is assumed to be a built-in operator and interpreted according to 7.6. [Note: Because .. , *, and :: cannot be overloaded, these operators are always built-in operators interpreted according to 7.6. ?: cannot be overloaded, but the rules in this subclause are used to determine the conversions to be applied to the second and third operands when they have class or enumeration type (7.6.16). —end note] [Example:

---

123) An implied object argument must be contrived to correspond to the implicit object parameter attributed to member functions during overload resolution. It is not used in the call to the selected function. Since the member functions all have the same implicit object parameter, the contrived object will not be the cause to select or reject a function.

124) Note that this construction can yield candidate call functions that cannot be differentiated one from the other by overload resolution because they have identical declarations or differ only in their return type. The call will be ambiguous if overload resolution cannot select a match to the call that is uniquely better than such undifferentiable functions.
struct String {
  String (const String&);
  String (const char*);
  operator const char* () const;
};
String operator + (const String&, const String&);

void f() {
  const char* p = "one" + "two"; // ill-formed because neither operand has class or enumeration type
  int I = 1 + 1; // always evaluates to 2 even if class or enumeration types exist
  // that would perform the operation.
}
— end example]

2 If either operand has a type that is a class or an enumeration, a user-defined operator function might be declared that implements this operator or a user-defined conversion can be necessary to convert the operand to a type that is appropriate for a built-in operator. In this case, overload resolution is used to determine which operator function or built-in operator is to be invoked to implement the operator. Therefore, the operator notation is first transformed to the equivalent function-call notation as summarized in Table 13 (where @ denotes one of the operators covered in the specified subclause). However, the operands are sequenced in the order prescribed for the built-in operator (7.6).

3 For a unary operator @ with an operand of a type whose cv-unqualified version is T1, and for a binary operator @ with a left operand of a type whose cv-unqualified version is T1 and a right operand of a type whose cv-unqualified version is T2, four sets of candidate functions, designated member candidates, non-member candidates, built-in candidates, and rewritten candidates, are constructed as follows:

(3.1) — If T1 is a complete class type or a class currently being defined, the set of member candidates is the result of the qualified lookup of T1::operator@ (12.3.1.1.1); otherwise, the set of member candidates is empty.

(3.2) — The set of non-member candidates is the result of the unqualified lookup of operator@ in the context of the expression according to the usual rules for name lookup in unqualified function calls (6.4.2) except that all member functions are ignored. However, if no operand has a class type, only those non-member functions in the lookup set that have a first parameter of type T1 or “reference to cv T1”, when T1 is an enumeration type, or (if there is a right operand) a second parameter of type T2 or “reference to cv T2”, when T2 is an enumeration type, are candidate functions.

(3.3) — For the operator ,, the unary operator &, or the operator ->, the built-in candidates set is empty. For all other operators, the built-in candidates include all of the candidate operator functions defined in 12.6 that, compared to the given operator,

(3.3.1) — have the same operator name, and

(3.3.2) — accept the same number of operands, and

(3.3.3) — accept operand types to which the given operand or operands can be converted according to 12.3.3.1, and

(3.3.4) — do not have the same parameter-type-list as any non-member candidate that is not a function template specialization.

(3.4) — For the relational (7.6.9) operators, the rewritten candidates include all member, non-member, and built-in candidates for the operator <=> for which the rewritten expression (x <=> y) @ 0 is well-formed

§ 12.3.1.2
using that \texttt{operator\texttt{<=>}}. For the relational (7.6.9) and three-way comparison (7.6.8) operators, the rewritten candidates also include a synthesized candidate, with the order of the two parameters reversed, for each member, non-member, and built-in candidate for the operator \texttt{<=>} for which the rewritten expression \texttt{0 @ (y <=> x)} is well-formed using that \texttt{operator\texttt{<=>}}. For the \texttt{!=} operator (7.6.10), the rewritten candidates include all member, non-member, and built-in candidates for the operator \texttt{==} for which the rewritten expression \texttt{(x == y)} is well-formed when contextually converted to \texttt{bool} using that \texttt{operator\texttt{==}}. For the equality operators, the rewritten candidates also include a synthesized candidate, with the order of the two parameters reversed, for each member, non-member, and built-in candidate for the operator \texttt{==} for which the rewritten expression \texttt{(y == x)} is well-formed when contextually converted to \texttt{bool} using that \texttt{operator\texttt{==}}. [\textit{Note: A candidate synthesized from a member candidate has its implicit object parameter as the second parameter, thus implicit conversions are considered for the first, but not for the second, parameter. — end note}] In each case, rewritten candidates are not considered in the context of the rewritten expression. For all other operators, the rewritten candidate set is empty.

4 For the built-in assignment operators, conversions of the left operand are restricted as follows:

\begin{enumerate}
\item[(4.1)] no temporaries are introduced to hold the left operand, and
\item[(4.2)] no user-defined conversions are applied to the left operand to achieve a type match with the left-most parameter of a built-in candidate.
\end{enumerate}

5 For all other operators, no such restrictions apply.

6 The set of candidate functions for overload resolution for some operator \texttt{\@} is the union of the member candidates, the non-member candidates, the built-in candidates, and the rewritten candidates for that operator \texttt{\@}.

7 The argument list contains all of the operands of the operator. The best function from the set of candidate functions is selected according to 12.3.2 and 12.3.3.\textsuperscript{125} [\textit{Example:}
\begin{verbatim}
struct A {
    operator int();
};
A operator+(const A&, const A&);
void m() {
    A a, b;
    a + b; // operator+(a, b) chosen over int(a) + int(b)
}
\end{verbatim}
— end example]

8 If a rewritten candidate is selected by overload resolution for a relational or three-way comparison operator \texttt{\@}, \texttt{x \@ y} is interpreted as the rewritten expression: \texttt{0 \@ (y <=\texttt{=>} x)} if the selected candidate is a synthesized candidate with reversed order of parameters, or \texttt{(x <=\texttt{=>} y) \@ 0} otherwise, using the selected rewritten \texttt{operator\texttt{<=>}} candidate. If a rewritten candidate is selected by overload resolution for a \texttt{!=} operator, \texttt{x != y} is interpreted as \texttt{(y == x)} ? \texttt{false} : \texttt{true} if the selected candidate is a synthesized candidate with reversed order of parameters, or \texttt{(x == y)} ? \texttt{false} : \texttt{true} otherwise, using the selected rewritten \texttt{operator==} candidate. If a rewritten candidate is selected by overload resolution for an \texttt{==} operator, \texttt{x == y} is interpreted as \texttt{(y == x)} ? \texttt{true} : \texttt{false} using the selected rewritten \texttt{operator==} candidate.

9 If a built-in candidate is selected by overload resolution, the operands of class type are converted to the types of the corresponding parameters of the selected operation function, except that the second standard conversion sequence of a user-defined conversion sequence (12.3.3.1.2) is not applied. Then the operator is treated as the corresponding built-in operator and interpreted according to 7.6. [\textit{Example:}
\begin{verbatim}
struct X {
    operator double();
};
struct Y {
    operator int*();
};
\end{verbatim}

\textsuperscript{125} If the set of candidate functions is empty, overload resolution is unsuccessful.
The second operand of operator \(\rightarrow\) is ignored in selecting an operator-\(\rightarrow\) function, and is not an argument when the operator-\(\rightarrow\) function is called. When operator-\(\rightarrow\) returns, the operator \(\rightarrow\) is applied to the value returned, with the original second operand.\(^{126}\)

If the operator is the operator \(\),\ the unary operator \&\, or the operator \(\rightarrow\); and there are no viable functions, then the operator is assumed to be the built-in operator and interpreted according to 7.6.

[Note: The lookup rules for operators in expressions are different than the lookup rules for operator function names in a function call, as shown in the following example:

```c
struct A { }
void operator + (A, A);

struct B {
    void operator + (B);
    void f () ;
};

A a;
void B::f() {
    operator+ (a,a);    // error: global operator hidden by member
    a + a;            // OK: calls global operator+
}

— end note]

12.3.1.3 Initialization by constructor

When objects of class type are direct-initialized (9.3), copy-initialized from an expression of the same or a derived class type (9.3), or default-initialized (9.3), overload resolution selects the constructor. For direct-initialization or default-initialization that is not in the context of copy-initialization, the candidate functions are all the constructors of the class of the object being initialized. For copy-initialization (including default initialization in the context of copy-initialization), the candidate functions are all the converting constructors (11.3.7.1) of that class. The argument list is the expression-list or assignment-expression of the initializer.

12.3.1.4 Copy-initialization of class by user-defined conversion

Under the conditions specified in 9.3, as part of a copy-initialization of an object of class type, a user-defined conversion can be invoked to convert an initializer expression to the type of the object being initialized. Overload resolution is used to select the user-defined conversion to be invoked. [Note: The conversion performed for indirect binding to a reference to a possibly cv-qualified class type is determined in terms of a corresponding non-reference copy-initialization. — end note] Assuming that “cv\(1\) T” is the type of the object being initialized, with T a class type, the candidate functions are selected as follows:

(1.1) — The converting constructors (11.3.7.1) of T are candidate functions.

(1.2) — When the type of the initializer expression is a class type “cv S”, the non-explicit conversion functions of S and its base classes are considered. When initializing a temporary object (11.3) to be bound to the first parameter of a constructor where the parameter is of type “reference to possibly cv-qualified T” and the constructor is called with a single argument in the context of direct-initialization of an object of type “cv2 T”, explicit conversion functions are also considered. Those that are not hidden within S and yield a type whose cv-unqualified version is the same type as T or is a derived class thereof are candidate functions. A call to a conversion function returning “reference to X” is a glvalue of type X, and such a conversion function is therefore considered to yield X for this process of selecting candidate functions.

\(^{126}\) If the value returned by the operator-\(\rightarrow\) function has class type, this may result in selecting and calling another operator-\(\rightarrow\) function. The process repeats until an operator-\(\rightarrow\) function returns a value of non-class type.
In both cases, the argument list has one argument, which is the initializer expression. [Note: This argument will be compared against the first parameter of the constructors and against the implicit object parameter of the conversion functions. — end note]

12.3.1.5 Initialization by conversion function

Under the conditions specified in 9.3, as part of an initialization of an object of non-class type, a conversion function can be invoked to convert an initializer expression of class type to the type of the object being initialized. Overload resolution is used to select the conversion function to be invoked. Assuming that "cv1 T" is the type of the object being initialized, and "cv S" is the type of the initializer expression, with S a class type, the candidate functions are selected as follows:

(1.1) — The conversion functions of S and its base classes are considered. Those non-explicit conversion functions that are not hidden within S and yield type T or a type that can be converted to type T via a standard conversion sequence (12.3.3.1.1) are candidate functions. For direct-initialization, those explicit conversion functions that are not hidden within S and yield type T or a type that can be converted to type T with a qualification conversion (7.3.5) are also candidate functions. Conversion functions that return a cv-qualified type are considered to yield the cv-unqualified version of that type for this process of selecting candidate functions. A call to a conversion function returning “reference to X” is a glvalue of type X, and such a conversion function is therefore considered to yield X for this process of selecting candidate functions.

The argument list has one argument, which is the initializer expression. [Note: This argument will be compared against the implicit object parameter of the conversion functions. — end note]

12.3.1.6 Initialization by conversion function for direct reference binding

Under the conditions specified in 9.3.3, a reference can be bound directly to the result of applying a conversion function to an initializer expression. Overload resolution is used to select the conversion function to be invoked. Assuming that “reference to cv1 T” is the type of the reference being initialized, and “cv S” is the type of the initializer expression, with S a class type, the candidate functions are selected as follows:

(1.1) — The conversion functions of S and its base classes are considered. Those non-explicit conversion functions that are not hidden within S and yield type “lvalue reference to cv2 T2” (when initializing an lvalue reference or an rvalue reference to function) or “cv2 T2” or “rvalue reference to cv2 T2” (when initializing an rvalue reference or an lvalue reference to function), where “cv1 T” is reference-compatible (9.3.3) with “cv2 T2”, are candidate functions. For direct-initialization, those explicit conversion functions that are not hidden within S and yield type “lvalue reference to cv2 T2” (when initializing an lvalue reference or an lvalue reference to function) or “rvalue reference to cv2 T2” (when initializing an rvalue reference or an rvalue reference to function), where T2 is the same type as T or can be converted to type T with a qualification conversion (7.3.5), are also candidate functions.

The argument list has one argument, which is the initializer expression. [Note: This argument will be compared against the implicit object parameter of the conversion functions. — end note]

12.3.1.7 Initialization by list-initialization

When objects of non-aggregate class type T are list-initialized such that 9.3.4 specifies that overload resolution is performed according to the rules in this subclause, overload resolution selects the constructor in two phases:

(1.1) — Initially, the candidate functions are the initializer-list constructors (9.3.4) of the class T and the argument list consists of the initializer list as a single argument.

(1.2) — If no viable initializer-list constructor is found, overload resolution is performed again, where the candidate functions are all the constructors of the class T and the argument list consists of the elements of the initializer list.

If the initializer list has no elements and T has a default constructor, the first phase is omitted. In copy-list-initialization, if an explicit constructor is chosen, the initialization is ill-formed. [Note: This differs from other situations (12.3.1.3, 12.3.1.4), where only converting constructors are considered for copy-initialization. This restriction only applies if this initialization is part of the final result of overload resolution. — end note]

12.3.1.8 Class template argument deduction

When resolving a placeholder for a deduced class type (9.1.7.6) where the template-name names a primary class template C, a set of functions and function templates is formed comprising:

(1.1) — If C is defined, for each constructor of C, a function template with the following properties:
The template parameters are the template parameters of `C` followed by the template parameters (including default template arguments) of the constructor, if any.

The types of the function parameters are those of the constructor.

The return type is the class template specialization designated by `C` and template arguments corresponding to the template parameters of `C`.

If `C` is not defined or does not declare any constructors, an additional function template derived as above from a hypothetical constructor `C()`.

An additional function template derived as above from a hypothetical constructor `C(C())`, called the *copy deduction candidate*.

For each *deduction-guide*, a function or function template with the following properties:

- The template parameters, if any, and function parameters are those of the *deduction-guide*.
- The return type is the *simple-template-id* of the *deduction-guide*.

Initialization and overload resolution are performed as described in 9.3 and 12.3.1.3, 12.3.1.4, or 12.3.1.7 (as appropriate for the type of initialization performed) for an object of a hypothetical class type, where the selected functions and function templates are considered to be the constructors of that class type for the purpose of forming an overload set, and the initializer is provided by the context in which class template argument deduction was performed. As an exception, the first phase in 12.3.1.7 (considering initializer-list constructors) is omitted if the initializer list consists of a single expression of type `cv U`, where `U` is a specialization of `C` or a class derived from a specialization of `C`. If the function or function template was generated from a constructor or *deduction-guide* that had an *explicit-specifier*, each such notional constructor is considered to have that same *explicit-specifier*. All such notional constructors are considered to be public members of the hypothetical class type.

```c++
// Example:
template <class T> struct A {
    explicit A(const T&, ...) noexcept; // #1
    A(T&&, ...); // #2
};

int i;
A a1 = { i, i }; // error: explicit constructor #1 selected in copy-list-initialization during deduction, // cannot deduce from non-forwarding rvalue reference in #2
A a2(i, i); // OK, #1 deduces to A<int> and also initializes
A a3(0, i); // OK, #2 deduces to A<int> and also initializes
A a4 = { 0, i }; // OK, #2 deduces to A<int> and also initializes

template <class T> A(const T&, const T&) -> A<T&>; // #3

template <class T> explicit A(T&&, T&&) -> A<T>; // #4

A a5 = { 0, 1 }; // error: explicit deduction guide #4 selected in copy-list-initialization during deduction
A a6(0, i); // OK, #4 deduces to A<int> and #2 initializes
A a7 = { 0, i }; // error: #3 deduces to A<int&>, #1 and #2 declare same constructor
A a8(i, i); // error: #3 deduces to A<int&>, #1 and #2 declare same constructor

template <class T> struct B {
    template <class U> using TA = T;
    template <class U> B(U, TA<U>);
};

B b((int*)0, (char*)0); // OK, deduces B<char>
```

### 12.3.2 Viable functions

From the set of candidate functions constructed for a given context (12.3.1), a set of viable functions is chosen, from which the best function will be selected by comparing argument conversion sequences and associated constraints (13.4.2) for the best fit (12.3.3). The selection of viable functions considers associated constraints.
if any, and relationships between arguments and function parameters other than the ranking of conversion sequences.

2 First, to be a viable function, a candidate function shall have enough parameters to agree in number with the arguments in the list.

   (2.1) — If there are \( m \) arguments in the list, all candidate functions having exactly \( m \) parameters are viable.

   (2.2) — A candidate function having fewer than \( m \) parameters is viable only if it has an ellipsis in its parameter list (9.2.3.5). For the purposes of overload resolution, any argument for which there is no corresponding parameter is considered to “match the ellipsis” (12.3.3.1.3).

   (2.3) — A candidate function having more than \( m \) parameters is viable only if the \( (m+1) \)st parameter has a default argument (9.2.3.6). For the purposes of overload resolution, the parameter list is truncated on the right, so that there are exactly \( m \) parameters.

3 Second, for a function to be viable, if it has associated constraints (13.4.2), those constraints shall be satisfied (13.4.1).

4 Third, for \( F \) to be a viable function, there shall exist for each argument an implicit conversion sequence (12.3.3.1) that converts that argument to the corresponding parameter of \( F \). If the parameter has reference type, the implicit conversion sequence includes the operation of binding the reference, and the fact that an lvalue reference to non-\( \text{const} \) cannot be bound to an rvalue and that an rvalue reference cannot be bound to an lvalue can affect the viability of the function (see 12.3.3.1.4).

### 12.3.3 Best viable function [over.match.best]

1 Define ICS\( i(F) \) as follows:

   (1.1) — If \( F \) is a static member function, ICS\( i(F) \) is defined such that ICS\( i(F) \) is neither better nor worse than ICS\( i(G) \) for any function \( G \), and, symmetrically, ICS\( i(G) \) is neither better nor worse than ICS\( i(F) \),

   (1.2) — let ICS\( i(F) \) denote the implicit conversion sequence that converts the \( i \)-th argument in the list to the type of the \( i \)-th parameter of viable function \( F \). 12.3.3.1 defines the implicit conversion sequences and 12.3.3.2 defines what it means for one implicit conversion sequence to be a better conversion sequence or worse conversion sequence than another.

2 Given these definitions, a viable function \( F_1 \) is defined to be a better function than another viable function \( F_2 \) if for all arguments \( i \), ICS\( i(F_1) \) is not a worse conversion sequence than ICS\( i(F_2) \), and then

   (2.1) — for some argument \( j \), ICS\( j(F_1) \) is a better conversion sequence than ICS\( j(F_2) \), or, if not that,

   (2.2) — the context is an initialization by user-defined conversion (see 9.3, 12.3.1.5, and 12.3.1.6) and the standard conversion sequence from the return type of \( F_1 \) to the destination type (i.e., the type of the entity being initialized) is a better conversion sequence than the standard conversion sequence from the return type of \( F_2 \) to the destination type [Example:

```
struct A {
    A();
    operator int();
    operator double();
} a;
int i = a; // a.operator int() followed by no conversion is better than
          // a.operator double() followed by a conversion to int
float x = a;  // ambiguous: both possibilities require conversions,
              // and neither is better than the other
```

— end example] or, if not that,

   (2.3) — the context is an initialization by conversion function for direct reference binding (12.3.1.6) of a reference to function type, the return type of \( F_1 \) is the same kind of reference (lvalue or rvalue) as the reference being initialized, and the return type of \( F_2 \) is not [Example:

```
template <class T> struct A {
    operator T&();  // #1
```
operator T&&(); // #2
};
typedef int Fn();
A<Fn> a;
Fn& lf = a;    // calls #1
Fn&& rf = a;  // calls #2

— end example] or, if not that,

(2.4) — F1 is not a function template specialization and F2 is a function template specialization, or, if not that,

(2.5) — F1 and F2 are function template specializations, and the function template for F1 is more specialized than the template for F2 according to the partial ordering rules described in 13.6.6.2, or, if not that,

(2.6) — F1 and F2 are non-template functions with the same parameter-type-lists, and F1 is more constrained than F2 according to the partial ordering of constraints described in 13.4.4, or if not that,

(2.7) — F1 is a constructor for a class D, F2 is a constructor for a base class B of D, and for all arguments the corresponding parameters of F1 and F2 have the same type. [Example:

```cpp
struct A {
    A(int = 0);
};
struct B: A {
    using A::A;
    B();
};

int main() {
    B b;     // OK, B::B()
}
— end example] or, if not that,

(2.8) — F2 is a rewritten candidate (12.3.1.2) and F1 is not [Example:

```cpp
struct S {
    friend auto operator<=>(const S&, const S&) = default; // #1
    friend bool operator<(const S&, const S&);            // #2
};
bool b = S() < S(); // calls #2
— end example] or, if not that,

(2.9) — F1 and F2 are rewritten candidates, and F2 is a synthesized candidate with reversed order of parameters and F1 is not [Example:

```cpp
struct S {
    friend std::weak_ordering operator<=>(const S&, int); // #1
    friend std::weak_ordering operator<=>(int, const S&); // #2
};
bool b = 1 < S(); // calls #2
— end example] or, if not that

(2.10) — F1 is generated from a deduction-guide (12.3.1.8) and F2 is not, or, if not that,

(2.11) — F1 is the copy deduction candidate (12.3.1.8) and F2 is not, or, if not that,

(2.12) — F1 is generated from a non-template constructor and F2 is generated from a constructor template. [Example:

```cpp
template <class T> struct A {
    using value_type = T;
    A(value_type);    // #1
    A(const A&);     // #2
    A(T, T, int);    // #3
    template<class U>
        A(int, T, U); // #4
        // #5 is the copy deduction candidate, A(A)
};
```
A x(1, 2, 3);  // uses #3, generated from a non-template constructor

template <class T>
A(T) -> A<T>;  // #6, less specialized than #5

A a(42);  // uses #6 to deduce A<int> and #1 to initialize
A b = a;  // uses #5 to deduce A<int> and #2 to initialize

template <class T>
A(A<T>) -> A<A<T>>;  // #7, as specialized as #5

A b2 = a;  // uses #7 to deduce A<A<int>> and #1 to initialize

— end example

If there is exactly one viable function that is a better function than all other viable functions, then it is the one selected by overload resolution; otherwise the call is ill-formed.\textsuperscript{129} [Example:

```cpp
void Fcn(const int*, short);
void Fcn(int*, int);

int i;
short s = 0;

void f() {
    Fcn(&i, s);  // is ambiguous because &i \to int* is better than &i \to const int*
    // but s \to short is also better than s \to int
    Fcn(&i, 1L);  // calls Fcn(int*, int), because &i \to int* is better than &i \to const int*
    // and 1L \to short and 1L \to int are indistinguishable
    Fcn(&i, 'c');  // calls Fcn(int*, int), because &i \to int* is better than &i \to const int*
    // and c \to int is better than c \to short
}

— end example]
```

If the best viable function resolves to a function for which multiple declarations were found, and if at least two of these declarations — or the declarations they refer to in the case of using-declarations — specify a default argument that made the function viable, the program is ill-formed. \textsuperscript{4} [Example:

```cpp
namespace A {
    extern "C" void f(int = 5);
}
namespace B {
    extern "C" void f(int = 5);
}

using A::f;
using B::f;

void use() {
    f(3);  // OK, default argument was not used for viability
    f();  // error: found default argument twice
}

— end example]
```

12.3.3.1 Implicit conversion sequences [over.best.ics]

An implicit conversion sequence is a sequence of conversions used to convert an argument in a function call to the type of the corresponding parameter of the function being called. The sequence of conversions is an

\textsuperscript{129} The algorithm for selecting the best viable function is linear in the number of viable functions. Run a simple tournament to find a function W that is not worse than any opponent it faced. Although another function F that W did not face might be at least as good as W, F cannot be the best function because at some point in the tournament F encountered another function G such that F was not better than G. Hence, either W is the best function or there is no best function. So, make a second pass over the viable functions to verify that W is better than all other functions.
Implicit conversion as defined in 7.3, which means it is governed by the rules for initialization of an object or reference by a single expression (9.3, 9.3.3).

2 Implicit conversion sequences are concerned only with the type, cv-qualification, and value category of the argument and how these are converted to match the corresponding properties of the parameter. [Note: Other properties, such as the lifetime, storage class, alignment, accessibility of the argument, whether the argument is a bit-field, and whether a function is deleted (9.4.3), are ignored. So, although an implicit conversion sequence can be defined for a given argument-parameter pair, the conversion from the argument to the parameter might still be ill-formed in the final analysis. — end note]

3 A well-formed implicit conversion sequence is one of the following forms:

- a standard conversion sequence (12.3.3.1.1),
- a user-defined conversion sequence (12.3.3.1.2), or
- an ellipsis conversion sequence (12.3.3.1.3).

4 However, if the target is

- the first parameter of a constructor or
- the implicit object parameter of a user-defined conversion function

and the constructor or user-defined conversion function is a candidate by

- 12.3.1.3, when the argument is the temporary in the second step of a class copy-initialization,
- 12.3.1.4, 12.3.1.5, or 12.3.1.6 (in all cases), or
- the second phase of 12.3.1.7 when the initializer list has exactly one element that is itself an initializer list, and the target is the first parameter of a constructor of class X, and the conversion is to X or reference to cv X,

user-defined conversion sequences are not considered. [Note: These rules prevent more than one user-defined conversion from being applied during overload resolution, thereby avoiding infinite recursion. — end note]

[Example:

```cpp
struct Y { Y(int); }; strut A { operator int(); }; Y y1 = A(); // error: A::operator int() is not a candidate

struct X { X(); }; struct B { operator X(); }; B b;
X x{(b)}; // error: B::operator X() is not a candidate

— end example]
```

5 For the case where the parameter type is a reference, see 12.3.3.1.4.

6 When the parameter type is not a reference, the implicit conversion sequence models a copy-initialization of the parameter from the argument expression. The implicit conversion sequence is the one required to convert the argument expression to a prvalue of the type of the parameter. [Note: When the parameter has a class type, this is a conceptual conversion defined for the purposes of Clause 12; the actual initialization is defined in terms of constructors and is not a conversion. — end note] Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion. [Example: A parameter of type A can be initialized from an argument of type const A. The implicit conversion sequence for that case is the identity sequence; it contains no “conversion” from const A to A. — end example] When the parameter has a class type and the argument expression has the same type, the implicit conversion sequence is an identity conversion. When the parameter has a class type and the argument expression has a derived class type, the implicit conversion sequence is a derived-to-base conversion from the derived class to the base class. [Note: There is no such standard conversion; this derived-to-base conversion exists only in the description of implicit conversion sequences. — end note] A derived-to-base conversion has Conversion rank (12.3.3.1.1).

7 In all contexts, when converting to the implicit object parameter or when converting to the left operand of an assignment operation only standard conversion sequences are allowed.

8 If no conversions are required to match an argument to a parameter type, the implicit conversion sequence is the standard conversion sequence consisting of the identity conversion (12.3.3.1.1).
If no sequence of conversions can be found to convert an argument to a parameter type, an implicit conversion sequence cannot be formed.

If there are multiple well-formed implicit conversion sequences converting the argument to the parameter type, the implicit conversion sequence associated with the parameter is defined to be the unique conversion sequence designated the ambiguous conversion sequence. For the purpose of ranking implicit conversion sequences as described in 12.3.3.2, the ambiguous conversion sequence is treated as a user-defined conversion sequence that is indistinguishable from any other user-defined conversion sequence. [Note: This rule prevents a function from becoming non-viable because of an ambiguous conversion sequence for one of its parameters.]

Example:

```cpp
class B;
class A { A (B&); };
class B { operator A () ; };
class C { C (B&); };
void f(A) { }
void f(C) { }
B b;
f(b); // ill-formed: ambiguous because there is a conversion b \rightarrow C (via constructor)
// and an (ambiguous) conversion b \rightarrow A (via constructor or conversion function)
void f(B) { }
f(b); // OK, unambiguous
```

The three forms of implicit conversion sequences mentioned above are defined in the following subclauses.

12.3.3.1.1 Standard conversion sequences

Table 14 summarizes the conversions defined in 7.3 and partitions them into four disjoint categories: Lvalue Transformation, Qualification Adjustment, Promotion, and Conversion. [Note: These categories are orthogonal with respect to value category, cv-qualification, and data representation: the Lvalue Transformations do not change the cv-qualification or data representation of the type; the Qualification Adjustments do not change the value category or data representation of the type; and the Promotions and Conversions do not change the value category or cv-qualification of the type. — end note]

Each conversion in Table 14 also has an associated rank (Exact Match, Promotion, or Conversion). These are used to rank standard conversion sequences (12.3.3.2). The rank of a conversion sequence is determined by considering the rank of each conversion in the sequence and the rank of any reference binding (12.3.3.1.4). If any of those has Conversion rank, the sequence has Conversion rank; otherwise, if any of those has Promotion rank, the sequence has Promotion rank; otherwise, the sequence has Exact Match rank.

12.3.3.1.2 User-defined conversion sequences

A user-defined conversion sequence consists of an initial standard conversion sequence followed by a user-defined conversion (11.3.7) followed by a second standard conversion sequence. If the user-defined conversion is specified by a constructor (11.3.7.1), the initial standard conversion sequence converts the source type to the type required by the argument of the constructor. If the user-defined conversion is specified by a conversion function (11.3.7.2), the initial standard conversion sequence converts the source type to the implicit object parameter of the conversion function.

The second standard conversion sequence converts the result of the user-defined conversion to the target type for the sequence; any reference binding is included in the second standard conversion sequence. Since an implicit conversion sequence is an initialization, the special rules for initialization by user-defined conversion apply when selecting the best user-defined conversion for a user-defined conversion sequence (see 12.3.3 and 12.3.3.1).

If the user-defined conversion is specified by a specialization of a conversion function template, the second standard conversion sequence shall have exact match rank.
Table 14: Conversions

</table>

4 A conversion of an expression of class type to the same class type is given Exact Match rank, and a conversion of an expression of class type to a base class of that type is given Conversion rank, in spite of the fact that a constructor (i.e., a user-defined conversion function) is called for those cases.

12.3.3.1.3 Ellipsis conversion sequences

An ellipsis conversion sequence occurs when an argument in a function call is matched with the ellipsis parameter specification of the function called (see 7.6.1.2).

12.3.3.1.4 Reference binding

When a parameter of reference type binds directly (9.3.3) to an argument expression, the implicit conversion sequence is the identity conversion, unless the argument expression has a type that is a derived class of the parameter type, in which case the implicit conversion sequence is a derived-to-base Conversion (12.3.3.1).

[Example:

```c
struct A {};
struct B : public A {} b;
int f(A&);
int f(B&);
int i = f(b); // calls f(B&), an exact match, rather than f(A&), a conversion
```

—end example] If the parameter binds directly to the result of applying a conversion function to the argument expression, the implicit conversion sequence is a user-defined conversion sequence (12.3.3.1.2), with the second standard conversion sequence either an identity conversion or, if the conversion function returns an entity of a type that is a derived class of the parameter type, a derived-to-base conversion.

2 When a parameter of reference type is not bound directly to an argument expression, the conversion sequence is the one required to convert the argument expression to the referenced type according to 12.3.3.1. Conceptually, this conversion sequence corresponds to copy-initializing a temporary of the referenced type with the argument expression. Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion.

3 Except for an implicit object parameter, for which see 12.3.1, an implicit conversion sequence cannot be formed if it requires binding an lvalue reference other than a reference to a non-volatile const type to an rvalue or binding an rvalue reference to an lvalue other than a function lvalue. [Note: This means, for example, that a candidate function cannot be a viable function if it has a non-const lvalue reference parameter (other than the implicit object parameter) and the corresponding argument would require a temporary to be created to initialize the lvalue reference (see 9.3.3). —end note]

4 Other restrictions on binding a reference to a particular argument that are not based on the types of the reference and the argument do not affect the formation of an implicit conversion sequence, however. [Example: A function with an “lvalue reference to int” parameter can be a viable candidate even if the corresponding argument is an int bit-field. The formation of implicit conversion sequences treats the int bit-field as an int lvalue and finds an exact match with the parameter. If the function is selected by overload resolution,
the call will nonetheless be ill-formed because of the prohibition on binding a non-const lvalue reference to a bit-field (9.3.3). — end example

12.3.3.1.5 List-initialization sequence

1 When an argument is an initializer list (9.3.4), it is not an expression and special rules apply for converting it to a parameter type.

2 If the initializer list is a designated-initializer-list, a conversion is only possible if the parameter has an aggregate type that can be initialized from the initializer list according to the rules for aggregate initialization (9.3.1), in which case the implicit conversion sequence is a user-defined conversion sequence whose second standard conversion sequence is an identity conversion. [Note: Aggregate initialization does not require that the members are declared in designation order. If, after overload resolution, the order does not match for the selected overload, the initialization of the parameter will be ill-formed (9.3.4). ]

3 Otherwise, if the parameter type is an aggregate class X and the initializer list has a single element of type cv U, where U is X or a class derived from X, the implicit conversion sequence is the one required to convert the element to the parameter type.

4 Otherwise, if the parameter type is a character array and the initializer list has a single element that is an appropriately-typed string literal (9.3.2), the implicit conversion sequence is the identity conversion.

5 Otherwise, if the parameter type is std::initializer_list<X> and all the elements of the initializer list can be implicitly converted to X, the implicit conversion sequence is the worst conversion necessary to convert an element of the list to X, or if the initializer list has no elements, the identity conversion. This conversion can be a user-defined conversion even in the context of a call to an initializer-list constructor. [Example:

```cpp
void f(std::initializer_list<double>); // #1
void f(std::initializer_list<complex<double>>); // #2
void f(std::initializer_list<std::string>); // #3
};
A a{ 1.0, 2.0 }; // OK, uses #1

void g(A);
g({ "foo", "bar" }); // OK, uses #3

typedef int IA[3];
void h(const IA&);
h({ 1, 2, 3 }); // OK: identity conversion
``` ]

— end example — end note

130) Since there are no parameters of array type, this will only occur as the referenced type of a reference parameter.
Otherwise, if the parameter type is “array of N X”, if there exists an implicit conversion sequence for each element of the array from the corresponding element of the initializer list (or from {} if there is no such element), the implicit conversion sequence is the worst such implicit conversion sequence.

Otherwise, if the parameter is a non-aggregate class X and overload resolution per 12.3.1.7 chooses a single best constructor C of X to perform the initialization of an object of type X from the argument initializer list:

1. If C is not an initializer-list constructor and the initializer list has a single element of type \(cv U\), where U is X or a class derived from X, the implicit conversion sequence has Exact Match rank if U is X, or Conversion rank if U is derived from X.

2. Otherwise, the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion.

If multiple constructors are viable but none is better than the others, the implicit conversion sequence is the ambiguous conversion sequence. User-defined conversions are allowed for conversion of the initializer list elements to the constructor parameter types except as noted in 12.3.3.1. [Example:

```cpp
struct A {
    A(std::initializer_list<int>);
};
void f(A);
f( {'a', 'b'} ); // OK: f(A(std::initializer_list<int>)) user-defined conversion

struct B {
    B(int, double);
};
void g(B);
g( {'a', 'b'} ); // OK: g(B(int, double)) user-defined conversion
g( {1.0, 1.0} ); // error: narrowing

void f(B);
f( {'a', 'b'} ); // error: ambiguous f(A) or f(B)
```

—end example—

Otherwise, if the parameter has an aggregate type which can be initialized from the initializer list according to the rules for aggregate initialization (9.3.1), the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion. [Example:

```cpp
struct A {
    int m1;
    double m2;
};

void f(A);
f( {'a', 'b'} ); // OK: f(A(int, double)) user-defined conversion
f( {1.0} ); // error: narrowing
—end example—

Otherwise, if the parameter is a reference, see 12.3.3.1.4. [Note: The rules in this subclause will apply for initializing the underlying temporary for the reference. —end note] [Example:

```cpp
double m2;
}

void f(const A &);
f( {'a', 'b'} );  // OK: f(A(int,double)) user-defined conversion
f( {1.0} );  // error: narrowing

void g(const double &);
g({1});  // same conversion as int to double

— end example
```

10 Otherwise, if the parameter type is not a class:

(10.1) — if the initializer list has one element that is not itself an initializer list, the implicit conversion sequence is the one required to convert the element to the parameter type; [Example:

```cpp
void f(int);
f( {'a'} );  // OK: same conversion as char to int
f( {1.0} );  // error: narrowing
— end example
```

(10.2) — if the initializer list has no elements, the implicit conversion sequence is the identity conversion. [Example:

```cpp
void f(int);
f( { } );  // OK: identity conversion
— end example
```

11 In all cases other than those enumerated above, no conversion is possible.

### 12.3.3.2 Ranking implicit conversion sequences

This subclause defines a partial ordering of implicit conversion sequences based on the relationships better conversion sequence and better conversion. If an implicit conversion sequence S1 is defined by these rules to be a better conversion sequence than S2, then it is also the case that S2 is a worse conversion sequence than S1. If conversion sequence S1 is neither better than nor worse than conversion sequence S2, S1 and S2 are said to be indistinguishable conversion sequences.

1 When comparing the basic forms of implicit conversion sequences (as defined in 12.3.3.1)

(2.1) — a standard conversion sequence (12.3.3.1.1) is a better conversion sequence than a user-defined conversion sequence or an ellipsis conversion sequence, and

(2.2) — a user-defined conversion sequence (12.3.3.1.2) is a better conversion sequence than an ellipsis conversion sequence (12.3.3.1.3).

2 Two implicit conversion sequences of the same form are indistinguishable conversion sequences unless one of the following rules applies:

(3.1) — List-initialization sequence L1 is a better conversion sequence than list-initialization sequence L2 if

(3.1.1) — L1 converts to std::initializer_list<X> for some X and L2 does not, or, if not that,

(3.1.2) — L1 converts to type "array of N1 T", L2 converts to type "array of N2 T", and N1 is smaller than N2,

even if one of the other rules in this paragraph would otherwise apply. [Example:

```cpp
void f1(int);
void f1(std::initializer_list<long>);  // #1
void g1() { f1({42}); }  // chooses #2

void f2(std::pair<const char*, const char*>);  // #3
void f2(std::initializer_list<std::string>);  // #4
void g2() { f2({"foo", "bar"}); }  // chooses #4
— end example
```

(3.2) — Standard conversion sequence S1 is a better conversion sequence than standard conversion sequence S2 if

§ 12.3.3.2
(3.2.1) S1 is a proper subsequence of S2 (comparing the conversion sequences in the canonical form defined by 12.3.3.1.1, excluding any Lvalue Transformation; the identity conversion sequence is considered to be a subsequence of any non-identity conversion sequence) or, if not that,

(3.2.2) the rank of S1 is better than the rank of S2, or S1 and S2 have the same rank and are distinguishable by the rules in the paragraph below, or, if not that,

(3.2.3) S1 and S2 include reference bindings (9.3.3) and neither refers to an implicit object parameter of a non-static member function declared without a ref-qualifier, and S1 binds an rvalue reference to an rvalue and S2 binds an lvalue reference [Example:]

```c
int i;
int f1();
int&& f2();
int g(const int&);
int g(const int&&);
int j = g(i); // calls g(const int&)
int k = g(f1()); // calls g(const int&&)
int l = g(f2()); // calls g(const int&&)
```

```c
struct A {
    && operator<<(int);
    void p() &;
    void p() &&;
};
&& operator<<(&&, char);
A() << 1; // calls A::operator<<(int)
A() << 'c'; // calls A::operator<<(&&, char)
A a;
a << 1; // calls A::operator<<(int)
a << 'c'; // calls A::operator<<(int)
A().p(); // calls A::p()&
a.p(); // calls A::p()&&

— end example] or, if not that,
```

(3.2.4) S1 and S2 include reference bindings (9.3.3) and S1 binds an lvalue reference to a function lvalue and S2 binds an rvalue reference to a function lvalue [Example:]

```c
int f(void(&)()); // #1
int f(void(&&)()); // #2
void g();
int i1 = f(g); // calls #1

— end example] or, if not that,
```

(3.2.5) S1 and S2 differ only in their qualification conversion and yield similar types T1 and T2 (7.3.5), respectively, and the cv-qualification signature of type T1 is a proper subset of the cv-qualification signature of type T2 [Example:]

```c
int f(const volatile int *);
int f(const int *);
int i;
int j = f(&i); // calls f(const int*)

— end example] or, if not that,
```

(3.2.6) S1 and S2 include reference bindings (9.3.3), and the types to which the references refer are the same type except for top-level cv-qualifiers, and the type to which the reference initialized by S2 refers is more cv-qualified than the type to which the reference initialized by S1 refers. [Example:]

```c
int f(const int &);
int f(int &);
g(const int &);
g(int);

int i;
int j = f(i); // calls f(int &)
in k = g(i); // ambiguous
```
struct X {
    void f() const;
    void f();
};
void g(const X& a, X b) {
    a.f(); // calls X::f() const
    b.f(); // calls X::f()
}

User-defined conversion sequence U1 is a better conversion sequence than another user-defined conversion sequence U2 if they contain the same user-defined conversion function or constructor or they initialize the same class in an aggregate initialization and in either case the second standard conversion sequence of U1 is better than the second standard conversion sequence of U2. [Example:

```c
struct A {
    operator short();
} a;
int f(int);
int f(float);
int i = f(a); // calls f(int), because short → int is
              // better than short → float.
```

— end example]

Standard conversion sequences are ordered by their ranks: an Exact Match is a better conversion than a Promotion, which is a better conversion than a Conversion. Two conversion sequences with the same rank are indistinguishable unless one of the following rules applies:

(4.1) — A conversion that does not convert a pointer or a pointer to member to bool is better than one that does.

(4.2) — A conversion that promotes an enumeration whose underlying type is fixed to its underlying type is better than one that promotes to the promoted underlying type, if the two are different.

(4.3) — If class B is derived directly or indirectly from class A, conversion of B* to A* is better than conversion of B* to void*, and conversion of A* to void* is better than conversion of B* to void*.

(4.4) — If class B is derived directly or indirectly from class A and class C is derived directly or indirectly from B,

(4.4.1) — conversion of C* to B* is better than conversion of C* to A*, [Example:

```c
struct A {};
struct B : public A {};
struct C : public B {};
C* pc;
int f(A*);
int f(B*);
int i = f(pc); // calls f(B*)
```

— end example]

(4.4.2) — binding of an expression of type C to a reference to type B is better than binding an expression of type C to a reference to type A,

(4.4.3) — conversion of A::* to B::* is better than conversion of A::* to C::*,

(4.4.4) — conversion of C to B is better than conversion of C to A,

(4.4.5) — conversion of B* to A* is better than conversion of C* to A*,

(4.4.6) — binding of an expression of type B to a reference to type A is better than binding an expression of type C to a reference to type A,

(4.4.7) — conversion of B::* to C::* is better than conversion of A::* to C::* and

(4.4.8) — conversion of B to A is better than conversion of C to A.

[Note: Compared conversion sequences will have different source types only in the context of comparing the second standard conversion sequence of an initialization by user-defined conversion (see 12.3.3); in all other contexts, the source types will be the same and the target types will be different. — end note]
12.4 Address of overloaded function

A use of an overloaded function name without arguments is resolved in certain contexts to a function, a pointer to function or a pointer to member function for a specific function from the overload set. A function template name is considered to name a set of overloaded functions in such contexts. A function with type F is selected for the function type FT of the target type required in the context if F (after possibly applying the function pointer conversion (7.3.13)) is identical to FT. [Note: That is, the class of which the function is a member is ignored when matching a pointer-to-member-function type. — end note] The target can be

1. an object or reference being initialized (9.3, 9.3.3, 9.3.4),
2. the left side of an assignment (7.6.19),
3. a parameter of a function (7.6.1.2),
4. a parameter of a user-defined operator (12.5),
5. the return value of a function, operator function, or conversion (8.6.3),
6. an explicit type conversion (7.6.1.3, 7.6.1.8, 7.6.3), or
7. a non-type template-parameter (13.3.2).

The overloaded function name can be preceded by the & operator. An overloaded function name shall not be used without arguments in contexts other than those listed. [Note: Any redundant set of parentheses surrounding the overloaded function name is ignored (7.5.3). — end note]

If the name is a function template, template argument deduction is done (13.9.2.2), and if the argument deduction succeeds, the resulting template argument list is used to generate a single function template specialization, which is added to the set of overloaded functions considered. [Note: As described in 13.9.1, if deduction fails and the function template name is followed by an explicit template argument list, the template-id is then examined to see whether it identifies a single function template specialization. If it does, the template-id is considered to be an lvalue for that function template specialization. The target type is not used in that determination. — end note]

Non-member functions and static member functions match targets of function pointer type or reference to function type. Non-static member functions match targets of pointer-to-member-function type. If a non-static member function is selected, the reference to the overloaded function name is required to have the form of a pointer to member as described in 7.6.2.1.

All functions with associated constraints that are not satisfied (13.4.2) are eliminated from the set of selected functions. If more than one function in the set remains, all function template specializations in the set are eliminated if the set also contains a function that is not a function template specialization. Any given non-template function F0 is eliminated if the set contains a second non-template function that is more constrained than F0 according to the partial ordering rules of 13.4.4. Any given function template specialization F1 is eliminated if the set contains a second function template specialization whose function template is more specialized than the function template of F1 according to the partial ordering rules of 13.6.6.2. After such eliminations, if any, there shall remain exactly one selected function.

[Example:

```c
int f(double);
int f(int);
int (*pfld)(double) = &f; // selects f(double)
int (*pfli)(int) = &f; // selects f(int)
int (*pfle)(...) = &f; // error: type mismatch
int (&rfli)(int) = f; // selects f(int)
int (&rfd)(double) = f; // selects f(double)
void g() {
    (int (*)(int))&f; // cast expression as selector
}
```

The initialization of pfle is ill-formed because no f() with type int(...) has been declared, and not because of any ambiguity. For another example,

```c
struct X {
    int f(int);
    static int f(long);
};
```
int (X::*p1)(int) = &X::f;  // OK
int (*p2)(int) = &X::f;    // error: mismatch
int (X::*p3)(long) = &X::f; // OK
int (X::*p4)(long) = &X::f; // error: mismatch
int (X::*p5)(int) = &X:(f); // error: wrong syntax for
                          // pointer to member
int (*p6)(long) = &(X::f); // OK

—end example

6 [Note: If f() and g() are both overloaded functions, the cross product of possibilities must be considered to resolve f(&g), or the equivalent expression f(g). —end note]

7 [Note: Even if B is a public base of D, we have
D* f();
B* (*p1)() = &f;  // error
void g(D*);
void (*p2)(B*) = &g; // error
—end note]

12.5 Overloaded operators [over.oper]

1 A function declaration having one of the following operator-function-ids as its name declares an operator function. A function template declaration having one of the following operator-function-ids as its name declares an operator function template. A specialization of an operator function template is also an operator function. An operator function is said to implement the operator named in its operator-function-id.

operator-function-id:
operator
operator: one of
new delete new[] delete[] co_await () [] -> -* ~
| = += -= *= /= %= ^= &= |=
|== == != < > <= >= <=> &&
|[] << >> <<= >>= ++ -- ,

[Note: The operators new[], delete[], (), and [] are formed from more than one token. The latter two operators are function call (7.6.1.2) and subscripting (7.6.1.1). —end note]

2 Both the unary and binary forms of
+ - * &
can be overloaded.

3 The following operators cannot be overloaded:
   . * :: ?:

   nor the preprocessing symbols # and ## (Clause 15).

4 Operator functions are usually not called directly; instead they are invoked to evaluate the operators they implement (12.5.1 – 12.5.7). They can be explicitly called, however, using the operator-function-id as the name of the function in the function call syntax (7.6.1.2). [Example:
   complex z = a.operator+(b);  // complex z = a+b;
   void* p = operator new(sizeof(int)*n);
—end example]

5 The allocation and deallocation functions, operator new, operator new[], operator delete and operator delete[], are described completely in 6.6.5.4. The attributes and restrictions found in the rest of this subclause do not apply to them unless explicitly stated in 6.6.5.4.

6 The co_await operator is described completely in 7.6.2.3. The attributes and restrictions found in the rest of this subclause do not apply to it unless explicitly stated in 7.6.2.3.

7 An operator function shall either be a non-static member function or be a non-member function that has at least one parameter whose type is a class, a reference to a class, an enumeration, or a reference to an
.enumeration. It is not possible to change the precedence, grouping, or number of operands of operators. The meaning of the operators \( = \), \( (\) unary \( ) \), \( \& \), \( , \) (comma), predefined for each type, can be changed for specific class and enumeration types by defining operator functions that implement these operators. Operator functions are inherited in the same manner as other base class functions.

8 The identities among certain predefined operators applied to basic types (for example, \(+a \equiv a+=1\)) need not hold for operator functions. Some predefined operators, such as \(+=\), require an operand to be an lvalue when applied to basic types; this is not required by operator functions.

9 An operator function cannot have default arguments (9.2.3.6), except where explicitly stated below. Operator functions cannot have more or fewer parameters than the number required for the corresponding operator, as described in the rest of this subclause.

10 Operators not mentioned explicitly in subclauses 12.5.3 through 12.5.7 act as ordinary unary and binary operators obeying the rules of 12.5.1 or 12.5.2.

12.5.1 Unary operators

A prefix unary operator shall be implemented by a non-static member function (11.3.1) with no parameters or a non-member function with one parameter. Thus, for any prefix unary operator \(@\), \(@x\) can be interpreted as either \(x\).\@() or \(\text{operator@}(x)\). If both forms of the operator function have been declared, the rules in 12.3.1.2 determine which, if any, interpretation is used. See 12.5.7 for an explanation of the postfix unary operators ++ and --.

2 The unary and binary forms of the same operator are considered to have the same name. [Note: Consequently, a unary operator can hide a binary operator from an enclosing scope, and vice versa. —end note]

12.5.2 Binary operators

A binary operator shall be implemented either by a non-static member function (11.3.1) with one parameter or by a non-member function with two parameters. Thus, for any binary operator \(\&\), \(x\\&y\) can be interpreted as either \(x\).\@\&(y) or \(\text{operator@}(x, y)\). If both forms of the operator function have been declared, the rules in 12.3.1.2 determine which, if any, interpretation is used.

12.5.3 Assignment

An assignment operator shall be implemented by a non-static member function with exactly one parameter. Because a copy assignment operator \(\text{operator=}\) is implicitly declared for a class if not declared by the user (11.3.5), a base class assignment operator is always hidden by the copy assignment operator of the derived class.

2 Any assignment operator, even the copy and move assignment operators, can be virtual. [Note: For a derived class \(D\) with a base class \(B\) for which a virtual copy(move) assignment has been declared, the copy(move) assignment operator in \(D\) does not override \(B\)'s virtual copy(move) assignment operator. [Example:]

```c
struct B {
    virtual int operator= (int);
    virtual B& operator= (const B&);
};
struct D : B {
    virtual int operator= (int);
    virtual D& operator= (const B&);
};
D dobj1;
D dobj2;
B* bptr = &dobj1;
void f() {
    bptr->operator=(99); // calls D::operator=(int)
    *bptr = 99; // ditto
    bptr->operator=(dobj2); // calls D::operator=(const B&)
    *bptr = dobj2; // ditto
    dobj1 = dobj2; // calls implicitly-declared D::operator=(const D&)
}
```

—end example] —end note]
12.5.4 Function call

operator() shall be a non-static member function with an arbitrary number of parameters. It can have default arguments. It implements the function call syntax

postfix-expression ( expression-listopt )

where the postfix-expression evaluates to a class object and the possibly empty expression-list matches the parameter list of an operator() member function of the class. Thus, a call x(arg1, ...) is interpreted as x.operator()(arg1, ...) for a class object x of type T if T::operator()(T1, T2, T3) exists and if the operator is selected as the best match function by the overload resolution mechanism (12.3.3).

12.5.5 Subscripting

operator[] shall be a non-static member function with exactly one parameter. It implements the subscripting syntax

postfix-expression [ expr-or-braced-init-list ]

Thus, a subscripting expression x[y] is interpreted as x.operator[](y) for a class object x of type T if T::operator[](T1) exists and if the operator is selected as the best match function by the overload resolution mechanism (12.3.3). [Example:

struct X {
 X operator[](std::initializer_list<int>); // prefix +a
 X operator++(int); // postfix +a
};

X x;
x[{1,2,3}] = 7; // OK: meaning x.operator[](1,2,3)
int a[10];
a[1,2,3] = 7; // error: built-in subscript operator
—end example]

12.5.6 Class member access

operator-> shall be a non-static member function taking no parameters. It implements the class member access syntax that uses ->.

postfix-expression -> templateopt id-expression

An expression x->m is interpreted as (x.operator->())->m for a class object x of type T if T::operator->() exists and if the operator is selected as the best match function by the overload resolution mechanism (12.3.3).

12.5.7 Increment and decrement

The user-defined function called operator++ implements the prefix and postfix ++ operator. If this function is a non-static member function with no parameters, or a non-member function with one parameter, it defines the prefix increment operator ++ for objects of that type. If the function is a non-static member function with one parameter (which shall be of type int) or a non-member function with two parameters (the second of which shall be of type int), it defines the postfix increment operator ++ for objects of that type. When the postfix increment is called as a result of using the ++ operator, the int argument will have value zero.131 [Example:

struct X {
 X& operator++(); // prefix +a
 X operator++(int); // postfix +a
};

struct Y {
 Y& operator++(); // prefix +b
 Y operator++(Y&, int); // postfix +b
};

void f(X a, Y b) {
  ++a; // a.operator++();
a++;  // a.operator++(0);
++b;  // operator++(b);
  b++;  // operator++(b, 0);

131) Calling operator++ explicitly, as in expressions like a.operator++(2), has no special properties: The argument to operator++ is 2.
The prefix and postfix decrement operators -- are handled analogously.

12.5.8 User-defined literals

**literal-operator-id:**

- `operator string-literal identifier`
- `operator user-defined-string-literal`

The string-literal or user-defined-string-literal in a literal-operator-id shall have no encoding-prefix and shall contain no characters other than the implicit terminating ‘\0’. The ud-suffix of the user-defined-string-literal or the identifier in a literal-operator-id is called a literal suffix identifier. Some literal suffix identifiers are reserved for future standardization; see 16.5.4.3.5. A declaration whose literal-operator-id uses such a literal suffix identifier is ill-formed, no diagnostic required.

A declaration whose declarator-id is a literal-operator-id shall be a declaration of a namespace-scope function or function template (it could be a friend function (11.8.3)), an explicit instantiation or specialization of a function template, or a using-declaration (9.8). A function declared with a literal-operator-id is a literal operator. A function template declared with a literal-operator-id is a literal operator template.

The declaration of a literal operator shall have a parameter-declaration-clause equivalent to one of the following:

- `const char*`
- `unsigned long long int` long double
- `char`
- `wchar_t`
- `char16_t`
- `char32_t`
- `const char*`, `std::size_t`
- `const wchar_t*`, `std::size_t`
- `const char8_t*`, `std::size_t`
- `const char16_t*`, `std::size_t`
- `const char32_t*`, `std::size_t`

If a parameter has a default argument (9.2.3.6), the program is ill-formed.

A raw literal operator is a literal operator with a single parameter whose type is `const char*`.

A numeric literal operator template is a literal operator template whose template-parameter-list has a single template-parameter that is a non-type template parameter pack (13.6.3) with element type `char`. A string literal operator template is a literal operator template whose template-parameter-list comprises a single non-type template-parameter of class type. The declaration of a literal operator template shall have an empty parameter-declaration-clause and shall declare either a numeric literal operator template or a string literal operator template.

Lliteral operators and literal operator templates shall not have C language linkage.

[Note: Literal operators and literal operator templates are usually invoked implicitly through user-defined literals (5.13.8). However, except for the constraints described above, they are ordinary namespace-scope functions and function templates. In particular, they are looked up like ordinary functions and function templates and they follow the same overload resolution rules. Also, they can be declared `inline` or `constexpr`, they may have internal, module, or external linkage, they can be called explicitly, their addresses can be taken, etc. — end note]

[Example:

```c
void operator "" _km(long double); // OK
string operator "" _i18n(const char*, std::size_t); // OK
template <char...> double operator "" _u03C0(); // OK: UCN for lowercase pi
float operator "" _e(const char*); // OK
```]
12.6 Built-in operators

The candidate operator functions that represent the built-in operators defined in 7.6 are specified in this subclause. These candidate functions participate in the operator overload resolution process as described in 12.3.1.2 and are used for no other purpose. [Note: Because built-in operators take only operands with non-class type, and operator overload resolution occurs only when an operand expression originally has class or enumeration type, operator overload resolution can resolve to a built-in operator only when an operand has a class type that has a user-defined conversion to a non-class type appropriate for the operator, or when an operand has an enumeration type that can be converted to a type appropriate for the operator. Also note that some of the candidate operator functions given in this subclause are more permissive than the built-in operators themselves. As described in 12.3.1.2, after a built-in operator is selected by overload resolution the expression is subject to the requirements for the built-in operator given in 7.6, and therefore to any additional semantic constraints given there. If there is a user-written candidate with the same name and parameter types as a built-in candidate operator function, the built-in operator function is hidden and is not included in the set of candidate functions. —end note]

In this subclause, the term promoted integral type is used to refer to those integral types which are preserved by integral promotion (7.3.6) (including e.g. int and long but excluding e.g. char). Similarly, the term promoted arithmetic type refers to floating-point types plus promoted integral types. [Note: In all cases where a promoted integral type or promoted arithmetic type is required, an operand of enumeration type will be acceptable by way of the integral promotions. —end note]

In the remainder of this subclause, vg represents either volatile or no cv-qualifier.

For every pair (T, vg), where T is an arithmetic type other than bool, there exist candidate operator functions of the form

\[ vq T* operator++(vq T*); \]
\[ T operator++(vq T*, int); \]

For every pair (T, vg), where T is an arithmetic type other than bool, there exist candidate operator functions of the form

\[ vq T* operator--(vq T*); \]
\[ T operator--(vq T*, int); \]

For every pair (T, vg), where T is a cv-qualified or cv-unqualified object type, there exist candidate operator functions of the form

\[ T*vgk operator++(T*vgk); \]
\[ T*vgk operator--(T*vgk); \]
\[ T* operator++(T*vgk, int); \]
\[ T* operator--(T*vgk, int); \]

For every cv-qualified or cv-unqualified object type T, there exist candidate operator functions of the form

\[ T* operator*(T*); \]

For every function type T that does not have cv-qualifiers or a ref-qualifier, there exist candidate operator functions of the form

\[ T* operator*(T*); \]

For every type T there exist candidate operator functions of the form

\[ T operator*(T*); \]

For every promoted arithmetic type T, there exist candidate operator functions of the form

\[ T operator+(T); \]
\[ T operator-(T); \]
For every promoted integral type \( T \), there exist candidate operator functions of the form
\[
T \text{ operator}-(T);
\]
For every quintuple \((C1, C2, T, cv1, cv2)\), where \( C2 \) is a class type, \( C1 \) is the same type as \( C2 \) or is a derived class of \( C2 \), and \( T \) is an object type or a function type, there exist candidate operator functions of the form
\[
cv12 T& \text{ operator}->*\((cv1 \ C1*, \ cv2 \ T \ C2::*);\)
\]
where \( cv12 \) is the union of \( cv1 \) and \( cv2 \). The return type is shown for exposition only; see 7.6.4 for the determination of the operator’s result type.

For every pair of promoted arithmetic types \( L \) and \( R \), there exist candidate operator functions of the form
\[
LR \text{ operator}\ast\((L, R)\);
LR \text{ operator}/\((L, R)\);
LR \text{ operator}+\((L, R)\);
LR \text{ operator}-\((L, R)\);
bool \text{ operator}==\((L, R)\);
bool \text{ operator}!=\((L, R)\);
bool \text{ operator}<\((L, R)\);
bool \text{ operator}>\((L, R)\);
bool \text{ operator}<=\((L, R)\);
bool \text{ operator}>=\((L, R)\);
\]
where \( LR \) is the result of the usual arithmetic conversions (7.4) between types \( L \) and \( R \).

For every integral type \( T \) there exists a candidate operator function of the form
\[
\text{std::strong_ordering} \text{ operator}\ll\ll\ll(T, T);
\]
For every pair of floating-point types \( L \) and \( R \), there exists a candidate operator function of the form
\[
\text{std::partial_ordering} \text{ operator}\ll\ll\ll(L, R);
\]
For every cv-qualified or cv-unqualified object type \( T \) there exist candidate operator functions of the form
\[
T* \text{ operator}+(T*, \ \text{std::ptrdiff}_t);
T& \text{ operator}[\](T*, \ \text{std::ptrdiff}_t);
T* \text{ operator}-(T*, \ \text{std::ptrdiff}_t);
T& \text{ operator}[\](std::ptrdiff_t, T*);
\]
For every \( T \), where \( T \) is a pointer to object type, there exist candidate operator functions of the form
\[
\text{std::ptrdiff}_t \text{ operator}-(T, T);
\]
For every \( T \), where \( T \) is an enumeration type or a pointer type, there exist candidate operator functions of the form
\[
\text{std::strong_equality} \text{ operator}\ll\ll\ll(T, T);
\]
For every \( T \), where \( T \) is a pointer-to-member type or \text{std::nullptr}_t, there exist candidate operator functions of the form
\[
\text{bool} \text{ operator}==\((T, T)\);
\text{bool} \text{ operator}!=\((T, T)\);
\text{bool} \text{ operator}<\((T, T)\);
\text{bool} \text{ operator}>\((T, T)\);
\text{bool} \text{ operator}<=\((T, T)\);
\text{bool} \text{ operator}>=\((T, T)\);
\]
where \( R \) is the result type specified in 7.6.8.

For every pair of promoted integral types \( L \) and \( R \), there exist candidate operator functions of the form
\[
LR \text{ operator}\%\((L, R)\);
LR \text{ operator}\&\((L, R)\);
LR \text{ operator}^\((L, R)\);
LR \text{ operator}!\((L, R)\);
L \text{ operator}<<\((L, R)\);
L \text{ operator}>>\((L, R)\);
\]
where \( LR \) is the result of the usual arithmetic conversions (7.4) between types \( L \) and \( R \).

21 For every triple \((L, vq, R)\), where \( L \) is an arithmetic type, and \( R \) is a promoted arithmetic type, there exist candidate operator functions of the form

\[
\begin{align*}
vq L & \text{ operator=}=(vq L, R); \\
vq L & \text{ operator**}=(vq L, R); \\
vq L & \text{ operator/}=(vq L, R); \\
vq L & \text{ operator=}=(vq L, R); \\
vq L & \text{ operator*=}=(vq L, R); \\
vq L & \text{ operator/=}=(vq L, R); \\
vq L & \text{ operator+=}=(vq L, R); \\
vq L & \text{ operator-=}=(vq L, R);
\end{align*}
\]

22 For every pair \((T, vq)\), where \( T \) is any type, there exist candidate operator functions of the form

\[
\begin{align*}
vq T & \text{ operator=}=(vq T, T);
\end{align*}
\]

23 For every pair \((T, vq)\), where \( T \) is an enumeration or pointer-to-member type, there exist candidate operator functions of the form

\[
\begin{align*}
vq T & \text{ operator=}=(vq T, T);
\end{align*}
\]

24 For every pair \((T, vq)\), where \( T \) is a cv-qualified or cv-unqualified object type, there exist candidate operator functions of the form

\[
\begin{align*}
vq T & \text{ operator=}=(vq T, T);
\end{align*}
\]

25 For every triple \((L, vq, R)\), where \( L \) is an integral type, and \( R \) is a promoted integral type, there exist candidate operator functions of the form

\[
\begin{align*}
vq L & \text{ operator%}=(vq L, R); \\
vq L & \text{ operator<<}=(vq L, R); \\
vq L & \text{ operator>>}=(vq L, R); \\
vq L & \text{ operator&}=(vq L, R); \\
vq L & \text{ operator^}=(vq L, R); \\
vq L & \text{ operator|}=(vq L, R);
\end{align*}
\]

26 There also exist candidate operator functions of the form

\[
\begin{align*}
\text{bool} & \text{ operator!}(\text{bool}); \\
\text{bool} & \text{ operator&&}(\text{bool, bool}); \\
\text{bool} & \text{ operator||}(\text{bool, bool});
\end{align*}
\]

27 For every pair of promoted arithmetic types \( L \) and \( R \), there exist candidate operator functions of the form

\[
\begin{align*}
LR & \text{ operator?}:(\text{bool, } L, R);
\end{align*}
\]

where \( LR \) is the result of the usual arithmetic conversions (7.4) between types \( L \) and \( R \). [Note: As with all these descriptions of candidate functions, this declaration serves only to describe the built-in operator for purposes of overload resolution. The operator “?:” cannot be overloaded. —end note]

28 For every type \( T \), where \( T \) is a pointer, pointer-to-member, or scoped enumeration type, there exist candidate operator functions of the form

\[
\begin{align*}
T & \text{ operator?}:(\text{bool, } T, T);
\end{align*}
\]
13 Templates

A template defines a family of classes, functions, or variables, an alias for a family of types, or a concept.

```
template-declaration:
  template-head declaration
  template-head concept-definition

template-head:
  template < template-parameter-list > requires-clause_opt

template-parameter-list:
  template-parameter
  template-parameter-list , template-parameter

requires-clause:
  requires constraint-logical-or-expression

constraint-logical-or-expression:
  constraint-logical-and-expression
  constraint-logical-or-expression || constraint-logical-and-expression

constraint-logical-and-expression:
  primary-expression
  constraint-logical-and-expression && primary-expression

concept-definition:
  concept concept-name = constraint-expression ;

concept-name:
  identifier

type-constraint:
  nested-name-specifier_opt concept-name
  nested-name-specifier_opt concept-name < template-argument-list_opt >
```

[Note: The > token following the template-parameter-list of a template-declaration may be the product of replacing a >> token by two consecutive > tokens (13.2). — end note]

2 The declaration in a template-declaration (if any) shall

(2.1) — declare or define a function, a class, or a variable, or
(2.2) — define a member function, a member class, a member enumeration, or a static data member of a class template or of a class nested within a class template, or
(2.3) — define a member template of a class or class template, or
(2.4) — be a deduction-guide, or
(2.5) — be an alias-declaration.

3 A template-declaration is a declaration. A template-declaration is also a definition if its template-head is followed by either a concept-definition or a declaration that defines a function, a class, a variable, or a static data member. A declaration introduced by a template declaration of a variable is a variable template. A variable template at class scope is a static data member template.

[Example:
```
template<class T>
  constexpr T pi = T(3.1415926535897932385L);

template<class T>
  T circular_area(T r) {
    return pi<T> * r * r ;
  }

struct matrix_constants {
  template<class T>
    using pauli = hermitian_matrix<T, 2> ;
  template<class T>
    constexpr static pauli<T> sigma1 = { { 0, 1 }, { 1, 0 } } ;
```]
template<class T>
    constexpr static pauli<T> sigma2 = { { 0, -1i }, { 1i, 0 } };

template<class T>
    constexpr static pauli<T> sigma3 = { { 1, 0 }, { 0, -1 } };

— end example]

A template-declaration can appear only as a namespace scope or class scope declaration. Its declaration shall not be an export-declaration. In a function template declaration, the last component of the declaraor-id shall not be a template-id. [Note: That last component may be an identifier, an operator-function-id, a conversion-function-id, or a literal-operator-id. In a class template declaration, if the class name is a simple-template-id, the declaration declares a class template partial specialization (13.6.5). — end note]

In a template-declaration, explicit specialization, or explicit instantiation the init-declarator-list in the declaration shall contain at most one declarator. When such a declaration is used to declare a class template, no declarator is permitted.

A type-constraint \( \mathcal{Q} \) that designates a concept \( \mathcal{C} \) can be used to constrain a contextually-determined type or template type parameter pack \( T \) with a constraint-expression \( E \) defined as follows. If \( Q \) is of the form \( \mathcal{C}\{A_1, \ldots, A_n\} \), then let \( E' \) be \( \mathcal{C}\{T, A_1, \ldots, A_n\} \). Otherwise, let \( E' \) be \( \mathcal{C}\{T\} \). If \( T \) is not a pack, then \( E \) is \( E' \), otherwise \( E \) is \( (E' \&\& \ldots) \). This constraint-expression \( E \) is called the immediately-declared constraint of \( T \). The concept designated by a type-constraint shall be a type concept (13.6.8).

A template name has linkage (6.5). Specializations (explicit or implicit) of a template that has internal linkage are distinct from all specializations in other translation units. A template, a template explicit specialization (13.8.3), and a class template partial specialization shall not have \( \mathcal{C} \) linkage. Use of a linkage specification other than "C++" or "C++" with any of these constructs is conditionally-supported, with implementation-defined semantics. Template definitions shall obey the one-definition rule (6.2). [Note: Default arguments for function templates and for member functions of class templates are considered definitions for the purpose of template instantiation (13.6) and must also obey the one-definition rule. — end note]

A class template shall not have the same name as any other template, class, function, variable, enumeration, enumerator, namespace, or type in the same scope (6.3), except as specified in 13.6.5. Except that a function template can be overloaded either by non-template functions (9.2.3.5) with the same name or by other function templates with the same name (13.9.3), a template name declared in namespace scope or in class scope shall be unique in that scope.

A templated entity is

(9.1) — a template,
(9.2) — an entity defined (6.1) or created (6.6.7) in a templated entity,
(9.3) — a member of a templated entity,
(9.4) — an enumerator for an enumeration that is a templated entity, or
(9.5) — the closure type of a lambda-expression (7.5.5.1) appearing in the declaration of a templated entity.

[Note: A local class, a local variable, or a friend function defined in a templated entity is a templated entity. — end note]

A template-declaration is written in terms of its template parameters. The optional requires-clause following a template-parameter-list allows the specification of constraints (13.4.2) on template arguments (13.3). The requires-clause introduces the constraint-expression that results from interpreting the constraint-logical-or-expression as a constraint-expression. The constraint-logical-or-expression of a requires-clause is an unevaluated operand (Clause 7). [Note: The expression in a requires-clause uses a restricted grammar to avoid ambiguities. Parentheses can be used to specify arbitrary expressions in a requires-clause. [Example:

```cpp
template<int N> requires N == sizeof new unsigned short
    int f();  // error: parentheses required around == expression
— end example]

— end note]
```

A function template, member function of a class template, variable template, or static data member of a class template shall be defined in every translation unit in which it is implicitly instantiated (13.8.1) unless the corresponding specialization is explicitly instantiated (13.8.2) in some translation unit; no diagnostic is required.
13.1 Template parameters

The syntax for template-parameters is:

```
template-parameter:
  type-parameter
  parameter-declaration

  type-parameter:
  type-parameter-key ...opt identifier_opt
  type-parameter-key identifier_opt = type-id
  type-constraint ...opt identifier_opt
  type-constraint identifier_opt = type-id
  template-head type-parameter-key ...opt identifier_opt
  template-head type-parameter-key identifier_opt = id-expression

type-parameter-key:
  class
typename
```

[Note: The > token following the template-parameter-list of a type-parameter may be the product of replacing a >> token by two consecutive > tokens (13.2). — end note]

There is no semantic difference between class and typename in a type-parameter-key. typename followed by an unqualified-id names a template type parameter. typename followed by a qualified-id denotes the type in a non-type parameter-declaration. A template-parameter of the form class identifier is a type-parameter.

[Example:

```
class T { /* ... */ };
int i;

template<class T, T i> void f(T t) {
  T t1 = i;  // template-parameters T and i
  ::T t2 = ::i;  // global namespace members T and i
}
```

] Here, the template f has a type-parameter called T, rather than an unnamed non-type template-parameter of class T. — end example] A storage class shall not be specified in a template-parameter declaration. Types shall not be defined in a template-parameter declaration.

A type-parameter whose identifier does not follow an ellipsis defines its identifier to be a typedef-name (if declared without template) or template-name (if declared with template) in the scope of the template declaration. [Note: A template argument may be a class template or alias template. For example,

```
template<class T> class myarray { /* ... */ };
```

] A storage class shall not be specified in a template-parameter declaration. Types shall not be defined in a template-parameter declaration.

A non-type template-parameter shall have one of the following (optionally cv-qualified) types:

1. a literal type that has strong structural equality (11.10.1),
2. an lvalue reference type,
3. a type that contains a placeholder type (9.1.7.5), or
4. a placeholder for a deduced class type (9.1.7.6).

[Note: Other types are disallowed either explicitly below or implicitly by the rules governing the form of template-arguments (13.3). — end note] The top-level cv-qualifiers on the template-parameter are ignored when determining its type.

When a non-type template-parameter of non-reference and non-class type is used as an initializer for a reference, a temporary is always used. An id-expression naming a non-type template-parameter of class

---

132) Since template template-parameters and template template-arguments are treated as types for descriptive purposes, the terms non-type parameter and non-type argument are used to refer to non-type, non-template parameters and arguments.
type T denotes a static storage duration object of type const T, known as a template parameter object, whose value is that of the corresponding template argument after it has been converted to the type of the template-parameter. All such template parameters in the program of the same type with the same value denote the same template parameter object. [Note: If an id-expression names a non-type non-reference template-parameter, then it is a prvalue if it has non-class type. Otherwise, if it is of class type T, it is an lvalue and has type const T (7.5.4.1). —end note] [Example:

```cpp
struct A { friend bool operator==(const A&, const A&) = default; }

template<const X& x, int i, A a> void f() {
  i++;
  // error: change of template-parameter value
  &x;
  // OK
  &i;
  // error: address of non-reference template-parameter
  &a;
  // OK
  int& ri = i;
  // error: non-const reference bound to temporary
  const int& cri = i;
  // OK: const reference bound to temporary
  const A& ra = a;
  // OK: const reference bound to a template parameter object
}
```
—end example]

7 A non-type template-parameter shall not be declared to have floating-point or void type. [Example:

```cpp
template<double d> class X;    // error
template<double* pd> class Y;  // OK
template<double& rd> class Z;  // OK
```
—end example]

8 A non-type template-parameter of type “array of T” or of function type T is adjusted to be of type “pointer to T”. [Example:

```cpp
template<int* a> struct R { /* ... */ };  // OK
template<int b[5]> struct S { /* ... */ };  // OK due to parameter adjustment
int p;
R<&p> v;                                  // OK due to implicit argument conversion
S<&p> x;
int v[5];
R<>& y;                                     // OK due to both adjustment and conversion
S<>& z;
```
—end example]

9 A type-parameter that starts with a type-constraint introduces the immediately-declared constraint (Clause 13) of the parameter. [Example:

```cpp
template<typename T> concept C1 = true;
template<typename... Ts> concept C2 = true;
template<typename T, typename U> concept C3 = true;

template<C1 T> struct s1;    // associates C1<T>
template<C1... T> struct s2; // associates (C1<T> && ...)
template<C2... T> struct s3; // associates (C2<T> && ...)
template<C3<int> T> struct s4; // associates C3<T, int>
template<C3<int... T> struct s5; // associates (C3<T, int> && ...)
```
—end example]

10 A non-type template parameter declared with a type that contains a placeholder type with a type-constraint introduces the immediately-declared constraint of the invented type corresponding to the placeholder (9.2.3.5).

11 A default template-argument is a template-argument (13.3) specified after = in a template-parameter. A default template-argument may be specified for any kind of template-parameter (type, non-type, template) that is not a template parameter pack (13.6.3). A default template-argument may be specified in a template declaration. A default template-argument shall not be specified in the template-parameter-lists of the definition of a member of a class template that appears outside of the member’s class. A default template-argument shall not be specified in a friend class template declaration. If a friend function template declaration specifies a default template-argument, that declaration shall be a definition and shall be the only declaration of the function template in the translation unit.

§ 13.1 338
The set of default template-arguments available for use is obtained by merging the default arguments from all prior declarations of the template in the same way default function arguments are (9.2.3.6). [Example:

```cpp
template<class T1, class T2 = int> class A;
template<class T1 = int, class T2> class A;
```

is equivalent to

```cpp
template<class T1 = int, class T2 = int> class A;
```

—end example]

If a template-parameter of a class template, variable template, or alias template has a default template-argument, each subsequent template-parameter shall either have a default template-argument supplied or be a template parameter pack. If a template-parameter of a primary class template, primary variable template, or alias template is a template parameter pack, it shall be the last template-parameter. A template parameter pack of a function template shall not be followed by another template parameter unless that template parameter can be deduced from the parameter-type-list (9.2.3.5) of the function template or has a default argument (13.9.2). A template parameter of a deduction guide template (13.10) that does not have a default argument shall be deducible from the parameter-type-list of the deduction guide template. [Example:

```cpp
template<class T1 = int, class T2> class B;
// error
```

```cpp
// U can be neither deduced from the parameter-type-list nor specified
template<class... T, class... U> void f() { } // error
template<class... T, class U> void g() { } // error
```

—end example]

A template-parameter shall not be given default arguments by two different declarations in the same scope. [Example:

```cpp
template<class T = int> class X;
template<class T = int> class X { /* ... */ }; // error
```

—end example]

When parsing a default template-argument for a non-type template-parameter, the first non-nested > is taken as the end of the template-parameter-list rather than a greater-than operator. [Example:

```cpp
template<int i = 3 > 4 >
```

```cpp
// syntax error
class X { /* ... */ }
```

```cpp
template<int i = (3 > 4) >
```

```cpp
// OK,
class Y { /* ... */ }
```

—end example]

A template-parameter of a template template-parameter is permitted to have a default template-argument. When such default arguments are specified, they apply to the template template-parameter in the scope of the template template-parameter. [Example:

```cpp
template <class T = float> struct B {}

template <template <class TT = float> class T> struct A {
inline void f();
inline void g();
};

template <template <class TT> class T> void A<T>::f() {
T> t;
// error: TT has no default template argument
}

template <template <class TT = char> class T> void A<T>::g() {
T<> t;
// OK, T<char>
}
```

—end example]

If a template-parameter is a type-parameter with an ellipsis prior to its optional identifier or is a parameter-declaration that declares a pack (9.2.3.5), then the template-parameter is a template parameter pack (13.6.3). A template parameter pack that is a parameter-declaration whose type contains one or more unexpanded packs is a pack expansion. Similarly, a template parameter pack that is a type-parameter with a template-parameter-list containing one or more unexpanded packs is a pack expansion. A type parameter pack with a type-constraint that contains an unexpanded parameter pack is a pack expansion. A template
parameter pack that is a pack expansion shall not expand a template parameter pack declared in the same

template-parameter-list. [Example:

\begin{verbatim}
template<
\ldots
Types
\ldots>
class Tuple;
// Types is a template type parameter pack

// but not a pack expansion

template<T, int... Dims>
struct multi_array;
// Dims is a non-type template parameter pack

// but not a pack expansion

template<T>
struct value_holder {
    template<T... Values>
    struct apply { };
// Values is a non-type template parameter pack
// and a pack expansion

template<T, T... Values>
struct static_array;
// error: Values expands template type parameter
// pack T within the same template parameter list
\end{verbatim}

—end example]

13.2 Names of template specializations

A template specialization (13.8) can be referred to by a template-id:

\begin{verbatim}

simple-template-id:
template-name < template-argument-list_opt >

template-id:
simple-template-id
operator-function-id < template-argument-list_opt >
literal-operator-id < template-argument-list_opt >

template-name:
identifier
template-argument-list:
template-argument . . . opt
template-argument-list , template-argument . . . opt
template-argument:
constant-expression
type-id
id-expression

[Note: The name lookup rules (6.4) are used to associate the use of a name with a template declaration; that
is, to identify a name as a template-name. — end note]

2 For a template-name to be explicitly qualified by the template arguments, the name must be considered to
refer to a template. [Note: Whether a name actually refers to a template cannot be known in some cases
until after argument dependent lookup is done (6.4.2). — end note] A name is considered to refer to a
template if name lookup finds a template-name or an overload set that contains a function template. A name
is also considered to refer to a template if it is an unqualified-id followed by a < and name lookup either finds
one or more functions or finds nothing.

3 When a name is considered to be a template-name, and it is followed by a <, the < is always taken as the
delimiter of a template-argument-list and never as the less-than operator. When parsing a template-argument-
list, the first non-nested > \cite{133} is taken as the ending delimiter rather than a greater-than operator. Similarly,
the first non-nested >> is treated as two consecutive but distinct > tokens, the first of which is taken as the
end of the template-argument-list and completes the template-id. [Note: The second > token produced by this
replacement rule may terminate an enclosing template-id construct or it may be part of a different construct
(e.g., a cast). — end note] [Example:

\begin{verbatim}
\texttt{template<
\ldots
int i>
class X { /* ... */ };}
\end{verbatim}

\begin{verbatim}
X< 1>2 > x1; // syntax error
X<(1>2)> x2; // OK
\end{verbatim}

\cite{133} A > that encloses the type-id of a \texttt{dynamic\_cast}, \texttt{static\_cast}, \texttt{reinterpret\_cast} or \texttt{const\_cast}, or which encloses the
template-arguments of a subsequent template-id, is considered nested for the purpose of this description.
template<class T> class Y { /* ... */ };
Y<X<1>> x3;  // OK, same as Y<X<1>> x3;
Y<X<6>>1>> x4;  // syntax error
Y<X<(6>>1)>> x5;  // OK

—end example

4 The keyword template is said to appear at the top level in a qualified-id if it appears outside of a template-argument-list or decltype-specifier. In a qualified-id of a declarator-id or in a qualified-id formed by a class-head-name (Clause 11) or enum-head-name (9.6), the keyword template shall not appear at the top level. In a qualified-id used as the name in a typename-specifier (13.7), elaborated-type-specifier (9.1.7.3), using-declaration (9.8), or class-or-decltype (11.6), an optional keyword template appearing at the top level is ignored. In these contexts, a < token is always assumed to introduce a template-argument-list. In all other contexts, when naming a template specialization of a member of an unknown specialization (13.7.2.1), the member template name shall be prefixed by the keyword template. [Example:

struct X {
    template<std::size_t> X* alloc();
    template<std::size_t> static X* adjust();
};
template<class T> void f(T* p) {
    T* p1 = p->template alloc<200>();  // ill-formed: < means less than
    T* p2 = p->template alloc<200>();  // OK: < starts template argument list
    T::adjust<100>();  // ill-formed: < means less than
    T::template adjust<100>();  // OK: < starts template argument list
}

—end example

5 A name prefixed by the keyword template shall be a template-id or the name shall refer to a class template or an alias template. [Note: The keyword template may not be applied to non-template members of class templates. —end note] [Note: As is the case with the typename prefix, the template prefix is allowed in cases where it is not strictly necessary; i.e., when the nested-name-specifier or the expression on the left of the -> or . is not dependent on a template-parameter, or the use does not appear in the scope of a template. —end note] [Example:

template <class T> struct A {
    void f(int);
    template <class U> void f(U);
};
template <class T> void f(T t) {
    A<T> a;
    a.template f<>()(t);  // OK: calls template
    a.template f<>()(t);  // error: not a template-id
}
template <class T> struct B {
    template <class T2> struct C { };
};
// OK: T::template C names a class template:
template <class T, template <class X> class TT = T::template C> struct D { };
D<B<int>> > db;

—end example

6 [Note: A simple-template-id that names a class template specialization is a class-name (11.2). Any other simple-template-id that names a type is a typedef-name. —end note]

7 A template-id is valid if

(7.1) there are at most as many arguments as there are parameters or a parameter is a template parameter pack (13.6.3),
(7.2) there is an argument for each non-deducible non-pack parameter that does not have a default template-argument,
(7.3) each template-argument matches the corresponding template-parameter (13.3),
— substitution of each template argument into the following template parameters (if any) succeeds, and
— if the template-id is non-dependent, the associated constraints are satisfied as specified in the next paragraph.

A simple-template-id shall be valid unless it names a function template specialization (13.9.2). [Example:

```c++
template<class T, T::type n = 0> class X;
struct S {
    using type = int;
};
using T1 = X<S, int, int>; // error: too many arguments
using T2 = X<>; // error: no default argument for first template parameter
using T3 = X<int>; // error: value 1 does not match type-parameter
using T4 = X<int>; // error: substitution failure for second template parameter
using T5 = X<S>; // OK
```
—end example]

When the template-name of a simple-template-id names a constrained non-function template or a constrained template template-parameter, but not a member template that is a member of an unknown specialization (13.7), and all template-arguments in the simple-template-id are non-dependent (13.7.2.4), the associated constraints (13.4.2) of the constrained template shall be satisfied (13.4.1). [Example:

```c++
template<typename T> concept C1 = sizeof(T) != sizeof(int);
template<typename T> using Ptr = T*;
S1<int>* p; // error: constraints not satisfied
Ptr<int> p; // error: constraints not satisfied
```

§ 13.3 Template arguments

There are three forms of template-argument, corresponding to the three forms of template-parameter: type, non-type and template. The type and form of each template-argument specified in a template-id shall match the type and form specified for the corresponding parameter declared by the template in its template-parameter-list. When the parameter declared by the template is a template parameter pack (13.6.3), it will correspond to zero or more template-arguments. [Example:

```c++
template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int);
};
```
T& elem(int i) { return v[i]; }
};

Array<int> v1(20);
typedef std::complex<double> dcomplex; // std::complex is a standard library template
Array<dcomplex> v2(30);
Array<dcomplex> v3(40);

void bar() {
    v1[3] = 7;
    v2[3] = v3.elem(4) = dcomplex(7,8);
}
—end example

2 In a template-argument, an ambiguity between a type-id and an expression is resolved to a type-id, regardless of the form of the corresponding template-parameter.134  [Example:

template<class T> void f();

template<int I> void f();

void g() {
    f<int>()();     // int() is a type-id: call the first f()
}
—end example]

3 The name of a template-argument shall be accessible at the point where it is used as a template-argument. [Note: If the name of the template-argument is accessible at the point where it is used as a template-argument, there is no further access restriction in the resulting instantiation where the corresponding template-parameter name is used. —end note]  [Example:

template<class T> class X {
    static T t;
};

class Y {
private:
    struct S { /* ... */ };  // OK: S is accessible
    X<S> x;                  // OK: X<Y::S> has a static member of type Y::S
                             // OK: even though Y::S is private
};

X<Y::S> y;  // error: S not accessible
—end example] For a template-argument that is a class type or a class template, the template definition has no special access rights to the members of the template-argument. [Example:

template <template <class TT> class T> class A {
    typename T<int>::S s;
};

template <class U> class B {
private:
    struct S { /* ... */ };  // ill-formed: A has no access to B::S
};

A<S> b;  // ill-formed: A has no access to B::S
—end example]

4 When template argument packs or default template-arguments are used, a template-argument list can be empty. In that case the empty <> brackets shall still be used as the template-argument-list. [Example:

template<class T = char> class String;
String<>* p;  // OK: String<char>

134) There is no such ambiguity in a default template-argument because the form of the template-parameter determines the allowable forms of the template-argument.
An explicit destructor call (11.3.6) for an object that has a type that is a class template specialization may explicitly specify the template-arguments. [Example:

```cpp
template<class T> struct A {
    ~A();
};
void f(A<int*>* p, A<int*>* q) {
    p->A<int>::~A(); // OK: destructor call
    q->A<int>::~A<int>(); // OK: destructor call
}
```
—end example]

5 If the use of a template-argument gives rise to an ill-formed construct in the instantiation of a template specialization, the program is ill-formed.

6 When name lookup for the name in a template-id finds an overload set, both non-template functions in the overload set and function templates in the overload set for which the template-arguments do not match the template-parameters are ignored. If none of the function templates have matching template-parameters, the program is ill-formed.

8 When a simple-template-id does not name a function, a default template-argument is implicitly instantiated (13.8.1) when the value of that default argument is needed. [Example:

```cpp
template<typename T, typename U = int> struct S { };
S<bool>* p; // the type of p is S<bool, int>*
The default argument for U is instantiated to form the type S<bool, int>*. —end example]
```

9 A template-argument followed by an ellipsis is a pack expansion (13.6.3).

13.3.1 Template type arguments

A template-argument for a template-parameter which is a type shall be a type-id.

[Example:

```cpp
template <class T> class X { };
template <class T> void f(T t) { }
struct {} unnamed_obj;
void f() {
    struct A { }; enum { e1 }; typedef struct { } B;
    B b;
    X<A> x1; // OK
    X<A*> x2; // OK
    X<B> x3; // OK
    f(e1); // OK
    f(unnamed_obj); // OK
    f(b); // OK
}
```
—end example] [Note: A template type argument may be an incomplete type (6.7). —end note]

13.3.2 Template non-type arguments

If the type T of a template-parameter (13.1) contains a placeholder type (9.1.7.5) or a placeholder for a deduced class type (9.1.7.6), the type of the parameter is the type deduced for the variable x in the invented declaration

```cpp
T x = template-argument ;
```
If a deduced parameter type is not permitted for a template-parameter declaration (13.1), the program is ill-formed.

2 A template-argument for a non-type template-parameter shall be a converted constant expression (7.7) of the type of the template-parameter. For a non-type template-parameter of reference or pointer type, or for each non-static data member of reference or pointer type in a non-type template-parameter of class type or subobject thereof, the reference or pointer value shall not refer to or be the address of (respectively):

(2.1) — a subobject (6.6.2),
(2.2) — a temporary object (6.6.7),
(2.3) — a string literal (5.13.5),
(2.4) — the result of a typeid expression (7.6.1.7), or
(2.5) — a predefined __func__ variable (9.4.1).

[Note: If the template-argument represents a set of overloaded functions (or a pointer or member pointer to such), the matching function is selected from the set (12.4). — end note]

3 [Example:

```c
template<const int* pci> struct X { /* ... */};
int ai[10];
X<ai> xi; // array to pointer and qualification conversions

struct Y { /* ... */};
template<const Y& b> struct Z { /* ... */};
Y y;
Z<y> z; // no conversion, but note extra cv-qualification

template<int (&pa)[5]> struct W { /* ... */};
int b[5];
W<b> w; // no conversion

void f(char);
void f(int);

template<void (*pf)(int)> struct A { /* ... */};
A<&f> a; // selects f(int)

template<auto n> struct B { /* ... */};
B<5> b1; // OK: template parameter type is int
B<"a"> b2; // OK: template parameter type is char
B<2.5> b3; // error: template parameter type cannot be double
```

—end example]

4 [Note: A string literal (5.13.5) is not an acceptable template-argument for a template-parameter of non-class type. [Example:

```c
template<class T, T p> class X { /* ... */};

X<const char*, "Studebaker"> x; // error: string literal as template-argument

const char p[] = "Vivisectionist";
X<const char*, p> y; // OK

struct A {
    constexpr A(const char*) {}
    friend bool operator==(const A&, const A&) = default;
};

X<A, "Pyrophoricity"> z; // OK, string literal is a constructor argument to A
```

—end example] — end note]
5 [Note: The address of an array element or non-static data member is not an acceptable template-argument.]

Example:

```cpp
template<int* p> class X { }

int a[10];
struct S { int m; static int s; } s;

X<&a[2]> x3;  // error: address of array element
X<&a.m> x4;   // error: address of non-static member
X<&S.s> x5;   // OK: address of static member
X<&S::s> x6;  // OK: address of static member

—end example] —end note]

6 [Note: A temporary object is not an acceptable template-argument when the corresponding template-parameter has reference type.]

Example:

```cpp
template<const int& CRI> struct B { /* ... */ };  // OK
B<1> b2;                                          // error: temporary would be required for template argument
int c = 1;
B<c> b1;                                          // OK

—end example] —end note]

13.3.3 Template template arguments [temp.arg.template]

1 A template-argument for a template template-parameter shall be the name of a class template or an alias template, expressed as id-expression. When the template-argument names a class template, only primary class templates are considered when matching the template template argument with the corresponding parameter; partial specializations are not considered even if their parameter lists match that of the template template parameter.

2 Any partial specializations (13.6.5) associated with the primary class template or primary variable template are considered when a specialization based on the template template-parameter is instantiated. If a specialization is not visible at the point of instantation, and it would have been selected had it been visible, the program is ill-formed, no diagnostic required. [Example:

```cpp
template<class T> class A { /* ... */ };

template<class T, class U = T> class B { /* ... */ };
```

§ 13.3.3 346

3 A template-argument matches a template template-parameter P when P is at least as specialized as the template-argument A. If P contains a template parameter pack, then A also matches P if each of A’s template parameters matches the corresponding template parameter in the template-head of P. Two template parameters match if they are of the same kind (type, non-type, template), for non-type template parameters, their types are equivalent (13.6.6.1), and for template template parameters, each of their corresponding template-template parameters matches, recursively. When P’s template-head contains a template parameter pack (13.6.3), the template parameter pack will match zero or more template parameters or template parameter packs in the template-head of A with the same type and form as the template parameter pack in P (ignoring whether those template parameters are template parameter packs).

[Example:

```cpp
template<class T> class A { /* ... */ };
template<class T, class U = T> class B { /* ... */ };
```
template<class ... Types> class C { /* ... */ };  

template<class auto n> class D { /* ... */ };  

template<template<class> class P> class X { /* ... */ };  

template<template<class ...> class Q> class Y { /* ... */ };  

template<template<int> class R> class Z { /* ... */ };  

X<A> xa;  // OK  
X<B> xb;  // OK  
X<C> xc;  // OK  
Y<A> ya;  // OK  
Y<B> yb;  // OK  
Y<C> yc;  // OK  
Z<D> zd;  // OK  

— end example  

Example:  

```
template<typename T> struct eval;
```

```
template<template<class, class...> class TT, class T1, class... Rest>
struct eval<TT<T1, Rest...>> { };  
```

```
template<class T1> struct A;
```

```
template<class T1, class T2> struct B;
```

```
template<int N> struct C;
```

```
template<class T1, int N> struct D;
```

```
template<class T1, class T2, int N = 17> struct E;
```

```
eval<A<int>> eA;  // OK: matches partial specialization of eval
```

```
eval<B<int, float>> eB;  // OK: matches partial specialization of eval
```

```
eval<C<17>> eC;  // error: C does not match TT in partial specialization
```

```
eval<D<int, 17>> eD;  // error: D does not match TT in partial specialization
```

```
eval<E<int, float>> eE;  // error: E does not match TT in partial specialization
```

— end example  

Example:  

```
template<type T> concept C = requires (T t) { t.f(); };
```

```
template<type T> concept D = C<T> && requires (T t) { t.g(); };
```

```
template<template<C> class P> struct S { };
```

```
template<C> struct X { };
```

```
template<D> struct Y { };
```

```
template<type T> struct Z { };
```

```
s<X> s1;  // OK, X and P have equivalent constraints  
s<P> s2;  // error: P is not at least as specialized as Y  
s<Z> s3;  // OK, P is at least as specialized as Z
```

— end example

4 A template template-parameter P is at least as specialized as a template template-argument A if, given
the following rewrite to two function templates, the function template corresponding to P is at least as
specialized as the function template corresponding to A according to the partial ordering rules for function
templates (13.6.6.2). Given an invented class template X with the template-head of A (including default
arguments and requires-clause, if any):

(4.1) Each of the two function templates has the same template parameters and requires-clause (if any),
respectively, as P or A.

(4.2) Each function template has a single function parameter whose type is a specialization of X with template
arguments corresponding to the template parameters from the respective function template where, for
each template parameter PP in the template-head of the function template, a corresponding template
argument AA is formed. If PP declares a template parameter pack, then AA is the pack expansion
PP... (13.6.3); otherwise, AA is the id-expression PP.

If the rewrite produces an invalid type, then P is not at least as specialized as A.
13.4 Template constraints

[Note: This subclause defines the meaning of constraints on template arguments. The abstract syntax and satisfaction rules are defined in 13.4.1. Constraints are associated with declarations in 13.4.2. Declarations are partially ordered by their associated constraints (13.4.4). —end note]

13.4.1 Constraints

A constraint is a sequence of logical operations and operands that specifies requirements on template arguments. The operands of a logical operation are constraints. There are three different kinds of constraints:

- conjunctions (13.4.1.1),
- disjunctions (13.4.1.1), and
- atomic constraints (13.4.1.2)

In order for a constrained template to be instantiated (13.8), its associated constraints (13.4.2) shall be satisfied as described in the following subclauses. [Note: Forming the name of a specialization of a class template, a variable template, or an alias template (13.2) requires the satisfaction of its constraints. Overload resolution (12.3.2) requires the satisfaction of constraints on functions and function templates. —end note]

13.4.1.1 Logical operations

There are two binary logical operations on constraints: conjunction and disjunction. [Note: These logical operations have no corresponding C++ syntax. For the purpose of exposition, conjunction is spelled using the symbol \( \land \) and disjunction is spelled using the symbol \( \lor \). The operands of these operations are called the left and right operands. In the constraint \( A \land B \), \( A \) is the left operand, and \( B \) is the right operand. —end note]

A conjunction is a constraint taking two operands. To determine if a conjunction is satisfied, the satisfaction of the first operand is checked. If that is not satisfied, the conjunction is not satisfied. Otherwise, the conjunction is satisfied if and only if the second operand is satisfied.

A disjunction is a constraint taking two operands. To determine if a disjunction is satisfied, the satisfaction of the first operand is checked. If that is satisfied, the disjunction is not satisfied. Otherwise, the disjunction is satisfied if and only if the second operand is satisfied.

[Example:

```cpp
template<typename T>
constexpr bool get_value() { return T::value; }

template<typename T>
requires (sizeof(T) > 1) && get_value<T>()
void f(T); // has associated constraint sizeof(T) > 1 \land get_value<T>()

void f(int);

f('a'); // OK: calls f(int)
```

In the satisfaction of the associated constraints (13.4.2) of \( f \), the constraint \( \text{sizeof(char)} > 1 \) is satisfied; the second operand is not checked for satisfaction. —end example]

13.4.1.2 Atomic constraints

An atomic constraint is formed from an expression \( E \) and a mapping from the template parameters that appear within \( E \) to template arguments involving the template parameters of the constrained entity, called the parameter mapping (13.4.2). [Note: Atomic constraints are formed by constraint normalization (13.4.3). \( E \) is never a logical AND expression (7.6.14) nor a logical OR expression (7.6.15). —end note]

Two atomic constraints are identical if they are formed from the same expression and the targets of the parameter mappings are equivalent according to the rules for expressions described in 13.6.6.1.

To determine if an atomic constraint is satisfied, the parameter mapping and template arguments are first substituted into its expression. If substitution results in an invalid type or expression, the constraint is not satisfied. Otherwise, the lvalue-to-rvalue conversion (7.3.1) is performed if necessary, and \( E \) shall be a constant expression of type \( \text{bool} \). The constraint is satisfied if and only if evaluation of \( E \) results in \( \text{true} \). [Example:

```cpp
template<typename T> concept C =
  sizeof(T) == 4 && !true; // requires atomic constraints sizeof(T) == 4 and !true
```

§ 13.4.1.2 348
template<typename T> struct S {
    constexpr operator bool() const { return true; }
};

template<typename T> requires (S<T>{})
void f(T);
// #1
void f(int);
// #2

void g() {
    f(0);
    // error: expression S<int>{} does not have type bool

    // while checking satisfaction of deduced arguments of #1;
    // call is ill-formed even though #2 is a better match
}

—end example

13.4.2 Constrained declarations

A template declaration (Clause 13) or function declaration (9.2.3.5) can be constrained by the use of a `requires-clause`. This allows the specification of constraints for that declaration as an expression:

```
constraint-expression:
    logical-or-expression
```

Constraints can also be associated with a declaration through the use of `type-constraints` in a `template-parameter-list`. Each of these forms introduces additional `constraint-expressions` that are used to constrain the declaration.

A template’s associated constraints are defined as follows:

1. If there are no introduced `constraint-expressions`, the declaration has no associated constraints.
2. Otherwise, if there is a single introduced `constraint-expression`, the associated constraints are the normal form (13.4.3) of that expression.
3. Otherwise, the associated constraints are the normal form of a logical AND expression (7.6.14) whose operands are in the following order:
   1. the `constraint-expression` introduced by each `type-constraint` (13.1) in the declaration’s `template-parameter-list`, in order of appearance, and
   2. the `constraint-expression` introduced by a `requires-clause` following a `template-parameter-list` (Clause 13), and
   3. the `constraint-expression` introduced by each `type-constraint` in the parameter-type-list of a function declaration, and
   4. the `constraint-expression` introduced by a trailing `requires-clause` (9.2) of a function declaration (9.2.3.5).

The formation of the associated constraints establishes the order in which constraints are instantiated when checking for satisfaction (13.4.1). [Example:

```
template<typename T> concept C = true;

template<C T> void f1(T);
template<typename T> requires C<T> void f2(T);
template<typename T> void f3(T) requires C<T>;
```

The functions `f1`, `f2`, and `f3` have the associated constraint `C<T>`.

