    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) \leq \text{std::forward<U>(u)});    

    using is_transparent = unspecified;
};
```

Returns: \( \text{std::forward<T>(t)} \leq \text{std::forward<U>(u)} \).

20.14.8 Concept-constrained comparisons

In this subclause, \( \text{BUILTIN_PTR_CMP(T, op, U)} \) for types \( T \) and \( U \) and where \( op \) is an equality (7.6.10) or relational operator (7.6.9) is a boolean constant expression. \( \text{BUILTIN_PTR_CMP(T, op, U)} \) is true if and only if \( op \) in the expression \( \text{declval<T>() op declval<U>()} \) resolves to a built-in operator comparing pointers.
There is an implementation-defined strict total ordering over all pointer values of a given type. This total ordering is consistent with the partial order imposed by the builtin operators <, >, <=, and >=.

```cpp
struct ranges::equal_to {
    template<class T, class U>
    requires EqualityComparableWith<T, U> || BUILTIN_PTR_CMP(T, ==, U)
    constexpr bool operator()(T& t, U& u) const;

effects: If the expression std::forward<T>(t) == std::forward<U>(u) results in a call to a built-in operator == comparing pointers of type P, the conversion sequences from both T and U to P shall be equality-preserving (18.2).
```

```cpp
struct ranges::not_equal_to {
    template<class T, class U>
    requires EqualityComparableWith<T, U> || BUILTIN_PTR_CMP(T, ==, U)
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;

    operator() has effects equivalent to: return !ranges::equal_to{}(std::forward<T>(t), std::forward<U>(u));
}
```

```cpp
struct ranges::greater {
    template<class T, class U>
    requires StrictTotallyOrderedWith<T, U> || BUILTIN_PTR_CMP(U, <, T)
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;

    operator() has effects equivalent to:
    return ranges::less{}(std::forward<U>(u), std::forward<T>(t));
}
```

```cpp
struct ranges::less {
    template<class T, class U>
    requires StrictTotallyOrderedWith<T, U> || BUILTIN_PTR_CMP(T, <, U)
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
}
```

```cpp
expects: If the expression std::forward<T>(t) < std::forward<U>(u) results in a call to a built-in operator < comparing pointers of type P, the conversion sequences from both T and U to P shall be equality-preserving (18.2). For any expressions ET and EU such that decltype((ET)) is T and decltype((EU)) is U, exactly one of ranges::less{}(ET, EU), ranges::less{}(EU, ET), or ranges::equal_to{}(ET, EU) shall be true.
```

```cpp
effects:

- If the expression std::forward<T>(t) < std::forward<U>(u) results in a call to a built-in operator < comparing pointers of type P: returns true if (the converted value of) t precedes u in the implementation-defined strict total order over pointers of type P and otherwise false.

- Otherwise, equivalent to: return std::forward<T>(t) < std::forward<U>(u);
```
struct ranges::greater_equal {
  template<class T, class U>
  requires StrictTotallyOrderedWith<T, U> || BUILTIN_PTR_CMP(T, <, U)
  constexpr bool operator()(T& t, U& u) const;

  using is_transparent = unspecified;
};

operator() has effects equivalent to:
  return !ranges::less{}(std::forward<T>(t), std::forward<U>(u));

struct ranges::less_equal {
  template<class T, class U>
  requires StrictTotallyOrderedWith<T, U> || BUILTIN_PTR_CMP(U, <, T)
  constexpr bool operator()(T& t, U& u) const;

  using is_transparent = unspecified;
};

operator() has effects equivalent to:
  return !ranges::less{}(std::forward<U>(u), std::forward<T>(t));

20.14.9 Logical operations

The library provides basic function object classes for all of the logical operators in the language (7.6.14, 7.6.15, 7.6.2.1).

20.14.9.1 Class template logical_and

template<class T = void> struct logical_and {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x && y.

template<> struct logical_and<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) && std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) && std::forward<U>(u));

Returns: std::forward<T>(t) && std::forward<U>(u).

20.14.9.2 Class template logical_or

template<class T = void> struct logical_or {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x || y.

template<> struct logical_or<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) || std::forward<U>(u));

  using is_transparent = unspecified;
};
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) || std::forward<U>(u));

Returns: std::forward<T>(t) || std::forward<U>(u).

20.14.9.3 Class template logical_not

template<class T = void> struct logical_not {
    constexpr bool operator()(const T& x) const;
};

constexpr bool operator()(const T& x) const;

Returns: !x.

template<> struct logical_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
-> decltype(!std::forward<T>(t));
    using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
-> decltype(!std::forward<T>(t));

2 Returns: !std::forward<T>(t).

20.14.10 Bitwise operations

The library provides basic function object classes for all of the bitwise operators in the language (7.6.11, 7.6.13, 7.6.12, 7.6.2.1).

20.14.10.1 Class template bit_and

template<class T = void> struct bit_and {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x & y.

template<> struct bit_and<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) & std::forward<U>(u));
    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) & std::forward<U>(u));

2 Returns: std::forward<T>(t) & std::forward<U>(u).

20.14.10.2 Class template bit_or

template<class T = void> struct bit_or {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x | y.

template<> struct bit_or<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) | std::forward<U>(u));

§ 20.14.10.2
using is_transparent = unspecified;
};
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) | std::forward<U>(u));

Returns: std::forward<T>(t) | std::forward<U>(u).

20.14.10.3 Class template bit_xor

template<class T = void> struct bit_xor {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1 Returns: x ^ y.

template<> struct bit_xor<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) ^ std::forward<U>(u));
    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) ^ std::forward<U>(u));

2 Returns: std::forward<T>(t) ^ std::forward<U>(u).

20.14.10.4 Class template bit_not

template<class T = void> struct bit_not {
    constexpr T operator()(const T& x) const;
};

constexpr T operator()(const T& x) const;

1 Returns: ~x.

template<> struct bit_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
    -> decltype(~std::forward<T>(t));
    using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&&) const
-> decltype(~std::forward<T>(t));

2 Returns: ~std::forward<T>(t).

20.14.11 Class identity

struct identity {
    template<class T>
    constexpr T&& operator()(T&& t) const noexcept;
    using is_transparent = unspecified;
};

template<class T>
constexpr T&& operator()(T&& t) const noexcept;

1 Effects: Equivalent to: return std::forward<T>(t);

20.14.12 Function template not_fn

template<class F> unspecified not_fn(F&& f);

1 In the text that follows:
(1.1) \( g \) is a value of the result of a \texttt{not_fn} invocation,
(1.2) \( \text{FD} \) is the type \texttt{decay_t<F>},
(1.3) \( \text{fd} \) is the target object of \( g \) (20.14.2) of type \( \text{FD} \), initialized with the \textit{initializer} \( (\text{std::forward<F>}(f)) \) (9.3),
(1.4) \( \text{call_args} \) is an argument pack used in a function call expression (7.6.1.2) of \( g \).

\textit{Mandates:} \( \text{is_constructible_v<FD, F> \&& is_move_constructible_v<FD>} \) is true.
\textit{Expects:} \( \text{FD} \) meets the \textit{Cpp17MoveConstructible} requirements.
\textit{Returns:} A perfect forwarding call wrapper \( g \) with call pattern \( \text{!invoke(fd, call_args...)} \).
\textit{Throws:} Any exception thrown by the initialization of \( \text{fd} \).

20.14.13 Function template \texttt{bind_front} 

\texttt{template<class F, class... Args>\
  \textit{unspecified} bind_front(F&& f, Args&&... args);} 

\begin{enumerate}
(1.1) \( g \) is a value of the result of a \texttt{bind_front} invocation,
(1.2) \( \text{FD} \) is the type \texttt{decay_t<F>},
(1.3) \( \text{fd} \) is the target object of \( g \) (20.14.2) of type \( \text{FD} \), initialized with the \textit{initializer} \( (\text{std::forward<F>}(f)) \) (9.3),
(1.4) \( \text{BoundArgs} \) is a pack that denotes \( \text{std::unwrap_ref_decay_t<Args>} \ldots \),
(1.5) \( \text{bound_args} \) is a pack of bound argument entities of \( g \) (20.14.2) of types \( \text{BoundArgs} \ldots \), initialized with \( \text{initializers} \) \( (\text{std::forward<Args>(args)}) \ldots \), respectively, and
(1.6) \( \text{call_args} \) is an argument pack used in a function call expression (7.6.1.2) of \( g \).
\end{enumerate}

\textit{Mandates:}
\[
\text{conjunction_v<is_constructible<FD, F>, is_move_constructible<FD>,}
\text{is_constructible<BoundArgs, Args>..., is_move_constructible<BoundArgs>...>}
\]
\textit{is true.}
\textit{Expects:} \( \text{FD} \) meets the \textit{Cpp17MoveConstructible} requirements. For each \( T_i \) in \( \text{BoundArgs} \), if \( T_i \) is an object type, \( T_i \) meets the \textit{Cpp17MoveConstructible} requirements.
\textit{Returns:} A perfect forwarding call wrapper \( g \) with call pattern \( \text{invoke(fd, bound_args..., call_args...)} \).
\textit{Throws:} Any exception thrown by the initialization of the state entities of \( g \) (20.14.2).

20.14.14 Function object binders

This subclause describes a uniform mechanism for binding arguments of callable objects.

20.14.14.1 Class template \texttt{is_bind_expression} 

\texttt{namespace std {\
  \texttt{template<class T> struct is_bind_expression; // see below}\
}}

\begin{enumerate}
\item The class template \texttt{is_bind_expression} can be used to detect function objects generated by \texttt{bind}. The function template \texttt{bind} uses \texttt{is_bind_expression} to detect subexpressions.
\item Instantiations of the \texttt{is_bind_expression} template shall meet the \textit{Cpp17UnaryTypeTrait} requirements (20.15.1). The implementation shall provide a definition that has a base characteristic of \texttt{true_type} if \( T \) is a type returned from \texttt{bind}, otherwise it shall have a base characteristic of \texttt{false_type}. A program may specialize this template for a program-defined type \( T \) to have a base characteristic of \texttt{true_type} to indicate that \( T \) should be treated as a subexpression in a \texttt{bind} call.
\end{enumerate}

20.14.14.2 Class template \texttt{is_placeholder} 

\texttt{namespace std {\
  \texttt{template<class T> struct is_placeholder; // see below}\
}}
The class template `is_placeholder` can be used to detect the standard placeholders _1, _2, and so on. The function template `bind` uses `is_placeholder` to detect placeholders.

Instantiations of the `is_placeholder` template shall meet the Cpp17UnaryTypeTrait requirements (20.15.1). The implementation shall provide a definition that has the base characteristic of `integral_constant<int, J>` if `T` is the type of `std::placeholders::_J`, otherwise it shall have a base characteristic of `integral_constant<int, 0>`. A program may specialize this template for a program-defined type `T` to have a base characteristic of `integral_constant<int, N>` with `N > 0` to indicate that `T` should be treated as a placeholder type.

20.14.14.3 Function template `bind`  

In the text that follows:

1. `FD` is the type `decay_t<F>`,
2. `fd` is an lvalue of type `FD` constructed from `std::forward<F>(f)`,
3. `Ti` is the `i`th type in the template parameter pack `BoundArgs`,
4. `TD` is the type `decay_t<Ti>`,
5. `ti` is the `i`th argument in the function parameter pack `bound_args`,
6. `td` is an lvalue of type `TD` constructed from `std::forward<Ti>(ti)`,
7. `Uj` is the `j`th deduced type of the `UnBoundArgs&...` parameter of the argument forwarding call wrapper, and
8. `uj` is the `j`th argument associated with `Uj`.

```cpp
template<class F, class... BoundArgs>
unspecified bind(F& f, BoundArgs&... bound_args);
```

2. `Requires`: `is_constructible_v<FD, F>` shall be `true`. For each `Ti` in `BoundArgs`, `is_constructible_v<decay_t<TD>, Ti>` shall be `true`. `INVOKE(fd, w_1, w_2, ..., w_N)` (20.14.3) shall be a valid expression for some values `w_1, w_2, ..., w_N`, where `N` has the value `sizeof...(bound_args)`. The cv-qualifiers `cv` of the call wrapper `g`, as specified below, shall be neither `volatile` nor `const volatile`.

3. `Returns`: An argument forwarding call wrapper `g` (20.14.3). The effect of `g(u_1, u_2, ..., u_M)` shall be

```cpp
INVOKE(fd, std::forward<V_1>(v_1), std::forward<V_2>(v_2), ..., std::forward<V_N>(v_N))
```

where the values and types of the bound arguments `v_1, v_2, ..., v_N` are determined as specified below. The copy constructor and move constructor of the argument forwarding call wrapper shall throw an exception if and only if the corresponding constructor of `FD` or of any of the types `TD_i` throws an exception.

4. `Throws`: Nothing unless the construction of `fd` or of one of the values `td_i` throws an exception.

5. `Remarks`: The return type shall meet the Cpp17MoveConstructible requirements. If all of `FD` and `TD_i` meet the Cpp17CopyConstructible requirements, then the return type shall meet the Cpp17CopyConstructible requirements. [Note: This implies that all of `FD` and `TD_i` are Cpp17MoveConstructible. — end note]

```cpp
template<class R, class F, class... BoundArgs>
unspecified bind(F& f, BoundArgs&... bound_args);
```

6. `Requires`: `is_constructible_v<FD, F>` shall be `true`. For each `Ti` in `BoundArgs`, `is_constructible_v<decay_t<TD>, Ti>` shall be `true`. `INVOKE(fd, w_1, w_2, ..., w_N)` shall be a valid expression for some values `w_1, w_2, ..., w_N`, where `N` has the value `sizeof...(bound_args)`. The cv-qualifiers `cv` of the call wrapper `g`, as specified below, shall be neither `volatile` nor `const volatile`.

7. `Returns`: An argument forwarding call wrapper `g` (20.14.3). The effect of `g(u_1, u_2, ..., u_M)` shall be

```cpp
INVOKE<R>(fd, std::forward<V_1>(v_1), std::forward<V_2>(v_2), ..., std::forward<V_N>(v_N))
```

where the values and types of the bound arguments `v_1, v_2, ..., v_N` are determined as specified below. The copy constructor and move constructor of the argument forwarding call wrapper shall throw an exception if and only if the corresponding constructor of `FD` or of any of the types `TD_i` throws an exception.
Throws: Nothing unless the construction of \( fd \) or of one of the values \( td_i \) throws an exception.

Remarks: The return type shall meet the `Cpp17MoveConstructible` requirements. If all of \( FD \) and \( TD_i \) meet the `Cpp17CopyConstructible` requirements, then the return type shall meet the `Cpp17CopyConstructible` requirements. [Note: This implies that all of \( FD \) and \( TD_i \) are `Cpp17MoveConstructible`. — end note]

The values of the `bound arguments` \( v_1, v_2, \ldots, v_N \) and their corresponding types \( V_1, V_2, \ldots, V_N \) depend on the types \( TD_i \) derived from the call to `bind` and the cv-qualifiers \( cv \) of the call wrapper \( g \) as follows:

\[
\begin{align*}
& (10.1) \quad \text{if } TD_i \text{ is `reference_wrapper<T>`}, \text{ the argument is } td_i.get() \text{ and its type } V_i \text{ is } T&; \\
& (10.2) \quad \text{if the value of } \text{is_bind_expression_v<TD}_i> \text{ is true, the argument is } td_i(\text{std::forward<U}_j\ldots)(u_j)\ldots) \text{ and its type } V_i \text{ is } \text{invoke_result_t<TD}_i&; \\
& (10.3) \quad \text{if the value } j \text{ of } \text{is_placeholder_v<TD}_i> \text{ is not zero, the argument is } \text{std::forward<U}_j\ldots}(u_j) \text{ and its type } V_i \text{ is } U_j&&; \\
& (10.4) \quad \text{otherwise, the value is } td_i \text{ and its type } V_i \text{ is } TD_i&; \text{ cv } k.
\end{align*}
\]

20.14.4 Placeholders

```cpp
namespace std::placeholders {
    // M is the implementation-defined number of placeholders
    see below _1;
    see below _2;
    ...
    see below _M;
}
```

All placeholder types shall be `Cpp17DefaultConstructible` and `Cpp17CopyConstructible`, and their default constructors and copy/move constructors shall not throw exceptions. It is implementation-defined whether placeholder types are `Cpp17CopyAssignable`. `Cpp17CopyAssignable` placeholders’ copy assignment operators shall not throw exceptions.

Placeholders should be defined as:

```cpp
inline constexpr unspecified _1{};
```

If they are not, they shall be declared as:

```cpp
extern unspecified _1;
```

20.14.15 Function template `mem_fn`

```cpp
template<class R, class T> unspecified mem_fn(R T::* pm) noexcept;
```

Returns: A simple call wrapper (20.14.2) \( fn \) such that the expression \( fn(t, a_2, \ldots, a_N) \) is equivalent to \( \text{INVOKE}(pm, t, a_2, \ldots, a_N) \) (20.14.3).

20.14.16 Polymorphic function wrappers

This subclause describes a polymorphic wrapper class that encapsulates arbitrary callable objects.

20.14.16.1 Class `bad_function_call`

An exception of type `bad_function_call` is thrown by `function::operator()` (20.14.16.2.4) when the function wrapper object has no target.

```cpp
namespace std {
    class bad_function_call : public exception {
        public:
            // see 17.9.2 for the specification of the special member functions
            const char* what() const noexcept override;
    }
}
```

Returns: An implementation-defined ntbs.

20.14.16.2 Class template `function`

```cpp
namespace std {
    template<class> class function; // not defined
}
```
The `function` class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (20.14.2), given a call signature (20.14.2), allowing functions to be first-class objects.
A callable type \(20.14.2\) \(F\) is \textit{Lvalue-Callable} for argument types \(\text{ArgTypes}\) and return type \(R\) if the expression \texttt{INVOKE<R>(\text{declval<F&>()}, \text{declval<ArgTypes>}())...)}\), considered as an unevaluated operand \((7.2)\), is well-formed \((20.14.3)\).

The \texttt{function} class template is a call wrapper \((20.14.2)\) whose call signature \((20.14.2)\) is \(R(\text{ArgTypes}...)\).

[\textit{Note}: The types deduced by the deduction guides for \texttt{function} may change in future versions of this International Standard. — end note]

\textbf{20.14.16.2.1 Constructors and destructor} \[\text{func.wrap.func.con}\]

\texttt{function()} noexcept;
\begin{itemize}
  \item \textit{Ensures}: \(*\texttt{this}.\)
\end{itemize}

\texttt{function(nullptr_t) noexcept;}
\begin{itemize}
  \item \textit{Ensures}: \(*\texttt{this}.\)
\end{itemize}

\texttt{function(const function& f);}  
\begin{itemize}
  \item \textit{Ensures}: \(*\texttt{this}\) if \!\(f\); otherwise, \(*\texttt{this}\) targets a copy of \(f.\texttt{target}()\).
\end{itemize}

\texttt{function(function&& f) noexcept;}
\begin{itemize}
  \item \textit{Ensures}: If \!\(f\), \(*\texttt{this}\) has no target; otherwise, \(*\texttt{this}\) is equivalent to the target of \(f\) before the construction, and \(f\) is in a valid state with an unspecified value.
\end{itemize}

\[\text{Note}: \text{Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where \(f\)'s target is an object holding only a pointer or reference to an object and a member function pointer. — end note}\]

\texttt{template<class F> function(F f);}  
\begin{itemize}
  \item \textit{Requires}: \(F\) shall be \texttt{Cpp17CopyConstructible}.
  
  \item \textit{Remarks}: This constructor template shall not participate in overload resolution unless \(F\) is Lvalue-Callable \((20.14.16.2)\) for argument types \(\text{ArgTypes}...\) and return type \(R\).
  
  \item \textit{Ensures}: \(*\texttt{this}\) if any of the following hold:
  \begin{itemize}
    \item \(f\) is a null function pointer value.
    \item \(f\) is a null member pointer value.
    \item \(F\) is an instance of the \texttt{function} class template, and \!\(f\).
  \end{itemize}

  Otherwise, \(*\texttt{this}\) targets a copy of \(f\) initialized with \texttt{std::move(f)}. \[\textit{Note}: \text{Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where \(f\)'s target is an object holding only a pointer or reference to an object and a member function pointer. — end note}\]

  \item \textit{Throws}: Shall not throw exceptions when \(f\) is a function pointer or a \texttt{reference_wrapper<T>} for some \(T\). Otherwise, may throw \texttt{bad_alloc} or any exception thrown by \(F\)'s copy or move constructor.
\end{itemize}

\texttt{template<class F> function(F) \rightarrow function<see below>;}  
\begin{itemize}
  \item \textit{Remarks}: This deduction guide participates in overload resolution only if \&\(F::\texttt{operator}()\) is well-formed when treated as an unevaluated operand. In that case, if \texttt{decltype(\&F::\texttt{operator}()\})} is of the form \(R(\texttt{G::*}(\texttt{A}...))\ \texttt{cv k_opt noexcept_opt}\) for a class type \(G\), then the deduced type is \texttt{function<R(A...)>}.
  
  \item \textit{Example}:
  \begin{verbatim}
  void f() {
    int i(5);
    function g = [&](double) { return i; }; // deduces function<int(double)>
  }
  \end{verbatim}

  \[\text{— end example}\]
function& operator=(const function& f);

14 Effects: As if by function(f).swap(*this);
15 Returns: *this.

function& operator=(function&& f);

16 Effects: Replaces the target of *this with the target of f.
17 Returns: *this.

function& operator=(nullptr_t) noexcept;

18 Effects: If *this != nullptr, destroys the target of this.
19 Ensures: !(*this).
20 Returns: *this.

template<class F> function& operator=(F&& f);

21 Effects: As if by:
22 function(std::forward<F>(f)).swap(*this);
23 Returns: *this.

Remarks: This assignment operator shall not participate in overload resolution unless decay_t<F> is
Lvalue-Callable (20.14.16.2) for argument types ArgTypes... and return type R.

template<class F> function& operator=(reference_wrapper<F> f) noexcept;

24 Effects: As if by: function(f).swap(*this);
25 Returns: *this.

~function();

26 Effects: If *this != nullptr, destroys the target of this.

20.14.16.2.2 Modifiers

void swap(function& other) noexcept;
1 Effects: Interchanges the targets of *this and other.

20.14.16.2.3 Capacity

explicit operator bool() const noexcept;
1 Returns: true if *this has a target, otherwise false.

20.14.16.2.4 Invocation

R operator()(ArgTypes... args) const;
1 Returns: INVOKE<R>(f, std::forward<ArgTypes>(args)...)(20.14.3), where f is the target object
2 (20.14.2) of *this.
2 Throws: bad_function_call if !*this; otherwise, any exception thrown by the wrapped callable
object.

20.14.16.2.5 Target access

const type_info& target_type() const noexcept;
1 Returns: If *this has a target of type T, typeid(T); otherwise, typeid(void).

template<class T> T* target() noexcept;
template<class T> const T* target() const noexcept;
2 Returns: If target_type() == typeid(T) a pointer to the stored function target; otherwise a null
pointer.
20.14.16.2.6 Null pointer comparison functions

```cpp
template<class R, class... ArgTypes>
bool operator==(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;
```

Returns: \!:f.

```cpp
template<class R, class... ArgTypes>
bool operator==(nullptr_t, const function<R(ArgTypes...)>& f) noexcept;
```

```cpp
Returns: (bool)f.
```

20.14.16.2.7 Specialized algorithms

```cpp
template<class R, class... ArgTypes>
void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2) noexcept;
```

Effects: As if by: \(f1\cdot\text{swap}\cdot(f2)\);

20.14.17 Searchers

This subclause provides function object types (20.14) for operations that search for a sequence \([\text{pat}\cdot\text{first}, \text{pat}\cdot\text{last})\) in another sequence \([\text{first}, \text{last})\) that is provided to the object’s function call operator. The first sequence (the pattern to be searched for) is provided to the object’s constructor, and the second (the sequence to be searched) is provided to the function call operator.

Each specialization of a class template specified in this subclause 20.14.17 shall meet the \texttt{Cpp17CopyConstructible} and \texttt{Cpp17CopyAssignable} requirements. Template parameters named

- \texttt{ForwardIterator},
- \texttt{ForwardIterator1},
- \texttt{ForwardIterator2},
- \texttt{RandomAccessIterator},
- \texttt{RandomAccessIterator1},
- \texttt{RandomAccessIterator2}, and
- \texttt{BinaryPredicate}

of templates specified in this subclause 20.14.17 shall meet the same requirements and semantics as specified in 25.1. Template parameters named \texttt{Hash} shall meet the \texttt{Cpp17Hash} requirements (Table 32).

The Boyer-Moore searcher implements the Boyer-Moore search algorithm. The Boyer-Moore-Horspool searcher implements the Boyer-Moore-Horspool search algorithm. In general, the Boyer-Moore searcher will use more memory and give better runtime performance than Boyer-Moore-Horspool.

20.14.17.1 Class template default_searcher

```cpp
template<class ForwardIterator1, class BinaryPredicate = equal_to<>>
class default_searcher {
    public:
        constexpr default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                                   BinaryPredicate pred = BinaryPredicate());

        template<class ForwardIterator2>
        constexpr pair<ForwardIterator2, ForwardIterator2>
        operator()(ForwardIterator2 first, ForwardIterator2 last) const;

    private:
        ForwardIterator1 pat_first_; // exposition only
        ForwardIterator1 pat_last_; // exposition only
        BinaryPredicate pred_; // exposition only
};
```
constexpr default_searcher(ForwardIterator pat_first, ForwardIterator pat_last, 
    BinaryPredicate pred = BinaryPredicate());

Effects: Constructs a default_searcher object, initializing pat_first_ with pat_first, pat_last_ 
with pat_last, and pred_ with pred.

Throws: Any exception thrown by the copy constructor of BinaryPredicate or ForwardIterator1.

template<class ForwardIterator2>
constexpr pair<ForwardIterator2, ForwardIterator2>
operator()(ForwardIterator2 first, ForwardIterator2 last) const;

Effects: Returns a pair of iterators i and j such that
— i == search(first, last, pat_first_, pat_last_, pred_), and
— if i == last, then j == last, otherwise j == next(i, distance(pat_first_, pat_last_)).

20.14.17.2 Class template boyer_moore_searcher

template<class RandomAccessIterator1, 
    class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>, 
    class BinaryPredicate = equal_to<>>
class boyer_moore_searcher {
public:
    boyer_moore_searcher(RandomAccessIterator1 pat_first, 
        RandomAccessIterator1 pat_last, 
        Hash hf = Hash(), 
        BinaryPredicate pred = BinaryPredicate());

    template<class RandomAccessIterator2>
    pair<RandomAccessIterator2, RandomAccessIterator2>
    operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

private:
    RandomAccessIterator1 pat_first_;  // exposition only
    RandomAccessIterator1 pat_last_;   // exposition only
    Hash hash_;                       // exposition only
    BinaryPredicate pred_;            // exposition only
};

boyer_moore_searcher(RandomAccessIterator1 pat_first, 
    RandomAccessIterator1 pat_last, 
    Hash hf = Hash(), 
    BinaryPredicate pred = BinaryPredicate());

Requires: The value type of RandomAccessIterator1 shall meet the Cpp17DefaultConstructible 
requirements, the Cpp17CopyAssignable requirements.

Requires: For any two values A and B of the type iterator_traits<RandomAccessIterator1>::value_type, 
if pred(A, B) == true, then hf(A) == hf(B) shall be true.

Effects: Constructs a boyer_moore_searcher object, initializing pat_first_ with pat_first, pat_last_ 
with pat_last, hash_ with hf, and pred_ with pred.

Throws: Any exception thrown by the copy constructor of RandomAccessIterator1, or by the default 
constructor, copy constructor, or the copy assignment operator of the value type of RandomAccess-
Iterator1, or the copy constructor or operator() of BinaryPredicate or Hash. May throw bad_alloc 
if additional memory needed for internal data structures cannot be allocated.

template<class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

Requires: RandomAccessIterator1 and RandomAccessIterator2 shall have the same value type.

Effects: Finds a subsequence of equal values in a sequence.

Returns: A pair of iterators i and j such that
\[ \text{i is the first iterator in the range } [\text{first}, \text{last} - (\text{pat_last} - \text{pat_first})) \text{ such that for every non-negative integer } n \text{ less than } \text{pat_last} - \text{pat_first} \text{ the following condition holds:} \]
\[ \text{pred}(*(i + n), *(\text{pat_first} + n)) \neq \text{false}, \text{ and} \]
\[ \text{j == next}(i, \text{distance}(\text{pat_first}, \text{pat_last})). \]

Returns \text{make_pair(first, first)} \text{ if } [\text{pat_first}, \text{pat_last}) \text{ is empty, otherwise returns make_pair(last, last) if no such iterator is found.} \]

**Complexity:** At most \((last - first) \times (\text{pat_last} - \text{pat_first})\) applications of the predicate.

### 20.14.17.3 Class template boyer_moore_horspool_searcher

```cpp
template<class RandomAccessIterator1,
        class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
        class BinaryPredicate = equal_to<>>
class boyer_moore_horspool_searcher {
public:
  boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,
                                RandomAccessIterator1 pat_last,
                                Hash hf = Hash(),
                                BinaryPredicate pred = BinaryPredicate());

  template<class RandomAccessIterator2>
  pair<RandomAccessIterator2, RandomAccessIterator2> operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

private:
  RandomAccessIterator1 pat_first_; // exposition only
  RandomAccessIterator1 pat_last_;  // exposition only
  Hash hash_;                       // exposition only
  BinaryPredicate pred_;            // exposition only
};
```

**Requires:** The value type of \text{RandomAccessIterator1} shall meet the \text{Cpp17DefaultConstructible}, \text{Cpp17CopyConstructible}, and \text{Cpp17CopyAssignable} requirements.

**Requires:** For any two values \text{A} and \text{B} of the type \text{iterator_traits<RandomAccessIterator1>::value_type}, if \text{pred(A, B) == true}, then \text{hf(A) == hf(B)} shall be true.

**Effects:** Constructs a boyer_moore_horspool_searcher object, initializing \text{pat_first} with \text{pat_first}, \text{pat_last} with \text{pat_last}, \text{hash} with \text{hf}, and \text{pred} with \text{pred}.

**Throws:** Any exception thrown by the copy constructor of \text{RandomAccessIterator1}, or by the default constructor, copy constructor, or the copy assignment operator of the value type of \text{RandomAccessIterator1} or the copy constructor or \text{operator()} of \text{BinaryPredicate} or \text{Hash}. May throw \text{bad_alloc} if additional memory needed for internal data structures cannot be allocated.

```cpp
template<class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2> operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
```

**Requires:** \text{RandomAccessIterator1} and \text{RandomAccessIterator2} shall have the same value type.

**Effects:** Finds a subsequence of equal values in a sequence.

**Returns:** A pair of iterators \text{i} and \text{j} such that
\[ \text{i is the first iterator in the range } [\text{first}, \text{last} - (\text{pat_last} - \text{pat_first})) \text{ such that for every non-negative integer } n \text{ less than } \text{pat_last} - \text{pat_first} \text{ the following condition holds:} \]
\[ \text{pred}(*(i + n), *(\text{pat_first} + n)) \neq \text{false}, \text{ and} \]
\[ \text{j == next}(i, \text{distance}(\text{pat_first}, \text{pat_last})). \]
Returns `make_pair(first, first)` if `[pat_first_, pat_last_)` is empty, otherwise returns `make_pair(last, last)` if no such iterator is found.

8 Complexity: At most `(last - first) * (pat_last_ - pat_first_)` applications of the predicate.

20.14.18 Class template `hash`

1 The unordered associative containers defined in 22.5 use specializations of the class template `hash` (20.14.1) as the default hash function.

2 Each specialization of `hash` is either enabled or disabled, as described below. [Note: Enabled specializations meet the `Cpp17Hash` requirements, and disabled specializations do not. —end note] Each header that declares the template `hash` provides enabled specializations of `hash` for `nullptr_t` and all cv-unqualified arithmetic, enumeration, and pointer types. For any type `Key` for which neither the library nor the user provides an explicit or partial specialization of the class template `hash`, `hash<Key>` is disabled.

3 If the library provides an explicit or partial specialization of `hash<Key>`, that specialization is enabled except as noted otherwise, and its member functions are `noexcept` except as noted otherwise.

4 If `T` is a disabled specialization of `hash`, these values are `false`: `is_default_constructible_v<T>`, `is_move_constructible_v<T>`, `is_copy_constructible_v<T>`, `is_move_assignable_v<T>`, and `is_copy_assignable_v<T>`. Disabled specializations of `hash` are not function object types (20.14). [Note: This means that the specialization of `hash` exists, but any attempts to use it as a `Cpp17Hash` will be ill-formed. —end note]

5 An enabled specialization `hash<Key>` will:

(5.1) — meet the `Cpp17Hash` requirements (Table 32), with `Key` as the function call argument type, the `Cpp17DefaultConstructible` requirements (Table 25), the `Cpp17CopyAssignable` requirements (Table 29),

(5.2) — be swappable (16.5.3.2) for lvalues,

(5.3) — meet the requirement that if `k1 == k2` is `true`, `h(k1) == h(k2)` is also `true`, where `h` is an object of type `hash<Key>` and `k1` and `k2` are objects of type `Key`;

(5.4) — meet the requirement that the expression `h(k)`, where `h` is an object of type `hash<Key>` and `k` is an object of type `Key`, shall not throw an exception unless `hash<Key>` is a program-defined specialization that depends on at least one program-defined type.

20.15 Metaprogramming and type traits

1 This subclause describes components used by C++ programs, particularly in templates, to support the widest possible range of types, optimise template code usage, detect type related user errors, and perform type inference and transformation at compile time. It includes type classification traits, type property inspection traits, and type transformations. The type classification traits describe a complete taxonomy of all possible C++ types, and state where in that taxonomy a given type belongs. The type property inspection traits allow important characteristics of types or of combinations of types to be inspected. The type transformations allow certain properties of types to be manipulated.

2 All functions specified in this subclause are signal-safe (17.13.4).

20.15.1 Requirements

1 A `Cpp17UnaryTypeTrait` describes a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the property being described. It shall be `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, and publicly and unambiguously derived, directly or indirectly, from its `base characteristic`, which is a specialization of the template `integral_constant` (20.15.3), with the arguments to the template `integral_constant` determined by the requirements for the particular property being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the `Cpp17UnaryTypeTrait`.

2 A `Cpp17BinaryTypeTrait` describes a relationship between two types. It shall be a class template that takes two template type arguments and, optionally, additional arguments that help define the relationship being described. It shall be `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, and publicly and unambiguously derived, directly or indirectly, from its `base characteristic`, which is a specialization of the template `integral_constant` (20.15.3), with the arguments to the template `integral_constant` determined by the requirements for the particular relationship being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the `Cpp17BinaryTypeTrait`.

§ 20.15.1 681
3 A `Cpp17TransformationTrait` modifies a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the modification. It shall define a publicly accessible nested type named `type`, which shall be a synonym for the modified type.

4 Unless otherwise specified, the behavior of a program that adds specializations for any of the templates specified in this subclause 20.15 is undefined.

5 Unless otherwise specified, an incomplete type may be used to instantiate a template specified in this subclause. The behavior of a program is undefined if:

(5.1) an instantiation of a template specified in this subclause directly or indirectly depends on an incompletely-defined object type `T`, and

(5.2) that instantiation could yield a different result were `T` hypothetically completed.

20.15.2 Header `<type_traits>` synopsis

```cpp
namespace std {
    // 20.15.3, helper class
    template<class T, T v> struct integral_constant;
    template<bool B> using bool_constant = integral_constant<bool, B>;
    using true_type = bool_constant<true>;
    using false_type = bool_constant<false>;

20.15.3 Helper classes

namespace std {
  template<class T, T v> struct integral_constant {
    static constexpr T value = v;
    using value_type = T;
    using type = integral_constant<T, v>;

    constexpr operator value_type() const noexcept { return value; }
    constexpr value_type operator()() const noexcept { return value; }
  };
}

1 The class template integral_constant, alias template bool_constant, and its associated typedef-names true_type and false_type are used as base classes to define the interface for various type traits.

20.15.4 Unary type traits

1 This subclause contains templates that may be used to query the properties of a type at compile time.

2 Each of these templates shall be a Cpp17UnaryTypeTrait (20.15.1) with a base characteristic of true_type if the corresponding condition is true, otherwise false_type.
20.15.4.1 Primary type categories

1 The primary type categories correspond to the descriptions given in subclause 6.7 of the C++ standard.

2 For any given type \( T \), the result of applying one of these templates to \( T \) and to \( cv \ T \) shall yield the same result.

3 [Note: For any given type \( T \), exactly one of the primary type categories has a value member that evaluates to true. — end note]

Table 45: Primary type category predicates  [tab:meta.unary.cat]

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class T&gt; struct is_void;</td>

<tr>
<td>template&lt;class T&gt; struct is_function;</td>
<td>T is a function type (6.7.2)</td>
<td></td>
</tr>
</tbody>
</table>

20.15.4.2 Composite type traits

1 These templates provide convenient compositions of the primary type categories, corresponding to the descriptions given in subclause 6.7.

2 For any given type \( T \), the result of applying one of these templates to \( T \) and to \( cv \ T \) shall yield the same result.

<td>T is a pointer-to-member type (6.7.2)</td>
<td></td>
</tr>
</tbody>
</table>

20.15.4.3 Type properties

1 These templates provide access to some of the more important properties of types.

2 It is unspecified whether the library defines any full or partial specializations of any of these templates.

3 For all of the class templates X declared in this subclause, instantiating that template with a template-argument that is a class template specialization may result in the implicit instantiation of the template argument if and only if the semantics of X require that the argument is a complete type.

4 For the purpose of defining the templates in this subclause, a function call expression declval<T>() for any type T is considered to be a trivial (6.7, 11.3.3) function call that is not an odr-use (6.2) of declval in the context of the corresponding definition notwithstanding the restrictions of 20.2.6.

---
5. [Example:]

```
is_const_v<const volatile int> // true
is_const_v<const int*> // false
is_const_v<const int&> // false
is_const_v<int[3]> // false
is_const_v<const int[3]> // true
```

— end example]  
6. [Example:]

§ 20.15.4.3 695
remove_const_t<const volatile int>  // volatile int
remove_const_t<const int* const>  // int*
remove_const_t<const int&>  // int

— end example]

[Example:
  
  // Given:
  struct P final { };  
  union U1 { };  
  union U2 final { };  

  // the following assertions hold:
  static_assert(!is_final_v<int>);  
  static_assert(is_final_v<P>);  
  static_assert(!is_final_v<U1>);  
  static_assert(is_final_v<U2>);

  — end example]

The predicate condition for a template specialization is_constructible<T, Args...> shall be satisfied if and only if the following variable definition would be well-formed for some invented variable t:

T t(declval<Args>()...);

[Note: These tokens are never interpreted as a function declaration. — end note] Access checking is performed as if in a context unrelated to T and any of the Args. Only the validity of the immediate context of the variable initialization is considered. [Note: The evaluation of the initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

The predicate condition for a template specialization has_unique_object_representations<T> shall be satisfied if and only if:

(9.1) — T is trivially copyable, and
(9.2) — any two objects of type T with the same value have the same object representation, where two objects of array or non-union class type are considered to have the same value if their respective sequences of direct subobjects have the same values, and two objects of union type are considered to have the same value if they have the same active member and the corresponding members have the same value.

The set of scalar types for which this condition holds is implementation-defined. [Note: If a type has padding bits, the condition does not hold; otherwise, the condition holds true for integral types. — end note]

20.15.5 Type property queries [meta.unary.prop.query]

This subclause contains templates that may be used to query properties of types at compile time.

<table>
<thead>
<tr>
<th>Template</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class T&gt;</td>
<td>alignof(T).</td>
</tr>
<tr>
<td>struct alignment_of;</td>
<td>Requires: alignof(T) shall be a valid expression (7.6.2.5)</td>
</tr>
<tr>
<td>template&lt;class T&gt;</td>
<td>If T names an array type, an integer value representing the number of</td>
</tr>
<tr>
<td>struct rank;</td>
<td>dimensions of T; otherwise, 0.</td>
</tr>
<tr>
<td>template&lt;class T, unsigned I = 0&gt;</td>
<td>If T is not an array type, or if it has rank less than or equal to I,</td>
</tr>
<tr>
<td>struct extent;</td>
<td>or if I is 0 and T has type “array of unknown bound of U”, then 0;</td>
</tr>
<tr>
<td></td>
<td>otherwise, the bound (9.2.3.4) of the I-th dimension of T, where</td>
</tr>
<tr>
<td></td>
<td>indexing of I is zero-based</td>
</tr>
</tbody>
</table>

2 Each of these templates shall be a Cpp17UnaryTypeTrait (20.15.1) with a base characteristic of integral_constant<size_t, Value>.

3 [Example:
// the following assertions hold:
assert(rank_v<int> == 0);
assert(rank_v<int[2]> == 1);
assert(rank_v<int[][4]> == 2);
— end example

// the following assertions hold:
assert(extent_v<int> == 0);
assert(extent_v<int[2]> == 2);
assert(extent_v<int[2][4]> == 2);
assert(extent_v<int[][4]> == 0);
assert((extent_v<int, 1>) == 0);
assert((extent_v<int[2], 1>) == 0);
assert((extent_v<int[2][4], 1>) == 4);
assert((extent_v<int[][4], 1>) == 4);
— end example

20.15.6 Relationships between types

This subclause contains templates that may be used to query relationships between types at compile time.

Each of these templates shall be a Cpp17BinaryTypeTrait (20.15.1) with a base characteristic of true_type if the corresponding condition is true, otherwise false_type.

Table 49: Type relationship predicates

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class T, class U&gt; struct is_same;</td>
<td>T and U name the same type with the same cv-qualifications</td>
<td></td>
</tr>
<tr>
<td>template&lt;class Base, class Derived&gt; struct is_base_of;</td>
<td>Base is a base class of Derived (11.6) without regard to cv-qualifiers or Base and Derived are not unions and name the same class type without regard to cv-qualifiers</td>
<td>If Base and Derived are non-union class types and are not possibly cv-qualified versions of the same type, Derived shall be a complete type. [Note: Base classes that are private, protected, or ambiguous are, nonetheless, base classes. — end note]</td>
</tr>
<tr>
<td>template&lt;class From, class To&gt; struct is_convertible;</td>
<td>see below</td>
<td>From and To shall be complete types, arrays of unknown bound, or cv void types.</td>
</tr>
<tr>
<td>template&lt;class From, class To&gt; struct is_nothrow_convertible;</td>
<td>is_convertible_v&lt;From, To&gt; is true and the conversion, as defined by is_convertible, is known not to throw any exceptions (7.6.2.6)</td>
<td>From and To shall be complete types, arrays of unknown bound, or cv void types.</td>
</tr>
<tr>
<td>template&lt;class Fn, class... ArgTypes&gt; struct is_invocable;</td>
<td>The expression INVOKE(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...) is well-formed when treated as an unevaluated operand</td>
<td>Fn and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>template&lt;class R, class Fn, class... ArgTypes&gt; struct is_invocable_r;</td>
<td>The expression INVOKE&lt;R&gt;(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...) is well-formed when treated as an unevaluated operand</td>
<td>Fn, R, and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
</tbody>
</table>
### Table 49: Type relationship predicates (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template&lt;class Fn, class... ArgTypes&gt;</code> <code>struct is_nothrow_invocable;</code></td>
<td><code>is_invocable_v&lt;Fn, ArgTypes...&gt;</code> is true and the expression <code>INVOKE(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;())...</code> is known not to throw any exceptions (7.6.2.6)</td>
<td>Fn and all types in the template parameter pack <code>ArgTypes</code> shall be complete types, <code>cv void</code>, or arrays of unknown bound.</td>
</tr>
<tr>
<td><code>template&lt;class R, class Fn, class... ArgTypes&gt;</code> <code>struct is_nothrow_invocable_r;</code></td>
<td><code>is_invocable_r_v&lt;R, Fn, ArgTypes...&gt;</code> is true and the expression <code>INVOKE&lt;R&gt;(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;())...</code> is known not to throw any exceptions (7.6.2.6)</td>
<td>Fn, R, and all types in the template parameter pack <code>ArgTypes</code> shall be complete types, <code>cv void</code>, or arrays of unknown bound.</td>
</tr>
</tbody>
</table>

3 For the purpose of defining the templates in this subclause, a function call expression `declval<T>()` for any type `T` is considered to be a trivial (6.7, 11.3.3) function call that is not an odr-use (6.2) of `declval` in the context of the corresponding definition notwithstanding the restrictions of 20.2.6.

4 [Example:

```cpp
struct B {};  // true
struct B1 : B {};  // true
struct B2 : B {};  // true
struct D : private B1, private B2 {};  // true

is_base_of_v<B, D>  // true
is_base_of_v<const B, D>  // true
is_base_of_v<const B, const D>  // true
is_base_of_v<B, const B>  // true
is_base_of_v<int, D>  // false
is_base_of_v<int, const B>  // false
is_base_of_v<B[3], D[3]>  // false
is_base_of_v<int, int>  // false
```

— end example]

5 The predicate condition for a template specialization `is_convertible<From, To>` shall be satisfied if and only if the return expression in the following code would be well-formed, including any implicit conversions to the return type of the function:

```cpp
To test() {
    return declval<From>();
}
```

[Note: This requirement gives well-defined results for reference types, void types, array types, and function types. — end note] Access checking is performed in a context unrelated to `To` and `From`. Only the validity of the immediate context of the expression of the return statement (8.6.3) (including initialization of the returned object or reference) is considered. [Note: The initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

### 20.15.7 Transformations between types

1 This subclause contains templates that may be used to transform one type to another following some predefined rule.

2 Each of the templates in this subclause shall be a `Cpp17TransformationTrait` (20.15.1).

### 20.15.7.1 Const-volatile modifications

[meta.trans cv]
Table 50: Const-volatile modifications  [tab:meta.trans.cv]

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class T>
| struct remove_const; | The member typedef type names the same type as T except that any top-level const-qualifier has been removed. [Example: remove_const_t<const volatile int> evaluates to volatile int, whereas remove_const_t<const int*> evaluates to const int*. — end example] |
| template<class T>
| struct remove_volatile; | The member typedef type names the same type as T except that any top-level volatile-qualifier has been removed. [Example: remove_volatile_t<const volatile int> evaluates to const int, whereas remove_volatile_t<const volatile int*> evaluates to volatile int*. — end example] |
| template<class T>
| struct remove_cv; | The member typedef type shall be the same as T except that any top-level cv-qualifier has been removed. [Example: remove_cv_t<const volatile int> evaluates to int, whereas remove_cv_t<const volatile int*> evaluates to const volatile int*. — end example] |
| template<class T>
| struct add_const; | type names the same type as T, otherwise T const. |
| template<class T>
| struct add_volatile; | type names the same type as T, otherwise T volatile. |
| template<class T>
| struct add_cv; | The member typedef type names the same type as add_const_t<add_volatile_t<T>>. |

20.15.7.2 Reference modifications  [meta.trans.ref]

Table 51: Reference modifications  [tab:meta.trans.ref]

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class T>
| struct remove_reference; | If T has type “reference to T1” then the member typedef type names T1; otherwise, type names T. |
| template<class T>
| struct add_lvalue_reference; | If T names a referenceable type (16.3.22) then the member typedef type names T&; otherwise, type names T. [Note: This rule reflects the semantics of reference collapsing (9.2.3.2). — end note] |
| template<class T>
| struct add_rvalue_reference; | If T names a referenceable type then the member typedef type names T&&; otherwise, type names T. [Note: This rule reflects the semantics of reference collapsing (9.2.3.2). For example, when a type T names a type T1&, the type add_rvalue_reference_t<T> is not an rvalue reference. — end note] |

20.15.7.3 Sign modifications  [meta.trans.sign]

Table 52: Sign modifications  [tab:meta.trans.sign]

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class T>
| struct make_signed; | If T names a (possibly cv-qualified) signed integer type (6.7.1) then the member typedef type names the type T; otherwise, if T names a (possibly cv-qualified) unsigned integer type then type names the corresponding signed integer type, with the same cv-qualifiers as T; otherwise, type names the signed integer type with smallest rank (6.7.4) for which sizeof(T) == sizeof(type), with the same cv-qualifiers as T. Requires: T shall be a (possibly cv-qualified) integral type or enumeration but not a bool type. |
Table 52: Sign modifications (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template&lt;class T&gt; struct make_unsigned;</code></td>
<td>If <code>T</code> names a (possibly cv-qualified) unsigned integer type (6.7.1) then the member typedef <code>type</code> names the type <code>T</code>; otherwise, if <code>T</code> names a (possibly cv-qualified) signed integer type then <code>type</code> names the corresponding unsigned integer type, with the same cv-qualifiers as <code>T</code>; otherwise, <code>type</code> names the unsigned integer type with smallest rank (6.7.4) for which <code>sizeof(T) == sizeof(type)</code>, with the same cv-qualifiers as <code>T</code>. Requires: <code>T</code> shall be a (possibly cv-qualified) integral type or enumeration but not a <code>bool</code> type.</td>
</tr>
</tbody>
</table>

20.15.7.4 Array modifications

Table 53: Array modifications

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template&lt;class T&gt; struct remove_extent;</code></td>
<td>If <code>T</code> names a type “array of <code>U</code>”, the member typedef <code>type</code> shall be <code>U</code>, otherwise <code>T</code>. [Note: For multidimensional arrays, only the first array dimension is removed. For a type “array of <code>const U</code>”, the resulting type is <code>const U</code>. —end note]</td>
</tr>
<tr>
<td><code>template&lt;class T&gt; struct remove_all_extents;</code></td>
<td>If <code>T</code> is “multi-dimensional array of <code>U</code>”, the resulting member typedef <code>type</code> is <code>U</code>, otherwise <code>T</code>.</td>
</tr>
</tbody>
</table>

1 [Example:]

// the following assertions hold:
assert((is_same_v<remove_extent_t<int>, int>));
assert((is_same_v<remove_extent_t<int[2]>, int>));
assert((is_same_v<remove_extent_t<int[2][3]>, int[3]>));
assert((is_same_v<remove_extent_t<int[2][3][2]>, int[3][2]>));
— end example]

2 [Example:]

// the following assertions hold:
assert((is_same_v<remove_all_extents_t<int>, int>));
assert((is_same_v<remove_all_extents_t<int[2]>, int>));
assert((is_same_v<remove_all_extents_t<int[2][3]>, int>));
assert((is_same_v<remove_all_extents_t<int[2][3][2]>, int>));
—end example]

20.15.7.5 Pointer modifications

Table 54: Pointer modifications

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template&lt;class T&gt; struct remove_pointer;</code></td>
<td>If <code>T</code> has type “(possibly cv-qualified) pointer to <code>T1</code>” then the member typedef <code>type</code> names <code>T1</code>; otherwise, it names <code>T</code>.</td>
</tr>
<tr>
<td><code>template&lt;class T&gt; struct add_pointer;</code></td>
<td>If <code>T</code> names a referenceable type (16.3.22) or a cv <code>void</code> type then the member typedef <code>type</code> names the same type as <code>remove_reference_t&lt;T&gt;*</code>; otherwise, <code>type</code> names <code>T</code>.</td>
</tr>
</tbody>
</table>

20.15.7.6 Other transformations

Table 55: Other transformations

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template&lt;class T&gt; struct type_identity;</code></td>
<td>The member typedef <code>type</code> names the type <code>T</code>.</td>
</tr>
</tbody>
</table>
Table 55: Other transformations (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| `template<size_t Len, size_t Align = default-alignment> struct aligned_storage;` | The value of `default-alignment` shall be the most stringent alignment requirement for any C++ object type whose size is no greater than `Len` (6.7). The member typedef `type` shall be a trivial standard-layout type suitable for use as uninitialized storage for any object whose size is at most `Len` and whose alignment is a divisor of `Align`. 

*Requires:* `Len` shall not be zero. `Align` shall be equal to `alignof(T)` for some type `T` or to `default-alignment`.

| `template<size_t Len, class... Types> struct aligned_union;` | The member typedef `type` shall be a trivial standard-layout type suitable for use as uninitialized storage for any object whose type is listed in `Types`; its size shall be at least `Len`. The static member `alignment_value` shall be an integral constant of type `size_t` whose value is the strictest alignment of all types listed in `Types`. 

*Requires:* At least one type is provided. Each type in the template parameter pack `Types` shall be a complete object type.

| `template<class T> struct remove_cvref;` | The member typedef `type` names the same type as `remove_cv_t<remove_reference_t<T>>`.

| `template<class T> struct decay;` | Let `U` be `remove_reference_t<T>`. If `is_array_v<U>` is `true`, the member typedef `type` shall equal `remove_extent_t<U>`. If `is_function_v<U>` is `true`, the member typedef `type` shall equal `add_pointer_t<U>`. Otherwise the member typedef `type` equals `remove_cv_t<U>`. 

*Note:* This behavior is similar to the value-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) conversions applied when an lvalue is used as an rvalue, but also strips `cv`-qualifiers from class types in order to more closely model by-value argument passing. 

*—end note*

| `template<bool B, class T = void> struct enable_if;` | If `B` is `true`, the member typedef `type` shall equal `T`; otherwise, there shall be no member `type`.

| `template<bool B, class T, class F> struct conditional;` | If `B` is `true`, the member typedef `type` shall equal `T`. If `B` is `false`, the member typedef `type` shall equal `F`.

| `template<class... T> struct common_type;` | Unless this trait is specialized (as specified in Note B, below), the member typedef `type` shall be defined or omitted as specified in Note A, below. If it is omitted, there shall be no member `type`. Each type in the template parameter pack `T` shall be complete, `cv void`, or an array of unknown bound.

| `template<class, class, template<class> class, template<class> class> struct basic_common_reference;` | Unless this trait is specialized (as specified in Note D, below), there shall be no member `type`.

| `template<class... T> struct common_reference;` | The member typedef-name `type` is defined or omitted as specified in Note C, below. Each type in the parameter pack `T` shall be complete or `cv void`.

| `template<class T> struct underlying_type;` | If `T` is an enumeration type, the member typedef `type` names the underlying type of `T` (9.6); otherwise, there is no member `type`. 

*Mandates:* `T` is not an incomplete enumeration type.

§ 20.15.7.6
Table 55: Other transformations (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template&lt;class Fn, class... ArgTypes&gt;</code> <code>struct invoke_result;</code></td>
<td>If the expression <code>INVOKE(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...)</code> is well-formed when treated as an unevaluated operand (7.2), the member typedef <code>type</code> names the type <code>decltype(INVOKE(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...));</code> otherwise, there shall be no member <code>type</code>. Access checking is performed as if in a context unrelated to <code>Fn</code> and <code>ArgTypes</code>. Only the validity of the immediate context of the expression is considered. [Note: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]</td>
</tr>
</tbody>
</table>

`Requires`: `Fn` and all types in the template parameter pack `ArgTypes` shall be complete types, `cv void`, or arrays of unknown bound.

1 [Note: A typical implementation would define `aligned_storage` as:

```cpp
template<size_t Len, size_t Alignment>
struct aligned_storage {
    typedef struct {
        alignas(Alignment) unsigned char __data[Len];
    } type;
};
```
—end note]

2 Let:

1\[(2.1) \quad \text{CREF}(A) \text{ be add_lvalue_reference_t<const remove_reference_t<A>>},\]
1\[(2.2) \quad \text{XREF}(A) \text{ denote a unary alias template } T \text{ such that } T<U> \text{ denotes the same type as } U \text{ with the addition of } A\text{'s cv and reference qualifiers, for a non-reference cv-unqualified type } U,\]
1\[(2.3) \quad \text{COPYCV(FROM, TO)} \text{ be an alias for type } TO \text{ with the addition of FROM's top-level cv-qualifiers. [Example: COPYCV(const int, volatile short) is an alias for const volatile short. — end example]}\]
1\[(2.4) \quad \text{COND_RES}(X, Y) \text{ be decltype(false ? declval<X(&)()>()() : declval<Y(&)()>()()}).\]

Given types `A` and `B`, let `X` be `remove_reference_t<A>`, let `Y` be `remove_reference_t<B>`, and let `COMMON-_REF(A, B)` be:

1\[(2.5) \quad \text{If } A \text{ and } B \text{ are both lvalue reference types, } \text{COMMON_REF}(A, B) \text{ is } \text{COND_RES}(\text{COPYCV}(X, Y) \&, \text{COPYCV}(Y, X) \&) \text{ if that type exists and is a reference type.}\]
1\[(2.6) \quad \text{Otherwise, let } C \text{ be } \text{remove_reference_t<COMMON_REF(Xk, Yk)>kk}. \text{ If } A \text{ and } B \text{ are both rvalue reference types, } C \text{ is well-formed, and } \text{is_convertible_v}<A, C> \&k \text{ is_convertible_v}<B, C> \text{ is true, then } \text{COMMON_REF}(A, B) \text{ is } C.\]
1\[(2.7) \quad \text{Otherwise, let } D \text{ be } \text{COMMON_REF(const Xk, Yk)}. \text{ If } A \text{ is an rvalue reference and } B \text{ is an lvalue reference and } D \text{ is well-formed and } \text{is_convertible_v}<A, D> \text{ is true, then } \text{COMMON_REF}(A, B) \text{ is } D.\]
1\[(2.8) \quad \text{Otherwise, if } A \text{ is an lvalue reference and } B \text{ is an rvalue reference, then } \text{COMMON_REF}(A, B) \text{ is } \text{COMMON-_REF}(B, A).\]
1\[(2.9) \quad \text{Otherwise, } \text{COMMON_REF}(A, B) \text{ is ill-formed.}\]

If any of the types computed above is ill-formed, then `COMMON_REF(A, B)` is ill-formed.

3 Note A: For the `common_type` trait applied to a template parameter pack `T` of types, the member `type` shall be either defined or not present as follows:

1\[(3.1) \quad \text{If } \text{sizeof...(T)} \text{ is zero, there shall be no member } type.\]
1\[(3.2) \quad \text{If } \text{sizeof...(T)} \text{ is one, let } T0 \text{ denote the sole type constituting the pack } T. \text{ The member typedef-name } type \text{ shall denote the same type, if any, as } \text{common_type_t<T0, T0>}; \text{ otherwise there shall be no member } type.\]
(3.3) — If sizeof...(T) is two, let the first and second types constituting T be denoted by T1 and T2, respectively, and let D1 and D2 denote the same types as decay_t<T1> and decay_t<T2>, respectively.

(3.3.1) — If is_same_v<T1, D1> is false or is_same_v<T2, D2> is false, let C denote the same type, if any, as common_type_t<T1, D1, D2>.

(3.3.2) — [Note: None of the following will apply if there is a specialization common_type<D1, D2>. — end note]

(3.3.3) — Otherwise, if

\[ \text{decay_t<declspec}(\text{false} ? \text{declval}<D1>() : \text{declval}<D2>()) \]

denotes a valid type, let C denote that type.

(3.3.4) — Otherwise, if COND_RES(CREF(D1), CREF(D2)) denotes a type, let C denote the type decay_t<COND_RES(CREF(D1), CREF(D2))>.

In either case, the member typedef-name type shall denote the same type, if any, as C. Otherwise, there shall be no member type.

(3.4) — If sizeof...(T) is greater than two, let T1, T2, and R, respectively, denote the first, second, and (pack of) remaining types constituting T. Let C denote the same type, if any, as common_type_t<T1, T2>. If there is such a type C, the member typedef-name type shall denote the same type, if any, as common_type_tC, R...>. Otherwise, there shall be no member type.

4 Note B: Notwithstanding the provisions of 20.15.2, and pursuant to 16.5.4.2.1, a program may specialize common_type<T1, T2> for types T1 and T2 such that is_same_v<T1, decay_t<T1>> and is_same_v<T2, decay_t<T2>> are each true. [Note: Such specializations are needed when only explicit conversions are desired between the template arguments. — end note] Such a specialization need not have a member named type, but if it does, that member shall be a typedef-name for an accessible and unambiguous cv-unqualified non-reference type C to which each of the types T1 and T2 is explicitly convertible. Moreover, common_type_t<T1, T2> shall denote the same type, if any, as does common_type_t<T2, T1>. No diagnostic is required for a violation of this Note’s rules.

5 Note C: For the common_reference trait applied to a parameter pack T of types, the member type shall be either defined or not present as follows:

(5.1) — If sizeof...(T) is zero, there shall be no member type.

(5.2) — Otherwise, if sizeof...(T) is one, let T0 denote the sole type in the pack T. The member typedef type shall denote the same type as T0.

(5.3) — Otherwise, if sizeof...(T) is two, let T1 and T2 denote the two types in the pack T. Then

(5.3.1) — If T1 and T2 are reference types and COMMON_REF(T1, T2) is well-formed, then the member typedef type denotes that type.

(5.3.2) — Otherwise, if basic_common_reference<remove_cvref_t<T1>>, remove_cvref_t<T2>>, XREF(T1), XREF(T2)>>::type is well-formed, then the member typedef type denotes that type.

(5.3.3) — Otherwise, if COND_RES(T1, T2) is well-formed, then the member typedef type denotes that type.

(5.3.4) — Otherwise, if common_type_t<T1, T2> is well-formed, then the member typedef type denotes that type.

(5.3.5) — Otherwise, there shall be no member type.

(5.4) — Otherwise, if sizeof...(T) is greater than two, let T1, T2, and Rest, respectively, denote the first, second, and (pack of) remaining types comprising T. Let C be the type common_reference_t<T1, T2>. Then:

(5.4.1) — If there is such a type C, the member typedef type shall denote the same type, if any, as common_reference_tC, Rest...>.

(5.4.2) — Otherwise, there shall be no member type.

6 Note D: Notwithstanding the provisions of 20.15.2, and pursuant to 16.5.4.2.1, a program may partially specialize basic_common_reference<T, U, TQual, UQual> for types T and U such that is_same_v<T, decay_t<T>> and is_same_v<U, decay_t<U>> are each true. [Note: Such specializations can be used to influence the result of common_reference, and are needed when only explicit conversions are desired between the template arguments. — end note] Such a specialization need not have a member named type, but if it does, that member shall be a typedef-name for an accessible and unambiguous type C to which each of the types...
TQual<T> and UQual<U> is convertible. Moreover, basic_common_reference<T, U, TQual, UQual>::type shall denote the same type, if any, as does basic_common_reference<U, T, UQual, TQual>::type. No diagnostic is required for a violation of these rules.

7 [Example: Given these definitions:

```cpp
using PF1 = bool (*)(());
using PF2 = short (*)(long);
struct S {
    operator PF2() const;
    double operator()(char, int&);
    void fn(long) const;
    char data;
};
using PMF = void (S::*)(long) const;
using PMD = char S::*;
```

the following assertions will hold:

```cpp
static_assert(is_same_v<invoke_result_t<S, int>, short>);
static_assert(is_same_v<invoke_result_t<S&, unsigned char, int&>, double>);
static_assert(is_same_v<invoke_result_t<PF1>, bool>);
static_assert(is_same_v<invoke_result_t<PMF, unique_ptr<S>, int>, void>);
static_assert(is_same_v<invoke_result_t<PMD, S, char&>, void>);
```

—end example]  

20.15.8 Logical operator traits [meta.logical]  

This subclause describes type traits for applying logical operators to other type traits.

```cpp
template<class... B> struct conjunction : see below { }
```

2 The class template conjunction forms the logical conjunction of its template type arguments.

3 For a specialization conjunction<B₁, ..., Bₙ>, if there is a template type argument Bᵢ for which bool(Bᵢ::value) is false, then instantiating conjunction<B₁, ..., Bₙ>::value does not require the instantiation of Bⱼ::value for j > i. [Note: This is analogous to the short-circuiting behavior of the built-in operator &&. —end note]

4 Every template type argument for which Bᵢ::value is instantiated shall be usable as a base class and shall have a member value which is convertible to bool, is not hidden, and is unambiguously available in the type.

5 The specialization conjunction<B₁, ..., Bₙ> has a public and unambiguous base that is either

1. the first type Bᵢ in the list true_type, B₁, ..., Bₙ for which bool(Bᵢ::value) is false, or
2. if there is no such Bᵢ, the last type in the list.

[Note: This means a specialization of conjunction does not necessarily inherit from either true_type or false_type. —end note]

6 The member names of the base class, other than conjunction and operator=, shall not be hidden and shall be unambiguously available in conjunction.

```cpp
template<class... B> struct disjunction : see below { }
```

7 The class template disjunction forms the logical disjunction of its template type arguments.

8 For a specialization disjunction<B₁, ..., Bₙ>, if there is a template type argument Bᵢ for which bool(Bᵢ::value) is true, then instantiating disjunction<B₁, ..., Bₙ>::value does not require the instantiation of Bⱼ::value for j > i. [Note: This is analogous to the short-circuiting behavior of the built-in operator ||. —end note]

9 Every template type argument for which Bᵢ::value is instantiated shall be usable as a base class and shall have a member value which is convertible to bool, is not hidden, and is unambiguously available in the type.

10 The specialization disjunction<B₁, ..., Bₙ> has a public and unambiguous base that is either
— the first type $B_i$ in the list $false_type$, $B_1, \ldots, B_N$ for which $bool(B_i::value)$ is true, or
— if there is no such $B_i$, the last type in the list.

[Note: This means a specialization of $disjunction$ does not necessarily inherit from either $true_type$ or $false_type$. — end note]

The member names of the base class, other than $disjunction$ and $operator=$, shall not be hidden and shall be unambiguously available in $disjunction$.

```cpp
template<class B> struct negation : see below { }
```

The class template $negation$ forms the logical negation of its template type argument. The type $negation<B>$ is a $Cpp17UnaryTypeTrait$ with a base characteristic of $bool_constant<!bool(B::value)>$.

## 20.15.9 Endian

Two common methods of byte ordering in multibyte scalar types are big-endian and little-endian in the execution environment. Big-endian is a format for storage of binary data in which the most significant byte is placed first, with the rest in descending order. Little-endian is a format for storage of binary data in which the least significant byte is placed first, with the rest in ascending order. This subclause describes the endianness of the scalar types of the execution environment.

```cpp
enum class endian {
    little = see below,
    big = see below,
    native = see below
};
```

If all scalar types have size 1 byte, then all of $endian::little$, $endian::big$, and $endian::native$ have the same value. Otherwise, $endian::little$ is not equal to $endian::big$. If all scalar types are big-endian, $endian::native$ is equal to $endian::big$. If all scalar types are little-endian, $endian::native$ is equal to $endian::little$. Otherwise, $endian::native$ is not equal to either $endian::big$ or $endian::little$.

## 20.15.10 Constant evaluation context

```cpp
constexpr bool is_constant_evaluated() noexcept;
```

Returns: $true$ if and only if evaluation of the call occurs within the evaluation of an expression or conversion that is manifestly constant-evaluated (7.7).

[Example:
```cpp
constexpr void f(unsigned char *p, int n) {
    if (std::is_constant_evaluated()) {
        // should not be a constexpr if statement
        for (int k = 0; k<n; ++k) p[k] = 0;
    } else {
        memset(p, 0, n);
        // not a core constant expression
    }
}
```
— end example]

## 20.16 Compile-time rational arithmetic

### 20.16.1 In general

This subclause describes the ratio library. It provides a class template $ratio$ which exactly represents any finite rational number with a numerator and denominator representable by compile-time constants of type $intmax_t$.

Throughout this subclause, the names of template parameters are used to express type requirements. If a template parameter is named $R1$ or $R2$, and the template argument is not a specialization of the $ratio$ template, the program is ill-formed.
20.16.2 Header <ratio> synopsis

namespace std {
    // 20.16.3, class template ratio
    template<intmax_t N, intmax_t D = 1> class ratio;

    // 20.16.4, ratio arithmetic
    template<class R1, class R2> using ratio_add = see below;
    template<class R1, class R2> using ratio_subtract = see below;
    template<class R1, class R2> using ratio_multiply = see below;
    template<class R1, class R2> using ratio_divide = see below;

    // 20.16.5, ratio comparison
    template<class R1, class R2> struct ratio_equal;
    template<class R1, class R2> struct ratio_not_equal;
    template<class R1, class R2> struct ratio_less;
    template<class R1, class R2> struct ratio_less_equal;
    template<class R1, class R2> struct ratio_greater;
    template<class R1, class R2> struct ratio_greater_equal;

    template<class R1, class R2>
    inline constexpr bool ratio_equal_v = ratio_equal<R1, R2>::value;
    template<class R1, class R2>
    inline constexpr bool ratio_not_equal_v = ratio_not_equal<R1, R2>::value;
    template<class R1, class R2>
    inline constexpr bool ratio_less_v = ratio_less<R1, R2>::value;
    template<class R1, class R2>
    inline constexpr bool ratio_less_equal_v = ratio_less_equal<R1, R2>::value;
    template<class R1, class R2>
    inline constexpr bool ratio_greater_v = ratio_greater<R1, R2>::value;
    template<class R1, class R2>
    inline constexpr bool ratio_greater_equal_v = ratio_greater_equal<R1, R2>::value;

    // 20.16.6, convenience SI typedefs
    using yocto = ratio<1, 1'000'000'000'000'000'000'000'000'; // see below
    using zepto = ratio<1, 1'000'000'000'000'000'000'000'000'; // see below
    using atto = ratio<1, 1'000'000'000'000'000'000'; // see below
    using femto = ratio<1, 1'000'000'000'000'; // see below
    using pico = ratio<1, 1'000'000'; // see below
    using nano = ratio<1, 1'000'; // see below
    using micro = ratio<1, 1'; // see below
    using milli = ratio<1, 1'; // see below
    using centi = ratio<1, 1'; // see below
    using deci = ratio<1, 1'; // see below
    using deca = ratio<1, 1'; // see below
    using hecto = ratio<1, 1'; // see below
    using kilo = ratio<1, 1'; // see below
    using mega = ratio<1, 1'; // see below
    using giga = ratio<1, 1'; // see below
    using tera = ratio<1, 1'; // see below
    using peta = ratio<1, 1'; // see below
    using exa = ratio<1, 1'; // see below
    using zetta = ratio<1, 1'; // see below
    using yotta = ratio<1, 1'; // see below
}

20.16.3 Class template ratio

namespace std {
    template<intmax_t N, intmax_t D = 1> class ratio {
    public:
        static constexpr intmax_t num;
        static constexpr intmax_t den;
        using type = ratio<num, den>;
    }
If the template argument \( D \) is zero or the absolute values of either of the template arguments \( N \) and \( D \) is not representable by type \( \text{intmax}_t \), the program is ill-formed. \([\text{Note: These rules ensure that infinite ratios are avoided and that for any negative input, there exists a representable value of its absolute value which is positive. This excludes the most negative value. — end note}]\)

The static data members \( \text{num} \) and \( \text{den} \) shall have the following values, where \( \text{gcd} \) represents the greatest common divisor of the absolute values of \( N \) and \( D \):

\[
\begin{align*}
(2.1) & \quad \text{num} \text{ shall have the value } \text{sign}(N) \times \text{sign}(D) \times \text{abs}(N) / \text{gcd}. \\
(2.2) & \quad \text{den} \text{ shall have the value } \text{abs}(D) / \text{gcd}.
\end{align*}
\]

### 20.16.4 Arithmetic on ratios

Each of the alias templates \( \text{ratio_add} \), \( \text{ratio_subtract} \), \( \text{ratio_multiply} \), and \( \text{ratio_divide} \) denotes the result of an arithmetic computation on two \( \text{ratio} \)s \( R1 \) and \( R2 \). With \( X \) and \( Y \) computed (in the absence of arithmetic overflow) as specified by Table 56, each alias denotes a \( \text{ratio}<U, V> \) such that \( U \) is the same as \( \text{ratio}\langle X, Y\rangle::\text{num} \) and \( V \) is the same as \( \text{ratio}\langle X, Y\rangle::\text{den} \).

If it is not possible to represent \( U \) or \( V \) with \( \text{intmax}_t \), the program is ill-formed. Otherwise, an implementation should yield correct values of \( U \) and \( V \). If it is not possible to represent \( X \) or \( Y \) with \( \text{intmax}_t \), the program is ill-formed unless the implementation yields correct values of \( U \) and \( V \).

#### Table 56: Expressions used to perform ratio arithmetic

<table>
<thead>
<tr>
<th>Type</th>
<th>Value of ( X )</th>
<th>Value of ( Y )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{ratio_add}&lt;R1, R2&gt; )</td>
<td>( R1::\text{num} \times R2::\text{den} + R1::\text{den} \times R2::\text{den} )</td>
<td>( R2::\text{num} \times R1::\text{den} )</td>
</tr>
<tr>
<td>( \text{ratio_subtract}&lt;R1, R2&gt; )</td>
<td>( R1::\text{num} \times R2::\text{den} - R1::\text{den} \times R2::\text{den} )</td>
<td>( R2::\text{num} \times R1::\text{den} )</td>
</tr>
<tr>
<td>( \text{ratio_multiply}&lt;R1, R2&gt; )</td>
<td>( R1::\text{num} \times R2::\text{num} )</td>
<td>( R1::\text{den} \times R2::\text{den} )</td>
</tr>
<tr>
<td>( \text{ratio_divide}&lt;R1, R2&gt; )</td>
<td>( R1::\text{num} \times R2::\text{den} )</td>
<td>( R1::\text{den} \times R2::\text{num} )</td>
</tr>
</tbody>
</table>

#### Example:

```cpp
static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::num == 1, "1/3+1/6 == 1/2");
static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::den == 2, "1/3+1/6 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::num == 1, "1/3*3/2 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::den == 2, "1/3*3/2 == 1/2");
```

// The following cases may cause the program to be ill-formed under some implementations

```cpp
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::num == 2, "1/\text{MAX}+1/\text{MAX} == 2/\text{MAX}");
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::den == INT_MAX, "1/\text{MAX}+1/\text{MAX} == 2/\text{MAX}");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::num == 1, "1/\text{MAX} \times 1/2 == 1/2");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::den == 2, "1/\text{MAX} \times 2/2 == 1/2");
```

— end example

### 20.16.5 Comparison of ratios

#### template<
class R1, class R2>

```cpp
struct ratio_equal : bool_constant<R1::num == R2::num && R1::den == R2::den> { };
```

#### template<
class R1, class R2>

```cpp
struct ratio_not_equal : bool_constant!<ratio_equal_v<R1, R2>> { };
```
template<class R1, class R2>
struct ratio_less : bool_constant<see below> { 
1    If R1::num × R2::den is less than R2::num × R1::den, ratio_less<R1, R2> shall be derived from 
bool_constant<true>; otherwise it shall be derived from bool_constant<false>. Implementations 
may use other algorithms to compute this relationship to avoid overflow. If overflow occurs, the program 
is ill-formed.
}

1
If R1::num × R2::den is less than R2::num × R1::den, ratio_less<R1, R2> shall be derived from 
bool_constant<true>; otherwise it shall be derived from bool_constant<false>. Implementations 
may use other algorithms to compute this relationship to avoid overflow. If overflow occurs, the program 
is ill-formed.

template<class R1, class R2>
struct ratio_less_equal : bool_constant<!ratio_less_v<R2, R1>> { 
}

template<class R1, class R2>
struct ratio_greater : bool_constant<ratio_less_v<R2, R1>> { 
}

template<class R1, class R2>
struct ratio_greater_equal : bool_constant<!ratio_less_v<R1, R2>> { 
}

20.16.6 SI types for ratio [ratio.si]

For each of the typedef-names yocto, zepto, zetta, and yotta, if both of the constants used in its specification 
are representable by intmax_t, the typedef shall be defined; if either of the constants is not representable by 
intmax_t, the typedef shall not be defined.

20.17 Class type_index [type.index]

20.17.1 Header <typeindex> synopsis [type.index.synopsis]

namespace std {
    class type_index;
    template<class T> struct hash;
    template<> struct hash<type_index>;
}

20.17.2 type_index overview [type.index.overview]

namespace std {
    class type_index {
        public:
            type_index(const type_info& rhs) noexcept;
            bool operator==(const type_index& rhs) const noexcept;
            bool operator!=(const type_index& rhs) const noexcept;
            bool operator<( const type_index& rhs) const noexcept;
            bool operator>( const type_index& rhs) const noexcept;
            bool operator<=(const type_index& rhs) const noexcept;
            bool operator>=(const type_index& rhs) const noexcept;
            size_t hash_code() const noexcept;
            const char* name() const noexcept;

        private:
            const type_info* target; // exposition only 
                    // Note that the use of a pointer here, rather than a reference, 
                    // means that the default copy/move constructor and assignment 
                    // operators will be provided and work as expected.
    };
}

The class type_index provides a simple wrapper for type_info which can be used as an index type in 
associative containers (22.4) and in unordered associative containers (22.5).

20.17.3 type_index members [type.index.members]

type_index(const type_info& rhs) noexcept;
1    Effects: Constructs a type_index object, the equivalent of target = &rhs.

bool operator==(const type_index& rhs) const noexcept;
2    Returns: *target == *rhs.target.
bool operator!=(const type_index& rhs) const noexcept;

Returns: *target != *rhs.target.

bool operator<(const type_index& rhs) const noexcept;

Returns: target->before(*rhs.target).

bool operator>(const type_index& rhs) const noexcept;

Returns: rhs.target->before(*target).

bool operator<=(const type_index& rhs) const noexcept;

Returns: !rhs.target->before(*target).

bool operator>=(const type_index& rhs) const noexcept;

Returns: !target->before(*rhs.target).

size_t hash_code() const noexcept;

Returns: target->hash_code().

const char* name() const noexcept;

Returns: target->name().

20.17.4 Hash support [type.index.hash]

template<> struct hash<type_index>;

For an object index of type type_index, hash<type_index>()(index) shall evaluate to the same result as index.hash_code().

20.18 Execution policies [execpol]

20.18.1 In general [execpol.general]

This subclause describes classes that are execution policy types. An object of an execution policy type indicates the kinds of parallelism allowed in the execution of an algorithm and expresses the consequent requirements on the element access functions. [Example:

```cpp
using namespace std;
vector<int> v = /* ... */;

// standard sequential sort
sort(v.begin(), v.end());

// explicitly sequential sort
sort(execution::seq, v.begin(), v.end());

// permitting parallel execution
sort(execution::par, v.begin(), v.end());

// permitting vectorization as well
sort(execution::par_unseq, v.begin(), v.end());
```

—end example] [Note: Because different parallel architectures may require idiosyncratic parameters for efficient execution, implementations may provide additional execution policies to those described in this standard as extensions. —end note]

20.18.2 Header <execution> synopsis [execution.syn]

namespace std {

// 20.18.3, execution policy type trait
template<class T> struct is_execution_policy;
template<class T> inline constexpr bool is_execution_policy_v = is_execution_policy<T>::value;
}

§ 20.18.2 709
namespace std::execution {
    // 20.18.4, sequenced execution policy
    class sequenced_policy;

    // 20.18.5, parallel execution policy
    class parallel_policy;

    // 20.18.6, parallel and unsequenced execution policy
    class parallel_unsequenced_policy;

    // 20.18.7, unsequenced execution policy
    class unsequenced_policy;

    // 20.18.8, execution policy objects
    inline constexpr sequenced_policy seq{ unspecified };
    inline constexpr parallel_policy par{ unspecified };
    inline constexpr parallel_unsequenced_policy par_unseq{ unspecified };
    inline constexpr unsequenced_policy unseq{ unspecified };
}

20.18.3 Execution policy type trait
[execpol.type]

template<class T> struct is_execution_policy { see below };

1. is_execution_policy can be used to detect execution policies for the purpose of excluding function signatures from otherwise ambiguous overload resolution participation.

2. is_execution_policy<T> shall be a Cpp17UnaryTypeTrait with a base characteristic of true_type if T is the type of a standard or implementation-defined execution policy, otherwise false_type.

[Note: This provision reserves the privilege of creating non-standard execution policies to the library implementation. — end note]

3. The behavior of a program that adds specializations for is_execution_policy is undefined.

20.18.4 Sequenced execution policy
[execpol.seq]

class execution::sequenced_policy { unspecified };

1. The class execution::sequenced_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and require that a parallel algorithm’s execution may not be parallelized.

2. During the execution of a parallel algorithm with the execution::sequenced_policy policy, if the invocation of an element access function exits via an uncaught exception, terminate() shall be called.

20.18.5 Parallel execution policy
[execpol.par]

class execution::parallel_policy { unspecified };

1. The class execution::parallel_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be parallelized.

2. During the execution of a parallel algorithm with the execution::parallel_policy policy, if the invocation of an element access function exits via an uncaught exception, terminate() shall be called.

20.18.6 Parallel and unsequenced execution policy
[execpol.parunseq]

class execution::parallel_unsequenced_policy { unspecified };

1. The class execution::parallel_unsequenced_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be parallelized and vectorized.

2. During the execution of a parallel algorithm with the execution::parallel_unsequenced_policy policy, if the invocation of an element access function exits via an uncaught exception, terminate() shall be called.
20.18.7 Unsequenced execution policy

The class `unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be vectorized, e.g., executed on a single thread using instructions that operate on multiple data items.

1 During the execution of a parallel algorithm with the `unsequenced_policy` policy, if the invocation of an element access function exits via an uncaught exception, `terminate()` shall be called.

20.18.8 Execution policy objects

```cpp
inline constexpr execution::unsequenced_policy execution::unseq{ unspecified };  // The header <execution> declares global objects associated with each type of execution policy.
```

20.19 Primitive numeric conversions

20.19.1 Header `<charconv>` synopsis

```cpp
namespace std {

// floating-point format for primitive numerical conversion
enum class chars_format {
    scientific = unspecified,
    fixed = unspecified,
    hex = unspecified,
    general = fixed | scientific
};

// primitive numerical output conversion
struct to_chars_result {
    char* ptr;
    errc ec;
};
to_chars_result to_chars(char* first, char* last, see below value, int base = 10);
to_chars_result to_chars(char* first, char* last, float value);
to_chars_result to_chars(char* first, char* last, double value);
to_chars_result to_chars(char* first, char* last, long double value);
to_chars_result to_chars(char* first, char* last, float value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, double value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, float value, chars_format fmt, int precision);
to_chars_result to_chars(char* first, char* last, double value, chars_format fmt, int precision);
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt, int precision);

// primitive numerical input conversion
struct from_chars_result {
    const char* ptr;
    errc ec;
};
from_chars_result from_chars(const char* first, const char* last, see below value, int base = 10);
```
The type `chars_format` is a bitmask type (16.4.2.2.4) with elements scientific, fixed, and hex.

20.19.2 Primitive numeric output conversion

All functions named `to_chars` convert `value` into a character string by successively filling the range `[first, last)`, where `[first, last)` is required to be a valid range. If the member `ec` of the return value is such that the value is equal to the value-initialized `errc`, the conversion was successful and the member `ptr` is the one-past-the-end pointer of the characters written. Otherwise, the member `ec` has the value `errc::value_too_large`, the member `ptr` has the value `last`, and the contents of the range `[first, last)` are unspecified.

The functions that take a floating-point `value` but not a `precision` parameter ensure that the string representation consists of the smallest number of characters such that there is at least one digit before the radix point (if present) and parsing the representation using the corresponding `from_chars` function recovers `value` exactly. [Note: This guarantee applies only if `to_chars` and `from_chars` are executed on the same implementation. — end note] If there are several such representations, the representation with the smallest difference from the floating-point argument value is chosen, resolving any remaining ties using rounding according to `round_to_nearest` (17.3.3.1).

The functions taking a `chars_format` parameter determine the conversion specifier for `printf` as follows: The conversion specifier is `f` if `fmt` is `chars_format::fixed`, `e` if `fmt` is `chars_format::scientific`, `a` (without leading "0x" in the result) if `fmt` is `chars_format::hex`, and `g` if `fmt` is `chars_format::general`. 

```c
from_chars_result from_chars(const char* first, const char* last, float& value,
   chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, double& value,
   chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, long double& value,
   chars_format fmt = chars_format::general);
```

§ 20.19.2 712
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt, int precision);

Requires: fmt has the value of one of the enumerators of chars_format.

Effects: value is converted to a string in the style of printf in the "C" locale with the given precision.

Throws: Nothing.

See also: ISO C 7.21.6.1

20.19.3 Primitive numeric input conversion [charconv.from.chars]

All functions named from_chars analyze the string [first, last) for a pattern, where [first, last) is required to be a valid range. If no characters match the pattern, value is unmodified, the member ptr of the return value is first and the member ec is equal to errc::invalid_argument. [Note: If the pattern allows for an optional sign, but the string has no digit characters following the sign, no characters match the pattern. — end note] Otherwise, the characters matching the pattern are interpreted as a representation of a value of the type of value. The member ptr of the return value points to the first character not matching the pattern, or has the value last if all characters match. If the parsed value is not in the range representable by the type of value, value is unmodified and the member ec of the return value is equal to errc::result_out_of_range. Otherwise, value is set to the parsed value, after rounding according to round_to_nearest (17.3.3.1), and the member ec is value-initialized.

from_chars_result from_chars(const char* first, const char* last, see below& value, int base = 10);

Requires: base has a value between 2 and 36 (inclusive).

Effects: The pattern is the expected form of the subject sequence in the "C" locale for the given nonzero base, as described for strtol, except that no "0x" or "0X" prefix shall appear if the value of base is 16, and except that '+' is the only sign that may appear, and only if value has a signed type.

Throws: Nothing.

Remarks: The implementation shall provide overloads for all signed and unsigned integer types and char as the referenced type of the parameter value.

from_chars_result from_chars(const char* first, const char* last, float& value, chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, double& value, chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, long double& value, chars_format fmt = chars_format::general);

Requires: fmt has the value of one of the enumerators of chars_format.

Effects: The pattern is the expected form of the subject sequence in the "C" locale, as described for strtod, except that

(7.1) the sign '+' may only appear in the exponent part;
(7.2) if fmt has chars_format::scientific set but not chars_format::fixed, the otherwise optional exponent part shall appear;
(7.3) if fmt has chars_format::fixed set but not chars_format::scientific, the optional exponent part shall not appear; and
(7.4) if fmt is chars_format::hex, the prefix "0x" or "0X" is assumed. [Example: The string 0x123 is parsed to have the value 0 with remaining characters x123. — end example]

In any case, the resulting value is one of at most two floating-point values closest to the value of the string matching the pattern.

Throws: Nothing.

21 Strings library [strings]

21.1 General [strings.general]

1 This Clause describes components for manipulating sequences of any non-array trivial standard-layout (6.7) type. Such types are called char-like types, and objects of char-like types are called char-like objects or simply characters.

2 The following subclauses describe a character traits class, string classes, and null-terminated sequence utilities, as summarized in Table 57.

Table 57: Strings library summary [tab:strings.summary]

21.2 Character traits [char.traits]

1 This subclause defines requirements on classes representing character traits, and defines a class template `char_traits<charT>`, along with five specializations, `char_traits<char>`, `char_traits<char8_t>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`, that meet those requirements.

2 Most classes specified in 21.3, 21.4, and Clause 29 need a set of related types and functions to complete the definition of their semantics. These types and functions are provided as a set of member typedef-names and functions in the template parameter traits used by each such template. This subclause defines the semantics of these members.

3 To specialize those templates to generate a string, string view, or iostream class to handle a particular character container type (16.3.3) C, that and its related character traits class X are passed as a pair of parameters to the string, string view, or iostream template as parameters charT and traits. If X::char_type is not the same type as C, the program is ill-formed.

21.2.1 Character traits requirements [char.traits.require]

1 In Table 58, X denotes a traits class defining types and functions for the character container type C; c and d denote values of type C; p and q denote values of type const C*; s denotes a value of type C*; n, i and j denote values of type size_t; e and f denote values of type X::int_type; pos denotes a value of type X::pos_type; and r denotes an lvalue of type C. Operations on X shall not throw exceptions.

2 The class template

```cpp
template<class charT> struct char_traits;
```

is provided in the header `<string>` as a basis for explicit specializations.

### 21.2.2 Traits typedefs

```
using int_type = see below;
```

1 Expects: `int_type` shall be able to represent all of the valid characters converted from the corresponding `char_type` values, as well as an end-of-file value, `eof()`.

```
using state_type = see below;
```

2 Expects: `state_type` meets the Cpp17Destructible (Table 30), Cpp17CopyAssignable (Table 29), Cpp17CopyConstructible (Table 27), and Cpp17DefaultConstructible (Table 25) requirements.

### 21.2.3 char_traits specializations

```
namespace std {
    template<> struct char_traits<char> {
        using char_type = char;
        using int_type = int;
        using off_type = streamoff;
        using pos_type = streampos;
        using state_type = mbstate_t;
        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
    }
}
```

1 The header `<string>` defines five specializations of the class template `char_traits`: `char_traits<char>`, `char_traits<char8_t>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`.

### 21.2.3.1 struct char_traits<char>

```
namespace std {
    template<> struct char_traits<char> {
        using char_type = char;
        using int_type = int;
        using off_type = streamoff;
        using pos_type = streampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
    }
}
```

225) If `eof()` can be held in `char_type` then some iostreams operations can give surprising results.
The type `mbstate_t` is defined in `<cwchar>` and can represent any of the conversion states that can occur in an implementation-defined set of supported multibyte character encoding rules.