```
template<typename T> concept C1 = true;
template<typename T> concept C2 = sizeof(T) > 0;
```

The associated constraints of `f4` and `f5` are `C1<T> ∧ C2<T>`. 

```
template<C1 T> void f4(T) requires C2<T>;
template<typename T> requires C1<T> && C2<T> void f5(T);
```

The associated constraints of `f6` are `C1<T> ∧ C2<T>`, and those of `f7` are `C2<T> ∧ C1<T>`. —end example]
13.4.3 Constraint normalization

The normal form of an expression \( E \) is a constraint (13.4.1) that is defined as follows:

- The normal form of an expression ( \( E \) ) is the normal form of \( E \).
- The normal form of an expression \( E_1 \lor E_2 \) is the disjunction (13.4.1.1) of the normal forms of \( E_1 \) and \( E_2 \).
- The normal form of an expression \( E_1 \land E_2 \) is the conjunction of the normal forms of \( E_1 \) and \( E_2 \).
- The normal form of an expression \( E_1 \land E_2 \) is the conjunction of the normal forms of \( E_1 \) and \( E_2 \).
- The normal form of an expression of an id-expression of the form \( C \langle A_1, A_2, \ldots, A_n \rangle \), where \( C \) names a concept, is the normal form of the constraint-expression of \( C \), after substituting \( A_1, A_2, \ldots, A_n \) for \( C \)'s respective template parameters in the parameter mappings in each atomic constraint. If any such substitution results in an invalid type or expression, the program is ill-formed; no diagnostic is required. [Example:

| template<typename T> concept A = T::value || true;
| template<typename U> concept B = A<U*>;
| template<typename V> concept C = B<V&>;

Normalization of \( B \)'s constraint-expression is valid and results in \( T::value \) (with the mapping \( T \mapsto U \)) \lor true (with an empty mapping), despite the expression \( T::value \) being ill-formed for a pointer type \( T \). Normalization of \( C \)'s constraint-expression results in the program being ill-formed, because it would form the invalid type \( T\&\* \) in the parameter mapping. —end example]

- The normal form of any other expression \( E \) is the atomic constraint whose expression is \( E \) and whose parameter mapping is the identity mapping.

The process of obtaining the normal form of a constraint-expression is called normalization. [Note: Normalization of constraint-expressions is performed when determining the associated constraints (13.4.1) of a declaration and when evaluating the value of an id-expression that names a concept specialization (7.5.4). —end note]

[Example:

| template<typename T> concept C1 = sizeof(T) == 1;
| template<typename T> concept C2 = C1<T>() && 1 == 2;
| template<typename T> concept C3 = requires { typename T::type; };
| template<typename T> concept C4 = requires (T x) { ++x; };

| template<C2 U> void f1(U); // #1
| template<C3 U> void f2(U); // #2
| template<C4 U> void f3(U); // #3

The associated constraints of \#1 are \( \text{sizeof}(T) == 1 \) (with mapping \( T \mapsto U \)) \land 1 == 2.
The associated constraints of \#2 are \( \text{requires} \{ \text{typename } T::\text{type}; \} \) (with mapping \( T \mapsto U \)).
The associated constraints of \#3 are \( \text{requires} \{ T x \}\{ ++x; \} \) (with mapping \( T \mapsto U \)). —end example]

13.4.4 Partial ordering by constraints

A constraint \( P \) subsumes a constraint \( Q \) if and only if, for every disjunctive clause \( P_i \) in the disjunctive normal form of \( P \), \( P_i \) subsumes every conjunctive clause \( Q_j \) in the conjunctive normal form of \( Q \), where

- a disjunctive clause \( P_i \) subsumes a conjunctive clause \( Q_j \) if and only if there exists an atomic constraint \( P_{ia} \) in \( P_i \) for which there exists an atomic constraint \( Q_{ja} \) in \( Q_j \) such that \( P_{ia} \) subsumes \( Q_{ja} \), and
- an atomic constraint \( A \) subsumes another atomic constraint \( B \) if and only if the \( A \) and \( B \) are identical using the rules described in 13.4.1.2.

[Example: Let \( A \) and \( B \) be atomic constraints (13.4.1.2). The constraint \( A \land B \) subsumes \( A \), but \( A \) does not subsume \( A \lor B \). The constraint \( A \) subsumes \( A \lor B \), but \( A \lor B \) does not subsume \( A \). Also note that every constraint subsumes itself. —end example]

[Note: The subsumption relation defines a partial ordering on constraints. This partial ordering is used to determine

135] A constraint is in disjunctive normal form when it is a disjunction of clauses where each clause is a conjunction of atomic constraints. [Example: For atomic constraints \( A \), \( B \), and \( C \), the disjunctive normal form of the constraint \( A \land (B \lor C) \) is \( (A \land B) \lor (A \land C) \). Its disjunctive clauses are \( (A \land B) \) and \( (A \land C) \). —end example]

136] A constraint is in conjunctive normal form when it is a conjunction of clauses where each clause is a disjunction of atomic constraints. [Example: For atomic constraints \( A \), \( B \), and \( C \), the constraint \( A \land (B \lor C) \) is in conjunctive normal form. Its conjunctive clauses are \( A \) and \( (B \lor C) \). —end example]
— the best viable candidate of non-template functions (12.3.3),
— the address of a non-template function (12.4),
— the matching of template template arguments (13.3.3),
— the partial ordering of class template specializations (13.6.5.2), and
— the partial ordering of function templates (13.6.6.2).

— end note

3 A declaration \( D_1 \) is \textit{at least as constrained} as a declaration \( D_2 \) if

(3.1) \( D_1 \) and \( D_2 \) are both constrained declarations and \( D_1 \)'s associated constraints subsume those of \( D_2 \); or
(3.2) \( D_2 \) has no associated constraints.

4 A declaration \( D_1 \) is \textit{more constrained} than another declaration \( D_2 \) when \( D_1 \) is at least as constrained as \( D_2 \), and \( D_2 \) is not at least as constrained as \( D_1 \). \textit{Example:}

\begin{verbatim}
template<typename T> concept C1 = requires(T t) { --t; };
template<typename T> concept C2 = C1<T> && requires(T t) { *t; };

// #1
template<C1 T> void f(T);
// #2
template<C2 T> void f(T);
// #3
template<C1 T> void g(T);
// #4

f(0); // selects #1
f((int*)0); // selects #2
g(true); // selects #3 because C1<bool> is not satisfied
g(0); // selects #4
\end{verbatim}

— end example

13.5 Type equivalence

1 Two \textit{template-ids} refer to the same class, function, or variable if

(1.1) \( \) their \textit{template-names}, \textit{operator-function-ids}, or \textit{literal-operator-ids} refer to the same template and
(1.2) \( \) their corresponding type \textit{template-arguments} are the same type and
(1.3) \( \) their corresponding non-type \textit{template-arguments} of pointer-to-member type refer to the same class member or are both the null member pointer value and
(1.4) \( \) their corresponding non-type \textit{template-arguments} of reference type refer to the same object or function and
(1.5) \( \) their remaining corresponding non-type \textit{template-arguments} have the same type and value after conversion to the type of the \textit{template-parameter}, where they are considered to have the same value if they compare equal with the \textit{==} operator (7.6.10), and
(1.6) \( \) their corresponding template \textit{template-arguments} refer to the same template.

\textit{Example:}

\begin{verbatim}
template<class E, int size> class buffer { /* ... */ };
buffer<char,2*512> x;
buffer<char,1024> y;
\end{verbatim}

declares \( x \) and \( y \) to be of the same type, and

\begin{verbatim}
template<class T, void(*err_fct)()> class list { /* ... */ }; list<int,&error_handler1> x1;
list<int,&error_handler2> x2;
list<int,&error_handler2> x3;
list<char,&error_handler2> x4;
\end{verbatim}

declares \( x2 \) and \( x3 \) to be of the same type. Their type differs from the types of \( x1 \) and \( x4 \).
x<Z<int> > z;

declares y and z to be of the same type. —end example

2 If an expression e is type-dependent (13.7.2.2), decltype(e) denotes a unique dependent type. Two such decltype-specifiers refer to the same type only if their expressions are equivalent (13.6.6.1). [Note: However, such a type may be aliased, e.g., by a typedef-name. — end note]

13.6 Template declarations

A template-id, that is, the template-name followed by a template-argument-list shall not be specified in the declaration of a primary template declaration. [Example:

```
template<class T1, class T2, int I> class A<T1, T2, I> { }; // error
template<class T1, int I> void sort<T1, I>(T1 data[I]); // error
```
—end example] [Note: However, this syntax is allowed in class template partial specializations (13.6.5). — end note]

2 For purposes of name lookup and instantiation, default arguments, type-constraints, requires-clauses (Clause 13), and noexcept-specifiers of function templates and of member functions of class templates are considered definitions; each default argument, type-constraint, requires-clause, or noexcept-specifier is a separate definition which is unrelated to the templated function definition or to any other default arguments type-constraints, requires-clauses, or noexcept-specifiers. For the purpose of instantiation, the substatements of a constexpr if statement (8.4.1) are considered definitions.

3 Because an alias-declaration cannot declare a template-id, it is not possible to partially or explicitly specialize an alias template.

13.6.1 Class templates

A class template defines the layout and operations for an unbounded set of related types.

[Example: A single class template List might provide an unbounded set of class definitions: one class List<T> for every type T, each describing a linked list of elements of type T. Similarly, a class template Array describing a contiguous, dynamic array might be defined like this:

```
template<class T> class Array {
  T* v;
  int sz;
public:
  explicit Array(int);
  T& operator[](int);
  T& elem(int i) { return v[i]; }
};
```

The prefix template<class T> specifies that a template is being declared and that a type-name T may be used in the declaration. In other words, Array is a parameterized type with T as its parameter. —end example]

3 When a member function, a member class, a member enumeration, a static data member or a member template of a class template is defined outside of the class template definition, the member definition is defined as a template definition in which the template-head is equivalent to that of the class template (13.6.6.1). The names of the template parameters used in the definition of the member may be different from the template parameter names used in the class template definition. The template argument list following the class template name in the member definition shall name the parameters in the same order as the one used in the template parameter list of the member. Each template parameter pack shall be expanded with an ellipsis in the template argument list. [Example:

```
template<class T1, class T2> struct A {
  void f1();
  void f2();
};

template<class T2, class T1> void A<T2,T1>::f1() { } // OK
```

```
template<class T2, class T1> void A<T1,T2>::f2() { } // error
```

```
template<class ... Types> struct B {
  void f3();
}```
void f4();

};

template<class ... Types> void B<Types ...>::f3() { } // OK
template<class ... Types> void B<Types>::f4() { } // error

template<typename T> concept C = true;
template<typename T> concept D = true;

template<C T> struct S {
    void f();
    void g();
    void h();
    template<D U> struct Inner;
};

template<C A> void S<A>::f() { } // OK: template-heads match
template<typename T> void S<T>::g() { } // error: no matching declaration for S<T>

template<typename T> requires C<T>
void S<T>::h() { } // error (no diagnostic required): template-heads are functionally equivalent but not equivalent

template<C X> template<D Y>
struct S<X>::Inner { }; // OK

— end example]

4 In a redeclaration, partial specialization, explicit specialization or explicit instantiation of a class template, the class-key shall agree in kind with the original class template declaration (9.1.7.3).

13.6.1.1 Member functions of class templates

da member function of a class template may be defined outside of the class template definition in which it is declared. [Example:

template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int i) { return v[i]; }
};

declares three member functions of a class template. The subscript function might be defined like this:

    template<class T> T& Array<T>::operator[](int i) {
        if (i<0 || sz<=i) error("Array: range error");
        return v[i];
    }

A constrained member function can be defined out of line:

    template<typename T> concept C = requires {
        typename T::type;
    };

    template<typename T> struct S {
        void f() requires C<T>;
        void g() requires C<T>;
    };

    template<typename T>
    void S<T>::f() requires C<T> { } // OK
    template<typename T>
    void S<T>::g() { } // error: no matching function in S<T>

— end example]
The template-arguments for a member function of a class template are determined by the template-arguments of the type of the object for which the member function is called. [Example: The template-argument for Array<T>::operator[] will be determined by the Array to which the subscripting operation is applied.]

```c
Array<int> v1(20);
Array<dcomplex> v2(30);

v1[3] = 7;  // Array<int>::operator[]
v2[3] = dcomplex(7,8);  // Array<dcomplex>::operator[]
```
—end example

13.6.1.2 Member classes of class templates [temp.mem.class]

A member class of a class template may be defined outside the class template definition in which it is declared. [Note: The member class must be defined before its first use that requires an instantiation (13.8.1). For example,

```c
template<class T> struct A {
    class B;
}
A<int>::B* b1;  // OK: requires A to be defined but not A::B
template<class T> class A<T>::B { };  // OK: requires A::B to be defined
```
—end note

13.6.1.3 Static data members of class templates [temp.static]

A definition for a static data member or static data member template may be provided in a namespace scope enclosing the definition of the static member’s class template. [Example:

```c
template<class T> class X {
    static T s;
};
template<class T> T X<T>::s = 0;

struct limits {
    template<class T>
        static const T min;  // declaration
};

template<class T>
    const T limits::min = { };  // definition
```
—end example]

An explicit specialization of a static data member declared as an array of unknown bound can have a different bound from its definition, if any. [Example:

```c
template <class T> struct A {
    static int i[];
};
template <class T> int A<T>::i[4];  // 4 elements
template <> int A<int>::i[] = { 1 };  // OK: 1 element
```
—end example]

13.6.1.4 Enumeration members of class templates [temp.mem.enum]

An enumeration member of a class template may be defined outside the class template definition. [Example:

```c
template<class T> struct A {
    enum E : T;
};
A<int> a;
template<class T> enum A<T>::E : T { e1, e2 };  // A<int>::E e = A<int>::e1;
```
13.6.2 Member templates

A template can be declared within a class or class template; such a template is called a member template. A member template can be defined within or outside its class definition or class template definition. A member template of a class template that is defined outside of its class template definition shall be specified with a template-head equivalent to that of the class template followed by a template-head equivalent to that of the member template (13.6.6.1). [Example:

```cpp
template<class T> struct string {
    template<class T2> int compare(const T2& s) {
        /* ... */
    }

    template<class T2> string(const string<T2>& s) {
    }
}
```
— end example] [Example:

```cpp
template<typename T> concept C1 = true;
template<typename T> concept C2 = sizeof(T) <= 4;

template<C1 T> struct S {
    template<C2 U> void f(U);
    template<C2 U> void g(U);
};

template<C1 T> template<C2 U>
void S<T>::f(U) { } // OK

template<C1 T> template<typename U>
void S<T>::g(U) { } // error: no matching function in S<T>
— end example]

A local class of non-closure type shall not have member templates. Access control rules (11.8) apply to member template names. A destructor shall not be a member template. A non-template member function (9.2.3.5) with a given name and type and a member function template of the same name, which could be used to generate a specialization of the same type, can both be declared in a class. When both exist, a use of that name and type refers to the non-template member unless an explicit template argument list is supplied. [Example:

```cpp
template <class T> struct A {
    void f(int);
    template <class T2> void f(T2);
};

template <> void A<int>::f(int) { } // non-template member function

template <> template <> void A<int>::f<>(int) { } // member function template specialization

int main() {
    A<char> ac;
    ac.f(1); // non-template
    ac.f('c'); // template
    ac.f<>(); // template
}
— end example]

A member function template shall not be virtual. [Example:

```cpp
template <class T> struct AA {
    template <class C> virtual void g(C); // error
    virtual void f(); // OK
};
— end example]

A specialization of a member function template does not override a virtual function from a base class. [Example:

```cpp
§ 13.6.2 355
```
class B {
    virtual void f(int);
};

class D : public B {
    template <class T> void f(T); // does not override B::f(int)
    void f(int i) { f<int>(i); } // overriding function that calls the template instantiation
};

— end example

A specialization of a conversion function template is referenced in the same way as a non-template conversion function that converts to the same type. [Example:

struct A {
    template <class T> operator T*();
};
template <class T> A::operator T*(){ return 0; }
template <> A::operator char*(){ return 0; } // specialization
template A::operator void*(); // explicit instantiation

int main() {
    A a;
    int* ip;
    ip = a.operator int*(); // explicit call to template operator A::operator int*()
}
— end example] [Note: There is no syntax to form a template-id (13.2) by providing an explicit template argument list (13.9.1) for a conversion function template (11.3.7.2). — end note]

A specialization of a conversion function template is not found by name lookup. Instead, any conversion function templates visible in the context of the use are considered. For each such operator, if argument deduction succeeds (13.9.2.3), the resulting specialization is used as if found by name lookup.

A using-declaration in a derived class cannot refer to a specialization of a conversion function template in a base class.

Overload resolution (12.3.3.2) and partial ordering (13.6.6.2) are used to select the best conversion function among multiple specializations of conversion function templates and/or non-template conversion functions.

13.6.3 Variadic templates [temp.variadic]

A template parameter pack is a template parameter that accepts zero or more template arguments. [Example:

template<class ... Types> struct Tuple { };

Tuple<> t0; // Types contains no arguments
Tuple<int> t1; // Types contains one argument: int
Tuple<int, float> t2; // Types contains two arguments: int and float
Tuple<0> error; // error: 0 is not a type
— end example]

A function parameter pack is a function parameter that accepts zero or more function arguments. [Example:

template<class ... Types> void f(Types ... args);

f(); // args contains no arguments
f(i); // args contains one argument: int
f(2, 1.0); // args contains two arguments: int and double
— end example]

An init-capture pack is a lambda capture that introduces an init-capture for each of the elements in the pack expansion of its initializer. [Example:

template <typename... Args>
void foo(Args... Args) {
    [...xs=Args] {
        bar(xs...); // xs is an init-capture pack
}
§ 13.6.3 356
A pack is a template parameter pack, a function parameter pack, or an init-capture pack. The number of elements of a template parameter pack or a function parameter pack is the number of arguments provided for the parameter pack. The number of elements of an init-capture pack is the number of elements in the pack expansion of its initializer.

A pack expansion consists of a pattern and an ellipsis, the instantiation of which produces zero or more instantiations of the pattern in a list (described below). The form of the pattern depends on the context in which the expansion occurs. Pack expansions can occur in the following contexts:

1. In a function parameter pack (9.2.3.5); the pattern is the parameter-declaration without the ellipsis.
2. In a using-declaration (9.8); the pattern is a using-declarator.
3. In a template parameter pack that is a pack expansion (13.1):
   - if the template parameter pack is a parameter-declaration; the pattern is the parameter-declaration without the ellipsis;
   - if the template parameter pack is a type-parameter; the pattern is the corresponding type-parameter without the ellipsis.
4. In an initializer-list (9.3); the pattern is an initializer-clause.
5. In a base-specifier-list (11.6); the pattern is a base-specifier.
6. In a mem-initializer-list (11.9.2) for a mem-initializer whose mem-initializer-id denotes a base class; the pattern is the mem-initializer.
7. In a template-argument-list (13.3); the pattern is a template-argument.
8. In an attribute-list (9.11.1); the pattern is an attribute.
9. In an alignment-specifier (9.11.2); the pattern is the alignment-specifier without the ellipsis.
10. In a capture-list (7.5.5); the pattern is a capture.
11. In a sizeof... expression (7.6.2.4); the pattern is an identifier.
12. In a fold-expression (7.5.6); the pattern is the cast-expression that contains an unexpanded pack.

[Example:

template<class ... Types> void f(Types ... rest);
template<class ... Types> void g(Types ... rest) {
    f(&rest ...); // &rest ... is a pack expansion; &rest is its pattern
}

— end example]

For the purpose of determining whether a pack satisfies a rule regarding entities other than packs, the pack is considered to be the entity that would result from an instantiation of the pattern in which it appears.

A pack whose name appears within the pattern of a pack expansion is expanded by that pack expansion. An appearance of the name of a pack is only expanded by the innermost enclosing pack expansion. The pattern of a pack expansion shall name one or more packs that are not expanded by a nested pack expansion; such packs are called unexpanded packs in the pattern. All of the packs expanded by a pack expansion shall have the same number of arguments specified. An appearance of a name of a pack that is not expanded is ill-formed. [Example:

```cpp
template<typename...> struct Tuple {};
template<typename T1, typename T2> struct Pair {};

template<class ... Args1> struct zip {
    template<class ... Args2> struct with {
        typedef Tuple<Pair<Args1, Args2> ... > type;
    };
};
```

§ 13.6.3 357
typedef zip<short, int>::with<unsigned short, unsigned>::type T1;
  // T1 is Tuple<Pair<short, unsigned short>, Pair<int, unsigned>>
typedef zip<short>::with<unsigned short, unsigned>::type T2;
  // error: different number of arguments specified for Args1 and Args2

template<class ... Args>
void g(Args ... args) {
  // OK: Args is expanded by the function parameter pack args
  f(const_cast<const Args*>(&args)...);
  // OK: "Args" and "args" are expanded
  f(5 ...);
  // error: pattern does not contain any packs
  f(args);
  // error: pack "args" is not expanded
  f(h(args ...) + args ...);
  // OK: first "args" expanded within h,
  // second "args" expanded within f
}

—end example

8 The instantiation of a pack expansion that is neither a sizeof... expression nor a fold-expression produces a list of elements $E_1, E_2, \ldots, E_N$, where $N$ is the number of elements in the pack expansion parameters. Each $E_i$ is generated by instantiating the pattern and replacing each pack expansion parameter with its $i$th element. Such an element, in the context of the instantiation, is interpreted as follows:

(8.1) — if the pack is a template parameter pack, the element is a template parameter (13.1) of the corresponding kind (type or non-type) designating the $i$th corresponding type or value template argument;

(8.2) — if the pack is a function parameter pack, the element is an id-expression designating the $i$th function parameter that resulted from instantiation of the function parameter pack declaration; otherwise

(8.3) — if the pack is an init-capture pack, the element is an id-expression designating the variable introduced by the $i$th init-capture that resulted from instantiation of the init-capture pack.

All of the $E_i$ become items in the enclosing list. [Note: The variety of list varies with the context: expression-list, base-specifier-list, template-argument-list, etc. — end note] When $N$ is zero, the instantiation of the expansion produces an empty list. Such an instantiation does not alter the syntactic interpretation of the enclosing construct, even in cases where omitting the list entirely would otherwise be ill-formed or would result in an ambiguity in the grammar. [Example:

```
template<class... T> struct X : T... { };
template<class... T> void f(T... values) {
  X<T...> x(values...);
}
```

```
template void f<>();       // OK: X<> has no base classes
                        // x is a variable of type X<> that is value-initialized
```

—end example

9 The instantiation of a sizeof... expression (7.6.2.4) produces an integral constant containing the number of elements in the pack it expands.

10 The instantiation of a fold-expression produces:

(10.1) — $(E_1 \ op\. E_2) \ op \cdots \ op \ E_N$ for a unary left fold,

(10.2) — $E_1 \ op \ (\cdots \ op \ (E_{N-1} \ op \ E_N))$ for a unary right fold,

(10.3) — $((E \ op \ E_1) \ op \ E_2) \ op \cdots \ op \ E_N$ for a binary left fold, and

(10.4) — $E_1 \ op \ (\cdots \ op \ (E_{N-1} \ op \ (E_N \ op \ E)))$ for a binary right fold.

In each case, $\ op$ is the fold-operator, $N$ is the number of elements in the pack expansion parameters, and each $E_i$ is generated by instantiating the pattern and replacing each pack expansion parameter with its $i$th element. For a binary fold-expression, $E$ is generated by instantiating the cast-expression that did not contain an unexpanded pack. [Example:

```
template<typename ...Args>
bool all(Args ...args) { return (... && args); }
```

```
bool b = all(true, true, true, false);
```

§ 13.6.3
Within the instantiation of all, the returned expression expands to \(((\text{true} \&\& \text{true}) \&\& \text{true}) \&\& \text{false}\), which evaluates to false. — end example] If \(N\) is zero for a unary fold-expression, the value of the expression is shown in Table 15; if the operator is not listed in Table 15, the instantiation is ill-formed.

Table 15: Value of folding empty sequences [tab:temp.fold.empty]

<table>
<thead>
<tr>
<th>Operator</th>
<th>Value when pack is empty</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;&amp;</td>
<td>true</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>void()</td>
</tr>
</tbody>
</table>

13.6.4 Friends [temp.friend]

A friend of a class or class template can be a function template or class template, a specialization of a function template or class template, or a non-template function or class. For a friend function declaration that is not a template declaration:

1. if the name of the friend is a qualified or unqualified template-id, the friend declaration refers to a specialization of a function template, otherwise,
2. if the name of the friend is a qualified-id and a matching non-template function is found in the specified class or namespace, the friend declaration refers to that function, otherwise,
3. if the name of the friend is a qualified-id and a matching function template is found in the specified class or namespace, the friend declaration refers to the deduced specialization of that function template (13.9.2.6), otherwise,
4. the name shall be an unqualified-id that declares (or redeclares) a non-template function.

[Example:

```cpp
template<class T> class task;
template<class T> task<T>* preempt(task<T>*)

template<class T> class task {
  friend void next_time();
  friend task<T>* process(task<T>*)
  friend task<T>* preempt<T>(task<T>*)
  template<class C> friend int func(C);

  friend class task<int>
  template<class P> friend class frd;
};
```

Here, each specialization of the task class template has the function next_time as a friend; because process does not have explicit template-arguments, each specialization of the task class template has an appropriately typed function process as a friend, and this friend is not a function template specialization; because the friend preempt has an explicit template-argument T, each specialization of the task class template has the appropriate specialization of the function template preempt as a friend; and each specialization of the task class template has all specializations of the function template func as friends. Similarly, each specialization of the task class template has the class template specialization task<int> as a friend, and has all specializations of the class template frd as friends. — end example]

A friend template may be declared within a class or class template. A friend function template may be defined within a class or class template, but a friend class template may not be defined in a class or class template. In these cases, all specializations of the friend class or friend function template are friends of the class or class template granting friendship. [Example:

```cpp
class A {
  template<class T> friend class B; // OK
  template<class T> friend void f(T){ /* ... */ } // OK
};
```

— end example]
A template friend declaration specifies that all specializations of that template, whether they are implicitly instantiated (13.8.1), partially specialized (13.6.5) or explicitly specialized (13.8.3), are friends of the class containing the template friend declaration. [Example:

```cpp
class X {
    template<class T> friend struct A;
    class Y { }; // OK
};

template<class T> struct A { X::Y ab; }; // OK
template<class T> struct A<T*> { X::Y ab; }; // OK
```
—end example]

A template friend declaration may declare a member of a dependent type to be a friend. The friend declaration shall declare a function or specify a type with an elaborated-type-specifier, in either case with a nested-name-specifier ending with a simple-template-id, C, whose template-name names a class template. The template parameters of the template friend declaration shall be deducible from C (13.9.2.5). In this case, a member of a specialization S of the class template is a friend of the class granting friendship if deduction of the template parameters of C from S succeeds, and substituting the deduced template arguments into the friend declaration produces a declaration that would be a valid redeclaration of the member of the specialization. [Example:

```cpp
template<class T> struct A {
    struct B { }; // grants friendship to A<int>::B even though
    void f(); // it is not a specialization of A<T>::B
    struct D { // does not grant friendship to A<int>::f()
        void g(); // because its return type does not match
    }; // a simple-template-id
    template<class T> friend void A<T>::D::g(); // ill-formed: A<T>::D does not end with
    template<class T> friend int *A<T>::::h(); // grants friendship to A<int>::h() and A<float>::h()
    template<class T> template<T U> friend T A<T>::::i(); // grants friendship to instantiations of A<T>::i() and
    // to A<int>::i(), and thereby to all specializations
};
```
—end example]

[Note: A friend declaration may first declare a member of an enclosing namespace scope (13.7.5). — end note]

A friend template shall not be declared in a local class.

Friend declarations shall not declare partial specializations. [Example:

```cpp
template<class T> class A { }; // grants friendship to A<int>::B even though
```

§ 13.6.4
When a friend declaration refers to a specialization of a function template, the function parameter declarations shall not include default arguments, nor shall the `inline`, `constexpr`, or `consteval` specifiers be used in such a declaration.

A non-template friend declaration shall not have a `requires-clause`.

### 13.6.5 Class template partial specializations

A primary class template declaration is one in which the class template name is an identifier. A template declaration in which the class template name is a `simple-template-id` is a partial specialization of the class template named in the `simple-template-id`. A partial specialization of a class template provides an alternative definition of the template that is used instead of the primary definition when the arguments in a specialization match those given in the partial specialization (13.6.5.1). The primary template shall be declared before any specializations of that template. A partial specialization shall be declared before the first use of a class template specialization that would make use of the partial specialization as the result of an implicit or explicit instantiation in every translation unit in which such a use occurs; no diagnostic is required.

Each class template partial specialization is a distinct template and definitions shall be provided for the members of a template partial specialization (13.6.5.3).

An example:

```cpp
template<class T1, class T2, int I> class A { };
```

The first declaration declares the primary (unspecialized) class template. The second and subsequent declarations declare partial specializations of the primary template. —end example]

A class template partial specialization may be constrained (Clause 13). [Example:

```cpp
template<typename T> concept C = true;
```

Both partial specializations are more specialized than the primary template. #1 is more specialized because the deduction of its template arguments from the template argument list of the class template specialization succeeds, while the reverse does not. #2 is more specialized because the template arguments are equivalent, but the partial specialization is more constrained (13.4.4). —end example]

The template parameters are specified in the angle bracket enclosed list that immediately follows the keyword `template`. For partial specializations, the template argument list is explicitly written immediately following the class template name. For primary templates, this list is implicitly described by the template parameter list. Specifically, the order of the template arguments is the sequence in which they appear in the template parameter list. [Example: The template argument list for the primary template in the example above is `<T1, T2, I>`. —end example] [Note: The template argument list shall not be specified in the primary template declaration. For example,

```cpp
template<class T1, class T2, int I> class A<T1, T2, I> { };
```

—end note]

A class template partial specialization may be declared in any scope in which the corresponding primary template may be defined (9.7.1.2, 11.3, 13.6.2). [Example:

```cpp
template<class T> struct A {
    struct C {
        template<class T2> struct B { }; 
        template<class T2> struct B<T2**> { }; // partial specialization #1
    }
`;
Partial specialization declarations themselves are not found by name lookup. Rather, when the primary template name is used, any previously-declared partial specializations of the primary template are also considered. One consequence is that a using-declaration which refers to a class template does not restrict the set of partial specializations which may be found through the using-declaration. [Example:

```cpp
namespace N {
    template<class T1, class T2> class A { }; // primary template
}

using N::A; // refers to the primary template

namespace N {
    template<class T> class A<T, T*> { }; // partial specialization
}

A<int,int*> a; // uses the partial specialization, which is found through the using-declaration
    // which refers to the primary template
```

— end example]

A non-type argument is non-specialized if it is the name of a non-type parameter. All other non-type arguments are specialized.

Within the argument list of a class template partial specialization, the following restrictions apply:

- The type of a template parameter corresponding to a specialized non-type argument shall not be dependent on a parameter of the specialization. [Example:

```cpp
template <class T, T t> struct C {}
template <class T> struct C<T, 1>; // error
```

— end example]

- The specialization shall be more specialized than the primary template (13.6.5.2).

- The template parameter list of a specialization shall not contain default template argument values.\footnote{There is no way in which they could be used.}

- An argument shall not contain an unexpanded pack. If an argument is a pack expansion (13.6.3), it shall be the last argument in the template argument list.

The usual access checking rules do not apply to non-dependent names used to specify template arguments of the simple-template-id of the partial specialization. [Note: The template arguments may be private types or objects that would normally not be accessible. Dependent names cannot be checked when declaring the partial specialization, but will be checked when substituting into the partial specialization. — end note]

13.6.5.1 Matching of class template partial specializations [temp.class.spec.match]

When a class template is used in a context that requires an instantiation of the class, it is necessary to determine whether the instantiation is to be generated using the primary template or one of the partial specializations. This is done by matching the template arguments of the class template specialization with the template argument lists of the partial specializations.

- If exactly one matching specialization is found, the instantiation is generated from that specialization.
If more than one matching specialization is found, the partial order rules (13.6.5.2) are used to determine whether one of the specializations is more specialized than the others. If none of the specializations is more specialized than all of the other matching specializations, then the use of the class template is ambiguous and the program is ill-formed.

If no matches are found, the instantiation is generated from the primary template.

A partial specialization matches a given actual template argument list if the template arguments of the partial specialization can be deduced from the actual template argument list (13.9.2), and the deduced template arguments satisfy the associated constraints of the partial specialization, if any (13.4.2). [Example:

```cpp
template<class T1, class T2, int I> class A { }; // #1
template<class T, int I> class A<T, T*, I> { }; // #2
template<class T1, class T2, int I> class A<T1*, T2, I> { }; // #3
template<class T> class A<int, T*, 5> { }; // #4
template<class T1, class T2, int I> class A<T1, T2*, I> { }; // #5
```

A<int, int, 1> a1; // uses #1
A<int, int*, 1> a2; // uses #2, T is int, I is 1
A<int, char*, 1> a3; // uses #4, T is char
A<int, char*, 1> a4; // uses #5, T1 is int, T2 is char, I is 1
A<int*, int*, 2> a5; // ambiguous: matches #3 and #5

—end example]

If the template arguments of a partial specialization cannot be deduced because of the structure of its template-parameter-list and the template-id, the program is ill-formed. [Example:

```cpp
template<int I, int J> struct A {}; // error
```

```cpp
template<int I> struct A<I+5, I*2> {}; // OK
```

```cpp
template<int I, int J, int K> struct B {}; // OK
```

—end example]

In a type name that refers to a class template specialization, (e.g., `A<int, int, 1>`) the argument list shall match the template parameter list of the primary template. The template arguments of a specialization are deduced from the arguments of the primary template.

13.6.5.2 Partial ordering of class template specializations [temp.class.order]

For two class template partial specializations, the first is more specialized than the second if, given the following rewrite to two function templates, the first function template is more specialized than the second according to the ordering rules for function templates (13.6.6.2):

[Example:

```cpp
template<int I, int J> struct A {};
```

```cpp
template <int I> struct A<int+5, I*2> {}; // error
```

```cpp
template <int I> struct A<i, I> {}; // OK
```

```cpp
template <int I, int J, int K> struct B {}; // OK
```
According to the ordering rules for function templates, the function template $B$ is more specialized than the function template $A$ and the function template $D$ is more specialized than the function template $C$. Therefore, the partial specialization #2 is more specialized than the partial specialization #1 and the partial specialization #4 is more specialized than the partial specialization #3.

—end example

Example:

```
#include <iostream>

struct A {
    int i, j;
    void f() { std::cout << i << j; }
    void g() { std::cout << i * j; }
    void h() { std::cout << i + j; }
};

void f(A a) { a.f(); }
void g(A a) { a.g(); }
void h(A a) { a.h(); }
```

```
int main() {
    A a = { 1, 2 }; f(a); g(a); h(a);
    A b = { 3, 4 }; g(b); h(b);
}
```
A<char, 2> a2;
a0.f(); // OK, uses definition of primary template’s member
a2.g(); // OK, uses definition of partial specialization’s member
a2.h(); // OK, uses definition of explicit specialization’s member
a2.f(); // ill-formed, no definition of f for A<T, 2>; the primary template is not used here
}

—end example

If a member template of a class template is partially specialized, the member template partial specializations are member templates of the enclosing class template; if the enclosing class template is instantiated (13.8.1, 13.8.2), a declaration for every member template partial specialization is also instantiated as part of creating the members of the class template specialization. If the primary member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the partial specializations of the member template are ignored for this specialization of the enclosing class template. If a partial specialization of the member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the primary member template and its other partial specializations are still considered for this specialization of the enclosing class template. [Example:

```cpp
template<class T> struct A {
    template<class T2> struct B {}; // #1
    template<class T2> struct B<T2*> {}; // #2
};

template<> template<class T2> struct A<short>::B {}; // #3
A<char>::B<int*> abcip; // uses #2
A<short>::B<int*> absip; // uses #3
A<char>::B<int> abci; // uses #1
—end example
```

13.6.6 Function templates

1 A function template defines an unbounded set of related functions. [Example: A family of sort functions might be declared like this:

```cpp
template<class T> class Array {
    template<class T2> void sort(Array<T>&);
};
—end example
```

2 A function template can be overloaded with other function templates and with non-template functions (9.2.3.5). A non-template function is not related to a function template (i.e., it is never considered to be a specialization), even if it has the same name and type as a potentially generated function template specialization.\[138\]

13.6.6.1 Function template overloading

1 It is possible to overload function templates so that two different function template specializations have the same type. [Example:

```cpp
// translation unit 1:
template<class T>
void f(T*);
void g(int* p) {
    f(p); // calls f<int*>(int*)
}

// translation unit 2:
template<class T>
void h(T*);
void h(int* p) {
    f(p); // calls f<int*>(int*)
}
—end example
```

2 Such specializations are distinct functions and do not violate the one-definition rule (6.2).

3 The signature of a function template is defined in Clause 3. The names of the template parameters are significant only for establishing the relationship between the template parameters and the rest of the signature. [Note: Two distinct function templates may have identical function return types and function parameter lists, even if overload resolution alone cannot distinguish them.

\[138\] That is, declarations of non-template functions do not merely guide overload resolution of function template specializations with the same name. If such a non-template function is odr-used (6.2) in a program, it must be defined; it will not be implicitly instantiated using the function template definition.
When an expression that references a template parameter is used in the function parameter list or the return type in the declaration of a function template, the expression that references the template parameter is part of the signature of the function template. This is necessary to permit a declaration of a function template in one translation unit to be linked with another declaration of the function template in another translation unit and, conversely, to ensure that function templates that are intended to be distinct are not linked with one another. [Example:

```cpp
template <int I, int J> A<I+J> f(A<I>, A<J>); // #1

template <int K, int L> A<K+L> f(A<K>, A<L>); // same as #1

template <int I, int J> A<I-J> f(A<I>, A<J>); // different from #1
```

—end example] [Note: Most expressions that use template parameters use non-type template parameters, but it is possible for an expression to reference a type parameter. For example, a template type parameter can be used in the `sizeof` operator. —end note]

Two expressions involving template parameters are considered equivalent if two function definitions containing the expressions would satisfy the one-definition rule (6.2), except that the tokens used to name the template parameters may differ as long as a token used to name a template parameter in one expression is replaced by another token that names the same template parameter in the other expression. Two lambda-expressions are never considered equivalent. [Note: The intent is to avoid lambda-expressions appearing in the signature of a function template with external linkage. —end note] For determining whether two dependent names (13.7.2) are equivalent, only the name itself is considered, not the result of name lookup in the context of the template. If multiple declarations of the same function template differ in the result of this name lookup, the result for the first declaration is used. [Example:

```cpp
template <int I, int J> void f(A<I+J>);

template <class T> decltype(g(T())) h();
int g(int);
t template <class T> decltype(g(T())) h() // redeclaration of h() uses the earlier lookup...
{ return g(T()); }
// ... although the lookup here does find g(int)
int i = h<int>(); // template argument substitution fails; g(int)
// was not in scope at the first declaration of h()
```

// ill-formed, no diagnostic required: the two expressions are functionally equivalent but not equivalent
```cpp
template <int N> void foo(const char (*)[sizeof(T)]{N});
```

// two different declarations because the non-dependent portions are not considered equivalent
```cpp
template <class T> void spam(decltype([]{} (*)[sizeof(T)]{N}));
t template <class T> void spam(decltype([]{} (*)[sizeof(T)]{N}));
```

—end example] Two expressions involving template parameters that are not equivalent are functionally equivalent if, for any given set of template arguments, the evaluation of the expression results in the same value.

Two template-heads are equivalent if their template-parameter-lists have the same length, corresponding template-parameters are equivalent, and if either has a requires-clause, they both have requires-clauses and the corresponding constraint-expressions are equivalent. Two template-parameters are equivalent under the following conditions:

1. they declare template parameters of the same kind,
2. if either declares a template parameter pack, they both do,
3. if they declare non-type template parameters, they have equivalent types,
4. if they declare template template parameters, their template parameters are equivalent, and
5. if either is declared with a qualified-concept-name, they both are, and the qualified-concept-names are equivalent.
When determining whether types or qualified-concept-names are equivalent, the rules above are used to compare expressions involving template parameters. Two template-heads are functionally equivalent if they accept and are satisfied by (13.4.1) the same set of template argument lists.

Two function templates are equivalent if they are declared in the same scope, have the same name, have equivalent template-heads, and have return types, parameter lists, and trailing requires-clauses (if any) that are equivalent using the rules described above to compare expressions involving template parameters. Two function templates are functionally equivalent if they are declared in the same scope, have the same name, accept and are satisfied by the same set of template argument lists, and have return types and parameter lists that are functionally equivalent using the rules described above to compare expressions involving template parameters. If the validity or meaning of the program depends on whether two constructs are equivalent, and they are functionally equivalent but not equivalent, the program is ill-formed, no diagnostic required.

[Note: This rule guarantees that equivalent declarations will be linked with one another, while not requiring implementations to use heroic efforts to guarantee that functionally equivalent declarations will be treated as distinct. For example, the last two declarations are functionally equivalent and would cause a program to be ill-formed:]

```c++
// guaranteed to be the same
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+10>);

// guaranteed to be different
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+11>);

// ill-formed, no diagnostic required
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+1+2+3+4>);
```

—end note

13.6.6.2 Partial ordering of function templates

1 If a function template is overloaded, the use of a function template specialization might be ambiguous because template argument deduction (13.9.2) may associate the function template specialization with more than one function template declaration. Partial ordering of overloaded function template declarations is used in the following contexts to select the function template to which a function template specialization refers:

1.1 — during overload resolution for a call to a function template specialization (12.3.3);

1.2 — when the address of a function template specialization is taken;

1.3 — when a placement operator delete that is a function template specialization is selected to match a placement operator new (6.6.5.4.2, 7.6.2.7);

1.4 — when a friend function declaration (13.6.4), an explicit instantiation (13.8.2) or an explicit specialization (13.8.3) refers to a function template specialization.

2 Partial ordering selects which of two function templates is more specialized than the other by transforming each template in turn (see next paragraph) and performing template argument deduction using the function type. The deduction process determines whether one of the templates is more specialized than the other. If so, the more specialized template is the one chosen by the partial ordering process. If both deductions succeed, the partial ordering selects the more constrained template as described by the rules in 13.4.4.

3 To produce the transformed template, for each type, non-type, or template template parameter (including template parameter packs (13.6.3) thereof) synthesize a unique type, value, or class template respectively and substitute it for each occurrence of that parameter in the function type of the template. [Note: The type replacing the placeholder in the type of the value synthesized for a non-type template parameter is also a unique synthesized type. — end note] If only one of the function templates \(M\) is a member function, and that function is a non-static member of some class \(A\), \(M\) is considered to have a new first parameter inserted in its function parameter list. Given \(cv\) as the cv-qualifiers of \(M\) (if any), the new parameter is of type “rvalue reference to cv A” if the optional ref-qualifier of \(M\) is && or if \(M\) has no ref-qualifier and the first parameter of the other template has rvalue reference type. Otherwise, the new parameter is of type “value reference to cv A”. [Note: This allows a non-static member to be ordered with respect to a non-member function and for the results to be equivalent to the ordering of two equivalent non-members. — end note] [Example:

```c++
struct A { 
};
```

§ 13.6.6.2

367
template<class T> struct B {
    template<class R> int operator*(R&); // #1
};

template<class T, class R> int operator*(T&, R&); // #2

// The declaration of B::operator* is transformed into the equivalent of
// template<class R> int operator*(B<A>&, R&); // #1a

int main() {
    A a;
    B<A> b;
    b * a; // calls #1a
}

— end example]

4 Using the transformed function template’s function type, perform type deduction against the other template as described in 13.9.2.4.

[Example:

template<class T> struct A { A(); };

template<class T> void f(T);
template<class T> void f(T*);
template<class T> void f(const T*);

template<class T> void g(T);
template<class T> void g(T&);

template<class T> void h(const T&);
template<class T> void h(A<T>&);

void m() {
    const int* p;
    f(p); // f(const T*) is more specialized than f(T) or f(T*)
    float x;
    g(x); // ambiguous: g(T) or g(T&)
    A<int> z;
    h(z); // overload resolution selects h(A<T>&)
    const A<int> z2;
    h(z2); // h(const T&) is called because h(A<T>&) is not callable
}

— end example]

5 [Note: Since partial ordering in a call context considers only parameters for which there are explicit call arguments, some parameters are ignored (namely, function parameter packs, parameters with default arguments, and ellipsis parameters). [Example:

template<class T> void f(T); // #1
template<class T> void f(T*, int=1); // #2
template<class T> void g(T); // #3

template<class T> void g(T*, ...); // #4

int main() {
    int* ip;
    f(ip); // calls #2
    g(ip); // calls #4
}

— end example] [Example:

template<class T, class U> struct A { };

template<class T, class U> void f(U, A<U, T*>& p = 0); // #1

template<class T, class U> void f(U, A<U, U*>& p = 0); // #2

template<class T> void g(T, T = T()); // #3

§ 13.6.6.2 368
template<class T, class... U> void g(T, U ...);  // #4

void h() {
    f<int>(42, (A<int, int>*)0);  // calls #2
    f<int>(42);  // error: ambiguous
    g(42);  // error: ambiguous
}

— end example] [Example:

template<class T, class... U> void f(T, U...);  // #1
template<class T> void f(T);  // #2
template<class T, class... U> void g(T*, U...);  // #3
template<class T> void g(T);  // #4

void h(int i) {
    f(&i);  // OK: calls #2
    g(&i);  // OK: calls #3
}

— end example] — end note]

13.6.7 Alias templates [temp.alias]

1 A template-declaration in which the declaration is an alias-declaration (Clause 9) declares the identifier to be an alias template. An alias template is a name for a family of types. The name of the alias template is a template-name.

2 When a template-id refers to the specialization of an alias template, it is equivalent to the associated type obtained by substitution of its template-arguments for the template-parameters in the type-id of the alias template. [Note: An alias template name is never deduced. — end note] [Example:

template<class T> struct Alloc { /* ... */ };
template<class T> using Vec = vector<T, Alloc<T>>;
Vec<int> v;  // same as vector<int, Alloc<int>> v;

template<class T>
    void process(Vec<T>& v)
    { /* ... */ }  

template<class T>
    void process(vector<T, Alloc<T>>& w)
    { /* ... */ }  // error: redefinition

template<template<class> class TT>
    void f(TT<int>);  

    f(v);  // error: Vec not deduced

    template<template<class, class> class TT>
        void g(TT<int, Alloc<int>>);  
    g(v);  // OK: TT = vector

— end example]

3 However, if the template-id is dependent, subsequent template argument substitution still applies to the template-id. [Example:

    template<typename...> using void_t = void;
    template<typename T> void_t<typename T::foo> f();
    f<int>();  // error, int does not have a nested type foo

— end example]

4 The type-id in an alias template declaration shall not refer to the alias template being declared. The type produced by an alias template specialization shall not directly or indirectly make use of that specialization. [Example:

    template <class T> struct A;
    template <class T> using B = typename A<T>::U;
template <class T> struct A {
    typedef B<T> U;
};
B<short> b;  // error: instantiation of B<short> uses own type via A<short>::U
— end example]

5 The type of a lambda-expression appearing in an alias template declaration is different between instantiations of that template, even when the lambda-expression is not dependent. [Example:

```cpp
template <class T>
using A = decltype([] { });  // A<int> and A<char> refer to different closure types
— end example]
```

### 13.6.8 Concept definitions

1 A **concept** is a template that defines constraints on its template arguments.

2 A **concept-definition** declares a concept. Its **identifier** becomes a **concept-name** referring to that concept within its scope. [Example:

```cpp
template<typename T>
concept C = requires(T x) {
    { x == x } -> bool;
};
```

```cpp
template<typename T>
requires C<T>  // C constrains f1(T) in constraint-expression
T f1(T x) { return x; }
```

```cpp
template<C<T>
// C, as a type-constraint, constrains f2(T)
T f2(T x) { return x; }
— end example]
```

3 A **concept-definition** shall appear at namespace scope (6.3.6).

4 A concept shall not have associated constraints (13.4.2).

5 A concept is not instantiated (13.8). [Note: An id-expression that denotes a concept specialization is evaluated as an expression (7.5.4). A concept cannot be explicitly instantiated (13.8.2), explicitly specialized (13.8.3), or partially specialized. — end note]

6 The first declared template parameter of a concept definition is its **prototype parameter**. A **type concept** is a concept whose prototype parameter is a type **template-parameter**.

### 13.7 Name resolution

1 Three kinds of names can be used within a template definition:

(1.1) — The name of the template itself, and names declared within the template itself.

(1.2) — Names dependent on a **template-parameter** (13.7.2).

(1.3) — Names from scopes which are visible within the template definition.

2 A name used in a template declaration or definition and that is dependent on a **template-parameter** is assumed not to name a type unless the applicable name lookup finds a type name or the name is qualified by the keyword **typename**. [Example:

```cpp
// no B declared here

class X;
```

```cpp
template<class T> class Y {
    class Z;  // forward declaration of member class

    void f() {
        X* a1;  // declare pointer to X
        T* a2;  // declare pointer to T
        Y* a3;  // declare pointer to Y<T>
        Z* a4;  // declare pointer to Z
    }

§ 13.7 370
```
typedef typename T::A TA;
TA* a5; // declare pointer to T's A
typename T::A* a6; // declare pointer to T's A
T::A* a7; // T::A is not a type name:
// multiplication of T::A by a7; ill-formed, no visible declaration of a7
B* a8; // B is not a type name:
// multiplication of B by a8; ill-formed, no visible declarations of B and a8
}  

/* end example */

typename-specifier:
  typename nested-name-specifier identifier
typename nested-name-specifier template<opt simple-template-id>

3 A typename-specifier denotes the type or class template denoted by the simple-type-specifier (9.1.7.2) formed by omitting the keyword typename. The usual qualified name lookup (6.4.3) is used to find the qualified-id even in the presence of typename. [Example:

```cpp
struct A {
  struct X { };  
  int X;
};
struct B {
  struct X { }; }

template<class T> void f(T t) {
  typename T::X x;
}
void foo() {
  A a;
  B b;
  f(b); // OK: T::X refers to B::X
  f(a); // error: T::X refers to the data member A::X not the struct A::X
}
/* end example */

4 A qualified name used as the name in a class-or-decltype (11.6) or an elaborated-type-specifier is implicitly assumed to name a type, without the use of the typename keyword. In a typename-specifier that immediately contains a nested-name-specifier that depends on a template parameter, the identifier or simple-template-id is implicitly assumed to name a type, without the use of the typename keyword. [Note: The typename keyword is not permitted by the syntax of these constructs. — end note]

5 A qualified-id is assumed to name a type if

(5.1) it is a qualified name in a type-id-only context (see below), or
(5.2) it is a decl-specifier of the decl-specifier-seq of a

(5.2.1) simple-declaration or a function-definition in namespace scope,
(5.2.2) member-declaration,
(5.2.3) parameter-declaration in a member-declaration\(^139\), unless that parameter-declaration appears in a default argument,
(5.2.4) parameter-declaration in a declarator of a function or function template declaration whose declarator-id is qualified, unless that parameter-declaration appears in a default argument,
(5.2.5) parameter-declaration in a lambda-declarator, unless that parameter-declaration appears in a default argument, or
(5.2.6) parameter-declaration of a (non-type) template-parameter.

A qualified name is said to be in a type-id-only context if it appears in a type-id, new-type-id, or defining-type-id and the smallest enclosing type-id, new-type-id, or defining-type-id is a new-type-id, defining-type-id, trailing-return-type, default argument of a type-parameter of a template, or type-id of a static_cast, const_cast, reinterpret_cast, or dynamic_cast. [Example:

\(^{139}\) This includes friend function declarations.

§ 13.7

371
template<class T> T::R f(); // OK, return type of a function declaration at global scope

template<class T> void f(T::R); // ill-formed (no diagnostic required), attempt to declare

// a void variable template

template<class T> struct S {
    using Ptr = PtrTraits<T>::Ptr; // OK, in a defining-type-id

    T::R f(T::P p) { // OK, class scope
        return static_cast<T::R>(p); // OK, type-id of a static_cast
    }

    auto g() -> S<T>::Ptr; // OK, trailing-return-type
};

template<typename T> void f() { // OK, trailing-return-type
    void (*pf)(T::X);
    // variable pf of type void* initialized with T::X

    void g(T::X); // error: T::X at block scope does not denote a type
    // (attempt to declare a void variable)
};

— end example

6 A qualified-id that refers to a member of an unknown specialization, that is not prefixed by typename, and that is not otherwise assumed to name a type (see above) denotes a non-type. [Example:

template <class T> void f(int i) {
    T::x * i; // expression, not the declaration of a variable i
}

struct Foo {
    typedef int x;
};

struct Bar {
    static int const x = 5;
};

int main() {
    f<Bar>(1); // OK
    f<Foo>(1); // error: Foo::x is a type
}

— end example

7 Within the definition of a class template or within the definition of a member of a class template following the declarator-id, the keyword typename is not required when referring to a member of the current instantiation (13.7.2.1). [Example:

template<class T> struct A {
    typedef int B;
    B b; // OK, no typename required
};

— end example

8 The validity of a template may be checked prior to any instantiation. [Note: Knowing which names are type names allows the syntax of every template to be checked in this way. — end note] The program is ill-formed, no diagnostic required, if:

(8.1) — no valid specialization can be generated for a template or a substatement of a constexpr if statement (8.4.1) within a template and the template is not instantiated, or

(8.2) — no substitution of template arguments into a type-constraint or requires-clause would result in a valid expression, or

(8.3) — every valid specialization of a variadic template requires an empty template parameter pack, or

(8.4) — a hypothetical instantiation of a template immediately following its definition would be ill-formed due to a construct that does not depend on a template parameter, or

(8.5) — the interpretation of such a construct in the hypothetical instantiation is different from the interpretation of the corresponding construct in any actual instantiation of the template. [Note: This can happen in situations including the following:

§ 13.7 372
— a type used in a non-dependent name is incomplete at the point at which a template is defined but is complete at the point at which an instantiation is performed, or

— lookup for a name in the template definition found a using-declaration, but the lookup in the corresponding scope in the instantiation does not find any declarations because the using-declaration was a pack expansion and the corresponding pack is empty, or

— an instantiation uses a default argument or default template argument that had not been defined at the point at which the template was defined, or

— constant expression evaluation (7.7) within the template instantiation uses

— the value of a const object of integral or unscoped enumeration type or

— the value of a constexpr object or

— the value of a reference or

— the definition of a constexpr function,

and that entity was not defined when the template was defined, or

— a class template specialization or variable template specialization that is specified by a non-dependent simple-template-id is used by the template, and either it is instantiated from a partial specialization that was not defined when the template was defined or it names an explicit specialization that was not declared when the template was defined.

—end note]

Otherwise, no diagnostic shall be issued for a template for which a valid specialization can be generated.

[Note: If a template is instantiated, errors will be diagnosed according to the other rules in this document. Exactly when these errors are diagnosed is a quality of implementation issue. — end note] [Example:

```cpp
int j;
template<class T> class X {
    void f(T t, int i, char* p) {
        t = i; // diagnosed if X::f is instantiated, and the assignment to t is an error
        p = i; // may be diagnosed even if X::f is not instantiated
        p = j; // may be diagnosed even if X::f is not instantiated
    }
    void g(T t) {
        // may be diagnosed even if X::g is not instantiated
    }
};

template<class... T> struct A {
    void operator++(int, T... t); // error: too many parameters
};
template<class... T> union X : T... { }; // error: union with base class
template<class... T> struct A : T..., T... { }; // error: duplicate base class

—end example]

9 When looking for the declaration of a name used in a template definition, the usual lookup rules (6.4.1, 6.4.2) are used for non-dependent names. The lookup of names dependent on the template parameters is postponed until the actual template argument is known (13.7.2). [Example:

```cpp
#include <iostream>
using namespace std;

template<class T> class Set {
    T* p;
public:
    Set();
    Set<T>(const Set<T>&);
    void printall() {
        for (int i = 0; i<cnt; i++)
            cout << p[i] << 'n';
    }
};
```

§ 13.7
In the example, i is the local variable i declared in printall, cnt is the member cnt declared in Set, and cout is the standard output stream declared in iostream. However, not every declaration can be found this way; the resolution of some names must be postponed until the actual template-arguments are known. For example, even though the name operator<< is known within the definition of printall() and a declaration of it can be found in <iostream>, the actual declaration of operator<< needed to print p[i] cannot be known until it is known what type T is (13.7.2). — end example]

If a name does not depend on a template-parameter (as defined in 13.7.2), a declaration (or set of declarations) for that name shall be in scope at the point where the name appears in the template definition; the name is bound to the declaration (or declarations) found at that point and this binding is not affected by declarations that are visible at the point of instantiation. [Example:

```cpp
void f(char);

template<class T> void g(T t) {
    f(1);  // f(char)
    f(T(1));  // dependent
    f(t);  // dependent
    dd++;  // not dependent; error: declaration for dd not found
}
```

— end example]

[Note: For purposes of name lookup, default arguments and noexcept-specifiers of function templates and default arguments and noexcept-specifiers of member functions of class templates are considered definitions (13.6). — end note]

### 13.7.1 Locally declared names

Like normal (non-template) classes, class templates have an injected-class-name (Clause 11). The injected-class-name can be used as a template-name or a type-name. When it is used with a template-argument-list, as a template-argument for a template template-parameter, or as the final identifier in the elaborated-type-specifier of a friend class template declaration, it is a template-name that refers to the class template itself. Otherwise, it is a type-name equivalent to the template-name followed by the template-arguments of the class template enclosed in <>.

Within the scope of a class template specialization or partial specialization, when the injected-class-name is used as a type-name, it is equivalent to the template-name followed by the template-arguments of the class template specialization or partial specialization enclosed in <>.

[Example:

```cpp
template<template<class> class T> class A { }
template<class T> class Y;
template<class Y<int>> {
    Y* p;  // meaning Y<int>
    Y<char>* q;  // meaning Y<char>
    A<Y>* a;  // meaning A<Y>
    class B {
        template<class Y> friend class Y;  // meaning ::Y
    };
}
```

— end example]

The injected-class-name of a class template or class template specialization can be used as either a template-name or a type-name wherever it is in scope.

[Example:

```cpp
template <class T> struct Base {  
    Base* p;
};
```
template <class T> struct Derived: public Base<T> {
    typename Derived::Base* p;       // meaning Derived::Base<T>
};

template<class T, template<class> class U = T::template Base> struct Third { }
Third<Derived<int> > t;       // OK: default argument uses injected-class-name as a template
—end example

4 A lookup that finds an injected-class-name (11.7) can result in an ambiguity in certain cases (for example, if it
is found in more than one base class). If all of the injected-class-names that are found refer to specializations
of the same class template, and if the name is used as a template-name, the reference refers to the class
template itself and not a specialization thereof, and is not ambiguous. [Example:

template <class T> struct Base { }
template <class T> struct Derived: Base<int>, Base<char> {
    typename Derived::Base b;       // error: ambiguous
    typename Derived::Base<double> d; // OK
};
—end example

5 When the normal name of the template (i.e., the name from the enclosing scope, not the injected-class-name)
is used, it always refers to the class template itself and not a specialization of the template. [Example:

template<class T> class X {
    X* p;                           // meaning X<T>
    X<T>* p2;
    X<int>* p3;
    ::X* p4;                       // error: missing template argument list
    ::::X does not refer to the injected-class-name
};
—end example

6 A template-parameter shall not be redeclared within its scope (including nested scopes). A template-parameter
shall not have the same name as the template name. [Example:

template<class T, int i> class Y {
    int T;                          // error: template-parameter redeclared
    void f() {                     // error: template-parameter redeclared
        char T;
    }
};

template<class X> class X;      // error: template-parameter redeclared
—end example

7 In the definition of a member of a class template that appears outside of the class template definition, the
name of a member of the class template hides the name of a template-parameter of any enclosing class
templates (but not a template-parameter of the member if the member is a class or function template).
[Example:

template<class T> struct A {
    struct B { /* ... */ };      
    typedef void C;
    void f();                     
    template<class U> void g(U);
};

template<class B> void A<B>::f() { 
    B b;                          // A's B, not the template parameter
}

template<class B> template<class C> void A<B>::g(C) { 
    B b;                          // A's B, not the template parameter
    C c;                          // the template parameter C, not A's C
}
8 In the definition of a member of a class template that appears outside of the namespace containing the class template definition, the name of a `template-parameter` hides the name of a member of this namespace. [Example:

```cpp
namespace N {
    class C { }
    template<class T> class B {
        void f(T);
    };
}
template<class C> void N::B<C>::f(C) {
    C b;
    // C is the template parameter, not N::C
}
— end example]

9 In the definition of a class template or in the definition of a member of such a template that appears outside of the template definition, for each non-dependent base class (13.7.2.1), if the name of the base class or the name of a member of the base class is the same as the name of a `template-parameter`, the base class name or member name hides the `template-parameter` name (6.3.10). [Example:

```cpp
struct A {
    struct B { /* ... */ }
    int a;
    int Y;
};
template<class B, class a> struct X : A {
    B b;
    // A's B
    a b;
    // error: A's a isn't a type name
};
— end example]

13.7.2 Dependent names [temp.dep]

1 Inside a template, some constructs have semantics which may differ from one instantiation to another. Such a construct depends on the template parameters. In particular, types and expressions may depend on the type and/or value of template parameters (as determined by the template arguments) and this determines the context for name lookup for certain names. An expression may be type-dependent (that is, its type may depend on a template parameter) or value-dependent (that is, its value when evaluated as a constant expression (7.7) may depend on a template parameter) as described in this subclause.

2 In an expression of the form:

```
postfix-expression ( expression-listopt )
```

where the postfix-expression is an `unqualified-id`, the `unqualified-id` denotes a dependent name if

(2.1) — any of the expressions in the `expression-list` is a pack expansion (13.6.3),

(2.2) — any of the expressions or `braced-init-lists` in the `expression-list` is type-dependent (13.7.2.2), or

(2.3) — the `unqualified-id` is a `template-id` in which any of the template arguments depends on a template parameter.

If an operand of an operator is a type-dependent expression, the operator also denotes a dependent name. [Note: Such names are unbound and are looked up at the point of the template instantiation (13.7.4.1) in both the context of the template definition and the context of the point of instantiation (13.7.4.2). — end note]

3 [Example:

```cpp
template<class T> struct X : B<T> {
    typename T::A* pa;
    void f(B<T>** pb) {
        static int i = B<T>::i;
        pb->j++;
    }

§ 13.7.2 376
```
The base class name `B<T>`, the type name `T::A`, the names `B<T>::i` and `pb->j` explicitly depend on the `template-parameter`. — end example

4 In the definition of a class or class template, the scope of a dependent base class (13.7.2.1) is not examined during unqualified name lookup either at the point of definition of the class template or member or during an instantiation of the class template or member. [Example:

```cpp
typedef double A;
template<class T> class B {
typedef int A;
};
template<class T> struct X : B<T> {
    A a; // a has type double
};
```

The type name `A` in the definition of `X<T>` binds to the typedef name defined in the global namespace scope, not to the typedef name defined in the base class `B<T>`. — end example] [Example:

```cpp
struct A {
    struct B { /* ... */ }; // B defined in A
    int a;
    int Y;
};
int a;

template<class T> struct Y : T {
    struct B { /* ... */ }; // The B defined in Y
    B b;
    void f(int i) { a = i; } // : : a
    Y* p; // Y<T>
};
Y<A> ya;
```

The members `A::B`, `A::a`, and `A::Y` of the template argument `A` do not affect the binding of names in `Y<A>`. — end example]

13.7.2.1 Dependent types [temp.dep.type]

1 A name refers to the current instantiation if it is

(1.1) — in the definition of a class template, a nested class of a class template, a member of a class template, or a member of a nested class of a class template, the injected-class-name (Clause 11) of the class template or nested class,

(1.2) — in the definition of a primary class template or a member of a primary class template, the name of the class template followed by the template argument list of the primary template (as described below) enclosed in `<>` (or an equivalent template alias specialization),

(1.3) — in the definition of a nested class of a class template, the name of the nested class referenced as a member of the current instantiation, or

(1.4) — in the definition of a partial specialization or a member of a partial specialization, the name of the class template followed by the template argument list of the partial specialization enclosed in `<>` (or an equivalent template alias specialization). If the `n`th template parameter is a template parameter pack, the `n`th template argument is a pack expansion (13.6.3) whose pattern is the name of the template parameter pack.

2 The template argument list of a primary template is a template argument list in which the `n`th template argument has the value of the `n`th template parameter of the class template. If the `n`th template parameter is a template parameter pack (13.6.3), the `n`th template argument is a pack expansion (13.6.3) whose pattern is the name of the template parameter pack.

3 A template argument that is equivalent to a template parameter can be used in place of that template parameter in a reference to the current instantiation. For a template `type-parameter`, a template argument
is equivalent to a template parameter if it denotes the same type. For a non-type template parameter, a template argument is equivalent to a template parameter if it is an identifier that names a variable that is equivalent to the template parameter. A variable is equivalent to a template parameter if

(3.1) — it has the same type as the template parameter (ignoring cv-qualification) and
(3.2) — its initializer consists of a single identifier that names the template parameter or, recursively, such a variable.

[Note: Using a parenthesized variable name breaks the equivalence. — end note]  [Example:

```cpp
template <class T> class A {
    A* p1; // A is the current instantiation
    A<T>* p2; // A<T> is the current instantiation
    A<T*>& p3; // A<T>& is the current instantiation
    ::A<T>* p4; // ::A<T> is the current instantiation
    class B {
        B* p1; // B is the current instantiation
        A<T>::B* p2; // A<T>::B is the current instantiation
    }
    A<T>* p5; // A<T> is the current instantiation
};
```

```cpp
template <class T> class A<T*> {
    A<T*>* p1; // A<T*> is the current instantiation
    A<T>* p2; // A<T> is not the current instantiation
};
```

```cpp
template <class T1, class T2, int I> struct B {
    B<T1, T2, I* b1; // refers to the current instantiation
    B<T2, T1, I*> b2; // not the current instantiation
    typedef T1 my_T1;
    static const int my_I = I;
    static const int my_I2 = I+0;
    static const int my_I3 = my_I;
    static const long my_I4 = I;
    static const int my_I5 = (I);
    B<my_T1, T2, my_I* b3; // refers to the current instantiation
    B<my_T1, T2, my_I2* b4; // not the current instantiation
    B<my_T1, T2, my_I3* b5; // refers to the current instantiation
    B<my_T1, T2, my_I4* b6; // not the current instantiation
    B<my_T1, T2, my_I5* b7; // not the current instantiation
};
```

— end example]

—end note]

4 A dependent base class is a base class that is a dependent type and is not the current instantiation. [Note: A base class can be the current instantiation in the case of a nested class naming an enclosing class as a base. [Example:

```cpp
template<class T> struct A {
    typedef int M;
    struct B {
        typedef void M;
        struct C;
    };
};
```

```cpp
template<class T> struct A<T>::B::C : A<T> {
    M m; // OK, A<T>::M
};
```

— end example] — end note]

5 A name is a member of the current instantiation if it is
An unqualified name that, when looked up, refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [Note: This can only occur when looking up a name in a scope enclosed by the definition of a class template. — end note]

A qualified-id in which the nested-name-specifier refers to the current instantiation and that, when looked up, refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [Note: If no such member is found, and the current instantiation has any dependent base classes, then the qualified-id is a member of an unknown specialization; see below. — end note]

An id-expression denoting the member in a class member access expression (7.6.1.4) for which the type of the object expression is the current instantiation, and the id-expression, when looked up (6.4.5), refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [Note: If no such member is found, and the current instantiation has any dependent base classes, then the id-expression is a member of an unknown specialization; see below. — end note]

Example:
```cpp
#include <iostream>

template <class T> class A {
    static const int i = 5;
    int n1[i];   // i refers to a member of the current instantiation
    int n2[A::i];  // A::i refers to a member of the current instantiation
    int n3[A<T>::i];  // A<T>::i refers to a member of the current instantiation
    int f();
};

template <class T> int A<T>::f() {
    return i;  // i refers to a member of the current instantiation
}
```

— end example]

A name is a dependent member of the current instantiation if it is a member of the current instantiation that, when looked up, refers to at least one member of a class that is the current instantiation.

A name is a member of an unknown specialization if it is

6 A qualified-id in which the nested-name-specifier names a dependent type that is not the current instantiation.

6 A qualified-id in which the nested-name-specifier refers to the current instantiation, the current instantiation has at least one dependent base class, and name lookup of the qualified-id does not find any member of a class that is the current instantiation or a non-dependent base class thereof.

An id-expression denoting the member in a class member access expression (7.6.1.4) in which either

6.3.1 — the type of the object expression is the current instantiation, the current instantiation has at least one dependent base class, and name lookup of the id-expression does not find a member of a class that is the current instantiation or a non-dependent base class thereof; or

6.3.2 — the type of the object expression is not the current instantiation and the object expression is type-dependent.

If a qualified-id in which the nested-name-specifier refers to the current instantiation is not a member of the current instantiation or a member of an unknown specialization, the program is ill-formed even if the template containing the qualified-id is not instantiated; no diagnostic required. Similarly, if the id-expression in a class member access expression for which the type of the object expression is the current instantiation does not refer to a member of the current instantiation or a member of an unknown specialization, the program is ill-formed even if the template containing the member access expression is not instantiated; no diagnostic required. [Example:
```cpp
#include <iostream>

template<class T> class A {
    typedef int type;
    void f() {
        A<T>::type i;  // OK: refers to a member of the current instantiation
        typename A<T>::other j;  // error: neither a member of the current instantiation nor
                                  // a member of an unknown specialization
    }
};
```

— end example]
If, for a given set of template arguments, a specialization of a template is instantiated that refers to a member of the current instantiation with a qualified-id or class member access expression, the name in the qualified-id or class member access expression is looked up in the template instantiation context. If the result of this lookup differs from the result of name lookup in the template definition context, name lookup is ambiguous.

[Example:

```cpp
struct A {
    int m;
};

struct B {
    int m;
};

template<typename T>
struct C : A, T {
    int f() { return this->m; }  // finds A::m in the template definition context
    int g() { return m; }        // finds A::m in the template definition context
};

template int C<B>::f();  // error: finds both A::m and B::m
template int C<B>::g();  // OK: transformation to class member access syntax
// does not occur in the template definition context; see 11.3.2
```

—end example]

A type is dependent if it is

(9.1)  a template parameter,
(9.2)  a member of an unknown specialization,
(9.3)  a nested class or enumeration that is a dependent member of the current instantiation,
(9.4)  a cv-qualified type where the cv-unqualified type is dependent,
(9.5)  a compound type constructed from any dependent type,
(9.6)  an array type whose element type is dependent or whose bound (if any) is value-dependent,
(9.7)  a function type whose exception specification is value-dependent,
(9.8)  denoted by a simple-template-id in which either the template name is a template parameter or any of the template arguments is a dependent type or an expression that is type-dependent or value-dependent or is a pack expansion [Note: This includes an injected-class-name (Clause 11) of a class template used without a template-argument-list. — end note], or
(9.9)  denoted by decltype(expression), where expression is type-dependent (13.7.2.2).

[Note: Because typedefs do not introduce new types, but instead simply refer to other types, a name that refers to a typedef that is a member of the current instantiation is dependent only if the type referred to is dependent. — end note]

13.7.2.2 Type-dependent expressions

Except as described below, an expression is type-dependent if any subexpression is type-dependent.

this is type-dependent if the class type of the enclosing member function is dependent (13.7.2.1).

An id-expression is type-dependent if it contains

(3.1)  an identifier associated by name lookup with one or more declarations declared with a dependent type,
(3.2)  an identifier associated by name lookup with a non-type template-parameter declared with a type that contains a placeholder type (9.1.7.5),
(3.3)  an identifier associated by name lookup with a variable declared with a type that contains a placeholder type (9.1.7.5) where the initializer is type-dependent,
(3.4)  an identifier associated by name lookup with one or more declarations of member functions of the current instantiation declared with a return type that contains a placeholder type,
(3.5)  an identifier associated by name lookup with a structured binding declaration (9.5) whose brace-or-equal-initializer is type-dependent,
— the identifier __func__ (9.4.1), where any enclosing function is a template, a member of a class template, or a generic lambda,

— the identifier introduced in a postcondition (9.11.4) to represent the result of a templated function whose declared return type contains a placeholder type,

— a template-id that is dependent,

— a conversion-function-id that specifies a dependent type, or

— a nested-name-specifier or a qualified-id that names a member of an unknown specialization;

or if it names a dependent member of the current instantiation that is a static data member of type “array of unknown bound of T” for some T (13.6.1.3). Expressions of the following forms are type-dependent only if the type specified by the type-id, simple-type-specifier or new-type-id is dependent, even if any subexpression is type-dependent:

```c
simple-type-specifier ( expression-listopt )
new placementopt new-type-id new-initializeropt
::opt new placementopt new-type-id new-initializeropt
dynamic_cast < type-id > ( expression )
static_cast < type-id > ( expression )
const_cast < type-id > ( expression )
reinterpret_cast < type-id > ( expression )
type-id cast-expression
```

4 Expressions of the following forms are never type-dependent (because the type of the expression cannot be dependent):

```c
literal
sizeof unary-expression
sizeof ( type-id )
sizeof ... ( identifier )
alignof ( type-id )
typeid ( expression )
typeid ( type-id )
::opt delete cast-expression
::opt delete [ ] cast-expression
throw assignment-expressionopt
noexcept ( expression )
```

[Note: For the standard library macro offsetof, see 17.2. — end note]

5 A class member access expression (7.6.1.4) is type-dependent if the expression refers to a member of the current instantiation and the type of the referenced member is dependent, or the class member access expression refers to a member of an unknown specialization. [Note: In an expression of the form x.y or xp->y the type of the expression is usually the type of the member y of the class of x (or the class pointed to by xp). However, if x or xp refers to a dependent type that is not the current instantiation, the type of y is always dependent. If x or xp refers to a non-dependent type or refers to the current instantiation, the type of y is the type of the class member access expression. — end note]

6 A braced-init-list is type-dependent if any element is type-dependent or is a pack expansion.

7 A fold-expression is type-dependent.

13.7.2.3 Value-dependent expressions [temp.dep.constexpr]

1 Except as described below, an expression used in a context where a constant expression is required is value-dependent if any subexpression is value-dependent.

2 An id-expression is value-dependent if:

(2.1) it is type-dependent,

(2.2) it is the name of a non-type template parameter,

(2.3) it names a static data member that is a dependent member of the current instantiation and is not initialized in a member-declarator,

(2.4) it names a static member function that is a dependent member of the current instantiation, or

(2.5) it is a constant with literal type and is initialized with an expression that is value-dependent.
Expressions of the following form are value-dependent if the unary-expression or expression is type-dependent or the type-id is dependent:

- `sizeof unary-expression`
- `sizeof ( type-id )`
- `typeid ( expression )`
- `typeid ( type-id )`
- `alignof ( type-id )`
- `noexcept ( expression )`

[Note: For the standard library macro `offsetof`, see 17.2. — end note]

Expressions of the following form are value-dependent if either the type-id or simple-type-specifier is dependent or the expression or cast-expression is value-dependent:

- `simple-type-specifier ( expression-list opt )`
- `static_cast < type-id > ( expression )`
- `const_cast < type-id > ( expression )`
- `reinterpret_cast < type-id > ( expression )`

Expressions of the following form are value-dependent:

- `sizeof ... ( identifier )`

An expression of the form `&qualified-id` where the qualified-id names a dependent member of the current instantiation is value-dependent. An expression of the form `&cast-expression` is also value-dependent if evaluating cast-expression as a core constant expression (7.7) succeeds and the result of the evaluation refers to a templated entity that is an object with static or thread storage duration or a member function.

13.7.2.4 Dependent template arguments

A type template-argument is dependent if the type it specifies is dependent.

A non-type template-argument is dependent if its type is dependent or the constant expression it specifies is value-dependent.

Furthermore, a non-type template-argument is dependent if the corresponding non-type template-parameter is of reference or pointer type and the template-argument designates or points to a member of the current instantiation or a member of a dependent type.

A template template-argument is dependent if it names a template-parameter or is a qualified-id that refers to a member of an unknown specialization.

13.7.3 Non-dependent names

Non-dependent names used in a template definition are found using the usual name lookup and bound at the point they are used. [Example:

```cpp
void g(double);
void h();

template<class T> class Z {
public:
    void f() {
        g(1); // calls g(double)
        h++; // ill-formed: cannot increment function; this could be diagnosed
              // either here or at the point of instantiation
    }
};

void g(int); // not in scope at the point of the template definition, not considered for the call g(1)
```

—end example]

13.7.4 Dependent name resolution

13.7.4.1 Point of instantiation

For a function template specialization, a member function template specialization, or a specialization for a member function or static data member of a class template, if the specialization is implicitly instantiated
because it is referenced from within another template specialization and the context from which it is referenced depends on a template parameter, the point of instantiation of the specialization is the point of instantiation of the enclosing specialization. Otherwise, the point of instantiation for such a specialization immediately follows the namespace scope declaration or definition that refers to the specialization.

2 If a function template or member function of a class template is called in a way which uses the definition of a default argument of that function template or member function, the point of instantiation of the default argument is the point of instantiation of the function template or member function specialization.

3 For a noexcept-specifier of a function template specialization or specialization of a member function of a class template, if the noexcept-specifier is implicitly instantiated because it is needed by another template specialization and the context that requires it depends on a template parameter, the point of instantiation of the noexcept-specifier is the point of instantiation of the specialization that requires it. Otherwise, the point of instantiation for such a noexcept-specifier immediately follows the namespace scope declaration or definition that requires the noexcept-specifier.

4 For a class template specialization, a class member template specialization, or a specialization for a class member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization, if the context from which the specialization is referenced depends on a template parameter, and if the specialization is not instantiated previous to the instantiation of the enclosing template, the point of instantiation is immediately before the point of instantiation of the enclosing template. Otherwise, the point of instantiation for such a specialization immediately precedes the namespace scope declaration or definition that refers to the specialization.

5 If a virtual function is implicitly instantiated, its point of instantiation is immediately following the point of instantiation of its enclosing class template specialization.

6 An explicit instantiation definition is an instantiation point for the specialization or specializations specified by the explicit instantiation.

7 A specialization for a function template, a member function template, or of a member function or static data member of a class template may have multiple points of instantiations within a translation unit, and in addition to the points of instantiation described above,

(7.1) — for any such specialization that has a point of instantiation within the top-level-declaration-seq of the translation unit, prior to the private-module-fragment (if any), the point after the top-level-declaration-seq of the translation-unit is also considered a point of instantiation, and

(7.2) — for any such specialization that has a point of instantiation within the private-module-fragment, the end of the translation unit is also considered a point of instantiation.

A specialization for a class template has at most one point of instantiation within a translation unit. A specialization for any template may have points of instantiation in multiple translation units. If two different points of instantiation give a template specialization different meanings according to the one-definition rule (6.2), the program is ill-formed, no diagnostic required.

13.7.4.2 Candidate functions

1 For a function call where the postfix-expression is a dependent name, the candidate functions are found using the usual lookup rules from the template definition context (6.4.1, 6.4.2). [Note: For the part of the lookup using associated namespaces (6.4.2), function declarations found in the template instantiation context are found by this lookup, as described in 6.4.2. — end note] If the call would be ill-formed or would find a better match had the lookup within the associated namespaces considered all the function declarations with external linkage introduced in those namespaces in all translation units, not just considering those declarations found in the template definition and template instantiation contexts, then the program has undefined behavior.

[Example:

Source file "X.h":

```cpp
namespace Q {
    struct X { }
};
```

Source file "G.h":

```cpp
namespace Q {
    void g_impl(X, X);
};
```
Module interface unit of M1:

```cpp
module;
#include "X.h"
#include "G.h"
export module M1;
export template<typename T>
void g(T t) {
    g_impl(t, Q::X{ });  // ADL in definition context finds Q::g_impl, g_impl not discarded
}
```

Module interface unit of M2:

```cpp
module;
#include "X.h"
export module M2;
import M1;
void h(Q::X x) {
    g(x);  // OK
}
```

— end example 

Example:

Module interface unit of Std:

```cpp
export module Std;
export template<typename Iter>
void indirect_swap(Iter lhs, Iter rhs)
{
    swap(*lhs, *rhs);  // swap not found by unqualified lookup, can be found only via ADL
}
```

Module interface unit of M:

```cpp
export module M;
import Std;
struct S { /* ... */ };
void swap(S& x, S& y){  // #1
    indirect_swap(x, y);  // finds #1 via ADL in instantiation context
}
```

— end example 

Example:

Source file "X.h":

```cpp
struct X { /* ... */ };
X operator+(X, X);
```

Module interface unit of F:

```cpp
export module F;
export template<typename T>
void f(T t) {
    t + t;
}
```

Module interface unit of M:

```cpp
module;
#include "X.h"
export module M;
import F;
void g(X x) {
    f(x);  // OK: instantiates t from F,
}
```
Example:
Module interface unit of A:

```cpp
export module A;
export template<typename T>
void f(T t) {
    cat(t, t);    // #1
    dog(t, t);    // #2
}
```

Module interface unit of B:

```cpp
export module B;
import A;
export template<typename T, typename U>
void g(T t, U u) {
    f(t);
}
```

Source file "foo.h", not an importable header:

```cpp
struct foo {
    friend int cat(foo, foo);
};
int dog(foo, foo);
```

Module interface unit of C1:

```cpp
module;
#include "foo.h"    // dog not referenced, discarded
export module C1;
import B;
export template<typename T>
void h(T t) {
    g(foo{ }, t);
}
```

Translation unit:

```cpp
import C1;
void i() {
    h(0);    // error: dog not found at #2
}
```

Importable header "bar.h":

```cpp
struct bar {
    friend int cat(bar, bar);
};
int dog(bar, bar);
```

Module interface unit of C2:

```cpp
module;
#include "bar.h"    // imports header unit "bar.h"
export module C2;
import B;
export template<typename T>
void j(T t) {
    g(bar{ }, t);
}
```

Translation unit:

```cpp
import C2;
void k() {
    j(0);    // OK, dog found in instantiation context:
}
```

§ 13.7.4.2 // operator+ is visible in instantiation context
Friend classes or functions can be declared within a class template. When a template is instantiated, the names of its friends are treated as if the specialization had been explicitly declared at its point of instantiation.

As with non-template classes, the names of namespace-scope friend functions of a class template specialization are not visible during an ordinary lookup unless explicitly declared at namespace scope (11.8.3). Such names may be found under the rules for associated classes (6.4.2).

Example:

```cpp
template<typename T> struct number {
  number(int);
  friend number gcd(number x, number y) { return 0; };
};

void g() {
  number<double> a(3), b(4);
  a = gcd(a, b); // finds gcd because number<double> is an associated class,
  // making gcd visible in its namespace (global scope)
  b = gcd(3, 4); // ill-formed; gcd is not visible
}
```

13.8 Template instantiation and specialization

The act of instantiating a function, a variable, a class, a member of a class template, or a member template is referred to as template instantiation.

A function instantiated from a function template is called an instantiated function. A class instantiated from a class template is called an instantiated class. A member function, a member class, a member enumeration, or a static data member of a class template instantiated from the member definition of the class template is called, respectively, an instantiated member function, member class, member enumeration, or static data member. A member function instantiated from a member function template is called an instantiated member function. A member class instantiated from a member class template is called an instantiated member class. A variable instantiated from a variable template is called an instantiated variable. A static data member instantiated from a static data member template is called an instantiated static data member.

An explicit specialization may be declared for a function template, a variable template, a class template, a member of a class template, or a member template. An explicit specialization declaration is introduced by `template<>`. In an explicit specialization declaration for a variable template, a class template, a member of a class template or a class member template, the name of the variable or class that is explicitly specialized shall be a simple-template-id. In the explicit specialization declaration for a function template or a member function template, the name of the function or member function explicitly specialized may be a template-id. Example:

```cpp
template<class T = int> struct A {
  static int x;
};

template<class U> void g(U) { }

template<> struct A<double> { }; // specialize for T == double
template<> struct A<int> { }; // specialize for T == int
template<> void g(char) { } // specialize for U == char
  // U is deduced from the parameter type
template<> void g<int>(int) { } // specialize for U == int
template<> int A<char>::x = 0; // specialize for T == char
```

140) Friend declarations do not introduce new names into any scope, either when the template is declared or when it is instantiated.
template<class T = int> struct B {
    static int x;
};
template<> int B<>::x = 1;  // specialize for T == int

An instantiated template specialization can be either implicitly instantiated (13.8.1) for a given argument list or be explicitly instantiated (13.8.2). A specialization is a class, variable, function, or class member that is either instantiated or explicitly specialized (13.8.3).

For a given template and a given set of template-arguments,

(5.1) — an explicit instantiation definition shall appear at most once in a program,
(5.2) — an explicit specialization shall be defined at most once in a program, as specified in 6.2, and
(5.3) — both an explicit instantiation and a declaration of an explicit specialization shall not appear in a program unless the explicit instantiation follows a declaration of the explicit specialization.

An implementation is not required to diagnose a violation of this rule.

The usual access checking rules do not apply to names in a declaration of an explicit instantiation or explicit specialization, with the exception of names appearing in a function body, default argument, base-clause, member-specification, enumerator-list, or static data member or variable template initializer. [Note: In particular, the template arguments and names used in the function declarator (including parameter types, return types and exception specifications) may be private types or objects that would normally not be accessible. — end note]

7 Each class template specialization instantiated from a template has its own copy of any static members. [Example:

    template<class T> class X {
        static T s;
    };  
    template<class T> T X<T>::s = 0;
    X<int> aa;
    X<char*> bb;

    X<int> has a static member s of type int and X<char*> has a static member s of type char*. — end example]

8 If a function declaration acquired its function type through a dependent type (13.7.2.1) without using the syntactic form of a function declarator, the program is ill-formed. [Example:

    template<class T> struct A {
        static T t;
    };  
    typedef int function();
    A<function> a;  // ill-formed: would declare A<function>::t as a static member function

    — end example]
void g(D<int>* p, D<char>* pp, D<double>* ppp) {
    f(p); // instantiation of D<int> required: call f(B<int>*)
    B<char>* q = pp; // instantiation of D<char> required: convert D<char>* to B<char>*
    delete ppp; // instantiation of D<double> required
}

— end example —

If a class template has been declared, but not defined, at the point of instantiation (13.7.4.1),
the instantiation yields an incomplete class type (6.7). [Example:

```cpp
template<class T>
struct X;

X<char> ch; // error: incomplete type
```
— end example —

[Note: Within a template declaration, a local class (11.5) or enumeration and the members of
a local class are never considered to be entities that can be separately instantiated (this includes their default
arguments, noexcept-specifiers, and non-static data member initializers, if any, but not their type-constraints
or requires-clauses). As a result, the dependent names are looked up, the semantic constraints are checked,
and any templates used are instantiated as part of the instantiation of the entity within which the local class
or enumeration is declared. — end note]

The implicit instantiation of a class template specialization causes

(2.1) — the implicit instantiation of the declarations, but not of the definitions, of the non-deleted class member
functions, member classes, scoped member enumerations, static data members, member templates, and
friends; and

(2.2) — the implicit instantiation of the definitions of deleted member functions, unscoped member enumerations,
and member anonymous unions.

The implicit instantiation of a class template specialization does not cause the implicit instantiation of default
arguments or noexcept-specifiers of the class member functions. [Example:

```cpp
template<class T>
struct C {
    void f() { T x; }
    void g() = delete;
};
C<char> c; // OK, definition of C<char>::f is not instantiated at this point
```
— end example —

However, for the purpose of determining whether an instantiated redeclaration is valid
according to 6.2 and 11.3, a declaration that corresponds to a definition in the template is considered to be a
definition. [Example:

```cpp
template<class T, class U>
struct Outer {
    template<class X, class Y>
        struct Inner;

    template<class X> struct Inner<T, Y>; // #1a
    template<class Y> struct Inner<T, Y> { }; // #1b; OK: valid redeclaration of #1a
    template<class Y> struct Inner<U, Y> { }; // #2
};

Outer<int, int> outer; // error at #2
```

Outer<int, int>::Inner<int, Y> is redeclared at #1b. (It is not defined but noted as being associated
with a definition in Outer<T, U>.) #2 is also a redeclaration of #1b. It is noted as associated with a
definition, so it is an invalid redeclaration of the same partial specialization.

```cpp
template< typename T > struct Friendly {
    template< typename U > friend int f(U) { return sizeof(T); } 
};
Friendly<char> fc;
Friendly<float> ff; // ill-formed: produces second definition of f(U)
— end example —

Unless a member of a class template or a member template has been explicitly instantiated or explicitly
specialized, the specialization of the member is implicitly instantiated when the specialization is referenced in
a context that requires the member definition to exist or if the existence of the definition of the member
affects the semantics of the program; in particular, the initialization (and any associated side effects) of a

§ 13.8.1

388
static data member does not occur unless the static data member is itself used in a way that requires the
definition of the static data member to exist.

4 Unless a function template specialization has been explicitly instantiated or explicitly specialized, the function
template specialization is implicitly instantiated when the specialization is referenced in a context that
requires a function definition to exist or if the existence of the definition affects the semantics of the program.
A function whose declaration was instantiated from a friend function definition is implicitly instantiated when
it is referenced in a context that requires a function definition to exist or if the existence of the definition
affects the semantics of the program. Unless a call is to a function template explicit specialization or to a
member function of an explicitly specialized class template, a default argument for a function template or a
member function of a class template is implicitly instantiated when the function is called in a context that
requires the value of the default argument.

5 [Example:

```cpp
template<class T> struct Z {
    void f();
    void g();
};

void h() {
    Z<int> a; // instantiation of class Z<int> required
    Z<char>* p; // instantiation of class Z<char> not required
    Z<double>* q; // instantiation of class Z<double> not required

    a.f(); // instantiation of Z<int>::f() required
    p->g(); // instantiation of class Z<char> required, and
             // instantiation of Z<char>::g() required
}
```

Nothing in this example requires `class Z<double>`, `Z<int>::g()`, or `Z<char>::f()` to be implicitly instan-
tiated. —end example]

6 Unless a variable template specialization has been explicitly instantiated or explicitly specialized, the variable
template specialization is implicitly instantiated when it is referenced in a context that requires a variable
definition to exist or if the existence of the definition affects the semantics of the program. A default template
argument for a variable template is implicitly instantiated when the variable template is referenced in a
context that requires the value of the default argument.

7 The existence of a definition of a variable or function is considered to affect the semantics of the program if
the variable or function is needed for constant evaluation by an expression (7.7), even if constant evaluation
of the expression is not required or if constant expression evaluation does not use the definition.

    [Example:

```cpp
template<typename T> constexpr int f() { return T::value; }
template<bool B, typename T> void g(decltype(B ? f<T>() : 0));
template<bool B, typename T> void g(...);

void x() {
    g<false, int>(0); // OK, B ? f<T>() : 0 is not potentially constant evaluated
    h<false, int>(0); // error, instantiates f<int> even though B evaluates to false and
                      // list-initialization of int from int cannot be narrowing
}
```

—end example]

8 If the function selected by overload resolution (12.3) can be determined without instantiating a class template
definition, it is unspecified whether that instantiation actually takes place. [Example:

```cpp
template <class T> struct S {
    operator int();
};

void f(int);
void f(S<int>&);
void f(S<float>);
```
void g(S<int>& sr) {
    f(sr);  // instantiation of S<int> allowed but not required
    // instantiation of S<float> allowed but not required
};

—end example]
The `noexcept-specifier` of a function template specialization is not instantiated along with the function declaration; it is instantiated when needed (14.4). If such an `noexcept-specifier` is needed but has not yet been instantiated, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the `noexcept-specifier` is done as if it were being done as part of instantiating the declaration of the specialization at that point.

[Note: 13.7.4.1 defines the point of instantiation of a template specialization. — end note]

There is an implementation-defined quantity that specifies the limit on the total depth of recursive instantiations (Annex B), which could involve more than one template. The result of an infinite recursion in instantiation is undefined. [Example:

```cpp
template<class T> class X {
    X<T>* p;    // OK
    X<T> a;    // implicit generation of X<T> requires
                // the implicit instantiation of X<T*> which requires
                // the implicit instantiation of X<T**> which ...
};
```
—end example]

17 The `type-constraints` and `requires-clause` of a template specialization or member function are not instantiated along with the specialization or function itself, even for a member function of a local class; substitution into the atomic constraints formed from them is instead performed as specified in 13.4.2 and 13.4.1.2 when determining whether the constraints are satisfied. [Note: The satisfaction of constraints is determined during name lookup or overload resolution (12.3). — end note] [Example:

```cpp
template< typename T> concept C = sizeof(T) > 2;
template< typename T> concept D = C<T> && sizeof(T) > 4;

template< typename T> struct S {
    S() requires C<T> { }    // #1
    S() requires D<T> { }    // #2
};
```

```cpp
S<char> s1;    // error: no matching constructor
S<char[8]> s2; // OK, calls #2
```

When `S<char>` is instantiated, both constructors are part of the specialization. Their constraints are not satisfied, and they suppress the implicit declaration of a default constructor for `S<char>` (11.3.4.1), so there is no viable constructor for `s1`. — end example] [Example:

```cpp
template< typename T> struct S1 {
    template< typename U>
    requires false
    struct Inner1;    // ill-formed, no diagnostic required
};
```

```cpp
template< typename T> struct S2 {
    template< typename U>
    requires (sizeof(T[-(int)sizeof(T)]) > 1)
    struct Inner2;    // ill-formed, no diagnostic required
};
```

The class `S1<T>::Inner1` is ill-formed, no diagnostic required, because it has no valid specializations. `S2` is ill-formed, no diagnostic required, since no substitution into the constraints of its `Inner2` template would result in a valid expression. — end example]

### 13.8.2 Explicit instantiation [temp.explicit]

1 A class, function, variable, or member template specialization can be explicitly instantiated from its template. A member function, member class or static data member of a class template can be explicitly instantiated from the member definition associated with its class template.
The syntax for explicit instantiation is:

```
explicit-instantiation:
      externopt template declaration
```

There are two forms of explicit instantiation: an explicit instantiation definition and an explicit instantiation declaration. An explicit instantiation declaration begins with the `extern` keyword.

An explicit instantiation shall not use a `storage-class-specifier` (9.1.1) other than `thread_local`. An explicit instantiation of a function template, member function of a class template, or variable template shall not use the `inline`, `constexpr`, or `consteval` specifiers. No `attribute-specifier-seq` (9.11.1) shall appertain to an explicit instantiation.

If the explicit instantiation is for a class or member class, the `elaborated-type-specifier` in the declaration shall include a `simple-template-id`; otherwise, the `declaration` shall be a `simple-declaration` whose `init-declarator-list` comprises a single `init-declarator` that does not have an `initializer`. If the explicit instantiation is for a function or member function, the `unqualified-id` in the `declarator` shall be either a `template-id` or, where all template arguments can be deduced, a `template-name`, `operator-function-id`.  

```
Example:

```template<class T> class Array { void mf(); };```
```template class Array<char>;```
```template void Array<int>::mf();```
```template<class T> void sort(Array<T>& v) { /* ... */ }```
```template void sort(Array<char>&); // argument is deduced here```
```namespace N {
   template<class T> void f(T&) { }
} template void N::f<int>(int&);```

A declaration of a function template, a variable template, a member function or static data member of a class template, or a member function template of a class or class template shall precede an explicit instantiation of that entity. A definition of a class template, a member class of a class template, or a member class template of a class or class template shall precede an explicit instantiation of that entity unless the explicit instantiation is preceded by an explicit specialization of the entity with the same template arguments. If the `declaration` of the explicit instantiation names an implicitly-declared special member function (11.3.3), the program is ill-formed.

The `declaration` in an `explicit-instantiation` and the `declaration` produced by the corresponding substitution into the templated function, variable, or class are two declarations of the same entity.  

```
Example:

```template<typename T> T var = {};```
```template float var<float>; // OK, instantiated variable has type float```
```template int var<int[16]>[]; // OK, absence of major array bound is permitted```
```template int *var<int>*; // error: instantiated variable has type int```
```template<typename T> auto av = T();```
```template int av<int>; // OK, variable with type int can be redeclared with type auto```
```template<typename T> auto f() {}```
```template void f<int>(); // error: function with deduced return type```

§ 13.8.2
Despite its syntactic form, the declaration in an explicit-instantiation for a variable is not itself a definition and does not conflict with the definition instantiated by an explicit instantiation definition for that variable.

For a given set of template arguments, if an explicit instantiation of a template appears after a declaration of an explicit specialization for that template, the explicit instantiation has no effect. Otherwise, for an explicit instantiation definition the definition of a function template, a variable template, a member function template, or a member function or static data member of a class template shall be present in every translation unit in which it is explicitly instantiated.

An explicit instantiation of a class, function template, or variable template specialization is placed in the namespace in which the template is defined. An explicit instantiation for a member of a class template is placed in the namespace where the enclosing class template is defined. An explicit instantiation for a member template is placed in the namespace where the enclosing class or class template is defined. [Example:

```cpp
namespace N {
    template<class T> class Y { void mf() { } };
}

using N::Y;
template class Y<int>;
// error: class template Y not visible in the global namespace

template class N::Y<char*>;
// OK: explicit instantiation in namespace N
template void N::Y<double>::mf();
// OK: explicit instantiation in namespace N
```
—end example]

A trailing template-argument can be left unspecified in an explicit instantiation of a function template specialization or of a member function template specialization provided it can be deduced from the type of a function parameter (13.9.2). [Example:

```cpp
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

// instantiate sort(Array<int>&) – template-argument deduced
template void sort<>()
```
—end example]

A trailing template-argument can be left unspecified in an explicit instantiation of a function template specialization or of a member function template specialization provided it can be deduced from the type of a function parameter (13.9.2). [Example:

```cpp
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

// instantiate sort(Array<int>&) – template-argument deduced
```
—end example]

[Note: An explicit instantiation of a constrained template shall satisfy that template’s associated constraints (13.4.2). The satisfaction of constraints is determined when forming the template name of an explicit instantiation in which all template arguments are specified (13.2), or, for explicit instantiations of function templates, during template argument deduction (13.9.2.6) when one or more trailing template arguments are left unspecified. —end note]

An explicit instantiation that names a class template specialization is also an explicit instantiation of the same kind (declaration or definition) of each of its members (not including members inherited from base classes and members that are templates) that has not been previously explicitly specialized in the translation unit containing the explicit instantiation, provided that the associated constraints, if any, of that member are satisfied by the template arguments of the explicit instantiation (13.4.2, 13.4.1), except as described below. [Note: In addition, it will typically be an explicit instantiation of certain implementation-dependent data about the class. —end note]

An explicit instantiation definition that names a class template specialization explicitly instantiates the class template specialization and is an explicit instantiation definition of only those members that have been defined at the point of instantiation.

Except for inline functions and variables, declarations with types deduced from their initializer or return value (9.1.7.5), const variables of literal types, variables of reference types, and class template specializations, explicit instantiation declarations have the effect of suppressing the implicit instantiation of the definition of the entity to which they refer. [Note: The intent is that an inline function that is the subject of an explicit instantiation declaration will still be implicitly instantiated when odr-used (6.2) so that the body can be considered for inlining, but that no out-of-line copy of the inline function would be generated in the translation unit. —end note]
If an entity is the subject of both an explicit instantiation declaration and an explicit instantiation definition in the same translation unit, the definition shall follow the declaration. An entity that is the subject of an explicit instantiation declaration and that is also used in a way that would otherwise cause an implicit instantiation (13.8.1) in the translation unit shall be the subject of an explicit instantiation definition somewhere in the program; otherwise the program is ill-formed, no diagnostic required. [Note: This rule does apply to inline functions even though an explicit instantiation declaration of such an entity has no other normative effect. This is needed to ensure that if the address of an inline function is taken in a translation unit in which the implementation chose to suppress the out-of-line body, another translation unit will supply the body. —end note] An explicit instantiation declaration shall not name a specialization of a template with internal linkage.

An explicit instantiation does not constitute a use of a default argument, so default argument instantiation is not done. [Example:

```c
char* p = 0;
template<class T> T g(T x = &p) { return x; }
template int g<int>(int); // OK even though &p isn't an int.
```
—end example]

### 13.8.3 Explicit specialization

1. An explicit specialization of any of the following:
   (1.1) — function template
   (1.2) — class template
   (1.3) — variable template
   (1.4) — member function of a class template
   (1.5) — static data member of a class template
   (1.6) — member class of a class template
   (1.7) — member enumeration of a class template
   (1.8) — member class template of a class or class template
   (1.9) — member function template of a class or class template

can be declared by a declaration introduced by `template<>`; that is:

```
explicit-specialization:
template <> declaration
```

[Example:

```c
template<class T> class stream;
template<> class stream<char> { /* ... */ };
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

template<> void sort<char*>(Array<char*>&);
```
Given these declarations, `stream<char>` will be used as the definition of streams of `char`; other streams will be handled by class template specializations instantiated from the class template. Similarly, `sort<char*>` will be used as the sort function for arguments of type `Array<char*>`; other `Array` types will be sorted by functions generated from the template. —end example]

2. An explicit specialization shall not use a `storage-class-specifier` (9.1.1) other than `thread_local`.

3. An explicit specialization may be declared in any scope in which the corresponding primary template may be defined (9.7.1.2, 11.3, 13.6.2).

4. A declaration of a function template, class template, or variable template being explicitly specialized shall precede the declaration of the explicit specialization. [Note: A declaration, but not a definition of the template is required. —end note] The definition of a class or class template shall precede the declaration of an explicit specialization for a member template of the class or class template. [Example:

```c
template<> class X<int> { /* ... */ };
```
` error: X not a template`
A member function, a member function template, a member class, a member enumeration, a member class template, a static data member, or a static data member template of a class template may be explicitly specialized for a class specialization that is implicitly instantiated; in this case, the definition of the class template shall precede the explicit specialization for the member of the class template. If such an explicit specialization for the member of a class template names an implicitly-declared special member function (11.3.3), the program is ill-formed.

A member of an explicitly specialized class is not implicitly instantiated from the member declaration of the class template; instead, the member of the class template specialization shall itself be explicitly defined if its definition is required. In this case, the definition of the class template explicit specialization shall be in scope at the point at which the member is defined. The definition of an explicitly specialized class is unrelated to the definition of a generated specialization. That is, its members need not have the same names, types, etc. as the members of a generated specialization. Members of an explicitly specialized class template are defined in the same manner as members of normal classes, and not using the template<> syntax. The same is true when defining a member of an explicitly specialized member class. However, template<> is used in defining a member of an explicitly specialized member class template that is specialized as a class template. [Example:

```c++

template<class T> struct A {
    struct B {
    }
    template<class U> struct C {
    }
};

template<> struct A<int> {
    void f(int);
};

void h() {
    A<int> a;
    a.f(16); // A<int>::f must be defined somewhere
}

// template<> not used for a member of an explicitly specialized class template
void A<int>::f(int) { /* ... */ }

// template<> also not used when defining a member of an explicitly specialized member class
template<> struct A<char>::B {
    void f();
};

void A<char>::B::f() { /* ... */ }

// template<> is used when defining a member of an explicitly specialized member class template
// specialized as a class template

// template<> required
```
If a template, a member template or a member of a class template is explicitly specialized then that specialization shall be declared before the first use of that specialization that would cause an implicit instantiation to take place, in every translation unit in which such a use occurs; no diagnostic is required. If the program does not provide a definition for an explicit specialization and either the specialization is used in a way that would cause an implicit instantiation to take place or the member is a virtual member function, the program is ill-formed, no diagnostic required. An implicit instantiation is never generated for an explicit specialization that is declared but not defined. [Example:

```cpp
class String {
};
template<class T> class Array { /* ... */
};
template<class T> void sort(Array<T>& v) { /* ... */

void f(Array<String>& v) {
    sort(v);
    // use primary template sort(Array<T>&), T is String
}

template<> void sort<String>(Array<String>& v);  // error: specialization after use of primary template
template<> void sort<typename Array<char>*>(Array<T>&)  
// OK: sort<String> not yet used

template<class T> struct A {
    enum E : T;
    enum class S : T;
};
template<> enum A<int>::E : int { eint };  // OK
template<> enum A<int>::S : int { sint };  // OK

template<class T> enum A<T>::E : T { eT }
// OK

template<class T> enum A<T>::S : T { sT }
// OK

template<> enum A<char>::E : char { echar }
// ill-formed, A<char>::E was instantiated when A<char> was instantiated

template<> enum A<char>::S : char { schar };  // OK
```

—end example]

The placement of explicit specialization declarations for function templates, class templates, variable templates, member functions of class templates, static data members of class templates, member classes of class templates, member enumerations of class templates, member class templates of class templates, member function templates of class templates, static data member templates of class templates, member functions of member templates of non-template classes, static data member templates of non-template classes, member function templates of class templates, etc., and the placement of partial specialization declarations of class templates, variable templates, member classes of non-template classes, static data member templates of non-template classes, member class templates of class templates, etc., can affect whether a program is well-formed according to the relative positioning of the explicit specialization declarations and their points of instantiation in the translation unit as specified above and below. When writing a specialization, be careful about its location; or to make it compile will be such a trial as to kindle its self-immolation.

A template explicit specialization is in the scope of the namespace in which the template was defined. [Example:

```cpp
namespace N {
    template<class T> class X { /* ... */
    template<class T> class Y { /* ... */

    template<> class X<int> { /* ... */
    template<> class Y<double>;
    // forward-declare intent to specialize for double

    template<> class N::Y<double>{ /* ... */
    template<> class N::Y<short> { /* ... */
    // OK: specialization in enclosing namespace

    } // N::Y<brace-closure>

    } // N::Y<brace-closure>

    } // N::Y<brace-closure>

    } // N::Y<brace-closure>

} // N<brace-closure>
```

—end example]

A simple-template-id that names a class template explicit specialization that has been declared but not defined can be used exactly like the names of other incompletely-defined classes (6.7). [Example:

```cpp
template<class T> class X;
template<> class X<int>;
```

X is a class template
X<int>* p; // OK: pointer to declared class X<int>
X<int> x;  // error: object of incomplete class X<int>

—end example

A trailing template-argument can be left unspecified in the template-id naming an explicit function template specialization provided it can be deduced from the function argument type. [Example:

```c
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v);
    // explicit specialization for sort(Array<int>&)
    // with deduced template-argument of type int
    template<> void sort(Array<int>&);
—end example
```

12 [Note: An explicit specialization of a constrained template shall satisfy that template’s associated constraints (13.4.2). The satisfaction of constraints is determined when forming the template name of an explicit specialization in which all template arguments are specified (13.2), or, for explicit specializations of function templates, during template argument deduction (13.9.2.6) when one or more trailing template arguments are left unspecified. — end note]

A function with the same name as a template and a type that exactly matches that of a template specialization is not an explicit specialization (13.6.6).

14 An explicit specialization of a function or variable template is inline only if it is declared with the inline specifier or defined as deleted, and independently of whether its function or variable template is inline. [Example:

```c
template<class T> void f(T) { /* ... */ }
template<class T> inline T g(T) { /* ... */ }
    // OK: inline
    template<> inline void f<>(int) { /* ... */ }
    // OK: not inline
—end example
```

15 [Note: For an explicit specialization of a function template, the contract conditions (9.11.4) of the explicit specialization are independent of those of the primary template. — end note]

An explicit specialization of a static data member of a template or an explicit specialization of a static data member template is a definition if the declaration includes an initializer; otherwise, it is a declaration. [Note: The definition of a static data member of a template that requires default-initialization must use a braced-init-list:

```c
template<> X Q<int>::x; // declaration
template<> X Q<int>::x (); // error: declares a function
template<> X Q<int>::x {}; // definition
—end note
```

17 A member or a member template of a class template may be explicitly specialized for a given implicit instantiation of the class template, even if the member or member template is defined in the class template definition. An explicit specialization of a member or member template is specified using the syntax for explicit specialization. [Example:

```c
template<class T> struct A {
    void f(T);
    template<class X1> void g1(T, X1);
    template<class X2> void g2(T, X2);
    void h(T) { }
};
    // specialization
    template<> void A<int>::f(int);
    // out of class member template definition
    template<class T> template<class X1> void A<T>::::g1(T, X1) { }
A member or a member template may be nested within many enclosing class templates. In an explicit specialization for such a member, the member declaration shall be preceded by a template<> for each enclosing class template that is explicitly specialized. [Example:

```cpp
template<class T1> class A {
    template<class T2> class B {
        void mf();
    };
    template<> template<> class A<int>::B<double>;
    template<> template<> template<class T> void A<int>::B<double>::mf1(T t) { }
    template <class Y> template <>
    void A<Y>::B<double>::mf2() { } // ill-formed; B<double> is specialized but its enclosing class template A is not
};
```

— end example]

20 A specialization of a member function template, member class template, or static data member template of a non-specialized class template is itself a template.

21 An explicit specialization declaration shall not be a friend declaration.

22 Default function arguments shall not be specified in a declaration or a definition for one of the following explicit specializations:

(22.1) — the explicit specialization of a function template;

(22.2) — the explicit specialization of a member function template;

(22.3) — the explicit specialization of a member function of a class template where the class template specialization to which the member function specialization belongs is implicitly instantiated. [Note: Default function arguments may be specified in the declaration or definition of a member function of a class template specialization that is explicitly specialized. — end note]

§ 13.8.3
13.9 Function template specializations

A function instantiated from a function template is called a function template specialization; so is an explicit specialization of a function template. Template arguments can be explicitly specified when naming the function template specialization, deduced from the context (e.g., deduced from the function arguments in a call to the function template specialization, see 13.9.2), or obtained from default template arguments.

1 Each function template specialization instantiated from a template has its own copy of any static variable.

[Example:

```cpp
template<class T> void f(T* p) {
    static T s;
}

void g(int a, char* b) {
    f(&a); // calls f<int>(int*)
    f(&b); // calls f<char*>(char**)  
}
```

Here `f<int>(int*)` has a static variable `s` of type `int` and `f<char*>(char**)` has a static variable `s` of type `char*`. — end example]

13.9.1 Explicit template argument specification

Template arguments can be specified when referring to a function template specialization that is not a specialization of a constructor template by qualifying the function template name with the list of template-arguments in the same way as template-arguments are specified in uses of a class template specialization.

[Example:

```cpp
template<class T> void sort(Array<T>& v);
void f(Array<dcomplex>& cv, Array<int>& ci) {
    sort<dcomplex>(cv); // sort(Array<dcomplex>&)
    sort<int>(ci); // sort(Array<int>&)
}
```

and

```cpp
template<class U, class V> U convert(V v);
void g(double d) {
    int i = convert<int,double>(d); // int convert(double)
    char c = convert<char,double>(d); // char convert(double)
}
```

— end example]

2 Template arguments shall not be specified when referring to a specialization of a constructor template (11.3.4, 6.4.3.1).

3 A template argument list may be specified when referring to a specialization of a function template

(3.1) — when a function is called,

(3.2) — when the address of a function is taken, when a function initializes a reference to function, or when a pointer to member function is formed,

(3.3) — in an explicit specialization,

(3.4) — in an explicit instantiation, or

(3.5) — in a friend declaration.

4 Trailing template arguments that can be deduced (13.9.2) or obtained from default template-arguments may be omitted from the list of explicit template-arguments. A trailing template parameter pack (13.6.3) not otherwise deduced will be deduced as an empty sequence of template arguments. If all of the template arguments can be deduced, they may all be omitted; in this case, the empty template argument list `<>` itself may also be omitted. In contexts where deduction is done and fails, or in contexts where deduction is not done, if a template argument list is specified and it, along with any default template arguments, identifies a single function template specialization, then the template-id is an lvalue for the function template specialization. [Example:

```cpp
template<class X, class Y> X f(Y);
```
template<class X, class Y, class ... Z> X g(Y);

void h() {
    int i = f<int>(5.6); // Y deduced as double
    int j = f(5.6); // ill-formed: X cannot be deduced
    f<void>(f<int, bool>); // ill-formed: f<int> does not denote a single function template specialization
    int k = g<int>(5.6); // Y deduced as double; Z deduced as an empty sequence
    f<void>(g<int, bool>); // Y for outer f deduced as int (*)(bool), // Z deduced as an empty sequence
}

— end example

5 [Note: An empty template argument list can be used to indicate that a given use refers to a specialization of a function template even when a non-template function (9.2.3.5) is visible that would otherwise be used. For example:

    template <class T> int f(T); // #1
    int f(int); // #2
    int k = f(1); // uses #2
    int l = f<> (1); // uses #1

— end note]

6 Template arguments that are present shall be specified in the declaration order of their corresponding template-parameters. The template argument list shall not specify more template-arguments than there are corresponding template-parameters unless one of the template-parameters is a template parameter pack.

    [Example:
     template<class X, class Y, class Z> X f(Y,Z);
     template<class ... Args> void f2();
     void g() {
       f<int*, const char*, double*, "aa", 3.0>;
       f<int*, const char*, "aa", 3.0>; // Z deduced as double
       f<int*, const char*>("aa",3.0); // Y deduced as const char*; Z deduced as double
       f<double*, 3.0>; // error: X cannot be deduced
       f2<char, short, int, long>(); // OK
     }
     — end example]

7 Implicit conversions (7.3) will be performed on a function argument to convert it to the type of the corresponding function parameter if the parameter type contains no template-parameters that participate in template argument deduction. [Note: Template parameters do not participate in template argument deduction if they are explicitly specified. For example,

    template<class T> void f(T);
    class Complex {
      Complex(double);
    };
    void g() {
      f<Complex>(1); // OK, means f<Complex>(Complex(1))
    }
    — end note]

8 [Note: Because the explicit template argument list follows the function template name, and because constructor templates (11.3.4) are named without using a function name (6.4.3.1), there is no way to provide an explicit template argument list for these function templates. — end note]

9 Template argument deduction can extend the sequence of template arguments corresponding to a template parameter pack, even when the sequence contains explicitly specified template arguments. [Example:

    template<class ... Types> void f(Types ... values);
    void g() {
      f<int*, float*>(0, 0, 0); // Types deduced as the sequence int*, float*, int
    }

§ 13.9.1 400
13.9.2 Template argument deduction

When a function template specialization is referenced, all of the template arguments shall have values. The values can be explicitly specified or, in some cases, be deduced from the use or obtained from default template-arguments. [Example:

```cpp
void f(Array<dcomplex>& cv, Array<int>& ci) {
    sort(cv); // calls sort(Array<dcomplex>&)
    sort(ci); // calls sort(Array<int>&)
}
```

and

```cpp
void g(double d) {
    int i = convert<int>(d); // calls convert<int,double>(double)
    int c = convert<char>(d); // calls convert<char,double>(double)
}
```

—end example]

When an explicit template argument list is specified, if the given template-id is not valid (13.2), type deduction fails. Otherwise, the specified template argument values are substituted for the corresponding template parameters as specified below.

After this substitution is performed, the function parameter type adjustments described in 9.2.3.5 are performed. [Example: A parameter type of “void (const int, int[5])” becomes “void(*)(int,int*)”. —end example] [Note: A top-level qualifier in a function parameter declaration does not affect the function type but still affects the type of the function parameter variable within the function. —end note] [Example:

```cpp
template <class T> void f(T t);
template <class X> void g(const X x);
template <class Z> void h(Z, Z*);
```

```cpp
int main() {
    // #1: function type is f(int), t is non const
    f<int>(1);
    // #2: function type is f(int), t is const
    f<const int>(1);
    // #3: function type is g(int), x is const
    g<int>(1);
    // #4: function type is g(int), x is const
    g<const int>(1);
    // #5: function type is h(int, const int*)
    h<const int>(1,0);
}
```

—end example]

[f<int>(1) and f<const int>(1) call distinct functions even though both of the functions called have the same function type. —end note]

The resulting substituted and adjusted function type is used as the type of the function template for template argument deduction. If a template argument has not been deduced and its corresponding template parameter has a default argument, the template argument is determined by substituting the template arguments determined for preceding template parameters into the default argument. If the substitution results in an invalid type, as described above, type deduction fails. [Example:

```cpp
template <class T, class U = double>
void f(T t = 0, U u = 0);
```

```cpp
void g() {
    f(1, 'c'); // f<int,char>(1,'c')
    f(1); // f<int,double>(1,0)
}
```
f(); // error: T cannot be deduced
f<int>(); // f<int, double>(0, 0)
f<int, char>(); // f<int, char>(0, 0)
}

—end example]

When all template arguments have been deduced or obtained from default template arguments, all uses of template parameters in the template parameter list of the template and the function type are replaced with the corresponding deduced or default argument values. If the substitution results in an invalid type, as described above, type deduction fails. If the function template has associated constraints (13.4.2), those constraints are checked for satisfaction (13.4.1). If the constraints are not satisfied, type deduction fails.

At certain points in the template argument deduction process it is necessary to take a function type that makes use of template parameters and replace those template parameters with the corresponding template arguments. This is done at the beginning of template argument deduction when any explicitly specified template arguments are substituted into the function type, and again at the end of template argument deduction when any template arguments that were deduced or obtained from default arguments are substituted.

The substitution occurs in all types and expressions that are used in the function type and in template parameter declarations. The expressions include not only constant expressions such as those that appear in array bounds or as nontype template arguments but also general expressions (i.e., non-constant expressions) inside sizeof, decltype, and other contexts that allow non-constant expressions. The substitution proceeds in lexical order and stops when a condition that causes deduction to fail is encountered. If substitution into different declarations of the same function template would cause template instantiations to occur in a different order or not at all, the program is ill-formed; no diagnostic required. [Note: The equivalent substitution in exception specifications is done only when the noexcept-specifier is instantiated, at which point a program is ill-formed if the substitution results in an invalid type or expression. — end note]

Example:

```cpp
template <class T> struct A { using X = typename T::X; };
template <class T> typename T::X f(typename A<T>::X);
template <class T> void f(...)
{
}
template <class T> typename T::X g(typename A<T>::X) -> typename T::X;
template <class T> void g(...)
{
}
template <class T> typename T::X h(typename A<T>::X);
template <class T> auto h(typename A<T>::X) -> typename T::X; // redeclaration
template <class T> void h(...)
{
}
void x()
{
    f<int>(0); // OK, substituting return type causes deduction to fail
    g<int>(0); // error, substituting parameter type instantiates A<int>
    h<int>(0); // ill-formed, no diagnostic required
}
—end example]
```

If a substitution results in an invalid type or expression, type deduction fails. An invalid type or expression is one that would be ill-formed, with a diagnostic required, if written using the substituted arguments. [Note: If no diagnostic is required, the program is still ill-formed. Access checking is done as part of the substitution process. — end note] Only invalid types and expressions in the immediate context of the function type, its template parameter types, and its explicit-specifier can result in a deduction failure. [Note: The substitution into types and expressions can result in effects such as the instantiation of class template specializations and/or function template specializations, the generation of implicitly-defined functions, etc. Such effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

A lambda-expression appearing in a function type or a template parameter is not considered part of the immediate context for the purposes of template argument deduction. [Note: The intent is to avoid requiring implementations to deal with substitution failure involving arbitrary statements. [Example:

```cpp
template <class T>
    auto f(T) -> decltype([]() { T::invalid; }());
void f(...);
    f(0); // error: invalid expression not part of the immediate context
```
Example:

```cpp
template <class T, std::size_t = sizeof([]() { T::invalid; })>
void g(T);
void g(...);
g(0); // error: invalid expression not part of the immediate context

template <class T>
auto h(T) -> decltype([]() { })
void h(...);
h(0); // error: invalid expression not part of the immediate context

template <class T>
auto i(T) -> decltype([]() -> typename T::invalid { });
void i(...);
i(0); // error: invalid expression not part of the immediate context

template <class T>
auto j(T t) -> decltype([](auto x) -> decltype(x.invalid) { } (t)); // #1
void j(...); // #2
j(0); // deduction fails on #1, calls #2
```

—end example] — end note]

[Example:

```cpp
struct X { };
struct Y {
    Y(X){}
};

template <class T> auto f(T t1, T t2) -> decltype(t1 + t2); // #1
X f(Y, Y); // #2

X x1, x2;
X x3 = f(x1, x2); // deduction fails on #1 (cannot add X+X), calls #2
```

—end example]

[Note: Type deduction may fail for the following reasons:

(11.1) Attempting to instantiate a pack expansion containing multiple packs of differing lengths.

(11.2) Attempting to create an array with an element type that is void, a function type, or a reference type, or attempting to create an array with a size that is zero or negative. [Example:

```cpp
template <class T> int f(T[5]);
int I = f<int>(0);
int j = f<void>(0); // invalid array
```

— end example]

(11.3) Attempting to use a type that is not a class or enumeration type in a qualified name. [Example:

```cpp
template <class T> int f(typename T::B*);
int i = f<int>(0);
```

— end example]

(11.4) Attempting to use a type in a nested-name-specifier of a qualified-id when that type does not contain the specified member, or

(11.4.1) the specified member is not a type where a type is required, or

(11.4.2) the specified member is not a template where a template is required, or

(11.4.3) the specified member is not a non-type where a non-type is required.

[Example:

```cpp
template <int I> struct X { };
template <template <class T> class> struct Z { };
template <class T> void f(typename T::Y*){}
template <class T> void g<X<T::N>>(){}
template <class T> void h<Z<T::template TT>>(){}
```
struct A {};  
struct B { int Y; };  
struct C {  
    typedef int N; 
};  
struct D {  
    typedef int TT; 
};

int main() {  
    // Deduction fails in each of these cases:  
    f<A>(0); // a does not contain a member Y  
    f<B>(0); // The Y member of B is not a type  
    g<C>(0); // The N member of C is not a non-type  
    h<D>(0); // The TT member of D is not a template
    
    — end example

— Attempting to create a pointer to reference type.
— Attempting to create a reference to void.
— Attempting to create “pointer to member of T” when T is not a class type. [Example:
    template <class T> int f(int T::*);
    int i = f<int>(0);  
    — end example

— Attempting to give an invalid type to a non-type template parameter. [Example:
    template <class T, T> struct S {};  
    template <class T> int f(S<T, T>()*);
    struct X {};  
    int i0 = f<X>(0);  
    — end example

— Attempting to perform an invalid conversion in either a template argument expression, or an expression used in the function declaration. [Example:
    template <class T, T*> int f(int);
    int i2 = f<int,1>(0); // can’t conv 1 to int*  
    — end example

— Attempting to create a function type in which a parameter has a type of void, or in which the return type is a function type or array type.
— end note

[Example: In the following example, assuming a signed char cannot represent the value 1000, a narrowing conversion (9.3.4) would be required to convert the template-argument of type int to signed char, therefore substitution fails for the second template (13.3.2).

    template <int> int f(int);
    template <signed char> int f(int);
    int i1 = f<1000>(0); // OK
    int i2 = f<1>(0);    // ambiguous; not narrowing
    — end example

13.9.2.1 Deducing template arguments from a function call [temp.deduct.call]

Template argument deduction is done by comparing each function template parameter type (call it P) that contains template-parameters that participate in template argument deduction with the type of the corresponding argument of the call (call it A) as described below. If removing references and cv-qualifiers from P gives std::initializer_list<P'> or P'[N] for some P' and N and the argument is a non-empty initializer list (9.3.4), then deduction is performed instead for each element of the initializer list independently, taking P' as separate function template parameter types P'_j and the jth initializer element as the corresponding argument. In the P'[N] case, if N is a non-type template parameter, N is deduced from the length of the
initializer list. Otherwise, an initializer list argument causes the parameter to be considered a non-deduced context (13.9.2.5). [Example:

```cpp
template<class T> void f(std::initializer_list<T>);  
f({1,2,3});  // T deduced as int
f({1, "asdf"});  // error: T deduced as both int and const char*

template<class T> void g(T);  
g({1,2,3});  // error: no argument deduced for T

template<class T, int N> void h(T const(&)[N]);  
h({1,2,3});  // T deduced as int; N deduced as 3

template<class T> void j(T const(&)[3]);  
j({42});  // T deduced as int; array bound not considered

struct Aggr { int i; int j; };  
template<typename N> void k(Aggr const(&)[N]);  
k({1,2,3});  // error: deduction fails, no conversion from int to Aggr
k({{{1},{2},{3}}});  // OK, N deduced as 3

template<int M, int N> void m(int const(&)[M][N]);  
m({{{1},{2},{3}}},Aggr());  // OK, T is Aggr, N is 3

template<typename T, int N> void o(T (* const (&)[N])(T)) { }  
o({ &f1, &f4 });  // OK, T deduced as int from first element, nothing
do({ &f1, static_cast<char(*)(char)>(&f4) });  // deduced from second element, N deduced as 2
```

—end example] For a function parameter pack that occurs at the end of the parameter-declaration-list, deduction is performed for each remaining argument of the call, taking the type \( P \) of the declarator-id of the function parameter pack as the corresponding function template parameter type. Each deduction deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. When a function parameter pack appears in a non-deduced context (13.9.2.5), the type of that pack is never deduced. [Example:

```cpp
template<class ... Types> void f(Types& ...);  
template<class T1, class ... Types> void g(T1, Types ...);  
template<class T1, class ... Types> void g1(Types ..., T1);  

void h(int x, float& y) {  
  const int z = x;  
f(x, y, z);  // Types deduced as int, float, const int
g(x, y, z);  // T1 deduced as int; Types deduced as float, int
gl(x, y, z);  // error: Types is not deduced
gl<int, int, int>(x, y, z);  // OK, no deduction occurs
}
```

—end example]

2 If \( P \) is not a reference type:

- If \( A \) is an array type, the pointer type produced by the array-to-pointer standard conversion (7.3.2) is used in place of \( A \) for type deduction; otherwise,
- If \( A \) is a function type, the pointer type produced by the function-to-pointer standard conversion (7.3.3) is used in place of \( A \) for type deduction; otherwise,
- If \( A \) is a cv-qualified type, the top-level cv-qualifiers of \( A \)'s type are ignored for type deduction.

3 If \( P \) is a cv-qualified type, the top-level cv-qualifiers of \( P \)'s type are ignored for type deduction. If \( P \) is a reference type, the type referred to by \( P \) is used for type deduction. [Example:
template<class T> int f(const T&);
int n1 = f(5); // calls f<int>(const int&)
const int i = 0;
int n2 = f(i); // calls f<int>(const int&)
template<class T> int g(volatile T&);
int n3 = g(i); // calls g<const int&>(const volatile int&)

— end example] A forwarding reference is an rvalue reference to a cv-unqualified template parameter that does not represent a template parameter of a class template (during class template argument deduction (12.3.1.8)). If \( P \) is a forwarding reference and the argument is an lvalue, the type "lvalue reference to \( A \)" is used in place of \( A \) for type deduction. [Example:

```
template<class T> int f(T&& heisenreference);
template<class T> int g(const T&&);
int i;
n1 = f(i); // calls f<int&>(int&)
n2 = f(0); // calls f<int>(int&&)
n3 = g(i); // error: would call g<int>(const int&&), which
           // would bind an rvalue reference to an lvalue
```

```
template<class T> struct A {
    template<class U>
    A(T&&, U&&, int*); // #1: T&& is not a forwarding reference.
                        // U&& is a forwarding reference.
    A(T&&, int*); // #2
};

template<class T> A(T&&, int*) -> A<T>; // #3: T&& is a forwarding reference.
```

int *ip;
A a{i, 0, ip}; // error: cannot deduce from #1
A a0{0, 0, ip}; // uses #1 to deduce A<int> and #1 to initialize
A a2{i, ip}; // uses #3 to deduce A<int&> and #2 to initialize

— end example]

4 In general, the deduction process attempts to find template argument values that will make the deduced \( A \) identical to \( A \) (after the type \( A \) is transformed as described above). However, there are three cases that allow a difference:

(4.1) — If the original \( P \) is a reference type, the deduced \( A \) (i.e., the type referred to by the reference) can be more cv-qualified than the transformed \( A \).

(4.2) — The transformed \( A \) can be another pointer or pointer-to-member type that can be converted to the deduced \( A \) via a function pointer conversion (7.3.13) and/or qualification conversion (7.3.5).

(4.3) — If \( P \) is a class and \( P \) has the form `simple-template-id`, then the transformed \( A \) can be a derived class \( D \) of the deduced \( A \). Likewise, if \( P \) is a pointer to a class of the form `simple-template-id`, the transformed \( A \) can be a pointer to a derived class \( D \) pointed to by the deduced \( A \). However, if there is a class \( C \) that is a (direct or indirect) base class of \( D \) and derived (directly or indirectly) from a class \( B \) and that would be a valid deduced \( A \), the deduced \( A \) cannot be \( B \) or pointer to \( B \), respectively. [Example:

```
template<typeNAME... > T struct X;
template <> struct X<> {}; // #1: template parameter not used
template<typeNAME T, typeNAME... Ts> struct X<T, Ts...>; // #2: template parameter used
struct D : X<int> {}; // #3: template parameter used
```

```
template<typeNAME... > T
int f(const X<Ts...>&);
int x = f(D()); // calls f<int>, not f<>
// B is X<>, C is X<int>
```

— end example]

5 These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced \( A \), the type deduction fails. [Note: If a template-parameter is not used in any of the function parameters of a function template, or is used only in a non-deduced context, its corresponding

§ 13.9.2.1

406
Template arguments cannot be deduced from a function call and the template argument must be explicitly specified. —end note

6 When \( P \) is a function type, function pointer type, or pointer-to-member-function type:

(6.1) If the argument is an overload set containing one or more function templates, the parameter is treated as a non-deduced context.

(6.2) If the argument is an overload set (not containing function templates), trial argument deduction is attempted using each of the members of the set. If deduction succeeds for only one of the overload set members, that member is used as the argument value for the deduction. If deduction succeeds for more than one member of the overload set the parameter is treated as a non-deduced context.

7 [Example:

// Only one function of an overload set matches the call so the function parameter is a deduced context.
template <class T> int f(T (*p)(T));
int g(int);
int i = f(g); // calls f(int (*)(int))
@end example]

8 [Example:

// Ambiguous deduction causes the second function parameter to be a non-deduced context.
template <class T> int f(T, T (*p)(T));
int g(int);
char g(char);
int i = f(1, g); // calls f(int, int (*)(int))
@end example]

9 [Example:

// The overload set contains a template, causing the second function parameter to be a non-deduced context.
template <class T> int f(T, T (*p)(T));
char g(char);
template <class T> T g(T);
int i = f(1, g); // calls f(int, int (*)(int))
@end example]

10 If deduction succeeds for all parameters that contain template parameters that participate in template argument deduction, and all template arguments are explicitly specified, deduced, or obtained from default template arguments, remaining parameters are then compared with the corresponding arguments. For each remaining parameter \( P \) with a type that was non-dependent before substitution of any explicitly-specified template arguments, if the corresponding argument \( A \) cannot be implicitly converted to \( P \), deduction fails.

[Note: Parameters with dependent types in which no template parameters participate in template argument deduction, and parameters that became non-dependent due to substitution of explicitly-specified template arguments, will be checked during overload resolution. —end note]

13.9.2.2 Deducing template arguments taking the address of a function template [temp.deduct.funcaddr]

Template arguments can be deduced from the type specified when taking the address of an overloaded function (12.4). The function template's function type and the specified type are used as the types of \( P \) and \( A \), and the deduction is done as described in 13.9.2.5.
A placeholder type (9.1.7.5) in the return type of a function template is a non-deduced context. If template argument deduction succeeds for such a function, the return type is determined from instantiation of the function body.

### 13.9.2.3 Deducing conversion function template arguments

Template argument deduction is done by comparing the return type of the conversion function template (call it \( P \)) with the type that is required as the result of the conversion (call it \( A \); see 9.3, 12.3.1.5, and 12.3.1.6 for the determination of that type) as described in 13.9.2.5.

1. If \( P \) is a reference type, the type referred to by \( P \) is used in place of \( P \) for type deduction and for any further references to or transformations of \( P \) in the remainder of this subclause.
2. If \( A \) is not a reference type:
   - If \( P \) is an array type, the pointer type produced by the array-to-pointer standard conversion (7.3.2) is used in place of \( P \) for type deduction; otherwise,
   - If \( P \) is a function type, the pointer type produced by the function-to-pointer standard conversion (7.3.3) is used in place of \( P \) for type deduction; otherwise,
   - If \( P \) is a cv-qualified type, the top-level cv-qualifiers of \( P \)'s type are ignored for type deduction.
3. If \( A \) is a cv-qualified type, the top-level cv-qualifiers of \( A \)'s type are ignored for type deduction. If \( A \) is a reference type, the type referred to by \( A \) is used for type deduction.
4. In general, the deduction process attempts to find template argument values that will make the deduced \( A \) identical to \( A \). However, there are four cases that allow a difference:
   - If the original \( A \) is a reference type, \( A \) can be more cv-qualified than the deduced \( A \) (i.e., the type referred to by the reference)
   - If the original \( A \) is a function pointer type, \( A \) can be “pointer to function” even if the deduced \( A \) is “pointer to noexcept function”.
   - If the original \( A \) is a pointer-to-member-function type, \( A \) can be “pointer to member of type function” even if the deduced \( A \) is “pointer to member of type noexcept function”.
   - The deduced \( A \) can be another pointer or pointer-to-member type that can be converted to \( A \) via a qualification conversion.
5. These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced \( A \), the type deduction fails.

### 13.9.2.4 Deducing template arguments during partial ordering

Template argument deduction is done by comparing certain types associated with the two function templates being compared.

Two sets of types are used to determine the partial ordering. For each of the templates involved there is the original function type and the transformed function type. [Note: The creation of the transformed type is described in 13.6.6.2. — end note] The deduction process uses the transformed type as the argument template and the original type of the other template as the parameter template. This process is done twice for each type involved in the partial ordering comparison: once using the transformed template-1 as the argument template and template-2 as the parameter template and again using the transformed template-2 as the argument template and template-1 as the parameter template.

3. The types used to determine the ordering depend on the context in which the partial ordering is done:
   - In the context of a function call, the types used are those function parameter types for which the function call has arguments.
   - In the context of a call to a conversion function, the return types of the conversion function templates are used.
   - In other contexts (13.6.6.2) the function template’s function type is used.
4. Each type nominated above from the parameter template and the corresponding type from the argument template are used as the types of \( P \) and \( A \).

---

141) Default arguments are not considered to be arguments in this context; they only become arguments after a function has been selected.
Before the partial ordering is done, certain transformations are performed on the types used for partial ordering:

(5.1) If \( P \) is a reference type, \( P \) is replaced by the type referred to.

(5.2) If \( A \) is a reference type, \( A \) is replaced by the type referred to.

If both \( P \) and \( A \) were reference types (before being replaced with the type referred to above), determine which of the two types (if any) is more cv-qualified than the other; otherwise the types are considered to be equally cv-qualified for partial ordering purposes. The result of this determination will be used below.

Remove any top-level cv-qualifiers:

(7.1) If \( P \) is a cv-qualified type, \( P \) is replaced by the cv-unqualified version of \( P \).

(7.2) If \( A \) is a cv-qualified type, \( A \) is replaced by the cv-unqualified version of \( A \).

Using the resulting types \( P \) and \( A \), the deduction is then done as described in 13.9.2.5. If \( P \) is a function parameter pack, the type \( A \) of each remaining parameter type of the argument template is compared with the type \( P \) of the declarator-id of the function parameter pack. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. Similarly, if \( A \) was transformed from a function parameter pack, it is compared with each remaining parameter type of the parameter template. If deduction succeeds for a given type, the type from the argument template is considered to be at least as specialized as the type from the parameter template. [Example:

```cpp
template<class... Args> void f(Args... args);  // #1
template<class T1, class... Args> void f(T1 a1, Args... args);  // #2
template<class T1, class T2> void f(T1 a1, T2 a2);  // #3
```

f();     // calls #1
f(1, 2, 3);  // calls #2
f(1, 2);    // calls #3; non-variadic template #3 is more specialized
            // than the variadic templates #1 and #2

— end example]

If, for a given type, the types are identical after the transformations above and both \( P \) and \( A \) were reference types (before being replaced with the type referred to above):

(9.1) if the type from the argument template was an lvalue reference and the type from the parameter template was not, the parameter type is not considered to be at least as specialized as the argument type; otherwise,

(9.2) if the type from the argument template is more cv-qualified than the type from the parameter template (as described above), the parameter type is not considered to be at least as specialized as the argument type.

Function template \( F \) is at least as specialized as function template \( G \) if, for each pair of types used to determine the ordering, the type from \( F \) is at least as specialized as the type from \( G \). \( F \) is more specialized than \( G \) if \( F \) is at least as specialized as \( G \) and \( G \) is not at least as specialized as \( F \).

If, after considering the above, function template \( F \) is at least as specialized as function template \( G \) and vice-versa, and if \( G \) has a trailing function parameter pack for which \( F \) does not have a corresponding parameter, and if \( F \) does not have a trailing function parameter pack, then \( F \) is more specialized than \( G \).

In most cases, deduction fails if not all template parameters have values, but for partial ordering purposes a template parameter may remain without a value provided it is not used in the types being used for partial ordering. [Note: A template parameter used in a non-deduced context is considered used. — end note]

[Example:

```cpp
template <class T> T f(int);  // #1
template <class T, class U> T f(U);  // #2
void g() {
    f<int>(1);  // calls #1
}
```

— end example]

[Note: Partial ordering of function templates containing template parameter packs is independent of the number of deduced arguments for those template parameter packs. — end note] [Example:

```cpp
template<class ...> struct Tuple { }
```

§ 13.9.2.4
template<class ... Types> void g(Tuple<Types ...>);  // #1

template<class T1, class ... Types> void g(Tuple<T1, Types ...>);  // #2

template<class T1, class ... Types> void g(Tuple<T1, Types& ...>);  // #3

g(Tuple<>()); // calls #1

// Example

g(Tuple<int, float>()); // calls #2

g(Tuple<int, float&>());  // calls #3

g(Tuple<int>());  // calls #3

— end example]

13.9.2.5 Deducing template arguments from a type [temp.deduct.type]

Template arguments can be deduced in several different contexts, but in each case a type that is specified
in terms of template parameters (call it $P$) is compared with an actual type (call it $A$), and an attempt is
made to find template argument values (a type for a type parameter, a value for a non-type parameter, or a
template for a template parameter) that will make $P$, after substitution of the deduced values (call it the
deducted $A$), compatible with $A$.

In some cases, the deduction is done using a single set of types $P$ and $A$, in other cases, there will be a set
of corresponding types $P$ and $A$. Type deduction is done independently for each $P/A$ pair, and the deduced
template argument values are then combined. If type deduction cannot be done for any $P/A$ pair, or if for any
pair the deduction leads to more than one possible set of deduced values, or if different pairs yield different
deduced values, or if any template argument remains neither deduced nor explicitly specified, template
argument deduction fails. The type of a type parameter is only deduced from an array bound if it is not
otherwise deduced.

A given type $P$ can be composed from a number of other types, templates, and non-type values:

(3.1) A function type includes the types of each of the function parameters and the return type.

(3.2) A pointer-to-member type includes the type of the class object pointed to and the type of the member
pointed to.

(3.3) A type that is a specialization of a class template (e.g., $A<int>$) includes the types, templates, and
non-type values referenced by the template argument list of the specialization.

(3.4) An array type includes the array element type and the value of the array bound.

In most cases, the types, templates, and non-type values that are used to compose $P$ participate in template
argument deduction. That is, they may be used to determine the value of a template argument, and template
argument deduction fails if the value so determined is not consistent with the values determined elsewhere.
In certain contexts, however, the value does not participate in type deduction, but instead uses the values of
template arguments that were either deduced elsewhere or explicitly specified. If a template parameter is
used only in non-deduced contexts and is not explicitly specified, template argument deduction fails. [Note:
Under 13.9.2.1, if $P$ contains no template-parameters that appear in deduced contexts, no deduction is done,
so $P$ and $A$ need not have the same form. — end note]

The non-deduced contexts are:

(5.1) The nested-name-specifier of a type that was specified using a qualified-id.

(5.2) The expression of a decltype-specifier.

(5.3) A non-type template argument or an array bound in which a subexpression references a template
parameter.

(5.4) A template parameter used in the parameter type of a function parameter that has a default argument
that is being used in the call for which argument deduction is being done.

(5.5) A function parameter for which argument deduction cannot be done because the associated function
argument is a function, or a set of overloaded functions (12.4), and one or more of the following apply:

(5.5.1) more than one function matches the function parameter type (resulting in an ambiguous deduction),
or

(5.5.2) no function matches the function parameter type, or

(5.5.3) the set of functions supplied as an argument contains one or more function templates.

(5.6) A function parameter for which the associated argument is an initializer list (9.3.4) but the parameter
does not have a type for which deduction from an initializer list is specified (13.9.2.1). [Example:
template<class T> void g(T);
g({1,2,3});         // error: no argument deduced for T

—end example\[ (5.7) \]

A function parameter pack that does not occur at the end of the parameter-declaration-list.

When a type name is specified in a way that includes a non-deduced context, all of the types that comprise that type name are also non-deduced. However, a compound type can include both deduced and non-deduced types. [Example: If a type is specified as A<T>::B<T2>, both T and T2 are non-deduced. Likewise, if a type is specified as A<T1>::X<T>, I, J, and T are non-deduced. If a type is specified as void f(typename A<T>::B, A<T>), the T in A<T>::B is non-deduced but the T in A<T> is deduced. —end example]\]

Here is an example in which different parameter/argument pairs produce inconsistent template argument deductions:

```cpp
template<class T> void f(T x, T y) { /* ... */ }
struct A { /* ... */ };  // T could be A or B
struct B : A { /* ... */ };  // T could be A or B
void g(A a, B b) {
    f(a,b);           // error: T could be A or B
    f(b,a);           // OK: T is B
    f(a,a);           // error: T could be A or B
    f(b,b);           // OK: T is B
}
```

Here is an example where two template arguments are deduced from a single function parameter/argument pair. This can lead to conflicts that cause type deduction to fail:

```cpp
template <class T, class U> void f( T (*)( T, U, U ) );
int g1( int, float, float);  // T is int and U is float
char g2( int, float, float);  // error: T could be char or int
int g3( int, char, float);  // error: U could be char or float
void r() {
    f(g1);           // OK: T is int and U is float
    f(g2);           // error: T could be char or int
    f(g3);           // error: U could be char or float
}
```

Here is an example where a qualification conversion applies between the argument type on the function call and the deduced template argument type:

```cpp
template<class T> void f(const T*) { }
int* p;
void s() {
    f(p);       // f(const int*)
}
```

Here is an example where the template argument is used to instantiate a derived class type of the corresponding function parameter type:

```cpp
template <class T> struct B { };  // A is used to instantiate D
template <class T> struct D : public B<T> {};  // D2 is instantiated
struct D2 : public B<int> {};  // D2 is instantiated
template <class T> void f(B<T>&){}
void t() {
    D<int> d;  // calls f(B<int>&)
    D2 d2;     // calls f(B<int>&)
}

—end example\[ (5.7) \]

A template type argument T, a template template argument TT or a template non-type argument i can be deduced if P and A have one of the following forms:
where (T) represents a parameter-type-list (9.2.3.5) where at least one parameter type contains a T, and () represents a parameter-type-list where no parameter type contains a T. Similarly, <T> represents template argument lists where at least one argument contains a T, <i> represents template argument lists where at least one argument contains an i and <> represents template argument lists where no argument contains a T or an i.

9 If P has a form that contains <T> or <i>, then each argument P_i of the respective template argument list of P is compared with the corresponding argument A_i of the corresponding template argument list of A. If the template argument list of P contains a pack expansion that is not the last template argument, the entire template argument list is a non-deduced context. If P_i is a pack expansion, then the pattern of P_i is compared with each remaining argument in the template argument list of A. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by P_i. During partial ordering (13.9.2.4), if A_i was originally a pack expansion:

— if P does not contain a template argument corresponding to A_i then A_i is ignored;
— otherwise, if P_i is not a pack expansion, template argument deduction fails.

[Example:

```cpp
template<class T, class... U> struct A { }; // #1
template<class T1, class T2, class... U> struct A<T1, T2*, U...> { }; // #2
```

— end example]

10 Similarly, if P has a form that contains (T), then each parameter type P_i of the respective parameter-type-list (9.2.3.5) of P is compared with the corresponding parameter type A_i of the corresponding parameter-type-list of A. If P and A are function types that originated from deduction when taking the address of a function template (13.9.2.2) or when deducing template arguments from a function declaration (13.9.2.6) and P_i and A_i are parameters of the top-level parameter-type-list of P and A, respectively, P_i is adjusted if it is a forwarding reference (13.9.2.1) and A_i is an lvalue reference, in which case the type of P_i is changed to be the template parameter type (i.e., T&& is changed to simply T). [Note: As a result, when P_i is T&& and A_i is X&, the adjusted P_i will be T, causing T to be deduced as X&. — end note] [Example:
template <class T> void f(T&&);

template <> void f(int&) { }  // #1

template <> void f(int&&) { }  // #2

void g(int i) {
    f(i);  // calls f<int&>(int&), i.e., #1
    f(0);  // calls f<int>(int&&), i.e., #2
}

—end example—

If the parameter-declaration corresponding to \( P_i \) is a function parameter pack, then the type of its declarator-id is compared with each remaining parameter type in the parameter-type-list of \( A \). Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. During partial ordering (13.9.2.4), if \( A_i \) was originally a function parameter pack:

(10.1) — if \( P \) does not contain a function parameter type corresponding to \( A_i \) then \( A_i \) is ignored;

(10.2) — otherwise, if \( P_i \) is not a function parameter pack, template argument deduction fails.

[Example:

    template<class T, class... U> void f(T*, U...) { }  // #1
    template<class T> void f(T) { }  // #2
    template void f(int*);  // selects #1

—end example—

11 These forms can be used in the same way as \( T \) is for further composition of types. [Example:

    X<int> (*)(char[6]) is of the form

    template-name<T> (*)(type[i])

    which is a variant of

    type (*)(T)

    where type is \( X<int> \) and \( T \) is char[6]. —end example—

12 Template arguments cannot be deduced from function arguments involving constructs other than the ones specified above.

13 When the value of the argument corresponding to a non-type template parameter \( P \) that is declared with a dependent type is deduced from an expression, the template parameters in the type of \( P \) are deduced from the type of the value. [Example:

    template<long n> struct A { };  
    template<typename T> struct C;
    template<typename T, T n> struct C<A<n>> {
        using Q = T;
    };

    using R = long;
    using R = C<A<2>>::Q;  // OK; \( T \) was deduced as long from the
    // template argument value in the type A<2>

—end example—

14 The type of \( N \) in the type \( T[N] \) is std::size_t. [Example:

    template<typename T> struct S;
    template<typename T, T n> struct S<int[n]> {
        using Q = T;
    };

    using V = decltype(sizeof 0);
    using V = S<int[42]>::Q;  // OK; \( T \) was deduced as std::size_t from the type int[42]

—end example—

15 [Example:

    template<class T, T i> void f(int (&a)[i]);
int v[10];
void g() {
f(v);        // OK: T is std::size_t
}

—end example

[Note: Except for reference and pointer types, a major array bound is not part of a function parameter type and cannot be deduced from an argument:

template<int i> void f1(int a[10][i]);
template<int i> void f2(int a[i][20]);
template<int i> void f3(int (&a)[i][20]);

void g() {
    int v[10][20];
f1(v);        // OK: i deduced as 20
f1<20>(v);    // error: cannot deduce template-argument i
f2(v);        // OK
f2<10>(v);    // OK
f3(v);        // OK: i deduced as 10
}

—end note]

[Note: If, in the declaration of a function template with a non-type template parameter, the non-type template parameter is used in a subexpression in the function parameter list, the expression is a non-deduced context as specified above. [Example:

template <int i> class A { /* ... */ };  
template <int i> void g(A<i+1>);  
template <int i> void f(A<i>, A<i+1>);
void k() {
    A<1> a1;
    A<2> a2;
g(a1);        // error: deduction fails for expression i+1
g<0>(a1);     // OK
f(a1, a2);    // OK
}

—end example] — end note]

[Note: Template parameters do not participate in template argument deduction if they are used only in non-deduced contexts. For example,

template<int i, typename T>
T deduce(typename A<T>::X x,  // T is not deduced here
    T t,                  // but T is deduced here
typename B<i>::Y y);   // i is not deduced here
A<int> a;
B<77> b;

int x = deduce<77>(a.xm, 62, b.ym);  // T deduced as int; a.xm must be convertible to A<int>::X  
// i is explicitly specified to be 77; b.ym must be convertible to B<77>::Y

—end note]

If P has a form that contains <i>, and if the type of i differs from the type of the corresponding template parameter of the template named by the enclosing simple-template-id, deduction fails. If P has a form that contains [i], and if the type of i is not an integral type, deduction fails.¹⁴² [Example:

    template<int i> class A { /* ... */ };  
template<short s> void f(A<s>);  
void k1() {
    A<1> a;
f(a);        // error: deduction fails for conversion from int to short

¹⁴²] Although the template-argument corresponding to a template-parameter of type bool may be deduced from an array bound, the resulting value will always be true because the array bound will be nonzero.
A template-argument can be deduced from a function, pointer to function, or pointer-to-member-function type. [Example:

```cpp
template<class T> void f(void(*)(T,int));
template<class T> void foo(T,int);
void g(int,int);
void g(char,int);
void h(int,int,int);
void h(char,int);
int m() {
f(&g); // error: ambiguous
  f(&h); // OK: void h(char,int) is a unique match
  f(&foo); // error: type deduction fails because foo is a template
}
```
—end example]

A template-type-parameter cannot be deduced from the type of a function default argument. [Example:

```cpp
template <class T> void f(T = 5, T = 7);
void g() {
f(1); // OK: call f<int>(1,7)
f(); // error: cannot deduce T
f<int>(); // OK: call f<int>(5,7)
}
```
—end example]

The template-argument corresponding to a template template-parameter is deduced from the type of the template-argument of a class template specialization used in the argument list of a function call. [Example:

```cpp
template <template <class T> class X> struct A { };
template <template <class T> class X> void f(A<X>); { }
template<class T> struct B { };
A<B> ab;
f(ab); // calls f(A<B>)
```
—end example]

[Note: Template argument deduction involving parameter packs (13.6.3) can deduce zero or more arguments for each parameter pack. — end note] [Example:

```cpp
template<class X> struct X { };
template<class X, class ... ArgTypes> struct X<X(R(int, ArgTypes ...)> { };
template<class T, class ... Types> struct Y { };
template<class T, class ... Types> struct Y<T, Types& ...> { };

template<class ... Types> int f(void (*)(Types ...));
void g(int, float);
X<int> x1; // uses primary template
X<int(int, float, double)> x2; // uses partial specialization; ArgTypes contains float, double
X<int(float, int)> x3; // uses primary template
Y<int> y1; // use primary template; Types is empty
Y<int&, float&, double&> y2; // uses partial specialization; T is int, Types contains float, double
Y<int, float, double> y3; // uses primary template; Types contains int, float, double
```
int fv = f(g);          // OK; Types contains int, float
—end example]  

13.9.2.6 Deducing template arguments from a function declaration
[temp.deduct.decl]

1 In a declaration whose declarator-id refers to a specialization of a function template, template argument
deduction is performed to identify the specialization to which the declaration refers. Specifically, this is done
for explicit instantiations (13.8.2), explicit specializations (13.8.3), and certain friend declarations (13.6.4).
This is also done to determine whether a deallocation function template specialization matches a placement
operator new (6.6.5.4.2, 7.6.2.7). In all these cases, P is the type of the function template being considered
as a potential match and A is either the function type from the declaration or the type of the deallocation
function that would match the placement operator new as described in 7.6.2.7. The deduction is done as
described in 13.9.2.5.

2 If, for the set of function templates so considered, there is either no match or more than one match after
partial ordering has been considered (13.6.6.2), deduction fails and, in the declaration cases, the program is
ill-formed.

13.9.3 Overload resolution
[temp.over]

1 When a call to the name of a function or function template is written (explicitly, or implicitly using the operator
notation), template argument deduction (13.9.2) and checking of any explicit template arguments (13.3)
are performed for each function template to find the template argument values (if any) that can be used
with that function template to instantiate a function template specialization that can be invoked with
the call arguments. For each function template, if the argument deduction and checking succeeds, the
template-arguments (deduced and/or explicit) are used to synthesize the declaration of a single function
template specialization which is added to the candidate functions set to be used in overload resolution. If,
for a given function template, argument deduction fails or the synthesized function template specialization
would be ill-formed, no such function is added to the set of candidate functions for that template. The
complete set of candidate functions includes all the synthesized declarations and all of the non-template
overloaded functions of the same name. The synthesized declarations are treated like any other functions in
the remainder of overload resolution, except as explicitly noted in 12.3.3.

2 [Example:

    template<class T> T max(T a, T b) { return a>b?a:b; }

    void f(int a, int b, char c, char d) {
        int m1 = max(a,b);            // max(int a, int b)
        char m2 = max(c,d);           // max(char a, char b)
        int m3 = max(a,c);            // error: cannot generate max(int,char)
    }

Adding the non-template function

    int max(int,int);

to the example above would resolve the third call, by providing a function that could be called for max(a,c)
after using the standard conversion of char to int for c. —end example]

3 [Example: Here is an example involving conversions on a function argument involved in template-argument
deduction:

    template<class T> struct B { /* ... */ };  
    template<class T> struct D : public B<T> { /* ... */ };  
    template<class T> void f(B<T>&);

    void g(B<int>& bi, D<int>& di) {
        f(bi);            // f(bi)
        f(di);            // f(B<int>&)di)
    }

143) The parameters of function template specializations contain no template parameter types. The set of conversions allowed on
deduced arguments is limited, because the argument deduction process produces function templates with parameters that either
match the call arguments exactly or differ only in ways that can be bridged by the allowed limited conversions. Non-deduced
arguments allow the full range of conversions. Note also that 12.3.3 specifies that a non-template function will be given preference
over a template specialization if the two functions are otherwise equally good candidates for an overload match.
Here is an example involving conversions on a function argument not involved in template-parameter deduction:

```cpp
template<class T> void f(T*, int); // #1
template<class T> void f(T, char); // #2

void h(int* pi, int i, char c) {
    f(pi, i); // #1: f<int>(pi, i)
    f(pi, c); // #2: f<int*>(pi, c)
    f(i, c); // #2: f<int>(i, c)
    f(i, i); // #2: f<int>(i, char(i))
}
```

Only the signature of a function template specialization is needed to enter the specialization in a set of candidate functions. Therefore only the function template declaration is needed to resolve a call for which a template specialization is a candidate. [Example:

```cpp
template<class T> void f(T); // declaration
void g() {
    f("Annemarie"); // call of f<const char*>  
    }  
```

The call of f is well-formed even if the template f is only declared and not defined at the point of the call. The program will be ill-formed unless a specialization for f<const char*>, either implicitly or explicitly generated, is present in some translation unit. —end example]}

13.10 Deduction guides [temp.deduct.guide]

Deduction guides are used when a template-name appears as a type specifier for a deduced class type (9.1.7.6). Deduction guides are not found by name lookup. Instead, when performing class template argument deduction (12.3.1.8), any deduction guides declared for the class template are considered.

deduction-guide:
    explicit opt template-name ( parameter-declaration-clause ) \rightarrow simple-template-id

[Example:

```cpp
template<class T, class D = int>
struct S {
    T data;
};
template<class U
    S(U) \rightarrow S<typename U::type>;

struct A {
    using type = short;
    operator type();
};
S x(A()); // x is of type S<short, int>
```

The same restrictions apply to the parameter-declaration-clause of a deduction guide as in a function declaration (9.2.3.5). The simple-template-id shall name a class template specialization. The template-name shall be the same identifier as the template-name of the simple-template-id. A deduction-guide shall be declared in the same scope as the corresponding class template and, for a member class template, with the same access. Two deduction guide declarations in the same translation unit for the same class template shall not have equivalent parameter-declaration-clauses.

§ 13.10
14 Exception handling

Exception handling provides a way of transferring control and information from a point in the execution of a thread to an exception handler associated with a point previously passed by the execution. A handler will be invoked only by throwing an exception in code executed in the handler’s try block or in functions called from the handler’s try block.

```
try-block:
  try compound-statement handler-seq
function-try-block:
  try ctor-initializer_opt compound-statement handler-seq
handler-seq:
  handler handler-seq_opt
handler:
  catch ( exception-declaration ) compound-statement
exception-declaration:
  attribute-specifier-seq_opt type-specifier-seq declarator
  attribute-specifier-seq_opt type-specifier-seq abstract-declarator_opt
  ...
```

The optional `attribute-specifier-seq` in an `exception-declaration` appertains to the parameter of the catch clause (14.3).

2 A `try-block` is a statement (Clause 8). [Note: Within this Clause “try block” is taken to mean both `try-block` and `function-try-block`. — end note]

3 A `goto` or `switch` statement shall not be used to transfer control into a try block or into a handler. [Example:

```c
void f() {
  goto l1;           // ill-formed
  goto l2;           // ill-formed
  try {
    goto l1;         // OK
    goto l2;         // ill-formed
    l1: ;
  } catch (...) {
    l2: ;
    goto l1;         // ill-formed
    goto l2;         // OK
  }
}
```

—end example] A `goto`, `break`, `return`, or `continue` statement can be used to transfer control out of a try block or handler. When this happens, each variable declared in the try block will be destroyed in the context that directly contains its declaration. [Example:

```c
lab: try {
  T1 t1;
  try {
    T2 t2;
    if (condition)
      goto lab;
  } catch(...) { /* handler 2 */ }
} catch(...) { /* handler 1 */ }
```

Here, executing `goto lab;` will destroy first `t2`, then `t1`, assuming the `condition` does not declare a variable. Any exception thrown while destroying `t2` will result in executing `handler 2`; any exception thrown while destroying `t1` will result in executing `handler 1`. —end example]

4 A `function-try-block` associates a `handler-seq` with the `ctor-initializer`, if present, and the `compound-statement`. An exception thrown during the execution of the `compound-statement` or, for constructors and destructors, during the initialization or destruction, respectively, of the class’s subobjects, transfers control to a handler
in a *function-try-block* in the same way as an exception thrown during the execution of a *try-block* transfers control to other handlers. [Example:

```c++
int f(int);
class C {
  int i;
  double d;
public:
  C(int, double);
};
C::C(int ii, double id)
try : i(f(ii)), d(id) {
  // constructor statements
} catch (...) {
  // handles exceptions thrown from the ctor-initializer and from the constructor statements
}
```

—end example]

5 In this Clause, “before” and “after” refer to the “sequenced before” relation (6.8.1).

### 14.1 Throwing an exception [except.throw]

1 Throwing an exception transfers control to a handler. [Note: An exception can be thrown from one of the following contexts: *throw-expressions* (7.6.18), allocation functions (6.6.5.4.1), *dynamic_cast* (7.6.1.6), *typeid* (7.6.1.7), *new-expressions* (7.6.2.7), and standard library functions (16.4.1.4). —end note] An object is passed and the type of that object determines which handlers can catch it. [Example:

```c++
throw "Help!";
```

can be caught by a handler of *const char* type:

```c++
try {
  // ...
} catch(const char* p) {
  // handle character string exceptions here
}
```

and

```c++
class Overflow {
public:
  Overflow(char,double,double);
};
void f(double x) {
  throw Overflow('+',x,3.45e107);
}
```

can be caught by a handler for exceptions of type *Overflow*:

```c++
try {
  f(1.2);
} catch(Overflow& oo) {
  // handle exceptions of type Overflow here
}
```

—end example]

2 When an exception is thrown, control is transferred to the nearest handler with a matching type (14.3); “nearest” means the handler for which the *compound-statement* or *ctor-initializer* following the *try* keyword was most recently entered by the thread of control and not yet exited.

3 Throwing an exception copy-initializes (9.3, 11.3.4.2) a temporary object, called the *exception object*. An lvalue denoting the temporary is used to initialize the variable declared in the matching *handler* (14.3). If the type of the exception object would be an incomplete type, an abstract class type (11.6.3), or a pointer to an incomplete type other than *cv void* the program is ill-formed.

§ 14.1 419
The memory for the exception object is allocated in an unspecified way, except as noted in 6.6.5.4.1. If a handler exits by rethrowing, control is passed to another handler for the same exception object. The points of potential destruction for the exception object are:

- when an active handler for the exception exits by any means other than rethrowing, immediately after the destruction of the object (if any) declared in the exception-declaration in the handler;
- when an object of type `std::exception_ptr` (17.9.6) that refers to the exception object is destroyed, before the destructor of `std::exception_ptr` returns.

Among all points of potential destruction for the exception object, there is an unspecified last one where the exception object is destroyed. All other points happen before that last one (6.8.2.1). [Note: No other thread synchronization is implied in exception handling. — end note] The implementation may then deallocate the memory for the exception object; any such deallocation is done in an unspecified way. [Note: A thrown exception does not propagate to other threads unless caught, stored, and rethrown using appropriate library functions; see 17.9.6 and 32.6. — end note]

When the thrown object is a class object, the constructor selected for the copy-initialization as well as the constructor selected for a copy-initialization considering the thrown object as an lvalue shall be non-deleted and accessible, even if the copy/move operation is elided (11.9.5). The destructor is potentially invoked (11.3.6).

An exception is considered caught when a handler for that exception becomes active (14.3). [Note: An exception can have active handlers and still be considered uncaught if it is rethrown. — end note]

If the exception handling mechanism handling an uncaught exception (14.5.2) directly invokes a function that exits via an exception, the function `std::terminate` is called (14.5.1). [Example:

```cpp
struct C {
    C() { }
    C(const C&) {
        if (std::uncaught_exceptions()) {
            throw 0;  // throw during copy to handler's exception-declaration object (14.3)
        }
    }
};

int main() {
    try {
        throw C();  // calls std::terminate if construction of the handler's
                    // exception-declaration object is not elided (11.9.5)
    } catch(C) { }
}
```

— end example] [Note: Consequently, destructors should generally catch exceptions and not let them propagate. — end note]

### 14.2 Constructors and destructors [except.ctor]

As control passes from the point where an exception is thrown to a handler, objects with automatic storage duration are destroyed by a process, specified in this subclause, called stack unwinding.

Each object with automatic storage duration is destroyed if it has been constructed, but not yet destroyed, since the try block was entered. If an exception is thrown during the destruction of temporaries or local variables for a `return` statement (8.6.3), the destructor for the returned object (if any) is also invoked. The objects are destroyed in the reverse order of the completion of their construction. [Example:

```cpp
struct A {};  

struct Y { ~Y() noexcept(false) { throw 0; } };  

A f() {  
try {
    A a;
    Y y;
    A b;
    return {};
    // #1
```
At #1, the returned object of type A is constructed. Then, the local variable b is destroyed (8.6). Next, the local variable y is destroyed, causing stack unwinding, resulting in the destruction of the returned object, followed by the destruction of the local variable a. Finally, the returned object is constructed again at #2. — end example]

3 If the initialization or destruction of an object other than by delegating constructor is terminated by an exception, the destructor is invoked for each of the object’s direct subobjects and, for a complete object, virtual base class subobjects, whose initialization has completed (9.3) and whose destructor has not yet begun execution, except that in the case of destruction, the variant members of a union-like class are not destroyed. [Note: If such an object has a reference member that extends the lifetime of a temporary object, this ends the lifetime of the reference member, so the lifetime of the temporary object is effectively not extended. — end note] The subobjects are destroyed in the reverse order of the completion of their construction. Such destruction is sequenced before entering a handler of the function-try-block of the constructor or destructor, if any.

4 If the compound-statement of the function-body of a delegating constructor for an object exits via an exception, the object’s destructor is invoked. Such destruction is sequenced before entering a handler of the function-try-block of a delegating constructor for that object, if any.

5 [Note: If the object was allocated by a new-expression (7.6.2.7), the matching deallocation function (6.6.5.4.2), if any, is called to free the storage occupied by the object. — end note]

14.3 Handling an exception [except.handle]

1 The exception-declaration in a handler describes the type(s) of exceptions that can cause that handler to be entered. The exception-declaration shall not denote an incomplete type, an abstract class type, or an rvalue reference type. The exception-declaration shall not denote a pointer or reference to an incomplete type, other than void*, const void*, volatile void*, or const volatile void*.

2 A handler of type “array of T” or function type T is adjusted to be of type “pointer to T”.

3 A handler is a match for an exception object of type E if

(3.1) — The handler is of type cv T or cv T& and E and T are the same type (ignoring the top-level cv-qualifiers), or

(3.2) — the handler is of type cv T or cv T& and T is an unambiguous public base class of E, or

(3.3) — the handler is of type cv T or const Tk where Tk is a pointer or pointer-to-member type and E is a pointer or pointer-to-member type that can be converted to Tk by one or more of

(3.3.1) — a standard pointer conversion (7.3.11) not involving conversions to pointers to private or protected or ambiguous classes

(3.3.2) — a function pointer conversion (7.3.13)

(3.3.3) — a qualification conversion (7.3.5), or

(3.4) — the handler is of type cv T or const Tk where Tk is a pointer or pointer-to-member type and E is std::nullptr_t.

[Note: A throw-expression whose operand is an integer literal with value zero does not match a handler of pointer or pointer-to-member type. A handler of reference to array or function type is never a match for any exception object (7.6.18). — end note]

[Example:

class Matherr { /* ... */ virtual void vf(); };  
class Overflow: public Matherr { /* ... */ };  
class Underflow: public Matherr { /* ... */ };  
class Zerodivide: public Matherr { /* ... */ };  

void f() {  
  try {  
    g();  
  }  

} catch (...) {  
  return {};  // #2  
}  
}
Here, the **Overflow** handler will catch exceptions of type **Overflow** and the **Matherr** handler will catch exceptions of type **Matherr** and of all types publicly derived from **Matherr** including exceptions of type **Underflow** and **Zerodivide**.  — end example

4 The handlers for a try block are tried in order of appearance. [Note: This makes it possible to write handlers that can never be executed, for example by placing a handler for a final derived class after a handler for a corresponding unambiguous public base class. — end note]

5 A ... in a handler’s exception-declaration functions similarly to ... in a function parameter declaration; it specifies a match for any exception. If present, a ... handler shall be the last handler for its try block.

6 If no match is found among the handlers for a try block, the search for a matching handler continues in a dynamically surrounding try block of the same thread.

7 A handler is considered active when initialization is complete for the parameter (if any) of the catch clause. [Note: The stack will have been unwound at that point. — end note] Also, an implicit handler is considered active when the function **std::terminate** is entered due to a throw. A handler is no longer considered active when the catch clause exits.

8 The exception with the most recently activated handler that is still active is called the currently handled exception.

9 If no matching handler is found, the function **std::terminate** is called; whether or not the stack is unwound before this call to **std::terminate** is implementation-defined (14.5.1).

10 Referring to any non-static member or base class of an object in the handler for a function-try-block of a constructor or destructor for that object results in undefined behavior.

11 The scope and lifetime of the parameters of a function or constructor extend into the handlers of a function-try-block.

12 Exceptions thrown in destructors of objects with static storage duration or in constructors of namespace-scope objects with static storage duration are not caught by a function-try-block on the main function (6.8.3.1). Exceptions thrown in destructors of objects with thread storage duration or in constructors of namespace-scope objects with thread storage duration are not caught by a function-try-block on the initial function of the thread.

13 If a **return** statement (8.6.3) appears in a handler of the function-try-block of a constructor, the program is ill-formed.

14 The currently handled exception is rethrown if control reaches the end of a handler of the function-try-block of a constructor or destructor. Otherwise, flowing off the end of the compound-statement of a handler of a function-try-block is equivalent to flowing off the end of the compound-statement of that function (see 8.6.3).

15 The variable declared by the exception-declaration, of type **cv T** or **cv T&**, is initialized from the exception object, of type **E**, as follows:

\[(15.1) \quad \text{if } T \text{ is a base class of } E, \text{ the variable is copy-initialized (9.3) from the corresponding base class subobject of the exception object;} \]

\[(15.2) \quad \text{otherwise, the variable is copy-initialized (9.3) from the exception object.} \]

The lifetime of the variable ends when the handler exits, after the destruction of any automatic objects initialized within the handler.

16 When the handler declares an object, any changes to that object will not affect the exception object. When the handler declares a reference to an object, any changes to the referenced object are changes to the exception object and will have effect should that object be rethrown.

### 14.4 Exception specifications

1 The predicate indicating whether a function cannot exit via an exception is called the exception specification of the function. If the predicate is false, the function has a potentially-throwing exception specification,
otherwise it has a non-throwing exception specification. The exception specification is either defined implicitly, or defined explicitly by using a noexcept-specifier as a suffix of a function declarator (9.2.3.5).

\[
\text{noexcept-specifier:}
\begin{align*}
\text{noexcept ( constant-expression )} \\
\text{noexcept}
\end{align*}
\]

2 In a noexcept-specifier, the constant-expression, if supplied, shall be a contextually converted constant expression of type bool (7.7); that constant expression is the exception specification of the function type in which the noexcept-specifier appears. A ( token that follows noexcept is part of the noexcept-specifier and does not commence an initializer (9.3). The noexcept-specifier noexcept without a constant-expression is equivalent to the noexcept-specifier noexcept(true).

3 If a declaration of a function does not have a noexcept-specifier, the declaration has a potentially throwing exception specification unless it is a destructor or a deallocation function or is defaulted on its first declaration, in which cases the exception specification is as specified below and no other declaration for that function shall have a noexcept-specifier. In an explicit instantiation (13.8.2) a noexcept-specifier may be specified, but is not required. If a noexcept-specifier is specified in an explicit instantiation directive, the exception specification shall be the same as the exception specification of all other declarations of that function. A diagnostic is required only if the exception specifications are not the same within a single translation unit.

4 If a virtual function has a non-throwing exception specification, all declarations, including the definition, of any function that overrides that virtual function in any derived class shall have a non-throwing exception specification, unless the overriding function is defined as deleted. [Example:

```cpp
struct B {
    virtual void f() noexcept;
    virtual void g();
    virtual void h() noexcept = delete;
};

struct D : B {
    void f(); // ill-formed
    void g() noexcept; // OK
    void h() = delete; // OK
};
```

The declaration of D::f is ill-formed because it has a potentially-throwing exception specification, whereas B::f has a non-throwing exception specification. —end example]

5 Whenever an exception is thrown and the search for a handler (14.3) encounters the outermost block of a function with a non-throwing exception specification, the function std::terminate is called (14.5.1). [Note: An implementation shall not reject an expression merely because, when executed, it throws or might throw an exception from a function with a non-throwing exception specification. —end note] [Example:

```cpp
extern void f(); // potentially-throwing

void g() noexcept {
    f(); // valid, even if f throws
    throw 42; // valid, effectively a call to std::terminate
}
```
The call to f is well-formed even though, when called, f might throw an exception. —end example]

6 An expression e is potentially-throwing if

- e is a function call (7.6.1.2) whose postfix-expression has a function type, or a pointer-to-function type, with a potentially-throwing exception specification, or
- e implicitly invokes a function (such as an overloaded operator, an allocation function in a new-expression, a constructor for a function argument, or a destructor if e is a full-expression (6.8.1)) that is potentially-throwing, or
- e is a throw-expression (7.6.18), or
- e is a dynamic_cast expression that casts to a reference type and requires a runtime check (7.6.1.6), or
- e is a typeid expression applied to a (possibly parenthesized) built-in unary * operator applied to a pointer to a polymorphic class type (7.6.1.7), or

§ 14.4 423
any of the immediate subexpressions (6.8.1) of e is potentially-throwing.

An implicitly-declared constructor for a class X, or a constructor without a noexcept-specifier that is defaulted on its first declaration, has a potentially-throwing exception specification if and only if any of the following constructs is potentially-throwing:

— a constructor selected by overload resolution in the implicit definition of the constructor for class X to initialize a potentially constructed subobject, or

— a subexpression of such an initialization, such as a default argument expression, or,

— for a default constructor, a default member initializer.

[Note: Even though destructors for fully-constructed subobjects are invoked when an exception is thrown during the execution of a constructor (14.2), their exception specifications do not contribute to the exception specification of the constructor, because an exception thrown from such a destructor would call the function std::terminate rather than escape the constructor (14.1, 14.5.1). — end note]

The exception specification for an implicitly-declared destructor, or a destructor without a noexcept-specifier, is potentially-throwing if and only if any of the destructors for any of its potentially constructed subobjects is potentially-throwing or the destructor is virtual and the destructor of any virtual base class is potentially-throwing.

The exception specification for an implicitly-declared assignment operator, or an assignment-operator without a noexcept-specifier that is defaulted on its first declaration, is potentially-throwing if and only if the invocation of any assignment operator in the implicit definition is potentially-throwing.

A deallocation function (6.6.5.4.2) with no explicit noexcept-specifier has a non-throwing exception specification.

The exception specification for a comparison operator (7.6.8, 7.6.9, 7.6.10) without a noexcept-specifier that is defaulted on its first declaration is potentially-throwing if and only if the invocation of any comparison operator in the implicit definition is potentially-throwing.

[Example:]

```cpp
struct A {
    A(int = (A(S), 0)) noexcept;
    A(const A&) noexcept;
    A(A&&) noexcept;
    ~A();
};
struct B {
    B() noexcept;
    B(const B&) = default;  // implicit exception specification is noexcept(true)
    B(B&&, int = (throw Y(), 0)) noexcept;
    ~B() noexcept(false);
};
```

Furthermore, if A::~A() were virtual, the program would be ill-formed since a function that overrides a virtual function from a base class shall not have a potentially-throwing exception specification if the base class function has a non-throwing exception specification. — end example]

An exception specification is considered to be needed when:

— in an expression, the function is the unique lookup result or the selected member of a set of overloaded functions (6.4, 12.3, 12.4);

— the function is odr-used (6.2) or, if it appears in an unevaluated operand, would be odr-used if the expression were potentially-evaluated;
The exception specification of a defaulted special member function is evaluated as described above only when needed; similarly, the noexcept-specifier of a specialization of a function template or member function of a class template is instantiated only when needed.

### 14.5 Special functions

The function \texttt{std::terminate} (14.5.1) is used by the exception handling mechanism for coping with errors related to the exception handling mechanism itself. The function \texttt{std::current_exception()} (17.9.6) and the class \texttt{std::nested\_exception} (17.9.7) can be used by a program to capture the currently handled exception.

#### 14.5.1 The std::terminate function

In some situations exception handling must be abandoned for less subtle error handling techniques. [Note: These situations are:

(1.1) — when the exception handling mechanism, after completing the initialization of the exception object but before activation of a handler for the exception (14.1), calls a function that exits via an exception, or

(1.2) — when the exception handling mechanism cannot find a handler for a thrown exception (14.3), or

(1.3) — when the search for a handler (14.3) encounters the outermost block of a function with a non-throwing exception specification (14.4), or

(1.4) — when the destruction of an object during stack unwinding (14.2) terminates by throwing an exception, or

(1.5) — when initialization of a non-local variable with static or thread storage duration (6.8.3.3) exits via an exception, or

(1.6) — when destruction of an object with static or thread storage duration exits via an exception (6.8.3.4), or

(1.7) — when execution of a function registered with \texttt{std::atexit} or \texttt{std::at\_quick\_exit} exits via an exception (17.5), or

(1.8) — when evaluation of the predicate of a contract (9.11.4) exits via an exception, or

(1.9) — when the violation handler invoked for a failed contract condition check (9.11.4) on a noexcept function exits via an exception, or

(1.10) — when the violation handler has completed after a failed contract check and the continuation mode is \texttt{off}, or

(1.11) — when a \texttt{throw\_expression} (7.6.18) with no operand attempts to rethrow an exception and no exception is being handled (14.1), or

(1.12) — when the function \texttt{std::nested\_exception::rethrow\_nested} is called for an object that has captured no exception (17.9.7), or

(1.13) — when execution of the initial function of a thread exits via an exception (32.3.2.2), or

(1.14) — for a parallel algorithm whose \texttt{ExecutionPolicy} specifies such behavior (20.18.4, 20.18.5, 20.18.6), when execution of an element access function (25.3.1) of the parallel algorithm exits via an exception (25.3.4), or

(1.15) — when the destructor or the move assignment operator is invoked on an object of type \texttt{std::thread} that refers to a joinable thread (32.3.2.3, 32.3.2.4), or

(1.16) — when a call to a \texttt{wait()}, \texttt{wait\_until()}, or \texttt{wait\_for()} function on a condition variable (32.5.3, 32.5.4) fails to meet a postcondition.

— end note]
In such cases, the function `std::terminate` is called (17.9.4). In the situation where no matching handler is found, it is implementation-defined whether or not the stack is unwound before `std::terminate` is called. In the situation where the search for a handler (14.3) encounters the outermost block of a function with a non-throwing exception specification (14.4), it is implementation-defined whether the stack is unwound, unwound partially, or not unwound at all before the function `std::terminate` is called. In all other situations, the stack shall not be unwound before the function `std::terminate` is called. An implementation is not permitted to finish stack unwinding prematurely based on a determination that the unwind process will eventually cause a call to the function `std::terminate`.

14.5.2 The `std::uncaught_exceptions()` function

An exception is considered uncaught after completing the initialization of the exception object (14.1) until completing the activation of a handler for the exception (14.3). [Note: As a consequence, an exception is considered uncaught during any stack unwinding resulting from it being thrown. — end note] If an exception is rethrown (7.6.18, 17.9.6), it is considered uncaught from the point of rethrow until the rethrown exception is caught. The function `std::uncaught_exceptions()` (17.9.5) returns the number of uncaught exceptions in the current thread.
15 Preprocessing directives

A preprocessing directive consists of a sequence of preprocessing tokens that satisfies the following constraints: The first token in the sequence is a # preprocessing token that (at the start of translation phase 4) either is the first character in the source file (optionally after white space containing no new-line characters) or follows white space containing at least one new-line character. The last token in the sequence is the first new-line character that follows the first token in the sequence. Thus, preprocessing directives are commonly called “lines”. These “lines” have no other syntactic significance, as all white space is equivalent except in certain situations during preprocessing (see the # character string literal creation operator in 15.5.2, for example).
A text line shall not begin with a # preprocessing token. A conditionally-supported-directive shall not begin with any of the directive names appearing in the syntax. A conditionally-supported-directive is conditionally-supported with implementation-defined semantics.

When in a group that is skipped (15.1), the directive syntax is relaxed to allow any sequence of preprocessing tokens to occur between the directive name and the following new-line character.

The only white-space characters that shall appear between preprocessing tokens within a preprocessing directive (from just after the introducing # preprocessing token through just before the terminating new-line character) are space and horizontal-tab (including spaces that have replaced comments or possibly other white-space characters in translation phase 3).

The implementation can process and skip sections of source files conditionally, include other source files, import macros from header units, and replace macros. These capabilities are called preprocessing, because conceptually they occur before translation of the resulting translation unit.

The preprocessing tokens within a preprocessing directive are not subject to macro expansion unless otherwise stated.

[Example: In:

```
#define EMPTY
EMPTY # include <file.h>
```

the sequence of preprocessing tokens on the second line is not a preprocessing directive, because it does not begin with a # at the start of translation phase 4, even though it will do so after the macro EMPTY has been replaced. — end example]

15.1 Conditional inclusion [cpp.cond]

defined-macro-expression:
  defined identifier
  defined ( identifier )

h-preprocessing-token:
  any preprocessing-token other than >

h-pp-tokens:
  h-preprocessing-token
  h-pp-tokens h-preprocessing-token

header-name-tokens:
  string-literal
  < h-pp-tokens >

has-include-expression:
  __has_include ( header-name )
  __has_include ( header-name-tokens )

has-attribute-expression:
  __has_cpp_attribute ( pp-tokens )

The expression that controls conditional inclusion shall be an integral constant expression except that identifiers (including those lexically identical to keywords) are interpreted as described below and it may contain zero or more defined-macro-expressions and/or has-include-expressions and/or has-attribute-expressions as unary operator expressions.

145) Because the controlling constant expression is evaluated during translation phase 4, all identifiers either are or are not macro names — there simply are no keywords, enumeration constants, etc.
A defined-macro-expression evaluates to 1 if the identifier is currently defined as a macro name (that is, if it is predefined or if it has one or more active macro definitions (15.4), for example because it has been the subject of a #define preprocessing directive without an intervening #undef directive with the same subject identifier), 0 if it is not.

The second form of has-include-expression is considered only if the first form does not match, in which case the preprocessing tokens are processed just as in normal text.

The header or source file identified by the parenthesized preprocessing token sequence in each contained has-include-expression is searched for as if that preprocessing token sequence were the pp-tokens in a #include directive, except that no further macro expansion is performed. If such a directive would not satisfy the syntactic requirements of a #include directive, the program is ill-formed. The has-include-expression evaluates to 1 if the search for the source file succeeds, and to 0 if the search fails.

Each has-attribute-expression is replaced by a non-zero pp-number matching the form of an integer-literal if the implementation supports an attribute with the name specified by interpreting the pp-tokens as an attribute-token, and by 0 otherwise. The program is ill-formed if the pp-tokens do not match the form of an attribute-token.

For an attribute specified in this document, the value of the has-attribute-expression is given by Table 16. For other attributes recognized by the implementation, the value is implementation-defined. [Note: It is expected that the availability of an attribute can be detected by any non-zero result. — end note]

The #ifdef and #ifndef directives, and the defined conditional inclusion operator, shall treat __has_-include and __has_cpp_attribute as if they were the names of defined macros. The identifiers __has_-include and __has_cpp_attribute shall not appear in any context not mentioned in this subclause.

Each preprocessing token that remains (in the list of preprocessing tokens that will become the controlling expression) after all macro replacements have occurred shall be in the lexical form of a token (5.6).

Preprocessing directives of the forms

```
# if  constant-expression new-line groupopt
# elif constant-expression new-line groupopt
```

check whether the controlling constant expression evaluates to nonzero.

Prior to evaluation, macro invocations in the list of preprocessing tokens that will become the controlling constant expression are replaced (except for those macro names modified by the defined unary operator), just as in normal text. If the token defined is generated as a result of this replacement process or use of the defined unary operator does not match one of the two specified forms prior to macro replacement, the behavior is undefined.

After all replacements due to macro expansion and evaluations of defined-macro-expressions and has-include-expressions have been performed, all remaining identifiers and keywords, except for true and false, are replaced with the pp-number 0, and then each preprocessing token is converted into a token. [Note: An alternative token (5.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not subject to this replacement. — end note]
The resulting tokens comprise the controlling constant expression which is evaluated according to the rules of 7.7 using arithmetic that has at least the ranges specified in 17.3. For the purposes of this token conversion and evaluation all signed and unsigned integer types act as if they have the same representation as, respectively, intmax_t or uintmax_t (17.4). [Note: Thus on an implementation where std::numeric_limits<int>::max() is 0x7FFF and std::numeric_limits<unsigned int>::max() is 0xFFFF, the integer literal 0x8000 is signed and positive within a #if expression even though it is unsigned in translation phase 7 (5.2). —end note] This includes interpreting character literals, which may involve converting escape sequences into execution character set members. Whether the numeric value for these character literals matches the value obtained when an identical character literal occurs in an expression (other than within a #if or #elif directive) is implementation-defined. [Note: Thus, the constant expression in the following #if directive and if statement (8.4.1) is not guaranteed to evaluate to the same value in these two contexts:

```c
if ('z' - 'a' == 25)
if ('z' - 'a' == 25)
```

—end note] Also, whether a single-character character literal may have a negative value is implementation-defined. Each subexpression with type bool is subjected to integral promotion before processing continues.

Preprocessing directives of the forms

```
#define identifier new-line group
```

check whether the identifier is or is not currently defined as a macro name. Their conditions are equivalent to #if defined identifier and #if !defined identifier respectively.

Each directive’s condition is checked in order. If it evaluates to false (zero), the group that it controls is skipped: directives are processed only through the name that determines the directive in order to keep track of the level of nested conditionals; the rest of the directives’ preprocessing tokens are ignored, as are the other preprocessing tokens in the group. Only the first group whose control condition evaluates to true (nonzero) is processed; any following groups are skipped and their controlling directives are processed as if they were in a group that is skipped. If none of the conditions evaluates to true, and there is a #else directive, the group controlled by the #else is processed; lacking a #else directive, all the groups until the #endif are skipped.146

[Example: This demonstrates a way to include a library optional facility only if it is available:

```c
#include <optional>
```

—end example]

As indicated by the syntax, a preprocessing token shall not follow a #else or #endif directive before the terminating new-line character. However, comments may appear anywhere in a source file, including within a preprocessing directive.

[146]
15.2 Source file inclusion

A `#include` directive shall identify a header or source file that can be processed by the implementation.

A preprocessing directive of the form

```
#include <h-char-sequence> new-line
```

searches a sequence of implementation-defined places for a header identified uniquely by the specified sequence between the `<` and `>` delimiters, and causes the replacement of that directive by the entire contents of the header. How the places are specified or the header identified is implementation-defined.

A preprocessing directive of the form

```
#include "q-char-sequence" new-line
```

does the same as the `#include` directive of the form above, except that the specified sequence is identified by double quotes (```) delimiters.

A preprocessing directive of the form

```
#include pp-tokens new-line
```

causes the replacement of that directive by the entire contents of the source file identified by the specified sequence between the `"` delimiters. The named source file is searched for in an implementation-defined manner. If this search is not supported, or if the search fails, the directive is reprocessed as if it read

```
#include <h-char-sequence> new-line
```

with the identical contained sequence (including `>` characters, if any) from the original directive.

A preprocessing directive of the form

```
#include pp-tokens new-line
```

causes the replacement of that directive by the entire contents of the source file identified by the specified sequence between the `"` delimiters. The named source file is searched for in an implementation-defined manner. If this search is not supported, or if the search fails, the directive is reprocessed as if it read

```
#include <h-char-sequence> new-line
```

with the identical contained sequence (including `>` characters, if any) from the original directive.

The implementation shall provide unique mappings for sequences consisting of one or more `nondigits` or `digits` (5.10) followed by a period (.) and a single `nondigit`. The first character shall not be a `digit`. The implementation may ignore distinctions of alphabetical case.

A `#include` preprocessing directive may appear in a source file that has been read because of a `#include` directive in another file, up to an implementation-defined nesting limit.

If the header identified by the `header-name` denotes an importable header (10.3), the preprocessing directive is instead replaced by the `preprocessing-tokens

```
import header-name;
```

[Note: Although an implementation may provide a mechanism for making arbitrary source files available to the `< >` search, in general programmers should use the `< >` form for headers provided with the implementation, and the `" "` form for sources outside the control of the implementation. For instance:

```
#include <stdio.h>
#include <unistd.h>
#include "usefullib.h"
#include "myprog.h"
```

—end note]

[Example: This illustrates macro-replaced `#include` directives:

```
#if VERSION == 1
#define INCFILE "vers1.h"
#elif VERSION == 2
#define INCFILE "vers2.h"  // and so on
#else
#define INCFILE "versN.h"
#endif
#include INCFILE
```

—end example]

Note that adjacent string literals are not concatenated into a single string literal (see the translation phases in 5.2); thus, an expansion that results in two string literals is an invalid directive.
15.3 Global module fragment

\textit{pp-global-module-fragment:}

\texttt{module ; pp-balanced-token-seq module}

1 If the first two preprocessing tokens at the start of phase 4 of translation are \texttt{module ;}, the result of preprocessing shall begin with a \textit{pp-global-module-fragment} for which all \texttt{preprocessing-tokens} in the \texttt{pp-balanced-token-seq} were produced directly or indirectly by source file inclusion (15.2), and for which the second \texttt{module} \texttt{preprocessing-token} was not produced by source file inclusion or macro replacement (15.5). Otherwise, the first two preprocessing tokens at the end of phase 4 of translation shall not be \texttt{module ;}.

15.4 Header units

\textit{import-seq:}

\texttt{top-level-token-seqopt export opt import}

\texttt{top-level-token-seq:}

\texttt{any pp-balanced-token-seq ending in ; or} \texttt{)}}

\textit{pp-import:}

\texttt{import header-name pp-import-suffixopt ;}

\texttt{import header-name-tokens pp-import-suffixopt ;}

\textit{pp-import-suffix:}

\texttt{pp-import-suffix-token}

\texttt{pp-import-suffix pp-import-suffix-token}

\textit{pp-import-suffix-token:}

\texttt{any pp-balanced-token other than ;}

\textit{pp-balanced-token-seq:}

\texttt{pp-balanced-token}

\texttt{pp-balanced-token-seq pp-balanced-token}

\textit{pp-balanced-token:}

\texttt{pp-ldelim pp-balanced-token-seqopt pp-rdelim}

\texttt{any preprocessing-token other than a pp-ldelim or pp-rdelim}

\texttt{pp-ldelim: one of}

\texttt{\{} \texttt{\{} \texttt{:\<: <\%}

\texttt{pp-rdelim: one of}

\texttt{\}} \texttt{\}}} \texttt{\texttt{:%>}

1 A sequence of \texttt{preprocessing-tokens} matching the form of a \texttt{pp-import} instructs the preprocessor to import macros from the header unit (10.3) denoted by the \texttt{header-name}. A \texttt{pp-import} is only recognized when the sequence of tokens produced by phase 4 of translation up to the \texttt{import} token forms an \texttt{import-seq}, and the \texttt{import} token is not within the \texttt{header-name-tokens} or \texttt{pp-import-suffix} of another \texttt{pp-import}. The \texttt{preprocessing-token} terminating a \texttt{pp-import} shall not have been produced by macro replacement (15.5). The point of macro import for a \texttt{pp-import} is immediately after the ; terminating the \texttt{pp-import}.

2 In the second form of \texttt{pp-import}, a \texttt{header-name} token is formed as if the \texttt{header-name-tokens} were the \texttt{pp-tokens} of a \texttt{#include} directive. The \texttt{header-name-tokens} are replaced by the \texttt{header-name} token. [Note: This ensures that imports are treated consistently by the preprocessor and later phases of translation. —end note]

3 Each \texttt{#define} directive encountered when preprocessing each translation unit in a program results in a distinct \texttt{macro definition}. Importing macros from a header unit makes macro definitions from a translation unit visible in other translation units. Each macro definition has at most one point of definition in each translation unit and at most one point of undefinition, as follows:

\begin{enumerate}
\item The point of definition of a macro definition within a translation unit is the point at which its \texttt{#define} directive occurs (in the translation unit containing the \texttt{#define} directive), or, if the macro name is not lexically identical to a keyword (5.11) or to the \texttt{identifiers module or import}, the first point of macro import of a translation unit containing a point of definition for the macro definition, if any (in any other translation unit).

\item The point of undefinition of a macro definition within a translation unit is the first point at which a \texttt{undef} directive naming the macro occurs after its point of definition, or the first point of macro import of a translation unit containing a point of undefinition for the macro definition, whichever (if any) occurs first.
\end{enumerate}
A macro directive is active at a source location if it has a point of definition in that translation unit preceding the location, and does not have a point of undefinition in that translation unit preceding the location.

If a macro would be replaced or redefined, and multiple macro definitions are active for that macro name, the active macro definitions shall all be valid redefinitions of the same macro (15.5). [Note: The relative order of \texttt{pp-imports} has no bearing on whether a particular macro definition is active. —end note]

[Example:

Importable header "a.h":
\[
\texttt{#define X 123} \quad // \#1 \\
\texttt{#define Y 45} \quad // \#2 \\
\texttt{#define Z a} \quad // \#3 \\
\texttt{#undef X} \quad // \text{point of undefinition of \#1 in "a.h"}
\]

Importable header "b.h":
\[
\texttt{import "a.h";} \quad // \text{point of definition of \#1, \#2, and \#3, point of undefinition of \#1 in "b.h"} \\
\texttt{#define X 456} \quad // \text{OK, \#1 is not active} \\
\texttt{#define Y 6} \quad // \text{error: \#2 is active}
\]

Importable header "c.h":
\[
\texttt{#define Y 45} \quad // \#4 \\
\texttt{#define Z c} \quad // \#5
\]

Importable header "d.h":
\[
\texttt{import "a.h";} \quad // \text{point of definition of \#1, \#2, and \#3, point of undefinition of \#1 in "d.h"} \\
\texttt{import "c.h";} \quad // \text{point of definition of \#4 and \#5 in "d.h"} \\
\texttt{int a = Y;} \quad // \text{OK, active macro definitions \#2 and \#3 are valid redefinitions} \\
\texttt{int c = Z;} \quad // \text{error: active macro definitions \#2 and \#3 are not valid redefinitions of Z}
\]

—end example]

15.5 Macro replacement
[cpp.replace]

Two replacement lists are identical if and only if the preprocessing tokens in both have the same number, ordering, spelling, and white-space separation, where all white-space separations are considered identical.

An identifier currently defined as an object-like macro (see below) may be redefined by another \texttt{#define} preprocessing directive provided that the second definition is an object-like macro definition and the two replacement lists are identical, otherwise the program is ill-formed. Likewise, an identifier currently defined as a function-like macro (see below) may be redefined by another \texttt{#define} preprocessing directive provided that the second definition is a function-like macro definition that has the same number and spelling of parameters, and the two replacement lists are identical, otherwise the program is ill-formed.

There shall be white-space between the identifier and the replacement list in the definition of an object-like macro.

If the \texttt{identifier-list} in the macro definition does not end with an ellipsis, the number of arguments (including those arguments consisting of no preprocessing tokens) in an invocation of a function-like macro shall equal the number of parameters in the macro definition. Otherwise, there shall be at least as many arguments in the invocation as there are parameters in the macro definition (excluding the \ldots). There shall exist a ) preprocessing token that terminates the invocation.

The identifiers \texttt{\_VA_ARGS\_} and \texttt{\_VA_OPT\_} shall occur only in the \texttt{replacement-list} of a function-like macro that uses the ellipsis notation in the parameters.

A parameter identifier in a function-like macro shall be uniquely declared within its scope.

The identifier immediately following the \texttt{define} is called the macro name. There is one name space for macro names. Any white-space characters preceding or following the replacement list of preprocessing tokens are not considered part of the replacement list for either form of macro.

If a \# preprocessing token, followed by an identifier, occurs lexically at the point at which a preprocessing directive could begin, the identifier is not subject to macro replacement.

A preprocessing directive of the form
\[
\texttt{\# define identifier replacement-list new-line}
\]
defines an object-like macro that causes each subsequent instance of the macro name\(^{148}\) to be replaced by the replacement list of preprocessing tokens that constitute the remainder of the directive.\(^{149}\) The replacement list is then rescanned for more macro names as specified below.

10 A preprocessing directive of the form

\[
\begin{align*}
\# \textbf{define} \text{identifier} \ ( \text{paren} \text{identifier-list}_{\text{opt}} \ ) \ & \text{replacement-list new-line} \\
\# \textbf{define} \text{identifier} \ ( \text{paren} \ldots \ ) \ & \text{replacement-list new-line} \\
\# \textbf{define} \text{identifier} \ ( \text{paren identifier-list} _{,} \ldots \ ) \ & \text{replacement-list new-line}
\end{align*}
\]

defines a function-like macro with parameters, whose use is similar syntactically to a function call. The parameters are specified by the optional list of identifiers, whose scope extends from their declaration in the identifier list until the new-line character that terminates the \#define preprocessing directive. Each subsequent instance of the function-like macro name followed by a ( as the next preprocessing token introduces the sequence of preprocessing tokens that is replaced by the replacement list in the definition (an invocation of the macro). The replaced sequence of preprocessing tokens is terminated by the matching ) preprocessing token, skipping intervening matched pairs of left and right parenthesis preprocessing tokens. Within the sequence of preprocessing tokens making up an invocation of a function-like macro, new-line is considered a normal white-space character.

11 The sequence of preprocessing tokens bounded by the outside-most matching parentheses forms the list of arguments for the function-like macro. The individual arguments within the list are separated by comma preprocessing tokens, but comma preprocessing tokens between matching inner parentheses do not separate arguments. If there are sequences of preprocessing tokens within the list of arguments that would otherwise act as preprocessing directives,\(^{150}\) the behavior is undefined.

12 If there is a ... immediately preceding the ) in the function-like macro definition, then the trailing arguments (if any), including any separating comma preprocessing tokens, are merged to form a single item: the variable arguments. The number of arguments so combined is such that, following merger, the number of arguments is either equal to or one more than the number of parameters in the macro definition (excluding the ...).

15.5.1 Argument substitution \[\text{cpp.subst}\]

\[
\begin{align*}
\text{va-opt-replacement}: \\
\quad \_\_\_\text{VA_OPT}\_\_ ( \text{pp-tokens}_{\text{opt}} )
\end{align*}
\]

After the arguments for the invocation of a function-like macro have been identified, argument substitution takes place. For each parameter in the replacement list that is neither preceded by a # or ## preprocessing token nor followed by a ## preprocessing token, the preprocessing tokens naming the parameter are replaced by a token sequence determined as follows:

1. If the parameter is of the form \text{va-opt-replacement}, the replacement preprocessing tokens are the preprocessing token sequence for the corresponding argument, as specified below.

   (1.1) Otherwise, the replacement preprocessing tokens are the preprocessing tokens of corresponding argument after all macros contained therein have been expanded. The argument’s preprocessing tokens are completely macro replaced before being substituted as if they formed the rest of the preprocessing file with no other preprocessing tokens being available.

   [Example:

   \[
   \begin{align*}
   \#\text{define} \text{LPAREN}() \\
   \#\text{define} \text{G(Q)} 42 \\
   \#\text{define} \text{F(R, X, \ldots)} \ _\_\_\text{VA_OPT}_\_\_ (\text{G R X} ) \\
   \text{int} \ x \ = \ \text{F(}\text{LPAREN}(), \ 0, \ <:-); \quad \// \text{replaced by int x = 42;}
   \end{align*}
   \]
   
   — end example\]

2 An identifier \_\_\_\text{VA_ARGS}\_\_ that occurs in the replacement list shall be treated as if it were a parameter, and the variable arguments shall form the preprocessing tokens used to replace it.

3 The identifier \_\_\_\text{VA_OPT}\_\_ shall always occur as part of the preprocessing token sequence \text{va-opt-replacement}; its closing ) is determined by skipping intervening pairs of matching left and right parentheses in its \text{pp-tokens}. The \text{pp-tokens} of a \text{va-opt-replacement} shall not contain \_\_\_\text{VA_OPT}\_\_. If the \text{pp-tokens} would be

\(^{148}\) Since, by macro-replacement time, all character literals and string literals are preprocessing tokens, not sequences possibly containing identifier-like subsequences (see 5.2, translation phases), they are never scanned for macro names or parameters.

\(^{149}\) An alternative token (5.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not possible to define a macro whose name is the same as that of an alternative token.

\(^{150}\) A \text{conditionally-supported-directive} is a preprocessing directive regardless of whether the implementation supports it.
ill-formed as the replacement list of the current function-like macro, the program is ill-formed. A va-opt-replacement is treated as if it were a parameter, and the preprocessing token sequence for the corresponding argument is defined as follows. If the substitution of __VA_ARGS__ as neither an operand of # nor ## consists of no preprocessing tokens, the argument consists of a single placemarker preprocessing token (15.5.3, 15.5.4). Otherwise, the argument consists of the results of the expansion of the contained pp-tokens as the replacement list of the current function-like macro before removal of placemarker tokens, rescanning, and further replacement. [Note: The placemarker tokens are removed before stringization (15.5.2), and can be removed by rescanning and further replacement (15.5.4). —end note] [Example:

```c
#define F(...) f(0, __VA_OPT__(), __VA_ARGS__)
#define G(X, ...) f(0, X, __VA_OPT__(), __VA_ARGS__)
#define SDEF(sname, ...) S sname __VA_OPT__(= { __VA_ARGS__ })
#define EMP
F(a, b, c) // replaced by f(0, a, b, c)
F() // replaced by f(0)
F(EMP) // replaced by f(0)

G(a, b, c) // replaced by f(0, a, b, c)
G(a) // replaced by f(0, a)
G(a) // replaced by f(0, a)

SDEF(foo); // replaced by S foo;
SDEF(bar, 1, 2); // replaced by S bar = { 1, 2 };

#define H1(X, ...) X __VA_OPT__(##) __VA_ARGS__ // ill-formed: ## may not appear at
// the beginning of a replacement list (15.5.3)
#define H2(X, Y, ...) __VA_OPT__(X ## Y,) __VA_ARGS__
H2(a, b, c, d) // replaced by ab, c, d
#define H3(X, ...) #__VA_OPT__(X##X X##X)
H3(, 0) // replaced by ""
#define H4(X, ...) __VA_OPT__(a X ## X##X) ## b
H4(, 1) // replaced by a b
#define H5A(...) __VA_OPT__()/**/__VA_OPT__()
#define H5B(X) a ## X ## b
#define H5C(X) H5B(X)
H5C(H5A()) // replaced by ab

—end example]
```

15.5.2 The # operator

1 Each # preprocessing token in the replacement list for a function-like macro shall be followed by a parameter as the next preprocessing token in the replacement list.

2 A character string literal is a string-literal with no prefix. If, in the replacement list, a parameter is immediately preceded by a # preprocessing token, both are replaced by a single character string literal preprocessing token that contains the spelling of the preprocessing token sequence for the corresponding argument (excluding placemarker tokens). Let the stringizing argument be the preprocessing token sequence for the corresponding argument with placemarker tokens removed. Each occurrence of white space between the stringizing argument’s preprocessing tokens becomes a single space character in the character string literal. White space before the first preprocessing token and after the last preprocessing token comprising the stringizing argument is deleted. Otherwise, the original spelling of each preprocessing token in the stringizing argument is retained in the character string literal, except for special handling for producing the spelling of string literals and character literals: a \ character is inserted before each " and \ character of a character literal or string literal (including the delimiting " characters). If the replacement that results is not a valid character string literal, the behavior is undefined. The character string literal corresponding to an empty stringizing argument is "". The order of evaluation of # and ## operators is unspecified.
15.5.3 The ## operator

A ## preprocessing token shall not occur at the beginning or at the end of a replacement list for either form of macro definition.

2 If, in the replacement list of a function-like macro, a parameter is immediately preceded or followed by a ## preprocessing token, the parameter is replaced by the corresponding argument’s preprocessing token sequence; however, if an argument consists of no preprocessing tokens, the parameter is replaced by a placemarker preprocessing token instead.

3 For both object-like and function-like macro invocations, before the replacement list is reexamined for more macro names to replace, each instance of a ## preprocessing token in the replacement list (not from an argument) is deleted and the preceding preprocessing token is concatenated with the following preprocessing token. Placemarker preprocessing tokens are handled specially: concatenation of two placemarkers results in a single placemarker preprocessing token, and concatenation of a placemarker with a non-placemarker preprocessing token results in the non-placemarker preprocessing token. If the result is not a valid preprocessing token, the behavior is undefined. The resulting token is available for further macro replacement. The order of evaluation of ## operators is unspecified.

[Example: In the following fragment:

#define hash_hash # ## #
#define mkstr(a) # a
#define in_between(a) mkstr(a)
#define join(c, d) in_between(c hash_hash d)

char p[] = join(x, y); // equivalent to char p[] = "x ## y";

The expansion produces, at various stages:

join(x, y)
in_between(x hash_hash y)
in_between(x ## y)
mkstr(x ## y)
"x ## y"

In other words, expanding hash_hash produces a new token, consisting of two adjacent sharp signs, but this new token is not the ## operator. — end example]

15.5.4 Rescanning and further replacement

After all parameters in the replacement list have been substituted and # and ## processing has taken place, all placemarker preprocessing tokens are removed. Then the resulting preprocessing token sequence is rescanned, along with all subsequent preprocessing tokens of the source file, for more macro names to replace.

2 If the name of the macro being replaced is found during this scan of the replacement list (not including the rest of the source file’s preprocessing tokens), it is not replaced. Furthermore, if any nested replacements encounter the name of the macro being replaced, it is not replaced. These nonreplaced macro name preprocessing tokens are no longer available for further replacement even if they are later (re)examined in contexts in which that macro name preprocessing token would otherwise have been replaced.

3 The resulting completely macro-replaced preprocessing token sequence is not processed as a preprocessing directive even if it resembles one, but all pragma unary operator expressions within it are then processed as specified in 15.11 below.

15.5.5 Scope of macro definitions

A macro definition lasts (independent of block structure) until a corresponding #undef directive is encountered or (if none is encountered) until the end of the translation unit. Macro definitions have no significance after translation phase 4.

A preprocessing directive of the form

    # undef identifier new-line

causes the specified identifier no longer to be defined as a macro name. It is ignored if the specified identifier is not currently defined as a macro name.

[Example: The simplest use of this facility is to define a “manifest constant”, as in

151) Placemarker preprocessing tokens do not appear in the syntax because they are temporary entities that exist only within translation phase 4.
Example: The following defines a function-like macro whose value is the maximum of its arguments. It has the advantages of working for any compatible types of the arguments and of generating in-line code without the overhead of function calling. It has the disadvantages of evaluating one or the other of its arguments a second time (including side effects) and generating more code than a function if invoked several times. It also cannot have its address taken, as it has none.