The two-argument member `assign` is defined identically to the built-in operator `=`. The two-argument members `eq` and `lt` are defined identically to the built-in operators `==` and `<` for type `unsigned char`.

The member `eof()` returns EOF.

21.2.3.2 struct char_traits<char8_t>

namespace std {
    template<> struct char_traits<char8_t> {
        using char_type = char8_t;
        using int_type = unsigned int;
        using off_type = streamoff;
        using pos_type = u8streampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    }
};

1 The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<` respectively.

2 The member `eof()` returns an implementation-defined constant that cannot appear as a valid UTF-8 code unit.

21.2.3.3 struct char_traits<char16_t>

namespace std {
    template<> struct char_traits<char16_t> {
        using char_type = char16_t;
        using int_type = uint_least16_t;
        using off_type = streamoff;
        using pos_type = u16streampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
    }
};

§ 21.2.3.3
The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<`, respectively.

The member `eof()` returns an implementation-defined constant that cannot appear as a valid UTF-16 code unit.

21.2.3.4 struct char_traits<char32_t>  

namespace std {
    template<> struct char_traits<char32_t> {
        using char_type = char32_t;
        using int_type = uint_least32_t;
        using off_type = streamoff;
        using pos_type = u32streampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n,
                                               const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}

The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<`, respectively.

The member `eof()` returns an implementation-defined constant that cannot appear as a valid UTF-16 code unit.

21.2.3.5 struct char_traits<wchar_t>  

namespace std {
    template<> struct char_traits<wchar_t> {
        using char_type = wchar_t;
        using int_type = wint_t;
        using off_type = streamoff;
        using pos_type = wstreampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n,
                                               const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}
static constexpr bool lt(char_type c1, char_type c2) noexcept;
static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
static constexpr size_t length(const char_type* s);
static constexpr const char_type* find(const char_type* s, size_t n,
                                       const char_type& a);
static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* assign(char_type* s, size_t n, char_type a);
static constexpr int_type not_eof(int_type c) noexcept;
static constexpr char_type to_char_type(int_type c) noexcept;
static constexpr int_type to_int_type(char_type c) noexcept;
static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
static constexpr int_type eof() noexcept;

1 The two-argument members assign, eq, and lt are defined identically to the built-in operators =, ==, and <, respectively.
2 The member eof() returns WEOF.

21.3 String classes [string.classes]

The header <string> defines the basic_string class template for manipulating varying-length sequences of char-like objects and five typedef-names, string, u8string, u16string, u32string, and wstring, that name the specializations basic_string<char>, basic_string<char8_t>, basic_string<char16_t>, basic_string<char32_t>, and basic_string<wchar_t>, respectively.

21.3.1 Header <string> synopsis [string.syn]

```cpp
#include <initializer_list>
namespace std {

    // 21.2. character traits
    template<class charT> struct char_traits;
    template<> struct char_traits<char>;
    template<> struct char_traits<char8_t>;
    template<> struct char_traits<char16_t>;
    template<> struct char_traits<char32_t>;
    template<> struct char_traits<wchar_t>;

    // 21.3.2. basic_string
    template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>
        class basic_string;

    template<class charT, class traits, class Allocator>
        basic_string<charT, traits, Allocator>
            operator+(const basic_string<charT, traits, Allocator>& lhs,
                       const basic_string<charT, traits, Allocator>& rhs);
    template<class charT, class traits, class Allocator>
        basic_string<charT, traits, Allocator>
            operator+(basic_string<charT, traits, Allocator>&& lhs,
                       const basic_string<charT, traits, Allocator>& rhs);
    template<class charT, class traits, class Allocator>
        basic_string<charT, traits, Allocator>
            operator+(basic_string<charT, traits, Allocator>&& lhs,
                       basic_string<charT, traits, Allocator>&& rhs);
    template<class charT, class traits, class Allocator>
        basic_string<charT, traits, Allocator>
            operator+(const basic_string<charT, traits, Allocator>&& lhs,
                       basic_string<charT, traits, Allocator>&& rhs);
```

§ 21.3.1

719
template<class charT, class traits, class Allocator>
    basic_string<charT, traits, Allocator>
    operator+(const charT* lhs,
              const basic_string<charT, traits, Allocator>& rhs);

template<class charT, class traits, class Allocator>

§ 21.3.1  722
The class template `basic_string` describes objects that can store a sequence consisting of a varying number of arbitrary char-like objects with the first element of the sequence at position zero. Such a sequence is also called a "string" if the type of the char-like objects that it holds is clear from context. In the rest of this Clause, the type of the char-like objects held in a `basic_string` object is designated by `charT`.

A specialization of `basic_string` is a contiguous container (22.2.1).

In all cases, `[data(), data() + size()]` is a valid range, `data() + size()` points at an object with value `charT()` (a “null terminator”), and `size() <= capacity()` is true.

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_string {
public:
    // types
    using traits_type = traits;
    using value_type = charT;
    using allocator_type = Allocator;
    using size_type = typename allocator_traits<Allocator>::size_type;
    using difference_type = typename allocator_traits<Allocator>::difference_type;
    using pointer = typename allocator_traits<Allocator>::pointer;
    using const_pointer = typename allocator_traits<Allocator>::const_pointer;
    using reference = value_type&;
    using const_reference = const value_type&;

        typename see below::size_type, typename see below::size_type,
        const Allocator& = Allocator())
        -> basic_string<charT, traits, Allocator>;

4 A size_type parameter type in a basic_string deduction guide refers to the size_type member type of the type deduced by the deduction guide.

21.3.2.1 General requirements [string.require]

1 If any operation would cause size() to exceed max_size(), that operation throws an exception object of type length_error.

2 If any member function or operator of basic_string throws an exception, that function or operator has no other effect on the basic_string object.

3 In every specialization basic_string<charT, traits, Allocator>, the type allocator_traits<Allocator>::value_type shall name the same type as charT. Every object of type basic_string<charT, traits, Allocator> uses an object of type Allocator to allocate and free storage for the contained charT objects as needed. The Allocator object used is obtained as described in 22.2.1. In every specialization basic_string<charT, traits, Allocator>, the type traits shall meet the character traits requirements (21.2). [Note: The program is ill-formed if traits::char_type is not the same type as charT. —end note]
References, pointers, and iterators referring to the elements of a `basic_string` sequence may be invalidated by the following uses of that `basic_string` object:

(4.1) Passing as an argument to any standard library function taking a reference to non-const `basic_string` as an argument.
(4.2) Calling non-const member functions, except `operator[]`, `at`, `data`, `front`, `back`, `begin`, `rbegin`, `end`, and `rend`.

### 21.3.2.2 Constructors and assignment operators

```cpp
explicit basic_string(const Allocator& a) noexcept;
```

Enforces: `size()` is equal to 0.

```cpp
basic_string(const basic_string& str);
```

Effects: Constructs an object whose value is that of `str` prior to this call.

Remarks: In the second form, `str` is left in a valid but unspecified state.

```cpp
basic_string(const basic_string& str, size_type pos, const Allocator& a = Allocator());
```

Effects: Let `n` be `npos` for the first overload. Equivalent to:

```cpp
basic_string(basic_string_view<charT, traits>(str).substr(pos, n), a)
```

```cpp
template<class T>
basic_string(const T& t, size_type pos, size_type n, const Allocator& a = Allocator());
```

Constraints: `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true.

Effects: Creates a variable, `sv`, as if by `basic_string_view<charT, traits> sv = t`; and then behaves the same as:

```cpp
basic_string(sv.substr(pos, n), a);
```

```cpp
template<class T>
explicit basic_string(const T& t, const Allocator& a = Allocator());
```

Constraints:

(7.1) `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and

(7.2) `is_convertible_v<const T&, const charT*>` is false.

Effects: Creates a variable, `sv`, as if by `basic_string_view<charT, traits> sv = t`; and then behaves the same as `basic_string(sv.data(), sv.size(), a)`.

```cpp
basic_string(const charT* s, size_type n, const Allocator& a = Allocator());
```

Expects: `[s, s + n)` is a valid range.

Effects: Constructs an object whose initial value is the range `[s, s + n)`.

Ensures: `size()` is equal to `n`, and `traits::compare(data(), s, n)` is equal to 0.

```cpp
basic_string(const charT* s, const Allocator& a = Allocator());
```

Constraints: `Allocator` is a type that qualifies as an allocator (22.2.1). [Note: This affects class template argument deduction. —end note]

Effects: Equivalent to: `basic_string(s, traits::length(s), a)`.

```cpp
basic_string(size_type n, charT c, const Allocator& a = Allocator());
```

Constraints: `Allocator` is a type that qualifies as an allocator (22.2.1). [Note: This affects class template argument deduction. —end note]

Effects: Constructs an object whose value consists of `n` copies of `c`.

---

226) For example, as an argument to non-member functions `swap()` (21.3.3.3), `operator>>()` (21.3.3.4), and `getline()` (21.3.3.4), or as an argument to `basic_string::swap()`.
template<class InputIterator>
  basic_string(InputIterator begin, InputIterator end, const Allocator& a = Allocator());

  Constraints: InputIterator is a type that qualifies as an input iterator (22.2.1).
  Effects: Constructs a string from the values in the range [begin, end), as indicated in Table 66.

basic_string(initializer_list<charT> il, const Allocator& a = Allocator());

  Effects: Equivalent to basic_string(il.begin(), il.end(), a).

basic_string(const basic_string& str, const Allocator& alloc);
basic_string(basic_string&& str, const Allocator& alloc);

  Effects: Constructs an object whose value is that of str prior to this call. The stored allocator is
  constructed from alloc. In the second form, str is left in a valid but unspecified state.
  Throws: The second form throws nothing if alloc == str.get_allocator().

template<class InputIterator, class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
  basic_string(InputIterator, InputIterator, Allocator = Allocator())->
  basic_string<typename iterator_traits<InputIterator>::value_type, char_traits<typename iterator_traits<InputIterator>::value_type>,
  Allocator>;

  Constraints: InputIterator is a type that qualifies as an input iterator, and Allocator is a type that
  qualifies as an allocator (22.2.1).

template<class charT, class traits, class Allocator = allocator<charT>>
  explicit basic_string(basic_string_view<charT, traits>, const Allocator& = Allocator())->
  basic_string<charT, traits, Allocator>;

  template<class charT, class traits, class Allocator = allocator<charT>>
  basic_string(basic_string_view<charT, traits>,
  typename see below::size_type, typename see below::size_type, const Allocator& = Allocator());

  Constraints: Allocator is a type that qualifies as an allocator (22.2.1).

basic_string& operator=(const basic_string& str);

  Effects: If *this and str are the same object, has no effect. Otherwise, replaces the value of *this
  with a copy of str.

  Returns: *this.

basic_string& operator=(basic_string&& str) noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
  allocator_traits<Allocator>::is_always_equal::value);

  Effects: Move assigns as a sequence container (22.2), except that iterators, pointers and references may
  be invalidated.

  Returns: *this.

template<class T>
  basic_string& operator=(const T& t);

  Constraints:
    — is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
    — is_convertible_v<const T&, const charT*> is false.

  Effects: Equivalent to:
    basic_string_view<charT, traits> sv = t;
return assign(sv);

basic_string& operator=(const charT* s);

Effects: Equivalent to: return *this = basic_string_view<charT, traits>(s);

basic_string& operator=(charT c);

Effects: Equivalent to:
return *this = basic_string_view<charT, traits>(addressof(c), 1);

basic_string& operator=(initializer_list<charT> il);

Effects: Equivalent to:
return *this = basic_string_view<charT, traits>(il.begin(), il.size());

21.3.2.3 Iterator support

iterator begin() noexcept;
const_iterator begin() const noexcept;
const_iterator cbegin() const noexcept;

Returns: An iterator referring to the first character in the string.

iterator end() noexcept;
const_iterator end() const noexcept;
const_iterator cend() const noexcept;

Returns: An iterator which is the past-the-end value.

reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
const_reverse_iterator crbegin() const noexcept;

Returns: An iterator which is semantically equivalent to reverse_iterator(end()).

reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;
const_reverse_iterator crend() const noexcept;

Returns: An iterator which is semantically equivalent to reverse_iterator(begin()).

21.3.2.4 Capacity

size_type size() const noexcept;
size_type length() const noexcept;

Returns: A count of the number of char-like objects currently in the string.

Complexity: Constant time.

size_type max_size() const noexcept;

Returns: The largest possible number of char-like objects that can be stored in a basic_string.

Complexity: Constant time.

void resize(size_type n, charT c);

Effects: Alters the value of *this as follows:

(5.1) — If \( n \leq \text{size()} \), erases the last \( \text{size()} - n \) elements.

(5.2) — If \( n > \text{size()} \), appends \( n - \text{size()} \) copies of \( c \).

void resize(size_type n);

Effects: Equivalent to resize(n, charT()).

size_type capacity() const noexcept;

Returns: The size of the allocated storage in the string.

Complexity: Constant time.
void reserve(size_type res_arg);

Effects: A directive that informs a basic_string of a planned change in size, so that the storage allocation can be managed accordingly. After reserve(), capacity() is greater or equal to the argument of reserve if reallocation happens; and equal to the previous value of capacity() otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of reserve().

Throws: length_error if res_arg > max_size() or any exceptions thrown by allocator_traits<Allocator>::allocate.

void shrink_to_fit();

Effects: shrink_to_fit is a non-binding request to reduce capacity() to size(). [Note: The request is non-binding to allow latitude for implementation-specific optimizations. — end note] It does not increase capacity(), but may reduce capacity() by causing reallocation.

Complexity: If the size is not equal to the old capacity, linear in the size of the sequence; otherwise constant.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator. [Note: If no reallocation happens, they remain valid. — end note]

void clear() noexcept;

Effects: Equivalent to: erase(begin(), end());

bool empty() const noexcept;

Effects: Equivalent to: return size() == 0;

21.3.2.5 Element access [string.access]

const_reference operator[](size_type pos) const;
reference operator[](size_type pos);

Expects: pos <= size().

Returns: *(begin() + pos) if pos < size(). Otherwise, returns a reference to an object of type charT with value charT(), where modifying the object to any value other than charT() leads to undefined behavior.

Throws: Nothing.

Complexity: Constant time.

const_reference at(size_type pos) const;
reference at(size_type pos);

Throws: out_of_range if pos >= size().

Returns: operator[](pos).

const charT& front() const;
charT& front();

Expects: !empty().

Effects: Equivalent to: return operator[](0);

const charT& back() const;
charT& back();

Expects: !empty().

Effects: Equivalent to: return operator[](size() - 1);

21.3.2.6 Modifiers [string.modifiers]

21.3.2.6.1 basic_string::operator+= [string.op.append]

basic_string& operator+=(const basic_string& str);

Effects: Equivalent to: return append(str);
template<class T>
basic_string& operator+=(const T& t);

Constraints:
(2.1) \text{is\_convertible\_v<const T&, basic\_string\_view<charT, traits>>} \text{ is true and}
(2.2) \text{is\_convertible\_v<const T&, const charT*} \text{ is false.}

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return append(sv);

basic_string& operator+=(const charT* s);
Effects: Equivalent to: return append(s);

basic_string& operator+=(charT c);
Effects: Equivalent to: return append(size_type{1}, c);

basic_string& operator+=(initializer_list<charT> il);
Effects: Equivalent to: return append(il);

21.3.2.6.2 basic\_string::append

basic_string& append(const basic_string& str);
Effects: Equivalent to: return append(str.data(), str.size());

basic_string& append(const basic_string& str, size_type pos, size_type n = npos);
Effects: Equivalent to:
return append(basic_string_view<charT, traits>(str).substr(pos, n));

template<class T>
basic_string& append(const T& t);
Constraints:
(3.1) \text{is\_convertible\_v<const T&, basic\_string\_view<charT, traits>>} \text{ is true and}
(3.2) \text{is\_convertible\_v<const T&, const charT*} \text{ is false.}

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return append(sv.data(), sv.size());

template<class T>
basic_string& append(const T& t, size_type pos, size_type n = npos);
Constraints:
(5.1) \text{is\_convertible\_v<const T&, basic\_string\_view<charT, traits>>} \text{ is true and}
(5.2) \text{is\_convertible\_v<const T&, const charT*} \text{ is false.}

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return append(sv.substr(pos, n));

basic_string& append(const charT* s, size_type n);
Expects: \([s, s + n)\) \text{ is a valid range.}
Effects: Appends a copy of the range \([s, s + n)\) to the string.
Returns: \(*this\).

basic_string& append(const charT* s);
Effects: Equivalent to: return append(s, traits::length(s));
basic_string& append(size_type n, charT c);
   Effects: Appends n copies of c to the string.
   Returns: *this.

template<class InputIterator>
   basic_string& append(InputIterator first, InputIterator last);
   Constraints: InputIterator is a type that qualifies as an input iterator (22.2.1).
   Effects: Equivalent to: return append(basic_string(first, last, get_allocator()));

basic_string& append(initializer_list<charT> il);
   Effects: Equivalent to: return append(il.begin(), il.size());

void push_back(charT c);
   Effects: Equivalent to append(size_type{1}, c).

21.3.2.6.3 basic_string::assign
   [string.assign]

basic_string& assign(const basic_string& str);
   Effects: Equivalent to: return *this = str;

basic_string& assign(basic_string& str)
   noexcept(algorithm_traits<Allocator>::propagate_on_container_move_assignment::value ||
                algorithm_traits<Allocator>::is_always_equal::value);
   Effects: Equivalent to: return *this = std::move(str);

basic_string& assign(const basic_string& str, size_type pos, size_type n = npos);
   Effects: Equivalent to:
   return assign(basic_string_view<charT, traits>(str).substr(pos, n));

template<class T>
   basic_string& assign(const T& t);
   Constraints:
(4.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(4.2) is_convertible_v<const T&, const charT*> is false.
   Effects: Equivalent to:
   basic_string_view<charT, traits> sv = t;
   return assign(sv.data(), sv.size());

template<class T>
   basic_string& assign(const T& t, size_type pos, size_type n = npos);
   Constraints:
(6.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(6.2) is_convertible_v<const T&, const charT*> is false.
   Effects: Equivalent to:
   basic_string_view<charT, traits> sv = t;
   return assign(sv.substr(pos, n));

basic_string& assign(const charT* s, size_type n);
   Expects: [s, s + n) is a valid range.
   Effects: Replaces the string controlled by *this with a copy of the range [s, s + n].
   Returns: *this.

basic_string& assign(const charT* s);
   Effects: Equivalent to: return assign(s, traits::length(s));
basic_string& assign(initializer_list<charT> il);

Effects: Equivalent to: return assign(il.begin(), il.size());

basic_string& assign(size_type n, charT c);

Effects: Equivalent to:
  clear();
  resize(n, c);
  return *this;

template<class InputIterator>
  basic_string& assign(InputIterator first, InputIterator last);

Constraints: InputIterator is a type that qualifies as an input iterator (22.2.1).

Effects: Equivalent to: return assign(basic_string(first, last, get_allocator()));

21.3.2.6.4 basic_string::insert

basic_string& insert(size_type pos, const basic_string& str);

Effects: Equivalent to: return insert(pos, str.data(), str.size());

basic_string& insert(size_type pos1, const basic_string& str, size_type pos2, size_type n = npos);

Effects: Equivalent to:
  return insert(pos1, basic_string_view<charT, traits>(str), pos2, n);

template<class T>
  basic_string& insert(size_type pos, const T& t);

Constraints:

(3.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(3.2) is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
  basic_string_view<charT, traits> sv = t;
  return insert(pos, sv.data(), sv.size());

template<class T>
  basic_string& insert(size_type pos1, const T& t, size_type pos2, size_type n = npos);

Constraints:

(5.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(5.2) is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
  basic_string_view<charT, traits> sv = t;
  return insert(pos1, sv.substr(pos2, n));

basic_string& insert(size_type pos, const charT* s, size_type n);

Expects: [s, s + n) is a valid range.

Throws:

(8.1) out_of_range if pos > size(),
(8.2) length_error if n > max_size() - size(), or
(8.3) any exceptions thrown by allocator_traits<Allocator>::allocate.

Effects: Inserts a copy of the range [s, s + n) immediately before the character at position pos if pos < size(), or otherwise at the end of the string.

Returns: *this.

basic_string& insert(size_type pos, const charT* s);

Effects: Equivalent to: return insert(pos, s, traits::length(s));

§ 21.3.2.6.4
basic_string& insert(size_type pos, size_type n, charT c);

Effects: Inserts n copies of c before the character at position pos if pos < size(), or otherwise at the end of the string.

Returns: *this

Throws:
- out_of_range if pos > size(),
- length_error if n > max_size() - size(), or
- any exceptions thrown by allocator_traits<Allocator>::allocate.

iterator insert(const_iterator p, charT c);

Expects: p is a valid iterator on *this.

Effects: Inserts a copy of c at the position p.

Returns: An iterator which refers to the inserted character.

iterator insert(const_iterator p, size_type n, charT c);

Expects: p is a valid iterator on *this.

Effects: Inserts n copies of c at the position p.

Returns: An iterator which refers to the first inserted character, or p if n == 0.

template<class InputIterator>
iterator insert(const_iterator p, InputIterator first, InputIterator last);

Constraints: InputIterator is a type that qualifies as an input iterator (22.2.1).

Expects: p is a valid iterator on *this.

Effects: Equivalent to insert(p - begin(), basic_string(first, last, get_allocator())).

Returns: An iterator which refers to the first inserted character, or p if first == last.

iterator insert(const_iterator p, initializer_list<charT> il);

Effects: Equivalent to: return insert(p, il.begin(), il.end());

21.3.2.6.5 basic_string::erase

basic_string& erase(size_type pos = 0, size_type n = npos);

Throws: out_of_range if pos > size().

Effects: Determines the effective length xlen of the string to be removed as the smaller of n and size() - pos. Removes the characters in the range [begin() + pos, begin() + pos + xlen).

Returns: *this.

iterator erase(const_iterator p);

Expects: p is a valid dereferenceable iterator on *this.

Throws: Nothing.

Effects: Removes the character referred to by p.

Returns: An iterator which points to the element immediately following p prior to the element being erased. If no such element exists, end() is returned.

iterator erase(const_iterator first, const_iterator last);

Expects: first and last are valid iterators on *this. [first, last) is a valid range.

Throws: Nothing.

Effects: Removes the characters in the range [first, last).

Returns: An iterator which points to the element pointed to by last prior to the other elements being erased. If no such element exists, end() is returned.
void pop_back();

Expects: !empty().

Throws: Nothing.

Effects: Equivalent to erase(end() - 1).

21.3.2.6.6 basic_string::replace

basic_string& replace(size_type pos1, size_type n1, const basic_string& str);

Effects: Equivalent to: return replace(pos1, n1, str.data(), str.size());

basic_string& replace(size_type pos1, size_type n1, const basic_string& str,
size_type pos2, size_type n2 = npos);

Effects: Equivalent to:

return replace(pos1, n1, basic_string_view<charT, traits>(str).substr(pos2, n2));

template<class T>

basic_string& replace(size_type pos1, size_type n1, const T& t);

Constraints:

(3.1) — is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(3.2) — is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return replace(pos1, n1, sv.data(), sv.size());

template<class T>

basic_string& replace(size_type pos1, size_type n1, const T& t,
size_type pos2, size_type n2 = npos);

Constraints:

(5.1) — is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(5.2) — is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return replace(pos1, n1, sv.substr(pos2, n2));

basic_string& replace(size_type pos1, size_type n1, const charT* s, size_type n2);

Expects: [s, s + n2) is a valid range.

Throws:

(8.1) — out_of_range if pos1 > size(),
(8.2) — length_error if the length of the resulting string would exceed max_size() (see below), or
(8.3) — any exceptions thrown by allocator_traits<Allocator>::allocate.

Effects: Determines the effective length xlen of the string to be removed as the smaller of n1
and size() - pos1. If size() - xlen >= max_size() - n2 throws length_error. Otherwise, the
function replaces the characters in the range [begin() + pos1, begin() + pos1 + xlen) with a
copy of the range [s, s + n2).

Returns: *this.

basic_string& replace(size_type pos, size_type n, const charT* s);

Effects: Equivalent to: return replace(pos, n, s, traits::length(s));

basic_string& replace(size_type pos1, size_type n1, size_type n2, charT c);

Throws:

(12.1) — out_of_range if pos1 > size(),
(12.2) — length_error if the length of the resulting string would exceed max_size() (see below), or
12.3) — any exceptions thrown by allocator_traits<Allocator>::allocate.

*Effects*: Determines the effective length xlen of the string to be removed as the smaller of n1
and size() - pos1. If size() - xlen >= max_size() - n2 throws length_error. Otherwise, the
function replaces the characters in the range [begin() + pos1, begin() + pos1 + xlen) with n2
copies of c.

*Returns*: *this.

basic_string& replace(const_iterator i1, const_iterator i2, const basic_string& str);

*Effects*: Equivalent to: return replace(i1, i2, basic_string_view<charT, traits>(str));

template<class T>
basic_string& replace(const_iterator i1, const_iterator i2, const T& t);

*Constraints:*

— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*> is false.

*Expects*: [begin(), i1) and [i1, i2) are valid ranges.

*Effects*: Equivalent to:

basic_string_view<charT, traits> sv = t;
return replace(i1 - begin(), i2 - i1, sv.data(), sv.size());

basic_string& replace(const_iterator i1, const_iterator i2, const charT* s, size_type n);

*Effects*: Equivalent to:

basic_string_view<charT, traits> sv = s;
return replace(i1, i2, sv.data(), sv.size());

basic_string& replace(const_iterator i1, const_iterator i2, const charT* s);

*Effects*: Equivalent to:

return replace(i1, i2, basic_string_view<charT, traits>(s));

basic_string& replace(const_iterator i1, const_iterator i2, size_type n, charT c);

*Expects*: [begin(), i1) and [i1, i2) are valid ranges.

*Effects*: Equivalent to:

return replace(i1 - begin(), i2 - i1, n, c);

template<class InputIterator>
basic_string& replace(const_iterator i1, const_iterator i2, InputIterator j1, InputIterator j2);

*Constraints*: InputIterator is a type that qualifies as an input iterator (22.2.1).

*Effects*: Equivalent to:

return replace(i1, i2, basic_string(j1, j2, get_allocator()));

basic_string& replace(const_iterator i1, const_iterator i2, initializer_list<charT> il);

*Effects*: Equivalent to:

return replace(i1, i2, il.begin(), il.size());

21.3.2.6.7 basic_string::copy [string.copy]

size_type copy(charT* s, size_type n, size_type pos = 0) const;

*Effects*: Equivalent to: return basic_string_view<charT, traits>(*this).copy(s, n, pos);

[Note: This does not terminate s with a null object. — end note]

21.3.2.6.8 basic_string::swap [string.swap]

void swap(basic_string& s)

noexcept(algorithm_traits<Allocator>::propagate_on_container_swap::value ||
algorithm_traits<Allocator>::is_always_equal::value);

*Expects*: algorithm_traits<Allocator>::propagate_on_container_swap::value is true or get_-
allocator() == s.get_allocator().

*Ensures*: *this contains the same sequence of characters that was in s, s contains the same sequence
of characters that was in *this.

*Throws*: Nothing.

*Complexity*: Constant time.
21.3.2.7 String operations

21.3.2.7.1 Accessors

const charT* c_str() const noexcept;
const charT* data() const noexcept;

1 Returns: A pointer p such that p + i == addressof(operator[](i)) for each i in [0, size()).
2 Complexity: Constant time.
3 Remarks: The program shall not modify any of the values stored in the character array; otherwise, the behavior is undefined.

charT* data() noexcept;
4 Returns: A pointer p such that p + i == addressof(operator[](i)) for each i in [0, size()).
5 Complexity: Constant time.
6 Remarks: The program shall not modify the value stored at p + size() to any value other than charT(); otherwise, the behavior is undefined.

operator basic_string_view<charT, traits>() const noexcept;
7 Effects: Equivalent to: return basic_string_view<charT, traits>(data(), size());

allocator_type get_allocator() const noexcept;
8 Returns: A copy of the Allocator object used to construct the string or, if that allocator has been replaced, a copy of the most recent replacement.

21.3.2.7.2 Searching

Let F be one of find, rfind, find_first_of, find_last_of, find_first_not_of, and find_last_not_of. Each member function of the form

size_type F(const basic_string& str, size_type pos) const noexcept;

has effects equivalent to: return F(basic_string_view<charT, traits>(str), pos);

size_type F(const charT* s, size_type pos) const;

has effects equivalent to: return F(basic_string_view<charT, traits>(s), pos);

size_type F(const charT* s, size_type pos, size_type n) const;

has effects equivalent to: return F(basic_string_view<charT, traits>(s, n), pos);

size_type F(charT c, size_type pos) const noexcept;

has effects equivalent to:

return F(basic_string_view<charT, traits>(addressof(c), 1), pos);

template<class T>
size_type find(const T& t, size_type pos = 0) const noexcept(see below);

template<class T>
size_type rfind(const T& t, size_type pos = npos) const noexcept(see below);

template<class T>
size_type find_first_of(const T& t, size_type pos = 0) const noexcept(see below);

template<class T>
size_type find_last_of(const T& t, size_type pos = npos) const noexcept(see below);

template<class T>
size_type find_first_not_of(const T& t, size_type pos = 0) const noexcept(see below);

template<class T>
size_type find_last_not_of(const T& t, size_type pos = npos) const noexcept(see below);

2 Constraints:

(2.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
© ISO/IEC

(2.2) — `is_convertible_v<const T&, const charT*>` is false.

*Effects:* Let \( G \) be the name of the function. Equivalent to:

```cpp
basic_string_view<charT, traits> s = *this, sv = t;
return s.G(sv, pos);
```

*Remarks:* The expression inside `noexcept` is equivalent to `is_nothrow_convertible_v<const T&, basic_string_view<charT, traits>>`.

### 21.3.2.7.3 basic_string::substr

basic_string substr(size_type pos = 0, size_type n = npos) const;

*Throws:* `out_of_range` if `pos > size()`.

*Effects:* Determines the effective length \( rlen \) of the string to copy as the smaller of \( n \) and `size() - pos`.

*Returns:* `basic_string(data()+pos, rlen)`.

### 21.3.2.7.4 basic_string::compare

*template<class T>*

```cpp
int compare(const T& t) const noexcept(see below);
```

*Constraints:*

- (1.1) `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- (1.2) `is_convertible_v<const T&, const charT*>>` is false.

*Effects:* Equivalent to:

```cpp
return basic_string_view<charT, traits>(*this).compare(t);
```

*Remarks:* The expression inside `noexcept` is equivalent to `is_nothrow_convertible_v<const T&, basic_string_view<charT, traits>>`.

*template<class T>*

```cpp
int compare(size_type pos1, size_type n1, const T& t) const;
```

*Constraints:*

- (4.1) `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and
- (4.2) `is_convertible_v<const T&, const charT*>>` is false.

*Effects:* Equivalent to:

```cpp
return basic_string_view<charT, traits>(*this).substr(pos1, n1).compare(t);
```

*template<class T>*

```cpp
int compare(size_type pos1, size_type n1, const basic_string& str) const;
```

*Effects:* Equivalent to:

```cpp
return compare(basic_string_view<charT, traits>(str));
```

*template<class T>*

```cpp
int compare(size_type pos1, size_type n1, const basic_string& str) const;
```

*Effects:* Equivalent to:

```cpp
return compare(pos1, n1, basic_string_view<charT, traits>(str));
```

*template<class T>*

```cpp
int compare(size_type pos1, size_type n1, const basic_string& str,
            size_type pos2, size_type n2 = npos) const;
```

*Effects:* Equivalent to:

```cpp
return compare(pos1, n1, basic_string_view<charT, traits>(str), pos2, n2);
```
int compare(const charT* s) const;

**Effects:** Equivalent to: return compare(basic_string_view<charT, traits>(s));

int compare(size_type pos, size_type n1, const charT* s) const;

**Effects:** Equivalent to: return compare(pos, n1, basic_string_view<charT, traits>(s));

int compare(size_type pos, size_type n1, const charT* s, size_type n2) const;

**Effects:** Equivalent to: return compare(pos, n1, basic_string_view<charT, traits>(s, n2));

### 21.3.2.7.5 basic_string::starts_with

bool starts_with(basic_string_view<charT, traits> x) const noexcept;

bool starts_with(charT x) const noexcept;

bool starts_with(const charT* x) const;

**Effects:** Equivalent to:

return basic_string_view<charT, traits>(data(), size()).starts_with(x);

### 21.3.2.7.6 basic_string::ends_with

bool ends_with(basic_string_view<charT, traits> x) const noexcept;

bool ends_with(charT x) const noexcept;

bool ends_with(const charT* x) const;

**Effects:** Equivalent to:

return basic_string_view<charT, traits>(data(), size()).ends_with(x);

### 21.3.3 Non-member functions

#### 21.3.3.1 operator+

```cpp
template<class charT, class traits, class Allocator>
basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs,
const basic_string<charT, traits, Allocator>& rhs);
```

**Effects:** Equivalent to:

```
basic_string<charT, traits, Allocator> r = lhs;
r.append(rhs);
return r;
```

```cpp
template<class charT, class traits, class Allocator>
basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>&& lhs,
const basic_string<charT, traits, Allocator>&& rhs);
```

**Effects:** Equivalent to:

```
lhs.append(rhs);
return std::move(lhs);
```

```cpp
template<class charT, class traits, class Allocator>
basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs,
basic_string<charT, traits, Allocator>&& rhs);
```

**Effects:** Equivalent to:

```
lhs.append(rhs);
return std::move(lhs);
```
except that both lhs and rhs are left in valid but unspecified states. [Note: If lhs and rhs have equal allocators, the implementation may move from either. — end note]

4 Effects: Equivalent to:
   rhs.insert(0, lhs);
   return std::move(rhs);

5 Effects: Equivalent to:
   basic_string<charT, traits, Allocator> r = rhs;
   r.insert(0, lhs);
   return r;

6 Effects: Equivalent to:
   basic_string<charT, traits, Allocator> r = rhs;
   r.insert(r.begin(), lhs);
   return r;

7 Effects: Equivalent to:
   rhs.insert(rhs.begin(), lhs);
   return std::move(rhs);

8 Effects: Equivalent to:
   basic_string<charT, traits, Allocator> r = lhs;
   r.push_back(rhs);
   return r;

9 Effects: Equivalent to:
   lhs.push_back(rhs);
   return std::move(lhs);

21.3.3.2 Non-member comparison functions

 template<class charT, class traits, class Allocator>
 bool operator==(const basic_string<charT, traits, Allocator>& lhs,
                const basic_string<charT, traits, Allocator>& rhs) noexcept;
 template<class charT, class traits, class Allocator>
 bool operator==(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);

§ 21.3.3.2
template<class charT, class traits, class Allocator>
bool operator==(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);

template<class charT, class traits, class Allocator>
bool operator!=(const basic_string<charT, traits, Allocator>& lhs,
               const basic_string<charT, traits, Allocator>& rhs) noexcept;

template<class charT, class traits, class Allocator>
bool operator!=(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);

template<class charT, class traits, class Allocator>
bool operator!=(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);

template<class charT, class traits, class Allocator>
bool operator<( const basic_string<charT, traits, Allocator>& lhs,
                const basic_string<charT, traits, Allocator>& rhs) noexcept;

template<class charT, class traits, class Allocator>
bool operator<( const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);

template<class charT, class traits, class Allocator>
bool operator<( const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);

template<class charT, class traits, class Allocator>
bool operator>( const basic_string<charT, traits, Allocator>& lhs,
                const basic_string<charT, traits, Allocator>& rhs) noexcept;

template<class charT, class traits, class Allocator>
bool operator>( const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);

template<class charT, class traits, class Allocator>
bool operator>( const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);

template<class charT, class traits, class Allocator>
bool operator<=(const basic_string<charT, traits, Allocator>& lhs,
                const basic_string<charT, traits, Allocator>& rhs) noexcept;

template<class charT, class traits, class Allocator>
bool operator<=(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);

template<class charT, class traits, class Allocator>
bool operator<=(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);

template<class charT, class traits, class Allocator>
bool operator>=(const basic_string<charT, traits, Allocator>& lhs,
                const basic_string<charT, traits, Allocator>& rhs) noexcept;

template<class charT, class traits, class Allocator>
bool operator>=(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);

template<class charT, class traits, class Allocator>
bool operator>=(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);

1 Effects: Let op be the operator. Equivalent to:

    return basic_string_view<charT, traits>(lhs) op basic_string_view<charT, traits>(rhs);

21.3.3.3 swap

template<class charT, class traits, class Allocator>
void swap(basic_string<charT, traits, Allocator>& lhs,
          basic_string<charT, traits, Allocator>& rhs) noexcept(noexcept(lhs.swap(rhs)));

1 Effects: Equivalent to lhs.swap(rhs).

21.3.3.4 Inserters and extractors

template<class charT, class traits, class Allocator>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&& is, basic_string<charT, traits, Allocator>& str);

1 Effects: Behaves as a formatted input function (29.7.4.2.1). After constructing a sentry object, if the
sentry converts to true, calls str.erase() and then extracts characters from is and appends them to
str as if by calling str.append(1, c). If is.width() is greater than zero, the maximum number n
of characters appended is is.width(); otherwise n is str.max_size(). Characters are extracted and
appended until any of the following occurs:
— \( n \) characters are stored;
— end-of-file occurs on the input sequence;
— \( \text{isspace}(c, \text{is.getloc()}) \) is true for the next available input character \( c \).

2 After the last character (if any) is extracted, \( \text{is.width}(0) \) is called and the \text{sentry} object is destroyed.

3 If the function extracts no characters, it calls \( \text{is.setstate(ios::failbit)} \), which may throw \( \text{ios-base::failure} \) (29.5.5.4).

4 \textit{Returns}: \( \text{is} \).

5 \begin{verbatim}
template<class charT, class traits, class Allocator>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os,
const basic_string<charT, traits, Allocator>& str);
\end{verbatim}

\textit{Effects}: Equivalent to: \( \text{return os << basic_string_view<charT, traits>(str)}; \)

6 \begin{verbatim}
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
getline(basic_istream<charT, traits>& is,
basic_string<charT, traits, Allocator>& str,
charT delim);
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
getline(basic_istream<charT, traits>&& is,
basic_string<charT, traits, Allocator>& str,
charT delim);
\end{verbatim}

\textit{Effects}: Behaves as an unformatted input function (29.7.4.3), except that it does not affect the value returned by subsequent calls to \( \text{basic_istream<>::gcount()} \). After constructing a \text{sentry} object, if the sentry converts to true, calls \( \text{str.erase()} \) and then extracts characters from \( \text{is} \) and appends them to \( \text{str} \) as if by calling \( \text{str.append(1, c)} \) until any of the following occurs:

6.1 end-of-file occurs on the input sequence (in which case, the \( \text{getline} \) function calls \( \text{is.setstate(ios_base::eofbit)} \)).

6.2 \( \text{traits::eq(c, delim)} \) for the next available input character \( c \) (in which case, \( c \) is extracted but not appended) (29.5.5.4)

6.3 \( \text{str.max_size()} \) characters are stored (in which case, the function calls \( \text{is.setstate(ios-base::failbit)} \) (29.5.5.4)

7 The conditions are tested in the order shown. In any case, after the last character is extracted, the \text{sentry} object is destroyed.

8 If the function extracts no characters, it calls \( \text{is.setstate(ios_base::failbit)} \) which may throw \( \text{ios_base::failure} \) (29.5.5.4).

9 \textit{Returns}: \( \text{is} \).

10 \begin{verbatim}
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
getline(basic_istream<charT, traits>& is,
basic_string<charT, traits, Allocator>& str,
ios_base::openmode mode);
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
getline(basic_istream<charT, traits>&& is,
basic_string<charT, traits, Allocator>& str,
ios_base::openmode mode);
\end{verbatim}

\textit{Effects}: Equivalent to: \( \text{c.erase(remove(c.begin(), c.end(), value), c.end())}; \)

\section*{21.3.3.5 Erasure} \label{string.eraser}

\begin{verbatim}
template<class charT, class traits, class Allocator, class U>
void erase(basic_string<charT, traits, Allocator>& c, const U& value);
\end{verbatim}

\textit{Effects}: Equivalent to: \( \text{c.erase(remove(c.begin(), c.end(), value), c.end())}; \)
template<class charT, class traits, class Allocator, class Predicate>
    void erase_if(basic_string<charT, traits, Allocator>& c, Predicate pred);

Effects: Equivalent to: c.erase(remove_if(c.begin(), c.end(), pred), c.end());

21.3.4 Numeric conversions

int stoi(const string& str, size_t* idx = nullptr, int base = 10);
long stol(const string& str, size_t* idx = nullptr, int base = 10);
unsigned long stoul(const string& str, size_t* idx = nullptr, int base = 10);
long long stoll(const string& str, size_t* idx = nullptr, int base = 10);
unsigned long long stoull(const string& str, size_t* idx = nullptr, int base = 10);

Effects: The first two functions call `strtol(str.c_str(), ptr, base)`, and the last three functions call `strtoul(str.c_str(), ptr, base)`, and `strtoull(str.c_str(), ptr, base)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx` != 0, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

Throws: invalid_argument if `strtol`, `strtoul`, or `strtoull` reports that no conversion could be performed. Throws out_of_range if `strtol`, `strtoul`, `strtoll` or `strtoull` sets `errno` to `ERANGE`, or if the converted value is outside the range of representable values for the return type.

float stof(const string& str, size_t* idx = nullptr);
double stod(const string& str, size_t* idx = nullptr);
long double stold(const string& str, size_t* idx = nullptr);

Effects: These functions call `strtof(str.c_str(), ptr)`, `strtod(str.c_str(), ptr)`, and `strtold(str.c_str(), ptr)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx` != 0, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

Throws: invalid_argument if `strtof`, `strtod`, or `strtold` reports that no conversion could be performed. Throws out_of_range if `strtof`, `strtod`, or `strtold` sets `errno` to `ERANGE` or if the converted value is outside the range of representable values for the return type.

string to_string(int val);
string to_string(unsigned val);
string to_string(long val);
string to_string(unsigned long val);
string to_string(long long val);
string to_string(float val);
string to_string(double val);
string to_string(long double val);

Returns: Each function returns a string object holding the character representation of the value of its argument that would be generated by calling `sprintf(buf, fmt, val)` with a format specifier of "%d", "%u", "%ld", "%lu", "%lld", "%llu", "%f", "%F", or "%Lf", respectively, where `buf` designates an internal character buffer of sufficient size.

int stoi(const wstring& str, size_t* idx = nullptr, int base = 10);
long stol(const wstring& str, size_t* idx = nullptr, int base = 10);
unsigned long stoul(const wstring& str, size_t* idx = nullptr, int base = 10);
long long stoll(const wstring& str, size_t* idx = nullptr, int base = 10);
unsigned long long stoull(const wstring& str, size_t* idx = nullptr, int base = 10);

Effects: The first two functions call `wcstol(str.c_str(), ptr, base)`, and the last three functions call `wcstoul(str.c_str(), ptr, base)`, `wcstoll(str.c_str(), ptr, base)`, and `wcstoull(str.c_str(), ptr, base)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store
at *idx. If the function does not throw an exception and idx != 0, the function stores in *idx the index of the first unconverted element of str.

**Returns:** The converted result.

**Throws:** invalid_argument if wcstol, wcstoul, wcstoll, or wcstoull reports that no conversion could be performed. Throws out_of_range if the converted value is outside the range of representable values for the return type.

```c
float stof(const wstring& str, size_t* idx = nullptr);
double stod(const wstring& str, size_t* idx = nullptr);
long double stold(const wstring& str, size_t* idx = nullptr);
```

**Effects:** These functions call wcstof(str.c_str(), ptr), wcstod(str.c_str(), ptr), and wcstold(str.c_str(), ptr), respectively. Each function returns the converted result, if any. The argument ptr designates a pointer to an object internal to the function that is used to determine what to store at *idx. If the function does not throw an exception and idx != 0, the function stores in *idx the index of the first unconverted element of str.

**Returns:** The converted result.

**Throws:** invalid_argument if wcstof, wcstod, or wcstold reports that no conversion could be performed. Throws out_of_range if wcstof, wcstod, or wcstold sets errno to ERANGE.

```c
wstring to_wstring(int val);
wstring to_wstring(unsigned val);
wstring to_wstring(long val);
wstring to_wstring(unsigned long val);
wstring to_wstring(long long val);
wstring to_wstring(unsigned long long val);
wstring to_wstring(float val);
wstring to_wstring(double val);
wstring to_wstring(long double val);
```

**Returns:** Each function returns a wstring object holding the character representation of the value of its argument that would be generated by calling swprintf(buf, buffsz, fmt, val) with a format specifier of L"%d", L"%u", L"%ld", L"%lu", L"%lld", L"%llu", L"%f", L"%f", or L"%Lf", respectively, where buf designates an internal character buffer of sufficient size buffsz.

### Hash support

```c
template<> struct hash<string>;
template<> struct hash<u8string>;
template<> struct hash<u16string>;
template<> struct hash<u32string>;
template<> struct hash<wstring>;
template<> struct hash<pmr::string>;
template<> struct hash<pmr::u8string>;
template<> struct hash<pmr::u16string>;
template<> struct hash<pmr::u32string>;
template<> struct hash<pmr::wstring>;
```

1. If S is one of these string types, SV is the corresponding string view type, and s is an object of type S, then hash<S>()(s) == hash<SV>()(SV(s)).

### Suffix for basic_string literals

```c
string operator"s(const char* str, size_t len);
u8string operator"s(const char8_t* str, size_t len);
u16string operator"s(const char16_t* str, size_t len);
```

1. **Returns:** string{str, len}.

2. **Returns:** u8string{str, len}.

3. **Returns:** u16string{str, len}.
u32string operator"s(const char32_t* str, size_t len);

Returns: u32string{str, len}.

wstring operator"s(const wchar_t* str, size_t len);

Returns: wstring{str, len}.

[Note: The same suffix s is used for chrono::duration literals denoting seconds but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. — end note]

21.4 String view classes [string.view]

The class template basic_string_view describes an object that can refer to a constant contiguous sequence of char-like (21.1) objects with the first element of the sequence at position zero. In the rest of this subclause, the type of the char-like objects held in a basic_string_view object is designated by charT.

[Note: The library provides implicit conversions from const charT* and std::basic_string<charT, ...> to std::basic_string_view<charT, ...> so that user code can accept just std::basic_string_view as a non-templated parameter wherever a sequence of characters is expected. User-defined types should define their own implicit conversions to std::basic_string_view in order to interoperate with these functions. — end note]

21.4.1 Header <string_view> synopsis [string.view.synop]

namespace std {

// 21.4.2, class template basic_string_view
template<class charT, class traits = char_traits<charT>>
class basic_string_view;

// 21.4.3, non-member comparison functions
template<class charT, class traits>  
constexpr bool operator==(basic_string_view<charT, traits> x, basic_string_view<charT, traits> y) noexcept;

template<class charT, class traits>  
constexpr bool operator!=(basic_string_view<charT, traits> x, basic_string_view<charT, traits> y) noexcept;

operator<<(basic_ostream<charT, traits>& os, basic_string_view<charT, traits> str);

// basic_string_view typedef names
using string_view = basic_string_view<char>;
using u8string_view = basic_string_view<char8_t>;
using u16string_view = basic_string_view<char16_t>;
using u32string_view = basic_string_view<char32_t>;
using wstring_view = basic_string_view<wchar_t>;

§ 21.4.1
// 21.4.5, hash support
template<class T> struct hash;
template<> struct hash<string_view>;
template<> struct hash<u8string_view>;
template<> struct hash<u16string_view>;
template<> struct hash<u32string_view>;
template<> struct hash<wstring_view>;

inline namespace literals {
    inline namespace string_view_literals {
        // 21.4.6, suffix for basic_string_view literals
        constexpr string_view operator"sv(const char* str, size_t len) noexcept;
        constexpr u8string_view operator"sv(const char8_t* str, size_t len) noexcept;
        constexpr u16string_view operator"sv(const char16_t* str, size_t len) noexcept;
        constexpr u32string_view operator"sv(const char32_t* str, size_t len) noexcept;
        constexpr wstring_view operator"sv(const wchar_t* str, size_t len) noexcept;
    }
}

1 The function templates defined in 20.2.2 and 23.7 are available when <string_view> is included.

21.4.2 Class template basic_string_view

```cpp
template<class charT, class traits = char_traits<charT>>
class basic_string_view {
public:
    // types
    using traits_type = traits;
    using value_type = charT;
    using pointer = value_type*;
    using const_pointer = const value_type*;
    using reference = value_type&;
    using const_reference = const value_type&;
    using const_iterator = implementation-defined; // see 21.4.2.2
    using iterator = const_iterator;
    using const_reverse_iterator = reverse_iterator<const_iterator>;
    using reverse_iterator = const_reverse_iterator;
    using size_type = size_t;
    using difference_type = ptrdiff_t;
    static constexpr size_type npos = size_type(-1);

    // 21.4.2.1, construction and assignment
    constexpr basic_string_view() noexcept;
    constexpr basic_string_view(const basic_string_view&) noexcept = default;
    constexpr basic_string_view& operator=(const basic_string_view&) noexcept = default;
    constexpr basic_string_view(const charT* str);
    constexpr basic_string_view(const charT* str, size_type len);

    // 21.4.2.2, iterator support
    constexpr const_iterator begin() const noexcept;
    constexpr const_iterator end() const noexcept;
    constexpr const_iterator cbegin() const noexcept;
    constexpr const_iterator cend() const noexcept;
    constexpr const_reverse_iterator rbegin() const noexcept;
    constexpr const_reverse_iterator rend() const noexcept;
    constexpr const_reverse_iterator crbegin() const noexcept;
    constexpr const_reverse_iterator crend() const noexcept;

    friend constexpr const_iterator begin(basic_string_view sv) noexcept { return sv.begin(); }
    friend constexpr const_iterator end(basic_string_view sv) noexcept { return sv.end(); }
```

227) Because basic_string_view refers to a constant sequence, iterator and const_iterator are the same type.

§ 21.4.2
// 21.4.2.3, capacity

constexpr size_type find_last_not_of(charT c, size_type pos = npos) const noexcept;
constexpr size_type find_last_not_of(const charT* s, size_type pos = 0) const;
constexpr size_type find_last_not_of(const charT* s, size_type pos, size_type n) const;
constexpr size_type find_last_not_of(const charT* s, size_type pos = npos) const;

private:
  const_pointer data_; // exposition only
  size_type size_; // exposition only
};

1. In every specialization basic_string_view<charT, traits>, the type traits shall meet the character traits requirements (21.2). [Note: The program is ill-formed if traits::char_type is not the same type as charT. —end note]

2. For a basic_string_view str, any operation that invalidates a pointer in the range [str.data(), str.data() + str.size()) invalidates pointers, iterators, and references returned from str’s member functions.

3. The complexity of basic_string_view member functions is \(O(1)\) unless otherwise specified.

### 21.4.2.1 Construction and assignment [string.view.cons]

```
constexpr basic_string_view() noexcept;
```

1. **Ensures**: size_ == 0 and data_ == nullptr.

```
constexpr basic_string_view(const charT* str);
```

2. **Expects**: [str, str + traits::length(str)) is a valid range.
3. **Effects**: Constructs a basic_string_view, initializing data_ with str and initializing size_ with traits::length(str).
4. **Complexity**: \(O(\text{traits::length(str)})\).

```
constexpr basic_string_view(const charT* str, size_type len);
```

5. **Expects**: [str, str + len) is a valid range.
6. **Effects**: Constructs a basic_string_view, initializing data_ with str and initializing size_ with len.

### 21.4.2.2 Iterator support [string.view.iterators]

```
using const_iterator = implementation-defined;
```

1. A type that meets the requirements of a constant Cpp17RandomAccessIterator (23.3.5.6), models ContiguousIterator (23.3.4.14), and meets the constexpr iterator requirements (23.3.1), whose value_type is the template parameter charT.

2. All requirements on container iterators (22.2) apply to basic_string_view::const_iterator as well.

```
constexpr const_iterator begin() const noexcept;
constexpr const_iterator cbegin() const noexcept;
```

3. **Returns**: An iterator such that
   - if !empty(), addressof(*begin()) == data_,
   - otherwise, an unspecified value such that [begin(), end()) is a valid range.

```
constexpr const_iterator end() const noexcept;
constexpr const_iterator cend() const noexcept;
```

4. **Returns**: begin() + size().

```
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;
```

5. **Returns**: const_reverse_iterator(end()).

```
constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;
```

6. **Returns**: const_reverse_iterator(begin()).
21.4.2.3 Capacity

```cpp
constexpr size_type size() const noexcept;
constexpr size_type length() const noexcept;
```

Returns: `size_`.

```cpp
constexpr size_type max_size() const noexcept;
```

Returns: The largest possible number of char-like objects that can be referred to by a `basic_string_view`.

```cpp
[[nodiscard]] constexpr bool empty() const noexcept;
```

Returns: `size_ == 0`.

21.4.2.4 Element access

```cpp
constexpr const_reference operator[](size_type pos) const;
```

Expects: `pos < size()`.

Returns: `data_[pos]`.

Throws: Nothing.

[Note: Unlike `basic_string::operator[]`, `basic_string_view::operator[](size())` has undefined behavior instead of returning `charT()`]. — end note

```cpp
constexpr const_reference at(size_type pos) const;
```

Throws: `out_of_range` if `pos >= size()`.

Returns: `data_[pos]`.

```cpp
constexpr const_reference front() const;
```

Expects: `!empty()`.

Returns: `data_[0]`.

Throws: Nothing.

```cpp
constexpr const_reference back() const;
```

Expects: `!empty()`.

Returns: `data_[size() - 1]`.

Throws: Nothing.

```cpp
constexpr const_pointer data() const noexcept;
```

Returns: `data_`.

[Note: Unlike `basic_string::data()` and string literals, `data()` may return a pointer to a buffer that is not null-terminated. Therefore it is typically a mistake to pass `data()` to a function that takes just a `const charT*` and expects a null-terminated string. — end note]

21.4.2.5 Modifiers

```cpp
constexpr void remove_prefix(size_type n);
```

Expects: `n <= size()`.

Effects: Equivalent to: `data_ += n; size_ -= n;`

```cpp
constexpr void remove_suffix(size_type n);
```

Expects: `n <= size()`.

Effects: Equivalent to: `size_ -= n;`

```cpp
constexpr void swap(basic_string_view& s) noexcept;
```

Effects: Exchanges the values of `*this` and `s`. 

§ 21.4.2.5
21.4.2.6 String operations

constexpr size_type copy(charT* s, size_type n, size_type pos = 0) const;

Let rlen be the smaller of n and size() - pos.

Throws: out_of_range if pos > size().

Expects: [s, s + rlen) is a valid range.

Effects: Equivalent to traits::copy(s, data() + pos, rlen).

Returns: rlen.

Complexity: O(rlen).

constexpr basic_string_view substr(size_type pos = 0, size_type n = npos) const;

Let rlen be the smaller of n and size() - pos.

Throws: out_of_range if pos > size().

Effects: Determines rlen, the effective length of the string to reference.

Returns: basic_string_view(data() + pos, rlen).

constexpr int compare(basic_string_view str) const noexcept;

Let rlen be the smaller of size() and str.size().

Effects: Determines rlen, the effective length of the strings to compare. The function then compares
the two strings by calling traits::compare(data(), str.data(), rlen).

Complexity: O(rlen).

Returns: The nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as
indicated in Table 59.

Table 59: compare() results

<table>
<thead>
<tr>
<th>Condition</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>size() &lt; str.size()</td>
<td>&lt; 0</td>
</tr>
<tr>
<td>size() == str.size()</td>
<td>0</td>
</tr>
<tr>
<td>size() &gt; str.size()</td>
<td>&gt; 0</td>
</tr>
</tbody>
</table>

constexpr int compare(size_type pos1, size_type n1, basic_string_view str) const;

Effects: Equivalent to: return substr(pos1, n1).compare(str);

constexpr int compare(size_type pos1, size_type n1, basic_string_view str,
size_type pos2, size_type n2) const;

Effects: Equivalent to: return substr(pos1, n1).compare(str.substr(pos2, n2));

constexpr int compare(const charT* s) const;

Effects: Equivalent to: return compare(basic_string_view(s));

constexpr int compare(size_type pos1, size_type n1, const charT* s) const;

Effects: Equivalent to: return substr(pos1, n1).compare(basic_string_view(s));

constexpr int compare(size_type pos1, size_type n1, const charT* s, size_type n2) const;

Effects: Equivalent to: return substr(pos1, n1).compare(basic_string_view(s, n2));

constexpr bool starts_with(basic_string_view x) const noexcept;

Effects: Equivalent to: return substr(0, x.size()) == x;

constexpr bool starts_with(charT x) const noexcept;

Effects: Equivalent to: return !empty() && traits::eq(front(), x);
constexpr bool starts_with(const charT* x) const;
**Effects:** Equivalent to: return starts_with(basic_string_view(x));

constexpr bool ends_with(basic_string_view x) const noexcept;
**Effects:** Equivalent to:
\[
\text{return size()} \geq x.\text{size()} \&\& \text{compare(size()} - x.\text{size()}, \text{npos}, x) == 0;
\]

constexpr bool ends_with(charT x) const noexcept;
**Effects:** Equivalent to:
\[
\text{return !empty()} \&\& \text{traits::eq(back(), x)};
\]

constexpr bool ends_with(const charT* x) const;
**Effects:** Equivalent to: return ends_with(basic_string_view(x));

### 21.4.2.7 Searching
[\text{string.view.find}]

Member functions in this subclause have complexity $O(size() \times str.size())$ at worst, although implementations should do better.

Let $F$ be one of $\text{find}, \text{rfind}, \text{find_first_of}, \text{find_last_of}, \text{find_first_not_of}, \text{and find_last_not_of}$.

- Each member function of the form
  \[
  \text{constexpr return-type } F(\text{const charT* } s, \text{size_type pos}) \text{ const;}
  \]
  has effects equivalent to: return $F(\text{basic_string_view(s)}, \text{pos});$

- Each member function of the form
  \[
  \text{constexpr return-type } F(\text{const charT* } s, \text{size_type pos}, \text{size_type n}) \text{ const;}
  \]
  has effects equivalent to: return $F(\text{basic_string_view(s, n)}, \text{pos});$

- Each member function of the form
  \[
  \text{constexpr return-type } F(\text{charT c, size_type pos}) \text{ const noexcept;}
  \]
  has effects equivalent to: return $F(\text{basic_string_view(addressof(c), 1), pos});$

constexpr size_type find(basic_string_view str, size_type pos = 0) const noexcept;
**Effects:** Determines $xpos$.
**Returns:** $xpos$ if the function can determine such a value for $xpos$. Otherwise, returns $\text{npos}$.

Let $xpos$ be the lowest position, if possible, such that the following conditions hold:

- $pos \leq xpos$
- $xpos + \text{str.size()} \leq \text{size}()$
- traits::eq(at(xpos + I), str.at(I)) for all elements I of the string referenced by str.

**Effects:** Determines $xpos$.
**Returns:** $xpos$ if the function can determine such a value for $xpos$. Otherwise, returns $\text{npos}$.

constexpr size_type rfind(basic_string_view str, size_type pos = $\text{npos}$) const noexcept;
**Effects:** Determines $xpos$.
**Returns:** $xpos$ if the function can determine such a value for $xpos$. Otherwise, returns $\text{npos}$.

Let $xpos$ be the highest position, if possible, such that the following conditions hold:

- $xpos \leq pos$
- $xpos + \text{str.size()} \leq \text{size}()$
- traits::eq(at(xpos + I), str.at(I)) for all elements I of the string referenced by str.

**Effects:** Determines $xpos$.
**Returns:** $xpos$ if the function can determine such a value for $xpos$. Otherwise, returns $\text{npos}$.

constexpr size_type find_first_of(basic_string_view str, size_type pos = 0) const noexcept;
**Effects:** Determines $xpos$.
**Returns:** $xpos$ if the function can determine such a value for $xpos$. Otherwise, returns $\text{npos}$.

Let $xpos$ be the lowest position, if possible, such that the following conditions hold:

- $pos \leq xpos$
- $xpos < \text{size}()$
- traits::eq(at(xpos), str.at(I)) for some element I of the string referenced by str.
Effects: Determines xpos.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

```
constexpr size_type find_last_of(basic_string_view str, size_type pos = npos) const noexcept;
```

Let xpos be the highest position, if possible, such that the following conditions hold:

(12.1) \( \text{xpos} \leq \text{pos} \)
(12.2) \( \text{xpos} < \text{size()} \)
(12.3) \( \text{traits::eq(at(xpos), str.at(I))} \) for some element I of the string referenced by str.

Effects: Determines xpos.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

```
constexpr size_type find_first_not_of(basic_string_view str, size_type pos = 0) const noexcept;
```

Let xpos be the lowest position, if possible, such that the following conditions hold:

(15.1) \( \text{pos} \leq \text{xpos} \)
(15.2) \( \text{xpos} < \text{size()} \)
(15.3) \( \text{traits::eq(at(xpos), str.at(I))} \) for no element I of the string referenced by str.

Effects: Determines xpos.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

```
constexpr size_type find_last_not_of(basic_string_view str, size_type pos = npos) const noexcept;
```

Let xpos be the highest position, if possible, such that the following conditions hold:

(18.1) \( \text{xpos} \leq \text{pos} \)
(18.2) \( \text{xpos} < \text{size()} \)
(18.3) \( \text{traits::eq(at(xpos), str.at(I))} \) for no element I of the string referenced by str.

Effects: Determines xpos.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

21.4.3 Non-member comparison functions

Let S be `basic_string_view<charT, traits>`, and sv be an instance of S. Implementations shall provide sufficient additional overloads marked `constexpr` and `noexcept` so that an object t with an implicit conversion to S can be compared according to Table 60.

Table 60: Additional `basic_string_view` comparison overloads

<table>
<thead>
<tr>
<th>Expression</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>t == sv</td>
<td>S(t) == sv</td>
</tr>
<tr>
<td>sv == t</td>
<td>sv == S(t)</td>
</tr>
<tr>
<td>t != sv</td>
<td>S(t) != sv</td>
</tr>
<tr>
<td>sv != t</td>
<td>sv != S(t)</td>
</tr>
<tr>
<td>t &lt; sv</td>
<td>S(t) &lt; sv</td>
</tr>
<tr>
<td>sv &lt; t</td>
<td>sv &lt; S(t)</td>
</tr>
<tr>
<td>t &gt; sv</td>
<td>S(t) &gt; sv</td>
</tr>
<tr>
<td>sv &gt; t</td>
<td>sv &gt; S(t)</td>
</tr>
<tr>
<td>t &lt;= sv</td>
<td>S(t) &lt;= sv</td>
</tr>
<tr>
<td>sv &lt;= t</td>
<td>sv &lt;= S(t)</td>
</tr>
<tr>
<td>t &gt;= sv</td>
<td>S(t) &gt;= sv</td>
</tr>
<tr>
<td>sv &gt;= t</td>
<td>sv &gt;= S(t)</td>
</tr>
</tbody>
</table>

Example: A sample conforming implementation for `operator==` would be:

§ 21.4.3 753
template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs,
basic_string_view<charT, traits> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}
template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs,
type_identity_t<basic_string_view<charT, traits>> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}
template<class charT, class traits>
constexpr bool operator==(type_identity_t<basic_string_view<charT, traits>> lhs,
basic_string_view<charT, traits> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}

— end example

template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs,
basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) == 0.

template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs,
basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) != 0.

template<class charT, class traits>
constexpr bool operator<(basic_string_view<charT, traits> lhs,
basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) < 0.

template<class charT, class traits>
constexpr bool operator>(basic_string_view<charT, traits> lhs,
basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) > 0.

template<class charT, class traits>
constexpr bool operator<=(basic_string_view<charT, traits> lhs,
basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) <= 0.

template<class charT, class traits>
constexpr bool operator>=(basic_string_view<charT, traits> lhs,
basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) >= 0.

21.4.4 Inserters and extractors

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, basic_string_view<charT, traits> str);

Effects: Behaves as a formatted output function (29.7.5.2.1) of os. Forms a character sequence seq, initially consisting of the elements defined by the range [str.begin(), str.end()]. Determines padding for seq as described in 29.7.5.2.1. Then inserts seq as if by calling os.rdbuf()->sputn(seq, n), where n is the larger of os.width() and str.size(); then calls os.width(0).

Returns: os

21.4.5 Hash support

template<> struct hash<string_view>;
template<> struct hash<u8string_view>;
template<> struct hash<u16string_view>;
template<> struct hash<u32string_view>;
template<> struct hash<wstring_view>;

The specialization is enabled (20.14.18). [Note: The hash value of a string view object is equal to the hash value of the corresponding string object (21.3.5). — end note]

### 21.4.6 Suffix for basic_string_view literals

[string.view.literals]

constexpr string_view operator"sv(const char* str, size_t len) noexcept;

Returns: string_view{str, len}.

constexpr u8string_view operator"sv(const char8_t* str, size_t len) noexcept;

Returns: u8string_view{str, len}.

constexpr u16string_view operator"sv(const char16_t* str, size_t len) noexcept;

Returns: u16string_view{str, len}.

constexpr u32string_view operator"sv(const char32_t* str, size_t len) noexcept;

Returns: u32string_view{str, len}.

constexpr wstring_view operator"sv(const wchar_t* str, size_t len) noexcept;

Returns: wstring_view{str, len}.

### 21.5 Null-terminated sequence utilities

[c.strings]

#### 21.5.1 Header <cctype> synopsis

[cctype.syn]

namespace std {
    int isalnum(int c);
    int isalpha(int c);
    int isblank(int c);
    int iscntrl(int c);
    int isdigit(int c);
    int isgraph(int c);
    int islower(int c);
    int isprint(int c);
    int ispunct(int c);
    int isspace(int c);
    int isupper(int c);
    int isxdigit(int c);
    int tolower(int c);
    int toupper(int c);
    
}

The contents and meaning of the header <cctype> are the same as the C standard library header <ctype.h>.

21.5.6 Multibyte / wide string and character conversion functions

```c
int mbsinit(const mbstate_t* ps);
size_t mblen(const char* s, size_t n, mbstate_t* ps);
size_t mbtowc(const char* s, wchar_t* pwc, size_t n, mbstate_t* ps);
size_t wcrtomb(char* s, wchar_t wc, mbstate_t* ps);
size_t mbstowcs(wchar_t* pwcs, const char* s, size_t n);
size_t wcstombs(char* s, const wchar_t* pwcs, size_t n);
size_t mbrlen(const char* s, size_t n, mbstate_t* ps);
size_t mbrtowc(wchar_t* pwc, const char* s, size_t n, mbstate_t* ps);
size_t wcrtomb(char* s, wchar_t wc, mbstate_t* ps);
size_t mbstowcs(wchar_t* dst, const char** src, size_t len);
size_t wcstombs(char* dst, const wchar_t** src, size_t len);

// 21.5.6, multibyte / wide string and character conversion functions

int mbsinit(const mbstate_t* ps);
size_t mblen(const char* s, size_t n, mbstate_t* ps);
size_t mbtowc(const char* s, wchar_t* pwc, const char* s, size_t n, mbstate_t* ps);
size_t wcrtomb(char* s, wchar_t wc, mbstate_t* ps);
size_t mbstowcs(wchar_t* dst, const char* src, size_t len, mbstate_t* ps);
size_t wcstombs(char* dst, wchar_t* src, size_t len, mbstate_t* ps);
```

1. The contents and meaning of the header `<cwchar>` are the same as the C standard library header `<wchar.h>`, except that it does not declare a type `wchar_t`.

2. [Note: The functions `wcschr`, `wcsrchr`, `wcsstr`, and `wmemchr` have different signatures in this document, but they have the same behavior as in the C standard library (16.2). —end note]

See also: ISO C 7.29

---

21.5.5 Header `<cuchar>` synopsis

```c
namespace std {
    using mbstate_t = see below;
    using size_t = see 17.2.4;

    size_t mbtowc(const char* s, wchar_t* pwc, size_t n);
    size_t wcrtomb(char* s, wchar_t wc, mbstate_t* ps);
    size_t mbstowcs(wchar_t* pwcs, const char* s, size_t n);
    size_t wcstombs(char* s, const wchar_t* pwcs, size_t n);
}
```

1. The contents and meaning of the header `<cuchar>` are the same as the C standard library header `<uchar.h>`, except that it declares the additional `mbtowc` and `wcrtomb` functions and does not declare types `char16_t` or `char32_t`.

See also: ISO C 7.28

---

21.5.6 Multibyte / wide string and character conversion functions

1. [Note: The headers `<cstdlib>` (17.2.2), `<cuchar>` (21.5.5), and `<cwchar>` (21.5.4) declare the functions described in this subclause. —end note]

```c
int mbsinit(const mbstate_t* ps);
int mblen(const char* s, size_t n);
size_t mbstowcs(wchar_t* pwcs, const char* s, size_t n);
size_t wcstombs(char* s, const wchar_t* pwcs, size_t n);
```

2. **Effects:** These functions have the semantics specified in the C standard library.

See also: ISO C 7.22.7.1, 7.22.8, 7.29.6.2.1

```c
int mbtowc(const char* s, wchar_t* pwc, size_t n);
int wcrtomb(char* s, wchar_t wc);
```

3. **Effects:** These functions have the semantics specified in the C standard library.

4. **Remarks:** Calls to these functions may introduce a data race (16.5.5.9) with other calls to the same function.

See also: ISO C 7.22.7

```c
size_t mblen(const char* s, size_t n, mbstate_t* ps);
size_t mbtowc(const char* s, wchar_t* pwc, size_t n, mbstate_t* ps);
size_t wcrtomb(const char* s, wchar_t wc, mbstate_t* ps);
size_t mbstowcs(wchar_t* dst, const char** src, size_t len, mbstate_t* ps);
size_t wcstombs(char* dst, const wchar_t** src, size_t len, mbstate_t* ps);
```
size_t wcsrtombs(char* dst, const wchar_t** src, size_t len, mbstate_t* ps);

Effects: These functions have the semantics specified in the C standard library.

Remarks: Calling these functions with an mbstate_t* argument that is a null pointer value may introduce a data race (16.5.5.9) with other calls to the same function with an mbstate_t* argument that is a null pointer value.

See also: ISO C 7.29.6.3

size_t mbrtoc8(char8_t* pc8, const char* s, size_t n, mbstate_t* ps);

Effects: If s is a null pointer, equivalent to mbrtoc8(nullptr, ",", 1, ps). Otherwise, the function inspects at most n bytes beginning with the byte pointed to by s to determine the number of bytes needed to complete the next multibyte character (including any shift sequences). If the function determines that the next multibyte character is complete and valid, it determines the values of the corresponding UTF-8 code units and then, if pc8 is not a null pointer, stores the value of the first (or only) such code unit in the object pointed to by pc8. Subsequent calls will store successive UTF-8 code units without consuming any additional input until all the code units have been stored. If the corresponding Unicode character is U+0000, the resulting state described is the initial conversion state.

Returns: The first of the following that applies (given the current conversion state):

(8.1) — 0, if the next n or fewer bytes complete the multibyte character that corresponds to the U+0000 Unicode character (which is the value stored).

(8.2) — between 1 and n (inclusive), if the next n or fewer bytes complete a valid multibyte character (which is the value stored); the value returned is the number of bytes that complete the multibyte character.

(8.3) — (size_t)(-3), if the next character resulting from a previous call has been stored (no bytes from the input have been consumed by this call).

(8.4) — (size_t)(-2), if the next n bytes contribute to an incomplete (but potentially valid) multibyte character, and all n bytes have been processed (no value is stored).

(8.5) — (size_t)(-1), if an encoding error occurs, in which case the next n or fewer bytes do not contribute to a complete and valid multibyte character (no value is stored); the value of the macro EILSEQ is stored in errno, and the conversion state is unspecified.

size_t c8rtomb(char* s, char8_t c8, mbstate_t* ps);

Effects: If s is a null pointer, equivalent to c8rtomb(buf, u8'\0', ps) where buf is an internal buffer. Otherwise, if c8 completes a sequence of valid UTF-8 code units, determines the number of bytes needed to represent the multibyte character (including any shift sequences), and stores the multibyte character representation in the array whose first element is pointed to by s. At most MB_CUR_MAX bytes are stored. If the multibyte character is a null character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state; the resulting state described is the initial conversion state.

Returns: The number of bytes stored in the array object (including any shift sequences). If c8 does not contribute to a sequence of char8_t corresponding to a valid multibyte character, the value of the macro EILSEQ is stored in errno, (size_t)(-1) is returned, and the conversion state is unspecified.

Remarks: Calls to c8rtomb with a null pointer argument for s may introduce a data race (16.5.5.9) with other calls to c8rtomb with a null pointer argument for s.
22 Containers library

22.1 General

1 This Clause describes components that C++ programs may use to organize collections of information.
2 The following subclauses describe container requirements, and components for sequence containers and associative containers, as summarized in Table 61.

22.2 Container requirements

22.2.1 General container requirements

1 Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.
2 All of the complexity requirements in this Clause are stated solely in terms of the number of operations on the contained objects. [Example: The copy constructor of type vector<vector<int>> has linear complexity, even though the complexity of copying each contained vector<int> is itself linear. —end example]
3 For the components affected by this subclause that declare an allocator_type, objects stored in these components shall be constructed using the function allocator_traits<allocator_type>::rebind_traits<U>::construct and destroyed using the function allocator_traits<allocator_type>::rebind_traits<U>::destroy (20.10.9.2), where U is either allocator_type::value_type or an internal type used by the container. These functions are called only for the container’s element type, not for internal types used by the container. [Note: This means, for example, that a node-based container might need to construct nodes containing aligned buffers and call construct to place the element into the buffer. —end note]
4 In Tables 62, 63, and 64 X denotes a container class containing objects of type T, a and b denote values of type X, u denotes an identifier, r denotes a non-const value of type X, and rv denotes a non-const rvalue of type X.

</tr>
</tbody>
</table>

Those entries marked “(Note A)” or “(Note B)” have linear complexity for array and have constant complexity for all other standard containers. [Note: The algorithm equal() is defined in Clause 25. — end note]

5 The member function size() returns the number of elements in the container. The number of elements is defined by the rules of constructors, inserts, and erases.

6 begin() returns an iterator referring to the first element in the container. end() returns an iterator which is the past-the-end value for the container. If the container is empty, then begin() == end().

7 In the expressions
   
i == j  
i != j  
i < j  
i <= j  
i >= j  
i > j  
i - j

   where i and j denote objects of a container’s iterator type, either or both may be replaced by an object of the container’s const_iterator type referring to the same element with no change in semantics.

8 Unless otherwise specified, all containers defined in this clause obtain memory using an allocator (see 16.5.3.5). [Note: In particular, containers and iterators do not store references to allocated elements other than through the allocator’s pointer type, i.e., as objects of type P or pointer_traits<P>::template rebind<unspecified>, where P is allocator_traits<allocator_type>::pointer. — end note] Copy constructors for these container types obtain an allocator by calling allocator_traits<allocator_type>::select_on_container_copy_construction on the allocator belonging to the container being copied. Move constructors obtain an allocator by move construction from the allocator belonging to the container being moved. Such move construction of the allocator shall not exit via an exception. All other constructors for these container types take a const allocator_type& argument. [Note: If an invocation of a constructor uses the default value of an optional allocator argument, then the allocator type must support value-initialization. — end note] A copy of this allocator is used for any memory allocation and element construction performed, by these constructors and by all member functions, during the lifetime of each container object or until the allocator is replaced. The allocator may be replaced only via assignment or swap(). Allocator replacement is performed by copy assignment, move assignment, or swapping of the allocator only if allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value, allocator_traits<allocator_type>::propagate_on_container_move_assignment::value, or allocator_traits<allocator_type>::propagate_on_container_swap::value is true within the implementation of the corresponding container operation. In all container types defined in this Clause, the member get_allocator() returns a copy of the allocator used to construct the container or, if that allocator has been replaced, a copy of the most recent replacement.
The expression `a.swap(b)`, for containers `a` and `b` of a standard container type other than `array`, shall exchange the values of `a` and `b` without invoking any move, copy, or swap operations on the individual container elements. Lvalues of any `Compare`, `Pred`, or `Hash` types belonging to `a` and `b` shall be swappable and shall be exchanged by calling `swap` as described in 16.5.3.2. If `allocator_traits<allocator_type>::propagate_on_container_swap::value` is `true`, then lvalues of type `allocator_type` shall be swappable and the allocators of `a` and `b` shall also be exchanged by calling `swap` as described in 16.5.3.2. Otherwise, the allocators shall not be swapped, and the behavior is undefined unless `a.get_allocator() == b.get_allocator()`. Every iterator referring to an element in one container before the swap shall refer to the same element in the other container after the swap. It is unspecified whether an iterator with value `a.end()` before the swap will have value `b.end()` after the swap.

If the iterator type of a container belongs to the bidirectional or random access iterator categories (23.3), the container is called reversible and meets the additional requirements in Table 63.

</tbody>
</table>

Unless otherwise specified (see 22.2.6.1, 22.2.7.1, 22.3.8.4, and 22.3.11.5) all container types defined in this Clause meet the following additional requirements:

1. **if an exception is thrown by an `insert()` or `emplace()` function while inserting a single element, that function has no effects.**
2. **if an exception is thrown by a `push_back()`, `push_front()`, `emplace_back()`, or `emplace_front()` function, that function has no effects.**
3. **no `erase()`, `clear()`, `pop_back()` or `pop_front()` function throws an exception.**
4. **no copy constructor or assignment operator of a returned iterator throws an exception.**
5. **no `swap()` function throws an exception.**
6. **no `swap()` function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped. [Note: The `end()` iterator does not refer to any element, so it may be invalidated. — end note]**

Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

A **contiguous container** is a container whose member types `iterator` and `const_iterator` meet the `Cpp17RandomAccessIterator` requirements (23.3.5.6) and model `ContiguousIterator` (23.3.4.14).

Table 64 lists operations that are provided for some types of containers but not others. Those containers for which the listed operations are provided shall implement the semantics described in Table 64 unless otherwise stated. If the iterators passed to `lexicographical_compare` meet the constexpr iterator requirements (23.3.1) then the operations described in Table 64 are implemented by constexpr functions.
Table 64: Optional container operations  [tab:container.opt]

<td>linear</td>
<td></td>
</tr>
</tbody>
</table>

[Note: The algorithm lexicographical_compare() is defined in Clause 25. — end note]

All of the containers defined in this Clause and in 21.3.2 except array meet the additional requirements of an allocator-aware container, as described in Table 65.

Given an allocator type A and given a container type X having a value_type identical to T and an allocator_type identical to allocator_traits<A>::rebind_alloc<T> and given an lvalue m of type A, a pointer p of type T*, an expression v of type (possibly const) T, and an rvalue rv of type T, the following terms are defined. If X is not allocator-aware, the terms below are defined as if A were allocator<T> — no allocator object needs to be created and user specializations of allocator<T> are not instantiated:

- **T is Cpp17DefaultInsertable into X** means that the following expression is well-formed:
  
  allocator_traits<A>::construct(m, p)

- **T is Cpp17MoveInsertable into X** means that an element of X is default-inserted if it is initialized by evaluation of the expression
  
  allocator_traits<A>::construct(m, p)

- **T is Cpp17CopyInsertable into X** means that the following expression is well-formed:
  
  allocator_traits<A>::construct(m, p, v)

  and its evaluation causes the following postcondition to hold: The value of *p is equivalent to the value of rv before the evaluation. [Note: rv remains a valid object. Its state is unspecified — end note]

- **T is Cpp17EmplaceConstructible into X from args**, for zero or more arguments args, means that the following expression is well-formed:
  
  allocator_traits<A>::construct(m, p, args)

  [Note: A container calls allocator_traits<A>::construct(m, p, args) to construct an element at p using args, with m == get_allocator(). The default construct in allocator will call ::new((void*)p) T(args), but specialized allocators may choose a different definition. — end note]

In Table 65, X denotes an allocator-aware container class with a value_type of T using allocator of type A, u denotes a variable, a and b denote non-const lvalues of type X, t denotes an lvalue or a const rvalue of type X, rv denotes a non-const rvalue of type X, and m is a value of type A.

</tbody>
</table>

The behavior of certain container member functions and deduction guides depends on whether types qualify as input iterators or allocators. The extent to which an implementation determines that a type cannot be an
input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators. Likewise, the extent to which an implementation determines that a type cannot be an allocator is unspecified, except that as a minimum a type \( A \) shall not qualify as an allocator unless it meets both of the following conditions:

\begin{align}
(17.1) & \quad \text{The qualified-id } A::\text{value_type} \text{ is valid and denotes a type (13.9.2).} \\
(17.2) & \quad \text{The expression } \text{declval}<A&>().\text{allocate(size_t{)}} \text{ is well-formed when treated as an unevaluated operand.}
\end{align}

### 22.2.2 Container data races

For purposes of avoiding data races (16.5.5.9), implementations shall consider the following functions to be \( \text{const: begin, end, rbegin, rend, front, back, data, find, lower_bound, upper_bound, equal_range, at} \) and, except in associative or unordered associative containers, \( \text{operator[]} \).

Notwithstanding 16.5.5.9, implementations are required to avoid data races when the contents of the contained object in different elements in the same container, excepting \( \text{vector<bool>}, \) are modified concurrently.

\[ \text{Note: For a vector<int} x \text{ with a size greater than one, } x[1] = 5 \text{ and } *x.\text{begin()} = 10 \text{ can be executed concurrently without a data race, but } x[0] = 5 \text{ and } *x.\text{begin()} = 10 \text{ executed concurrently may result in a data race. As an exception to the general rule, for a vector<bool} y \text{, } y[0] = true \text{ may race with } y[1] = true. \quad \text{— end note}} \]

### 22.2.3 Sequence containers

A sequence container organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides four basic kinds of sequence containers: \( \text{vector, forward_list, list, and deque} \). In addition, \( \text{array} \) is provided as a sequence container which provides limited sequence operations because it has a fixed number of elements. The library also provides container adaptors that make it easy to construct abstract data types, such as \( \text{stacks or queues} \), out of the basic sequence container kinds (or out of other kinds of sequence containers that the user might define).

\[ \text{Note: The sequence containers offer the programmer different complexity trade-offs and should be used accordingly. vector is the type of sequence container that should be used by default. array should be used when the container has a fixed size known during translation. list or forward_list should be used when there are frequent insertions and deletions from the middle of the sequence. deque is the data structure of choice when most insertions and deletions take place at the beginning or at the end of the sequence. When choosing a container, remember vector is best; leave a comment to explain if you choose from the rest! \quad \text{— end note}} \]

In Tables 66 and 67, \( \text{X} \) denotes a sequence container class, \( \text{a} \) denotes a value of type \( \text{X} \) containing elements of type \( \text{T} \), \( \text{u} \) denotes the name of a variable being declared, \( \text{A} \) denotes \( \text{X::allocator_type} \) if the qualified-id \( \text{X::allocator_type} \) is valid and denotes a type (13.9.2) and \( \text{allocator<T>} \) if it doesn’t, \( \text{i} \) and \( \text{j} \) denote iterators that meet the \( \text{Cpp17InputIterator} \) requirements and refer to elements implicitly convertible to \( \text{value_type} \), \( [\text{i}, \text{j}] \) denotes a valid range, \( \text{il} \) designates an object of type \( \text{initializer_list<value_type>} \), \( \text{n} \) denotes a value of type \( \text{X::size_type} \), \( \text{p} \) denotes a valid constant iterator to \( \text{a} \), \( \text{q} \) denotes a valid dereferenceable constant iterator to \( \text{a} \), \( [\text{q1}, \text{q2}] \) denotes a valid range of constant iterators in \( \text{a}, \text{t} \) denotes an lvalue or a const rvalue of \( \text{value_type} \), and \( \text{rv} \) denotes a non-const rvalue of \( \text{value_type} \). \( \text{Args} \) denotes a template parameter pack; \( \text{args} \) denotes a function parameter pack with the pattern \( \text{Args&&} \).

The complexities of the expressions are sequence dependent.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Assertion/note</th>
</tr>
</thead>
</table>
| `a.erase(q1,q2)` | iterator | *Expects:* For `vector` and `deque`, `T` is `Cpp17MoveAssignable`.  
*Effects:* Erases the elements in the range `[q1, q2)`. |
| `a.clear()` | void | *Effects:* Destroys all elements in `a`. Invalidates all references, pointers, and iterators referring to the elements of `a` and may invalidate the past-the-end iterator.  
*Ensures:* `a.empty()` is true.  
*Complexity:* Linear. |
| `a.assign(i,j)` | void | *Expects:* `T` is `Cpp17EmplaceConstructible` into `X` from `*i` and assignable from `*i`. For `vector`, if the iterator does not meet the forward iterator requirements (23.3.5.4), `T` is also `Cpp17MoveInsertable` into `X`. Neither `i` nor `j` are iterators into `a`.  
*Effects:* Replaces elements in `a` with a copy of `[i, j)`. Invalidates all references, pointers and iterators referring to the elements of `a`. For `vector` and `deque`, also invalidates the past-the-end iterator. Each iterator in the range `[i, j)` shall be dereferenced exactly once. |
| `a.assign(il)` | void | `a.assign(il.begin(), il.end())`. |
| `a.assign(n,t)` | void | *Expects:* `T` is `Cpp17CopyInsertable` into `X` and `Cpp17CopyAssignable`. `t` is not a reference into `a`.  
*Effects:* Replaces elements in `a` with `n` copies of `t`. Invalidates all references, pointers and iterators referring to the elements of `a`. For `vector` and `deque`, also invalidates the past-the-end iterator. |

5 The iterator returned from `a.insert(p, t)` points to the copy of `t` inserted into `a`.  
6 The iterator returned from `a.insert(p, rv)` points to the copy of `rv` inserted into `a`.  
7 The iterator returned from `a.insert(p, n, t)` points to the copy of the first element inserted into `a`, or `p` if `n == 0`.  
8 The iterator returned from `a.insert(p, i, j)` points to the copy of the first element inserted into `a`, or `p` if `i == j`.  
9 The iterator returned from `a.insert(p, il)` points to the copy of the first element inserted into `a`, or `p` if `il` is empty.  
10 The iterator returned from `aemplace(p, args)` points to the new element constructed from `args` into `a`.  
11 The iterator returned from `a.erase(q)` points to the element immediately following `q` prior to the element being erased. If no such element exists, `a.end()` is returned.  
12 The iterator returned by `a.erase(q1, q2)` points to the element pointed to by `q2` prior to any elements being erased. If no such element exists, `a.end()` is returned.  
13 For every sequence container defined in this Clause and in Clause 21:  

13.1 If the constructor

```cpp
template<class InputIterator>  
X(InputIterator first, InputIterator last,  
const allocator_type& alloc = allocator_type());
```
is called with a type `InputIterator` that does not qualify as an input iterator, then the constructor shall not participate in overload resolution.

(13.2) If the member functions of the forms:

```cpp
template<class InputIterator>
return-type F(const_iterator p,
             InputIterator first, InputIterator last);   // such as insert

template<class InputIterator>
return-type F(InputIterator first, InputIterator last);   // such as append, assign

template<class InputIterator>
return-type F(const_iterator i1, const_iterator i2,
              InputIterator first, InputIterator last);   // such as replace
```

are called with a type `InputIterator` that does not qualify as an input iterator, then these functions shall not participate in overload resolution.

(13.3) A deduction guide for a sequence container shall not participate in overload resolution if it has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter, or if it has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.

Table 67 lists operations that are provided for some types of sequence containers but not others. An implementation shall provide these operations for all container types shown in the “container” column, and shall implement them so as to take amortized constant time.

</tr>
<tr>
<td>a.at(n)</td>
<td>reference; const_reference</td>
<td>*(a.begin() + n) for constant a</td>
<td>basic_string, array, deque, vector</td>
</tr>
</tbody>
</table>

15 The member function `at()` provides bounds-checked access to container elements. `at()` throws `out_of_range` if n >= a.size().

### 22.2.4 Node handles

#### 22.2.4.1 Overview

A node handle is an object that accepts ownership of a single element from an associative container (22.2.6) or an unordered associative container (22.2.7). It may be used to transfer that ownership to another container with compatible nodes. Containers with compatible nodes have the same node handle type. Elements may be transferred in either direction between container types in the same row of Table 68.

| map<K, T, C1, A> | map<K, T, C2, A> |
| map<K, T, C1, A> | multimap<K, T, C2, A> |
| set<K, C1, A>    | set<K, C2, A>     |
| set<K, C1, A>    | multiset<K, C2, A> |
| unordered_map<K, T, H1, E1, A> | unordered_map<K, T, H2, E2, A> |
| unordered_map<K, T, H1, E1, A> | unordered_multimap<K, T, H2, E2, A> |
| unordered_set<K, H1, E1, A> | unordered_set<K, H2, E2, A> |
| unordered_set<K, H1, E1, A> | unordered_multiset<K, H2, E2, A> |

2 If a node handle is not empty, then it contains an allocator that is equal to the allocator of the container when the element was extracted. If a node handle is empty, it contains no allocator.