```
define max(a, b) ((a) > (b) ? (a) : (b))
```

The parentheses ensure that the arguments and the resulting expression are bound properly. — end example]

Example: To illustrate the rules for redefinition and reexamination, the sequence

```c
#define x 3
#undef x
#define x 2
#define g f
#define m(a) a[w]
#define w 0,1
#define t(a) a
#define p() int
#define q(x) x
#define r(x,y) x ## y
#define str(x) # x

f(y+1) + f(f(z)) % t(t(g)(0) + t)(1);
g(x+(3,4)-w) | h 5) & m
(f)~m(m);
p() i[q()] = { q(1), r(2,3), r(4,), r(5), r(, )};
char c[2][6] = { str(hello), str() };
results in
f(2 * (y+1)) + f(2 * (f(2 * (z[0])))) % f(2 * (0)) + t(1);
f(2 * (2+(3,4)-0,1)) | f(2 * (~5)) & f(2 * (0,1))~m(0,1);
int i[1] = { 1, 23, 4, 5, };
char c[2][6] = { "hello", " " };
```

— end example]

Example: To illustrate the rules for creating character string literals and concatenating tokens, the sequence

```c
#define str(s) # s
#define xstr(s) str(s)
#define debug(s, t) printf("x" # s = %d, x" # t = %s, \n x ## s, x ## t)
#define INCFILE(n) vers ## n
#define glue(a, b) a ## b
#define xglue(a, b) glue(a, b)
#define HIGHLOW "hello"
#define LOW LOW", world"

debug(1, 2);
puts(str(strncmp("abc\0d", "abc", '\4') 
== 0) str(: @n), s);
#include xstr(INCFILE(2).h)
#include glue(HIGH, LOW);
xglue(HIGH, LOW)

results in
printf("x" "1" = %d, x" "2" = %s, x1, x2);
puts(\"strncmp(\"abc\0d\", \"abc\", '\4\') == 0" ": @n", s);
```
or, after concatenation of the character string literals,

```c
#include "vers2.h"  // after macro replacement, before file access
"hello";
"hello" = "world"
```

7  [Example: To illustrate the rules for placemarker preprocessing tokens, the sequence

```c
#define t(x,y,z) x ## y ## z
int j[] = { t(1,2,3), t(,4,5), t(6,,7), t(8,9,),
            t(10,,), t(,,11), t(,,12), t(,,) };
```

results in

```c
int j[] = { 123, 45, 67, 89,
            10, 11, 12, };
```

—end example]

8  [Example: To demonstrate the redefinition rules, the following sequence is valid.

```c
#define OBJ_LIKE (1-1)
#define OBJ_LIKE /* white space */ (1-1) /* other */
#define FUNC_LIKE(a) ( a ) // note the white space */
    a /* other stuff on this line */
#define FUNC_LIKE(b) ( a )
```

But the following redefinitions are invalid:

```c
#define OBJ_LIKE (0) // different token sequence
#define OBJ_LIKE (1 - 1) // different white space
#define FUNC_LIKE(b) ( a ) // different parameter usage
#define FUNC_LIKE(b) ( b ) // different parameter spelling
```

—end example]

9  [Example: Finally, to show the variable argument list macro facilities:

```c
#define debug(...) fprintf(stderr, __VA_ARGS__)
#define showlist(...) puts(#__VA_ARGS__)
#define report(test, ...) ((test) ? puts(#test) : printf(__VA_ARGS__))
```

results in

```c
fprintf(stderr, "Flag")
fprintf(stderr, "X = %d\n", x);
puts("The first, second, and third items.");
(report(x>y, "x is %d but y is %d", x, y));
```

—end example]

### 15.6 Line control

1  The string literal of a `#line` directive, if present, shall be a character string literal.

2  The `line number` of the current source line is one greater than the number of new-line characters read or introduced in translation phase 1 (§5.2) while processing the source file to the current token.

3  A preprocessing directive of the form

```c
# line digit-sequence new-line
```
causes the implementation to behave as if the following sequence of source lines begins with a source line that has a line number as specified by the digit sequence (interpreted as a decimal integer). If the digit sequence specifies zero or a number greater than 2147483647, the behavior is undefined.

4 A preprocessing directive of the form
   
   \# line digit-sequence * s-char-sequence_opt * new-line
   
   sets the presumed line number similarly and changes the presumed name of the source file to be the contents of the character string literal.

5 A preprocessing directive of the form
   
   \# line pp-tokens new-line

   (that does not match one of the two previous forms) is permitted. The preprocessing tokens after line on the directive are processed just as in normal text (each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined; otherwise, the result is processed as appropriate.

15.7 Error directive [cpp.error]

1 A preprocessing directive of the form

   \# error pp-tokens_opt new-line

   causes the implementation to produce a diagnostic message that includes the specified sequence of preprocessing tokens, and renders the program ill-formed.

15.8 Pragma directive [cpp.pragma]

1 A preprocessing directive of the form

   \# pragma pp-tokens_opt new-line

   causes the implementation to behave in an implementation-defined manner. The behavior might cause translation to fail or cause the translator or the resulting program to behave in a non-conforming manner. Any pragma that is not recognized by the implementation is ignored.

15.9 Null directive [cpp.null]

1 A preprocessing directive of the form

   \# new-line

   has no effect.

15.10 Predefined macro names [cpp.predefined]

1 The following macro names shall be defined by the implementation:

   __cplusplus
   The integer literal 201703L. [Note: It is intended that future versions of this International Standard will replace the value of this macro with a greater value. — end note]

   __DATE__
   The date of translation of the source file: a character string literal of the form "Mmm dd yyyy", where the names of the months are the same as those generated by the asctime function, and the first character of dd is a space character if the value is less than 10. If the date of translation is not available, an implementation-defined valid date shall be supplied.

   __FILE__
   The presumed name of the current source file (a character string literal).\(^{152}\)

   __LINE__
   The presumed line number (within the current source file) of the current source line (an integer literal).\(^{153}\)

\(^{152}\) The presumed source file name can be changed by the \#line directive.
\(^{153}\) The presumed line number can be changed by the \#line directive.
The integer literal 1 if the implementation is a hosted implementation or the integer literal 0 if it is not.

An integer literal of type std::size_t whose value is the alignment guaranteed by a call to \texttt{operator new(std::size\_t)} or \texttt{operator new[]}(std::size\_t). [Note: Larger alignments will be passed to \texttt{operator new(std::size\_t, \text{std::align\_val\_t})}, etc. (7.6.2.7). —end note]

The time of translation of the source file: a character string literal of the form "hh:mm:ss" as in the time generated by the \texttt{asctime} function. If the time of translation is not available, an implementation-defined valid time shall be supplied.

The names listed in Table 17.

The macros defined in Table 17 shall be defined to the corresponding integer literal. [Note: Future versions of this International Standard might replace the values of these macros with greater values. —end note]

2 The following macro names are conditionally defined by the implementation:

__STDC__
Whether __STDC__ is predefined and if so, what its value is, are implementation-defined.

__STDC_MB_MIGHT_NEQ_WC__
The integer literal 1, intended to indicate that, in the encoding for wchar_t, a member of the basic character set need not have a code value equal to its value when used as the lone character in an ordinary character literal.

__STDC_VERSION__
Whether __STDC_VERSION__ is predefined and if so, what its value is, are implementation-defined.

__STDC_ISO_10646__
An integer literal of the form yyyymmL (for example, 199712L). If this symbol is defined, then every character in the Unicode required set, when stored in an object of type wchar_t, has the same value as the code point of that character. The Unicode required set consists of all the characters that are defined by ISO/IEC 10646, along with all amendments and technical corrigenda as of the specified year and month.

__STDCPP_STRICT_POINTER_SAFETY__
Defined, and has the value integer literal 1, if and only if the implementation has strict pointer safety (6.6.5.4.3).

__STDCPP_THREADS__
Defined, and has the value integer literal 1, if and only if a program can have more than one thread of execution (6.8.2).

3 The values of the predefined macros (except for __FILE__ and __LINE__) remain constant throughout the translation unit.

4 If any of the pre-defined macro names in this subclause, or the identifier defined, is the subject of a #define or a #undef preprocessing directive, the behavior is undefined. Any other predefined macro names shall begin with a leading underscore followed by an uppercase letter or a second underscore.

15.11 Pragma operator

A unary operator expression of the form:

__Pragma ( string-literal )

is processed as follows: The string literal is destringized by deleting the L prefix, if present, deleting the leading and trailing double-quotes, replacing each escape sequence \" by a double-quote, and replacing each escape sequence \ by a single backslash. The resulting sequence of characters is processed through
translation phase 3 to produce preprocessing tokens that are executed as if they were the *pp-tokens* in a pragma directive. The original four preprocessing tokens in the unary operator expression are removed.

2 [Example:

```c
#pragma listing on ".\listing.dir"
```

can also be expressed as:

```c
#define LISTING(x) PRAGMA(listing on #x)
#define PRAGMA(x) _Pragma(#x)
```

```c
LISTING( ..\listing.dir )
```

— end example]
16 Library introduction

16.1 General

This Clause describes the contents of the \textit{C++ standard library}, how a well-formed \textit{C++} program makes use of the library, and how a conforming implementation may provide the entities in the library.

The following subclauses describe the definitions (16.3), method of description (16.4), and organization (16.5.1) of the library. 16.5, Clause 17 through Clause 32, and Annex D specify the contents of the library, as well as library requirements and constraints on both well-formed \textit{C++} programs and conforming implementations.

Detailed specifications for each of the components in the library are in Clause 17–Clause 32, as shown in Table 18.

Table 18: Library categories

</tbody>
</table>

The language support library (Clause 17) provides components that are required by certain parts of the \textit{C++} language, such as memory allocation (7.6.2.7, 7.6.2.8) and exception processing (Clause 14).

The concepts library (Clause 18) describes library components that \textit{C++} programs may use to perform compile-time validation of template arguments and perform function dispatch based on properties of types.

The diagnostics library (Clause 19) provides a consistent framework for reporting errors in a \textit{C++} program, including predefined exception classes.

The general utilities library (Clause 20) includes components used by other library elements, such as a predefined storage allocator for dynamic storage management (6.6.5.4), and components used as infrastructure in \textit{C++} programs, such as tuples, function wrappers, and time facilities.

The strings library (Clause 21) provides support for manipulating text represented as sequences of type \texttt{char}, sequences of type \texttt{char8_t}, sequences of type \texttt{char16_t}, sequences of type \texttt{char32_t}, sequences of type \texttt{wchar_t}, and sequences of any other character-like type.

The localization library (Clause 28) provides extended internationalization support for text processing.

The containers (Clause 22), iterators (Clause 23), ranges (Clause 24), and algorithms (Clause 25) libraries provide a \textit{C++} program with access to a subset of the most widely used algorithms and data structures.

The numerics library (Clause 26) provides numeric algorithms and complex number components that extend support for numeric processing. The \texttt{valarray} component provides support for \textit{n}-at-a-time processing, potentially implemented as parallel operations on platforms that support such processing. The random number component provides facilities for generating pseudo-random numbers.
The input/output library (Clause 29) provides the iostream components that are the primary mechanism for C++ program input and output. They can be used with other elements of the library, particularly strings, locales, and iterators.

The regular expressions library (Clause 30) provides regular expression matching and searching.

The atomic operations library (Clause 31) allows more fine-grained concurrent access to shared data than is possible with locks.

The thread support library (Clause 32) provides components to create and manage threads, including mutual exclusion and interthread communication.

16.2 The C standard library

The C++ standard library also makes available the facilities of the C standard library, suitably adjusted to ensure static type safety.

The descriptions of many library functions rely on the C standard library for the semantics of those functions. In some cases, the signatures specified in this document may be different from the signatures in the C standard library, and additional overloads may be declared in this document, but the behavior and the preconditions (including any preconditions implied by the use of an ISO C restrict qualifier) are the same unless otherwise stated.

16.3 Definitions

[library.c]

The C++ standard library also makes available the facilities of the C standard library, suitably adjusted to ensure static type safety.

The descriptions of many library functions rely on the C standard library for the semantics of those functions. In some cases, the signatures specified in this document may be different from the signatures in the C standard library, and additional overloads may be declared in this document, but the behavior and the preconditions (including any preconditions implied by the use of an ISO C restrict qualifier) are the same unless otherwise stated.

16.3.1 arbitrary-positional stream

stream (described in Clause 29) that can seek to any integral position within the length of the stream

[Note 1 to entry: Every arbitrary-positional stream is also a repositionable stream. — end note]

16.3.2 character

(Clause 21, Clause 28, Clause 29, and Clause 30) object which, when treated sequentially, can represent text

[Note 1 to entry: The term does not mean only char, char8_t, char16_t, char32_t, and wchar_t objects, but any value that can be represented by a type that provides the definitions specified in these Clauses. — end note]

16.3.3 character container type

class or a type used to represent a character

[Note 1 to entry: It is used for one of the template parameters of the string, iostream, and regular expression class templates. — end note]

16.3.4 comparison function

operator function (12.5) for any of the equality (7.6.10) or relational (7.6.9) operators

16.3.5 component

group of library entities directly related as members, parameters, or return types

[Note 1 to entry: For example, the class template basic_string and the non-member function templates that operate on strings are referred to as the string component. — end note]

16.3.6 constant subexpression

expression whose evaluation as subexpression of a conditional-expression CE (7.6.16) would not prevent CE from being a core constant expression (7.7)
16.3.7 deadlock
situation wherein one or more threads are unable to continue execution because each is blocked waiting for one or more of the others to satisfy some condition

16.3.8 default behavior
(implementation) specific behavior provided by the implementation, within the scope of the required behavior

16.3.9 default behavior
(specification) description of replacement function and handler function semantics

16.3.10 direct-non-list-initialization
direct-initialization (9.3) that is not list-initialization (9.3.4)

16.3.11 expression-equivalent
expressions that all have the same effects, either are all potentially-throwing (14.4) or are all not potentially-throwing, and either are all constant subexpressions or are all not constant subexpressions

[Example: For a value x of type int and a function f that accepts integer arguments, the expressions f(x + 2), f(2 + x), and f(1 + x + 1) are expression-equivalent. — end example]

16.3.12 handler function
non-reserved function whose definition may be provided by a C++ program

[Note 1 to entry: A C++ program may designate a handler function at various points in its execution by supplying a pointer to the function when calling any of the library functions that install handler functions (Clause 17). — end note]

16.3.13 iostream class templates
templates, defined in Clause 29, that take two template arguments

[Note 1 to entry: The arguments are named charT and traits. The argument charT is a character container class, and the argument traits is a class which defines additional characteristics and functions of the character type represented by charT necessary to implement the iostream class templates. — end note]

16.3.14 modifier function
class member function (11.3.1) other than a constructor, assignment operator, or destructor that alters the state of an object of the class

16.3.15 move assignment
assignment of an rvalue of some object type to a modifiable lvalue of the same type

16.3.16 move construction
direct-initialization of an object of some type with an rvalue of the same type

16.3.17 NTCTS
sequence of values that have character type that precede the terminating null character type value charT()

16.3.18 observer function
class member function (11.3.1) that accesses the state of an object of the class but does not alter that state

[Note 1 to entry: Observer functions are specified as const member functions (11.3.2.1). — end note]
16.3.19  
program-defined specialization
explicit template specialization or partial specialization that is not part of the C++ standard library and not defined by the implementation

16.3.20  
program-defined type
non-closure class type or enumeration type that is not part of the C++ standard library and not defined by the implementation, or a closure type of a non-implementation-provided lambda expression, or an instantiation of a program-defined specialization

[Note 1 to entry: Types defined by the implementation include extensions (4.1) and internal types used by the library. — end note]

16.3.21  
projection
(function object argument) transformation that an algorithm applies before inspecting the values of elements

[Example:
std::pair<int, std::string_view> pairs[] = {{2, "foo"}, {1, "bar"}, {0, "baz"}};
std::ranges::sort(pairs, std::ranges::less{}, [] (auto const& p) { return p.first; });
sorts the pairs in increasing order of their first members:
{{0, "baz"}, {1, "bar"}, {2, "foo"}}
— end example]

16.3.22  
referenceable type
type that is either an object type, a function type that does not have cv-qualifiers or a ref-qualifier, or a reference type

[Note 1 to entry: The term describes a type to which a reference can be created, including reference types. — end note]

16.3.23  
replacement function
non-reserved function whose definition is provided by a C++ program

[Note 1 to entry: Only one definition for such a function is in effect for the duration of the program’s execution, as the result of creating the program (5.2) and resolving the definitions of all translation units (6.5). — end note]

16.3.24  
repositional stream
stream (described in Clause 29) that can seek to a position that was previously encountered

16.3.25  
required behavior
description of replacement function and handler function semantics applicable to both the behavior provided by the implementation and the behavior of any such function definition in the program

[Note 1 to entry: If such a function defined in a C++ program fails to meet the required behavior when it executes, the behavior is undefined. — end note]

16.3.26  
reserved function
function, specified as part of the C++ standard library, that is defined by the implementation

[Note 1 to entry: If a C++ program provides a definition for any reserved function, the results are undefined. — end note]
16.3.27 stable algorithm
algorithm that preserves, as appropriate to the particular algorithm, the order of elements

[Note 1 to entry: Requirements for stable algorithms are given in 16.5.5.7. — end note]

16.3.28 traits class
class that encapsulates a set of types and functions necessary for class templates and function templates to manipulate objects of types for which they are instantiated

16.3.29 valid but unspecified state
value of an object that is not specified except that the object’s invariants are met and operations on the object behave as specified for its type

[Example: If an object x of type std::vector<int> is in a valid but unspecified state, x.empty() can be called unconditionally, and x.front() can be called only if x.empty() returns false. — end example]

16.4 Method of description
This subclause describes the conventions used to specify the C++ standard library. 16.4.1 describes the structure of the normative Clause 17 through Clause 32 and Annex D. 16.4.2 describes other editorial conventions.

16.4.1 Structure of each clause

16.4.1.1 Elements

1 Each library clause contains the following elements, as applicable:154

(1.1) — Summary
(1.2) — Requirements
(1.3) — Detailed specifications
(1.4) — References to the C standard library

16.4.1.2 Summary
The Summary provides a synopsis of the category, and introduces the first-level subclauses. Each subclause also provides a summary, listing the headers specified in the subclause and the library entities provided in each header.

2 The contents of the summary and the detailed specifications include:

(2.1) — macros
(2.2) — values
(2.3) — types and alias templates
(2.4) — classes and class templates
(2.5) — functions and function templates
(2.6) — objects and variable templates
(2.7) — concepts

16.4.1.3 Requirements
Requirements describe constraints that shall be met by a C++ program that extends the standard library. Such extensions are generally one of the following:

(1.1) — Template arguments
(1.2) — Derived classes
(1.3) — Containers, iterators, and algorithms that meet an interface convention or model a concept

154) To save space, items that do not apply to a Clause are omitted. For example, if a Clause does not specify any requirements, there will be no “Requirements” subclause.
2 The string and istream components use an explicit representation of operations required of template arguments. They use a class template `char_traits` to define these constraints.

3 Interface convention requirements are stated as generally as possible. Instead of stating “class `X` has to define a member function `operator++()`”, the interface requires “for any object `x` of class `X`, `++x` is defined”. That is, whether the operator is a member is unspecified.

4 Requirements are stated in terms of well-defined expressions that define valid terms of the types that meet the requirements. For every set of well-defined expression requirements there is either a named concept or a table that specifies an initial set of the valid expressions and their semantics. Any generic algorithm (Clause 25) that uses the well-defined expression requirements is described in terms of the valid expressions for its template type parameters.

5 The library specification uses a typographical convention for naming requirements. Names in italic type that begin with the prefix `Cpp17` refer to sets of well-defined expression requirements typically presented in tabular form, possibly with additional prose semantic requirements. For example, `Cpp17Destructible` (Table 30) is such a named requirement. Names in constant width type refer to library concepts which are presented as a concept definition (Clause 13), possibly with additional prose semantic requirements. For example, `Destructible` (18.4.10) is such a named requirement.

6 Template argument requirements are sometimes referenced by name. See 16.4.2.2.

7 In some cases the semantic requirements are presented as C++ code. Such code is intended as a specification of equivalence of a construct to another construct, not necessarily as the way the construct must be implemented.

8 Required operations of any concept defined in this document need not be total functions; that is, some arguments to a required operation may result in the required semantics failing to be met. [Example: The required `<` operator of the `StrictTotallyOrdered` concept (18.5.4) does not meet the semantic requirements of that concept when operating on NaNs. — end example] This does not affect whether a type models the concept.

9 A declaration may explicitly impose requirements through its associated constraints (13.4.2). When the associated constraints refer to a concept (13.6.8), the semantic constraints specified for that concept are additionally imposed on the use of the declaration.

### 16.4.1.4 Detailed specifications

The detailed specifications each contain the following elements:

1. **name and brief description**
2. **synopsis (class definition or function declaration, as appropriate)**
3. **restrictions on template arguments, if any**
4. **description of class invariants**
5. **description of function semantics**

Descriptions of class member functions follow the order (as appropriate): 156

1. **constructor(s) and destructor**
2. **copying, moving & assignment functions**
3. **comparison functions**
4. **modifier functions**
5. **observer functions**
6. **operators and other non-member functions**

Descriptions of function semantics contain the following elements (as appropriate): 157

1. **Requires:** the preconditions for calling the function.

---

155) Although in some cases the code given is unambiguously the optimum implementation.

156) To save space, items that do not apply to a class are omitted. For example, if a class does not specify any comparison functions, there will be no “Comparison functions” subclause.

157) To save space, elements that do not apply to a function are omitted. For example, if a function specifies no preconditions, there will be no `<Expects:` element.
— **Constraints**: the conditions for the function’s participation in overload resolution (12.3). [Note: Failure to meet such a condition results in the function’s silent non-viability. — end note] [Example: An implementation might express such a condition via a constraint-expression (13.4.2). — end example]

— **Mandates**: the conditions that, if not met, render the program ill-formed. [Example: An implementation might express such a condition via the constant-expression in a static_assert-declaration (Clause 9). If the diagnostic is to be emitted only after the function has been selected by overload resolution, an implementation might express such a condition via a constraint-expression (13.4.2) and also define the function as deleted. — end example]

— **Expects**: the conditions (sometimes termed preconditions) that the function assumes to hold whenever it is called. [Example: An implementation might express such conditions via an attribute such as [[expects]] (9.11.4). However, some such conditions might not lend themselves to expression via code. — end example]

— **Effects**: the actions performed by the function.

— **Synchronization**: the synchronization operations (6.8.2) applicable to the function.

— **Ensures**: the conditions (sometimes termed observable results or postconditions) established by the function.

— **Returns**: a description of the value(s) returned by the function.

— **Throws**: any exceptions thrown by the function, and the conditions that would cause the exception.

— **Complexity**: the time and/or space complexity of the function.

— **Remarks**: additional semantic constraints on the function.

**Error conditions**: the error conditions for error codes reported by the function.

Whenever the `Effects` element specifies that the semantics of some function `F` are Equivalent to some code sequence, then the various elements are interpreted as follows. If `F`’s semantics specifies any `Constraints` or `Mandates` elements, then those requirements are logically imposed prior to the equivalent-to semantics. Next, the semantics of the code sequence are determined by the `Constraints`, `Mandates`, `Expects`, `Effects`, `Synchronization`, `Ensures`, `Returns`, `Throws`, `Complexity`, `Remarks`, and `Error conditions` specified for the function invocations contained in the code sequence. The value returned from `F` is specified by `F`’s `Returns` element, or if `F` has no `Returns` element, a non-void return from `F` is specified by the `return` statements (8.6.3) in the code sequence. If `F`’s semantics contains a `Throws`, `Ensures`, or `Complexity` element, then that supersedes any occurrences of that element in the code sequence.

For non-reserved replacement and handler functions, Clause 17 specifies two behaviors for the functions in question: their required and default behavior. The default behavior describes a function definition provided by the implementation. The required behavior describes the semantics of a function definition provided by either the implementation or a C++ program. Where no distinction is explicitly made in the description, the behavior described is the required behavior.

If the formulation of a complexity requirement calls for a negative number of operations, the actual requirement is zero operations.\(^{158}\)

Complexity requirements specified in the library clauses are upper bounds, and implementations that provide better complexity guarantees meet the requirements.

Error conditions specify conditions where a function may fail. The conditions are listed, together with a suitable explanation, as the `enum class errc` constants (19.5).

### 16.4.1.5 C library

[structure.see.also]

1 Paragraphs labeled “SEE ALSO” contain cross-references to the relevant portions of other standards (Clause 2).

### 16.4.2 Other conventions

[conventions]

1 This subclause describes several editorial conventions used to describe the contents of the C++ standard library. These conventions are for describing implementation-defined types (16.4.2.2), and member functions (16.4.2.3).

\(^{158}\) This simplifies the presentation of complexity requirements in some cases.
16.4.2.1 Exposition-only functions

Several function templates defined in Clause 17 through Clause 32 and Annex D are only defined for the purpose of exposition. The declaration of such a function is followed by a comment ending in \textit{exposition only}. The following function is defined for exposition only to aid in the specification of the library:

\begin{verbatim}
template<class T> constexpr decay_t<T> decay-copy(T&& v)
    noexcept(is_nothrow_convertible_v<T, decay_t<T>>) // exposition only
    { return std::forward<T>(v); }
\end{verbatim}

16.4.2.2 Type descriptions

16.4.2.2.1 General

The Requirements subclauses may describe names that are used to specify constraints on template arguments. These names are used in library Clauses to describe the types that may be supplied as arguments by a C++ program when instantiating template components from the library.

16.4.2.2.2 Exposition-only types

Several types defined in Clause 17 through Clause 32 and Annex D are defined for the purpose of exposition. The declaration of such a type is followed by a comment ending in \textit{exposition only}. \[Example:
\begin{verbatim}
namespace std {
    extern "C" using some-handler = int(int, void*, double); // exposition only
}
\end{verbatim}\]

The type placeholder \texttt{some-handler} can now be used to specify a function that takes a callback parameter with C language linkage. \[end example\]

16.4.2.2.3 Enumerated types

Several types defined in Clause 29 are enumerated types. Each enumerated type may be implemented as an enumeration or as a synonym for an enumeration.

The enumerated type \texttt{enumerated} can be written:

\begin{verbatim}
enum enumerated { V0, V1, V2, V3, ... };
inline const enumerated C0(V0);
inline const enumerated C1(V1);
inline const enumerated C2(V2);
inline const enumerated C3(V3);
\end{verbatim}

Here, the names \texttt{C0}, \texttt{C1}, etc. represent enumerated elements for this particular enumerated type. All such elements have distinct values.

16.4.2.2.4 Bitmask types

Several types defined in Clause 17 through Clause 32 and Annex D are bitmask types. Each bitmask type can be implemented as an enumerated type that overloads certain operators, as an integer type, or as a bitset (20.9.2). The bitmask type \texttt{bitmask} can be written:

\begin{verbatim}
// For exposition only.
// int_type is an integral type capable of representing all values of the bitmask type.
enum bitmask : int_type {
    V0 = 1 << 0, V1 = 1 << 1, V2 = 1 << 2, V3 = 1 << 3, ...
};
\end{verbatim}

159) Examples from 16.5.3 include: \texttt{Cpp17EqualityComparable}, \texttt{Cpp17LessThanComparable}, \texttt{Cpp17CopyConstructible}. Examples from 23.3 include: \texttt{Cpp17InputIterator}, \texttt{Cpp17ForwardIterator}.

160) Such as an integer type, with constant integer values (6.7.1).
inline constexpr bitmask C0(V0);
inline constexpr bitmask C1(V1);
inline constexpr bitmask C2(V2);
inline constexpr bitmask C3(V3);

constexpr bitmask operator&(bitmask X, bitmask Y) {
    return static_cast<bitmask>(
        static_cast<int_type>(X) & static_cast<int_type>(Y));
}

constexpr bitmask operator|(bitmask X, bitmask Y) {
    return static_cast<bitmask>(
        static_cast<int_type>(X) | static_cast<int_type>(Y));
}

constexpr bitmask operator^(bitmask X, bitmask Y) {
    return static_cast<bitmask>(
        static_cast<int_type>(X) ^ static_cast<int_type>(Y));
}

constexpr bitmask operator~(bitmask X) {
    return static_cast<bitmask>(
        ~static_cast<int_type>(X));
}

bitmask& operator&=(bitmask& X, bitmask Y) {
    X = X & Y; return X;
}

bitmask& operator|=(bitmask& X, bitmask Y) {
    X = X | Y; return X;
}

bitmask& operator^=(bitmask& X, bitmask Y) {
    X = X ^ Y; return X;
}

Here, the names C0, C1, etc. represent bitmask elements for this particular bitmask type. All such elements have distinct, nonzero values such that, for any pair Ci and Cj where i ≠ j, Ci & Cj is nonzero and Cj & Ci is zero. Additionally, the value 0 is used to represent an empty bitmask, in which no bitmask elements are set.

The following terms apply to objects and values of bitmask types:

(4.1) — To set a value Y in an object X is to evaluate the expression X |= Y.

(4.2) — To clear a value Y in an object X is to evaluate the expression X &= ~Y.

(4.3) — The value Y is set in the object X if the expression X & Y is nonzero.

16.4.2.2.5 Character sequences [character.seq]

The C standard library makes widespread use of characters and character sequences that follow a few uniform conventions:

(1.1) — A letter is any of the 26 lowercase or 26 uppercase letters in the basic execution character set.

(1.2) — The decimal-point character is the (single-byte) character used by functions that convert between a (single-byte) character sequence and a value of one of the floating-point types. It is used in the character sequence to denote the beginning of a fractional part. It is represented in Clause 17 through Clause 32 and Annex D by a period, '.', which is also its value in the "C" locale, but may change during program execution by a call to setlocale(int, const char*), or by a change to a locale object, as described in 28.3 and Clause 29.

(1.3) — A character sequence is an array object (9.2.3.4) A that can be declared as TA[N], where T is any of the types char, unsigned char, or signed char (6.7.1), optionally qualified by any combination of const or volatile. The initial elements of the array have defined contents up to and including an element determined by some predicate. A character sequence can be designated by a pointer value S that points to its first element.

161) declared in <clocale> (28.5).
16.4.2.2.5.1 Byte strings

1 A null-terminated byte string, or NTBS, is a character sequence whose highest-addressed element with defined content has the value zero (the terminating null character); no other element in the sequence has the value zero.\(^{162}\)

2 The length of an NTBS is the number of elements that precede the terminating null character. An empty NTBS has a length of zero.

3 The value of an NTBS is the sequence of values of the elements up to and including the terminating null character.

4 A static NTBS is an NTBS with static storage duration.\(^{163}\)

16.4.2.2.5.2 Multibyte strings

1 A null-terminated multibyte string, or NTMBS, is an NTBS that constitutes a sequence of valid multibyte characters, beginning and ending in the initial shift state.\(^{164}\)

2 A static NTMBS is an NTMBS with static storage duration.

16.4.2.2.6 Customization Point Object types

1 A customization point object is a function object (20.14) with a literal class type that interacts with program-defined types while enforcing semantic requirements on that interaction.

2 The type of a customization point object shall model \texttt{Semiregular} (18.6).

3 All instances of a specific customization point object type shall be equal (18.2).

4 The type \(T\) of a customization point object shall model \texttt{Invocable<\texttt{const T\&}, Args...>} (18.7.2) when the types in \texttt{Args...} meet the requirements specified in that customization point object’s definition. When the types of \texttt{Args...} do not meet the customization point object’s requirements, \(T\) shall not have a function call operator that participates in overload resolution.

5 Each customization point object type constrains its return type to model a particular concept.

6 \textit{Note:} Many of the customization point objects in the library evaluate function call expressions with an unqualified name which results in a call to a program-defined function found by argument dependent name lookup (6.4.2). To preclude such an expression resulting in a call to unconstrained functions with the same name in namespace \texttt{std}, customization point objects specify that lookup for these expressions is performed in a context that includes deleted overloads matching the signatures of overloads defined in namespace \texttt{std}. When the deleted overloads are viable, program-defined overloads need be more specialized (13.6.6.2) or more constrained (13.4.4) to be used by a customization point object. —end note

16.4.2.3 Functions within classes

1 For the sake of exposition, Clause 17 through Clause 32 and Annex D do not describe copy/move constructors, assignment operators, or (non-virtual) destructors with the same apparent semantics as those that can be generated by default (11.3.4.2, 11.3.5, 11.3.6). It is unspecified whether the implementation provides explicit definitions for such member function signatures, or for virtual destructors that can be generated by default.

16.4.2.4 Operators

1 In this library, whenever a declaration is provided for an \texttt{operator!=, operator>, operator<=, or operator>=} for a type \(T\), its requirements and semantics are as follows, unless explicitly specified otherwise.

\begin{verbatim}
bool operator!=(const T& x, const T& y);
\end{verbatim}

2 Requires: Type \(T\) is \texttt{Cpp17EqualityComparable} (Table 23).

3 Returns: \(!\ (x == y)\).

\begin{verbatim}
bool operator>(const T& x, const T& y);
\end{verbatim}

4 Requires: Type \(T\) is \texttt{Cpp17LessThanComparable} (Table 24).

5 Returns: \(y < x\).

\(^{162}\) Many of the objects manipulated by function signatures declared in \texttt{<cstring>} (21.5) are character sequences or NTBSs. The size of some of these character sequences is limited by a length value, maintained separately from the character sequence.\(^{163}\) A string literal, such as \texttt{"abc"}, is a static NTBS.\(^{164}\) An NTBS that contains characters only from the basic execution character set is also an NTMBS. Each multibyte character then consists of a single byte.
bool operator<=(const T& x, const T& y);

Requires: Type T is Cpp17LessThanComparable (Table 24).

Returns: !(y < x).

bool operator>=(const T& x, const T& y);

Requires: Type T is Cpp17LessThanComparable (Table 24).

Returns: !(x < y).

16.4.2.5 Private members
Clause 17 through Clause 32 and Annex D do not specify the representation of classes, and intentionally omit specification of class members (11.3). An implementation may define static or non-static class members, or both, as needed to implement the semantics of the member functions specified in Clause 17 through Clause 32 and Annex D.

For the sake of exposition, some subclauses provide representative declarations, and semantic requirements, for private members of classes that meet the external specifications of the classes. The declarations for such members are followed by a comment that ends with exposition only, as in:

```
streambuf* sb;  // exposition only
```

An implementation may use any technique that provides equivalent observable behavior.

16.5 Library-wide requirements
This subclause specifies requirements that apply to the entire C++ standard library. Clause 17 through Clause 32 and Annex D specify the requirements of individual entities within the library.

Requirements specified in terms of interactions between threads do not apply to programs having only a single thread of execution.

Within this subclause, 16.5.1 describes the library’s contents and organization, 16.5.2 describes how well-formed C++ programs gain access to library entities, 16.5.3 describes constraints on types and functions used with the C++ standard library, 16.5.4 describes constraints on well-formed C++ programs, and 16.5.5 describes constraints on conforming implementations.

16.5.1 Library contents and organization
16.5.1.1 describes the entities and macros defined in the C++ standard library. 16.5.1.2 lists the standard library headers and some constraints on those headers. 16.5.1.3 lists requirements for a freestanding implementation of the C++ standard library.

16.5.1.1 Library contents
The C++ standard library provides definitions for the entities and macros described in the synopses of the C++ standard library headers (16.5.1.2).

All library entities except operator new and operator delete are defined within the namespace std or namespaces nested within namespace std. It is unspecified whether names declared in a specific namespace are declared directly in that namespace or in an inline namespace inside that namespace.

Whenever a name x defined in the standard library is mentioned, the name x is assumed to be fully qualified as ::std::x, unless explicitly described otherwise. For example, if the Effects: element for library function F is described as calling library function G, the function ::std::G is meant.

16.5.1.2 Headers
Each element of the C++ standard library is declared or defined (as appropriate) in a header. The C++ standard library provides the C++ library headers, shown in Table 19.

The facilities of the C standard library are provided in the additional headers shown in Table 20.

---

165) The C standard library headers (D.6) also define names within the global namespace, while the C++ headers for C library facilities (16.5.1.2) may also define names within the global namespace.

166) This gives implementers freedom to use inline namespaces to support multiple configurations of the library.

167) A header is not necessarily a source file, nor are the sequences delimited by < and > in header names necessarily valid source file names (15.2).

168) It is intentional that there is no C++ header for any of these C headers: <stdatomic.h>, <stdnoreturn.h>, <threads.h>.

Table 20: C++ headers for C library facilities  [tab:headers.cpp.c]

| `<cassert>` | `<cfloat>` | `<climits>` | `<csetjmp>` | `<cstddef>` | `<cstdint>` | `<cstdlib>` | `<cstring>` | `<ctime>` |
| `<cctype>`  | `<cfenv>` | `<cinttypes>` | `<csignal>` | `<cstdio>` | `<cstdint>` | `<cstdlib>` | `<cstring>` | `<ctime>` |
| `<cerrno>` | `<clocale>` | `<cmath>` | `<cstdarg>` | `<cstdio>` | `<cstring>` | `<ctime>` |       |
| `<csetjmp>` | `<csetjmp>` | `<csetjmp>` | `<csetjmp>` | `<ctime>` |       |       |       |

4 Except as noted in Clause 16 through Clause 32 and Annex D, the contents of each header name is the same as that of the corresponding header name.h as specified in the C standard library (Clause 2). In the C++ standard library, however, the declarations (except for names which are defined as macros in C) are within namespace scope (6.3.6) of the namespace std. It is unspecified whether these names (including any overloads added in Clause 17 through Clause 32 and Annex D) are first declared within the global namespace scope and are then injected into namespace std by explicit using-declarations (9.8).

5 Names which are defined as macros in C shall be defined as macros in the C++ standard library, even if C grants license for implementation as functions. [Note: The names defined as macros in C include the following: assert, offsetof, setjmp, va_arg, va_end, and va_start. —end note]

6 Names that are defined as functions in C shall be defined as functions in the C++ standard library.169

7 Identifiers that are keywords or operators in C++ shall not be defined as macros in C++ standard library headers.170

8 D.6, C standard library headers, describes the effects of using the name.h (C header) form in a C++ program.171

9 Annex K of the C standard describes a large number of functions, with associated types and macros, which “promote safer, more secure programming” than many of the traditional C library functions. The names of the functions have a suffix of .s: most of them provide the same service as the C library function with the unsuffixed name, but generally take an additional argument whose value is the size of the result array. If any C++ header is included, it is implementation-defined whether any of these names is declared in the global namespace. (None of them is declared in namespace std.) Table 21 lists the Annex K names that may be declared in some header. These names are also subject to the restrictions of 16.5.4.3.2.

169) This disallows the practice, allowed in C, of providing a masking macro in addition to the function prototype. The only way to achieve equivalent inline behavior in C++ is to provide a definition as an extern inline function.

170) In particular, including the standard header `<iso646.h>` has no effect.

171) The *.h* headers dump all their names into the global namespace, whereas the newer forms keep their names in namespace std. Therefore, the newer forms are the preferred forms for all uses except for C++ programs which are intended to be strictly compatible with C.

16.5.1.3 Freestanding implementations

1 Two kinds of implementations are defined: hosted and freestanding (4.1); the kind of the implementation is implementation-defined. For a hosted implementation, this document describes the set of available headers.

2 A freestanding implementation has an implementation-defined set of headers. This set shall include at least the headers shown in Table 22.

Table 22: C++ headers for freestanding implementations

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>17.2</td>
<td>&lt;cstring&gt;</td>
</tr>
<tr>
<td>17.3</td>
<td>&lt;cstdio&gt;, &lt;cstdlib&gt;, &lt;limits&gt;, &lt;version&gt;</td>
</tr>
<tr>
<td>17.4</td>
<td>&lt;cassert&gt;</td>
</tr>
<tr>
<td>17.5</td>
<td>&lt;ctime&gt;</td>
</tr>
<tr>
<td>17.6</td>
<td>&lt;cassert&gt;</td>
</tr>
<tr>
<td>17.7</td>
<td>&lt;cassert&gt;</td>
</tr>
<tr>
<td>17.9</td>
<td>&lt;cassert&gt;</td>
</tr>
<tr>
<td>17.10</td>
<td>&lt;cassert&gt;</td>
</tr>
<tr>
<td>17.12</td>
<td>&lt;cassert&gt;</td>
</tr>
<tr>
<td>17.13</td>
<td>&lt;cassert&gt;</td>
</tr>
<tr>
<td>Clause 18</td>
<td>&lt;cassert&gt;</td>
</tr>
<tr>
<td>20.15</td>

</tr>
<tr>
<td>26.5</td>
<td>&lt;cassert&gt;</td>
</tr>
<tr>
<td>Clause 31</td>
<td>&lt;cassert&gt;</td>
</tr>
</tbody>
</table>

3 The supplied version of the header <cstdlib> shall declare at least the functions abort, atexit, at_quick_exit, exit, and quick_exit (17.5). The other headers listed in this table shall meet the same requirements as for a hosted implementation.

16.5.2 Using the library

16.5.2.1 Overview

1 Subclause 16.5.2 describes how a C++ program gains access to the facilities of the C++ standard library. 16.5.2.2 describes effects during translation phase 4, while 16.5.2.3 describes effects during phase 8 (5.2).
16.5.2.2 Headers
1 The entities in the C++ standard library are defined in headers, whose contents are made available to a translation unit when it contains the appropriate #include preprocessing directive (15.2).
2 A translation unit may include library headers in any order (Clause 5). Each may be included more than once, with no effect different from being included exactly once, except that the effect of including either <cassert> or <assert.h> depends each time on the lexically current definition of NDEBUG.172
3 A translation unit shall include a header only outside of any declaration or definition, and shall include the header lexically before the first reference in that translation unit to any of the entities declared in that header. No diagnostic is required.

16.5.2.3 Linkage
1 Entities in the C++ standard library have external linkage (6.5). Unless otherwise specified, objects and functions have the default extern "C++" linkage (9.10).
2 Whether a name from the C standard library declared with external linkage has extern "C" or extern "C++" linkage is implementation-defined. It is recommended that an implementation use extern "C++" linkage for this purpose.173
3 Objects and functions defined in the library and required by a C++ program are included in the program prior to program startup.
4 See also replacement functions (16.5.4.6), runtime changes (16.5.4.7).

16.5.3 Requirements on types and expressions
16.5.3.1 describes requirements on types and expressions used to instantiate templates defined in the C++ standard library. 16.5.3.2 describes the requirements on swappable types and swappable expressions. 16.5.3.3 describes the requirements on pointer-like types that support null values. 16.5.3.4 describes the requirements on hash function objects. 16.5.3.5 describes the requirements on storage allocators.

16.5.3.1 Template argument requirements
1 The template definitions in the C++ standard library refer to various named requirements whose details are set out in Tables 23–30. In these tables, T is an object or reference type to be supplied by a C++ program instantiating a template; a, b, and c are values of type (possibly const) T; s and t are modifiable lvalues of type T; u denotes an identifier; rv is an rvalue of type T; and v is an lvalue of type (possibly const) T or an rvalue of type const T.
2 In general, a default constructor is not required. Certain container class member function signatures specify T() as a default argument. T() shall be a well-defined expression (9.3) if one of those signatures is called using the default argument (9.2.3.6).

Table 23: Cpp17EqualityComparable requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>a == b</td>
<td>convertible to bool</td>
<td>== is an equivalence relation, that is, it has the following properties:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>— For all a, a == a.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>— If a == b, then b == a.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>— If a == b and b == c, then a == c.</td>
</tr>
</tbody>
</table>

172) This is the same as the C standard library.
173) The only reliable way to declare an object or function signature from the C standard library is by including the header that declares it, notwithstanding the latitude granted in 7.1.4 of the C Standard.

<td>t is equivalent to v, the value of v is unchanged</td>
</tr>
</tbody>
</table>

16.5.3.2 Swappable requirements [swappable.requirements]

This subclause provides definitions for swappable types and expressions. In these definitions, let t denote an expression of type T, and let u denote an expression of type U.

§ 16.5.3.2
Table 30: Cpp17Destructible requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>u.~T()</td>
<td>All resources owned by u are reclaimed, no exception is propagated.</td>
</tr>
</tbody>
</table>

2 An object \( t \) is **swappable with** an object \( u \) if and only if:

\[(2.1)\] the expressions \( \text{swap}(t, u) \) and \( \text{swap}(u, t) \) are valid when evaluated in the context described below, and

\[(2.2)\] these expressions have the following effects:

\[(2.2.1)\] the object referred to by \( t \) has the value originally held by \( u \) and

\[(2.2.2)\] the object referred to by \( u \) has the value originally held by \( t \).

3 The context in which \( \text{swap}(t, u) \) and \( \text{swap}(u, t) \) are evaluated shall ensure that a binary non-member function named “swap” is selected via overload resolution (12.3) on a candidate set that includes:

\[(3.1)\] the two \( \text{swap} \) function templates defined in <utility> (20.2) and

\[(3.2)\] the lookup set produced by argument-dependent lookup (6.4.2).

[Note: If \( T \) and \( U \) are both fundamental types or arrays of fundamental types and the declarations from the header <utility> are in scope, the overall lookup set described above is equivalent to that of the qualified name lookup applied to the expression \( \text{std::swap}(t, u) \) or \( \text{std::swap}(u, t) \) as appropriate. —end note]

[Note: It is unspecified whether a library component that has a swappable requirement includes the header <utility> to ensure an appropriate evaluation context. —end note]

4 An rvalue or lvalue \( t \) is **swappable** if and only if \( t \) is swappable with any rvalue or lvalue, respectively, of type \( T \).

5 A type \( X \) meeting any of the iterator requirements (23.3) meets the **Cpp17ValueSwappable** requirements if, for any dereferenceable object \( x \) of type \( X \), \( *x \) is swappable.

[Example: User code can ensure that the evaluation of \( \text{swap} \) calls is performed in an appropriate context under the various conditions as follows:

```cpp
#include <utility>

// Requires: std::forward<T>(t) shall be swappable with std::forward<U>(u).
template<class T, class U>
void value_swap(T&& t, U&& u) {
    using std::swap;
    swap(std::forward<T>(t), std::forward<U>(u)); // OK: uses “swappable with” conditions
    // for rvalues and lvalues
}

// Requires: lvalues of T shall be swappable.
template<class T>
void lv_swap(T& t1, T& t2) {
    using std::swap;
    swap(t1, t2); // OK: uses swappable conditions for lvalues of type T
}

namespace N {
    struct A { int m; };
    struct Proxy { A* a; }; // User code
    Proxy proxy(A& a) { return Proxy{ &a }; }
    void swap(A& x, Proxy p) {
        std::swap(x.m, p.a->m); // OK: uses context equivalent to swappable
        // conditions for fundamental types
    }
    void swap(Proxy p, A& x) { swap(x, p); } // satisfy symmetry constraint
}
```
int main() {
    int i = 1, j = 2;
    lv_swap(i, j);
    assert(i == 2 && j == 1);

    N::A a1 = { 5 }, a2 = { -5 };
    value_swap(a1, proxy(a2));
    assert(a1.m == -5 && a2.m == 5);
}

— end example]

16.5.3.3 Cpp17NullablePointer requirements [nullablepointer.requirements]

1 A Cpp17NullablePointer type is a pointer-like type that supports null values. A type P meets the Cpp17NullablePointer requirements if:

(1.1) — P meets the Cpp17EqualityComparable, Cpp17DefaultConstructible, Cpp17CopyConstructible, Cpp17CopyAssignable, and Cpp17Destructible requirements,
(1.2) — lvalues of type P are swappable (16.5.3.2),
(1.3) — the expressions shown in Table 31 are valid and have the indicated semantics, and
(1.4) — P meets all the other requirements of this subclause.

2 A value-initialized object of type P produces the null value of the type. The null value shall be equivalent only to itself. A default-initialized object of type P may have an indeterminate value. [Note: Operations involving indeterminate values may cause undefined behavior. — end note]

3 An object p of type P can be contextually converted to bool (7.3). The effect shall be as if p != nullptr had been evaluated in place of p.

4 No operation which is part of the Cpp17NullablePointer requirements shall exit via an exception.

5 In Table 31, u denotes an identifier, t denotes a non-const lvalue of type P, a and b denote values of type (possibly const) P, and np denotes a value of type (possibly const) std::nullptr_t.

Table 31: Cpp17NullablePointer requirements [tab:cpp17.nullablepointer]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>P u(np);</td>
<td></td>
<td>Ensures: u == nullptr</td>
</tr>
<tr>
<td>P u = np;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>P(np)</td>
<td></td>
<td>Ensures: P(np) == nullptr</td>
</tr>
<tr>
<td>t = np P&amp;</td>
<td></td>
<td>Ensures: t == nullptr</td>
</tr>
<tr>
<td>a != b</td>
<td>contextually convertible to bool</td>
<td>!(a == b)</td>
</tr>
<tr>
<td>a == np</td>
<td>contextually convertible to bool</td>
<td>a == P()</td>
</tr>
<tr>
<td>np == a</td>
<td>contextually convertible to bool</td>
<td>np == a</td>
</tr>
<tr>
<td>a != np</td>
<td>contextually convertible to bool</td>
<td>!(a == np)</td>
</tr>
</tbody>
</table>

16.5.3.4 Cpp17Hash requirements [hash.requirements]

1 A type H meets the Cpp17Hash requirements if:

(1.1) — it is a function object type (20.14),
(1.2) — it meets the Cpp17CopyConstructible (Table 27) and Cpp17Destructible (Table 30) requirements, and
(1.3) — the expressions shown in Table 32 are valid and have the indicated semantics.

2 Given Key is an argument type for function objects of type H, in Table 32 h is a value of type (possibly const) H, u is an lvalue of type Key, and k is a value of a type convertible to (possibly const) Key.

16.5.3.5 Cpp17Allocator requirements [allocator.requirements]

1 The library describes a standard set of requirements for allocators, which are class-type objects that encapsulate the information about an allocation model. This information includes the knowledge of pointer types, the type of their difference, the type of the size of objects in this allocation model, as well as the memory allocation
Table 32: Cpp17Hash requirements  

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>h(k)</td>
<td>size_t</td>
<td>The value returned shall depend only on the argument k for the duration of the program. [Note: Thus all evaluations of the expression h(k) with the same value for k yield the same result for a given execution of the program. — end note] [Note: For two different values t1 and t2, the probability that h(t1) and h(t2) compare equal should be very small, approaching (1.0 / \text{numeric_limits&lt;size_t&gt;::max()}). — end note]</td>
</tr>
<tr>
<td>h(u)</td>
<td>size_t</td>
<td>Shall not modify u.</td>
</tr>
</tbody>
</table>

and deallocation primitives for it. All of the string types (Clause 21), containers (Clause 22) (except array), string buffers and string streams (Clause 29), and match_results (Clause 30) are parameterized in terms of allocators.

The class template allocator_traits (20.10.9) supplies a uniform interface to all allocator types. Table 33 describes the types manipulated through allocators. Table 34 describes the requirements on allocator types and thus on types used to instantiate allocator_traits. A requirement is optional if the last column of Table 34 specifies a default for a given expression. Within the standard library allocator_traits template, an optional requirement that is not supplied by an allocator is replaced by the specified default expression. A user specialization of allocator_traits may provide different defaults and may provide defaults for different requirements than the primary template. Within Tables 33 and 34, the use of move and forward always refers to std::move and std::forward, respectively.

</table>

3 Note A: The member class template rebind in the table above is effectively a typedef template. [Note: In general, if the name Allocator is bound to SomeAllocator<T>, then Allocator::rebind<U>::other is the same type as SomeAllocator<U>::value_type is T and SomeAllocator<U>::value_type is U. —end note] If Allocator is a class template instantiation of the form SomeAllocator<T, Args>, where Args is zero or more type arguments, and Allocator does not supply a rebind member template, the standard allocator_traits template uses SomeAllocator<U, Args> in place of Allocator::rebind<U>::other by default. For allocator types that are not template instantiations of the above form, no default is provided.

4 Note B: If X::propagate_on_container_copy_assignment::value is true, X shall meet the Cpp17CopyAssignable requirements (Table 29) and the copy operation shall not throw exceptions. If X::propagate_on_container_move_assignment::value is true, X shall meet the Cpp17MoveAssignable requirements (Table 28) and the move operation shall not throw exceptions. If X::propagate_on_container_swap::value is true, values of type X shall be swappable (16.5.3.2) and the swap operation shall not throw exceptions.

5 An allocator type X shall meet the Cpp17CopyConstructible requirements (Table 27). The X::pointer, X::const_pointer, X::void_pointer, and X::const_void_pointer types shall meet the Cpp17NullablePointer requirements (Table 31). No constructor, comparison function, copy operation, move operation, or swap operation on these pointer types shall exit via an exception. X::pointer and X::const_pointer shall also meet the requirements for a Cpp17RandomAccessIterator (23.3.5.6) and the additional requirement that, when a and (a + n) are dereferenceable pointer values for some integral value n,

\[
\text{addressof}(\text{*(a + n)}) == \text{addressof}(\text{a}) + n
\]

is true.

6 Let x1 and x2 denote objects of (possibly different) types X::void_pointer, X::const_void_pointer, X::pointer, or X::const_pointer. Then, x1 and x2 are equivalently-valued pointer values, if and only if both x1 and x2 can be explicitly converted to the two corresponding objects px1 and px2 of type X::const_pointer, using a sequence of static_casts using only these four types, and the expression px1 == px2 evaluates to true.

7 Let w1 and w2 denote objects of type X::void_pointer. Then for the expressions

\[
w1 == w2
\]

\[
w1 != w2
\]
either or both objects may be replaced by an equivalently-valued object of type X::const_void_pointer with no change in semantics.

8 Let p1 and p2 denote objects of type X::pointer. Then for the expressions

\[
\begin{align*}
& p1 == p2 \\
& p1 != p2 \\
& p1 < p2 \\
& p1 <= p2 \\
& p1 > p2 \\
& p1 >= p2 \\
& p1 - p2
\end{align*}
\]

either or both objects may be replaced by an equivalently-valued object of type X::const_pointer with no change in semantics.

9 An allocator may constrain the types on which it can be instantiated and the arguments for which its construct or destroy members may be called. If a type cannot be used with a particular allocator, the allocator class or the call to construct or destroy may fail to instantiate.

10 If the alignment associated with a specific over-aligned type is not supported by an allocator, instantiation of the allocator for that type may fail. The allocator also may silently ignore the requested alignment. 

[Note: Additionally, the member function allocate for that type may fail by throwing an object of type bad_alloc. — end note]

11 [Example: The following is an allocator class template supporting the minimal interface that meets the requirements of Table 34:

\[
\begin{align*}
& \text{template}<\text{class}\ Tp> \\
& \text{struct SimpleAllocator} \\
& \quad \text{typedef Tp value_type; } \\
& \quad \text{SimpleAllocator(ctor args); } \\
& \quad \text{template<class T> SimpleAllocator(const SimpleAllocator<T>& other);} \\
& \quad \text{[modiscard]} Tp* allocate(std::size_t n); \\
& \quad \text{void deallocate(Tp* p, std::size_t n);} \\
& \}; \\
& \text{template<class T, class U> } \\
& \text{bool operator==(const SimpleAllocator<T>&, const SimpleAllocator<U>&); } \\
& \text{template<class T, class U> } \\
& \text{bool operator!=(const SimpleAllocator<T>&, const SimpleAllocator<U>&); } \\
& \text{— end example}
\end{align*}
\]

16.5.3.5.1 Allocator completeness requirements [allocator.requirements.completeness]

1 If X is an allocator class for type T, X additionally meets the allocator completeness requirements if, whether or not T is a complete type:

(1.1) — X is a complete type, and

(1.2) — all the member types of allocator_traits<X> (20.10.9) other than value_type are complete types.

16.5.4 Constraints on programs [constraints]

16.5.4.1 Overview [constraints.overview]

1 Subclause 16.5.4 describes restrictions on C++ programs that use the facilities of the C++ standard library. The following subclauses specify constraints on the program's use of namespaces (16.5.4.2.1), its use of various reserved names (16.5.4.3), its use of headers (16.5.4.4), its use of standard library classes as base classes (16.5.4.5), its definitions of replacement functions (16.5.4.6), and its installation of handler functions during execution (16.5.4.7).

16.5.4.2 Namespace use [namespace.constraints]

16.5.4.2.1 Namespace std [namespace.std]

1 Unless otherwise specified, the behavior of a C++ program is undefined if it adds declarations or definitions to namespace std or to a namespace within namespace std.

§ 16.5.4.2.1 464
Unless explicitly prohibited, a program may add a template specialization for any standard library class template to namespace std provided that (a) the added declaration depends on at least one program-defined type and (b) the specialization meets the standard library requirements for the original template. The behavior of a C++ program is undefined if it declares an explicit or partial specialization of any standard library variable template, except where explicitly permitted by the specification of that variable template.

The behavior of a C++ program is undefined if it declares

1. an explicit specialization of any member function of a standard library class template, or
2. an explicit specialization of any member function template of a standard library class or class template, or
3. an explicit or partial specialization of any member class template of a standard library class or class template, or
4. a deduction guide for any standard library class template.

A program may explicitly instantiate a class template defined in the standard library only if the declaration (a) depends on the name of at least one program-defined type and (b) the instantiation meets the standard library requirements for the original template.

Let \( F \) denote a standard library function (16.5.5.4), a standard library static member function, or an instantiation of a standard library function template. Unless \( F \) is designated an addressable function, the behavior of a C++ program is unspecified (possibly ill-formed) if it explicitly or implicitly attempts to form a pointer to \( F \). [Note: Possible means of forming such pointers include application of the unary & operator (7.6.2.1), addressof (20.10.11.2), or a function-to-pointer standard conversion (7.3.3). — end note] Moreover, the behavior of a C++ program is unspecified (possibly ill-formed) if it attempts to form a reference to \( F \) or if it attempts to form a pointer-to-member designating either a standard library non-static member function (16.5.5.5) or an instantiation of a standard library member function template.

Other than in namespace std or in a namespace within namespace std, a program may provide an overload for any library function template designated as a customization point, provided that (a) the overload’s declaration depends on at least one user-defined type and (b) the overload meets the standard library requirements for the customization point. [Note: This permits a (qualified or unqualified) call to the customization point to invoke the most appropriate overload for the given arguments. — end note]

A translation unit shall not declare namespace std to be an inline namespace (9.7.1).

16.5.4.2.2 Namespace posix

The behavior of a C++ program is undefined if it adds declarations or definitions to namespace posix or to a namespace within namespace posix unless otherwise specified. The namespace posix is reserved for use by ISO/IEC 9945 and other POSIX standards.

16.5.4.2.3 Namespaces for future standardization

Top level namespaces with a name starting with std and followed by a non-empty sequence of digits are reserved for future standardization. The behavior of a C++ program is undefined if it adds declarations or definitions to such a namespace. [Example: The top level namespace std2 is reserved for use by future revisions of this International Standard. — end example]

16.5.4.3 Reserved names

The C++ standard library reserves the following kinds of names:

1. macros
2. global names
3. names with external linkage

---

175) Any library code that instantiates other library templates must be prepared to work adequately with any user-supplied specialization that meets the minimum requirements of this document.
176) Any library customization point must be prepared to work adequately with any user-defined overload that meets the minimum requirements of this document. Therefore an implementation may elect, under the as-if rule (6.8.1), to provide any customization point in the form of an instantiated function object (20.14) even though the customization point’s specification is in the form of a function template. The template parameters of each such function object and the function parameters and return type of the object’s \( \text{operator}() \) must match those of the corresponding customization point’s specification.
If a program declares or defines a name in a context where it is reserved, other than as explicitly allowed by this Clause, its behavior is undefined.

16.5.4.3.1 Zombie names

In namespace std, the following names are reserved for previous standardization:

(1.1) auto_ptr,
(1.2) auto_ptr_ref,
(1.3) binary_function,
(1.4) binary_negate,
(1.5) bind1st,
(1.6) bind2nd,
(1.7) binder1st,
(1.8) binder2nd,
(1.9) const_mem_fun1_ref_t,
(1.10) const_mem_fun1_t,
(1.11) const_mem_fun_ref_t,
(1.12) const_mem_fun_t,
(1.13) get_temporary_buffer,
(1.14) get_unexpected,
(1.15) gets,
(1.16) is_literal_type,
(1.17) is_literal_type_v,
(1.18) mem_fun1_ref_t,
(1.19) mem_fun1_t,
(1.20) mem_fun_ref_t,
(1.21) mem_fun_ref,
(1.22) mem_fun_t,
(1.23) mem_fun,
(1.24) not1,
(1.25) not2,
(1.26) pointer_to_binary_function,
(1.27) pointer_to_unary_function,
(1.28) ptr_fun,
(1.29) random_shuffle,
(1.30) raw_storage_iterator,
(1.31) result_of,
(1.32) result_of_t,
(1.33) return_temporary_buffer,
(1.34) set_unexpected,
(1.35) unary_function,
(1.36) unary_negate,
(1.37) uncaught_exception,
(1.38) unexpected, and
(1.39) unexpected_handler.
The following names are reserved as member types for previous standardization, and may not be used as a name for object-like macros in portable code:

- argument_type,
- first_argument_type,
- io_state,
- open_mode,
- second_argument_type, and
- seek_dir.

The name stossc is reserved as a member function for previous standardization, and may not be used as a name for function-like macros in portable code.

The header names `<ccomplex>`, `<ciso646>`, `<cstdalign>`, `<cstdbool>`, and `<ctgmath>` are reserved for previous standardization.

### 16.5.4.3.2 Macro names

A translation unit that includes a standard library header shall not `#define` or `#undef` names declared in any standard library header.

A translation unit shall not `#define` or `#undef` names lexically identical to keywords, to the identifiers listed in Table 4, to the `attribute-tokens` described in 9.11, or to the identifiers `expects` or `ensures`, except that the names `likely` and `unlikely` may be defined as function-like macros (15.5).

### 16.5.4.3.3 External linkage

Each name declared as an object with external linkage in a header is reserved to the implementation to designate that library object with external linkage, both in namespace `std` and in the global namespace.

Each global function signature declared with external linkage in a header is reserved to the implementation to designate that function signature with external linkage.

Each name from the C standard library declared with external linkage is reserved to the implementation for use as a name with `extern "C"` linkage, both in namespace `std` and in the global namespace.

Each function signature from the C standard library declared with external linkage is reserved to the implementation for use as a function signature with both `extern "C"` and `extern "C++"` linkage, or as a name of namespace scope in the global namespace.

### 16.5.4.3.4 Types

For each type T from the C standard library, the types `::T` and `std::T` are reserved to the implementation and, when defined, `::T` shall be identical to `std::T`.

### 16.5.4.3.5 User-defined literal suffixes

Literal suffix identifiers (12.5.8) that do not start with an underscore are reserved for future standardization.

### 16.5.4.4 Headers

If a file with a name equivalent to the derived file name for one of the C++ standard library headers is not provided as part of the implementation, and a file with that name is placed in any of the standard places for a source file to be included (15.2), the behavior is undefined.

Virtual member function signatures defined for a base class in the C++ standard library may be overridden in a derived class defined in the program (11.6.2).

---

177) The list of such reserved names includes `errno`, declared or defined in `<cerrno>`.
178) The list of such reserved function signatures with external linkage includes `setjmp(jmp_buf)`, declared or defined in `<csetjmp>`, and `va_end(va_list)`, declared or defined in `<cstdlib>`.
179) The function signatures declared in `<cuchar>`, `<cwchar>`, and `<cwctype>` are always reserved, notwithstanding the restrictions imposed in subclause 4.5.1 of Amendment 1 to the C Standard for these headers.
180) These types are `clock_t, div_t, FILE, fpos_t, lconv, ldiv_t, mbstate_t, ptdiff_t, sig_atomic_t, size_t, time_t, tm, va_list, wctrans_t, wctype_t, and wint_t.`
16.5.4.6 Replacement functions

Clause 17 through Clause 32 and Annex D describe the behavior of numerous functions defined by the C++ standard library. Under some circumstances, however, certain of these function descriptions also apply to replacement functions defined in the program (16.3).

A C++ program may provide the definition for any of the following dynamic memory allocation function signatures declared in header `<new>` (6.6.5.4, 17.6):

- `operator new(std::size_t)`
- `operator new(std::size_t, std::align_val_t)`
- `operator new(std::size_t, const std::nothrow_t&)`
- `operator new(std::size_t, std::align_val_t, const std::nothrow_t&)`
- `operator delete(void*)`
- `operator delete(void*, std::size_t)`
- `operator delete(void*, std::align_val_t)`
- `operator delete(void*, std::size_t, std::align_val_t)`
- `operator delete(void*, const std::nothrow_t&)`
- `operator delete(void*, std::align_val_t, const std::nothrow_t&)`
- `operator new[](std::size_t)`
- `operator new[](std::size_t, std::align_val_t)`
- `operator new[](std::size_t, const std::nothrow_t&)`
- `operator new[](std::size_t, std::align_val_t, const std::nothrow_t&)`
- `operator delete[](void*)`
- `operator delete[](void*, std::size_t)`
- `operator delete[](void*, std::align_val_t)`
- `operator delete[](void*, std::size_t, std::align_val_t)`
- `operator delete[](void*, const std::nothrow_t&)`
- `operator delete[](void*, std::align_val_t, const std::nothrow_t&)`

The program's definitions are used instead of the default versions supplied by the implementation (17.6). Such replacement occurs prior to program startup (6.2, 6.8.3). The program's declarations shall not be specified as `inline`. No diagnostic is required.

16.5.4.7 Handler functions

The C++ standard library provides a default version of the following handler function (Clause 17):

- `terminate_handler`

A C++ program may install different handler functions during execution, by supplying a pointer to a function defined in the program or the library as an argument to (respectively):

- `set_new_handler`
- `set_terminate`

See also subclauses 17.6.3, Storage allocation errors, and 17.9, Exception handling.

A C++ program can get a pointer to the current handler function by calling the following functions:

- `get_new_handler`
- `get_terminate`

Calling the `set_*` and `get_*` functions shall not incur a data race. A call to any of the `set_*` functions shall synchronize with subsequent calls to the same `set_*` function and to the corresponding `get_*` function.

16.5.4.8 Other functions

In certain cases (replacement functions, handler functions, operations on types used to instantiate standard library template components), the C++ standard library depends on components supplied by a C++ program. If these components do not meet their requirements, this document places no requirements on the implementation.

In particular, the effects are undefined in the following cases:

- for replacement functions (17.6.2), if the installed replacement function does not implement the semantics of the applicable `Required behavior:` paragraph.
- for handler functions (17.6.3.3, 17.9.4.1), if the installed handler function does not implement the semantics of the applicable `Required behavior:` paragraph.
for types used as template arguments when instantiating a template component, if the operations on the type do not implement the semantics of the applicable Requirements subclause (16.5.3.5, 22.2, 23.3, 25.2, 26.2). Operations on such types can report a failure by throwing an exception unless otherwise specified.

— if any replacement function or handler function or destructor operation exits via an exception, unless specifically allowed in the applicable Required behavior: paragraph.

— if an incomplete type (6.7) is used as a template argument when instantiating a template component or evaluating a concept, unless specifically allowed for that component.

16.5.4.9 Function arguments

Each of the following applies to all arguments to functions defined in the C++ standard library, unless explicitly stated otherwise.

— If an argument to a function has an invalid value (such as a value outside the domain of the function or a pointer invalid for its intended use), the behavior is undefined.

— If a function argument is described as being an array, the pointer actually passed to the function shall have a value such that all address computations and accesses to objects (that would be valid if the pointer did point to the first element of such an array) are in fact valid.

— If a function argument binds to an rvalue reference parameter, the implementation may assume that this parameter is a unique reference to this argument. Note: If the parameter is a generic parameter of the form `T&&` and an lvalue of type `A` is bound, the argument binds to an lvalue reference (13.9.2.1) and thus is not covered by the previous sentence. —end note Note: If a program casts an lvalue to an xvalue while passing that lvalue to a library function (e.g., by calling the function with the argument `std::move(x)`), the program is effectively asking that function to treat that lvalue as a temporary object. The implementation is free to optimize away aliasing checks which might be needed if the argument was an lvalue. — end note

16.5.4.10 Library object access

The behavior of a program is undefined if calls to standard library functions from different threads may introduce a data race. The conditions under which this may occur are specified in 16.5.5.9. Note: Modifying an object of a standard library type that is shared between threads risks undefined behavior unless objects of that type are explicitly specified as being shareable without data races or the user supplies a locking mechanism. —end note

— If an object of a standard library type is accessed, and the beginning of the object’s lifetime (6.6.3) does not happen before the access, or the access does not happen before the end of the object’s lifetime, the behavior is undefined unless otherwise specified. Note: This applies even to objects such as mutexes intended for thread synchronization. — end note

16.5.4.11 Requires paragraph

Violation of any preconditions specified in a function’s Requires: element results in undefined behavior unless the function’s Throws: element specifies throwing an exception when the precondition is violated.

Violation of any preconditions specified in a function’s Expects: element results in undefined behavior.

16.5.4.12 Semantic requirements

If the semantic requirements of a declaration’s constraints (16.4.1.3) are not modeled at the point of use, the program is ill-formed, no diagnostic required.

16.5.5 Conforming implementations

16.5.5.1 Overview

Subclause 16.5.5 describes the constraints upon, and latitude of, implementations of the C++ standard library.

An implementation’s use of headers is discussed in 16.5.5.2, its use of macros in 16.5.5.3, non-member functions in 16.5.5.4, member functions in 16.5.5.5, data race avoidance in 16.5.5.9, access specifiers in 16.5.5.10, class derivation in 16.5.5.11, and exceptions in 16.5.5.12.
16.5.5.2 Headers

1 A C++ header may include other C++ headers. A C++ header shall provide the declarations and definitions that appear in its synopsis. A C++ header shown in its synopsis as including other C++ headers shall provide the declarations and definitions that appear in the synopses of those other headers.

2 Certain types and macros are defined in more than one header. Every such entity shall be defined such that any header that defines it may be included after any other header that also defines it (6.2).

3 The C standard library headers (D.6) shall include only their corresponding C++ standard library header, as described in 16.5.1.2.

16.5.5.3 Restrictions on macro definitions

1 The names and global function signatures described in 16.5.1.1 are reserved to the implementation.

2 All object-like macros defined by the C standard library and described in this Clause as expanding to integral constant expressions are also suitable for use in \#if preprocessing directives, unless explicitly stated otherwise.

16.5.5.4 Non-member functions

1 It is unspecified whether any non-member functions in the C++ standard library are defined as inline (9.1.6).

2 A call to a non-member function signature described in Clause 17 through Clause 32 and Annex D shall behave as if the implementation declared no additional non-member function signatures.\[181\]

3 An implementation shall not declare a non-member function signature with additional default arguments.

4 Unless otherwise specified, calls made by functions in the standard library to non-operator, non-member functions do not use functions from another namespace which are found through argument-dependent name lookup (6.4.2). \[Note: The phrase “unless otherwise specified” applies to cases such as the swappable with requirements (16.5.3.2). The exception for overloaded operators allows argument-dependent lookup in cases like that of ostream_iterator::operator= (23.6.2.2): \]

Effects:

```plaintext
*out_stream << value;
if (delim != 0)
  *out_stream << delim;
return *this;
```

—end note\]

16.5.5.5 Member functions

1 It is unspecified whether any member functions in the C++ standard library are defined as inline (9.1.6).

2 For a non-virtual member function described in the C++ standard library, an implementation may declare a different set of member function signatures, provided that any call to the member function that would select an overload from the set of declarations described in this document behaves as if that overload were selected. \[Note: For instance, an implementation may add parameters with default values, or replace a member function with default arguments with two or more member functions with equivalent behavior, or add additional signatures for a member function name. —end note\]

16.5.5.6 Constexpr functions and constructors

1 This document explicitly requires that certain standard library functions are constexpr (9.1.5). An implementation shall not declare any standard library function signature as constexpr except for those where it is explicitly required. Within any header that provides any non-defining declarations of constexpr functions or constructors an implementation shall provide corresponding definitions.

16.5.5.7 Requirements for stable algorithms

1 When the requirements for an algorithm state that it is “stable” without further elaboration, it means:

1.1 For the sort algorithms the relative order of equivalent elements is preserved.

1.2 For the remove and copy algorithms the relative order of the elements that are not removed is preserved.

\[181\) A valid C++ program always calls the expected library non-member function. An implementation may also define additional non-member functions that would otherwise not be called by a valid C++ program.
— For the merge algorithms, for equivalent elements in the original two ranges, the elements from the first range (preserving their original order) precede the elements from the second range (preserving their original order).

16.5.5.8 Reentrancy

Except where explicitly specified in this document, it is implementation-defined which functions in the C++ standard library may be recursively reentered.

16.5.5.9 Data race avoidance

This subclause specifies requirements that implementations shall meet to prevent data races (6.8.2). Every standard library function shall meet each requirement unless otherwise specified. Implementations may prevent data races in cases other than those specified below.

1 A C++ standard library function shall not directly or indirectly access objects (6.8.2) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s arguments, including this.

2 A C++ standard library function shall not directly or indirectly modify objects (6.8.2) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s non-const arguments, including this.

3 [Note: This means, for example, that implementations can’t use a static object for internal purposes without synchronization because it could cause a data race even in programs that do not explicitly share objects between threads. — end note]

4 A C++ standard library function shall not access objects indirectly accessible via its arguments or via elements of its container arguments except by invoking functions required by its specification on those container elements.

5 Operations on iterators obtained by calling a standard library container or string member function may access the underlying container, but shall not modify it. [Note: In particular, container operations that invalidate iterators conflict with operations on iterators associated with that container. — end note]

6 Implementations may share their own internal objects between threads if the objects are not visible to users and are protected against data races.

7 Unless otherwise specified, C++ standard library functions shall perform all operations solely within the current thread if those operations have effects that are visible (6.8.2) to users.

8 [Note: This allows implementations to parallelize operations if there are no visible side effects. — end note]

16.5.5.10 Protection within classes

It is unspecified whether any function signature or class described in Clause 17 through Clause 32 and Annex D is a friend of another class in the C++ standard library.

16.5.5.11 Derived classes

An implementation may derive any class in the C++ standard library from a class with a name reserved to the implementation.

2 Certain classes defined in the C++ standard library are required to be derived from other classes in the C++ standard library. An implementation may derive such a class directly from the required base or indirectly through a hierarchy of base classes with names reserved to the implementation.

3 In any case:

(3.1) — Every base class described as virtual shall be virtual;
(3.2) — Every base class not specified as virtual shall not be virtual;
(3.3) — Unless explicitly stated otherwise, types with distinct names shall be distinct types.\(^{182}\)

4 All types specified in the C++ standard library shall be non-final types unless otherwise specified.

\(^{182}\) There is an implicit exception to this rule for types that are described as synonyms for basic integral types, such as size_t (17.2) and streamoff (29.5.2).
16.5.5.12 Restrictions on exception handling

Any of the functions defined in the C++ standard library can report a failure by throwing an exception of a type described in its `Throws:` paragraph, or of a type derived from a type named in the `Throws:` paragraph that would be caught by an exception handler for the base type.

Functions from the C standard library shall not throw exceptions except when such a function calls a program-supplied function that throws an exception.

Destructor operations defined in the C++ standard library shall not throw exceptions. Every destructor in the C++ standard library shall behave as if it had a non-throwing exception specification.

Functions defined in the C++ standard library that do not have a `Throws:` paragraph but do have a potentially-throwing exception specification may throw implementation-defined exceptions. Implementations should report errors by throwing exceptions or derived from the standard exception classes (17.6.3.1, 17.9, 19.2).

An implementation may strengthen the exception specification for a non-virtual function by adding a non-throwing exception specification.

16.5.5.13 Restrictions on storage of pointers

Objects constructed by the standard library that may hold a user-supplied pointer value or an integer of type `std::intptr_t` shall store such values in a traceable pointer location (6.6.5.4.3). [Note: Other libraries are strongly encouraged to do the same, since not doing so may result in accidental use of pointers that are not safely derived. Libraries that store pointers outside the user’s address space should make it appear that they are stored and retrieved from a traceable pointer location. — end note]

16.5.5.14 Value of error codes

Certain functions in the C++ standard library report errors via a `std::error_code` (19.5.3.1) object. That object’s `category()` member shall return `std::system_category()` for errors originating from the operating system, or a reference to an implementation-defined `error_category` object for errors originating elsewhere. The implementation shall define the possible values of `value()` for each of these error categories. [Example: For operating systems that are based on POSIX, implementations should define the `std::system_category()` values as identical to the POSIX `errno` values, with additional values as defined by the operating system’s documentation. Implementations for operating systems that are not based on POSIX should define values identical to the operating system’s values. For errors that do not originate from the operating system, the implementation may provide enums for the associated values. — end example]

16.5.5.15 Moved-from state of library types

Objects of types defined in the C++ standard library may be moved from (11.3.4.2). Move operations may be explicitly specified or implicitly generated. Unless otherwise specified, such moved-from objects shall be placed in a valid but unspecified state.

---

183) That is, the C library functions can all be treated as if they are marked `noexcept`. This allows implementations to make performance optimizations based on the absence of exceptions at runtime.

184) The functions `qsort()` and `bsearch()` (25.10) meet this condition.

185) In particular, they can report a failure to allocate storage by throwing an exception of type `bad_alloc`, or a class derived from `bad_alloc` (17.6.3.1).
17 Language support library
[language.support]

17.1 General [support.general]

1 This Clause describes the function signatures that are called implicitly, and the types of objects generated implicitly, during the execution of some C++ programs. It also describes the headers that declare these function signatures and define any related types.

2 The following subclauses describe common type definitions used throughout the library, characteristics of the predefined types, functions supporting start and termination of a C++ program, support for dynamic memory management, support for dynamic type identification, support for contract violation handling, support for exception processing, support for initializer lists, and other runtime support, as summarized in Table 35.

Table 35: Language support library summary [tab:support.summary]

17.2 Common definitions [support.types]

17.2.1 Header `<cstdlib>` synopsis [cstddef.syn]

```cpp
namespace std {
    using ptrdiff_t = see below;
    using size_t = see below;
    using max_align_t = see below;
    using nullptr_t = decltype(nullptr);

    enum class byte : unsigned char {};

    // 17.2.5, byte type operations
    template<class IntType>
    constexpr byte operator<<(byte b, IntType shift) noexcept;
    template<class IntType>
    constexpr byte operator>>(byte b, IntType shift) noexcept;
    template<class IntType>
    constexpr byte operator|==(byte b, byte r) noexcept;
    template<class IntType>
    constexpr byte operator|=(byte b, byte r) noexcept;
    template<class IntType>
    constexpr byte operator&=(byte b, byte r) noexcept;
    template<class IntType>
    constexpr byte operator^=(byte b, byte r) noexcept;
    // § 17.2.1 473
```
constexpr byte operator ~(byte b) noexcept;

template<class IntType>
constexpr IntType to_integer(byte b) noexcept;
}

#define NULL see below
#define offsetof(P, D) see below

The contents and meaning of the header `<cstddef>` are the same as the C standard library header `<stddef.h>`, except that it does not declare the type wchar_t, that it also declares the type byte and its associated operations (17.2.5), and as noted in 17.2.3 and 17.2.4.

See also: ISO C 7.19

17.2.2 Header `<cstdlib>` synopsis [cstdlib.syn]

namespace std {
  using size_t = see below;
  using div_t = see below;
  using ldiv_t = see below;
  using lldiv_t = see below;
}

#define NULL see below
#define EXIT_FAILURE see below
#define EXIT_SUCCESS see below
#define RAND_MAX see below
#define MB_CUR_MAX see below

namespace std {
  // Exposition-only function type aliases
  extern "C" using c_atexit_handler = void(); // exposition only
  extern "C++" using atexit_handler = void(); // exposition only
  extern "C" using c_compare_pred = int(const void*, const void*); // exposition only
  extern "C++" using compare_pred = int(const void*, const void*); // exposition only

  // 17.5, start and termination
  [[noreturn]] void abort() noexcept;
  int atexit(c_atexit_handler* func) noexcept;
  int atexit(atexit_handler* func) noexcept;
  int at_quick_exit(c_atexit_handler* func) noexcept;
  int at_quick_exit(atexit_handler* func) noexcept;
  [[noreturn]] void exit(int status);
  [[noreturn]] void _Exit(int status) noexcept;
  [[noreturn]] void quick_exit(int status) noexcept;

div_t div(int numer, int denom);
ldiv_t div(long int numer, long int denom);  // see 16.2
lldiv_t div(long long int numer, long long int denom);  // see 16.2
ldiv_t ldiv(long int numer, long int denom);
lldiv_t lldiv(long long int numer, long long int denom);

1 The contents and meaning of the header <cstdlib> are the same as the C standard library header <stdlib.h>, except that it does not declare the type wchar_t, and except as noted in 17.2.3, 17.2.4, 17.5, 20.10.12, 21.5.6, 25.10, 26.6.9, and 26.8.2. [Note: Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (16.2). — end note]

See also: ISO C 7.22

17.2.3 Null pointers

1 The type nullptr_t is a synonym for the type of a nullptr expression, and it has the characteristics described in 6.7.1 and 7.3.11. [Note: Although nullptr’s address cannot be taken, the address of another nullptr_t object that is an lvalue can be taken. — end note]

2 The macro NULL is an implementation-defined null pointer constant.186

See also: ISO C 7.19

17.2.4 Sizes, alignments, and offsets

1 The macro offsetof(type, member-designator) has the same semantics as the corresponding macro in the C standard library header <stddef.h>, but accepts a restricted set of type arguments in this document. Use of the offsetof macro with a type other than a standard-layout class (11.1) is conditionally-supported.187 The expression offsetof(type, member-designator) is never type-dependent (13.7.2.2) and it is value-dependent (13.7.2.3) if and only if type is dependent. The result of applying the offsetof macro to a static

186) Possible definitions include 0 and 0L, but not (void*)0.
187) Note that offsetof is required to work as specified even if unary operator& is overloaded for any of the types involved.
data member or a function member is undefined. No operation invoked by the `offsetof` macro shall throw an exception and `nothrow(offsetof(type, member-designator))` shall be `true`.

The type `ptrdiff_t` is an implementation-defined signed integer type that can hold the difference of two subscripts in an array object, as described in 7.6.6.

The type `size_t` is an implementation-defined unsigned integer type that is large enough to contain the size in bytes of any object (7.6.2.4).

[Note: It is recommended that implementations choose types for `ptrdiff_t` and `size_t` whose integer conversion ranks (6.7.4) are no greater than that of `signed long int` unless a larger size is necessary to contain all the possible values. — end note]

The type `max_align_t` is a trivial standard-layout type whose alignment requirement is at least as great as that of every scalar type, and whose alignment requirement is supported in every context (6.6.6).

See also: ISO C 7.19

### 17.2.5 byte type operations

#### [support.types.byteops]

```cpp
template<class IntType>
constexpr byte& operator<<=(byte& b, IntType shift) noexcept;

Constraints: `is_integral_v<IntType>` is true.

Effects: Equivalent to: `return b = b << shift;`

template<class IntType>
constexpr byte operator<<(byte b, IntType shift) noexcept;

Constraints: `is_integral_v<IntType>` is true.

Effects: Equivalent to:
```
return static_cast<byte>(static_cast<unsigned char>(
    static_cast<unsigned int>(b) << shift));
```

template<class IntType>
constexpr byte& operator>>=(byte& b, IntType shift) noexcept;

Constraints: `is_integral_v<IntType>` is true.

Effects: Equivalent to:
```
return b >> shift;
```

template<class IntType>
constexpr byte operator>>(byte b, IntType shift) noexcept;

Constraints: `is_integral_v<IntType>` is true.

Effects: Equivalent to:
```
return static_cast<byte>(static_cast<unsigned char>(static_cast<unsigned int>(b) >> shift));
```

constexpr byte& operator|=(byte& l, byte r) noexcept;

Effects: Equivalent to:
```
return l = l | r;
```

constexpr byte operator|(byte l, byte r) noexcept;

Effects: Equivalent to:
```
return static_cast<byte>(static_cast<unsigned char>(static_cast<unsigned int>(l) | static_cast<unsigned int>(r)));
```

constexpr byte& operator&=(byte& l, byte r) noexcept;

Effects: Equivalent to:
```
return l = l & r;
```

constexpr byte operator&(byte l, byte r) noexcept;

Effects: Equivalent to:
```
return static_cast<byte>(static_cast<unsigned char>(static_cast<unsigned int>(l) & static_cast<unsigned int>(r)));
```

§ 17.2.5
constexpr byte& operator^=(byte& l, byte r) noexcept;

Effects: Equivalent to: return l = l ^ r;

constexpr byte operator^(byte l, byte r) noexcept;

Effects: Equivalent to:

    return static_cast<byte>(static_cast<unsigned char>(static_cast<unsigned int>(l) ^
    static_cast<unsigned int>(r)));

constexpr byte operator~(byte b) noexcept;

Effects: Equivalent to:

    return static_cast<byte>(static_cast<unsigned char>(
    ~static_cast<unsigned int>(b)));

template<class IntType>
constexpr IntType to_integer(byte b) noexcept;

Constraints: is_integral_v<IntType> is true.

Effects: Equivalent to: return static_cast<IntType>(b);

17.3 Implementation properties

17.3.1 General

The headers <limits> (17.3.2), <climits> (17.3.5), and <cfloat> (17.3.6) supply characteristics of implementa-
tion-dependent arithmetic types (6.7.1).

The header <version> supplies implementation-dependent information about the C++ standard library (e.g., version number and release date).

The macros in Table 36 are defined after inclusion of the header <version> or one of the corresponding headers specified in the table. [Note: Future versions of this International Standard might replace the values of these macros with greater values. —end note]

17.3.2 Header <limits> synopsis

namespace std {
    // 17.3.3, floating-point type properties
    enum float_round_style;
    enum float_denorm_style;

    // 17.3.4, class template numeric_limits
    template<class T> class numeric_limits;

    template<class T> class numeric_limits<const T>;
    template<class T> class numeric_limits<volatile T>;
    template<class T> class numeric_limits<const volatile T>;

    template<> class numeric_limits<bool>;

    template<> class numeric_limits<char>;
    template<> class numeric_limits<signed char>;
    template<> class numeric_limits<unsigned char>;
    template<> class numeric_limits<char8_t>;
    template<> class numeric_limits<char16_t>;
    template<> class numeric_limits<char32_t>;
    template<> class numeric_limits<wchar_t>;

    template<> class numeric_limits<short>;
    template<> class numeric_limits<int>;

§ 17.3.2
17.3.3 Floating-point type properties

17.3.3.1 Type float_round_style

namespace std {
    enum float_round_style {
        round_indeterminate = -1,
        round_toward_zero = 0,
        round_to_nearest = 1,
        round_toward_infinity = 2,
        round_toward_neg_infinity = 3
    };
}

1 The rounding mode for floating-point arithmetic is characterized by the values:

(1.1) — round_indeterminate if the rounding style is indeterminable
(1.2) — round_toward_zero if the rounding style is toward zero
(1.3) — round_to_nearest if the rounding style is to the nearest representable value
(1.4) — round_toward_infinity if the rounding style is toward infinity
(1.5) — round_toward_neg_infinity if the rounding style is toward negative infinity

17.3.3.2 Type float_denorm_style

namespace std {
    enum float_denorm_style {
        denorm_indeterminate = -1,
        denorm_absent = 0,
        denorm_present = 1
    };
}

1 The presence or absence of subnormal numbers (variable number of exponent bits) is characterized by the values:

(1.1) — denorm_indeterminate if it cannot be determined whether or not the type allows subnormal values
(1.2) — denorm_absent if the type does not allow subnormal values
(1.3) — denorm_present if the type does allow subnormal values

17.3.4 Class template numeric_limits

The numeric_limits class template provides a C++ program with information about various properties of the implementation’s representation of the arithmetic types.

namespace std {
    template<class T> class numeric_limits {
        public:
            static constexpr bool is_specialized = false;
            static constexpr T min() noexcept { return T(); }
            static constexpr T max() noexcept { return T(); }
            static constexpr T lowest() noexcept { return T(); }
        }
    }

§ 17.3.4
For all members declared static constexpr in the numeric_limits template, specializations shall define these values in such a way that they are usable as constant expressions.

The default numeric_limits<T> template shall have all members, but with 0 or false values.

Specializations shall be provided for each arithmetic type, both floating-point and integer, including bool. The member is_specialized shall be true for all such specializations of numeric_limits.

The value of each member of a specialization of numeric_limits on a cv-qualified type cv T shall be equal to the value of the corresponding member of the specialization on the unqualified type T.

Non-arithmetic standard types, such as complex<T> (26.4.2), shall not have specializations.

17.3.4.1 numeric_limits members

Each member function defined in this subclause is signal-safe (17.13.4).

static constexpr T min() noexcept;
Minimum finite value.

For floating-point types with subnormal numbers, returns the minimum positive normalized value.

Meaningful for all specializations in which is_bounded != false, or is_bounded == false && is_signed == false.

static constexpr T max() noexcept;
Maximum finite value.

Meaningful for all specializations in which is_bounded != false.

---

188) Equivalent to CHAR_MIN, SHRT_MIN, FLT_MIN, DBL_MIN, etc.
189) Equivalent to CHAR_MAX, SHRT_MAX, FLT_MAX, DBL_MAX, etc.
static constexpr T lowest() noexcept;
A finite value \( x \) such that there is no other finite value \( y \) where \( y < x \).\(^{190}\)
Meaningful for all specializations in which \texttt{is\_bounded} \(!= \texttt{false}\).

static constexpr int digits;
Number of \texttt{radix} digits that can be represented without change.
For integer types, the number of non-sign bits in the representation.
For floating-point types, the number of \texttt{radix} digits in the mantissa.\(^{191}\)

static constexpr int digits10;
Number of base 10 digits that can be represented without change.\(^{192}\)
Meaningful for all specializations in which \texttt{is\_bounded} \(!= \texttt{false}\).

static constexpr int max_digits10;
Number of base 10 digits required to ensure that values which differ are always differentiated.
Meaningful for all floating-point types.

static constexpr bool is_signed;
\texttt{true} if the type is signed.
Meaningful for all specializations.

static constexpr bool is_integer;
\texttt{true} if the type is integer.
Meaningful for all specializations.

static constexpr bool is_exact;
\texttt{true} if the type uses an exact representation. All integer types are exact, but not all exact types are integer. For example, rational and fixed-exponent representations are exact but not integer.
Meaningful for all specializations.

static constexpr int radix;
For floating-point types, specifies the base or \texttt{radix} of the exponent representation (often 2).\(^{193}\)
For integer types, specifies the base of the representation.\(^{194}\)
Meaningful for all specializations.

static constexpr T epsilon() noexcept;
Machine epsilon: the difference between 1 and the least value greater than 1 that is representable.\(^{195}\)
Meaningful for all floating-point types.

static constexpr T round_error() noexcept;
Measure of the maximum rounding error.\(^{196}\)

static constexpr int min_exponent;
Minimum negative integer such that \texttt{radix} raised to the power of one less than that integer is a normalized floating-point number.\(^{197}\)

\(^{190}\) \texttt{lowest()} is necessary because not all floating-point representations have a smallest (most negative) value that is the negative of the largest (most positive) finite value.

\(^{191}\) Equivalent to \texttt{FLT\_MANT\_DIG}, \texttt{DBL\_MANT\_DIG}, \texttt{LDBL\_MANT\_DIG}.
\(^{192}\) Equivalent to \texttt{FLT\_DIG}, \texttt{DBL\_DIG}, \texttt{LDBL\_DIG}.
\(^{193}\) Equivalent to \texttt{FLT\_RADIX}.
\(^{194}\) Distinguishes types with bases other than 2 (e.g. BCD).
\(^{195}\) Equivalent to \texttt{FLT\_EPSILON}, \texttt{DBL\_EPSILON}, \texttt{LDBL\_EPSILON}.
\(^{196}\) Rounding error is described in LIA-1 Section 5.2.4 and Annex C Rationale Section C.5.2.4 — Rounding and rounding constants.
\(^{197}\) Equivalent to \texttt{FLT\_MIN\_EXP}, \texttt{DBL\_MIN\_EXP}, \texttt{LDBL\_MIN\_EXP}.
Meaningful for all floating-point types.

```cpp
static constexpr int min_exponent10;
```

Minimum negative integer such that 10 raised to that power is in the range of normalized floating-point numbers.\(^{198}\) Meaningful for all floating-point types.

```cpp
static constexpr int max_exponent;
```

Maximum positive integer such that \(\text{radix}\) raised to the power one less than that integer is a representable finite floating-point number.\(^{199}\) Meaningful for all floating-point types.

```cpp
static constexpr int max_exponent10;
```

Maximum positive integer such that 10 raised to that power is in the range of representable finite floating-point numbers.\(^{200}\) Meaningful for all floating-point types.

```cpp
static constexpr bool has_infinity;
```

\texttt{true} if the type has a representation for positive infinity. Meaningful for all floating-point types.

```cpp
static constexpr bool has_quiet_NaN;
```

\texttt{true} if the type has a representation for a quiet (non-signaling) “Not a Number”.\(^{201}\) Meaningful for all floating-point types.

```cpp
static constexpr bool has_signaling_NaN;
```

\texttt{true} if the type has a representation for a signaling “Not a Number”.\(^{202}\) Meaningful for all floating-point types.

```cpp
static constexpr float_denorm_style has_denorm;
```

denorm_present if the type allows subnormal values (variable number of exponent bits)\(^{203}\), denorm_absent if the type does not allow subnormal values, and denorm_indeterminate if it is indeterminate at compile time whether the type allows subnormal values. Meaningful for all floating-point types.

```cpp
static constexpr bool has_denorm_loss;
```

\texttt{true} if loss of accuracy is detected as a denormalization loss, rather than as an inexact result.\(^{204}\) Meaningful for all floating-point types.

```cpp
static constexpr T infinity() noexcept;
```

Representation of positive infinity, if available.\(^{205}\)

Meaningful for all specializations for which \texttt{has_infinity} \(!= \texttt{false}\). Required in specializations for which \texttt{is_iec559} \(!= \texttt{false}\).

\(^{198}\) Equivalent to \texttt{FLT_MIN_10_EXP}, \texttt{DBL_MIN_10_EXP}, \texttt{LDBL_MIN_10_EXP}.

\(^{199}\) Equivalent to \texttt{FLT_MAX_EXP}, \texttt{DBL_MAX_EXP}, \texttt{LDBL_MAX_EXP}.

\(^{200}\) Equivalent to \texttt{FLT_MAX_10_EXP}, \texttt{DBL_MAX_10_EXP}, \texttt{LDBL_MAX_10_EXP}.

\(^{201}\) Required by LIA-1.

\(^{202}\) Required by LIA-1.

\(^{203}\) Required by LIA-1.

\(^{204}\) See ISO/IEC/IEEE 60559.

\(^{205}\) Required by LIA-1.
static constexpr T quiet_NaN() noexcept;
  Representation of a quiet “Not a Number”, if available.\(^\text{206}\)
  Meaningful for all specializations for which has_quiet_NaN != false. Required in specializations for which is_iec559 != false.

static constexpr T signaling_NaN() noexcept;
  Representation of a signaling “Not a Number”, if available.\(^\text{207}\)
  Meaningful for all specializations for which has_signaling_NaN != false. Required in specializations for which is_iec559 != false.

static constexpr T denorm_min() noexcept;
  Minimum positive subnormal value.\(^\text{208}\)
  Meaningful for all floating-point types.
  In specializations for which has_denorm == false, returns the minimum positive normalized value.

static constexpr bool is_iec559;
  true if and only if the type adheres to ISO/IEC/IEEE 60559.\(^\text{209}\)
  Meaningful for all floating-point types.

static constexpr bool is_bounded;
  true if the set of values representable by the type is finite.\(^\text{210}\) [Note: All fundamental types (6.7.1) are bounded. This member would be false for arbitrary precision types. — end note]
  Meaningful for all specializations.

static constexpr bool is_modulo;
  true if the type is modulo.\(^\text{211}\) A type is modulo if, for any operation involving +, -, or * on values of that type whose result would fall outside the range min(), max(), the value returned differs from the true value by an integer multiple of max() - min() + 1.
  [Example: is_modulo is false for signed integer types (6.7.1) unless an implementation, as an extension to this document, defines signed integer overflow to wrap. — end example]
  Meaningful for all specializations.

static constexpr bool traps;
  true if, at program startup, there exists a value of the type that would cause an arithmetic operation using that value to trap.\(^\text{212}\)
  Meaningful for all specializations.

static constexpr bool tinyness_before;
  true if tinyness is detected before rounding.\(^\text{213}\)
  Meaningful for all floating-point types.

static constexpr float_round_style round_style;
  The rounding style for the type.\(^\text{214}\)
  Meaningful for all floating-point types. Specializations for integer types shall return round_toward_-zero.

\(^{206}\) Required by LIA-1.
\(^{207}\) Required by LIA-1.
\(^{208}\) Required by LIA-1.
\(^{210}\) Required by LIA-1.
\(^{211}\) Required by LIA-1.
\(^{212}\) Required by LIA-1.
\(^{213}\) Required by LIA-1.
\(^{214}\) Equivalent to FLT_ROUNDS. Required by LIA-1.
17.3.4.2 numeric_limits specializations

1 All members shall be provided for all specializations. However, many values are only required to be meaningful under certain conditions (for example, `epsilon()` is only meaningful if `is_integer` is `false`). Any value that is not “meaningful” shall be set to 0 or `false`.

2 [Example:

```c++
namespace std {
    template<> class numeric_limits<float> {
        public:
            static constexpr bool is_specialized = true;

            static constexpr float min() noexcept { return 1.17549435E-38F; }
            static constexpr float max() noexcept { return 3.40282347E+38F; }
            static constexpr float lowest() noexcept { return -3.40282347E+38F; }
            static constexpr int digits = 24;
            static constexpr int digits10 = 6;
            static constexpr int max_digits10 = 9;

            static constexpr bool is_signed = true;
            static constexpr bool is_integer = false;
            static constexpr bool is_exact = false;
            static constexpr int radix = 2;
            static constexpr float epsilon() noexcept { return 1.19209290E-07F; }
            static constexpr float round_error() noexcept { return 0.5F; }
            static constexpr int min_exponent = -125;
            static constexpr int min_exponent10 = -37;
            static constexpr int max_exponent = +128;
            static constexpr int max_exponent10 = +38;

            static constexpr bool has_infinity = true;
            static constexpr bool has_quiet_NaN = true;
            static constexpr bool has_signaling_NaN = true;
            static constexpr float_denorm_style has_denorm = denorm_absent;
            static constexpr bool has_denorm_loss = false;
            static constexpr bool is_iec559 = true;
            static constexpr bool is_bounded = true;
            static constexpr bool is_modulo = false;
            static constexpr bool traps = true;
            static constexpr bool tinyness_before = true;

            static constexpr float_denorm_style round_style = round_to_nearest;
    };
}
```

—end example]

3 The specialization for `bool` shall be provided as follows:

```c++
namespace std {
    template<> class numeric_limits<bool> {
        public:
            static constexpr bool is_specialized = true;

            static constexpr bool min() noexcept { return false; }
            static constexpr bool max() noexcept { return true; }
            static constexpr bool lowest() noexcept { return false; }
    };
}
```

§ 17.3.4.2 485
static constexpr int digits = 1;
static constexpr int digits10 = 0;
static constexpr int max_digits10 = 0;

static constexpr bool is_signed = false;
static constexpr bool is_integer = true;
static constexpr bool is_exact = true;
static constexpr int radix = 2;
static constexpr bool epsilon() noexcept { return 0; }
static constexpr bool round_error() noexcept { return 0; }

static constexpr int min_exponent = 0;
static constexpr int min_exponent10 = 0;
static constexpr int max_exponent = 0;
static constexpr int max_exponent10 = 0;

static constexpr bool has_infinity = false;
static constexpr bool has_quiet_NaN = false;
static constexpr bool has_signaling_NaN = false;
static constexpr float_denorm_style has_denorm = denorm_absent;
static constexpr bool has_denorm_loss = false;
static constexpr bool infinity() noexcept { return 0; }
static constexpr bool quiet_NaN() noexcept { return 0; }
static constexpr bool signaling_NaN() noexcept { return 0; }
static constexpr bool denorm_min() noexcept { return 0; }

static constexpr bool is_iec559 = false;
static constexpr bool is_bounded = true;
static constexpr bool is_modulo = false;
static constexpr bool traps = false;
static constexpr bool tinyness_before = false;
static constexpr float_round_style round_style = round_toward_zero;

1 The header `<climits>` defines all macros the same as the C standard library header `<limits.h>`. [Note: The types of the constants defined by macros in `<climits>` are not required to match the types to which the macros refer. —end note]

17.4 Integer types

namespace std {
    using int8_t = signed integer type; // optional
    using int16_t = signed integer type; // optional
    using int32_t = signed integer type; // optional
    using int64_t = signed integer type; // optional
    using int_fast8_t = signed integer type;
    using int_fast16_t = signed integer type;
    using int_fast32_t = signed integer type;
    using int_fast64_t = signed integer type;
    using int_least8_t = signed integer type;
    using int_least16_t = signed integer type;
    using int_least32_t = signed integer type;
    using int_least64_t = signed integer type;
using intmax_t = signed integer type;  
using intptr_t = signed integer type; // optional

using uint8_t = unsigned integer type; // optional
using uint16_t = unsigned integer type; // optional
using uint32_t = unsigned integer type; // optional
using uint64_t = unsigned integer type; // optional

using uint_fast8_t = unsigned integer type;
using uint_fast16_t = unsigned integer type;
using uint_fast32_t = unsigned integer type;
using uint_fast64_t = unsigned integer type;

using uint_least8_t = unsigned integer type;
using uint_least16_t = unsigned integer type;
using uint_least32_t = unsigned integer type;
using uint_least64_t = unsigned integer type;

using uintmax_t = unsigned integer type;
using uintptr_t = unsigned integer type; // optional

The header also defines numerous macros of the form:

INT_[FAST LEAST]{8 16 32 64}_MIN
[U]INT_[FAST LEAST]{8 16 32 64}_MAX
INT{MAX PTR}_MIN
[U]INT{MAX PTR}_MAX
{PTRDIFF SIG_ATOMIC WCHAR WINT}{_MAX _MIN}
SIZE_MAX

plus function macros of the form:

[U]INT{8 16 32 64 MAX}_C

The header defines all types and macros the same as the C standard library header <stdint.h>.

See also: ISO C 7.20

17.5 Start and termination

1 [support.start.term] [Note: The header <cstdlib> (17.2.2) declares the functions described in this subclause. — end note]

[[noreturn]] void _Exit(int status) noexcept;

Effects: This function has the semantics specified in the C standard library.

Remarks: The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to atexit() (6.8.3.4). The function _Exit is signal-safe (17.13.4).

[[noreturn]] void abort() noexcept;

Effects: This function has the semantics specified in the C standard library.

Remarks: The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to atexit() (6.8.3.4). The function abort is signal-safe (17.13.4).

int atexit(c-atexit-handler* f) noexcept;
int atexit(atexit-handler* f) noexcept;

Effects: The atexit() functions register the function pointed to by f to be called without arguments at normal program termination. It is unspecified whether a call to atexit() that does not happen before (6.8.2) a call to exit() will succeed. [Note: The atexit() functions do not introduce a data race (16.5.5.9). — end note]

Implementation limits: The implementation shall support the registration of at least 32 functions.

Returns: The atexit() function returns zero if the registration succeeds, nonzero if it fails.
[[noretur]] void exit(int status);

**Effects:**

- First, objects with thread storage duration and associated with the current thread are destroyed. Next, objects with static storage duration are destroyed and functions registered by calling `atexit` are called.\(^{215}\) See 6.8.3.4 for the order of destructions and calls. (Automatic objects are not destroyed as a result of calling `exit()`.)\(^{216}\)

  If control leaves a registered function called by `exit` because the function does not provide a handler for a thrown exception, the function `std::terminate` shall be called (14.5.1).

- Next, all open C streams (as mediated by the function signatures declared in `<cstdio>`) with unwritten buffered data are flushed, all open C streams are closed, and all files created by calling `tmpfile()` are removed.

- Finally, control is returned to the host environment. If `status` is zero or `EXIT_SUCCESS`, an implementation-defined form of the status `successful termination` is returned. If `status` is `EXIT_FAILURE`, an implementation-defined form of the status `unsuccessful termination` is returned. Otherwise the status returned is implementation-defined.\(^{217}\)

    int at_quick_exit(c-atexit-handler* f) noexcept;

**Effects:** The `at_quick_exit()` functions register the function pointed to by `f` to be called without arguments when `quick_exit` is called. It is specified whether a call to `at_quick_exit()` that does not happen before (6.8.2) all calls to `quick_exit` will succeed. \[Note: The `at_quick_exit()` functions do not introduce a data race (16.5.9). \] \[end note\] \[Note: The order of registration may be indeterminate if `at_quick_exit` was called from more than one thread. \] \[end note\] \[Note: The `at_quick_exit` registrations are distinct from the `atexit` registrations, and applications may need to call both registration functions with the same argument. \] \[end note\]

**Implementation limits:** The implementation shall support the registration of at least 32 functions.

**Returns:** Zero if the registration succeeds, nonzero if it fails.

[[noretur]] void quick_exit(int status) noexcept;

**Effects:** Functions registered by calls to `at_quick_exit` are called in the reverse order of their registration, except that a function shall be called after any previously registered functions that had already been called at the time it was registered. Objects shall not be destroyed as a result of calling `quick_exit`. If control leaves a registered function called by `quick_exit` because the function does not provide a handler for a thrown exception, the function `std::terminate` shall be called. \[Note: A function registered via `at_quick_exit` is invoked by the thread that calls `quick_exit`, which can be a different thread than the one that registered it, so registered functions should not rely on the identity of objects with thread storage duration. \] \[end note\] After calling registered functions, `quick_exit` shall call `_Exit(status)`.

**Remarks:** The function `quick_exit` is signal-safe (17.13.4) when the functions registered with `at_` `quick_exit` are.

**See also:** ISO C 7.22.4

### 17.6 Dynamic memory management

The header `<new>` defines several functions that manage the allocation of dynamic storage in a program. It also defines components for reporting storage management errors.

#### 17.6.1 Header `<new>` synopsis

```cpp
namespace std {
    class bad_alloc;
    class bad_array_new_length;
}
```

\(^{215}\) A function is called for every time it is registered.

\(^{216}\) Objects with automatic storage duration are all destroyed in a program whose `main` function (6.8.3.1) contains no automatic objects and executes the call to `exit()`. Control can be transferred directly to such a `main` function by throwing an exception that is caught in `main`.

\(^{217}\) The macros `EXIT_FAILURE` and `EXIT_SUCCESS` are defined in `<cstdlib>`.
struct destroying_delete_t {
    explicit destroying_delete_t() = default;
};

inline constexpr destroying_delete_t destroying_delete{};

enum class align_val_t : size_t {};

struct nothrow_t { explicit nothrow_t() = default; }
extern const nothrow_t nothrow;

using new_handler = void (*)();
new_handler get_new_handler() noexcept;
new_handler set_new_handler(new_handler new_p) noexcept;

// 17.6.4, pointer optimization barrier
template<class T> [[nodiscard]] constexpr T* launder(T* p) noexcept;

// 17.6.5, hardware interference size
inline constexpr size_t hardware_destructive_interference_size = implementation-defined;
inline constexpr size_t hardware_constructive_interference_size = implementation-defined;

[[nodiscard]] void* operator new(std::size_t size);
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment);
[[nodiscard]] void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;

void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, const std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

17.6.2 Storage allocation and deallocation

Except where otherwise specified, the provisions of 6.6.5.4 apply to the library versions of operator new and operator delete. If the value of an alignment argument passed to any of these functions is not a valid alignment value, the behavior is undefined.

17.6.2.1 Single-object forms

[[nodiscard]] void* operator new(std::size_t size);
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment);

**Effects:** The allocation functions (6.6.5.4.1) called by a new-expression (7.6.2.7) to allocate size bytes of storage. The second form is called for a type with new-extended alignment, and allocates storage with the specified alignment. The first form is called otherwise, and allocates storage suitably aligned to represent any object of that size provided the object’s type does not have new-extended alignment.

**Replaceable:** A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

**Required behavior:** Return a non-null pointer to suitably aligned storage (6.6.5.4), or else throw a bad_alloc exception. This requirement is binding on any replacement versions of these functions.

**Default behavior:**

1. Executes a loop: Within the loop, the function first attempts to allocate the requested storage. Whether the attempt involves a call to the C standard library functions malloc or aligned_alloc is unspecified.
2. Returns a pointer to the allocated storage if the attempt is successful. Otherwise, if the current new_handler (17.6.3.5) is a null pointer value, throws bad_alloc.
3. Otherwise, the function calls the current new_handler function (17.6.3.3). If the called function returns, the loop repeats.
4. The loop terminates when an attempt to allocate the requested storage is successful or when a called new_handler function does not return.

[[nodiscard]] void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;

**Effects:** Same as above, except that these are called by a placement version of a new-expression when a C++ program prefers a null pointer result as an error indication, instead of a bad_alloc exception.

**Replaceable:** A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library.

**Required behavior:** Return a non-null pointer to suitably aligned storage (6.6.5.4), or else return a null pointer. Each of these nothrow versions of operator new returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

**Default behavior:** Calls operator new(size), or operator new(size, alignment), respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

[Example:

```cpp
T* p1 = new T; // throws bad_alloc if it fails
T* p2 = new(nothrow) T; // returns nullptr if it fails
```

—end example]

void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, std::size_t size, std::align_val_t alignment) noexcept;

**Effects:** The deallocation functions (6.6.5.4.2) called by a delete-expression (7.6.2.8) to render the value of ptr invalid.

**Replaceable:** A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a size parameter is defined, the program should also define the corresponding function with a size parameter. If a function with a size parameter is defined, the program shall also define the corresponding version without the size parameter. [Note: The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. —end note]

**Effects:** ptr is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) operator new(std::size_t) or operator new(std::size_t, std::align_val_t) which has not been invalidated by an intervening call to operator delete.
§ 17.6.2.2 Array forms

[][nodiscard] void* operator new[](std::size_t size);
[][nodiscard] void* operator new[](std::size_t size, std::align_val_t alignment);

**Effects:** The allocation functions (6.6.5.4.1) called by the array form of a new-expression (7.6.2.7) to allocate size bytes of storage. The second form is called for a type with new-extended alignment, and allocates storage with the specified alignment. The first form is called otherwise, and allocates storage suitably aligned to represent any array object of that size or smaller, provided the object’s type does not have new-extended alignment.\(^\text{218}\)

**Replaceable:** A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

**Required behavior:** Same as for the corresponding single-object forms. This requirement is binding on any replacement versions of these functions.

**Default behavior:** Returns operator new(size), or operator new(size, alignment), respectively.

[][nodiscard] void* operator new[](std::size_t size, const std::nothrow_t&) noexcept;

\(^\text{218}\) It is not the direct responsibility of operator new[] or operator delete[] to note the repetition count or element size of the array. Those operations are performed elsewhere in the array new and delete expressions. The array new expression, may, however, increase the size argument to operator new[] to obtain space to store supplemental information.
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;

**Effects:** Same as above, except that these are called by a placement version of a *new-expression* when a C++ program prefers a null pointer result as an error indication, instead of a bad_alloc exception.

**Replaceable:** A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library.

**Required behavior:** Return a non-null pointer to suitably aligned storage (6.6.5.4), or else return a null pointer. Each of these nothrow versions of *operator new[]* returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

**Default behavior:** Calls *operator new[](size)*, or *operator new[](size, alignment)*, respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

void operator delete[](void* ptr) noexcept;
void operator delete[](void* ptr, std::size_t size) noexcept;
void operator delete[](void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
void operator delete[](void* ptr, std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;

**Effects:** The deallocation functions (6.6.5.4.2) called by the array form of a *delete-expression* to render the value of *ptr* invalid.

**Replaceable:** A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a *size* parameter is defined, the program should also define the corresponding function with a *size* parameter. If a function with a *size* parameter is defined, the program shall also define the corresponding version without the *size* parameter. [Note: The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. —end note]

**Effects:** *ptr* is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) *operator new[]*(std::size_t) or *operator new[]*(std::size_t, std::align_val_t) which has not been invalidated by an intervening call to *operator delete[]*.  

**Effects:** If an implementation has strict pointer safety (6.6.5.4.3) then *ptr* is a safely-derived pointer.

**Effects:** If the *alignment* parameter is not present, *ptr* was returned by an allocation function without an *alignment* parameter. If present, the *alignment* argument is equal to the *alignment* argument passed to the allocation function that returned *ptr*. If present, the *size* argument is equal to the *size* argument passed to the allocation function that returned *ptr*.

**Required behavior:** A call to an *operator delete[]* with a *size* parameter may be changed to a call to the corresponding *operator delete[]* without a *size* parameter, without affecting memory allocation. [Note: A conforming implementation is for *operator delete[]*(void* ptr, std::size_t size) to simply call *operator delete[]*(ptr). —end note]

**Default behavior:** The functions that have a *size* parameter forward their other parameters to the corresponding function without a *size* parameter. The functions that do not have a *size* parameter forward their parameters to the corresponding *operator delete* (single-object) function.

void operator delete[](void* ptr, const std::nothrow_t&) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

**Effects:** The deallocation functions (6.6.5.4.2) called by the implementation to render the value of *ptr* invalid when the constructor invoked from a nothrow placement version of the array *new-expression* throws an exception.

**Replaceable:** A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library.

**Effects:** *ptr* is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) *operator new[]*(std::size_t) or *operator new[]*(std::size_t, std::align_val_t) which has not been invalidated by an intervening call to *operator delete[].

**Effects:** If an implementation has strict pointer safety (6.6.5.4.3) then *ptr* is a safely-derived pointer.
Expects: If the alignment parameter is not present, ptr was returned by an allocation function without an alignment parameter. If present, the alignment argument is equal to the alignment argument passed to the allocation function that returned ptr.

Default behavior: Calls operator delete[](ptr), or operator delete[](ptr, alignment), respectively.

17.6.2.3 Non-allocating forms

These functions are reserved; a C++ program may not define functions that displace the versions in the C++ standard library (16.5.4). The provisions of 6.6.5.4 do not apply to these reserved placement forms of operator new and operator delete.

[[nodiscard]] void* operator new(std::size_t size, void* ptr) noexcept;

Returns: ptr.

Remarks: Intentionally performs no other action.

Example: This can be useful for constructing an object at a known address:

```cpp
void* place = operator new(sizeof(Something));
Something* p = new (place) Something();
```

—end example

[[nodiscard]] void* operator new[](std::size_t size, void* ptr) noexcept;

Returns: ptr.

Remarks: Intentionally performs no other action.

void operator delete(void* ptr, void*) noexcept;

Effects: Intentionally performs no action.

Expects: If an implementation has strict pointer safety (6.6.5.4.3) then ptr is a safely-derived pointer.

Remarks: Default function called when any part of the initialization in a placement new-expression that invokes the library’s non-array placement operator new terminates by throwing an exception (7.6.2.7).

void operator delete[](void* ptr, void*) noexcept;

Effects: Intentionally performs no action.

Expects: If an implementation has strict pointer safety (6.6.5.4.3) then ptr is a safely-derived pointer.

Remarks: Default function called when any part of the initialization in a placement new-expression that invokes the library’s array placement operator new terminates by throwing an exception (7.6.2.7).

17.6.2.4 Data races

For purposes of determining the existence of data races, the library versions of operator new, user replacement versions of global operator new, the C standard library functions aligned_alloc, calloc, and malloc, the library versions of operator delete, user replacement versions of operator delete, the C standard library function free, and the C standard library function realloc shall not introduce a data race (16.5.5.9). Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before (6.8.2) the next allocation (if any) in this order.

17.6.3 Storage allocation errors

17.6.3.1 Class bad_alloc

namespace std {
    class bad_alloc : public exception {
        public:
            // see 17.9.2 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}

The class bad_alloc defines the type of objects thrown as exceptions by the implementation to report a failure to allocate storage.

§ 17.6.3.1
const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

17.6.3.2 Class bad_array_new_length

namespace std {
    class bad_array_new_length : public bad_alloc {
    public:
        // see 17.9.2 for the specification of the special member functions
        const char* what() const noexcept override;
    }
}

The class bad_array_new_length defines the type of objects thrown as exceptions by the implementation to report an attempt to allocate an array of size less than zero or greater than an implementation-defined limit (7.6.2.7).

const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

17.6.3.3 Type new_handler

using new_handler = void (*)();

The type of a handler function to be called by operator new() or operator new[] () (17.6.2) when they cannot satisfy a request for additional storage.

Required behavior: A new_handler shall perform one of the following:

(2.1) — make more storage available for allocation and then return;
(2.2) — throw an exception of type bad_alloc or a class derived from bad_alloc;
(2.3) — terminate execution of the program without returning to the caller.

17.6.3.4 set_new_handler

new_handler set_new_handler(new_handler new_p) noexcept;

Effects: Establishes the function designated by new_p as the current new_handler.

Returns: The previous new_handler.

Remarks: The initial new_handler is a null pointer.

17.6.3.5 get_new_handler

new_handler get_new_handler() noexcept;

Returns: The current new_handler. [Note: This may be a null pointer value. — end note]

17.6.4 Pointer optimization barrier

template<class T> [[nodiscard]] constexpr T* launder(T* p) noexcept;

Mandates: !is_function_v<T> && !is_void_v<T> is true.

Expects: p represents the address A of a byte in memory. An object X that is within its lifetime (6.6.3) and whose type is similar (7.3.5) to T is located at the address A. All bytes of storage that would be reachable through the result are reachable through p (see below).

Returns: A value of type T * that points to X.

Remarks: An invocation of this function may be used in a core constant expression whenever the value of its argument may be used in a core constant expression. A byte of storage is reachable through a pointer value that points to an object Y if it is within the storage occupied by Y, an object that is pointer-interconvertible with Y, or the immediately-enclosing array object if Y is an array element.

[Note: If a new object is created in storage occupied by an existing object of the same type, a pointer to the original object can be used to refer to the new object unless the type contains const or reference members; in the latter cases, this function can be used to obtain a usable pointer to the new object. See 6.6.3. — end note]
6

[Example:

```cpp
struct X { const int n; }
X *p = new X(3);
const int a = p->n;
new (p) X(5); // p does not point to new object (6.6.3) because X::n is const
const int b = p->n; // undefined behavior
const int c = std::launder(p)->n; // OK
```
—end example]

17.6.5 Hardware interference size

inline constexpr size_t hardware_destructive_interference_size = implementation-defined;

This number is the minimum recommended offset between two concurrently-accessed objects to avoid additional performance degradation due to contention introduced by the implementation. It shall be at least alignof(max_align_t).

[Example:

```cpp
struct keep_apart {
    alignas(hardware_destructive_interference_size) atomic<int> cat;
    alignas(hardware_destructive_interference_size) atomic<int> dog;
};
```
—end example]

inline constexpr size_t hardware_constructive_interference_size = implementation-defined;

This number is the maximum recommended size of contiguous memory occupied by two objects accessed with temporal locality by concurrent threads. It shall be at least alignof(max_align_t).

[Example:

```cpp
struct together {
    atomic<int> dog;
    int puppy;
};
struct kennel {
    // Other data members...
    alignas(sizeof(together)) together pack;
    // Other data members...
};
static_assert(sizeof(together) <= hardware_constructive_interference_size);
```
—end example]

17.7 Type identification

The header `<typeinfo>` defines a type associated with type information generated by the implementation. It also defines two types for reporting dynamic type identification errors.

17.7.1 Header `<typeinfo>` synopsis

```cpp
namespace std {
    class type_info;
    class bad_cast;
    class bad_typeid;
}
```

17.7.2 Class type_info

```cpp
namespace std {
    class type_info {
        public:
            virtual ~type_info();
            bool operator==(const type_info& rhs) const noexcept;
            bool operator!=(const type_info& rhs) const noexcept;
            bool before(const type_info& rhs) const noexcept;
            size_t hash_code() const noexcept;
            const char* name() const noexcept;
    }
```
The class `type_info` describes type information generated by the implementation (7.6.1.7). Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoding rule, and collating sequence for types are all unspecified and may differ between programs.

```cpp
bool operator==(const type_info& rhs) const noexcept;
```

**Effects:** Compares the current object with `rhs`.

**Returns:** `true` if the two values describe the same type.

```cpp
bool operator!=(const type_info& rhs) const noexcept;
```

**Returns:** `!(*this == rhs)`.

```cpp
bool before(const type_info& rhs) const noexcept;
```

**Effects:** Compares the current object with `rhs`.

**Returns:** `true` if `*this` precedes `rhs` in the implementation’s collation order.

```cpp
size_t hash_code() const noexcept;
```

**Returns:** An unspecified value, except that within a single execution of the program, it shall return the same value for any two `type_info` objects which compare equal.

**Remarks:** An implementation should return different values for two `type_info` objects which do not compare equal.

```cpp
const char* name() const noexcept;
```

**Returns:** An implementation-defined `ntbs`.

**Remarks:** The message may be a null-terminated multibyte string (16.4.2.2.5.2), suitable for conversion and display as a `wstring` (21.3, 28.4.1.4)

### 17.7.3 Class `bad_cast`

```cpp
namespace std {
    class bad_cast : public exception {
        public:
            // see 17.9.2 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}
```

The class `bad_cast` defines the type of objects thrown as exceptions by the implementation to report the execution of an invalid `dynamic_cast` expression (7.6.1.6).

```cpp
const char* what() const noexcept override;
```

**Returns:** An implementation-defined `ntbs`.

### 17.7.4 Class `bad_typeid`

```cpp
namespace std {
    class bad_typeid : public exception {
        public:
            // see 17.9.2 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}
```

The class `bad_typeid` defines the type of objects thrown as exceptions by the implementation to report a null pointer in a `typeid` expression (7.6.1.7).
const char* what() const noexcept override;

Returns: An implementation-defined NTBS.

17.8 Contract violation handling [support.contract]

17.8.1 Header <contract> synopsis [contract.syn]
The header <contract> defines a type for reporting information about contract violations generated by the implementation.

namespace std {
    class contract_violation;
}

17.8.2 Class contract_violation [support.contract cviol]

namespace std {
    class contract_violation {
        public:
            uint_least32_t line_number() const noexcept;
            string_view file_name() const noexcept;
            string_view function_name() const noexcept;
            string_view comment() const noexcept;
            string_view assertion_level() const noexcept;
    };
}

1 The class contract_violation describes information about a contract violation generated by the implementation.

uint_least32_t line_number() const noexcept;

Returns: The source code location where the contract violation happened (9.11.4). If the location is unknown, an implementation may return 0.

string_view file_name() const noexcept;

Returns: The source file name where the contract violation happened (9.11.4). If the file name is unknown, an implementation may return string_view{}.

string_view function_name() const noexcept;

Returns: The name of the function where the contract violation happened (9.11.4). If the function name is unknown, an implementation may return string_view{}.

string_view comment() const noexcept;

Returns: Implementation-defined text describing the predicate of the violated contract.

string_view assertion_level() const noexcept;

Returns: Text describing the assertion-level of the violated contract.

17.9 Exception handling [support.exception]

The header <exception> defines several types and functions related to the handling of exceptions in a C++ program.

17.9.1 Header <exception> synopsis [exception.syn]

namespace std {
    class exception;
    class bad_exception;
    class nested_exception;

    using terminate_handler = void (*)(void);
    terminate_handler get_terminate() noexcept;
    terminate_handler set_terminate(terminate_handler f) noexcept;
    [[noreturn]] void terminate() noexcept;

    int uncaught_exceptions() noexcept;

§ 17.9.1 498
using exception_ptr = unspecified;

exception_ptr current_exception() noexcept;
[[noreturn]] void rethrow_exception(exception_ptr p);
template<class E> exception_ptr make_exception_ptr(E e) noexcept;

template<class T> [[noreturn]] void throw_with_nested(T&& t);
template<class E> void rethrow_if_nested(const E& e);
}

17.9.2 Class exception

namespace std {
  class exception {
    public:
      exception() noexcept;
      exception(const exception&) noexcept;
      exception& operator=(const exception&) noexcept;
      virtual ~exception();
      virtual const char* what() const noexcept;
    }
  }

1 The class exception defines the base class for the types of objects thrown as exceptions by C++ standard library components, and certain expressions, to report errors detected during program execution.

2 Each standard library class T that derives from class exception has the following publicly accessible member functions, each of them having a non-throwing exception specification (14.4):

   (2.1) — default constructor (unless the class synopsis shows other constructors)
   (2.2) — copy constructor
   (2.3) — copy assignment operator

The copy constructor and the copy assignment operator meet the following postcondition: If two objects lhs and rhs both have dynamic type T and lhs is a copy of rhs, then strcmp(lhs.what(), rhs.what()) is equal to 0. The what() member function of each such T satisfies the constraints specified for exception::what() (see below).

exception(const exception& rhs) noexcept;
exception& operator=(const exception& rhs) noexcept;

3 Ensures: If *this and rhs both have dynamic type exception then the value of the expression strcmp(what(), rhs.what()) shall equal 0.

virtual ~exception();

4 Effects: Destroys an object of class exception.

virtual const char* what() const noexcept;

5 Returns: An implementation-defined NTBS.

6 Remarks: The message may be a null-terminated multibyte string (16.4.2.2.5.2), suitable for conversion and display as a wstring (21.3, 28.4.1.4). The return value remains valid until the exception object from which it is obtained is destroyed or a non-const member function of the exception object is called.

17.9.3 Class bad_exception

namespace std {
  class bad_exception : public exception {
    public:
      // see 17.9.2 for the specification of the special member functions
      const char* what() const noexcept override;
    }
  }

1 The class bad_exception defines the type of the object referenced by the exception_ptr returned from a call to current_exception (17.9.6) when the currently active exception object fails to copy.
const char* what() const noexcept override;

Returns: An implementation-defined NTBS.

17.9.4 Abnormal termination

17.9.4.1 Type terminate_handler

using terminate_handler = void (*)(void);

1 The type of a handler function to be called by std::terminate() when terminating exception processing.

Required behavior: A terminate_handler shall terminate execution of the program without returning to the caller.

Default behavior: The implementation’s default terminate_handler calls abort().

17.9.4.2 set_terminate

terminate_handler set_terminate(terminate_handler f) noexcept;

1 Effects: Establishes the function designated by f as the current handler function for terminating exception processing.

2 Remarks: It is unspecified whether a null pointer value designates the default terminate_handler.

Returns: The previous terminate_handler.

17.9.4.3 get_terminate

terminate_handler get_terminate() noexcept;

1 Returns: The current terminate_handler. [Note: This may be a null pointer value. — end note]

17.9.4.4 terminate

[[noreturn]] void terminate() noexcept;

1 Remarks: Called by the implementation when exception handling must be abandoned for any of several reasons (14.5.1). May also be called directly by the program.

2 Effects: Calls a terminate_handler function. It is unspecified which terminate_handler function will be called if an exception is active during a call to set_terminate. Otherwise calls the current terminate_handler function. [Note: A default terminate_handler is always considered a callable handler in this context. — end note]

17.9.5 uncaught_exceptions

int uncaught_exceptions() noexcept;

1 Returns: The number of uncaught exceptions (14.5.2).

2 Remarks: When uncaught_exceptions() > 0, throwing an exception can result in a call of the function std::terminate (14.5.1).

17.9.6 Exception propagation

using exception_ptr = unspecified;

The type exception_ptr can be used to refer to an exception object.

1 exception_ptr meets the requirements of Cpp17NullablePointer (Table 31).

2 Two non-null values of type exception_ptr are equivalent and compare equal if and only if they refer to the same exception.

3 The default constructor of exception_ptr produces the null value of the type.

4 exception_ptr shall not be implicitly convertible to any arithmetic, enumeration, or pointer type.

5 [Note: An implementation might use a reference-counted smart pointer as exception_ptr. — end note]

For purposes of determining the presence of a data race, operations on exception_ptr objects shall access and modify only the exception_ptr objects themselves and not the exceptions they refer to.
Use of `rethrow_exception` on `exception_ptr` objects that refer to the same exception object shall not introduce a data race. [Note: If `rethrow_exception` rethrows the same exception object (rather than a copy), concurrent access to that rethrown exception object may introduce a data race. Changes in the number of `exception_ptr` objects that refer to a particular exception do not introduce a data race. — end note]

```cpp
exception_ptr current_exception() noexcept;
```

*Returns:* An `exception_ptr` object that refers to the currently handled exception (14.3) or a copy of the currently handled exception, or a null `exception_ptr` object if no exception is being handled. The referenced object shall remain valid at least as long as there is an `exception_ptr` object that refers to it. If the function needs to allocate memory and the attempt fails, it returns an `exception_ptr` object that refers to an instance of `bad_alloc`. It is unspecified whether the return values of two successive calls to `current_exception` refer to the same exception object. [Note: That is, it is unspecified whether `current_exception` creates a new copy each time it is called. — end note] If the attempt to copy the current exception object throws an exception, the function returns an `exception_ptr` object that refers to the thrown exception or, if this is not possible, to an instance of `bad_exception`. [Note: The copy constructor of the thrown exception may also fail, so the implementation is allowed to substitute a `bad_exception` object to avoid infinite recursion. — end note]

```cpp
[[noreturn]] void rethrow_exception(exception_ptr p);
```

*Expects:* `p` is not a null pointer.

*Throws:* The exception object to which `p` refers.

```cpp
template<class E> exception_ptr make_exception_ptr(E e) noexcept;
```

*Effects:* Creates an `exception_ptr` object that refers to a copy of `e`, as if:

```cpp
try {
    throw e;
} catch(...) {
    return current_exception();
}
```

[Note: This function is provided for convenience and efficiency reasons. — end note]

### 17.9.7 nested_exception

```cpp
namespace std {
    class nested_exception {
        public:
            nested_exception() noexcept;
            nested_exception(const nested_exception&) noexcept = default;
            nested_exception& operator=(const nested_exception&) noexcept = default;
            virtual ~nested_exception() = default;

            // access functions
            [[noreturn]] void rethrow_nested() const;
            exception_ptr nested_ptr() const noexcept;
    };

template<class T> [[noreturn]] void throw_with_nested(T&& t);
template<class E> void rethrow_if_nested(const E& e);
}
```

1 The class `nested_exception` is designed for use as a mixin through multiple inheritance. It captures the currently handled exception and stores it for later use.

2 [Note: `nested_exception` has a virtual destructor to make it a polymorphic class. Its presence can be tested for with `dynamic_cast`. — end note]

```cpp
nested_exception() noexcept;
```

*Effects:* The constructor calls `current_exception()` and stores the returned value.
[[noreturn]] void rethrow_nested() const;

Effects: If nested_ptr() returns a null pointer, the function calls the function std::terminate. Otherwise, it throws the stored exception captured by *this.

exception_ptr nested_ptr() const noexcept;

Returns: The stored exception captured by this nested_exception object.

template<class T> [[noreturn]] void throw_with_nested(T&& t);

Let U be decay_t<T>.

Expects: U meets the Cpp17CopyConstructible requirements.

Throws: If is_class_v<U> && !is_final_v<U> && !is_base_of_v<nested_exception, U> is true, an exception of unspecified type that is publicly derived from both U and nested_exception and constructed from std::forward<T>(t), otherwise std::forward<T>(t).

template<class E> void rethrow_if_nested(const E& e);

Effects: If E is not a polymorphic class type, or if nested_exception is an inaccessible or ambiguous base class of E, there is no effect. Otherwise, performs:

```c++
if (auto p = dynamic_cast<const nested_exception*>(addressof(e)))
  p->rethrow_nested();
```

17.10 Initializer lists

The header <initializer_list> defines a class template and several support functions related to list-initialization (see 9.3.4). All functions specified in this subclause are signal-safe (17.13.4).

17.10.1 Header <initializer_list> synopsis

```c++
namespace std {
  template<class E> class initializer_list {
    public:
      using value_type = E;
      using reference = const E&;
      using const_reference = const E&;
      using size_type = size_t;
      using iterator = const E*;
      using const_iterator = const E*;

      constexpr initializer_list() noexcept;
      constexpr size_t size() const noexcept; // number of elements
      constexpr const E* begin() const noexcept; // first element
      constexpr const E* end() const noexcept; // one past the last element
    }

  // 17.10.4, initializer list range access
  template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;
  template<class E> constexpr const E* end(initializer_list<E> il) noexcept;
}
```

An object of type initializer_list<E> provides access to an array of objects of type const E. [Note: A pair of pointers or a pointer plus a length would be obvious representations for initializer_list. initializer_list is used to implement initializer lists as specified in 9.3.4. Copying an initializer list does not copy the underlying elements. — end note]

If an explicit specialization or partial specialization of initializer_list is declared, the program is ill-formed.

17.10.2 Initializer list constructors

```c++
constexpr initializer_list() noexcept;

Ensures: size() == 0.
```
17.10.3 Initializer list access

```cpp
constexpr const E* begin() const noexcept;
```

Returns: A pointer to the beginning of the array. If `size() == 0` the values of `begin()` and `end()` are unspecified but they shall be identical.

```cpp
constexpr const E* end() const noexcept;
```

Returns: `begin() + size()`.

```cpp
constexpr size_t size() const noexcept;
```

Returns: The number of elements in the array.

Complexity: Constant time.

17.10.4 Initializer list range access

```cpp
template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;
```

Returns: `il.begin()`.

```cpp
template<class E> constexpr const E* end(initializer_list<E> il) noexcept;
```

Returns: `il.end()`.

17.11 Comparisons

17.11.1 Header `<compare>` synopsis

The header `<compare>` specifies types, objects, and functions for use primarily in connection with the three-way comparison operator (7.6.8).

```cpp
namespace std {
  // 17.11.2, comparison category types
  class weak_equality;
  class strong_equality;
  class partial_ordering;
  class weak_ordering;
  class strong_ordering;

  // named comparison functions
  constexpr bool is_eq (weak_equality cmp) noexcept { return cmp == 0; }
  constexpr bool is_neq (weak_equality cmp) noexcept { return cmp != 0; }
  constexpr bool is_lt (partial_ordering cmp) noexcept { return cmp < 0; }
  constexpr bool is_lteq(partial_ordering cmp) noexcept { return cmp <= 0; }
  constexpr bool is_gt (partial_ordering cmp) noexcept { return cmp > 0; }
  constexpr bool is_gteq(partial_ordering cmp) noexcept { return cmp >= 0; }

  // 17.11.3, common comparison category type
  template<class... Ts>
  struct common_comparison_category {
    using type = see below;
  };
  template<class... Ts>
  using common_comparison_category_t = typename common_comparison_category<Ts...>::type;

  // 17.11.4, comparison algorithms
  template<class T> constexpr strong_ordering strong_order(const T& a, const T& b);
  template<class T> constexpr weak_ordering weak_order(const T& a, const T& b);
  template<class T> constexpr partial_ordering partial_order(const T& a, const T& b);
  template<class T> constexpr strong_equality strong_equal(const T& a, const T& b);
  template<class T> constexpr weak_equality weak_equal(const T& a, const T& b);
}
```
17.11.2 Comparison category types

17.11.2.1 Preamble

The types `weak_equality`, `strong_equality`, `partial_ordering`, `weak_ordering`, and `strong_ordering` are collectively termed the comparison category types. Each is specified in terms of an exposition-only data member named `value` whose value typically corresponds to that of an enumerator from one of the following exposition-only enumerations:

```cpp
enum class eq { equal = 0, equivalent = equal,
    nonequal = 1, nonequivalent = nonequal }; // exposition only
enum class ord { less = -1, greater = 1 };       // exposition only
enum class ncmp { unordered = -127 };          // exposition only
```

[Note: The types `strong_ordering` and `weak_equality` correspond, respectively, to the terms total ordering and equivalence in mathematics. — end note]

The relational and equality operators for the comparison category types are specified with an anonymous parameter of unspecified type. This type shall be selected by the implementation such that these parameters can accept literal 0 as a corresponding argument. [Example: `nullptr_t` meets this requirement. — end example] In this context, the behavior of a program that supplies an argument other than a literal 0 is undefined.

For the purposes of this subclause, substitutability is the property that \( f(a) == f(b) \) is true whenever \( a == b \) is true, where \( f \) denotes a function that reads only comparison-salient state that is accessible via the argument’s public const members.

17.11.2.2 Class `weak_equality`

The `weak_equality` type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits only equality and inequality comparisons, and (b) does not imply substitutability.

```cpp
namespace std {
    class weak_equality {
        int value; // exposition only

        // exposition-only constructor
        constexpr explicit weak_equality(eq v) noexcept : value(int(v)) {} // exposition only

    public:
        // valid values
        static const weak_equality equivalent;
        static const weak_equality nonequivalent;

        // comparisons
        friend constexpr bool operator==(weak_equality v, unspecified) noexcept;
        friend constexpr bool operator!=(weak_equality v, unspecified) noexcept;
        friend constexpr bool operator==(unspecified, weak_equality v) noexcept;
        friend constexpr bool operator!=(unspecified, weak_equality v) noexcept;
        friend constexpr weak_equality operator<=>(weak_equality v, unspecified) noexcept;
        friend constexpr weak_equality operator<=>(unspecified, weak_equality v) noexcept;
    }

    // valid values' definitions
    inline constexpr weak_equality weak_equality::equivalent(eq::equivalent);
    inline constexpr weak_equality weak_equality::nonequivalent(eq::nonequivalent);
}
```

```cpp
// Returns: v.value == 0.
constexpr bool operator==(weak_equality v, unspecified) noexcept;
constexpr bool operator==(unspecified, weak_equality v) noexcept;

// Returns: v.value != 0.
constexpr bool operator!=(weak_equality v, unspecified) noexcept;
constexpr bool operator!=(unspecified, weak_equality v) noexcept;
```
constexpr weak_equality operator<=>(weak_equality v, unspecified) noexcept;  
constexpr weak_equality operator<=>(unspecified, weak_equality v) noexcept;  

Returns: v.

17.11.2.3 Class strong_equality

The strong_equality type is typically used as the result type of a three-way comparison operator (7.6.8) 
that (a) admits only equality and inequality comparisons, and (b) does imply substitutability.

namespace std {
    class strong_equality {
        int value;  // exposition only
    
    // exposition-only constructor
    constexpr explicit strong_equality(eq v) noexcept : value(int(v)) {}  // exposition only

    public:
    // valid values
    static const strong_equality equal;
    static const strong_equality nonequal;
    static const strong_equality equivalent;
    static const strong_equality nonequivalent;

    // conversion
    constexpr operator weak_equality() const noexcept;

    // comparisons
    friend constexpr bool operator==(strong_equality v, unspecified) noexcept;
    friend constexpr bool operator!=(strong_equality v, unspecified) noexcept;
    friend constexpr bool operator==(unspecified, strong_equality v) noexcept;
    friend constexpr bool operator!=(unspecified, strong_equality v) noexcept;
    friend constexpr strong_equality operator<=>(strong_equality v, unspecified) noexcept;
    friend constexpr strong_equality operator<=>(unspecified, strong_equality v) noexcept;
};

// valid values' definitions
inline constexpr strong_equality strong_equality::equal(eq::equal);
inline constexpr strong_equality strong_equality::nonequal(eq::nonequal);
inline constexpr strong_equality strong_equality::equivalent(eq::equivalent);
inline constexpr strong_equality strong_equality::nonequivalent(eq::nonequivalent);
}

constexpr operator weak_equality() const noexcept;

Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent.

constexpr bool operator==(strong_equality v, unspecified) noexcept;
constexpr bool operator==(unspecified, strong_equality v) noexcept;

Returns: v.value == 0.

constexpr bool operator!=(strong_equality v, unspecified) noexcept;
constexpr bool operator!=(unspecified, strong_equality v) noexcept;

Returns: v.value != 0.

constexpr strong_equality operator<=>(strong_equality v, unspecified) noexcept;
constexpr strong_equality operator<=>(unspecified, strong_equality v) noexcept;

Returns: v.

17.11.2.4 Class partial_ordering

The partial_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) 
that (a) admits all of the six two-way comparison operators (7.6.9, 7.6.10), (b) does not imply substitutability, 
and (c) permits two values to be incomparable.219

---

219) That is, a < b, a == b, and a > b might all be false.
namespace std {

class partial_ordering {
    int value; // exposition only
    bool is_ordered; // exposition only

    // exposition-only constructors
    constexpr explicit partial_ordering(eq v) noexcept : value(int(v)), is_ordered(true) {} // exposition only
    constexpr explicit partial_ordering(ord v) noexcept : value(int(v)), is_ordered(true) {} // exposition only
    constexpr explicit partial_ordering(ncmp v) noexcept : value(int(v)), is_ordered(false) {} // exposition only

public:
    // valid values
    static const partial_ordering less;
    static const partial_ordering equivalent;
    static const partial_ordering greater;
    static const partial_ordering unordered;
    // conversion
    constexpr operator weak_equality() const noexcept;
    // comparisons
    friend constexpr bool operator==(partial_ordering v, unspecified) noexcept;
    friend constexpr bool operator!=(partial_ordering v, unspecified) noexcept;
    friend constexpr bool operator<(partial_ordering v, unspecified) noexcept;
    friend constexpr bool operator<=(partial_ordering v, unspecified) noexcept;
    friend constexpr bool operator>(partial_ordering v, unspecified) noexcept;
    friend constexpr bool operator>=(partial_ordering v, unspecified) noexcept;
    friend constexpr bool operator==(unspecified, partial_ordering v) noexcept;
    friend constexpr bool operator!=(unspecified, partial_ordering v) noexcept;
    friend constexpr bool operator<(unspecified, partial_ordering v) noexcept;
    friend constexpr bool operator<=(unspecified, partial_ordering v) noexcept;
    friend constexpr bool operator>(unspecified, partial_ordering v) noexcept;
    friend constexpr bool operator>=(unspecified, partial_ordering v) noexcept;

    // valid values' definitions
    inline constexpr partial_ordering partial_ordering::less(ord::less);
    inline constexpr partial_ordering partial_ordering::equivalent(eq::equivalent);
    inline constexpr partial_ordering partial_ordering::greater(ord::greater);
    inline constexpr partial_ordering partial_ordering::unordered(ncmp::unordered);
};

constexpr operator weak_equality() const noexcept;

2 Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent. [Note: The result is independent of the is_ordered member. —end note]

constexpr bool operator==(partial_ordering v, unspecified) noexcept;
constexpr bool operator<(partial_ordering v, unspecified) noexcept;
constexpr bool operator<=(partial_ordering v, unspecified) noexcept;
constexpr bool operator>(partial_ordering v, unspecified) noexcept;
constexpr bool operator>=(partial_ordering v, unspecified) noexcept;

3 Returns: For operator@, v.is_ordered && v.value @ 0.

constexpr bool operator==(unspecified, partial_ordering v) noexcept;
constexpr bool operator<(unspecified, partial_ordering v) noexcept;
constexpr bool operator<=(unspecified, partial_ordering v) noexcept;
constexpr bool operator>(unspecified, partial_ordering v) noexcept;
constexpr bool operator>=(unspecified, partial_ordering v) noexcept;

§ 17.11.2.4 506
constexpr bool operator>=(unspecified, partial_ordering v) noexcept;

Returns: For operator@, v.is_ordered & & 0 < v.value.

constexpr bool operator!=(partial_ordering v, unspecified) noexcept;
constexpr bool operator!=(unspecified, partial_ordering v) noexcept;

Returns: For operator@, !v.is_ordered || v.value != 0.

constexpr partial_ordering operator<= (partial_ordering v, unspecified) noexcept;

Returns: v.

constexpr partial_ordering operator <= (unspecified, partial_ordering v) noexcept;

Returns: v < 0 ? partial_ordering::greater : v > 0 ? partial_ordering::less : v.

17.11.2.5 Class weak_ordering
[cmp.weakord]
The weak_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits all of the six two-way comparison operators (7.6.9, 7.6.10), and (b) does not imply substitutability.

namespace std {
    class weak_ordering {
        int value; // exposition only

        // exposition-only constructors
        constexpr explicit weak_ordering(eq v) noexcept : value(int(v)) {} // exposition only
        constexpr explicit weak_ordering(ord v) noexcept : value(int(v)) {} // exposition only

        public:
            // valid values
            static const weak_ordering less;
            static const weak_ordering equivalent;
            static const weak_ordering greater;

            // conversions
            constexpr operator weak_equality() const noexcept;
            constexpr operator partial_ordering() const noexcept;

            // comparisons
            friend constexpr bool operator==(weak_ordering v, unspecified) noexcept;
            friend constexpr bool operator!=(weak_ordering v, unspecified) noexcept;
            friend constexpr bool operator<(weak_ordering v, unspecified) noexcept;
            friend constexpr bool operator>(weak_ordering v, unspecified) noexcept;
            friend constexpr bool operator<=(weak_ordering v, unspecified) noexcept;
            friend constexpr bool operator>=(weak_ordering v, unspecified) noexcept;
            friend constexpr weak_ordering operator<=>(weak_ordering v, unspecified) noexcept;
            friend constexpr weak_ordering operator<=>(unspecified, weak_ordering v) noexcept;

        };

        // valid values' definitions
        inline constexpr weak_ordering weak_ordering::less(ord::less);
        inline constexpr weak_ordering weak_ordering::equivalent(eq::equivalent);
        inline constexpr weak_ordering weak_ordering::greater(ord::greater);
    }

constexpr operator weak_equality() const noexcept;

constexpr operator partial_ordering() const noexcept;

Returns:
value == 0 ? partial_ordering::equivalent :
value < 0 ? partial_ordering::less :
(partial_ordering::greater

constexpr bool operator==(weak_ordering v, unspecified) noexcept;
constexpr bool operator!=(weak_ordering v, unspecified) noexcept;
constexpr bool operator< (weak_ordering v, unspecified) noexcept;
constexpr bool operator> (weak_ordering v, unspecified) noexcept;
constexpr bool operator<=(weak_ordering v, unspecified) noexcept;
constexpr bool operator>=(weak_ordering v, unspecified) noexcept;

Returns: v.value @ 0 for operator@.

constexpr weak_ordering operator<=>(weak_ordering v, unspecified) noexcept;

Returns: v.< 0 ? weak_ordering::greater : v > 0 ? weak_ordering::less : v.

17.11.2.6 Class strong_ordering

The strong_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits all of the six two-way comparison operators (7.6.9, 7.6.10), and (b) does imply substitutability.

namespace std {
    class strong_ordering {
        int value; // exposition only

        // exposition-only constructors
        constexpr explicit strong_ordering(eq v) noexcept : value(int(v)) {} // exposition only
        constexpr explicit strong_ordering(ord v) noexcept : value(int(v)) {} // exposition only

    public:
        // valid values
        static const strong_ordering less;
        static const strong_ordering equal;
        static const strong_ordering equivalent;
        static const strong_ordering greater;

        // conversions
        constexpr operator weak_equality() const noexcept;
        constexpr operator strong_equality() const noexcept;
        constexpr operator partial_ordering() const noexcept;
        constexpr operator weak_ordering() const noexcept;

        // comparisons
        friend constexpr bool operator==(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator!=(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator<(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator>(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator<=(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator>=(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator==(unspecified, strong_ordering v) noexcept;
        friend constexpr bool operator!=(unspecified, strong_ordering v) noexcept;

    } // class
} // namespace std
friend constexpr bool operator< (unspecified, strong_ordering v) noexcept;
friend constexpr bool operator> (unspecified, strong_ordering v) noexcept;
friend constexpr bool operator<=(unspecified, strong_ordering v) noexcept;
friend constexpr bool operator>=(unspecified, strong_ordering v) noexcept;
friend constexpr strong_ordering operator<=>(strong_ordering v, unspecified) noexcept;
friend constexpr strong_ordering operator<=>(unspecified, strong_ordering v) noexcept;
};

// valid values' definitions
inline constexpr strong_ordering strong_ordering::less(ord::less);
inline constexpr strong_ordering strong_ordering::equal(eq::equal);
inline constexpr strong_ordering strong_ordering::equivalent(eq::equivalent);
inline constexpr strong_ordering strong_ordering::greater(ord::greater);

constexpr operator weak_equality() const noexcept;
Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent.

constexpr operator strong_equality() const noexcept;
Returns: value == 0 ? strong_equality::equal : strong_equality::nonequal.

constexpr operator partial_ordering() const noexcept;
Returns:
value == 0 ? partial_ordering::equivalent :
value < 0 ? partial_ordering::less :
partial_ordering::greater

constexpr operator weak_ordering() const noexcept;
Returns:
value == 0 ? weak_ordering::equivalent :
value < 0 ? weak_ordering::less :
weak_ordering::greater

operator==(strong_ordering v, unspecified) noexcept;
operator!=(strong_ordering v, unspecified) noexcept;
operator< (strong_ordering v, unspecified) noexcept;
operator> (strong_ordering v, unspecified) noexcept;
operator<=(strong_ordering v, unspecified) noexcept;
operator>=(strong_ordering v, unspecified) noexcept;

Returns: v.value @ 0 for operator@.

operator==(unspecified, strong_ordering v) noexcept;
operator!=(unspecified, strong_ordering v) noexcept;
operator< (unspecified, strong_ordering v) noexcept;
operator> (unspecified, strong_ordering v) noexcept;
operator<=(unspecified, strong_ordering v) noexcept;
operator>=(unspecified, strong_ordering v) noexcept;

Returns: 0 @ v.value for operator@.

strong_ordering operator<=(strong_ordering v, unspecified) noexcept;
Returns: v.

strong_ordering operator<=(unspecified, strong_ordering v) noexcept;
Returns: v < 0 ? strong_ordering::greater : v > 0 ? strong_ordering::less : v.

17.11.3 Class template common_comparison_category [cmp.common]
The type common_comparison_category provides an alias for the strongest comparison
category to which all of the template arguments can be converted. [Note: A comparison
category type is stronger than another if they are distinct types and an instance of the
former can be converted to an instance of the latter. — end note]
template<class... Ts>
struct common_comparison_category {
    using type = see below;
};

Remarks: The member typedef-name type denotes the common comparison type (11.10.3) of Ts..., the expanded parameter pack. [Note: This is well-defined even if the expansion is empty or includes a type that is not a comparison category type. — end note]

17.11.4 Comparison algorithms

template<class T> constexpr strong_ordering strong_order(const T& a, const T& b);

Effects: Compares two values and produces a result of type strong_ordering:

(1.1) If numeric_limits<T>::is_iec559 is true, returns a result of type strong_ordering that is consistent with the totalOrder operation as specified in ISO/IEC/IEEE 60559.

(1.2) Otherwise, returns a <=> b if that expression is well-formed and convertible to strong_ordering.

(1.3) Otherwise, if the expression a <=> b is well-formed, then the function is defined as deleted.

(1.4) Otherwise, if the expressions a == b and a < b are each well-formed and convertible to bool, then

(1.4.1) if a == b is true, returns strong_ordering::equal;

(1.4.2) otherwise, if a < b is true, returns strong_ordering::less;

(1.4.3) otherwise, returns strong_ordering::greater.

(1.5) Otherwise, the function is defined as deleted.

template<class T> constexpr weak_ordering weak_order(const T& a, const T& b);

Effects: Compares two values and produces a result of type weak_ordering:

(2.1) Returns a <=> b if that expression is well-formed and convertible to weak_ordering.

(2.2) Otherwise, if the expression a <=> b is well-formed, then the function is defined as deleted.

(2.3) Otherwise, if the expressions a == b and a < b are each well-formed and convertible to bool, then

(2.3.1) if a == b is true, returns weak_ordering::equivalent;

(2.3.2) otherwise, if a < b is true, returns weak_ordering::less;

(2.3.3) otherwise, returns weak_ordering::greater.

(2.4) Otherwise, the function is defined as deleted.

template<class T> constexpr partial_ordering partial_order(const T& a, const T& b);

Effects: Compares two values and produces a result of type partial_ordering:

(3.1) Returns a <=> b if that expression is well-formed and convertible to partial_ordering.

(3.2) Otherwise, if the expression a <=> b is well-formed, then the function is defined as deleted.

(3.3) Otherwise, if the expressions a == b and a < b are each well-formed and convertible to bool, then

(3.3.1) if a == b is true, returns partial_ordering::equivalent;

(3.3.2) otherwise, if a < b is true, returns partial_ordering::less;

(3.3.3) otherwise, returns partial_ordering::greater.

(3.4) Otherwise, the function is defined as deleted.

template<class T> constexpr strong_equality strong_equal(const T& a, const T& b);

Effects: Compares two values and produces a result of type strong_equality:

(4.1) Returns a <=> b if that expression is well-formed and convertible to strong_equality.

(4.2) Otherwise, if the expression a <=> b is well-formed, then the function is defined as deleted.
Otherwise, if the expression $a == b$ is well-formed and convertible to $bool$, then

- if $a == b$ is true, returns `strong_equality::equal`;
- otherwise, returns `strong_equality::nonequal`.

Otherwise, the function is defined as deleted.

```cpp
template<class T> constexpr weak_equality weak_equal(const T& a, const T& b);
```

**Effects:** Compares two values and produces a result of type `weak_equality`:

- Returns `a <=> b` if that expression is well-formed and convertible to `weak_equality`.
- Otherwise, if the expression `a <=> b` is well-formed, then the function is defined as deleted.
- Otherwise, if the expression `a == b` is well-formed and convertible to `bool`, then
  - if `a == b` is true, returns `weak_equality::equivalent`;
  - otherwise, returns `weak_equality::nonequivalent`.
- Otherwise, the function is defined as deleted.

17.12 Coroutines

The header `<coroutine>` defines several types providing compile and run-time support for coroutines in a C++ program.

17.12.1 Header `<coroutine>` synopsis

```cpp
namespace std {
  // 17.12.2, coroutine traits
  template<class R, class... ArgTypes>
  struct coroutine_traits;

  // 17.12.3, coroutine handle
  template<class Promise = void>
  struct coroutine_handle;

  // 17.12.3.6, comparison operators
  constexpr bool operator==(coroutine_handle<> x, coroutine_handle<> y) noexcept;
  constexpr bool operator!=(coroutine_handle<> x, coroutine_handle<> y) noexcept;
  constexpr bool operator<(coroutine_handle<> x, coroutine_handle<> y) noexcept;
  constexpr bool operator>(coroutine_handle<> x, coroutine_handle<> y) noexcept;
  constexpr bool operator<=(coroutine_handle<> x, coroutine_handle<> y) noexcept;
  constexpr bool operator>=(coroutine_handle<> x, coroutine_handle<> y) noexcept;

  // 17.12.3.7, hash support
  template<class T> struct hash;
  template<class P> struct hash<coroutine_handle<P>>;

  // 17.12.4, no-op coroutines
  struct noop_coroutine_promise;

  template<> struct coroutine_handle<noop_coroutine_promise>;
  using noop_coroutine_handle = coroutine_handle<noop_coroutine_promise>;

  noop_coroutine_handle noop_coroutine() noexcept;

  // 17.12.5, trivial awaitsables
  struct suspend_never;
  struct suspend_always;
}
```

17.12.2 Coroutine traits

This subclause defines requirements on classes representing coroutine traits, and defines the class template `coroutine_traits` that meets those requirements.
17.12.2.1 Class template coroutine_traits

The header `<coroutine>` defines the primary template `coroutine_traits` such that if `ArgTypes` is a parameter pack of types and if the qualified-id `R::promise_type` is valid and denotes a type (13.9.2), then `coroutine_traits<R,ArgTypes...>` has the following publicly accessible member:

```cpp
using promise_type = typename R::promise_type;
```

Otherwise, `coroutine_traits<R,ArgTypes...>` has no members.

Program-defined specializations of this template shall define a publicly accessible nested type named `promise_type`.

17.12.3 Class template coroutine_handle

namespace std {

    template<class Promise>
    struct coroutine_handle : coroutine_handle<> {
        // 17.12.3.1, construct/reset
        using coroutine_handle<>::coroutine_handle;
        static coroutine_handle from_promise(Promise&);
        coroutine_handle& operator=(nullptr_t) noexcept;
        // 17.12.3.2, export/import
        static constexpr coroutine_handle from_address(void* addr);
        // 17.12.3.5, promise access
        Promise& promise() const;
    };

    template<>
    struct coroutine_handle<void> {
        // 17.12.3.1, construct/reset
        constexpr coroutine_handle() noexcept;
        constexpr coroutine_handle(nullptr_t) noexcept;
        coroutine_handle& operator=(nullptr_t) noexcept;
        // 17.12.3.2, export/import
        constexpr void* address() const noexcept;
        static constexpr coroutine_handle from_address(void* addr);
        // 17.12.3.3, observers
        explicit operator bool() const noexcept;
        bool done() const;
        // 17.12.3.4, resumption
        void operator()() const;
        void resume() const;
        void destroy() const;
        private:
            void* ptr; // exposition only
    };

    template<>
    constexpr coroutine_handle() noexcept;
    constexpr coroutine_handle(nullptr_t) noexcept;
}

An object of type `coroutine_handle<T>` is called a coroutine handle and can be used to refer to a suspended or executing coroutine. A default-constructed `coroutine_handle` object does not refer to any coroutine.

If a program declares an explicit or partial specialization of `coroutine_handle`, the behavior is undefined.

17.12.3.1 Construct/reset

```cpp
constexpr coroutine_handle() noexcept;
constexpr coroutine_handle(nullptr_t) noexcept;
```

Ensures: `address() == nullptr`. 

§ 17.12.3.1
static coroutine_handle from_promise(Promise& p);

    Requires: p is a reference to a promise object of a coroutine.
    Returns: A coroutine handle h referring to the coroutine.
    Ensures: addressof(h.promise()) == addressof(p).

coroutine_handle& operator=(nullptr_t) noexcept;

    Ensures: address() == nullptr.
    Returns: *this.

17.12.3.2 Export/import

constexpr void* address() const noexcept;

    Returns: ptr.

static constexpr coroutine_handle<> coroutine_handle<>::from_address(void* addr);
static constexpr coroutine_handle<Promise> coroutine_handle<Promise>::from_address(void* addr);

    Requires: addr was obtained via a prior call to address.
    Ensures: from_address(address()) == *this.

17.12.3.3 Observers

constexpr explicit operator bool() const noexcept;

    Returns: address() != nullptr.

bool done() const;

    Requires: *this refers to a suspended coroutine.
    Returns: true if the coroutine is suspended at its final suspend point, otherwise false.

17.12.3.4 Resumption

void operator()() const;

    Requires: *this refers to a suspended coroutine.

void resume() const;

    Requires: *this refers to a suspended coroutine.
    Effects: Resumes the execution of the coroutine. If the coroutine was suspended at its final suspend point, behavior is undefined.

void destroy() const;

    Requires: *this refers to a suspended coroutine.
    Effects: Destroys the coroutine (9.4.4).

17.12.3.5 Promise access

Promise& promise() const;

    Requires: *this refers to a coroutine.
    Returns: A reference to the promise of the coroutine.

17.12.3.6 Comparison operators

constexpr bool operator==(coroutine_handle<> x, coroutine_handle<> y) noexcept;

    Returns: x.address() == y.address().

§ 17.12.3.6
constexpr bool operator<(coroutine_handle<> x, coroutine_handle<> y) noexcept;

Returns: less<>(x.address(), y.address()).

17.12.3.7 Hash support

template<class P> struct hash<coroutine_handle<P>>;

The specialization is enabled (20.14.18).

17.12.4 No-op coroutines

17.12.4.1 Class noop_coroutine_promise

struct noop_coroutine_promise {};

The class noop_coroutine_promise defines the promise type for the coroutine referred to by noop_coroutine_handle (17.12.1).

17.12.4.2 Class coroutine_handle<noop_coroutine_promise>

namespace std {

    template<>
    struct coroutine_handle<noop_coroutine_promise> : coroutine_handle<> {

        // 17.12.4.2.1, observers
        constexpr explicit operator bool() const noexcept;
        constexpr bool done() const noexcept;

        // 17.12.4.2.2, resumption
        constexpr void operator()() const noexcept;
        constexpr void resume() const noexcept;
        constexpr void destroy() const noexcept;

        // 17.12.4.2.3, promise access
        noop_coroutine_promise& promise() const noexcept;

        // 17.12.4.2.4, address
        constexpr void* address() const noexcept;
    private:
        coroutine_handle<unspecified>;
    };
}

17.12.4.2.1 Observers

constexpr explicit operator bool() const noexcept;

Returns: true.

constexpr bool done() const noexcept;

Returns: false.

17.12.4.2.2 Resumption

constexpr void operator()() const noexcept;
constexpr void resume() const noexcept;
constexpr void destroy() const noexcept;

Effects: None.

Remarks: If noop_coroutine_handle is converted to coroutine_handle<*>, calls to operator(), resume and destroy on that handle will also have no observable effects.

17.12.4.2.3 Promise access

noop_coroutine_promise& promise() const noexcept;

Returns: A reference to the promise object associated with this coroutine handle.
17.12.4.2.4 Address

constexpr void* address() const noexcept;

1

Returns: ptr.

2

Remarks: A noop_coroutine_handle’s ptr is always a non-null pointer value.

17.12.4.3 Function noop_coroutine

noop_coroutine_handle noop_coroutine() noexcept;

1

Returns: A handle to a coroutine that has no observable effects when resumed or destroyed.

2

Remarks: A handle returned from noop_coroutine may or may not compare equal to a handle returned from another invocation of noop_coroutine.

17.12.5 Trivial awaitsables

namespace std {

struct suspend_never {
    constexpr bool await_ready() const noexcept { return true; }
    constexpr void await_suspend(coroutine_handle<>) const noexcept {}  
    constexpr void await_resume() const noexcept {}  
};

struct suspend_always {
    constexpr bool await_ready() const noexcept { return false; }
    constexpr void await_suspend(coroutine_handle<>) const noexcept {}  
    constexpr void await_resume() const noexcept {}  
};

}  

[Note: The types suspend_never and suspend_always can be used to indicate that an await-expression should either never suspend or always suspend, and in either case not produce a value. — end note]

17.13 Other runtime support

1

Headers <csetjmp> (nonlocal jumps), <csignal> (signal handling), <cstdarg> (variable arguments), and <cstdlib> (runtime environment getenv, system), provide further compatibility with C code.

2

Calls to the function getenv (17.2.2) shall not introduce a data race (16.5.5.9) provided that nothing modifies the environment. [Note: Calls to the POSIX functions setenv and putenv modify the environment. — end note]

3

A call to the setlocale function (28.5) may introduce a data race with other calls to the setlocale function or with calls to functions that are affected by the current C locale. The implementation shall behave as if no library function other than locale::global calls the setlocale function.

17.13.1 Header <cstdarg> synopsis

namespace std {
    using va_list = see below;
}

#define va_arg(V, P) see below
#define va_copy(VDST, VSRC) see below
#define va_end(V) see below
#define va_start(V, P) see below

1

The contents of the header <cstdarg> are the same as the C standard library header <stdarg.h>, with the following changes: The restrictions that ISO C places on the second parameter to the va_start macro in header <stdarg.h> are different in this document. The parameter parmN is the rightmost parameter in the variable parameter list of the function definition (the one just before the ...). 220 If the parameter parmN is a pack expansion (13.6.3) or an entity resulting from a lambda capture (7.5.5), the program is ill-formed, no diagnostic required. If the parameter parmN is of a reference type, or of a type that is not compatible with the type that results when passing an argument for which there is no parameter, the behavior is undefined.

See also: ISO C 7.16.1.1

220) Note that va_start is required to work as specified even if unary operator& is overloaded for the type of parmN.

17.13.2 Header `<csetjmp>` synopsis

namespace std {
    using jmp_buf = see below;
    // [noreturn] void longjmp(jmp_buf env, int val);
}

#define setjmp(env) see below

The contents of the header `<csetjmp>` are the same as the C standard library header `<setjmp.h>`.

1 The function signature `longjmp(jmp_buf jbuf, int val)` has more restricted behavior in this document. A `setjmp/longjmp` call pair has undefined behavior if replacing the `setjmp` and `longjmp` by `catch` and `throw` would invoke any non-trivial destructors for any automatic objects. A call to `setjmp` or `longjmp` has undefined behavior if invoked in a suspension context of a coroutine (7.6.2.3).

See also: ISO C 7.13

17.13.3 Header `<csignal>` synopsis

namespace std {
    using sig_atomic_t = see below;

    // 17.13.4, signal handlers
    extern "C" using signal-handler = void(int); // exposition only
    signal-handler* signal(int sig, signal-handler* func);
    int raise(int sig);
}

#define SIG_DFL see below
#define SIG_ERR see below
#define SIG_IGN see below
#define SIGABRT see below
#define SIGFPE see below
#define SIGILL see below
#define SIGINT see below
#define SIGSEGV see below
#define SIGTERM see below

The contents of the header `<csignal>` are the same as the C standard library header `<signal.h>`.

17.13.4 Signal handlers

A call to the function `signal` synchronizes with any resulting invocation of the signal handler so installed.

2 A plain lock-free atomic operation is an invocation of a function `f` from Clause 31, such that:

(2.1) — `f` is the function `atomic_is_lock_free()`, or
(2.2) — `f` is the member function `is_lock_free()`, or
(2.3) — `f` is a non-static member function invoked on an object `A`, such that `A.is_lock_free()` yields `true`, or
(2.4) — `f` is a non-member function, and for every pointer-to-atomic argument `A` passed to `f`, `atomic_is_lock_free(A)` yields `true`.

3 An evaluation is signal-safe unless it includes one of the following:

(3.1) — a call to any standard library function, except for plain lock-free atomic operations and functions explicitly identified as signal-safe. [Note: This implicitly excludes the use of `new` and `delete` expressions that rely on a library-provided memory allocator. — end note]

(3.2) — an access to an object with thread storage duration;
(3.3) — a `dynamic_cast` expression;
(3.4) — throwing of an exception;
(3.5) — control entering a `try-block` or `function-try-block`;

§ 17.13.4
initialization of a variable with static storage duration requiring dynamic initialization (6.8.3.3, 8.7)

Waiting for the completion of the initialization of a variable with static storage duration (8.7).

A signal handler invocation has undefined behavior if it includes an evaluation that is not signal-safe.

The function `signal` is signal-safe if it is invoked with the first argument equal to the signal number corresponding to the signal that caused the invocation of the handler.

See also: ISO C 7.14

---

221) Such initialization might occur because it is the first odr-use (6.2) of that variable.
18 Concepts library [concepts]

18.1 General [concepts.general]
1 This Clause describes library components that C++ programs may use to perform compile-time validation of template arguments and perform function dispatch based on properties of types. The purpose of these concepts is to establish a foundation for equational reasoning in programs.

2 The following subclauses describe language-related concepts, comparison concepts, object concepts, and callable concepts as summarized in Table 37.

Table 37: Fundamental concepts library summary [tab:concepts.summary]

<table>
<thead>
<tr>
<th>Subclause</th>

</tr>
<tr>
<td>18.7</td>
<td>Callable concepts</td>
</tr>
</tbody>
</table>

18.2 Equality preservation [concepts.equality]
1 An expression is **equality-preserving** if, given equal inputs, the expression results in equal outputs. The inputs to an expression are the set of the expression’s operands. The output of an expression is the expression’s result and all operands modified by the expression.

2 Not all input values need be valid for a given expression; e.g., for integers \( a \) and \( b \), the expression \( a / b \) is not well-defined when \( b = 0 \). This does not preclude the expression \( a / b \) being equality-preserving. The **domain** of an expression is the set of input values for which the expression is required to be well-defined.

3 Expressions required by this document to be equality-preserving are further required to be **stable**: two evaluations of such an expression with the same input objects are required to have equal outputs absent any explicit intervening modification of those input objects. [Note: This requirement allows generic code to reason about the current values of objects based on knowledge of the prior values as observed via equality-preserving expressions. It effectively forbids spontaneous changes to an object, changes to an object from another thread of execution, changes to an object as side effects of non-modifying expressions, and changes to an object as side effects of modifying a distinct object if those changes could be observable to a library function via an equality-preserving expression that is required to be valid for that object. —end note]

4 Expressions declared in a **requires-expression** in this document are required to be equality-preserving, except for those annotated with the comment “not required to be equality-preserving.” An expression so annotated may be equality-preserving, but is not required to be so.

5 An expression that may alter the value of one or more of its inputs in a manner observable to equality-preserving expressions is said to modify those inputs. This document uses a notational convention to specify which expressions declared in a **requires-expression** modify which inputs: except where otherwise specified, an expression operand that is a non-constant lvalue or rvalue may be modified. Operands that are constant lvalues or rvalues are required to not be modified.

6 Where a **requires-expression** declares an expression that is non-modifying for some constant lvalue operand, additional variations of that expression that accept a non-constant lvalue or (possibly constant) rvalue for the given operand are also required except where such an expression variation is explicitly required with differing semantics. These **implicit expression variations** are required to meet the semantic requirements of the declared expression. The extent to which an implementation validates the syntax of the variations is unspecified.

7 [Example:]

```cpp
    template<class T> concept C = requires(T a, T b, const T c, const T d) {
        c == d; // #1
        a = std::move(b); // #2
    }
```
a = c;       // #3
);

For the above example:

(7.1) — Expression #1 does not modify either of its operands, #2 modifies both of its operands, and #3 modifies only its first operand a.

(7.2) — Expression #1 implicitly requires additional expression variations that meet the requirements for c == d (including non-modification), as if the expressions

\[
c == std::move(d); \quad c == std::move(b);
\]

\[
std::move(c) == d; \quad std::move(c) == b;
\]

\[
std::move(c) == std::move(d); \quad std::move(c) == std::move(b);
\]

\[
a == d; \quad a == b;
\]

\[
std::move(a) == d; \quad std::move(a) == b;
\]

\[
std::move(a) == std::move(d); \quad std::move(a) == std::move(b);
\]

had been declared as well.

(7.3) — Expression #3 implicitly requires additional expression variations that meet the requirements for a = c (including non-modification of the second operand), as if the expressions a = b and a = std::move(c) had been declared. Expression #3 does not implicitly require an expression variation with a non-constant rvalue second operand, since expression #2 already specifies exactly such an expression explicitly.

—end example

8 [Example: The following type T meets the explicitly stated syntactic requirements of concept C above but does not meet the additional implicit requirements:

```cpp
struct T {
    bool operator==(const T& ) const { return true; }
    bool operator==(T& ) = delete;
};
```

T fails to meet the implicit requirements of C, so T satisfies but does not model C. Since implementations are not required to validate the syntax of implicit requirements, it is unspecified whether an implementation diagnoses as ill-formed a program that requires C<T>. —end example]

18.3 Header <concepts> synopsis

```cpp
namespace std {
    // 18.4, language-related concepts
    // 18.4.2, concept Same
    template<class T, class U>
    concept Same = see below;

    // 18.4.3, concept DerivedFrom
    template<class Derived, class Base>
    concept DerivedFrom = see below;

    // 18.4.4, concept ConvertibleTo
    template<class From, class To>

    // 18.7.2, concept Invocable
    template<class F, class... Args>
        concept Invocable = see below;

    // 18.7.3, concept RegularInvocable
    template<class F, class... Args>
        concept RegularInvocable = see below;

    // 18.7.4, concept Predicate
    template<class F, class... Args>
        concept Predicate = see below;

    // 18.7.5, concept Relation
    template<class R, class T, class U>
        concept Relation = see below;

    // 18.7.6, concept StrictWeakOrder
    template<class R, class T, class U>
        concept StrictWeakOrder = see below;
}

18.4 Language-related concepts

18.4.1 General

This subclause contains the definition of concepts corresponding to language features. These concepts express
to relationships between types, type classifications, and fundamental type properties.

18.4.2 Concept Same

template<class T, class U>
    concept Same = same-impl<T, U> && same-impl<U, T>;

(Note: Same<T, U> subsumes Same<U, T> and vice versa. — end note)

18.4.3 Concept DerivedFrom

template<class Derived, class Base>
    concept DerivedFrom =
        is_base_of_v<Base, Derived> &&
        is_convertible_v<Derived*, const volatile Base*>;

(Note: DerivedFrom<Derived, Base> is satisfied if and only if Derived is publicly and unambiguously
derived from Base, or Derived and Base are the same class type ignoring cv-qualifiers. — end note)

18.4.4 Concept ConvertibleTo

The ConvertibleTo concept requires an expression of a particular type and value category to be both
implicitly and explicitly convertible to some other type. The implicit and explicit conversions are required to
produce equal results.

template<class From, class To>
    concept ConvertibleTo =
        is_convertible_v<From, To> &&
        requires(From (f())) {
            static_cast<To>(f());
        };

Let test be the invented function:
To test(From (kf)()) {
    return f();
}

for some types From and To, and let f be a function with no arguments and return type From such that f() is equality-preserving. From and To model ConvertibleTo<From, To> only if:

(2.1) To is not an object or reference-to-object type, or static_cast<To>(f()) is equal to test(f).

(2.2) From is not a reference-to-object type, or

(2.2.1) If From is an rvalue reference to a non const-qualified type, the resulting state of the object referenced by f() after either above expression is valid but unspecified (16.5.5.15).

(2.2.2) Otherwise, the object referred to by f() is not modified by either above expression.

18.4.5 Concept CommonReference

For two types T and U, if common_reference_t<T, U> is well-formed and denotes a type C such that both ConvertibleTo<T, C> and ConvertibleTo<U, C> are modeled, then T and U share a common reference type, C. [Note: C could be the same as T, or U, or it could be a different type. C may be a reference type. —end note]

template<class T, class U>
concept CommonReference =
    Same<common_reference_t<T, U>, common_reference_t<U, T>> &&
    ConvertibleToT, common_reference_t<T, U>>, ConvertibleToU, common_reference_t<T, U>>;

Let C be common_reference_t<T, U>. Let t1 and t2 be equality-preserving expressions (18.2) such that decltype((t1)) and decltype((t2)) are each T, and let u1 and u2 be equality-preserving expressions such that decltype((u1)) and decltype((u2)) are each U. T and U model CommonReference<T, U> only if:

(2.1) C(t1) equals C(t2) if and only if t1 equals t2, and

(2.2) C(u1) equals C(u2) if and only if u1 equals u2.

[Note: Users can customize the behavior of CommonReference by specializing the basic_common_reference class template (20.15.7.6). —end note]

18.4.6 Concept Common

If T and U can both be explicitly converted to some third type, C, then T and U share a common type, C. [Note: C could be the same as T, or U, or it could be a different type. C might not be unique. —end note]

template<class T, class U>
concept Common =
    Same<common_type_t<T, U>, common_type_t<U, T>> &&
    requires {
        static_cast<common_type_t<T, U>>(declval<T>());
        static_cast<common_type_t<T, U>>(declval<U>());
    } &&
    CommonReference<
        add_lvalue_reference_t<const T>,
        add_lvalue_reference_t<const U> &&
        CommonReference<
            add_lvalue_reference_t<const common_type_t<T, U>>,
            common_type_t<T>,
            add_lvalue_reference_t<const U>>,
            add_lvalue_reference_t<const U>>;

Let C be common_type_t<T, U>. Let t1 and t2 be equality-preserving expressions (18.2) such that decltype((t1)) and decltype((t2)) are each T, and let u1 and u2 be equality-preserving expressions such that decltype((u1)) and decltype((u2)) are each U. T and U model Common<T, U> only if:

(2.1) C(t1) equals C(t2) if and only if t1 equals t2, and

(2.2) C(u1) equals C(u2) if and only if u1 equals u2.
3  [Note: Users can customize the behavior of Common by specializing the common_type class template (20.15.7.6). — end note]

18.4.7 Integral concepts  [concepts.integral]

```cpp
template<class T>
concept Integral = is_integral_v<T>;
template<class T>
concept SignedIntegral = Integral<T> && is_signed_v<T>;
template<class T>
concept UnsignedIntegral = Integral<T> && !SignedIntegral<T>;
```

1  [Note: SignedIntegral can be modeled even by types that are not signed integral types (6.7.1); for example, char. — end note]

2  [Note: UnsignedIntegral can be modeled even by types that are not unsigned integral types (6.7.1); for example, bool. — end note]

18.4.8 Concept Assignable  [concept.assignable]

```cpp
template<class LHS, class RHS>
concept Assignable =
    is_lvalue_reference_v<LHS> &&
    CommonReference<const remove_reference_t<LHS>&, const remove_reference_t<RHS>&> &&
    requires(LHS lhs, RHS&& rhs) {
        lhs = std::forward<RHS>(rhs) } -> Same<LHS>;
```

1  Let:

1.1  lhs be an lvalue that refers to an object lcopy such that decltype((lhs)) is LHS,

1.2  rhs be an expression such that decltype((rhs)) is RHS, and

1.3  rcopy be a distinct object that is equal to rhs.

2  LHS and RHS model Assignable<LHS, RHS> only if

1.4  addressof(lhs = rhs) == addressof(lcopy).

1.5  After evaluating lhs = rhs:

1.5.1  lhs is equal to rcopy, unless rhs is a non-const xvalue that refers to lcopy.

1.5.2  If rhs is a non-const xvalue, the resulting state of the object to which it refers is valid but unspecified (16.5.5.15).

1.5.3  Otherwise, if rhs is a glvalue, the object to which it refers is not modified.

2  [Note: Assignment need not be a total function (16.4.1.3); in particular, if assignment to an object x can result in a modification of some other object y, then x = y is likely not in the domain of =. — end note]

18.4.9 Concept Swappable  [concept.swappable]

1  Let t1 and t2 be equality-preserving expressions that denote distinct equal objects of type T, and let u1 and u2 similarly denote distinct equal objects of type U. [Note: t1 and u1 can denote distinct objects, or the same object. — end note] An operation exchanges the values denoted by t1 and u1 if and only if the operation modifies neither t2 nor u2 and:

1.1  If T and U are the same type, the result of the operation is that t1 equals u2 and u1 equals t2.

1.2  If T and U are different types that model CommonReference<const Tk, const Uk>, the result of the operation is that C(t1) equals C(u2) and C(u1) equals C(t2) where C is common_reference_t<const Tk, const Uk>.

2  The name ranges::swap denotes a customization point object (16.4.2.2.6). The expression ranges::swap(E1, E2) for some subexpressions E1 and E2 is expression-equivalent to an expression S determined as follows:

2.1  S is (void)swap(E1, E2) if E1 or E2 has class or enumeration type (6.7.2) and that expression is valid, with overload resolution performed in a context that includes the declaration

---

222) The name swap is used here unqualified.
and does not include a declaration of ranges::swap. If the function selected by overload resolution does not exchange the values denoted by E1 and E2, the program is ill-formed with no diagnostic required.

(2.2) — Otherwise, if E1 and E2 are lvalues of array types (6.7.2) with equal extent and ranges::swap(*E1, *E2) is a valid expression, S is (void)ranges::swap_ranges(E1, E2), except that noexcept(S) is equal to noexcept(ranges::swap(*E1, *E2)).

(2.3) — Otherwise, if E1 and E2 are lvalues of the same type T that models MoveConstructible<T> and Assignable<T&>, T, S is an expression that exchanges the denoted values. S is a constant expression if

(2.3.1) — T is a literal type (6.7),
(2.3.2) — both E1 = std::move(E2) and E2 = std::move(E1) are constant subexpressions (16.3.6), and
(2.3.3) — the full-expressions of the initializers in the declarations

        T t1(std::move(E1));
        T t2(std::move(E2));

are constant subexpressions.

        noexcept(S) is equal to is_nothrow_move_constructible_v<T> && is_nothrow_move_assignable_v<T>.

(2.4) — Otherwise, ranges::swap(E1, E2) is ill-formed. [Note: This case can result in substitution failure when ranges::swap(E1, E2) appears in the immediate context of a template instantiation. — end note]

3 [Note: Whenever ranges::swap(E1, E2) is a valid expression, it exchanges the values denoted by E1 and E2 and has type void. — end note]

template<class T>
void swap(T& t1, T& t2) = delete;

template<class T>
void swap(T& t1, T& t2) { ranges::swap(t1, t2); }

4 [Note: The semantics of the Swappable and SwappableWith concepts are fully defined by the ranges::swap customization point. — end note]

[Example: User code can ensure that the evaluation of swap calls is performed in an appropriate context under the various conditions as follows:

#include <cassert>
#include <concepts>
#include <utility>

namespace ranges = std::ranges;

template<class T, std::SwappableWith<T> U>
void value_swap(T&& t, U&& u) {
    ranges::swap(std::forward<T>(t), std::forward<U>(u));
}

template<std::Swappable T>
void lv_swap(T& t1, T& t2) {
    ranges::swap(t1, t2);
}
namespace N {
    struct A { int m; }
    struct Proxy { A* a; }
    Proxy proxy(A& a) { return Proxy{ &a }; }

    void swap(A& x, Proxy p) {
        ranges::swap(x.m, p.a->m);
    }
    void swap(Proxy p, A& x) { swap(x, p); // satisfy symmetry requirement }

    void swap(Proxy p, A& x) { swap(x, p); // satisfy symmetry requirement }

    int main() {
        int i = 1, j = 2;
        lv_swap(i, j);
        assert(i == 2 && j == 1);
        N::A a1 = { 5 }, a2 = { -5 };
        value_swap(a1, proxy(a2));
        assert(a1.m == -5 && a2.m == 5);
    }
}

18.4.10 Concept Destructible

The Destructible concept specifies properties of all types, instances of which can be destroyed at the end of their lifetime, or reference types.

\[ \text{template<class T> concept Destructible = is_nothrow_destructible_v<T>;} \]

[Note: Unlike the Cpp17Destructible requirements (Table 30), this concept forbids destructors that are potentially throwing, even if a particular invocation of the destructor does not actually throw. — end note]

18.4.11 Concept Constructible

The Constructible concept constrains the initialization of a variable of a given type with a particular set of argument types.

\[ \text{template<class T, class... Args> concept Constructible = Destructible<T> && is_constructible_v<T, Args...>;} \]

18.4.12 Concept DefaultConstructible

\[ \text{template<class T> concept DefaultConstructible = Constructible<T>;} \]

18.4.13 Concept MoveConstructible

\[ \text{template<class T> concept MoveConstructible = Constructible<T, T> && ConvertibleTo<T, T>;} \]

18.4.14 Concept CopyConstructible

\[ \text{template<class T> concept CopyConstructible = MoveConstructible<T> && Constructible<T, const T&> && ConvertibleTo<T, const T&>;} \]
Constructible<T, const T> && ConvertibleTo<const T, T>;

If T is an object type, then let v be an lvalue of type (possibly const) T or an rvalue of type const T. T models CopyConstructible only if

1. After the definition T u = v;, u is equal to v.
2. T(v) is equal to v.

18.5 Comparison concepts

18.5.1 General

This subclause describes concepts that establish relationships and orderings on values of possibly differing object types.

18.5.2 Concept Boolean

The Boolean concept specifies the requirements on a type that is usable in Boolean contexts.

template<class B>
concept Boolean = Movable<remove_cvref_t<B>> && // (see 18.6)
requires(const remove_reference_t<B>& b1,
          const remove_reference_t<B>& b2, const bool a) {
    { b1 } -> ConvertibleTo<bool>;
    { !b1 } -> ConvertibleTo<bool>;
    { b1 && a } -> Same<bool>;
    { b1 || a } -> Same<bool>;
    { b1 && b2 } -> Same<bool>;
    { a && b2 } -> Same<bool>;
    { b1 || b2 } -> Same<bool>;
    { a || b2 } -> Same<bool>;
    { b1 == b2 } -> ConvertibleTo<bool>;
    { b1 == a } -> ConvertibleTo<bool>;
    { a == b2 } -> ConvertibleTo<bool>;
    { b1 != b2 } -> ConvertibleTo<bool>;
    { a != b2 } -> ConvertibleTo<bool>;
};

For some type B, let b1 and b2 be values of type const remove_reference_t<B>. B models Boolean only if

1. bool(b1) == !bool(!b1).
2. (b1 && b2), (b1 && bool(b2)), and (bool(b1) && b2) are all equal to (bool(b1) && bool(b2)), and have the same short-circuit evaluation.
3. (b1 || b2), (b1 || bool(b2)), and (bool(b1) || b2) are all equal to (bool(b1) || bool(b2)), and have the same short-circuit evaluation.
4. bool(b1 == b2), bool(b1 == bool(b2)), and bool(bool(b1) == b2) are all equal to (bool(b1) == bool(b2)).
5. bool(b1 != b2), bool(b1 != bool(b2)), and bool(bool(b1) != b2) are all equal to (bool(b1) != bool(b2)).

[Example: The types bool, true_type (20.15.2), and bitset<N>::reference (20.9.2) are Boolean types. Pointers, smart pointers, and types with only explicit conversions to bool are not Boolean types. —end example]

18.5.3 Concept EqualityComparable

template<class T, class U>
concept weakly-equality-comparable-with = // exposition only
requires(const remove_reference_t<T>& t,
          const remove_reference_t<U>& u) {
    { t == u } -> Boolean;
    { t != u } -> Boolean;
    { u == t } -> Boolean;
}
For some types $T$ and $U$, let $t$ and $u$ be lvalues of types $\text{const remove_reference_t}<T>$ and $\text{const remove_reference_t}<U>$ respectively. $T$ and $U$ model \textit{weakly-equality-comparable-with}<T, U> only if:

1. $t == u, u == t, t != u,$ and $u != t$ have the same domain.
2. $\text{bool}(u == t) == \text{bool}(t == u)$.
3. $\text{bool}(t != u) == !\text{bool}(t == u)$.
4. $\text{bool}(u != t) == \text{bool}(t != u)$.

\begin{verbatim}
18.5.4 Concept StrictTotallyOrdered \[concept.stricttotallyordered\]
\end{verbatim}
const remove_reference_t<T>&,
const remove_reference_t<U>&) &&
EqualityComparableWith<T, U> &&
requires(const remove_reference_t<T>& t,
const remove_reference_t<U>& u) {
    { t < u } -> Boolean;
    { t > u } -> Boolean;
    { t <= u } -> Boolean;
    { t >= u } -> Boolean;
    { u < t } -> Boolean;
    { u > t } -> Boolean;
    { u <= t } -> Boolean;
    { u >= t } -> Boolean;
};

For some types T and U, let t be an lvalue of type const remove_reference_t<T>, u be an lvalue of
type const remove_reference_t<U>, and C be:

common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>
T and U model StrictTotallyOrderedWith<T, U> only if

(2.1)  bool(t < u) == bool(C(t) < C(u)).
(2.2)  bool(t > u) == bool(C(t) > C(u)).
(2.3)  bool(t <= u) == bool(C(t) <= C(u)).
(2.4)  bool(t >= u) == bool(C(t) >= C(u)).
(2.5)  bool(u < t) == bool(C(u) < C(t)).
(2.6)  bool(u > t) == bool(C(u) > C(t)).
(2.7)  bool(u <= t) == bool(C(u) <= C(t)).
(2.8)  bool(u >= t) == bool(C(u) >= C(t)).

18.6 Object concepts  [concepts.object]

This subclause describes concepts that specify the basis of the value-oriented programming style on which
the library is based.

1

template<class T>
    concept Movable = is_object_v<T> && MoveConstructible<T> && Assignable<T&, T> && Swappable<T>;
template<class T>
    concept Copyable = CopyConstructible<T> && Movable<T> && Assignable<T&, const T&>;
template<class T>
    concept Semiregular = Copyable<T> && DefaultConstructible<T>;
template<class T>
    concept Regular = Semiregular<T> && EqualityComparable<T>;

[Note: The Semiregular concept is modeled by types that behave similarly to built-in types like int,
except that they might not be comparable with ==. — end note]

[Note: The Regular concept is modeled by types that behave similarly to built-in types like int and
that are comparable with ==. — end note]

18.7 Callable concepts  [concepts.callable]

18.7.1 General  [concepts.callable.general]

The concepts in this subclause describe the requirements on function objects (20.14) and their arguments.

18.7.2 Concept Invocable  [concept.invocable]

The Invocable concept specifies a relationship between a callable type (20.14.2) F and a set of argument

types Args... which can be evaluated by the library function invoke (20.14.4).

template<class F, class... Args>
    concept Invocable = requires(F& f, Args&... args) {
        invoke(std::forward<F>(f), std::forward<Args>(args)...); // not required to be equality-preserving
18.7.3 Concept RegularInvocable

```cpp
template<class F, class... Args>
concept RegularInvocable = Invocable<F, Args...>;
```

The `invoke` function call expression shall be equality-preserving and shall not modify the function object or the arguments (18.2). [Note: This requirement supersedes the annotation in the definition of `Invocable`. — end note]

1 [Example: A random number generator does not model `RegularInvocable`. — end example]

3 [Note: The distinction between `Invocable` and `RegularInvocable` is purely semantic. — end note]

18.7.4 Concept Predicate

```cpp
template<class F, class... Args>
concept Predicate = RegularInvocable<F, Args...> && Boolean<invoke_result_t<F, Args...>>;
```

18.7.5 Concept Relation

```cpp
template<class R, class T, class U>
concept Relation =
    Predicate<R, T, T> && Predicate<R, U, U> &&
    Predicate<R, T, U> && Predicate<R, U, T>;
```

18.7.6 Concept StrictWeakOrder

```cpp
template<class R, class T, class U>
concept StrictWeakOrder = Relation<R, T, U>;
```

A `Relation` models `StrictWeakOrder` only if it imposes a `strict weak ordering` on its arguments.

The term `strict` refers to the requirement of an irreflexive relation (\( \neg \text{comp}(x, x) \) for all \( x \)), and the term `weak` to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define `equiv(a, b)` as `\neg \text{comp}(a, b) && \neg \text{comp}(b, a)`, then the requirements are that `comp` and `equiv` both be transitive relations:

\[\begin{align*}
(2.1) & \quad \text{comp}(a, b) && \text{comp}(b, c) \implies \text{comp}(a, c) \\
(2.2) & \quad \text{equiv}(a, b) && \text{equiv}(b, c) \implies \text{equiv}(a, c)
\end{align*}\]

3 [Note: Under these conditions, it can be shown that

\[\begin{align*}
(3.1) & \quad \text{equiv} \text{ is an equivalence relation,} \\
(3.2) & \quad \text{comp} \text{ induces a well-defined relation on the equivalence classes determined by equiv, and} \\
(3.3) & \quad \text{the induced relation is a strict total ordering.} \\
& \quad \text{— end note}
\end{align*}\]
19 Diagnostics library

19.1 General

This Clause describes components that C++ programs may use to detect and report error conditions.

The following subclauses describe components for reporting several kinds of exceptional conditions, documenting program assertions, and a global variable for error number codes, as summarized in Table 38.

Table 38: Diagnostics library summary

19.2 Exception classes

The C++ standard library provides classes to be used to report certain errors (16.5.5.12) in C++ programs. In the error model reflected in these classes, errors are divided into two broad categories: logic errors and runtime errors.

The distinguishing characteristic of logic errors is that they are due to errors in the internal logic of the program. In theory, they are preventable.

By contrast, runtime errors are due to events beyond the scope of the program. They cannot be easily predicted in advance. The header `<stdexcept>` defines several types of predefined exceptions for reporting errors in a C++ program. These exceptions are related by inheritance.

19.2.1 Header `<stdexcept>` synopsis

```cpp
namespace std {
    class logic_error;
    class domain_error;
    class invalid_argument;
    class length_error;
    class out_of_range;
    class runtime_error;
    class range_error;
    class overflow_error;
    class underflow_error;
}
```

19.2.2 Class `logic_error`

```cpp
namespace std {
    class logic_error : public exception {
        public:
        explicit logic_error(const string& what_arg);
        explicit logic_error(const char* what_arg);
    };
}
```

The class `logic_error` defines the type of objects thrown as exceptions to report errors presumably detectable before the program executes, such as violations of logical preconditions or class invariants.

$log\_error(const\_string& what\_arg);$

1 Ensures: `strcmp(what(), what\_arg.c\_str()) == 0.`
logic_error(const char* what_arg);

\textit{Ensures:} strcmp(what(), what_arg) == 0.

\subsection*{19.2.3 Class domain_error}

```cpp
namespace std {
    class domain_error : public logic_error {
        public:
            explicit domain_error(const string& what_arg);
            explicit domain_error(const char* what_arg);
    };
}
```

The class \texttt{domain_error} defines the type of objects thrown as exceptions by the implementation to report domain errors.