3 Class `node-handle` is for exposition only.

4 If a user-defined specialization of `pair` exists for `pair<const Key, T>` or `pair<Key, T>`, where `Key` is the container’s `key_type` and `T` is the container’s `mapped_type`, the behavior of operations involving node handles is undefined.

```cpp
template<unsplash> class node-handle { public:  // These type declarations are described in Tables 69 and 70.  using value_type = see below; // not present for map containers  using key_type = see below; // not present for set containers  using mapped_type = see below; // not present for set containers  using allocator_type = see below; }
```

§ 22.2.4.1 770
private:
using container_node_type = unspecified;
using ator_traits = allocator_traits<allocator_type>;

typename ator_traits::template rebind_traits<container_node_type>::pointer ptr_;  
onoptional<allocator_type> alloc_;  

public:

// 22.2.4.2, constructors, copy, and assignment
constexpr
node-handle() noexcept : ptr_(), alloc_() {}  
node-handle(node-handle&&) noexcept;  
node-handle& operator=(node-handle&&);  

// 22.2.4.3, destructor
~node-handle();  

// 22.2.4.4, observers
value_type& value() const;  
key_type& key() const;  
mapped_type& mapped() const;  
allocator_type get_allocator() const;  
explicit operator bool() const noexcept;  
[[nodiscard]] bool empty() const noexcept;  

// 22.2.4.5, modifiers

void swap(node-handle&&)  
    noexcept(ator_traits::propagate_on_container_swap::value ||  
        ator_traits::is_always_equal::value);  

friend void swap(node-handle& x, node-handle& y) noexcept(noexcept(x.swap(y))) {  
    x.swap(y);  
}  

22.2.4.2  Constructors, copy, and assignment  

node-handle(node-handle&& nh) noexcept;  

1  Effects: Constructs a node-handle object initializing ptr_ with nh.ptr_. Move constructs alloc_ with nh.alloc_. Assigns nullptr to nh.ptr_ and assigns nullopt to nh.alloc_.

node-handle& operator=(node-handle&& nh);  

2  Effects: Either !alloc_ or ator_traits::propagate_on_container_move_assignment::value is true, or alloc_ == nh.alloc_.

3  Effects:
(3.1) — If ptr_ != nullptr, destroys the value_type subobject in the container_node_type object pointed to by ptr_ by calling ator_traits::destroy, then deallocates ptr_ by calling ator_traits::template rebind_traits<container_node_type>::deallocate.
(3.2) — Assigns nh.ptr_ to ptr_.
(3.3) — If !alloc_ or ator_traits::propagate_on_container_move_assignment::value is true, move assigns nh.alloc_ to alloc_.
(3.4) — Assigns nullptr to nh.ptr_ and assigns nullopt to nh.alloc_.

4  Returns: *this.
5  Throws: Nothing.

22.2.4.3  Destructor  

~node-handle();  

1  Effects: If ptr_ != nullptr, destroys the value_type subobject in the container_node_type object pointed to by ptr_ by calling ator_traits::destroy, then deallocates ptr_ by calling ator_traits::template rebind_traits<container_node_type>::deallocate.
traits::template rebind_traits<container_node_type>::deallocate.

22.2.4.4 Observers

value_type& value() const;

- **Expects:** empty() == false.
- **Returns:** A reference to the value_type subobject in the container_node_type object pointed to by ptr_.
- **Throws:** Nothing.

key_type& key() const;

- **Expects:** empty() == false.
- **Returns:** A non-const reference to the key_type member of the value_type subobject in the container_node_type object pointed to by ptr_.
- **Throws:** Nothing.
- **Remarks:** Modifying the key through the returned reference is permitted.

mapped_type& mapped() const;

- **Expects:** empty() == false.
- **Returns:** A reference to the mapped_type member of the value_type subobject in the container_node_type object pointed to by ptr_.
- **Throws:** Nothing.

allocator_type get_allocator() const;

- **Expects:** empty() == false.
- **Returns:** *alloc_.
- **Throws:** Nothing.

explicit operator bool() const noexcept;

- **Returns:** ptr_ != nullptr.

[[nodiscard]] bool empty() const noexcept;

- **Returns:** ptr_ == nullptr.

22.2.4.5 Modifiers

void swap(node-handle nh);

- **noexcept:** (ator_traits::propagate_on_container_swap::value ||
  ator_traits::is_always_equal::value);
- **Expects:** !alloc_. or !nh.alloc_. or ator_traits::propagate_on_container_swap::value is true, or alloc_ == nh.alloc_.
- **Effects:** Calls swap(ptr_, nh.ptr_). If !alloc_. or !nh.alloc_. or ator_traits::propagate_on_container_swap::value is true calls swap(alloc_, nh.alloc_).

22.2.5 Insert return type

The associative containers with unique keys and the unordered containers with unique keys have a member function insert that returns a nested type insert_return_type. That return type is a specialization of the template specified in this subclause.

template<class Iterator, class NodeType>
struct insert-return-type
{
  Iterator position;
  bool inserted;
  NodeType node;
};
In Table 69, the name `insert-return-type` is exposition only. `insert-return-type` has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

### 22.2.6 Associative containers

Associative containers provide fast retrieval of data based on keys. The library provides four basic kinds of associative containers: `set`, `multiset`, `map`, and `multimap`.

Each associative container is parameterized on `Key` and an ordering relation `Compare` that induces a strict weak ordering (25.7) on elements of `Key`. In addition, `map` and `multimap` associate an arbitrary mapped type `T` with the `Key`. The object of type `Compare` is called the comparison object of a container.

The phrase “equivalence of keys” means the equivalence relation imposed by the comparison object. That is, two keys `k1` and `k2` are considered to be equivalent if for the comparison object `comp`, `comp(k1, k2) == false && comp(k2, k1) == false`. [Note: This is not necessarily the same as the result of `k1 == k2`. —end note] For any two keys `k1` and `k2` in the same container, calling `comp(k1, k2)` shall always return the same value.

An associative container supports unique keys if it may contain at most one element for each key. Otherwise, it supports equivalent keys. The `set` and `map` classes support unique keys; the `multiset` and `multimap` classes support equivalent keys. For `multiset` and `multimap`, `insert`, `emplace`, and `erase` preserve the relative ordering of equivalent elements.

For `set` and `multiset` the value type is the same as the key type. For `map` and `multimap` it is equal to `pair<const Key, T>`.

**iterator** of an associative container is of the bidirectional iterator category. For associative containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type. [Note: `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists. —end note]

The associative containers meet all the requirements of Allocator-aware containers (22.2.1), except that for `map` and `multimap`, the requirements placed on `value_type` in Table 65 apply instead to `key_type` and `mapped_type`. [Note: For example, in some cases `key_type` and `mapped_type` are required to be `Cpp17CopyAssignable` even though the associated `value_type`, `pair<const key_type, mapped_type>`, is not `Cpp17CopyAssignable`. —end note]

In Table 69, `X` denotes an associative container class, `a` denotes a value of type `X`, `a2` denotes a value of a type with nodes compatible with type `X` (Table 68), `b` denotes a possibly `const` value of type `X`, `u` denotes the name of a variable being declared, `a_uniq` denotes a value of type `X` when `X` supports unique keys, `a_eq` denotes a value of type `X` when `X` supports multiple keys, `a_tran` denotes a possibly `const` value of type `X` when the qualified-id `X::key_compare::is_transparent` is valid and denotes a type (13.9.2), `i` and `j` meet the `Cpp17InputIterator` requirements and refer to elements implicitly convertible to `value_type`, `[i, j)` denotes a valid range, `p` denotes a valid constant iterator to `a`, `q` denotes a valid dereferenceable constant iterator to `a`, `r` denotes a valid dereferenceable iterator to `a`, `[q1, q2)` denotes a valid range of constant iterators in `a`, `i1` designates an object of type `initializer_list<value_type>`, `t` denotes a value of type `X::value_type`, `k` denotes a value of type `X::key_type` and `c` denotes a possibly `const` value of type `X::key_compare`, `k1` is a value such that `a` is partitioned (25.7) with respect to `c(r, k1)`, with `r` the key value of `e` and `e` in `a`; `ku` is a value such that `a` is partitioned with respect to `!c(ku, r)`; `ke` is a value such that `a` is partitioned with respect to `c(r, ke)` and `!c(ke, r)`, with `c(r, ke)` implying `!c(ke, r)`. `A` denotes the storage allocator used by `X`, if any, or `allocator<X::value_type>` otherwise, `m` denotes an allocator of a type convertible to `A`, and `nh` denotes a non-const rvalue of type `X::node_type`.

</tbody>
</table>

9 The insert and emplace members shall not affect the validity of iterators and references to the container, and the erase members shall invalidate only iterators and references to the erased elements.

10 The extract members invalidate only iterators to the removed element; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a node_type is undefined behavior. References and pointers to an element obtained while it is owned by a node_type are invalidated if the element is successfully inserted.

11 The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators i and j such that distance from i to j is positive, the following condition holds:

\[
\text{value_comp}(\ast j, \ast i) = \text{false}
\]

12 For associative containers with unique keys the stronger condition holds:

\[
\text{value_comp}(\ast i, \ast j) \neq \text{false}
\]

13 When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, through either a copy constructor or an assignment operator, the target container shall...
then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.

The member function templates find, count, contains, lower_bound, upper_bound, and equal_range shall not participate in overload resolution unless the qualified-id Compare::is_transparent is valid and denotes a type (13.9.2).

A deduction guide for an associative container shall not participate in overload resolution if any of the following are true:

(15.1)  — It has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

(15.2)  — It has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.

(15.3)  — It has a Compare template parameter and a type that qualifies as an allocator is deduced for that parameter.

22.2.6.1 Exception safety guarantees

For associative containers, no clear() function throws an exception. erase(k) does not throw an exception unless that exception is thrown by the container’s Compare object (if any).

For associative containers, if an exception is thrown by any operation from within an insert or emplace function inserting a single element, the insertion has no effect.

For associative containers, no swap function throws an exception unless that exception is thrown by the swap of the container’s Compare object (if any).

22.2.7 Unordered associative containers

Unordered associative containers provide an ability for fast retrieval of data based on keys. The worst-case complexity for most operations is linear, but the average case is much faster. The library provides four unordered associative containers: unordered_set, unordered_map, unordered_multiset, and unordered_multimap.

Unordered associative containers conform to the requirements for Containers (22.2), except that the expressions a == b and a != b have different semantics than for the other container types.

Each unordered associative container is parameterized by Key, by a function object type Hash that meets the Cpp17Hash requirements (16.5.3.4) and acts as a hash function for argument values of type Key, and by a binary predicate Pred that induces an equivalence relation on values of type Key. Additionally, unordered_map and unordered_multimap associate an arbitrary mapped type T with the Key.

The container’s object of type Hash — denoted by hash — is called the hash function of the container. The container’s object of type Pred — denoted by pred — is called the key equality predicate of the container.

Two values k1 and k2 are considered equivalent if the container’s key equality predicate pred(k1, k2) is valid and returns true when passed those values. If k1 and k2 are equivalent, the container’s hash function shall return the same value for both. [Note: Thus, when an unordered associative container is instantiated with a non-default Pred parameter it usually needs a non-default Hash parameter as well. — end note] For any two keys k1 and k2 in the same container, calling pred(k1, k2) shall always return the same value. For any key k in a container, calling hash(k) shall always return the same value.

An unordered associative container supports unique keys if it may contain at most one element for each key. Otherwise, it supports equivalent keys. unordered_set and unordered_map support unique keys. unordered_multiset and unordered_multimap support equivalent keys. In containers that support equivalent keys, elements with equivalent keys are adjacent to each other in the iteration order of the container. Thus, although the absolute order of elements in an unordered container is not specified, its elements are grouped into equivalent-key groups such that all elements of each group have equivalent keys. Mutating operations on unordered containers shall preserve the relative order of elements within each equivalent-key group unless otherwise specified.

For unordered_set and unordered_multiset the value type is the same as the key type. For unordered_map and unordered_multimap it is pair<const Key, T>.

For unordered containers where the value type is the same as the key type, both iterator and const_iterator are constant iterators. It is unspecified whether or not iterator and const_iterator are the same.
type. [Note: iterator and const_iterator have identical semantics in this case, and iterator is convertible to const_iterator. Users can avoid violating the one-definition rule by always using const_iterator in their function parameter lists. — end note]

9 The elements of an unordered associative container are organized into buckets. Keys with the same hash code appear in the same bucket. The number of buckets is automatically increased as elements are added to an unordered associative container, so that the average number of elements per bucket is kept below a bound. Rehashing invalidates iterators, changes ordering between elements, and changes which buckets elements appear in, but does not invalidate pointers or references to elements. For unordered_multiset and unordered_multimap, rehashing preserves the relative ordering of equivalent elements.

10 The unordered associative containers meet all the requirements of Allocator-aware containers (22.2.1), except that for unordered_map and unordered_multimap, the requirements placed on value_type in Table 65 apply instead to key_type and mapped_type. [Note: For example, key_type and mapped_type are sometimes required to be Cpp17CopyAssignable even though the associated value_type, pair<const key_type, mapped_type>, is not Cpp17CopyAssignable. — end note]

11 In Table 70:

- (11.1) X denotes an unordered associative container class,
- (11.2) a denotes a value of type X,
- (11.3) a2 denotes a value of a type with nodes compatible with type X (Table 68),
- (11.4) b denotes a possibly const value of type X,
- (11.5) a_uniq denotes a value of type X when X supports unique keys,
- (11.6) a_eq denotes a value of type X when X supports equivalent keys,
- (11.7) a_tran denotes a possibly const value of type X when the qualified-id X::hasher::transparent_key_equal is valid and denotes a type (13.9.2),
- (11.8) i and j denote input iterators that refer to value_type,
- (11.9) [i, j) denotes a valid range,
- (11.10) p and q2 denote valid constant iterators to a,
- (11.11) q and q1 denote valid dereferenceable constant iterators to a,
- (11.12) r denotes a valid dereferenceable iterator to a,
- (11.13) [q1, q2) denotes a valid range in a,
- (11.14) il denotes a value of type initializer_list<value_type>,
- (11.15) t denotes a value of type X::value_type,
- (11.16) k denotes a value of type key_type,
- (11.17) hf denotes a possibly const value of type hasher,
- (11.18) eq denotes a possibly const value of type key_equal,
- (11.19) ke is a value such that
- (11.19.1) eq(r1, ke) == eq(ke, r1)
- (11.19.2) hf(r1) == hf(ke) if eq(r1, ke) is true, and
- (11.19.3) (eq(r1, ke) && eq(r1, r2)) == eq(r2, ke)
where r1 and r2 are keys of elements in a_tran,
- (11.20) n denotes a value of type size_type,
- (11.21) z denotes a value of type float,
- (11.22) nh denotes a non-const rvalue of type X::node_type, and
- (11.23) hk and hke denote values of type size_t.

</table>

12 Two unordered containers \(a\) and \(b\) compare equal if \(a.size() == b.size()\) and, for every equivalent-key group \([Ea1, Ea2)\) obtained from \(a.equal_range(Ea1)\), there exists an equivalent-key group \([Eb1, Eb2)\) obtained from \(b.equal_range(Ea1)\), such that \(\text{is_permutation}(Ea1, Ea2, Eb1, Eb2)\) returns true. For `unordered_set` and `unordered_map`, the complexity of `operator==` (i.e., the number of calls to the `==` operation) is linear in the number of elements in the container.
operator of the value_type, to the predicate returned by key_eq(), and to the hasher returned by hash_function(). For unordered_multiset and unordered_multimap, the complexity of operator== is proportional to $\sum E_i^2$ in the average case and to $N^2$ in the worst case, where $N$ is a.size(). For unordered_multiset and unordered_multimap, the complexity of operator== is proportional to $\sum E_i^2$ in the average case and to $N^2$ in the worst case, where $N$ is a.size(), and $E_i$ is the size of the $i$th equivalent-key group in a. However, if the respective elements of each corresponding pair of equivalent-key groups $E_n$ and $E_b$ are arranged in the same order (as is commonly the case, e.g., if a and b are unmodified copies of the same container), then the average-case complexity for unordered_multiset and unordered_multimap becomes proportional to $N$ (but worst-case complexity remains $O(N^2)$, e.g., for a pathologically bad hash function). The behavior of a program that uses operator== or operator!= on unordered containers is undefined unless the Pred function object has the same behavior for both containers and the equality comparison function for Key is a refinement of the partition into equivalent-key groups produced by Pred.

The iterator types iterator and const_iterator of an unordered associative container are of at least the forward iterator category. For unordered associative containers where the key type and value type are the same, both iterator and const_iterator are constant iterators.

The insert and emplace members shall not affect the validity of references to container elements, but may invalidate all iterators to the container. The erase members shall invalidate only iterators and references to the erased elements, and preserve the relative order of the elements that are not erased.

The insert and emplace members shall not affect the validity of iterators if $(N+n) \leq z \cdot B$, where $N$ is the number of elements in the container prior to the insert operation, $n$ is the number of elements inserted, $B$ is the container’s bucket count, and $z$ is the container’s maximum load factor.

The extract members invalidate only iterators to the removed element, and preserve the relative order of the elements that are not erased; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a node_type is undefined behavior. References and pointers to an element obtained while it is owned by a node_type are invalidated if the element is successfully inserted.

If the qualified-id Hash::transparent_key_equal is valid and denotes a type (13.9.2), then the program is ill-formed if either:

1. $\text{qualified-id Hash::transparent_key_equal::is_transparent}$ is not valid or does not denote a type, or
2. Pred is a different type than equal_to<Key> or Hash::transparent_key_equal.

The member function templates find, count, equal_range, and contains shall not participate in overload resolution unless the qualified-id Hash::transparent_key_equal is valid and denotes a type (13.9.2).

A deduction guide for an unordered associative container shall not participate in overload resolution if any of the following are true:

1. It has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
2. It has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.
3. It has a Hash template parameter and an integral type or a type that qualifies as an allocator is deduced for that parameter.
4. It has a Pred template parameter and a type that qualifies as an allocator is deduced for that parameter.

### 22.2.7.1 Exception safety guarantees

1. For unordered associative containers, no clear() function throws an exception. erase(k) does not throw an exception unless that exception is thrown by the container’s Hash or Pred object (if any).
2. For unordered associative containers, if an exception is thrown by any operation other than the container’s hash function from within an insert or emplace function inserting a single element, the insertion has no effect.
3. For unordered associative containers, no swap function throws an exception unless that exception is thrown by the swap of the container’s Hash or Pred object (if any).

---

228) Equality comparison is a refinement of partitioning if no two objects that compare equal fall into different partitions.
For unordered associative containers, if an exception is thrown from within a `rehash()` function other than by the container’s hash function or comparison function, the `rehash()` function has no effect.

22.3 Sequence containers

22.3.1 In general

The headers `<array>`, `<deque>`, `<forward_list>`, `<list>`, and `<vector>` define class templates that meet the requirements for sequence containers.

The following exposition-only alias template may appear in deduction guides for sequence containers:

```cpp
template<class InputIterator>
    using iter_value_type = typename iterator_traits<InputIterator>::value_type; // exposition only
```

22.3.2 Header `<array>` synopsis

```cpp
#include <initializer_list>
namespace std {
    // 22.3.7, class template array
    template<class T, size_t N> struct array;
    template<class T, size_t N>
        constexpr bool operator==(const array<T, N>& x, const array<T, N>& y);
    template<class T, size_t N>
        constexpr bool operator!=(const array<T, N>& x, const array<T, N>& y);
    template<class T, size_t N>
        constexpr bool operator< (const array<T, N>& x, const array<T, N>& y);
    template<class T, size_t N>
        constexpr bool operator> (const array<T, N>& x, const array<T, N>& y);
    template<class T, size_t N>
        constexpr bool operator<=(const array<T, N>& x, const array<T, N>& y);
    template<class T, size_t N>
        constexpr bool operator>=(const array<T, N>& x, const array<T, N>& y);
    template<class T, size_t N>
        constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));
    // 22.3.7.6, tuple interface to class template array
    template<class T> struct tuple_size;
    template<size_t I, class T> struct tuple_element;
    template<class T, size_t N>
        struct tuple_size<array<T, N>>;
    template<size_t I, class T, size_t N>
        struct tuple_element<I, array<T, N>>;
    template<size_t I, class T, size_t N>
        constexpr T& get(array<T, N>&) noexcept;
    template<size_t I, class T, size_t N>
        constexpr T&& get(array<T, N>&&) noexcept;
    template<size_t I, class T, size_t N>
        constexpr const T& get(const array<T, N>&) noexcept;
    template<size_t I, class T, size_t N>
        constexpr const T&& get(const array<T, N>&&) noexcept;
}
```

22.3.3 Header `<deque>` synopsis

```cpp
#include <initializer_list>
namespace std {
    // 22.3.8, class template deque
    template<class T, class Allocator = allocator<T>> class deque;
    template<class T, class Allocator>
        bool operator==(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
    template<class T, class Allocator>
        bool operator!=(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
}
```
template<class T, class Allocator>
bool operator< (const deque<T, Allocator>& x, const deque<T, Allocator>& y);
template<class T, class Allocator>
bool operator> (const deque<T, Allocator>& x, const deque<T, Allocator>& y);
template<class T, class Allocator>
bool operator<=(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
template<class T, class Allocator>
bool operator>=(const deque<T, Allocator>& x, const deque<T, Allocator>& y);

template<class T, class Allocator>
void swap(deque<T, Allocator>& x, deque<T, Allocator>& y)
    noexcept(noexcept(x.swap(y)));

template<class T, class Allocator, class U>
void erase(deque<T, Allocator>& c, const U& value);

namespace pmr {
    template<class T>
    using deque = std::deque<T, polymorphic_allocator<T>>;
}

22.3.4 Header <forward_list> synopsis
[forward.list.syn]
#include <initializer_list>

namespace std {
    // 22.3.9, class template
    template<class T, class Allocator = allocator<T>> class forward_list;

    template<class T, class Allocator>
    bool operator== (const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);
    template<class T, class Allocator>
    bool operator!= (const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);
    template<class T, class Allocator>
    bool operator< (const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);
    template<class T, class Allocator>
    bool operator> (const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);
    template<class T, class Allocator>
    bool operator<=(const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);
    template<class T, class Allocator>
    bool operator>=(const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);

    template<class T, class Allocator>
    void swap(forward_list<T, Allocator>& x, forward_list<T, Allocator>& y)
        noexcept(noexcept(x.swap(y)));

    template<class T, class Allocator, class U>
    void erase(forward_list<T, Allocator>& c, const U& value);

    namespace pmr {
        template<class T>
        using forward_list = std::forward_list<T, polymorphic_allocator<T>>;
    }
}

22.3.5 Header <list> synopsis
[list.syn]
#include <initializer_list>

§ 22.3.5 795
namespace std {

// 22.3.10, class template list
template<class T, class Allocator = allocator<T>> class list;

template<class T, class Allocator>
bool operator==(const list<T, Allocator>& x, const list<T, Allocator>& y);

template<class T, class Allocator>
bool operator!=(const list<T, Allocator>& x, const list<T, Allocator>& y);

template<class T, class Allocator>
bool operator<( const list<T, Allocator>& x, const list<T, Allocator>& y);

template<class T, class Allocator>
bool operator>( const list<T, Allocator>& x, const list<T, Allocator>& y);

template<class T, class Allocator>
bool operator<=(const list<T, Allocator>& x, const list<T, Allocator>& y);

template<class T, class Allocator>
bool operator>=(const list<T, Allocator>& x, const list<T, Allocator>& y);

template<class T, class Allocator>
void swap(list<T, Allocator>& x, list<T, Allocator>& y)
    noexcept(noexcept(x.swap(y)));

template<class T, class Allocator, class U>
void erase(list<T, Allocator>& c, const U& value);

template<class T, class Allocator, class Predicate>
void erase_if(list<T, Allocator>& c, Predicate pred);

namespace pmr {
    template<class T>
    using list = std::list<T, polymorphic_allocator<T>>;
}
}

22.3.6 Header <vector> synopsis

#include <initializer_list>

namespace std {

// 22.3.11, class template vector
template<class T, class Allocator = allocator<T>> class vector;

template<class T, class Allocator>
bool operator==(const vector<T, Allocator>& x, const vector<T, Allocator>& y);

template<class T, class Allocator>

void swap(vector<T, Allocator>& x, vector<T, Allocator>& y)
    noexcept(noexcept(x.swap(y)));

template<class T, class Allocator, class U>
void erase(vector<T, Allocator>& c, const U& value);

template<class T, class Allocator, class Predicate>
void erase_if(vector<T, Allocator>& c, Predicate pred);

// 22.3.12, class vector<bool>
template<class Allocator> class vector<bool, Allocator>;
// hash support
template<class T> struct hash;
template<class Allocator> struct hash<vector<bool, Allocator>>;

namespace pmr {
    template<class T>
    using vector = std::vector<T, polymorphic_allocator<T>>;
}

22.3.7 Class template array

22.3.7.1 Overview

1. The header `<array>` defines a class template for storing fixed-size sequences of objects. An array is a contiguous container (22.2.1). An instance of array<T, N> stores N elements of type T, so that size() == N is an invariant.

2. An array is an aggregate (9.3.1) that can be list-initialized with up to N elements whose types are convertible to T.

3. An array meets all of the requirements of a container and of a reversible container (22.2), except that a default constructed array object is not empty and that swap does not have constant complexity. An array meets some of the requirements of a sequence container (22.2.3). Descriptions are provided here only for operations on array that are not described in one of these tables and for operations where there is additional semantic information.

4. The types iterator and const_iterator meet the constexpr iterator requirements (23.3.1).

namespace std {
    template<class T, size_t N>
    struct array {
        // types
        using value_type = T;
        using pointer = T*;
        using const_pointer = const T*;
        using reference = T&;
        using const_reference = const T&;
        using size_type = size_t;
        using difference_type = ptrdiff_t;
        using iterator = implementation-defined; // see 22.2
        using const_iterator = implementation-defined; // see 22.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // no explicit construct/copy/destroy for aggregate type
        constexpr void fill(const T& u);
        constexpr void swap(array&) noexcept(is_nothrow_swappable_v<T>);

        // iterators
        constexpr iterator begin() noexcept;
        constexpr const_iterator begin() const noexcept;
        constexpr iterator end() noexcept;
        constexpr const_iterator end() const noexcept;
        constexpr reverse_iterator rbegin() noexcept;
        constexpr const_reverse_iterator rbegin() const noexcept;
        constexpr reverse_iterator rend() noexcept;
        constexpr const_reverse_iterator rend() const noexcept;
    }
}
22.3.7.2 Constructors, copy, and assignment [array.cons]

1 The conditions for an aggregate (9.3.1) shall be met. Class array relies on the implicitly-declared special member functions (11.3.4.1, 11.3.6, and 11.3.4.2) to conform to the container requirements table in 22.2. In addition to the requirements specified in the container requirements table, the implicit move constructor and move assignment operator for array require that T be Cpp17MoveConstructible or Cpp17MoveAssignable, respectively.

2 template<class T, class... U>
   array(T, U...) -> array<T, 1 + sizeof...(U)>;

22.3.7.3 Member functions [array.members]

1 constexpr size_type size() const noexcept;

2 constexpr T* data() noexcept;
   constexpr const T* data() const noexcept;

3 constexpr void fill(const T& u);

4 constexpr void swap(array& y) noexcept(is_nothrow_swappable_v<T>);

5 [Note: Unlike the swap function for other containers, array::swap takes linear time, may exit via an exception, and does not cause iterators to become associated with the other container. — end note]

22.3.7.4 Specialized algorithms [array.special]

1 template<class T, size_t N>
   constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));

2 Constraints: N == 0 or is_swappable_v<T> is true.

3 Effects: As if by x.swap(y).

Complexity: Linear in N.
22.3.7.5  Zero-sized arrays

1. `array` shall provide support for the special case \( N == 0 \).
2. In the case that \( N == 0 \), `begin()` == `end()` == unique value. The return value of `data()` is unspecified.
3. The effect of calling `front()` or `back()` for a zero-sized array is undefined.
4. Member function `swap()` shall have a non-throwing exception specification.

22.3.7.6  Tuple interface

```cpp
template<class T, size_t N>
struct tuple_size<array<T, N>> : integral_constant<size_t, N> { };
```

```cpp
template<size_t I, class T, size_t N>
struct tuple_element<I, array<T, N>> { 
  using type = T;
};
```

1. `Mandates: I < N` is true.

```cpp
template<size_t I, class T, size_t N>
constexpr T& get(array<T, N>& a) noexcept;
```

```cpp
template<size_t I, class T, size_t N>
constexpr T&& get(array<T, N>&& a) noexcept;
```

```cpp
template<size_t I, class T, size_t N>
constexpr const T& get(const array<T, N>& a) noexcept;
```

```cpp
template<size_t I, class T, size_t N>
constexpr const T&& get(const array<T, N>&& a) noexcept;
```

1. `Mandates: I < N` is true.

2. `Returns: A reference to the \( I^{th} \) element of \( a \), where indexing is zero-based.`

22.3.8  Class template `deque`

22.3.8.1  Overview

1. A `deque` is a sequence container that supports random access iterators (23.3.5.6). In addition, it supports constant time insert and erase operations at the beginning or the end; insert and erase in the middle take linear time. That is, a deque is especially optimized for pushing and popping elements at the beginning and end. Storage management is handled automatically.

2. A `deque` meets all of the requirements of a container, of a reversible container (given in tables in 22.2), of a sequence container, including the optional sequence container requirements (22.2.3), and of an allocator-aware container (Table 65). Descriptions are provided here only for operations on `deque` that are not described in one of these tables or for operations where there is additional semantic information.

```cpp
namespace std {
  template<class T, class Allocator = allocator<T>>
  class deque { 
  public:
    // types
    using value_type = T;
    using allocator_type = Allocator;
    using pointer = typename allocator_traits<Allocator>::pointer;
    using const_pointer = typename allocator_traits<Allocator>::const_pointer;
    using reference = value_type&;
    using const_reference = const value_type&;
    using size_type = implementation-defined; // see 22.2
    using difference_type = implementation-defined; // see 22.2
    using iterator = implementation-defined; // see 22.2
    using const_iterator = implementation-defined; // see 22.2
    using reverse_iterator = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    // 22.3.8.2, construct/copy/destroy
    deque() : deque(Allocator()) {} 
  explicit deque(const Allocator&);
```
explicit deque(size_type n, const Allocator& = Allocator());
deque(size_type n, const T& value, const Allocator& = Allocator());
template<class InputIterator>
deque(InputIterator first, InputIterator last, const Allocator& = Allocator());
deque(const deque& x);
deque(deque&&);
deque(const deque&, const Allocator&);
deque(deque&&, const Allocator&);
deque(initializer_list<T>, const Allocator& = Allocator());

~deque();
deque& operator=(const deque& x);
deque& operator=(deque&& x)
  noexcept(allocator_traits<Allocator>::is_always_equal::value);
deque& operator=(initializer_list<T>);
template<class InputIterator>
void assign(InputIterator first, InputIterator last);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

// iterators
iterator begin() noexcept;
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;

const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// 22.3.8.3, capacity
[[nodiscard]] bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
void resize(size_type sz);
void resize(size_type sz, const T& c);
void shrink_to_fit();

// element access
reference operator[](size_type n);
const_reference operator[](size_type n) const;
reference at(size_type n);
const_reference at(size_type n) const;
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// 22.3.8.4, modifiers
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);

void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);

void pop_front();
void pop_back();

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);

void swap(deque&);

noexcept(algorithm_traits<Allocator>::is_always_equal::value);
void clear() noexcept;

};

template<class InputIterator, class Allocator = allocator<

iter-value-type

<InputIterator>>>

deque(InputIterator, InputIterator, Allocator = Allocator())

-> deque<iter-value-type<InputIterator>, Allocator>;

// swap
template<class T, class Allocator>

void swap(deque<T, Allocator>& x, deque<T, Allocator>& y)

noexcept(x.swap(y));
}

22.3.8.2 Constructors, copy, and assignment [deque.cons]

explicit deque(const Allocator&);
\begin{enumerate}
\item Effects: Constructs an empty deque, using the specified allocator.
\item Complexity: Constant.
\end{enumerate}

explicit deque(size_type n, const Allocator& = Allocator());
\begin{enumerate}
\item Effects: Constructs a deque with n default-inserted elements using the specified allocator.
\item Expects: T is Cpp17DefaultInsertable into *this.
\item Complexity: Linear in n.
\end{enumerate}

deque(size_type n, const T& value, const Allocator& = Allocator());
\begin{enumerate}
\item Effects: Constructs a deque with n copies of value, using the specified allocator.
\item Expects: T is Cpp17CopyInsertable into *this.
\item Complexity: Linear in n.
\end{enumerate}

template<class InputIterator>

deque(InputIterator first, InputIterator last, const Allocator& = Allocator());
\begin{enumerate}
\item Effects: Constructs a deque equal to the range [first, last), using the specified allocator.
\item Complexity: Linear in distance(first, last).
\end{enumerate}

22.3.8.3 Capacity [deque.capacity]

void resize(size_type sz);
\begin{enumerate}
\item Expects: T is Cpp17MoveInsertable and Cpp17DefaultInsertable into *this.
\item Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() default-inserted elements to the sequence.
\end{enumerate}

\begin{enumerate}
\item Expects: T is Cpp17CopyInsertable into *this.
\item Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() copies of c to the sequence.
\end{enumerate}
void shrink_to_fit();

Expect: T is Cpp17MoveInsertable into *this.

Effects: shrink_to_fit is a non-binding request to reduce memory use but does not change the size of the sequence. [Note: The request is non-binding to allow latitude for implementation-specific optimizations. —end note] If the size is equal to the old capacity, or if an exception is thrown other than by the move constructor of a non-Cpp17CopyInsertable T, then there are no effects.

Complexity: If the size is not equal to the old capacity, linear in the size of the sequence; otherwise constant.

Remarks: If the size is not equal to the old capacity, then invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

22.3.8.4 Modifiers

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);

Effects: An insertion in the middle of the deque invalidates all the iterators and references to elements of the deque. An insertion at either end of the deque invalidates all the iterators to the deque, but has no effect on the validity of references to elements of the deque.

Remarks: If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of T there are no effects. If an exception is thrown while inserting a single element at either end, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-Cpp17CopyInsertable T, the effects are unspecified.

Complexity: The complexity is linear in the number of elements inserted plus the lesser of the distances to the beginning and end of the deque. Inserting a single element at either the beginning or end of a deque always takes constant time and causes a single call to a constructor of T.

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_front();
void pop_back();

Effects: An erase operation that erases the last element of a deque invalidates only the past-the-end iterator and all iterators and references to the erased elements. An erase operation that erases the first element of a deque but not the last element invalidates only iterators and references to the erased elements. An erase operation that erases neither the first element nor the last element of a deque invalidates the past-the-end iterator and all iterators and references to all the elements of the deque. [Note: pop_front and pop_back are erase operations. —end note]

Complexity: The number of calls to the destructor of T is the same as the number of elements erased, but the number of calls to the assignment operator of T is no more than the lesser of the number of elements before the erased elements and the number of elements after the erased elements.

Throws: Nothing unless an exception is thrown by the assignment operator of T.

22.3.8.5 Erasure

template<class T, class Allocator, class U>
void erase(deque<T, Allocator>& c, const U& value);

Effects: Equivalent to: c.erase(remove(c.begin(), c.end(), value), c.end());

template<class T, class Allocator, class Predicate>
void erase_if(deque<T, Allocator>& c, Predicate pred);

Effects: Equivalent to: c.erase(remove_if(c.begin(), c.end(), pred), c.end());

22.3.9 Class template forward_list

22.3.9.1 Overview

A forward_list is a container that supports forward iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Fast random access to list elements is not supported. [Note: It is intended that forward_list have zero space or time overhead relative to a hand-written C-style singly linked list. Features that would conflict with that goal have been omitted. — end note]

A forward_list meets all of the requirements of a container (Table 62), except that the size() member function is not provided and operator== has linear complexity. A forward_list also meets all of the requirements for an allocator-aware container (Table 65). In addition, a forward_list provides the assign member functions (Table 66) and several of the optional container requirements (Table 67). Descriptions are provided here only for operations on forward_list that are not described in that table or for operations where there is additional semantic information.

[Note: Modifying any list requires access to the element preceding the first element of interest, but in a forward_list there is no constant-time way to access a preceding element. For this reason, ranges that are modified, such as those supplied to erase and splice, must be open at the beginning. — end note]

namespace std {

noexcept(noexcept(x.swap(y)));

4 An incomplete type T may be used when instantiating forward_list if the allocator meets the allocator completeness requirements (16.5.3.5.1). T shall be complete before any member of the resulting specialization of forward_list is referenced.

22.3.9.2 Constructors, copy, and assignment

[forwardlist.cons]
explicit forward_list(const Allocator&);
1 Effects: Constructs an empty forward_list object using the specified allocator.
2 Complexity: Constant.

explicit forward_list(size_type n, const Allocator& = Allocator());
3 Expects: T is Cpp17DefaultInsertable into *this.
4 Effects: Constructs a forward_list object with n default-inserted elements using the specified allocator.
5 Complexity: Linear in n.

forward_list(size_type n, const T& value, const Allocator& = Allocator());
6 Expects: T is Cpp17CopyInsertable into *this.
7 Effects: Constructs a forward_list object with n copies of value using the specified allocator.
8 Complexity: Linear in n.

template<class InputIterator>
forward_list(InputIterator first, InputIterator last, const Allocator& = Allocator());
9 Effects: Constructs a forward_list object equal to the range [first, last).
10 Complexity: Linear in distance(first, last).

22.3.9.3 Iterators

[forwardlist.iter]
iterator before_begin() noexcept;
const_iterator before_begin() const noexcept;
const_iterator cbefore_begin() const noexcept;
1 Returns: A non-dereferenceable iterator that, when incremented, is equal to the iterator returned by begin().
2 Effects: cbefore_begin() is equivalent to const_cast<forward_list const&>(*this).before_-begin().
3 Remarks: before_begin() == end() shall equal false.

22.3.9.4 Element access

[forwardlist.access]
reference front();
const_reference front() const;

Returns: *begin()

22.3.9.5 Modifiers

None of the overloads of insert_after shall affect the validity of iterators and references, and erase_after shall invalidate only iterators and references to the erased elements. If an exception is thrown during insert_after there shall be no effect. Inserting n elements into a forward_list is linear in n, and the number of calls to the copy or move constructor of T is exactly equal to n. Erasing n elements from a forward_list is linear in n and the number of calls to the destructor of type T is exactly equal to n.

template<class... Args> reference emplace_front(Args&&... args);

Effects: Inserts an object of type value_type constructed with value_type(std::forward<Args>(args)...) at the beginning of the list.

void push_front(const T& x);
void push_front(T&& x);

Effects: Inserts a copy of x at the beginning of the list.

void pop_front();
Effects: As if by erase_after(before_begin()).

iterator insert_after(const_iterator position, const T& x);
iterator insert_after(const_iterator position, T&& x);

Expects: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
Effects: Inserts a copy of x after position.
Returns: An iterator pointing to the copy of x.

iterator insert_after(const_iterator position, size_type n, const T& x);

Expects: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
Effects: Inserts n copies of x after position.
Returns: An iterator pointing to the last inserted copy of x or position if n == 0.

template<class InputIterator>
iterator insert_after(const_iterator position, InputIterator first, InputIterator last);

Expects: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()). Neither first nor last are iterators in *this.
Effects: Inserts copies of elements in [first, last) after position.
Returns: An iterator pointing to the last inserted element or position if first == last.

iterator insert_after(const_iterator position, initializer_list<T> il);

Effects: insert_after(p, il.begin(), il.end()).
Returns: An iterator pointing to the last inserted element or position if il is empty.

template<class... Args>
iterator emplace_after(const_iterator position, Args&&... args);

Expects: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
Effects: Inserts an object of type value_type constructed with value_type(std::forward<Args>(args)...) after position.
Returns: An iterator pointing to the new object.

iterator erase_after(const_iterator position);

Expects: The iterator following position is dereferenceable.
Effects: Erases the element pointed to by the iterator following position.
Returns: An iterator pointing to the element following the one that was erased, or end() if no such element exists.
22.3.9.6 Operations

In this subclause, arguments for a template parameter named Predicate or BinaryPredicate shall meet the corresponding requirements in 25.2. For merge and sort, the definitions and requirements in 25.7 apply.

```cpp
void splice_after(const_iterator position, forward_list& x);
void splice_after(const_iterator position, forward_list&& x);

Expects: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
get_allocator() == x.get_allocator() is true. addressof(x) != this is true.

Effects: Inserts the contents of x after position, and x becomes empty. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: \( \Theta(distance(x.begin(), x.end())) \)
```

```cpp
void splice_after(const_iterator position, forward_list& x, const_iterator i);
void splice_after(const_iterator position, forward_list&& x, const_iterator i);

Expects: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()). The iterator following i is a dereferenceable iterator in x. get_allocator() == x.get_allocator() is true.

Effects: Inserts the element following i into *this, following position, and removes it from x. The result is unchanged if position == i or position == ++i. Pointers and references to *++i continue to refer to the same element but as a member of *this. Iterators to *++i continue to refer to the same element, but now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: \( \Theta(1) \)
```

```cpp
void splice_after(const_iterator position, forward_list& x, const_iterator first, const_iterator last);
```
void splice_after(const_iterator position, forward_list&& x, const_iterator first, const_iterator last);

  **Expects:** position is before_begin() or is a dereferenceable iterator in the range [begin(), end()). (first, last) is a valid range in x, and all iterators in the range (first, last) are dereferenceable. position is not an iterator in the range (first, last). get_allocator() == x.get_allocator() is true.

  **Effects:** Inserts elements in the range (first, last) after position and removes the elements from x. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

  **Complexity:** $O(distance(first, last))$

size_type remove(const T& value);

  **Effects:** Erases all the elements in the list referred to by a list iterator i for which the following conditions hold: *i == value (for remove()), pred(*i) is true (for remove_if()). Invalidates only the iterators and references to the erased elements.

  **Returns:** The number of elements erased.

  **Throws:** Nothing unless an exception is thrown by the equality comparison or the predicate.

  **Remarks:** Stable (16.5.5.7).

  **Complexity:** Exactly distance(begin(), end()) applications of the corresponding predicate.

size_type unique();

  **Effects:** Erases all but the first element from every consecutive group of equal elements referred to by the iterator i in the range [first + 1, last) for which *i == *(i - 1) (for the version with no arguments) or pred(*i, *(i - 1)) (for the version with a predicate argument) holds. Invalidates only the iterators and references to the erased elements.

  **Returns:** The number of elements erased.

  **Throws:** Nothing unless an exception is thrown by the equality comparison or the predicate.

  **Complexity:** If the range [first, last) is not empty, exactly (last - first) - 1 applications of the corresponding predicate, otherwise no applications of the predicate.

void merge(forward_list& x);
void merge(forward_list&& x);

  **Expects:** *this and x are both sorted with respect to the comparator operator< (for the first two overloads) or comp (for the last two overloads), and get_allocator() == x.get_allocator() is true.

  **Effects:** Merges the two sorted ranges [begin(), end()) and [x.begin(), x.end()). x is empty after the merge. If an exception is thrown other than by a comparison there are no effects. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

  **Remarks:** Stable (16.5.5.7).

  **Complexity:** At most distance(begin(), end()) + distance(x.begin(), x.end()) - 1 comparisons.

void sort();

  **Effects:** Sorts the list according to the operator< or the comp function object. If an exception is thrown, the order of the elements in *this is unspecified. Does not affect the validity of iterators and references.

  **Remarks:** Stable (16.5.5.7).
Complexity: Approximately $N \log N$ comparisons, where $N$ is $\text{distance}(\text{begin}(), \text{end}())$.

```cpp
void reverse() noexcept;
```

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

### 22.3.9.7 Erasure

```cpp
template<class T, class Allocator, class U>
void erase(forward_list<T, Allocator>& c, const U& value);
```

Effects: Equivalent to: `erase_if(c, [&] (auto& elem) { return elem == value; });`

```cpp
template<class T, class Allocator, class Predicate>
void erase_if(forward_list<T, Allocator>& c, Predicate pred);
```

Effects: Equivalent to: `c.remove_if(pred);`

### 22.3.10 Class template list

#### 22.3.10.1 Overview

A list is a sequence container that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Unlike vectors (22.3.11) and deques (22.3.8), fast random access to list elements is not supported, but many algorithms only need sequential access anyway.

A list meets all of the requirements of a container, of a reversible container (given in two tables in 22.2), of a sequence container, including most of the optional sequence container requirements (22.2.3), and of an allocator-aware container (Table 65). The exceptions are the `operator[]` and `at` member functions, which are not provided. Descriptions are provided here only for operations on list that are not described in one of these tables or for operations where there is additional semantic information.

```cpp
namespace std {
    template<class T, class Allocator = allocator<T>>
    class list {
    public:
        // using value_type = T;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 22.2
        using difference_type = implementation-defined; // see 22.2
        using iterator = implementation-defined; // see 22.2
        using const_iterator = std::reverse_iterator<iterator>;
        using reverse_iterator = std::reverse_iterator<const_iterator>;

        list() : list(Allocator()) {} explicit list(const Allocator&);
        explicit list(size_type n, const Allocator& = Allocator());
        list(size_type n, const T& value, const Allocator& = Allocator());
        template<class InputIterator>
        list(InputIterator first, InputIterator last, const Allocator& = Allocator());
        list(const list& x);
        list(list&& x);
        list(const list&, const Allocator&);
        list(list&, const Allocator&);
        list(initializer_list<T>, const Allocator& = Allocator());

    } // list
}
```

229) These member functions are only provided by containers whose iterators are random access iterators.
-list();
list& operator=(const list& x);
list& operator=(list&& x)
   noexcept(allocator_traits<Allocator>::is_always_equal::value);
list& operator=(initializer_list<T>);

// iterator
iterator     begin()  noexcept;
const_iterator begin() const noexcept;
iterator     end() noexcept;
const_iterator end() const noexcept;
reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator rend() noexcept;

void push_front(T&& x);
void pop_front();
void push_back(const T& x);
void push_back(T&& x);
void pop_back();

template<class... Args> iterator emplace(const_iterator position, Args&&... args);
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T> il);

iterator erase(const_iterator position);
iterator erase(const_iterator position, const_iterator last);
void swap(list&) noexcept(allocator_traits<Allocator>::is_always_equal::value);
void clear() noexcept;

// 22.3.10.5, list operations
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);
void splice(const_iterator position, list&& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);
void splice(const_iterator position, list& x, const_iterator first, const_iterator last);

size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);

size_type unique();
template<class BinaryPredicate>
size_type unique(BinaryPredicate binary_pred);

void merge(list& x);
void merge(list&& x);
template<class Compare> void merge(list& x, Compare comp);
template<class Compare> void merge(list&& x, Compare comp);

void sort();
template<class Compare> void sort(Compare comp);

void reverse() noexcept;
};

template<class InputIterator, class Allocator = allocator<
   iter-value-type<InputIterator>>>
list(InputIterator, InputIterator, Allocator = Allocator())
   -> list<
   iter-value-type<InputIterator>, Allocator>;

// swap
template<class T, class Allocator>
void swap(list<T, Allocator>& x, list<T, Allocator>& y)
   noexcept(noexcept(x.swap(y)));

An incomplete type T may be used when instantiating list if the allocator meets the allocator completeness
requirements (16.5.3.5.1). T shall be complete before any member of the resulting specialization of list is referenced.

### 22.3.10.2 Constructors, copy, and assignment

**explicit list(const Allocator&)**;

*Effects*: Constructs an empty list, using the specified allocator.

*Complexity*: Constant.

**explicit list(size_type n, const Allocator&Allocator()**;

*Expects*: T is Cpp17DefaultInsertable into *this.

*Effects*: Constructs a list with n default-inserted elements using the specified allocator.

*Complexity*: Linear in n.

**list(size_type n, const T& value, const Allocator& Allocator()**;

*Expects*: T is Cpp17CopyInsertable into *this.

*Effects*: Constructs a list with n copies of value, using the specified allocator.

*Complexity*: Linear in n.

**template<class InputIterator>**

list(InputIterator first, InputIterator last, const Allocator& Allocator()**;

*Effects*: Constructs a list equal to the range [first, last).

*Complexity*: Linear in distance(first, last).
22.3.10.3 Capacity

void resize(size_type sz);

1 Expects: T is Cpp17DefaultInsertable into *this.
2 Effects: If size() < sz, appends sz - size() default-inserted elements to the sequence. If sz <= size(), equivalent to:
   list<T>::iterator it = begin();
   advance(it, sz);
   erase(it, end());

void resize(size_type sz, const T& c);

3 Expects: T is Cpp17CopyInsertable into *this.
4 Effects: As if by:
   if (sz > size())
      insert(end(), sz-size(), c);
   else if (sz < size()) {
      iterator i = begin();
      advance(i, sz);
      erase(i, end());
   } else  
       // do nothing

22.3.10.4 Modifiers

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
   iterator insert(const_iterator position, InputIterator first,
                   InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);

1 Remarks: Does not affect the validity of iterators and references. If an exception is thrown there are no effects.
2 Complexity: Insertion of a single element into a list takes constant time and exactly one call to a constructor of T. Insertion of multiple elements into a list is linear in the number of elements inserted, and the number of calls to the copy constructor or move constructor of T is exactly equal to the number of elements inserted.

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_front();
void pop_back();
void clear() noexcept;

3 Effects: Invalidates only the iterators and references to the erased elements.
4 Throws: Nothing.
5 Complexity: Erasing a single element is a constant time operation with a single call to the destructor of T. Erasing a range in a list is linear time in the size of the range and the number of calls to the destructor of type T is exactly equal to the size of the range.
22.3.10.5 Operations

Since lists allow fast insertion and erasing from the middle of a list, certain operations are provided specifically for them. In this subclause, arguments for a template parameter named `Predicate` or `BinaryPredicate` shall meet the corresponding requirements in 25.2. For `merge` and `sort`, the definitions and requirements in 25.7 apply.

`list` provides three splice operations that destructively move elements from one list to another. The behavior of splice operations is undefined if `get_allocator() != x.get_allocator()`.

```cpp
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);

Expects: addressof(x) != this
Effects: Inserts the contents of x before position and x becomes empty. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.
Throws: Nothing.
Complexity: Constant time.
```

```cpp
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);

Expects: i is a valid dereferenceable iterator of x.
Effects: Inserts an element pointed to by i from list x before position and removes the element from x. The result is unchanged if position == i or position == ++i. Pointers and references to *i continue to refer to this same element but as a member of *this. Iterators referring to *i (including i itself) continue to refer to the same element, but now behave as iterators into *this, not into x.
Throws: Nothing.
Complexity: Constant time.
```

```cpp
void splice(const_iterator position, list& x, const_iterator first, const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);

Expects: [first, last) is a valid range in x. position is not an iterator in the range [first, last).
Effects: Inserts elements in the range [first, last) before position and removes the elements from x. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.
Throws: Nothing.
Complexity: Constant time if addressof(x) == this; otherwise, linear time.
```

```cpp
size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);

Effects: Erases all the elements in the list referred to by a list iterator i for which the following conditions hold: *i == value, pred(*i) != false. Invalidates only the iterators and references to the erased elements.
Returns: The number of elements erased.
Throws: Nothing unless an exception is thrown by *i == value or pred(*i) != false.
Remarks: Stable (16.5.5.7).
Complexity: Exactly size() applications of the corresponding predicate.
```

230) As specified in 16.5.3.5, the requirements in this Clause apply only to lists whose allocators compare equal.
template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);

Effects: Erases all but the first element from every consecutive group of equal elements referred to by the iterator \(i\) in the range \([\textit{first} + 1, \textit{last})\) for which \(*i == *(i-1)\) (for the version of \texttt{unique} with no arguments) or \(\texttt{pred}(*i, *(i - 1))\) (for the version of \texttt{unique} with a predicate argument) holds. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by \(*i == *(i-1)\) or \(\texttt{pred}(*i, *(i - 1))\)

Complexity: If the range \([\textit{first}, \textit{last})\) is not empty, exactly \((\textit{last} - \textit{first}) - 1\) applications of the corresponding predicate, otherwise no applications of the predicate.

```cpp
void merge(list& x);
void merge(list&& x);
template<class Compare> void merge(list& x, Compare comp);
template<class Compare> void merge(list&& x, Compare comp);
```

Effects: If \texttt{addressof(x) == this}, does nothing; otherwise, merges the two sorted ranges \([\texttt{begin()}, \texttt{end}())\) and \([x.\texttt{begin()}, x.\texttt{end}())\). The result is a range in which the elements will be sorted in non-decreasing order according to the ordering defined by \texttt{comp}; that is, for every iterator \(i\), in the range other than the first, the condition \(\texttt{comp}(*i, *(i - 1))\) will be \texttt{false}. Pointers and references to the moved elements of \(x\) now refer to those same elements but as members of \*\texttt{this}. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into \*\texttt{this}, not into \(x\).

Remarks: Stable (16.5.5.7). If \texttt{addressof(x) != this}, the range \([x.\texttt{begin()}, x.\texttt{end}())\) is empty after the merge. No elements are copied by this operation.

Complexity: At most \(\texttt{size()} + x.\texttt{size()} - 1\) applications of \texttt{comp} if \texttt{addressof(x) != this}; otherwise, no applications of \texttt{comp} are performed. If an exception is thrown other than by a comparison there are no effects.

```cpp
void reverse() noexcept;
```

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

```cpp
void sort();
template<class Compare> void sort(Compare comp);
```

Effects: Sorts the list according to the \texttt{operator<} or a \texttt{Compare} function object. If an exception is thrown, the order of the elements in \*\texttt{this} is unspecified. Does not affect the validity of iterators and references.

Remarks: Stable (16.5.5.7).

Complexity: Approximately \(N \log N\) comparisons, where \(N == \texttt{size}()\).

### 22.3.10.6 Erasure

```cpp
template<class T, class Allocator, class U>
void erase(list<T, Allocator>& c, const U& value);
```

Effects: Equivalent to: \(\texttt{erase}(_\texttt{if}(_c, [&](_\texttt{auto} elem) \{ return elem == value; \}))\);

```cpp
template<class T, class Allocator, class Predicate>
void erase_if(list<T, Allocator>& c, Predicate pred);
```

Effects: Equivalent to: \(\texttt{c.remove\_if}(\texttt{pred})\);
22.3.11 Class template `vector`

22.3.11.1 Overview

A `vector` is a sequence container that supports (amortized) constant time insert and erase operations at the end; insert and erase in the middle take linear time. Storage management is handled automatically, though hints can be given to improve efficiency.

A `vector` meets all of the requirements of a container and of a reversible container (given in two tables in 22.2), of a sequence container, including most of the optional sequence container requirements (22.2.3), of an allocator-aware container (Table 65), and, for an element type other than `bool`, of a contiguous container (22.2.1). The exceptions are the `push_front`, `pop_front`, and `emplace_front` member functions, which are not provided. Descriptions are provided here only for operations on `vector` that are not described in one of these tables or for operations where there is additional semantic information.

namespace std {
    template<class T, class Allocator = allocator<T>>
    class vector {
    public:
        // types
        using value_type = T;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 22.2
        using difference_type = implementation-defined; // see 22.2
        using iterator = implementation-defined; // see 22.2
        using const_iterator = implementation-defined; // see 22.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // 22.3.11.2, construct/copy/destroy
        vector() noexcept(noexcept(Allocator())) : vector(Allocator()) { }
        explicit vector(const Allocator&) noexcept;
        explicit vector(size_type n, const Allocator& = Allocator());
        vector(size_type n, const T& value, const Allocator& = Allocator());
        template<class InputIterator>
        vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
        vector(const vector& x);
        vector(vector&&) noexcept;
        vector(const vector&, const Allocator&);
        vector(vector&&, const Allocator&);
        vector(initializer_list<T>, const Allocator& = Allocator());
        ~vector();
        vector& operator=(const vector& x);
        vector& operator=(vector&& x) noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
                                                allocator_traits<Allocator>::is_always_equal::value);
        vector& operator=(initializer_list<T>);
        template<class InputIterator>
        void assign(InputIterator first, InputIterator last);
        void assign(size_type n, const T& u);
        void assign(initializer_list<T>);
        allocator_type get_allocator() const noexcept;

        // iterators
        iterator begin() noexcept;
        const_iterator begin() const noexcept;
        iterator end() noexcept;
        const_iterator end() const noexcept;

        const_reverse_iterator rbegin() const noexcept;
        reverse_iterator rend() noexcept;
        const_reverse_iterator rend() const noexcept;
    }
const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// 22.3.11.3, capacity
[[nodiscard]] bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
size_type capacity() const noexcept;
void resize(size_type sz);
void resize(size_type sz, const T& c);
void reserve(size_type n);
void shrink_to_fit();

// 22.3.11.4, data access
reference operator[](size_type n);
const_reference operator[](size_type n) const;
const_reference at(size_type n) const;
reference at(size_type n);
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// 22.3.11.5, modifiers
template<class... Args> reference emplace_back(Args&&... args);
void push_back(const T& x);
void push_back(T&& x);
void pop_back();
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T> il);
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void swap(vector&);
    noexcept(algorithm_traits<Allocator>::propagate_on_container_swap::value ||
                    algorithm_traits<Allocator>::is_always_equal::value);
    void clear() noexcept;
};

template<class InputIterator, class Allocator = allocator<iter_value_type<InputIterator>>> vector(InputIterator, InputIterator, Allocator = Allocator());

// swap
template<class T, class Allocator>
    void swap(vector<T, Allocator>& x, vector<T, Allocator>& y)
    noexcept(noexcept(x.swap(y)));
}

3 An incomplete type T may be used when instantiating vector if the allocator meets the allocator completeness requirements (16.5.3.5.1). T shall be complete before any member of the resulting specialization of vector is referenced.
22.3.11.2 Constructors, copy, and assignment

`explicit vector(const Allocator& noexcept;`

*Effects:* Constructs an empty `vector`, using the specified allocator.
*Complexity:* Constant.

`explicit vector(size_type n, const Allocator& = Allocator());`

*Expects:* `T` is `Cpp17DefaultInsertable` into `*this`.
*Effects:* Constructs a `vector` with `n` default-inserted elements using the specified allocator.
*Complexity:* Linear in `n`.

`vector(size_type n, const T& value, const Allocator& = Allocator());`

*Expects:* `T` is `Cpp17CopyInsertable` into `*this`.
*Effects:* Constructs a `vector` with `n` copies of `value`, using the specified allocator.
*Complexity:* Linear in `n`.

`template<class InputIterator> vector(InputIterator first, InputIterator last, const Allocator& = Allocator());`

*Effects:* Constructs a `vector` equal to the range `[first, last)`, using the specified allocator.
*Complexity:* Makes only `N` calls to the copy constructor of `T` (where `N` is the distance between `first` and `last`) and no reallocations if iterators `first` and `last` are of forward, bidirectional, or random access categories. It makes order `N` calls to the copy constructor of `T` and order `log N` reallocations if they are just input iterators.

22.3.11.3 Capacity

`size_type capacity() const noexcept;`

*Returns:* The total number of elements that the vector can hold without requiring reallocation.
*Complexity:* Constant time.

`void reserve(size_type n);`

*Expects:* `T` is `Cpp17MoveInsertable` into `*this`.
*Effects:* A directive that informs a `vector` of a planned change in size, so that it can manage the storage allocation accordingly. After `reserve()`, `capacity()` is greater or equal to the argument of `reserve` if reallocation happens; and equal to the previous value of `capacity()` otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of `reserve()`. If an exception is thrown other than by the move constructor of a non-`Cpp17CopyInsertable` type, there are no effects.
*Complexity:* It does not change the size of the sequence and takes at most linear time in the size of the sequence.
*Throws:* `length_error` if `n > max_size()`.231

*Remarks:* Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator. [Note: If no reallocation happens, they remain valid. — end note] No reallocation shall take place during insertions that happen after a call to `reserve()` until an insertion would make the size of the vector greater than the value of `capacity()`.

`void shrink_to_fit();`

*Expects:* `T` is `Cpp17MoveInsertable` into `*this`.
*Effects:* `shrink_to_fit` is a non-binding request to reduce `capacity()` to `size()`. [Note: The request is non-binding to allow latitude for implementation-specific optimizations. — end note] It does not increase `capacity()`, but may reduce `capacity()` by causing reallocation. If an exception is thrown other than by the move constructor of a non-`Cpp17CopyInsertable` `T` there are no effects.

231) `reserve()` uses `Allocator::allocate()` which may throw an appropriate exception.
Complexity: If reallocation happens, linear in the size of the sequence.
Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator. [Note: If no reallocation happens, they remain valid. —end note]

```cpp
void swap(vector&amp; x)
    noexcept(algorithm_traits&lt;Allocator&gt;::propagate_on_container_swap::value ||
             allocator_traits&lt;Allocator&gt;::is_always_equal::value);
```

Effects: Exchanges the contents and capacity() of *this with that of x.
Complexity: Constant time.

```cpp
void resize(size_type sz);
```

Effects: Exchanges the contents and capacity() of *this with that of x.
Complexity: Constant time.

```cpp
Effects: If sz &lt; size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() default-inserted elements to the sequence.
Remarks: If an exception is thrown other than by the move constructor of a non-Cpp17CopyInsertable T there are no effects.

```cpp
void resize(size_type sz, const T&amp; c);
```

Effects: If sz &lt; size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() copies of c to the sequence.
Remarks: If an exception is thrown there are no effects.

### 22.3.11.4 Data

```cpp
T* data() noexcept;
const T* data() const noexcept;
```

Returns: A pointer such that [data(), data() + size()) is a valid range. For a non-empty vector, data() == addressof(front()).
Complexity: Constant time.

### 22.3.11.5 Modifiers

```cpp
iterator insert(const_iterator position, const T&amp; x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T&amp; x);
```

```cpp
template<class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
```

```cpp
iterator insert(const_iterator position, initializer_list&lt;T&gt;);
```

```cpp
template&lt;class... Args&gt; reference emplace_back(Args&amp;&amp;... args);

template&lt;class... Args&gt; iterator emplace(const_iterator position, Args&amp;&amp;... args);
```

```cpp
void push_back(const T&amp; x);
void push_back(T&amp; x);
```

Remarks: Causes reallocation if the new size is greater than the old capacity. Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator. If no reallocation happens, then references, pointers, and iterators before the insertion point remain valid but those at or after the insertion point, including the past-the-end iterator, are invalidated. If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of T or by any InputIterator operation there are no effects. If an exception is thrown while inserting a single element at the end and T is Cpp17CopyInsertable or is_nothrow_move_constructible_v&lt;T&gt; is true, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-Cpp17CopyInsertable T, the effects are unspecified.

Complexity: If reallocation happens, linear in the number of elements of the resulting vector; otherwise, linear in the number of elements inserted plus the distance to the end of the vector.
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_back();

Effects: Invalidates iterators and references at or after the point of the erase.

Complexity: The destructor of T is called the number of times equal to the number of the elements
erased, but the assignment operator of T is called the number of times equal to the number of elements
in the vector after the erased elements.

Throws: Nothing unless an exception is thrown by the assignment operator or move assignment operator
of T.

22.3.11.6 Erasure

template<class T, class Allocator, class U>
void erase(vector<T, Allocator>& c, const U& value);

Effects: Equivalent to: c.erase(remove(c.begin(), c.end(), value), c.end());

template<class T, class Allocator, class Predicate>
void erase_if(vector<T, Allocator>& c, Predicate pred);

Effects: Equivalent to: c.erase(remove_if(c.begin(), c.end(), pred), c.end());

22.3.12 Class vector<bool>

To optimize space allocation, a specialization of vector for bool elements is provided:

namespace std {
  template<class Allocator>
  class vector<bool, Allocator> {
    public:
      // types
      using value_type = bool;
      using allocator_type = Allocator;
      using pointer = implementation-defined;
      using const_pointer = implementation-defined;
      using const_reference = bool;
      using size_type = implementation-defined; // see 22.2
      using difference_type = implementation-defined; // see 22.2
      using iterator = implementation-defined; // see 22.2
      using const_iterator = implementation-defined; // see 22.2
      using reverse_iterator = std::reverse_iterator<iterator>;
      using const_reverse_iterator = std::reverse_iterator<const_iterator>;

      // bit reference
      class reference {
        friend class vector;
        reference() noexcept;
        reference(const reference&) = default;
        operator bool() const noexcept;
        operator=(const bool x) noexcept;
        operator=(const reference& x) noexcept;
        void flip() noexcept; // flips the bit
      };

      // construct/copy/destroy
      vector() : vector(Allocator()) {}
      explicit vector(const Allocator&);
      explicit vector(size_type n, const Allocator& = Allocator());
      vector(size_type n, const bool& value, const Allocator& = Allocator());
      template<InputIterator>
        vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
      vector(const vector& x);
      vector(vector&& x);

    § 22.3.12
vector(const vector&, const Allocator&);
vector(vector&&, const Allocator&);
vector(initializer_list<bool>, const Allocator& = Allocator());
~vector();
vector& operator=(const vector& x);
vector& operator=(vector&& x);
vector& operator=(initializer_list<bool>);
template<class InputIterator>
  void assign(InputIterator first, InputIterator last);
void assign(size_type n, const bool& t);
void assign(initializer_list<bool>);
allocator_type get_allocator() const noexcept;

// iterators
iterator begin() noexcept;
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;
const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// capacity
[[nodiscard]] bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
size_type capacity() const noexcept;
void resize(size_type sz, bool c = false);
void reserve(size_type n);
void shrink_to_fit();

// element access
reference operator[](size_type n);
const_reference operator[](size_type n) const;
const_reference at(size_type n) const;
reference at(size_type n);
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// modifiers
template<class... Args> reference emplace_back(Args&&... args);
void push_back(const bool& x);
void pop_back();
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
iterator insert(const_iterator position, const bool& x);
iterator insert(const_iterator position, size_type n, const bool& x);
template<class InputIterator>
  iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<bool> il);

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void swap(vector&);
static void swap(reference x, reference y) noexcept;
void flip() noexcept; // flips all bits
void clear() noexcept;
Unless described below, all operations have the same requirements and semantics as the primary `vector` template, except that operations dealing with the `bool` value type map to bit values in the container storage and `allocator_traits::construct` (20.10.9.2) is not used to construct these values.

3 There is no requirement that the data be stored as a contiguous allocation of `bool` values. A space-optimized representation of bits is recommended instead.

4 `reference` is a class that simulates the behavior of references of a single bit in `vector<bool>`. The conversion function returns `true` when the bit is set, and `false` otherwise. The assignment operator sets the bit when the argument is (convertible to) `true` and clears it otherwise. `flip` reverses the state of the bit.

```cpp
void flip() noexcept;
```

5 **Effects:** Replaces each element in the container with its complement.

```cpp
class reference {
    static void swap(reference x, reference y) noexcept;
}
```

6 **Effects:** Exchanges the contents of `x` and `y` as if by:

```cpp
bool b = x;
x = y;
y = b;
```

```cpp
template<class Allocator> struct hash<vector<bool, Allocator>>;
```

7 The specialization is enabled (20.14.18).

## 22.4 Associative containers

### 22.4.1 In general

1 The header `<map>` defines the class templates `map` and `multimap`; the header `<set>` defines the class templates `set` and `multiset`.

2 The following exposition-only alias templates may appear in deduction guides for associative containers:

```cpp
namespace std {
    // 22.4.4, class template
    template<class Key, class T, class Compare = less<Key>,
    class Allocator = allocator<pair<const Key, T>>>
    class map;
}
```

22.4.2 Header `<map>` synopsis

```cpp
#include < initializer_list >
```

```cpp
namespace std {
    // 22.4.4, class template
    template<class Key, class T, class Compare = less<Key>,
    class Allocator = allocator<pair<const Key, T>>>
    bool operator==(const map<Key, T, Compare, Allocator>& x,
    const map<Key, T, Compare, Allocator>& y);
    template<class Key, class T, class Compare, class Allocator>
    bool operator!=(const map<Key, T, Compare, Allocator>& x,
    const map<Key, T, Compare, Allocator>& y);
    template<class Key, class T, class Compare, class Allocator>
    bool operator==(const map<Key, T, Compare, Allocator>& x,
    const map<Key, T, Compare, Allocator>& y);
    template<class Key, class T, class Compare, class Allocator>
    bool operator!=(const map<Key, T, Compare, Allocator>& x,
    const map<Key, T, Compare, Allocator>& y);
```
template<class Key, class T, class Compare, class Allocator>
bool operator< (const map<Key, T, Compare, Allocator>& x,
               const map<Key, T, Compare, Allocator>& y);

template<class Key, class T, class Compare, class Allocator>
bool operator> (const map<Key, T, Compare, Allocator>& x,
               const map<Key, T, Compare, Allocator>& y);

template<class Key, class T, class Compare, class Allocator>
bool operator<=(const map<Key, T, Compare, Allocator>& x,
                const map<Key, T, Compare, Allocator>& y);

template<class Key, class T, class Compare, class Allocator>
bool operator>=(const map<Key, T, Compare, Allocator>& x,
                const map<Key, T, Compare, Allocator>& y);

template<class Key, class T, class Compare, class Allocator>
void swap(map<Key, T, Compare, Allocator>& x,
          map<Key, T, Compare, Allocator>& y)
  noexcept(noexcept(x.swap(y)));

template<class Key, class T, class Compare, class Allocator, class Predicate>
void erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);

// 22.4.5, class template multimap
template<class Key, class T, class Compare = less<Key>,
         class Allocator = allocator<pair<const Key, T>>> class multimap;

#include <algorithm>
#include <utility>

namespace pmr {
  using map = std::map<Key, T, Compare, polymorphic_allocator<pair<const Key, T>>>;
  using multimap = std::multimap<Key, T, Compare, polymorphic_allocator<pair<const Key, T>>>;
}

§ 22.4.2
22.4.3 Header <set> synopsis

#include <initializer_list>

namespace std {
    // 22.4.6, class template set
    template<class Key, class Compare = less<Key>, class Allocator = allocator<Key>>
        class set;

        template<class Key, class Compare, class Allocator>
            bool operator==(const set<Key, Compare, Allocator>& x,
                            const set<Key, Compare, Allocator>& y);

        template<class Key, class Compare, class Allocator>
            bool operator!=(const set<Key, Compare, Allocator>& x,
                            const set<Key, Compare, Allocator>& y);

        template<class Key, class Compare, class Allocator>
            bool operator< (const set<Key, Compare, Allocator>& x,
                            const set<Key, Compare, Allocator>& y);

        template<class Key, class Compare, class Allocator>
            bool operator> (const set<Key, Compare, Allocator>& x,
                            const set<Key, Compare, Allocator>& y);

        template<class Key, class Compare, class Allocator>
            bool operator<=(const set<Key, Compare, Allocator>& x,
                            const set<Key, Compare, Allocator>& y);

        template<class Key, class Compare, class Allocator>
            bool operator>=(const set<Key, Compare, Allocator>& x,
                            const set<Key, Compare, Allocator>& y);

        template<class Key, class Compare, class Allocator>

22.4.4 Class template map

22.4.4.1 Overview

1 A map is an associative container that supports unique keys (contains at most one of each key value) and
provides for fast retrieval of values of another type T based on the keys. The map class supports bidirectional
iterators.

2 A map meets all of the requirements of a container, of a reversible container (22.2), of an associative
container (22.2.6), and of an allocator-aware container (Table 65). A map also provides most operations
described in 22.2.6 for unique keys. This means that a map supports the a_uniq operations in 22.2.6 but not
the a_eq operations. For a map<Key,T> the key_type is Key and the value_type is pair<const Key,T>.
Descriptions are provided here only for operations on map that are not described in one of those tables or for
operations where there is additional semantic information.

namespace std {
    template<class Key, class T, class Compare = less<Key>,
             class Allocator = allocator<pair<const Key, T>>>
    class map {
        public:
            // types
            using key_type = Key;
            using mapped_type = T;
            using value_type = pair<const Key, T>;
            using key_compare = Compare;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 22.2

        noexcept(noexcept(x.swap(y)));

22.4.4.2 Constructors, copy, and assignment [map.cons]

explicit map(const Compare& comp, const Allocator& = Allocator());

    Effects: Constructs an empty map using the specified comparison object and allocator.

    Complexity: Constant.

template<class InputIterator>
    map(InputIterator first, InputIterator last,
        const Compare& comp = Compare(), const Allocator& = Allocator());

    Effects: Constructs an empty map using the specified comparison object and allocator, and inserts
    elements from the range [first, last).

    Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise
    N log N, where N is last - first.

22.4.4.3 Element access [map.access]

    mapped_type& operator[](const key_type& x);

    Effects: Equivalent to: return try_emplace(x).first->second;

    mapped_type& operator[](key_type&& x);

    Effects: Equivalent to: return try_emplace(move(x)).first->second;

    mapped_type& at(const key_type& x);
    const mapped_type& at(const key_type& x) const;

    Returns: A reference to the mapped_type corresponding to x in *this.

    Throws: An exception object of type out_of_range if no such element is present.
Complexity: Logarithmic.

22.4.4.4 Modifiers

[map.modifiers]

template<class P>
  pair<iterator, bool> insert(P&& x);
template<class P>
  iterator insert(const_iterator position, P&& x);

Constraints: is_constructible_v<value_type, P&&> is true.

Effects: The first form is equivalent to return emplace(std::forward<P>(x)). The second form is equivalent to return emplace_hint(position, std::forward<P>(x)).

template<class... Args>
  pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);
template<class... Args>
  iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);

Expects: value_type is Cpp17EmplaceConstructible into map from piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class... Args>
  pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
template<class... Args>
  iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);

Expects: value_type is Cpp17EmplaceConstructible into map from piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
  pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
template<class M>
  iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.

Effects: value_type is Cpp17EmplaceConstructible into map from k, forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with k, std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
  pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
template<class M>
  iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.
Expects: value_type is Cpp17EmplaceConstructible into map from move(k), forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with std::move(k), std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

### 22.4.4.5 Erasure [map.erasure]

```cpp
template<class Key, class T, class Compare, class Allocator, class Predicate>
void erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:

```cpp
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
```

### 22.4.5 Class template multimap [multimap]

#### 22.4.5.1 Overview [multimap.overview]

A multimap is an associative container that supports equivalent keys (possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type T based on the keys. The multimap class supports bidirectional iterators.

A multimap meets all of the requirements of a container and of a reversible container (22.2), of an associative container (22.2.6), and of an allocator-aware container (Table 65). A multimap also provides most operations described in 22.2.6 for equal keys. This means that a multimap supports the key_eq operations in 22.2.6 but not the key_uniq operations. For a multimap<Key,T> the key_type is Key and the value_type is pair<const Key, T>. Descriptions are provided here only for operations on multimap that are not described in one of those tables or for operations where there is additional semantic information.

```cpp
namespace std {
    template<class Key, class T, class Compare = less<Key>,
             class Allocator = allocator<pair<const Key, T>>>
    class multimap {
        public:
            // types
            using key_type = Key;
            using mapped_type = T;
            using value_type = pair<const Key, T>;
            using key_compare = Compare;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 22.2
            using difference_type = implementation-defined; // see 22.2
            using iterator = implementation-defined; // see 22.2
            using const_iterator = implementation-defined; // see 22.2
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    class Allocator = allocator<iter-to-alloc-type<InputIterator>>>
multimap(InputIterator, InputIterator, Compare = Compare(), Allocator = Allocator())
    -> multimap<iter-key-type<InputIterator>, iter-mapped-type<InputIterator>,
    Compare, Allocator>;

template<class Key, class T, class Compare = less<Key>,
    class Allocator = allocator<pair<const Key, T>>> multimap(initializer_list<pair<Key, T>>, Compare = Compare(), Allocator = Allocator())
    -> multimap<Key, T, Compare, Allocator>;

template<class InputIterator, class Allocator>
multimap<InputIterator, InputIterator, Allocator>)
    -> multimap<iter-key-type<InputIterator>, iter-mapped-type<InputIterator>,
    less<iter-key-type<InputIterator>>, Allocator>;

template<class Key, class T, class Allocator>
multimap(initializer_list<pair<Key, T>>, Allocator)
    -> multimap<Key, T, less<Key>, Allocator>;

// swap
template<class Key, class T, class Compare, class Allocator>
void swap(multimap<Key, T, Compare, Allocator>& x,
    multimap<Key, T, Compare, Allocator>& y)
    noexcept(noexcept(x.swap(y))));

22.4.5.2 Constructors [multimap.cons]

explicit multimap(const Compare& comp, const Allocator& = Allocator());

1 Effects: Constructs an empty multimap using the specified comparison object and allocator.

2 Complexity: Constant.

template<class InputIterator>
multimap(InputIterator first, InputIterator last,
    const Compare& comp = Compare(),
    const Allocator& = Allocator());

3 Effects: Constructs an empty multimap using the specified comparison object and allocator, and inserts elements from the range [first, last).

4 Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise N log N, where N is last - first.

22.4.5.3 Modifiers [multimap.modifiers]

template<class P> iterator insert(P&& x);

1 Mandates: is_constructible_v<value_type, P&&> is true.

2 Effects: The first form is equivalent to return emplace(std::forward<P>(x)). The second form is equivalent to return emplace_hint(position, std::forward<P>(x)).

22.4.5.4 Erasure [multimap.erosure]

template<class Key, class T, class Compare, class Allocator, class Predicate>
void erase_if(multimap<Key, T, Compare, Allocator>& c, Predicate pred);

1 Effects: Equivalent to:

    for (auto i = c.begin(), last = c.end(); i != last; ) {
        if (pred(*i)) {
            i = c.erase(i);
        } else {
            ++i;
    }
A **set** is an associative container that supports unique keys (contains at most one of each key value) and provides for fast retrieval of the keys themselves. The **set** class supports bidirectional iterators.

A **set** meets all of the requirements of a container, of a reversible container (22.2), of an associative container (22.2.6), and of an allocator-aware container (Table 65). A **set** also provides most operations described in 22.2.6 for unique keys. This means that a **set** supports the a\_uniq operations in 22.2.6 but not the a\_eq operations. For a **set<Key>** both the key\_type and value\_type are Key. Descriptions are provided here only for operations on **set** that are not described in one of these tables and for operations where there is additional semantic information.

22.4.6.2 Constructors, copy, and assignment

explicit set(const Compare& comp, const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison objects and allocator.

Complexity: Constant.

template<class InputIterator>
set(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison object and allocator, and inserts elements from the range [first, last).
Complexity: Linear in N if the range \([\text{first, last})\) is already sorted using \(\text{comp}\) and otherwise \(N \log N\), where \(N\) is \(\text{last} - \text{first}\).

22.4.6.3 Erasure

```cpp
template<class Key, class Compare, class Allocator, class Predicate>
void erase_if(set<Key, Compare, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:
```cpp```
```
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
```
```
```

22.4.7 Class template multiset

22.4.7.1 Overview

A `multiset` is an associative container that supports equivalent keys (possibly contains multiple copies of the same key value) and provides for fast retrieval of the keys themselves. The `multiset` class supports bidirectional iterators.

A `multiset` meets all of the requirements of a container, of a reversible container (22.2), of an associative container (22.2.6), and of an allocator-aware container (Table 65). `multiset` also provides most operations described in 22.2.6 for duplicate keys. This means that a `multiset` supports the `a_eq` operations in 22.2.6 but not the `a_uniq` operations. For a `multiset<Key>` both the `key_type` and `value_type` are `Key`. Descriptions are provided here only for operations on `multiset` that are not described in one of these tables and for operations where there is additional semantic information.

```cpp```
```
namespace std {
  template<class Key, class Compare = less<Key>,
           class Allocator = allocator<Key>>
  class multiset {
    public:
      // types
      using key_type = Key;
      using key_compare = Compare;
      using value_type = Key;
      using value_compare = Compare;
      using allocator_type = Allocator;
      using pointer = typename allocator_traits<Allocator>::pointer;
      using const_pointer = typename allocator_traits<Allocator>::const_pointer;
      using reference = value_type&;
      using const_reference = const value_type&;
      using size_type = implementation-defined; // see 22.2
      using difference_type = implementation-defined; // see 22.2
      using iterator = implementation-defined; // see 22.2
      using const_iterator = implementation-defined; // see 22.2
      using reverse_iterator = std::reverse_iterator<iterator>;
      using const_reverse_iterator = std::reverse_iterator<const_iterator>;
      using node_type = unspecified;

      // 22.4.7.2, construct/copy/destroy
      multiset(): multiset(Compare()) {}
      explicit multiset(const Compare& comp, const Allocator& = Allocator());
      template<class InputIterator>
      multiset(InputIterator first, InputIterator last,

noexcept(noexcept(x.swap(y)));

22.4.7.2 Constructors

explicit multiset(const Compare& comp, const Allocator& = Allocator());

Effects: Constructs an empty multiset using the specified comparison object and allocator.

Complexity: Constant.

template<class InputIterator>
multiset(InputIterator first, InputIterator last,
const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty multiset using the specified comparison object and allocator, and inserts elements from the range \([\text{first}, \text{last})\).

Complexity: Linear in \(N\) if the range \([\text{first}, \text{last})\) is already sorted using \(\text{comp}\) and otherwise \(N \log N\), where \(N\) is \(\text{last} - \text{first}\).

22.4.7.3 Erasure

template<class Key, class Compare, class Allocator, class Predicate>
void erase_if(multiset<Key, Compare, Allocator>& c, Predicate pred);

Effects: Equivalent to:

```cpp
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
```

22.5 Unordered associative containers

22.5.1 In general

The header `<unordered_map>` defines the class templates `unordered_map` and `unordered_multimap`; the header `<unordered_set>` defines the class templates `unordered_set` and `unordered_multiset`.

The exposition-only alias templates `iter-value-type`, `iter-key-type`, `iter-mapped-type`, and `iter-to-alloc-type` defined in 22.4.1 may appear in deduction guides for unordered containers.

22.5.2 Header `<unordered_map>` synopsis

```cpp
#include <initializer_list>

namespace std {

    // 22.5.4, class template unordered_map
    template<class Key,
        class T,
        class Hash = hash<Key>,
        class Pred = equal_to<Key>,
        class Alloc = allocator<pair<const Key, T>>>
        class unordered_map;

    // 22.5.5, class template unordered_multimap
    template<class Key,
        class T,
        class Hash = hash<Key>,
        class Pred = equal_to<Key>,
        class Alloc = allocator<pair<const Key, T>>>
        class unordered_multimap;

}
```
template<class Key, class T, class Hash, class Pred, class Alloc>
bool operator==(const unordered_map<Key, T, Hash, Pred, Alloc>& a,
const unordered_map<Key, T, Hash, Pred, Alloc>& b);

template<class Key, class T, class Hash, class Pred, class Alloc>
bool operator!=(const unordered_map<Key, T, Hash, Pred, Alloc>& a,
const unordered_map<Key, T, Hash, Pred, Alloc>& b);

template<class Key, class T, class Hash, class Pred, class Alloc>
bool operator==(const unordered_multimap<Key, T, Hash, Pred, Alloc>& a,
const unordered_multimap<Key, T, Hash, Pred, Alloc>& b);

template<class Key, class T, class Hash, class Pred, class Alloc>
bool operator!=(const unordered_multimap<Key, T, Hash, Pred, Alloc>& a,
const unordered_multimap<Key, T, Hash, Pred, Alloc>& b);

template<class Key, class T, class Hash, class Pred, class Alloc>
void swap(unordered_map<Key, T, Hash, Pred, Alloc>& x,
unordered_map<Key, T, Hash, Pred, Alloc>& y)
noexcept(noexcept(x.swap(y)));

template<class Key, class T, class Hash, class Pred, class Alloc>
void swap(unordered_multimap<Key, T, Hash, Pred, Alloc>& x,
unordered_multimap<Key, T, Hash, Pred, Alloc>& y)
noexcept(noexcept(x.swap(y)));

template<class K, class T, class H, class P, class A, class Predicate>
void erase_if(unordered_map<K, T, H, P, A>& c, Predicate pred);

template<class K, class T, class H, class P, class A, class Predicate>
void erase_if(unordered_multimap<K, T, H, P, A>& c, Predicate pred);

namespace pmr {
    template<class Key,
class T,
class Hash = hash<Key>,
class Pred = equal_to<Key>>
using unordered_map =
std::unordered_map<Key, T, Hash, Pred,
polymorphic_allocator<pair<const Key, T>>;}

namespace pmr {
    template<class Key,
class T,
class Hash = hash<Key>,
class Pred = equal_to<Key>>
using unordered_multimap =
std::unordered_multimap<Key, T, Hash, Pred,
polymorphic_allocator<pair<const Key, T>>;}
}

22.5.3 Header <unordered_set> synopsis

#include <initializer_list>

namespace std {
    // 22.5.6, class template unordered_set
template<
class Key,
class Hash = hash<Key>,
class Pred = equal_to<Key>,
class Alloc = allocator<Key>>
class unordered_set;

§ 22.5.3

22.5.4 Class template unordered_map

22.5.4.1 Overview

An unordered_map is an unordered associative container that supports unique keys (an unordered_map contains at most one of each key value) and that associates values of another type mapped_type with the keys. The unordered_map class supports forward iterators.

An unordered_map meets all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 65). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_map supports the a_uniq operations in that table, not the a_eq operations. For an unordered_map<Key, T> the key type is Key, the mapped type is T, and the value type is pair<const Key, T>.

§ 22.5.4.1
This subclause only describes operations on `unordered_map` that are not described in one of the requirement tables, or for which there is additional semantic information.

```cpp
namespace std {
  template<class Key,
           class T,
           class Hash = hash<Key>,
           class Pred = equal_to<Key>,
           class Allocator = allocator<pair<const Key, T>>>
  class unordered_map {
    public:
      using key_type = Key;
      using mapped_type = T;
      using value_type = pair<const Key, T>;
      using hasher = Hash;
      using key_equal = see 22.2.7;
      using allocator_type = Allocator;
      using pointer = typename allocator_traits<Allocator>::pointer;
      using const_pointer = typename allocator_traits<Allocator>::const_pointer;
      using reference = value_type&;
      using const_reference = const value_type&;
      using size_type = implementation-defined; // see 22.2
      using difference_type = implementation-defined; // see 22.2
      using iterator = implementation-defined; // see 22.2
      using const_iterator = implementation-defined; // see 22.2
      using local_iterator = implementation-defined; // see 22.2
      using const_local_iterator = implementation-defined; // see 22.2
      using node_type = unspecified;
      using insert_return_type = insert-return-type<iterator, node_type>;

      // 22.5.4.2, construct/copy/destroy
      unordered_map();
      explicit unordered_map(size_type n,
                              const hasher& hf = hasher(),
                              const key_equal& eql = key_equal(),
                              const allocator_type& a = allocator_type());
      template<class InputIterator>
      unordered_map(InputIterator f, InputIterator l,
                     size_type n = see below,
                     const hasher& hf = hasher(),
                     const key_equal& eql = key_equal(),
                     const allocator_type& a = allocator_type());

noexcept(noexcept(x.swap(y)));
}

A size_type parameter type in an unordered_map deduction guide refers to the size_type member type of the type deduced by the deduction guide.

22.5.4.2 Constructors [unord.map.cnstr]

unordered_map() : unordered_map(size_type(see below)) { }
explicit unordered_map(size_type n,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_map using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.

template<class InputIterator>
unordered_map(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
unordered_map(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_map using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

22.5.4.3 Element access [unord.map.elem]

mapped_type& operator[](const key_type& k);
Effects: Equivalent to: return try_emplace(k).first->second;

mapped_type& operator[](key_type&& k);
Effects: Equivalent to: return try_emplace(move(k)).first->second;

mapped_type& at(const key_type& k);
const mapped_type& at(const key_type& k) const;
Returns: A reference to x.second, where x is the (unique) element whose key is equivalent to k.

Throws: An exception object of type out_of_range if no such element is present.

22.5.4.4 Modifiers [unord.map.modifiers]

template<class P>
pair<iterator, bool> insert(P&& obj);
Constraints: is_constructible_v<value_type, P&&> is true.
Effects: Equivalent to: return emplace(std::forward<P>(obj));

template<class P>
iterator insert(const_iterator hint, P&& obj);

Constraints: is_constructible_v<value_type, P&&> is true.

Effects: Equivalent to: return emplace_hint(hint, std::forward<P>(obj));

template<class... Args>
pair<iterator, bool> try_emplace(const_iterator hint, P&& obj);

Expects: value_type is Cpp17EmplaceConstructible into unordered_map from piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class... Args>
pair<iterator, bool> try_emplace(const_iterator hint, const key_type& k, Args&&... args);

template<class... Args>
iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);

Expects: value_type is Cpp17EmplaceConstructible into unordered_map from piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.

Expects: value_type is Cpp17EmplaceConstructible into unordered_map from k, std::forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with k, std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.

Expects: value_type is Cpp17EmplaceConstructible into unordered_map from std::move(k), std::forward<M>(obj).

§ 22.5.4.4
22.5.4.5 Erasure

```cpp
template<class K, class T, class H, class P, class A, class Predicate>
void erase_if(unordered_map<K, T, H, P, A>& c, Predicate pred);
```

**Effects:** Equivalent to:

```cpp
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
```

22.5.5 Class template unordered_multimap

22.5.5.1 Overview

An unordered_multimap is an unordered associative container that supports equivalent keys (an instance of unordered_multimap may contain multiple copies of each key value) and that associates values of another type mapped_type with the keys. The unordered_multimap class supports forward iterators.