```cpp
domain_error(const string& what_arg);

\textit{Ensures:} strcmp(what(), what_arg.c_str()) == 0.
```

```cpp
domain_error(const char* what_arg);

\textit{Ensures:} strcmp(what(), what_arg) == 0.
```

\subsection*{19.2.4 Class invalid_argument}

```cpp
namespace std {
    class invalid_argument : public logic_error {
        public:
            explicit invalid_argument(const string& what_arg);
            explicit invalid_argument(const char* what_arg);
    };
}
```

The class \texttt{invalid_argument} defines the type of objects thrown as exceptions to report an invalid argument.

```cpp
invalid_argument(const string& what_arg);

\textit{Ensures:} strcmp(what(), what_arg.c_str()) == 0.
```

```cpp
invalid_argument(const char* what_arg);

\textit{Ensures:} strcmp(what(), what_arg) == 0.
```

\subsection*{19.2.5 Class length_error}

```cpp
namespace std {
    class length_error : public logic_error {
        public:
            explicit length_error(const string& what_arg);
            explicit length_error(const char* what_arg);
    };
}
```

The class \texttt{length_error} defines the type of objects thrown as exceptions to report an attempt to produce an object whose length exceeds its maximum allowable size.

```cpp
length_error(const string& what_arg);

\textit{Ensures:} strcmp(what(), what_arg.c_str()) == 0.
```

```cpp
length_error(const char* what_arg);

\textit{Ensures:} strcmp(what(), what_arg) == 0.
```

\subsection*{19.2.6 Class out_of_range}

```cpp
namespace std {
    class out_of_range : public logic_error {
        public:
            explicit out_of_range(const string& what_arg);
            explicit out_of_range(const char* what_arg);
    };
}
```
The class \texttt{out\_of\_range} defines the type of objects thrown as exceptions to report an argument value not in its expected range.

\begin{verbatim}
out_of_range(const string& what_arg);
\end{verbatim}

\textit{Ensures:} \texttt{strcmp(what(), what\_arg\_c\_str()) == 0}.

\begin{verbatim}
out_of_range(const char* what_arg);
\end{verbatim}

\textit{Ensures:} \texttt{strcmp(what(), what\_arg) == 0}.

\subsection*{19.2.7 Class runtime\_error}

namespace std {
    class runtime_error : public exception {
        public:
            explicit runtime_error(const string& what_arg);
            explicit runtime_error(const char* what_arg);
    };
}

The class \texttt{runtime\_error} defines the type of objects thrown as exceptions to report errors presumably detectable only when the program executes.

\begin{verbatim}
runtime_error(const string& what_arg);
\end{verbatim}

\textit{Ensures:} \texttt{strcmp(what(), what\_arg\_c\_str()) == 0}.

\begin{verbatim}
runtime_error(const char* what_arg);
\end{verbatim}

\textit{Ensures:} \texttt{strcmp(what(), what\_arg) == 0}.

\subsection*{19.2.8 Class range\_error}

namespace std {
    class range_error : public runtime_error {
        public:
            explicit range_error(const string& what_arg);
            explicit range_error(const char* what_arg);
    };
}

The class \texttt{range\_error} defines the type of objects thrown as exceptions to report range errors in internal computations.

\begin{verbatim}
range_error(const string& what_arg);
\end{verbatim}

\textit{Ensures:} \texttt{strcmp(what(), what\_arg\_c\_str()) == 0}.

\begin{verbatim}
range_error(const char* what_arg);
\end{verbatim}

\textit{Ensures:} \texttt{strcmp(what(), what\_arg) == 0}.

\subsection*{19.2.9 Class overflow\_error}

namespace std {
    class overflow_error : public runtime_error {
        public:
            explicit overflow_error(const string& what_arg);
            explicit overflow_error(const char* what_arg);
    };
}

The class \texttt{overflow\_error} defines the type of objects thrown as exceptions to report an arithmetic overflow error.

\begin{verbatim}
overflow_error(const string& what_arg);
\end{verbatim}

\textit{Ensures:} \texttt{strcmp(what(), what\_arg\_c\_str()) == 0}. 

\section*{§ 19.2.9}
overflow_error(const char* what_arg);

Ensures: strcmp(what(), what_arg) == 0.

19.2.10 Class underflow_error

namespace std {
    class underflow_error : public runtime_error {
        public:
            explicit underflow_error(const string& what_arg);
            explicit underflow_error(const char* what_arg);
    };
}

The class underflow_error defines the type of objects thrown as exceptions to report an arithmetic underflow error.

underflow_error(const string& what_arg);

Ensures: strcmp(what(), what_arg.c_str()) == 0.

underflow_error(const char* what_arg);

Ensures: strcmp(what(), what_arg) == 0.

19.3 Assertions

The header <cassert> provides a macro for documenting C++ program assertions and a mechanism for disabling the assertion checks.

19.3.1 Header <cassert> synopsis

#define assert(E) see below

The contents are the same as the C standard library header <assert.h>, except that a macro named static_assert is not defined.

See also: ISO C 7.2

19.3.2 The assert macro

An expression assert(E) is a constant subexpression (16.3.6), if

(1.1) - NDEBUG is defined at the point where assert is last defined or redefined, or

(1.2) - E contextually converted to bool (7.3) is a constant subexpression that evaluates to the value true.

19.4 Error numbers

The contents of the header <cerrno> are the same as the POSIX header <errno.h>, except that errno shall be defined as a macro. [Note: The intent is to remain in close alignment with the POSIX standard. — end note] A separate errno value shall be provided for each thread.

19.4.1 Header <cerrno> synopsis

§ 19.4.1
1 The meaning of the macros in this header is defined by the POSIX standard.

See also: ISO C 7.5

19.5 System error support

This subclause describes components that the standard library and C++ programs may use to report error conditions originating from the operating system or other low-level application program interfaces.

Components described in this subclause shall not change the value of \texttt{errno} (19.4). Implementations should leave the error states provided by other libraries unchanged.

19.5.1 Header \texttt{<system\_error>} synopsis

namespace std {

bool operator!=(const error_condition& lhs, const error_code& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;

§ 19.5.1
bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;
bool operator< (const error_code& lhs, const error_code& rhs) noexcept;
bool operator< (const error_condition& lhs, const error_condition& rhs) noexcept;

// 19.5.6, hash support
template<class T> struct hash;
template<> struct hash<error_code>;
template<> struct hash<error_condition>;

// 19.5, system error support
template<class T>
inline constexpr bool is_error_code_enum_v = is_error_code_enum<T>::value;
template<class T>
inline constexpr bool is_error_condition_enum_v = is_error_condition_enum<T>::value;

1 The value of each enum errc constant shall be the same as the value of the <cerrno> macro shown in
the above synopsis. Whether or not the <system_error> implementation exposes the <cerrno> macros is
unspecified.

2 The is_error_code_enum and is_error_condition_enum may be specialized for program-defined types
to indicate that such types are eligible for class error_code and class error_condition automatic
conversions, respectively.

19.5.2 Class error_category

19.5.2.1 Overview

1 The class error_category serves as a base class for types used to identify the source and encoding of a
particular category of error code. Classes may be derived from error_category to support categories of errors
in addition to those defined in this document. Such classes shall behave as specified in this subclause 19.5.2.
[Note: error_category objects are passed by reference, and two such objects are equal if they have the same
address. This means that applications using custom error_category types should create a single object of
each such type. — end note]

namespace std {

    class error_category {
    public:
        constexpr error_category() noexcept;
        virtual ~error_category();
        error_category(const error_category&) = delete;
        error_category& operator=(const error_category&) = delete;
        virtual const char* name() const noexcept = 0;
        virtual error_condition default_error_condition(int ev) const noexcept;
        virtual bool equivalent(int code, const error_condition& condition) const noexcept;
        virtual bool equivalent(const error_code& code, int condition) const noexcept;
        virtual string message(int ev) const = 0;
        bool operator==(const error_category& rhs) const noexcept;
        bool operator!=(const error_category& rhs) const noexcept;
        bool operator< (const error_category& rhs) const noexcept;
    }

    const error_category& generic_category() noexcept;
    const error_category& system_category() noexcept;
}

19.5.2.2 Virtual members

virtual const char* name() const noexcept = 0;

1 Returns: A string naming the error category.

virtual error_condition default_error_condition(int ev) const noexcept;

2 Returns: error_condition(ev, *this).
virtual bool equivalent(int code, const error_condition& condition) const noexcept;
3    \[ Returns: default_error_condition(code) == condition. \]
virtual bool equivalent(const error_code& code, int condition) const noexcept;
4    \[ Returns: \*this == code.category() && code.value() == condition. \]
virtual string message(int ev) const = 0;
5    \[ Returns: A string that describes the error condition denoted by ev. \]

19.5.2.3 Non-virtual members [syserr.errcat.nonvirtuals]

bool operator==(const error_category& rhs) const noexcept;
1    \[ Returns: this == \&rhs. \]
bool operator!=(const error_category& rhs) const noexcept;
2    \[ Returns: !(*this == rhs). \]
bool operator<(const error_category& rhs) const noexcept;
3    \[ Returns: less<const error_category*>()(this, \&rhs). \]
\[ Note: less (20.14.7) provides a total ordering for pointers. \] —end note

19.5.2.4 Program-defined classes derived from error_category [syserr.errcat.derived]

virtual const char* name() const noexcept = 0;
1    \[ Returns: A string naming the error category. \]
virtual error_condition default_error_condition(int ev) const noexcept;
2    \[ Returns: An object of type error_condition that corresponds to ev. \]
virtual bool equivalent(int code, const error_condition& condition) const noexcept;
3    \[ Returns: true if, for the category of error represented by \*this, code is considered equivalent to condition; otherwise, false. \]
virtual bool equivalent(const error_code& code, int condition) const noexcept;
4    \[ Returns: true if, for the category of error represented by \*this, code is considered equivalent to condition; otherwise, false. \]

19.5.2.5 Error category objects [syserr.errcat.objects]

const error_category& generic_category() noexcept;
1    \[ Returns: A reference to an object of a type derived from class error_category. All calls to this function shall return references to the same object. \]
\[ Remarks: The object’s default_error_condition and equivalent virtual functions shall behave as specified for the class error_category. The object’s name virtual function shall return a pointer to the string "generic". \]
const error_category& system_category() noexcept;
3    \[ Returns: A reference to an object of a type derived from class error_category. All calls to this function shall return references to the same object. \]
\[ Remarks: The object’s equivalent virtual functions shall behave as specified for class error_category. The object’s name virtual function shall return a pointer to the string "system". The object’s default_error_condition virtual function shall behave as follows:
If the argument ev corresponds to a POSIX errno value posv, the function shall return error_condition(posv, generic_category()). Otherwise, the function shall return error_condition(ev, system_category()). What constitutes correspondence for any given operating system is unspecified. \]
\[ Note: The number of potential system error codes is large and unbounded, and some may not correspond to any POSIX errno value. Thus implementations are given latitude in determining correspondence. \] —end note
19.5.3 Class error_code

19.5.3.1 Overview

The class error_code describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces. [Note: Class error_code is an adjunct to error reporting by exception. — end note]

namespace std {
    class error_code {
        public:
            // 19.5.3.2, constructors
            error_code() noexcept;
            error_code(int val, const error_category& cat) noexcept;
            template<class ErrorCodeEnum>
                error_code(ErrorCodeEnum e) noexcept;
            // 19.5.3.3, modifiers
            void assign(int val, const error_category& cat) noexcept;
            template<class ErrorCodeEnum>
                error_code& operator=(ErrorCodeEnum e) noexcept;
            void clear() noexcept;
            // 19.5.3.4, observers
            int value() const noexcept;
            const error_category& category() const noexcept;
            error_condition default_error_condition() const noexcept;
            string message() const;
            explicit operator bool() const noexcept;
        private:
            int val_; // exposition only
            const error_category* cat_; // exposition only
    };
    // 19.5.3.5, non-member functions
    error_code make_error_code(errc e) noexcept;
    template<class charT, class traits>
        basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>& os, const error_code& ec);
}

19.5.3.2 Constructors

error_code() noexcept;

Ensures: val_ == 0 and cat_ == &system_category().

error_code(int val, const error_category& cat) noexcept;

Ensures: val_ == val and cat_ == &cat.

template<class ErrorCodeEnum>
    error_code(ErrorCodeEnum e) noexcept;

Constraints: is_error_code_enum_v<ErrorCodeEnum> is true.

Ensures: *this == make_error_code(e).

19.5.3.3 Modifiers

void assign(int val, const error_category& cat) noexcept;

Ensures: val_ == val and cat_ == &cat.

template<class ErrorCodeEnum>
    error_code& operator=(ErrorCodeEnum e) noexcept;

Constraints: is_error_code_enum_v<ErrorCodeEnum> is true.
void clear() noexcept;

Ensures: value() == 0 and category() == system_category().

19.5.3.4 Observers

int value() const noexcept;

Returns: val_.

const error_category& category() const noexcept;

Returns: *cat_.

error_condition default_error_condition() const noexcept;

Returns: category().default_error_condition(value()).

string message() const;

Returns: category().message(value()).

explicit operator bool() const noexcept;

Returns: value() != 0.

19.5.3.5 Non-member functions

error_code make_error_code(errc e) noexcept;

Returns: error_code(static_cast<int>(e), generic_category()).

template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const error_code& ec);

Effects: Equivalent to: return os << ec.category().name() << ':' << ec.value();

19.5.4 Class error_condition

19.5.4.1 Overview

The class error_condition describes an object used to hold values identifying error conditions. [Note: error_condition values are portable abstractions, while error_code values (19.5.3) are implementation specific. — end note]

namespace std {
    class error_condition {
        public:
            // 19.5.4.2, constructors
            error_condition() noexcept;
            error_condition(int val, const error_category& cat) noexcept;
            template<class ErrorConditionEnum>
                error_condition(ErrorConditionEnum e) noexcept;

            // 19.5.4.3, modifiers
            void assign(int val, const error_category& cat) noexcept;
            template<class ErrorConditionEnum>
                error_condition& operator=(ErrorConditionEnum e) noexcept;
            void clear() noexcept;

            // 19.5.4.4, observers
            int value() const noexcept;
            const error_category& category() const noexcept;
            string message() const;
            explicit operator bool() const noexcept;

§ 19.5.4.1

540
19.5.4.2 Constructors

```cpp
error_condition() noexcept;
Ensures: val_ == 0 and cat_ == &generic_category().
```

```cpp
error_condition(int val, const error_category& cat) noexcept;
Ensures: val_ == val and cat_ == &cat.
```

```cpp
template<class ErrorConditionEnum>
error_condition(ErrorConditionEnum e) noexcept;
Constraints: is_error_condition_enum_v<ErrorConditionEnum> is true.
Ensures: *this == make_error_condition(e).
```

19.5.4.3 Modifiers

```cpp
void assign(int val, const error_category& cat) noexcept;
Ensures: val_ == val and cat_ == &cat.
```

```cpp
template<class ErrorConditionEnum>
error_condition& operator=(ErrorConditionEnum e) noexcept;
Constraints: is_error_condition_enum_v<ErrorConditionEnum> is true.
Ensures: *this == make_error_condition(e).
Returns: *this.
```

```cpp
void clear() noexcept;
Ensures: value() == 0 and category() == generic_category().
```

19.5.4.4 Observers

```cpp
int value() const noexcept;
Returns: val_.
```

```cpp
const error_category& category() const noexcept;
Returns: *cat_.
```

```cpp
string message() const;
Returns: category().message(value()).
```

```cpp
explicit operator bool() const noexcept;
Returns: value() != 0.
```

19.5.4.5 Non-member functions

```cpp
error_condition make_error_condition(errc e) noexcept;
Returns: error_condition(static_cast<int>(e), generic_category()).
```

19.5.5 Comparison functions

```cpp
bool operator==(const error_code& lhs, const error_code& rhs) noexcept;
Returns:
    lhs.category() == rhs.category() && lhs.value() == rhs.value()
```
bool operator==(const error_code& lhs, const error_condition& rhs) noexcept;

Returns:
    lhs.category().equivalent(lhs.value(), rhs) || rhs.category().equivalent(lhs, rhs.value())

bool operator==(const error_condition& lhs, const error_code& rhs) noexcept;

Returns:
    rhs.category().equivalent(rhs.value(), lhs) || lhs.category().equivalent(rhs, lhs.value())

bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;

Returns:
    lhs.category() == rhs.category() && lhs.value() == rhs.value()

bool operator!=(const error_code& lhs, const error_code& rhs) noexcept;
bool operator!=(const error_code& lhs, const error_condition& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_code& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;

Returns: !(lhs == rhs).

bool operator<(const error_code& lhs, const error_code& rhs) noexcept;

Returns:
    lhs.category() < rhs.category() ||
    (lhs.category() == rhs.category() && lhs.value() < rhs.value())

bool operator<(const error_condition& lhs, const error_condition& rhs) noexcept;

Returns:
    lhs.category() < rhs.category() ||
    (lhs.category() == rhs.category() && lhs.value() < rhs.value())

19.5.6 System error hash support
[syserr.hash]

template<> struct hash<error_code>;
template<> struct hash<error_condition>;

The specializations are enabled (20.14.18).

19.5.7 Class system_error
[syserr.syserr]
19.5.7.1 Overview
[syserr.syserr.overview]

The class system_error describes an exception object used to report error conditions that have an associated error code. Such error conditions typically originate from the operating system or other low-level application program interfaces.

[Note: If an error represents an out-of-memory condition, implementations are encouraged to throw an exception object of type bad_alloc (17.6.3.1) rather than system_error. — end note]

namespace std {
    class system_error : public runtime_error {
        public:
            system_error(error_code ec, const string& what_arg);
            system_error(error_code ec, const char* what_arg);
            system_error(error_code ec);
            system_error(int ev, const error_category& ecat, const string& what_arg);
            system_error(int ev, const error_category& ecat, const char* what_arg);
            system_error(int ev, const error_category& ecat);
            const error_code& code() const noexcept;
            const char* what() const noexcept override;
        };
    }
}
19.5.7.2 Members

system_error(error_code ec, const string& what_arg);

Ensures: code() == ec and
string_view(what()).find(what_arg.c_str()) != string_view::npos.

system_error(error_code ec, const char* what_arg);

Ensures: code() == ec and string_view(what()).find(what_arg) != string_view::npos.

system_error(error_code ec);

Ensures: code() == ec.

system_error(int ev, const error_category& ecat, const string& what_arg);

Ensures: code() == error_code(ev, ecat) and
string_view(what()).find(what_arg.c_str()) != string_view::npos.

system_error(int ev, const error_category& ecat, const char* what_arg);

Ensures: code() == error_code(ev, ecat) and
string_view(what()).find(what_arg) != string_view::npos.

system_error(int ev, const error_category& ecat);

Ensures: code() == error_code(ev, ecat).

const error_code& code() const noexcept;

Returns: ec or error_code(ev, ecat), from the constructor, as appropriate.

const char* what() const noexcept override;

Returns: An NTBS incorporating the arguments supplied in the constructor.

[Note: The returned NTBS might be the contents of what_arg + ": " + code.message(). — end note]
20 General utilities library

20.1 General

This Clause describes utilities that are generally useful in C++ programs; some of these utilities are used by other elements of the C++ standard library. These utilities are summarized in Table 39.

20.2 Utility components

20.2.1 Header <utility> synopsis

The header <utility> contains some basic function and class templates that are used throughout the rest of the library.

```cpp
#include <initializer_list>  // see 17.10.1
namespace std {
  // 20.2.2, swap
  template<class T>
  constexpr void swap(T& a, T& b) noexcept(see below);
  template<class T, size_t N>
  constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);

  // 20.2.3, exchange
  template<class T, class U = T>
  constexpr T exchange(T& obj, U&& new_val);

  // 20.2.4, forward/move
  template<class T>
  constexpr T&& forward(remove_reference_t<T>& t) noexcept;
  template<class T>
  constexpr T&& forward(remove_reference_t<T>&& t) noexcept;
  template<class T>
  constexpr remove_reference_t<T>&& move(T&&) noexcept;
```

§ 20.1
template<class T>
  constexpr conditional_t<
    !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>
  move_if_noexcept(T& x) noexcept;

// 20.2.5, as_const
template<class T>
  constexpr add_const_t<T> as_const(T& t) noexcept;
  template<class T>
  void as_const(const T&) = delete;

// 20.2.6, declval
template<class T>
  add_rvalue_reference_t<T> declval() noexcept;  // as unevaluated operand

// 20.3, Compile-time integer sequences
template<class T, T...>
  struct integer_sequence;
  template<size_t... I>
    using index_sequence = integer_sequence<size_t, I...>;

template<class T, T N>
  using make_integer_sequence = integer_sequence<T, see below>;

template<class T, T N>
  using make_index_sequence = make_integer_sequence<size_t, N>;

template<class... T>
  using index_sequence_for = make_index_sequence<sizeof...(T)>

// 20.4, class template pair
template<class T1, class T2>
  struct pair;

  template<class T1, class T2>
    constexpr bool operator==(const pair<T1, T2>&, const pair<T1, T2>&);

  template<class T1, class T2>
    constexpr bool operator!=(const pair<T1, T2>&, const pair<T1, T2>&);

  template<class T1, class T2>
    constexpr bool operator< (const pair<T1, T2>&, const pair<T1, T2>&);

  template<class T1, class T2>
    constexpr bool operator> (const pair<T1, T2>&, const pair<T1, T2>&);

  template<class T1, class T2>
    constexpr bool operator<=(const pair<T1, T2>&, const pair<T1, T2>&);

  template<class T1, class T2>
    constexpr bool operator>=(const pair<T1, T2>&, const pair<T1, T2>&);

  template<class T1, class T2>
    constexpr void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));

  template<class T1, class T2>
    constexpr void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));

// 20.4.4, tuple-like access to pair
  template<class T> struct tuple_size;
  template<size_t I, class T> struct tuple_element;

  template<class T1, class T2> struct tuple_size<pair<T1, T2>>;

  template<size_t I, class T1, class T2> struct tuple_element<I, pair<T1, T2>>;

  template<size_t I, class T1, class T2>
    constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>& x) noexcept;

  template<size_t I, class T1, class T2>
    constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>& x) noexcept;
template<
    size_t I,
    class T1,
    class T2
>
constexpr const tuple_element_t<I, pair<T1, T2>>&
    get(const pair<T1, T2>&) noexcept;

template<
    size_t I,
    class T1,
    class T2
>
constexpr const tuple_element_t<I, pair<T1, T2>>&
    get(const pair<T1, T2>&&) noexcept;

template<
    class T1,
    class T2
>
constexpr T1&
    get(pair<T1, T2>&) noexcept;

template<
    class T1,
    class T2
>
constexpr const T1&
    get(const pair<T1, T2>&) noexcept;

template<
    class T1,
    class T2
>
constexpr T1&&
    get(pair<T1, T2>&& p) noexcept;

template<
    class T1,
    class T2
>
constexpr const T1&&
    get(const pair<T1, T2>&& p) noexcept;

template<
    class T2,
    class T1
>
constexpr T2&
    get(pair<T1, T2>& p) noexcept;

template<
    class T2,
    class T1
>
constexpr const T2&
    get(const pair<T1, T2>& p) noexcept;

template<
    class T2,
    class T1
>
constexpr T2&&
    get(pair<T1, T2>&& p) noexcept;

template<
    class T2,
    class T1
>
constexpr const T2&&
    get(const pair<T1, T2>&& p) noexcept;

// 20.4.5, pair piecewise construction
struct piecewise_construct_t {
    explicit piecewise_construct_t() = default;
};
inline constexpr piecewise_construct_t piecewise_construct{};

// in-place construction
struct in_place_t {
    explicit in_place_t() = default;
};
inline constexpr in_place_t in_place{};

template<class T>
    struct in_place_type_t {
    explicit in_place_type_t() = default;
};

template<class T>
inline constexpr in_place_type_t<T> in_place_type{};

template<size_t I>
    struct in_place_index_t {
    explicit in_place_index_t() = default;
};

template<size_t I>
inline constexpr in_place_index_t<I> in_place_index{};

20.2.2 swap

template<class T>
    constexpr void swap(T& a, T& b) noexcept(see below);

Remarks: This function is a designated customization point (16.5.4.2.1) and shall not participate in overload resolution unless is_move_constructible_v<T> is true and is_move_assignable_v<T> is true. The expression inside noexcept is equivalent to:

    is_nothrow_move_constructible_v<T> && is_nothrow_move_assignable_v<T>

Requires: Type T shall be Cpp17MoveConstructible (Table 26) and Cpp17MoveAssignable (Table 28).

Effects: Exchanges values stored in two locations.

template<class T, size_t N>
    constexpr void swap(T&(a)[N], T&(b)[N]) noexcept(is_nothrow_swappable_v<T>);

Remarks: This function shall not participate in overload resolution unless is_swappable_v<T> is true.

Requires: a[i] shall be swappable with (16.5.3.2) b[i] for all i in the range [0, N).

Effects: As if by swap_ranges(a, a + N, b).
20.2.3 exchange

```cpp
template<class T, class U = T>
constexpr T exchange(T& obj, U&& new_val);
```

**Effects:** Equivalent to:
- `T old_val = std::move(obj);`
- `obj = std::forward<U>(new_val);`
- `return old_val;`

20.2.4 Forward/move helpers

The library provides templated helper functions to simplify applying move semantics to an lvalue and to simplify the implementation of forwarding functions. All functions specified in this subclause are signal-safe (17.13.4).

```cpp
template<class T> constexpr T&& forward(remove_reference_t<T>& t) noexcept;
```

**Returns:** `static_cast<T&&>(t)`.

**Remarks:** If the second form is instantiated with an lvalue reference type, the program is ill-formed.

**Example:**
```cpp
template<class T, class A1, class A2>
shared_ptr<T> factory(A1&& a1, A2&& a2) {
    return shared_ptr<T>(new T(std::forward<A1>(a1), std::forward<A2>(a2)));
}
```

```cpp
struct A {
    A(int&, const double&);
};
```

```cpp
void g() {
    shared_ptr<A> sp1 = factory<A>(2, 1.414); // error: 2 will not bind to int&
    int i = 2;
    shared_ptr<A> sp2 = factory<A>(i, 1.414); // OK
}
```

In the first call to `factory`, `A1` is deduced as `int`, so 2 is forwarded to `A`'s constructor as an rvalue. In the second call to `factory`, `A1` is deduced as `int&`, so `i` is forwarded to `A`'s constructor as an lvalue. In both cases, `A2` is deduced as `double`, so 1.414 is forwarded to `A`'s constructor as an rvalue.

```cpp
template<class T> constexpr remove_reference_t<T>&& move(T&& t) noexcept;
```

**Returns:** `static_cast<remove_reference_t<T>&&>(t)`.

**Example:**
```cpp
template<class T, class A1>
shared_ptr<T> factory(A1&& a1) {
    return shared_ptr<T>(new T(std::forward<A1>(a1)));}
```

```cpp
struct A {
    A();
    A(const A&); // copies from lvalues
    A(A&&); // moves from rvalues
};
```

```cpp
void g() {
    A a;
    shared_ptr<A> sp1 = factory<A>(a); // "a" binds to A(const A&)
    shared_ptr<A> sp1 = factory<A>(std::move(a)); // "a" binds to A(A&&)
}
```

In the first call to `factory`, `A1` is deduced as `A&`, so `a` is forwarded as a non-const lvalue. This binds to the constructor `A(const A&)`, which copies the value from `a`. In the second call to `factory`, because of
the call \texttt{std::move(a)}, \texttt{A1} is deduced as \texttt{A}, so \texttt{a} is forwarded as an rvalue. This binds to the constructor \texttt{A(A&&)}, which moves the value from \texttt{a}. \textit{— end example}

\begin{verbatim}
template<class T> constexpr conditional_t<!is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&> move_if_noexcept(T& x) noexcept;
\end{verbatim}

\begin{enumerate}
\item Returns: \texttt{std::move(x)}.
\end{enumerate}

20.2.5 Function template \texttt{as\_const} \textit{utility.as\_const}

\begin{verbatim}
template<class T> constexpr add_const_t<T>& as_const(T& t) noexcept;
\end{verbatim}

\begin{enumerate}
\item Returns: \texttt{t}.
\end{enumerate}

20.2.6 Function template \texttt{declval} \textit{declval}

\begin{verbatim}
template<class T> add_rvalue_reference_t<T> declval() noexcept; // as unevaluated operand
\end{verbatim}

\begin{enumerate}
\item The library provides the function template \texttt{declval} to simplify the definition of expressions which occur as unevaluated operands (7.2).
\item Remarks: If this function is odr-used (6.2), the program is ill-formed.
\item Remarks: The template parameter \texttt{T} of \texttt{declval} may be an incomplete type.
\end{enumerate}

\begin{verbatim}
template<class To, class From> decltype(static_cast<To>(declval<From>())) convert(From&&);
\end{verbatim}

\begin{enumerate}
\item declares a function template \texttt{convert} which only participates in overloading if the type \texttt{From} can be explicitly converted to type \texttt{To}. For another example see class template \texttt{common\_type} (20.15.7.6). \textit{— end example}
\end{enumerate}

20.3 Compile-time integer sequences \textit{intseq}

20.3.1 In general \textit{intseq.general}

\begin{enumerate}
\item The library provides a class template that can represent an integer sequence. When used as an argument to a function template the template parameter pack defining the sequence can be deduced and used in a pack expansion. \textit{[Note: The \texttt{index\_sequence} alias template is provided for the common case of an integer sequence of type \texttt{size\_t}; see also 20.5.3.5. — end note]}
\end{enumerate}

20.3.2 Class template \texttt{integer\_sequence} \textit{intseq.intseq}

\begin{verbatim}
namespace std {
    template<class T, T... I> struct integer_sequence {
        using value_type = T;
        static constexpr size_t size() noexcept { return sizeof...(I); }
    };
}
\end{verbatim}

\begin{enumerate}
\item \texttt{T} shall be an integer type.
\end{enumerate}

20.3.3 Alias template \texttt{make\_integer\_sequence} \textit{intseq.make}

\begin{verbatim}
template<class T, T N>
    using make_integer_sequence = integer_sequence<T, see below>;
\end{verbatim}

\begin{enumerate}
\item If \texttt{N} is negative the program is ill-formed. The alias template \texttt{make\_integer\_sequence} denotes a specialization of \texttt{integer\_sequence} with \texttt{N} template non-type arguments. The type \texttt{make\_integer\_sequence\texttt{<T, N>}} denotes the type \texttt{integer\_sequence\texttt{<T, 0, 1, ..., N-1>}}. \textit{[Note: \texttt{make\_integer\_sequence\texttt{<int, 0>}} denotes the type \texttt{integer\_sequence\texttt{<int>}} — end note]}
\end{enumerate}

20.4 Pairs \textit{pairs}

20.4.1 In general \textit{pairs.general}

\begin{enumerate}
\item The library provides a template for heterogeneous pairs of values. The library also provides a matching function template to simplify their construction and several templates that provide access to \texttt{pair} objects as if they were \texttt{tuple} objects (see 20.5.3.6 and 20.5.3.7).
\end{enumerate}
20.4.2 Class template pair

namespace std {
    template<class T1, class T2>
    struct pair {
        using first_type = T1;
        using second_type = T2;
        T1 first;
        T2 second;

        pair(const pair&) = default;
        pair(pair&&) = default;
        constexpr explicit(see below) pair();
        constexpr explicit(see below) pair(const T1& x, const T2& y);
        template<class U1, class U2>
            constexpr explicit(see below) pair(U1&& x, U2&& y);
        template<class U1, class U2>
            constexpr explicit(see below) pair(const pair<U1, U2>& p);
        template<class U1, class U2>
            constexpr explicit(see below) pair(pair<U1, U2>&& p);
        template<class... Args1, class... Args2>
            constexpr pair(piecewise_construct_t,
                tuple<Args1...> first_args, tuple<Args2...> second_args);

        constexpr pair& operator=(const pair& p);
        template<class U1, class U2>
            constexpr pair& operator=(const pair<U1, U2>& p);
        constexpr pair& operator=(pair&& p) noexcept(see below);
        template<class U1, class U2>
            constexpr pair& operator=(pair<U1, U2>&& p);

        constexpr void swap(pair& p) noexcept(see below);
    };
}

1 Constructors and member functions of pair shall not throw exceptions unless one of the element-wise operations specified to be called for that operation throws an exception.

2 The defaulted move and copy constructor, respectively, of pair shall be a constexpr function if and only if all required element-wise initializations for copy and move, respectively, would satisfy the requirements for a constexpr function.

3 If (is_trivially_destructible_v<T1> && is_trivially_destructible_v<T2>) is true, then the destructor of pair is trivial.

constexpr explicit(see below) pair();

Effects: Value-initializes first and second.

Remarks: This constructor shall not participate in overload resolution unless is_default_constructible_v<first_type> is true and is_default_constructible_v<second_type> is true. [Note: This behavior can be implemented by a constructor template with default template arguments. — end note]

The expression inside explicit evaluates to true if and only if either first_type or second_type is not implicitly default-constructible. [Note: This behavior can be implemented with a trait that checks whether a const first_type& or a const second_type& can be initialized with {}. — end note]

constexpr explicit(see below) pair(const T1& x, const T2& y);

Effects: Initializes first with x and second with y.

Remarks: This constructor shall not participate in overload resolution unless is_copy_constructible_v<first_type> is true and is_copy_constructible_v<second_type> is true. The expression inside explicit is equivalent to:
!is_convertible_v<const first_type&, first_type> ||
!is_convertible_v<const second_type&, second_type>

template<class U1, class U2> constexpr explicit(see below) pair(U1&& x, U2&& y);

Effects: Initializes first with std::forward<U1>(x) and second with std::forward<U2>(y).
Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<
first_type, U1&&> is true and is_constructible_v<second_type, U2&&> is true. The expression inside explicit is equivalent to:
!is_convertible_v<U1, first_type> || !is_convertible_v<U2, second_type>

template<class U1, class U2> constexpr explicit(see below) pair(const pair<U1, U2>& p);

Effects: Initializes members from the corresponding members of the argument.
Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<
first_type, const U1&> is true and is_constructible_v<second_type, const U2&> is true. The expression inside explicit is equivalent to:
!is_convertible_v<const U1&, first_type> || !is_convertible_v<const U2&, second_type>

template<class U1, class U2> constexpr explicit(see below) pair(pair<U1, U2>&& p);

Effects: Initializes first with std::forward<U1>(p.first) and second with std::forward<U2>(p.second).
Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<
first_type, U1&&> is true and is_constructible_v<second_type, U2&&> is true. The expression inside explicit is equivalent to:
!is_convertible_v<const U1&, first_type> || !is_convertible_v<const U2&, second_type>

template<class... Args1, class... Args2>
constexpr pair(piecewise_construct_t,
tuple<Args1...> first_args, tuple<Args2...> second_args);

Requires: is_constructible_v<first_type, Args1&&...> is true and is_constructible_v<second_type, Args2&&...> is true.
Effects: Initializes first with arguments of types Args1... obtained by forwarding the elements of first_args and initializes second with arguments of types Args2... obtained by forwarding the elements of second_args. (Here, forwarding an element x of type U within a tuple object means calling std::forward<U>(x).) This form of construction, whereby constructor arguments for first and second are each provided in a separate tuple object, is called piecewise construction.

constexpr pair& operator=(const pair& p);

Effects: Assigns p.first to first and p.second to second.
Remarks: This operator shall be defined as deleted unless is_copy_assignable_v<first_type> is true and is_copy_assignable_v<second_type> is true.
Returns: *this.

template<class U1, class U2> constexpr pair& operator=(const pair<U1, U2>& p);

Effects: Assigns p.first to first and p.second to second.
Remarks: This operator shall not participate in overload resolution unless is_assignable_v<
first_type, const U1&> is true and is_assignable_v<second_type, const U2&> is true.
Returns: *this.

constexpr pair& operator=(pair&& p) noexcept(see below);

Effects: Assigns to first with std::forward<first_type>(p.first) and to second with std::forward<second_type>(p.second).
Remarks: This operator shall not participate in overload resolution unless is_move_assignable_v<
first_type> is true and is_move_assignable_v<second_type> is true.
Remarks: The expression inside noexcept is equivalent to:

§ 20.4.2
is_nothrow_move_assignable_v<T1> && is_nothrow_move_assignable_v<T2>

Returns: *this.

```cpp
template<class U1, class U2> constexpr pair& operator=(pair<U1, U2>&& p);
```

Effects: Assigns to first with std::forward<U1>(p.first) and to second with std::forward<U2>(p.second).

Remarks: This operator shall not participate in overload resolution unless is_assignable_v<first_type, U1&> is true and is_assignable_v<second_type, U2&> is true.

Returns: *this.

```cpp
constexpr void swap(pair& p) noexcept;
```

Requires: first shall be swappable with (16.5.3.2) p.first and second shall be swappable with p.second.

Effects: Swaps first with p.first and second with p.second.

Remarks: The expression inside noexcept is equivalent to:

```cpp
is_nothrow_swappable_v<first_type> && is_nothrow_swappable_v<second_type>
```

### 20.4.3 Specialized algorithms

#### Example: In place of:

```cpp
return pair<int, double>(5, 3.1415926); // explicit types
```
a C++ program may contain:

```cpp
    return make_pair(5, 3.1415926); // types are deduced
```

— end example]

### 20.4.4 Tuple-like access to pair

```cpp
    template<class T1, class T2>
    struct tuple_size<pair<T1, T2>> : integral_constant<size_t, 2> { };  

    template<size_t I, class T1, class T2>
    struct tuple_element<I, pair<T1, T2>> {
        using type = see below; 
    };  

    Requires: I < 2. The program is ill-formed if I is out of bounds.

    Type: The type T1 if I == 0, otherwise the type T2.
```

```cpp
    template<size_t I, class T1, class T2>
    constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>& p) noexcept;  

    template<size_t I, class T1, class T2>
    constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>& p) noexcept;  

    template<size_t I, class T1, class T2>
    constexpr tuple_element_t<I, pair<T1, T2>>&& get(pair<T1, T2>&& p) noexcept;  

    template<size_t I, class T1, class T2>
    constexpr const tuple_element_t<I, pair<T1, T2>>&& get(const pair<T1, T2>&& p) noexcept;  

    Requires: T1 and T2 are distinct types. Otherwise, the program is ill-formed.

    Returns: A reference to p.first.
```

```cpp
    template<class T2, class T1>
    constexpr T1& get(pair<T1, T2>& p) noexcept;  

    template<class T2, class T1>
    constexpr const T1& get(const pair<T1, T2>& p) noexcept;  

    template<class T2, class T1>
    constexpr T1&& get(pair<T1, T2>&& p) noexcept;  

    template<class T2, class T1>
    constexpr const T1&& get(const pair<T1, T2>&& p) noexcept;  

    Requires: T1 and T2 are distinct types. Otherwise, the program is ill-formed.

    Returns: A reference to p.second.
```

### 20.4.5 Piecewise construction

```cpp
    struct piecewise_construct_t {
        explicit piecewise_construct_t() = default; 
    };  

    inline constexpr piecewise_construct_t piecewise_construct{};
```

The `struct piecewise_construct_t` is an empty class type used as a unique type to disambiguate constructor and function overloading. Specifically, `pair` has a constructor with `piecewise_construct_t` as the first argument, immediately followed by two `tuple` (20.5) arguments used for piecewise construction of the elements of the `pair` object.

§ 20.4.5 552
20.5 Tuples

20.5.1 In general

This subclause describes the tuple library that provides a tuple type as the class template `tuple` that can be instantiated with any number of arguments. Each template argument specifies the type of an element in the `tuple`. Consequently, tuples are heterogeneous, fixed-size collections of values. An instantiation of `tuple` with two arguments is similar to an instantiation of `pair` with the same two arguments. See 20.4.

20.5.2 Header `<tuple>` synopsis

```cpp
namespace std {
  // 20.5.3, class template tuple
  template<class... Types>
  class tuple;

  // 20.5.3.4, tuple creation functions
  inline constexpr unspecified ignore;
  template<class... TTypes>
  constexpr tuple<unwrap_ref_decay_t<TTypes>...> make_tuple(TTypes&&...);
  template<class... TTypes>
  constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&...) noexcept;
  template<class... TTypes>

  tuple(allocator_arg_t, Alloc, UTypes...) -> tuple<UTypes...>;

template<class Alloc, class T1, class T2>
  tuple(allocator_arg_t, Alloc, pair<T1, T2>) -> tuple<T1, T2>;

template<class Alloc, class... UTypes>
  tuple(allocator_arg_t, Alloc, tuple<UTypes...>) -> tuple<UTypes...>;

20.5.3.1 Construction

1 In the descriptions that follow, let i be in the range [0, sizeof...(Types)) in order, Ti be the ith type in Types, and Ui be the ith type in a template parameter pack named UTypes, where indexing is zero-based.

2 For each tuple constructor, an exception is thrown only if the construction of one of the types in Types throws an exception.
The defaulted move and copy constructor, respectively, of `tuple` shall be a constexpr function if and only if all required element-wise initializations for copy and move, respectively, would satisfy the requirements for a constexpr function. The defaulted move and copy constructor of `tuple<>` shall be constexpr functions.

If `is_trivially_destructible_v<T_i>` is true for all `T_i`, then the destructor of `tuple` is trivial.

```cpp
constexpr explicit(see below) tuple();
```

**Effects:** Value-initializes each element.

**Remarks:** This constructor shall not participate in overload resolution unless `is_default_constructible_v<T_i>` is true for all `i`. [Note: This behavior can be implemented with a constructor template with default template arguments. —end note] The expression inside `explicit` evaluates to `true` if and only if `T_i` is not implicitly default-constructible for at least one `i`. [Note: This behavior can be implemented with a trait that checks whether a `const T_i&` can be initialized with `{}`. —end note]

```cpp
constexpr explicit(see below) tuple(const Types&...);
```

**Effects:** Initializes each element with the value of the corresponding parameter.

**Remarks:** This constructor shall not participate in overload resolution unless `sizeof...(Types) >= 1` and `is_copy_constructible_v<T_i>` is true for all `i`. The expression inside `explicit` is equivalent to:

```cpp
!conjunction_v<is_convertible<const Types&, Types>...>
```

```cpp
tuple(const tuple& u) = default;
```

**Requires:** `is_copy_constructible_v<T_i>` is true for all `i`.

**Effects:** Initializes each element of `*this` with the corresponding element of `u`.

```cpp
tuple(tuple&& u) = default;
```

**Requires:** `is_move_constructible_v<T_i>` is true for all `i`.

**Effects:** For all `i`, initializes the `i`th element of `*this` with `std::forward<T_i>(get<i>(u))`.

```cpp
template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>& u);
```

**Effects:** Initializes each element of `*this` with the corresponding element of `u`.

**Remarks:** This constructor shall not participate in overload resolution unless

1. `sizeof...(Types) == sizeof...(UTypes)`
2. `is_constructible_v<T_i, const U&>` is true for all `i`, and
3. either `sizeof...(Types) != 1`, or (when `Types...` expands to `T` and `UTypes...` expands to `U`) `is_convertible_v<const tuple<U>&, T>`, `is_constructible_v<T, const tuple<U>&>`, and `is_same_v<T, U>` are all false.

The expression inside `explicit` is equivalent to:

```cpp
!conjunction_v<is_convertible<const UTypes&, Types>...>
```

```cpp
template<class... UTypes> constexpr explicit(see below) tuple(tuple<UTypes...>&& u);
```

**Effects:** For all `i`, initializes the `i`th element of `*this` with `std::forward<U_i>(get<i>(u))`.

**Remarks:** This constructor shall not participate in overload resolution unless

1. `sizeof...(Types) == sizeof...(UTypes)`
2. `is_constructible_v<T_i, U_i&&>` is true for all `i`, and
either sizeof...(Types) != 1, or (when Types... expands to T and UTypes... expands to U) is_convertible_v<tuple< U>, T>, is_constructible_v<T, tuple< U>>, and is_same_v< T, U> are all false.

The expression inside explicit is equivalent to:

\( \neg \text{conjunction}_v<\text{is_convertible}<\text{UTypes}, \text{Types}>... > \)

```
template<class U1, class U2> constexpr explicit(see below) tuple(const pair<U1, U2>& u);
```

**Effects:** Initializes the first element with u.first and the second element with u.second.

**Remarks:** This constructor shall not participate in overload resolution unless sizeof...(Types) == 2, is_constructible_v<T0, const U1&> is true and is_constructible_v<T1, const U2&> is true.

The expression inside explicit is equivalent to:

\( \neg \text{is_convertible}_v<\text{const U1&}, T0> \lor \neg \text{is_convertible}_v<\text{const U2&}, T1> \)

```
template<class U1, class U2> constexpr explicit(see below) tuple(pair<U1, U2>&& u);
```

**Effects:** Initializes the first element with std::forward<U1>(u.first) and the second element with std::forward<U2>(u.second).

**Remarks:** This constructor shall not participate in overload resolution unless sizeof...(Types) == 2, is_constructible_v<T0, U1&&> is true and is_constructible_v<T1, U2&&> is true.

The expression inside explicit is equivalent to:

\( \neg \text{is_convertible}_v<\text{U1}, T0> \lor \neg \text{is_convertible}_v<\text{U2}, T1> \)

```
template<class Alloc> constexpr tuple(allocator_arg_t, const Alloc& a);
```

```
template<class Alloc> constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, const Types&...);
```

```
template<class Alloc, class... UTypes> constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, UTypes&&...);
```

```
template<class Alloc> constexpr tuple(allocator_arg_t, const Alloc& a, const tuple&);
```

```
template<class Alloc> constexpr tuple(allocator_arg_t, const Alloc& a, tuple&&);
```

```
template<class Alloc, class U1, class U2> constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&);
```

```
template<class Alloc, class U1, class U2> constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&&);
```

**Requires:** Alloc shall meet the Cpp17Allocator requirements (Table 34).

**Effects:** Equivalent to the preceding constructors except that each element is constructed with uses-allocator construction (20.10.8.2).

### 20.5.3.2 Assignment

**[tuple.assign]**

For each tuple assignment operator, an exception is thrown only if the assignment of one of the types in Types
throws an exception. In the function descriptions that follow, let \( i \) be in the range \([0, \text{sizeof}(\text{Types})]\) in order, \( T_i \) be the \( i \)th type in Types, and \( U_i \) be the \( i \)th type in a template parameter pack named UTypes, where indexing is zero-based.

```
constexpr tuple& operator=(const tuple& u);
```

**Effects:** Assigns each element of u to the corresponding element of *this.
Remarks: This operator shall be defined as deleted unless `is_copy_assignable_v<T_i>` is true for all i.

Returns: `*this`.

```cpp
constexpr tuple& operator=(tuple&& u) noexcept;
```

Effects: For all i, assigns `std::forward<T_i>(get<i>(u))` to `get<i>(*this)`.

Remarks: This operator shall not participate in overload resolution unless `is_move_assignable_v<T_i>` is true for all i.

Remarks: The expression inside `noexcept` is equivalent to the logical AND of the following expressions:

\[
\text{is_nothrow_move_assignable_v<T_i>}
\]

where `T_i` is the `i`th type in `Types`.

Returns: `*this`.

```cpp
template<class... UTypes> constexpr tuple& operator=(const tuple<UTypes...>& u);
```

Effects: Assigns each element of `u` to the corresponding element of `*this`.

Remarks: This operator shall not participate in overload resolution unless `sizeof...(Types) == sizeof...(UTypes)` and `is_assignable_v<T_i&, const U_i&>` is true for all i.

Returns: `*this`.

```cpp
template<class U1, class U2> constexpr tuple& operator=(const pair<U1, U2>& u);
```

Effects: Assigns `u.first` to the first element of `*this` and `u.second` to the second element of `*this`.

Remarks: This operator shall not participate in overload resolution unless `sizeof...(Types) == 2` and `is_assignable_v<T_0&, const U1&>` is true for the first type `T_0` in `Types` and `is_assignable_v<T_1&, const U2&>` is true for the second type `T_1` in `Types`.

Returns: `*this`.

```cpp
template<class U1, class U2> constexpr tuple& operator=(pair<U1, U2>&& u);
```

Effects: Assigns `std::forward<U1>(u.first)` to the first element of `*this` and `std::forward<U2>(u.second)` to the second element of `*this`.

Remarks: This operator shall not participate in overload resolution unless `sizeof...(Types) == 2` and `is_assignable_v<T_0&, U1&&>` is true for the first type `T_0` in `Types` and `is_assignable_v<T_1&, U2&&>` is true for the second type `T_1` in `Types`.

Returns: `*this`.

20.5.3.3 swap

```cpp
constexpr void swap(tuple& rhs) noexcept;
```

Requires: Each element in `*this` shall be swappable with (16.5.3.2) the corresponding element in `rhs`.

Effects: Calls `swap` for each element in `*this` and its corresponding element in `rhs`.

Remarks: The expression inside `noexcept` is equivalent to the logical AND of the following expressions:

\[
\text{is_nothrow_swappable_v<T_i>}
\]

where `T_i` is the `i`th type in `Types`.

Throws: Nothing unless one of the element-wise `swap` calls throws an exception.

20.5.3.4 Tuple creation functions

In the function descriptions that follow, the members of a template parameter pack `XTypes` are denoted by `X_i` for `i` in `[0, sizeof...(XTypes))` in order, where indexing is zero-based.
template<class... TTypes>
constexpr tuple<unwrap_ref_decay_t<TTypes>...> make_tuple(TTypes&&... t);

Returns: tuple<unwrap_ref_decay_t<TTypes>...>(std::forward<TTypes>(t)...)．

[Example:
int i; float j;
make_tuple(1, ref(i), cref(j))
creates a tuple of type tuple<int, int&, const float&>. —end example]

template<class... TTypes>
constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&... t) noexcept;

Effects: Constructs a tuple of references to the arguments in t suitable for forwarding as arguments to a function. Because the result may contain references to temporary variables, a program shall ensure that the return value of this function does not outlive any of its arguments (e.g., the program should typically not store the result in a named variable).

Returns: tuple<TTypes&&...>(std::forward<TTypes>(t)...).

template<class... TTypes>
constexpr tuple<TTypes&...> tie(TTypes&... t) noexcept;

Returns: tuple<TTypes&...>(t...). When an argument in t is ignore, assigning any value to the corresponding tuple element has no effect.

[Example: tie functions allow one to create tuples that unpack tuples into variables. ignore can be used for elements that are not needed:

int i; std::string s;
tie(i, ignore, s) = make_tuple(42, 3.14, "C++");
// i == 42, s == "C++"
—end example]

template<class... Tuples>
constexpr tuple<CTypes...> tuple_cat(Tuples&&... tpls);

In the following paragraphs, let Ti be the i th type in Tuples, Ui be remove_reference_t<Ti>, and tp i be the i th parameter in the function parameter pack tpls, where all indexing is zero-based.

Requires: For all i, Ui shall be the type cvi tuple<Argsi>..., where cvi is the (possibly empty) i th cv-qualifier-seq and Argsi is the template parameter pack representing the element types in Ui. Let Aik be the k th type in Argsi. For all Aik the following requirements shall be met:

(9.1) — If Ti is deduced as an lvalue reference type, then is_constructible_v<Aik, cvi Aik&> == true otherwise
(9.2) — is_constructible_v<Aik, cvi Aik&&> == true.

Remarks: The types in CTypes shall be equal to the ordered sequence of the extended types Args0, ..., Args1, ..., Argsn−1, ..., Argsn,..., where n is equal to sizeof...(Tuples). Let ei,... be the i th ordered sequence of tuple elements of the resulting tuple object corresponding to the type sequence Argsi.

Returns: A tuple object constructed by initializing the k1 th type element eik in ei... with get<k1>(std::forward<Ti>(tp i)) for each valid k1 and each group ei in order.

[Note: An implementation may support additional types in the template parameter pack Tuples that support the tuple-like protocol, such as pair and array. —end note]

20.5.3.5 Calling a function with a tuple of arguments [tuple.apply]

template<class F, class Tuple>
constexpr decltype(auto) apply(F&& f, Tuple&& t);

Effects: Given the exposition-only function:

template<class F, class Tuple, size_t... I>
constexpr decltype(auto) apply-impl(F&& f, Tuple&& t, index_sequence<I>...)
{
// exposition only

§ 20.5.3.5 559
return `INVOKE`\((\text{std::forward\(F\)(f)}, \text{std::get\(I\)(\text{std::forward\(T\)(t)})...}; // see \text{20.14.3}
}

Equivalent to:

\[
\text{return } \text{apply-impl}\left(\text{std::forward\(F\)(f)}, \text{std::forward\(T\)(t)}, \text{make_index_sequence\(\text{tuple\_size\_v<\text{remove\_reference\_t\(T\)>}}\)}\right);\
\]

\[
\text{template<class } T, \text{ class } T\text{uple}\>
\text{constexpr } T \text{ make\_from\_tuple}(T\text{uple\&\& } t);\]

\text{Effects: Given the exposition-only function:}

\[
\text{template<class } T, \text{ class Tuple, size\_t... } I\>
\text{constexpr } T \text{ make\_from\_tuple\_impl}(\text{Tuple\&\& } t, \text{index\_sequence\(\text{I...}\)} ) \{ \text{ // exposition only} \\
\text{return } T(\text{get\(I\)}(\text{std::forward\(T\)(t)})...);\}
\]

Equivalent to:

\[
\text{return } \text{make\_from\_tuple\_impl\(...\!\!\!\!\!\!\!\!\!\!\!\!\!(T}\left(\text{forward\(T\)(t)}, \text{make_index_sequence\(\text{tuple\_size\_v<\text{remove\_reference\_t\(T\)>}}\)}\right);\}
\]

\text{[Note: The type of } T \text{ must be supplied as an explicit template parameter, as it cannot be deduced from the argument list. —end note]}

\section*{20.5.3.6 Tuple helper classes} [tuple.helper]

\text{template<class } T \text{> struct tuple\_size;}

\text{Remarks: All specializations of } \text{tuple\_size} \text{ shall meet the } Cpp17UnaryTypeTrait \text{ requirements (20.15.1)} \text{ with a base characteristic of } \text{integral\_constant\<size\_t, } N\text{> for some } N.

\text{template<... Types>}
\text{struct tuple\_size<tuple<Types...>> : public integral\_constant<size\_t, sizeof...<Types>> \{ \};}

\text{template<size\_t I, class... Types>
\text{struct tuple\_element<I, tuple<Types...>> \{}
\text{using type = TI;}
\text{\};}

\text{Requires: } I < \text{sizeof...<Types>}. \text{ The program is ill-formed if } I \text{ is out of bounds.}

\text{Type: } TI \text{ is the type of the } I^{th} \text{ element of } Types, \text{ where indexing is zero-based.}

\text{template<class } T \text{> struct tuple\_size<const } T\text{>;
\text{template<class } T \text{> struct tuple\_size<volatile } T\text{>;
\text{template<class } T \text{> struct tuple\_size<const volatile } T\text{>;

\text{Let } TS \text{ denote } \text{tuple\_size\<T\>} \text{ of the cv-unqualified type } T. \text{ If the expression } TS::\text{value} \text{ is well-formed when treated as an unevaluated operand, then each of the three templates shall meet the } Cpp17UnaryTypeTrait \text{ requirements (20.15.1)} \text{ with a base characteristic of}

\[
\text{integral\_constant<size\_t, TS::value>}
\]

\text{Otherwise, they shall have no member value.}

Access checking is performed as if in a context unrelated to } TS \text{ and } T. \text{ Only the validity of the immediate context of the expression is considered. [Note: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. —end note]}

\text{In addition to being available via inclusion of the } <\text{tuple}> \text{ header, the three templates are available when any of the headers } <\text{array}>, <\text{ranges}>, <\text{span}>, \text{ or } <\text{utility}> \text{ are included.}

\text{template<size\_t I, class } T \text{> struct tuple\_element<I, const } T\text{>;
\text{template<size\_t I, class } T \text{> struct tuple\_element<I, volatile } T\text{>;
template<
    size_t I, class T
> struct tuple_element<I, const volatile T> {

    Let TE denote \( \text{tuple_element}_t(I, T) \) of the cv-unqualified type \( T \). Then each of the three templates shall meet the \textit{Cpp17TransformationTrait} requirements (20.15.1) with a member typedef \textit{type} that names the following type:

    (7.1) — for the first specialization, \textit{add\_const\_t}\( <\text{TE}> \),
    (7.2) — for the second specialization, \textit{add\_volatile\_t}\( <\text{TE}> \), and
    (7.3) — for the third specialization, \textit{add\_cv\_t}\( <\text{TE}> \).

    In addition to being available via inclusion of the \textit{<tuple>} header, the three templates are available when any of the headers \textit{<array>}, \textit{<ranges>}, \textit{<span>}, or \textit{<utility>} are included.

20.5.3.7 Element access

\begin{verbatim}
template<
    size_t I, class... Types>
    constexpr tuple_element_t<I, tuple<Types...>>&
    get(tuple<Types...>& t) noexcept;

    template<
    size_t I, class... Types>
    constexpr tuple_element_t<I, tuple<Types...>>&&
    get(tuple<Types...>&& t) noexcept; // Note A

    template<
    size_t I, class... Types>
    constexpr const tuple_element_t<I, tuple<Types...>>&
    get(const tuple<Types...>& t) noexcept;

    template<
    size_t I, class... Types>
    constexpr const tuple_element_t<I, tuple<Types...>>&&
    get(const tuple<Types...>&& t) noexcept; // Note B
\end{verbatim}

1 Requires: \( I < \text{sizeof}(...(\text{Types})) \). The program is ill-formed if \( I \) is out of bounds.
2 Returns: A reference to the I\(^{th}\) element of \( t \), where indexing is zero-based.
3 \[ \text{Note A:} \] If a type \( T \) in \textit{Types} is some reference type \( X& \), the return type is \( X& \), not \( X&& \). However, if the element type is a non-reference type \( T \), the return type is \( T&& \). — end note
4 \[ \text{Note B:} \] Constness is shallow. If a type \( T \) in \textit{Types} is some reference type \( X& \), the return type is \( X& \), not \( \text{const } X& \). However, if the element type is a non-reference type \( T \), the return type is \( \text{const } T& \). This is consistent with how constness is defined to work for member variables of reference type. — end note

\begin{verbatim}
template<class T, class... Types>
    constexpr T&
    get(tuple<Types...>& t) noexcept;

    template<class T, class... Types>
    constexpr T&&
    get(tuple<Types...>&& t) noexcept;

    template<class T, class... Types>
    constexpr const T&
    get(const tuple<Types...>& t) noexcept;

    template<class T, class... Types>
    constexpr const T&&
    get(const tuple<Types...>&& t) noexcept;
\end{verbatim}

5 Requires: The type \( T \) occurs exactly once in \textit{Types}. Otherwise, the program is ill-formed.
6 Returns: A reference to the element of \( t \) corresponding to the type \( T \) in \textit{Types}.
7 \[ \text{Example:} \]

\begin{verbatim}
const tuple<int, const int, double, double>& t(1, 2, 3.4, 5.6);
const int& i1 = get<int>(t);    // OK. Not ambiguous. i1 == 1
const int& i2 = get<const int>(t); // OK. Not ambiguous. i2 == 2
const double& d = get<double>(t); // ERROR: ill-formed
\end{verbatim}

— end example

8 \[ \text{Note:} \] The reason \textit{get} is a non-member function is that if this functionality had been provided as a member function, code where the type depended on a template parameter would have required using the \textit{template} keyword. — end note

20.5.3.8 Relational operators

\begin{verbatim}
template<class... TTypes, class... UTypes>
    constexpr bool
    operator==(const tuple<TTypes...>&& t, const tuple<UTypes...>&& u);
\end{verbatim}

1 Requires: For all \( i \), where \( 0 <= i < \text{sizeof}(...(\text{TTypes})) \), \( \text{get}\langle i\rangle(t) == \text{get}\langle i\rangle(u) \) is a valid expression returning a type that is convertible to bool. \( \text{sizeof}(...(\text{TTypes})) == \text{sizeof}(...(\text{UTypes})) \).
Returns: true if \( \text{get}<i>(t) == \text{get}<i>(u) \) for all \( i \), otherwise false. For any two zero-length tuples \( e \) and \( f \), \( e == f \) returns true.

Effects: The elementary comparisons are performed in order from the zeroth index upwards. No comparisons or element accesses are performed after the first equality comparison that evaluates to false.

\[
\text{template<class... TTypes, class... UTypes>}
\]
\[
\text{constexpr bool operator!= (const tuple<TTypes...>& t, const tuple<UTypes...>& u);}
\]

Returns: \( ! (t == u) \).

\[
\text{template<class... TTypes, class... UTypes>}
\]
\[
\text{constexpr bool operator< (const tuple<TTypes...>& t, const tuple<UTypes...>& u);}
\]

Requires: For all \( i \), where \( 0 <= i \) and \( i < \text{sizeof...(TTypes)} \), both \( \text{get}<i>(t) < \text{get}<i>(u) \) and \( \text{get}<i>(u) < \text{get}<i>(t) \) are valid expressions returning types that are convertible to bool. \( \text{sizeof...(TTypes)} == \text{sizeof...(UTypes)} \).

Returns: The result of a lexicographical comparison between \( t \) and \( u \). The result is defined as:
\[
(\text{bool})(\text{get}<0>(t) < \text{get}<0>(u)) || (! (\text{bool})(\text{get}<0>(u) < \text{get}<0>(t)) && t_{\text{tail}} < u_{\text{tail}}),
\]
where \( r_{\text{tail}} \) for some tuple \( r \) is a tuple containing all but the first element of \( r \). For any two zero-length tuples \( e \) and \( f \), \( e < f \) returns false.

\[
\text{template<class... TTypes, class... UTypes>}
\]
\[
\text{constexpr bool operator> (const tuple<TTypes...>& t, const tuple<UTypes...>& u);}
\]

Returns: \( u < t \).

\[
\text{template<class... TTypes, class... UTypes>}
\]
\[
\text{constexpr bool operator<= (const tuple<TTypes...>& t, const tuple<UTypes...>& u);}
\]

Returns: \( ! (u < t) \).

\[
\text{template<class... TTypes, class... UTypes>}
\]
\[
\text{constexpr bool operator>= (const tuple<TTypes...>& t, const tuple<UTypes...>& u);}
\]

Returns: \( ! (t < u) \).

Note: The above definitions for comparison functions do not require \( t_{\text{tail}} \) (or \( u_{\text{tail}} \)) to be constructed. It may not even be possible, as \( t \) and \( u \) are not required to be copy constructible. Also, all comparison functions are short circuited; they do not perform element accesses beyond what is required to determine the result of the comparison.

--- end note ---

20.5.3.9 Tuple traits

\[
\text{template<class... Types, class Alloc>}
\]
\[
\struct \text{uses_allocator<tuple<Types...>, Alloc> : true_type { }};
\]

Requires: Alloc shall meet the Cpp17Allocator requirements (Table 34).

Note: Specialization of this trait informs other library components that tuple can be constructed with an allocator, even though it does not have a nested allocator_type. — end note ---

20.5.3.10 Tuple specialized algorithms

\[
\text{template<class... Types>}
\]
\[
\text{constexpr void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below);}
\]

Remarks: This function shall not participate in overload resolution unless \( \text{is\_swappable\_v<T> is true for every type T in Types. The expression inside noexcept is equivalent to:}
\]
\[
\text{noexcept(x.swap(y))}
\]

Effects: As if by \( x\_\text{swap}(y) \).

20.6 Optional objects

20.6.1 In general

This subclause describes class template optional that represents optional objects. An optional object is an object that contains the storage for another object and manages the lifetime of this contained object, if any.
The contained object may be initialized after the optional object has been initialized, and may be destroyed before the optional object has been destroyed. The initialization state of the contained object is tracked by the optional object.

20.6.2 Header `<optional>` synopsis

```cpp
namespace std {
    // 20.6.3, class template optional
template<class T>
    class optional;

    // 20.6.4, no-value state indicator
    struct nullopt_t{see below};
    inline constexpr nullopt_t nullopt(unspecified);

    // 20.6.5, class bad_optional_access
class bad_optional_access;

    // 20.6.6, relational operators
template<class T, class U>
    constexpr bool operator==(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator!=(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator<(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator>(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator<=(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator>=(const optional<T>&, const optional<U>&);

    // 20.6.7, comparison with nullopt
    template<class T> constexpr bool operator==(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator==(nullopt_t, const optional<T>&) noexcept;
    template<class T> constexpr bool operator!=(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator!=(nullopt_t, const optional<T>&) noexcept;
    template<class T> constexpr bool operator<(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator<(nullopt_t, const optional<T>&) noexcept;
    template<class T> constexpr bool operator>(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator>(nullopt_t, const optional<T>&) noexcept;
    template<class T> constexpr bool operator<=(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator<=(nullopt_t, const optional<T>&) noexcept;
    template<class T> constexpr bool operator>=(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator>=(nullopt_t, const optional<T>&) noexcept;

    // 20.6.8, comparison with T
    template<class T, class U> constexpr bool operator==(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator==(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator!=(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator!=(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator<(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator<(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator>(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator>(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator<=(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator<=(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator>=(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator>=(const T&, const optional<U>&);

    // 20.6.9, specialized algorithms
    template<class T>
        void swap(optional<T>&, optional<T>&) noexcept(see below);
```
template<class T>
constexpr optional<see below> make_optional(T&&);

template<class T, class... Args>
constexpr optional<T> make_optional(Args&&... args);

template<class T, class U, class... Args>
constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);

// 20.6.10, hash support
struct hash
{
    template<class T> struct hash_optional<T>;
}

20.6.3 Class template optional

namespace std {
    template<class T>
    class optional {
    public:
        using value_type = T;

        // 20.6.3.1, constructors
        constexpr optional() noexcept;
        constexpr optional(nullopt_t) noexcept;
        constexpr optional(const optional&);
        constexpr optional(optional&&) noexcept(see below);
        template<class... Args>
        constexpr explicit optional(in_place_t, Args&&...);
        template<class U, class... Args>
        constexpr explicit optional(in_place_t, initializer_list<U>, Args&&...);
        template<class U = T> explicit(see below) constexpr optional(U&&);
        template<class U> explicit(see below) optional(const optional<U>&);
        template<class U> explicit(see below) optional(optional<U>&&);

        // 20.6.3.2, destructor
        ~optional();

        // 20.6.3.3, assignment
        optional& operator=(nullopt_t) noexcept;
        optional& operator=(const optional&);
        optional& operator=(optional&&) noexcept(see below);
        template<class U = T> optional& operator=(U&&);
        template<class U> optional& operator=(const optional<U>&);
        template<class U> optional& operator=(optional<U>&&);
        template<class... Args> T& emplace(Args&&...);
        template<class U, class... Args> T& emplace(initializer_list<U>, Args&&...);

        // 20.6.3.4, swap
        void swap(optional&) noexcept(see below);

        // 20.6.3.5, observers
        constexpr const T* operator->() const;
        constexpr T* operator->();
        constexpr const T& operator*() const&;
        constexpr T& operator*() &;
        constexpr T&& operator*() &&;
        constexpr const T&& operator*() const&&;
        constexpr std::optional operator bool() const noexcept;
        constexpr bool has_value() const noexcept;
        constexpr const T& value() const;
        constexpr T& value() &;
        constexpr T&& value() &&;
    }
}
### Constructors

**optional()**

```cpp
constexpr optional() noexcept;
```

**optional(nullopt_t)**

```cpp
constexpr optional(nullopt_t) noexcept;
```

1. **Ensures:** `*this` does not contain a value.

2. **Remarks:** No contained value is initialized. For every object type `T` these constructors shall be constexpr constructors (9.1.5).

**optional(const optional& rhs)**

```cpp
constexpr optional(const optional& rhs);
```

3. **Effects:** If `rhs` contains a value, initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `*rhs`.

4. **Ensures:** `bool(rhs) == bool(*this)`.

5. **Throws:** Any exception thrown by the selected constructor of `T`.

6. **Remarks:** This constructor shall be defined as deleted unless `is_copy_constructible_v<T>` is true. If `is_trivially_copy_constructible_v<T>` is true, this constructor is trivial.

**optional(optional&& rhs) noexcept(see below)**

7. **Effects:** If `rhs` contains a value, initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `std::move(*rhs)`. `bool(rhs)` is unchanged.

8. **Ensures:** `bool(rhs) == bool(*this)`.

9. **Throws:** Any exception thrown by the selected constructor of `T`.

10. **Remarks:** The expression inside `noexcept` is equivalent to `is_nothrow_move_constructible_v<T>`. This constructor shall not participate in overload resolution unless `is_move_constructible_v<T>` is true. If `is_trivially_move_constructible_v<T>` is true, this constructor is trivial.

**optional(in_place_t, Args&&... args)**

```cpp
template<class... Args> constexpr explicit optional(in_place_t, Args&&... args);
```

11. **Effects:** Initializes the contained value as if direct-non-list-initializing an object of type `T` with the arguments `std::forward<Args>(args)`.

12. **Ensures:** `*this` contains a value.

13. **Throws:** Any exception thrown by the selected constructor of `T`. 

---

1. Any instance of `optional<T>` at any given time either contains a value or does not contain a value. When an instance of `optional<T>` contains a value, it means that an object of type `T`, referred to as the optional object’s contained value, is allocated within the storage of the optional object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate its contained value. The contained value shall be allocated in a region of the `optional<T>` storage suitably aligned for the type `T`. When an object of type `optional<T>` is contextually converted to `bool`, the conversion returns `true` if the object contains a value; otherwise the conversion returns `false`.

2. Member `val` is provided for exposition only. When an `optional<T>` object contains a value, `val` points to the contained value.

3. `T` shall be an object type other than `cv in_place_t` or `cv nullopt_t` and shall meet the `Cpp17Destructible` requirements (Table 30).
Remarks: If T's constructor selected for the initialization is a constexpr constructor, this constructor shall be a constexpr constructor. This constructor shall not participate in overload resolution unless is_constructible_v<T, Args...> is true.

```cpp
template<class U, class... Args>
constexpr explicit optional(in_place_t, initializer_list<U> il, Args&&... args);
```

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the arguments il, std::forward<Args>(args)....

Ensures: *this contains a value.

Thros: Any exception thrown by the selected constructor of T.

Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<T, initializer_list<U>&, Args&&...> is true. If T's constructor selected for the initialization is a constexpr constructor, this constructor shall be a constexpr constructor.

```cpp
template<class U = T> explicit(optional(U&& v);
```

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the expression std::forward<U>(v).

Ensures: *this contains a value.

Thros: Any exception thrown by the selected constructor of T.

Remarks: If T's selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor. This constructor shall not participate in overload resolution unless is_constructible_v<T, U&&> is true, is_same_v<remove_cvref_t<U>, in_place_t> is false, and is_same_v<remove_cvref_t<U>, optional> is false. The expression inside explicit is equivalent to:

```cpp
!is_convertible_v<const optional<U>&, T>
```

```cpp
template<class U> explicit(const optional<U>& rhs);
```

Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object of type T with the expression *rhs.

Ensures: bool(rhs) == bool(*this).

Thros: Any exception thrown by the selected constructor of T.

Remarks: This constructor shall not participate in overload resolution unless

(26.1) is_constructible_v<T, const optional<U>&> is true,
(26.2) is_constructible_v<T, optional<U>&> is false,
(26.3) is_constructible_v<T, optional<U>&&> is false,
(26.4) is_constructible_v<T, const optional<U>&> is false,
(26.5) is_convertible_v<optional<U>&, T> is false,
(26.6) is_constructible_v<optional<U>&&, T> is false,
(26.7) is_convertible_v<const optional<U>&, T> is false, and
(26.8) is_convertible_v<const optional<U>&&, T> is false.

The expression inside explicit is equivalent to:

```cpp
!is_convertible_v<const optional<U>&, T>
```

```cpp
template<class U> explicit(optional(optional<U>&& rhs);
```

Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object of type T with the expression std::move(*rhs). bool(rhs) is unchanged.

Ensures: bool(rhs) == bool(*this).

Thros: Any exception thrown by the selected constructor of T.

Remarks: This constructor shall not participate in overload resolution unless

(30.1) is_constructible_v<T, U&&> is true,
— \texttt{is\_constructible\_v<T, \text{optional}<U>&>} is false,
— \texttt{is\_constructible\_v<T, \text{optional}<U>&&>} is false,
— \texttt{is\_constructible\_v<T, \text{const optional}<U>&>} is false,
— \texttt{is\_constructible\_v<T, \text{const optional}<U>&&>} is false,
— \texttt{is\_convertible\_v<\text{optional}<U>&, T>} is false,
— \texttt{is\_convertible\_v<\text{optional}<U>&&}, T>} is false,
— \texttt{is\_convertible\_v<\text{const optional}<U>&, T>} is false, and
— \texttt{is\_convertible\_v<\text{const optional}<U>&&}, T>} is false.

The expression inside \texttt{explicit} is equivalent to:
\[!\texttt{is\_convertible\_v<U, T>}\]

\section*{20.6.3.2 Destructor \hfill [optional.dtor]}
\begin{verbatim}
~optional();
\end{verbatim}

\begin{itemize}
\item \textit{Effects:} If \texttt{is\_trivially\_destructible\_v<T> != true} and \texttt{*this} contains a value, calls
val->\texttt{T::~T();}
\item \textit{Remarks:} If \texttt{is\_trivially\_destructible\_v<T>} is \texttt{true}, then this destructor is trivial.
\end{itemize}

\section*{20.6.3.3 Assignment \hfill [optional.assign]}
\begin{verbatim}
optional<T>& operator=(nullopt_t) noexcept;
\end{verbatim}

\begin{itemize}
\item \textit{Effects:} If \texttt{*this} contains a value, calls \texttt{val->\texttt{T::~T();}} to destroy the contained value; otherwise no effect.
\item \textit{Returns:} \texttt{*this}.
\item \textit{Ensures:} \texttt{*this} does not contain a value.
\end{itemize}

\begin{verbatim}
constexpr optional<T>& operator=(const optional& rhs);
\end{verbatim}

\begin{itemize}
\item \textit{Effects:} See Table 40.
\end{itemize}

Table 40: \texttt{optional::operator=(const optional&)} effects \hfill [tab:optional.assign.copy]

<table>
<thead>
<tr>
<th>rhs contains a value</th>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>assigns \texttt{rhs} to the contained value</td>
<td>initializes the contained value as if direct-non-list-initializing an object of type \texttt{T} with \texttt{*rhs}</td>
<td></td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling \texttt{val-&gt;\texttt{T::~T();}}</td>
<td>no effect</td>
</tr>
</tbody>
</table>

\begin{itemize}
\item \textit{Returns:} \texttt{*this}.
\item \textit{Ensures:} \texttt{bool(rhs) == bool(*this)}.
\item \textit{Remarks:} If any exception is thrown, the result of the expression \texttt{bool(*this)} remains unchanged. If an exception is thrown during the call to \texttt{T}’s copy constructor, no effect. If an exception is thrown during the call to \texttt{T}’s copy assignment, the state of its contained value is as defined by the exception safety guarantee of \texttt{T}’s copy assignment. This operator shall be defined as deleted unless \texttt{is\_copy\_constructible\_v<T> is true} and \texttt{is\_copy\_assignable\_v<T> is true}. If \texttt{is\_trivially\_copy\_constructible\_v<T> \&\& is\_trivially\_copy\_assignable\_v<T> \&\& is\_trivially\_destructible\_v<T> is true}, this assignment operator is trivial.
\end{itemize}

\begin{verbatim}
constexpr optional& operator=(optional&& rhs) noexcept(see below);
\end{verbatim}

\begin{itemize}
\item \textit{Effects:} See Table 41. The result of the expression \texttt{bool(rhs)} remains unchanged.
\item \textit{Returns:} \texttt{*this}.
\item \textit{Ensures:} \texttt{bool(rhs) == bool(*this)}.
\end{itemize}
Table 41: `optional::operator=(optional&&)` effects

<table>
<thead>
<tr>
<th>rhs contains a value</th>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>assigns <code>std::move(*rhs)</code> to the contained value</td>
<td>initializes the contained value as if direct-non-list-initializing an object of type <code>T</code> with <code>std::move(*rhs)</code></td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling <code>val-&gt;T::~T()</code></td>
<td>no effect</td>
</tr>
</tbody>
</table>

Remarks: The expression inside `noexcept` is equivalent to:

```
  is_nothrow_move_assignable_v<T> && is_nothrow_move_constructible_v<T>
```

If any exception is thrown, the result of the expression `bool(*this)` remains unchanged. If an exception is thrown during the call to `T`'s move constructor, the state of `*rhs.val` is determined by the exception safety guarantee of `T`'s move constructor. If an exception is thrown during the call to `T`'s move assignment, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of `T`'s move assignment.

This operator shall not participate in overload resolution unless `is_move_constructible_v<T>` is true and `is_move_assignable_v<T>` is true. If `is_trivially_move_constructible_v<T> && is_trivially_move_assignable_v<T> && is_trivially_destructible_v<T>` is true, this assignment operator is trivial.

```
template<class U = T> optional<T>& operator=(U&& v);
```

Effects: If `*this` contains a value, assigns `std::forward<U>(v)` to the contained value; otherwise initializes the contained value as if direct-non-list-initializing object of type `T` with `std::forward<U>(v)`.

Returns: `*this`.

Ensures: `*this` contains a value.

Remarks: If any exception is thrown, the result of the expression `bool(*this)` remains unchanged. If an exception is thrown during the call to `T`'s constructor, the state of `v` is determined by the exception safety guarantee of `T`'s constructor. If an exception is thrown during the call to `T`'s assignment, the state of `*val` and `v` is determined by the exception safety guarantee of `T`'s assignment. This function shall not participate in overload resolution unless `is_same_v<remove_cvref_t<U>, optional>` is false, `conjunction_v<is_scalar<T>, is_same<T, decay_t<U>>>` is false, `is_constructible_v<T, U>` is true, and `is_assignable_v<T&, U>` is true.

```
template<class U> optional<T>& operator=(const optional<U>& rhs);
```

Effects: See Table 42.

Table 42: `optional::operator=(const optional<U>&)` effects

<table>
<thead>
<tr>
<th>rhs contains a value</th>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>assigns <code>*rhs</code> to the contained value</td>
<td>initializes the contained value as if direct-non-list-initializing an object of type <code>T</code> with <code>*rhs</code></td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling <code>val-&gt;T::~T()</code></td>
<td>no effect</td>
</tr>
</tbody>
</table>

Returns: `*this`.

Ensures: `bool(rhs) == bool(*this)`.

Remarks: If any exception is thrown, the result of the expression `bool(*this)` remains unchanged. If an exception is thrown during the call to `T`'s constructor, the state of `*rhs.val` is determined by the exception safety guarantee of `T`'s constructor. If an exception is thrown during the call to `T`'s
assignment, the state of \(*val\) and \(*\text{rhs.val}\) is determined by the exception safety guarantee of \(T\)'s assignment. This function shall not participate in overload resolution unless

\begin{align*}
(20.1) & \quad \text{is}\_\text{constructible}_v<T, \text{const } U&> \text{ is true}, \\
(20.2) & \quad \text{is}\_\text{assignable}_v<T&, \text{const } U&> \text{ is true}, \\
(20.3) & \quad \text{is}\_\text{constructible}_v<T, \text{optional } U>& \text{ is false}, \\
(20.4) & \quad \text{is}\_\text{constructible}_v<T, \text{optional } U>&& \text{ is false}, \\
(20.5) & \quad \text{is}\_\text{constructible}_v<T, \text{const } \text{optional } U>& \text{ is false}, \\
(20.6) & \quad \text{is}\_\text{constructible}_v<T, \text{const } \text{optional } U>&& \text{ is false}, \\
(20.7) & \quad \text{is}\_\text{convertible}_v<\text{optional } U>&, T \text{ is false}, \\
(20.8) & \quad \text{is}\_\text{convertible}_v<\text{optional } U>&& \text{ is false}, \\
(20.9) & \quad \text{is}\_\text{convertible}_v<\text{const } \text{optional } U>&, T \text{ is false}, \\
(20.10) & \quad \text{is}\_\text{convertible}_v<\text{const } \text{optional } U>&& \text{ is false}, \quad \text{and} \\
(20.11) & \quad \text{is}\_\text{assignable}_v<T&, \text{optional } U&> \text{ is false}, \\
(20.12) & \quad \text{is}\_\text{assignable}_v<T&, \text{optional } U>&& \text{ is false}, \\
(20.13) & \quad \text{is}\_\text{assignable}_v<T&, \text{const } \text{optional } U>& \text{ is false}, \quad \text{and} \\
(20.14) & \quad \text{is}\_\text{assignable}_v<T&, \text{const } \text{optional } U>&& \text{ is false}.
\end{align*}

\[\text{template<class } U\text{> optional<T>& operator=(optional<U>&& rhs);}\]

**Effects:** See Table 43. The result of the expression `bool(rhs)` remains unchanged.

Table 43: `optional::operator=(optional<U>&&)` effects

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textbf{rhs contains a value}</td>
<td>assigns <code>std::move(*rhs)</code> to the contained value</td>
</tr>
<tr>
<td>\textbf{rhs does not contain a value}</td>
<td>destroys the contained value by calling <code>val-&gt;T::~T()</code></td>
</tr>
</tbody>
</table>

**Returns:** `*this`.

**Ensures:** `bool(rhs) == bool(*this)`.

**Remarks:** If any exception is thrown, the result of the expression `bool(*this)` remains unchanged. If an exception is thrown during the call to \(T\)'s constructor, the state of \(*\text{rhs.val}\) is determined by the exception safety guarantee of \(T\)'s constructor. If an exception is thrown during the call to \(T\)'s assignment, the state of \(*val\) and \(*\text{rhs.val}\) is determined by the exception safety guarantee of \(T\)'s assignment. This function shall not participate in overload resolution unless

\begin{align*}
(24.1) & \quad \text{is}\_\text{constructible}_v<T, U> \text{ is true}, \\
(24.2) & \quad \text{is}\_\text{assignable}_v<T&, U> \text{ is true}, \\

\]

### 20.6.3.4 Swap

\[
\begin{align*}
\text{void swap(optional& rhs) noexcept(see below);} \\
\hspace{1cm} \text{Requires: Lvalues of type T shall be swappable and is_move_constructible_v<T> is true.}\end{align*}
\]
\[
\begin{align*}
\text{Effects: See Table 44.}\end{align*}
\]

Table 44: optional::swap(optional&) effects

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>calls swap(*(*this), *rhs)</td>
</tr>
<tr>
<td></td>
<td>initializes the contained value of *this as if direct-non-list-initializing an object of type T with the expression std::move(*rhs), followed by rhs.val-&gt;T::~T(); postcondition is that *this contains a value and rhs does not contain a value</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>initializes the contained value of rhs as if direct-non-list-initializing an object of type T with the expression std::move(*(*this)), followed by val-&gt;T::~T(); postcondition is that *this does not contain a value and rhs contains a value</td>
</tr>
<tr>
<td></td>
<td>no effect</td>
</tr>
</tbody>
</table>

§ 20.6.3.4 570
Throws: Any exceptions thrown by the operations in the relevant part of Table 44.
Remarks: The expression inside noexcept is equivalent to:

\[
\text{is_nothrow_move_constructible_v<T> } \&\& \text{ is_nothrow_swappable_v<T>}
\]

If any exception is thrown, the results of the expressions bool(*this) and bool(rhs) remain unchanged. If an exception is thrown during the call to function swap, the state of *val and *rhs.val is determined by the exception safety guarantee of swap for lvalues of T. If an exception is thrown during the call to T’s move constructor, the state of *val and *rhs.val is determined by the exception safety guarantee of T’s move constructor.

### 20.6.3.5 Observers

```cpp
constexpr const T* operator->() const;
constexpr T* operator->();

Requires: *this contains a value.
Returns: val.
Throws: Nothing.
Remarks: These functions shall be constexpr functions.
```

```cpp
constexpr const T& operator*() const&;
constexpr T& operator*() &;

Requires: *this contains a value.
Returns: *val.
Throws: Nothing.
Remarks: These functions shall be constexpr functions.
```

```cpp
constexpr T&& operator*() &&;
constexpr const T&& operator*() const&&;

Requires: *this contains a value.
Effects: Equivalent to:

\[
\text{return std::move(*val)}
\]
```

```cpp
constexpr explicit operator bool() const noexcept;

Returns: true if and only if *this contains a value.
Remarks: This function shall be a constexpr function.
```

```cpp
constexpr bool has_value() const noexcept;

Returns: true if and only if *this contains a value.
Remarks: This function shall be a constexpr function.
```

```cpp
constexpr const T& value() const&;
constexpr T& value() &;

Effects: Equivalent to:

\[
\text{return bool(*this) } ? \text{*val : throw bad_optional_access();}
\]
```

```cpp
constexpr T&& value() &&;
constexpr const T&& value() const&&;

Effects: Equivalent to:

\[
\text{return bool(*this) } ? \text{std::move(*val) : throw bad_optional_access();}
\]
```

```cpp
template<class U> constexpr T value_or(U&& v) const&;

Effects: Equivalent to:

\[
\text{return bool(*this) } ? \text{*this : static_cast<T>(std::forward<U>(v))};
\]
```

Remarks: If is_copy_constructible_v<T> \&\& is_convertible_v<U\&, T> is false, the program is ill-formed.
template<
class U>
constexpr T
value_or(U&& v) &&;

Effects: Equivalent to:
return
bool(*this) ? std::move(**this) : static_cast<T>(std::forward<U>(v));

Remarks: If is_move_constructible_v<T> && is_convertible_v<
U&&, T> is false, the program is ill-formed.

20.6.3.6 Modifiers
void
reset() noexcept;

Effects: If *this contains a value, calls val->T::~T() to destroy
the contained value; otherwise no effect.

Ensures: *this does not contain a value.

20.6.4 No-value state indicator

struct nullopt_t{\textit{see below}};
inline constexpr nullopt_t
nullopt(unspecified);

The struct nullopt_t is an empty class type used as a unique type
to indicate the state of not containing a value for optional
objects. In particular, optional<T> has a constructor with nullopt_t
as a single argument; this indicates that an optional object
not containing a value shall be constructed.

Type nullopt_t shall not have a default constructor or an
initializer-list constructor, and shall not be an
aggregate.

20.6.5 Class bad_optional_access

class
bad_optional_access : public exception {
public:
    const char* what() const noexcept override;
};

The class bad_optional_access defines the type of objects thrown as exceptions
to report the situation where an attempt is made to access the
value of an optional object that does not contain a value.

Returns: An implementation-defined ntbs.

20.6.6 Relational operators

template<class T, class U>
constexpr bool
operator==(const optional<T>& x, const optional<U>& y);

Requires: The expression *x == *y shall be well-formed and its result shall be
convertible to bool.
[Note: T need not be \textit{Cpp17EqualityComparable}. — end note]

Returns: If bool(x) \texttt{!} bool(y), false; otherwise if bool(x) \texttt{==} false, true;
otherwise *x \texttt{==} *y.

Remarks: Specializations of this function template for which *x \texttt{==} *y
shall be constexpr functions.

template<class T, class U>
constexpr bool
operator!=(const optional<T>& x, const optional<U>& y);

Requires: The expression *x \texttt{!=} *y shall be well-formed and its result shall
be convertible to bool.

Returns: If bool(x) \texttt{!} bool(y), true; otherwise, if bool(x) \texttt{==} false, false;
otherwise *x \texttt{!=} *y.

Remarks: Specializations of this function template for which *x \texttt{!=} *y
shall be constexpr functions.

template<class T, class U>
constexpr bool
operator<(const optional<T>& x, const optional<U>& y);

Requires: *x \texttt{<} *y shall be well-formed and its result shall
be convertible to bool.

Returns: If !y, false; otherwise, if !x, true; otherwise *x \texttt{<} *y.

Remarks: Specializations of this function template for which *x \texttt{<} *y
shall be constexpr functions.
template<class T, class U> constexpr bool operator>(const optional<T>& x, const optional<U>& y);

Requires: The expression \( *x > *y \) shall be well-formed and its result shall be convertible to \( \text{bool} \).

Returns: If \(!x\), \( \text{false} \); otherwise, if \(!y\), \( \text{true} \); otherwise \( *x > *y \).

Remarks: Specializations of this function template for which \( *x > *y \) is a core constant expression shall be constexpr functions.

template<class T, class U> constexpr bool operator<=(const optional<T>& x, const optional<U>& y);

Requires: The expression \( *x <= *y \) shall be well-formed and its result shall be convertible to \( \text{bool} \).

Returns: If \(!x\), \( \text{true} \); otherwise, if \(!y\), \( \text{false} \); otherwise \( *x <= *y \).

Remarks: Specializations of this function template for which \( *x <= *y \) is a core constant expression shall be constexpr functions.

template<class T, class U> constexpr bool operator>=(const optional<T>& x, const optional<U>& y);

Requires: The expression \( *x >= *y \) shall be well-formed and its result shall be convertible to \( \text{bool} \).

Returns: If \(!y\), \( \text{true} \); otherwise, if \(!x\), \( \text{false} \); otherwise \( *x >= *y \).

Remarks: Specializations of this function template for which \( *x >= *y \) is a core constant expression shall be constexpr functions.

20.6.7 Comparison with nullopt

(template<class T> constexpr bool operator==(const optional<T>& x, nullopt_t) noexcept;template<class T> constexpr bool operator==(nullopt_t, const optional<T>& x) noexcept;

1 Returns: \(!x\).

template<class T> constexpr bool operator!=(const optional<T>& x, nullopt_t) noexcept;template<class T> constexpr bool operator!=(nullopt_t, const optional<T>& x) noexcept;

2 Returns: \( \text{bool}(x) \).

template<class T> constexpr bool operator<(const optional<T>& x, nullopt_t) noexcept;template<class T> constexpr bool operator<(nullopt_t, const optional<T>& x) noexcept;

3 Returns: \( \text{false} \).

template<class T> constexpr bool operator<=(const optional<T>& x, nullopt_t) noexcept;template<class T> constexpr bool operator<=(nullopt_t, const optional<T>& x) noexcept;

4 Returns: \( \text{false} \).

template<class T> constexpr bool operator>=(const optional<T>& x, nullopt_t) noexcept;template<class T> constexpr bool operator>=(nullopt_t, const optional<T>& x) noexcept;

5 Returns: \( \text{false} \).

20.6.8 Comparison with T

(template<class T, class U> constexpr bool operator==(const optional<T>& x, const U& v);

1 Requires: The expression \( *x == v \) shall be well-formed and its result shall be convertible to \( \text{bool} \).

[Note: \( T \) need not be \text{Cpp17EqualityComparable}. — end note]
2 Effects: Equivalent to: return bool(x) ? *x == v : false;

3 template<class T, class U> constexpr bool operator==(const T& v, const optional<U>& x);
   Requires: The expression v == *x shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? v == *x : false;

4 template<class T, class U> constexpr bool operator==(const optional<T>& x, const U& v);
   Requires: The expression *x != v shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? v != *x : true;

5 template<class T, class U> constexpr bool operator!=(const optional<T>& x, const U& v);
   Requires: The expression v != *x shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? v != *x : true;

6 template<class T, class U> constexpr bool operator!=(const T& v, const optional<U>& x);
   Requires: The expression *x != v shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? *x != v : true;

7 template<class T, class U> constexpr bool operator<(const optional<T>& x, const U& v);
   Requires: The expression *x < v shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? *x < v : true;

8 template<class T, class U> constexpr bool operator<(const T& v, const optional<U>& x);
   Requires: The expression v < *x shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? v < *x : true;

9 template<class T, class U> constexpr bool operator>(const optional<T>& x, const U& v);
   Requires: The expression *x > v shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? *x > v : false;

10 template<class T, class U> constexpr bool operator>(const T& v, const optional<U>& x);
    Requires: The expression v > *x shall be well-formed and its result shall be convertible to bool.
    Effects: Equivalent to: return bool(x) ? v > *x : false;

11 template<class T, class U> constexpr bool operator<=(const optional<T>& x, const U& v);
   Requires: The expression *x <= v shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? *x <= v : true;

12 template<class T, class U> constexpr bool operator<=(const T& v, const optional<U>& x);
   Requires: The expression v <= *x shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? v <= *x : false;

13 template<class T, class U> constexpr bool operator>=(const optional<T>& x, const U& v);
   Requires: The expression *x >= v shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? *x >= v : false;

14 template<class T, class U> constexpr bool operator>=(const T& v, const optional<U>& x);
   Requires: The expression v >= *x shall be well-formed and its result shall be convertible to bool.
   Effects: Equivalent to: return bool(x) ? v >= *x : true;

15 template<class T> void swap(optional<T>& x, optional<T>& y) noexcept(noexcept(x.swap(y)));
   Effects: Calls x.swap(y).
   Remarks: This function shall not participate in overload resolution unless is_move_constructible_<
             v<T> is true and is_swappable_v<T> is true.

16 template<class T> constexpr optional<decay_t<T>> make_optional(T&& v);
   Returns: optional<decay_t<T>>((std::forward<T>(v)).

20.6.9 Specialized algorithms

2 template<class T> void swap(optional<T>& x, optional<T>& y) noexcept(noexcept(x.swap(y)));
   Effects: Calls x.swap(y).
   Remarks: This function shall not participate in overload resolution unless is_move_constructible_<
            v<T> is true and is_swappable_v<T> is true.

3 template<class T> constexpr optional<decay_t<T>> make_optional(T&& v);
   Returns: optional<decay_t<T>>((std::forward<T>(v)).
template<class T, class... Args>
constexpr optional<T> make_optional(Args&&... args);

Effects: Equivalent to: return optional<T>(in_place, std::forward<Args>(args)...);

Effects: Equivalent to: return optional<T>(in_place, il, std::forward<Args>(args)...);

20.6.10 Hash support

template<class T> struct hash<optional<T>>;

The specialization hash<optional<T>> is enabled (20.14.18) if and only if hash<remove_const_t<T>> is enabled. When enabled, for an object o of type optional<T>, if bool(o) == true, then hash<optional<T>>()(o) shall evaluate to the same value as hash<remove_const_t<T>>()(o); otherwise it evaluates to an unspecified value. The member functions are not guaranteed to be noexcept.

20.7 Variants

20.7.1 In general

A variant object holds and manages the lifetime of a value. If the variant holds a value, that value’s type has to be one of the template argument types given to variant. These template arguments are called alternatives.

20.7.2 Header <variant> synopsis

namespace std {

// 20.7.3, class template
template<class... Types>
class variant;

// 20.7.4, variant helper classes

template<class T> struct variant_size;       // not defined
template<class T> struct variant_size<const T>;

template<class... Types>
void swap(variant<Types...>&, variant<Types...>&) noexcept(see below);

// 20.7.11, class bad_variant_access
class bad_variant_access;
Any instance of `variant` at any given time either holds a value of one of its alternative types or holds no value. When an instance of `variant` holds a value of alternative type `T`, it means that a value of type `T`, referred to as the `variant` object’s contained value, is allocated within the storage of the `variant` object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the contained value. The contained value shall be allocated in a region of the `variant` storage suitably aligned for all types in `Types`.  

---

§ 20.7.3
All types in \texttt{Types} shall be (possibly cv-qualified) object types that are not arrays.

A program that instantiates the definition of \texttt{variant} with no template arguments is ill-formed.

## 20.7.3.1 Constructors

In the descriptions that follow, let \( i \) be in the range \([0, \text{sizeof}...(\text{Types}))\), and \( T_i \) be the \( i^{\text{th}} \) type in \texttt{Types}.

\begin{verbatim}
constexpr \texttt{variant}() noexcept(see below);
\end{verbatim}

\textit{Effects:} Constructs a \texttt{variant} holding a value-initialized value of type \( T_0 \).
\textit{Ensures:} \texttt{valueless_by_exception()} is false and \texttt{index()} is 0.
\textit{Throws:} Any exception thrown by the value-initialization of \( T_0 \).
\textit{Remarks:} This function shall be \texttt{constexpr} if and only if the value-initialization of the alternative type \( T_0 \) would satisfy the requirements for a \texttt{constexpr} function. The expression inside \texttt{noexcept} is equivalent to \texttt{is_nothrow_default_constructible_v<T_0>}. This function shall not participate in overload resolution unless \texttt{is_default_constructible_v<T_0> is true}. [Note: See also class \texttt{monostate}. — end note]

\begin{verbatim}
constexpr \texttt{variant}(\text{const \texttt{variant}& w});
\end{verbatim}

\textit{Effects:} If \( w \) holds a value, initializes the \texttt{variant} to hold the same alternative as \( w \) and direct-initializes the contained value with \texttt{get\<j\>(w)}, where \( j = w.index() \). Otherwise, initializes the \texttt{variant} to not hold a value.
\textit{Throws:} Any exception thrown by direct-initializing any \( T_i \) for all \( i \).
\textit{Remarks:} This constructor shall be defined as deleted unless \texttt{is_copy_constructible_v<T_i> is true} for all \( i \). If \texttt{is_trivially_copy_constructible_v<T_i> is true} for all \( i \), this constructor is trivial.

\begin{verbatim}
constexpr \texttt{variant}(<\text{\texttt{variant}&& w});
\end{verbatim}

\textit{Effects:} If \( w \) holds a value, initializes the \texttt{variant} to hold the same alternative as \( w \) and direct-initializes the contained value with \texttt{get\<j\>(\text{std::move}(w))}, where \( j = w.index() \). Otherwise, initializes the \texttt{variant} to not hold a value.
\textit{Throws:} Any exception thrown by move-constructing any \( T_i \) for all \( i \).
\textit{Remarks:} The expression inside \texttt{noexcept} is equivalent to the logical AND of \texttt{is_nothrow_move_constructible_v<T_i>} for all \( i \). This function shall not participate in overload resolution unless \texttt{is_move_constructible_v<T_i>} is true for all \( i \). If \texttt{is_trivially_move_constructible_v<T_i>} is true for all \( i \), this constructor is trivial.

\begin{verbatim}
template<class T> constexpr \texttt{variant}(\text{\texttt{T&& t});
\end{verbatim}

Let \( T_j \) be a type that is determined as follows: build an imaginary function \( \text{FUN}(T_j) \) for each alternative type \( T_j \), for which \( T_j \ x[] = \{\text{std::forward}<T>(t)\} \); is well-formed for some invented variable \( x \) and, if \( T_j \) is \texttt{cv bool.remove_cvref_t<T>} is \texttt{bool}. The overload \( \text{FUN}(T_j) \) selected by overload resolution for the expression \( \text{FUN}(\text{std::forward}<T>(t)) \) defines the alternative \( T_j \) which is the type of the contained value after construction.

\textit{Effects:} Initializes \(*\texttt{this} to hold the alternative type \( T_j \) and direct-initializes the contained value as if direct-non-list-initializing it with \texttt{std::forward}<T>(t).
\textit{Ensures:} \texttt{holds_alternative<T_j>()(*this)} is true.
\textit{Throws:} Any exception thrown by the initialization of the selected alternative \( T_j \).
\textit{Remarks:} This function shall not participate in overload resolution unless
\begin{align*}
(16.1) & \quad \text{sizeof}...(\text{Types}) \text{ is nonzero,} \\
(16.2) & \quad \text{is_same_v<remove_cvref_t<T>, variant> is false,} \\
(16.3) & \quad \text{remove_cvref_t<T> is neither a specialization of in_place_type_t nor a specialization of in_place_index_t,} \\
(16.4) & \quad \text{is_constructible_v<T_j, T> is true, and} \\
(16.5) & \quad \text{the expression FUN(std::forward<T>(t)) (with FUN being the above-mentioned set of imaginary functions) is well-formed.}
\end{align*}
Note: variant<string, string> v("abc");
is ill-formed, as both alternative types have an equally viable constructor for the argument. — end

The expression inside noexcept is equivalent to is_nothrow_constructible_v<T, T>. If T’s selected
constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

template<class T, class... Args> constexpr(constexpr) explicit variant(in_place_type_t<T>, Args&&... args);

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the
arguments std::forward<Args>(args)....

Ensures: holds_alternative<T>(*this) is true.

Throws: Any exception thrown by calling the selected constructor of T.

Remarks: This function shall not participate in overload resolution unless there is exactly one occurrence
of T in Types and is_constructible_v<T, Args...> is true. If T’s selected constructor is a constexpr
constructor, this constructor shall be a constexpr constructor.

template<class T, class U, class... Args>
constexpr explicit variant(in_place_type_t<T>, initializer_list<U> il, Args&&... args);

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the
arguments il, std::forward<Args>(args)....

Ensures: holds_alternative<T>(*this) is true.

Throws: Any exception thrown by calling the selected constructor of T.

Remarks: This function shall not participate in overload resolution unless there is exactly one occurrence
of T in Types and is_constructible_v<T, initializer_list<U>&, Args...> is true. If T’s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

template<size_t I, class... Args>
constexpr explicit variant(in_place_index_t<I>, Args&&... args);

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the
arguments std::forward<Args>(args)....

Ensures: index() is I.

Throws: Any exception thrown by calling the selected constructor of T.

Remarks: This function shall not participate in overload resolution unless
— I is less than sizeof...(Types) and
— is_constructible_v<T, Args...> is true.

If T’s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

template<size_t I, class U, class... Args>
constexpr explicit variant(in_place_index_t<I>, initializer_list<U> il, Args&&... args);

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the
arguments il, std::forward<Args>(args)....

Ensures: index() is I.

Remarks: This function shall not participate in overload resolution unless
— I is less than sizeof...(Types) and
— is_constructible_v<T, initializer_list<U>&, Args...> is true.

If T’s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

20.7.3.2 Destructor

~variant();

Effects: If valueless_by_exception() is false, destroys the currently contained value.

Remarks: If is_trivially_destructible_v<T_I> is true for all T_i, then this destructor is trivial.
### 20.7.3.3 Assignment

```cpp
constexpr variant& operator=(const variant& rhs);
```

1. Let \( j \) be \( \text{rhs.index()} \).

2. **Effects:**
   - If neither \(*\text{this}\) nor \( \text{rhs} \) holds a value, there is no effect.
   - Otherwise, if \(*\text{this}\) holds a value but \( \text{rhs} \) does not, destroys the value contained in \(*\text{this}\) and sets \(*\text{this}\) to not hold a value.
   - Otherwise, if \( \text{index()} == j \), assigns the value contained in \( \text{rhs} \) to the value contained in \(*\text{this}\).
   - Otherwise, if either \( \text{is_nothrow_copy_constructible_v<T_j> \&\& is_nothrow_move_constructible_v<T_j>} \) is true or \( \text{is_trivially_copy_constructible_v<T_j> \&\& is_trivially_move_constructible_v<T_j>} \) is true for all \( i \), this assignment operator is trivial.

3. **Returns:** \(*\text{this}\).

4. **Ensures:** \( \text{index()} == \text{rhs.index()} \).

5. **Remarks:** This operator shall be defined as deleted unless \( \text{is_copy_constructible_v<T_i> \&\& is_copy_assignable_v<T_i>} \) is true for all \( i \). If \( \text{is_trivially_copy_constructible_v<T_i> \&\& is_trivially_move_constructible_v<T_i>} \) is true for all \( i \), this assignment operator is trivial.

```cpp
constexpr variant& operator=(variant&& rhs) noexcept(
```

6. Let \( j \) be \( \text{rhs.index()} \).

7. **Effects:**
   - If neither \(*\text{this}\) nor \( \text{rhs} \) holds a value, there is no effect.
   - Otherwise, if \(*\text{this}\) holds a value but \( \text{rhs} \) does not, destroys the value contained in \(*\text{this}\) and sets \(*\text{this}\) to not hold a value.
   - Otherwise, if \( \text{index()} == j \), assigns \( \text{get<}j\text{>(std::move(rhs))} \) to the value contained in \(*\text{this}\).
   - Otherwise, equivalent to \( \text{emplace<}j\text{>(std::move(rhs))} \).

8. **Returns:** \(*\text{this}\).

9. **Remarks:** This function shall not participate in overload resolution unless \( \text{is_move_constructible_v<T_i> \&\& is_move_assignable_v<T_i>} \) is true for all \( i \). If \( \text{is_trivially_move_constructible_v<T_i> \&\& is_trivially_move_assignable_v<T_i>} \) is true for all \( i \), this assignment operator is trivial. The expression inside \text{noexcept} is equivalent to: \( \text{is_nothrow_move_constructible_v<T_i> \&\& is_nothrow_move_assignable_v<T_i>} \) for all \( i \).

```cpp
template<class T> variant& operator=(T&& t) noexcept(
```

10. Let \( T_j \) be a type that is determined as follows: build an imaginary function \( \text{FUN(T_i)} \) for each alternative \( T_i \) for which \( T_i \_x[] = \{\text{std::forward<T>(t)}\} \) is well-formed for some invented variable \( x \) and, if \( T_i \) is \text{cv bool}, \text{remove_cvref_t<T>} \) is bool. The overload \( \text{FUN(T_j)} \) selected by overload resolution for the expression \( \text{FUN(std::forward<T>(t))} \) defines the alternative \( T_j \) which is the type of the contained value after assignment.

11. **Effects:**
   - If \(*\text{this}\) holds a \( T_j \), assigns \( \text{std::forward<T>(t)} \) to the value contained in \(*\text{this}\).
   - Otherwise, if \( \text{is_nothrow_constructible_v<T_j> \&\& is_nothrow_move_constructible_v<T_j>} \) is true, equivalent to \( \text{emplace<}j\text{>(std::forward<T>(t))} \).
   - Otherwise, equivalent to \( \text{operator=(variant(std::forward<T>(t)))} \).
Ensures: `holds_alternative<T_j>(*this)` is `true`, with `T_j` selected by the imaginary function overload resolution described above.

Returns: `*this`.

Remarks: This function shall not participate in overload resolution unless

- `is_same_v<remove_cvref_t<T>, variant>` is `false`,
- `is_assignable_v<T, & T> & is_constructible_v<T_j, T>` is `true`, and
- the expression `FUN(std::forward<T>(t))` (with `FUN` being the above-mentioned set of imaginary functions) is well-formed.

[Note:

```c++
variant<string, string> v;
v = "abc";
```

is ill-formed, as both alternative types have an equally viable constructor for the argument. — end note]

The expression inside `noexcept` is equivalent to:

```
is_nothrow_assignable_v<T, & T> & is_nothrow_constructible_v<T_j, T>
```

- If an exception is thrown during the assignment of `std::forward<T>(t)` to the value contained in `*this`, the state of the contained value and `t` are as defined by the exception safety guarantee of the assignment expression; `valueless_by_exception()` will be `false`.
- If an exception is thrown during the initialization of the contained value, the `variant` object might not hold a value.

20.7.3.4 Modifiers [variant.mod]

```c++
template<class T, class... Args> T& emplace(Args&&... args);
```

Let `I` be the zero-based index of `T` in `Types`.

Effects: Equivalent to: `return emplace<I>(std::forward<Args>(args)...);`

Remarks: This function shall not participate in overload resolution unless `is_constructible_v<T, Args...>` is `true`, and `T` occurs exactly once in `Types`.

```c++
template<class T, class U, class... Args> T& emplace(initializer_list<U> il, Args&&... args);
```

Let `I` be the zero-based index of `T` in `Types`.

Effects: Equivalent to: `return emplace<I>(il, std::forward<Args>(args)...);`

Remarks: This function shall not participate in overload resolution unless `is_constructible_v<T, initializer_list<U>&, Args...>` is `true`, and `T` occurs exactly once in `Types`.

```c++
template<size_t I, class... Args>
variant_alternative_t<I, variant<Types...>>& emplace(Args&&... args);
```

Requires: `I < sizeof...(Types)`.

Effects: Destroys the currently contained value if `valueless_by_exception()` is `false`. Then initializes the contained value as if direct-non-list-initializing a value of type `T_I` with the arguments `std::forward<Args>(args)...`.

Ensures: `index()` is `I`.

Returns: A reference to the new contained value.

Throws: Any exception thrown during the initialization of the contained value.

Remarks: This function shall not participate in overload resolution unless `is_constructible_v<T_I, Args...>` is `true`. If an exception is thrown during the initialization of the contained value, the `variant` might not hold a value.

```c++
template<size_t I, class U, class... Args>
variant_alternative_t<I, variant<Types...>>& emplace(initializer_list<U> il, Args&&... args);
```

Requires: `I < sizeof...(Types)`. 

§ 20.7.3.4
Effects: Destroys the currently contained value if `valueless_by_exception()` is false. Then initializes the contained value as if direct-non-list-initializing a value of type `T_i` with the arguments `il, std::forward<Args>(args)`.

Ensures: `index()` is `I`.

Returns: A reference to the new contained value.

Throws: Any exception thrown during the initialization of the contained value.

Remarks: This function shall not participate in overload resolution unless `is_constructible_v<T_i, initializer_list<U>&, Args...>` is true. If an exception is thrown during the initialization of the contained value, the `variant` might not hold a value.

### 20.7.3.5 Value status

```cpp
constexpr bool valueless_by_exception() const noexcept;
```

**Effects:** Returns `false` if and only if the `variant` holds a value.

**Note:** A `variant` might not hold a value if an exception is thrown during a type-changing assignment or emplacement. The latter means that even a `variant<float, int>` can become `valueless_by_exception()`, for instance by

```cpp
struct S { operator int() { throw 42; };
    variant<float, int> v(12.f);
    v.emplace<1>(S());
```

—end note

```cpp
constexpr size_t index() const noexcept;
```

**Effects:** If `valueless_by_exception()` is `true`, returns `variant_npos`. Otherwise, returns the zero-based index of the alternative of the contained value.

### 20.7.3.6 Swap

```cpp
void swap(variant& rhs) noexcept(see below);
```

**Requires:** Lvalues of type `T_i` shall be swappable (16.5.3.2) and `is_move_constructible_v<T_i>` shall be `true` for all `i`.

**Effects:**

(2.1) — If `valueless_by_exception()` && `rhs.valueless_by_exception()` no effect.

(2.2) — Otherwise, if `index() == rhs.index()`, calls `swap(get<i>(*this), get<i>(rhs))` where `i` is `index()`.

(2.3) — Otherwise, exchanges values of `rhs` and `*this`.

**Throws:** If `index() == rhs.index()`, any exception thrown by `swap(get<i>(*this), get<i>(rhs))` with `i` being `index()`. Otherwise, any exception thrown by the move constructor of `T_i` or `T_j` with `i` being `index()` and `j` being `rhs.index()`.

**Remarks:** If an exception is thrown during the call to function `swap(get<i>(*this), get<i>(rhs))`, the states of the contained values of `*this` and of `rhs` are determined by the exception safety guarantee of `swap` for lvalues of `T_i` with `i` being `index()`. If an exception is thrown during the exchange of the values of `*this` and `rhs`, the states of the values of `*this` and of `rhs` are determined by the exception safety guarantee of `variant`'s move constructor. The expression inside `noexcept` is equivalent to the logical AND of `is_nothrow_move_constructible_v<T_i>` && `is_nothrow_swappable_v<T_i>` for all `i`.

### 20.7.4 variant helper classes

```cpp
template<class T> struct variant_size;
```

**Remarks:** All specializations of `variant_size` shall meet the `Cpp17UnaryTypeTrait` requirements (20.15.1) with a base characteristic of `integral_constant<size_t, N>` for some `N`.

```cpp
template<class T> class variant_size<const T>;
template<class T> class variant_size<volatile T>;
```
Let VS denote \( \text{variant\_size}\langle T \rangle \) of the cv-unqualified type \( T \). Then each of the three templates shall meet the Cpp17UnaryTypeTrait requirements (20.15.1) with a base characteristic of \( \text{integral\_constant}\langle \text{size\_t}, \text{VS}\cdot\text{value} \rangle \).

Let VA denote \( \text{variant\_alternative}\langle I, T \rangle \) of the cv-unqualified type \( T \). Then each of the three templates shall meet the Cpp17TransformationTrait requirements (20.15.1) with a member typedef that names the following type:

- for the first specialization, \( \text{add\_const\_t}\langle \text{VA}\cdot\text{type} \rangle \),
- for the second specialization, \( \text{add\_volatile\_t}\langle \text{VA}\cdot\text{type} \rangle \), and
- for the third specialization, \( \text{add\_cv\_t}\langle \text{VA}\cdot\text{type} \rangle \).

\( \text{variant\_alternative}\langle I, \text{variant}\langle \text{Types}\ldots\rangle \rangle \)::type

\[ \text{Requires: } I < \text{sizeof}\ldots\langle \text{Types} \rangle. \text{ The program is ill-formed if } I \text{ is out of bounds.} \]

\[ \text{Value: } \text{The type } T_I. \]

### 20.7.5 Value access

\[ \text{requires: } \text{holds\_alternative}(\text{const } \text{variant}\langle \text{Types}\ldots\rangle & v) \noexcept; \]

\[ \text{Returns: } \text{true if } \text{index()} \text{ is equal to the zero-based index of } T \text{ in } \text{Types}. \]

\[ \text{Explicitly: } \text{get}(\text{variant}\langle \text{Types}\ldots\rangle & v); \]

\[ \text{get}(\text{variant}\langle \text{Types}\ldots\rangle && v); \]

\[ \text{get}(\text{const } \text{variant}\langle \text{Types}\ldots\rangle & v); \]

\[ \text{get}(\text{const } \text{variant}\langle \text{Types}\ldots\rangle && v); \]

\[ \text{Requires: } I < \text{sizeof}\ldots\langle \text{Types} \rangle. \text{ Otherwise, the program is ill-formed.} \]

\[ \text{Effects: If } v.\text{index()} \text{ is } I, \text{ returns a reference to the object stored in the } \text{variant}. \text{ Otherwise, throws an exception of type } \text{bad\_variant\_access}. \]

\[ \text{constexpr } T & \text{ get}(\text{variant}\langle \text{Types}\ldots\rangle & v); \]

\[ \text{constexpr } T && \text{ get}(\text{variant}\langle \text{Types}\ldots\rangle && v); \]

\[ \text{constexpr } \text{const } T & \text{ get}(\text{const } \text{variant}\langle \text{Types}\ldots\rangle & v); \]

\[ \text{constexpr } \text{const } T && \text{ get}(\text{const } \text{variant}\langle \text{Types}\ldots\rangle && v); \]

\[ \text{Requires: } \text{The type } T \text{ occurs exactly once in } \text{Types}. \text{ Otherwise, the program is ill-formed.} \]

\[ \text{Effects: If } v \text{ holds a value of type } T, \text{ returns a reference to that value. Otherwise, throws an exception of type } \text{bad\_variant\_access}. \]

\[ \text{constexpr } \text{add\_pointer\_t}\langle \text{variant\_alternative}\langle I, \text{variant}\langle \text{Types}\ldots\rangle \rangle \rangle \text{ get\_if}(\text{variant}\langle \text{Types}\ldots\rangle & v) \noexcept; \]

\[ \text{constexpr } \text{add\_pointer\_t}\langle \text{const } \text{variant\_alternative}\langle I, \text{variant}\langle \text{Types}\ldots\rangle \rangle \rangle \text{ get\_if}(\text{const } \text{variant}\langle \text{Types}\ldots\rangle & v) \noexcept; \]

\[ \text{Requires: } I < \text{sizeof}\ldots\langle \text{Types} \rangle. \text{ Otherwise, the program is ill-formed.} \]

\[ \text{Returns: A pointer to the value stored in the } \text{variant}, \text{ if } v \neq \text{nullptr} \text{ and } v.\text{index()} == I. \text{ Otherwise, returns } \text{nullptr}. \]

\[ \text{§ 20.7.5} \]

583

\[ \text{N4820} \]
template<class T, class... Types>
constexpr add_pointer_t<T>
get_if(variant<Types...>* v) noexcept;

template<class T, class... Types>
constexpr add_pointer_t<const T>
get_if(const variant<Types...>* v) noexcept;

Requires: The type T occurs exactly once in Types. Otherwise, the program is ill-formed.

Effects: Equivalent to: return get_if<i>(v); with i being the zero-based index of T in Types.

20.7.6 Relational operators

template<class... Types>
constexpr bool operator==(const variant<Types...>& v, const variant<Types...>& w);

Requires: get<i>(v) == get<i>(w) is a valid expression returning a type that is convertible to bool, for all i.

Returns: If v.index() != w.index(), false; otherwise if v.valueless_by_exception(), true; otherwise get<i>(v) == get<i>(w) with i being v.index().

template<class... Types>
constexpr bool operator!=(const variant<Types...>& v, const variant<Types...>& w);

Requires: get<i>(v) != get<i>(w) is a valid expression returning a type that is convertible to bool, for all i.

Returns: If v.index() != w.index(), true; otherwise if v.valueless_by_exception(), false; otherwise get<i>(v) != get<i>(w) with i being v.index().

template<class... Types>
constexpr bool operator<(const variant<Types...>& v, const variant<Types...>& w);

Requires: get<i>(v) < get<i>(w) is a valid expression returning a type that is convertible to bool, for all i.

Returns: If w.valueless_by_exception(), false; otherwise if v.valueless_by_exception(), true; otherwise, if v.index() < w.index(), true; otherwise if v.index() > w.index(), false; otherwise get<i>(v) < get<i>(w) with i being v.index().

template<class... Types>
constexpr bool operator>(const variant<Types...>& v, const variant<Types...>& w);

Requires: get<i>(v) > get<i>(w) is a valid expression returning a type that is convertible to bool, for all i.

Returns: If v.valueless_by_exception(), false; otherwise if w.valueless_by_exception(), true; otherwise, if v.index() > w.index(), true; otherwise if v.index() < w.index(), false; otherwise get<i>(v) > get<i>(w) with i being v.index().

template<class... Types>
constexpr bool operator<=(const variant<Types...>& v, const variant<Types...>& w);

Requires: get<i>(v) <= get<i>(w) is a valid expression returning a type that is convertible to bool, for all i.

Returns: If w.valueless_by_exception(), true; otherwise if v.valueless_by_exception(), false; otherwise, if v.index() < w.index(), true; otherwise if v.index() > w.index(), false; otherwise get<i>(v) <= get<i>(w) with i being v.index().

template<class... Types>
constexpr bool operator>=(const variant<Types...>& v, const variant<Types...>& w);

Requires: get<i>(v) >= get<i>(w) is a valid expression returning a type that is convertible to bool, for all i.

Returns: If v.valueless_by_exception(), true; otherwise if w.valueless_by_exception(), false; otherwise, if v.index() > w.index(), true; otherwise if v.index() < w.index(), false; otherwise get<i>(v) >= get<i>(w) with i being v.index().
20.7.7 Visitation

template<class Visitor, class... Variants>
constexpr see below visit(Visitor&& vis, Variants&&... vars);

Let \( n \) be \( \text{sizeof}(\ldots(	ext{Variants})) \). Let \( m \) be a pack of \( n \) values of type \( \text{size}_t \). Such a pack is called valid if \( 0 \leq m_i < \text{variant\_size\_v<remove\_reference\_t<
\text{Variants},
\ldots>} \) for all \( 0 \leq i < n \). For each valid pack \( m \), let \( e(m) \) denote the expression:

\[
\text{INVOKE}(\text{std::forward}<\text{Visitor}(\text{vis}), \text{get}<m>(\text{std::forward}<\text{Variants}(\text{vars})\ldots)) \quad // \text{see 20.14.3}
\]

for the first form and

\[
\text{INVOKE}<R>(\text{std::forward}<\text{Visitor}(\text{vis}), \text{get}<m>(\text{std::forward}<\text{Variants}(\text{vars})\ldots)) \quad // \text{see 20.14.3}
\]

for the second form.

 Requires: For each valid pack \( m \), \( e(m) \) shall be a valid expression. All such expressions shall be of the same type and value category; otherwise, the program is ill-formed.

 Returns: \( e(m) \), where \( m \) is the pack for which \( m_i \) is \( \text{vars}_i\_\text{index}() \) for all \( 0 \leq i < n \). The return type is \( \text{decltype}(e(m)) \) for the first form.

 Throws: \text{bad\_variant\_access} if any \text{variant} in \text{vars} is \text{valueless\_by\_exception}().

 Complexity: For \( n \leq 1 \), the invocation of the callable object is implemented in constant time, i.e., for \( n = 1 \), it does not depend on the number of alternative types of \text{Variants}_0. For \( n > 1 \), the invocation of the callable object has no complexity requirements.

20.7.8 Class monostate

struct monostate{};

The class \text{monostate} can serve as a first alternative type for a \text{variant} to make the \text{variant} type default constructible.

20.7.9 monostate relational operators

constexpr bool operator==(monostate, monostate) noexcept { return true; }
constexpr bool operator!=(monostate, monostate) noexcept { return false; }
constexpr bool operator<(monostate, monostate) noexcept { return false; }
constexpr bool operator>(monostate, monostate) noexcept { return false; }
constexpr bool operator<=(monostate, monostate) noexcept { return true; }
constexpr bool operator>=(monostate, monostate) noexcept { return true; }

[Note: \text{monostate} objects have only a single state; they thus always compare equal. — end note]

20.7.10 Specialized algorithms

template<class... Types>
void swap(variant<Types...>& v, variant<Types...>& w) noexcept(see below);

 Effects: Equivalent to \( v.\text{swap}(w) \).

 Remarks: This function shall not participate in overload resolution unless \( \text{is\_move\_constructible\_v<T_1>} \) \&\& \( \text{is\_swappable\_v<T_1>} \) is true for all \( i \). The expression inside \( \text{noexcept} \) is equivalent to \( \text{noexcept}(v.\text{swap}(w)) \).

20.7.11 Class bad_variant_access

class bad_variant_access : public exception {
public:
// see 17.9.9 for the specification of the special member functions
const char* what() const noexcept override;
};

Objects of type \text{bad\_variant\_access} are thrown to report invalid accesses to the value of a \text{variant} object.

 const char* what() const noexcept override;

 Returns: An implementation-defined ntbs.
20.7.12 Hash support

```
template<class... Types> struct hash<variant<Types...>>;
```

1 The specialization `hash<variant<Types...>>` is enabled (20.14.18) if and only if every specialization in `hash<remove_const_t<Types>>...` is enabled. The member functions are not guaranteed to be noexcept.

```
template<> struct hash<monostate>;
```

2 The specialization is enabled (20.14.18).

20.8 Storage for any type

1 This subclause describes components that C++ programs may use to perform operations on objects of a discriminated type.

2 [Note: The discriminated type may contain values of different types but does not attempt conversion between them, i.e., 5 is held strictly as an `int` and is not implicitly convertible either to "5" or to 5.0. This indifference to interpretation but awareness of type effectively allows safe, generic containers of single values, with no scope for surprises from ambiguous conversions. —end note]

20.8.1 Header <any> synopsis

```
namespace std {
  // 20.8.2, class bad_any_cast
  class bad_any_cast;

  // 20.8.3, class any
  class any;

  // 20.8.4, non-member functions
  void swap(any& x, any& y) noexcept;
  template<class T, class... Args>
  any make_any(Args&& ...args);
  template<class T, class U, class... Args>
  any make_any(initializer_list<U> il, Args&& ...args);

  template<class T>
  T any_cast(const any& operand);
  template<class T>
  T any_cast(any& operand);
  template<class T>
  T any_cast(any&& operand);

  template<class T>
  const T* any_cast(const any* operand) noexcept;
  template<class T>
  T* any_cast(any* operand) noexcept;
}
```

20.8.2 Class bad_any_cast

```
class bad_any_cast : public bad_cast {
  public:
    // see 17.9.2 for the specification of the special member functions
    const char* what() const noexcept override;
};
```

1 Objects of type `bad_any_cast` are thrown by a failed `any_cast` (20.8.4).

```
const char* what() const noexcept override;
```

2 Returns: An implementation-defined NTBS.
20.8.3 Class any

namespace std {
    class any {
    public:
        // 20.8.3.1, construction and destruction
        constexpr any() noexcept;
        any(const any& other);
        any(any&& other) noexcept;
        template<class T>
            any(T&& value);
        template<class T, class... Args>
            explicit any(in_place_type_t<T>, Args&&...);
        template<class T, class U, class... Args>
            explicit any(in_place_type_t<T>, initializer_list<U>, Args&&...);
        ~any();
        // 20.8.3.2, assignments
        any& operator=(const any& rhs);
        any& operator=(any&& rhs) noexcept;
        template<class T>
            any& operator=(T&& rhs);
        // 20.8.3.3, modifiers
        template<class T, class... Args>
            decay_t<T>& emplace(Args&&...);
        template<class T, class U, class... Args>
            decay_t<T>& emplace(initializer_list<U>, Args&&...);
        void reset() noexcept;
        void swap(any& rhs) noexcept;
        // 20.8.3.4, observers
        bool has_value() const noexcept;
        const type_info& type() const noexcept;
    };
}

1 An object of class any stores an instance of any type that meets the constructor requirements or it has no value, and this is referred to as the state of the class any object. The stored instance is called the contained value. Two states are equivalent if either they both have no value, or they both have a value and the contained values are equivalent.

2 The non-member any_cast functions provide type-safe access to the contained value.

3 Implementations should avoid the use of dynamically allocated memory for a small contained value. However, any such small-object optimization shall only be applied to types T for which is_nothrow_move_constructible_v<T> is true. [Example: A contained value of type int could be stored in an internal buffer, not in separately-allocated memory. — end example]

20.8.3.1 Construction and destruction

constexpr any() noexcept;

1 Ensures: has_value() is false.

any(const any& other);

2 Effects: If other.has_value() is false, constructs an object that has no value. Otherwise, equivalent to any(in_place_type<T>, any_cast<const T&>(other)) where T is the type of the contained value.

3 Throws: Any exceptions arising from calling the selected constructor for the contained value.
any(any&& other) noexcept;

Effects: If other.has_value() is false, constructs an object that has no value. Otherwise, constructs an object of type any that contains either the contained value of other, or contains an object of the same type constructed from the contained value of other considering that contained value as an rvalue.

Ensures: other is left in a valid but otherwise unspecified state.

template<class T>
any(T& value);

Let VT be decay_t<T>.

Requires: VT shall meet the Cpp17CopyConstructible requirements.

Effects: Constructs an object of type any that contains an object of type VT direct-initialized with std::forward<T>(value).

Remarks: This constructor shall not participate in overload resolution unless VT is not the same type as any, VT is not a specialization of in_place_type_t, and is_copy_constructible_v<VT> is true.

Throws: Any exception thrown by the selected constructor of VT.

template<class T, class... Args>
explicit any(in_place_type_t<T>, Args&&... args);

Let VT be decay_t<T>.

Requires: VT shall meet the Cpp17CopyConstructible requirements.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments std::forward<Args>(args)....

Ensures: *this contains a value of type VT.

Throws: Any exception thrown by the selected constructor of VT.

Remarks: This constructor shall not participate in overload resolution unless is_copy_constructible_v<VT> is true and is_constructible_v<VT, Args...> is true.

template<class T, class U, class... Args>
explicit any(in_place_type_t<T>, initializer_list<U> il, Args&&... args);

Let VT be decay_t<T>.

Requires: VT shall meet the Cpp17CopyConstructible requirements.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments il, std::forward<Args>(args)....

Ensures: *this contains a value.

Throws: Any exception thrown by the selected constructor of VT.

Remarks: This constructor shall not participate in overload resolution unless is_copy_constructible_v<VT> is true and is_constructible_v<VT, initializer_list<U>&, Args...> is true.

~any();

Effects: As if by reset().

20.8.3.2 Assignment

any& operator=(const any& rhs);

Effects: As if by any(rhs).swap(*this). No effects if an exception is thrown.

Returns: *this.

Throws: Any exceptions arising from the copy constructor for the contained value.

any& operator=(any&& rhs) noexcept;

Effects: As if by any(std::move(rhs)).swap(*this).

Returns: *this.
Ensures: The state of *this is equivalent to the original state of rhs and rhs is left in a valid but otherwise unspecified state.

template<class T>
any& operator=(T&& rhs);

Let VT be decay_t<T>.

Requires: VT shall meet the Cpp17CopyConstructible requirements.

Effects: Constructs an object tmp of type any that contains an object of type VT direct-initialized with std::forward<T>(rhs), and tmp.swap(*this). No effects if an exception is thrown.

Returns: *this.

Remarks: This operator shall not participate in overload resolution unless VT is not the same type as any and is_copy_constructible_v<VT> is true.

Throws: Any exception thrown by the selected constructor of VT.

20.8.3.3 Modifiers

template<class T, class... Args>
decay_t<T>& emplace(Arg&&... args);

Let VT be decay_t<T>.

Requires: VT shall meet the Cpp17CopyConstructible requirements.

Effects: Calls reset(). Then initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments std::forward<Arge>(args)... .

Ensures: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of VT.

Remarks: If an exception is thrown during the call to VT's constructor, *this does not contain a value, and any previously contained value has been destroyed. This function shall not participate in overload resolution unless is_copy_constructible_v<VT> is true and is_constructible_v<VT, Args...> is true.

template<class T, class U, class... Args>
decay_t<T>& emplace(initializer_list<U> il, Arg&&... args);

Let VT be decay_t<T>.

Requires: VT shall meet the Cpp17CopyConstructible requirements.

Effects: Calls reset(). Then initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments il, std::forward<Arge>(args)... .

Ensures: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of VT.

Remarks: If an exception is thrown during the call to VT's constructor, *this does not contain a value, and any previously contained value has been destroyed. The function shall not participate in overload resolution unless is_copy_constructible_v<VT> is true and is_constructible_v<VT, initializer_list<U>&, Args...> is true.

void reset() noexcept;

Effects: If has_value() is true, destroys the contained value.

Ensures: has_value() is false.

void swap(any& rhs) noexcept;

Effects: Exchanges the states of *this and rhs.
20.8.3.4 Observers

```cpp
bool has_value() const noexcept;
1
Returns: true if *this contains an object, otherwise false.
```

```cpp
const type_info& type() const noexcept;
2
Returns: typeid(T) if *this has a contained value of type T, otherwise typeid(void).
[Note: Useful for querying against types known either at compile time or only at runtime. — end note]
```

20.8.4 Non-member functions

```cpp
void swap(any& x, any& y) noexcept;
1
Effects: As if by x.swap(y).
```

```cpp
template<class T, class... Args>
any make_any(Args&& ...args);
2
Effects: Equivalent to: return any(in_place_type<T>, std::forward<Args>(args)...);
```

```cpp
template<class T, class U, class... Args>
any make_any(initializer_list<U> il, Args&& ...args);
3
Effects: Equivalent to: return any(in_place_type<T>, il, std::forward<Args>(args)...);
```

```cpp
template<class T>
T any_cast(const any& operand);
template<class T>
T any_cast(any& operand);
template<class T>
T any_cast(any&& operand);
4
Let U be the type remove_cvref_t<T>.
5
Requires: For the first overload, is_constructible_v<T, const U&> is true. For the second overload, is_constructible_v<T, U&> is true. For the third overload, is_constructible_v<T, U> is true. Otherwise the program is ill-formed.
6
Returns: For the first and second overload, static_cast<T>(*any_cast<U>(&operand)). For the third overload, static_cast<T>(any_cast<T>(std::move(any_cast<const T&>(operand)))).
7
Throws: bad_any_cast if operand.type() != typeid(remove_reference_t<T>).*
8
[Example:]
```cpp
any x(5);
assert(any_cast<int>(x) == 5); // x holds int
any_cast<int&>(x) = 10; // cast to reference
```

```cpp
x = "Meow"; // x holds const char*
assert(strcmp(any_cast<const char*>(x), "Meow") == 0);
```

```cpp
x = string("Meow"); // x holds string
string s, s2("Jane");
s = move(any_cast<string&>(x)); // move from any
assert(s == "Meow");
any_cast<string&>(x) = move(s2); // move to any
assert(any_cast<const string&>(x) == "Jane");
```

```cpp
string cat("Meow");
const any y(cat); // const y holds string
assert(any_cast<const string&>(y) == cat);
```

```cpp
any_cast<string&>(y); // error; cannot
// any_cast away const
```
template<class T>
const T* any_cast(const any* operand) noexcept;
template<class T>
T* any_cast(any* operand) noexcept;

Returns: If operand != nullptr && operand->type() == typeid(T), a pointer to the object contained by operand; otherwise, nullptr.

[Example:
bool is_string(const any& operand) {
  return any_cast<string>(&operand) != nullptr;
}
—end example]

20.9 Bitsets
20.9.1 Header <bitset> synopsis

#include <string>
#include <iosfwd>  // for istream (29.7.1), ostream (29.7.2), see 29.3.1

namespace std {
    template<size_t N> class bitset;

    // 20.9.4, bitset operators
    template<size_t N>
    bitset<N> operator&=(const bitset<N>&, const bitset<N>&) noexcept;
    template<size_t N>
    bitset<N> operator|=(const bitset<N>&, const bitset<N>&) noexcept;
    template<size_t N>
    bitset<N> operator^=(const bitset<N>&, const bitset<N>&) noexcept;
    template<class charT, class traits, size_t N>
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
    template<class charT, class traits, size_t N>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
}

The header <bitset> defines a class template and several related functions for representing and manipulating fixed-size sequences of bits.

20.9.2 Class template bitset

namespace std {
    template<size_t N> class bitset {
        public:
        // bit reference
        class reference {
            friend class bitset;
            reference() noexcept;
            reference(const reference&) = default;
            ~reference();
            reference operator=(bool x) noexcept;  // for b[i] = x;
            reference operator=(const reference&) noexcept;  // for b[i] = b[j];
            bool operator~() const noexcept;  // flips the bit
            operator bool() const noexcept;  // for x = b[i];
            reference flip() noexcept;  // for b[i].flip();
        };

        // 20.9.2.1, constructors
        constexpr bitset() noexcept;
    };

    constexpr bitset() noexcept;
constexpr bitset(unsigned long long val) noexcept;

template<class charT, class traits, class Allocator>
explicit bitset(
    const basic_string<charT, traits, Allocator>& str,
    typename basic_string<charT, traits, Allocator>::size_type pos = 0,
    typename basic_string<charT, traits, Allocator>::size_type n
    = basic_string<charT, traits, Allocator>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));

template<class charT>
explicit bitset(
    const charT* str,
    typename basic_string<charT>::size_type n = basic_string<charT>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));

// 20.9.2.2, bitset operations
bitset<N>& operator&=(const bitset<N>& rhs) noexcept;
bitset<N>& operator|=(const bitset<N>& rhs) noexcept;
bitset<N>& operator^=(const bitset<N>& rhs) noexcept;
bitset<N>& operator<<=(size_t pos) noexcept;
bitset<N>& operator>>=(size_t pos) noexcept;
bitset<N>& set() noexcept;
bitset<N>& set(size_t pos, bool val = true);
bitset<N>& reset() noexcept;
bitset<N>& reset(size_t pos);
bitset<N> operator~() const noexcept;
bitset<N>& flip() noexcept;
bitset<N>& flip(size_t pos);

// element access
constexpr bool operator[](size_t pos) const; // for b[i];
reference operator[](size_t pos); // for b[i];

unsigned long to_ulong() const;
unsigned long long to_ullong() const;

template<class charT = char,
    class traits = char_traits<charT>,
    class Allocator = allocator<charT>>
basic_string<charT, traits, Allocator>
to_string(charT zero = charT('0'), charT one = charT('1')) const;

size_t count() const noexcept;
constexpr size_t size() const noexcept;
bool operator==(const bitset<N>& rhs) const noexcept;
bool operator!=(const bitset<N>& rhs) const noexcept;
bool test(size_t pos) const;
bool all() const noexcept;
bool any() const noexcept;
bool none() const noexcept;
bitset<N>& operator<<=(size_t pos) const noexcept;
bitset<N>& operator>>=(size_t pos) const noexcept;

// 20.9.3, hash support
template<class T> struct hash;

template<size_t N> struct hash<bitset<N>>;

1 The class template bitset<N> describes an object that can store a sequence consisting of a fixed number of bits, N.
2 Each bit represents either the value zero (reset) or one (set). To toggle a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position pos. When converting between an object
of class `bitset<N>` and a value of some integral type, bit position `pos` corresponds to the bit value `1 << pos`. The integral value corresponding to two or more bits is the sum of their bit values.

3 The functions described in this subclause can report three kinds of errors, each associated with a distinct exception:

1. (3.1) an invalid-argument error is associated with exceptions of type `invalid_argument` (19.2.4);
2. (3.2) an out-of-range error is associated with exceptions of type `out_of_range` (19.2.6);
3. (3.3) an overflow error is associated with exceptions of type `overflow_error` (19.2.9).

### 20.9.2.1 Constructors

```cpp
constexpr bitset() noexcept;
```

**Effects:** Constructs an object of class `bitset<N>`, initializing all bits to zero.

```cpp
constexpr bitset(unsigned long long val) noexcept;
```

**Effects:** Constructs an object of class `bitset<N>`, initializing the first `M` bit positions to the corresponding bit values in `val`. `M` is the smaller of `N` and the number of bits in the value representation (6.7) of `unsigned long long`. If `M < N`, the remaining bit positions are initialized to zero.

```cpp
template<class charT, class traits, class Allocator>
external bitset(
    const basic_string<charT, traits, Allocator>& str,
    typename basic_string<charT, traits, Allocator>::size_type pos = 0,
    typename basic_string<charT, traits, Allocator>::size_type n = basic_string<charT, traits, Allocator>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
```

**Throws:** `out_of_range` if `pos > str.size()` or `invalid_argument` if an invalid character is found (see below).

**Effects:** Determines the effective length `rlen` of the initializing string as the smaller of `n` and `str.size()` - `pos`. The function then throws `invalid_argument` if any of the `rlen` characters in `str` beginning at position `pos` is other than `zero` or `one`. The function uses `traits::eq()` to compare the character values.

Otherwise, the function constructs an object of class `bitset<N>`, initializing the first `M` bit positions to values determined from the corresponding characters in the string `str`. `M` is the smaller of `N` and `rlen`.

An element of the constructed object has value zero if the corresponding character in `str`, beginning at position `pos`, is `zero`. Otherwise, the element has the value one. Character position `pos + M - 1` corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions.

If `M < N`, remaining bit positions are initialized to zero.

```cpp
template<class charT>
external bitset(
    const charT* str,
    typename basic_string<charT>::size_type n = basic_string<charT>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
```

**Effects:** Constructs an object of class `bitset<N>` as if by:

```cpp
bitset(n == basic_string<charT>::npos ? basic_string<charT>(str) : basic_string<charT>(str, n), 0, n, zero, one)
```

### 20.9.2.2 Members

```cpp
bitset<N>& operator=(const bitset<N>& rhs) noexcept;
```

**Effects:** Clears each bit in `*this` for which the corresponding bit in `rhs` is clear, and leaves all other bits unchanged.
Returns: *this.

bitset<N>& operator|=(const bitset<N>& rhs) noexcept;
Effects: Sets each bit in *this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.
Returns: *this.

bitset<N>& operator^=(const bitset<N>& rhs) noexcept;
Effects: Toggles each bit in *this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.
Returns: *this.

bitset<N>& operator<<=(size_t pos) noexcept;
Effects: Replaces each bit at position I in *this with a value determined as follows:
— If I < pos, the new value is zero;
— If I >= pos, the new value is the previous value of the bit at position I - pos.
Returns: *this.

bitset<N>& operator>>=(size_t pos) noexcept;
Effects: Replaces each bit at position I in *this with a value determined as follows:
— If pos >= N - I, the new value is zero;
— If pos < N - I, the new value is the previous value of the bit at position I + pos.
Returns: *this.

bitset<N>& set() noexcept;
Effects: Sets all bits in *this.
Returns: *this.

bitset<N>& set(size_t pos, bool val = true);
Throws: out_of_range if pos does not correspond to a valid bit position.
Effects: Stores a new value in the bit at position pos in *this. If val is true, the stored value is one, otherwise it is zero.
Returns: *this.

bitset<N>& reset() noexcept;
Effects: Resets all bits in *this.
Returns: *this.

bitset<N>& reset(size_t pos);
 Throws: out_of_range if pos does not correspond to a valid bit position.
Effects: Resets the bit at position pos in *this.
Returns: *this.

bitset<N> operator~() const noexcept;
Effects: Constructs an object x of class bitset<N> and initializes it with *this.
Returns: x.flip().

bitset<N>& flip() noexcept;
Effects: Toggles all bits in *this.
Returns: *this.

bitset<N>& flip(size_t pos);
Throws: out_of_range if pos does not correspond to a valid bit position.
Effects: Toggles the bit at position pos in *this.

Returns: *this.

unsigned long to_ulong() const;

Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented as type unsigned long.

Returns: x.

unsigned long long to_uullong() const;

Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented as type unsigned long long.

Returns: x.

template<class charT = char,
  class traits = char_traits<charT>,
  class Allocator = allocator<charT>>
basic_string<charT, traits, Allocator>
to_string(charT zero = charT('0'), charT one = charT('1')) const;

Effects: Constructs a string object of the appropriate type and initializes it to a string of length N characters. Each character is determined by the value of its corresponding bit position in *this. Character position N - 1 corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions. Bit value zero becomes the character zero, bit value one becomes the character one.

Returns: The created object.

size_t count() const noexcept;

Returns: A count of the number of bits set in *this.

constexpr size_t size() const noexcept;

Returns: N.

bool operator==(const bitset<N>& rhs) const noexcept;

Returns: true if the value of each bit in *this equals the value of the corresponding bit in rhs.

bool operator!=(const bitset<N>& rhs) const noexcept;

Returns: true if !(this == rhs).

bool test(size_t pos) const;

Throws: out_of_range if pos does not correspond to a valid bit position.

Returns: true if the bit at position pos in *this has the value one.

bool all() const noexcept;

Returns: count() == size().

bool any() const noexcept;

Returns: count() != 0.

bool none() const noexcept;

Returns: count() == 0.

bitset<N> operator<<=(size_t pos) const noexcept;

Returns: bitset<N>(*this) <<= pos.

bitset<N> operator>>=(size_t pos) const noexcept;

Returns: bitset<N>(*this) >>= pos.
constexpr bool operator[](size_t pos) const;

Requires: pos shall be valid.

Returns: true if the bit at position pos in *this has the value one, otherwise false.

Throws: Nothing.

bitset<N>::reference operator[](size_t pos);

Requires: pos shall be valid.

Returns: An object of type bitset<N>::reference such that (*this)[pos] == this->test(pos),
and such that (*this)[pos] = val is equivalent to this->set(pos, val).

Throws: Nothing.

Remarks: For the purpose of determining the presence of a data race (6.8.2), any access or update
through the resulting reference potentially accesses or modifies, respectively, the entire underlying
bitset.

20.9.3 bitset hash support

template<size_t N> struct hash<bitset<N>>;

The specialization is enabled (20.14.18).

20.9.4 bitset operators

bitset<N> operator&(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;

Returns: bitset<N>(lhs) &= rhs.

bitset<N> operator|(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;

Returns: bitset<N>(lhs) |= rhs.

bitset<N> operator^(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;

Returns: bitset<N>(lhs) ^= rhs.

template<class charT, class traits, size_t N>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, bitset<N>& x);

A formatted input function (29.7.4.2).

Effects: Extracts up to N characters from is. Stores these characters in a temporary object str of type
basic_string<charT, traits>, then evaluates the expression x = bitset<N>(str). Characters are
extracted and stored until any of the following occurs:

(5.1) N characters have been extracted and stored;
(5.2) end-of-file occurs on the input sequence;
(5.3) the next input character is neither is.widen('0') nor is.widen('1') (in which case the input
character is not extracted).

If no characters are stored in str, calls is.setstate(ios_base::failbit) (which may throw ios_
base::failure (29.5.5.4)).

Returns: is.

template<class charT, class traits, size_t N>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);

Returns:

os << x.template to_string<charT, traits, allocator<charT>>(
    use_facet<ctype<charT>>(os.getloc())).widen('0'),
    use_facet<ctype<charT>>(os.getloc())).widen('1'))

(see 29.7.5.2).
20.10 Memory [memory]

20.10.1 In general [memory.general]

This subclause describes the contents of the header <memory> (20.10.2) and some of the contents of the header <cstdlib> (17.2.2).

20.10.2 Header <memory> synopsis [memory.syn]

The header <memory> defines several types and function templates that describe properties of pointers and pointer-like types, manage memory for containers and other template types, destroy objects, and construct multiple objects in uninitialized memory buffers (20.10.3–20.10.11). The header also defines the templates unique_ptr, shared_ptr, weak_ptr, and various function templates that operate on objects of these types (20.11).

```cpp
namespace std {
    // 20.10.3, pointer traits
    template<class Ptr> struct pointer_traits;
    template<class T> struct pointer_traits<T*>;

    // 20.10.4, pointer conversion
    template<class T> constexpr T* to_address(T* p) noexcept;
    template<class Ptr> auto to_address(const Ptr& p) noexcept;

    // 20.10.5, pointer safety
    enum class pointer_safety { relaxed, preferred, strict }
    void declare_reachable(void* p);
    template<class T> T* undeclare_reachable(T* p);
    void declare_no_pointers(char* p, size_t n);
    void undeclare_no_pointers(char* p, size_t n);
    pointer_safety get_pointer_safety() noexcept;

    // 20.10.6, pointer alignment
    void* align(size_t alignment, size_t size, void*& ptr, size_t& space);

The class template `pointer_traits` supplies a uniform interface to certain attributes of pointer-like types.

```cpp
namespace std {
    template<class Ptr> struct pointer_traits {
        using pointer = Ptr;
        using element_type = see below;
        using difference_type = see below;

        template<class U> using rebind = see below;

        static pointer pointer_to(see below r);
    }

    template<class T> struct pointer_traits<T*> {
        using pointer = T*;
        using element_type = T;
        using difference_type = ptrdiff_t;

        template<class U> using rebind = U*;

        static constexpr pointer pointer_to(see below r) noexcept;
    }
}
```

### 20.10.3.1 Member types

**Type:** `Ptr::element_type` if the qualified-id `Ptr::element_type` is valid and denotes a type (13.9.2); otherwise, `T` if `Ptr` is a class template instantiation of the form `SomePointer<T, Args>`, where `Args` is zero or more type arguments; otherwise, the specialization is ill-formed.

**Type:** `Ptr::difference_type` if the qualified-id `Ptr::difference_type` is valid and denotes a type (13.9.2); otherwise, `ptrdiff_t`.

**Alias template:** `Ptr::rebind<U>` if the qualified-id `Ptr::rebind<U>` is valid and denotes a type (13.9.2); otherwise, `SomePointer<U, Args>` if `Ptr` is a class template instantiation of the form `SomePointer<T, Args>`, where `Args` is zero or more type arguments; otherwise, the instantiation of `rebind` is ill-formed.
20.10.3.2 Member functions

```
static pointer pointer_traits::pointer_to(see below r);
static constexpr pointer pointer_traits<T*>::pointer_to(see below r) noexcept;
```

1. Remarks: If `element_type` is `cv void`, the type of `r` is unspecified; otherwise, it is `element_type&`.
2. Returns: The first member function returns a pointer to `r` obtained by calling `Ptr::pointer_to(r)` through which indirection is valid; an instantiation of this function is ill-formed if `Ptr` does not have a matching `pointer_to` static member function. The second member function returns `addressof(r)`.

20.10.3.3 Optional members

```
static element_type* to_address(pointer p) noexcept;
```

1. Specializations of `pointer_traits` may define the member declared in this subclause to customize the behavior of the standard library.
2. Returns: A pointer of type `element_type*` that references the same location as the argument `p`.
3. [Note: This function should be the inverse of `pointer_to`. If defined, it customizes the behavior of the non-member function `to_address` (20.10.4). —end note]

20.10.4 Pointer conversion

```
template<class T> constexpr T* to_address(T* p) noexcept;
```

1. Requires: `T` is not a function type. Otherwise the program is ill-formed.

```
template<class Ptr> auto to_address(const Ptr& p) noexcept;
```

3. Returns: `pointer_traits<Ptr>::to_address(p)` if that expression is well-formed (see 20.10.3.3), otherwise `to_address(p.operator->())`.

20.10.5 Pointer safety

```
void declare_reachable(void* p);
```

1. A complete object is `declared reachable` while the number of calls to `declare_reachable` with an argument referencing the object exceeds the number of calls to `undeclare_reachable` with an argument referencing the object.
2. Requires: `p` shall be a safely-derived pointer (6.6.5.4.3) or a null pointer value.
3. Effects: If `p` is not null, the complete object referenced by `p` is subsequently declared reachable (6.6.5.4.3).
4. Throws: May throw `bad_alloc` if the system cannot allocate additional memory that may be required to track objects declared reachable.

```
template<class T> T* undeclare_reachable(T* p);
```

5. Requires: If `p` is not null, the complete object referenced by `p` shall have been previously declared reachable, and shall be live (6.6.3) from the time of the call until the last `undeclare_reachable(p)` call on the object.
8. [Note: It is expected that calls to `declare_reachable(p)` will consume a small amount of memory in addition to that occupied by the referenced object until the matching call to `undeclare_reachable(p)` is encountered. Long running programs should arrange that calls are matched. —end note]

```
void declare_no_pointers(char* p, size_t n);
```

9. Requires: No bytes in the specified range are currently registered with `declare_no_pointers()`. If the specified range is in an allocated object, then it shall be entirely within a single allocated object. The object shall be live until the corresponding `undeclare_no_pointers()` call. [Note: In a garbage-collecting implementation, the fact that a region in an object is registered with `declare_no_pointers()` should not prevent the object from being collected. —end note]
Effects: The \( n \) bytes starting at \( p \) no longer contain traceable pointer locations, independent of their type. Hence indirection through a pointer located there is undefined if the object it points to was created by global operator new and not previously declared reachable. [Note: This may be used to inform a garbage collector or leak detector that this region of memory need not be traced. — end note]

Throws: Nothing.

[Note: Under some conditions implementations may need to allocate memory. However, the request can be ignored if memory allocation fails. — end note]

```cpp
void undeclare_no_pointers(char* p, size_t n);
```

Requires: The same range shall previously have been passed to declare_no_pointers().

Effects: Unregisters a range registered with declare_no_pointers() for destruction. It shall be called before the lifetime of the object ends.

Throws: Nothing.

```cpp
pointer_safety get_pointer_safety() noexcept;
```

Returns: `pointer_safety::strict` if the implementation has strict pointer safety (6.6.5.4.3). It is implementation-defined whether get_pointer_safety returns `pointer_safety::relaxed` or `pointer_safety::preferred` if the implementation has relaxed pointer safety.

### 20.10.6 Pointer alignment

```cpp
void* align(size_t alignment, size_t size, void*& ptr, size_t& space);
```

Effects: If it is possible to fit \( size \) bytes of storage aligned by \( alignment \) into the buffer pointed to by \( ptr \) with length \( space \), the function updates \( ptr \) to represent the first possible address of such storage and decreases \( space \) by the number of bytes used for alignment. Otherwise, the function does nothing.

Requires:

1. \( alignment \) shall be a power of two
2. \( ptr \) shall represent the address of contiguous storage of at least \( space \) bytes

Returns: A null pointer if the requested aligned buffer would not fit into the available space, otherwise the adjusted value of \( ptr \).

[Note: The function updates its \( ptr \) and \( space \) arguments so that it can be called repeatedly with possibly different \( alignment \) and \( size \) arguments for the same buffer. — end note]

```cpp
template<size_t N, class T>
[[nodiscard]] constexpr T* assume_aligned(T* ptr);
```

Mandates: \( N \) is a power of two.

Expects: \( ptr \) points to an object \( X \) of a type similar (7.3.5) to \( T \), where \( X \) has alignment \( N \) (6.6.6).

Returns: \( ptr \).

Throws: Nothing.

[Note: The alignment assumption on an object \( X \) expressed by a call to assume_aligned may result in generation of more efficient code. It is up to the program to ensure that the assumption actually holds. The call does not cause the compiler to verify or enforce this. An implementation might only make the assumption for those operations on \( X \) that access \( X \) through the pointer returned by assume_aligned. — end note]

### 20.10.7 Allocator argument tag

```cpp
namespace std {
    struct allocator_arg_t { explicit allocator_arg_t() = default; };
    inline constexpr allocator_arg_t allocator_arg{};
}
```

223) `pointer_safety::preferred` might be returned to indicate that a leak detector is running so that the program can avoid spurious leak reports.
The allocator_arg_t struct is an empty class type used as a unique type to disambiguate constructor and function overloading. Specifically, several types (see tuple 20.5) have constructors with allocator_arg_t as the first argument, immediately followed by an argument of a type that meets the Cpp17Allocator requirements (Table 34).

20.10.8 uses_allocator

20.10.8.1 uses_allocator trait

```c++
template<class T, class Alloc> struct uses_allocator;
```

Remarks: Automatically detects whether T has a nested allocator_type that is convertible from Alloc. Meets the Cpp17BinaryTypeTrait requirements (20.15.1). The implementation shall provide a definition that is derived from true_type if the qualified-id T::allocator_type is valid and denotes a type (13.9.2) and is_convertible_v<Alloc, T::allocator_type> != false, otherwise it shall be derived from false_type. A program may specialize this template to derive from true_type for a program-defined type T that does not have a nested allocator_type but nonetheless can be constructed with an allocator where either:

- the first argument of a constructor has type allocator_arg_t and the second argument has type Alloc or
- the last argument of a constructor has type Alloc.

20.10.8.2 Uses-allocator construction

Uses-allocator construction with allocator alloc and constructor arguments args... refers to the construction of an object of type T such that alloc is passed to the constructor of T if T uses an allocator type compatible with alloc. When applied to the construction of an object of type T, it is equivalent to initializing it with the value of the expression make_obj_using_allocator<T>(alloc, args...), described below.

The following utility functions support three conventions for passing alloc to a constructor:

1. If T does not use an allocator compatible with alloc, then alloc is ignored.
2. Otherwise, if T has a constructor invocable as T(allocator_arg, alloc, args...) (leading-allocator convention), then uses-allocator construction chooses this constructor form.
3. Otherwise, if T has a constructor invocable as T(args..., alloc) (trailing-allocator convention), then uses-allocator construction chooses this constructor form.

The uses_allocator_construction_args function template takes an allocator and argument list and produces (as a tuple) a new argument list matching one of the above conventions. Additionally, overloads are provided that treat specializations of pair such that uses-allocator construction is applied individually to the first and second data members. The make_obj_using_allocator and uninitialized_construct_using_allocator function templates apply the modified constructor arguments to construct an object of type T as a return value or in-place, respectively. [Note: For uses_allocator_construction_args and make_obj_using_allocator, type T is not deduced and must therefore be specified explicitly by the caller. —end note]

```c++
template<class T, class Alloc, class... Args>
auto uses_allocator_construction_args(const Alloc& alloc, Args&&... args) -> see below;
```

Constraints: T is not a specialization of pair.

Returns: A tuple value determined as follows:

1. If uses_allocator_v<T, Alloc> is false and is_constructible_v<T, Args...> is true, return forward_as_tuple(std::forward<Args>(args)...).
2. Otherwise, if uses_allocator_v<T, Alloc> is true and is_constructible_v<T, allocator_arg_t, Alloc, Args...> is true, return tuple<allocator_arg_t, const Alloc&, Args&&...>(
   allocator_arg, alloc, std::forward<Args>(args)...)
3. Otherwise, if uses_allocator_v<T, Alloc> is true and is_constructible_v<T, Args..., Alloc> is true, return forward_as_tuple(std::forward<Args>(args)..., alloc).

Otherwise, the program is ill-formed.
[Note: This definition prevents a silent failure to pass the allocator to a constructor of a type for which 
uses_allocator_v<T, Alloc> is true. — end note]

template<class T, class Alloc, class Tuple1, class Tuple2>
auto uses_allocator_construction_args(const Alloc& alloc, piecewise_construct_t,
    Tuple1&& x, Tuple2&& y) -> see below;

Constraints: T is a specialization of pair.

Effects: For T specified as pair<T1, T2>, equivalent to:

return make_tuple(
    piecewise_construct,
    apply([&alloc](auto&&... args1) {
        return uses_allocator_construction_args<T1>(
            alloc, std::forward<dec_type<args1>>(args1)...); }, std::forward<Tuple1>(x)),
    apply([&alloc](auto&&... args2) {
        return uses_allocator_construction_args<T2>(
            alloc, std::forward<dec_type<args2>>(args2)...); }, std::forward<Tuple2>(y)));

template<class T, class Alloc>
auto uses_allocator_construction_args(const Alloc& alloc) -> see below;

Constraints: T is a specialization of pair.

Effects: Equivalent to:

return uses_allocator_construction_args<T>(alloc, piecewise_construct, 
    tuple<{}>, tuple<{}>);

template<class T, class Alloc, class U, class V>
auto uses_allocator_construction_args(const Alloc& alloc, U&& u, V&& v) -> see below;

Constraints: T is a specialization of pair.

Effects: Equivalent to:

return uses_allocator_construction_args<T>(alloc, piecewise_construct, 
    forward_as_tuple(std::forward<U>(u)),
    forward_as_tuple(std::forward<V>(v)));

template<class T, class Alloc, class U, class V>
auto uses_allocator_construction_args(const Alloc& alloc, const pair<U,V>& pr) -> see below;

Constraints: T is a specialization of pair.

Effects: Equivalent to:

return uses_allocator_construction_args<T>(alloc, piecewise_construct, 
    forward_as_tuple(pr.first),
    forward_as_tuple(pr.second));

template<class T, class Alloc, class U, class V>
auto uses_allocator_construction_args(const Alloc& alloc, pair<U,V>&& pr) -> see below;

Constraints: T is a specialization of pair.

Effects: Equivalent to:

return uses_allocator_construction_args<T>(alloc, piecewise_construct, 
    forward_as_tuple(std::move(pr).first),
    forward_as_tuple(std::move(pr).second));

template<class T, class Alloc, class... Args>
T make_obj_using_allocator(const Alloc& alloc, Args&&... args);

Effects: Equivalent to:

return make_from_tuple<T>(uses_allocator_construction_args<T>(
    alloc, std::forward<Args>(args)...));

§ 20.10.8.2 608
template<class T, class Alloc, class... Args>
    T* uninitialized_construct_using_allocator(T* p, const Alloc& alloc, Args&&... args);

Effects: Equivalent to:
    return ::new(static_cast<void*>(p))
        T(make_obj_using_allocator<T>(alloc, std::forward<Args>(args)...));

20.10.9 Allocator traits

The class template allocator_traits supplies a uniform interface to all allocator types. An allocator cannot be a non-class type, however, even if allocator_traits supplies the entire required interface. [Note: Thus, it is always possible to create a derived class from an allocator. —end note]

namespace std {
    template<class Alloc> struct allocator_traits {
        using allocator_type = Alloc;
        using value_type = typename Alloc::value_type;
        using pointer = see below;
        using const_pointer = see below;
        using void_pointer = see below;
        using const_void_pointer = see below;
        using difference_type = see below;
        using size_type = see below;
        using propagate_on_container_copy_assignment = see below;
        using propagate_on_container_move_assignment = see below;
        using propagate_on_container_swap = see below;
        using is_always_equal = see below;
        template<class T> using rebind_alloc = see below;
        template<class T> using rebind_traits = allocator_traits<rebind_alloc<T>>;

        [[nodiscard]] static pointer allocate(Alloc& a, size_type n);
        [[nodiscard]] static pointer allocate(Alloc& a, size_type n, const_void_pointer hint);
        static void deallocate(Alloc& a, pointer p, size_type n);
        template<class T, class... Args>
            static void construct(Alloc& a, T* p, Args&&... args);
        template<class T>
            static void destroy(Alloc& a, T* p);
        static size_type max_size(const Alloc& a) noexcept;
        static Alloc select_on_container_copy_construction(const Alloc& rhs);
    };
}

20.10.9.1 Member types

using pointer = see below;

Type: Alloc::pointer if the qualified-id Alloc::pointer is valid and denotes a type (13.9.2); otherwise, value_type*.

using const_pointer = see below;

Type: Alloc::const_pointer if the qualified-id Alloc::const_pointer is valid and denotes a type (13.9.2); otherwise, pointer_traits<pointer>::rebind<const value_type>.
using void_pointer = see below;

Type: Alloc::void_pointer if the qualified-id Alloc::void_pointer is valid and denotes a type (13.9.2); otherwise, pointer_traits<pointer>::rebind<void>.

using const_void_pointer = see below;

Type: Alloc::const_void_pointer if the qualified-id Alloc::const_void_pointer is valid and denotes a type (13.9.2); otherwise, pointer_traits<pointer>::rebind<const void>.

using difference_type = see below;

Type: Alloc::difference_type if the qualified-id Alloc::difference_type is valid and denotes a type (13.9.2); otherwise, pointer_traits<pointer>::difference_type.

using size_type = see below;

Type: Alloc::size_type if the qualified-id Alloc::size_type is valid and denotes a type (13.9.2); otherwise, make_unsigned_t<difference_type>.

using propagate_on_container_copy_assignment = see below;

Type: Alloc::propagate_on_container_copy_assignment if the qualified-id Alloc::propagate_on_container_copy_assignment is valid and denotes a type (13.9.2); otherwise false_type.

using propagate_on_container_move_assignment = see below;

Type: Alloc::propagate_on_container_move_assignment if the qualified-id Alloc::propagate_on_container_move_assignment is valid and denotes a type (13.9.2); otherwise false_type.

using propagate_on_container_swap = see below;

Type: Alloc::propagate_on_container_swap if the qualified-id Alloc::propagate_on_container_swap is valid and denotes a type (13.9.2); otherwise false_type.

using is_always_equal = see below;

Type: Alloc::is_always_equal if the qualified-id Alloc::is_always_equal is valid and denotes a type (13.9.2); otherwise is_empty<Alloc>::type.

template<class T> using rebind_alloc = see below;

Alias template: Alloc::rebind<T>::other if the qualified-id Alloc::rebind<T>::other is valid and denotes a type (13.9.2); otherwise, Alloc<T, Args> if Alloc is a class template instantiation of the form Alloc<U, Args>, where Args is zero or more type arguments; otherwise, the instantiation of rebind_alloc is ill-formed.

20.10.9.2 Static member functions

[[nodiscard]] static pointer allocate(Alloc& a, size_type n);

Returns: a.allocate(n).

[[nodiscard]] static pointer allocate(Alloc& a, size_type n, const_void_pointer hint);

Returns: a.allocate(n, hint) if that expression is well-formed; otherwise, a.allocate(n).

static void deallocate(Alloc& a, pointer p, size_type n);

Effects: Calls a.deallocate(p, n).

Throws: Nothing.

template<class T, class... Args>
static void construct(Alloc& a, T* p, Args&&... args);

Effects: Calls a.construct(p, std::forward<Args>(args)...) if that call is well-formed; otherwise, invokes ::new (static_cast<void*>(p)) T(std::forward<Args>(args)...) if Alloc is a class template instantiation of the form Alloc<Us, Args>, where Args is zero or more type arguments; otherwise, the instantiation of rebind_construct is ill-formed.

template<class T>
static void destroy(Alloc& a, T* p);

Effects: Calls a.destroy(p) if that call is well-formed; otherwise, invokes p-&gt;~T().
static size_type max_size(const Alloc& a) noexcept;

Returns: a.max_size() if that expression is well-formed; otherwise, numeric_limits<size_type>::max()/sizeof(value_type).

static Alloc select_on_container_copy_construction(const Alloc& rhs);

Returns: rhs.select_on_container_copy_construction() if that expression is well-formed; otherwise, rhs.

### 20.10.10 The default allocator

All specializations of the default allocator meet the allocator completeness requirements (16.5.3.5.1).

```cpp
namespace std {
    template<class T> class allocator {
    public:
        using value_type = T;
        using size_type = size_t;
        using difference_type = ptrdiff_t;
        using propagate_on_container_move_assignment = true_type;
        using is_always_equal = true_type;
        constexpr allocator() noexcept;
        constexpr allocator(const allocator&) noexcept;
        template<class U> constexpr allocator(const allocator<U>&) noexcept;
        ~allocator();
        allocator& operator=(const allocator&) = default;
        [[nodiscard]] T* allocate(size_t n);
        void deallocate(T* p, size_t n);
    };
}
```

### 20.10.10.1 Members

Except for the destructor, member functions of the default allocator shall not introduce data races (6.8.2) as a result of concurrent calls to those member functions from different threads. Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before the next allocation (if any) in this order.

```cpp
[[nodiscard]] T* allocate(size_t n);
```

Returns: A pointer to the initial element of an array of storage of size n * sizeof(T), aligned appropriately for objects of type T.

Remarks: the storage is obtained by calling ::operator new (17.6.2), but it is unspecified when or how often this function is called.

Throws: bad_alloc if the storage cannot be obtained.

void deallocate(T* p, size_t n);

Requires: p shall be a pointer value obtained from allocate(). n shall equal the value passed as the first argument to the invocation of allocate which returned p.

Effects: deallocates the storage referenced by `p`.

Remarks: Uses ::operator delete (17.6.2), but it is unspecified when this function is called.

### 20.10.10.2 Operators

```cpp
template<class T, class U>
bool operator==(const allocator<T>&, const allocator<U>&) noexcept;
```

Returns: true.

```cpp
template<class T, class U>
bool operator!=(const allocator<T>&, const allocator<U>&) noexcept;
```

Returns: false.
20.10.11 Specialized algorithms

1 Throughout this subclause, the names of template parameters are used to express type requirements for those algorithms defined directly in namespace std.

(1.1) If an algorithm’s template parameter is named InputIterator, the template argument shall meet the Cpp17InputIterator requirements (23.3.5.2).

(1.2) If an algorithm’s template parameter is named ForwardIterator, the template argument shall meet the Cpp17ForwardIterator requirements (23.3.5.4), and is required to have the property that no exceptions are thrown from increment, assignment, comparison, or indirection through valid iterators.

2 Unless otherwise specified, if an exception is thrown in the following algorithms, objects constructed by a placement new-expression (7.6.2.7) are destroyed in an unspecified order before allowing the exception to propagate.

3 In the description of the algorithms, operator - is used for some of the iterator categories for which it need not be defined. In these cases, the value of the expression b - a is the number of increments of a needed to make bool(a == b) be true.

4 The following additional requirements apply for those algorithms defined in namespace std::ranges:

(4.1) The entities defined in the std::ranges namespace in this subclause are not found by argument-dependent name lookup (6.4.2). When found by unqualified (6.4.1) name lookup for the postfix-expression in a function call (7.6.1.2), they inhibit argument-dependent name lookup.

(4.2) Overloads of algorithms that take Range arguments (24.4.2) behave as if they are implemented by calling ranges::begin and ranges::end on the Range(s) and dispatching to the overload that takes separate iterator and sentinel arguments.

(4.3) The number and order of deducible template parameters for algorithm declarations is unspecified, except where explicitly stated otherwise. [Note: Consequently, these algorithms may not be called with explicitly-specified template argument lists. —end note]

5 [Note: When invoked on ranges of potentially overlapping subobjects (6.6.2), the algorithms specified in this subclause 20.10.11 result in undefined behavior. —end note]

6 Some algorithms defined in this clause make use of the exposition-only function voidify:

   template<class T>
   void* voidify(T& obj) noexcept {
      return const_cast<void*>(static_cast<const volatile void*>(addressof(obj)));
   }

20.10.11.1 Special memory concepts

1 Some algorithms in this subclause are constrained with the following exposition-only concepts:

   template<class I>
   concept no-throw-input-iterator = // exposition only
      InputIterator<I> &&
      is_lvalue_reference_v<iter_reference_t<I>> &&
      Same<remove_cvref_t<iter_reference_t<I>>, iter_value_t<I>>;

2 A type I models no-throw-input-iterator only if no exceptions are thrown from increment, copy construction, move construction, copy assignment, move assignment, or indirection through valid iterators.

3 [Note: This concept allows some InputIterator (23.3.4.9) operations to throw exceptions. —end note]

   template<class S, class I>
   concept no-throw-sentinel = Sentinel<S, I>; // exposition only

4 Types S and I model no-throw-sentinel only if no exceptions are thrown from copy construction, move construction, copy assignment, move assignment, or comparisons between valid values of type I and S.

5 [Note: This concept allows some Sentinel (23.3.4.7) operations to throw exceptions. —end note]
template<class R>
concept no-throw-input-range = // exposition only
  Range<R> &&
  no-throw-input-iterator<iterator_t<R>> &&
  no-throw-sentinel<sentinel_t<R>, iterator_t<R>>;

A type R models no-throw-input-range only if no exceptions are thrown from calls to ranges::begin and ranges::end on an object of type R.

template<class I>
concept no-throw-forward_iterator = // exposition only
  no-throw-input-iterator<I> &&
  ForwardIterator<I> &&
  no-throw-sentinel<I, I>;

[Note: This concept allows some ForwardIterator (23.3.4.11) operations to throw exceptions. — end note]

template<class R>
concept no-throw-forward-range = // exposition only
  no-throw-input-range<R> &&
  no-throw-forward-iterator<iterator_t<R>>;

20.10.11.2 addressof

template<class T> constexpr T* addressof(T& r) noexcept;

Returns: The actual address of the object or function referenced by r, even in the presence of an overloaded operator&.

Remarks: An expression addressof(E) is a constant subexpression (16.3.6) if E is an lvalue constant subexpression.

20.10.11.3 uninitialized_default_construct

namespace ranges {
  template<no-throw-forward-iterator I, no-throw-sentinel<I> S>
  requires DefaultConstructible<iter_value_t<I>>
  I uninitialized_default_construct(I first, S last);

  template<no-throw-forward-range R>
  requires DefaultConstructible<iter_value_t<iterator_t<R>>>,
  safe_iterator_t<R> uninitialized_default_construct(R&& r);
}

Effects: Equivalent to:

for (; first != last; ++first)
  ::new (voidify(*first))
  typename iterator_traits<ForwardIterator>::value_type;

return first;

template<class ForwardIterator, class Size>
ForwardIterator uninitialized_default_construct_n(ForwardIterator first, Size n);

Effects: Equivalent to:

for (; n > 0; (void)**first, --n)
  ::new (voidify(*first))
  typename iterator_traits<ForwardIterator>::value_type;

return first;
namespace ranges {
    template<no-throw-forward-iterator I>
    requires DefaultConstructible<iter_value_t<I>>
    I uninitialized_default_construct_n(I first, iter_difference_t<I> n);
}

Effects: Equivalent to:
    return uninitialized_default_construct(counted_iterator(first, n),
                                            default_sentinel).base();

20.10.11.4 uninitialized_value_construct

template<class ForwardIterator>
void uninitialized_value_construct(ForwardIterator first, ForwardIterator last);

Effects: Equivalent to:
    for (; first != last; ++first)
        ::new (voidify(*first))
        typename iterator_traits<ForwardIterator>::value_type();

namespace ranges {
    template<no-throw-forward-iterator I, no-throw-sentinel<I> S>
    requires DefaultConstructible<iter_value_t<I>>
    I uninitialized_value_construct(I first, S last);
    template<no-throw-forward-range R>
    requires DefaultConstructible<iter_value_t<iterator_t<R>>>>
    safe_iterator_t<R> uninitialized_value_construct(R&& r);
}

Effects: Equivalent to:
    for (; first != last; ++first)
        ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>()
        return first;

namespace ranges {
    template<no-throw-forward-iterator I>
    requires DefaultConstructible<iter_value_t<I>>
    I uninitialized_value_construct_n(I first, iter_difference_t<I> n);
}

Effects: Equivalent to:
    return uninitialized_value_construct(counted_iterator(first, n),
                                          default_sentinel).base();

20.10.11.5 uninitialized_copy

template<class InputIterator, class ForwardIterator>
ForwardIterator uninitialized_copy(InputIterator first, InputIterator last,
                                    ForwardIterator result);

Effects: [result, (last - first)) shall not overlap with [first, last).

Effects: Equivalent to:
    for (; first != last; ++result, (void) ++first)
        ::new (voidify(*result))
        typename iterator_traits<ForwardIterator>::value_type(*first);

Returns: result.
namespace ranges {
  template<InputIterator I, Sentinel<I> S1,
           no-throw-forward-iterator O, no-throw-sentinel<O> S2>
  requires Constructible<iter_value_t<O>, iter_reference_t<I>>
  uninitialized_copy_result<I, O>
  uninitialized_copy(I ifirst, S1 ilast, O ofirst, S2 olast);
  template<InputRange IR, no-throw-forward-range OR>
  requires Constructible<iter_value_t<iterator_t<OR>>, iter_reference_t<iterator_t<IR>>>,
  uninitialized_copy_result<safe_iterator_t<IR>, safe_iterator_t<OR>>
  uninitialized_copy(IR&& input_range, OR&& output_range);
}

4 Expects: [ofirst, olast) shall not overlap with [ifirst, ilast).
5 Effects: Equivalent to:
   for (; ifirst != ilast && ofirst != olast; ++ofirst, (void)++ifirst) {
     ::new (voidify(*ofirst)) remove_reference_t<iter_reference_t<O>>(*ifirst);
   }
   return {ifirst, ofirst};

6 Expects: [result, n) shall not overlap with [first, n).
7 Effects: Equivalent to:
   for ( ; n > 0; ++result, (void) ++first, --n) {
     ::new (voidify(*result))
     typename iterator_traits<ForwardIterator>::value_type(*first);
   }
8 Returns: result.

namespace ranges {
  template<InputIterator I, no-throw-forward-iterator O, no-throw-sentinel<O> S>
  requires Constructible<iter_value_t<O>, iter_reference_t<I>>
  uninitialized_copy_n_result<I, O>
  uninitialized_copy_n(I ifirst, iter_difference_t<I> n, O ofirst, S olast);
}

9 Expects: [ofirst, olast) shall not overlap with [ifirst, n).
10 Effects: Equivalent to:
    auto t = uninitialized_copy(counted_iterator(ifirst, n),
                                 default_sentinel, ofirst, olast);
    return {t.in.base(), t.out};

20.10.11.6 uninitialized_move

1 Expects: [result, (last - first)) shall not overlap with [first, last).
2 Effects: Equivalent to:
   for (; first != last; (void)++result, ++first)
     ::new (voidify(*result))
     typename iterator_traits<ForwardIterator>::value_type(std::move(*first));
   return result;

namespace ranges {
  template<InputIterator I, Sentinel<I> S1,
           no-throw-forward-iterator O, no-throw-sentinel<O> S2>
  requires Constructible<iter_value_t<O>, iterЏvalue_reference_t<I>>
  uninitialized_move_result<I, O>
  uninitialized_move(I ifirst, S1 ilast, O ofirst, S2 olast);
}
template<InputRange IR, no-throw-forward-range OR>

uninitialized_move_result<safe_iterator_t<IR>, safe_iterator_t<OR>>

uninitialized_move(IR&& input_range, OR&& output_range);

3  Expects: [ofirst, olast) shall not overlap with [ifirst, ilast).

4  Effects: Equivalent to:

   for (; ifirst != ilast && ofirst != olast; ++ofirst, (void)++ifirst) {
      ::new (voidify(*ofirst))
      remove_reference_t<iter_reference_t<O>>(ranges::iter_move(ifirst));
   }  return {ifirst, ofirst};

5  [Note: If an exception is thrown, some objects in the range [first, last) are left in a valid, but

     unspecified state. —end note]

template<class InputIterator, class Size, class ForwardIterator>

pair<InputIterator, ForwardIterator>

uninitialized_move_n(InputIterator first, Size n, ForwardIterator result);

6  Expects: [result, n) shall not overlap with [first, n).

7  Effects: Equivalent to:

   for (; n > 0; ++result, (void) ++first, --n)
      ::new (voidify(*result))
      typename iterator_traits<ForwardIterator>::value_type(std::move(*first));
   return {first, result};

namespace ranges {

   template<InputIterator I, no-throw-forward-iterator O, no-throw-sentinel<I> S>

   requires Constructible<iter_value_t<O>, iter_rvalue_reference_t<I>>

   uninitialized_move_n_result<I, O>

   uninitialized_move_n(I ifirst, iter_difference_t<I> n, O ofirst, S olast);

7  Expects: [ofirst, olast) shall not overlap with [ifirst, n).

8  Effects: Equivalent to:

   auto t = uninitialized_move(counted_iterator(ifirst, n),

   default_sentinel, ofirst, olast);
   return {t.in.base(), t.out};

9  [Note: If an exception is thrown, some objects in the range [first, n) are left in a valid but unspecified

     state. —end note]

20.10.11.7 uninitialized_fill

template<class ForwardIterator, class T>

void uninitialized_fill(ForwardIterator first, ForwardIterator last, const T& x);

1  Effects: Equivalent to:

   for (; first != last; ++first)
      ::new (voidify(*first))
      typename iterator_traits<ForwardIterator>::value_type(x);

namespace ranges {

   template<no-throw-forward-iterator I, no-throw-sentinel<I> S, class T>

   requires Constructible<iter_value_t<I>, const T&>

   I uninitialized_fill(I first, S last, const T& x);

   template<no-throw-forward-range R, class T>

   requires Constructible<iter_value_t<iterator_t<R>>, const T&>

   safe_iterator_t<R> uninitialized_fill(R&& r, const T& x);

2  Effects: Equivalent to:
for (; first != last; ++first) {
    ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>(x);
}  
return first;

template<class ForwardIterator, class Size, class T>
ForwardIterator uninitialized_fill_n(ForwardIterator first, Size n, const T& x);

Effects: Equivalent to:
for (; n--; ++first) 
    ::new (voidify(*first))
    typename iterator_traits<ForwardIterator>::value_type(x);
return first;

namespace ranges {
    template<no-throw-forward-iterator I, class T>
    requires Constructible<iter_value_t<I>, const T&>
    I uninitialized_fill_n(I first, iter_difference_t<I> n, const T& x);
}

Effects: Equivalent to:
return uninitialized_fill(counted_iterator(first, n), default_sentinel, x).base();

20.10.11.8 destroy

template<class T>
void destroy_at(T* location);

namespace ranges {
    template<Destructible T>
    void destroy_at(T* location) noexcept;
}

Effects:
(1.1) If T is an array type, equivalent to destroy(begin(*location), end(*location)).
(1.2) Otherwise, equivalent to location->~T().

template<class ForwardIterator>
void destroy(ForwardIterator first, ForwardIterator last);

Effects: Equivalent to:
for (; first!=last; ++first)
    destroy_at(addressof(*first));

namespace ranges {
    template<no-throw-input-iterator I, no-throw-sentinel<I> S>
    requires Destructible<iter_value_t<I>>
    I destroy(I first, S last) noexcept;
    template<no-throw-input-range R>
    requires Destructible<iter_value_t<iterator_t<R>>> 
    safe_iterator_t<R> destroy(R&& r) noexcept;
}

Effects: Equivalent to:
for (; first != last; ++first)
    destroy_at(addressof(*first));
return first;

template<class ForwardIterator, class Size>
ForwardIterator destroy_n(ForwardIterator first, Size n);

Effects: Equivalent to:
for (; n > 0; (void)++first, --n)
    destroy_at(addressof(*first));
return first;
namespace ranges {
    template<no-throw-input-iterator I>
    requires Destructible<iter_value_t<I>>
    I destroy_n(I first, iter_difference_t<I> n) noexcept;
}

Effects: Equivalent to:
return destroy(counted_iterator(first, n), default_sentinel).base();

20.10.12 C library memory allocation

[Note: The header <cstdlib> (17.2.2) declares the functions described in this subclause. — end note]

void* aligned_alloc(size_t alignment, size_t size);
void* calloc(size_t nmemb, size_t size);
void* malloc(size_t size);
void* realloc(void* ptr, size_t size);

Effects: These functions have the semantics specified in the C standard library.

Remarks: These functions do not attempt to allocate storage by calling :operator new() (17.6).

Storage allocated directly with these functions is implicitly declared reachable (see 6.6.5.4.3) on allocation, ceases to be declared reachable on deallocation, and need not cease to be declared reachable as the result of an undeclare_reachable() call. [Note: This allows existing C libraries to remain unaffected by restrictions on pointers that are not safely derived, at the expense of providing far fewer garbage collection and leak detection options for malloc()-allocated objects. It also allows malloc() to be implemented with a separate allocation arena, bypassing the normal declare_reachable() implementation. The above functions should never intentionally be used as a replacement for declare_reachable(), and newly written code is strongly encouraged to treat memory allocated with these functions as though it were allocated with operator new. — end note]

void free(void* ptr);

Effects: This function has the semantics specified in the C standard library.

Remarks: This function does not attempt to deallocate storage by calling :operator delete().

See also: ISO C 7.22.3

20.11 Smart pointers

20.11.1 Class template unique_ptr

A unique pointer is an object that owns another object and manages that other object through a pointer. More precisely, a unique pointer is an object u that stores a pointer to a second object p and will dispose of p when u is itself destroyed (e.g., when leaving block scope (8.7)). In this context, u is said to own p.

The mechanism by which u disposes of p is known as p’s associated deleter, a function object whose correct invocation results in p’s appropriate disposition (typically its deletion).

Let the notation u.p denote the pointer stored by u, and let u.d denote the associated deleter. Upon request, u can reset (replace) u.p and u.d with another pointer and deleter, but properly disposes of its owned object via the associated deleter before such replacement is considered completed.

Each object of a type U instantiated from the unique_ptr template specified in this subclause has the strict ownership semantics, specified above, of a unique pointer. In partial satisfaction of these semantics, each such U is Cpp17MoveConstructible and Cpp17MoveAssignabe, but is not Cpp17CopyConstructible nor Cpp17CopyAssignabe. The template parameter T of unique_ptr may be an incomplete type.

[Note: The uses of unique_ptr include providing exception safety for dynamically allocated memory, passing ownership of dynamically allocated memory to a function, and returning dynamically allocated memory from a function. — end note]

20.11.1.1 Default deleters

20.11.1.1 In general

The class template default_delete serves as the default deleter (destruction policy) for the class template unique_ptr.

The template parameter T of default_delete may be an incomplete type.
20.11.1.1.2  default_delete

```cpp
namespace std {
    template<class T> struct default_delete {
        constexpr default_delete() noexcept = default;
        template<class U> default_delete(const default_delete<U>&) noexcept;
        void operator()(T*) const;
    };
}
```

template<class U> default_delete(const default_delete<U>& other) noexcept;

1  **Effects:** Constructs a `default_delete` object from another `default_delete<U>` object.

2  **Remarks:** This constructor shall not participate in overload resolution unless `U*` is implicitly convertible to `T*`.

```cpp
void operator()(T* ptr) const;
```

3  **Effects:** Calls `delete` on `ptr`.

4  **Remarks:** If `T` is an incomplete type, the program is ill-formed.

20.11.1.1.3  default_delete<T[]>

```cpp
namespace std {
    template<class T> struct default_delete<T[]> {
        constexpr default_delete() noexcept = default;
        template<class U> default_delete(const default_delete<U[]>&) noexcept;
        template<class U> void operator()(U* ptr) const;
    };
}
```

template<class U> default_delete(const default_delete<U[]>& other) noexcept;

1  **Effects:** Constructs a `default_delete` object from another `default_delete<U[]>` object.

2  **Remarks:** This constructor shall not participate in overload resolution unless `U(*)[]` is convertible to `T(*)[]`.

```cpp
template<class U> void operator()(U* ptr) const;
```

3  **Effects:** Calls `delete[]` on `ptr`.

4  **Remarks:** If `U` is an incomplete type, the program is ill-formed. This function shall not participate in overload resolution unless `U(*)[]` is convertible to `T(*)[]`.

20.11.1.2  unique_ptr for single objects

```cpp
namespace std {
    template<class T, class D = default_delete<T>> class unique_ptr {
        public:
            using pointer = see below;
            using element_type = T;
            using deleter_type = D;

        // 20.11.2.1, constructors
            constexpr unique_ptr() noexcept;
            explicit unique_ptr(pointer p) noexcept;
            unique_ptr(pointer p, see below d1) noexcept;
            unique_ptr(pointer p, see below d2) noexcept;
            unique_ptr(unique_ptr&& u) noexcept;
            constexpr unique_ptr(nullptr_t) noexcept;
            template<class U, class E>
                unique_ptr(unique_ptr<U, E>&& u) noexcept;

        // 20.11.2.2, destructor
            ~unique_ptr();
    }
}
```
// 20.11.1.2.3, assignment
unique_ptr& operator=(unique_ptr& u) noexcept;
template<class U, class E>
  unique_ptr& operator=(unique_ptr<U, D&& u) noexcept;
unique_ptr& operator=(nullptr_t) noexcept;

// 20.11.1.2.4, observers
add_lvalue_reference_t<T> operator*() const;
pointer operator->() const noexcept;
pointer get() const noexcept;
deleter_type& get_deleter() noexcept;
const deleter_type& get_deleter() const noexcept;
explicit operator bool() const noexcept;

// 20.11.1.2.5, modifiers
pointer release() noexcept;
void reset(pointer p = pointer()) noexcept;
void swap(unique_ptr& u) noexcept;

// disable copy from lvalue
unique_ptr(const unique_ptr&) = delete;
unique_ptr& operator=(const unique_ptr&) = delete;

1 The default type for the template parameter D is default_delete. A client-supplied template argument D shall be a function object type (20.14), lvalue reference to function, or lvalue reference to function object type for which, given a value d of type D and a value ptr of type unique_ptr<T, D>::pointer, the expression d(ptr) is valid and has the effect of disposing of the pointer as appropriate for that deleter.

2 If the deleter’s type D is not a reference type, D shall meet the Cpp17Destructible requirements (Table 30).

3 If the qualified-id remove_reference_t<D>::pointer is valid and denotes a type (13.9.2), then unique_ptr<T, D>::pointer shall be a synonym for remove_reference_t<D>::pointer. Otherwise unique_ptr<T, D>::pointer shall be a synonym for element_type*. The type unique_ptr<T, D>::pointer shall meet the Cpp17NullablePointer requirements (Table 31).

4 [Example: Given an allocator type X (Table 34) and letting A be a synonym for allocator_traits<X>, the types A::pointer, A::const_pointer, A::void_pointer, and A::const_void_pointer may be used as unique_ptr<T, D>::pointer. —end example]

20.11.1.2.1 Constructors
constexpr unique_ptr() noexcept;
constexpr unique_ptr(nullptr_t) noexcept;

1 Requires: D shall meet the Cpp17DefaultConstructible requirements (Table 25), and that construction shall not throw an exception.

2 Effects: Constructs a unique_ptr object that owns nothing, value-initializing the stored pointer and the stored deleter.

3 Ensures: get() == nullptr. get_deleter() returns a reference to the stored deleter.

4 Remarks: If is_pointer_v<deleter_type> is true or is_default_constructible_v<deleter_type> is false, this constructor shall not participate in overload resolution.

explicit unique_ptr(pointer p) noexcept;

5 Requires: D shall meet the Cpp17DefaultConstructible requirements (Table 25), and that construction shall not throw an exception.

6 Effects: Constructs a unique_ptr which owns p, initializing the stored pointer with p and value-initializing the stored deleter.

7 Ensures: get() == p. get_deleter() returns a reference to the stored deleter.

8 Remarks: If is_pointer_v<deleter_type> is true or is_default_constructible_v<deleter_type> is false, this constructor shall not participate in overload resolution. If class template argument
deduction (12.3.1.8) would select the function template corresponding to this constructor, then the program is ill-formed.

unique_ptr(pointer p, const D& d) noexcept;
unique_ptr(pointer p, remove_reference_t<D>&& d) noexcept;

Requires: For the first constructor, if D is not a reference type, D shall meet the Cpp17CopyConstructible requirements and such construction shall not exit via an exception. For the second constructor, if D is not a reference type, D shall meet the Cpp17MoveConstructible requirements and such construction shall not exit via an exception.

Effects: Constructs a unique_ptr object which owns p, initializing the stored pointer with p and initializing the deleter from std::forward<decltype(d)>(d).

Remarks: If D is a reference type, the second constructor is defined as deleted. These constructors shall not participate in overload resolution unless is_constructible_v<D, decltype(d)> is true.

Ensures: get() == p. get_deleter() returns a reference to the stored deleter. If D is a reference type then get_deleter() returns a reference to the lvalue d.

Remarks: If class template argument deduction (12.3.1.8) would select a function template corresponding to either of these constructors, then the program is ill-formed.

[Example:
D d;
unique_ptr<int, D> p1(new int, D()); // D must be Cpp17MoveConstructible
unique_ptr<int, D> p2(new int, d); // D must be Cpp17CopyConstructible
unique_ptr<D&> p3(new int, d); // p3 holds a reference to d
unique_ptr<int, const D&> p4(new int, D()); // error: rvalue deleter object combined
// with reference deleter type
— end example]

unique_ptr(unique_ptr&& u) noexcept;

Requires: If D is not a reference type, D shall meet the Cpp17MoveConstructible requirements (Table 26). Construction of the deleter from an rvalue of type D shall not throw an exception.

Effects: Constructs a unique_ptr from u. If D is a reference type, this deleter is copy constructed from u’s deleter; otherwise, this deleter is move constructed from u’s deleter. [Note: The construction of the deleter can be implemented with std::forward<D> — end note]

Ensures: get() yields the value u.get() yielded before the construction. u.get() == nullptr. get_deleter() returns a reference to the stored deleter that was constructed from u.get_deleter(). If D is a reference type then get_deleter() and u.get_deleter() both reference the same lvalue deleter.

template<class U, class E> unique_ptr(unique_ptr<U, E>&& u) noexcept;

Requires: If E is not a reference type, construction of the deleter from an rvalue of type E shall be well-formed and shall not throw an exception. Otherwise, E is a reference type and construction of the deleter from an lvalue of type E shall be well-formed and shall not throw an exception.

Remarks: This constructor shall not participate in overload resolution unless:

(19.1) unique_ptr<U, E>::pointer is implicitly convertible to pointer,
(19.2) U is not an array type, and
(19.3) either D is a reference type and E is the same type as D, or D is not a reference type and E is implicitly convertible to D.

Effects: Constructs a unique_ptr from u. If E is a reference type, this deleter is copy constructed from u’s deleter; otherwise, this deleter is move constructed from u’s deleter. [Note: The deleter constructor can be implemented with std::forward<E> — end note]

Ensures: get() yields the value u.get() yielded before the construction. u.get() == nullptr. get_deleter() returns a reference to the stored deleter that was constructed from u.get_deleter().

§ 20.11.2.1
20.11.1.2.2 Destructor

~unique_ptr();

Requires: The expression get_deleter()(get()) shall be well-formed, shall have well-defined behavior, and shall not throw exceptions. [Note: The use of default_delete requires T to be a complete type. — end note]

Effects: If get() == nullptr there are no effects. Otherwise get_deleter()(get()).

20.11.1.2.3 Assignment

unique_ptr& operator=(unique_ptr&& u) noexcept;

Requires: If D is not a reference type, D shall meet the Cpp17MoveAssignable requirements (Table 28) and assignment of the deleter from an rvalue of type D shall not throw an exception. Otherwise, D is a reference type; remove_reference_t<D> shall meet the Cpp17CopyAssignable requirements and assignment of the deleter from an lvalue of type D shall not throw an exception.

Effects: Calls reset(u.release()) followed by get_deleter() = std::forward<D>(u.get_deleter()).

Returns: *this.

Ensures: u.get() == nullptr.

template<class U, class E> unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;

Requires: If E is not a reference type, assignment of the deleter from an rvalue of type E shall be well-formed and shall not throw an exception. Otherwise, E is a reference type and assignment of the deleter from an lvalue of type E shall be well-formed and shall not throw an exception.

Remarks: This operator shall not participate in overload resolution unless:

(6.1) unique_ptr<U, E>::pointer is implicitly convertible to pointer, and
(6.2) U is not an array type, and
(6.3) is_assignable_v<D&, E&&> is true.

Effects: Calls reset(u.release()) followed by get_deleter() = std::forward<E>(u.get_deleter()).

Returns: *this.

Ensures: u.get() == nullptr.

unique_ptr& operator=(nullptr_t) noexcept;

Effects: As if by reset().

Ensures: get() == nullptr.

Returns: *this.

20.11.1.2.4 Observers

add_lvalue_reference_t<T> operator*() const;

Requires: get() != nullptr.

Returns: *get().

pointer operator->() const noexcept;

Requires: get() != nullptr.

Returns: get().

[Note: The use of this function typically requires that T be a complete type. — end note]

pointer get() const noexcept;

Returns: The stored pointer.
deleter_type& get_deleter() noexcept;
const deleter_type& get_deleter() const noexcept;

Returns: A reference to the stored deleter.

explicit operator bool() const noexcept;

Returns: get() != nullptr.

20.11.1.2.5 Modifiers

pointer release() noexcept;

Ensures: get() == nullptr.

Returns: The value get() had at the start of the call to release.

void reset(pointer p = pointer()) noexcept;

Requires: The expression get_deleter()(get()) shall be well-formed, shall have well-defined behavior, and shall not throw exceptions.

Effects: Assigns p to the stored pointer, and then if and only if the old value of the stored pointer, old_p, was not equal to nullptr, calls get_deleter()(old_p). [Note: The order of these operations is significant because the call to get_deleter() may destroy *this. —end note]

Ensures: get() == p. [Note: The postcondition does not hold if the call to get_deleter() destroys *this since this->get() is no longer a valid expression. —end note]

void swap(unique_ptr& u) noexcept;

Requires: get_deleter() shall be swappable (16.5.3.2) and shall not throw an exception under swap.

Effects: Invokes swap on the stored pointers and on the stored deleters of *this and u.