An unordered_multimap meets all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 65). It provides the operations described in the preceding requirements table for equivalent keys; that is, an unordered_multimap supports the a_eq operations in that table, not the a_uniq operations. For an unordered_multimap<Key, T> the key type is Key, the mapped type is T, and the value type is pair<const Key, T>.

This subclause only describes operations on unordered_multimap that are not described in one of the requirement tables, or for which there is additional semantic information.

```cpp
namespace std {
    template<class Key,
             class T,
             class Hash = hash<Key>,
             class Pred = equal_to<Key>,
             class Allocator = allocator<pair<const Key, T>>>
    class unordered_multimap {
        public:
            // types
            using key_type = Key;
            using mapped_type = T;
            using value_type = pair<const Key, T>;
            using hasher = Hash;
            using key_equal = see 22.2.7;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 22.2
            using difference_type = implementation-defined; // see 22.2
            using iterator = implementation-defined; // see 22.2
            using const_iterator = implementation-defined; // see 22.2
            using local_iterator = implementation-defined; // see 22.2
            using const_local_iterator = implementation-defined; // see 22.2
            using node_type = unspecified;

    } // class
```

// swap
template<class Key, class T, class Hash, class Pred, class Alloc>
void swap(unordered_multimap<Key, T, Hash, Pred, Alloc>& x, unordered_multimap<Key, T, Hash, Pred, Alloc>& y)
noexcept(noexcept(x.swap(y)));

A size_type parameter type in an unordered_multimap deduction guide refers to the size_type member type of the type deduced by the deduction guide.

22.5.5.2 Constructors

unordered_multimap() : unordered_multimap(size_type(see below)) { }
explicit unordered_multimap(size_type n,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multimap using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.

template<class InputIterator>
unordered_multimap(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
unordered_multimap(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multimap using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

22.5.5.3 Modifiers

template<class P>
iterator insert(P&& obj);

Constraints: is_constructible_v<value_type, P&&> is true.

Effects: Equivalent to: return emplace(std::forward<P>(obj));
template<class P>
    iterator insert(const_iterator hint, P&& obj);

3 Constraints: `is_constructible_v<value_type, P&&>` is true.

4 Effects: Equivalent to: return emplace_hint(hint, std::forward<P>(obj));

22.5.5.4 Erasure

template<class K, class T, class H, class P, class A, class Predicate>
    void erase_if(unordered_multimap<K, T, H, P, A>& c, Predicate pred);

1 Effects: Equivalent to:
   for (auto i = c.begin(), last = c.end(); i != last; ) {
       if (pred(*i)) {
           i = c.erase(i);
       } else {
           ++i;
       }
   }

22.5.6 Class template unordered_set

22.5.6.1 Overview

An unordered_set is an unordered associative container that supports unique keys (an unordered_set contains at most one of each key value) and in which the elements’ keys are the elements themselves. The unordered_set class supports forward iterators.

An unordered_set meets all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 65). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_set supports the a_uniq operations in that table, not the a_eq operations. For an unordered_set<Key> the key type and the value type are both Key. The iterator and const_iterator types are both constant iterator types. It is unspecified whether they are the same type.

This subclause only describes operations on unordered_set that are not described in one of the requirement tables, or for which there is additional semantic information.

template<class T, class Hash, class Allocator>
unordered_set(initializer_list<T>, typename see below::size_type, Hash, Allocator)
    -> unordered_set<T, Hash, equal_to<T>, Allocator>;
// swap
template<class Key, class Hash, class Pred, class Alloc>
void swap(unordered_set<Key, Hash, Pred, Alloc>& x,
          unordered_set<Key, Hash, Pred, Alloc>& y)
    noexcept(noexcept(x.swap(y)));}

A size_type parameter type in an unordered_set deduction guide refers to the size_type member type of the type deduced by the deduction guide.

22.5.6.2 Constructors [unord.set.cnstr]

unordered_set() : unordered_set(size_type(see below)) { }
explicit unordered_set(size_type n,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type()); 1

Effects: Constructs an empty unordered_set using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.

template<class InputIterator>
unordered_set(InputIterator f, InputIterator l,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());
unordered_set(initializer_list<value_type> il,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type()); 3

Effects: Constructs an empty unordered_set using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

22.5.6.3 Erasure [unord.set.erasure]

template<class K, class H, class P, class A, class Predicate>
void erase_if(unordered_set<K, H, P, A>& c, Predicate pred); 1

Effects: Equivalent to:

for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}

22.5.7 Class template unordered_multiset [unord.multiset]

22.5.7.1 Overview [unord.multiset.overview]

An unordered_multiset is an unordered associative container that supports equivalent keys (an instance of unordered_multiset may contain multiple copies of the same key value) and in which each element’s key is the element itself. The unordered_multiset class supports forward iterators.

An unordered_multiset meets all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 65). It provides the operations described in the preceding requirements table for equivalent keys; that is, an unordered_multiset supports the a_eq operations in
that table, not the `a_uniq` operations. For an `unordered_multiset<Key>` the key type and the value type are both `Key`. The iterator and `const_iterator` types are both constant iterator types. It is unspecified whether they are the same type.

3 This subclause only describes operations on `unordered_multiset` that are not described in one of the requirement tables, or for which there is additional semantic information.

```cpp
namespace std {
    template<class Key, 
             class Hash = hash<Key>, 
             class Pred = equal_to<Key>, 
             class Allocator = allocator<Key>>
    class unordered_multiset {
    public:
        // types
        using key_type = Key;
        using value_type = Key;
        using hasher = Hash;
        using key_equal = see 22.2.7;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 22.2
        using difference_type = implementation-defined; // see 22.2
        using iterator = implementation-defined; // see 22.2
        using const_iterator = implementation-defined; // see 22.2
        using local_iterator = implementation-defined; // see 22.2
        using const_local_iterator = implementation-defined; // see 22.2
        using node_type = unspecified;
    
    // 22.5.7.2, construct/copy/destroy
    unordered_multiset();
    explicit unordered_multiset(size_type n,

};

template<class InputIterator,
class Hash = hash<iter_value_type<InputIterator>>>,
class Pred = equal_to<iter_value_type<InputIterator>>>,
class Allocator = allocator<iter_value_type<InputIterator>>>

§ 22.5.7.1
unordered_multiset(InputIterator, InputIterator, see below::size_type = see below,  
  Hash = Hash(), Pred = Pred(), Allocator = Allocator())
-> unordered_multiset<iter-value-type<InputIterator>>,  
  Hash, Pred, Allocator>;

template<class T, class Hash = hash<T>,  
  class Pred = equal_to<T>, class Allocator = allocator<T>>
unordered_multiset(initializer_list<T>, typename see below::size_type = see below,  
  Hash = Hash(), Pred = Pred(), Allocator = Allocator())
-> unordered_multiset<T, Hash, Pred, Allocator>;

template<class InputIterator, class Allocator>
unordered_multiset(InputIterator, InputIterator, typename see below::size_type, Allocator)
-> unordered_multiset<iter-value-type<InputIterator>,  
  hash<iter-value-type<InputIterator>>,  
  equal_to<iter-value-type<InputIterator>>,  
  Allocator>;

template<class InputIterator, class Allocator>
unordered_multiset(InputIterator, InputIterator, typename see below::size_type,  
  Hash, Allocator)
-> unordered_multiset<iter-value-type<InputIterator>, Hash,  
  equal_to<iter-value-type<InputIterator>>, Allocator>;

template<class T, class Allocator>
unordered_multiset(initializer_list<T>, typename see below::size_type,  
  Hash, Allocator)
-> unordered_multiset<T, Hash, equal_to<T>, Allocator>;

template<class T, class Hash, class Allocator>
unordered_multiset(initializer_list<T>, typename see below::size_type, Hash, Allocator)
-> unordered_multiset<T, Hash, equal_to<T>, Allocator>;

// swap
template<class Key, class Hash, class Pred, class Alloc>
void swap(unordered_multiset<Key, Hash, Pred, Alloc>& x,  
  unordered_multiset<Key, Hash, Pred, Alloc>& y)  
  noexcept(noexcept(x.swap(y)));  
}

A size_type parameter type in an unordered_multiset deduction guide refers to the size_type member type of the type deduced by the deduction guide.

### 22.5.7.2 Constructors

unordered_multiset() : unordered_multiset(size_type(see below)) { }  
explicit unordered_multiset(size_type n,  
  const hasher& hf = hasher(),  
  const key_equal& eql = key_equal(),  
  const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.

template<class InputIterator>
unordered_multiset(InputIterator f, InputIterator l,  
  size_type n = see below,  
  const hasher& hf = hasher(),  
  const key_equal& eql = key_equal(),  
  const allocator_type& a = allocator_type());
unordered_multiset(initializer_list<value_type> il,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

22.5.7.3 Erasure

template<class K, class H, class P, class A, class Predicate>
void erase_if(unordered_multiset<K, H, P, A>& c, Predicate pred);

Effects: Equivalent to:

    for (auto i = c.begin(), last = c.end(); i != last; ) {
        if (pred(*i)) {
            i = c.erase(i);
        } else {
            ++i;
        }
    }

22.6 Container adaptors

22.6.1 In general

The headers <queue> and <stack> define the container adaptors queue, priority_queue, and stack.

The container adaptors each take a Container template parameter, and each constructor takes a Container reference argument. This container is copied into the Container member of each adaptor. If the container takes an allocator, then a compatible allocator may be passed in to the adaptor’s constructor. Otherwise, normal copy or move construction is used for the container argument. The first template parameter T of the container adaptors shall denote the same type as Container::value_type.

For container adaptors, no swap function throws an exception unless that exception is thrown by the swap of the adaptor’s Container or Compare object (if any).

A deduction guide for a container adaptor shall not participate in overload resolution if any of the following are true:

(4.1) — It has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

(4.2) — It has a Compare template parameter and a type that qualifies as an allocator is deduced for that parameter.

(4.3) — It has a Container template parameter and a type that qualifies as an allocator is deduced for that parameter.

(4.4) — It has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.

(4.5) — It has both Container and Allocator template parameters, and uses_allocator_v<Container, Allocator> is false.

22.6.2 Header <queue> synopsis

#include <initializer_list>

namespace std {

template<class T, class Container = deque<T>> class queue;

    template<class T, class Container>
    bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);

§ 22.6.2 862
template<class T, class Container>
bool operator!=<const queue<T, Container>& x, const queue<T, Container>& y>;
template<class T, class Container>
bool operator< (const queue<T, Container>& x, const queue<T, Container>& y);
template<class T, class Container>
bool operator> (const queue<T, Container>& x, const queue<T, Container>& y);
template<class T, class Container>
bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);
template<class T, class Container>
bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);

template<class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));
template<class T, class Container, class Alloc>
struct uses_allocator<queue<T, Container>, Alloc>;

} // end of namespace std

22.6.3 Header <stack> synopsis

#include <initializer_list>

namespace std {

template<class T, class Container = deque<T>>
class stack;

} // end of namespace std

22.6.4 Class template queue

22.6.4.1 Definition

Any sequence container supporting operations front(), back(), push_back() and pop_front() can be used to instantiate queue. In particular, list (22.3.10) and deque (22.3.8) can be used.

namespace std {

template<class T, class Container = deque<T>>
class queue {
public:
    using value_type = typename Container::value_type;
    using reference = typename Container::reference;
} // end of class queue

§ 22.6.4.1
using const_reference = typename Container::const_reference;
using size_type = typename Container::size_type;
using container_type = Container;

protected:
  Container c;

public:
queue() : queue(Container()) {}
explicit queue(const Container&);
explicit queue(Container&&);
template<class Alloc> explicit queue(const Alloc&);
template<class Alloc> queue(const Container&, const Alloc&);
template<class Alloc> queue(Container&&, const Alloc&);
template<class Alloc> queue(const queue&);

[[nodiscard]] bool empty() const { return c.empty(); }
size_type size() const { return c.size(); }
reference front() { return c.front(); }
const_reference front() const { return c.front(); }
reference back() { return c.back(); }
const_reference back() const { return c.back(); }

void push(const value_type& x) { c.push_back(x); }
void push(value_type&& x) { c.push_back(std::move(x)); }

template<class... Args>
decltype(auto) emplace(Args&&... args)
  { return c.emplace_back(std::forward<Args>(args)...); }
void pop() { c.pop_front(); }

void swap(queue& q) noexcept(is_nothrow_swappable_v<Container>)
  { using std::swap; swap(c, q.c); }

};

template<class Container>
queue(Container) -> queue<typename Container::value_type, Container>;

template<class Container, class Allocator>
queue(Container, Allocator) -> queue<typename Container::value_type, Container>;

template<class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));

template<class T, class Container, class Alloc>
struct uses_allocator<queue<T, Container>, Alloc> :
  uses_allocator<Container, Alloc>::type 
{ }

22.6.4.2 Constructors

explicit queue(const Container& cont);

Effects: Initializes c with cont.

explicit queue(Container&& cont);

Effects: Initializes c with std::move(cont).

22.6.4.3 Constructors with allocators

If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution.

template<class Alloc> explicit queue(const Alloc& a);

Effects: Initializes c with a.
template<class Alloc> queue(const container_type& cont, const Alloc& a);

Effects: Initializes c with cont as the first argument and a as the second argument.

template<class Alloc> queue(container_type&& cont, const Alloc& a);

Effects: Initializes c with std::move(cont) as the first argument and a as the second argument.

template<class Alloc> queue(const queue& q, const Alloc& a);

Effects: Initializes c with q.c as the first argument and a as the second argument.

template<class Alloc> queue(queue&& q, const Alloc& a);

Effects: Initializes c with std::move(q.c) as the first argument and a as the second argument.

22.6.4.4 Operators [queue.ops]

template<class T, class Container>
bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c == y.c.

template<class T, class Container>
bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c != y.c.

template<class T, class Container>
bool operator<( const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c < y.c.

template<class T, class Container>
bool operator>( const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c > y.c.

template<class T, class Container>
bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c <= y.c.

template<class T, class Container>
bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c >= y.c.

22.6.5 Specialized algorithms [queue.special]

template<class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));

Constraints: is_swappable_v<Container> is true.

Effects: As if by x.swap(y).

22.6.5 Class template priority_queue [priority.queue]

22.6.5.1 Overview [priqueue.overview]

Any sequence container with random access iterator and supporting operations front(), push_back() and pop_back() can be used to instantiate priority_queue. In particular, vector (22.3.11) and deque (22.3.8) can be used. Instantiating priority_queue also involves supplying a function or function object for making priority comparisons; the library assumes that the function or function object defines a strict weak ordering (25.7).

namespace std {
    template<class T, class Container = vector<T>,
             class Compare = less<typename Container::value_type>>
    class priority_queue {
        public:
            using value_type = typename Container::value_type;

    }

§ 22.6.5.1
using reference = typename Container::reference;
using const_reference = typename Container::const_reference;
using size_type = typename Container::size_type;
using container_type = Container;
using value_compare = Compare;

protected:
  Container c;
  Compare comp;

public:
  priority_queue() : priority_queue(Compare()) {} 
  explicit priority_queue(const Compare& x) : priority_queue(x, Container()) {} 
  priority_queue(const Compare& x, const Container&); 
  priority_queue(const Compare& x, Container&&);
  template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, const Compare& x, 
                   const Container&);
  template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, 
                   const Compare& x = Compare(), Container&& = Container());
  template<class Alloc> explicit priority_queue(const Alloc&);
  template<class Alloc> priority_queue(const Compare&, const Alloc&);
  template<class Alloc> priority_queue(const Compare&, const Container&, 
                                       const Alloc&);
  template<class Alloc> priority_queue(const Compare&, Container&&, 
                                        const Alloc&);
  template<class Alloc> priority_queue(const priority_queue&, 
                                        const Alloc&);
  template<class Alloc> priority_queue(priority_queue&&, 
                                        const Alloc&);

  [[nodiscard]] bool empty() const { return c.empty(); } 
  size_type size() const { return c.size(); } 
  const_reference top() const { return c.front(); }
  void push(const value_type& x);
  void push(value_type&& x);
  template<class... Args> void emplace(Args&&... args);
  void pop();
  void swap(priority_queue& q) noexcept(is_nothrow_swappable_v<Container> && 
          is_nothrow_swappable_v<Compare>)
    { using std::swap; swap(c, q.c); swap(comp, q.comp); }

  template<class Compare, class Container>
    priority_queue(Compare, Container) 
        -> priority_queue<typename Container::value_type, Container, Compare>;
  template<class InputIterator, 
           class Compare = less<typename iterator_traits<InputIterator>::value_type>, 
           class Container = vector<typename iterator_traits<InputIterator>::value_type>>
    priority_queue(InputIterator, InputIterator, Compare = Compare(), Container = Container()) 
        -> priority_queue<typename iterator_traits<InputIterator>::value_type, 
                           Container, Compare>;
  template<class Compare, class Container, class Allocator>
    priority_queue(Compare, Container, Allocator) 
        -> priority_queue<typename Container::value_type, Container, Compare>;

  // no equality is provided
  template<class T, class Container, class Compare>
    void swap(priority_queue<T, Container, Compare>& x, 
              priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));
  template<class T, class Container, class Compare, class Alloc>
    struct uses_allocator<priority_queue<T, Container, Compare>, Alloc> 
        : uses_allocator<Container, Alloc>::type { 
      }
22.6.5.2 Constructors

priority_queue(const Compare& x, const Container& y);
priority_queue(const Compare& x, Container&& y);

1  Expects: x defines a strict weak ordering (25.7).

2  Effects: Initializes comp with x and c with y (copy constructing or move constructing as appropriate);
calls make_heap(c.begin(), c.end(), comp).

template<class InputIterator>
priority_queue(InputIterator first, InputIterator last, const Compare& x, const Container& y);
template<class InputIterator>
priority_queue(InputIterator first, InputIterator last, const Compare& x = Compare(),
  Container&& y = Container());

3  Expects: x defines a strict weak ordering (25.7).

4  Effects: Initializes comp with x and c with y (copy constructing or move constructing as appropriate);
calls c.insert(c.end(), first, last); and finally calls make_heap(c.begin(), c.end(), comp).

22.6.5.3 Constructors with allocators

If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution.

template<class Alloc> explicit priority_queue(const Alloc& a);

2  Effects: Initializes c with a and value-initializes comp.

template<class Alloc> priority_queue(const Compare& compare, const Alloc& a);

3  Effects: Initializes c with a and initializes comp with compare.

template<class Alloc>
priority_queue(const Compare& compare, const Container& cont, const Alloc& a);

4  Effects: Initializes c with cont as the first argument and a as the second argument, and initializes
comp with compare; calls make_heap(c.begin(), c.end(), comp).

template<class Alloc>
priority_queue(const Compare& compare, Container&& cont, const Alloc& a);

5  Effects: Initializes c with std::move(cont) as the first argument and a as the second argument, and
initializes comp with compare; calls make_heap(c.begin(), c.end(), comp).

template<class Alloc> priority_queue(const priority_queue& q, const Alloc& a);

6  Effects: Initializes c with q.c as the first argument and a as the second argument, and initializes comp
with q.comp.

template<class Alloc> priority_queue(priority_queue&& q, const Alloc& a);

7  Effects: Initializes c with std::move(q.c) as the first argument and a as the second argument, and
initializes comp with std::move(q.comp).

22.6.5.4 Members

void push(const value_type& x);

1  Effects: As if by:
c.push_back(x);
push_heap(c.begin(), c.end(), comp);

void push(value_type&& x);

2  Effects: As if by:
c.push_back(std::move(x));
push_heap(c.begin(), c.end(), comp);
template<class... Args> void emplace(Args&&... args)  

**Effects:** As if by:

c.emplace_back(std::forward<Args>(args)...);
push_heap(c.begin(), c.end(), comp);

void pop();

**Effects:** As if by:

pop_heap(c.begin(), c.end(), comp);
c.pop_back();

### 22.6.5.5 Specialized algorithms

template<class T, class Container, class Compare>
void swap(priority_queue<T, Container, Compare>& x, priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));

**Constraints:** is_swappable_v<Container> is true and is_swappable_v<Compare> is true.

**Effects:** As if by x.swap(y).

### 22.6.6 Class template stack

Any sequence container supporting operations back(), push_back() and pop_back() can be used to instantiate stack. In particular, vector (22.3.11), list (22.3.10) and deque (22.3.8) can be used.

#### 22.6.6.1 Definition

namespace std {
    template<class T, class Container = deque<T>>
    class stack {
        public:
            using value_type = typename Container::value_type;
            using reference = typename Container::reference;
            using const_reference = typename Container::const_reference;
            using size_type = typename Container::size_type;
            using container_type = Container;

        protected:
            Container c;

        public:
            stack() : stack(Container()) {}
            explicit stack(const Container&);
            explicit stack(Container&&);
            template<class Alloc> explicit stack(const Alloc&);
            template<class Alloc> stack(const container_type&, const Alloc&);
            template<class Alloc> stack(allocator_type, const Alloc&);
            template<class Alloc> stack(stack&&, const Alloc&);
            [[nodiscard]] bool empty() const { return c.empty(); }
            size_type size() const { return c.size(); }
            reference top() { return c.back(); }
            const_reference top() const { return c.back(); }
            void push(const value_type& x) { c.push_back(x); }
            void push(value_type&& x) { c.push_back(std::move(x)); }
            template<class... Args>
            decltype(auto) emplace(Args&&... args) {
                return c.emplace_back(std::forward<Args>(args)...);
            }
            void pop() { c.pop_back(); }
            void swap(stack&& s) noexcept(is_nothrow_swappable_v<Container>) {
                using std::swap; swap(c, s.c);
            }
    };

§ 22.6.6.1 868
template<class Container>
    stack(Container) -> stack<typename Container::value_type, Container>;

template<class Container, class Allocator>
    stack(Container, Allocator) -> stack<typename Container::value_type, Container>;

template<class T, class Container, class Alloc>
    struct uses_allocator<stack<T, Container>, Alloc> : uses_allocator<Container, Alloc>::type { };

22.6.6.2 Constructors [stack.cons]

explicit stack(const Container& cont);

   Effects: Initializes c with cont.

explicit stack(Container&& cont);

   Effects: Initializes c with std::move(cont).

22.6.6.3 Constructors with allocators [stack.cons.alloc]

1. If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution.

template<class Alloc> explicit stack(const Alloc& a);

   Effects: Initializes c with a.

template<class Alloc> stack(const container_type& cont, const Alloc& a);

   Effects: Initializes c with cont as the first argument and a as the second argument.

template<class Alloc> stack(container_type&& cont, const Alloc& a);

   Effects: Initializes c with std::move(cont) as the first argument and a as the second argument.

template<class Alloc> stack(const stack& s, const Alloc& a);

   Effects: Initializes c with s.c as the first argument and a as the second argument.

template<class Alloc> stack(stack&& s, const Alloc& a);

   Effects: Initializes c with std::move(s.c) as the first argument and a as the second argument.

22.6.6.4 Operators [stack.ops]

template<class T, class Container>
    bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);

   Returns: x.c == y.c.

template<class T, class Container>
    bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);

   Returns: x.c != y.c.

template<class T, class Container>
    bool operator<( const stack<T, Container>& x, const stack<T, Container>& y);

   Returns: x.c < y.c.

template<class T, class Container>
    bool operator>( const stack<T, Container>& x, const stack<T, Container>& y);

   Returns: x.c > y.c.

template<class T, class Container>
    bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);

   Returns: x.c <= y.c.

§ 22.6.6.4
template<class T, class Container>
bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: x.c >= y.c.

22.6.6.5 Specialized algorithms

```
template<class T, class Container>
void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));
```

Constraints: is_swappable_v<Container> is true.

Effects: As if by x.swap(y).

22.7 Views

22.7.1 General

The header <span> defines the view span.

22.7.2 Header <span> synopsis

```
namespace std {
    // constants
    inline constexpr size_t dynamic_extent = numeric_limits<size_t>::max();

    // 22.7.3, class template span
    template<class ElementType, size_t Extent = dynamic_extent>
    class span {
      public:
        // constants and types
        using element_type = ElementType;
        using value_type = remove_cv_t<ElementType>;
        using index_type = size_t;
        using difference_type = ptrdiff_t;
        using pointer = element_type*;

      // 22.7.3.7, views of object representation
      template<class ElementType, size_t Extent>
      span<const byte, Extent <= dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent> as_bytes(span<ElementType, Extent> s) noexcept;

      template<class ElementType, size_t Extent>
      span<byte, Extent <= dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent> as_writable_bytes(span<ElementType, Extent> s) noexcept;

      // 22.7.3.8, tuple interface
      template<class T> class tuple_size;
      template<size_t I, class T> class tuple_element;
      template<class ElementType, size_t Extent>
      struct tuple_size<span<ElementType, Extent>>;
      template<class ElementType>
      struct tuple_size<span<ElementType, dynamic_extent>>;  // not defined
      template<size_t I, class ElementType, size_t Extent>
      struct tuple_element<I, span<ElementType, Extent>>;
      template<size_t I, class ElementType, size_t Extent>
      constexpr ElementType& get(span<ElementType, Extent>) noexcept;
    }
}
```

22.7.3 Class template span

22.7.3.1 Overview

A span is a view over a contiguous sequence of objects, the storage of which is owned by some other object.

All member functions of span have constant time complexity.

```
namespace std {
    template<class ElementType, size_t Extent = dynamic_extent>
    class span {
      public:
        // constants and types
        using element_type = ElementType;
        using value_type = remove_cv_t<ElementType>;

span(Container&) -> span<typename Container::value_type>;
template<class Container>
span(const Container&) -> span<const typename Container::value_type>;

ElementType is required to be a complete object type that is not an abstract class type.

### 22.7.3.2 Constructors, copy, and assignment

constexpr span() noexcept;

Constraints: Extent <= 0 is true.
Ensures: size() == 0 && data() == nullptr.

constexpr span(pointer ptr, index_type count);

Expects: [ptr, ptr + count) is a valid range. If extent is not equal to dynamic_extent, then count is equal to extent.
Effects: Constructs a span that is a view over the range [ptr, ptr + count).
Ensures: size() == count && data() == ptr.
Throws: Nothing.

constexpr span(pointer first, pointer last);

Expects: [first, last) is a valid range. If extent is not equal to dynamic_extent, then last - first is equal to extent.
Effects: Constructs a span that is a view over the range [first, last).
Ensures: size() == last - first && data() == first.
Throws: Nothing.

template<size_t N> constexpr span(element_type (&arr)[N]) noexcept;
template<size_t N> constexpr span(array<value_type, N>& arr) noexcept;
template<size_t N> constexpr span(const array<value_type, N>& arr) noexcept;

Constraints:

— extent == dynamic_extent || N == extent is true, and
— remove_pointer_t<decltype(data(arr))>(*)[] is convertible to ElementType(*[]).

Effects: Constructs a span that is a view over the supplied array.
Ensures: size() == N && data() == data(arr).

template<class Container> constexpr span(Container& cont);
template<class Container> constexpr span(const Container& cont);

Constraints:

— extent == dynamic_extent is true,
— Container is not a specialization of span,
Container is not a specialization of array,
is_array_v<Container> is false,
data(cont) and size(cont) are both well-formed, and
remove_pointer_t<decltype(data(cont))>(*)[] is convertible to ElementType(*)[].

| Expect | | Effect | | Ensure | | Throw |
|---|---|---|---|---|---|
| [data(cont), data(cont) + size(cont)] is a valid range. | | Constructs a span that is a view over the range [data(cont), data(cont) + size(cont)]. | | size() == size(cont) &amp; data() == data(cont). | | What and when data(cont) and size(cont) throw. |

constexpr span(const span&amp; other) noexcept = default;

Ensure: other.size() == size() &amp; other.data() == data().

template<class OtherElementType, size_t OtherExtent>
constexpr span(const span& OtherElement, OtherExtent&amp; s) noexcept;

Constraints:

- Extent == dynamic_extent || Extent == OtherExtent is true, and
- OtherElementType(*)[] is convertible to ElementType(*)[].

Effect: Constructs a span that is a view over the range [s.data(), s.data() + s.size()].

Ensure: size() == s.size() &amp; data() == s.data().

constexpr span&amp; operator=(const span&amp; other) noexcept = default;

Ensure: other.size() == size() &amp; other.data() == data().

22.7.3.3 Subviews

template&lt;size_t Count&gt; constexpr span&lt;element_type, Count&gt; first() const;

Expect: Count &lt;= size() is true.

Effect: Equivalent to: return {data(), Count};

template&lt;size_t Count&gt; constexpr span&lt;element_type, Count&gt; last() const;

Expect: Count &lt;= size() is true.

Effect: Equivalent to: return {data() + (size() - Count), Count};

template&lt;size_t Offset, size_t Count = dynamic_extent&gt;
constexpr span&lt;element_type, see below&gt; subspan() const;

Expect:
Offset &lt;= size() &amp;&amp; (Count == dynamic_extent || Offset + Count &lt;= size())
is true.

Effect: Equivalent to:
return span&lt;ElementType, see below&gt;
(data() + Offset, Count != dynamic_extent ? Count : size() - Offset);

Remarks: The second template argument of the returned span type is:
Count != dynamic_extent ? Count :
(Extent != dynamic_extent ? Extent - Offset : dynamic_extent)

constexpr span&lt;element_type, dynamic_extent&gt; first(index_type count) const;

Expect: count &lt;= size() is true.

Effect: Equivalent to: return {data(), count};

constexpr span&lt;element_type, dynamic_extent&gt; last(index_type count) const;

Expect: count &lt;= size() is true.
11  Effects: Equivalent to: return \{(data()) + (size() - count), count\};

constexpr span<element_type, dynamic_extent> subspan(
    index_type offset, index_type count = dynamic_extent) const;

12  Expects:
    offset <= size() && (count == dynamic_extent || offset + count <= size())
    is true.

13  Effects: Equivalent to:
    return \{(data()) + offset, count == dynamic_extent ? size() - offset : count\};

22.7.3.4 Observers

constexpr index_type size() const noexcept;
1  Effects: Equivalent to: return size_;

constexpr index_type size_bytes() const noexcept;
2  Effects: Equivalent to: return size() * sizeof(element_type);

[[nodiscard]] constexpr bool empty() const noexcept;
3  Effects: Equivalent to: return size() == 0;

22.7.3.5 Element access

constexpr reference operator[](index_type idx) const;
1  Expects: idx < size() is true.

2  Effects: Equivalent to: return *(data()) + idx);

constexpr reference front() const;
3  Expects: empty() is false.

4  Effects: Equivalent to: return *data();

constexpr reference back() const;
5  Expects: empty() is false.

6  Effects: Equivalent to: return *(data()) + (size() - 1));

constexpr pointer data() const noexcept;
7  Effects: Equivalent to: return data_;

22.7.3.6 Iterator support

using iterator = implementation-defined;
using const_iterator = implementation-defined;

1  The types model ContiguousIterator (23.3.4.14), meet the Cpp17RandomAccessIterator requirements (23.3.5.6), and meet the requirements for constexpr iterators (23.3.1). All requirements on container iterators (22.2) apply to span::iterator and span::const_iterator as well.

constexpr iterator begin() const noexcept;
2  Returns: An iterator referring to the first element in the span. If empty() is true, then it returns the same value as end().

constexpr iterator end() const noexcept;
3  Returns: An iterator which is the past-the-end value.

constexpr reverse_iterator rbegin() const noexcept;
4  Effects: Equivalent to: return reverse_iterator(end());

constexpr reverse_iterator rend() const noexcept;
5  Returns: Equivalent to: return reverse_iterator(begin());
constexpr const_iterator cbegin() const noexcept;

Returns: A constant iterator referring to the first element in the span. If empty() is true, then it returns the same value as cend().

constexpr const_iterator cend() const noexcept;

Returns: A constant iterator which is the past-the-end value.

constexpr const_reverse_iterator crbegin() const noexcept;

Effects: Equivalent to: return const_reverse_iterator(cend());

constexpr const_reverse_iterator crend() const noexcept;

Effects: Equivalent to: return const_reverse_iterator(cbegin());

22.7.3.7 Views of object representation

```cpp
template<class ElementType, size_t Extent>
span<const byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
as_bytes(span<ElementType, Extent> s) noexcept;
```

Effects: Equivalent to: return {reinterpret_cast<const byte*>(s.data()), s.size_bytes()};

```cpp
template<class ElementType, size_t Extent>
span<byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
as_writable_bytes(span<ElementType, Extent> s) noexcept;
```

Constraints: is_const_v<ElementType> is false.

Effects: Equivalent to: return {reinterpret_cast<byte*>(s.data()), s.size_bytes()};

22.7.3.8 Tuple interface

```cpp
template<class ElementType, size_t Extent>
struct tuple_size<span<ElementType, Extent>>
: integral_constant<size_t, Extent> { };
```

```cpp
template<size_t I, class ElementType, size_t Extent>
struct tuple_element<I, span<ElementType, Extent>> {
  using type = ElementType;
};
```

Mandates: Extent != dynamic_extent && I < Extent is true.

```cpp
template<size_t I, class ElementType, size_t Extent>
constexpr ElementType& get(span<ElementType, Extent> s) noexcept;
```

Mandates: Extent != dynamic_extent && I < Extent is true.

Returns: A reference to the I\textsuperscript{th} element of s, where indexing is zero-based.
23 Iterators library

23.1 General

This Clause describes components that C++ programs may use to perform iterations over containers (Clause 22), streams (29.7), stream buffers (29.6), and other ranges (Clause 24).

The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators, and stream iterators, as summarized in Table 71.

Table 71: Iterators library summary

<table>
<thead>

23.3 Iterator requirements

23.3.1 In general

Iterators are a generalization of pointers that allow a C++ program to work with different data structures (for example, containers and ranges) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but
also the semantics and complexity assumptions of iterators. An input iterator \(i\) supports the expression \(*i\), resulting in a value of some object type \(T\), called the \textit{value type} of the iterator. An output iterator \(i\) has a non-empty set of types that are \textit{writable} to the iterator; for each such type \(T\), the expression \(*i = o\) is valid where \(o\) is a value of type \(T\). For every iterator type \(X\), there is a corresponding signed integer type called the \textit{difference type} of the iterator.

Since iterators are an abstraction of pointers, their semantics are a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This document defines six categories of iterators, according to the operations defined on them: \textit{input iterators}, \textit{output iterators}, \textit{forward iterators}, \textit{bidirectional iterators}, \textit{random access iterators}, and \textit{contiguous iterators}, as shown in Table 72.

Table 72: Relations among iterator categories

```
<table>
<thead>
<tr>
<th>Contiguous</th>
<th>Random Access</th>
<th>Bidirectional</th>
<th>Forward</th>
<th>Input</th>
<th>Output</th>
</tr>
</thead>
</table>
```

The six categories of iterators correspond to the iterator concepts \texttt{InputIterator} (23.3.4.9), \texttt{OutputIterator} (23.3.4.10), \texttt{ForwardIterator} (23.3.4.11), \texttt{BidirectionalIterator} (23.3.4.12) \texttt{RandomAccessIterator} (23.3.4.13), and \texttt{ContiguousIterator} (23.3.4.14), respectively. The generic term \textit{iterator} refers to any type that models the \texttt{Iterator} concept (23.3.4.6).

Forward iterators meet all the requirements of input iterators and can be used whenever an input iterator is specified; Bidirectional iterators also meet all the requirements of forward iterators and can be used whenever a forward iterator is specified; Random access iterators also meet all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified; Contiguous iterators also meet all the requirements of random access iterators and can be used whenever a random access iterator is specified.

Iterators that further meet the requirements of output iterators are called \textit{mutable iterators}. Nonmutable iterators are referred to as \textit{constant iterators}.

In addition to the requirements in this subclause, the nested \texttt{typedef-names} specified in 23.3.2.3 shall be provided for the iterator type. [Note: Either the iterator type must provide the \texttt{typedef-names} directly (in which case \texttt{iterator_traits} pick them up automatically), or an \texttt{iterator_traits} specialization must provide them. —end note]

Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type \(T\) there is an iterator value that points past the last element of a corresponding sequence. These values are called \textit{past-the-end} values. Values of an iterator \(i\) for which the expression \(*i\) is defined are called \textit{dereferenceable}. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any sequence. [Example: After the declaration of an uninitialized pointer \(x\) (as with \texttt{int* x;}), \(x\) must always be assumed to have a singular value of a pointer. —end example] Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value, the assignment of a non-singular value to an iterator that holds a singular value, and, for iterators that meet the \texttt{Cpp17DefaultConstructible} requirements, using a value-initialized iterator as the source of a copy or move operation. [Note: This guarantee is not offered for default-initialization, although the distinction only matters for types with trivial default constructors such as pointers or aggregates holding pointers. —end note] In these cases the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.

Most of the library's algorithmic templates that operate on data structures have interfaces that use ranges. A \textit{range} is an iterator and a \textit{sentinel} that designate the beginning and end of the computation, or an iterator and a count that designate the beginning and the number of elements to which the computation is to be applied.\(^{232}\)

An iterator and a sentinel denoting a range are comparable. A range \([i, s]\) is empty if \(i == s\); otherwise, \([i, s]\) refers to the elements in the data structure starting with the element pointed to by \(i\) and up to but not including the element, if any, pointed to by the first iterator \(j\) such that \(j == s\).

A sentinel \(s\) is called \textit{reachable} from an iterator \(i\) if and only if there is a finite sequence of applications of the expression \;++\(i\) that makes \(i == s\). If \(s\) is reachable from \(i\), \([i, s]\) denotes a valid range.

\(^{232}\) The sentinel denoting the end of a range may have the same type as the iterator denoting the beginning of the range, or a different type.
A counted range \([i, n)\) is empty if \(n == 0\); otherwise, \([i, n)\) refers to the \(n\) elements in the data structure starting with the element pointed to by \(i\) and up to but not including the element, if any, pointed to by the result of \(n\) applications of \(++i\). A counted range \([i, n)\) is valid if and only if \(n == 0\); or \(n\) is positive, \(i\) is dereferenceable, and \([++i, --n)\) is valid.

The result of the application of library functions to invalid ranges is undefined.

All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables and concept definitions for the iterators do not specify complexity.

 Destruction of a non-forward iterator may invalidate pointers and references previously obtained from that iterator.

An invalid iterator is an iterator that may be singular.\(^{233}\)

Iterators are called constexpr iterators if all operations provided to meet iterator category requirements are constexpr functions, except for

\[ (16.1) \] — a pseudo-destructor call \((7.5.4.3)\), and

\[ (16.2) \] — the construction of an iterator with a singular value.

[Note: For example, the types “pointer to int” and \texttt{reverse_iterator<int*>} are constexpr iterators. — end note]

23.3.2 Associated types

23.3.2.1 Incrementable traits

To implement algorithms only in terms of incrementable types, it is often necessary to determine the difference type that corresponds to a particular incrementable type. Accordingly, it is required that if \(WI\) is the name of a type that models the \texttt{WeaklyIncrementable} concept \((23.3.4.4)\), the type

\texttt{iter_difference_t<WI>}

be defined as the incrementable type’s difference type.

```cpp
namespace std {
    template<class> struct incrementable_traits { };  
    template<class T>
    requires is_object_v<T>
    struct incrementable_traits<T> { 
        using difference_type = ptrdiff_t;
    }; 
    template<class I>
    struct incrementable_traits<const I>
    : incrementable_traits<I> { }; 
    template<class T>
    requires requires { typename T::difference_type; }  
    struct incrementable_traits<T> { 
        using difference_type = typename T::difference_type;
    }; 
    template<class T>
    requires (!requires { typename T::difference_type; } &&
    requires(const T& a, const T& b) { { a - b } -> Integral; })
    struct incrementable_traits<T> { 
        using difference_type = make_signed_t<decltype(declval<T>() - declval<T>())>;
    }; 
    template<class T>
    using iter_difference_t = see below;
}
```

\(233\) This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.
The type `iter_difference_t<I>` denotes

(2.1) — `incrementable_traits<I>::difference_type` if `iterator_traits<I>` names a specialization generated from the primary template, and
(2.2) — `iterator_traits<I>::difference_type` otherwise.

Users may specialize `incrementable_traits` on program-defined types.

### 23.3.2.2 Readable traits [readable.traits]

To implement algorithms only in terms of readable types, it is often necessary to determine the value type that corresponds to a particular readable type. Accordingly, it is required that if `R` is the name of a type that models the `Readable` concept (23.3.4.2), the type

```
iter_value_t<R>
```

be defined as the readable type’s value type.

```cpp
template<class> struct cond_value_type { }; // exposition only
template<class T>
    requires is_object_v<T>
struct cond_value_type {
    using value_type = remove_cv_t<T>;
};
template<class> struct readable_traits { };
template<class T>
struct readable_traits<T*> {
    : cond_value_type<T> { };
};
template<class I>
    requires is_array_v<I>
struct readable_traits<I> {
    using value_type = remove_cv_t<remove_extent_t<I>>;
};
template<class I>
struct readable_traits<const I> {
    : readable_traits<I> { };
};
template<class T>
    requires requires { typename T::value_type; }
struct readable_traits<T> {
    : cond_value_type<typename T::value_type> { };
};
template<class T>
    requires requires { typename T::element_type; }
struct readable_traits<T> {
    : cond_value_type<typename T::element_type> { };
};
template<class T> using iter_value_t = see below;
```

The type `iter_value_t<I>` denotes

(2.1) — `readable_traits<I>::value_type` if `iterator_traits<I>` names a specialization generated from the primary template, and
(2.2) — `iterator_traits<I>::value_type` otherwise.

Class template `readable_traits` may be specialized on program-defined types.

[Note: Some legacy output iterators define a nested type named `value_type` that is an alias for `void`. These types are not `Readable` and have no associated value types. — end note]

[Note: Smart pointers like `shared_ptr<int>` are `Readable` and have an associated value type, but a smart pointer like `shared_ptr<void>` is not `Readable` and has no associated value type. — end note]
23.3.2.3 Iterator traits

To implement algorithms only in terms of iterators, it is sometimes necessary to determine the iterator category that corresponds to a particular iterator type. Accordingly, it is required that if \( I \) is the type of an iterator, the type

\[
\textnormal{iterator_traits}<I>::\text{iterator\_category}
\]

be defined as the iterator's iterator category. In addition, the types

\[
\textnormal{iterator_traits}<I>::\text{pointer}
\]

\[
\textnormal{iterator_traits}<I>::\text{reference}
\]

shall be defined as the iterator's pointer and reference types; that is, for an iterator object \( a \) of class type, the same type as \( \text{decltype}(a.\text{operator}\rightarrow()) \) and \( \text{decltype}(\&a) \), respectively. The type \( \text{iterator\_traits}<I>::\text{pointer} \) shall be void for an iterator of class type \( I \) that does not support \( \text{operator}\rightarrow \). Additionally, in the case of an output iterator, the types

\[
\textnormal{iterator_traits}<I>::\text{value\_type}
\]

\[
\textnormal{iterator_traits}<I>::\text{difference\_type}
\]

\[
\textnormal{iterator_traits}<I>::\text{reference}
\]

may be defined as void.

2 The definitions in this subclause make use of the following exposition-only concepts:

```cpp
template<class I>
concept cpp17-iterator = 
    Copyable<I> && requires(I i) {
    *i } -> can-reference;
    ++i } -> Same<I&>;
    *i++ } -> can-reference;
};

template<class I>
concept cpp17-input-iterator =
    cpp17-iterator<I> && EqualityComparable<I> && requires(I i) {
    typename incrementable_traits<I>::difference_type;
    typename readable_traits<I>::value_type;
    typename common_reference_t<iter_reference_t<I>&&,
        typename readable_traits<I>::value_type&>;
    typename common_reference_t<decltype(*i++)&&,
        typename readable_traits<I>::value_type&>;
    requires SignedIntegral<typename incrementable_traits<I>::difference_type>;
};

template<class I>
concept cpp17-forward-iterator =
    cpp17-input-iterator<I> && Constructible<I> &&
    is_lvalue_reference_v<iter_reference_t<I>> &&
    Same<remove_cvref_t<iter_reference_t<I>>, typename readable_traits<I>::value_type> &&
    requires(I i) {
    i++ } -> const I&;
    *i++ } -> Same<iter_reference_t<I>>;
};

template<class I>
concept cpp17-bidirectional-iterator =
    cpp17-forward-iterator<I> && requires(I i) {
    --i } -> Same<I&>;
    i-- } -> const I&;
    *i-- } -> Same<iter_reference_t<I>>;
};

template<class I>
concept cpp17-random-access-iterator =
    cpp17-bidirectional-iterator<I> && StrictTotallyOrdered<I> &&
    requires(I i, typename incrementable_traits<I>::difference_type n) {
```
The members of a specialization \texttt{iterator_traits<I>} generated from the \texttt{iterator_traits} primary template are computed as follows:

\begin{enumerate}
\item If \texttt{I} has valid (13.9.2) member types \texttt{difference_type}, \texttt{value_type}, \texttt{reference}, and \texttt{iterator_category}, then \texttt{iterator_traits<I>} has the following publicly accessible members:

\begin{verbatim}
using iterator_category = typename I::iterator_category;
using value_type = typename I::value_type;
using difference_type = typename I::difference_type;
using pointer = see below;
using reference = typename I::reference;
\end{verbatim}

If the qualified-id \texttt{I::pointer} is valid and denotes a type, then \texttt{iterator_traits<I>::pointer} names that type; otherwise, it names \texttt{void}.

\item Otherwise, if \texttt{I} satisfies the exposition-only concept \texttt{cpp17-input-iterator}, \texttt{iterator_traits<I>} has the following publicly accessible members:

\begin{verbatim}
using iterator_category = see below;
using value_type = typename readable_traits<I>::value_type;
using difference_type = typename incrementable_traits<I>::difference_type;
using pointer = see below;
using reference = see below;
\end{verbatim}

\item If the qualified-id \texttt{I::pointer} is valid and denotes a type, \texttt{pointer} names that type. Otherwise, if \texttt{declval<IN>()::operator->()} is well-formed, then \texttt{pointer} names that type. Otherwise, \texttt{pointer} names \texttt{void}.

\item Otherwise, if \texttt{I} satisfies the exposition-only concept \texttt{cpp17-input-iterator}, then \texttt{iterator_traits<I>} has the following publicly accessible members:

\begin{verbatim}
using iterator_category = output_iterator_tag;
using value_type = void;
using difference_type = see below;
using pointer = void;
using reference = void;
\end{verbatim}

If the qualified-id \texttt{incrementable_traits<I>::difference_type} is valid and denotes a type, then \texttt{difference_type} names that type; otherwise, it names \texttt{void}.

\item Otherwise, \texttt{iterator_traits<I>} has no members by any of the above names.
\end{enumerate}

Explicit or partial specializations of \texttt{iterator_traits} may have a member type \texttt{iterator_concept} that is used to indicate conformance to the iterator concepts (23.3.4).

\texttt{iterator_traits} is specialized for pointers as

\begin{verbatim}
namespace std {
    template<class T>
    requires is_object_v<T>
    \}
\end{verbatim}
struct iterator_traits<T*> {
    using iterator_concept = contiguous_iterator_tag;
    using iterator_category = random_access_iterator_tag;
    using value_type = remove_cv_t<T>;
    using difference_type = ptrdiff_t;
    using pointer = T*;
    using reference = T&;
};

Example: To implement a generic reverse function, a C++ program can do the following:

```cpp
template<class BI>
void reverse(BI first, BI last) {
    typename iterator_traits<BI>::difference_type n =
        distance(first, last);
    --n;
    while(n > 0) {
        typename iterator_traits<BI>::value_type tmp = *first;
        *first++ = *--last;
        *last = tmp;
        n -= 2;
    }
}
```

23.3.3 Customization points

23.3.3.1 ranges::iter_move

The name ranges::iter_move denotes a customization point object (16.4.2.2.6). The expression ranges::iter_move(E) for some subexpression E is expression-equivalent to:

1. **iter_move(E)**, if that expression is valid, with overload resolution performed in a context that does not include a declaration of ranges::iter_move.
2. Otherwise, if the expression *E is well-formed:
   1. If *E is an lvalue, std::move(*E);
   2. Otherwise, *E.
3. Otherwise, ranges::iter_move(E) is ill-formed. [Note: This case can result in substitution failure when ranges::iter_move(E) appears in the immediate context of a template instantiation. — end note]

2 If ranges::iter_move(E) is not equal to *E, the program is ill-formed with no diagnostic required.

23.3.3.2 ranges::iter_swap

The name ranges::iter_swap denotes a customization point object (16.4.2.2.6) that exchanges the values (18.4.9) denoted by its arguments.

Let iter-exchange-move be the exposition-only function:

```cpp
template<class X, class Y>
constexpr iter_value_t<remove_reference_t<X>> iter-exchange-move(X&& x, Y&& y) noexcept(noexcept(iter_value_t<remove_reference_t<X>>(iter_move(x))) &&
    noexcept(*x = iter_move(y)));
```

3 Effects: Equivalent to:

   ```cpp
   iter_value_t<remove_reference_t<X>> old_value(iter_move(x));
   *x = iter_move(y);
   return old_value;
   ```

4 The expression ranges::iter_swap(E1, E2) for some subexpressions E1 and E2 is expression-equivalent to:

   ```cpp
   (void)iter_swap(E1, E2), if that expression is valid, with overload resolution performed in a context that includes the declaration
   ```
template<class I1, class I2>
void iter_swap(I1, I2) = delete;

and does not include a declaration of ranges::iter_swap. If the function selected by overload resolution
does not exchange the values denoted by E1 and E2, the program is ill-formed with no diagnostic
required.

(4.2) — Otherwise, if the types of E1 and E2 each model Readable, and if the reference types of E1 and E2
model SwappableWith (18.4.9), then ranges::swap(*E1, *E2).

(4.3) — Otherwise, if the types T1 and T2 of E1 and E2 model IndirectlyMovableStorable<T1, T2> and
IndirectlyMovableStorable<T2, T1>, then (void)(*E1 = iter-exchange-move(E2, E1)), except
that E1 is evaluated only once.

(4.4) — Otherwise, ranges::iter_swap(E1, E2) is ill-formed. [Note: This case can result in substitution
failure when ranges::iter_swap(E1, E2) appears in the immediate context of a template instantiation.
— end note]

23.3.4 Iterator concepts

23.3.4.1 General

1 For a type I, let ITER_TRAITS(I) denote the type I if iterator_traits<I> names a specialization generated
from the primary template. Otherwise, ITER_TRAITS(I) denotes iterator_traits<I>.

(1.1) — If the qualified-id ITER_TRAITS(I)::iterator_concept is valid and names a type, then ITER_-_CONCEPT(I) denotes that type.

(1.2) — Otherwise, if the qualified-id ITER_TRAITS(I)::iterator_category is valid and names a type, then
ITER_CONCEPT(I) denotes that type.

(1.3) — Otherwise, if iterator_traits<I> names a specialization generated from the primary template, then
ITER_CONCEPT(I) denotes random_access_iterator_tag.

(1.4) — Otherwise, ITER_CONCEPT(I) does not denote a type.

2 [Note: ITER_TRAITS enables independent syntactic determination of an iterator’s category and concept.
— end note] [Example:

struct I {
    using value_type = int;
    using difference_type = int;

    int operator*() const;
    & operator*();
    I& operator++();
    I operator++(int);
    I& operator--();
    I operator--(int);

    bool operator==(I) const;
    bool operator!=(I) const;
};

iterator_traits<I>::iterator_category denotes input_iterator_tag, and ITER_CONCEPT(I) denotes
random_access_iterator_tag. — end example]

23.3.4.2 Concept Readable

1 Types that are readable by applying operator* model the Readable concept, including pointers, smart
pointers, and iterators.

template<class In>
concept Readable =
    requires {
        typename iter_value_t<In>;
        typename iter_reference_t<In>;
        typename iter_rvalue_reference_t<In>;
    } &
    CommonReference<iter_reference_t<In>>&, iter_value_t<In>&
    &
    CommonReference<iter_reference_t<In>>&, iter_rvalue_reference_t<In>&&
    &
    CommonReference<iter_rvalue_reference_t<In>&&, const iter_value_t<In>&&>;
§ 23.3.4.2
2 Given a value \( i \) of type \( I \), \( I \) models Readable only if the expression \( *i \) is equality-preserving. [Note: The expression \( *i \) is indirectly required to be valid via the exposition-only dereferenceable concept (23.2). — end note]

23.3.4.3 Concept Writable

The \textbf{Writable} concept specifies the requirements for writing a value into an iterator’s referenced object.

\begin{verbatim}
template<class Out, class T>
concept Writable =
    requires(Out&& o, T&& t) {
        *o = std::forward<T>(t); // not required to be equality-preserving
        *std::forward<Out>(o) = std::forward<T>(t); // not required to be equality-preserving
        const_cast<const iter_reference_t<Out>&&>(*o) =
            std::forward<T>(t); // not required to be equality-preserving
        const_cast<const iter_reference_t<Out>&&>(*std::forward<Out>(o)) =
            std::forward<T>(t); // not required to be equality-preserving
    };
\end{verbatim}

2 Let \( E \) be an an expression such that \texttt{decltype((E))} is \( T \), and let \( o \) be a dereferenceable object of type \( Out \). \( Out \) and \( T \) model \textbf{Writable}<\( Out, T \) only if

\begin{enumerate}
  \item \[ (2.1) \]
  \begin{itemize}
    \item If \( Out \) and \( T \) model \textbf{Readable}<\( Out \) \&\& \textbf{Same}<\textbf{iter_value_t}<\textbf{Out}, \textbf{decay_t}<\textbf{T}>>, then \( *o \) after any above assignment is equal to the value of \( E \) before the assignment.
  \item After evaluating any above assignment expression, \( o \) is not required to be dereferenceable.
  \item If \( E \) is an xvalue (7.2.1), the resulting state of the object it denotes is valid but unspecified (16.5.5.15).
  \item [Note: The only valid use of an \texttt{operator*} is on the left side of the assignment statement. Assignment through the same value of the writable type happens only once. — end note]
  \item [Note: \textbf{Writable} has the awkward \texttt{const_cast} expressions to reject iterators with prvalue non-proxy reference types that permit rvalue assignment but do not also permit \texttt{const} rvalue assignment. Consequently, an iterator type \( I \) that returns \texttt{std::string} by value does not model \textbf{Writable}<\( I, \texttt{std::string} \). — end note]
\end{itemize}
\end{enumerate}

23.3.4.4 Concept WeaklyIncrementable

The \textbf{WeaklyIncrementable} concept specifies the requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are not required to be equality-preserving, nor is the type required to be \textbf{EqualityComparable}.

\begin{verbatim}
template<class I>
concept WeaklyIncrementable =
    Semiregular<1> \&\&
    requires(I i) {
        typename iter_difference_t<I>;
        requires SignedIntegral<iter_difference_t<I> >;
        { ++i } \rightarrow Same<1>&; // not required to be equality-preserving
        i++; // not required to be equality-preserving
    };
\end{verbatim}

2 Let \( i \) be an object of type \( I \). When \( i \) is in the domain of both pre- and post-increment, \( i \) is said to be \textit{incrementable}. \( I \) models \textbf{WeaklyIncrementable}<\( I \) only if

\begin{enumerate}
  \item \[ (2.1) \]
  \begin{itemize}
    \item The expressions ++\( i \) and \( i++ \) have the same domain.
  \item If \( i \) is incrementable, then both ++\( i \) and \( i++ \) advance \( i \) to the next element.
  \item If \( i \) is incrementable, then \texttt{addressof}(++\( i \)) is equal to \texttt{addressof}(\( i \)).
\end{itemize}
\end{enumerate}

3 [Note: For \textbf{WeaklyIncrementable} types, \( a \) equals \( b \) does not imply that ++\( a \) equals ++\( b \). (Equality does not guarantee the substitution property or referential transparency.) Algorithms on weakly incremental types should never attempt to pass through the same incremental value twice. They should be single-pass algorithms. These algorithms can be used with istreams as the source of the input data through the \texttt{istream_iterator} class template. — end note]

23.3.4.5 Concept Incrementable

The \textbf{Incrementable} concept specifies requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are required to be equality-preserving, and the type is
required to be EqualityComparable. [Note: This supersedes the annotations on the increment expressions in the definition of WeaklyIncrementable. —end note]

```cpp
template<class I>
conceps Incrementable =
   Regular<I> &&
   WeaklyIncrementable<I> &&
   requires(I i) { 
      { i++ } -> Same<I>;
   };
```

2 Let a and b be incrementable objects of type I. I models Incrementable only if

1. If bool(a == b) then bool(a++ == b).
2. If bool(a == b) then bool(((void)a++, a) == ++b).

3 [Note: The requirement that a equals b implies ++a equals ++b (which is not true for weakly incrementable types) allows the use of multi-pass one-directional algorithms with types that model Incrementable. —end note]
Let $i$ be an iterator of type $I$, and $s$ a sentinel of type $S$ such that $[i, s)$ denotes a range. Let $N$ be the smallest number of applications of $++i$ necessary to make bool($i == s$) be true. $S$ and $I$ model SizedSentinel $S$, $I$ only if

1. If $N$ is representable by `iter_difference_t< I >`, then $s - i$ is well-defined and equals $N$.
2. If $-N$ is representable by `iter_difference_t< I >`, then $i - s$ is well-defined and equals $-N$.

[Note: disable_sized_sentinel allows use of sentinels and iterators with the library that satisfy but do not in fact model SizedSentinel. —end note]

[Example: The SizedSentinel concept is modeled by pairs of RandomAccessIterators (23.3.4.13) and by counted iterators and their sentinels (23.5.6.1). —end example]

### 23.3.4.9 Concept InputIterator

The InputIterator concept defines requirements for a type whose referenced values can be read (from the requirement for Readable (23.3.4.2)) and which can be both pre- and post-incremented. [Note: Unlike the Cpp17InputIterator requirements (23.3.5.2), the InputIterator concept does not need equality comparison since iterators are typically compared to sentinels. —end note]

```cpp
template<class I>
concept InputIterator =
    Iterator<I> &&
    Readable<I> &&
    requires { typename ITER_CONCEPT(I); } &&
    DerivedFrom<ITER_CONCEPT(I), input_iterator_tag>;
```

### 23.3.4.10 Concept OutputIterator

The OutputIterator concept defines requirements for a type that can be used to write values (from the requirement for Writable (23.3.4.3)) and which can be both pre- and post-incremented. [Note: Output iterators are not required to model EqualityComparable. —end note]

```cpp
template<class I, class T>
concept OutputIterator =
    Iterator<I> &&
    Writable<I, T> &&
    requires(I i, T&& t) {
        *i++ = std::forward<T>(t); // not required to be equality-preserving
    };
```

Let $E$ be an expression such that `decltype((E))` is $T$, and let $i$ be a dereferenceable object of type $I$. $I$ and $T$ model OutputIterator $I$, $T$ only if $*i++ = E$; has effects equivalent to:

```cpp
*i = E;
++i;
```

[Note: Algorithms on output iterators should never attempt to pass through the same iterator twice. They should be single-pass algorithms. —end note]

### 23.3.4.11 Concept ForwardIterator

The ForwardIterator concept adds equality comparison and the multi-pass guarantee, specified below.

```cpp
template<class I>
concept ForwardIterator =
    InputIterator<I> &&
    DerivedFrom<ITER_CONCEPT(I), forward_iterator_tag> &&
    Incrementable<I> &&
    Sentinel<I, I>;
```

The domain of `==` for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators of the same type may be compared and shall compare equal to other value-initialized iterators of the same type. [Note: Value-initialized iterators behave as if they refer past the end of the same empty sequence. —end note]

Pointers and references obtained from a forward iterator into a range $[i, s)$ shall remain valid while $[i, s)$ continues to denote a range.
Two dereferenceable iterators \( a \) and \( b \) of type \( X \) offer the multi-pass guarantee if:

- \( a == b \) implies \( *a == ++b \) and
- The expression \((\text{void}[])\{X x; (++x;)(a), *a\}\) is equivalent to the expression \(*a\).

[Note: The requirement that \( a == b \) implies \( *a == ++b \) and the removal of the restrictions on the number of assignments through a mutable iterator (which applies to output iterators) allow the use of multi-pass one-directional algorithms with forward iterators. — end note]

23.3.4.12 Concept BidirectionalIterator

The \texttt{BidirectionalIterator}\footnote{template<class I>  
concept BidirectionalIterator =  
ForwardIterator<I> &&  
DerivedFrom<ITER\_CONCEPT(I), bidirectional\_iterator\_tag> &&  
requires(I i) {  
  { --i } -> Same<I&>;  
  { i-- } -> Same<I>;  
};} concept adds the ability to move an iterator backward as well as forward.

2 A bidirectional iterator \( r \) is decrementable if and only if there exists some \( q \) such that \( ++q == r \). Decrementable iterators \( r \) shall be in the domain of the expressions \(--r\) and \( r--\).

3 Let \( a \) and \( b \) be equal objects of type \( I \). \( I \) models \texttt{BidirectionalIterator} only if:

- If \( a \) and \( b \) are decrementable, then all of the following are \texttt{true}:
  - \( \text{addressof}(--a) == \text{addressof}(a) \)
  - \( \text{bool}(a-- == b) \)
  - after evaluating both \( a-- \) and \( --b \), \( \text{bool}(a == b) \) is still \texttt{true}
  - \( \text{bool}(++(--a) == b) \)
- If \( a \) and \( b \) are incrementable, then \( \text{bool}(-(++a) == b) \).

23.3.4.13 Concept RandomAccessIterator

The \texttt{RandomAccessIterator}\footnote{template<class I>  
concept RandomAccessIterator =  
BidirectionalIterator<I> &&  
DerivedFrom<ITER\_CONCEPT(I), random\_access\_iterator\_tag> &&  
StrictTotallyOrdered<I> &&  
SizedSentinel<I, I> &&  
requires(I i, const I j, const iter\_difference_t<I> n) {  
  { i += n } -> Same<I&>;  
  { j + n } -> Same<I>;  
  { n + j } -> Same<I>;  
  { i -= n } -> Same<I&>;  
  { j[n] } -> Same<iter\_reference_t<I>>;  
};} concept adds support for constant-time advancement with \(+, \text{+}, \text{-=}, \text{-}\), as well as the computation of distance in constant time with \(-\). Random access iterators also support array notation via subscripting.

2 Let \( a \) and \( b \) be valid iterators of type \( I \) such that \( b \) is reachable from \( a \) after \( n \) applications of \( ++a \), let \( D \) be \texttt{iter\_difference_t<I>}, and let \( n \) denote a value of type \( D \). \( I \) models \texttt{RandomAccessIterator} only if

- \( (a += n) \) is equal to \( b \).
- \( \text{addressof}(a += n) \) is equal to \( \text{addressof}(a) \).
- \( (a + n) \) is equal to \( (a += n) \).
- For any two positive values \( x \) and \( y \) of type \( D \), if \( (a + D(x + y)) \) is valid, then \( (a + D(x + y)) \) is equal to \( (a + x) + y \).
- \( (a + D(0)) \) is equal to \( a \).
23.3.4.14 Concept ContiguousIterator

The ContiguousIterator concept provides a guarantee that the denoted elements are stored contiguously in memory.

```
template<class I>
concept ContiguousIterator =
    RandomAccessIterator<I> &&
    DerivedFrom<ITER_CONCEPT(I), contiguous_iterator_tag> &&
    is_lvalue_reference_v<iter_reference_t<I>> &&
    Same<iter_value_t<I>, remove_cvref_t<iter_reference_t<I>>;}
```

Let a and b be dereferenceable iterators of type I such that b is reachable from a, and let D be iter_difference_t<I>. The type I models ContiguousIterator only if `addressof(*(a + D(b - a)))` is equal to `addressof(*a) + D(b - a)`.

23.3.5 C++17 iterator requirements

The Cpp17Iterator requirements form the basis of the iterator taxonomy; every iterator meets the Cpp17Iterator requirements. This set of requirements specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to read (23.3.5.2) or write (23.3.5.3) values, or to provide a richer set of iterator movements (23.3.5.4, 23.3.5.5, 23.3.5.6).

A type X meets the Cpp17Iterator requirements if:

1. X meets the Cpp17CopyConstructible, Cpp17CopyAssignable, and Cpp17Destructible requirements (16.5.3.1) and lvalues of type X are swappable (16.5.3.2), and
2. the expressions in Table 73 are valid and have the indicated semantics.

### Table 73: Cpp17Iterator requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>*r</td>
<td>unspecified</td>
<td></td>
<td>Expects: r is dereferenceable.</td>
</tr>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

23.3.5.2 Input iterators

A class or pointer type X meets the requirements of an input iterator for the value type T if X meets the Cpp17Iterator (23.3.5.1) and Cpp17EqualityComparable (Table 23) requirements and the expressions in Table 74 are valid and have the indicated semantics.

In Table 74, the term the domain of `==` is used in the ordinary mathematical sense to denote the set of values over which `==` is (required to be) defined. This set can change over time. Each algorithm places additional requirements on the domain of `==` for the iterator values it uses. These requirements can be inferred from the uses that algorithm makes of `==` and `!=`. [Example: The call `find(a, b, x)` is defined only if the value of a has the property p defined as follows: b has property p and a value i has property p if (*i==x) or if (*i!=x and ++i has property p). — end example]
### Table 74: Cpp17InputIterator requirements (in addition to Cpp17Iterator)  
[tab:inputiterator]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>a != b</td>
<td>contextually convertible to bool</td>
<td>!(a == b)</td>
<td><code>Expects: (a, b) is in the domain of ==.</code></td>
</tr>
<tr>
<td>*a</td>
<td>reference, convertible to T</td>
<td></td>
<td><code>Expects: a is dereferenceable. The expression (void)*a, *a is equivalent to *a. If a == b and (a, b) is in the domain of == then *a is equivalent to *b.</code></td>
</tr>
<tr>
<td>a-&gt;m</td>
<td>(*a).m</td>
<td></td>
<td><code>Expects: a is dereferenceable.</code></td>
</tr>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td></td>
<td><code>Expects: r is dereferenceable. Ensures: r is dereferenceable or r is past-the-end; any copies of the previous value of r are no longer required to be dereferenceable nor to be in the domain of ==.</code></td>
</tr>
<tr>
<td>(void)r++</td>
<td>equivalent to (void)++r</td>
<td></td>
<td></td>
</tr>
<tr>
<td>*r++</td>
<td>convertible to T</td>
<td><code>{ T tmp = *r; ++r; return tmp; }</code></td>
<td><code>Remarks: After this operation r is not required to be dereferenceable. Ensures: r is incrementable.</code></td>
</tr>
</tbody>
</table>

3 **Note:** For input iterators, `a == b` does not imply `++a == ++b`. (Equality does not guarantee the substitution property or referential transparency.) Algorithms on input iterators should never attempt to pass through the same iterator twice. They should be single pass algorithms. Value type T is not required to be a Cpp17CopyAssignable type (Table 29). These algorithms can be used with istreams as the source of the input data through the istream_iterator class template. — end note

### 23.3.5.3 Output iterators  
[output.iterators]

A class or pointer type X meets the requirements of an output iterator if X meets the Cpp17Iterator requirements (23.3.5.1) and the expressions in Table 75 are valid and have the indicated semantics.

### Table 75: Cpp17OutputIterator requirements (in addition to Cpp17Iterator)  
[tab:outputiterator]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>*r = o</td>
<td>result is not used</td>
<td></td>
<td><code>Remarks: After this operation r is not required to be dereferenceable. Ensures: r is incrementable.</code></td>
</tr>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td></td>
<td><code>addressof(r) == addressof(++)r.</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><code>Remarks: After this operation r is not required to be dereferenceable. Ensures: r is incrementable.</code></td>
</tr>
<tr>
<td>r++</td>
<td>convertible to const X&amp;</td>
<td><code>{ X tmp = r; ++r; return tmp; }</code></td>
<td><code>Remarks: After this operation r is not required to be dereferenceable. Ensures: r is incrementable.</code></td>
</tr>
</tbody>
</table>
Table 75: \textit{Cpp17OutputIterator} requirements (in addition to \textit{Cpp17Iterator}) (continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>(*r++ = o)</td>
<td>result is not used</td>
<td>Remarks: After this operation (r) is not required to be dereferenceable. Ensures: (r) is incrementable.</td>
<td></td>
</tr>
</tbody>
</table>

2 \textit{Note}: The only valid use of an \texttt{operator*} is on the left side of the assignment statement. Assignment through the same value of the iterator happens only once. Algorithms on output iterators should never attempt to pass through the same iterator twice. They should be single-pass algorithms. Equality and inequality might not be defined. \textit{— end note]}

23.3.5.4 Forward iterators \[forward.iterators]\n
1 A class or pointer type \(X\) meets the requirements of a forward iterator if

\begin{enumerate}
\item \(X\) meets the \textit{Cpp17InputIterator} requirements \(23.3.5.2\),
\item \(X\) meets the \textit{Cpp17DefaultConstructible} requirements \(16.5.3.1\),
\item if \(X\) is a mutable iterator, \texttt{reference} is a reference to \(T\); if \(X\) is a constant iterator, \texttt{reference} is a reference to \texttt{const T},
\item the expressions in Table 76 are valid and have the indicated semantics, and
\item objects of type \(X\) offer the multi-pass guarantee, described below.
\end{enumerate}

2 The domain of \texttt{==} for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators may be compared and shall compare equal to other value-initialized iterators of the same type. \textit{[Note: Value-initialized iterators behave as if they refer past the end of the same empty sequence. — end note]}

3 Two dereferenceable iterators \(a\) and \(b\) of type \(X\) offer the \textit{multi-pass guarantee} if:

\begin{enumerate}
\item \(a == b\) implies \(++a == +++b\) and
\item \(X\) is a pointer type or the expression \texttt{(void)++X(a)}, \(\ast a\) is equivalent to the expression \(\ast a\).
\end{enumerate}

4 \textit{Note: The requirement that \(a == b\) implies \(++a == +++b\) (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through a mutable iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators. — end note]}

Table 76: \textit{Cpp17ForwardIterator} requirements (in addition to \textit{Cpp17InputIterator}) \[tab:forwarditerator]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>(r++)</td>
<td>convertible to (X) (tmp = r); (\texttt{const X}&amp; ++r;) (\text{\return tmp;})</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(*r++)</td>
<td>\texttt{reference}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5 If \(a\) and \(b\) are equal, then either \(a\) and \(b\) are both dereferenceable or else neither is dereferenceable.

6 If \(a\) and \(b\) are both dereferenceable, then \(a == b\) if and only if \(\ast a\) and \(\ast b\) are bound to the same object.

23.3.5.5 Bidirectional iterators \[bidirectional.iterators]\n
1 A class or pointer type \(X\) meets the requirements of a bidirectional iterator if, in addition to meeting the \textit{Cpp17ForwardIterator} requirements, the following expressions are valid as shown in Table 77.

§ 23.3.5.5 896
Table 77: Cpp17BidirectionalIterator requirements (in addition to Cpp17ForwardIterator)  
<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>--r</td>
<td>X&amp;</td>
<td>Expects: there exists s such that r == ++s. Ensures: r is dereferenceable. --(++r) == r. --r == --s implies r == s. addressof(r) == addressof(--r).</td>
<td></td>
</tr>
<tr>
<td>r--</td>
<td>convertible to</td>
<td>{ X tmp = r; --r; return tmp; }</td>
<td></td>
</tr>
<tr>
<td>*r--</td>
<td>reference</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2 [Note: Bidirectional iterators allow algorithms to move iterators backward as well as forward. — end note]

23.3.5.6 Random access iterators  
A class or pointer type X meets the requirements of a random access iterator if, in addition to meeting the Cpp17BidirectionalIterator requirements, the following expressions are valid as shown in Table 78.

Table 78: Cpp17RandomAccessIterator requirements (in addition to Cpp17BidirectionalIterator)  
<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>r += n</td>
<td>X&amp;</td>
<td>{ difference_type m = n; if (m &gt;= 0) while (m--) ++r; else while (m++) --r; return r; }</td>
<td>a + n == n + a.</td>
</tr>
<tr>
<td>a + n</td>
<td>X</td>
<td>{ X tmp = a; return tmp += n; }</td>
<td></td>
</tr>
<tr>
<td>n + a</td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>r -= n</td>
<td>X&amp;</td>
<td>return r += -n;</td>
<td>Expects: the absolute value of n is in the range of representable values of difference_type.</td>
</tr>
<tr>
<td>a - n</td>
<td>X</td>
<td>{ X tmp = a; return tmp -= n; }</td>
<td></td>
</tr>
<tr>
<td>b - a</td>
<td>difference_-type</td>
<td>return n</td>
<td>Expects: there exists a value n of type difference_type such that a + n == b. b == a + (b - a).</td>
</tr>
<tr>
<td>a[n]</td>
<td>convertible to</td>
<td>*(a + n)</td>
<td></td>
</tr>
<tr>
<td>a &lt; b</td>
<td>contextually convertible to bool</td>
<td>b - a &gt; 0</td>
<td>&lt; is a total ordering relation</td>
</tr>
<tr>
<td>a &gt; b</td>
<td>contextually convertible to bool</td>
<td>b &lt; a</td>
<td>&gt; is a total ordering relation opposite to &lt;.</td>
</tr>
<tr>
<td>a &gt;= b</td>
<td>contextually convertible to bool</td>
<td>!(a &lt; b)</td>
<td></td>
</tr>
</tbody>
</table>
Table 78: Cpp17RandomAccessIterator requirements (in addition to Cpp17BidirectionalIterator) (continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>a &lt;= b</td>
<td>contextually convertible to bool.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

23.3.6 Indirect callable requirements

23.3.6.1 General

1 There are several concepts that group requirements of algorithms that take callable objects (20.14.2) as arguments.

23.3.6.2 Indirect callables

1 The indirect callable concepts are used to constrain those algorithms that accept callable objects (20.14.2) as arguments.

```cpp
namespace std {
  template<class F, class I>
  concept IndirectUnaryInvocable =
    Readable<I> &&
    CopyConstructible<
      F&&
    Invocable<F&&, iter_value_t<I>&> &&
    Invocable<F&&, iter_reference_t<I>> &&
    Invocable<F&&, iter_common_reference_t<I>> &&
    CommonReference<
      invoke_result_t<F&&, iter_value_t<I>&>,
      invoke_result_t<F&&, iter_reference_t<I>>;

template<class F, class I>
  concept IndirectRegularUnaryInvocable =
    Readable<I> &&
    CopyConstructible<
      F&&
    RegularInvocable<F&&, iter_value_t<I>&> &&
    RegularInvocable<F&&, iter_reference_t<I>> &&
    RegularInvocable<F&&, iter_common_reference_t<I>> &&
    CommonReference<
      invoke_result_t<F&&, iter_value_t<I>&>,
      invoke_result_t<F&&, iter_reference_t<I>>;

template<class F, class I>
  concept IndirectUnaryPredicate =
    Readable<I> &&
    CopyConstructible<
      F&&
    Predicate<F&&, iter_value_t<I>&> &&
    Predicate<F&&, iter_reference_t<I>> &&
    Predicate<F&&, iter_common_reference_t<I>>;

template<class F, class I1, class I2 = I1>
  concept IndirectRelation =
    Readable<I1> &&
    CopyConstructible<
      F&&
    Relation<F&&, iter_value_t<I1>&, iter_value_t<I2>&> &&
    Relation<F&&, iter_value_t<I1>&, iter_reference_t<I2>> &&
    Relation<F&&, iter_reference_t<I1>, iter_value_t<I2>&> &&
    Relation<F&&, iter_reference_t<I1>, iter_reference_t<I2>> &&
    Relation<F&&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;

template<class F, class I1, class I2 = I1>
  concept IndirectStrictWeakOrder =
    Readable<I1> &&
    CopyConstructible<
      F&&
    StrictWeakOrder<F&&, iter_value_t<I1>&, iter_value_t<I2>&> &&
```
StrictWeakOrder<F&, iter_value_t<I1>&, iter_reference_t<I2>&> &&
StrictWeakOrder<F&, iter_reference_t<I1>, iter_value_t<I2>&> &&
StrictWeakOrder<F&, iter_reference_t<I1>, iter_reference_t<I2>> &&
StrictWeakOrder<F&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;

23.3.6.3 Class template projected [projected]

Class template projected is used to constrain algorithms that accept callable objects and projections (16.3.21). It combines a Readable type I and a callable object type Proj into a new Readable type whose reference type is the result of applying Proj to the iter_reference_t of I.

namespace std {
    template<Readable I, IndirectRegularUnaryInvocable<I> Proj>
    struct projected {
        using value_type = remove_cvref_t<indirect_result_t<Proj&, I>>;
        indirect_result_t<Proj&, I> operator*() const; // not defined
    };

    template<WeaklyIncrementable I, class Proj>
    struct incrementable_traits<projected<I, Proj>> {
        using difference_type = iter_difference_t<I>;
    };
}

23.3.7 Common algorithm requirements [alg.req]

23.3.7.1 General [alg.req.general]

There are several additional iterator concepts that are commonly applied to families of algorithms. These group together iterator requirements of algorithm families. There are three relational concepts that specify how element values are transferred between Readable and Writable types: IndirectlyMovable, IndirectlyCopyable, and IndirectlySwappable. There are three relational concepts for rearrangements: Permutable, Mergeable, and Sortable. There is one relational concept for comparing values from different sequences: IndirectlyComparable.

2 [Note: The ranges::less function object type used in the concepts below imposes constraints on the concepts’ arguments in addition to those that appear in the concepts’ bodies (20.14.8). — end note]

23.3.7.2 Concept IndirectlyMovable [alg.req.ind.move]

The IndirectlyMovable concept specifies the relationship between a Readable type and a Writable type between which values may be moved.

template<class In, class Out>
concept IndirectlyMovable =
    Readable<In> &&
    Writable<Out, iter_rvalue_reference_t<In>>;

The IndirectlyMovableStorable concept augments IndirectlyMovable with additional requirements enabling the transfer to be performed through an intermediate object of the Readable type’s value type.

template<class In, class Out>
concept IndirectlyMovableStorable =
    IndirectlyMovable<In, Out> &&
    Writable<Out, iter_value_t<In>> &&
    Movable<iter_value_t<In>> &&
    Constructible<iter_value_t<In>, iter_rvalue_reference_t<In>> &&
    Assignable<iter_value_t<In>&, iter_rvalue_reference_t<In>>;

Let i be a dereferenceable value of type In. In and Out model IndirectlyMovableStorable<In, Out> only if after the initialization of the object obj in

iter_value_t<In> obj(ranges::iter_move(i));

obj is equal to the value previously denoted by *i. If iter_rvalue_reference_t<In> is an rvalue reference type, the resulting state of the value denoted by *i is valid but unspecified (16.5.5.15).
23.3.7.3 Concept IndirectlyCopyable

The IndirectlyCopyable concept specifies the relationship between a Readable type and a Writable type between which values may be copied.

```cpp
template<class In, class Out>
concept IndirectlyCopyable =
    Readable<In> &&
    Writable<Out, iter_reference_t<In>>;
```

2 The IndirectlyCopyableStorable concept augments IndirectlyCopyable with additional requirements enabling the transfer to be performed through an intermediate object of the Readable type’s value type. It also requires the capability to make copies of values.

```cpp
template<class In, class Out>
concept IndirectlyCopyableStorable =
    IndirectlyCopyable<In, Out> &&
    Writable<Out, const iter_value_t<In>&> &&
    Copyable<iter_value_t<In>> &&
    Constructible<iter_value_t<In>, iter_reference_t<In>> &&
    Assignable<iter_value_t<In>&, iter_reference_t<In>>;
```

3 Let i be a dereferenceable value of type In. In and Out model IndirectlyCopyableStorable<In, Out> only if after the initialization of the object obj in

```cpp
iter_value_t<In> obj(*i);
```

obj is equal to the value previously denoted by *i. If iter_reference_t<In> is an rvalue reference type, the resulting state of the value denoted by *i is valid but unspecified (16.5.5.15).

23.3.7.4 Concept IndirectlySwappable

The IndirectlySwappable concept specifies a swappable relationship between the values referenced by two Readable types.

```cpp
template<class I1, class I2 = I1>
concept IndirectlySwappable =
    Readable<I1> && Readable<I2> &&
    requires(I1& i1, I2& i2) {
        ranges::iter_swap(i1, i1);
        ranges::iter_swap(i2, i2);
        ranges::iter_swap(i1, i2);
        ranges::iter_swap(i2, i1);
    };
```

23.3.7.5 Concept IndirectlyComparable

The IndirectlyComparable concept specifies the common requirements of algorithms that compare values from two different sequences.

```cpp
template<class I1, class I2, class R, class P1 = identity,
    class P2 = identity>
concept IndirectlyComparable =
    IndirectRelation<R, projected<I1, P1>, projected<I2, P2>>;
```

23.3.7.6 Concept Permutable

The Permutable concept specifies the common requirements of algorithms that reorder elements in place by moving or swapping them.

```cpp
template<class I>
concept Permutable =
    ForwardIterator<I> &&
    IndirectlyMovableStorable<I, I> &&
    IndirectlySwappable<I, I>;
```

23.3.7.7 Concept Mergeable

The Mergeable concept specifies the requirements of algorithms that merge sorted sequences into an output sequence by copying elements.
template<class I1, class I2, class Out, class R = ranges::less,
         class P1 = identity, class P2 = identity>
concep
concept Mergeable =
  InputIterator<I1> &&
  InputIterator<I2> &&
  WeaklyIncrementable<Out> &&
 间接Copyable<I1, Out> &&
  IndirectlyCopyable<I2, Out> &&
  IndirectStrictWeakOrder<R, projected<I1, P1>, projected<I2, P2>>;

23.3.7.8 Concept Sortable [alg.req.sortable]
1 The Sortable concept specifies the common requirements of algorithms that permute sequences into ordered
sequences (e.g., sort).

template<class I, class R = ranges::less, class P = identity>
concep
concept Sortable =
  Permutable<I> &&
  IndirectStrictWeakOrder<R, projected<I, P>>;

23.4 Iterator primitives [iterator.primitives]
1 To simplify the use of iterators, the library provides several classes and functions.

23.4.1 Standard iterator tags [std.iterator.tags]
1 It is often desirable for a function template specialization to find out what is the most specific cate-
gory of its iterator argument, so that the function can select the most efficient algorithm at compile
time. To facilitate this, the library introduces category tag classes which are used as compile time tags
for algorithm selection. They are: output_iterator_tag, input_iterator_tag, forward_iterator_tag, bidirectional_iterator_tag, random_access_iterator_tag, and contiguous_iterator_tag. For every
iterator of type I, iterator_traits<I>::iterator_category shall be defined to be a category tag that
describes the iterator’s behavior. Additionally, iterator_traits<I>::iterator_concept may be used to
indicate conformance to the iterator concepts (23.3.4).

namespace std {
  struct output_iterator_tag {);
  struct input_iterator_tag {);
  struct forward_iterator_tag: public input_iterator_tag {);
  struct bidirectional_iterator_tag: public forward_iterator_tag {;
  struct random_access_iterator_tag: public bidirectional_iterator_tag {;
  struct contiguous_iterator_tag: public random_access_iterator_tag {;
}

2 [Example: For a program-defined iterator BinaryTreeIterator, it could be included into the bidirectional
iterator category by specializing the iterator_traits template:

template<class T> struct iterator_traits<BinaryTreeIterator<T>> {
  using iterator_category = bidirectional_iterator_tag;
  using difference_type = ptrdiff_t;
  using value_type = T;
  using pointer = T*;
  using reference = T&;
};

— end example]

3 [Example: If evolve() is well-defined for bidirectional iterators, but can be implemented more efficiently for
random access iterators, then the implementation is as follows:

template<class BidirectionalIterator>
inline void
evolve(BidirectionalIterator first, BidirectionalIterator last)
{
  evolve(first, last,
         typename iterator_traits<BidirectionalIterator>::iterator_category());
}
template<class BidirectionalIterator>
void evolve(BidirectionalIterator first, BidirectionalIterator last,
bidirectional_iterator_tag) {
    // more generic, but less efficient algorithm
}

template<class RandomAccessIterator>
void evolve(RandomAccessIterator first, RandomAccessIterator last,
random_access_iterator_tag) {
    // more efficient, but less generic algorithm
}
—end example]

23.4.2 Iterator operations

Since only random access iterators provide + and − operators, the library provides two function templates `advance` and `distance`. These function templates use + and − for random access iterators (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use ++ to provide linear time implementations.

template<class InputIterator, class Distance>
constexpr void advance(InputIterator& i, Distance n);

Expects: `n` is negative only for bidirectional iterators.

Effects: Increments `i` by `n` if `n` is non-negative, and decrements `i` by −`n` otherwise.

template<class InputIterator>
constexpr typename iterator_traits<InputIterator>::difference_type
distance(InputIterator first, InputIterator last);

Expects: `last` is reachable from `first`, or `InputIterator` meets the `Cpp17RandomAccessIterator` requirements and `first` is reachable from `last`.

Effects: If `InputIterator` meets the `Cpp17RandomAccessIterator` requirements, returns `(last - first)`; otherwise, returns the number of increments needed to get from `first` to `last`.

template<class InputIterator>
constexpr InputIterator next(InputIterator x,
    typename iterator_traits<InputIterator>::difference_type n = 1);

Effects: Equivalent to: `advance(x, n); return x;`

template<class BidirectionalIterator>
constexpr BidirectionalIterator prev(BidirectionalIterator x,
    typename iterator_traits<BidirectionalIterator>::difference_type n = 1);

Effects: Equivalent to: `advance(x, −n); return x;`

23.4.3 Range iterator operations

The library includes the function templates `ranges::advance`, `ranges::distance`, `ranges::next`, and `ranges::prev` to manipulate iterators. These operations adapt to the set of operators provided by each iterator category to provide the most efficient implementation possible for a concrete iterator type. [Example: `ranges::advance` uses the + operator to move a `RandomAccessIterator` forward `n` steps in constant time. For an iterator type that does not model `RandomAccessIterator`, `ranges::advance` instead performs `n` individual increments with the ++ operator. —end example]
The function call expression at #1 invokes std::ranges::distance, not std::distance, despite that (a) the iterator type returned from begin(vec) and end(vec) may be associated with namespace std and (b) std::distance is more specialized (13.6.6.2) than std::ranges::distance since the former requires its first two parameters to have the same type. —end example

3 The number and order of deducible template parameters for the function templates defined in this subclause is unspecified, except where explicitly stated otherwise.

### 23.4.3.1 ranges::advance

```cpp
template<Iterator I>
constexpr void ranges::advance(I& i, iter_difference_t<I> n);  
^ Expects: If I does not model BidirectionalIterator, n is not negative.

(2.1) — If I models RandomAccessIterator, equivalent to i += n.
(2.2) — Otherwise, if n is non-negative, increments i by n.
(2.3) — Otherwise, decrements i by -n.
```

```cpp
template<Iterator I, Sentinel<I> S>
constexpr void ranges::advance(I& i, S bound);  
^ Expects: [i, bound) denotes a range.

(4.1) — If I and S model Assignable<I&, S>, equivalent to i = std::move(bound).
(4.2) — Otherwise, if S and I model SizedSentinel<S, I>, equivalent to ranges::advance(i, bound - i).
(4.3) — Otherwise, while bool(i != bound) is true, increments i.
```

```cpp
template<Iterator I, Sentinel<I> S>
constexpr iter_difference_t<I> ranges::advance(I& i, iter_difference_t<I> n, S bound);  
^ Expects: If n > 0, [i, bound) denotes a range. If n == 0, [i, bound) or [bound, i) denotes a range. If n < 0, [bound, i) denotes a range, I models BidirectionalIterator, and I and S model Same<I, S>.

(6.1) — If S and I model SizedSentinel<S, I>:
(6.1.1) — If |n| ≥ |bound - i|, equivalent to ranges::advance(i, bound).
(6.1.2) — Otherwise, equivalent to ranges::advance(i, n).
(6.2) — Otherwise,
(6.2.1) — if n is non-negative, while bool(i != bound) is true, increments i but at most n times.
(6.2.2) — Otherwise, while bool(i != bound) is true, decrements i but at most -n times.

^ Returns: n - M, where M is the difference between the ending and starting positions of i.
```

### 23.4.3.2 ranges::distance

```cpp
template<Iterator I, Sentinel<I> S>
constexpr iter_difference_t<I> ranges::distance(I first, S last);  
^ Expects: [first, last) denotes a range, or (last, first) denotes a range and S and I model Same<S, I> && SizedSentinel<S, I>.

(2) — If S and I model SizedSentinel<S, I>, returns (last - first); otherwise, returns the number of increments needed to get from first to last.
```

```cpp
template<Range R>
constexpr iter_difference_t<iterator_t<R>> ranges::distance(R&& r);  
^ Effects: If R models SizedRange, equivalent to:

```cpp
return ranges::size(r);  
^ // 24.3.9
```
Otherwise, equivalent to:

```cpp
textual I ranges::next(I x);
```

1 **Effects:** Equivalent to: `++x; return x;`

```cpp
textual I ranges::next(I x, iter_difference_t<I> n);
```

2 **Effects:** Equivalent to: `ranges::advance(x, n); return x;`

```cpp
textual I, Sentinel<I> S
  textual I ranges::next(I x, S bound);
```

3 **Effects:** Equivalent to: `ranges::advance(x, bound); return x;`

```cpp
textual I, Sentinel<I> S
  textual I ranges::next(I x, S n, S bound);
```

4 **Effects:** Equivalent to: `ranges::advance(x, n, bound); return x;`

23.4.3.4 `ranges::prev`

```cpp
textual BidirectionalIterator I
  textual I ranges::prev(I x);
```

1 **Effects:** Equivalent to: `--x; return x;`

```cpp
textual BidirectionalIterator I
  textual I ranges::prev(I x, iter_difference_t<I> n);
```

2 **Effects:** Equivalent to: `ranges::advance(x, -n); return x;`

```cpp
textual BidirectionalIterator I
  textual I ranges::prev(I x, iter_difference_t<I> n, I bound);
```

3 **Effects:** Equivalent to: `ranges::advance(x, -n, bound); return x;`

23.5 Iterator adaptors

23.5.1 Reverse iterators

1 Class template `reverse_iterator` is an iterator adaptor that iterates from the end of the sequence defined by its underlying iterator to the beginning of that sequence.

23.5.1.1 Class template `reverse_iterator`

```cpp
namespace std {
  template<class Iterator>
  class reverse_iterator {
    public:
      using iterator_type = Iterator;
      using iterator_concept = see below;
      using iterator_category = see below;
      using value_type = iter_value_t<Iterator>;
      using difference_type = iter_difference_t<Iterator>;
      using pointer = typename iterator_traits<Iterator>::pointer;
      using reference = iter_reference_t<Iterator>;

      textual reverse_iterator();
      textual explicit reverse_iterator(Iterator x);
      template<class U> textual reverse_iterator(const reverse_iterator<U>& u);
      template<class U> textual reverse_iterator& operator=(const reverse_iterator<U>& u);

      textual Iterator base() const;
      textual reference operator*() const;
      textual pointer operator->() const requires see below;
  };
} // namespace std
```
 constexpr reverse_iterator& operator++();
 constexpr reverse_iterator operator++(int);
 constexpr reverse_iterator& operator--();
 constexpr reverse_iterator operator--(int);

 constexpr reverse_iterator operator+ (difference_type n) const;
 constexpr reverse_iterator& operator+=(difference_type n);
 constexpr reverse_iterator operator- (difference_type n) const;
 constexpr reverse_iterator& operator-=(difference_type n);

 constexpr unspecified operator[](difference_type n) const;

 friend constexpr iter_rvalue_reference_t<Iterator>
 iter_move(const reverse_iterator& i) noexcept(see below);
 template<IndirectlySwappable<Iterator> Iterator2>
 friend constexpr void
 iter_swap(const reverse_iterator& x,
 const reverse_iterator<Iterator2>& y) noexcept(see below);

 protected:
   Iterator current;
};

1 The member typedef-name iterator_concept denotes
   — random_access_iterator_tag if Iterator models RandomAccessIterator, and
   — bidirectional_iterator_tag otherwise.

2 The member typedef-name iterator_category denotes
   — random_access_iterator_tag if the type iterator_traits<Iterator>::iterator_category models DerivedFrom<random_access_iterator_tag>, and
   — iterator_traits<Iterator>::iterator_category otherwise.

23.5.1.2 Requirements [reverse.iter.requirements]  [reverse.iter.requirements]

1 The template parameter Iterator shall either meet the requirements of a Cpp17BidirectionalIterator (23.3.5.5) or model BidirectionalIterator (23.3.4.12).

2 Additionally, Iterator shall either meet the requirements of a Cpp17RandomAccessIterator (23.3.5.6) or model RandomAccessIterator (23.3.4.13) if the definitions of any of the members
   — operator+, operator-, operator==, operator!=(23.5.1.6), or
   — operator[] (23.5.1.5),
   or the non-member operators (23.5.1.7)
   — operator<, operator>, operator<=, operator>=, operator-, or operator+ (23.5.1.8)
   are instantiated (13.8.1).

23.5.1.3 Construction and assignment [reverse.iter.cons]

 constexpr reverse_iterator& operator++();

1 Effects: Value-initializes current. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a value-initialized iterator of type Iterator.

 constexpr explicit reverse_iterator(Iterator x);

2 Effects: Initializes current with x.

 template<typename U> constexpr reverse_iterator(const reverse_iterator<U>& u);

3 Effects: Initializes current with u.current.
template<class U>
constexpr reverse_iterator&
operator=(const reverse_iterator<U>& u);

Effects: Assigns u.base() to current.

Returns: *this.

23.5.1.4 Conversion

constexpr Iterator base() const; // explicit

Returns: current.

23.5.1.5 Element access

constexpr reference operator*() const;

Effects: As if by:
    Iterator tmp = current;
    return *--tmp;

constexpr pointer operator->() const
    requires (is_pointer_v<Iterator> ||
        requires (const Iterator i) { i.operator->(); });

Effects:
(2.1) If Iterator is a pointer type, equivalent to: return prev(current);
(2.2) Otherwise, equivalent to: return prev(current).operator->();

constexpr unspecified operator[](difference_type n) const;

Returns: current[-n-1].

23.5.1.6 Navigation

constexpr reverse_iterator operator+(difference_type n) const;

Returns: reverse_iterator(current-n).

constexpr reverse_iterator operator-(difference_type n) const;

Returns: reverse_iterator(current+n).

constexpr reverse_iterator& operator++();

Effects: As if by: --current;

Returns: *this.

constexpr reverse_iterator& operator++(int);

Effects: As if by:
    reverse_iterator tmp = *this;
    --current;
    return tmp;

constexpr reverse_iterator& operator--();

Effects: As if by ++current.

Returns: *this.

constexpr reverse_iterator& operator--(int);

Effects: As if by:
    reverse_iterator tmp = *this;
    ++current;
    return tmp;

§ 23.5.1.6
constexpr reverse_iterator& operator+= (difference_type n);

   Effects: As if by: current -= n;

   Returns: *this.

constexpr reverse_iterator& operator-=(difference_type n);

   Effects: As if by: current += n;

   Returns: *this.

23.5.1.7 Comparisons

\[\text{reverse.iter.cmp}\]

template<class Iterator1, class Iterator2>
constexpr bool operator==(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

   Constraints: x.base() == y.base() is well-formed and convertible to bool.

   Returns: x.base() == y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator!=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

   Constraints: x.base() != y.base() is well-formed and convertible to bool.

   Returns: x.base() != y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator<(n
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

   Constraints: x.base() < y.base() is well-formed and convertible to bool.

   Returns: x.base() < y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator>(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

   Constraints: x.base() > y.base() is well-formed and convertible to bool.

   Returns: x.base() > y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator<=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

   Constraints: x.base() >= y.base() is well-formed and convertible to bool.

   Returns: x.base() >= y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator>=(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

   Constraints: x.base() <= y.base() is well-formed and convertible to bool.

   Returns: x.base() <= y.base().

23.5.1.8 Non-member functions

\[\text{reverse.iter.nonmember}\]

template<class Iterator1, class Iterator2>
constexpr auto operator-(
    const reverse_iterator<Iterator1>& x,
const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());

Returns: y.base() - x.base().

template<class Iterator>
const reverse_iterator<Iterator>& operator+(  
    typename reverse_iterator<Iterator>::difference_type n,  
    const reverse_iterator<Iterator>& x);  

Returns: reverse_iterator<Iterator>(x.base() - n).

friend constexpr iter_rvalue_reference_t<Iterator>  
    iter_move(const reverse_iterator& i) noexcept(see below);

Effects: Equivalent to:
    auto tmp = i.base();  
    return ranges::iter_move(--tmp);

Remarks: The expression in noexcept is equivalent to:
    is_nothrow_copy_constructible_v<Iterator> &&  
    noexcept(ranges::iter_move(--declval<Iterator&>()))

template<IndirectlySwappable<Iterator> Iterator2>  
friend constexpr void  
    iter_swap(const reverse_iterator& x,  
        const reverse_iterator<Iterator2>& y) noexcept(see below);

Effects: Equivalent to:
    auto xttmp = x.base();  
    auto yttmp = y.base();  
    ranges::iter_swap(--xttmp, --yttmp);

Remarks: The expression in noexcept is equivalent to:
    is_nothrow_copy_constructible_v<Iterator> &&  
    is_nothrow_copy_constructible_v<Iterator2> &&  
    noexcept(ranges::iter_swap(--declval<Iterator&>(), --declval<Iterator2&>()))

template<class Iterator>
    const reverse_iterator<Iterator> make_reverse_iterator(Iterator i);

Returns: reverse_iterator<Iterator>(i).

23.5.2 Insert iterators [insert.iterators]

To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called insert iterators, are provided in the library. With regular iterator classes,

while (first != last) *result++ = *first++;

causes a range [first, last) to be copied into a range starting with result. The same code with result being an insert iterator will insert corresponding elements into the container. This device allows all of the copying algorithms in the library to work in the insert mode instead of the regular overwrite mode.

An insert iterator is constructed from a container and possibly one of its iterators pointing to where insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators meet the requirements of output iterators. operator* returns the insert iterator itself. The assignment operator=(const T& x) is defined on insert iterators to allow writing into them, it inserts x right before where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the container where the insertion takes place. back_insert_iterator inserts elements at the end of a container, front_insert_iterator inserts elements at the beginning of a container, and insert_iterator inserts elements where the iterator points to in a container. back_inserter, front_inserter, and inserter are three functions making the insert iterators out of a container.

23.5.2.1 Class template back_insert_iterator [back.insert.iterator]

namespace std {
    template<class Container>
    class back_insert_iterator {
protected:
Container* container = nullptr;

public:
  using iterator_category = output_iterator_tag;
  using value_type = void;
  using difference_type = ptrdiff_t;
  using pointer = void;
  using reference = void;
  using container_type = Container;

  constexpr back_insert_iterator() noexcept = default;
  constexpr explicit back_insert_iterator(Container& x);
  constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
  constexpr back_insert_iterator& operator=(typename Container::value_type&& value);
  constexpr back_insert_iterator& operator*();
  constexpr back_insert_iterator& operator++();
  constexpr back_insert_iterator operator++(int);
};

23.5.2.1.1 Operations

constexpr explicit back_insert_iterator(Container& x);
Effects: Initializes container with addressof(x).

constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
Effects: As if by: container->push_back(value);
Returns: *this.

constexpr back_insert_iterator& operator=(typename Container::value_type&& value);
Effects: As if by: container->push_back(std::move(value));
Returns: *this.

constexpr back_insert_iterator& operator*();
Returns: *this.

constexpr back_insert_iterator& operator++();
constexpr back_insert_iterator operator++(int);
Returns: *this.

23.5.2.1.2 back_inserter

template<class Container>
constexpr back_insert_iterator<Container> back_inserter(Container& x);
Returns: back_insert_iterator<Container>(x).

23.5.2.2 Class template front_insert_iterator

namespace std {
  template<class Container>
  class front_insert_iterator {
    protected:
    Container* container = nullptr;

    public:
      using iterator_category = output_iterator_tag;
      using value_type = void;
      using difference_type = ptrdiff_t;
      using pointer = void;
      using reference = void;
      using container_type = Container;

    § 23.5.2.2
23.5.2.2.1 Operations

constexpr explicit front_insert_iterator(Container& x);
  
  Effects: Initializes container with addressof(x).

constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
  
  Effects: As if by: container->push_front(value);
  Returns: *this.

constexpr front_insert_iterator& operator=(typename Container::value_type&& value);
  
  Effects: As if by: container->push_front(std::move(value));
  Returns: *this.

constexpr front_insert_iterator& operator*();
  
  Returns: *this.

constexpr front_insert_iterator& operator++();
constexpr front_insert_iterator operator++(int);
  
  Returns: *this.

23.5.2.2.2 front_inserter

template<class Container>
constexpr front_insert_iterator<Container> front_inserter(Container& x);
  
  Returns: front_insert_iterator<Container>(x).

23.5.2.3 Class template insert_iterator

namespace std {
  template<class Container>
  class insert_iterator {
    protected:
      Container* container = nullptr;
      ranges::iterator_t<Container> iter = ranges::iterator_t<Container>();

    public:
      using iterator_category = output_iterator_tag;
      using value_type = void;
      using difference_type = ptrdiff_t;
      using pointer = void;
      using reference = void;
      using container_type = Container;

      insert_iterator() = default;
      constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
      constexpr insert_iterator& operator=(const typename Container::value_type& value);
      constexpr insert_iterator& operator=(typename Container::value_type&& value);

      constexpr insert_iterator& operator*();
      constexpr insert_iterator& operator++();
      constexpr insert_iterator& operator++(int);
23.5.2.3.1 Operations

```cpp
constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
```

**Effects:** Initializes container with `addressof(x)` and iter with `i`.

```cpp
constexpr insert_iterator& operator=(const typename Container::value_type& value);
```

**Effects:** As if by:

```cpp
iter = container->insert(iter, value);
++iter;
```

**Returns:** *this.

```cpp
constexpr insert_iterator& operator=(typename Container::value_type&& value);
```

**Effects:** As if by:

```cpp
iter = container->insert(iter, std::move(value));
++iter;
```

**Returns:** *this.

```cpp
constexpr insert_iterator& operator*();
```

**Returns:** *this.

```cpp
constexpr insert_iterator& operator++();
constexpr insert_iterator& operator++(int);
```

**Returns:** *this.

23.5.2.3.2 inserter

```cpp
template<class Container>
tconstexpr inserter(Container& x, ranges::iterator_t<Container> i);
```

**Returns:** `insert_iterator<Container>(x, i)`.

23.5.3 Move iterators and sentinels

Class template `move_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator’s indirection operator to an rvalue. Some generic algorithms can be called with move iterators to replace copying with moving.

```cpp
list<string> s;
// populate the list s
vector<string> v1(s.begin(), s.end()); // copies strings into v1
vector<string> v2(make_move_iterator(s.begin()), make_move_iterator(s.end())); // moves strings into v2
```

— end example]

23.5.3.1 Class template `move_iterator`

namespace std {
    template<class Iterator>
    class move_iterator {
    public:
        using iterator_type = Iterator;
        using iterator_concept = input_iterator_tag;
        using iterator_category = see below;
        using value_type = iter_value_t<Iterator>;
        using difference_type = iter_difference_t<Iterator>;
        using pointer = Iterator;
        using reference = iter_rvalue_reference_t<Iterator>;
    }
constexpr move_iterator();
constexpr explicit move_iterator(Iterator i);
template<class U> constexpr move_iterator(const move_iterator<U>& u);
template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);

constexpr iterator_type base() const;
constexpr reference operator*() const;
constexpr move_iterator& operator++();
constexpr auto operator++(int);
constexpr move_iterator& operator--();
constexpr move_iterator operator--(int);
constexpr move_iterator operator+(difference_type n) const;
constexpr move_iterator& operator+=(difference_type n);
constexpr move_iterator operator-(difference_type n) const;
constexpr move_iterator& operator-=(difference_type n);
constexpr reference operator[](difference_type n) const;

template<Sentinel<Iterator> S>
friend constexpr bool operator==(const move_iterator& x, const move_sentinel<S>& y);

friend constexpr iter_difference_t<Iterator>
operator-(const move_sentinel<S>& x, const move_iterator& y);

friend constexpr iter_rvalue_reference_t<Iterator>
iter_move(const move_iterator& i)
noexcept(noexcept(ranges::iter_move(i.current)));

friend constexpr void
iter_swap(const move_iterator& x, const move_iterator<Iterator2>& y)
noexcept(noexcept(ranges::iter_swap(x.current, y.current)));

private:
    Iterator current;  // exposition only
};

1 The member typedef-name iterator_category denotes
   — random_access_iterator_tag if the type iterator_traits<Iterator>::iterator_category models
    DerivedFrom<random_access_iterator_tag>, and
   — iterator_traits<Iterator>::iterator_category otherwise.

23.5.3.2 Requirements [move.iter.requirements]

The template parameter Iterator shall either meet the Cpp17InputIterator requirements (23.3.5.2) or model InputIterator (23.3.4.9). Additionally, if any of the bidirectional traversal functions are instantiated, the template parameter shall either meet the Cpp17BidirectionalIterator requirements (23.3.5.5) or model BidirectionalIterator (23.3.4.12). If any of the random access traversal functions are instantiated, the template parameter shall either meet the Cpp17RandomAccessIterator requirements (23.3.5.6) or model RandomAccessIterator (23.3.4.13).

§ 23.5.3.2 912
23.5.3.3 Construction and assignment

```cpp
constexpr move_iterator();
```  
Effects: Constructs a `move_iterator`, value-initializing `current`. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a value-initialized iterator of type `Iterator`.

```cpp
constexpr explicit move_iterator(Iterator i);
```  
Effects: Constructs a `move_iterator`, initializing `current` with `i`.

```cpp
template<class U> constexpr move_iterator(const move_iterator<U>& u);
```  
Mandates: `U` is convertible to `Iterator`.

Effects: Constructs a `move_iterator`, initializing `current` with `u.base()`.

```cpp
template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);
```  
Mandates: `U` is convertible to `Iterator`.

Effects: Assigns `u.base()` to `current`.

23.5.3.4 Conversion

```cpp
constexpr Iterator base() const;
```  
Returns: `current`.

23.5.3.5 Element access

```cpp
constexpr reference operator*() const;
```  
Effects: Equivalent to:

```cpp
return ranges::iter_move(current);
```

```cpp
constexpr reference operator[](difference_type n) const;
```  
Effects: Equivalent to:

```cpp
ranges::iter_move(current + n);
```

23.5.3.6 Navigation

```cpp
constexpr move_iterator& operator++();
```  
Effects: As if by `++current`.

Returns: `*this`.

```cpp
constexpr auto operator++(int);
```  
Effects: If `Iterator` models `ForwardIterator`, equivalent to:

```cpp
move_iterator tmp = *this;
++current;
return tmp;
```

Otherwise, equivalent to `++current`.

```cpp
constexpr move_iterator& operator--();
```  
Effects: As if by `--current`.

Returns: `*this`.

```cpp
constexpr move_iterator operator--(int);
```  
Effects: As if by:

```cpp
move_iterator tmp = *this;
--current;
return tmp;
```

```cpp
constexpr move_iterator operator+(difference_type n) const;
```  
Returns: `move_iterator(current + n)`.
constexpr move_iterator& operator+=(difference_type n);

Effects: As if by: current += n;

Returns: *this.

constexpr move_iterator operator-(difference_type n) const;

Returns: move_iterator(current - n).

constexpr move_iterator& operator-=(difference_type n);

Effects: As if by: current -= n;

Returns: *this.

23.5.3.7 Comparisons

template<class Iterator1, class Iterator2>
constexpr bool operator==(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: x.base() == y.base() is well-formed and convertible to bool.

Returns: x.base() == y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator!=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: x.base() < y.base() is well-formed and convertible to bool.

Returns: !(x == y).

template<class Iterator1, class Iterator2>
constexpr bool operator<(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: y.base() < x.base() is well-formed and convertible to bool.

Returns: y < x.

template<class Iterator1, class Iterator2>
constexpr bool operator<=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: y.base() < x.base() is well-formed and convertible to bool.

Returns: !(y < x).

§ 23.5.3.7 914
23.5.3.8 Non-member functions

```cpp
template<class Iterator1, class Iterator2>
constexpr auto operator-(const move_iterator<Iterator1>& x,
                        const move_iterator<Iterator2>& y)
-> decltype(x.base() - y.base());

template<SizedSentinel<Iterator> S>
friend constexpr iter_difference_t<Iterator>
operator-(const move_sentinel<S>& x, const move_iterator& y);

template<SizedSentinel<Iterator> S>
friend constexpr iter_difference_t<Iterator>
operator-(const move_iterator& x, const move_sentinel<S>& y);

1 Returns: x.base() - y.base().

template<class Iterator>
constexpr move_iterator<Iterator>
operator+(iter_difference_t<Iterator> n, const move_iterator<Iterator>& x);

2 Constraints: x + n is well-formed and has type Iterator.

Returns: x + n.

friend constexpr iter_rvalue_reference_t<Iterator>
iter_move(const move_iterator& i)
noexcept(noexcept(ranges::iter_move(i.current)));

4 Effects: Equivalent to: return ranges::iter_move(i.current);

template<IndirectlySwappable<Iterator> Iterator2>
friend constexpr void
iter_swap(const move_iterator& x, const move_iterator<Iterator2>& y)
noexcept(noexcept(ranges::iter_swap(x.current, y.current)));

5 Effects: Equivalent to: ranges::iter_swap(x.current, y.current).

template<class Iterator>
constexpr move_iterator<Iterator> make_move_iterator(Iterator i);

6 Returns: move_iterator<Iterator>(i).
```

23.5.3.9 Class template move_sentinel

```cpp
1 Class template move_sentinel is a sentinel adaptor useful for denoting ranges together with move_iterator. When an input iterator type I and sentinel type S model Sentinel<S, I>, move_sentinel<S> and move_iterator<I> model Sentinel<move_sentinel<S>, move_iterator<I>> as well.

2 [Example: A move_if algorithm is easily implemented with copy_if using move_iterator and move_sentinel:

```cpp
template<InputIterator I, Sentinel<I> S, WeaklyIncrementable O,
         IndirectUnaryPredicate<I> Pred>
requires IndirectlyMovable<I, O>
void move_if(I first, S last, O out, Pred pred) {
    std::ranges::copy_if(move_iterator<I>{first}, move_sentinel<S>{last}, out, pred);
}

— end example]
```

namespace std {

```cpp
template<Semiregular S>
class move_sentinel {
public:
    constexpr move_sentinel();
    constexpr explicit move_sentinel(S s);
    template<class S2>
    requiresConvertibleTo<const S2&, S
    constexpr move_sentinel(S sentinel(S2)s);
    template<class S2>
    requires Assignable<S2, const S2&>
    constexpr move_sentinel& operator=(const move_sentinel<S2>& s);
```
constexpr S base() const;
private:
    S last;   // exposition only
};

23.5.3.10 Operations [move.sent.ops]

constexpr move_sentinel();

1 Effects: Value-initializes last. If is_trivially_default_constructible_v<S> is true, then this constructor is a constexpr constructor.

constexpr explicit move_sentinel(S s);

2 Effects: Initializes last with std::move(s).

template<class S2>
requires ConvertibleTo<const S2&, S>
constexpr move_sentinel(const move_sentinel<S2>& s);

3 Effects: Initializes last with s.last.

template<class S2>
requires Assignable<S&, const S2&>
constexpr move_sentinel& operator=(const move_sentinel<S2>& s);

4 Effects: Equivalent to: last = s.last; return *this;

23.5.4 Common iterators [iterators.common]

23.5.4.1 Class template common_iterator [common.iterator]

1 Class template common_iterator is an iterator/sentinel adaptor that is capable of representing a non-common range of elements (where the types of the iterator and sentinel differ) as a common range (where they are the same). It does this by holding either an iterator or a sentinel, and implementing the equality comparison operators appropriately.

2 [Note: The common_iterator type is useful for interfacing with legacy code that expects the begin and end of a range to have the same type. — end note]

3 [Example:

    template<class ForwardIterator>
    void fun(ForwardIterator begin, ForwardIterator end);

    list<int> s;
    // populate the list s
    using CI = common_iterator<counted_iterator<list<int>::iterator>, default_sentinel_t>;
    // call fun on a range of 10 ints
    fun(CI(counted_iterator(s.begin(), 10)), CI(default_sentinel));

    — end example]

namespace std {
    template<Iterator I, Sentinel<I> S>
    requires (!Same<I, S>)
    class common_iterator {
    public:
        constexpr common_iterator() = default;
        constexpr common_iterator(I i);
        constexpr common_iterator(S s);
        template<class I2, class S2>
        requires ConvertibleTo<const I2&, I> && ConvertibleTo<const S2&, S>
        constexpr common_iterator(const common_iterator<I2, S2>& x);  

        template<class I2, class S2>
        requires Assignable<I&, const I2&> && Assignable<S&, const S2&>
        common_iterator& operator=(const common_iterator<I2, S2>& x);
DECLTYPE(AUTO) operator*();
decltype(AUTO) operator*() const
  requires dereferenceable<const I>;
decltype(AUTO) operator->() const
  requires see below;

common_iterator& operator++();
decltype(AUTO) operator++(int);

template<class I2, Sentinel<I> S2>
  requires Sentinel<S, I2>
friend bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);
template<class I2, Sentinel<I> S2>
  requires Sentinel<S, I2> && EqualityComparableWith<I, I2>
friend bool operator!=(const common_iterator& x, const common_iterator<I2, S2>& y);
template<class I2, Sentinel<I> S2>
  requires Sentinel<S, I2>
friend bool operator!=(const common_iterator& x, const common_iterator<I2, S2>& y);
template<SizedSentinel<I> I2, SizedSentinel<I> S2>
  requires SizedSentinel<S, I2>
friend iter_difference_t<I2> operator-(const common_iterator& x, const common_iterator<I2, S2>& y);

friend iter_rvalue_reference_t<I> iter_move(const common_iterator& i)
  noexcept(noexcept(ranges::iter_move(const I&())));

private:
  variant<I, S> v_; // exposition only
};

template<class I, class S>
struct incrementable_traits<common_iterator<I, S>> {
  using difference_type = iter_difference_t<I>;
};

template<InputIterator I, class S>
struct iterator_traits<common_iterator<I, S>> {
  using iterator_concept = see below;
  using iterator_category = see below;
  using value_type = iter_value_t<I>;
  using difference_type = iter_difference_t<I>;
  using pointer = see below;
  using reference = iter_reference_t<I>;
};

§ 23.5.4.2 Associated types

The nested typedef-names of the specialization of iterator_traits for common_iterator<I, S> are defined as follows.

(1.1) — iterator_concept denotes forward_iterator_tag if I models ForwardIterator; otherwise it denotes input_iterator_tag.

(1.2) — iterator_category denotes forward_iterator_tag if iterator_traits<I>::iterator_category models DerivedFrom<forward_iterator_tag>; otherwise it denotes input_iterator_tag.
— If the expression \( a \).operator\(->() \) is well-formed, where \( a \) is an lvalue of type \( \text{const common_iterator<}I, S\text{>} \), then \( \text{pointer} \) denotes the type of that expression. Otherwise, \( \text{pointer} \) denotes \( \text{void} \).

### 23.5.4.3 Constructors and conversions

[common.iter.const]

```cpp
constexpr common_iterator(I i);  
\[\text{Effects: Initializes } v_\text{ as if by } v_\{\text{in_place_type<}I\text{>, std::move(i)}\}.\]
```

```cpp
constexpr common_iterator(S s);  
\[\text{Effects: Initializes } v_\text{ as if by } v_\{\text{in_place_type<}S\text{>, std::move(s)}\}.\]
```

```cpp
\template<class I2, class S2> 
\\text{requires ConvertibleTo<}\text{const I2&, I}\text{> && ConvertibleTo<}\text{const S2&, S}\text{>}
\\text{constexpr common_iterator(const common_iterator<}I2, S2\text{>& x);}
\\[\text{Effects: } x.v_.\text{valueless_by_exception()} = \text{false}.\]
```

```cpp
\template<class I2, class S2> 
\\text{requires ConvertibleTo<}\text{const I2&, I}\text{> && ConvertibleTo<}\text{const S2&, S}\text{> && Assignable<}I, const I2&\text{> && Assignable<}S, const S2&\text{>}
\\text{common_iterator& operator=(const common_iterator<}I2, S2\text{>& x);}
\\[\text{Effects: Equivalent to:}\]
```

1. If \(v_.\text{index()} = x.v_.\text{index()}\), then \(\text{return } get<i>(v_); = get<i>(x.v_);\).
2. Otherwise, \(v_.\text{emplace}<i>(\text{get<i>(x.v_)});\)

where \(i\) is \(x.v_.\text{index()}\).

### 23.5.4.4 Accessors

[common.iter.access]

```cpp
decltype(auto) operator*();
```

```cpp
\text{dectype(auto) operator*() const}
\text{requires dereferenceable<}\text{const I}\text{>};
\[\text{Effects: holds_alternative<}I\text{>(v_).}\]
```

```cpp
\text{dectype(auto) operator->() const}
\text{requires see below;}
```

The expression in the requires clause is equivalent to:

```cpp
\text{Readable<}\text{const I}\text{> &&}
\text{requires(const I& i) \{ i.operator->(); \} ||}
\text{is_reference_v<}\text{iter_reference_t<}I\text{> ||}
\text{Constructible<}\text{iter_value_t<}I\text{>, iter_reference_t<}I\text{>>}}
```

```cpp
\[\text{Effects: holds_alternative<}I\text{>(v_).}\]
```

### 23.5.4.4.918
proxy(iter_reference_t<I>&& x)
  : keep_(std::move(x)) {}

public:
  const iter_value_t<I>* operator->() const {
    return addressof(keep_);
  }
};

23.5.4.5 Navigation

common_iterator& operator++();

1 Expect: holds_alternative<I>(v_).
2 Effects: Equivalent to ++get<I>(v_).
3 Returns: *this.

decltype(auto) operator++(int);

4 Expect: holds_alternative<I>(v_).
5 Effects: If I models ForwardIterator, equivalent to:

common_iterator tmp = *this;
++*this;
return tmp;

Otherwise, equivalent to: return get<I>(v_++);

23.5.4.6 Comparisons

template<class I2, Sentinel<I> S2>
requires Sentinel<S, I2>
friend bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);

1 Expect: x.v_.valueless_by_exception() and y.v_.valueless_by_exception() are each false.
2 Returns: true if i == j, and otherwise get<i>(x.v_) == get<j>(y.v_), where i is x.v_.index() and j is y.v_.index().

template<class I2, Sentinel<I> S2>
requires Sentinel<S, I2> && EqualityComparableWith<I, I2>
friend bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);

3 Expect: x.v_.valueless_by_exception() and y.v_.valueless_by_exception() are each false.
4 Returns: true if i and j are each 1, and otherwise get<i>(x.v_) == get<j>(y.v_), where i is x.v_.index() and j is y.v_.index().

template<class I2, Sentinel<I> S2>
requires Sentinel<S, I2>
friend bool operator!=(const common_iterator& x, const common_iterator<I2, S2>& y);

5 Expect: Equivalent to: return !(x == y);

template<SizedSentinel<I> I2, SizedSentinel<I> S2>
requires SizedSentinel<S, I2>
friend iter_difference_t<I2> operator-(const common_iterator& x, const common_iterator<I2, S2>& y);

6 Expect: x.v_.valueless_by_exception() and y.v_.valueless_by_exception() are each false.
7 Returns: 0 if i and j are each 1, and otherwise get<i>(x.v_) - get<j>(y.v_), where i is x.v_.index() and j is y.v_.index().
23.5.4.7 Customization

friend iter_rvalue_reference_t<I> iter_move(const common_iterator& i)
    noexcept(noexcept(ranges::iter_move(declval<const I&>())))
    requires InputIterator<I>;

1  Expects: holds_alternative<I>(v_).
2  Effects: Equivalent to: return ranges::iter_move(get<I>(i.v_));

template<IndirectlySwappable<I> I2, class S2>
friend void iter_swap(const common_iterator& x, const common_iterator<I2, S2>& y)
    noexcept(noexcept(ranges::iter_swap(declval<const I&>(), declval<const I2&>())));

3  Expects: holds_alternative<I>(x.v_) and holds_alternative<I2>(y.v_) are each true.
4  Effects: Equivalent to ranges::iter_swap(get<I>(x.v_), get<I2>(y.v_)).

23.5.5 Default sentinels

namespace std {
    struct default_sentinel_t { };}

1 Class default_sentinel_t is an empty type used to denote the end of a range. It can be used together with
    iterator types that know the bound of their range (e.g., counted_iterator (23.5.6.1)).

23.5.6 Counted iterators

23.5.6.1 Class template counted_iterator

1 Class template counted_iterator is an iterator adaptor with the same behavior as the underlying iterator
    except that it keeps track of the distance to the end of its range. It can be used together with default_
    sentinel in calls to generic algorithms to operate on a range of N elements starting at a given position
    without needing to know the end position a priori.

2 [Example:

    list<string> s;
    // populate the list s with at least 10 strings
    vector<string> v;
    // copies 10 strings into v:
    ranges::copy(counted_iterator(s.begin(), 10), default_sentinel, back_inserter(v));
    — end example]

3 Two values i1 and i2 of types counted_iterator<I1> and counted_iterator<I2> refer to elements of the
    same sequence if and only if next(i1.base(), i1.count()) and next(i2.base(), i2.count()) refer to
    the same (possibly past-the-end) element.

namespace std {
    template<Iterator I>
    class counted_iterator {
        public:
            using iterator_type = I;

            constexpr counted_iterator() = default;
            constexpr counted_iterator(I x, iter_difference_t<I> n);
        template<class I2>
            requires ConvertibleTo<const I2&, I>
            constexpr counted_iterator(const counted_iterator<I2>& x);
        template<class I2>
            requires Assignable<I&, const I2&>
            constexpr counted_iterator& operator=(const counted_iterator<I2>& x);

            constexpr I base() const;
            constexpr iter_difference_t<I> count() const noexcept;
            constexpr decltype(auto) operator*();
            constexpr decltype(auto) operator*() const
                requires dereferenceable<const I>;

§ 23.5.6.1
constexpr counted_iterator& operator++();
decltype(auto) operator++(int);
constexpr counted_iterator operator++(int)
    requires ForwardIterator<I>;
constexpr counted_iterator& operator--()
    requires BidirectionalIterator<I>;
constexpr counted_iterator operator--(int)
    requires BidirectionalIterator<I>;

constexpr counted_iterator operator+(iter_difference_t<I> n) const

    using pointer = void;
};

23.5.6.2 Constructors and conversions

constexpr counted_iterator(I i, iter_difference_t<I> n);

1 Expects: n >= 0.
2 Effects: Initializes current with i and length with n.

template<class I2>
requires ConvertibleTo<const I2&, I>
constexpr counted_iterator(const counted_iterator<I2>& x);

3 Effects: Initializes current with x.current and length with x.length.

template<class I2>
requires Assignable<I&, const I2&>
constexpr counted_iterator& operator=(const counted_iterator<I2>& x);

4 Effects: Assigns x.current to current and x.length to length.
5 Returns: *this.

23.5.6.3 Accessors

constexpr I base() const;

1 Effects: Equivalent to: return current;

constexpr iter_difference_t<I> count() const noexcept;

2 Effects: Equivalent to: return length;

23.5.6.4 Element access

constexpr decltype(auto) operator*();
constexpr decltype(auto) operator*() const
    requires dereferenceable<const I>;

1 Effects: Equivalent to: return *current;

constexpr decltype(auto) operator[](iter_difference_t<I> n) const
    requires RandomAccessIterator<I>;

2 Expects: n < length.
3 Effects: Equivalent to: return current[n];

23.5.6.5 Navigation

constexpr counted_iterator& operator++();

1 Expects: length > 0.

§ 23.5.6.5
Effects: Equivalent to:
   ++current;
   --length;
   return *this;

decltype(auto) operator++(int);

Effects: length > 0.

Effects: Equivalent to:
   --length;
   try { return current++; } 
   catch(...) { ++length; throw; }

constexpr counted_iterator operator++(int)
   requires ForwardIterator<I>;

Effects: Equivalent to:
   counted_iterator tmp = *this;
   +++this;
   return tmp;

constexpr counted_iterator& operator--();
   requires BidirectionalIterator<I>

Effects: Equivalent to:
   --current;

Effects: Equivalent to: return y.length;

constexpr counted_iterator& operator-=(iter_difference_t<I> n)
    requires RandomAccessIterator<I>;

Expects: -n <= length.

Effects: Equivalent to:
    current -= n;
    length += n;
    return *this;

23.5.6.6 Comparisons [counted.iter.cmp]

template<Common<I> I2>
    friend constexpr bool operator==(const counted_iterator& x, const counted_iterator<I2>& y);

Expects: x and y refer to elements of the same sequence (23.5.6.1).

Effects: Equivalent to: return x.length == y.length;

template<Common<I> I2>
    friend constexpr bool operator==(const counted_iterator& x, default_sentinel_t);

template<Common<I> I2>
    friend constexpr bool operator==(default_sentinel_t, const counted_iterator& y);

Effects: Equivalent to: return x.length == 0;

template<Common<I> I2>
    friend constexpr bool operator!=(const counted_iterator& x, const counted_iterator<I2>& y);

Effects: Equivalent to: return !(x == y);

template<Common<I> I2>
    friend constexpr bool operator!=(const counted_iterator& x, default_sentinel_t);

Effects: Equivalent to: return y.length < x.length;

[Note: The argument order in the Effects: element is reversed because length counts down, not up. —end note]

template<Common<I> I2>
    friend constexpr bool operator<(const counted_iterator& x, const counted_iterator<I2>& y);

Effects: Equivalent to: return y < x;

template<Common<I> I2>
    friend constexpr bool operator<(const counted_iterator& x, default_sentinel_t);

Effects: Equivalent to: return !(y < x);
template<Common<I> I2>
friend constexpr bool operator>=(
    const counted_iterator& x, const counted_iterator<I2>& y);

Effects: Equivalent to: return !(x < y);

23.5.6.7 Customizations

friend constexpr iter_rvalue_reference_t<I>
iter_move(const counted_iterator& i)
noexcept(noexcept(ranges::iter_move(i.current)))
requires InputIterator<I>;
1
Effects: Equivalent to: return ranges::iter_move(i.current);

template<IndirectlySwappable<I> I2>
friend constexpr void
iter_swap(const counted_iterator& x, const counted_iterator<I2>& y)
noexcept(noexcept(ranges::iter_swap(x.current, y.current)));
2
Effects: Equivalent to ranges::iter_swap(x.current, y.current).

23.5.7 Unreachable sentinel

23.5.7.1 Class unreachable_sentinel_t

Class unreachable_sentinel_t can be used with any WeaklyIncrementable type to denote the “upper bound” of an unbounded interval.

[Example:

```cpp
char* p;
// set p to point to a character buffer containing newlines
char* nl = find(p, unreachable_sentinel, '\n');
```

Provided a newline character really exists in the buffer, the use of unreachable_sentinel above potentially makes the call to find more efficient since the loop test against the sentinel does not require a conditional branch. — end example]

```cpp
namespace std {
    struct unreachable_sentinel_t {
        template<WeaklyIncrementable I>
        friend constexpr bool operator==(unreachable_sentinel_t, const I&) noexcept;
        template<WeaklyIncrementable I>
        friend constexpr bool operator==(const I&, unreachable_sentinel_t) noexcept;
        template<WeaklyIncrementable I>
        friend constexpr bool operator!=(unreachable_sentinel_t, const I&) noexcept;
        template<WeaklyIncrementable I>
        friend constexpr bool operator!=(const I&, unreachable_sentinel_t) noexcept;
    };
}
```

23.5.7.2 Comparisons

```cpp
template<WeaklyIncrementable I>
friend constexpr bool operator==(unreachable_sentinel_t, const I&) noexcept;
template<WeaklyIncrementable I>
friend constexpr bool operator==(const I&, unreachable_sentinel_t) noexcept;
```

1 Returns: false.

```cpp
template<WeaklyIncrementable I>
friend constexpr bool operator!=(unreachable_sentinel_t, const I&) noexcept;
template<WeaklyIncrementable I>
friend constexpr bool operator!=(const I&, unreachable_sentinel_t) noexcept;
```

2 Returns: true.
23.6 Stream iterators

To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

[Example:
partial_sum(istream_iterator<double, char>(cin),
   istream_iterator<double, char>(),
   ostream_iterator<double, char>(cout, "\n"));
reads a file containing floating-point numbers from cin, and prints the partial sums onto cout. — end example]

23.6.1 Class template istream_iterator

The class template istream_iterator is an input iterator (23.3.5.2) that reads successive elements from the input stream for which it was constructed.

namespace std {
  template<class T, class charT = char, class traits = char_traits<charT>,
   class Distance = ptrdiff_t>
  class istream_iterator {
    public:
      using iterator_category = input_iterator_tag;
      using value_type = T;
      using difference_type = Distance;
      using pointer = const T*;
      using reference = const T&;
      using char_type = charT;
      using traits_type = traits;
      using istream_type = basic_istream<charT,traits>;

      constexpr istream_iterator();
      constexpr istream_iterator(default_sentinel_t);
      istream_iterator(istream_type& s);
      istream_iterator(const istream_iterator& x) = default;
      ~istream_iterator() = default;
      istream_iterator& operator=(const istream_iterator&);
      const T& operator*() const;
      const T* operator->() const;
      istream_iterator& operator++();
      istream_iterator operator++(int);

      friend bool operator==(const istream_iterator& i, default_sentinel_t);
      friend bool operator==(default_sentinel_t, const istream_iterator& i);
      friend bool operator!=(const istream_iterator& x, default_sentinel_t y);
      friend bool operator!=(default_sentinel_t x, const istream_iterator& y);

    private:
      basic_istream<charT,traits>* in_stream; // exposition only
      T value; // exposition only
  }
}

The type T shall meet the Cpp17DefaultConstructible, Cpp17CopyConstructible, and Cpp17CopyAssignable requirements.

23.6.1.1 Constructors and destructor

constexpr istream_iterator();
constexpr istream_iterator(default_sentinel_t);

Effects: Constructs the end-of-stream iterator, value-initializing value.

Ensures: in_stream == nullptr is true.
Remarks: If the initializer \( T() \) in the declaration `auto x = T();` is a constant initializer (7.7), then these constructors are `constexpr` constructors.

`istream_iterator(istream_type& s);`

**Effects:** Initializes `in_stream` with `addressof(s)`, value-initializes `value`, and then calls `operator++()`.

`istream_iterator(const istream_iterator& x) = default;`

**Ensures:** `in_stream == x.in_stream` is true.

**Remarks:** If `is_trivially_copy_constructible_v<T>` is true, then this constructor is trivial.

`~istream_iterator() = default;`

**Remarks:** If `is_trivially_destructible_v<T>` is true, then this destructor is trivial.

23.6.1.2 Operations

```cpp
const T& operator*() const;

Expects: `in_stream != nullptr` is true.

Returns: `value`.

const T* operator->() const;

Expects: `in_stream != nullptr` is true.

Returns: `addressof(value)`.

istream_iterator& operator++();

Expects: `in_stream != nullptr` is true.

Effects: Equivalent to:

```cpp
    if (!(*in_stream >> value))
    in_stream = nullptr;
```

Returns: `*this`.

istream_iterator operator++(int);

Expects: `in_stream != nullptr` is true.

Effects: Equivalent to:

```cpp
    istream_iterator tmp = *this;
    ++*this;
    return tmp;
```

template<class T, class charT, class traits, class Distance>
bool operator==(const istream_iterator<T,charT,traits,Distance>& x, const istream_iterator<T,charT,traits,Distance>& y);

Returns: `x.in_stream == y.in_stream`.

friend bool operator==(default_sentinel_t, const istream_iterator& i);
friend bool operator==(const istream_iterator& i, default_sentinel_t);

Returns: `!i.in_stream`.

template<class T, class charT, class traits, class Distance>
bool operator!=(const istream_iterator<T,charT,traits,Distance>& x, const istream_iterator<T,charT,traits,Distance>& y);

friend bool operator!=(default_sentinel_t x, const istream_iterator& y);
friend bool operator!=(const istream_iterator& x, default_sentinel_t y);

Returns: `!(x == y)`

23.6.2 Class template `ostream_iterator`

`ostream_iterator` writes (using `operator<<`) successive elements onto the output stream from which it was constructed. If it was constructed with `charT*` as a constructor argument, this string, called a *delimiter string*, is written to the stream after every `T` is written.
namespace std {
  template<class T, class charT = char, class traits = char_traits<charT>>
  class ostream_iterator {
    public:
      using iterator_category = output_iterator_tag;
      using value_type = void;
      using difference_type = ptrdiff_t;
      using pointer = void;
      using reference = void;
      using char_type = charT;
      using traits_type = traits;
      using ostream_type = basic_ostream<charT,traits>;
      constexpr ostreambuf_iterator() noexcept = default;
      ostream_iterator(ostream_type& s);
      ostream_iterator(ostream_type& s, const charT* delimiter);
      ostream_iterator(const ostream_iterator& x);
      ~ostream_iterator();
      ostream_iterator& operator=(const ostream_iterator&);
      ostream_iterator& operator=(const T& value);
      ostream_iterator& operator*();
      ostream_iterator& operator++();
      ostream_iterator& operator++(int);
    private:
      basic_ostream<charT,traits>* out_stream = nullptr;
      // exposition only
      const charT* delim = nullptr;
      // exposition only
    };
  };

23.6.2.1 Constructors and destructor

ostream_iterator(ostream_type& s);
1 Effects: Initializes out_stream with addressof(s) and delim with nullptr.

ostream_iterator(ostream_type& s, const charT* delimiter);
2 Effects: Initializes out_stream with addressof(s) and delim with delimiter.

23.6.2.2 Operations

ostream_iterator& operator=(const T& value);
1 Effects: As if by:
    *out_stream << value;
    if (delim) *out_stream << delim;
    return *this;

ostream_iterator& operator*();
2 Returns: *this.

ostream_iterator& operator++();
ostream_iterator& operator++(int);
3 Returns: *this.

23.6.3 Class template istreambuf_iterator

The class template istreambuf_iterator defines an input iterator (23.3.5.2) that reads successive characters from the streambuf for which it was constructed. operator* provides access to the current input character, if any. Each time operator++ is evaluated, the iterator advances to the next input character. If the end of stream is reached (streambuf_type::sgetc() returns traits::eof()), the iterator becomes equal to the end-of-stream iterator value. The default constructor istreambuf_iterator() and the constructor istreambuf_iterator(nullptr) both construct an end-of-stream iterator object suitable for use as an
end-of-range. All specializations of `istreambuf_iterator` shall have a trivial copy constructor, a `constexpr` default constructor, and a trivial destructor.

2 The result of `operator*()` on an end-of-stream iterator is undefined. For any other iterator value a `char_type` value is returned. It is impossible to assign a character via an input iterator.

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class istreambuf_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type = charT;
        using difference_type = typename traits::off_type;
        using pointer = unspecified;
        using reference = charT;
        using char_type = charT;
        using traits_type = traits;
        using int_type = typename traits::int_type;
        using streambuf_type = basic_streambuf<charT,traits>;
        using istream_type = basic_istream<charT,traits>;

        class proxy;  // exposition only
        constexpr istreambuf_iterator() noexcept;
        constexpr istreambuf_iterator(default_sentinel_t) noexcept;
        istreambuf_iterator(const istreambuf_iterator&) noexcept = default;
        istreambuf_iterator(const istreambuf_iterator& r) noexcept;
        istreambuf_iterator(istream_type& s) noexcept;
        istreambuf_iterator(streambuf_type* s) noexcept;

    private:
        streambuf_type* sbuf_;  // exposition only
    }
}
```

### 23.6.3.1 Class `istreambuf_iterator::proxy` [istreambuf.iterator.proxy]

1 Class `istreambuf_iterator<charT,traits>::proxy` is for exposition only. An implementation is permitted to provide equivalent functionality without providing a class with this name. Class `istreambuf_iterator<charT,traits>::proxy` provides a temporary placeholder as the return value of the post-increment operator (`operator++`). It keeps the character pointed to by the previous value of the iterator for some possible future access to get the character.

```cpp
namespace std {
    template<class charT, class traits>
    class istreambuf_iterator<charT, traits>::proxy { // exposition only
    public:
        charT operator*() { return keep_; }
    }
}
```
23.6.3.2 Constructors

For each `istreambuf_iterator` constructor in this subclause, an end-of-stream iterator is constructed if and only if the exposition-only member `sbuf_` is initialized with a null pointer value.

```cpp
constexpr istreambuf_iterator() noexcept;
constexpr istreambuf_iterator(default_sentinel_t) noexcept;
istreambuf_iterator(istream_type& s) noexcept;
istreambuf_iterator(streambuf_type* s) noexcept;
istreambuf_iterator(const proxy& p) noexcept;
```

Effects:
- Initializes `sbuf_` with `nullptr`.
- Initializes `sbuf_` with `s.rdbuf()`.
- Initializes `sbuf_` with `s`.
- Initializes `sbuf_` with `p.sbuf_`.

23.6.3.3 Operations

```cpp
charT operator*() const

istreambuf_iterator& operator++();
proxy operator++(int);
bool equal(const istreambuf_iterator& b) const;
```

Returns:
- The character obtained via the `streambuf` member `sbuf_->sgetc()`.
- As if by `sbuf_->sbumpc()`.
- `proxy` with `sbuf_`.
- `true` if and only if both iterators are at end-of-stream, or neither is at end-of-stream, regardless of what `streambuf` object they use.

```cpp
template<class charT, class traits>
bool operator==(const istreambuf_iterator<charT, traits>& a,
const istreambuf_iterator<charT, traits>& b);
friend bool operator==(default_sentinel_t s, const istreambuf_iterator& i);
friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);
template<class charT, class traits>
bool operator!=(const istreambuf_iterator<charT, traits>& a,
const istreambuf_iterator<charT, traits>& b);
friend bool operator!=(default_sentinel_t a, const istreambuf_iterator& b);
friend bool operator!=(const istreambuf_iterator& a, default_sentinel_t b);
```

Returns:
- `a.equal(b)`.
- `i.equal(s)`.
- `!a.equal(b)`.

23.6.4 Class template ostreambuf_iterator

The class template `ostreambuf_iterator` writes successive characters onto the output stream from which it was constructed.

```cpp
namespace std {

template<class charT, class traits = char_traits<charT>>
class ostreambuf_iterator {
public:
    using iterator_category = output_iterator_tag;
    using value_type = void;
    using difference_type = ptrdiff_t;
```
using pointer = void;
using reference = void;
using char_type = charT;
using traits_type = traits;
using streambuf_type = basic_streambuf<charT,traits>;
using ostream_type = basic_ostream<charT,traits>;

constexpr ostreambuf_iterator() noexcept = default;
ostreambuf_iterator(ostream_type& s) noexcept;
ostreambuf_iterator(streambuf_type* s) noexcept;
ostreambuf_iterator& operator=(charT c);
ostreambuf_iterator& operator*();
ostreambuf_iterator& operator++();
ostreambuf_iterator& operator++(int);
bool failed() const noexcept;

private:
    streambuf_type* sbuf_ = nullptr; // exposition only
};

23.6.4.1 Constructors

ostreambuf_iterator(ostream_type& s) noexcept;
1
    Expects: s.rdbuf() is not a null pointer.
2
    Effects: Initializes sbuf_ with s.rdbuf().

ostreambuf_iterator(streambuf_type* s) noexcept;
3
    Expects: s is not a null pointer.
4
    Effects: Initializes sbuf_ with s.

23.6.4.2 Operations

ostreambuf_iterator& operator=(charT c);
1
    Effects: If failed() yields false, calls sbuf_->sputc(c); otherwise has no effect.
2
    Returns: *this.

ostreambuf_iterator& operator*();
3
    Returns: *this.

ostreambuf_iterator& operator++();
ostreambuf_iterator& operator++(int);
4
    Returns: *this.

bool failed() const noexcept;
5
    Returns: true if in any prior use of member operator=, the call to sbuf_->sputc() returned traits::eof(); or false otherwise.

23.7 Range access

In addition to being available via inclusion of the <iterator> header, the function templates in 23.7 are available when any of the following headers are included: <array>, <deque>, <forward_list>, <list>, <map>, <regex>, <set>, <span>, <string>, <string_view>, <unordered_map>, <unordered_set>, and <vector>. Each of these templates is a designated customization point (16.5.4.2.1).

template<class C> constexpr auto begin(C& c) -> decltype(c.begin());
template<class C> constexpr auto begin(const C& c) -> decltype(c.begin());
2
    Returns: c.begin().
template<class C> constexpr auto end(C& c) -> decltype(c.end());
Returns: c.end().

template<class C> constexpr auto end(const C& c) -> decltype(c.end());

template<class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept;
Returns: array.

template<class T, size_t N> constexpr T* end(T (&array)[N]) noexcept;
Returns: array + N.

template<class C> constexpr auto cbegin(const C& c) noexcept(noexcept(std::begin(c)))
-> decltype(std::begin(c));
Returns: std::begin(c).

template<class C> constexpr auto cend(const C& c) noexcept(noexcept(std::end(c)))
-> decltype(std::end(c));
Returns: std::end(c).

template<class C> constexpr auto rbegin(C& c) -> decltype(c.rbegin());
template<class C> constexpr auto rbegin(const C& c) -> decltype(c.rbegin());
Returns: c.rbegin().

template<class C> constexpr auto rend(C& c) -> decltype(c.rend());
template<class C> constexpr auto rend(const C& c) -> decltype(c.rend());
Returns: c.rend().

template<class T, size_t N> constexpr reverse_iterator<T*> rbegin(T (&array)[N]);
Returns: reverse_iterator<T*>(array + N).

template<class T, size_t N> constexpr reverse_iterator<T*> rend(T (&array)[N]);
Returns: reverse_iterator<T*>(array).

template<class E> constexpr reverse_iterator<const E*> rbegin(initializer_list<E> il);
Returns: reverse_iterator<const E*>(il.end()).

template<class E> constexpr reverse_iterator<const E*> rend(initializer_list<E> il);
Returns: reverse_iterator<const E*>(il.begin()).

template<class C> constexpr auto crbegin(const C& c) -> decltype(std::rbegin(c));
Returns: std::rbegin(c).

template<class C> constexpr auto crend(const C& c) -> decltype(std::rend(c));
Returns: std::rend(c).

template<class C> constexpr auto size(const C& c) -> decltype(c.size());
Returns: c.size().

template<class C> constexpr auto ssize(const C& c)
-> common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>;
Returns: static_cast<common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>>(c.size())

template<class T, ptrdiff_t N> constexpr ptrdiff_t ssize(const T (&array)[N]) noexcept;
Returns: N.

template<class C> constexpr auto ssize(const C& c)
-> common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>;
Returns: static_cast<common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>>(c.size())

template<class T, ptrdiff_t N> constexpr ptrdiff_t ssize(const T (&array)[N]) noexcept;
Returns: N.

§ 23.7
template<class C> [[nodiscard]] constexpr auto empty(const C& c) -> decltype(c.empty());
   Returns: c.empty().

template<class T, size_t N> [[nodiscard]] constexpr bool empty(const T (&array)[N]) noexcept;
   Returns: false.

template<class E> [[nodiscard]] constexpr bool empty(initializer_list<E> il) noexcept;
   Returns: il.size() == 0.

template<class C> constexpr auto data(C& c) -> decltype(c.data());
template<class C> constexpr auto data(const C& c) -> decltype(c.data());
   Returns: c.data().

template<class T, size_t N> constexpr T* data(T (&array)[N]) noexcept;
   Returns: array.

template<class E> constexpr const E* data(initializer_list<E> il) noexcept;
   Returns: il.begin().
24 Ranges library

24.1 General

This clause describes components for dealing with ranges of elements.

The following subclauses describe range and view requirements, and components for range primitives as summarized in Table 79.

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>24.3 Range access</td>
<td><code>&lt;ranges&gt;</code></td>
</tr>
<tr>
<td>24.4 Requirements</td>
<td></td>
</tr>
<tr>
<td>24.5 Range utilities</td>
<td></td>
</tr>
<tr>
<td>24.6 Range factories</td>
<td></td>
</tr>
<tr>
<td>24.7 Range adaptors</td>
<td></td>
</tr>
</tbody>
</table>

24.2 Header `<ranges>` synopsis

```cpp
#include <initializer_list>
#include <iterator>
namespace std::ranges {
    inline namespace unspecified {
        // 24.3, range access
        inline constexpr unspecified begin = unspecified;

24.3 Range access

In addition to being available via inclusion of the <ranges> header, the customization point objects in 24.3
are available when <iterator> is included.

24.3.1 ranges::begin

The name ranges::begin denotes a customization point object (16.4.2.2.6). The expression ranges::begin(E) for some subexpression E is expression-equivalent to:

(1.1) — E + 0 if E is an lvalue of array type (6.7.2).
(1.2) — Otherwise, if E is an lvalue, decay-copy(E.begin()) if it is a valid expression and its type I models Iterator.
(1.3) — Otherwise, decay-copy(begin(E)) if it is a valid expression and its type I models Iterator with overload resolution performed in a context that includes the declarations:

```cpp
template<class T> void begin(T&&) = delete;
template<class T> void begin(initializer_list<T>&&) = delete;
```

and does not include a declaration of ranges::begin.

(1.4) — Otherwise, ranges::begin(E) is ill-formed. [Note: This case can result in substitution failure when ranges::begin(E) appears in the immediate context of a template instantiation. — end note]

2 [Note: Whenever ranges::begin(E) is a valid expression, its type models Iterator. — end note]

24.3.2 ranges::end

The name ranges::end denotes a customization point object (16.4.2.2.6). The expression ranges::end(E) for some subexpression E is expression-equivalent to:
© ISO/IEC

— E + extent_v<T> if E is an lvalue of array type (6.7.2) T.

— Otherwise, if E is an lvalue, decay-copy(E.end()) if it is a valid expression and its type S models Sentinel<decaytype(ranges::begin(E))>.

— Otherwise, decay-copy(end(E)) if it is a valid expression and its type S models Sentinel<decaytype(ranges::begin(E))> with overload resolution performed in a context that includes the declarations:

```cpp
template<class T> void end(T&&) = delete;
template<class T> void end(initializer_list<T>&&) = delete;
```

and does not include a declaration of ranges::end.

— Otherwise, ranges::end(E) is ill-formed. [Note: This case can result in substitution failure when ranges::end(E) appears in the immediate context of a template instantiation. — end note]

2 [Note: Whenever ranges::end(E) is a valid expression, the types S and I of ranges::end(E) and ranges::begin(E) model Sentinel<S, I>. — end note]

24.3.3 ranges::cbegin

The name ranges::cbegin denotes a customization point object (16.4.2.2.6). The expression ranges::cbegin(E) for some subexpression E of type T is expression-equivalent to:

— ranges::begin(static_cast<const T&>(E)) if E is an lvalue.

— Otherwise, ranges::begin(static_cast<const T&&>(E)).

2 [Note: Whenever ranges::cbegin(E) is a valid expression, its type models Iterator. — end note]

24.3.4 ranges::cend

The name ranges::cend denotes a customization point object (16.4.2.2.6). The expression ranges::cend(E) for some subexpression E of type T is expression-equivalent to:

— ranges::end(static_cast<const T&>(E)) if E is an lvalue.

— Otherwise, ranges::end(static_cast<const T&&>(E)).

2 [Note: Whenever ranges::cend(E) is a valid expression, the types S and I of ranges::cend(E) and ranges::cbegin(E) model Sentinel<S, I>. — end note]

24.3.5 ranges::rbegin

The name ranges::rbegin denotes a customization point object (16.4.2.2.6). The expression ranges::rbegin(E) for some subexpression E of type T is expression-equivalent to:

— If E is an lvalue, decay-copy(E.rbegin()) if it is a valid expression and its type I models Iterator.

— Otherwise, decay-copy(rbegin(E)) if it is a valid expression and its type I models Iterator with overload resolution performed in a context that includes the declaration:

```cpp
template<class T> void rbegin(T&&) = delete;
```

and does not include a declaration of ranges::rbegin.

— Otherwise, make_reverse_iterator(ranges::end(E)) if both ranges::begin(E) and ranges::end(E) are valid expressions of the same type I which models BidirectionalIterator (23.3.4.12).

— Otherwise, ranges::rbegin(E) is ill-formed. [Note: This case can result in substitution failure when ranges::rbegin(E) appears in the immediate context of a template instantiation. — end note]

2 [Note: Whenever ranges::rbegin(E) is a valid expression, its type models Iterator. — end note]

24.3.6 ranges::rend

The name ranges::rend denotes a customization point object (16.4.2.2.6). The expression ranges::rend(E) for some subexpression E is expression-equivalent to:

— If E is an lvalue, decay-copy(E.rend()) if it is a valid expression and its type S models Sentinel<decaytype(ranges::rbegin(E))>.

— Otherwise, decay-copy(rend(E)) if it is a valid expression and its type S models Sentinel<decaytype(ranges::rbegin(E))> with overload resolution performed in a context that includes the declaration:
template<class T> void rend(T&&) = delete;

and does not include a declaration of ranges::rend.

(1.3) — Otherwise, make_reverse_iterator(ranges::begin(E)) if both ranges::begin(E) and ranges::end(E) are valid expressions of the same type I which models BidirectionalIterator (23.3.4.12).

(1.4) — Otherwise, ranges::rend(E) is ill-formed. [Note: This case can result in substitution failure when ranges::rend(E) appears in the immediate context of a template instantiation. — end note]

2 [Note: Whenever ranges::rend(E) is a valid expression, the types S and I of ranges::rend(E) and ranges::rbegin(E) model Sentinel<S, I>. — end note]

24.3.7 ranges::crbegin

The name ranges::crbegin denotes a customization point object (16.4.2.2.6). The expression ranges::crbegin(E) for some subexpression E of type T is expression-equivalent to:

(1.1) — ranges::rbegin(static_cast<const T&>(E)) if E is an lvalue.

(1.2) — Otherwise, ranges::rbegin(static_cast<const T&&>(E)).

[Note: Whenever ranges::crbegin(E) is a valid expression, its type models Iterator. — end note]

24.3.8 ranges::crend

The name ranges::crend denotes a customization point object (16.4.2.2.6). The expression ranges::crend(E) for some subexpression E of type T is expression-equivalent to:

(1.1) — ranges::rend(static_cast<const T&>(E)) if E is an lvalue.

(1.2) — Otherwise, ranges::rend(static_cast<const T&&>(E)).

[Note: Whenever ranges::crend(E) is a valid expression, the types S and I of ranges::crend(E) and ranges::crbegin(E) model Sentinel<S, I>. — end note]

24.3.9 ranges::size

The name size denotes a customization point object (16.4.2.2.6). The expression ranges::size(E) for some subexpression E with type T is expression-equivalent to:

(1.1) — decay-copy(extent_v<T>) if T is an array type (6.7.2).

(1.2) — Otherwise, if disable_sized_range<remove_cv_t<T>> (24.4.3) is false:

(1.2.1) — decay-copy(E.size()) if it is a valid expression and its type I models Integral.

(1.2.2) — Otherwise, decay-copy(size(E)) if it is a valid expression and its type I models Integral with overload resolution performed in a context that includes the declaration:

    template<class T> void size(T&) = delete;

and does not include a declaration of ranges::size.

(1.3) — Otherwise, (ranges::end(E) - ranges::begin(E)) if it is a valid expression and the types I and S of ranges::begin(E) and ranges::end(E) (respectively) model both SizedSentinel<S, I> (23.3.4.8) and ForwardIterator<1>. However, E is evaluated only once.

(1.4) — Otherwise, ranges::size(E) is ill-formed. [Note: This case can result in substitution failure when ranges::size(E) appears in the immediate context of a template instantiation. — end note]

2 [Note: Whenever ranges::size(E) is a valid expression, its type models Integral. — end note]

24.3.10 ranges::empty

The name empty denotes a customization point object (16.4.2.2.6). The expression ranges::empty(E) for some subexpression E is expression-equivalent to:

(1.1) — bool((E).empty()) if it is a valid expression.

(1.2) — Otherwise, (ranges::size(E) == 0) if it is a valid expression.

(1.3) — Otherwise, EQ, where EQ is bool(ranges::begin(E) == ranges::end(E)) except that E is only evaluated once, if EQ is a valid expression and the type of ranges::begin(E) models ForwardIterator.
— Otherwise, `ranges::empty(E)` is ill-formed. [Note: This case can result in substitution failure when `ranges::empty(E)` appears in the immediate context of a template instantiation. — end note]

2 [Note: Whenever `ranges::empty(E)` is a valid expression, it has type bool. — end note]

### 24.3.11 ranges::data

The name `data` denotes a customization point object (16.4.2.2.6). The expression `ranges::data(E)` for some subexpression `E` is expression-equivalent to:

1. If `E` is an lvalue, `decay-copy(E.data())` if it is a valid expression of pointer to object type.
2. Otherwise, if `ranges::begin(E)` is a valid expression whose type models `ContiguousIterator`, `ranges::begin(E) == ranges::end(E) ? nullptr : addressof(*ranges::begin(E))` except that `E` is evaluated only once.
3. Otherwise, `ranges::data(E)` is ill-formed. [Note: This case can result in substitution failure when `ranges::data(E)` appears in the immediate context of a template instantiation. — end note]

2 [Note: Whenever `ranges::data(E)` is a valid expression, it has pointer to object type. — end note]

### 24.3.12 ranges::cdata

The name `cdata` denotes a customization point object (16.4.2.2.6). The expression `ranges::cdata(E)` for some subexpression `E` of type `T` is expression-equivalent to:

1. `ranges::data(static_cast<const T&>(E))` if `E` is an lvalue.
2. Otherwise, `ranges::data(static_cast<const T&&>(E))`.

2 [Note: Whenever `ranges::cdata(E)` is a valid expression, it has pointer to object type. — end note]

### 24.4 Range requirements

#### 24.4.1 General

Ranges are an abstraction that allow a C++ program to operate on elements of data structures uniformly. Calling `ranges::begin` on a range returns an object whose type models `Iterator` (23.3.4.6). Calling `ranges::end` on a range returns an object whose type models `Sentinel<S, I>` together with the type `I` of the object returned by `ranges::begin`, models `Sentinel<S, I>`. The library formalizes the interfaces, semantics, and complexity of ranges to enable algorithms and range adaptors that work efficiently on different types of sequences.

The `Range` concept requires that `ranges::begin` and `ranges::end` return an iterator and a sentinel, respectively. The `SizedRange` concept refines `Range` with the requirement that the number of elements in the range can be determined in constant time using the `ranges::size` function. The `View` concept specifies requirements on a `Range` type with constant-time copy and assign operations.

Several refinements of `Range` group requirements that arise frequently in concepts and algorithms. Common ranges are ranges for which `ranges::begin` and `ranges::end` return objects of the same type. Random access ranges are ranges for which `ranges::begin` returns a type that models `RandomAccessIterator` (23.3.4.13). (Contiguous, bidirectional, forward, input, and output ranges are defined similarly.) Viewable ranges can be converted to views.

#### 24.4.2 Ranges

The `Range` concept defines the requirements of a type that allows iteration over its elements by providing an iterator and sentinel that denote the elements of the range.

```cpp
template<class T>
concept range-impl = // exposition only
  requires(T&& t) {
    ranges::begin(std::forward<T>(t)); // sometimes equality-preserving (see below)
    ranges::end(std::forward<T>(t));
  }

template<class T>
concept Range = range-impl<T>;
```

§ 24.4.2 940
template<class T>
class forwarding-range = // exposition only
    Range<T> && range-impl<T>;

The required expressions `ranges::begin<std::forward<T>(t))` and `ranges::end(std::forward<T>(t))` of the `range-impl` concept do not require implicit expression variations (18.2). Given an expression `E` such that `decltype((E))` is `T`, `T` models `range-impl` only if

1. `ranges::begin(E), ranges::end(E)` denotes a range (23.3.1),
2. both `ranges::begin(E)` and `ranges::end(E)` are amortized constant time and non-modifying, and
3. if the type of `ranges::begin(E)` models `ForwardIterator`, `ranges::begin(E)` is equality-preserving.

[Note: Equality preservation of both `ranges::begin` and `ranges::end` enables passing a `Range` whose iterator type models `ForwardIterator` to multiple algorithms and making multiple passes over the range by repeated calls to `ranges::begin` and `ranges::end`. Since `ranges::begin` is not required to be equality-preserving when the return type does not model `ForwardIterator`, repeated calls might not return equal values or might not be well-defined; `ranges::begin` should be called at most once for such a range. — end note]

Given an expression `E` such that `decltype((E))` is `T` and an lvalue `t` that denotes the same object as `E`, `T` models `forwarding-range` only if

1. `ranges::begin(E)` and `ranges::begin(t)` are expression-equivalent,
2. `ranges::end(E)` and `ranges::end(t)` are expression-equivalent, and
3. the validity of iterators obtained from the object denoted by `E` is not tied to the lifetime of that object.

[Note: Since the validity of iterators is not tied to the lifetime of an object whose type models `forwarding-range`, a function can accept arguments of such a type by value and return iterators obtained from it without danger of dangling. — end note]

[Example: Specializations of class template `subrange` (24.5.3) model `forwarding-range`. `subrange` provides non-member rvalue overloads of `begin` and `end` with the same semantics as its member lvalue overloads, and `subrange`'s iterators - since they are “borrowed” from some other range - do not have validity tied to the lifetime of a `subrange` object. — end example]

### 24.4.3 Sized ranges [range.sized]

The `SizedRange` concept specifies the requirements of a `Range` type that knows its size in constant time with the `size` function.

```cpp
template<class T>
class SizedRange =
    Range<T> &&
    !disable_sized_range<remove_cvref_t<T>> &&
    requires(T& t) { ranges::size(t); };
```

Given an lvalue `t` of type `remove_reference_t<T>`, `T` models `SizedRange` only if

1. `ranges::size(t)` is $O(1)$, does not modify `t`, and is equal to `ranges::distance(t)`, and
2. if `iterator_t<T>` models `ForwardIterator`, `ranges::size(t)` is well-defined regardless of the evaluation of `ranges::begin(t)`. [Note: `ranges::size(t)` is otherwise not required to be well-defined after evaluating `ranges::begin(t)`. For example, `ranges::size(t)` might be well-defined for a `SizedRange` whose iterator type does not model `ForwardIterator` only if evaluated before the first call to `ranges::begin(t)`. — end note]

[Note: The complexity requirement for the evaluation of `ranges::size` is non-amortized, unlike the case for the complexity of the evaluations of `ranges::begin` and `ranges::end` in the `Range` concept. — end note]

[Note: `disable_sized_range` allows use of range types with the library that satisfy but do not in fact model `SizedRange`. — end note]
24.4.4 Views

The `View` concept specifies the requirements of a `Range` type that has constant time copy, move, and assignment operators; that is, the cost of these operations is not proportional to the number of elements in the `View`.

[Example: Examples of `View` are:

- A `Range` type that wraps a pair of iterators.
- A `Range` type that holds its elements by `shared_ptr` and shares ownership with all its copies.
- A `Range` type that generates its elements on demand.

Most containers (Clause 22) are not views since copying the container copies the elements, which cannot be done in constant time. — end example]

```cpp
template<class T>
inline constexpr bool enable_view = see below;
```

```cpp
template<class T>
concept View =
    Range<T> && Semiregular<T> && enable_view<T>;
```

Since the difference between `Range` and `View` is largely semantic, the two are differentiated with the help of `enable_view`.

For a type `T`, the default value of `enable_view<T>` is:

(4.1) If `DerivedFrom<T, view_base>` is true, true.

(4.2) Otherwise, if `T` is a specialization of class template `initializer_list` (17.10), `set` (22.4.6), `multiset` (22.4.7), `unordered_set` (22.5.6), `unordered_multiset` (22.5.7), or `match_results` (30.10), false.

(4.3) Otherwise, if both `T` and `const T` model `Range` and `iter_reference_t<iterator_t<T>>` is not the same type as `iter_reference_t<iterator_t<const T>>`, false. [Note: Deep const-ness implies element ownership, whereas shallow const-ness implies reference semantics. — end note]

(4.4) Otherwise, true.

Pursuant to 16.5.4.2.1, users may specialize `enable_view` to true for types which model `View`, and false for types which do not.

24.4.5 Other range refinements

The `OutputRange` concept specifies requirements of a `Range` type for which `ranges::begin` returns a model of `OutputIterator` (23.3.4.10). `InputRange`, `ForwardRange`, `BidirectionalRange`, and `RandomAccessRange` are defined similarly.

```cpp
template<class R, class T>
conceputal OutputRange =
    Range<R> && OutputIterator<iterator_t<R>, T>;
```

```cpp
template<class T>
concept InputRange =
    Range<T> && InputIterator<iterator_t<T>>;
```

```cpp
template<class T>
concept ForwardRange =
    InputRange<T> && ForwardIterator<iterator_t<T>>;
```

```cpp
template<class T>
concept BidirectionalRange =
    ForwardRange<T> && BidirectionalIterator<iterator_t<T>>;
```

```cpp
template<class T>
concept RandomAccessRange =
    BidirectionalRange<T> && RandomAccessIterator<iterator_t<T>>;
```

§ 24.4.5
ContiguousRange additionally requires that the ranges::data customization point (24.3.11) is usable with the range.

```cpp
template<class T>
concept ContiguousRange =
  RandomAccessRange<T> && ContiguousIterator<iterator_t<T>> &&
  requires(T& t) {
    { ranges::data(t) } -> Same<add_pointer_t<iter_reference_t<iterator_t<T>>>;
  };
```

The CommonRange concept specifies requirements of a Range type for which ranges::begin and ranges::end return objects of the same type. [Example: The standard containers (Clause 22) model CommonRange. — end example]

```cpp
template<class T>
concept CommonRange =
  Range<T> && Same<iterator_t<T>, sentinel_t<T>>;
```

The ViewableRange concept specifies the requirements of a Range type that can be converted to a View safely.

```cpp
template<class T>
concept ViewableRange =
  Range<T> && (forwarding-range<T> || View<decay_t<T>>);
```

## 24.5 Range utilities

1. The components in this subclause are general utilities for representing and manipulating ranges.

### 24.5.1 Helper concepts

Many of the types in this subclause are specified in terms of the following exposition-only concepts:

```cpp
template<class R>
concept simple_view = // exposition only
  View<R> && Range<const R> &&
  Same<iterator_t<R>, iterator_t<const R>> &&
  Same<sentinel_t<R>, sentinel_t<const R>>;
```

```cpp
template<InputIterator I>
concept has_arrow = // exposition only
  is_pointer_v<I> || requires(I i) { i.operator->();};
```

```cpp
template<class T, class U>
concept not_same_as = // exposition only
  !Same<remove_cvref_t<T>, remove_cvref_t<U>>;
```

### 24.5.2 View interface

The class template view_interface is a helper for defining View-like types that offer a container-like interface. It is parameterized with the type that is derived from it.

```cpp
namespace std::ranges {
  template<class D>
  requires is_class_v<D> && Same<D, remove_cv_t<D>>
  class view_interface : public view_base {
  private:
    constexpr D& derived() noexcept { // exposition only
      return static_cast<D&>(*this);
    }
    constexpr const D& derived() const noexcept {
      return static_cast<const D&>(*this);
    }
  public:
    constexpr bool empty() requires ForwardRange<D> {
      return ranges::begin(derived()) == ranges::end(derived());
    }
  };
} n4820
```
constexpr bool empty() const requires ForwardRange<const D> {
    return ranges::begin(derived()) == ranges::end(derived());
}

cconstexpr explicit operator bool() requires requires { ranges::empty(derived()); } {
    return !ranges::empty(derived());
}

cconstexpr explicit operator bool() const requires requires { ranges::empty(derived()); } {
    return !ranges::empty(derived());
}

cconstexpr auto data() requires ContiguousIterator<iterator_t<D>> {
    return ranges::empty(derived()) ? nullptr : addressof(*ranges::begin(derived()));
}

cconstexpr auto data() const requires Range<const D> && ContiguousIterator<iterator_t<const D>> {
    return ranges::empty(derived()) ? nullptr : addressof(*ranges::begin(derived()));
}

cconstexpr auto size() requires ForwardRange<D> && SizedSentinel<sentinel_t<D>, iterator_t<D>> {
    return ranges::end(derived()) - ranges::begin(derived());
}

cconstexpr auto size() const requires ForwardRange<const D> && SizedSentinel<sentinel_t<const D>, iterator_t<const D>> {
    return ranges::end(derived()) - ranges::begin(derived());
}

cconstexpr decltype(auto) front() requires ForwardRange<D>;  
cconstexpr decltype(auto) front() const requires ForwardRange<const D>;

cconstexpr decltype(auto) back() requires BidirectionalRange<D> && CommonRange<D>; 
cconstexpr decltype(auto) back() const 
requires BidirectionalRange<const D> && CommonRange<const D>;

template<RandomAccessRange R = D>
cconstexpr decltype(auto) operator[](iter_difference_t<iterator_t<R>> n) {
    return ranges::begin(derived())[n];
}

template<RandomAccessRange R = const D>
cconstexpr decltype(auto) operator[](iter_difference_t<iterator_t<R>> n) const {
    return ranges::begin(derived())[n];
}

2 The template parameter D for view_interface may be an incomplete type. Before any member of the resulting specialization of view_interface other than special member functions is referenced, D shall be complete, and model both DerivedFrom<view_interface<D>> and View.

24.5.2.1 Members

constexpr decltype(auto) front() requires ForwardRange<D>; 
constexpr decltype(auto) front() const requires ForwardRange<const D>;

1 Expects: !empty().

2 Effects: Equivalent to: return *ranges::begin(derived());

cconstexpr decltype(auto) back() requires BidirectionalRange<D> && CommonRange<D>; 
cconstexpr decltype(auto) back() const requires BidirectionalRange<const D> && CommonRange<const D>;

3 Expects: !empty().
Effects: Equivalent to: `return *ranges::prev(ranges::end(derived()));`

### 24.5.3 Sub-ranges

The `subrange` class template combines together an iterator and a sentinel into a single object that models the `View` concept. Additionally, it models the `SizedRange` concept when the final template parameter is `subrange_kind::sized`.

```cpp
namespace std::ranges {
    template<class T>
    struct pair_like {
        // exposition only
        is_reference_v<T> && requires(T t) {
            typename tuple_size<T>::type; // ensures tuple_size<T> is complete
            requires DerivedFrom<tuple_size<T>, integral_constant<size_t, 2>>;
            typename tuple_element_t<0, remove_const_t<T>>;
            typename tuple_element_t<1, remove_const_t<T>>;
            { get<0>(t) } -> const tuple_element_t<0, T>&;
            { get<1>(t) } -> const tuple_element_t<1, T>&;
        };
    }

    template<class T, class U, class V>
    concept pair_like_convertible_to = // exposition only
        !Range<T> && pair_like<remove_reference_t<T>> &&
        requires(T&& t) {
            { get<0>(std::forward<T>(t)) } -> ConvertibleTo<U>;
            { get<1>(std::forward<T>(t)) } -> ConvertibleTo<V>;
        };

    template<class T, class U, class V>

§ 24.5.3
namespace std {
    using ranges::get;
}

24.5.3.1 Constructors and conversions

constexpr subrange(I i, S s) requires (!StoreSize);
1  Expects: [i, s) is a valid range.
2  Effects: Initializes begin_ with i and end_ with s.

constexpr subrange(I i, S s, iter_difference_t<I> n)
3  requires (K == subrange_kind::sized);
4  Expects: [i, s) is a valid range, and n == ranges::distance(i, s).
5  Effects: Initializes begin_ with i and end_ with s. If StoreSize is true, initializes size_ with n.

[Note: Accepting the length of the range and storing it to later return from size() enables subrange to model SizedRange even when it stores an iterator and sentinel that do not model SizedSentinel.
—end note]

template<not-same-as<subrange> R>
requires forwarding-range<R> &
    ConvertibleTo<iterator_t<R>, I> & ConvertibleTo<sentinel_t<R>, S>
constexpr subrange(R&& r) requires (!StoreSize || SizedRange<R>);
6  Effects: Equivalent to:

(6.1)  If StoreSize is true, subrange{ranges::begin(r), ranges::end(r), ranges::size(r)}.
(6.2)  Otherwise, subrange{ranges::begin(r), ranges::end(r)}.

template<not-same-as<subrange> PairLike>
requires pair-like-convertible-from<PairLike, const I&, const S&>
constexpr operator PairLike() const;
7  Effects: Equivalent to: return PairLike(begin_, end_);

24.5.3.2 Accessors

constexpr I begin() const;
1  Effects: Equivalent to: return begin_;

constexpr S end() const;
2  Effects: Equivalent to: return end_;

constexpr bool empty() const;
3  Effects: Equivalent to: return begin_ == end_;

constexpr iter_difference_t<I> size() const
4  requires (K == subrange_kind::sized);
5  Effects:

(4.1)  If StoreSize is true, equivalent to: return size_;
(4.2)  Otherwise, equivalent to: return end_ - begin_;

[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) const;
5  Effects: Equivalent to:

auto tmp = *this;
    tmp.advance(n);
    return tmp;

[Note: If I does not model ForwardIterator, next can invalidate *this. —end note]
[noexcept] constexpr subrange prev(iter_difference_t<I> n = 1) const
  requires BidirectionalIterator<I>;
7
Effects: Equivalent to:
  auto tmp = *this;
  tmp.advance(-n);
  return tmp;

constexpr subrange& advance(iter_difference_t<I> n);
8
Effects: Equivalent to:
(8.1) — If StoreSize is true,
    size_ -= n - ranges::advance(begin_, n, end_);
    return *this;
(8.2) — Otherwise,
    ranges::advance(begin_, n, end_);
    return *this;

template<size_t N, class I, class S, subrange_kind K>
  requires (N < 2)
constexpr auto get(const subrange<I, S, K>& r);
9
Effects: Equivalent to:
  if constexpr (N == 0)
    return r.begin();
  else
    return r.end();

24.5.4 Dangling iterator handling
[range.dangling]

The tag type dangling is used together with the template aliases safe_iterator_t and safe_subrange_t
to indicate that an algorithm that typically returns an iterator into or subrange of a Range argument does
not return an iterator or subrange which could potentially reference a range whose lifetime has ended for a
particular rvalue Range argument which does not model forwarding-range (24.4.2).

namespace std::ranges {
  struct dangling {
    constexpr dangling() noexcept = default;
    template<class... Args>
      constexpr dangling(Args&&...) noexcept { }
  };
}

[Example:

vector<int> f();
auto result1 = ranges::find(f(), 42);        // #1
static_assert(Same<decltype(result1), ranges::dangling>);
auto vec = f();
auto result2 = ranges::find(vec, 42);       // #2
static_assert(Same<decltype(result2), vector<int>::iterator>);
auto result3 = ranges::find(subrange{vec}, 42); // #3
static_assert(Same<decltype(result3), vector<int>::iterator>);

The call to ranges::find at #1 returns ranges::dangling since f() is an rvalue vector: the vector could
potentially be destroyed before a returned iterator is dereferenced. However, the calls at #2 and #3 both
return iterators since the lvalue vec and specializations of subrange model forwarding-range. — end
example]

24.6 Range factories
[range.factories]

This subclause defines range factories, which are utilities to create a View.

2 Range factories are declared in namespace std::ranges::view.
24.6.1 Empty view

24.6.1.1 Overview

empty_view produces a View of no elements of a particular type.

[Example:

```cpp
eempty_view<int> e;
static_assert(ranges::empty(e));
static_assert(0 == e.size());
```

—end example]

24.6.1.2 Class template empty_view

```cpp
namespace std::ranges {
    template<class T>
    requires is_object_v<T>
    class empty_view : public view_interface<empty_view<T>> {
        public:
            static constexpr T* begin() noexcept { return nullptr; }
            static constexpr T* end() noexcept { return nullptr; }
            static constexpr T* data() noexcept { return nullptr; }
            static constexpr ptrdiff_t size() noexcept { return 0; }
            static constexpr bool empty() noexcept { return true; }

        friend constexpr T* begin(empty_view) noexcept { return nullptr; }
        friend constexpr T* end(empty_view) noexcept { return nullptr; }
    }
}
```

24.6.2 Single view

24.6.2.1 Overview

single_view produces a View that contains exactly one element of a specified value.

[Example:

```cpp
s{4};
for (int i : s)
    cout << i; // prints 4
```

—end example]

24.6.2.2 Class template single_view

```cpp
namespace std::ranges {
    template<CopyConstructible T>
    requires is_object_v<T>
    class single_view : public view_interface<single_view<T>> {
        private:
            semiregular<box<T>> value_; // exposition only (see 24.7.2)
        public:
            constexpr single_view() = default;
            constexpr explicit single_view(const T& t);
            constexpr explicit single_view(T&& t);
            template<class... Args>
            requires Constructible<T, Args...>
            constexpr single_view(in_place_t, Args&&... args);

       _constexpr T* begin() noexcept;
        constexpr const T* begin() const noexcept;
        constexpr T* end() noexcept;
        constexpr const T* end() const noexcept;
        static constexpr ptrdiff_t size() noexcept;
        constexpr T* data() noexcept;
        constexpr const T* data() const noexcept;
    }
}
```
constexpr explicit single_view(const T& t);

1  Effects: Initializes value_ with t.

constexpr explicit single_view(T&& t);

2  Effects: Initializes value_ with std::move(t).

template<class... Args>
constexpr single_view(in_place_t, Args&&... args);

3  Effects: Initializes value_ as if by value_{in_place, std::forward<Args>(args)...}.

constexpr T* begin() noexcept;
constexpr const T* begin() const noexcept;

4  Effects: Equivalent to: return data();

constexpr T* end() noexcept;
constexpr const T* end() const noexcept;

5  Effects: Equivalent to: return data() + 1;

static constexpr ptrdiff_t size() noexcept;

6  Effects: Equivalent to: return 1;

constexpr T* data() noexcept;
constexpr const T* data() const noexcept;

7  Effects: Equivalent to: return value_.operator->();

24.6.2.3 view::single

1  The name view::single denotes a customization point object (16.4.2.2.6). For some subexpression E, the expression view::single(E) is expression-equivalent to single_view(E).

24.6.3 Iota view

24.6.3.1 Overview

1  iota_view generates a sequence of elements by repeatedly incrementing an initial value.

2  [Example:

for (int i : iota_view{1, 10})
    cout << i << ' '; // prints: 1 2 3 4 5 6 7 8 9

—end example]

24.6.3.2 Class template iota_view

namespace std::ranges {
    template<class I>
    concept Decrementable = // exposition only
                    see below;

    template<class I>
    concept Advanceable = // exposition only
                    see below;

    template<WeaklyIncrementable W, Semiregular Bound = unreachable_sentinel_t>
    requires weakly-equality-comparable-with<W, Bound>
    class iota_view : public view_interface<iota_view<W, Bound>> {
        private:
            // 24.6.3.3, class iota_view::iterator
            struct iterator;
            // exposition only

            // 24.6.3.4, class iota_view::sentinel
            struct sentinel;
            // exposition only

            W value_ = W();
            // exposition only

            Bound bound_ = Bound();
            // exposition only

        public:
            iota_view() = default;
            constexpr explicit iota_view(W value);
constexpr iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);

constexpr iterator begin() const;
constexpr sentinel end() const;
constexpr iterator end() const requires Same<W, Bound>;

constexpr auto size() const
requires (Same<W, Bound> && Advanceable<W>) ||
(Integral<W> && Integral<Bound>) ||
SizedSentinel<Bound, W>
{ return bound_ - value_; }
};

template<class W, class Bound>
requires (!Integral<W> || !Integral<Bound> || is_signed_v<W> == is_signed_v<Bound>)
iota_view(W, Bound) -> iota_view<W, Bound>;
}

The exposition-only **Decrementable** concept is equivalent to:

```
template<class I>
concept Decrementable =
  Incrementable<I> && requires(I i) {
    { --i } -> Same<I&>;
    { i-- } -> Same<I>;
  };
```

When an object is in the domain of both pre- and post-decrement, the object is said to be **decrementable**.

Let a and b be equal objects of type I. I models **Decrementable** only if

(3.1) - If a and b are decrementable, then the following are all true:
  (3.1.1) - addressof(--a) == addressof(a)
  (3.1.2) - bool(a-- == b)
  (3.1.3) - bool(((void)a--, a) == --b)
  (3.1.4) - bool(++(--a) == b).

(3.2) - If a and b are incrementable, then bool(---(++a) == b).