20.11.1.3 unique_ptr for array objects with a runtime length

namespace std {
    template<class T, class D> class unique_ptr<T[], D> {
        public:
            using pointer = see below;
            using element_type = T;
            using deleter_type = D;

            // 20.11.1.3.1, constructors
            constexpr unique_ptr() noexcept;
            template<class U> explicit unique_ptr(U p) noexcept;
            template<class U> unique_ptr(U p, see below d) noexcept;
            unique_ptr(unique_ptr&& u) noexcept;
            template<class U, class E>
                unique_ptr(unique_ptr<U, E>&& u) noexcept;
            constexpr unique_ptr(nullptr_t) noexcept;

            // destructor
            ~unique_ptr();

            // assignment
            unique_ptr& operator=(unique_ptr&& u) noexcept;
            template<class U, class E>
                unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
            unique_ptr& operator=(nullptr_t) noexcept;

            // 20.11.1.3.3, observers
            T& operator[](size_t i) const;
            pointer get() const noexcept;
            deleter_type& get_deleter() noexcept;
            const deleter_type& get_deleter() const noexcept;
            explicit operator bool() const noexcept;

§ 20.11.1.3
1 A specialization for array types is provided with a slightly altered interface.

(1.1) — Conversions between different types of unique_ptr<T[], D> that would be disallowed for the corresponding pointer-to-array types, and conversions to or from the non-array forms of unique_ptr, produce an ill-formed program.

(1.2) — Pointers to types derived from T are rejected by the constructors, and by reset.

(1.3) — The observers operator* and operator-> are not provided.

(1.4) — The indexing observer operator[] is provided.

(1.5) — The default deleter will call delete[].

2 Descriptions are provided below only for members that differ from the primary template.

3 The template argument T shall be a complete type.

20.11.1.3.1 Constructors

template<class U> explicit unique_ptr(U p) noexcept;

1 This constructor behaves the same as the constructor in the primary template that takes a single parameter of type pointer except that it additionally shall not participate in overload resolution unless

(1.1) — U is the same type as pointer, or

(1.2) — pointer is the same type as element_type*, U is a pointer type V*, and V(*)[] is convertible to element_type(*)[].

template<class U> unique_ptr(U p, see below d) noexcept;
template<class U> unique_ptr(U p, see below d) noexcept;

2 These constructors behave the same as the constructors in the primary template that take a parameter of type pointer and a second parameter except that they shall not participate in overload resolution unless either

(2.1) — U is the same type as pointer,

(2.2) — U is nullptr_t, or

(2.3) — pointer is the same type as element_type*, U is a pointer type V*, and V(*)[] is convertible to element_type(*)[].

template<class U, class E> unique_ptr(unique_ptr<U, E>&& u) noexcept;

3 This constructor behaves the same as in the primary template, except that it shall not participate in overload resolution unless all of the following conditions hold, where UP is unique_ptr<U, E>:

(3.1) — U is an array type, and

(3.2) — pointer is the same type as element_type*, and

(3.3) — UP::pointer is the same type as UP::element_type*, and

(3.4) — UP::element_type(*)[] is convertible to element_type(*)[], and

(3.5) — either D is a reference type and E is the same type as D, or D is not a reference type and E is implicitly convertible to D.

[Note: This replaces the overload-resolution specification of the primary template — end note]
20.11.1.3.2 Assignment

```
template<class U, class E>
unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
```

1 This operator behaves the same as in the primary template, except that it shall not participate in overloaded resolution unless all of the following conditions hold, where UP is `unique_ptr<U, E>`:

- U is an array type, and
- `pointer` is the same type as `element_type*`, and
- `UP::pointer` is the same type as `UP::element_type*`, and
- `UP::element_type(*)[]` is convertible to `element_type(*)[]`, and
- `is_assignable_v<D&, E&&>` is true.

[Note: This replaces the overload-resolution specification of the primary template — end note]

20.11.1.3.3 Observers

```
T& operator[](size_t i) const;
```

1 Requires: `i < the number of elements in the array to which the stored pointer points.`

2 Returns: `get()[i].`

20.11.1.3.4 Modifiers

```
void reset(nullptr_t p = nullptr) noexcept;
```

1 Effects: Equivalent to `reset(pointer())`.

```
template<class U>
void reset(U p) noexcept;
```

2 This function behaves the same as the `reset` member of the primary template, except that it shall not participate in overload resolution unless either

- U is the same type as `pointer`, or
- `pointer` is the same type as `element_type*`, U is a pointer type `V*`, and `V(*)[]` is convertible to `element_type(*)[]`.

20.11.1.4 Creation

```
template<class T, class... Args> unique_ptr<T> make_unique(Args&&... args);
```

1 Remarks: This function shall not participate in overload resolution unless T is not an array.

2 Returns: `unique_ptr<T>({new T(std::forward<Args>(args)...))}.`

```
template<class T>
unique_ptr<T> make_unique(size_t n);
```

3 Remarks: This function shall not participate in overload resolution unless T is an array of unknown bound.

4 Returns: `unique_ptr<T>({new remove_extent_t<T>[n]()}).`

```
template<class T, class... Args> unspecified make_unique(Args&&... = delete;
```

5 Remarks: This function shall not participate in overload resolution unless T is an array of known bound.

```
template<class T>
unique_ptr<T> make_unique_default_init();
```

6 Constraints: T is not an array.

7 Returns: `unique_ptr<T>({new T}).`

```
template<class T>
unique_ptr<T> make_unique_default_init(size_t n);
```

8 Constraints: T is an array of unknown bound.

9 Returns: `unique_ptr<T>({new remove_extent_t<T>[n]}).`

```
template<class T, class... Args> unspecified make_unique_default_init(Args&&... = delete;
```

10 Constraints: T is an array of known bound.
20.11.1.5 Specialized algorithms [unique.ptr.special]

```
template<class T, class D> void swap(unique_ptr<T, D>& x, unique_ptr<T, D>& y) noexcept;

Remarks: This function shall not participate in overload resolution unless is_swappable_v<D> is true.

Effects: Calls x.swap(y).
```

```
template<class T1, class D1, class T2, class D2>
bool operator==(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: x.get() == y.get().
```

```
template<class T1, class D1, class T2, class D2>
bool operator!=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: x.get() != y.get().
```

```
template<class T1, class D1, class T2, class D2>
bool operator<(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: less<CT>()(x.get(), y.get()).
```

```
Remarks: If unique_ptr<T1, D1>::pointer is not implicitly convertible to CT or unique_ptr<T2, D2>::pointer is not implicitly convertible to CT, the program is ill-formed.
```

```
template<class T1, class D1, class T2, class D2>
bool operator>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: y < x.
```

```
template<class T1, class D1, class T2, class D2>
bool operator<=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: !(y < x).
```

```
template<class T1, class D1, class T2, class D2>
bool operator>=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: !(x < y).
```

```
template<class T, class D>
bool operator==(const unique_ptr<T, D>& x, nullptr_t) noexcept;
template<class T, class D>
bool operator==(nullptr_t, const unique_ptr<T, D>& x) noexcept;

Returns: !x.
```

```
template<class T, class D>
bool operator!=(const unique_ptr<T, D>& x, nullptr_t) noexcept;
template<class T, class D>
bool operator!=(nullptr_t, const unique_ptr<T, D>& x) noexcept;

Returns: (bool)x.
```

```
template<class T, class D>
bool operator<(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
bool operator<(nullptr_t, const unique_ptr<T, D>& x);
```

```
Requires: The specialization less<unique_ptr<T, D>::pointer> shall be a function object type (20.14) that induces a strict weak ordering (25.7) on the pointer values.
```

```
Returns: The first function template returns less<unique_ptr<T, D>::pointer>()(x.get(), nullptr)
```
The second function template returns
less<unique_ptr<T, D>::pointer>()(nullptr, x.get())

```cpp
template<class T, class D>
bool operator>(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
bool operator>(nullptr_t, const unique_ptr<T, D>& x);
```

Returns: The first function template returns nullptr < x. The second function template returns x < nullptr.

```cpp
template<class T, class D>
bool operator<=(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
bool operator<=(nullptr_t, const unique_ptr<T, D>& x);
```

Returns: The first function template returns !(nullptr < x). The second function template returns !(x < nullptr).

```cpp
template<class E, class T, class Y, class D>
basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const unique_ptr<Y, D>& p);
```

Effects: Equivalent to: os << p.get();

Returns: os.

Remarks: This function shall not participate in overload resolution unless os << p.get() is a valid expression.

20.11.2 Class bad_weak_ptr

```cpp
namespace std {
    class bad_weak_ptr : public exception {
        const char* what() const noexcept override;
    }
}
```

An exception of type bad_weak_ptr is thrown by the shared_ptr constructor taking a weak_ptr.

```cpp
const char* what() const noexcept override;
```

Returns: An implementation-defined NTBS.

20.11.3 Class template shared_ptr

```cpp
namespace std {
    template<class T> class shared_ptr {
        using element_type = remove_extent_t<T>;
        using weak_type = weak_ptr<T>;
    }
}
```

The shared_ptr class template stores a pointer, usually obtained via new. shared_ptr implements semantics of shared ownership; the last remaining owner of the pointer is responsible for destroying the object, or otherwise releasing the resources associated with the stored pointer. A shared_ptr is said to be empty if it does not own a pointer.
// 20.11.3.1, constructors
constexpr shared_ptr() noexcept;
constexpr shared_ptr(nullptr_t) noexcept : shared_ptr() {} 

template<class Y>
  explicit shared_ptr(Y* p);
template<class Y, class D>
  shared_ptr(Y* p, D d);
template<class Y, class D, class A>
  shared_ptr(Y* p, D d, A a);
template<class D>
  shared_ptr(nullptr_t p, D d);
template<class D, class A>
  shared_ptr(nullptr_t p, D d, A a);
template<class Y>
  shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;

template<class Y>
  shared_ptr(shared_ptr<Y>&& r, element_type* p) noexcept;

shared_ptr(const shared_ptr& r) noexcept;
template<class Y>
  shared_ptr(const shared_ptr<Y>& r) noexcept;

shared_ptr(shared_ptr&& r) noexcept;
template<class Y>
  shared_ptr(shared_ptr<Y>&& r) noexcept;

template<class Y, class D>
  shared_ptr(unique_ptr<Y, D>&& r);

// 20.11.3.2, destructor
~shared_ptr();

// 20.11.3.3, assignment
shared_ptr& operator=(const shared_ptr& r) noexcept;
template<class Y>
  shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;

shared_ptr& operator=(shared_ptr&& r) noexcept;
template<class Y>
  shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;

template<class Y, class D>
  shared_ptr& operator=(unique_ptr<Y, D>&& r);

// 20.11.3.4, modifiers
void swap(shared_ptr& r) noexcept;
void reset() noexcept;
template<class Y>
  void reset(Y* p);
template<class Y, class D>
  void reset(Y* p, D d);
template<class Y, class D, class A>
  void reset(Y* p, D d, A a);

// 20.11.3.5, observers
element_type* get() const noexcept;
T* operator*() const noexcept;
T* operator->() const noexcept;
element_type& operator[](ptrdiff_t i) const;
long use_count() const noexcept;
explicit operator bool() const noexcept;

template<class U>
  bool owner_before(const shared_ptr<U>& b) const noexcept;

template<class U>
  bool owner_before(const weak_ptr<U>& b) const noexcept;
template<class T>
  shared_ptr<weak_ptr<T>) -> shared_ptr<T>
;  
template<class T, class D>
  shared_ptr(unique_ptr<T, D>) -> shared_ptr<T>
;  

Specializations of shared_ptr shall be Cpp17CopyConstructible, Cpp17CopyAssignable, and Cpp17LessThanComparable, allowing their use in standard containers. Specializations of shared_ptr shall be contextually convertible to bool, allowing their use in boolean expressions and declarations in conditions. The template parameter T of shared_ptr may be an incomplete type.

[Example:
  if (shared_ptr<X> px = dynamic_pointer_cast<X>(py)) {
    // do something with px
  }
  
  —end example]

For purposes of determining the presence of a data race, member functions shall access and modify only the shared_ptr and weak_ptr objects themselves and not objects they refer to. Changes in use_count() do not reflect modifications that can introduce data races.

For the purposes of subclause 20.11, a pointer type Y* is said to be compatible with a pointer type T* when either Y* is convertible to T*, or Y is U[N] and T is cv U[].

20.11.3.1 Constructors

In the constructor definitions below, enables shared_from_this with p, for a pointer p of type Y*, means that if Y has an unambiguous and accessible base class that is a specialization of enable_shared_from_this (20.11.6), then remove_cv_t<Y>* shall be implicitly convertible to T* and the constructor evaluates the statement:

  if (p != nullptr && p->weak_this.expired())
    p->weak_this = shared_ptr<remove_cv_t<Y>>(*this, const_cast<remove_cv_t<Y>*>(p));

The assignment to the weak_this member is not atomic and conflicts with any potentially concurrent access to the same object (6.8.2).

constexpr shared_ptr() noexcept;

Effects: Constructs an empty shared_ptr object.

Ensures: use_count() == 0 && get() == nullptr.

template<class Y> explicit shared_ptr(Y* p);

Requires: Y shall be a complete type. The expression delete[] p, when T is an array type, or delete p, when T is not an array type, shall have well-defined behavior, and shall not throw exceptions.

Effects: When T is not an array type, constructs a shared_ptr object that owns the pointer p. Otherwise, constructs a shared_ptr that owns p and a deleter of an unspecified type that calls delete[] p. When T is not an array type, enables shared_from_this with p. If an exception is thrown, delete p is called when T is not an array type, delete[] p otherwise.

Ensures: use_count() == 1 && get() == p.

Throws: bad_alloc, or an implementation-defined exception when a resource other than memory could not be obtained.

Remarks: When T is an array type, this constructor shall not participate in overload resolution unless the expression delete[] p is well-formed and either T is U[N] and Y(*)[N] is convertible to T*, or T is U[] and Y(*)[] is convertible to T*. When T is not an array type, this constructor shall not participate in overload resolution unless the expression delete p is well-formed and Y* is convertible to T*.

template<class Y, class D> shared_ptr(Y* p, D d);

template<class Y, class D, class A> shared_ptr(Y* p, D d, A a);

template<class D> shared_ptr(nullptr_t p, D d);
template<class D, class A> shared_ptr(nullptr_t p, D d, A a);

Requires: Construction of \( d \) and a deleter of type \( D \) initialized with \( \text{std::move}(d) \) shall not throw exceptions. The expression \( d(p) \) shall have well-defined behavior and shall not throw exceptions. \( A \) shall meet the \( \text{Cpp17Allocator} \) requirements (Table 34).

Effects: Constructs a \( \text{shared_ptr} \) object that owns the object \( p \) and the deleter \( d \). When \( T \) is not an array type, the first and second constructors enable \( \text{shared_from_this} \) with \( p \). The second and fourth constructors shall use a copy of \( a \) to allocate memory for internal use. If an exception is thrown, \( d(p) \) is called.

Ensures: \( \text{use_count()} = 1 \) \&\& \( \text{get()} = p \).

Throws: \( \text{bad_alloc} \), or an implementation-defined exception when a resource other than memory could not be obtained.

Remarks: When \( T \) is an array type, this constructor shall not participate in overload resolution unless \( \text{is_move_constructible_v} \langle D \rangle \) is \( \text{true} \), the expression \( d(p) \) is well-formed, and either \( T \) is \( U[N] \) and \( Y(*)[N] \) is convertible to \( T* \), or \( T \) is \( U[] \) and \( Y(*)[] \) is convertible to \( T* \). When \( T \) is not an array type, this constructor shall not participate in overload resolution unless \( \text{is_move_constructible_v} \langle D \rangle \) is \( \text{true} \), the expression \( d(p) \) is well-formed, and \( Y* \) is convertible to \( T* \).

\[ \text{template<class Y> shared_ptr(const shared_ptr<Y>& r, element_type* p)} \] noexcept;
\[ \text{template<class Y> shared_ptr(shared_ptr<Y>&& r, element_type* p)} \] noexcept;

Effects: Constructs a \( \text{shared_ptr} \) instance that stores \( p \) and shares ownership with the initial value of \( r \).

Ensures: \( \text{get()} = p \). For the second overload, \( r \) is empty and \( r.get() = \text{nullptr} \).

[Note: To avoid the possibility of a dangling pointer, the user of this constructor should ensure that \( p \) remains valid at least until the ownership group of \( r \) is destroyed. —end note]

[Note: This constructor allows creation of an empty \( \text{shared_ptr} \) instance with a non-null stored pointer. —end note]

\[ \text{shared_ptr(const shared_ptr& r)} \] noexcept;
\[ \text{template<class Y> shared_ptr(const shared_ptr<Y>& r)} \] noexcept;

Remarks: The second constructor shall not participate in overload resolution unless \( Y* \) is compatible with \( T* \).

Effects: If \( r \) is empty, constructs an empty \( \text{shared_ptr} \) object; otherwise, constructs a \( \text{shared_ptr} \) object that shares ownership with \( r \).

Ensures: \( \text{get()} = r.get() \) \&\& \( \text{use_count()} = r\text{.use_count()} \).

\[ \text{shared_ptr(shared_ptr& r)} \] noexcept;
\[ \text{template<class Y> shared_ptr(shared_ptr<Y>&& r)} \] noexcept;

Remarks: The second constructor shall not participate in overload resolution unless \( Y* \) is compatible with \( T* \).

Effects: Move constructs a \( \text{shared_ptr} \) instance from \( r \).

Ensures: \( *\text{this} \) shall contain the old value of \( r \). \( r \) shall be empty. \( r\text{.get()} = \text{nullptr} \).

\[ \text{template<class Y> explicit shared_ptr(const weak_ptr<Y>& r)} \];

Effects: Constructs a \( \text{shared_ptr} \) object that shares ownership with \( r \) and stores a copy of the pointer stored in \( r \). If an exception is thrown, the constructor has no effect.

Ensures: \( \text{use_count()} = r\text{.use_count()} \).

Throws: \( \text{bad_weak_ptr} \) when \( r\text{.expired()} \).

Remarks: This constructor shall not participate in overload resolution unless \( Y* \) is compatible with \( T* \).

\[ \text{template<class Y, class D> shared_ptr(unique_ptr<Y, D>&& r)} \];

Remarks: This constructor shall not participate in overload resolution unless \( Y* \) is compatible with \( T* \) and \( \text{unique_ptr<Y, D>::pointer} \) is convertible to \( \text{element_type*} \).
Effects: If \( r.\text{get}() == \text{nullptr} \), equivalent to \( \text{shared\_ptr}() \). Otherwise, if \( D \) is not a reference type, equivalent to \( \text{shared\_ptr}(r.\text{release}(), r.\text{get\_deleter}()) \). Otherwise, equivalent to \( \text{shared\_ptr}(r.\text{release}(), \text{ref}(r.\text{get\_deleter}())) \). If an exception is thrown, the constructor has no effect.

20.11.3.2 Destructor

\[ \text{\texttt{\~\texttt{shared\_ptr}();}} \]

Effects:

- If \( *\text{this} \) is empty or shares ownership with another \( \text{shared\_ptr} \) instance (\( \text{use\_count}() > 1 \)), there are no side effects.
- Otherwise, if \( *\text{this} \) owns an object \( p \) and a deleter \( d \), \( d(p) \) is called.
- Otherwise, \( *\text{this} \) owns a pointer \( p \), and \( \text{delete } p \) is called.

[Note: Since the destruction of \( *\text{this} \) decreases the number of instances that share ownership with \( *\text{this} \) by one, after \( *\text{this} \) has been destroyed all \( \text{shared\_ptr} \) instances that shared ownership with \( *\text{this} \) will report a \( \text{use\_count}() \) that is one less than its previous value. — end note]

20.11.3.3 Assignment

\[ \text{\texttt{shared\_ptr\& }\texttt{operator=\texttt{const shared\_ptr\& r) noexcept;}} \]

Effects: Equivalent to \( \text{shared\_ptr}(r).\text{swap}(\ast\text{this}) \).

Returns: \( \ast\text{this} \).

[Note: The use count updates caused by the temporary object construction and destruction are not observable side effects, so the implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary. In particular, in the example:

\[
\begin{align*}
\text{shared\_ptr<int> } p(\text{new } \text{int}); \\
\text{shared\_ptr<void> } q(p); \\
p = p; \\
q = p; \\
\end{align*}
\]
both assignments may be no-ops. — end note]

\[ \text{\texttt{shared\_ptr\& }\texttt{operator=(shared\_ptr\&& r) noexcept;}} \]

Effects: Equivalent to \( \text{shared\_ptr(\text{std::move(r))}.swap(\ast\text{this})} \).

Returns: \( \ast\text{this} \).

\[ \text{\texttt{template<class Y> shared\_ptr\& }\texttt{operator=(const shared\_ptr<Y\&> r) noexcept;}} \]

Effects: Equivalent to \( \text{shared\_ptr(\text{std::move(r))}.swap(\ast\text{this})} \).

Returns: \( \ast\text{this} \).

20.11.3.4 Modifiers

\[ \text{\texttt{void swap(shared\_ptr\& r) noexcept;}} \]

Effects: Exchanges the contents of \( \ast\text{this} \) and \( r \).

\[ \text{\texttt{void reset() noexcept;}} \]

Effects: Equivalent to \( \text{shared\_ptr()}.\text{swap}(\ast\text{this}) \).

\[ \text{\texttt{template<class Y> void reset(Y* p);}} \]

Effects: Equivalent to \( \text{shared\_ptr(p)}.\text{swap}(\ast\text{this}) \).

\[ \text{\texttt{template<class Y, class D> void reset(Y* p, D d);}} \]

Effects: Equivalent to \( \text{shared\_ptr(p, d)}.\text{swap}(\ast\text{this}) \).

\[ \text{\texttt{template<class Y, class D, class A> void reset(Y* p, D d, A a);}} \]

Effects: Equivalent to \( \text{shared\_ptr(p, d, a)}.\text{swap}(\ast\text{this}) \).
20.11.3.5 Observers

```cpp
1  element_type* get() const noexcept;
   Returns: The stored pointer.

2  T& operator*() const noexcept;
   Requires: get() != 0.
   Returns: *get().
   Remarks: When T is an array type or cv void, it is unspecified whether this member function is
declared. If it is declared, it is unspecified what its return type is, except that the declaration (although
not necessarily the definition) of the function shall be well-formed.

3  T* operator->() const noexcept;
   Requires: get() != 0.
   Returns: get().
   Remarks: When T is an array type, it is unspecified whether this member function is declared. If it is
declared, it is unspecified what its return type is, except that the declaration (although not necessarily
the definition) of the function shall be well-formed.

4  element_type& operator[](ptrdiff_t i) const;
   Requires: get() != 0 && i >= 0. If T is U[N], i < N.
   Returns: get()[i].
   Remarks: When T is not an array type, it is unspecified whether this member function is declared.
If it is declared, it is unspecified what its return type is, except that the declaration (although not
necessarily the definition) of the function shall be well-formed.

5  long use_count() const noexcept;
   Returns: The number of shared_ptr objects, *this included, that share ownership with *this, or 0
when *this is empty.
   Synchronization: None.
   [Note: get() == nullptr does not imply a specific return value of use_count(). — end note]
   [Note: weak_ptr<T>::lock() can affect the return value of use_count(). — end note]
   [Note: When multiple threads can affect the return value of use_count(), the result should be treated
as approximate. In particular, use_count() == 1 does not imply that accesses through a previously
destroyed shared_ptr have in any sense completed. — end note]

6  explicit operator bool() const noexcept;
   Returns: get() != 0.

7  template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
   template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;
   Returns: An unspecified value such that
   (18.1) x.owner_before(y) defines a strict weak ordering as defined in 25.7;
   (18.2) under the equivalence relation defined by owner_before, !a.owner_before(b) && !b.owner_-_before(a), two
shared_ptr or weak_ptr instances are equivalent if and only if they share
ownership or are both empty.
```

20.11.3.6 Creation

```
1 The common requirements that apply to all make_shared, allocate_shared, make_shared_default_init,
and allocate_shared_default_init overloads, unless specified otherwise, are described below.

```
template<class T, class A, ...>
  shared_ptr<T> allocate_shared(const A& a, args);

template<class T, ...>
  shared_ptr<T> make_shared_default_init(args);

template<class T, class A, ...>
  shared_ptr<T> allocate_shared_default_init(const A& a, args);

---

Requires: A shall meet the Cpp17Allocator requirements (Table 34).

Effects: Allocates memory for an object of type T (or \( U[N] \) when T is \( U[] \), where N is determined from args as specified by the concrete overload). The object is initialized from args as specified by the concrete overload. The allocate_shared and allocate_shared_default_init templates use a copy of a (rebound for an unspecified value_type) to allocate memory. If an exception is thrown, the functions have no effect.

Returns: A shared_ptr instance that stores and owns the address of the newly constructed object.

Ensures: \( r.\text{get}() \neq 0 \) \&\& \( r.\text{use}\_\text{count}() == 1 \), where \( r \) is the return value.

Throws: bad_alloc, or an exception thrown from allocate or from the initialization of the object.

Remarks:

(7.1) — Implementations should perform no more than one memory allocation. [Note: This provides efficiency equivalent to an intrusive smart pointer. — end note]

(7.2) — When an object of an array type \( U \) is specified to have an initial value of \( v \) (of the same type), this shall be interpreted to mean that each array element of the object has as its initial value the corresponding element from \( v \).

(7.3) — When an object of an array type is specified to have a default initial value, this shall be interpreted to mean that each array element of the object has a default initial value.

(7.4) — When a (sub)object of a non-array type \( U \) is specified to have an initial value of \( v \), or \( U(1...) \), where 1... is a list of constructor arguments, make_shared shall initialize this (sub)object via the expression \( \text{::new}(pv) \ U(v) \) or \( \text{::new}(pv) \ U(1...) \) respectively, where \( pv \) has type void* and points to storage suitable to hold an object of type \( U \).

(7.5) — When a (sub)object of a non-array type \( U \) is specified to have an initial value of \( v \), or \( U(1...) \), where 1... is a list of constructor arguments, allocate_shared shall initialize this (sub)object via the expression

(7.5.1) — allocator_traits<A2>::construct(a2, pv, v) or

(7.5.2) — allocator_traits<A2>::construct(a2, pv, 1...)

respectively, where \( pv \) points to storage suitable to hold an object of type \( U \) and \( a2 \) of type \( A2 \) is a rebound copy of the allocator \( a \) passed to allocate_shared such that its value_type is remove_cv_t<U>.

(7.6) — When a (sub)object of non-array type \( U \) is specified to have a default initial value, make_shared shall initialize this (sub)object via the expression \( \text{::new}(pv) \ U() \), where \( pv \) has type void* and points to storage suitable to hold an object of type \( U \).

(7.7) — When a (sub)object of non-array type \( U \) is specified to have a default initial value, allocate_shared shall initialize this (sub)object via the expression allocator_traits<A2>::construct(a2, pv), where \( pv \) points to storage suitable to hold an object of type \( U \) and \( a2 \) of type \( A2 \) is a rebound copy of the allocator \( a \) passed to allocate_shared such that its value_type is remove_cv_t<U>.

(7.8) — When a (sub)object of non-array type \( U \) is initialized by make_shared_default_init or allocate_shared_default_init, it is initialized via the expression \( \text{::new}(pv) \ U() \), where \( pv \) has type void* and points to storage suitable to hold an object of type \( U \).

(7.9) — Array elements are initialized in ascending order of their addresses.

(7.10) — When the lifetime of the object managed by the return value ends, or when the initialization of an array element throws an exception, the initialized elements are destroyed in the reverse order of their original construction.

(7.11) — When a (sub)object of non-array type \( U \) that was initialized by make_shared is to be destroyed, it is destroyed via the expression \( pv->U() \) where \( pv \) points to that object of type \( U \).
— When a (sub)object of non-array type \( U \) that was initialized by `allocate_shared` is to be destroyed, it is destroyed via the expression `allocator_traits<A2>::destroy(a2, pv)` where `pv` points to that object of type `remove_cv_t<U>` and `a2` of type `A2` is a rebound copy of the allocator `a` passed to `allocate_shared` such that its `value_type` is `remove_cv_t<U>`.

[Note: These functions will typically allocate more memory than `sizeof(T)` to allow for internal bookkeeping structures such as reference counts. — end note]

```cpp
template<class T, class... Args>
shared_ptr<T> make_shared(Args&&... args); // T is not array

template<class T, class A, class... Args>
shared_ptr<T> allocate_shared(const A& a, Args&&... args); // T is not array
```
8
9

Returns: A `shared_ptr` to an object of type `T` with an initial value `T(forward<Args>(args)...)`.

Remarks: These overloads shall only participate in overload resolution when `T` is not an array type. The `shared_ptr` constructors called by these functions enable `shared_from_this` with the address of the newly constructed object of type `T`.

```cpp
[Example:
  shared_ptr<int> p = make_shared<int>(); // shared_ptr to int
  shared_ptr<vector<int>> q = make_shared<vector<int>>(16, 1);
  // shared_ptr to vector of 16 elements with value 1
— end example]
```

```cpp
template<class T> shared_ptr<T> make_shared(size_t N); // T is U[]

template<class T, class A>
shared_ptr<T> allocate_shared(const A& a, size_t N); // T is U[]
```
11
12

Returns: A `shared_ptr` to an object of type `U[N]` with a default initial value, where `U` is `remove_extent_t<T>`.

Remarks: These overloads shall only participate in overload resolution when `T` is of the form `U[]`.

```cpp
[Example:
  shared_ptr<double[]> p = make_shared<double[]>(1024);
  // shared_ptr to a value-initialized double[1024]
  shared_ptr<double[2][2]> q = make_shared<double[2][2]>(6);
  // shared_ptr to a value-initialized double[2][2]
— end example]
```

```cpp
template<class T> shared_ptr<T> make_shared(); // T is U[N]

template<class T, class A>
shared_ptr<T> allocate_shared(const A& a); // T is U[N]
```
14
15

Returns: A `shared_ptr` to an object of type `T` with a default initial value.

Remarks: These overloads shall only participate in overload resolution when `T` is of the form `U[N]`.

```cpp
[Example:
  shared_ptr<double[1024]> p = make_shared<double[1024]>();
  // shared_ptr to a value-initialized double[1024]
  shared_ptr<double[6][2][2]> q = make_shared<double[6][2][2]>();
  // shared_ptr to a value-initialized double[6][2][2]
— end example]
```

```cpp
template<class T, class A>
shared_ptr<T> allocate_shared(const A& a, size_t N, const remove_extent_t<T>& u); // T is U[]
```
17

Returns: A `shared_ptr` to an object of type `U[N]`, where `U` is `remove_extent_t<T>` and each array element has an initial value of `u`. 

§ 20.11.3.6
Remarks: These overloads shall only participate in overload resolution when T is of the form U[].

Example:

```cpp
template<class T>
shared_ptr<T> make_shared(const remove_extent_t<T>& u);
// T is U[N]
template<class T, class A>
shared_ptr<T> allocate_shared(const A& a,
        const remove_extent_t<T>& u);  // T is U[N]
```

Returns: A shared_ptr to an object of type T, where each array element of type remove_extent_t<T> has an initial value of u.

Remarks: These overloads shall only participate in overload resolution when T is of the form U[].

Example:

```cpp
shared_ptr<double[1024]> p = make_shared<double[1024]>(1.0);
// shared_ptr to a double[1024], where each element is 1.0
shared_ptr<double[6][2]> q = make_shared<double[6][2]>({1.0, 0.0});
// shared_ptr to a double[6][2], where each double[2] element is {1.0, 0.0}
// shared_ptr to a vector<int>[4], where each vector has contents {1, 2}
```

— end example

template<class T>
shared_ptr<T> make_shared_default_init();
template<class T, class A>
shared_ptr<T> allocate_shared_default_init(const A& a);

Constraints: T is not an array of unknown bound.

Returns: A shared_ptr to an object of type T.

Example:

```cpp
struct X { double data[1024]; };
shared_ptr<X> p = make_shared_default_init<X>();
// shared_ptr to a default-initialized X, where each element in X::data has an indeterminate value
shared_ptr<double[1024]> q = make_shared_default_init<double[1024]>();
// shared_ptr to a default-initialized double[1024], where each element has an indeterminate value
```

— end example

template<class T>
shared_ptr<T> make_shared_default_init(size_t N);
template<class T, class A>
shared_ptr<T> allocate_shared_default_init(const A& a, size_t N);

Constraints: T is an array of unknown bound.

Returns: A shared_ptr to an object of type U[N], where U is remove_extent_t<T>.

Example:

```cpp
shared_ptr<double[]> p = make_shared_default_init<double[]>(1024);
// shared_ptr to a default-initialized double[1024], where each element has an indeterminate value
```

— end example

20.11.3.7 Comparison

```cpp
template<class T, class U>
```

§ 20.11.3.7 635
bool operator==(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;

Returns: a.get() == b.get().

template<class T, class U>
bool operator<(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;

Returns: less<>()(a.get(), b.get()).

[Note: Defining a comparison function allows shared_ptr objects to be used as keys in associative containers. — end note]

template<class T>
bool operator==(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator==(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: !a.

template<class T>
bool operator!=(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator!=(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: (bool)a.

template<class T>
bool operator<(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator<(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: The first function template returns less<typename shared_ptr<T>::element_type*>(a.get(), nullptr)
The second function template returns less<typename shared_ptr<T>::element_type*>(nullptr, a.get())

template<class T>
bool operator<=(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator<=(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: The first function template returns !nullptr < a. The second function template returns !a < nullptr.

template<class T>
bool operator>=(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator>=(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: The first function template returns !a < nullptr. The second function template returns !nullptr < a.

20.11.3.8 Specialized algorithms

template<class T>
void swap(shared_ptr<T>& a, shared_ptr<T>& b) noexcept;

Effects: Equivalent to a.swap(b).
20.11.3.9 Casts

template<class T, class U>
shared_ptr<T> static_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
shared_ptr<T> static_pointer_cast(shared_ptr<U>&& r) noexcept;

1 Requires: The expression static_cast<T*>(U*)nullptr shall be well-formed.
2 Returns:
   shared_ptr<T>(R, static_cast<typename shared_ptr<T>::element_type*>(r.get()))
where R is r for the first overload, and std::move(r) for the second.
3 [Note: The seemingly equivalent expression shared_ptr<T>(static_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

template<class T, class U>
shared_ptr<T> dynamic_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
shared_ptr<T> dynamic_pointer_cast(shared_ptr<U>&& r) noexcept;

4 Requires: The expression dynamic_cast<T*>(U*)nullptr shall be well-formed. The expression dynamic_cast<typename shared_ptr<T>::element_type*>(r.get()) shall be well formed and shall have well-defined behavior.
5 Returns:
   — When dynamic_cast<typename shared_ptr<T>::element_type*>(r.get()) returns a non-null value p, shared_ptr<T>(R, p), where R is r for the first overload, and std::move(r) for the second.
5.1 [Note: The seemingly equivalent expression shared_ptr<T>(dynamic_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

   — Otherwise, shared_ptr<T>().
6 [Note: The seemingly equivalent expression shared_ptr<T>(static_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

template<class T, class U>
shared_ptr<T> const_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
shared_ptr<T> const_pointer_cast(shared_ptr<U>&& r) noexcept;

7 Requires: The expression const_cast<T*>(U*)nullptr shall be well-formed.
8 Returns:
   shared_ptr<T>(R, const_cast<typename shared_ptr<T>::element_type*>(r.get()))
where R is r for the first overload, and std::move(r) for the second.
9 [Note: The seemingly equivalent expression shared_ptr<T>(const_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

template<class T, class U>
shared_ptr<T> reinterpret_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
shared_ptr<T> reinterpret_pointer_cast(shared_ptr<U>&& r) noexcept;

10 Requires: The expression reinterpret_cast<T*>(U*)nullptr shall be well-formed.
11 Returns:
   shared_ptr<T>(R, reinterpret_cast<typename shared_ptr<T>::element_type*>(r.get()))
where R is r for the first overload, and std::move(r) for the second.
12 [Note: The seemingly equivalent expression shared_ptr<T>(reinterpret_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. — end note]
D* get_deleter(const shared_ptr<T>& p) noexcept;

Returns: If p owns a deleter d of type cv-unqualified D, returns addressof(d); otherwise returns nullptr. The returned pointer remains valid as long as there exists a shared_ptr instance that owns d. [Note: It is unspecified whether the pointer remains valid longer than that. This can happen if the implementation doesn’t destroy the deleter until all weak_ptr instances that share ownership with p have been destroyed. — end note]

20.11.3.11 I/O

[util.smartptr.shared.io]

template<class E, class T, class Y>
  basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const shared_ptr<Y>& p);

Effects: As if by: os << p.get();

Returns: os.

20.11.4 Class template weak_ptr

[util.smartptr.weak]

The weak_ptr class template stores a weak reference to an object that is already managed by a shared_ptr. To access the object, a weak_ptr can be converted to a shared_ptr using the member function lock.

namespace std {
  template<class T> class weak_ptr {
    public:
      using element_type = remove_extent_t<T>;

      // 20.11.4.1, constructors
      constexpr weak_ptr() noexcept;
      template<class Y>
        weak_ptr(const shared_ptr<Y>& r) noexcept;
      weak_ptr(const weak_ptr& r) noexcept;
      template<class Y>
        weak_ptr(const weak_ptr<Y>& r) noexcept;
      weak_ptr(weak_ptr&& r) noexcept;
      template<class Y>
        weak_ptr(weak_ptr<Y>&& r) noexcept;

      // 20.11.4.2, destructor
      ~weak_ptr();

      // 20.11.4.3, assignment
      weak_ptr& operator=(const weak_ptr& r) noexcept;
      template<class Y>
        weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
      template<class Y>
        weak_ptr& operator=(const shared_ptr<Y>& r) noexcept;
      weak_ptr& operator=(weak_ptr&& r) noexcept;
      template<class Y>
        weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;

      // 20.11.4.4, modifiers
      void swap(weak_ptr& r) noexcept;
      void reset() noexcept;

      // 20.11.4.5, observers
      long use_count() const noexcept;
      bool expired() const noexcept;
      shared_ptr<T> lock() const noexcept;
      template<class U>
        bool owner_before(const shared_ptr<U>& b) const noexcept;
      template<class U>
        bool owner_before(const weak_ptr<U>& b) const noexcept;
    };

    template<class T>
      weak_ptr(shared_ptr<T>&) -> weak_ptr<T>;
Specializations of `weak_ptr` shall be `Cpp17CopyConstructible` and `Cpp17CopyAssignable`, allowing their use in standard containers. The template parameter `T` of `weak_ptr` may be an incomplete type.

20.11.4.1 Constructors

```cpp
constexpr weak_ptr() noexcept;
Effects: Constructs an empty weak_ptr object.
Ensures: use_count() == 0.

weak_ptr(const weak_ptr& r) noexcept;
Effects: If `r` is empty, constructs an empty weak_ptr object; otherwise, constructs a weak_ptr object that shares ownership with `r` and stores a copy of the pointer stored in `r`.
Ensures: use_count() == r.use_count().

weak_ptr(weak_ptr&& r) noexcept;
Effects: Move constructs a weak_ptr instance from `r`.
Ensures: *this shall contain the old value of `r`, `r` shall be empty. r.use_count() == 0.
```

20.11.4.2 Destructor

```cpp
~weak_ptr();
Effects: Destroys this weak_ptr object but has no effect on the object its stored pointer points to.
```

20.11.4.3 Assignment

```cpp
weak_ptr& operator=(const weak_ptr& r) noexcept;
Effects: Equivalent to weak_ptr(r).swap(*this).

weak_ptr& operator=(weak_ptr&& r) noexcept;
Effects: Equivalent to weak_ptr(std::move(r)).swap(*this).
```

20.11.4.4 Modifiers

```cpp
void swap(weak_ptr& r) noexcept;
Effects: Exchanges the contents of *this and `r`.

void reset() noexcept;
Effects: Equivalent to weak_ptr().swap(*this).
```
20.11.4.5 Observers

```cpp
long use_count() const noexcept;
```

Returns: 0 if *this is empty; otherwise, the number of shared_ptr instances that share ownership with *this.

```cpp
bool expired() const noexcept;
```

Returns: use_count() == 0.

```cpp
shared_ptr<T> lock() const noexcept;
```

Returns: expired() ? shared_ptr<T>() : shared_ptr<T>(*this), executed atomically.

```cpp
template<class U> bool owner_before(const shared_ptr<U>& a, const shared_ptr<U>& b) const noexcept;
template<class U> bool owner_before(const weak_ptr<U>& a, const shared_ptr<U>& b) const noexcept;
```

Returns: An unspecified value such that

- (4.1) x.owner_before(y) defines a strict weak ordering as defined in 25.7;
- (4.2) under the equivalence relation defined by owner_before, !a.owner_before(b) && !b.owner_before(a), two shared_ptr or weak_ptr instances are equivalent if and only if they share ownership or are both empty.

20.11.4.6 Specialized algorithms

```cpp
template<class T>
void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;
```

Effects: Equivalent to a.swap(b).

20.11.5 Class template owner_less

The class template owner_less allows ownership-based mixed comparisons of shared and weak pointers.

```cpp
namespace std {
    template<class T = void> struct owner_less;
    template<class T> struct owner_less<shared_ptr<T>> {
        bool operator()(const shared_ptr<T>&, const shared_ptr<T>&) const noexcept;
        bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
        bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
    };
    template<class T> struct owner_less<weak_ptr<T>> {
        bool operator()(const weak_ptr<T>&, const weak_ptr<T>&) const noexcept;
        bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
        bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
    };
    template<> struct owner_less<void> {
        template<class T, class U>
        bool operator()(const shared_ptr<T>&, const shared_ptr<U>&) const noexcept;
        template<class T, class U>
        bool operator()(const shared_ptr<T>&, const weak_ptr<U>&) const noexcept;
        template<class T, class U>
        bool operator()(const weak_ptr<T>&, const shared_ptr<U>&) const noexcept;
        template<class T, class U>
        bool operator()(const weak_ptr<T>&, const weak_ptr<U>&) const noexcept;
        using is_transparent = unspecified;
    };
}
```

- operator() (x, y) shall return x.owner_before(y). [Note: Note that
- (2.1) operator() defines a strict weak ordering as defined in 25.7;]
— under the equivalence relation defined by \( \text{operator}(), !\text{operator}() \) (a, b) \&\& !\text{operator}() (b, a),

— end note]

20.11.6 Class template enable_shared_from_this

A class \( T \) can inherit from \( \text{enable\_shared\_from\_this}\langle T \rangle \) to inherit the \text{shared\_from\_this} member functions that obtain a \text{shared\_ptr} instance pointing to \(*\text{this}.*

1

[Example:

struct X: public enable_shared_from_this<X> { };

int main() {
    shared_ptr<X> p(new X);
    shared_ptr<X> q = p->shared_from_this();
    assert(p == q);
    assert(!p.owner_before(q) \&\& !q.owner_before(p)); // p and q share ownership
}
— end example]

namespace std {
    template<class T> class enable_shared_from_this {
        protected:
            constexpr enable_shared_from_this() noexcept;
            enable_shared_from_this(const enable_shared_from_this&) noexcept;
            enable_shared_from_this& operator=(const enable_shared_from_this&) noexcept;
            ~enable_shared_from_this();
        public:
            shared_ptr<T> shared_from_this();
            shared_ptr<T const> shared_from_this() const;
            weak_ptr<T> weak_from_this() noexcept;
            weak_ptr<T const> weak_from_this() const noexcept;
        private:
            mutable weak_ptr<T> weak_this; // exposition only
    };
}

3

The template parameter \( T \) of \( \text{enable\_shared\_from\_this} \) may be an incomplete type.

constexpr enable_shared_from_this() noexcept;
    enable_shared_from_this(const enable_shared_from_this<T>&) noexcept;

4

Effects: Value-initializes weak_this.

enable_shared_from_this<T>& operator=(const enable_shared_from_this<T>&) noexcept;

5

Returns: *this.

6

[Note: weak_this is not changed. — end note]

shared_ptr<T> shared_from_this();
    shared_ptr<T const> shared_from_this() const;

7

Returns: shared_ptr<T>(weak_this).

weak_ptr<T> weak_from_this() noexcept;
    weak_ptr<T const> weak_from_this() const noexcept;

8

Returns: weak_this.

20.11.7 Smart pointer hash support

template<class T, class D> struct hash<unique_ptr<T, D>>;

1

Letting \( \text{UP} \) be \( \text{unique\_ptr}\langle T, D \rangle \), the specialization \( \text{hash}\langle \text{UP} \rangle \) is enabled (20.14.18) if and only if \( \text{hash}\langle \text{typename} \ \text{UP}::\text{pointer} \rangle \) is enabled. When enabled, for an object \( p \) of type \( \text{UP} \), \( \text{hash}\langle \text{UP} \rangle() (p) \)
shall evaluate to the same value as `hash<typename UP::pointer>(p.get())`. The member functions are not guaranteed to be `noexcept`.

```cpp
template<class T> struct hash<shared_ptr<T>>;
```

For an object `p` of type `shared_ptr<T>`, `hash<shared_ptr<T>>(p)` shall evaluate to the same value as `hash<typename shared_ptr<T>::element_type*>(p.get())`.

### 20.11.8 Atomic specializations for smart pointers

The library provides partial specializations of the `atomic` template for shared-ownership smart pointers. The behavior of all operations is as specified in 31.7, unless specified otherwise. The template parameter `T` of these partial specializations may be an incomplete type.

All changes to an atomic smart pointer in this subclause, and all associated `use_count` increments, are guaranteed to be performed atomically. Associated `use_count` decrements are sequenced after the atomic operation, but are not required to be part of it. Any associated deletion and deallocation are sequenced after the atomic update step and are not part of the atomic operation. [Note: If the atomic operation uses locks, locks acquired by the implementation will be held when any `use_count` adjustments are performed, and will not be held when any destruction or deallocation resulting from this is performed. — end note]

#### 20.11.8.1 Atomic specialization for `shared_ptr`

```cpp
namespace std {
    template<class T> struct atomic<shared_ptr<T>> {
        using value_type = shared_ptr<T>;
        static constexpr bool is_always_lock_free = implementation-defined;

        bool is_lock_free() const noexcept;
        void store(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        shared_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
        operator shared_ptr<T>() const noexcept;
        shared_ptr<T> exchange(shared_ptr<T> desired,
                               memory_order order = memory_order::seq_cst) const noexcept;

        bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired,
                                   memory_order success, memory_order failure) noexcept;
        bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
                                       memory_order success, memory_order failure) noexcept;

        bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired,
                                   memory_order order = memory_order::seq_cst) const noexcept;
        bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
                                       memory_order order = memory_order::seq_cst) const noexcept;

        constexpr atomic() noexcept = default;
        atomic(shared_ptr<T> desired) noexcept;
        atomic(const atomic&) = delete;
        void operator=(const atomic&) = delete;
        void operator=(shared_ptr<T> desired) noexcept;
    }

    private:
    shared_ptr<T> p;  // exposition only
};
```

`atomic()` initializes `p{}`.

`atomic(shared_ptr<T> desired)` initializes the object with the value `desired`. Initialization is not an atomic operation (6.8.2). [Note: It is possible to have an access to an atomic object `A` race with its construction, for
example, by communicating the address of the just-constructed object \( A \) to another thread via `memory_order::relaxed` operations on a suitable atomic pointer variable, and then immediately accessing \( A \) in the receiving thread. This results in undefined behavior. — end note

```cpp
void store(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
```

**Requires:** The `order` argument shall not be `memory_order::consume`, `memory_order::acquire`, nor `memory_order::acq_rel`.

**Effects:** Atomically replaces the value pointed to by `this` with the value of `desired` as if by `p.swap(desired)`. Memory is affected according to the value of `order`.

```cpp
void operator=(shared_ptr<T> desired) noexcept;
```

**Effects:** Equivalent to `store(desired)`.

```cpp
shared_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
```

**Requires:** `order` shall not be `memory_order::release` nor `memory_order::acq_rel`.

**Effects:** Memory is affected according to the value of `order`.

**Returns:** Atomically returns `p`.

```cpp
operator shared_ptr<T>() const noexcept;
```

**Effects:** Equivalent to: `return load();`

```cpp
shared_ptr<T> exchange(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
```

**Effects:** Atomically replaces `p` with `desired` as if by `p.swap(desired)`. Memory is affected according to the value of `order`. This is an atomic read-modify-write operation (6.8.2.1).

**Returns:** Atomically returns the value of `p` immediately before the effects.

```cpp
bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired,
   memory_order success, memory_order failure) noexcept;
```

**Requires:** `failure` shall not be `memory_order::release` nor `memory_order::acq_rel`.

**Effects:** If `p` is equivalent to `expected`, assigns `desired` to `p` and has synchronization semantics corresponding to the value of `success`, otherwise assigns `p` to `expected` and has synchronization semantics corresponding to the value of `failure`.

**Returns:** `true` if `p` was equivalent to `expected`, `false` otherwise.

**Remarks:** Two `shared_ptr` objects are equivalent if they store the same pointer value and either share ownership or are both empty. The weak form may fail spuriously. See 31.7.1.

If the operation returns `true`, `expected` is not accessed after the atomic update and the operation is an atomic read-modify-write operation (6.8.2) on the memory pointed to by `this`. Otherwise, the operation is an atomic load operation on that memory, and `expected` is updated with the existing value read from the atomic object in the attempted atomic update. The `use_count` update corresponding to the write to `expected` is part of the atomic operation. The write to `expected` itself is not required to be part of the atomic operation.

```cpp
bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
   memory_order order = memory_order::seq_cst) noexcept;
```

**Effects:** Equivalent to:

```cpp
   return compare_exchange_weak(expected, desired, order, fail_order);
```

where `fail_order` is the same as `order` except that a value of `memory_order::acq_rel` shall be replaced by the value `memory_order::acquire` and a value of `memory_order::release` shall be replaced by the value `memory_order::relaxed`.

```cpp
bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
   memory_order order = memory_order::seq_cst) noexcept;
```

**Effects:** Equivalent to:
return compare_exchange_strong(expected, desired, order, fail_order);

where fail_order is the same as order except that a value of memory_order::acq_rel shall be replaced by the value memory_order::acquire and a value of memory_order::release shall be replaced by the value memory_order::relaxed.

20.11.8.2 Atomic specialization for weak_ptr

namespace std {
    template<class T> struct atomic<weak_ptr<T>> {
        using value_type = weak_ptr<T>
        static constexpr bool is_always_lock_free = implementation-defined;

        bool is_lock_free() const noexcept;
        void store(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        weak_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
        operator weak_ptr<T>() const noexcept;
        weak_ptr<T> exchange(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order success, memory_order failure) noexcept;
        bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order success, memory_order failure) noexcept;
        bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        constexpr atomic() noexcept = default;
        atomic(weak_ptr<T> desired) noexcept;
        atomic(const atomic&) = delete;
        void operator=(const atomic&) = delete;
        void operator=(weak_ptr<T> desired) noexcept;

        private:
            weak_ptr<T> p; // exposition only
    };
}

constexpr atomic() noexcept = default;
atomic(weak_ptr<T> desired) noexcept;

Effects: Initializes p().
atomic(weak_ptr<T> desired) noexcept;

Effects: Initializes the object with the value desired. Initialization is not an atomic operation (6.8.2). [Note: It is possible to have an access to an atomic object A race with its construction, for example, by communicating the address of the just-constructed object A to another thread via memory_order::relaxed operations on a suitable atomic pointer variable, and then immediately accessing A in the receiving thread. This results in undefined behavior. — end note]

void store(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Requires: The order argument shall not be memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.

Effects: Atomically replaces the value pointed to by this with the value of desired as if by p.swap(desired). Memory is affected according to the value of order.

void operator=(weak_ptr<T> desired) noexcept;

Effects: Equivalent to store(desired).

weak_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;

Requires: order shall not be memory_order::release nor memory_order::acq_rel.
operator weak_ptr<T>() const noexcept;

Effects: Equivalent to: return load();

weak_ptr<T> exchange(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Effects: Atomically replaces p with desired as if by p.swap(desired). Memory is affected according to the value of order. This is an atomic read-modify-write operation (6.8.2.1).

Returns: Atomically returns the value of p immediately before the effects.

bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order success, memory_order failure) noexcept;

Returns: true if p was equivalent to expected, false otherwise.

Remarks: Two weak_ptr objects are equivalent if they store the same pointer value and either share ownership or are both empty. The weak form may fail spuriously. See 31.7.1.

If the operation returns true, expected is not accessed after the atomic update and the operation is an atomic read-modify-write operation (6.8.2) on the memory pointed to by this. Otherwise, the operation is an atomic load operation on that memory, and expected is updated with the existing value read from the atomic object in the attempted atomic update. The use_count update corresponding to the write to expected is part of the atomic operation. The write to expected itself is not required to be part of the atomic operation.

bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Effects: Equivalent to:

return compare_exchange_weak(expected, desired, order, fail_order);

where fail_order is the same as order except that a value of memory_order::acq_rel shall be replaced by the value memory_order::acquire and a value of memory_order::release shall be replaced by the value memory_order::relaxed.

bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Effects: Equivalent to:

return compare_exchange_strong(expected, desired, order, fail_order);

where fail_order is the same as order except that a value of memory_order::acq_rel shall be replaced by the value memory_order::acquire and a value of memory_order::release shall be replaced by the value memory_order::relaxed.

20.12 Memory resources

20.12.1 Header <memory_resource> synopsis

namespace std::pmr {
    // 20.12.2, class memory_resource
    class memory_resource;

    bool operator==(const memory_resource& a, const memory_resource& b) noexcept;
    bool operator!=(const memory_resource& a, const memory_resource& b) noexcept;

    // 20.12.3, class template polymorphic_allocator
    template<class Tp> class polymorphic_allocator;
template<class T1, class T2>
  bool operator==(const polymorphic_allocator<T1>& a,
                  const polymorphic_allocator<T2>& b) noexcept;

template<class T1, class T2>
  bool operator!=(const polymorphic_allocator<T1>& a,
                  const polymorphic_allocator<T2>& b) noexcept;

// 20.12.4, global memory resources
memory_resource* new_delete_resource() noexcept;
memory_resource* null_memory_resource() noexcept;
memory_resource* set_default_resource(memory_resource* r) noexcept;
memory_resource* get_default_resource() noexcept;

// 20.12.5, pool resource classes
struct pool_options;
class synchronized_pool_resource;
class unsynchronized_pool_resource;
class monotonic_buffer_resource;

20.12.2 Class memory_resource

The memory_resource class is an abstract interface to an unbounded set of classes encapsulating memory resources.

namespace std::pmr {
  class memory_resource {
    static constexpr size_t max_align = alignof(max_align_t);  // exposition only

  public:
    memory_resource() = default;
    memory_resource(const memory_resource&) = default;
    virtual ~memory_resource();
    memory_resource& operator=(const memory_resource&) = default;
    [[nodiscard]] void* allocate(size_t bytes, size_t alignment = max_align);
    void deallocate(void* p, size_t bytes, size_t alignment = max_align);
    bool is_equal(const memory_resource& other) const noexcept;

  private:
    virtual void* do_allocate(size_t bytes, size_t alignment) = 0;
    virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;
    virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;
  }
}

20.12.2.1 Public member functions

~memory_resource();

1 Effects: Destroys this memory_resource.

[[nodiscard]] void* allocate(size_t bytes, size_t alignment = max_align);

2 Effects: Equivalent to: return do_allocate(bytes, alignment);

void deallocate(void* p, size_t bytes, size_t alignment = max_align);

3 Effects: Equivalent to do_deallocate(p, bytes, alignment).

bool is_equal(const memory_resource& other) const noexcept;

4 Effects: Equivalent to: return do_is_equal(other);
20.12.2.2 Private virtual member functions

virtual void* do_allocate(size_t bytes, size_t alignment) = 0;

1. **Requires:** alignment shall be a power of two.
2. **Returns:** A derived class shall implement this function to return a pointer to allocated storage (6.6.5.4.1) with a size of at least bytes, aligned to the specified alignment.
3. **Throws:** A derived class implementation shall throw an appropriate exception if it is unable to allocate memory with the requested size and alignment.

virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;

4. **Requires:** p shall have been returned from a prior call to allocate(bytes, alignment) on a memory resource equal to *this, and the storage at p shall not yet have been deallocated.
5. **Effects:** A derived class shall implement this function to dispose of allocated storage.
6. **Throws:** Nothing.

virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;

7. **Returns:** A derived class shall implement this function to return true if memory allocated from this can be deallocated from other and vice-versa, otherwise false. [Note: The most-derived type of other might not match the type of this. For a derived class D, an implementation of this function could immediately return false if dynamic_cast<const D*>(&other) == nullptr. — end note]

20.12.2.3 Equality

bool operator==(const memory_resource& a, const memory_resource& b) noexcept;

1. **Returns:** &a == &b || a.is_equal(b).

bool operator!=(const memory_resource& a, const memory_resource& b) noexcept;

2. **Returns:** !(a == b).

20.12.3 Class template polymorphic_allocator

A specialization of class template pmr::polymorphic_allocator meets the Cpp17Allocator requirements (Table 34). Constructed with different memory resources, different instances of the same specialization of pmr::polymorphic_allocator can exhibit entirely different allocation behavior. This runtime polymorphism allows objects that use polymorphic_allocator to behave as if they used different allocator types at run time even though they use the same static allocator type.

All specializations of class template pmr::polymorphic_allocator meet the allocator completeness requirements (16.5.3.5.1).

namespace std::pmr {

    template<class Tp = byte> class polymorphic_allocator {
        memory_resource* memory_rsrc; // exposition only

        public:
            using value_type = Tp;

            // 20.12.3.1, constructors
            polymorphic_allocator() noexcept;
            polymorphic_allocator(memory_resource* r);

            polymorphic_allocator(const polymorphic_allocator& other) = default;

            template<class U>
                polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;

            polymorphic_allocator& operator=(const polymorphic_allocator& rhs) = delete;

            // 20.12.3.2, member functions
            [[nodiscard]] Tp* allocate(size_t n);
            void deallocate(Tp* p, size_t n);

    } // polymorphic_allocator

} // namespace std::pmr

§ 20.12.3
void* allocate_bytes(size_t nbytes, size_t alignment = alignof(max_align_t));
void deallocate_bytes(void* p, size_t nbytes, size_t alignment = alignof(max_align_t));
template<class T> T* allocate_object(size_t n = 1);
template<class T> void deallocate_object(T* p, size_t n = 1);
template<class T, class... CtorArgs> T* new_object(CtorArgs&&... ctor_args);
template<class T> void delete_object(T* p);

template<class T, class... Args>
void construct(T* p, Args&&... args);

template<class T>
void destroy(T* p);

polymorphic_allocator select_on_container_copy_construction() const;
memory_resource* resource() const;
};

20.12.3.1 Constructors

polymorphic_allocator() noexcept;

Effects: Sets memory_rsrc to get_default_resource().

polymorphic_allocator(memory_resource* r);

Requires: r is non-null.
Effects: Sets memory_rsrc to r.
Throws: Nothing.
[Note: This constructor provides an implicit conversion from memory_resource*. — end note]

template<class U> polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;

Effects: Sets memory_rsrc to other.resource().

20.12.3.2 Member functions

[[nodiscard]] Tp* allocate(size_t n);

Effects: If SIZE_MAX / sizeof(Tp) < n, throws length_error. Otherwise equivalent to:
return static_cast<Tp*>(memory_rsrc->allocate(n * sizeof(Tp), alignof(Tp)));

void deallocate(Tp* p, size_t n);

Requires: p was allocated from a memory resource x, equal to *memory_rsrc, using x.allocate(n *
sizeof(Tp), alignof(Tp)).
Effects: Equivalent to memory_rsrc->deallocate(p, n * sizeof(Tp), alignof(Tp)).
Throws: Nothing.

void* allocate_bytes(size_t nbytes, size_t alignment = alignof(max_align_t));

Effects: Equivalent to: return memory_rsrc->allocate(nbytes, alignment);

[Note: The return type is void* (rather than, e.g., byte*) to support conversion to an arbitrary pointer
type U* by static_cast<U*>, thus facilitating construction of a U object in the allocated memory.
— end note]

void deallocate_bytes(void* p, size_t nbytes, size_t alignment = alignof(max_align_t));

Effects: Equivalent to memory_rsrc->deallocate(p, nbytes, alignment).

template<class T>
T* allocate_object(size_t n = 1);

Effects: Allocates memory suitable for holding an array of n objects of type T, as follows:

— if SIZE_MAX / sizeof(T) < n, throws length_error,
otherwise equivalent to:

```cpp
return static_cast<T*>(allocate_bytes(n*sizeof(T), alignof(T)));
```

**Note:** T is not deduced and must therefore be provided as a template argument. — end note

```cpp
template<class T>
void deallocate_object(T* p, size_t n = 1);
```

**Effects:** Equivalent to deallocate_bytes(p, n*sizeof(T), alignof(T)).

```cpp
template<class T, class CtorArgs...>
T* new_object(CtorArgs&&... ctor_args);
```

**Effects:** Allocates and constructs an object of type T, as follows.
Equivalent to:
```cpp
T* p = allocate_object<T>();
try {
  construct(p, std::forward<CtorArgs>(ctor_args)...);
} catch (...) {
  deallocate_object(p);
  throw;
}
return p;
```

**Note:** T is not deduced and must therefore be provided as a template argument. — end note

```cpp
template<class T>
void delete_object(T* p);
```

**Effects:** Equivalent to:
```cpp
destroy(p);
deallocate_object(p);
```

```cpp
template<class T, class... Args>
void construct(T* p, Args&&... args);
```

**Mandates:** Uses-allocator construction of T with allocator *this (see 20.10.8.2) and constructor arguments std::forward<Args>(args)... is well-formed.

**Effects:** Construct a T object in the storage whose address is represented by p by uses-allocator construction with allocator *this and constructor arguments std::forward<Args>(args)....

**Throws:** Nothing unless the constructor for T throws.

```cpp
template<class T>
void destroy(T* p);
```

**Effects:** As if by p->~T().

```cpp
polymorphic_allocator select_on_container_copy_construction() const;
```

**Returns:** polymorphic_allocator().

**Note:** The memory resource is not propagated. — end note

```cpp
memory_resource* resource() const;
```

**Returns:** memory_rsrc.

**20.12.3.3 Equality**

```cpp
template<class T1, class T2>
bool operator==(const polymorphic_allocator<T1>& a,
               const polymorphic_allocator<T2>& b) noexcept;
```

**Returns:** *a.resource() == *b.resource().

```cpp
template<class T1, class T2>
bool operator!=(const polymorphic_allocator<T1>& a,
               const polymorphic_allocator<T2>& b) noexcept;
```

**Returns:** !(a == b).
20.12.4 Access to program-wide memory_resource objects

memory_resource* new_delete_resource() noexcept;
1 Returns: A pointer to a static-duration object of a type derived from memory_resource that can serve as a resource for allocating memory using ::operator new and ::operator delete. The same value is returned every time this function is called. For a return value p and a memory resource r, p->is_equal(r) returns &r == p.

memory_resource* null_memory_resource() noexcept;
2 Returns: A pointer to a static-duration object of a type derived from memory_resource for which allocate() always throws bad_alloc and for which deallocate() has no effect. The same value is returned every time this function is called. For a return value p and a memory resource r, p->is_equal(r) returns &r == p.

The default memory_resource pointer is a pointer to a memory resource that is used by certain facilities when an explicit memory resource is not supplied through the interface. Its initial value is the return value of new_delete_resource().

memory_resource* set_default_resource(memory_resource* r) noexcept;
4 Effects: If r is non-null, sets the value of the default memory resource pointer to r, otherwise sets the default memory resource pointer to new_delete_resource().
5 Returns: The previous value of the default memory resource pointer.
6 Remarks: Calling the set_default_resource and get_default_resource functions shall not incur a data race. A call to the set_default_resource function shall synchronize with subsequent calls to the set_default_resource and get_default_resource functions.

memory_resource* get_default_resource() noexcept;
7 Returns: The current value of the default memory resource pointer.

20.12.5 Pool resource classes

20.12.5.1 Classes synchronized_pool_resource and unsynchronized_pool_resource

The synchronized_pool_resource and unsynchronized_pool_resource classes (collectively called pool resource classes) are general-purpose memory resources having the following qualities:

(1.1) — Each resource frees its allocated memory on destruction, even if deallocate has not been called for some of the allocated blocks.

(1.2) — A pool resource consists of a collection of pools, serving requests for different block sizes. Each individual pool manages a collection of chunks that are in turn divided into blocks of uniform size, returned via calls to do_allocate. Each call to do_allocate(size, alignment) is dispatched to the pool serving the smallest blocks accommodating at least size bytes.

(1.3) — When a particular pool is exhausted, allocating a block from that pool results in the allocation of an additional chunk of memory from the upstream allocator (supplied at construction), thus replenishing the pool. With each successive replenishment, the chunk size obtained increases geometrically. [Note: By allocating memory in chunks, the pooling strategy increases the chance that consecutive allocations will be close together in memory. — end note]

(1.4) — Allocation requests that exceed the largest block size of any pool are fulfilled directly from the upstream allocator.

(1.5) — A pool_options struct may be passed to the pool resource constructors to tune the largest block size and the maximum chunk size.

A synchronized_pool_resource may be accessed from multiple threads without external synchronization and may have thread-specific pools to reduce synchronization costs. An unsynchronized_pool_resource class may not be accessed from multiple threads simultaneously and thus avoids the cost of synchronization entirely in single-threaded applications.

namespace std::pmr {
struct pool_options {
  size_t max_blocks_per_chunk = 0;
};

```cpp
size_t largest_required_pool_block = 0;
};

class synchronized_pool_resource : public memory_resource {
public:
    synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

    synchronized_pool_resource()
        : synchronized_pool_resource(pool_options(), get_default_resource()) {}
    explicit synchronized_pool_resource(memory_resource* upstream)
        : synchronized_pool_resource(pool_options(), upstream) {} 
    explicit synchronized_pool_resource(const pool_options& opts)
        : synchronized_pool_resource(opts, get_default_resource()) {} 

    synchronized_pool_resource(const synchronized_pool_resource&) = delete;
    virtual ~synchronized_pool_resource();

    synchronized_pool_resource& operator=(const synchronized_pool_resource&) = delete;

    void release();
    memory_resource* upstream_resource() const;
    pool_options options() const;

protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;

    bool do_is_equal(const memory_resource& other) const noexcept override;
};

class unsynchronized_pool_resource : public memory_resource {
public:
    unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

    unsynchronized_pool_resource()
        : unsynchronized_pool_resource(pool_options(), get_default_resource()) {} 
    explicit unsynchronized_pool_resource(memory_resource* upstream)
        : unsynchronized_pool_resource(pool_options(), upstream) {} 
    explicit unsynchronized_pool_resource(const pool_options& opts)
        : unsynchronized_pool_resource(opts, get_default_resource()) {} 

    unsynchronized_pool_resource(const unsynchronized_pool_resource&) = delete;
    virtual ~unsynchronized_pool_resource();

    unsynchronized_pool_resource& operator=(const unsynchronized_pool_resource&) = delete;

    void release();
    memory_resource* upstream_resource() const;
    pool_options options() const;

protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;

    bool do_is_equal(const memory_resource& other) const noexcept override;
};

20.12.5.2 pool_options data members

The members of `pool_options` comprise a set of constructor options for pool resources. The effect of each option on the pool resource behavior is described below:

---

20.12.5.2 pool_options data members
size_t max_blocks_per_chunk;

The maximum number of blocks that will be allocated at once from the upstream memory resource (20.12.6) to replenish a pool. If the value of max_blocks_per_chunk is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose to use a smaller value than is specified in this field and may use different values for different pools.

size_t largest_required_pool_block;

The largest allocation size that is required to be fulfilled using the pooling mechanism. Attempts to allocate a single block larger than this threshold will be allocated directly from the upstream memory resource. If largest_required_pool_block is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose a pass-through threshold larger than specified in this field.

20.12.5.3 Constructors and destructors

synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);
unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

Requires: upstream is the address of a valid memory resource.

Effects: Constructs a pool resource object that will obtain memory from upstream whenever the pool resource is unable to satisfy a memory request from its own internal data structures. The resulting object will hold a copy of upstream, but will not own the resource to which upstream points.

[Note: The intention is that calls to upstream->allocate() will be substantially fewer than calls to this->allocate() in most cases. — end note] The behavior of the pooling mechanism is tuned according to the value of the opts argument.

Throws: Nothing unless upstream->allocate() throws. It is unspecified if, or under what conditions, this constructor calls upstream->allocate().

virtual ~synchronized_pool_resource();
virtual ~unsynchronized_pool_resource();

Effects: Calls release().

20.12.5.4 Members

void release();

Effects: Calls upstream_resource()->deallocate() as necessary to release all allocated memory.

[Note: The memory is released back to upstream_resource() even if deallocate has not been called for some of the allocated blocks. — end note]

memory_resource* upstream_resource() const;

Returns: The value of the upstream argument provided to the constructor of this object.

pool_options options() const;

Returns: The options that control the pooling behavior of this resource. The values in the returned struct may differ from those supplied to the pool resource constructor in that values of zero will be replaced with implementation-defined defaults, and sizes may be rounded to unspecified granularity.

void* do_allocate(size_t bytes, size_t alignment) override;

Returns: A pointer to allocated storage (6.6.5.4.1) with a size of at least bytes. The size and alignment of the allocated memory shall meet the requirements for a class derived from memory_resource (20.12.2).

Effects: If the pool selected for a block of size bytes is unable to satisfy the memory request from its own internal data structures, it will call upstream_resource()->allocate() to obtain more memory. If bytes is larger than that which the largest pool can handle, then memory will be allocated using upstream_resource()->allocate().

Throws: Nothing unless upstream_resource()->allocate() throws.

void do_deallocate(void* p, size_t bytes, size_t alignment) override;

Effects: Returns the memory at p to the pool. It is unspecified if, or under what circumstances, this operation will result in a call to upstream_resource()->deallocate().
20.12.6 Class monotonic_buffer_resource

A monotonic_buffer_resource is a special-purpose memory resource intended for very fast memory allocations in situations where memory is used to build up a few objects and then is released all at once when the memory resource object is destroyed. It has the following qualities:

1. A call to deallocate has no effect, thus the amount of memory consumed increases monotonically until the resource is destroyed.
2. The program can supply an initial buffer, which the allocator uses to satisfy memory requests.
3. When the initial buffer (if any) is exhausted, it obtains additional buffers from an upstream memory resource supplied at construction. Each additional buffer is larger than the previous one, following a geometric progression.
4. It is intended for access from one thread of control at a time. Specifically, calls to allocate and deallocate do not synchronize with one another.
5. It frees the allocated memory on destruction, even if deallocate has not been called for some of the allocated blocks.

namespace std::pmr {
    class monotonic_buffer_resource : public memory_resource {
        memory_resource* upstream_rsrc;  // exposition only
        void* current_buffer;            // exposition only
        size_t next_buffer_size;         // exposition only

    public:
        explicit monotonic_buffer_resource(memory_resource* upstream);
        monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);
        monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);

        monotonic_buffer_resource() :
            monotonic_buffer_resource(get_default_resource()) {} // exposition only
        explicit monotonic_buffer_resource(size_t initial_size) :
            monotonic_buffer_resource(initial_size, get_default_resource()) {} // exposition only
        monotonic_buffer_resource(void* buffer, size_t buffer_size) :
            monotonic_buffer_resource(buffer, buffer_size, get_default_resource()) {} // exposition only

        monotonic_buffer_resource(const monotonic_buffer_resource&) = delete;
        virtual ~monotonic_buffer_resource();
        monotonic_buffer_resource& operator=(const monotonic_buffer_resource&) = delete;

        void release();
        memory_resource* upstream_resource() const;

    protected:
        void* do_allocate(size_t bytes, size_t alignment) override;
        void do_deallocate(void* p, size_t bytes, size_t alignment) override;
        bool do_is_equal(const memory_resource& other) const noexcept override;
    }
}

20.12.6.1 Constructors and destructor

Requires: upstream shall be the address of a valid memory resource. initial_size, if specified, shall be greater than zero.
Effects: Sets upstream_rsrrc to upstream and current_buffer to nullptr. If initial_size is specified, sets next_buffer_size to at least initial_size; otherwise sets next_buffer_size to an implementation-defined size.

monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);

Requires: upstream shall be the address of a valid memory resource. buffer_size shall be no larger than the number of bytes in buffer.

Effects: Sets upstream_rsrrc to upstream, current_buffer to buffer, and next_buffer_size to buffer_size (but not less than 1), then increases next_buffer_size by an implementation-defined growth factor (which need not be integral).

~monotonic_buffer_resource();

Effects: Calls release().

20.12.6.2 Members

void release();

Effects: Calls upstream_rsrrc->deallocate() as necessary to release all allocated memory.

[Note: The memory is released back to upstream_rsrrc even if some blocks that were allocated from this have not been deallocated from this. — end note]

memory_resource* upstream_resource() const;

Returns: The value of upstream_rsrrc.

void* do_allocate(size_t bytes, size_t alignment) override;

Returns: A pointer to allocated storage (6.6.5.4.1) with a size of at least bytes. The size and alignment of the allocated memory shall meet the requirements for a class derived from memory_resource (20.12.2).

Effects: If the unused space in current_buffer can fit a block with the specified bytes and alignment, then allocate the return block from current_buffer; otherwise set current_buffer to upstream_rsrrc->allocate(n, m), where n is not less than max(bytes, next_buffer_size) and m is not less than alignment, and increase next_buffer_size by an implementation-defined growth factor (which need not be integral), then allocate the return block from the newly-allocated current_buffer.

Throws: Nothing unless upstream_rsrrc->allocate() throws.

void do_deallocate(void* p, size_t bytes, size_t alignment) override;

Effects: None.

Throws: Nothing.

Remarks: Memory used by this resource increases monotonically until its destruction.

bool do_is_equal(const memory_resource& other) const noexcept override;

Returns: this == &other.

20.13 Class template scoped_allocator_adaptor

20.13.1 Header <scoped_allocator> synopsis

namespace std {
  // class template scoped_allocator_adaptor
  template<class OuterAlloc, class... InnerAlloc>
  class scoped_allocator_adaptor;

  // 20.13.5, scoped allocator operators
  template<class OuterA1, class OuterA2, class... InnerAllocs>
  bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a, const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
  template<class OuterA1, class OuterA2, class... InnerAllocs>
  bool operator!=(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a, const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
}
The class template `scoped_allocator_adaptor` is an allocator template that specifies an allocator resource (the outer allocator) to be used by a container (as any other allocator does) and also specifies an inner allocator resource to be passed to the constructor of every element within the container. This adaptor is instantiated with one outer and zero or more inner allocator types. If instantiated with only one allocator type, the inner allocator becomes the `scoped_allocator_adaptor` itself, thus using the same allocator resource for the container and every element within the container and, if the elements themselves are containers, each of their elements recursively. If instantiated with more than one allocator, the first allocator is the outer allocator for use by the container, the second allocator is passed to the constructors of the container’s elements, and, if the elements themselves are containers, the third allocator is passed to the elements’ elements, and so on. If containers are nested to a depth greater than the number of allocators, the last allocator is used repeatedly, as in the single-allocator case, for any remaining recursions. [Note: The `scoped_allocator_adaptor` is derived from the outer allocator type so it can be substituted for the outer allocator type in most expressions. — end note]

```cpp
namespace std {
    template<class OuterAlloc, class... InnerAllocs>
    class scoped_allocator_adaptor : public OuterAlloc {
    private:
        using OuterTraits = allocator_traits<OuterAlloc>; // exposition only
        scoped_allocator_adaptor<InnerAllocs...> inner;    // exposition only
    public:
        using outer_allocator_type = OuterAlloc;
        using inner_allocator_type = see below;
        using value_type = typename OuterTraits::value_type;
        using size_type = typename OuterTraits::size_type;
        using difference_type = typename OuterTraits::difference_type;
        using pointer = typename OuterTraits::pointer;
        using const_pointer = typename OuterTraits::const_pointer;
        using void_pointer = typename OuterTraits::void_pointer;
        using const_void_pointer = typename OuterTraits::const_void_pointer;

        using propagate_on_container_copy_assignment = see below;
        using propagate_on_container_move_assignment = see below;
        using propagate_on_container_swap = see below;
        using is_always_equal = see below;

        template<class Tp> struct rebind {
            using other = scoped_allocator_adaptor<
                OuterTraits::template rebind_alloc<Tp>, InnerAllocs...>;
        };

        scoped_allocator_adaptor();
        template<class OuterA2>
        scoped_allocator_adaptor(OuterA2&& outerAlloc,
                                  const InnerAllocs&... innerAllocs) noexcept;
        scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;
        scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;

        template<class OuterA2>
        scoped_allocator_adaptor(
            const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& other) noexcept;
        template<class OuterA2>
        scoped_allocator_adaptor(
            scoped_allocator_adaptor<OuterA2, InnerAllocs...>&& other) noexcept;

        scoped_allocator_adaptor& operator=(const scoped_allocator_adaptor&) = default;
        scoped_allocator_adaptor& operator=(scoped_allocator_adaptor&&) = default;
        ~scoped_allocator_adaptor();
    }
}
```

§ 20.13.1
inner_allocator_type& inner_allocator() noexcept;
const inner_allocator_type& inner_allocator() const noexcept;
outer_allocator_type& outer_allocator() noexcept;
const outer_allocator_type& outer_allocator() const noexcept;

[[nodiscard]] pointer allocate(size_type n);
[[nodiscard]] pointer allocate(size_type n, const_void_pointer hint);
deallocate(pointer p, size_type n);
size_type max_size() const;

template<class T, class... Args>
void construct(T* p, Args&&... args);

template<class T>
void destroy(T* p);

scoped_allocator_adaptor select_on_container_copy_construction() const;

};

template<class OuterAlloc, class... InnerAllocs>
scoped_allocator_adaptor(OuterAlloc, InnerAllocs...)
-> scoped_allocator_adaptor<OuterAlloc, InnerAllocs...>;

20.13.2 Member types

using inner_allocator_type = see below;

Type: scoped_allocator_adaptor<OuterAlloc> if sizeof...(InnerAllocs) is zero; otherwise,
scoped_allocator_adaptor<InnerAllocs...>.

using propagate_on_container_copy_assignment = see below;

Type: true_type if allocator_traits<A>::propagate_on_container_copy_assignment::value is
true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using propagate_on_container_move_assignment = see below;

Type: true_type if allocator_traits<A>::propagate_on_container_move_assignment::value is
true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using propagate_on_container_swap = see below;

Type: true_type if allocator_traits<A>::propagate_on_container_swap::value is true for any
A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using is_always_equal = see below;

Type: true_type if allocator_traits<A>::is_always_equal::value is true for every A in the set
of OuterAlloc and InnerAllocs...; otherwise, false_type.

20.13.3 Constructors

scoped_allocator_adaptor();

Effects: Value-initializes the OuterAlloc base class and the inner allocator object.

template<class OuterA2>
scoped_allocator_adaptor(OuterA2& outerAlloc, const InnerAllocs&... innerAllocs) noexcept;

Effects: Initializes the OuterAlloc base class with std::forward<OuterA2>(outerAlloc) and inner
with innerAllocs... (hence recursively initializing each allocator within the adaptor with the
corresponding allocator from the argument list).

Remarks: This constructor shall not participate in overload resolution unless is_constructible_<
v<OuterAlloc, OuterA2> is true.

scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;

Effects: Initializes each allocator within the adaptor with the corresponding allocator from other.
scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;

Effects: Move constructs each allocator within the adaptor with the corresponding allocator from other.

template<class OuterA2>
scoped_allocator_adaptor(  
    const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& other) noexcept;

Effects: Initializes each allocator within the adaptor with the corresponding allocator from other.

Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<OuterAlloc, const OuterA2&> is true.

template<class OuterA2>
scoped_allocator_adaptor(scoped_allocator_adaptor<OuterA2, InnerAllocs...>&& other) noexcept;

Effects: Initializes each allocator within the adaptor with the corresponding allocator rvalue from other.

Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<OuterAlloc, OuterA2> is true.

20.13.4 Members

In the construct member functions, \texttt{OUTERMOST}(x) is \texttt{OUTERMOST}(x.outer_allocator()) if the expression \texttt{x.outer_allocator()} is valid (13.9.2) and \texttt{x} otherwise; \texttt{OUTERMOST_ALLOC_TRAITS(x)} is \texttt{allocator_traits<remove_reference_t<decltype(OUTERMOST(*this))>>}. [Note: \texttt{OUTERMOST}(x) and \texttt{OUTERMOST_ALLOC_TRAITS(x)} are recursive operations. It is incumbent upon the definition of \texttt{outer_allocator()} to ensure that the recursion terminates. It will terminate for all instantiations of \texttt{scoped_allocator_adaptor}. — end note]

inner_allocator_type& inner_allocator() noexcept;

Returns: *this if sizeof...(InnerAllocs) is zero; otherwise, inner.

outer_allocator_type& outer_allocator() noexcept;

Returns: static_cast<OuterAlloc&>(*this).

const outer_allocator_type& outer_allocator() const noexcept;

Returns: static_cast<const OuterAlloc&>(*this).

[[nodiscard]] pointer allocate(size_type n);

Returns: allocator_traits<OuterAlloc>::allocate(outer_allocator(), n).

[[nodiscard]] pointer allocate(size_type n, const void_pointer hint);

Returns: allocator_traits<OuterAlloc>::allocate(outer_allocator(), n, hint).

deallocate(pointer p, size_type n) noexcept;

Effects: As if by: allocator_traits<OuterAlloc>::deallocate(outer_allocator(), p, n);

size_type max_size() const;

Returns: allocator_traits<OuterAlloc>::max_size(outer_allocator()).

template<class T, class... Args>
void construct(T* p, Args&&... args);

Effects: Equivalent to:

apply([p, this](auto&&... newargs) {
    \texttt{OUTERMOST_ALLOC_TRAITS(*this)}::construct(
        \texttt{OUTERMOST(*this)}, p,
        std::forward<decltype(newargs)>(newargs)...);
    },
    uses_allocator_construction_args<T>(inner_allocator(),
        std::forward<Args>(args)...));

§ 20.13.4
template<class T>
  void destroy(T* p);

Effects: Calls OUTERMOST_ALLOC_TRAITS(*this)::destroy(OUTERMOST(*this), p).

scoped_allocator_adaptor select_on_container_copy_construction() const;

Returns: A new scoped_allocator_adaptor object where each allocator A in the adaptor is initialized from the result of calling allocator_traits<A>::select_on_container_copy_construction() on the corresponding allocator in *this.

20.13.5 Operators [scoped.adaptor.operations]

template<class OuterA1, class OuterA2, class... InnerAllocs>
  bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                  const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;

Returns: If sizeof...(InnerAllocs) is zero,
  a.outer_allocator() == b.outer_allocator()
otherwise
  a.outer_allocator() == b.outer_allocator() && a.inner_allocator() == b.inner_allocator()

template<class OuterA1, class OuterA2, class... InnerAllocs>
  bool operator!=(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                  const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;

Returns: !(a == b).

20.14 Function objects [function.objects]

A function object type is an object type (6.7) that can be the type of the postfix-expression in a function call (7.6.1.2, 12.3.1.1). A function object is an object of a function object type. In the places where one would expect to pass a pointer to a function to an algorithmic template (Clause 25), the interface is specified to accept a function object. This not only makes algorithmic templates work with pointers to functions, but also enables them to work with arbitrary function objects.

20.14.1 Header <functional> synopsis [functional.syn]

namespace std {
  // 20.14.4, invoke
template<class F, class... Args>
  invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
    noexcept(is_nothrow_invocable_v<F, Args...>);

  // 20.14.5, reference_wrapper

[Example: If a C++ program wants to have a by-element addition of two vectors \( a \) and \( b \) containing \( \texttt{double} \) and put the result into \( a \), it can do:

\[
\text{transform}(a\text{.begin()}, a\text{.end()}, b\text{.begin()}, a\text{.begin()}, \text{plus}\text{\langle double\rangle}());
\]

— end example]

[Example: To negate every element of \( a \):

\[
\text{transform}(a\text{.begin()}, a\text{.end()}, a\text{.begin()}, \text{negate}\text{\langle double\rangle}());
\]

— end example]

### 20.14.2 Definitions

The following definitions apply to this Clause:

1. A **call signature** is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.
2. A **callable type** is a function object type (20.14) or a pointer to member.
3. A **callable object** is an object of a callable type.
4. A **call wrapper type** is a type that holds a callable object and supports a call operation that forwards to that object.
5. A **call wrapper** is an object of a call wrapper type.
6. A **target object** is the callable object held by a call wrapper.
7. A call wrapper type may additionally hold a sequence of objects and references that may be passed as arguments to the target object. These entities are collectively referred to as **bound argument entities**.
8. The target object and bound argument entities of the call wrapper are collectively referred to as **state entities**.

### 20.14.3 Requirements

Define \( \text{INVOK}e(f, t_1, t_2, \ldots, t_N) \) as follows:

1. (1.1) \( (t_1\text{.}\text{*f})(t_2, \ldots, t_N) \) when \( f \) is a pointer to a member function of a class \( T \) and \( \text{is\_base\_of\_v}\text{\langle T, remove\_reference\_t\langle\text{decltype}(t_1)\rangle\rangle} \) is true;
2. (1.2) \( (t_1\text{.get()}\text{.}\text{*f})(t_2, \ldots, t_N) \) when \( f \) is a pointer to a member function of a class \( T \) and \( \text{remove\_cvref\_t}\text{\langle decltype}\text{\langle t_1\rangle\rangle} \) is a specialization of \texttt{reference\_wrapper};
3. (1.3) \( ((*t_1).\text{\*f})(t_2, \ldots, t_N) \) when \( f \) is a pointer to a member function of a class \( T \) and \( t_1 \) does not satisfy the previous two items;
4. (1.4) \( t_1\text{.}\text{\*f} \) when \( N == 1 \) and \( f \) is a pointer to data member of a class \( T \) and \( \text{is\_base\_of\_v}\text{\langle T, remove\_reference\_t\langle\text{decltype}(t_1)\rangle\rangle} \) is true;
5. (1.5) \( t_1\text{.get()}\text{.}\text{\*f} \) when \( N == 1 \) and \( f \) is a pointer to data member of a class \( T \) and \( \text{remove\_cvref\_t}\text{\langle decltype}\text{\langle t_1\rangle\rangle} \) is a specialization of \texttt{reference\_wrapper};
6. (1.6) \( ((*t_1).\text{\*f}\rangle \langle 1 \rangle f \text{ is a pointer to data member of a class } T \text{ and } t_1 \text{ does not satisfy the previous two items;}
7. (1.7) \( f(t_1, t_2, \ldots, t_N) \) in all other cases.

Define \( \text{INVOK}e\langle R\rangle(f, t_1, t_2, \ldots, t_N) \) as \texttt{static\_cast\langle void\rangle}(\text{INVOK}e(f, t_1, t_2, \ldots, t_N)) \) if \( R \) is \texttt{cv\_void}, otherwise \( \text{INVOK}e(f, t_1, t_2, \ldots, t_N) \) implicitly converted to \( R \).

Every call wrapper (20.14.2) is \texttt{Cpp17MoveConstructible}. A **argument forwarding call wrapper** is a call wrapper that can be called with an arbitrary argument list and delivers the arguments to the wrapped callable object as references. This forwarding step delivers rvalue arguments as rvalue references and lvalue arguments as lvalue references. A **simple call wrapper** is an argument forwarding call wrapper that is \texttt{Cpp17CopyConstructible} and \texttt{Cpp17CopyAssignable} and whose copy constructor, move constructor, copy assignment operator, and move assignment operator do not throw exceptions. [Note: In a typical implementation, argument forwarding call wrappers have an overloaded function call operator of the form

\[
\text{template<class... UnBoundArgs>}
R \text{operator()}(\text{UnBoundArgs}&\ldots\text{\_unbound\_args})\text{\_cv\_qual};
\]

— end note]
A perfect forwarding call wrapper is an argument forwarding call wrapper that forwards its state entities to the underlying call expression. This forwarding step delivers a state entity of type \( T \) as \( cv\ T\& \) when the call is performed on an lvalue of the call wrapper type and as \( cv\ T\&& \) otherwise, where \( cv \) represents the cv-qualifiers of the call wrapper and where \( cv \) shall be neither volatile nor const volatile.

A call pattern defines the semantics of invoking a perfect forwarding call wrapper. A postfix call performed on a perfect forwarding call wrapper is expression-equivalent (16.3.11) to an expression \( e \) determined from its call pattern \( cp \) by replacing all occurrences of the arguments of the call wrapper and its state entities with references as described in the corresponding forwarding steps.

The copy/move constructor of a perfect forwarding call wrapper has the same apparent semantics as if memberwise copy/move of its state entities were performed (11.3.4.2). [Note: This implies that each of the copy/move constructors has the same exception specification as the corresponding implicit definition and is declared as constexpr if the corresponding implicit definition would be considered to be constexpr. — end note]

Perfect forwarding call wrappers returned by a given standard library function template have the same type if the types of their corresponding state entities are the same.

### 20.14.4 Function template \texttt{invoke} [func.invoke]

```cpp
template<class F, class... Args>
invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
  noexcept(is_nothrow_invocable_v<F, Args...>);
```

Returns: \texttt{INVOLVE}(std::forward\langle F\rangle (f), std::forward\langle Args\rangle (args)...). (20.14.3).

### 20.14.5 Class template \texttt{reference_wrapper} [refwrap]

```cpp
namespace std {
  template<class T> class reference_wrapper {
    public:
      // types
      using type = T;
      
      // construct/copy/destroy
      template<class U>
      reference_wrapper(U&& u) noexcept(see below);
      reference_wrapper(const reference_wrapper& x) noexcept;
      
      // assignment
      reference_wrapper& operator=(const reference_wrapper& x) noexcept;
      
      // access
      operator T& () const noexcept;
      T& get() const noexcept;
      
      // invocation
      template<class... ArgTypes>
      invoke_result_t<T&, ArgTypes...> operator()(ArgTypes&&...) const;
    
    template<class T>
    reference_wrapper(T&) -> reference_wrapper<T>;
  }
```

\texttt{reference_wrapper\langle T\rangle} is a \textit{Cpp17CopyConstructible} and \textit{Cpp17CopyAssignable} wrapper around a reference to an object or function of type \( T \).

\texttt{reference_wrapper\langle T\rangle} is a trivially copyable type (6.7).

The template parameter \( T \) of \texttt{reference_wrapper} may be an incomplete type.

### 20.14.5.1 Constructors and destructor [refwrap.const]

```cpp
template<class U>
reference_wrapper(U&& u) noexcept(see below);
```

Remarks: Let \textit{FUN} denote the exposition-only functions
This constructor shall not participate in overload resolution unless the expression \texttt{FUN(declval\textless U\textgreater ()}) is well-formed and \texttt{is\_same\_v\textless remove\_cvref\_t\textless U\textgreater , reference\_wrapper\textgreater } is \texttt{false}. The expression inside \texttt{noexcept} is equivalent to \texttt{noexcept(FUN(declval\textless U\textgreater ()}).

\texttt{Effects:} Creates a variable \( r \) as if by \texttt{T \& r = std::forward\textless U\textgreater (u)}, then constructs a \texttt{reference\_wrapper} object that stores a reference to \( r \).

\texttt{reference\_wrapper(const reference\_wrapper\& x) noexcept;}

\texttt{Effects:} Constructs a \texttt{reference\_wrapper} object that stores a reference to \texttt{x.get()}.  

\texttt{20.14.5.2 Assignment} \hspace{1cm} \texttt{[refwrap.assign]}  
\texttt{reference\_wrapper\& operator=(const reference\_wrapper\& x) noexcept;}  
\texttt{1 Ensures: \texttt{*this} stores a reference to \texttt{x.get()}.}

\texttt{20.14.5.3 Access} \hspace{1cm} \texttt{[refwrap.access]}  
\texttt{operator T\& () const noexcept;}  
\texttt{1 Returns: The stored reference.}

\texttt{T\& get() const noexcept;}  
\texttt{2 Returns: The stored reference.}

\texttt{20.14.5.4 Invocation} \hspace{1cm} \texttt{[refwrap.invoke]}  
\texttt{template<class... ArgTypes> \hspace{1cm}}  
\texttt{invoke\_result\_t\textless T\&, ArgTypes...\textgreater}  
\texttt{operator()\textless (ArgTypes\&&... args) const;}  
\texttt{1 Mandates: \texttt{T} is a complete type.}

\texttt{2 Returns: \texttt{INVOKE(get(), std::forward\textless ArgTypes\textgreater (args)...}} \texttt{. \texttt{(20.14.3)}}

\texttt{20.14.5.5 Helper functions} \hspace{1cm} \texttt{[refwrap.helpers]}  
\texttt{template<class T> reference\_wrapper\langle T\rangle ref(T\& t) noexcept;}  
\texttt{1 Returns: \texttt{reference\_wrapper\langle T\rangle}(t).}

\texttt{template<class T> reference\_wrapper\langle T\rangle ref(reference\_wrapper\langle T\rangle t) noexcept;}  
\texttt{3 Returns: \texttt{ref(t.get()).}}

\texttt{template<class T> reference\_wrapper\langle const T\rangle cref(const T\& t) noexcept;}  
\texttt{4 Returns: \texttt{reference\_wrapper <const T\rangle}(t).}

\texttt{template<class T> reference\_wrapper\langle const T\rangle cref(reference\_wrapper\langle T\rangle t) noexcept;}  
\texttt{5 Returns: \texttt{cref(t.get()).}}

\texttt{20.14.5.6 Transformation type trait unwrap\_reference} \hspace{1cm} \texttt{[refwrap.unwrappref]}  
\texttt{template<class T> struct unwrap\_reference;}  
\texttt{1 If \texttt{T} is a specialization \texttt{reference\_wrapper\langle X\rangle} for some type \texttt{X}, the member typedef \texttt{type of unwrap\_reference\langle T\rangle} is \texttt{X\&}, otherwise it is \texttt{T}.}

\texttt{20.14.6 Arithmetic operations} \hspace{1cm} \texttt{[arithmetic.operations]}  
\texttt{1 The library provides basic function object classes for all of the arithmetic operators in the language (7.6.5, 7.6.6).}
20.14.6.1 Class template plus

```cpp
template<class T = void> struct plus {
  constexpr T operator()(const T& x, const T& y) const;
};
```

```cpp
constexpr T operator()(const T& x, const T& y) const;
```

Returns: \(x + y\).

```cpp
template<> struct plus<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) + std::forward<U>(u));
};
```

Using `is_transparent = unspecified;`.

```cpp
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) + std::forward<U>(u));
```

Returns: \(\text{std::forward}(t) + \text{std::forward}(u)\).

20.14.6.2 Class template minus

```cpp
template<class T = void> struct minus {
  constexpr T operator()(const T& x, const T& y) const;
};
```

```cpp
constexpr T operator()(const T& x, const T& y) const;
```

Returns: \(x - y\).

```cpp
template<> struct minus<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) - std::forward<U>(u));
};
```

Using `is_transparent = unspecified;`.

```cpp
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) - std::forward<U>(u));
```

Returns: \(\text{std::forward}(t) - \text{std::forward}(u)\).

20.14.6.3 Class template multiplies

```cpp
template<class T = void> struct multiplies {
  constexpr T operator()(const T& x, const T& y) const;
};
```

```cpp
constexpr T operator()(const T& x, const T& y) const;
```

Returns: \(x \times y\).

```cpp
template<> struct multiplies<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) * std::forward<U>(u));
};
```

Using `is_transparent = unspecified;`.

```cpp
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) * std::forward<U>(u));
```

Returns: \(\text{std::forward}(t) \times \text{std::forward}(u)\).

20.14.6.4 Class template divides

```cpp
template<class T = void> struct divides {
  constexpr T operator()(const T& x, const T& y) const;
};
```

```cpp
constexpr T operator()(const T& x, const T& y) const;
```

Returns: \(x / y\).
};
constexpr T operator()(const T& x, const T& y) const;

1 Returns: x / y.

template<>
struct divides<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) / std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) / std::forward<U>(u));

2 Returns: std::forward<T>(t) / std::forward<U>(u).

20.14.6.5 Class template modulus [arithmetic.operations.modulus]

template<class T = void> struct modulus {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1 Returns: x % y.

template<>
struct modulus<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) % std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) % std::forward<U>(u));

2 Returns: std::forward<T>(t) % std::forward<U>(u).

20.14.6.6 Class template negate [arithmetic.operations.negate]

template<class T = void> struct negate {
  constexpr T operator()(const T& x) const;
};

constexpr T operator()(const T& x) const;

1 Returns: -x.

template<>
struct negate<void> {
  template<class T> constexpr auto operator()(T&& t) const
    -> decltype(-std::forward<T>(t));

  using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
  -> decltype(-std::forward<T>(t));

2 Returns: -std::forward<T>(t).

20.14.7 Comparisons [comparisons]

1 The library provides basic function object classes for all of the comparison operators in the language (7.6.9, 7.6.10).

2 For templates less, greater, less_equal, and greater_equal, the specializations for any pointer type yield a strict total order that is consistent among those specializations and is also consistent with the partial order imposed by the built-in operators <, >, <=, >=. [Note: When a < b is well-defined for pointers a and b of type P, this implies (a < b) == less<P>()(a, b), (a > b) == greater<P>()(a, b), and so
forth. — end note] For template specializations `less<void>`, `greater<void>`, `less_equal<void>`, and `greater_equal<void>`, if the call operator calls a built-in operator comparing pointers, the call operator yields a strict total order that is consistent among those specializations and is also consistent with the partial order imposed by those built-in operators.

20.14.7.1 Class template `equal_to`  

```cpp
template<class T = void> struct equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

Returns: `x == y`.

```cpp
template<> struct equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) == std::forward<U>(u));
};
```

Using is_transparent = unspecified;

Returns: `std::forward<T>(t) == std::forward<U>(u)`.

20.14.7.2 Class template `not_equal_to`  

```cpp
template<class T = void> struct not_equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

Returns: `x != y`.

```cpp
template<> struct not_equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) != std::forward<U>(u));
};
```

Using is_transparent = unspecified;

Returns: `std::forward<T>(t) != std::forward<U>(u)`.

20.14.7.3 Class template `greater`  

```cpp
template<class T = void> struct greater {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

Returns: `x > y`.

```cpp
template<> struct greater<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) > std::forward<U>(u));
};
```

Using is_transparent = unspecified;

Returns: `std::forward<T>(t) > std::forward<U>(u)`.
20.14.7.4 Class template less

```cpp
template<class T = void> struct less {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

Returns: \( x < y \).

```cpp
template<> struct less<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) < std::forward<U>(u));

    using is_transparent = unspecified;
};
```

Returns: \( \text{std::forward<T>(t)} < \text{std::forward<U>(u)} \).

20.14.7.5 Class template greater_equal

```cpp
template<class T = void> struct greater_equal {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

Returns: \( x \geq y \).

```cpp
template<> struct greater_equal<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) \geq \text{std::forward<U>(u)});    

    using is_transparent = unspecified;
};
```

Returns: \( \text{std::forward<T>(t)} \geq \text{std::forward<U>(u)} \).

20.14.7.6 Class template less_equal

```cpp
template<class T = void> struct less_equal {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

Returns: \( x \leq y \).

```cpp
template<> struct less_equal<void> {