The exposition-only **Advanceable** concept is equivalent to:

```
template<class I>
concept Advanceable =
  Decrementable<I> && StrictTotallyOrdered<I> &&
  requires(I i, const I j, const iter_difference_t<I> n) {
    { i += n } -> Same<I&>;
    { i -= n } -> Same<I&>;
    { j + n } -> Same<I>;
    { n + j } -> Same<I>;
    { j - n } -> Same<I>;
    { j - j } -> Same<iter_difference_t<I>>;
  };
```

Let a and b be objects of type I such that b is reachable from a after n applications of ++a, for some value n of type iter_difference_t<I>, and let D be iter_difference_t<I>. I models **Advanceable** only if

(4.1) - (a += n) is equal to b.
(4.2) - addressof(a += n) is equal to addressof(a).
(4.3) - (a + n) is equal to (a += n).
(4.4) - For any two positive values x and y of type D, if (a + D(x + y)) is well-defined, then (a + D(x + y)) is equal to ((a + x) + y).
(4.5) - (a + D(0)) is equal to a.
(4.6) - If (a + D(n - 1)) is well-defined, then (a + n) is equal to ++(a + D(n - 1)).
(4.7) \( (b += -n) \) is equal to \( a \).
(4.8) \( (b -= n) \) is equal to \( a \).
(4.9) \( \text{addressof}(b -= n) \) is equal to \( \text{addressof}(b) \).
(4.10) \( (b - n) \) is equal to \( (b -= n) \).
(4.11) \( (b - a) \) is equal to \( n \).
(4.12) \( (a - b) \) is equal to \( -n \).
(4.13) \( \text{bool}(a <= b) \) is true.

```cpp
constexpr explicit iota_view(W value);
```

\*Expects: Bound denotes unreachable_sentinel_t or Bound() is reachable from value.\*

```cpp
constexpr iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);
```

\*Expects: Bound denotes unreachable_sentinel_t or bound is reachable from value.\*

```cpp
constexpr iterator begin() const;
```

\*Effects: Equivalent to: return iterator{value_};\*

```cpp
constexpr sentinel end() const;
```

\*Effects: Equivalent to: return sentinel{bound_};\*

```cpp
constexpr iterator end() const requires Same<W, Bound>;
```

\*Effects: Equivalent to: return iterator{bound_};\*

### 24.6.3.3 Class iota_view::iterator

namespace std::ranges {
    template<class W, class Bound>
    struct iota_view<W, Bound>::iterator {
        private:
            W value_ = W(); // exposition only
        public:
            using iterator_category = see below;
            using value_type = W;
            using difference_type = iter_difference_t<W>;
            iterator() = default;
            constexpr explicit iterator(W value);

            constexpr W operator*() const noexcept(is_nothrow_copy_constructible_v<W>);
            constexpr iterator& operator++();
            constexpr void operator++(int);
            constexpr iterator operator++(int) requires Incrementable<W>;
            constexpr iterator& operator--() requires Decrementable<W>;
            constexpr iterator operator--(int) requires Decrementable<W>;
            constexpr iterator& operator+=(difference_type n) requires Advanceable<W>;
            constexpr iterator& operator+=(difference_type n) requires Advanceable<W>;
            constexpr iterator& operator-=(difference_type n) requires Advanceable<W>;
            constexpr iterator operator[](difference_type n) const
                requires Advanceable<W>;

            friend constexpr bool operator==(const iterator& x, const iterator& y)
                requires EqualityComparable<W>;
    }
}
friend constexpr bool operator!=(const iterator& x, const iterator& y)
    requires EqualityComparable<W>;
friend constexpr bool operator<(const iterator& x, const iterator& y)
    requires StrictTotallyOrdered<W>;
friend constexpr bool operator>(const iterator& x, const iterator& y)
    requires StrictTotallyOrdered<W>;
friend constexpr bool operator<=(const iterator& x, const iterator& y)
    requires StrictTotallyOrdered<W>;
friend constexpr bool operator>=(const iterator& x, const iterator& y)
    requires StrictTotallyOrdered<W>;
friend constexpr iterator operator+(iterator i, difference_type n)
    requires Advanceable<W>;
friend constexpr iterator operator+(difference_type n, iterator i)
    requires Advanceable<W>;
friend constexpr iterator operator-(iterator i, difference_type n)
    requires Advanceable<W>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires Advanceable<W>;

iterator::iterator_category is defined as follows:
(1.1) — If W models Advanceable, then iterator_category is random_access_iterator_tag.
(1.2) — Otherwise, if W models Decrementable, then iterator_category is bidirectional_iterator_tag.
(1.3) — Otherwise, if W models Incrementable, then iterator_category is forward_iterator_tag.
(1.4) — Otherwise, iterator_category is input_iterator_tag.

[Note: Overloads for iter_move and iter_swap are omitted intentionally. — end note]
constexpr explicit iterator(W value);
Effects: Initializes value_ with value.

constexpr W operator*() const noexcept(is_nothrow_copy_constructible_v<W>);
Effects: Equivalent to: return value_;}

[Note: The noexcept clause is needed by the default iter_move implementation. — end note]
constexpr iterator& operator++();
Effects: Equivalent to:
    ++value_; return *this;

constexpr void operator++(int);
Effects: Equivalent to +++this.

constexpr iterator operator++(int) requires Incrementable<W>;
Effects: Equivalent to:
    auto tmp = *this;
    +++this;
    return tmp;

constexpr iterator& operator--() requires Decrementable<W>;
Effects: Equivalent to:
    --value_; return *this;
constexpr iterator operator--(int) requires Decrementable<W>;

Effects: Equivalent to:
auto tmp = *this;
--*this;
return tmp;

constexpr iterator& operator+=(difference_type n) requires Advanceable<W>;

Effects: Equivalent to:
value_ += n;
return *this;

constexpr iterator& operator-=(difference_type n) requires Advanceable<W>;

Effects: Equivalent to:
value_ -= n;
return *this;

constexpr W operator[](difference_type n) const requires Advanceable<W>;

Effects: Equivalent to: return value_ + n;

friend constexpr bool operator==(const iterator& x, const iterator& y) requires EqualityComparable<W>;

Effects: Equivalent to: return x.value_ == y.value_;

friend constexpr bool operator!=(const iterator& x, const iterator& y) requires EqualityComparable<W>;

Effects: Equivalent to: return !(x == y);

friend constexpr bool operator<(const iterator& x, const iterator& y) requires StrictTotallyOrdered<W>;

Effects: Equivalent to: return x.value_ < y.value_;

friend constexpr bool operator<=(const iterator& x, const iterator& y) requires StrictTotallyOrdered<W>;

Effects: Equivalent to: return !(y < x);

friend constexpr bool operator>(const iterator& x, const iterator& y) requires StrictTotallyOrdered<W>;

Effects: Equivalent to: return y < x;

friend constexpr bool operator>=(const iterator& x, const iterator& y) requires StrictTotallyOrdered<W>;

Effects: Equivalent to: return !(x < y);

friend constexpr iterator operator+(iterator i, difference_type n) requires Advanceable<W>;

Effects: Equivalent to: return iterator{i.value_ + n};

friend constexpr iterator operator+(difference_type n, iterator i) requires Advanceable<W>;

Effects: Equivalent to: return i + n;

friend constexpr iterator operator-(iterator i, difference_type n) requires Advanceable<W>;

Effects: Equivalent to: return i + -n;
friend constexpr difference_type operator-(const iterator& x, const iterator& y) 
requires Advanceable<W>; 

Effects: Equivalent to: return x.value_ - y.value_; 

24.6.3.4 Class iota_view::sentinel

namespace std::ranges {
    template<class W, class Bound>
    struct iota_view<W, Bound>::sentinel {
        private:
            Bound bound_ = Bound(); // exposition only
        public:
            sentinel() = default;
            constexpr explicit sentinel(Bound bound);
            friend constexpr explicit sentinel(Bound bound);
            friend constexpr bool operator==(const iterator& x, const sentinel& y);
            friend constexpr bool operator==(const sentinel& x, const iterator& y);
            friend constexpr bool operator!=(const iterator& x, const sentinel& y);
            friend constexpr bool operator!=(const sentinel& x, const iterator& y);
    };
}

customexpr explicit sentinel(Bound bound);

Effects: Initializes bound_ with bound.

friend constexpr bool operator==(const iterator& x, const sentinel& y);

Effects: Equivalent to: return x.value_ == y.bound_; 

friend constexpr bool operator==(const sentinel& x, const iterator& y);

Effects: Equivalent to: return y == x; 

friend constexpr bool operator!=(const iterator& x, const sentinel& y);

Effects: Equivalent to: return !(x == y); 

friend constexpr bool operator!=(const sentinel& x, const iterator& y);

Effects: Equivalent to: return !(y == x); 

24.6.3.5 view::iota

The name view::iota denotes a customization point object (16.4.2.2.6). For some subexpressions E and F, the expressions view::iota(E) and view::iota(E, F) are expression-equivalent to iota_view{E} and iota_view{E, F}, respectively.

24.7 Range adaptors

This subclause defines range adaptors, which are utilities that transform a Range into a View with custom behaviors. These adaptors can be chained to create pipelines of range transformations that evaluate lazily as the resulting view is iterated.

Range adaptors are declared in namespace std::ranges::view.

The bitwise OR operator is overloaded for the purpose of creating adaptor chain pipelines. The adaptors also support function call syntax with equivalent semantics.

[Example:

vector<int> ints{0,1,2,3,4,5};
auto even = [](int i){ return 0 == i % 2; }; 
auto square = [](int i) { return i * i; }; 
for (int i : ints | view::filter(even) | view::transform(square)) {
    cout << i << " "; // prints: 0 4 16
} 
assert(ranges::equal(ints | view::filter(even), view::filter(ints, even)));
— end example]
24.7.1 Range adaptor objects

A range adaptor closure object is a unary function object that accepts a ViewableRange argument and returns a View. For a range adaptor closure object \( C \) and an expression \( R \) such that \( \text{decltype}((R)) \) models ViewableRange, the following expressions are equivalent and yield a View:

\[
\begin{align*}
C(R) \\
R | C
\end{align*}
\]

Given an additional range adaptor closure object \( D \), the expression \( C | D \) is well-formed and produces another range adaptor closure object such that the following two expressions are equivalent:

\[
\begin{align*}
R | C | D \\
R | (C | D)
\end{align*}
\]

A range adaptor object is a customization point object (16.4.2.2.6) that accepts a ViewableRange as its first argument and returns a View.

If a range adaptor object accepts only one argument, then it is a range adaptor closure object.

If a range adaptor object accepts more than one argument, then the following expressions are equivalent:

\[
\begin{align*}
&\text{adaptor}(\text{range, args}...) \\
&\text{adaptor}(\text{args}...)(\text{range}) \\
&R | \text{adaptor}(\text{args}...)
\end{align*}
\]

In this case, \( \text{adaptor}(\text{args}...) \) is a range adaptor closure object.

24.7.2 Semiregular wrapper

Many types in this subclause are specified in terms of an exposition-only class template \( \text{semiregular-box} \). \( \text{semiregular-box}<T> \) behaves exactly like \( \text{optional}<T> \) with the following differences:

1. \( \text{semiregular-box}<T> \) constrains its type parameter \( T \) with \( \text{CopyConstructible}<T> \land \text{is_object_}\lt v<T> \).

2. If \( T \) models DefaultConstructible, the default constructor of \( \text{semiregular-box}<T> \) is equivalent to:

\[
\text{constexpr} \ \text{semiregular-box}() \ \text{noexcept}(\text{is_nothrow_default_constructible_v<T>}) \\
\text{semiregular-box}\{\text{in\_place}\}
\]

3. If \( \text{Assignable}<T, \text{const T}&> \) is not modeled, the copy assignment operator is equivalent to:

\[
\text{semiregular-box} \& \text{operator}=(\text{const semiregular-box} \& \text{that}) \\
\text{noexcept}(\text{is_nothrow_copy_constructible_v<T>}) \\
\{ \\
\text{if (that) emplace(*that);} \\
\text{else reset();} \\
\text{return *this;} \\
\}
\]

4. If \( \text{Assignable}<T, T> \) is not modeled, the move assignment operator is equivalent to:

\[
\text{semiregular-box} \& \text{operator}=\text{(semiregular-box&} \text{that}) \\
\text{noexcept}(\text{is_nothrow_move_constructible_v<T>}) \\
\{ \\
\text{if (that) emplace(std::move(*that));} \\
\text{else reset();} \\
\text{return *this;} \\
\}
\]

24.7.3 All view

\( \text{view::all} \) returns a View that includes all elements of its Range argument.

The name \( \text{view::all} \) denotes a range adaptor object (24.7.1). For some subexpression \( E \), the expression \( \text{view::all}(E) \) is expression-equivalent to:

1. \( \text{decay-copy}(E) \) if the decayed type of \( E \) models View.

2. Otherwise, \( \text{ref_view}(E) \) if that expression is well-formed.

3. Otherwise, \( \text{subrange}(E) \).
24.7.3.1 Class template ref_view

ref_view is a View of the elements of some other Range.

```cpp
namespace std::ranges {
    template<Range R>
    requires is_object_v<R>
    class ref_view : public view_interface<ref_view<R>> {
        private:
            R* r_ = nullptr; // exposition only
        public:
            constexpr ref_view() noexcept = default;
            template<not_same_as<ref_view> T>
            requires see below
            constexpr ref_view(T&& t);

            constexpr R& base() const { return *r_; }
            constexpr iterator_t<R> begin() const { return ranges::begin(*r_); }
            constexpr sentinel_t<R> end() const { return ranges::end(*r_); }
            constexpr bool empty() const
                requires requires { ranges::empty(*r_); }
            { return ranges::empty(*r_); } // The expression in the requires-clause is equivalent to
            constexpr auto size() const requires SizedRange<R>
                requires ConvertibleTo<T, R&> && requires { FUN(declval<T>(); ) }
            { return ranges::size(*r_); }
            constexpr auto data() const requires ContiguousRange<R>
                requires ConvertibleTo<T, R&> && requires { FUN(declval<T>(); ) }
            { return ranges::data(*r_); }

            friend constexpr iterator_t<R> begin(ref_view r)
                requires see below
            { return r.begin(); }
            friend constexpr sentinel_t<R> end(ref_view r)
                requires see below
            { return r.end(); }
            template<class R>
            ref_view(R&) -> ref_view<R>;
    }
    template<class R>
    ref_view(R&) -> ref_view<R>;
}
```

Remarks: Let FUN denote the exposition-only functions

```cpp
void FUN(R&);
void FUN(R&&) = delete;
```

The expression in the requires-clause is equivalent to

```cpp
ConvertibleTo<T, R&> && requires { FUN(declval<T>(); ) ); }
```

Effects: Initializes r_ with addressof(static_cast<R&>(std::forward<T>(t))).

24.7.4 Filter view

24.7.4.1 Overview

filter_view presents a View of an underlying sequence without the elements that fail to satisfy a predicate.

[Example:

```cpp
vector<int> is{ 0, 1, 2, 3, 4, 5, 6 };
filter_view evens(is, [](int i) { return 0 == i % 2; });
for (int i : evens)
    cout << i << ' '; // prints: 0 2 4 6
```]
24.7.4.2 Class template filter_view

```cpp
namespace std::ranges {
    template<InputRange V, IndirectUnaryPredicate<iterator_t<V>> Pred>
    requires View<V> && is_object_v<Pred>
    class filter_view : public view_interface<filter_view<V, Pred>> {
        private:
            V base_ = V(); // exposition only
            semiregular_box<Pred> pred_; // exposition only

            // 24.7.4.3, class filter_view::iterator
            class iterator;
            // exposition only
            // 24.7.4.4, class filter_view::sentinel
            class sentinel;
            // exposition only

        public:
            filter_view() = default;
            constexpr filter_view(V base, Pred pred);
            template<InputRange R>
            requires ViewableRange<R> && Constructible<V, all_view<R>>
            constexpr filter_view(R&& r, Pred pred);

            constexpr V base() const;
            constexpr iterator begin();
            constexpr auto end() {
                if constexpr (CommonRange<V>)
                    return iterator{*this, ranges::end(base_)};
                else
                    return sentinel{*this};
            }
        };

    template<class R, class Pred>
    filter_view(R&&, Pred) -> filter_view<all_view<R>, Pred>;
}
```

1. Effects: Initializes base_ with std::move(base) and initializes pred_ with std::move(pred).

```cpp
template<InputRange R>
    requires ViewableRange<R> && Constructible<V, all_view<R>>
    constexpr filter_view(R&& r, Pred pred);
```

2. Effects: Initializes base_ with view::all(std::forward<R>(r)) and initializes pred_ with std::move(pred).

```cpp
constexpr V base() const;
```

3. Effects: Equivalent to: return base_.

```cpp
constexpr iterator begin();
```

4. Expects: pred_.has_value().

5. Returns: {*this, ranges::find_if(base_, ref(*pred_))}.

6. Remarks: In order to provide the amortized constant time complexity required by the Range concept, this function caches the result within the filter_view for use on subsequent calls.

24.7.4.3 Class filter_view::iterator

```cpp
namespace std::ranges {
    template<class V, class Pred>
    class filter_view<V, Pred>::iterator {
        private:
            iterator_t<V> current_ = iterator_t<V>(); // exposition only
            filter_view* parent_ = nullptr; // exposition only
```

§ 24.7.4.3 958
```cpp
public:
using iterator_concept = see below;
using iterator_category = see below;
using value_type = iter_value_t<iterator_t<V>>;
using difference_type = iter_difference_t<iterator_t<V>>;

iterator() = default;
constexpr iterator(filter_view& parent, iterator_t<V> current);

constexpr iterator_t<V> base() const;
constexpr iter_reference_t<iterator_t<V>> operator*() const;
constexpr iterator_t<V> operator->() const;
constexpr iterator& operator++();
constexpr void operator++(int);
constexpr iterator operator++(int) requires ForwardRange<V>;

constexpr iterator& operator--() requires BidirectionalRange<V>;
constexpr iterator operator--(int) requires BidirectionalRange<V>;

friend constexpr bool operator==(const iterator& x, const iterator& y) requires EqualityComparable<iterator_t<V>>;
friend constexpr bool operator!=(const iterator& x, const iterator& y) requires EqualityComparable<iterator_t<V>>;

friend constexpr iter_rvalue_reference_t<iterator_t<V>> iter_move(const iterator& i) noexcept(noexcept(ranges::iter_move(i.current_)));
friend constexpr void iter_swap(const iterator& x, const iterator& y) noexcept(noexcept(ranges::iter_swap(x.current_, y.current_)));

};
```

1 Modification of the element a filter_view::iterator denotes is permitted, but results in undefined behavior if the resulting value does not satisfy the filter predicate.

2 iterator::iterator_concept is defined as follows:
   (2.1) If V models BidirectionalRange, then iterator_concept denotes bidirectional_iterator_tag.
   (2.2) Otherwise, if V models ForwardRange, then iterator_concept denotes forward_iterator_tag.
   (2.3) Otherwise, iterator_concept denotes input_iterator_tag.

3 iterator::iterator_category is defined as follows:
   (3.1) Let C denote the type iterator_traits<iterator_t<V>>::iterator_category.
   (3.2) If C models DerivedFrom<bidirectional_iterator_tag>, then iterator_category denotes bidirectional_iterator_tag.
   (3.3) Otherwise, if C models DerivedFrom<forward_iterator_tag>, then iterator_category denotes forward_iterator_tag.
   (3.4) Otherwise, iterator_category denotes input_iterator_tag.

4 Effects: Initializes current_ with current and parent_ with addressof(parent).

5 Effects: Equivalent to: return current_;

6 Effects: Equivalent to: return *current_;
constexpr iterator_t<V> operator->() const
requires has-arrow<iterator_t<V>>;

Effects: Equivalent to: return current_

constexpr iterator& operator++();

Effects: Equivalent to:
    current_ = ranges::find_if(++current_, ranges::end(parent_->base_), ref(*parent_->pred_));
    return *this;

constexpr void operator++(int);

Effects: Equivalent to +++this.

constexpr iterator operator++(int) requires ForwardRange<V>;

Effects: Equivalent to:
    auto tmp = *this;
    +++this;
    return tmp;

constexpr iterator& operator--() requires BidirectionalRange<V>;

Effects: Equivalent to:
    do
        --current_
    while (!invoke(*parent_->pred_, *current_));
    return *this;

constexpr iterator operator--(int) requires BidirectionalRange<V>;

Effects: Equivalent to:
    auto tmp = *this;
    --*this;
    return tmp;

friend constexpr bool operator==(const iterator& x, const iterator& y)
requires EqualityComparable<iterator_t<V>>;

Effects: Equivalent to: return x.current_ == y.current_

friend constexpr bool operator!=(const iterator& x, const iterator& y)
requires EqualityComparable<iterator_t<V>>;

Effects: Equivalent to: return !(x == y);

friend constexpr iter_rvalue_reference_t<iterator_t<V>> iter_move(const iterator& i)
noexcept(noexcept(ranges::iter_move(i.current_)));

Effects: Equivalent to: return ranges::iter_move(i.current_);

friend constexpr void iter_swap(const iterator& x, const iterator& y)
requires IndirectlySwappable<iterator_t<V>>;

Effects: Equivalent to: ranges::iter_swap(x.current_, y.current_).

24.7.4.4 Class filter_view::sentinel

namespace std::ranges {
    template<class V, class Pred>
    class filter_view<V, Pred>::sentinel {
    private:
        sentinel_t<V> end_ = sentinel_t<V>(); // exposition only

    public:
        sentinel() = default;
        constexpr explicit sentinel(filter_view& parent);
        constexpr sentinel_t<V> base() const;

    } // sentinel
} // ranges

§ 24.7.4.4
friend constexpr bool operator==(const iterator& x, const sentinel& y);
friend constexpr bool operator==(const sentinel& x, const iterator& y);
friend constexpr bool operator!=(const iterator& x, const sentinel& y);
friend constexpr bool operator!=(const sentinel& x, const iterator& y);
};

constexpr explicit sentinel(filter_view& parent);

Effects: Initializes end_ with ranges::end(parent).

castexpr sentinel_t<V> base() const;

Effects: Equivalent to: return end_;

friend constexpr bool operator==(const iterator& x, const sentinel& y);

Effects: Equivalent to: return x.current_ == y.end_;  
friend constexpr bool operator==(const sentinel& x, const iterator& y);

Effects: Equivalent to: return y == x;
friend constexpr bool operator!=(const iterator& x, const sentinel& y);

Effects: Equivalent to: return !(x == y);
friend constexpr bool operator!=(const sentinel& x, const iterator& y);

Effects: Equivalent to: return !(y == x);

24.7.4.5 view::filter [range.filter.adaptor]

The name view::filter denotes a range adaptor object (24.7.1). For some subexpressions E and P, the expression view::filter(E, P) is expression-equivalent to filter_view{E, P}.

24.7.5 Transform view [range.transform]

24.7.5.1 Overview [range.transform.overview]

transform_view presents a View of an underlying sequence after applying a transformation function to each element.

[Example:

vector<int> is{ 0, 1, 2, 3, 4};
transform_view squares(is, [](int i) { return i * i; });
for (int i : squares)
    cout << i << " ";  // prints: 0 1 4 9 16
— end example]

24.7.5.2 Class template transform_view [range.transform.view]

namespace std::ranges {
    template<InputRange V, CopyConstructible F>
    requires View<V> & & is_object_v<F> & &
    RegularInvocable<F$, iter_reference_t<iterator_t<V>>>  
class transform_view : public view_interface<transform_view<V, F>> {  
private:
    // 24.7.5.3, class template transform_view::iterator
    template<bool> struct iterator;  // exposition only
    // 24.7.5.4, class template transform_view::sentinel
    template<bool> struct sentinel;  // exposition only

    V base_ = V();  // exposition only
    semiregular-box<F> fun_;  // exposition only

public:
    transform_view() = default;
    constexpr transform_view(V base, F fun);

§ 24.7.5.2 961
template<InputRange R>  
  requires ViewableRange<R> && Constructible<V, all_view<R>>  
constexpr transform_view(R&& r, F fun);

constexpr V base() const;

constexpr iterator<false> begin();
constexpr iterator<true> begin() const  
  requires Range<const V> &&  
              RegularInvocable<const F&, iter_reference_t<iterator_t<const V>>>;

constexpr sentinel<false> end();
constexpr iterator<false> end() requires CommonRange<V>;
constexpr sentinel<true> end() const  
  requires Range<const V> &&  
              RegularInvocable<const F&, iter_reference_t<iterator_t<const V>>>;

constexpr auto size() requires SizedRange<V> { return ranges::size(base_); }  
constexpr auto size() const requires SizedRange<const V>  
{ return ranges::size(base_); }

}  
transform_view(V base, F fun);

Effects: Initializes base_ with std::move(base) and fun_ with std::move(fun).

Effects: Equivalent to: return base_;  

Effects: Equivalent to: return iterator<false>(*this, ranges::begin(base_));  

Effects: Equivalent to: return iterator<true>(*this, ranges::begin(base_));  

Effects: Equivalent to: return sentinel<false>(ranges::end(base_));  

Effects: Equivalent to: return iterator<false>(*this, ranges::end(base_));
constexpr sentinel<true> end() const
requires Range<const V> &&
    RegularInvocable<const F&, iter_reference_t<iterator_t<const V>>>;

Effects: Equivalent to:
return sentinel<true>{ranges::end(base_)};

constexpr iterator<true> end() const
requires CommonRange<const V> &&
    RegularInvocable<const F&, iter_reference_t<iterator_t<const V>>>;

Effects: Equivalent to:
return iterator<true>{*this, ranges::end(base_)};

24.7.5.3 Class template transform_view::iterator

namespace std::ranges {
    template<class V, class F>
    template<bool Const>
    class transform_view<V, F>::iterator {
    private:
        using Parent = // exposition only
            conditional_t<Const, const transform_view, transform_view>;
        using Base = // exposition only
            conditional_t<Const, const V, V>;
        iterator_t<Base> current_ = // exposition only
            iterator_t<Base>();
        Parent* parent_ = nullptr; // exposition only
    public:
        using iterator_concept = see below;
        using iterator_category = see below;
        using value_type = remove_cvref_t<invoke_result_t<F&, iter_reference_t<iterator_t<Base>>>>;
        using difference_type = iter_difference_t<iterator_t<Base>>;

        iterator() = default;
        constexpr iterator(Parent& parent, iterator_t<Base> current);
        constexpr iterator(iterator<!Const> i)
            requires Const && ConvertibleTo<iterator_t<V>, iterator_t<Base>>;
        constexpr iterator_t<Base> base() const;
        constexpr decltype(auto) operator*() const
            { return invoke(*parent_->fun_, *current_); }
        constexpr iterator& operator++();
        constexpr void operator++(int);
        constexpr iterator operator++(int) requires ForwardRange<Base>;
        constexpr iterator& operator--() requires BidirectionalRange<Base>;
        constexpr iterator operator--(int) requires BidirectionalRange<Base>;
        constexpr iterator& operator+=(difference_type n)
            requires RandomAccessRange<Base>;
        constexpr iterator& operator-=(difference_type n)
            requires RandomAccessRange<Base>;
        constexpr decltype(auto) operator[](difference_type n) const
            requires RandomAccessRange<Base>
            { return invoke(*parent_->fun_, current_[n]); }
        friend constexpr bool operator===(const iterator& x, const iterator& y)
            requires EqualityComparable<iterator_t<Base>>;
        friend constexpr bool operator!=(const iterator& x, const iterator& y)
            requires EqualityComparable<iterator_t<Base>>;
    }
friend constexpr bool operator<(const iterator& x, const iterator& y) requires RandomAccessRange<Base>;
friend constexpr bool operator>(const iterator& x, const iterator& y) requires RandomAccessRange<Base>;
friend constexpr bool operator<=(const iterator& x, const iterator& y) requires RandomAccessRange<Base>;
friend constexpr bool operator>=(const iterator& x, const iterator& y) requires RandomAccessRange<Base>;
friend constexpr iterator operator+(iterator i, difference_type n) requires RandomAccessRange<Base>;
friend constexpr iterator operator+(difference_type n, iterator i) requires RandomAccessRange<Base>;
friend constexpr iterator operator-(iterator i, difference_type n) requires RandomAccessRange<Base>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y) requires RandomAccessRange<Base>;
friend constexpr decltype(auto) iter_move(const iterator& i) noexcept(noexcept(invoke(*i.parent_->fun_, *i.current_))) {
  if constexpr (is_lvalue_reference_v<decltype(*i)>)
    return std::move(*i);
  else
    return *i;
}
friend constexpr void iter_swap(const iterator& x, const iterator& y) noexcept(noexcept(ranges::iter_swap(x.current_, y.current_))) requires IndirectlySwappable<iterator_t<Base>>;

iterator::iterator_concept is defined as follows:

(1.1) — If \( V \) models RandomAccessRange, then iterator_concept denotes random_access_iterator_tag.
(1.2) — Otherwise, if \( V \) models BidirectionalRange, then iterator_concept denotes bidirectional_iterator_tag.
(1.3) — Otherwise, if \( V \) models ForwardRange, then iterator_concept denotes forward_iterator_tag.
(1.4) — Otherwise, iterator_concept denotes input_iterator_tag.

Let \( C \) denote the type iterator_traits<iterator_t<Base>::iterator_category>. If \( C \) models Derived-From<contiguous_iterator_tag>, then iterator_category denotes random_access_iterator_tag; otherwise, iterator_category denotes \( C \).

constexpr iterator(Parent& parent, iterator_t<Base> current);

Effects: Initializes current_ with current and parent_ with addressof(parent).

constexpr iterator<!Const> i requires Const && ConvertibleTo<iterator_t<V>, iterator_t<Base>>;

Effects: Initializes current_ with std::move(i.current_) and parent_ with i.parent_.

constexpr iterator_t<Base> base() const;

Effects: Equivalent to: return current_;

constexpr iterator& operator++();

Effects: Equivalent to:

++current_;
return *this;
constexpr void operator++(int);
    \textit{Effects:} Equivalent to \texttt{++current_}.

constexpr iterator operator++(int) requires ForwardRange<Base>;
    \textit{Effects:} Equivalent to:
    \begin{verbatim}
    auto tmp = *this;
    ***this;
    return tmp;
    \end{verbatim}

constexpr iterator& operator--() requires BidirectionalRange<Base>;
    \textit{Effects:} Equivalent to:
    \begin{verbatim}
    --current_;
    return *this;
    \end{verbatim}

constexpr iterator& operator--(int) requires BidirectionalRange<Base>;
    \textit{Effects:} Equivalent to:
    \begin{verbatim}
    auto tmp = *this;
    --*this;
    return tmp;
    \end{verbatim}

constexpr iterator& operator+=(difference_type n) requires RandomAccessRange<Base>;
    \textit{Effects:} Equivalent to:
    \begin{verbatim}
    current_ += n;
    return *this;
    \end{verbatim}

constexpr iterator& operator-=(difference_type n) requires RandomAccessRange<Base>;
    \textit{Effects:} Equivalent to:
    \begin{verbatim}
    current_ -= n;
    return *this;
    \end{verbatim}

friend constexpr bool operator==(const iterator& x, const iterator& y) requires EqualityComparable<iterator_t<Base>>;
    \textit{Effects:} Equivalent to:
    \begin{verbatim}
    return x.current_ == y.current_;
    \end{verbatim}

friend constexpr bool operator!=(const iterator& x, const iterator& y) requires EqualityComparable<iterator_t<Base>>;
    \textit{Effects:} Equivalent to:
    \begin{verbatim}
    return !(x == y);
    \end{verbatim}

friend constexpr bool operator<(const iterator& x, const iterator& y) requires RandomAccessRange<Base>;
    \textit{Effects:} Equivalent to:
    \begin{verbatim}
    return x.current_ < y.current_;
    \end{verbatim}

friend constexpr bool operator>(const iterator& x, const iterator& y) requires RandomAccessRange<Base>;
    \textit{Effects:} Equivalent to:
    \begin{verbatim}
    return y < x;
    \end{verbatim}

friend constexpr bool operator<=(const iterator& x, const iterator& y) requires RandomAccessRange<Base>;

   Effects: Equivalent to: return !(y == x);

friend constexpr iter_difference_t<iterator_t<Base>>
   operator-(const iterator<Const>& x, const sentinel& y)
   requires SizedSentinel<sentinel_t<Base>, iterator_t<Base>>;
   Effects: Equivalent to: return x.current_ - y.end_; 

friend constexpr iter_difference_t<iterator_t<Base>>
   operator-(const sentinel& y, const iterator<Const>& x)
   requires SizedSentinel<sentinel_t<Base>, iterator_t<Base>>;
   Effects: Equivalent to: return x.end_ - y.current_; 

24.7.5.5 view::transform
   [range.transform.adaptor]
   The name view::transform denotes a range adaptor object (24.7.1). For some subexpressions E and F, the expression view::transform(E, F) is expression-equivalent to transform_view{E, F}.

24.7.6 Take view
   [range.take]
24.7.6.1 Overview
   [range.take.overview]
   take_view produces a View of the first N elements from another View, or all the elements if the adapted View contains fewer than N.

   [Example:
    vector<int> is{0,1,2,3,4,5,6,7,8,9};
    take_view few{is, 5};
    for (int i : few)
        cout << i << ' '; // prints: 0 1 2 3 4
   —end example]

24.7.6.2 Class template take_view
   [range.take.view]
 namespace std::ranges {
   template<View V>
   class take_view : public view_interface<take_view<V>> {
     private:
       V base_ = V(); // exposition only
       iter_difference_t<iterator_t<V>> count_ = 0; // exposition only
       // 24.7.6.3, class template take_view::sentinel
       template<Bool> struct sentinel;
       // exposition only
     public:
       take_view() = default;
       constexpr take_view(V base, iter_difference_t<iterator_t<V>> count);
       template<ViewableRange R>
           requires Constructible<V, all_view<R>>
       constexpr take_view(R&& r, iter_difference_t<iterator_t<V>> count);
       constexpr V base() const;

       constexpr auto begin() requires (!simple_view<V>) {

    auto n = ranges::size(base_);
    return ranges::min(n, static_cast<decltype(n)>(count_));
};

template<Range R>
take_view(R&&, iter_difference_t<iterator_t<R>>)
    -> take_view<all_view<R>>;
}

constexpr take_view(V base, iter_difference_t<iterator_t<V>> count);

Effects: Initializes base_ with std::move(base) and count_ with count.

template<ViewableRange R>
requires Constructible<V, all_view<R>>
take_view(R&& r, iter_difference_t<iterator_t<V>> count);

Effects: Initializes base_ with view::all(std::forward<R>(r)) and count_ with count.

constexpr V base() const;

Effects: Equivalent to: return base_;
class take_view<V>::sentinel {
  private:
    using Base = conditional_t<Const, const V, V>; // exposition only
    using CI = counted_iterator<iterator_t<Base>>; // exposition only
    sentinel_t<Base> end_ = sentinel_t<Base>(); // exposition only
  public:
    sentinel() = default;
    constexpr explicit sentinel(sentinel_t<Base> end);
    constexpr sentinel(sentinel<!Const> s)
      requires Const && ConvertibleTo<sentinel_t<V>, sentinel_t<Base>>;
    constexpr sentinel_t<Base> base() const;
    friend constexpr bool operator==(const sentinel& x, const CI& y);
    friend constexpr bool operator==(const CI& y, const sentinel& x);
    friend constexpr bool operator!=(const sentinel& x, const CI& y);
    friend constexpr bool operator!=(const CI& y, const sentinel& x);
  }
}

constexpr explicit sentinel(sentinel_t<Base> end);

1 Effects: Initializes end_ with end.

constexpr sentinel(sentinel<!Const> s)
  requires Const && ConvertibleTo<sentinel_t<V>, sentinel_t<Base>>;
2 Effects: Initializes end_ with std::move(s.end_).

constexpr sentinel_t<Base> base() const;
3 Effects: Equivalent to: return end_;

friend constexpr bool operator==(const sentinel& x, const CI& y);
4 Effects: Equivalent to: return y.count() == 0 || y.base() == x.end_;

friend constexpr bool operator!=(const sentinel& x, const CI& y);
5 Effects: Equivalent to: return !(x == y);

24.7.6.4 view::take
1 The name view::take denotes a range adaptor object (24.7.1). For some subexpressions E and F, the expression view::take(E, F) is expression-equivalent to take_view{E, F}.

24.7.7 Join view
24.7.7.1 Overview
1 join_view flattens a View of ranges into a View.

2 [Example:
   vector<string> ss{"hello", " ", "world", "!"};
   join_view greeting(ss);
   for (char ch : greeting)
     cout << ch; // prints: hello world!
   — end example]
using InnerRng = // exposition only
    iter_reference_t<iterator_t<V>>;
    // 24.7.7.3, class template join_view:iterator
template<bool Const>
    struct iterator; // exposition only
    // 24.7.7.4, class template join_view:sentinel
template<bool Const>
    struct sentinel; // exposition only

V base_ = V(); // exposition only
all_view<InnerRng> inner_ = // exposition only, present only when !is_reference_v<InnerRng>
    all_view<InnerRng>();

public:
    join_view() = default;
    constexpr explicit join_view(V base);

template<InputRange R>
    requires ViewableRange<R> && Constructible<V, all_view<R>>
    constexpr explicit join_view(R&& r);

    constexpr auto begin() {
        return iterator<simple-view>V{}(*this, ranges::begin(base_));
    }

    constexpr auto begin() const
        requires InputRange<const V> && is_reference_v<iter_reference_t<iterator_t<const V>>> {
        return iterator<true>{*this, ranges::begin(base_)};
    }

    constexpr auto end() {
        if constexpr (ForwardRange<V> &&
            is_reference_v<InnerRng> && ForwardRange<InnerRng> &&
            CommonRange<V> && CommonRange<InnerRng>)
            return iterator<simple-view>V{}(*this, ranges::end(base_));
        else
            return sentinel<simple-view>V{}(*this);
    }

    constexpr auto end() const
        requires InputRange<const V> && is_reference_v<iter_reference_t<iterator_t<const V>>> {
        if constexpr (ForwardRange<const V> &&
            is_reference_v<iter_reference_t<iterator_t<const V>>> &&
            ForwardRange<iter_reference_t<iterator_t<const V>>> &&
            CommonRange<const V> &&
            CommonRange<iter_reference_t<iterator_t<const V>>>)
            return iterator<true>{*this, ranges::end(base_)};
        else
            return sentinel<true>{*this};
    }

    template<class R>
        explicit join_view(R&&) -> join_view<all_view<R>>;

    constexpr explicit join_view(V base);

Effects: Initializes base_ with std::move(base).

template<InputRange R>
    requires ViewableRange<R> && Constructible<V, all_view<R>>
constexpr explicit join_view(R&& r);

Effects: Initializes base_ with view::all(std::forward<R>(r)).

### 24.7.7.3 Class template join_view::iterator

```cpp
namespace std::ranges {
    template<class V>
    template<bool Const>
    struct join_view<V>::iterator {
        private:
            using Parent = // exposition only
                conditional_t<Const, const join_view, join_view>;
            using Base = conditional_t<Const, const V, V>; // exposition only

        static constexpr bool ref_is_glvalue = // exposition only
            is_reference_v<iter_reference_t<iterator_t<Base>>>;

        iterator_t<Base> outer_ = iterator_t<Base>(); // exposition only
        iterator_t<iter_reference_t<iterator_t<Base>>> inner_ = // exposition only
            iterator_t<iter_reference_t<iterator_t<Base>>>();
        Parent* parent_ = nullptr; // exposition only

        constexpr void satisfy(); // exposition only

        public:
            using iterator_concept = see below;
            using iterator_category = see below;
            using value_type = iter_value_t<iterator_t<iter_reference_t<iterator_t<Base>>>;
            using difference_type = see below;

            iterator() = default;
            constexpr iterator(Parent& parent, iterator_t<V> outer);
            constexpr iterator(iterator<!Const> i) requires Const &&
               ConvertibleTo<iterator_t<V>, iterator_t<Base>>, &&
               ConvertibleTo<iterator_t<InnerRng>,
                iterator_t<iter_reference_t<iterator_t<Base>>>>;

            constexpr decltype(auto) operator*() const { return *inner_; }

            constexpr iterator_t<Base> operator->() const requires has-arrow<iterator_t<Base>>;

            constexpr iterator& operator++();
            constexpr void operator++(int);
            constexpr iterator operator++(int) requires ref_is_glvalue && ForwardRange<Base> &&
               ForwardRange<iter_reference_t<iterator_t<Base>>>;

            constexpr iterator& operator--();
            constexpr void operator--(int) requires ref_is_glvalue && BidirectionalRange<Base> &&
               BidirectionalRange<iter_reference_t<iterator_t<Base>>>;

            constexpr iterator operator--(int) requires ref_is_glvalue && BidirectionalRange<Base> &&
               BidirectionalRange<iter_reference_t<iterator_t<Base>>>;

            friend constexpr bool operator==(const iterator& x, const iterator& y) requires ref_is_glvalue && EqualityComparable<iterator_t<Base>> &&
               EqualityComparable<iter_reference_t<iterator_t<Base>>>;
        }
    }
}
```

§ 24.7.7.3
friend constexpr bool operator!=(const iterator& x, const iterator& y)  
requires ref_is_glvalue && EqualityComparable<iterator_t<Base>> &&  
EqualityComparable<iterator_t<iter_reference_t<iterator_t<Base>>>;  

friend constexpr decltype(auto) iter_move(const iterator& i)  
noexcept(noexcept(ranges::iter_move(i.inner_))) {  
  return ranges::iter_move(i.inner_);  
}  

friend constexpr void iter_swap(const iterator& x, const iterator& y)  
noexcept(noexcept(ranges::iter_swap(x.inner_, y.inner_)));  
};  

2 iterator::iterator_concept is defined as follows:  

(2.1) — If ref_is_glvalue is true,  

(2.1.1) — If Base and iter_reference_t<iterator_t<Base>> each model BidirectionalRange, then  
iterator_concept denotes bidirectional_iterator_tag.  

(2.1.2) — Otherwise, if Base and iter_reference_t<iterator_t<Base>> each model ForwardRange, then  
iterator_concept denotes forward_iterator_tag.  

(2.2) — Otherwise, iterator_concept denotes input_iterator_tag.  

3 iterator::iterator_category is defined as follows:  

(3.1) — Let OUTER denote iterator_traits<iterator_t<Base>>::iterator_category, and let INNER denote  
iterator_traits<iterator_t<iter_reference_t<iterator_t<Base>>>>::iterator_category.  

(3.2) — If ref_is_glvalue is true,  

(3.2.1) — If OUTER and INNER each model DerivedFrom<bidirectional_iterator_tag>, iterator_category denotes bidirectional_iterator_tag.  

(3.2.2) — Otherwise, if OUTER and INNER each model DerivedFrom<forward_iterator_tag>, iterator_category denotes forward_iterator_tag.  

(3.3) — Otherwise, iterator_category denotes input_iterator_tag.  

4 iterator::difference_type denotes the type:  

common_type_t<  
  iter_difference_t<iterator_t<Base>>,  
  iter_difference_t<iterator_t<iter_reference_t<iterator_t<Base>>>>>  

5 join_view iterators use the satisfy function to skip over empty inner ranges.  

cconstexpr void satisfy(); // exposition only

Effects: Equivalent to:  

auto update_inner = [this](iter_reference_t<iterator_t<Base>> x) -> decltype(auto) {  
  if constexpr (ref_is_glvalue) // x is a reference  
    return (x);  
  // (x) is an lvalue  
  else  
    return (parent_->inner_ = view::all(x));  
};  

for (; outer_ != ranges::end(parent_->base_); ++outer_) {  
  auto& inner = update_inner(*outer_);  
  inner_ = ranges::begin(inner);  
  if (inner_ != ranges::end(inner))  
    return;  
}  

if constexpr (ref_is_glvalue)  
  inner_ = iterator_t<iter_reference_t<iterator_t<Base>>>();  

cconstexpr iterator(Parent& parent, iterator_t<V> outer)  

Effects: Initializes outer_ with outer and parent_ with addressof(parent); then calls satisfy().
constexpr iterator<iterator<!Const> i)  
requires Const &&  
ConvertibleTo<iterator_t<Base>, iterator_t<i>> &&  
ConvertibleTo<iterator_t<InnerRng>, iterator_t<iter_reference_t<iterator_t<Base>>>;

Effects: Initializes outer_ with std::move(i.outer_), inner_ with std::move(i.inner_), and parent_ with i.parent_.

constexpr iterator_t<Base> operator->() const  
requires has-arrow<iterator_t<Base>>;

Effects: Equivalent to return inner_;

constexpr iterator& operator++();

Let inner-range be:

— If ref_is_glvalue is true, *outer_.
— Otherwise, parent_->inner_.

Effects: Equivalent to:

auto&& inner_rng = inner-range;
if (++inner_ == ranges::end(inner_rng)) {
  ++outer_;  
  satisfy();
} 
return *this;

constexpr void operator++(int);

Effects: Equivalent to: +++this.

constexpr iterator operator++(int)  
requires ref_is_glvalue && ForwardRange<Base> &&  
ForwardRange<iter_reference_t<iterator_t<Base>>>;

Effects: Equivalent to:

auto tmp = *this;  
+++this;  
return tmp;

constexpr iterator& operator--();  
requires ref_is_glvalue && BidirectionalRange<Base> &&  
BidirectionalRange<iter_reference_t<iterator_t<Base>>>;

Effects: Equivalent to:

if (outer_ == ranges::end(parent_->base_))  
inner_ = ranges::end(*--outer_);  
while (inner_ == ranges::begin(*outer_))  
inner_ = ranges::end(*--outer_);  
--inner_;  
return *this;

constexpr iterator operator--(int)  
requires ref_is_glvalue && BidirectionalRange<Base> &&  
BidirectionalRange<iter_reference_t<iterator_t<Base>>>;

Effects: Equivalent to:

auto tmp = *this;  
--*this;  
---*this;  
return tmp;

friend constexpr bool operator==(const iterator& x, const iterator& y)  
requires ref_is_glvalue && EqualityComparable<iterator_t<Base>> &&  
EqualityComparable<iter_reference_t<iterator_t<Base>>>;

Effects: Equivalent to: return x.outer_ == y.outer_ && x.inner_ == y.inner_;
friend constexpr bool operator!=(const iterator& x, const iterator& y) 
    requires ref_is_glvalue && EqualityComparable< iterator_t< Base >> && 
    EqualityComparable< iterator_t< iter_reference_t< iterator_t< Base >> >>;

17 Effects: Equivalent to: return !(x == y);

friend constexpr void iter_swap(const iterator& x, const iterator& y) 
    noexcept(noexcept(ranges::iter_swap(x.inner_, y.inner_)));

18 Effects: Equivalent to: return ranges::iter_swap(x.inner_, y.inner_);

24.7.7.4 Class template `join_view::sentinel` [range.join.sentinel]

namespace std::ranges {
    template<class V>
    template<bool Const>
    struct join_view<V>::sentinel {
        private:
            using Parent = // exposition only
                conditional_t<Const, const join_view, join_view>;
            using Base = conditional_t<Const, const V, V>; // exposition only
            sentinel_t<Base> end_ = sentinel_t<Base>(); // exposition only
        public:
            sentinel() = default;
            constexpr explicit sentinel(Parent& parent);
            constexpr sentinel(sentinel<!Const> s) 
                requires Const && ConvertibleTo<sentinel_t<V>, sentinel_t<Base>>;
            friend constexpr bool operator==(const iterator<Const>& x, const sentinel& y);
            friend constexpr bool operator==(const sentinel& x, const iterator<Const>& y);
            friend constexpr bool operator!=(const iterator<Const>& x, const sentinel& y);
            friend constexpr bool operator!=(const sentinel& x, const iterator<Const>& y);
        }
    };

constexpr explicit sentinel(Parent& parent);

1 Effects: Initializes end_ with ranges::end(parent.base_).

constexpr sentinel(!Const) s) 
    requires Const && ConvertibleTo<sentinel_t<V>, sentinel_t<Base>>;

2 Effects: Initializes end_ with std::move(s.end_).

friend constexpr bool operator==(const iterator<Const>& x, const sentinel& y);

3 Effects: Equivalent to: return x.outer_ == y.end_;

friend constexpr bool operator==(const sentinel& x, const iterator<Const>& y);

4 Effects: Equivalent to: return y == x;

friend constexpr bool operator!=(const iterator<Const>& x, const sentinel& y);

5 Effects: Equivalent to: return !(x == y);

friend constexpr bool operator!=(const sentinel& x, const iterator<Const>& y);

6 Effects: Equivalent to: return !(y == x);

24.7.7.5 view::join [range.join.adaptor]

The name view::join denotes a range adaptor object (24.7.1). For some subexpression E, the expression view::join(E) is expression-equivalent to join_view{E}.

24.7.8 Split view [range.split]

24.7.8.1 Overview [range.split.overview]

split_view takes a View and a delimiter, and splits the View into subranges on the delimiter. The delimiter can be a single element or a View of elements.
2 [Example:

```cpp
string str{"the quick brown fox");
split_view sentence(str, ' ');
for (auto word : sentence) {
    for (char ch : word)
        cout << ch;
    cout << '*';
}
// The above prints: the*quick*brown*fox*
```

—end example]

24.7.8.2 Class template `split_view`

```cpp
namespace std::ranges {
    template<auto> struct require_constant; // exposition only

template<class R>
    concept tiny_range =
        SizedRange<R> &&
        requires { typename require_constant<remove_reference_t<R>::size()>; } &&
        (remove_reference_t<R>::size() <= 1);

template<InputRange V, ForwardRange Pattern>
    requires View<V> && View<Pattern> &&
        IndirectlyComparable<iterator_t<V>, iterator_t<Pattern>>, ranges::equal_to &&
        (ForwardRange<V> || tiny-range<Pattern>)
    class split_view : public view_interface<split_view<V, Pattern>> {
private:
    V base_ = V();
    Pattern pattern_ = Pattern();
    iterator_t<V> current_ = iterator_t<V>();
    // exposition only, present only if !ForwardRange<V>
    // 24.7.8.3, class template split_view::outer_iterator
    template<bool> struct outer_iterator;
    // exposition only
    // 24.7.8.5, class template split_view::inner_iterator
    template<bool> struct inner_iterator;
public:

        return outer_iterator<true>{*this, ranges::end(base_)};
    else
        return default_sentinel;
}

};
template<class R, class P>
split_view(R&&, P&&) -> split_view<all_view<R>, all_view<P>>;

template<InputRange R>
split_view(R&&, iter_value_t<iterator_t<R>>)
    -> split_view<all_view<R>, single_view<iter_value_t<iterator_t<R>>>>;

constexpr split_view(V base, Pattern pattern);
1 Effects: Initializes base_ with std::move(base), and pattern_ with std::move(pattern).

template<InputRange R, ForwardRange P>
requires Constructible<V, all_view<R>> && Constructible<Pattern, all_view<P>>
constexpr split_view(R&& r, P&& p);
2 Effects: Initializes base_ with view::all(std::forward<R>(r)) and pattern_ with view::all(std::forward<P>(p)).

template<InputRange R>
requires Constructible<V, all_view<R>> && Constructible<Pattern, single_view<iter_value_t<iterator_t<R>>>>
constexpr split_view(R&& r, iter_value_t<iterator_t<R>> e);
3 Effects: Initializes base_ with view::all(std::forward<R>(r)) and pattern_ with single_view{std::move(e)}.

24.7.8.3 Class template split_view::outer_iterator

namespace std::ranges {
template<class V, class Pattern>
template<bool Const>
struct split_view<V, Pattern>::outer_iterator {
    private:
        using Parent = // exposition only
            conditional_t<Const, const split_view, split_view>;
        using Base = // exposition only
            conditional_t<Const, const V, V>;
        Parent* parent_ = nullptr; // exposition only
        iterator_t<Base> current_ = // exposition only, present only if V models ForwardRange
            iterator_t<Base>();

    public:
        using iterator_concept =
            conditional_t<ForwardRange<Base>, forward_iterator_tag, input_iterator_tag>;
        using iterator_category = input_iterator_tag;
        // 24.7.8.4, class split_view::outer_iterator::value_type
        struct value_type;
        using difference_type = iter_difference_t<iterator_t<Base>>;

        outer_iterator() = default;
        constexpr explicit outer_iterator(Parent& parent)
            requires (!ForwardRange<Base>);
        constexpr outer_iterator(Parent& parent, iterator_t<Base> current)
            requires ForwardRange<Base>;
constexpr outer_iterator<!Const> operator++(int) {
    auto tmp = *this;
    +++tmp;
    return tmp;
} else
    +++this;
}

friend constexpr bool operator==(const outer_iterator& x, const outer_iterator& y) 
    requires ForwardRange<Base>;  
friend constexpr bool operator!=(const outer_iterator& x, const outer_iterator& y) 
    requires ForwardRange<Base>; 
friend constexpr bool operator==(const outer_iterator& x, default_sentinel_t); 
friend constexpr bool operator==(default_sentinel_t, const outer_iterator& x); 
friend constexpr bool operator!=(const outer_iterator& x, default_sentinel_t y); 
friend constexpr bool operator!=(default_sentinel_t y, const outer_iterator& x); 
};

Many of the following specifications refer to the notional member current of outer_iterator. current is equivalent to current_ if V models ForwardRange, and parent_ -> current_ otherwise.

constexpr explicit outer_iterator(Parent& parent) 
    requires (!ForwardRange<Base>);

Effects: Initializes parent_ with addressof(parent).

constexpr outer_iterator(Parent& parent, iterator_t<Base> current) 
    requires ForwardRange<Base>;

Effects: Initializes parent_ with addressof(parent) and current_ with current.

constexpr outer_iterator<outer_iterator<!Const> i) 
    requires Const && ConvertibleTo<iterator_t<V>, iterator_t<const V>>;

Effects: Initializes parent_ with i.parent_ and current_ with std::move(i.current_).

constexpr value_type operator*() const;

Effects: Equivalent to: return value_type{*this};

constexpr outer_iterator& operator++();

Effects: Equivalent to:

    const auto end = ranges::end(parent_ -> base_);
    if (current == end) return *this;
    const auto [pbegin, pend] = subrange{parent_ -> pattern_};
    if (pbegin == pend) ++current;
    else {
        do {
            const auto [b, p] = ranges::mismatch(current, end, pbegin, pend);
            if (p == pend) {
                current = b; // The pattern matched; skip it
                break;
            }
        } while (++current != end);
    }
    return *this;

Effects: Equivalent to:

    auto cur = x.i_.current;
    auto end = ranges::end(x.i_.parent_->base_);

§ 24.7.8.5 979
if (cur == end) return true;
auto [pcur, pend] = subrange(x.i_.parent_->pattern_);
if (pcur == pend) return x.incremented_

    do {
        if (*cur != *pcur) return false;
        if (++pcur == pend) return true;
    } while (++cur != end);
return false;

friend constexpr bool operator!=(const inner_iterator& x, default_sentinel_t y);
friend constexpr bool operator!=(default_sentinel_t y, const inner_iterator& x);

Effects: Equivalent to: return !(x == y);

friend constexpr void iter_swap(const inner_iterator& x, const inner_iterator& y)
    noexcept(noexcept(ranges::iter_swap(x.i_.current, y.i_.current)))
    requires IndirectlySwappable<iterator_t<Base>>;

Effects: Equivalent to ranges::iter_swap(x.i_.current, y.i_.current).

24.7.8.6 view::split

The name view::split denotes a range adaptor object (24.7.1). For some subexpressions E and F, the expression view::split(E, F) is expression-equivalent to split_view(E, F).

24.7.9 Counted view

A counted view presents a View of the elements of the counted range (23.3.1) [i, n) for some iterator i and non-negative integer n.

The name view::counted denotes a customization point object (16.4.2.2.6). Let E and F be expressions, and let T be decay_t<decltype((E))>. Then the expression view::counted(E, F) is expression-equivalent to:

1. If T models Iterator and decltype(F) models convertible_to<iter_difference_t<T>>, subrange{E, E + static_cast<iter_difference_t<T>>(F)} if T models RandomAccessIterator.
2. Otherwise, subrange{counted_iterator{E, F}, default_sentinel}.
3. Otherwise, view::counted(E, F) is ill-formed. [Note: This case can result in substitution failure when view::counted(E, F) appears in the immediate context of a template instantiation. —end note]

24.7.10 Common view

24.7.10.1 Overview

common_view takes a View which has different types for its iterator and sentinel and turns it into a View of the same elements with an iterator and sentinel of the same type.

[Note: common_view is useful for calling legacy algorithms that expect a range’s iterator and sentinel types to be the same. —end note]

[Example:
// Legacy algorithm:
template<class ForwardIterator>
size_t count(ForwardIterator first, ForwardIterator last);

template<ForwardRange R>
void my_algo(R&& r) {
    auto&& common = common_view{r};
    auto cnt = count(common.begin(), common.end());
    // ...
}

—end example]
24.7.10.2 Class template common_view

namespace std::ranges {
    template<View V>
    requires (!CommonRange<V>)
    class common_view : public view_interface<common_view<V>> {
        private:
            V base_ = V(); // exposition only
        public:
            common_view() = default;
            constexpr explicit common_view(V r);
            template<ViewableRange R>
            requires (!CommonRange<R> && Constructible<V, all_view<R>>)
            constexpr explicit common_view(R&& r);
            constexpr V base() const;
            constexpr auto size() requires SizedRange<V> {
                return ranges::size(base_);
            }
            constexpr auto size() const requires SizedRange<const V> {
                return ranges::size(base_);
            }
            constexpr auto begin() {
                if constexpr (RandomAccessRange<V> && SizedRange<V>)
                    return ranges::begin(base_);
                else
                    return common_iterator<iterator_t<V>, sentinel_t<V>>(ranges::begin(base_));
            }
            constexpr auto begin() const requires Range<const V> {
                if constexpr (RandomAccessRange<const V> && SizedRange<const V>)
                    return ranges::begin(base_);
                else
                    return common_iterator<iterator_t<const V>, sentinel_t<const V>>(ranges::begin(base_));
            }
            constexpr auto end() {
                if constexpr (RandomAccessRange<V> && SizedRange<V>)
                    return ranges::begin(base_) + ranges::size(base_);
                else
                    return common_iterator<iterator_t<V>, sentinel_t<V>>(ranges::end(base_));
            }
            constexpr auto end() const requires Range<const V> {
                if constexpr (RandomAccessRange<const V> && SizedRange<const V>)
                    return ranges::begin(base_) + ranges::size(base_);
                else
                    return common_iterator<iterator_t<const V>, sentinel_t<const V>>(ranges::end(base_));
            }
    }
}

constexpr explicit common_view(V base);

1 Effects: Initializes base_ with std::move(base).

template<ViewableRange R>
    requires (!CommonRange<R> && Constructible<V, all_view<R>>)
constexpr explicit common_view(R&& r);

Effects: Initializes base_ with view::all(std::forward<R>(r)).

constexpr V base() const;

Effects: Equivalent to: return base_;
template<class R>
    reverse_view(R&&) -> reverse_view<all_view<R>>;
}

constexpr explicit reverse_view(V base);

Effects: Initializes base_ with std::move(base).

template<ViewableRange R>
    requires BidirectionalRange<R> && Constructible<V, all_view<R>>
    constexpr explicit reverse_view(R&& r);

Effects: Initializes base_ with view::all(std::forward<R>(r)).

constexpr V base() const;

Effects: Equivalent to: return base_;

constexpr reverse_iterator<iterator_t<V>> begin();
Returns:
    make_reverse_iterator(ranges::next(ranges::begin(base_), ranges::end(base_)))
Remarks: In order to provide the amortized constant time complexity required by the Range concept, this function caches the result within the reverse_view for use on subsequent calls.

constexpr reverse_iterator<iterator_t<V>> begin() requires CommonRange<V>;
constexpr reverse_iterator<iterator_t<const V>> begin() const requires CommonRange<const V>;

Effects: Equivalent to: return make_reverse_iterator(ranges::end(base_));

constexpr reverse_iterator<iterator_t<const V>> end();
constexpr reverse_iterator<iterator_t<const V>> end() const requires CommonRange<const V>;

Effects: Equivalent to: return make_reverse_iterator(ranges::begin(base_));

### 24.7.11.3 view::reverse

The name view::reverse denotes a range adaptor object (24.7.1). For some subexpression E, the expression view::reverse(E) is expression-equivalent to:

1. If the type of E is a (possibly cv-qualified) specialization of reverse_view, equivalent to E.base().
2. Otherwise, if the type of E is cv-qualified subrange<reverse_iterator<I>, reverse_iterator<I>, K> for some iterator type I and value K of type subrange_kind,
   1. If K is subrange_kind::sized, equivalent to:
      subrange<I, I, K>(E.end().base(), E.begin().base(), E.size())
   2. Otherwise, equivalent to:
      subrange<I, I, K>(E.end().base(), E.begin().base())

However, in either case E is evaluated only once.
3. Otherwise, equivalent to reverse_view(E).
25 Algorithms library

25.1 General

This Clause describes components that C++ programs may use to perform algorithmic operations on containers (Clause 22) and other sequences.

The following subclauses describe components for non-modifying sequence operations, mutating sequence operations, sorting and related operations, and algorithms from the ISO C library, as summarized in Table 80.

<table>

</tr>
</tbody>
</table>

25.2 Algorithms requirements

All of the algorithms are separated from the particular implementations of data structures and are parameterized by iterator types. Because of this, they can work with program-defined data structures, as long as these data structures have iterator types satisfying the assumptions on the algorithms.

The entities defined in the std::ranges namespace in this Clause are not found by argument-dependent name lookup (6.4.2). When found by unqualified (6.4.1) name lookup for the postfix-expression in a function call (7.6.1.2), they inhibit argument-dependent name lookup.

Example:

```cpp
void foo() {
  using namespace std::ranges;
  std::vector<int> vec{1,2,3};
  find(begin(vec), end(vec), 2); // #1
}
```

The function call expression at #1 invokes std::ranges::find, not std::find, despite that (a) the iterator type returned from begin(vec) and end(vec) may be associated with namespace std and (b) std::find is more specialized (13.6.6.2) than std::ranges::find since the former requires its first two parameters to have the same type. — end example]

For purposes of determining the existence of data races, algorithms shall not modify objects referenced through an iterator argument unless the specification requires such modification.

Throughout this Clause, where the template parameters are not constrained, the names of template parameters are used to express type requirements.

1. If an algorithm’s template parameter is named InputIterator, InputIterator1, or InputIterator2, the template argument shall meet the Cpp17InputIterator requirements (23.3.5.2).
2. If an algorithm’s template parameter is named OutputIterator, OutputIterator1, or OutputIterator2, the template argument shall meet the Cpp17OutputIterator requirements (23.3.5.3).
3. If an algorithm’s template parameter is named ForwardIterator, ForwardIterator1, or ForwardIterator2, the template argument shall meet the Cpp17ForwardIterator requirements (23.3.5.4).
4. If an algorithm’s template parameter is named BidirectionalIterator, BidirectionalIterator1, or BidirectionalIterator2, the template argument shall meet the Cpp17BidirectionalIterator requirements (23.3.5.5).
If an algorithm’s template parameter is named `RandomAccessIterator`, `RandomAccessIterator1`, or `RandomAccessIterator2`, the template argument shall meet the `Cpp17RandomAccessIterator` requirements (23.3.5.6).

If an algorithm’s Effects: element specifies that a value pointed to by any iterator passed as an argument is modified, then that algorithm has an additional type requirement: The type of that argument shall meet the requirements of a mutable iterator (23.3). [Note: This requirement does not affect arguments that are named `OutputIterator`, `OutputIterator1`, or `OutputIterator2`, because output iterators must always be movable, nor does it affect arguments that are constrained, for which mutability requirements are expressed explicitly. — end note]

Both in-place and copying versions are provided for certain algorithms. When such a version is provided for algorithm it is called `algorithm_copy`. Algorithms that take predicates end with the suffix `_if` (which follows the suffix `_copy`).

When not otherwise constrained, the `Predicate` parameter is used whenever an algorithm expects a function object (20.14) that, when applied to the result of dereferencing the corresponding iterator, returns a value testable as `true`. In other words, if an algorithm takes `Predicate` as its argument and `first` as its iterator argument with value type T, it should work correctly in the construct `pred(*first)` contextually converted to `bool` (7.3). The function object `pred` shall not apply any non-constant function through the dereferenced iterator. Given a glvalue `u` of type (possibly `const`) T that designates the same object as `*first`, `pred(u)` shall be a valid expression that is equal to `pred(*first)`.

When not otherwise constrained, the `BinaryPredicate` parameter is used whenever an algorithm expects a function object that when applied to the result of dereferencing two corresponding iterators or to dereferencing an iterator and type T when T is part of the signature returns a value testable as `true`. In other words, if an algorithm takes `BinaryPredicate` as its argument and `first1` and `first2` as its iterator arguments with respective value types `T1` and `T2`, it should work correctly in the construct `binary_pred(*first1, *first2)` contextually converted to `bool` (7.3). Unless otherwise specified, `BinaryPredicate` always takes the first iterator’s `value_type` as its first argument, that is, in those cases when T value is part of the signature, it should work correctly in the construct `binary_pred(*first1, value)` contextually converted to `bool` (7.3). `binary_pred` shall not apply any non-constant function through the dereferenced iterators. Given a glvalue `u` of type (possibly `const`) T1 that designates the same object as `*first1`, and a glvalue v of type (possibly `const`) T2 that designates the same object as `*first2`, `binary_pred(u, *first2)`, `binary_pred(*first1, v)`, and `binary_pred(u, v)` shall each be a valid expression that is equal to `binary_pred(*first1, *first2)`, and `binary_pred(u, value)` shall be a valid expression that is equal to `binary_pred(*first1, value)`.

The parameters `UnaryOperation`, `UnaryOperation1`, and `UnaryOperation2` are used whenever an algorithm expects a function object (20.14).

[Note: Unless otherwise specified, algorithms that take function objects as arguments are permitted to copy those function objects freely. Programmers for whom object identity is important should consider using a wrapper class that points to a noncopied implementation object such as `reference_wrapper<T>` (20.14.5), or some equivalent solution. — end note]

When the description of an algorithm gives an expression such as `*first == value` for a condition, the expression shall evaluate to either `true` or `false` in boolean contexts.

In the description of the algorithms, operator `+` is used for some of the iterator categories for which it does not have to be defined. In these cases the semantics of `a + n` are the same as those of

```cpp
auto tmp = a;
for (; n < 0; ++n) --tmp;
for (; n > 0; --n) ++tmp;
return tmp;
```

Similarly, operator `-` is used for some combinations of iterators and sentinel types for which it does not have to be defined. If `[a, b)` denotes a range, the semantics of `b - a` in these cases are the same as those of

```cpp
iter_difference_t<remove_reference_t<decltype(a)>> n = 0;
for (auto tmp = a; tmp != b; ++tmp) ++n;
return n;
```

---

234) The decision whether to include a copying version was usually based on complexity considerations. When the cost of doing the operation dominates the cost of copy, the copying version is not included. For example, `sort_copy` is not included because the cost of sorting is much more significant, and users might as well do `copy` followed by `sort`. 

§ 25.2 985
and if \([b, a)\) denotes a range, the same as those of

\[
\begin{align*}
\text{iter_difference_t<remove_reference_t<\text{decltype(b)>> n} &= 0; \\
\text{for (auto tmp = b; tmp != a; ++tmp) --n; } \\
\text{return n; }
\end{align*}
\]

13 In the description of algorithm return values, a sentinel value \(s\) denoting the end of a range \([i, s)\) is sometimes returned where an iterator is expected. In these cases, the semantics are as if the sentinel is converted into an iterator using \(\text{ranges::next}(i, s)\).

14 Overloads of algorithms that take \(\text{Range}\) arguments (24.4.2) behave as if they are implemented by calling \(\text{ranges::begin}\) and \(\text{ranges::end}\) on the \(\text{Range}\)(s) and dispatching to the overload in namespace \(\text{ranges}\) that takes separate iterator and sentinel arguments.

15 The number and order of deducible template parameters for algorithm declarations are unspecified, except where explicitly stated otherwise. [\textbf{Note:} Consequently, the algorithms may not be called with explicitly-specified template argument lists. —\textit{end note}] The class templates \(\text{binary_transform_result}, \text{for_each_result}, \text{minmax_result}, \text{mismatch_result}, \text{copy_result},\) and \(\text{partition_copy_result}\) have the template parameters, data members, and special members specified below. They have no base classes or members other than those specified.

### 25.3 Parallel algorithms

[\textit{algorithms.parallel}]  
This subclause describes components that C++ programs may use to perform operations on containers and other sequences in parallel.

#### 25.3.1 Terms and definitions

[\textit{algorithms.parallel.defns}]  
A \textit{parallel algorithm} is a function template listed in this document with a template parameter named \textit{ExecutionPolicy}.

2 Parallel algorithms access objects indirectly accessible via their arguments by invoking the following functions:

\begin{enumerate}
\item All operations of the categories of the iterators that the algorithm is instantiated with.
\item Operations on those sequence elements that are required by its specification.
\item User-provided function objects to be applied during the execution of the algorithm, if required by the specification.
\item Operations on those function objects required by the specification. [\textbf{Note:} See 25.2. —\textit{end note}] These functions are herein called \textit{element access functions}. [\textbf{Example:} The \textit{sort} function may invoke the following element access functions:

\item Operations of the random-access iterator of the actual template argument (as per 23.3.5.6), as implied by the name of the template parameter \textit{RandomAccessIterator}.
\item The \textit{swap} function on the elements of the sequence (as per the preconditions specified in 25.7.1.1).
\item The user-provided \textit{Compare} function object.
\end{enumerate}

—\textit{end example}]

3 A standard library function is \textit{vectorization-unsafe} if it is specified to synchronize with another function invocation, or another function invocation is specified to synchronize with it, and if it is not a memory allocation or deallocation function. [\textbf{Note:} Implementations must ensure that internal synchronization inside standard library functions does not prevent forward progress when those functions are executed by threads of execution with weakly parallel forward progress guarantees. —\textit{end note}] [\textbf{Example:}

\[
\begin{align*}
\text{int x} &= 0; \\
\text{std::mutex m; } \\
\text{void f()} \{ \\
\text{int a[]} &= \{1,2\}; \\
\text{std::for_each(std::execution::par_unseq, std::begin(a), std::end(a), \&[](int) \{ \\
\text{std::lock_guard<mutex> guard(m); \quad // incorrect: lock_guard constructor calls m.lock() } \\
\text{++x;} \\
\text{\}); \\
\text{\}); }
\end{align*}
\]
The above program may result in two consecutive calls to m.lock() on the same thread of execution (which may deadlock), because the applications of the function object are not guaranteed to run on different threads of execution. — end example

25.3.2 Requirements on user-provided function objects  [algorithms.parallel.user]

1 Unless otherwise specified, function objects passed into parallel algorithms as objects of type Predicate, BinaryPredicate, Compare, UnaryOperation, BinaryOperation, BinaryOperation1, BinaryOperation2, and the operators used by the analogous overloads to these parallel algorithms that could be formed by the invocation with the specified default predicate or operation (where applicable) shall not directly or indirectly modify objects via their arguments, nor shall they rely on the identity of the provided objects.

25.3.3 Effect of execution policies on algorithm execution  [algorithms.parallel.exec]

1 Parallel algorithms have template parameters named ExecutionPolicy (20.18) which describe the manner in which the execution of these algorithms may be parallelized and the manner in which they apply the element access functions.

2 If an object is modified by an element access function, the algorithm will perform no other unsynchronized accesses to that object. The modifying element access functions are those which are specified as modifying the object. [Note: For example, swap, ++, --, @=, and assignments modify the object. For the assignment and @= operators, only the left argument is modified. — end note]

3 Unless otherwise stated, implementations may make arbitrary copies of elements (with type T) from sequences where is_trivially_copy_constructible_v<T> and is_trivially_destructible_v<T> are true. [Note: This implies that user-supplied function objects should not rely on object identity of arguments for such input sequences. Users for whom the object identity of the arguments to these function objects is important should consider using a wrapping iterator that returns a non-copied implementation object such as reference_wrapper<T> (20.14.5) or some equivalent solution. — end note]

4 The invocations of element access functions in parallel algorithms invoked with an execution policy object of type execution::sequenced_policy all occur in the calling thread of execution. [Note: The invocations are not interleaved; see 6.8.1. — end note]

5 The invocations of element access functions in parallel algorithms invoked with an execution policy object of type execution::unsequenced_policy are permitted to execute in an unordered fashion in the calling thread of execution, unsequenced with respect to one another in the calling thread of execution. [Note: This means that multiple function object invocations may be interleaved on a single thread of execution, which overrides the usual guarantee from 6.8.1 that function executions do not overlap with one another. — end note] The behavior of a program is undefined if it invokes a vectorization-unsafe standard library function from user code called from a execution::unsequenced_policy algorithm. [Note: Because execution::unsequenced_policy allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock. — end note]

6 The invocations of element access functions in parallel algorithms invoked with an execution policy object of type execution::parallel_policy are permitted to execute either in the invoking thread of execution or in a thread of execution implicitly created by the library to support parallel algorithm execution. If the threads of execution created by thread (32.3.2) provide concurrent forward progress guarantees (6.8.2.2), then a thread of execution implicitly created by the library will provide parallel forward progress guarantees; otherwise, the provided forward progress guarantee is implementation-defined. Any such invocations executing in the same thread of execution are indeterminately sequenced with respect to each other. [Note: It is the caller’s responsibility to ensure that the invocation does not introduce data races or deadlocks. — end note]

[Example:
  int a[] = {0,1};
  std::vector<int> v;
  std::for_each(std::execution::par, std::begin(a), std::end(a), [&]() mutable { v.push_back(i*2+1); // incorrect: data race });

  The program above has a data race because of the unsynchronized access to the container v. — end example]

[Example:
  std::atomic<int> x{0};
  int a[] = {1,2};

§ 25.3.3 987
© ISO/IEC

The example depends on the order of execution of the iterations, and will not terminate if both iterations are executed sequentially on the same thread of execution. —end example] [Example:

```cpp
int x = 0;
std::mutex m;
int a[] = {1, 2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&]() { std::lock_guard<mutex> guard(m);
++x;
});
```

The above example synchronizes access to object x ensuring that it is incremented correctly. —end example]

7 The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `std::execution::parallel_unsequenced_policy` are permitted to execute in an unordered fashion in unspecified threads of execution, and unsequenced with respect to one another within each thread of execution. These threads of execution are either the invoking thread of execution or threads of execution implicitly created by the library; the latter will provide weakly parallel forward progress guarantees. [Note: This means that multiple function object invocations may be interleaved on a single thread of execution, which overrides the usual guarantee from 6.8.1 that function executions do not overlap with one another. —end note] The behavior of a program is undefined if it invokes a vectorization-unsafe standard library function from user code called from a `std::execution::parallel_unsequenced_policy` algorithm. [Note: Because `std::execution::parallel_unsequenced_policy` allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock. —end note]

8 [Note: The semantics of invocation with `std::execution::unsequenced_policy`, `std::execution::parallel_policy`, or `std::execution::parallel_unsequenced_policy` allow the implementation to fall back to sequential execution if the system cannot parallelize an algorithm invocation, e.g., due to lack of resources. —end note]

9 If an invocation of a parallel algorithm uses threads of execution implicitly created by the library, then the invoking thread of execution will either

(9.1) — temporarily block with forward progress guarantee delegation (6.8.2.2) on the completion of these library-managed threads of execution, or

(9.2) — eventually execute an element access function;

the thread of execution will continue to do so until the algorithm is finished. [Note: In blocking with forward progress guarantee delegation in this context, a thread of execution created by the library is considered to have finished execution as soon as it has finished the execution of the particular element access function that the invoking thread of execution logically depends on. —end note]

10 The semantics of parallel algorithms invoked with an execution policy object of implementation-defined type are implementation-defined.

25.3.4 Parallel algorithm exceptions [algorithms.parallel.exceptions]

During the execution of a parallel algorithm, if temporary memory resources are required for parallelization and none are available, the algorithm throws a `std::bad_alloc` exception.

During the execution of a parallel algorithm, if the invocation of an element access function exits via an uncaught exception, the behavior is determined by the `std::execution_policy`.

25.3.5 ExecutionPolicy algorithm overloads [algorithms.parallel.overloads]

Parallel algorithms are algorithm overloads. Each parallel algorithm overload has an additional template type parameter named `std::execution_policy`, which is the first template parameter. Additionally, each parallel algorithm overload has an additional function parameter of type `std::execution_policy&&`, which is the first function parameter. [Note: Not all algorithms have parallel algorithm overloads. —end note]

Unless otherwise specified, the semantics of `std::execution_policy` algorithm overloads are identical to their overloads without.
Unless otherwise specified, the complexity requirements of `ExecutionPolicy` algorithm overloads are relaxed from the complexity requirements of the overloads without as follows: when the guarantee says “at most expr” or “exactly expr” and does not specify the number of assignments or swaps, and expr is not already expressed with $O()$ notation, the complexity of the algorithm shall be $O(expr)$.

Parallel algorithms shall not participate in overload resolution unless `is_execution_policy_v<remove_cvref_t<ExecutionPolicy>>` is true.

### 25.4 Header `<algorithm>` synopsis

```cpp
#include <initializer_list>

namespace std {

§ 25.4
25.5 Non-modifying sequence operations

25.5.1 All of

```cpp
template<class InputIterator, class Predicate>
constexpr bool all_of(InputIterator first, InputIterator last, Predicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool all_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);
```

```cpp
template<InputIterator I, Sentinel<I> S, class Proj = identity, IndirectUnaryPredicate<projected<I, Proj>> Pred>
customexpr bool all_of(I first, S last, Pred pred, Proj proj = {});
```

```cpp
template<InputRange R, class Proj = identity, IndirectUnaryPredicate<iterator_t<R>, Proj>>
customexpr bool all_of(R&& r, Pred pred, Proj proj = {});
```

1. Let \( E \) be \( \text{pred}(*i) \) and \( \text{invoke} (\text{pred}, \text{invoke} (\text{proj}, *i)) \) for the overloads in namespace `std` and `std::ranges`, respectively.

2. Returns: `false` if \( E \) is `false` for some iterator \( i \) in the range \([\text{first}, \text{last})\), and `true` otherwise.

3. Complexity: At most \( \text{last} - \text{first} \) applications of the predicate and any projection.

25.5.2 Any of

```cpp
template<class InputIterator, class Predicate>
constexpr bool any_of(InputIterator first, InputIterator last, Predicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool any_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);
```

```cpp
template<InputIterator I, Sentinel<I> S, class Proj = identity, IndirectUnaryPredicate<projected<I, Proj>> Pred>
customexpr bool any_of(I first, S last, Pred pred, Proj proj = {});
```

```cpp
template<InputRange R, class Proj = identity, IndirectUnaryPredicate<iterator_t<R>, Proj>>
customexpr bool any_of(R&& r, Pred pred, Proj proj = {});
```

1. Let \( E \) be \( \text{pred}(*i) \) and \( \text{invoke} (\text{pred}, \text{invoke} (\text{proj}, *i)) \) for the overloads in namespace `std` and `std::ranges`, respectively.

2. Returns: `true` if \( E \) is `true` for some iterator \( i \) in the range \([\text{first}, \text{last})\), and `false` otherwise.

3. Complexity: At most \( \text{last} - \text{first} \) applications of the predicate and any projection.

25.5.3 None of

```cpp
template<class InputIterator, class Predicate>
constexpr bool none_of(InputIterator first, InputIterator last, Predicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool none_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);
```

```cpp
template<InputIterator I, Sentinel<I> S, class Proj = identity, IndirectUnaryPredicate<projected<I, Proj>> Pred>
customexpr bool none_of(I first, S last, Pred pred, Proj proj = {});
```

```cpp
template<InputRange R, class Proj = identity, IndirectUnaryPredicate<iterator_t<R>, Proj>>
customexpr bool none_of(R&& r, Pred pred, Proj proj = {});
```

1. Let \( E \) be \( \text{pred}(*i) \) and \( \text{invoke} (\text{pred}, \text{invoke} (\text{proj}, *i)) \) for the overloads in namespace `std` and `std::ranges`, respectively.

2. Returns: `false` if \( E \) is `false` for some iterator \( i \) in the range \([\text{first}, \text{last})\), and `true` otherwise.

3. Complexity: At most \( \text{last} - \text{first} \) applications of the predicate and any projection.
template<InputRange R, class Proj = identity,
    IndirectUnaryPredicate<projected<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::none_of(R&& r, Pred pred, Proj proj = {});

Let $E$ be $\text{pred}(*i)$ and $\text{invoke}($pred, $\text{invoke}($proj, $*i))$ for the overloads in namespace std and
std::ranges, respectively.

Returns: false if $E$ is true for some iterator $i$ in the range $[\text{first}, \text{last})$, and true otherwise.

Complexity: At most $\text{last} - \text{first}$ applications of the predicate and any projection.

25.5.4 For each

template<class InputIterator, class Function>
constexpr Function for_each(InputIterator first, InputIterator last, Function f);

Requires: Function shall meet the Cpp17MoveConstructible requirements (Table 26). [Note: Function
need not meet the requirements of Cpp17CopyConstructible (Table 27). — end note]

Effects: Applies $f$ to the result of dereferencing every iterator in the range $[\text{first}, \text{last})$, starting
from $\text{first}$ and proceeding to $\text{last} - 1$. [Note: If the type of $\text{first}$ meets the requirements of a
mutable iterator, $f$ may apply non-constant functions through the dereferenced iterator. — end note]

Returns: $f$.

Complexity: Applies $f$ exactly $\text{last} - \text{first}$ times.

Remarks: If $f$ returns a result, the result is ignored.

template<class ExecutionPolicy, class ForwardIterator, class Function>
void for_each(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    Function f);

Requires: Function shall meet the Cpp17CopyConstructible requirements.

Effects: Applies $f$ to the result of dereferencing every iterator in the range $[\text{first}, \text{last})$. [Note: If the type of $\text{first}$ meets the requirements of a mutable iterator, $f$ may apply non-constant functions through the dereferenced iterator. — end note]

Complexity: Applies $f$ exactly $\text{last} - \text{first}$ times.

Remarks: If $f$ returns a result, the result is ignored. Implementations do not have the freedom granted
under 25.3.3 to make arbitrary copies of elements from the input sequence.

[Note: Does not return a copy of its Function parameter, since parallelization may not permit efficient
state accumulation. — end note]

template<InputIterator I, Sentinel<I> S, class Proj = identity,
    IndirectUnaryInvocable<projected<I, Proj>> Fun>
constexpr ranges::for_each_result<I, Fun>
ranges::for_each(I first, S last, Fun f, Proj proj = {});

template<InputRange R, class Proj = identity,
    IndirectUnaryInvocable<projected<iterator_t<R>, Proj>> Fun>
constexpr ranges::for_each_result<safe_iterator_t<R>, Fun>
ranges::for_each(R&& r, Fun f, Proj proj = {});

Effects: Calls $\text{invoke}($f, $\text{invoke}($proj, $*i))$ for every iterator $i$ in the range $[\text{first}, \text{last})$, starting
from $\text{first}$ and proceeding to $\text{last} - 1$. [Note: If the result of $\text{invoke}($proj, $*i)$ is a mutable
reference, $f$ may apply non-constant functions. — end note]

Returns: $\{\text{last}, \text{std::move}(f)\}$.

Complexity: Applies $f$ and $\text{proj}$ exactly $\text{last} - \text{first}$ times.

Remarks: If $f$ returns a result, the result is ignored.

[Note: The overloads in namespace ranges require Fun to model CopyConstructible. — end note]

template<class InputIterator, class Size, class Function>
constexpr InputIterator for_each_n(InputIterator first, Size n, Function f);

Requires: Function shall meet the Cpp17MoveConstructible requirements [Note: Function need not
meet the requirements of Cpp17CopyConstructible. — end note]
Requires: n >= 0.

Effects: Applies f to the result of dereferencing every iterator in the range [first, first + n) in order. [Note: If the type of first meets the requirements of a mutable iterator, f may apply non-constant functions through the dereferenced iterator. — end note]

Returns: first + n.

Remarks: If f returns a result, the result is ignored.

template<class ExecutionPolicy, class ForwardIterator, class Size, class Function>
ForwardIterator for_each_n(ExecutionPolicy&& exec, ForwardIterator first, Size n, Function f);

Requires: Function shall meet the Cpp17CopyConstructible requirements.

Effects: Applies f to the result of dereferencing every iterator in the range [first, first + n). [Note: If the type of first meets the requirements of a mutable iterator, f may apply non-constant functions through the dereferenced iterator. — end note]

Returns: first + n.

Remarks: If f returns a result, the result is ignored. Implementations do not have the freedom granted under 25.3.3 to make arbitrary copies of elements from the input sequence.

25.5.5 Find

template<class InputIterator, class T>
constexpr InputIterator find(InputIterator first, InputIterator last, const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>
ForwardIterator find(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, const T& value);

template<class InputIterator, class Predicate>
constexpr InputIterator find_if(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator find_if(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);

template<class InputIterator, class Predicate>
constexpr InputIterator find_if_not(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator find_if_not(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);

template<InputIterator I, Sentinel<I> S, class T, class Proj = identity>
requires IndirectRelation<ranges::equal_to, projected<I, Proj>, const T*>.
constexpr I ranges::find(I first, S last, const T& value, Proj proj = {});

template<InputRange R, class T, class Proj = identity>
requires IndirectRelation<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>.
constexpr safe_iterator_t<R> ranges::find(R&& r, const T& value, Proj proj = {});

template<InputIterator I, Sentinel<I> S, class Proj = identity, IndirectUnaryPredicate<projected<I, Proj>> Pred>
constexpr I ranges::find_if(I first, S last, Pred pred, Proj proj = {});

template<InputRange R, class Proj = identity, IndirectUnaryPredicate<projected<iterator_t<R>, Proj>> Pred>
constexpr safe_iterator_t<R> ranges::find_if(R&& r, Pred pred, Proj proj = {});

template<InputIterator I, Sentinel<I> S, class Proj = identity, IndirectUnaryPredicate<projected<I, Proj>> Pred>
constexpr I ranges::find_if_not(I first, S last, Pred pred, Proj proj = {});
template<InputRange R, class Proj = identity,
           IndirectUnaryPredicate<projected<iterator_t<R>, Proj>> Pred>
constexpr safe_iterator_t<R>
ranges::find_if_not(R&& r, Pred pred, Proj proj = {});

1 Let $E$ be:

- (1.1) $i == \text{value}$ for find,
- (1.2) $\text{pred}(i) \neq \text{false}$ for find_if,
- (1.3) $\text{pred}(i) == \text{false}$ for find_if_not,
- (1.4) $\text{invoke}(\text{proj}, i) == \text{value}$ for ranges::find,
- (1.5) $\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, i)) \neq \text{false}$ for ranges::find_if,
- (1.6) $\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, i)) == \text{false}$ for ranges::find_if_not.

2 Returns: The first iterator $i$ in the range $[\text{first}, \text{last})$ for which $E$ is true. Returns last if no such iterator is found.

3 Complexity: At most last - first applications of the corresponding predicate and any projection.

25.5.6 Find end

1 Let $E$ be:

- (1.1) $\text{pred}$ be equal_to{} for the overloads with no parameter $\text{pred}$.
- (1.2) $E$ be:
  - (1.2.1) $\text{pred}((i + n), *(\text{first2} + n))$ for the overloads in namespace std,
invoke(pred, invoke(proj1, *(i + n)), invoke(proj2, *(first2 + n))) for the overloads in namespace ranges.

i be last1 if (first2, last2) is empty, or if (last2 - first2) > (last1 - first1) is true, or if there is no iterator in the range [first1, last1 - (last2 - first2)) such that for every non-negative integer n < (last2 - first2), E is true. Otherwise i is the last such iterator in [first1, last1 - (last2 - first2)).

Returns:

— i for the overloads in namespace std, and

— {i, i + (i == last1 ? 0 : last2 - first2)) for the overloads in namespace ranges.

Complexity: At most (last2 - first2) * (last1 - first1 - (last2 - first2) + 1) applications of the corresponding predicate and any projections.

25.5.7 Find first

§ 25.5.7 1029
Effects: Finds an element that matches one of a set of values.

Returns: The first iterator \( i \) in the range \([first1, last1)\) such that for some iterator \( j \) in the range \([first2, last2)\) \( E \) holds. Returns \( last1 \) if \([first2, last2)\) is empty or if no such iterator is found.

Complexity: At most \((last1-first1) \times (last2-first2)\) applications of the corresponding predicate and any projections.

### 25.5.8 Adjacent find

\[
\text{template<class ForwardIterator>}
\text{constexpr ForwardIterator}
\text{adjacent_find(ForwardIterator first, ForwardIterator last);} \\
\text{template<class ExecutionPolicy, class ForwardIterator>}
\text{ForwardIterator}
\text{adjacent_find(ExecutionPolicy&& exec,}
\text{ ForwardIterator first, ForwardIterator last);} \\
\text{template<class ForwardIterator, class BinaryPredicate>}
\text{constexpr ForwardIterator}
\text{adjacent_find(ForwardIterator first, ForwardIterator last,}
\text{ BinaryPredicate pred);} \\
\text{template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>}
\text{ForwardIterator}
\text{adjacent_find(ExecutionPolicy&& exec,}
\text{ ForwardIterator first, ForwardIterator last,}
\text{ BinaryPredicate pred);} \\
\text{template<ForwardIterator I, Sentinel<I> S, class Proj = identity,
IndirectRelation<projected<I, Proj>> Pred = ranges::equal_to>
\text{constexpr I ranges::adjacent_find(I first, S last, Pred pred = {}, Proj proj = {});} \\
\text{template<ForwardRange R, class Proj = identity,
IndirectRelation<projected<iterator_t<R>, Proj>> Pred = ranges::equal_to>
\text{constexpr safe_iterator_t<R> ranges::adjacent_find(R&& r, Pred pred = {}, Proj proj = {});} \\
\]

Let \( E \) be:

1. \( *i == *(i + 1) \) for the overloads with no parameter \( \text{pred} \),
2. \( \text{pred}(*i, *(i + 1)) \neq \text{false} \) for the overloads with a parameter \( \text{pred} \) and no parameter \( \text{proj} \),
3. \( \text{invoke}((\text{pred}), \text{invoke}((\text{proj}), *i), \text{invoke}((\text{proj}), *(i + 1))) \neq \text{false} \) for the overloads with both parameters \( \text{pred} \) and \( \text{proj} \).

Returns: The first iterator \( i \) such that both \( i \) and \( i + 1 \) are in the range \([first, last)\) for which \( E \) holds. Returns \( last \) if no such iterator is found.

Complexity: For the overloads with no \( \text{ExecutionPolicy} \), exactly

\[
\min((i - first) + 1, (last - first) - 1)
\]

applications of the corresponding predicate, where \( i \) is \( \text{adjacent\_find} \)'s return value. For the overloads with an \( \text{ExecutionPolicy} \), \( O(last - first) \) applications of the corresponding predicate, and no more than twice as many applications of any projection.

### 25.5.9 Count

\[
\text{template<class InputIterator, class T>}
\text{constexpr typename iterator_traits<InputIterator>::difference_type}
\text{count(InputIterator first, InputIterator last, const T& value);} \\
\text{template<class ExecutionPolicy, class ForwardIterator, class T>}
\text{typename iterator_traits<ForwardIterator>::difference_type}
\text{count(ExecutionPolicy&& exec,}
\text{ ForwardIterator first, ForwardIterator last, const T& value);} \\
\text{template<class InputIterator, class Predicate>
\text{constexpr typename iterator_traits<InputIterator>::difference_type}
\text{count_if(InputIterator first, InputIterator last, Predicate pred);} \\
\]

§ 25.5.9
template<
    class ExecutionPolicy,
    class ForwardIterator,
    class Predicate
>
typename iterator_traits<ForwardIterator>::difference_type
count_if(
    ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last, Predicate pred);

template<
    InputIterator I,
    Sentinel<I> S,
    class T,
    class Proj = identity
>
requires IndirectRelation<
    ranges::equal_to, projected<I, Proj>, const T*> // (1.1)
constexpr iter_difference_t<I>
ranges::count(I first, S last, const T& value, Proj proj = {});

template<
    InputRange R,
    class Proj = identity
>
requires IndirectRelation<
    ranges::equal_to, projected<iterator_t<R>, Proj>, const T*> // (1.2)
constexpr iter_difference_t<iterator_t<R>>
ranges::count(R&& r, const T& value, Proj proj = {});

template<
    InputIterator I,
    Sentinel<I> S,
    class Proj = identity,
    IndirectUnaryPredicate<projected<I, Proj>> Pred
>
constexpr iter_difference_t<I>
ranges::count_if(I first, S last, Pred pred, Proj proj = {});

template<
    InputRange R,
    class Proj = identity,
    IndirectUnaryPredicate<projected<iterator_t<R>, Proj>> Pred
>
constexpr iter_difference_t<iterator_t<R>>
ranges::count_if(R&& r, Pred pred, Proj proj = {}); // (1.3)

Let E be:
  (1.1)  
      *i == value for the overloads with no parameter pred or proj,
  (1.2)  
      pred(*i) != false for the overloads with a parameter pred but no parameter proj,
  (1.3)  
      invoke(proj, *i) == value for the overloads with a parameter proj but no parameter pred,
  (1.4)  
      invoke(pred, invoke(proj, *i)) != false for the overloads with both parameters proj and pred.

Effects: Returns the number of iterators i in the range [first, last) for which E holds.

Complexity: Exactly last - first applications of the corresponding predicate and any projection.

25.5.10 Mismatch

template<
    class InputIterator1,
    class InputIterator2
>
constexpr pair<InputIterator1, InputIterator2>
mismatch(InputIterator1 first1, InputIterator1 last1,
         InputIterator2 first2);

template<
    class ExecutionPolicy,
    class ForwardIterator1,
    class ForwardIterator2
>
pair<ForwardIterator1, ForwardIterator2>
mismatch(ExecutionPolicy&& exec,
         ForwardIterator1 first1, ForwardIterator1 last1,
         ForwardIterator2 first2);

template<
    class InputIterator1,
    class InputIterator2,
    class BinaryPredicate
>
constexpr pair<InputIterator1, InputIterator2>
mismatch(InputIterator1 first1, InputIterator1 last1,
         InputIterator2 first2, BinaryPredicate pred);

template<
    class ExecutionPolicy,
    class ForwardIterator1,
    class ForwardIterator2,
    class BinaryPredicate
>
pair<ForwardIterator1, ForwardIterator2>
mismatch(ExecutionPolicy&& exec,
         ForwardIterator1 first1, ForwardIterator1 last1,
         ForwardIterator2 first2, BinaryPredicate pred);

§ 25.5.10
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
    pair<ForwardIterator1, ForwardIterator2>
mismatch(ExecutionPolicy&& exec,
            ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2,
         class BinaryPredicate>
    constexpr pair<InputIterator1, InputIterator2>
mismatch(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, InputIterator2 last2,
             BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
    pair<ForwardIterator1, ForwardIterator2>
mismatch(ExecutionPolicy&& exec,
            ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2, ForwardIterator2 last2,
            BinaryPredicate pred);

template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
         class Proj1 = identity, class Proj2 = identity,
         IndirectRelation<projected<I1, Proj1>,
                         projected<I2, Proj2>> Pred = ranges::equal_to
    constexpr ranges::mismatch_result<I1, I2>
ranges::mismatch(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
                  Proj1 proj1 = {}, Proj2 proj2 = {});

template<InputRange R1, InputRange R2,
         class Proj1 = identity, class Proj2 = identity,
         IndirectRelation<projected<iterator_t<R1>, Proj1>,
                         projected<iterator_t<R2>, Proj2>> Pred = ranges::equal_to
    constexpr ranges::mismatch_result<safe_iterator_t<R1>, safe_iterator_t<R2>>
ranges::mismatch(R1&& r1, R2&& r2, Pred pred = {},
                  Proj1 proj1 = {}, Proj2 proj2 = {});

1  Let last2 be first2 + (last1 - first1) for the overloads with no parameter last2 or r2.
2  Let E be:
   (2.1) — !(*(first1 + n) == *(first2 + n)) for the overloads with no parameter pred,
   (2.2) — pred(*(first1 + n), *(first2 + n)) == false for the overloads with a parameter pred
          and no parameter proj1,
   (2.3) — !invoke(pred, invoke(proj1, *(first1 + n)), invoke(proj2, *(first2 + n))) for
          the overloads with both parameters pred and proj1.
3  Let N be min(last1 - first1, last2 - first2).
4  Returns: { first1 + n, first2 + n }, where n is the smallest integer in [0, N) such that E holds,
       or N if no such integer exists.
5  Complexity: At most N applications of the corresponding predicate and any projections.

25.5.11 Equal [alg.equal]

template<class InputIterator1, class InputIterator2>
    constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                          InputIterator2 first2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
    bool equal(ExecutionPolicy&& exec,
               ForwardIterator1 first1, ForwardIterator1 last1,
               ForwardIterator2 first2);

template<class InputIterator1, class InputIterator2,
         class BinaryPredicate>
    constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                          InputIterator2 first2, BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, BinaryPredicate pred);

template<class InputIterator1, class InputIterator2>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2, class BinaryPredicate>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);

template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires IndirectlyComparable<I1, I2, Pred, Proj1, Proj2>
constexpr bool ranges::equal(I1 first1, S1 last1, I2 first2, S2 last2,
Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

template<InputRange R1, InputRange R2, class Pred = ranges::equal_to,
class Proj1 = identity, class Proj2 = identity>
requires IndirectlyComparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr bool ranges::equal(R1&& r1, R2&& r2, Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

1 Let:
   (1.1) $\text{last2 be first2 + (last1 - first1)}$ for the overloads with no parameter last2 or r2,
   (1.2) $\text{pred be equal_to{}}$ for the overloads with no parameter pred,
   (1.3) $E$ be:
      (1.3.1) $\text{pred(*i, *(first2 + (i - first1)))}$ for the overloads with no parameter proj1,
      (1.3.2) $\text{invoke(pred, invoke(proj1, *i), invoke(proj2, *(first2 + (i - first1))))}$ for
               the overloads with parameter proj1.

2 Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if $E$
   holds for every iterator $i$ in the range $\text{[first1, last1)}$ Otherwise, returns false.

3 Complexity: If the types of first1, last1, first2, and last2:
   (3.1) meet the Cpp17RandomAccessIterator requirements (23.3.5.6) for the overloads in
         namespace std, or
   (3.2) pairwise model SizedSentinel (23.3.4.8) for the overloads in namespace ranges,
         and last1 - first1 != last2 - first2, then no applications of the corresponding predicate
         and each projection; otherwise,
   (3.3) For the overloads with no ExecutionPolicy, at most $\min(\text{last1 - first1, last2 - first2})$
         applications of the corresponding predicate and any projections.
   (3.4) For the overloads with an ExecutionPolicy, $O(\min(\text{last1 - first1, last2 - first2}))$
         applications of the corresponding predicate.
25.5.12 Is permutation [alg.is.permutation]

```cpp
template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
   ForwardIterator2 first2);

template<class ForwardIterator1, class ForwardIterator2,
   class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
   ForwardIterator2 first2, BinaryPredicate pred);

template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
   ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2,
   class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
   ForwardIterator2 first2, ForwardIterator2 last2, BinaryPredicate pred);
```

1 **Requires:** `ForwardIterator1` and `ForwardIterator2` shall have the same value type. The comparison function shall be an equivalence relation.

2 **Remarks:** If `last2` was not given in the argument list, it denotes `first2 + (last1 - first1)` below.

3 **Returns:** If `last1 - first1 != last2 - first2`, return `false`. Otherwise return `true` if there exists a permutation of the elements in the range `[first2, first2 + (last1 - first1))`, beginning with `ForwardIterator2 begin`, such that `equal(first1, last1, begin)` returns `true` or `equal(first1, last1, begin, pred)` returns `true`; otherwise, returns `false`.

4 **Complexity:** No applications of the corresponding predicate if `ForwardIterator1` and `ForwardIterator2` meet the requirements of random access iterators and `last1 - first1 != last2 - first2`. Otherwise, exactly `last1 - first1` applications of the corresponding predicate if `equal(first1, last1, first2, last2)` would return `true` if `pred` was not given in the argument list or `equal(first1, last1, first2, last2, pred)` would return `true` if `pred` was given in the argument list; otherwise, at worst \( \Theta(N^2) \), where \( N \) has the value `last1 - first1`.

```cpp
template<ForwardIterator I1, Sentinel<I1> S1, ForwardIterator I2,
   Sentinel<I2> S2, class Pred = ranges::equal_to, class Proj1 = identity,
   class Proj2 = identity>
requires IndirectlyComparable<I1, I2, Pred, Proj1, Proj2>
constexpr bool ranges::is_permutation(I1 first1, S1 last1, I2 first2, S2 last2,
   Pred pred = {},
   Proj1 proj1 = {}, Proj2 proj2 = {});

template<ForwardRange R1, ForwardRange R2, class Pred = ranges::equal_to,
   class Proj1 = identity, class Proj2 = identity>
requires IndirectlyComparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr bool ranges::is_permutation(R1&& r1, R2&& r2, Pred pred = {},
   Proj1 proj1 = {}, Proj2 proj2 = {});
```

5 **Returns:** If `last1 - first1 != last2 - first2`, return `false`. Otherwise return `true` if there exists a permutation of the elements in the range `[first2, last2)`, bounded by `[pfirst, plast)`, such that `ranges::equal(first1, last1, pfirst, plast, pred, proj1, proj2)` returns `true`; otherwise, returns `false`.

6 **Complexity:** No applications of the corresponding predicate and projections if:

   (6.1) `S1` and `I1` model `SizedSentinel`,
   (6.2) `S2` and `I2` model `SizedSentinel`, and
   (6.3) `last1 - first1 != last2 - first2`.

Otherwise, exactly `last1 - first1` applications of the corresponding predicate and projections if `ranges::equal(first1, last1, first2, last2, pred, proj1, proj2)` would return `true`; otherwise, at worst \( \Theta(N^2) \), where \( N \) has the value `last1 - first1`.

25.5.13 Search [alg.search]

```cpp
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator1
```

§ 25.5.13 1034
search(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
search(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2,
    class BinaryPredicate>
constexpr ForwardIterator1
search(ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2,
    BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
    class BinaryPredicate>
ForwardIterator1
search(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2,
    BinaryPredicate pred);

Returns: The first iterator i in the range [first1, last1 - (last2-first2)) such that for every non-negative integer n less than last2 - first2 the following corresponding conditions hold: *(i + n) == *(first2 + n), pred(*(i + n), *(first2 + n)) != false. Returns first1 if [first2, last2) is empty, otherwise returns last1 if no such iterator is found.

Complexity: At most (last1 - first1) * (last2 - first2) applications of the corresponding predicate.

template<ForwardIterator I1, Sentinel<I1> S1, ForwardIterator I2,
Sentinel<I2> S2, class Pred = ranges::equal_to,
class Proj1 = identity, class Proj2 = identity>
constexpr subrange<I1>
ranges::search(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
    Proj1 proj1 = {}, Proj2 proj2 = {});

template<ForwardRange R1, ForwardRange R2, class Pred = ranges::equal_to,
class Proj1 = identity, class Proj2 = identity>
constexpr safe_subrange_t<R1>
ranges::search(R1&& r1, R2&& r2, Pred pred = {},
    Proj1 proj1 = {}, Proj2 proj2 = {});

Returns:
(3.1) \{i, i + (last2 - first2)\}, where i is the first iterator in the range [first1, last1 - (last2 - first2)) such that for every non-negative integer n less than last2 - first2 the condition
bool(invoke(pred, invoke(proj1, *(i + n)), invoke(proj2, *(first2 + n))))
is true:
(3.2) \{last1, last1\} if no such iterator exists.

Complexity: At most (last1 - first1) * (last2 - first2) applications of the corresponding predicate and projections.

template<class ForwardIterator, class Size, class T>
constexpr ForwardIterator
search_n(ForwardIterator first, ForwardIterator last,
    Size count, const T& value);

template<class ExecutionPolicy, class ForwardIterator, class Size, class T>
ForwardIterator
search_n(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    Size count, const T& value);
template<class ForwardIterator, class Size, class T, 
class BinaryPredicate>
constexpr ForwardIterator
search_n(ForwardIterator first, ForwardIterator last, 
    Size count, const T& value, 
    BinaryPredicate pred); 

// Returns: The first iterator \( i \) in the range \([\text{first}, \text{last}-\text{count})\) such that for every non-negative integer \( n \) less than \( \text{count} \) the following corresponding conditions hold: \( *(i + n) == \text{value}, \ pred(*(i + n),\text{value}) != false \). Returns last if no such iterator is found.

// Complexity: At most last - first applications of the corresponding predicate.

template<class ForwardIterator I, Sentinel<I> S, class T, 
class Pred = ranges::equal_to, class Proj = identity>
constexpr subrange<I>
ranges::search_n(I first, S last, iter_difference_t<I> count, 
    const T& value, Pred pred = {}, Proj proj = {}); 

// Returns: \( \{i, i + \text{count}\} \) where \( i \) is the first iterator in the range \([\text{first}, \text{last} - \text{count})\) such that for every non-negative integer \( n \) less than \( \text{count} \), the following condition holds: \( \text{invoke(pred, invoke(proj, *(i + n)), value)} \). Returns \( \{\text{last}, \text{last}\} \) if no such iterator is found.

// Complexity: At most last - first applications of the corresponding predicate and projection.

template<class ForwardIterator, class Searcher>
constexpr ForwardIterator
search(ForwardIterator first, ForwardIterator last, const Searcher& searcher); 

// Effects: Equivalent to: return searcher(first, last).first;

// Remarks: Searcher need not meet the Cpp17CopyConstructible requirements.

25.6 Mutating sequence operations

25.6.1 Copy

Let \( N \) be \( \text{last} - \text{first} \).

// Requires: result shall not be in the range \([\text{first}, \text{last})\).
Effects: Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result}, \text{result} + N)\) starting from \text{first} and proceeding to \text{last}. For each non-negative integer \(n < N\), performs \(*(\text{result} + n) = *(\text{first} + n)\).

Returns:
(4.1) \(\text{result} + N\) for the overload in namespace \text{std}, or
(4.2) \{\text{last}, \text{result} + N\} for the overloads in namespace \text{ranges}.

Complexity: Exactly \(N\) assignments.

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 copy(ExecutionPolicy&& policy,
   ForwardIterator1 first, ForwardIterator1 last,
   ForwardIterator2 result);
```

Requires: The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) shall not overlap.

Effects: Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\). For each non-negative integer \(n < (\text{last} - \text{first})\), performs \(*(\text{result} + n) = *(\text{first} + n)\).

Returns: \(\text{result} + (\text{last} - \text{first})\).

Complexity: Exactly \(\text{last} - \text{first}\) assignments.

```cpp
template<class InputIterator, class Size, class OutputIterator>
constexpr OutputIterator copy_n(InputIterator first, Size n,
   OutputIterator result);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class Size, class ForwardIterator2>
ForwardIterator2 copy_n(ExecutionPolicy&& exec,
   ForwardIterator1 first, Size n,
   ForwardIterator2 result);
```

```cpp
template<InputIterator I, WeaklyIncrementable O>
requires IndirectlyCopyable\(\text{I}, \text{O}\)
constexpr ranges::copy_n_result\(\text{I}, \text{O}\)
ranges::copy_n(I first, iter_difference_t\(\text{I}\) n, O result);
```

Let \(M\) be \(\max(n, 0)\).

Effects: For each non-negative integer \(i < M\), performs \(*(\text{result} + i) = *(\text{first} + i)\).

Returns:
(12.1) \(\text{result} + M\) for the overloads in namespace \text{std}, or
(12.2) \{\text{first} + M, \text{result} + M\} for the overload in namespace \text{ranges}.

Complexity: Exactly \(M\) assignments.

```cpp
template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator copy_if(InputIterator first, InputIterator last,
   OutputIterator result, Predicate pred);
```

```cpp
template<classExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
   class Predicate>
ForwardIterator2 copy_if(ExecutionPolicy&& exec,
   ForwardIterator1 first, ForwardIterator1 last,
   ForwardIterator2 result, Predicate pred);
```

```cpp
template<InputIterator I, Sentinel\(\text{I}\) S, WeaklyIncrementable O, class Proj = identity,
   IndirectUnaryPredicate<projected\(\text{I}, \text{Proj}\)>> Pred>
requires IndirectlyCopyable\(\text{I}, \text{O}\)
constexpr ranges::copy_if_result\(\text{I}, \text{O}\)
ranges::copy_if(I first, S last, O result, Pred pred, Proj proj = {});
```

```cpp
template<InputRange R, WeaklyIncrementable O, class Proj = identity,
   IndirectUnaryPredicate<projected\(\text{iterator_t}\text{\(\text{R}\)}, \text{Proj}\)>> Pred>
requires IndirectlyCopyable\(\text{iterator_t}\text{\(\text{R}\)}, \text{O}\)
constexpr ranges::copy_if_result\(\text{safe_iterator_t}\text{\(\text{R}\)}, \text{O}\)
```
ranges::copy_if(R&& r, O result, Pred pred, Proj proj = {});

Let $E$ be:

- \( \text{bool}(\text{pred}(*i)) \) for the overloads in namespace `std`, or
- \( \text{bool}((\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, *i))) \) for the overloads in namespace `ranges`.

and $N$ be the number of iterators $i$ in the range `[first, last)` for which the condition $E$ holds.

**Requires:** The ranges `[first, last)` and `[result, result + (last - first))` shall not overlap.

**Note:** For the overload with an `ExecutionPolicy`, there may be a performance cost if `iterator_traits<ForwardIterator>::value_type` is not `Cpp17MoveConstructible` (Table 26). — end note

**Effects:** Copies all of the elements referred to by the iterator $i$ in the range `[first, last)` for which $E$ is true.

**Returns:**

- \( \text{result} + N \) for the overloads in namespace `std`, or
- \( \{\text{last}, \text{result} + N\} \) for the overloads in namespace `ranges`.

**Complexity:** Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate and any projection.

**Remarks:** Stable (16.5.5.7).

```cpp
template<class BidirectionalIterator1, class BidirectionalIterator2>
constexpr BidirectionalIterator2
copy_backward(BidirectionalIterator1 first,
            BidirectionalIterator1 last,
            BidirectionalIterator2 result);
```

```cpp
template<BidirectionalIterator I1, Sentinel<I1> S1, BidirectionalIterator I2>
requires IndirectlyCopyable<I1, I2>
constexpr ranges::copy_backward_result<I1, I2>
ranges::copy_backward(I1 first, S1 last, I2 result);
```

```cpp
template<BidirectionalRange R, BidirectionalIterator I>
requires IndirectlyCopyable<iterator_t<R>, I>
constexpr ranges::copy_backward_result<safe_iterator_t<R>, I>
ranges::copy_backward(R&& r, I result);
```

Let $N$ be \( \text{last} - \text{first} \).

**Requires:** `result` shall not be in the range `[first, last]`.

**Effects:** Copies elements in the range `[first, last)` into the range `[result - N, result)` starting from \( \text{last} - 1 \) and proceeding to \( \text{first} \)\(^{235}\) For each positive integer $n \leq N$, performs \( \text{result} - n = \text{*(last} - n) \).

**Returns:**

- \( \text{result} - N \) for the overload in namespace `std`, or
- \( \{\text{last}, \text{result} - N\} \) for the overloads in namespace `ranges`.

**Complexity:** Exactly $N$ assignments.

25.6.2 Move

```cpp
template<class InputIterator, class OutputIterator>
constexpr OutputIterator move(InputIterator first, InputIterator last,
OutputIterator result);
```

```cpp
template<InputIterator I, Sentinel<I> S, WeaklyIncrementable O>
requires IndirectlyMovable<I, O>
constexpr ranges::move_result<I, O>
ranges::move(I first, S last, O result);
```

\(^{235}\) `copy_backward` should be used instead of `copy` when \( \text{last} \) is in the range `[result - N, result)`.

§ 25.6.2 1038
template<InputRange R, WeaklyIncrementable O>
requires IndirectlyMovable<iterator_t<R>, O>
constexpr ranges::move_result<safe_iterator_t<R>, O>
ranges::move(R&& r, O result);

Let \( E \) be

\((1.1)\) \( \text{std::move(*(first + n))} \) for the overload in namespace std, or

\((1.2)\) \( \text{ranges::iter_move(first + n)} \) for the overloads in namespace ranges.

Let \( N \) be \( last - first \).

**Requires:** \( result \) shall not be in the range \([first, last)\).

**Effects:** Moves elements in the range \([first, last)\) into the range \([result, result + N)\) starting from \( first \) and proceeding to \( last \). For each non-negative integer \( n < N \), performs \( *(result + n) = E \).

**Returns:**

\((4.1)\) \( result + N \) for the overload in namespace std, or

\((4.2)\) \( \{last, result + N\} \) for the overloads in namespace ranges.

**Complexity:** Exactly \( N \) assignments.

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 move(ExecutionPolicy&& policy,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result);

Let \( N \) be \( last - first \).

**Requires:** The ranges \([first, last)\) and \([result, result + N)\) shall not overlap.

**Effects:** Moves elements in the range \([first, last)\) into the range \([result, result + N)\). For each non-negative integer \( n < N \), performs \( *(result + n) = \text{std::move}(*(first + n)) \).

**Returns:** \( result + N \).

**Complexity:** Exactly \( N \) assignments.

template<class BidirectionalIterator1, class BidirectionalIterator2>
constexpr BidirectionalIterator2
move_backward(BidirectionalIterator1 first, BidirectionalIterator1 last,
BidirectionalIterator2 result);

template<BidirectionalIterator I1, Sentinel<I1> S1, BidirectionalIterator I2>
requires IndirectlyMovable<I1, I2>
constexpr ranges::move_backward_result<I1, I2>
ranges::move_backward(I1 first, S1 last, I2 result);

template<BidirectionalRange R, BidirectionalIterator I>
requires IndirectlyMovable<iterator_t<R>, I>
constexpr ranges::move_backward_result<safe_iterator_t<R>, I>
ranges::move_backward(R&& r, I result);

Let \( E \) be

\((11.1)\) \( \text{std::move(*(last - n))} \) for the overload in namespace std, or

\((11.2)\) \( \text{ranges::iter_move(last - n)} \) for the overloads in namespace ranges.

Let \( N \) be \( last - first \).

**Requires:** \( result \) shall not be in the range \([first, last)\).

**Effects:** Moves elements in the range \([first, last)\) into the range \([result - N, result)\) starting from \( last - 1 \) and proceeding to \( first \). For each positive integer \( n \leq N \), performs \( *(result - n) = E \).

**Returns:**

\((14.1)\) \( result - N \) for the overload in namespace std, or

\(^{236}\) **move_backward** should be used instead of **move** when \( last \) is in the range \([result - N, result)\).
25.6.3 Swap

Let:

1. last2 be first2 + (last1 - first1) for the overloads with no parameter named last2, and
2. \( M \) be \( \min(last1 - first1, last2 - first2) \).

Requires: The two ranges \([first1, last1)\) and \([first2, last2)\) shall not overlap. For the overloads in namespace \( \text{std} \), \(*(first1 + n)\) shall be swappable with \((16.5.3.2) \)*\((first2 + n)\).

Effects: For each non-negative integer \( n < M \) performs:

1. swap\((*(first1 + n), *(first2 + n))\) for the overloads in namespace \( \text{std} \), or
2. ranges::iter_swap\((first1 + n, first2 + n)\) for the overloads in namespace \( \text{ranges} \).

Returns:

1. last2 for the overloads in namespace \( \text{std} \), or
2. \{"first1 + M, first2 + M\} for the overloads in namespace \( \text{ranges} \).

Complexity: Exactly \( M \) swaps.

25.6.4 Transform

Requires: \( a \) and \( b \) shall be dereferenceable. \(*a\) shall be swappable with \((16.5.3.2) \)*\(b\).

Effects: As if by \( \text{swap}(*a, *b)\).
template<class InputIterator1, class InputIterator2,  
  class OutputIterator, class BinaryOperation>
constexpr OutputIterator  
transform(InputIterator1 first1, InputIterator1 last1,  
  InputIterator2 first2, OutputIterator result,  
  BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,  
  class ForwardIterator, class BinaryOperation>
ForwardIterator  
transform(ExecutionPolicy&& exec,  
  ForwardIterator1 first1, ForwardIterator1 last1,  
  ForwardIterator2 first2, ForwardIterator result,  
  BinaryOperation binary_op);

template<InputIterator I, Sentinel<I> S, WeaklyIncrementable O,  
CopyConstructible F, class Proj = identity>
requires Writable<O, indirect_result_t<F&>, projected<I, Proj>>
constexpr ranges::unary_transform_result<I, O>  
ranges::transform(I first1, S last1, O result, F op, Proj proj = {});

template<InputRange R, WeaklyIncrementable O, CopyConstructible F,  
class Proj = identity>
requires Writable<O, indirect_result_t<F&>, projected<iterator_t<R>, Proj>>
constexpr ranges::unary_transform_result<safe_iterator_t<R>, O>  
ranges::transform(R&& r, O result, F op, Proj proj = {});

template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,  
WeaklyIncrementable O, CopyConstructible F, class Proj1 = identity,  
class Proj2 = identity>
requires Writable<O, indirect_result_t<F&>, projected<I1, Proj1>,  
projected<I2, Proj2>>
constexpr ranges::binary_transform_result<I1, I2, O>  
ranges::transform(I1 first1, S1 last1, I2 first2, S2 last2, O result,  
  F binary_op, Proj1 proj1 = {}, Proj2 proj2 = {});

Requires: op and binary_op shall not invalidate iterators or subranges, nor modify elements in the ranges

Let:

1
  (1.1) last2 be first2 + (last1 - first1) for the overloads with parameter first2 but no parameter last2,
(1.2) N be last1 - first1 for unary transforms, or min(last1 - first1, last2 - first2) for binary transforms, and
(1.3) E be
  (1.3.1) op(*(first1 + (i - result))) for unary transforms defined in namespace std,
  (1.3.2) binary_op(*(first1 + (i - result)), *(first2 + (i - result))) for binary transforms defined in namespace std,
  (1.3.3) invoke(op, invoke(proj, *(first1 + (i - result)))) for unary transforms defined in namespace ranges, or
  (1.3.4) invoke(binary_op, invoke(proj1, *(first1 + (i - result))), invoke(proj2,  
               *(first2 + (i - result)))) for binary transforms defined in namespace ranges.

2

§ 25.6.4 1041
Effects: Assigns through every iterator \(i\) in the range \([\text{result}, \text{result} + N]\) a new corresponding value equal to \(E\).

Returns:

\(\text{result} + N\) for the overloads defined in namespace std,

\(\{\text{first1} + N, \text{result} + N\}\) for unary transforms defined in namespace ranges, or

\(\{\text{first1} + N, \text{first2} + N, \text{result} + N\}\) for binary transforms defined in namespace ranges.

Complexity: Exactly \(N\) applications of \(\text{op}\) or \(\text{binary\_op}\), and any projections. This requirement also applies to the overload with an \(\text{ExecutionPolicy}\).

Remarks: \(\text{result}\) may be equal to \(\text{first1}\) or \(\text{first2}\).

25.6.5 Replace

```cpp
template<class ForwardIterator, class T>
constexpr void replace(ForwardIterator first, ForwardIterator last, const T& old_value, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator, class T>
void replace(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, const T& old_value, const T& new_value);

template<class ForwardIterator, class Predicate, class T>
constexpr void replace_if(ForwardIterator first, ForwardIterator last, Predicate pred, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator, class Predicate, class T>
void replace_if(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred, const T& new_value);

template<InputIterator I, Sentinel<I> S, class T1, class T2, class Proj = identity>
requires Writable<I, const T2&> && IndirectRelation<ranges::equal_to, projected<I, Proj>, const T1*> 
constexpr I ranges::replace(I first, S last, const T1& old_value, const T2& new_value, Proj proj = {});

template<InputRange R, class T1, class T2, class Proj = identity>
requires Writable<iterator_t<R>, const T2&> && IndirectRelation<ranges::equal_to, projected<iterator_t<R>, Proj>, const T1*> 
constexpr safe_iterator_t<R> ranges::replace(R&& r, const T1& old_value, const T2& new_value, Proj proj = {});

template<InputIterator I, Sentinel<I> S, class T, class Proj = identity, IndirectUnaryPredicate<projected<I, Proj>> Pred>
requires Writable<I, const T&> 
constexpr I ranges::replace_if(I first, S last, Pred pred, const T& new_value, Proj proj = {});

template<InputRange R, class T, class Proj = identity, IndirectUnaryPredicate<projected<iterator_t<R>, Proj>> Pred>
requires Writable<iterator_t<R>, const T&> 
constexpr safe_iterator_t<R> ranges::replace_if(R&& r, Pred pred, const T& new_value, Proj proj = {});
```

Let \(E\) be

1. \(\text{bool}\left(*i == \text{old\_value}\right)\) for replace,
2. \(\text{bool}\left(\text{pred}\left(*i\right)\right)\) for replace_if,
3. \(\text{bool}\left(\text{invoke}\left(\text{proj}, *i\right) == \text{old\_value}\right)\) for ranges::replace, or
4. \(\text{bool}\left(\text{invoke}\left(\text{proj}, \text{invoke}\left(\text{proj}, *i\right)\right)\right)\) for ranges::replace_if.

\(^{237}\) The use of fully closed ranges is intentional.
2 \textit{Requires:} The expression \texttt{*first = new\_value} shall be valid.

3 \textit{Effects:} Substitutes elements referred by the iterator \texttt{i} in the range \texttt{[first, last)} with \texttt{new\_value}, when \texttt{E} is true.

4 \textit{Returns:} \texttt{last} for the overloads in namespace \texttt{ranges}.

5 \textit{Complexity:} Exactly \texttt{last - first} applications of the corresponding predicate and any projection.

6 Let \texttt{E} be

\begin{align}
&\quad \texttt{bool(*\texttt{first + (i - result)} == old\_value)} \text{ for replace\_copy}, \\
&\quad \texttt{bool(pred(*\texttt{first + (i - result)}))} \text{ for replace\_copy\_if},
\end{align}

§ 25.6.5
(6.3) \[ \text{bool}(\text{invoke}(\text{proj}, *(\text{first} + (i - \text{result})))) \equiv \text{old_value} \] for \text{ranges}::\text{replace}_\text{copy},

(6.4) \[ \text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, *(\text{first} + (i - \text{result})))))) \] for \text{ranges}::\text{replace}_\text{copy}_\text{if}.

Requires: The results of the expressions \*\text{first} and new\_value shall be writable (23.3.1) to the result output iterator. The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) shall not overlap.

Effects: Assigns to every iterator \(i\) in the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\) either new\_value or \(*(\text{first} + (i - \text{result}))\) depending on whether \(E\) holds.

Returns:

(9.1) \(\text{result} + (\text{last} - \text{first})\) for the overloads in namespace \text{std}, or

(9.2) \(\{\text{last}, \text{result} + (\text{last} - \text{first})\}\) for the overloads in namespace \text{ranges}.

Complexity: Exactly \(\text{last} - \text{first}\) applications of the corresponding predicate and any projection.

25.6.6 Fill

[alg.fill]

```cpp
template<class ForwardIterator, class T>
constexpr void fill(ForwardIterator first, ForwardIterator last, const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>
void fill(ExecutionPolicy&& exec,
          ForwardIterator first, ForwardIterator last, const T& value);

template<class OutputIterator, class Size, class T>
constexpr OutputIterator fill_n(OutputIterator first, Size n, const T& value);

template<class ExecutionPolicy, class ForwardIterator, class Size, class T>
ForwardIterator fill_n(ExecutionPolicy&& exec,
                       ForwardIterator first, Size n, const T& value);

template<class T, OutputIterator<const T&> O, Sentinel<O> S>
constexpr O ranges::fill(O first, S last, const T& value);

template<class T, OutputRange<const T&> R>
constexpr safe_iterator_t<R> ranges::fill(R&& r, const T& value);
```

Let \(N\) be \(\max(0, n)\) for the \text{fill}_\text{n} algorithms, and \(\text{last} - \text{first}\) for the fill algorithms.

Requires: The expression \(\text{value}\) shall be writable (23.3.1) to the output iterator. The type \(\text{Size}\) shall be convertible to an integral type (7.3.8, 11.3.7).

Effects: Assigns \(\text{value}\) through all the iterators in the range \([\text{first}, \text{first} + N)\).

Returns: \(\text{first} + N\).

Complexity: Exactly \(N\) assignments.

25.6.7 Generate

[alg.generate]

```cpp
template<class ForwardIterator, class Generator>
constexpr void generate(ForwardIterator first, ForwardIterator last, Generator gen);

template<class ExecutionPolicy, class ForwardIterator, class Generator>
void generate(ExecutionPolicy&& exec,
              ForwardIterator first, ForwardIterator last, Generator gen);
```

```cpp
template<class OutputIterator, class Size, class Generator>
constexpr OutputIterator generate_n(OutputIterator first, Size n, Generator gen);

template<class ExecutionPolicy, class ForwardIterator, class Size, class Generator>
ForwardIterator generate_n(ExecutionPolicy&& exec,
                            ForwardIterator first, Size n, Generator gen);
```
template<Iterator O, Sentinel<O> S, CopyConstructible F>
requires Invocable<F&> && Writable<O, invoke_result_t<F&>>
constexpr O ranges::generate(O first, S last, F gen);

template<class R, CopyConstructible F>
requires Invocable<F&> && OutputRange<R, invoke_result_t<F&>>
constexpr safe_iterator_t<R> ranges::generate(R&& r, F gen);

template<Iterator O, CopyConstructible F>
requires Invocable<F&> && Writable<O, invoke_result_t<F&>>
constexpr O ranges::generate_n(O first, iter_difference_t<O> n, F gen);

Let \( N \) be \( \max(0, n) \) for the \texttt{generate_n} algorithms, and \( \text{last} - \text{first} \) for the \texttt{generate} algorithms.

Releases: Size shall be convertible to an integral type (7.3.8, 11.3.7).

Effects: Assigns the result of successive evaluations of \texttt{gen()} through each iterator in the range [\texttt{first}, first + \( N \)].

Returns: \texttt{first + N}.

Complexity: Exactly \( N \) evaluations of \texttt{gen()} and assignments.

### 25.6.8 Remove

[alg.remove]

```cpp
template<class ForwardIterator, class T>
constexpr ForwardIterator remove(ForwardIterator first, ForwardIterator last, const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>
ForwardIterator remove(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, const T& value);

template<class ForwardIterator, class Predicate>
constexpr ForwardIterator remove_if(ForwardIterator first, ForwardIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator remove_if(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);
```

Let \( E \) be

\begin{align}
1 & \quad \text{bool}(i == \text{value}) \quad \text{for remove}, \\
2 & \quad \text{bool}(
\text{pred}(i)) \quad \text{for remove_if}, \\
3 & \quad \text{bool}(\text{invoke}(\text{proj}, i) == \text{value}) \quad \text{for ranges::remove, or} \\
4 & \quad \text{bool}(\text{invoke}(
\text{pred, invoke}(
\text{proj}, i))) \quad \text{for ranges::remove_if}.
\end{align}

Releases: For the algorithms in namespace \texttt{std}, the type of \*\texttt{first} shall meet the \texttt{Cpp17MoveAssignable} requirements (Table 28).
Eliminates all the elements referred to by iterator i in the range [first, last) for which E holds.

Returns: The end of the resulting range.

Remarks: Stable (16.5.5.7).

Complexity: Exactly last - first applications of the corresponding predicate and any projection.

[Note: Each element in the range [ret, last) has a valid but unspecified state, because the algorithms can eliminate elements by moving from elements that were originally in that range. — end note]

```
template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
remove_copy(InputIterator first, InputIterator last,
            OutputIterator result, const T& value);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class T>
ForwardIterator2
remove_copy(ExecutionPolicy&& exec,
            ForwardIterator1 first, ForwardIterator1 last,
            ForwardIterator2 result, const T& value);

template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator
remove_copy_if(InputIterator first, InputIterator last,
                OutputIterator result, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class Predicate>
ForwardIterator2
remove_copy_if(ExecutionPolicy&& exec,
               ForwardIterator1 first, ForwardIterator1 last,
               ForwardIterator2 result, Predicate pred);

template<InputIterator I, Sentinel<I> S, WeaklyIncrementable O, class T,
          class Proj = identity>
requires IndirectlyCopyable<I, O> &&
        IndirectRelation<ranges::equal_to, projected<I, Proj>, const T*>>
constexpr ranges::remove_copy_result<I, O>
ranges::remove_copy(I first, S last, O result, const T& value, Proj proj = {});

template<InputRange R, WeaklyIncrementable O, class T, class Proj = identity>
requires IndirectlyCopyable<iterator_t<R>, O> &&
        IndirectRelation<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>>
constexpr ranges::remove_copy_result<safe_iterator_t<R>, O>
ranges::remove_copy(R&& r, O result, const T& value, Proj proj = {});

template<InputIterator I, Sentinel<I> S, WeaklyIncrementable O,
          class Proj = identity, IndirectUnaryPredicate<projected<I>, Proj>> Pred>
requires IndirectlyCopyable<I, O>
constexpr ranges::remove_copy_if_result<I, O>
ranges::remove_copy_if(I first, S last, O result, Pred pred, Proj proj = {});

template<InputRange R, WeaklyIncrementable O, class Proj = identity,
          IndirectUnaryPredicate<projected<iterator_t<R>>, Proj>> Pred>
requires IndirectlyCopyable<iterator_t<R>, O>
constexpr ranges::remove_copy_if_result<safe_iterator_t<R>, O>
ranges::remove_copy_if(R&& r, O result, Pred pred, Proj proj = {});
```

Let E be

(8.1) \( \text{bool(*i == value)} \) for remove_copy,
(8.2) \( \text{bool(pred(*i))} \) for remove_copy_if,
(8.3) \( \text{bool(invoke(proj, *i) == value)} \) for ranges::remove_copy, or
(8.4) \( \text{bool(invoke(pred, invoke(proj, *i)))} \) for ranges::remove_copy_if.

Let \( N \) be the number of elements in [first, last) for which \( E \) is false.
Requires: The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) shall not overlap. The expression \(*\text{result} = *\text{first}\) shall be valid. \(\textbf{[Note:}\) For the overloads with an ExecutionPolicy, there may be a performance cost if \text{iterator_traits<ForwardIterator1>::value_type} does not meet the \text{Cpp17MoveConstructible} (Table 26) requirements. \textbf{— end note]\)

Effects: Copies all the elements referred to by the iterator \(i\) in the range \([\text{first}, \text{last})\) for which \(E\) is false.

Returns:

\(\text{(12.1)}\)

\(- \text{ result} + N\), for the algorithms in namespace \text{std}, or

\(\text{(12.2)}\)

\(- \{\text{last}, \text{result} + N\}\), for the algorithms in namespace \text{ranges}.

Complexity: Exactly \(\text{last} - \text{first}\) applications of the corresponding predicate and any projection.

Remarks: Stable (16.5.5.7).

25.6.9 Unique

\[\textbf{[alg.unique]}\]

\text{template\langle class ForwardIterator\rangle\}
\text{constexpr ForwardIterator unique(ForwardIterator first, ForwardIterator last);}\n
\text{template\langle class ExecutionPolicy, class ForwardIterator\rangle\}
\text{ForwardIterator unique(ExecutionPolicy\&\& exec,}

Let pred be equal_to{} for the overloads in namespace std with no parameter pred, and let E be

(6.1) — bool(pred(*i, *(i - 1))) for the overloads in namespace std, or

(6.2) — bool(invoke(comp, invoke(proj, *i), invoke(proj, *(i - 1)))) for the overloads in namespace ranges.

Requires:

7 — The ranges [first, last) and [result, result+(last-first)) shall not overlap.

7.2 — For the overloads in namespace std:

7.2.1 — The comparison function shall be an equivalence relation.

7.2.2 — The expression *result = *first shall be valid.

7.2.3 — For the overloads with no ExecutionPolicy, let T be the value type of InputIterator. If InputIterator meets the Cpp17ForwardIterator requirements, then there are no additional requirements for T. Otherwise, if OutputIterator meets the Cpp17ForwardIterator requirements and its value type is the same as T, then T shall meet the Cpp17CopyAssignable (Table 29) requirements. Otherwise, T shall meet both the Cpp17CopyConstructible (Table 27) and Cpp17CopyAssignable requirements. [Note: For the overloads with an ExecutionPolicy, there may be a performance cost if the value type of ForwardIterator1 does not meet both the Cpp17CopyConstructible and Cpp17CopyAssignable requirements. — end note]

Effects: Copies only the first element from every consecutive group of equal elements referred to by the iterator i in the range [first, last) for which E holds.

Returns:

9.1 — result + N for the overloads in namespace std, or

9.2 — {last, result + N} for the overloads in namespace ranges

Complexity: Exactly last - first - 1 applications of the corresponding predicate and no more than twice as many applications of any projection.

25.6.10 Reverse [alg.reverse]
constexpr void reverse(BidirectionalIterator first, BidirectionalIterator last);

template<class ExecutionPolicy, class BidirectionalIterator>
void reverse(ExecutionPolicy&& exec,
             BidirectionalIterator first, BidirectionalIterator last);

template<BidirectionalIterator I, Sentinel<I> S>
requires Permutable<I>
constexpr I ranges::reverse(I first, S last);

template<BidirectionalRange R>
requires Permutable<iterator_t<R>>
constexpr safe_iterator_t<R> ranges::reverse(R&& r);

1
Requires: For the overloads in namespace std, BidirectionalIterator shall meet the Cpp17Value-
Swappable requirements (16.5.3.2).

2
Effects: For each non-negative integer \(i < (last - first) / 2\), applies std::iter_swap, or ranges::
iter_swap for the overloads in namespace ranges, to all pairs of iterators \(first + i\), \((last - i) - 1\).

3
Returns: last for the overloads in namespace ranges.

4
Complexity: Exactly \((last - first)/2\) swaps.

template<class BidirectionalIterator, class OutputIterator>
constexpr OutputIterator
reverse_copy(BidirectionalIterator first, BidirectionalIterator last,
            OutputIterator result);

template<class ExecutionPolicy, class BidirectionalIterator, class ForwardIterator>
ForwardIterator
reverse_copy(ExecutionPolicy&& exec,
            BidirectionalIterator first, BidirectionalIterator last,
            ForwardIterator result);

template<BidirectionalIterator I, Sentinel<I> S, WeaklyIncrementable O>
requires IndirectlyCopyable<I, O>
constexpr ranges::reverse_copy_result<I, O>
ranges::reverse_copy(I first, S last, O result);

template<BidirectionalRange R, WeaklyIncrementable O>
requires IndirectlyCopyable<iterator_t<R>, O>
constexpr ranges::reverse_copy_result<safe_iterator_t<R>, O>
ranges::reverse_copy(R&& r, O result);

5
Let \(N\) be last - first.

6
Requires: The ranges \([first, last)\) and \([result, result + N)\) shall not overlap.

7
Effects: Copies the range \([first, last)\) to the range \([result, result + N)\) such that for every non-
negative integer \(i < N\) the following assignment takes place: 
\(\ast(result + N - 1 - i) = \ast(first + i)\).

8
Returns:

(8.1) — \(result + N\) for the overloads in namespace std, or

(8.2) — \{last, result + N\} for the overloads in namespace ranges.

9
Complexity: Exactly \(N\) assignments.

25.6.11 Rotate

template<class ForwardIterator>
constexpr ForwardIterator
rotate(ForwardIterator first, ForwardIterator middle, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
rotate(ExecutionPolicy&& exec,
       ForwardIterator first, ForwardIterator middle, ForwardIterator last);
template<Permutable I, Sentinel<I> S>
constexpr subrange<I> ranges::rotate(I first, I middle, S last);

1. **Requires:** \([first, middle)\) and \([middle, last)\) shall be valid ranges. For the overloads in namespace `std`, `ForwardIterator` shall meet the `Cpp17ValueSwappable` requirements (16.5.3.2), and the type of `*first` shall meet the `Cpp17MoveConstructible` (Table 26) and `Cpp17MoveAssignable` (Table 28) requirements.

2. **Effects:** For each non-negative integer \(i < (last - first)\), places the element from the position \(first + i\) into position \(first + (i + (last - middle)) \% (last - first)\). [Note: This is a left rotate. — end note]

3. **Returns:**
   - \((3.1)\) `first + (last - middle)` for the overloads in namespace `std`, or
   - \((3.2)\) `{first + (last - middle), last}` for the overload in namespace `ranges`.

4. **Complexity:** At most \(last - first\) swaps.

template<ForwardRange R>
requires Permutable<iterator_t<R>>
constexpr safe_subrange_t<R> ranges::rotate(R&& r, iterator_t<R> middle);

5. **Effects:** Equivalent to: `return ranges::rotate(ranges::begin(r), middle, ranges::end(r));`

template<class ForwardIterator, class OutputIterator>
constexpr OutputIterator
rotate_copy(ForwardIterator first, ForwardIterator middle, ForwardIterator last, OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
rotate_copy(ExecutionPolicy&& exec, ForwardIterator1 first, ForwardIterator1 middle, ForwardIterator1 last, ForwardIterator2 result);

template<ForwardIterator I, Sentinel<I> S, WeaklyIncrementable O>
requires IndirectlyCopyable<I, O>
constexpr ranges::rotate_copy_result<I, O>
ranges::rotate_copy(I first, I middle, S last, O result);

6. **Requires:** \([first, middle)\) and \([middle, last)\) shall be valid ranges. The ranges \([first, last)\) and \([result, result + N)\) shall not overlap.

7. **Effects:** Copies the range \([first, last)\) to the range \([result, result + N)\) such that for each non-negative integer \(i < N\) the following assignment takes place: \(*(result + i) = *(first + (i + (middle - first)) \% N)\).

8. **Returns:**
   - \((9.1)\) `result + N` for the overloads in namespace `std`, or
   - \((9.2)\) `{last, result + N}` for the overload in namespace `ranges`.

9. **Complexity:** Exactly \(N\) assignments.

10. **Effects:** Equivalent to:
    `return ranges::rotate_copy(ranges::begin(r), middle, ranges::end(r), result);`

25.6.12 Sample

```cpp
template<class PopulationIterator, class SampleIterator, class Distance, class UniformRandomBitGenerator>
SampleIterator sample(PopulationIterator first, PopulationIterator last,
```
SampleIterator out, Distance n, 
UniformRandomBitGenerator&& g);

1  Requires:
(1.1) — PopulationIterator shall meet the Cpp17InputIterator requirements (23.3.5.2).
(1.2) — SampleIterator shall meet the Cpp17OutputIterator requirements (23.3.5.3).
(1.3) — SampleIterator shall meet the Cpp17RandomAccessIterator requirements (23.3.5.6) unless PopulationIterator meets the Cpp17ForwardIterator requirements (23.3.5.4).
(1.4) — PopulationIterator’s value type shall be writable (23.3.1) to out.
(1.5) — Distance shall be an integer type.
(1.6) — remove_reference_t<UniformRandomBitGenerator> shall meet the requirements of a uniform random bit generator type (26.6.2.3).
(1.7) — out shall not be in the range [first, last).

2  Effects: Copies \( \min(last - first, n) \) elements (the sample) from [first, last) (the population) to out such that each possible sample has equal probability of appearance. \[Note: Algorithms that obtain such effects include selection sampling and reservoir sampling. — end note\]

3  Returns: The end of the resulting sample range.

4  Complexity: \( O(last - first) \).

5  Remarks:
(5.1) — Stable if and only if PopulationIterator meets the Cpp17ForwardIterator requirements.
(5.2) — To the extent that the implementation of this function makes use of random numbers, the object g shall serve as the implementation’s source of randomness.

25.6.13 Shuffle

[alg.random.shuffle]

\[
\text{template<class RandomAccessIterator, class UniformRandomBitGenerator>}
\text{void shuffle(RandomAccessIterator first,}
\text{ RandomAccessIterator last,}
\text{ UniformRandomBitGenerator&& g);} \\
\text{template<RandomAccessIterator I, Sentinel<I> S, class Gen>}
\text{requires Permutable<I> &&}
\text{ UniformRandomBitGenerator<remove_reference_t<Gen>>}
\text{I ranges::shuffle(I first, S last, Gen&& g);} \\
\text{template<RandomAccessRange R, class Gen>}
\text{requires Permutable<iterator_t<R>> &&}
\text{ UniformRandomBitGenerator<remove_reference_t<Gen>>}
\text{safe_iterator_t<R> ranges::shuffle(R&& r, Gen&& g);} \\
\]

1  Requires: For the overload in namespace std:
(1.1) — RandomAccessIterator shall meet the Cpp17ValueSwappable requirements (16.5.3.2).
(1.2) — The type remove_reference_t<UniformRandomBitGenerator> shall meet the uniform random bit generator (26.6.2.3) requirements.

2  Effects: Permutates the elements in the range [first, last) such that each possible permutation of those elements has equal probability of appearance.

3  Returns: last for the overloads in namespace ranges.

4  Complexity: Exactly \( (last - first) - 1 \) swaps.

5  Remarks: To the extent that the implementation of this function makes use of random numbers, the object referenced by g shall serve as the implementation’s source of randomness.

25.6.14 Shift

[alg.shift]

\[
\text{template<class ForwardIterator>}
\text{constexpr ForwardIterator}
\text{shift_left(ForwardIterator first, ForwardIterator last,}
\text{ typename iterator_traits<ForwardIterator>::difference_type n);} \\
\]

§ 25.6.14
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
shift_left(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
typename iterator_traits<ForwardIterator>::difference_type n);

1 Requires: The type of *first shall meet the Cpp17MoveAssignable requirements.
2 Effects: If n <= 0 or n >= last - first, does nothing. Otherwise, moves the element from position
first + n + i into position first + i for each non-negative integer i < (last - first) - n. In
the first overload case, does so in order starting from i = 0 and proceeding to i = (last - first) -
1.  
3 Returns: first + (last - first - n) if n is positive and n < last - first, otherwise first if n
is positive, otherwise last.
4 Complexity: At most (last - first) - n assignments.

template<class ForwardIterator>
constexpr ForwardIterator
shift_right(ForwardIterator first, ForwardIterator last,
typename iterator_traits<ForwardIterator>::difference_type n);

5 Requires: The type of *first shall meet the Cpp17MoveAssignable requirements. ForwardIterator
shall meet the Cpp17BidirectionalIterator requirements (23.3.5.5) or the Cpp17ValueSwappable require-
ments.
6 Effects: If n <= 0 or n >= last - first, does nothing. Otherwise, moves the element from position
first + i into position first + n + i for each non-negative integer i < (last - first) - n. In
the first overload case, if ForwardIterator meets the Cpp17BidirectionalIterator requirements, does
so in order starting from i = (last - first) - n - 1 and proceeding to i = 0.
7 Returns: first + n if n is positive and n < last - first, otherwise last if n is positive, otherwise
first.
8 Complexity: At most (last - first) - n assignments or swaps.

25.7 Sorting and related operations

1 The operations in 25.7 defined directly in namespace std have two versions: one that takes a function object
type Compare and one that uses an operator<.
2 Compare is a function object type (20.14) that meets the requirements for a template parameter named
BinaryPredicate (25.2). The return value of the function call operation applied to an object of type Compare,
when contextually converted to bool (7.3), yields true if the first argument of the call is less than the second,
and false otherwise. Compare comp is used throughout for algorithms assuming an ordering relation.
3 For all algorithms that take Compare, there is a version that uses operator< instead. That is, comp(*i, *j)
!= false defaults to *i < *j != false. For algorithms other than those described in 25.7.3, comp shall
induce a strict weak ordering on the values.
4 The term strict refers to the requirement of an irreflexive relation (!comp(x, x) for all x), and the term
weak to requirements that are not as strong as those for a total ordering, but stronger than those for a partial
ordering. If we define equiv(a, b) as !comp(a, b) && !comp(b, a), then the requirements are that comp
and equiv both be transitive relations:

- For all x, y, z, if comp(a, b) && comp(b, c) implies comp(a, c)  
- For all x, y, z, if equiv(a, b) && equiv(b, c) implies equiv(a, c)

[Note: Under these conditions, it can be shown that

- equiv is an equivalence relation,
- comp induces a well-defined relation on the equivalence classes determined by equiv, and
- the induced relation is a strict total ordering.

-end note]
A sequence is sorted with respect to a \texttt{comp} and \texttt{proj} for a comparator and projection \texttt{comp} and \texttt{proj} if for every iterator \texttt{i} pointing to the sequence and every non-negative integer \texttt{n} such that \texttt{i} + \texttt{n} is a valid iterator pointing to an element of the sequence,
\[ \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, *(\texttt{i} + \texttt{n})), \text{invoke}(\text{proj}, \texttt{i}))) \]
is false.

A sequence \texttt{[start, finish)} is partitioned with respect to an expression \texttt{f(e)} if there exists an integer \texttt{n} such that for all \texttt{0 \leq i < (finish - start)}, \texttt{f(*((start + i)))} is true if and only if \texttt{i < n}.

In the descriptions of the functions that deal with ordering relationships we frequently use a notion of equivalence to describe concepts such as stability. The equivalence to which we refer is not necessarily an \texttt{operator==}, but an equivalence relation induced by the strict weak ordering. That is, two elements \texttt{a} and \texttt{b} are considered equivalent if and only if !(\texttt{a < b}) \\&\& !(\texttt{b < a}).

### 25.7.1 Sorting

#### 25.7.1.1 sort

```cpp
template<class RandomAccessIterator>
constexpr void sort(RandomAccessIterator first, RandomAccessIterator last);
template<class ExecutionPolicy, class RandomAccessIterator>
void sort(ExecutionPolicy&& exec,
RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
constexpr void sort(RandomAccessIterator first, RandomAccessIterator last,
Compare comp);
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void sort(ExecutionPolicy&& exec,
RandomAccessIterator first, RandomAccessIterator last,
Compare comp);
```

```cpp
template<RandomAccessIterator I, Sentinel<I> S, class Comp = ranges::less,
class Proj = identity>
requires Sortable<I, Comp, Proj>
constexpr I
ranges::sort(I first, S last, Comp comp = {}, Proj proj = {});
```

```cpp
template<RandomAccessRange R, class Comp = ranges::less, class Proj = identity>
requires Sortable<iterator_t<R>, Comp, Proj>
constexpr safe_iterator_t<R>
ranges::sort(R&& r, Comp comp = {}, Proj proj = {});
```

1. Let \texttt{comp} be \texttt{less{}} and \texttt{proj} be \texttt{identity{}} for the overloads with no parameters by those names.
2. \textbf{Requires:} For the overloads in namespace \texttt{std}, \texttt{RandomAccessIterator} shall meet the \texttt{Cpp17Value-Swappable} requirements (16.5.3.2) and the type of \texttt{*first} shall meet the \texttt{Cpp17MoveConstructible} (Table 26) and \texttt{Cpp17MoveAssignable} (Table 28) requirements.
3. \textbf{Effects:} Sorts the elements in the range \texttt{[first, last)} with respect to \texttt{comp} and \texttt{proj}.
4. \textbf{Returns:} \texttt{last}, for the overloads in namespace \texttt{ranges}.
5. \textbf{Complexity:} Let \texttt{N} be \texttt{last - first}. $O(N \log N)$ comparisons and projections.

#### 25.7.1.2 stable_sort

```cpp
template<class RandomAccessIterator>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last);
template<class ExecutionPolicy, class RandomAccessIterator>
void stable_sort(ExecutionPolicy&& exec,
RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last,
Compare comp);
```

\section*{§ 25.7.1.2}
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void stable_sort(ExecutionPolicy&& exec,
    RandomAccessIterator first, RandomAccessIterator last,
    Compare comp);

template<RandomAccessIterator I, Sentinel<I> S, class Comp = ranges::less,
    class Proj = identity>
I ranges::stable_sort(I first, S last, Comp comp = {}, Proj proj = {});

template<RandomAccessRange R, class Comp = ranges::less, class Proj = identity>
safe_iterator_t<R>
ranges::stable_sort(R&& r, Comp comp = {}, Proj proj = {});

1 Let \( \text{comp} \) be \text{less}\{} and \( \text{proj} \) be \text{identity}\{} for the overloads with no parameters by those names.

2 Requires: For the overloads in namespace \text{std}, \text{RandomAccessIterator} shall meet the \text{Cpp17ValueSwappable} requirements (16.5.3.2) and the type of \*first shall meet the \text{Cpp17MoveConstructible} (Table 26) and \text{Cpp17MoveAssignable} (Table 28) requirements.

Effects: Sorts the elements in the range \([\text{first}, \text{last})\) with respect to \text{comp} and \text{proj}.

Returns: \text{last} for the overloads in namespace \text{ranges}.

Complexity: Let \( N \) be \text{last} - \text{first}. If enough extra memory is available, \( N \log(N) \) comparisons. Otherwise, at most \( N \log_2(N) \) comparisons. In either case, twice as many projections as the number of comparisons.

Remarks: Stable (16.5.5.7).

### 25.7.1.3 partial_sort

template<class RandomAccessIterator>
constexpr void partial_sort(RandomAccessIterator first,
    RandomAccessIterator middle,
    RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void partial_sort(ExecutionPolicy&& exec,
    RandomAccessIterator first,
    RandomAccessIterator middle,
    RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void partial_sort(RandomAccessIterator first,
    RandomAccessIterator middle,
    RandomAccessIterator last,
    Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void partial_sort(ExecutionPolicy&& exec,
    RandomAccessIterator first,
    RandomAccessIterator middle,
    RandomAccessIterator last,
    Compare comp);

template<RandomAccessIterator I, Sentinel<I> S, class Comp = ranges::less,
    class Proj = identity>
constexpr I
ranges::partial_sort(I first, I middle, S last, Comp comp = {}, Proj proj = {});

1 Let \( \text{comp} \) be \text{less}\{} and \( \text{proj} \) be \text{identity}\{} for the overloads with no parameters by those names.

2 Requires: \([\text{first}, \text{middle})\) and \([\text{middle}, \text{last})\) shall be valid ranges. For the overloads in namespace \text{std}, \text{RandomAccessIterator} shall meet the \text{Cpp17ValueSwappable} requirements (16.5.3.2) and the type of \*first shall meet the \text{Cpp17MoveConstructible} (Table 26) and \text{Cpp17MoveAssignable} (Table 28) requirements.
Effects: Places the first middle - first elements from the range [first, last) as sorted with respect to comp and proj into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

Returns: last for the overload in namespace ranges.

Complexity: Approximately (last - first) * log(middle - first) comparisons, and twice as many projections.

template<RandomAccessRange R, class Comp = ranges::less, class Proj = identity>
requires Sortable<iterator_t<R>, Comp, Proj>
constexpr safe_iterator_t<R>
ranges::partial_sort(R&& r, iterator_t<R> middle, Comp comp = {}, Proj proj = {});

Effects: Equivalent to:

return ranges::partial_sort(ranges::begin(r), middle, ranges::end(r), comp, proj);

25.7.1.4 partial_sort_copy

template<class InputIterator, class RandomAccessIterator>
constexpr RandomAccessIterator
partial_sort_copy(InputIterator first, InputIterator last,
RandomAccessIterator result_first,
RandomAccessIterator result_last);

template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator>
RandomAccessIterator
partial_sort_copy(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
RandomAccessIterator result_first,
RandomAccessIterator result_last);

template<class InputIterator, class RandomAccessIterator,
class Compare>
constexpr RandomAccessIterator
partial_sort_copy(InputIterator first, InputIterator last,
RandomAccessIterator result_first,
RandomAccessIterator result_last,
Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator,
class Compare>
RandomAccessIterator
partial_sort_copy(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
RandomAccessIterator result_first,
RandomAccessIterator result_last,
Compare comp);

template<InputIterator I1, Sentinel<I1> S1, RandomAccessIterator I2, Sentinel<I2> S2,
class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires IndirectlyCopyable<I1, I2> && Sortable<I2>, Comp, Proj2> &&
IndirectStrictWeakOrder<Comp, projected<I1, Proj1>, projected<I2, Proj2>>
constexpr I2
ranges::partial_sort_copy(I1 first, S1 last, I2 result_first, S2 result_last,
Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<InputRange R1, RandomAccessRange R2, class Comp = ranges::less,
class Proj1 = identity, class Proj2 = identity>
requires IndirectlyCopyable<iterator_t<R1>, iterator_t<R2>>, & Sortable<iterator_t<R2>, Comp, Proj2> &&
IndirectStrictWeakOrder<Comp, projected<iterator_t<R1>, Proj1>,
projected<iterator_t<R2>, Proj2>>
constexpr safe_iterator_t<R2>
ranges::partial_sort_copy(R1&& r, R2&& result_r, Comp comp = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

Let N be min(last - first, result_last - result_first). Let comp be less{}, and proj1 and proj2 be identity{} for the overloads with no parameters by those names.
Requires: For the overloads in namespace std, RandomAccessIterator shall meet the Cpp17ValueSwappable requirements (16.5.3.2), the type of *result_first shall meet the Cpp17MoveConstructible (Table 26) and Cpp17MoveAssignable (Table 28) requirements, and the expression *first shall be writable (23.3.1) to result_first.

Expects: For iterators a1 and b1 in [first, last), and iterators x2 and y2 in [result_first, result_last), after evaluating the assignment *y2 = *b1, let E be the value of

```cpp
bool:invoke(comp, invoke(proj1, *a1), invoke(proj2, *y2));
```

Then, after evaluating the assignment *x2 = *a1, E is equal to

```cpp
bool:invoke(comp, invoke(proj2, *x2), invoke(proj2, *y2));
```

[Note: Writing a value from the input range into the output range does not affect how it is ordered by comp and proj1 or proj2. — end note]

Effects: Places the first N elements as sorted with respect to comp and proj2 into the range [result_first, result_first + N).

Returns: result_first + N.

Complexity: Approximately (last - first) * log N comparisons, and twice as many projections.

25.7.1.5 is_sorted

```cpp
template<class ForwardIterator>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last);
```

Effects: Equivalent to:

```cpp
return is_sorted_until(first, last) == last;
```

```cpp
template<class ExecutionPolicy, class ForwardIterator>
bool is_sorted(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);
```

Effects: Equivalent to:

```cpp
return is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last) == last;
```

```cpp
template<class ForwardIterator, class Compare>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last,
Compare comp);
```

Effects: Equivalent to:

```cpp
return is_sorted_until(first, last, comp) == last;
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Compare>
bool is_sorted(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Compare comp);
```

Effects: Equivalent to:

```cpp
return is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last;
```

```cpp
template<ForwardIterator I, Sentinel<I> S, class Proj = identity,
IndirectStrictWeakOrder<projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::is_sorted(I first, S last, Comp comp = {}, Proj proj = {});
```

```cpp
template<ForwardRange R, class Proj = identity,
IndirectStrictWeakOrder<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr bool ranges::is_sorted(R&& r, Comp comp = {}, Proj proj = {});
```

Effects: Equivalent to:

```cpp
return ranges::is_sorted_until(first, last, comp, proj) == last;
```

```cpp
template<class ForwardIterator>
constexpr ForwardIterator
is_sorted_until(ForwardIterator first, ForwardIterator last);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
is_sorted_until(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);
```
template<class ForwardIterator, class Compare>
constexpr ForwardIterator
    is_sorted_until(ForwardIterator first, ForwardIterator last,
                   Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator
    is_sorted_until(ExecutionPolicy&& exec,
                    ForwardIterator first, ForwardIterator last,
                    Compare comp);

template<ForwardIterator I, Sentinel<I> S, class Proj = identity,
          IndirectStrictWeakOrder<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::is_sorted_until(I first, S last, Comp comp = {}, Proj proj = {});

template<ForwardRange R, class Proj = identity,
          IndirectStrictWeakOrder<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr safe_iterator_t<R>
    ranges::is_sorted_until(R&& r, Comp comp = {}, Proj proj = {});

Let \( \text{comp} \) be \text{less}{} and \( \text{proj} \) be \text{identity}{} for the overloads with no parameters by those names.

Returns: The last iterator \( i \) in \([\text{first}, \text{last}]\) for which the range \([\text{first}, i)\)
is sorted with respect to \( \text{comp} \) and \( \text{proj} \).

Complexity: Linear.

25.7.2 Nth element

[alg.nth.element]

template<class RandomAccessIterator>
constexpr void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
                           RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void nth_element(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator nth,
                 RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
                           RandomAccessIterator last, Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void nth_element(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator nth,
                 RandomAccessIterator last, Compare comp);

template<RandomAccessIterator I, Sentinel<I> S, class Comp = ranges::less,
         class Proj = identity>
requires Sortable<I, S, Comp> = ranges::less,
class Proj = identity
constexpr I
    ranges::nth_element(I first, I nth, S last, Comp comp = {}, Proj proj = {});

Let \( \text{comp} \) be \text{less}{} and \( \text{proj} \) be \text{identity}{} for the overloads with no parameters by those names.

Requires: \([\text{first}, \text{nth})\) and \([\text{nth}, \text{last})\) shall be valid ranges. For the overloads in namespace \text{std},
\text{RandomAccessIterator} shall meet the Cpp17ValueSwappable requirements (16.5.3.2), and the type of \( \text{first} \) shall meet the Cpp17MoveConstructible (Table 26) and Cpp17MoveAssignable (Table 28) requirements.

Effects: After \text{nth_element} the element in the position pointed to by \text{nth} is the element that would be
in that position if the whole range were sorted with respect to \( \text{comp} \) and \( \text{proj} \), unless \text{nth} == \text{last}.
Also for every iterator \( i \) in the range \([\text{first}, \text{nth})\) and every iterator \( j \) in the range \([\text{nth}, \text{last})\) it
holds that: \( \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, *j), \text{invoke}(\text{proj}, *i))) \) is \text{false}.

Returns: last for the overload in namespace ranges.

Complexity: For the overloads with no \text{ExecutionPolicy}, linear on average. For the overloads with an \text{ExecutionPolicy}, \( O(N) \) applications of the predicate, and \( O(N \log N) \) swaps, where \( N = \text{last} - \text{first} \).
template<RandomAccessRange R, class Comp = ranges::less, class Proj = identity>
requires Sortable<iterator_t<R>, Comp, Proj>
constexpr safe_iterator_t<R>
ranges::nth_element(R&& r, iterator_t<R> nth, Comp comp = {}, Proj proj = {});

Effects: Equivalent to:
return ranges::nth_element(ranges::begin(r), nth, ranges::end(r), comp, proj);

25.7.3 Binary search

All of the algorithms in this subclause are versions of binary search and assume that the sequence being searched is partitioned with respect to an expression formed by binding the search key to an argument of the comparison function. They work on non-random access iterators minimizing the number of comparisons, which will be logarithmic for all types of iterators. They are especially appropriate for random access iterators, because these algorithms do a logarithmic number of steps through the data structure. For non-random access iterators they execute a linear number of steps.

25.7.3.1 lower_bound

template<class ForwardIterator, class T>
constexpr ForwardIterator
lower_bound(ForwardIterator first, ForwardIterator last, const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr ForwardIterator
lower_bound(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);

template<ForwardIterator I, Sentinel<I> S, class T, class Proj = identity, IndirectStrictWeakOrder<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::lower_bound(I first, S last, const T& value, Comp comp = {}, Proj proj = {});

template<ForwardRange R, class T, class Proj = identity, IndirectStrictWeakOrder<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr safe_iterator_t<R>
ranges::lower_bound(R&& r, const T& value, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for overloads with no parameters by those names.

Requires: The elements e of [first, last) shall be partitioned with respect to the expression
bool:invoke(comp, invoke(proj, e), value)).

Returns: The furthermost iterator i in the range [first, last) such that for every iterator j in the range [first, i), bool:invoke(comp, invoke(proj, *j), value)) is true.

Complexity: At most $\log_2(last - first) + O(1)$ comparisons and projections.

25.7.3.2 upper_bound

template<class ForwardIterator, class T>
constexpr ForwardIterator
upper_bound(ForwardIterator first, ForwardIterator last, const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr ForwardIterator
upper_bound(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);

template<ForwardIterator I, Sentinel<I> S, class T, class Proj = identity, IndirectStrictWeakOrder<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::upper_bound(I first, S last, const T& value, Comp comp = {}, Proj proj = {});
template<ForwardRange R, class T, class Proj = identity,
        IndirectStrictWeakOrder<const T*, projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr safe_iterator_t<R>
    ranges::upper_bound(R&& r, const T& value, Comp comp = {}, Proj proj = {});

1. Let `comp` be `less{}` and `proj` be `identity{}` for overloads with no parameters by those names.

2. **Requires:** The elements `e` of `[first, last)` shall be partitioned with respect to the expression

   `!bool(invoke(comp, value, invoke(proj, e)))`.

3. **Returns:** The furthermore iterator `i` in the range `[first, last)` such that for every iterator `j` in the

   range `[first, i)`, `!bool(invoke(comp, value, invoke(proj, *j)))` is true.

4. **Complexity:** At most $\log_2(last - first) + \Theta(1)$ comparisons and projections.

### 25.7.3.3 equal_range

```cpp
template<class ForwardIterator, class T>
constexpr pair<ForwardIterator, ForwardIterator>
equal_range(ForwardIterator first, ForwardIterator last, const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr pair<ForwardIterator, ForwardIterator>
equal_range(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);
```

```cpp
template<ForwardIterator I, Sentinel<I> S, class T, class Proj = identity,
        IndirectStrictWeakOrder<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr subrange<I>
ranges::equal_range(I first, S last, const T& value, Comp comp = {}, Proj proj = {});
```

1. Let `comp` be `less{}` and `proj` be `identity{}` for overloads with no parameters by those names.

2. **Requires:** The elements `e` of `[first, last)` shall be partitioned with respect to the expressions

   `bool(invoke(comp, invoke(proj, e), value))` and `!bool(invoke(comp, value, invoke(proj, e)))`. Also, for all elements `e` of `[first, last)`, `bool(comp(e, value))` shall imply `!bool(comp(value, e))` for the overloads in namespace `std`.

3. **Returns:**

   (3.1) For the overloads in namespace `std`:

   `{lower_bound(first, last, value, comp),
    upper_bound(first, last, value, comp)}`

   (3.2) For the overloads in namespace `ranges`:

   `{ranges::lower_bound(first, last, value, comp, proj),
    ranges::upper_bound(first, last, value, comp, proj)}`

4. **Complexity:** At most $2 \times \log_2(last - first) + \Theta(1)$ comparisons and projections.

### 25.7.3.4 binary_search

```cpp
template<class ForwardIterator, class T>
constexpr bool
binary_search(ForwardIterator first, ForwardIterator last, const T& value);
```

```cpp
template<class ForwardIterator, class T, class Compare>
constexpr bool
binary_search(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);
```
template<ForwardIterator I, Sentinel<I> S, class T, class Proj = identity,
         IndirectStrictWeakOrder<const T*, projected<I>, Proj>>
constexpr bool ranges::binary_search(I first, S last, const T& value, Comp comp = {},
         Proj proj = {});

template<ForwardRange R, class T, class Proj = identity,
         IndirectStrictWeakOrder<const T*, projected<iterator_t<R>>, Proj>>
constexpr bool ranges::binary_search(R&& r, const T& value, Comp comp = {},
         Proj proj = {});

Let comp be less{} and proj be identity{} for overloads with no parameters by those names.

Requires: The elements e of [first, last) shall be partitioned with respect to the expressions
bool(involve(comp, involve(proj, e), value)) and !bool(involve(comp, value, involve(proj,
         e))). Also, for all elements e of [first, last), bool(comp(e, value)) shall imply !bool(comp( value,
         e)) for the overloads in namespace std.

Returns: true if and only if for some iterator i in the range [first, last), !bool(involve(comp,
         involve(proj, *i), value)) && !bool(involve(comp, value, involve(proj, *i))) is true.

Complexity: At most \(\log_2(\text{last} - \text{first}) + \Theta(1)\) comparisons and projections.

---

25.7.4 Partitions

template<class InputIterator, class Predicate>
constexpr bool is_partitioned(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool is_partitioned(ExecutionPolicy&& exec,
         ForwardIterator first, ForwardIterator last, Predicate pred);

template<InputIterator I, Sentinel<I> S, class Proj = identity,
         IndirectUnaryPredicate<projected<I>, Proj>>
constexpr bool ranges::is_partitioned(I first, S last, Pred pred, Proj proj = {});

template<InputRange R, class Proj = identity,
         IndirectUnaryPredicate<projected<iterator_t<R>>, Proj>>
constexpr bool ranges::is_partitioned(R&& r, Pred pred, Proj proj = {});

Let proj be identity{} for the overloads with no parameter named proj.

Returns: true if and only if the elements e of [first, last) are partitioned with respect to the expression
bool(involve(pred, involve(proj, e))).

Complexity: Linear. At most last - first applications of pred and proj.

---

template<class ForwardIterator, class Predicate>
constexpr ForwardIterator partition(ForwardIterator first, ForwardIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator partition(ExecutionPolicy&& exec,
         ForwardIterator first, ForwardIterator last, Predicate pred);

template<Permutable I, Sentinel<I> S, class Proj = identity,
         IndirectUnaryPredicate<projected<I>, Proj>>
constexpr I
ranges::partition(I first, S last, Pred pred, Proj proj = {});

template<ForwardRange R, class Proj = identity,
         IndirectUnaryPredicate<projected<iterator_t<R>>, Proj>>
requires Permutable<iterator_t<R>>
constexpr safe_iterator_t<R>
ranges::partition(R&& r, Pred pred, Proj proj = {});

Let proj be identity{} for the overloads with no parameter named proj and let \(E(x)\) be bool(involve( pred,
         involve(proj, x))).

Requires: For the overloads in namespace std, ForwardIterator shall meet the Cpp17ValueSwappable
requirements (16.5.3.2).
Effects: Places all the elements \(e\) in \([\text{first}, \text{last})\) that satisfy \(E(e)\) before all the elements that do not.

Returns: An iterator \(i\) such that \(E(*j\) is true for every iterator \(j\) in \([\text{first}, i)\) and false for every iterator \(j\) in \([i, \text{last})\).

Complexity: Let \(N = \text{last} - \text{first}:

(8.1) — For the overload with no ExecutionPolicy, exactly \(N\) applications of the predicate and projection. At most \(N/2\) swaps if the type of \(\text{first}\) meets the Cpp17BidirectionalIterator requirements for the overloads in namespace std or models BidirectionalIterator for the overloads in namespace ranges, and at most \(N\) swaps otherwise.

(8.2) — For the overload with an ExecutionPolicy, \(O(N \log N)\) swaps and \(O(N)\) applications of the predicate.

```cpp
template<class BidirectionalIterator, class Predicate>
BidirectionalIterator
stable_partition(BidirectionalIterator first, BidirectionalIterator last, Predicate pred);

template<class ExecutionPolicy, class BidirectionalIterator, class Predicate>
BidirectionalIterator
stable_partition(ExecutionPolicy&& exec,
                BidirectionalIterator first, BidirectionalIterator last, Predicate pred);
```

Let \(proj\) be \text{identity}{} for the overloads with no parameter named \(proj\) and let \(E(x)\) be \text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, x))).

Requires: For the overloads in namespace std, BidirectionalIterator shall meet the Cpp17Value-Swappable requirements (16.5.3.2) and the type of \(*\text{first}\) shall meet the Cpp17MoveConstructible (Table 26) and Cpp17MoveAssignable (Table 28) requirements.

Effects: Places all the elements \(e\) in \([\text{first}, \text{last})\) that satisfy \(E(e)\) before all the elements that do not. The relative order of the elements in both groups is preserved.

Returns: An iterator \(i\) such that for every iterator \(j\) in \([\text{first}, i)\), \(E(*j)\) is true, and for every iterator \(j\) in the range \([i, \text{last})\), \(E(*j)\) is false.

Complexity: Let \(N = \text{last} - \text{first}:

(12.1) — For the overloads with no ExecutionPolicy, at most \(N \log N\) swaps, but only \(O(N)\) swaps if there is enough extra memory. Exactly \(N\) applications of the predicate and projection.

(12.2) — For the overload with an ExecutionPolicy, \(O(N \log N)\) swaps and \(O(N)\) applications of the predicate.

```cpp
template<class InputIterator, class OutputIterator1, class OutputIterator2, class Predicate>
constexpr pair<OutputIterator1, OutputIterator2>
partition_copy(InputIterator first, InputIterator last,
                OutputIterator1 out_true, OutputIterator2 out_false, Predicate pred);
```

§ 25.7.4 1061
template<InputIterator I, Sentinel<I> S, WeaklyIncrementable O1, WeaklyIncrementable O2, class Proj = identity, IndirectUnaryPredicate<Projected<I, Proj>> Pred>
  requires IndirectlyCopyable<I, O1> && IndirectlyCopyable<I, O2>
  constexpr ranges::partition_copy_result<I, O1, O2>
  ranges::partition_copy(I first, S last, O1 out_true, O2 out_false, Pred pred, Proj proj = {});

template<InputRange R, WeaklyIncrementable O1, WeaklyIncrementable O2, class Proj = identity, IndirectUnaryPredicate<Projected<iterator_t<R>, Proj>> Pred>
  requires IndirectlyCopyable<iterator_t<R>, O1> && IndirectlyCopyable<iterator_t<R>, O2>
  constexpr ranges::partition_copy_result<safe_iterator_t<R>, O1, O2>
  ranges::partition_copy(R&& r, O1 out_true, O2 out_false, Pred pred, Proj proj = {});

Let proj be identity{} for the overloads with no parameter named proj and let $E(x) = \text{bool}(\text{invoke(pred, invoke(proj, x)))}$.

Requires: The input range and output ranges shall not overlap. For the overloads in namespace std, the expression $*\text{first}$ shall be writable (23.3.1) to out_true and out_false. [Note: For the overload with an ExecutionPolicy, there may be a performance cost if first’s value type does not meet the Cpp17CopyConstructible requirements. — end note]

Effects: For each iterator $i$ in $[\text{first}, \text{last})$, copies $i$ to the output range beginning with out_true if $E(i)$ is true, or to the output range beginning with out_false otherwise.

Returns: Let o1 be the end of the output range beginning at out_true, and o2 the end of the output range beginning at out_false. Returns

- $\{\text{o1, o2}\}$ for the overloads in namespace std, or
- $\{\text{last, o1, o2}\}$ for the overloads in namespace ranges.

Complexity: Exactly last - first applications of pred and proj.

template<class ForwardIterator, class Predicate> constexpr ForwardIterator partition_point(ForwardIterator first, ForwardIterator last, Predicate pred);

template<ForwardIterator I, Sentinel<I> S, class Proj = identity, IndirectUnaryPredicate<Projected<I, Proj>> Pred>
  constexpr I ranges::partition_point(I first, S last, Pred pred, Proj proj = {});

template<ForwardRange R, class Proj = identity, IndirectUnaryPredicate<Projected<iterator_t<R>, Proj>> Pred>
  constexpr safe_iterator_t<R> ranges::partition_point(R&& r, Pred pred, Proj proj = {});

Let proj be identity{} for the overloads with no parameter named proj and let $E(x) = \text{bool}(\text{invoke(pred, invoke(proj, x)))}$.

Requires: The elements $e$ of $[\text{first}, \text{last})$ shall be partitioned with respect to $E(e)$.

Returns: An iterator mid such that $E(*i)$ is true for all iterators $i$ in $[\text{first, mid})$, and false for all iterators $i$ in $[\text{mid, last})$.

Complexity: $\Theta(\log(\text{last} - \text{first}))$ applications of pred and proj.

25.7.5 Merge

template<class InputIterator1, class InputIterator2, class OutputIterator>
  constexpr OutputIterator merge(InputIterator1 first1, InputIterator1 last1,
  InputIterator2 first2, InputIterator2 last2, OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator>
  ForwardIterator merge(ExecutionPolicy&& exec,
  ForwardIterator1 first1, ForwardIterator1 last1,
Let \( N \) be \((last1 - first1) + (last2 - first2)\). Let \( comp \) be \{\}, \( proj1 \) be \{\}, and \( proj2 \) be \{\}, for the overloads with no parameters by those names.

**Requires:** The ranges \([first1, last1)\) and \([first2, last2)\) shall be sorted with respect to \( comp \) and \( proj1 \) or \( proj2 \), respectively. The resulting range shall not overlap with either of the original ranges.

**Effects:** Copies all the elements of the two ranges \([first1, last1)\) and \([first2, last2)\) into the range \([result, result_last)\), where \( result_last \) is \( result + N \). If an element \( a \) precedes \( b \) in an input range, \( a \) is copied into the output range before \( b \). If \( e1 \) is an element of \([first1, last1)\) and \( e2 \) of \([first2, last2)\), \( e2 \) is copied into the output range before \( e1 \) if and only if \( bool(invoke(comp, invoke(proj2, e2), invoke(proj1, e1))) \) is true.

**Returns:**

- \( result_last \) for the overloads in namespace \( std \), or

- \( \{last1, last2, result_last\} \) for the overloads in namespace \( ranges \).

**Complexity:**

- For the overloads with no \( ExecutionPolicy \), at most \( N - 1 \) comparisons and applications of each projection.

- For the overloads with an \( ExecutionPolicy \), \( O(N) \) comparisons.

**Remarks:** Stable (16.5.5.7).
template<class BidirectionalIterator, class Compare>
void inplace_merge(BidirectionalIterator first,
                   BidirectionalIterator middle,
                   BidirectionalIterator last, Compare comp);

template<class ExecutionPolicy, class BidirectionalIterator, class Compare>
void inplace_merge(ExecutionPolicy&& exec,
                   BidirectionalIterator first,
                   BidirectionalIterator middle,
                   BidirectionalIterator last, Compare comp);

template<BidirectionalIterator I, Sentinel<I> S, class Comp = ranges::less,
         class Proj = identity>
requires Sortable<I, Comp, Proj>
I ranges::inplace_merge(I first, I middle, S last, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

Requires: [first, middle) and [middle, last) shall be valid ranges sorted with respect to comp and proj. For the overloads in namespace std, BidirectionalIterator shall meet the Cpp17Value-Swappable requirements (16.5.3.2) and the type of *first shall meet the Cpp17MoveConstructible (Table 26) and Cpp17MoveAssignable (Table 28) requirements.

Effects: Merges two sorted consecutive ranges [first, middle) and [middle, last), putting the result of the merge into the range [first, last). The resulting range is sorted with respect to comp and proj.

Returns: last for the overload in namespace ranges.

Complexity: Let N = last - first:
(11.1) For the overloads with no ExecutionPolicy, and if enough additional memory is available, exactly N - 1 comparisons.
(11.2) Otherwise, \( \mathcal{O}(N \log N) \) comparisons.
In either case, twice as many projections as comparisons.

Remarks: Stable (16.5.5.7).

template<BidirectionalRange R, class Comp = ranges::less, class Proj = identity>
requires Sortable<iterator_t<R>, Comp, Proj>
safe_iterator_t<R>
ranges::inplace_merge(R&& r, iterator_t<R> middle, Comp comp = {}, Proj proj = {});

Effects: Equivalent to:
return ranges::inplace_merge(ranges::begin(r), middle, ranges::end(r), comp, proj);

25.7.6 Set operations on sorted structures

This subclause defines all the basic set operations on sorted structures. They also work with multisets (22.4.7) containing multiple copies of equivalent elements. The semantics of the set operations are generalized to multisets in a standard way by defining set_union to contain the maximum number of occurrences of every element, set_intersection to contain the minimum, and so on.

25.7.6.1 includes

template<class InputIterator1, class InputIterator2>
constexpr bool includes(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool includes(ExecutionPolicy&& exec,
              ForwardIterator1 first1, ForwardIterator1 last1,
              ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2, class Compare>
constexpr bool includes(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2,
                        Compare comp);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare>
bool includes(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
Compare comp);

template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
class Proj1 = identity, class Proj2 = identity,
IndirectStrictWeakOrder<projected<I1, Proj1>,
projected<I2, Proj2>> Comp = ranges::less>
constexpr bool ranges::includes(I1 first1, S1 last1, I2 first2, S2 last2, Comp comp = {}),
Proj1 proj1 = {}, Proj2 proj2 = {});

template<InputRange R1, InputRange R2, class Proj1 = identity,
class Proj2 = identity,
IndirectStrictWeakOrder<projected<iterator_t<R1>, Proj1>,
projected<iterator_t<R2>, Proj2>> Comp = ranges::less>
constexpr bool ranges::includes(R1&& r1, R2&& r2, Comp comp = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

1. Let \( \text{comp} \) be \( \text{less}\{\} \), \( \text{proj1} \) be \( \text{identity}\{\} \), and \( \text{proj2} \) be \( \text{identity}\{\} \), for the overloads with no parameters by those names.

2. \textbf{Requires:} The ranges \([\text{first1, last1})\) and \([\text{first2, last2})\) shall be sorted with respect to \( \text{comp} \) and \( \text{proj1} \) or \( \text{proj2} \), respectively.

3. \textbf{Returns:} true if and only if \([\text{first2, last2})\) is a subsequence of \([\text{first1, last1})\). [Note: A sequence \( S \) is a subsequence of another sequence \( T \) if \( S \) can be obtained from \( T \) by removing some, all, or none of \( T \)'s elements and keeping the remaining elements in the same order. — end note]

4. \textbf{Complexity:} At most \( 2 \ast ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1 \) comparisons and applications of each projection.

25.7.6.2 \textbf{set_union} \[\text{set.union}\]

template<class InputIterator1, class InputIterator2,
class OutputIterator>
constexpr OutputIterator
set_union(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator>
ForwardIterator
set_union(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result);

template<class InputIterator1, class InputIterator2,
class OutputIterator, class Compare>
constexpr OutputIterator
set_union(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator, class Compare>
ForwardIterator
set_union(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result, Compare comp);

template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
WeaklyIncrementable O, class Comp = ranges::less,
class Proj1 = identity, class Proj2 = identity>
requires Mergeable<I1, I2, O, Comp, Proj1, Proj2>
Let `comp` be `less{}` and `proj1` and `proj2` be `identity{}` for the overloads with no parameters by those names.

Requires: The ranges `[first1, last1)` and `[first2, last2)` shall be sorted with respect to `comp` and `proj1` or `proj2`, respectively. The resulting range shall not overlap with either of the original ranges.

Effects: Constructs a sorted union of the elements from the two ranges; that is, the set of elements that are present in one or both of the ranges.

Returns: Let `result_last` be the end of the constructed range. Returns

1. `result_last` for the overloads in namespace `std`, or
2. `{last1, last2, result_last}` for the overloads in namespace `ranges`.

Complexity: At most `2 * ((last1 - first1) + (last2 - first2)) - 1` comparisons and applications of each projection.

Remarks: Stable (16.5.5.7). If `[first1, last1)` contains `m` elements that are equivalent to each other and `[first2, last2)` contains `n` elements that are equivalent to them, then all `m` elements from the first range are copied to the output range, in order, and then the final `max(n - m, 0)` elements from the second range are copied to the output range, in order.

§ 25.7.6.3  set_intersection
template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
    WeaklyIncrementable O, class Comp = ranges::less,
    class Proj1 = identity, class Proj2 = identity>
requires Mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_intersection_result<I1, I2, O>
ranges::set_intersection(I1 first1, S1 last1, I2 first2, S2 last2, O result,
    Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<InputRange R1, InputRange R2, WeaklyIncrementable O,
    class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires Mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_intersection_result<safe_iterator_t<R1>, safe_iterator_t<R2>, O>
ranges::set_intersection(R1&& r1, R2&& r2, O result,
    Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

Let comp be less{}, and proj1 and proj2 be identity{} for the overloads with no parameters by
those names.

Requires: The ranges [first1, last1) and [first2, last2) shall be sorted with respect to comp
and proj1 or proj2, respectively. The resulting range shall not overlap with either of the original
ranges.

Effects: Constructs a sorted intersection of the elements from the two ranges; that is, the set of elements
that are present in both of the ranges.

Returns: Let result_last be the end of the constructed range. Returns

(4.1) — result_last for the overloads in namespace std, or
(4.2) — {last1, last2, result_last} for the overloads in namespace ranges.

Complexity: At most 2 * ((last1 - first1) + (last2 - first2)) - 1 comparisons and applica-
tions of each projection.

Remarks: Stable (16.5.5.7). If [first1, last1) contains m elements that are equivalent to each other
and [first2, last2) contains n elements that are equivalent to them, the first min(m, n) elements
are copied from the first range to the output range, in order.

25.7.6.4 set_difference

template<class InputIterator1, class InputIterator2,
    class OutputIterator>
constexpr OutputIterator
set_difference(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, InputIterator2 last2,
    OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
    class ForwardIterator>
ForwardIterator
set_difference(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2,
    ForwardIterator result);

template<class InputIterator1, class InputIterator2,
    class OutputIterator, class Compare>
constexpr OutputIterator
set_difference(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, InputIterator2 last2,
    OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
    class ForwardIterator, class Compare>
ForwardIterator
set_difference(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2,
    ForwardIterator result, Compare comp);
template<
  InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
  WeaklyIncrementable O,
  class Comp = ranges::less,
  class Proj1 = identity, class Proj2 = identity>
requires Mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_difference_result<I1, O>
ranges::set_difference(I1 first1, S1 last1, I2 first2, S2 last2, O result,
  Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<InputRange R1, InputRange R2, WeaklyIncrementable O,
  class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires Mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_difference_result<safe_iterator_t<R1>, O>
ranges::set_difference(R1&& r1, R2&& r2, O result,
  Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

1. Let \( \text{comp} \) be \( \text{less}\{\} \), and \( \text{proj1} \) and \( \text{proj2} \) be \( \text{identity}\{\} \) for the overloads with no parameters by those names.

2. Requires: The ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) shall be sorted with respect to \( \text{comp} \) and \( \text{proj1} \) or \( \text{proj2} \), respectively. The resulting range shall not overlap with either of the original ranges.

3. Effects: Copies the elements of the range \([\text{first1}, \text{last1})\) which are not present in the range \([\text{first2}, \text{last2})\) to the range beginning at \( \text{result} \). The elements in the constructed range are sorted.

4. Returns: Let \( \text{result}_\text{last} \) be the end of the constructed range. Returns

\[
\begin{align*}
&- \text{result}_\text{last} \quad \text{for the overloads in namespace std, or} \\
&- \{\text{last1}, \text{result}_\text{last}\} \quad \text{for the overloads in namespace ranges.}
\end{align*}
\]

5. Complexity: At most \( 2 \ast ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1 \) comparisons and applications of each projection.

6. Remarks: If \([\text{first1}, \text{last1})\) contains \( m \) elements that are equivalent to each other and \([\text{first2}, \text{last2})\) contains \( n \) elements that are equivalent to them, the last \( \max(m - n, 0) \) elements from \([\text{first1}, \text{last1})\) is copied to the output range, in order.
template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2,
      WeaklyIncrementable O, class Comp = ranges::less,
      class Proj1 = identity, class Proj2 = identity>
requires Mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_symmetric_difference_result<I1, I2, O>
ranges::set_symmetric_difference(I1 first1, S1 last1, I2 first2, S2 last2, O result,
                                 Comp comp = {}, Proj1 proj1 = {},
                                 Proj2 proj2 = {});

template<InputRange R1, InputRange R2, WeaklyIncrementable O,
          class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires Mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_symmetric_difference_result<safe_iterator_t<R1>, safe_iterator_t<R2>, O>
ranges::set_symmetric_difference(R1&& r1, R2&& r2, O result, Comp comp = {},
                                  Proj1 proj1 = {}, Proj2 proj2 = {});

Let comp be less{}, and proj1 and proj2 be identity{} for the overloads with no parameters by those names.

Requirements: The resulting range shall not overlap with either of the original ranges. The ranges [first1, last1) and [first2, last2) shall be sorted with respect to comp and proj1 or proj2, respectively. The resulting range shall not overlap with either of the original ranges.

Effects: Copies the elements of the range [first1, last1) that are not present in the range [first2, last2), and the elements of the range [first2, last2) that are not present in the range [first1, last1) to the range beginning at result. The elements in the constructed range are sorted.

Returns: Let result_last be the end of the constructed range. Returns

- result_last for the overloads in namespace std, or
- {last1, last2, result_last} for the overloads in namespace ranges.

Complexity: At most 2 * ((last1 - first1) + (last2 - first2)) - 1 comparisons and applications of each projection.

Remarks: Stable (16.5.5.7). If [first1, last1) contains m elements that are equivalent to each other and [first2, last2) contains n elements that are equivalent to them, then |m - n| of those elements shall be copied to the output range: the last m - n of these elements from [first1, last1) if m > n, and the last n - m of these elements from [first2, last2) if m < n. In either case, the elements are copied in order.

25.7.7 Heap operations

A random access range [a, b) is a heap with respect to comp and proj for a comparator and projection comp and proj if its elements are organized such that:

1. With N = b - a, for all i, 0 < i < N, bool(invoke(comp, invoke(proj, a[⌊(i-1)/2⌋])), invoke(proj, a[i]))) is false.
2. *a may be removed by pop_heap, or a new element added by push_heap, in $O(\log N)$ time.

These properties make heaps useful as priority queues.

25.7.7.1 push_heap

template<class RandomAccessIterator>
constexpr void push_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void push_heap(RandomAccessIterator first, RandomAccessIterator last,
                         Compare comp);

template<RandomAccessIterator I, Sentinel<I> S, class Comp = ranges::less,
          class Proj = identity>
requires Sortable<I, Comp, Proj>
constexpr I
ranges::push_heap(I first, S last, Comp comp = {}, Proj proj = {});
template<typename RandomAccessRange R, typename class Comp = ranges::less, typename class Proj = identity>
requires Sortable<iterator_t<R>, Comp, Proj>
constexpr safe_iterator_t<R>
ranges::push_heap(R&& r, Comp comp = {}, Proj proj = {});

1. Let comp be `less{}` and proj be `identity{}` for the overloads with no parameters by those names.
2. Requires: The range `[first, last - 1)` shall be a valid heap with respect to comp and proj. For the overloads in namespace std, the type of `*first` shall meet the Cpp17MoveConstructible requirements (Table 26) and the Cpp17MoveAssignable requirements (Table 28).
3. Effects: Places the value in the location `last - 1` into the resulting heap `[first, last)`.
4. Returns: last for the overloads in namespace ranges.
5. Complexity: At most `log(last - first)` comparisons and twice as many projections.

25.7.7.2 pop_heap

```cpp
template<typename RandomAccessIterator>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<typename RandomAccessIterator, typename class Compare>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

```cpp
template<typename RandomAccessIterator I, typename Sentinel<I> S, typename class Comp = ranges::less, typename class Proj = identity>
requires Sortable<I, Comp, Proj>
constexpr I
ranges::pop_heap(I first, S last, Comp comp = {}, Proj proj = {});
```

1. Let comp be `less{}` and proj be `identity{}` for the overloads with no parameters by those names.
2. Requires: The range `[first, last)` shall be a valid non-empty heap with respect to comp and proj. For the overloads in namespace std, `RandomAccessIterator` shall meet the Cpp17ValueSwappable requirements (16.5.3.2) and the type of `*first` shall meet the Cpp17MoveConstructible (Table 26) and Cpp17MoveAssignable (Table 28) requirements.
3. Effects: Swaps the value in the location `first` with the value in the location `last - 1` and makes `[first, last - 1)` into a heap with respect to comp and proj.
4. Returns: last for the overloads in namespace ranges.
5. Complexity: At most `2 log(last - first)` comparisons and twice as many projections.

25.7.7.3 make_heap

```cpp
template<typename RandomAccessIterator>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<typename RandomAccessIterator, typename class Compare>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

```cpp
template<typename RandomAccessIterator I, typename Sentinel<I> S, typename class Comp = ranges::less, typename class Proj = identity>
requires Sortable<I, Comp, Proj>
constexpr I
ranges::make_heap(I first, S last, Comp comp = {}, Proj proj = {});
```

1. Let comp be `less{}` and proj be `identity{}` for the overloads with no parameters by those names.
2 Requires: For the overloads in namespace std, the type of *first shall meet the Cpp17MoveConstructible (Table 26) and Cpp17MoveAssignable (Table 28) requirements.

3 Effects: Constructs a heap with respect to comp and proj out of the range [first, last).

4 Returns: last for the overloads in namespace ranges.

5 Complexity: At most 3(last - first) comparisons and twice as many projections.

### 25.7.7.4 sort_heap

```cpp
template<class RandomAccessIterator>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

```cpp
template<RandomAccessIterator I, Sentinel<I> S, class Comp = ranges::less, class Proj = identity>
requires Sortable<I, Comp, Proj>
constexpr I
ranges::sort_heap(I first, S last, Comp comp = {}, Proj proj = {});
```

```cpp
template<RandomAccessRange R, class Comp = ranges::less, class Proj = identity>
requires Sortable<iterator_t<R>, Comp, Proj>
constexpr safe_iterator_t<R>
ranges::sort_heap(R&& r, Comp comp = {}, Proj proj = {});
```

1 Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

2 Requires: The range [first, last) shall be a valid heap with respect to comp and proj. For the overloads in namespace std, RandomAccessIterator shall meet the Cpp17ValueSwappable requirements (16.5.3.2) and the type of *first shall meet the Cpp17MoveConstructible (Table 26) and Cpp17MoveAssignable (Table 28) requirements.

3 Effects: Sorts elements in the heap [first, last) with respect to comp and proj.

4 Returns: last for the overloads in namespace ranges.

5 Complexity: At most 2N log N comparisons, where N = last - first, and twice as many projections.

### 25.7.7.5 is_heap

```cpp
template<class RandomAccessIterator>
constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last);
```

1 Effects: Equivalent to: return is_heap_until(first, last) == last;

```cpp
template<class ExecutionPolicy, class RandomAccessIterator>
bool is_heap(ExecutionPolicy&& exec, RandomAccessIterator first, RandomAccessIterator last);
```

2 Effects: Equivalent to:

```cpp
return is_heap_until(std::forward<ExecutionPolicy>(exec), first, last) == last;
```

```cpp
template<class RandomAccessIterator, class Compare>
constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

3 Effects: Equivalent to: return is_heap_until(first, last, comp) == last;

```cpp
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
bool is_heap(ExecutionPolicy&& exec, RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

4 Effects: Equivalent to:

```cpp
return is_heap_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last;
```
template<RandomAccessIterator I, Sentinel<I> S, class Proj = identity,
    IndirectStrictWeakOrder<projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::is_heap(I first, S last, Comp comp = {}, Proj proj = {});

template<RandomAccessRange R, class Proj = identity,
    IndirectStrictWeakOrder<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr bool ranges::is_heap(R&& r, Comp comp = {}, Proj proj = {});

Effects: Equivalent to: return ranges::is_heap_until(first, last, comp, proj) == last;

template<class RandomAccessIterator>
constexpr RandomAccessIterator
is_heap_until(RandomAccessIterator first, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
RandomAccessIterator
is_heap_until(ExecutionPolicy&& exec,
    RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr RandomAccessIterator
is_heap_until(RandomAccessIterator first, RandomAccessIterator last,
    Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
RandomAccessIterator
is_heap_until(ExecutionPolicy&& exec,
    RandomAccessIterator first, RandomAccessIterator last,
    Compare comp);

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

Returns: The last iterator i in [first, last] for which the range [first, i) is a heap with respect to comp and proj.

Complexity: Linear.

25.7.8 Minimum and maximum

template<class T>
constexpr const T& min(const T& a, const T& b);

template<class T, class Compare>
constexpr const T& min(const T& a, const T& b, Compare comp);

Note: That the first form, type T shall be Cpp17LessThanComparable (Table 24).

Returns: The smaller value.

Remarks: Returns the first argument when the arguments are equivalent. An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

Complexity: Exactly one comparison and two applications of the projection, if any.
template<Copyable T, class Proj = identity, 
    IndirectStrictWeakOrder<projected<const T*, Proj>> Comp = ranges::less>
constexpr T ranges::min(initializer_list<T> r, Comp comp = {}, Proj proj = {});

template<InputRange R, class Proj = identity, 
    IndirectStrictWeakOrder<projected<iterator_t<R>, Proj>> Comp = ranges::less>
requires IndirectCopyableStorable<iterator_t<R>, Proj>>
constexpr iterator_t<R> ranges::min(R&& r, Comp comp = {}, Proj proj = {});

Requires: ranges::distance(r) > 0. For the overloads in namespace std, T shall be Cpp17CopyConstructible. For the first form, type T shall be Cpp17LessThanComparable.

Returns: The smallest value in the input range.

Remarks: Returns a copy of the leftmost element when several elements are equivalent to the smallest. An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

Complexity: Exactly ranges::distance(r) - 1 comparisons and twice as many applications of the projection, if any.

template<class T>
constexpr const T& max(const T& a, const T& b);

template<class T, class Compare>
constexpr const T& max(const T& a, const T& b, Compare comp);

template<class T, class Proj = identity, 
    IndirectStrictWeakOrder<projected<const T*, Proj>> Comp = ranges::less>
constexpr const T& ranges::max(const T& a, const T& b, Comp comp = {}, Proj proj = {});

Requires: For the first form, type T shall be Cpp17LessThanComparable (Table 24).

Returns: The larger value.

Remarks: Returns the first argument when the arguments are equivalent. An invocation may explicitly specify an argument for the template parameter T of the overloads in namespace std.

Complexity: Exactly one comparison and two applications of the projection, if any.

template<class T>
constexpr pair<const T&, const T&> minmax(const T& a, const T& b);

template<class T, class Compare>
constexpr pair<const T&, const T&> minmax(const T& a, const T& b, Compare comp);

§ 25.7.8 1073
template<class T, class Proj = identity,\n    IndirectStrictWeakOrder<projected<const T*, Proj>> Comp = ranges::less>\nconstexpr ranges::minmax_result<const T&>\nranges::minmax(const T& a, const T& b, Comp comp = {}, Proj proj = {});\n\nRequires: For the first form, type T shall be Cpp17LessThanComparable (Table 24).\nReturns: {b, a} if b is smaller than a, and {a, b} otherwise.\nRemarks: An invocation may explicitly specify an argument for the template parameter T of the\noverloads in namespace std.\nComplexity: Exactly one comparison and two applications of the projection, if any.

template<class T>\nconstexpr pair<T, T> minmax(initializer_list<T> t);

template<class T, class Compare>\nconstexpr pair<T, T> minmax(initializer_list<T> t, Compare comp);

template<Copyable T, class Proj = identity,\n    IndirectStrictWeakOrder<projected<const T*, Proj>> Comp = ranges::less>\nconstexpr ranges::minmax_result<initializer_list<T>>\nranges::minmax(initializer_list<T> r, Comp comp = {}, Proj proj = {});

ranges::maxmin_element(R&& r, Comp comp = {}, Proj proj = {});
\end{verbatim}

31 \textit{Returns:} \{first, first\} if \([\textit{first}, \textit{last})\) is empty, otherwise \{m, M\}, where \textit{m} is the first iterator in \([\textit{first}, \textit{last})\) such that no iterator in the range refers to a smaller element, and where \textit{M} is the last iterator\footnote{1075} in \([\textit{first}, \textit{last})\) such that no iterator in the range refers to a larger element.

\footnote{1075} This behavior intentionally differs from \textit{max_element}. 

\section{25.7.8}
32  \textbf{Complexity:} Let $N$ be last - first. At most $\max(\left\lfloor \frac{3}{2}(N - 1) \right\rfloor, 0)$ comparisons and twice as many applications of the projection, if any.

25.7.9 \textbf{Bounded value} \hfill [alg.clamp]

\texttt{template<class } T \texttt{>
    constexpr const } T \texttt{& clamp(const } T \texttt{& v, const } T \texttt{& lo, const } T \texttt{& hi);}  
\texttt{template<class } T, \texttt{class Compare>
    constexpr const } T \texttt{& clamp(const } T \texttt{& v, const } T \texttt{& lo, const } T \texttt{& hi, Compare comp);}

\textbf{Requires:} The value of } lo \textbf{ shall be no greater than hi. For the first form, type } T \textbf{ shall be } \texttt{Cpp17LessThanComparable} (Table 24).

\textbf{Returns:} lo if } v \textbf{ is less than } lo, hi if hi is less than } v, otherwise } v.

[Note: If NaN is avoided, } T \textbf{ can be a floating-point type. — end note]

\textbf{Complexity:} At most two comparisons.

25.7.10 \textbf{Lexicographical comparison} \hfill [alg.lex.comparison]

\texttt{template<class InputIterator1, class InputIterator2>
    constexpr bool lexicographical_compare(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2);}  
\texttt{template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
    bool lexicographical_compare(ExecutionPolicy&& exec, }
\texttt{ForwardIterator1 first1, Forward Iterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2);}  
\texttt{template<class InputIterator1, class InputIterator2, class Compare>
    constexpr bool lexicographical_compare(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, Compare comp);}  
\texttt{template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare>
    bool lexicographical_compare(ExecutionPolicy&& exec, }
\texttt{ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, Compare comp);}  
\texttt{template<InputIterator I1, Sentinel<I1> S1, InputIterator I2, Sentinel<I2> S2, class Proj1 = identity, class Proj2 = identity, IndirectStrictWeakOrder<projected<I1, Proj1>, projected<I2, Proj2>> Comp = ranges::less>
    constexpr bool ranges::lexicographical_compare(I1 first1, S1 last1, I2 first2, S2 last2, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});}  
\texttt{template<InputRange R1, InputRange R2, class Proj1 = identity, class Proj2 = identity, IndirectStrictWeakOrder<projected<iterator_t<R1>, Proj1>, projected<iterator_t<R2>, Proj2>> Comp = ranges::less>
    constexpr bool ranges::lexicographical_compare(R1&& r1, R2&& r2, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});}

\textbf{Returns:} true if and only if the sequence of elements defined by the range [first1, last1) is lexicographically less than the sequence of elements defined by the range [first2, last2).

\textbf{Complexity:} At most $2 \min(last1 - first1, last2 - first2)$ applications of the corresponding comparison and each projection, if any.

\textbf{Remarks:} If two sequences have the same number of elements and their corresponding elements (if any) are equivalent, then neither sequence is lexicographically less than the other. If one sequence is a
proper prefix of the other, then the shorter sequence is lexicographically less than the longer sequence. Otherwise, the lexicographical comparison of the sequences yields the same result as the comparison of the first corresponding pair of elements that are not equivalent.

[Example: ranges::lexicographical_compare(I1, S1, I2, S2, Comp, Proj1, Proj2) could be implemented as:

```cpp
for ( ; first1 != last1 && first2 != last2 ; ++first1, (void) ++first2) {
    if (invoke(comp, invoke(proj1, *first1), invoke(proj2, *first2))) return true;
    if (invoke(comp, invoke(proj2, *first2), invoke(proj1, *first1))) return false;
}
return first1 == last1 && first2 != last2;
—end example]

[Note: An empty sequence is lexicographically less than any non-empty sequence, but not less than any empty sequence. — end note]

25.7.11  Three-way comparison algorithms [alg.3way]

```

template<class T, class U> constexpr auto compare_3way(const T& a, const U& b);

1  Effects: Compares two values and produces a result of the strongest applicable comparison category type:

(1.1) — Returns a <=> b if that expression is well-formed.
(1.2) — Otherwise, if the expressions a == b and a < b are each well-formed and convertible to bool, returns
        strong_ordering::equal when a == b is true, otherwise returns strong_ordering::less
        when a < b is true, and otherwise returns strong_ordering::greater.
(1.3) — Otherwise, if the expression a == b is well-formed and convertible to bool, returns
        strong_equality::equal when a == b is true, and otherwise returns strong_equality::nonequal.
(1.4) — Otherwise, the function is defined as deleted.

template<class InputIterator1, class InputIterator2, class Cmp>
constexpr auto
lexicographical_compare_3way(InputIterator1 b1, InputIterator1 e1, 
  InputIterator2 b2, InputIterator2 e2, 
  Cmp comp)
-> common_comparison_category_t<decltype(comp(*b1, *b2)), strong_ordering>;

2  Requires: Cmp shall be a function object type whose return type is a comparison category type.

3  Effects: Lexicographically compares two ranges and produces a result of the strongest applicable
            comparison category type. Equivalent to:

        for ( ; b1 != e1 && b2 != e2 ; void(++b1), void(++b2) )
            if (auto cmp = comp(*b1,*b2); cmp != 0)
                return cmp;
        return b1 != e1 ? strong_ordering::greater : 
                     b2 != e2 ? strong_ordering::less : 
                     strong_ordering::equal;

```

template<class InputIterator1, class InputIterator2>
constexpr auto
lexicographical_compare_3way(InputIterator1 b1, InputIterator1 e1, 
  InputIterator2 b2, InputIterator2 e2);

4  Effects: Equivalent to:

        return lexicographical_compare_3way(b1, e1, b2, e2, 
            [](const auto& t, const auto& u) {
                return compare_3way(t, u); 
            });

25.7.12  Permutation generators [alg.permutation.generators]

template<class BidirectionalIterator>
constexpr bool next_permutation(BidirectionalIterator first, 
  BidirectionalIterator last);

§ 25.7.12 1077
template<class BidirectionalIterator, class Compare>
constexpr bool next_permutation(BidirectionalIterator first,
BidirectionalIterator last, Compare comp);

template<BidirectionalIterator I, Sentinel<I> S, class Comp = ranges::less,
class Proj = identity>
constexpr bool
ranges::next_permutation(I first, S last, Comp comp = {}, Proj proj = {});

template<BidirectionalRange R, class Comp = ranges::less,
class Proj = identity>
requires Sortable<iterator_t<R>, Comp, Proj>
constexpr bool
ranges::next_permutation(R&& r, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for overloads with no parameters by those names.

Requires: For the overloads in namespace std, BidirectionalIterator shall meet the Cpp17Value-
Swappable requirements (16.5.3.2).

Effects: Takes a sequence defined by the range [first, last) and transforms it into the next permut-
tation. The next permutation is found by assuming that the set of all permutations is lexicographically
sorted with respect to comp and proj. If no such permutation exists, transforms the sequence into the
first permutation; that is, the ascendingly-sorted one.

Returns: true if and only if a next permutation was found.

Complexity: At most (last - first) / 2 swaps.

template<class BidirectionalIterator>
constexpr bool prev_permutation(BidirectionalIterator first,
BidirectionalIterator last);

template<class BidirectionalIterator, class Compare>
constexpr bool prev_permutation(BidirectionalIterator first,
BidirectionalIterator last, Compare comp);

Let comp be less{} and proj be identity{} for overloads with no parameters by those names.

Requires: For the overloads in namespace std, BidirectionalIterator shall meet the Cpp17Value-
Swappable requirements (16.5.3.2).

Effects: Takes a sequence defined by the range [first, last) and transforms it into the previous permut-
tation. The previous permutation is found by assuming that the set of all permutations is lexicographically
sorted with respect to comp and proj. If no such permutation exists, transforms the sequence into the
last permutation; that is, the descendingly-sorted one.

Returns: true if and only if a previous permutation was found.

Complexity: At most (last - first) / 2 swaps.

}

25.9 Generalized numeric operations [numeric.ops]

[Note: The use of closed ranges as well as semi-open ranges to specify requirements throughout this subclause
is intentional. — end note]

25.9.1 Definitions [numerics.defns]

1 Define GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN) as follows:

(1.1) a1 when N is 1, otherwise

(1.2) op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK),
    GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) for any K where 1 < K + 1 = M ≤ N.

2 Define GENERALIZED_SUM(op, a1, ..., aN) as GENERALIZED_NONCOMMUTATIVE_SUM(op, b1, ..., bN),
where b1, ..., bN may be any permutation of a1, ..., aN.

25.9.2 Accumulate [accumulate]

template<class InputIterator, class T>
T accumulate(InputIterator first, InputIterator last, T init);
template<class InputIterator, class T, class BinaryOperation>
T accumulate(InputIterator first, InputIterator last, T init,
    BinaryOperation binary_op);

1 Requires: T shall meet the Cpp17CopyConstructible (Table 27) and Cpp17CopyAssignable (Table 29)
requirements. In the range [first, last], binary_op shall neither modify elements nor invalidate
iterators or subranges.239

239) The use of fully closed ranges is intentional.
Effects: Computes its result by initializing the accumulator acc with the initial value init and then modifies it with \( acc = \text{std::move}(acc) + \ast i \) or \( acc = \text{binary_op}(\text{std::move}(acc), \ast i) \) for every iterator \( i \) in the range \([\text{first}, \text{last})\) in order.

25.9.3 Reduce

```
25.9.3 1083
```

\[
\text{template}<\text{class InputIterator}>
\]
\[
\text{typename iterator_traits<InputIterator>::value_type}
\]
\[
\text{reduce(InputIterator first, InputIterator last);}
\]

Effects: Equivalent to:

\[
\text{return reduce(first, last,}
\text{typename iterator_traits<InputIterator>::value_type());}
\]

```
25.9.3 2
```

\[
\text{template}<\text{class ExecutionPolicy, class ForwardIterator}>
\]
\[
\text{typename iterator_traits<ForwardIterator>::value_type}
\]
\[
\text{reduce(ExecutionPolicy&& exec,}
\text{ForwardIterator first, ForwardIterator last);}
\]

Effects: Equivalent to:

\[
\text{return reduce(\text{std::forward<ExecutionPolicy>(exec)}, first, last,}
\text{typename iterator_traits<ForwardIterator>::value_type());}
\]

```
25.9.3 3
```

\[
\text{template}<\text{class InputIterator, class T}>
\]
\[
\text{T reduce(InputIterator first, InputIterator last, T init);}
\]

Effects: Equivalent to:

\[
\text{return reduce(first, last, init, plus<>());}
\]

```
25.9.3 4
```

\[
\text{template}<\text{class ExecutionPolicy, class ForwardIterator, class T}>
\]
\[
\text{T reduce(ExecutionPolicy&& exec,}
\text{ForwardIterator first, ForwardIterator last, T init);}
\]

Effects: Equivalent to:

\[
\text{return reduce(\text{std::forward<ExecutionPolicy>(exec)}, first, last, init, plus<>());}
\]

```
25.9.3 5
```

\[
\text{template}<\text{class InputIterator, class T, class BinaryOperation}>
\]
\[
\text{T reduce(InputIterator first, InputIterator last, T init,}
\text{BinaryOperation binary_op);}
\]

```
25.9.3 6
```

\[
\text{template}<\text{class ExecutionPolicy, class ForwardIterator, class T, class BinaryOperation}>
\]
\[
\text{T reduce(ExecutionPolicy&& exec,}
\text{ForwardIterator first, ForwardIterator last, T init,}
\text{BinaryOperation binary_op);}
\]

Requires:

\[
(5.1) \quad \text{\text{T shall be \text{Cpp17MoveConstructible} (Table 26).}
\]

\[
(5.2) \quad \text{All of binary_op(init, \ast first), binary_op(*first, init), binary_op(init, init), and}
\text{binary_op(*first, *first) shall be convertible to T.}
\]

\[
(5.3) \quad \text{binary_op shall neither invalidate iterators or subranges, nor modify elements in the range}
\text{\([first, last)\).}
\]

Returns: \text{GENERALIZED_SUM(binary_op, init, \ast i, ...) for every i in \([first, last)\).}

Complexity: \( O(last - first) \) applications of \text{binary_op}.

\[
[\text{Note: The difference between reduce and accumulate is that reduce applies binary_op in an}
\text{unspecified order, which yields a nondeterministic result for non-associative or non-commutative}
\text{binary_op such as floating-point addition. — end note}]
\]
25.9.4 Inner product

\[
\text{template}<\text{class InputIterator1, class InputIterator2, class T}>
T \text{inner_product(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, T init);};
\]

\[
\text{template}<\text{class InputIterator1, class InputIterator2, class T, class BinaryOperation1, class BinaryOperation2}>
T \text{inner_product(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, T init, BinaryOperation1 binary_op1, BinaryOperation2 binary_op2);};
\]

1 \textbf{Requires:} T shall meet the \textit{Cpp17CopyConstructible} (Table 27) and \textit{Cpp17CopyAssignable} (Table 29) requirements. In the ranges \([\text{first1, last1}]\) and \([\text{first2, first2 + (last1 - first1)}]\) \text{binary_op1} and \text{binary_op2} shall neither modify elements nor invalidate iterators or subranges.

2 \textbf{Effects:} Computes its result by initializing the accumulator acc with the initial value init and then modifying it with \(\text{acc} = \text{std::move(acc)} + (*i1) * (*i2)\) or \(\text{acc} = \text{binary_op1(\text{std::move(acc)}, \text{binary_op2(*i1, *i2)})}\) for every iterator \(i1\) in the range \([\text{first1, last1}]\) and iterator \(i2\) in the range \([\text{first2, first2 + (last1 - first1)}]\) in order.

25.9.5 Transform reduce

\[
\text{template}<\text{class InputIterator1, class InputIterator2, class T}>
T \text{transform_reduce(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, T init);};
\]

1 \textbf{Effects:} Equivalent to:
\[
\text{return transform_reduce(first1, last1, first2, init, plus<>(), multiplies<>());}
\]

\[
\text{template}<\text{class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T}>
T \text{transform_reduce(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, T init);};
\]

2 \textbf{Effects:} Equivalent to:
\[
\text{return transform_reduce(\text{std::forward<ExecutionPolicy>(exec)}, first1, last1, first2, init, plus<>(), multiplies<>());}
\]

\[
\text{template}<\text{class InputIterator1, class InputIterator2, class T, class BinaryOperation1, class BinaryOperation2}>
T \text{transform_reduce(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, T init, BinaryOperation1 binary_op1, BinaryOperation2 binary_op2);};
\]

\[
\text{template}<\text{class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T, class BinaryOperation1, class BinaryOperation2}>
T \text{transform_reduce(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, T init, BinaryOperation1 binary_op1, BinaryOperation2 binary_op2);};
\]

3 \textbf{Requires:}
\begin{enumerate}
\item T shall be \textit{Cpp17MoveConstructible} (Table 26).
\item All of
\item binary_op1(init, init).
\end{enumerate}

\textsuperscript{241) The use of fully closed ranges is intentional.}
(3.2.2) binary_op1(init, binary_op2(*first1, *first2)),
(3.2.3) binary_op1(binary_op2(*first1, *first2), init), and
(3.2.4) binary_op1(binary_op2(*first1, *first2), binary_op2(*first1, *first2))
shall be convertible to T.

(3.3) Neither binary_op1 nor binary_op2 shall invalidate subranges, nor modify elements in the ranges [first1, last1] and [first2, first2 + (last1 - first1)].

Returns:
GENERALIZED_SUM(binary_op1, init, binary_op2(*i, *(first2 + (i - first1))), ...)
for every iterator i in [first1, last1).

Complexity: Θ(last1 - first1) applications each of binary_op1 and binary_op2.

template<class InputIterator, class T, class BinaryOperation, class UnaryOperation>
T transform_reduce(InputIterator first, InputIterator last, T init, BinaryOperation binary_op, UnaryOperation unary_op);

template<class ExecutionPolicy, class ForwardIterator, class T, class BinaryOperation, class UnaryOperation>
T transform_reduce(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, T init, BinaryOperation binary_op, UnaryOperation unary_op);

Requires:
(6.1) T shall be Cpp17MoveConstructible (Table 26).
(6.2) All of
(6.2.1) binary_op(init, init),
(6.2.2) binary_op(init, unary_op(*first)),
(6.2.3) binary_op(unary_op(*first), init), and
(6.2.4) binary_op(unary_op(*first), unary_op(*first))
shall be convertible to T.
(6.3) Neither unary_op nor binary_op shall invalidate subranges, nor modify elements in the range [first, last].

Returns:
GENERALIZED_SUM(binary_op, init, unary_op(*i), ...)
for every iterator i in [first, last).

Complexity: Θ(last - first) applications each of unary_op and binary_op.

[Note: transform_reduce does not apply unary_op to init. — end note]

25.9.6 Partial sum

template<class InputIterator, class OutputIterator>
OutputIterator partial_sum(InputIterator first, InputIterator last, OutputIterator result);

template<class InputIterator, class OutputIterator, class BinaryOperation>
OutputIterator partial_sum(InputIterator first, InputIterator last, OutputIterator result, BinaryOperation binary_op);

Requires: InputIterator's value type shall be constructible from the type of *first. The result of the expression std::move(acc) + *i or binary_op(std::move(acc), *i) shall be implicitly convertible to InputIterator's value type. acc shall be writable (23.3.1) to the result output iterator. In the
ranges \([first, last]\) and \([result, result + (last - first)]\) binary_op shall neither modify elements nor invalidate iterators or subranges.\(^{242}\)

**Effects:** For a non-empty range, the function creates an accumulator \(acc\) whose type is `InputIterator`'s value type, initializes it with \(*first\), and assigns the result to \(*result\). For every iterator \(i\) in \([first + 1, last)\) in order, \(acc\) is then modified by \(acc = std::move(acc) + *i\) or \(acc = binary_op(std::move(acc), *i)\) and the result is assigned to \(*(result + (i - first))\).

**Returns:** \(result + (last - first)\).

**Complexity:** Exactly \((last - first) - 1\) applications of the binary operation.

**Remarks:** \(result\) may be equal to \(first\).

### 25.9.7 Exclusive scan

[exclusive.scan]

**Effects:** Equivalent to:

\[
\text{return exclusive_scan(first, last, result, init, plus<>());}
\]

**Effects:** Equivalent to:

\[
\text{return exclusive_scan(std::forward<ExecutionPolicy>(exec), first, last, result, init, plus<>());}
\]

**Requires:**

1. \(T\) shall be `Cpp17MoveConstructible` (Table 26).
2. All of `binary_op(init, init), binary_op(init, *first), and binary_op(*first, *first)` shall be convertible to \(T\).
3. `binary_op` shall neither invalidate iterators or subranges, nor modify elements in the ranges \([first, last]\) or \([result, result + (last - first)]\).

**Effects:** For each integer \(K\) in \([0, last - first)\) assigns through \(result + K\) the value of:

\[
\text{GENERALIZED_NONCOMMUTATIVE_SUM} (binary_op, init, *(first + 0), *(first + 1), \ldots, *(first + K - 1))
\]

**Returns:** The end of the resulting range beginning at \(result\).

**Complexity:** \(O(\text{last - first})\) applications of `binary_op`.

**Remarks:** \(result\) may be equal to \(first\).

[Note: The difference between `exclusive_scan` and `inclusive_scan` is that `exclusive_scan` excludes the \(i^{th}\) input element from the \(i^{th}\) sum. If `binary_op` is not mathematically associative, the behavior of `exclusive_scan` may be nondeterministic. — end note]

\(^{242}\) The use of fully closed ranges is intentional.
25.9.8 Inclusive scan

```cpp
template<class InputIterator, class OutputIterator>
OutputIterator inclusive_scan(InputIterator first, InputIterator last, OutputIterator result);
```

Effects: Equivalent to:

```cpp
return inclusive_scan(first, last, result, plus<>());
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 inclusive_scan(ExecutionPolicy&& exec,
                                 ForwardIterator1 first, ForwardIterator1 last,
                                 ForwardIterator2 result);
```

Effects: Equivalent to:

```cpp
return inclusive_scan(std::forward<ExecutionPolicy>(exec), first, last, result, plus<>());
```

```cpp
template<class InputIterator, class OutputIterator, class BinaryOperation>
OutputIterator inclusive_scan(InputIterator first, InputIterator last,
                                OutputIterator result, BinaryOperation binary_op);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryOperation>
ForwardIterator2 inclusive_scan(ExecutionPolicy&& exec,
                                 ForwardIterator1 first, ForwardIterator1 last,
                                 ForwardIterator2 result, BinaryOperation binary_op);
```

```cpp
template<class InputIterator, class OutputIterator, class T>
OutputIterator inclusive_scan(InputIterator first, InputIterator last,
                                OutputIterator result, BinaryOperation binary_op, T init);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryOperation, class T>
ForwardIterator2 inclusive_scan(ExecutionPolicy&& exec,
                                 ForwardIterator1 first, ForwardIterator1 last,
                                 ForwardIterator2 result, BinaryOperation binary_op, T init);
```

Requires:

(3.1) If init is provided, T shall be Cpp17MoveConstructible (Table 26); otherwise, ForwardIterator1's
value type shall be Cpp17MoveConstructible.

(3.2) If init is provided, all of binary_op(init, init), binary_op(init, *first), and binary_op(*first, *first)
shall be convertible to T; otherwise, binary_op(*first, *first) shall be
convertible to ForwardIterator1's value type.

(3.3) binary_op shall neither invalidate iterators or subranges, nor modify elements in the ranges
[first, last) or [result, result + (last - first)].

Effects: For each integer K in [0, last - first) assigns through result + K the value of

(4.1) GENERALIZED_NONCOMMUTATIVE_SUM

    binary_op, init, *(first + 0), *(first + 1), ..., *(first + K)

if init is provided, or

(4.2) GENERALIZED_NONCOMMUTATIVE_SUM

    binary_op, *(first + 0), *(first + 1), ..., *(first + K)

otherwise.

Returns: The end of the resulting range beginning at result.

Complexity: \( \Theta(\text{last - first}) \) applications of binary_op.

Remarks: result may be equal to first.

[Note: The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes
the \( i \)th input element in the \( i \)th sum. If binary_op is not mathematically associative, the behavior of
inclusive_scan may be nondeterministic. — end note]

25.9.9 Transform exclusive scan

```cpp
template<class InputIterator, class OutputIterator, class T,
         class BinaryOperation, class UnaryOperation>
```
OutputIterator transform_exclusive_scan(InputIterator first, InputIterator last,
    OutputIterator result, T init,
    BinaryOperation binary_op, UnaryOperation unary_op);

template<class ExecutionPolicy,
    class ForwardIterator1, class ForwardIterator2, class T,
    class BinaryOperation, class UnaryOperation>
ForwardIterator2 transform_exclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result, T init,
    BinaryOperation binary_op, UnaryOperation unary_op);

1 \textbf{Requires:}
\begin{enumerate}[\textbullet]
\item T shall be Cpp17MoveConstructible (Table 26).
\item All of
\begin{enumerate}[\textbullet]
\item binary_op(init, init),
\item binary_op(init, unary_op(*first)), and
\item binary_op(unary_op(*first), unary_op(*first))
\end{enumerate}
shall be convertible to T.
\item Neither unary_op nor binary_op shall invalidate iterators or subranges, nor modify elements in the ranges [first, last] or [result, result + (last - first)].
\end{enumerate}

2 \textbf{Effects:} For each integer \(K\) in \([0, \text{last - first})\) assigns through result + \(K\) the value of:
\[
\text{GENERALIZED_NONCOMMUTATIVE\_SUM} \\
\text{binary_op, init,} \\
\text{unary_op(*first + 0), unary_op(*(first + 1)), ..., unary_op(*(first + K - 1))}
\]

3 \textbf{Returns:} The end of the resulting range beginning at result.

4 \textbf{Complexity:} \(O(\text{last - first})\) applications each of unary_op and binary_op.

5 \textbf{Remarks:} result may be equal to first.

6 \textbf{[Note:} The difference between transform_exclusive_scan and transform_inclusive_scan is that transform_exclusive_scan excludes the \(i\)th input element from the \(i\)th sum. If binary_op is not mathematically associative, the behavior of transform_exclusive_scan may be nondeterministic. transform_exclusive_scan does not apply unary_op to init. \textbf{— end note}]}

25.9.10 Transform inclusive scan

OutputIterator transform_inclusive_scan(InputIterator first, InputIterator last,
    OutputIterator result,
    BinaryOperation binary_op, UnaryOperation unary_op);

template<class ExecutionPolicy,
    class ForwardIterator1, class ForwardIterator2,
    class BinaryOperation, class UnaryOperation>
ForwardIterator2 transform_inclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result,
    BinaryOperation binary_op, UnaryOperation unary_op);

template<class InputIterator, class OutputIterator,
    class BinaryOperation, class UnaryOperation,
    class T>
OutputIterator transform_inclusive_scan(InputIterator first, InputIterator last,
    OutputIterator result,
    BinaryOperation binary_op, UnaryOperation unary_op, T init);

template<class ExecutionPolicy,
    class ForwardIterator1, class ForwardIterator2,
    class BinaryOperation, class UnaryOperation,
    class T>
ForwardIterator2 transform_inclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result,
BinaryOperation binary_op, UnaryOperation unary_op, T init);

1

Requires:

(1.1) If init is provided, T shall be Cpp17MoveConstructible (Table 26); otherwise, ForwardIterator1’s value type shall be Cpp17MoveConstructible.

(1.2) If init is provided, all of
(1.2.1) binary_op(init, init),
(1.2.2) binary_op(init, unary_op(*first)), and
(1.2.3) binary_op(unary_op(*first), unary_op(*first)) shall be convertible to T; otherwise, binary_op(unary_op(*first), unary_op(*first)) shall be convertible to ForwardIterator1’s value type.

(1.3) Neither unary_op nor binary_op shall invalidate iterators or subranges, nor modify elements in the ranges [first, last) or [result, result + (last - first)].

2

Effects: For each integer K in [0, last - first) assigns through result + K the value of
(2.1) GENERALIZED_NONCOMMUTATIVE_SUM(
    binary_op, init,
    unary_op(*(first + 0)), unary_op(*(first + 1)), ..., unary_op(*(first + K)))
    if init is provided, or
(2.2) GENERALIZED_NONCOMMUTATIVE_SUM(
    binary_op,
    unary_op(*(first + 0)), unary_op(*(first + 1)), ..., unary_op(*(first + K)))
    otherwise.

Returns: The end of the resulting range beginning at result.
Complexity: O(last - first) applications each of unary_op and binary_op.
Remarks: result may be equal to first.

[Note: The difference between transform_exclusive_scan and transform_inclusive_scan is that transform_inclusive_scan includes the i-th input element in the i-th sum. If binary_op is not mathematically associative, the behavior of transform_inclusive_scan may be nondeterministic. transform_inclusive_scan does not apply unary_op to init. — end note]

25.9.11 Adjacent difference

template<class InputIterator, class OutputIterator>
OutputIterator
adjacent_difference(InputIterator first, InputIterator last, OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec,
                   ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result);

template<class InputIterator, class OutputIterator, class BinaryOperation>
OutputIterator
adjacent_difference(InputIterator first, InputIterator last,
                    OutputIterator result, BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryOperation>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec,
                    ForwardIterator1 first, ForwardIterator1 last,
                    ForwardIterator2 result, BinaryOperation binary_op);

1 Let T be the value type of decltype(first). For the overloads that do not take an argument binary_op, let binary_op be an lvalue that denotes an object of type minus<>. 

2 Requires:
For the overloads with no **ExecutionPolicy**, \( T \) shall be *Cpp17MoveAssignable* (Table 28) and shall be constructible from the type of \(*\text{first} \). \( \text{acc} \) (defined below) shall be writable (23.3.1) to the **result** output iterator. The result of the expression *binary_op*(val, std::move(acc)) shall be writable to the **result** output iterator.

For the overloads with an **ExecutionPolicy**, the result of the expressions *binary_op*(\(*\text{first} \), \(*\text{first} \)) and \(*\text{first} \) shall be writable to **result**.

For all overloads, in the ranges \([\text{first}, \text{last}] \) and \([\text{result}, \text{result} + (\text{last} - \text{first})]\), *binary_op* shall neither modify elements nor invalidate iterators or subranges.\(^{243}\)

**Effects:** For the overloads with no **ExecutionPolicy** and a non-empty range, the function creates an accumulator \( \text{acc} \) of type \( T \), initializes it with \(*\text{first} \), and assigns the result to \(*\text{result} \). For every iterator \( i \) in \([\text{first} + 1, \text{last})\) in order, creates an object \( \text{val} \) whose type is \( T \), initializes it with \(*i \), computes *binary_op*(val, std::move(acc)), assigns the result to \(*(\text{result} + (i - \text{first})) \), and move assigns from \( \text{val} \) to \( \text{acc} \).

For the overloads with an **ExecutionPolicy** and a non-empty range, performs \(*\text{result} = \*\text{first} \). Then, for every \( d \) in \([1, \text{last} - \text{first} - 1]\), performs \(*(\text{result} + d) = \text{binary_op}(\*\text{(first} + d), \*((\text{first} + (d - 1)))\). \n
**Returns:** result + (last - first).

**Complexity:** Exactly \((\text{last} - \text{first}) - 1\) applications of the binary operation.

**Remarks:** For the overloads with no **ExecutionPolicy**, \( \text{result} \) may be equal to \(*\text{first} \). For the overloads with an **ExecutionPolicy**, the ranges \([\text{first}, \text{last}) \) and \([\text{result}, \text{result} + (\text{last} - \text{first})]\) shall not overlap.
25.9.15 Midpoint
[numeric.ops.midpoint]

template<class T>
constexpr T midpoint(T a, T b) noexcept;

1 Constraints: T is an arithmetic type other than bool.
2 Returns: Half the sum of a and b. If T is an integer type and the sum is odd, the result is rounded towards a.
3 Remarks: No overflow occurs. If T is a floating-point type, at most one inexact operation occurs.

template<class T>
constexpr T* midpoint(T* a, T* b);

4 Constraints: T is a complete object type.
5 Expects: a and b point to, respectively, elements x[i] and x[j] of the same array object x. [Note: An object that is not an array element is considered to belong to a single-element array for this purpose; see 7.6.2.1. A pointer past the last element of an array x of n elements is considered to be equivalent to a pointer to a hypothetical element x[n] for this purpose; see 6.7.2. — end note]
6 Returns: A pointer to x[i + (j - i) / 2], where the result of the division is truncated towards zero.

26 Numerics library

26.1 General

This Clause describes components that C++ programs may use to perform seminumerical operations.

The following subclauses describe components for complex number types, random number generation, numeric (n-at-a-time) arrays, generalized numeric algorithms, and mathematical functions for floating-point types, as summarized in Table 81.

Table 81: Numerics library summary

</tbody>
</table>

26.2 Numeric type requirements

The complex and valarray components are parameterized by the type of information they contain and manipulate. A C++ program shall instantiate these components only with a numeric type. A numeric type is a cv-unqualified object type \( T \) that meets the \texttt{Cpp17DefaultConstructible}, \texttt{Cpp17CopyConstructible}, \texttt{Cpp17CopyAssignable}, and \texttt{Cpp17Destructible} requirements (16.5.3.1).

If any operation on \( T \) throws an exception the effects are undefined.

In addition, many member and related functions of \texttt{valarray<}\( T \)\texttt{>} can be successfully instantiated and will exhibit well-defined behavior if and only if \( T \) meets additional requirements specified for each such member or related function.

[Example: It is valid to instantiate \texttt{valarray<complex>}, but operator\( () \) will not be successfully instantiated for \texttt{valarray<complex> operands, since complex does not have any ordering operators. — end example}]

26.3 The floating-point environment

26.3.1 Header <cfenv> synopsis

```cpp
#define FE_ALL_EXCEPT see below
#define FE_DIVBYZERO see below // optional
#define FE_INEXACT see below // optional
#define FE_INVALID see below // optional
#define FE_OVERFLOW see below // optional
#define FE_UNDERFLOW see below // optional

#define FE_DOWNWARD see below // optional
#define FE_TONEAREST see below // optional
#define FE_TOWARDZERO see below // optional
#define FE_UPWARD see below // optional

#define FE_DFL_ENV see below
```

namespace std {
    // types
    using fenv_t = object type;
    using fexcept_t = integer type;

244) In other words, value types. These include arithmetic types, pointers, the library class complex, and instantiations of valarray for value types.
The contents and meaning of the header `<cfenv>` are the same as the C standard library header `<fenv.h>`. [Note: This document does not require an implementation to support the FENV_ACCESS pragma; it is implementation-defined (15.8) whether the pragma is supported. As a consequence, it is implementation-defined whether these functions can be used to test floating-point status flags, set floating-point control modes, or run under non-default mode settings. If the pragma is used to enable control over the floating-point environment, this document does not specify the effect on floating-point evaluation in constant expressions. —end note]

The floating-point environment has thread storage duration (6.6.5.2). The initial state for a thread’s floating-point environment is the state of the floating-point environment of the thread that constructs the corresponding thread object (32.3.2) at the time it constructed the object. [Note: That is, the child thread gets the floating-point state of the parent thread at the time of the child’s creation. —end note]

A separate floating-point environment shall be maintained for each thread. Each function accesses the environment corresponding to its calling thread.

See also: ISO C 7.6

### 26.4 Complex numbers

The header `<complex>` defines a class template, and numerous functions for representing and manipulating complex numbers.

The effect of instantiating the template `complex` for any type other than `float`, `double`, or `long double` is unspecified. The specializations `complex<float>`, `complex<double>`, and `complex<long double>` are literal types (6.7).

If the result of a function is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

If \( z \) is an lvalue of type `cv complex<T>` then:

1. the expression `reinterpret_cast<cv T(&)[2]>(z)` shall be well-formed,
2. `reinterpret_cast<cv T(&)[2]>(z)[0]` shall designate the real part of \( z \), and
3. `reinterpret_cast<cv T(&)[2]>(z)[1]` shall designate the imaginary part of \( z \).

Moreover, if \( a \) is an expression of type `cv complex<T>*` and the expression \( a[i] \) is well-defined for an integer expression \( i \), then:

1. `reinterpret_cast<cv T*>(a)[2*i]` shall designate the real part of \( a[i] \), and
2. `reinterpret_cast<cv T*>(a)[2*i + 1]` shall designate the imaginary part of \( a[i] \).

### 26.4.1 Header `<complex>` synopsis

```cpp
namespace std {
    // 26.4.2, class template complex
    template<class T> class complex;

    // 26.4.3, specializations
    template<> class complex<float>;
    template<> class complex<double>;
    template<> class complex<long double>;
}
```
// 26.4.6, operators

```cpp
// Template operators for complex types.

template<class T> constexpr complex<T> operator+(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator+(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator+(const T&, const complex<T>&);

// Subtraction operators.

template<class T> constexpr complex<T> operator-(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator-(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator-(const T&, const complex<T>&);

// Multiplication operators.

template<class T> constexpr complex<T> operator*(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator*(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator*(const T&, const complex<T>&);

// Division operators.

template<class T> constexpr complex<T> operator/(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator/(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator/(const T&, const complex<T>&);

// Unary operators.

template<class T> constexpr complex<T> operator+(const complex<T>&);
template<class T> constexpr complex<T> operator-(const complex<T>&);
```

// 26.4.7, values

```cpp
// Functions to extract values from complex numbers.

template<class T> constexpr T real(const complex<T>&);
template<class T> constexpr T imag(const complex<T>&);

// Functions to compute absolute value and norm.

template<class T> T abs(const complex<T>&);
template<class T> T norm(const complex<T>&);

// Functions to compute conjugates and projections.

template<class T> complex<T> conj(const complex<T>&);
template<class T> complex<T> proj(const complex<T>&);
```

// 26.4.8, transcendentals

```cpp
// Functions for trigonometric and hyperbolic functions.

template<class T> complex<T> acos(const complex<T>&);
template<class T> complex<T> asin(const complex<T>&);
template<class T> complex<T> atan(const complex<T>&);

// Functions for inverse hyperbolic functions.

template<class T> complex<T> acosh(const complex<T>&);
template<class T> complex<T> asinh(const complex<T>&);
template<class T> complex<T> atanh(const complex<T>&);

// Exponential and logarithmic functions.

template<class T> complex<T> cos(const complex<T>&);
template<class T> complex<T> sinh(const complex<T>&);
template<class T> complex<T> sinh(const complex<T>&);
```

// 26.4.9, power and square root

```cpp
// Functions for exponentiation and square root.

template<class T> complex<T> exp(const complex<T>&);
template<class T> log(const complex<T>&);
```
template<class T> complex<T> sin (const complex<T>&);
template<class T> complex<T> sinh (const complex<T>&);
template<class T> complex<T> sqrt (const complex<T>&);
template<class T> complex<T> tan (const complex<T>&);
template<class T> complex<T> tanh (const complex<T>&);

// 26.4.10, complex literals
inline namespace literals {
inline namespace complex_literals {
constexpr complex<long double> operator"il(long double);
constexpr complex<long double> operator"il(unsigned long long);
constexpr complex<double> operator"il(long double);
constexpr complex<double> operator"il(unsigned long long);
constexpr complex<float> operator"il(float);
constexpr complex<float> operator"il(unsigned long long);
}
}

26.4.2 Class template complex
namespace std {
template<class T> class complex {
public:
  using value_type = T;
  constexpr complex(const T& re = T(), const T& im = T());
  constexpr complex(const complex&);
  template<class X> constexpr complex(const complex<X>&);
  constexpr T real() const;
  constexpr void real(T);
  constexpr T imag() const;
  constexpr void imag(T);
  constexpr complex& operator= (const T&);
  constexpr complex& operator+=(const T&);
  constexpr complex& operator-=(const T&);
  constexpr complex& operator*=(const T&);
  constexpr complex& operator/=(const T&);
  template<class X> constexpr complex& operator= (const complex<X>&);
  template<class X> constexpr complex& operator+=(const complex<X>&);
  template<class X> constexpr complex& operator-=(const complex<X>&);
  template<class X> constexpr complex& operator*=(const complex<X>&);
  template<class X> constexpr complex& operator/=(const complex<X>&);
};
}

1 The class complex describes an object that can store the Cartesian components, real() and imag(), of a complex number.

26.4.3 Specializations
namespace std {
  template<> class complex<float> {
public:
    using value_type = float;
    constexpr complex(float re = 0.0f, float im = 0.0f);
    constexpr complex(const complex<float>&) = default;
    constexpr explicit complex(const complex<double>&);
    constexpr explicit complex(const complex<long double>&);
  };
}
constexpr float real() const;
constexpr void real(float);
constexpr float imag() const;
constexpr void imag(float);

constexpr complex& operator= (float);
constexpr complex& operator+= (float);
constexpr complex& operator-= (float);
constexpr complex& operator*= (float);
constexpr complex& operator/= (float);

constexpr complex& operator=(const complex&);
template<class X> constexpr complex& operator=(const complex<X>&);
template<class X> constexpr complex& operator+=(const complex<X>&);
template<class X> constexpr complex& operator-=(const complex<X>&);
template<class X> constexpr complex& operator*=(const complex<X>&);
template<class X> constexpr complex& operator/=(const complex<X>&);

}
constexpr complex& operator*=(long double);
constexpr complex& operator/=(long double);

constexpr complex& operator=(const complex&);
template<class X> constexpr complex& operator=(const complex<X>&);
template<class X> constexpr complex& operator+=(const complex<X>&);
template<class X> constexpr complex& operator-=(const complex<X>&);
template<class X> constexpr complex& operator*=(const complex<X>&);
template<class X> constexpr complex& operator/=(const complex<X>&);
};

26.4.4 Member functions

template<class T> constexpr complex(const T& re = T(), const T& im = T());

1 Effects: Constructs an object of class complex.
2 Ensures: real() == re && imag() == im.

constexpr T real() const;
3 Returns: The value of the real component.

customexpr void real(T val);
4 Effects: Assigns val to the real component.

customexpr T imag() const;
5 Returns: The value of the imaginary component.

customexpr void imag(T val);
6 Effects: Assigns val to the imaginary component.

26.4.5 Member operators

constexpr complex& operator+=(const T& rhs);
1 Effects: Adds the scalar value rhs to the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.
2 Returns: *this.

constexpr complex& operator-=(const T& rhs);
3 Effects: Subtracts the scalar value rhs from the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.
4 Returns: *this.

constexpr complex& operator*=(const T& rhs);
5 Effects: Multiplies the scalar value rhs by the complex value *this and stores the result in *this.
6 Returns: *this.

constexpr complex& operator/=(const T& rhs);
7 Effects: Divides the scalar value rhs into the complex value *this and stores the result in *this.
8 Returns: *this.

template<class X> constexpr complex& operator+=(const complex<X>& rhs);
9 Effects: Adds the complex value rhs to the complex value *this and stores the sum in *this.
10 Returns: *this.

template<class X> constexpr complex& operator-=(const complex<X>& rhs);
11 Effects: Subtracts the complex value rhs from the complex value *this and stores the difference in *this.
template<class X> constexpr complex& operator*=(const complex<X>& rhs);

Effects: Multiplies the complex value \( \text{rhs} \) by the complex value \( \text{*this} \) and stores the product in \( \text{this} \).

Returns: \( \text{this} \).

template<class X> constexpr complex& operator/=(const complex<X>& rhs);

Effects: Divides the complex value \( \text{rhs} \) into the complex value \( \text{this} \) and stores the quotient in \( \text{this} \).

Returns: \( \text{this} \).

26.4.6 Non-member operations [complex.ops]

template<class T> constexpr complex<T> operator+(const complex<T>& lhs);

Returns: complex\( T \)(lhs).

Remarks: unary operator.

template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const complex<T>& rhs);

Returns: complex\( T \)(lhs) += rhs.

template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const T& rhs);

Returns: complex\( T \)(lhs) += rhs.

template<class T> constexpr complex<T> operator+(const T& lhs, const complex<T>& rhs);

Returns: complex\( T \)(lhs) += rhs.

template<class T> constexpr complex<T> operator-(const complex<T>& lhs);

Returns: complex\( T \)(-lhs.real(), -lhs.imag()).

Remarks: unary operator.

template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const complex<T>& rhs);

Returns: complex\( T \)(lhs) -= rhs.

template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const T& rhs);

Returns: complex\( T \)(lhs) -= rhs.

template<class T> constexpr complex<T> operator-(const T& lhs, const complex<T>& rhs);

Returns: complex\( T \)(lhs) -= rhs.

template<class T> constexpr complex<T> operator*(const complex<T>& lhs, const complex<T>& rhs);

Returns: complex\( T \)(lhs) *= rhs.

template<class T> constexpr complex<T> operator*(const complex<T>& lhs, const T& rhs);

Returns: complex\( T \)(lhs) *= rhs.

template<class T> constexpr complex<T> operator/(const complex<T>& lhs, const complex<T>& rhs);

Returns: complex\( T \)(lhs) /= rhs.

template<class T> constexpr bool operator==(const complex<T>& lhs, const complex<T>& rhs);

Returns: \( \text{lhs.real()} == \text{rhs.real()} \) \&\& \( \text{lhs.imag()} == \text{rhs.imag()} \).

Remarks: The imaginary part is assumed to be \( T() \), or 0.0, for the \( T \) arguments.

template<class T> constexpr bool operator!=(const complex<T>& lhs, const complex<T>& rhs);

Returns: \( \text{rhs.real()} != \text{lhs.real()} \) \|\| \( \text{rhs.imag()} != \text{lhs.imag()} \).

template<class T, class charT, class traits>
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, complex<T>& x);

Requires: The input values shall be convertible to \( T \).

Effects: Extracts a complex number \( x \) of the form: \( u, (u) \), or \( (u, v) \), where \( u \) is the real part and \( v \) is the imaginary part (29.7.4.2).
N4820

© ISO/IEC

14

If bad input is encountered, calls is.setstate(ios_base::failbit) (which may throw ios::failure
(29.5.5.4)).

15

Returns: is.

16

Remarks: This extraction is performed as a series of simpler extractions. Therefore, the skipping of
whitespace is specified to be the same for each of the simpler extractions.
template<class T, class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& o, const complex<T>& x);

17

Effects: Inserts the complex number x onto the stream o as if it were implemented as follows:
basic_ostringstream<charT, traits> s;
s.flags(o.flags());
s.imbue(o.getloc());
s.precision(o.precision());
s << ’(’ << x.real() << "," << x.imag() << ’)’;
return o << s.str();

18

[Note: In a locale in which comma is used as a decimal point character, the use of comma as a field
separator can be ambiguous. Inserting showpoint into the output stream forces all outputs to show an
explicit decimal point character; as a result, all inserted sequences of complex numbers can be extracted
unambiguously. — end note]

26.4.7

Value operations

[complex.value.ops]

template<class T> constexpr T real(const complex<T>& x);
1

Returns: x.real().
template<class T> constexpr T imag(const complex<T>& x);

2

Returns: x.imag().
template<class T> T abs(const complex<T>& x);

3

Returns: The magnitude of x.
template<class T> T arg(const complex<T>& x);

4

Returns: The phase angle of x, or atan2(imag(x), real(x)).
template<class T> constexpr T norm(const complex<T>& x);

5

Returns: The squared magnitude of x.
template<class T> constexpr complex<T> conj(const complex<T>& x);

6

Returns: The complex conjugate of x.
template<class T> complex<T> proj(const complex<T>& x);

7

Returns: The projection of x onto the Riemann sphere.

8

Remarks: Behaves the same as the C function cproj. See also: ISO C 7.3.9.5
template<class T> complex<T> polar(const T& rho, const T& theta = T());

9
10

Requires: rho shall be non-negative and non-NaN. theta shall be finite.
Returns: The complex value corresponding to a complex number whose magnitude is rho and whose
phase angle is theta.

26.4.8

Transcendentals

[complex.transcendentals]

template<class T> complex<T> acos(const complex<T>& x);
1

Returns: The complex arc cosine of x.

2

Remarks: Behaves the same as the C function cacos. See also: ISO C 7.3.5.1
template<class T> complex<T> asin(const complex<T>& x);

3

Returns: The complex arc sine of x.
§ 26.4.8

1099


Remarks: Behaves the same as the C function \texttt{casin}. See also: ISO C 7.3.5.2

\begin{verbatim}
template<class T> complex<T> atan(const complex<T>& x);
\end{verbatim}

Returns: The complex arc tangent of \(x\).

Remarks: Behaves the same as the C function \texttt{catan}. See also: ISO C 7.3.5.3

\begin{verbatim}
template<class T> complex<T> acosh(const complex<T>& x);
\end{verbatim}

Returns: The complex arc hyperbolic cosine of \(x\).

Remarks: Behaves the same as the C function \texttt{cacosh}. See also: ISO C 7.3.6.1

\begin{verbatim}
template<class T> complex<T> asinh(const complex<T>& x);
\end{verbatim}

Returns: The complex arc hyperbolic sine of \(x\).

Remarks: Behaves the same as the C function \texttt{casinh}. See also: ISO C 7.3.6.2

\begin{verbatim}
template<class T> complex<T> atanh(const complex<T>& x);
\end{verbatim}

Returns: The complex arc hyperbolic tangent of \(x\).

Remarks: Behaves the same as the C function \texttt{catanh}. See also: ISO C 7.3.6.3

\begin{verbatim}
template<class T> complex<T> cos(const complex<T>& x);
\end{verbatim}

Returns: The complex cosine of \(x\).

\begin{verbatim}
template<class T> complex<T> sinh(const complex<T>& x);
\end{verbatim}

Returns: The complex hyperbolic sine of \(x\).

\begin{verbatim}
template<class T> complex<T> sqrt(const complex<T>& x);
\end{verbatim}

Returns: The complex square root of \(x\), in the range of the right half-plane. [\textit{Note: The semantics of this function are intended to be the same in C++ as they are for} \texttt{csqrt} in C. \textit{— end note}]

Remarks: The branch cuts are along the negative real axis.
template<class T> complex<T> tan(const complex<T>& x);

Returns: The complex tangent of x.

template<class T> complex<T> tanh(const complex<T>& x);

Returns: The complex hyperbolic tangent of x.

26.4.9 Additional overloads

The following function templates shall have additional overloads:

```
arg
conj
imag
real
```

where norm, conj, imag, and real are constexpr overloads.

The additional overloads shall be sufficient to ensure:

- If the argument has type long double, then it is effectively cast to complex<long double>.
- Otherwise, if the argument has type double or an integer type, then it is effectively cast to complex<double>.
- Otherwise, if the argument has type float, then it is effectively cast to complex<float>.

Function template pow shall have additional overloads sufficient to ensure, for a call with at least one argument of type complex<T>:

- If either argument has type complex<long double> or type long double, then both arguments are effectively cast to complex<long double>.
- Otherwise, if either argument has type complex<double>, double, or an integer type, then both arguments are effectively cast to complex<double>.
- Otherwise, if either argument has type complex<float> or float, then both arguments are effectively cast to complex<float>.

26.4.10 Suffixes for complex number literals

This subclause describes literal suffixes for constructing complex number literals. The suffixes i, il, and if create complex numbers of the types complex<double>, complex<long double>, and complex<float> respectively, with their imaginary part denoted by the given literal number and the real part being zero.

```
constexpr complex<long double> operator"il(long double d);
constexpr complex<long double> operator"il(unsigned long long d);
```

Returns: complex<long double>{0.0L, static_cast<long double>(d)}.

```
constexpr complex<double> operator"i(long double d);
constexpr complex<double> operator"i(unsigned long long d);
```

Returns: complex<double>{0.0, static_cast<double>(d)}.

```
constexpr complex<float> operator"if(long double d);
constexpr complex<float> operator"if(unsigned long long d);
```

Returns: complex<float>{0.0f, static_cast<float>(d)}.

26.5 Bit manipulation

26.5.1 General

The header <bit> provides components to access, manipulate and process both individual bits and bit sequences.

26.5.2 Header <bit> synopsis

```
namespace std {
    // 26.5.3, bit_cast
    template<typename To, typename From>
    constexpr To bit_cast(const From& from) noexcept;
```

§ 26.5.2
// 26.5.4, integral powers of 2
template<class T>
constexpr bool ispow2(T x) noexcept;

template<class T>
constexpr T ceil2(T x) noexcept;

template<class T>
constexpr T floor2(T x) noexcept;

template<class T>
constexpr T log2p1(T x) noexcept;

26.5.3 Function template bit_cast

```
template<typename To, typename From>
constexpr To bit_cast(const From& from) noexcept;
```

1 Returns: An object of type To. Each bit of the value representation of the result is equal to the corresponding bit in the object representation of from. Padding bits of the To object are unspecified. If there is no value of type To corresponding to the value representation produced, the behavior is undefined. If there are multiple such values, which value is produced is unspecified.

2 Remarks: This function shall not participate in overload resolution unless:

(2.1) sizeof(To) == sizeof(From) is true;
(2.2) is_trivially_copyable_v<To> is true; and
(2.3) is_trivially_copyable_v<From> is true.

This function shall be constexpr if and only if To, From, and the types of all subobjects of To and From are types T such that:

(2.4) is_union_v<T> is false;
(2.5) is_pointer_v<T> is false;
(2.6) is_member_pointer_v<T> is false;
(2.7) is_volatile_v<T> is false; and
(2.8) T has no non-static data members of reference type.

26.5.4 Integral powers of 2

```
template<class T>
constexpr bool ispow2(T x) noexcept;
```

1 Returns: true if x is an integral power of two; false otherwise.

2 Remarks: This function shall not participate in overload resolution unless T is an unsigned integer type (6.7.1).

```
template<class T>
constexpr T ceil2(T x) noexcept;
```

3 Returns: The minimal value y such that ispow2(y) is true and y >= x; if y is not representable as a value of type T, the result is an unspecified value.

4 Remarks: This function shall not participate in overload resolution unless T is an unsigned integer type (6.7.1).

```
template<class T>
constexpr T floor2(T x) noexcept;
```

5 Returns: If x == 0, 0; otherwise the maximal value y such that ispow2(y) is true and y <= x.

6 Remarks: This function shall not participate in overload resolution unless T is an unsigned integer type (6.7.1).

```
template<class T>
constexpr T log2p1(T x) noexcept;
```

7 Returns: If x == 0, 0; otherwise one plus the base-2 logarithm of x, with any fractional part discarded.
Remarks: This function shall not participate in overload resolution unless \( T \) is an unsigned integer type (6.7.1).

26.6 Random number generation

This subclause defines a facility for generating (pseudo-)random numbers.

In addition to a few utilities, four categories of entities are described: uniform random bit generators, random number engines, random number engine adaptors, and random number distributions. These categorizations are applicable to types that meet the corresponding requirements, to objects instantiated from such types, and to templates producing such types when instantiated. [Note: These entities are specified in such a way as to permit the binding of any uniform random bit generator object \( e \) as the argument to any random number distribution object \( d \), thus producing a zero-argument function object such as given by \( \text{bind}(d,e) \). — end note]

Each of the entities specified via this subclause has an associated arithmetic type (6.7.1) identified as result_type. With \( T \) as the result_type thus associated with such an entity, that entity is characterized:

- as boolean or equivalently as boolean-valued, if \( T \) is \( \text{bool} \);
- otherwise as integral or equivalently as integer-valued, if \( \text{numeric_limits}<T>::\text{is_integer} \) is true;
- otherwise as floating or equivalently as real-valued.

If integer-valued, an entity may optionally be further characterized as signed or unsigned, according to \( \text{numeric_limits}<T>::\text{is_signed} \).

Unless otherwise specified, all descriptions of calculations in this subclause use mathematical real numbers.

Throughout this subclause, the operators \( \&\& \), \( |\| \), and \( \oplus \) denote the respective conventional bitwise operations. Further:

- the operator \( \ll \) denotes a bitwise left shift with zero-valued bits appearing in the low bits of the result, and
- the operator \( \lll \) denotes a bitwise left shift with zero-valued bits appearing in the low bits of the result, and whose result is always taken modulo \( 2^w \).

26.6.1 Header \texttt{<random> synopsis}

```cpp
#include <initializer_list>

namespace std {

// 26.6.2.3, uniform random bit generator requirements

26.6.2 Requirements

26.6.2.1 General requirements

Throughout this subclause 26.6, the effect of instantiating a template:

(1.1) that has a template type parameter named Sseq is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of seed sequence (26.6.2.2).

(1.2) that has a template type parameter named URBG is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of uniform random bit generator (26.6.2.3).

(1.3) that has a template type parameter named Engine is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of random number engine (26.6.2.4).

(1.4) that has a template type parameter named RealType is undefined unless the corresponding template argument is cv-unqualified and is one of float, double, or long double.

(1.5) that has a template type parameter named IntType is undefined unless the corresponding template argument is cv-unqualified and is one of short, int, long, long long, unsigned short, unsigned int, unsigned long, or unsigned long long.
— that has a template type parameter named `UIntType` is undefined unless the corresponding template argument is cv-unqualified and is one of `unsigned short`, `unsigned int`, `unsigned long`, or `unsigned long long`.

2 Throughout this subclause 26.6, phrases of the form “x is an iterator of a specific kind” shall be interpreted as equivalent to the more formal requirement that “x is a value of a type meeting the requirements of the specified iterator type”.

3 Throughout this subclause 26.6, any constructor that can be called with a single argument and that meets a requirement specified in this subclause shall be declared `explicit`.

### 26.6.2.2 Seed sequence requirements

1 A seed sequence is an object that consumes a sequence of integer-valued data and produces a requested number of unsigned integer values \( i \), \( 0 \leq i < 2^{32} \), based on the consumed data. [Note: Such an object provides a mechanism to avoid replication of streams of random variates. This can be useful, for example, in applications requiring large numbers of random number engines. — end note]

2 A class \( S \) meets the requirements of a seed sequence if the expressions shown in Table 82 are valid and have the indicated semantics, and if \( S \) also meets all other requirements of this subclause 26.6.2.2. In that Table and throughout this subclause:

(2.1) — \( T \) is the type named by \( S \)'s associated `result_type`;
(2.2) — \( q \) is a value of \( S \) and \( r \) is a possibly const value of \( S \);
(2.3) — \( ib \) and \( ie \) are input iterators with an unsigned integer `value_type` of at least 32 bits;
(2.4) — \( rb \) and \( re \) are mutable random access iterators with an unsigned integer `value_type` of at least 32 bits;
(2.5) — \( ob \) is an output iterator; and
(2.6) — \( il \) is a value of `initializer_list<T>`.

26.6.2.3 Uniform random bit generator requirements

A uniform random bit generator \(g\) of type \(G\) is a function object returning unsigned integer values such that each value in the range of possible results has (ideally) equal probability of being returned. [Note: The degree to which \(g\)'s results approximate the ideal is often determined statistically. — end note]

\[
\text{template}<\text{class } G> \\
\text{concept UniformRandomBitGenerator =} \\
\text{Invocable}<G&> \&\& \text{UnsignedIntegral}<\text{invoke_result_t}<G&>> \&\& \\
\text{requires} \\
\{ \text{G::min()} \} \to \text{Same}<\text{invoke_result_t}<G&>>; \\
\{ \text{G::max()} \} \to \text{Same}<\text{invoke_result_t}<G&>>; \\
\};
\]

2 Let \(g\) be an object of type \(G\). \(G\) models UniformRandomBitGenerator only if

1. \(\text{G::min()}\) and \(\text{G::max()}\) are constant expressions (7.7),
2. \(\text{G::min()} < \text{G::max()}\),
3. \(\text{G::min()} \leq g()\),
4. \(g() \leq \text{G::max()}\), and
5. \(g()\) has amortized constant complexity.

3 A class \(G\) meets the uniform random bit generator requirements if \(G\) models UniformRandomBitGenerator, \(\text{invoke_result_t}<G&>\) is an unsigned integer type (6.7.1), and \(G\) provides a nested typedef-name result_type that denotes the same type as \(\text{invoke_result_t}<G&>\).

26.6.2.4 Random number engine requirements

A random number engine (commonly shortened to engine) \(e\) of type \(E\) is a uniform random bit generator that additionally meets the requirements (e.g., for seeding and for input/output) specified in this subclause.

2 At any given time, \(e\) has a state \(e_i\) for some integer \(i \geq 0\). Upon construction, \(e\) has an initial state \(e_0\). An engine’s state may be established via a constructor, a seed function, assignment, or a suitable operator>>()

3 \(E\)'s specification shall define:

1. the size of \(E\)'s state in multiples of the size of result_type, given as an integral constant expression;
2. the transition algorithm TA by which \(e\)'s state \(e_i\) is advanced to its successor state \(e_{i+1}\); and
3. the generation algorithm GA by which an engine’s state is mapped to a value of type result_type.

4 A class \(E\) that meets the requirements of a uniform random bit generator (26.6.2.3) also meets the requirements of a random number engine if the expressions shown in Table 83 are valid and have the indicated semantics, and if \(E\) also meets all other requirements of this subclause 26.6.2.4. In that Table and throughout this subclause:

1. \(T\) is the type named by \(E\)'s associated result_type;
2. \(e\) is a value of \(E\), \(v\) is an lvalue of \(E\), \(x\) and \(y\) are (possibly const) values of \(E\);
3. \(s\) is a value of \(T\);
4. \(q\) is an lvalue meeting the requirements of a seed sequence (26.6.2.2);
5. \(z\) is a value of type unsigned long long;
— *os* is an lvalue of the type of some class template specialization `basic_ostream<charT, traits>;` and
— *is* is an lvalue of the type of some class template specialization `basic_istream<charT, traits>;`

where `charT` and `traits` are constrained according toClause 21 and Clause 29.

Table 83: Random number engine requirements  [tab:rand.req.eng]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Pre/post-condition</th>
<th>Complexity</th>
</tr>
</thead>
<tbody>
<tr>
<td>E()</td>
<td>void</td>
<td>Creates an engine with the same initial state as all other default-constructed engines of type E.</td>
<td>(O(\text{size of state}))</td>
</tr>
<tr>
<td>E(x)</td>
<td>void</td>
<td>Creates an engine that compares equal to x.</td>
<td>(O(\text{size of state}))</td>
</tr>
<tr>
<td>E(s)</td>
<td>void</td>
<td>Creates an engine with initial state determined by s.</td>
<td>(O(\text{size of state}))</td>
</tr>
<tr>
<td>E(q)(^{245})</td>
<td>void</td>
<td>Creates an engine with an initial state that depends on a sequence produced by one call to <code>q.generate</code>.</td>
<td>same as complexity of <code>q.generate</code> called on a sequence whose length is size of state</td>
</tr>
<tr>
<td>e.seed()</td>
<td>void</td>
<td>Ensures: (e == E()). same as (E())</td>
<td></td>
</tr>
<tr>
<td>e.seed(s)</td>
<td>void</td>
<td>Ensures: (e == E(s)). same as (E(s))</td>
<td></td>
</tr>
<tr>
<td>e.seed(q)</td>
<td>void</td>
<td>Ensures: (e == E(q)). same as (E(q))</td>
<td></td>
</tr>
<tr>
<td>e()</td>
<td>T</td>
<td>Advances e’s state (e_i) to (e_{i+1}) (= TA(e_i)) and returns (GA(e_i)).</td>
<td>per 26.6.2.3</td>
</tr>
<tr>
<td>e.discard(z)</td>
<td>void</td>
<td>Advances e’s state (e_i) to (e_{i+z}) by any means equivalent to (z) consecutive calls e().</td>
<td>no worse than the complexity of (z) consecutive calls e()</td>
</tr>
<tr>
<td>x == y</td>
<td>bool</td>
<td>This operator is an equivalence relation. With (S_x) and (S_y) as the infinite sequences of values that would be generated by repeated future calls to <code>x()</code> and <code>y()</code>, respectively, returns <code>true</code> if (S_x = S_y); else returns <code>false</code>.</td>
<td>(O(\text{size of state}))</td>
</tr>
<tr>
<td>x != y</td>
<td>bool</td>
<td>! (x == y).</td>
<td>(O(\text{size of state}))</td>
</tr>
<tr>
<td>os &lt;&lt; x</td>
<td>reference to the type of os</td>
<td>With os.fmtflags set to ios_base::dec</td>
<td>ios_base::left and the fill character set to the space character, writes to os the textual representation of x’s current state. In the output, adjacent numbers are separated by one or more space characters. Ensures: The os.fmtflags and fill character are unchanged.</td>
</tr>
</tbody>
</table>

\(^{245}\) This constructor (as well as the subsequent corresponding `seed()` function) may be particularly useful to applications requiring a large number of independent random sequences.

\(^{246}\) This operation is common in user code, and can often be implemented in an engine-specific manner so as to provide significant performance improvements over an equivalent naive loop that makes \(z\) consecutive calls e().

<td>is &gt;&gt; v</td>
<td>reference to the type of is</td>
<td>With is.fmtflags set to (\text{ios_base::dec}), sets v's state as determined by reading its textual representation from is. If bad input is encountered, ensures that v's state is unchanged by the operation and calls is.setstate(ios::failbit) (which may throw ios::failure (29.5.5.4)). If a textual representation written via os &lt;&lt; x was subsequently read via is &gt;&gt; v, then x == v provided that there have been no intervening invocations of x or of v. Requires: is provides a textual representation that was previously written using an output stream whose imbued locale was the same as that of is, and whose type's template specialization arguments charT and traits were respectively the same as those of is. Ensures: The is.fmtflags are unchanged.</td>
<td>(\mathcal{O}(\text{size of state}))</td>
</tr>
</tbody>
</table>

5 E shall meet the Cpp17CopyConstructible (Table 27) and Cpp17CopyAssignable (Table 29) requirements. These operations shall each be of complexity no worse than \(\mathcal{O}(\text{size of state})\).

26.6.2.5 Random number engine adaptor requirements [rand.req.adapt]

1 A random number engine adaptor (commonly shortened to adapter) \(a\) of type \(A\) is a random number engine that takes values produced by some other random number engine, and applies an algorithm to those values in order to deliver a sequence of values with different randomness properties. An engine \(b\) of type \(B\) adapted in this way is termed a base engine in this context. The expression \(a.base()\) shall be valid and shall return a const reference to \(a\)'s base engine.

2 The requirements of a random number engine type shall be interpreted as follows with respect to a random number engine adaptor type.

\[A::A();\]

3 Effects: The base engine is initialized as if by its default constructor.

bool operator==(const A& a1, const A& a2);

4 Returns: true if \(a1\)'s base engine is equal to \(a2\)'s base engine. Otherwise returns false.

\[A::A(result\_type s);\]

5 Effects: The base engine is initialized with \(s\).

template<class Sseq> A::A(Sseq& q);

6 Effects: The base engine is initialized with \(q\).

void seed();

7 Effects: With \(b\) as the base engine, invokes \(b.seed()\).
void seed(result_type s);

Effects: With b as the base engine, invokes b.seed(s).

template<class Sseq> void seed(Sseq& q);

Effects: With b as the base engine, invokes b.seed(q).

A shall also meet the following additional requirements:

1. The complexity of each function shall not exceed the complexity of the corresponding function applied to the base engine.
2. The state of A shall include the state of its base engine. The size of A’s state shall be no less than the size of the base engine.
3. Copying A’s state (e.g., during copy construction or copy assignment) shall include copying the state of the base engine of A.
4. The textual representation of A shall include the textual representation of its base engine.

### 26.6.2.6 Random number distribution requirements [rand.req.dist]

A random number distribution (commonly shortened to distribution) d of type D is a function object returning values that are distributed according to an associated mathematical probability density function \( p(z) \) or according to an associated discrete probability function \( P(z_i) \). A distribution’s specification identifies its associated probability function \( p(z) \) or \( P(z_i) \).

An associated probability function is typically expressed using certain externally-supplied quantities known as the parameters of the distribution. Such distribution parameters are identified in this context by writing, for example, \( p(z \mid a,b) \) or \( P(z_i \mid a,b) \), to name specific parameters, or by writing, for example, \( p(z \mid \{p\}) \) or \( P(z_i \mid \{p\}) \), to denote a distribution’s parameters \( p \) taken as a whole.

A class D meets the requirements of a random number distribution if the expressions shown in Table 84 are valid and have the indicated semantics, and if D and its associated types also meet all other requirements of this subclause 26.6.2.6. In that Table and throughout this subclause,

1. \( D \) is the type named by D’s associated result_type;
2. \( P \) is the type named by D’s associated param_type;
3. \( d \) is a value of D, and \( x \) and \( y \) are (possibly const) values of D;
4. \( \text{glb} \) and \( \text{lub} \) are values of T respectively corresponding to the greatest lower bound and the least upper bound on the values potentially returned by \( d \)’s operator(), as determined by the current values of \( d \)’s parameters;
5. \( p \) is a (possibly const) value of P;
6. g, g1, and g2 are lvalues of a type meeting the requirements of a uniform random bit generator (26.6.2.3);
7. os is an lvalue of the type of some class template specialization basic_ostream<charT, traits>;
8. is is an lvalue of the type of some class template specialization basic_istream<charT, traits>;

where charT and traits are constrained according to Clause 21 and Clause 29.

</tr>
</tbody>
</table>

4. `D` shall meet the `Cpp17CopyConstructible (Table 27)` and `Cpp17CopyAssignable (Table 29)` requirements.
5. The sequence of numbers produced by repeated invocations of `d(g)` shall be independent of any invocation of `os << d` or of any `const` member function of `D` between any of the invocations `d(g)`.
6. If a textual representation is written using `os << x` and that representation is restored into the same or a different object `y` of the same type using `is >> y`, repeated invocations of `y(g)` shall produce the same sequence of numbers as would repeated invocations of `x(g)`.
7. It is unspecified whether `D::param_type` is declared as a (nested) `class` or via a `typedef`. In this subclause 26.6, declarations of `D::param_type` are in the form of `typedef` for convenience of exposition only.
8. `P` shall meet the `Cpp17CopyConstructible (Table 27)`, `Cpp17CopyAssignable (Table 29)`, and `Cpp17Equality-Comparable (Table 23)` requirements.
9. For each of the constructors of `D` taking arguments corresponding to parameters of the distribution, `P` shall have a corresponding constructor subject to the same requirements and taking arguments identical in number, type, and default values. Moreover, for each of the member functions of `D` that return values corresponding to parameters of the distribution, `P` shall have a corresponding member function with the identical name, type, and semantics.
10. `P` shall have a declaration of the form
    ```
    using distribution_type = D;
    ```

### 26.6.3 Random number engine class templates [rand.eng]

1. Each type instantiated from a class template specified in this subclause 26.6.3 meets the requirements of a random number engine (26.6.2.4) type.
2. Except where specified otherwise, the complexity of each function specified in this subclause 26.6.3 is constant.
3. Except where specified otherwise, no function described in this subclause 26.6.3 throws an exception.
4. Every function described in this subclause 26.6.3 that has a function parameter `q` of type `Sseq&` for a template type parameter named `Sseq` that is different from type `seed_seq` throws what and when the invocation of `q.generate` throws.
5. Descriptions are provided in this subclause 26.6.3 only for engine operations that are not described in 26.6.2.4 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.
6. Each template specified in this subclause 26.6.3 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.
For every random number engine and for every random number engine adaptor X defined in this subclause (26.6.3) and in subclause 26.6.4:

(7.1) if the constructor

\[ \text{template<class Sseq> explicit X(Sseq& q);} \]

is called with a type Sseq that does not qualify as a seed sequence, then this constructor shall not participate in overload resolution;

(7.2) if the member function

\[ \text{template<class Sseq> void seed(Sseq& q);} \]

is called with a type Sseq that does not qualify as a seed sequence, then this function shall not participate in overload resolution.

The extent to which an implementation determines that a type cannot be a seed sequence is unspecified, except that as a minimum a type shall not qualify as a seed sequence if it is implicitly convertible to X::result_type.

26.6.3.1 Class template linear_congruential_engine

A linear_congruential_engine random number engine produces unsigned integer random numbers. The state \( x_i \) of a linear_congruential_engine object \( x \) is of size 1 and consists of a single integer. The transition algorithm is a modular linear function of the form \( T_A(x_i) = (a \cdot x_i + c) \mod m \); the generation algorithm is \( G_A(x_i) = x_i + 1 \).

\[ \text{template<class UIntType, UIntType a, UIntType c, UIntType m>} \]
\[ \text{class linear_congruential_engine { public:} \]
\[ \text{using result_type = UIntType; } \]
\[ \text{// engine characteristics} \]
\[ \text{static constexpr result_type multiplier = a; } \]
\[ \text{static constexpr result_type increment = c; } \]
\[ \text{static constexpr result_type modulus = m; } \]
\[ \text{static constexpr result_type min() \{ return c == 0u ? 1u: 0u; } \]
\[ \text{static constexpr result_type max() \{ return m - 1u; } \]
\[ \text{static constexpr result_type default_seed = 1u; } \]
\[ \text{// constructors and seeding functions} \]
\[ \text{linear_congruential_engine() : linear_congruential_engine(default_seed) \{ } \]
\[ \text{explicit linear_congruential_engine(result_type s); } \]
\[ \text{template<class Sseq> explicit linear_congruential_engine(Sseq& q); } \]
\[ \text{void seed(result_type s = default_seed); } \]
\[ \text{template<class Sseq> void seed(Sseq& q); } \]
\[ \text{// generating functions} \]
\[ \text{result_type operator()(); } \]
\[ \text{void discard(unsigned long long z);} \]
\];

2 If the template parameter \( m \) is 0, the modulus \( m \) used throughout this subclause 26.6.3.1 is \( \text{numeric_limits<result_type>::max()} \) plus 1. [Note: \( m \) need not be representable as a value of type result_type. -- end note]

3 If the template parameter \( m \) is not 0, the following relations shall hold: \( a < m \) and \( c < m \).

4 The textual representation consists of the value of \( x_i \).

\[ \text{explicit linear_congruential_engine(result_type s);} \]

\[ \text{Effects: Constructs a linear_congruential_engine object. If c mod m is 0 and s mod m is 0, sets the engine's state to 1, otherwise sets the engine's state to s mod m.} \]
template<class Sseq> explicit linear_congruential_engine(Sseq& q);

**Effects:** Constructs a `linear_congruential_engine` object. With \( k = \left\lceil \log_2 m \right\rceil \) and \( a \) an array (or equivalent) of length \( k + 3 \), invokes \( q \).generate\((a + 0, a + k + 3)\) and then computes \( S = \left( \sum_{j=0}^{k-1} a_j + 3 \cdot 2^{32} \right) \mod m \). If \( c \mod m \) is 0 and \( S \) is 0, sets the engine’s state to 1, else sets the engine’s state to \( S \).

### 26.6.3.2 Class template `mersenne_twister_engine`

A `mersenne_twister_engine` random number engine produces unsigned integer random numbers in the closed interval \([0, 2^w - 1]\). The state \( x_i \) of a `mersenne_twister_engine` object \( x \) is of size \( n \) and consists of a sequence \( X \) of \( n \) values of the type delivered by \( x \); all subscripts applied to \( X \) are to be taken modulo \( n \).

The transition algorithm employs a twisted generalized feedback shift register defined by shift values \( n \) and \( m \), a twist value \( r \), and a conditional xor-mask \( a \). To improve the uniformity of the result, the bits of the raw shift register are additionally tempered (i.e., scrambled) according to a bit-scrambling matrix defined by values \( u, d, s, b, t, c, \) and \( \ell \).

The state transition is performed as follows:

1. Concatenate the upper \( w - r \) bits of \( X_{i-n} \) with the lower \( r \) bits of \( X_{i+1-n} \) to obtain an unsigned integer value \( Y \).
2. With \( \alpha = a \cdot (Y \text{ bitand 1}) \), set \( X_i \) to \( X_i + m - n \text{ xor} (Y \text{ rshift 1}) \text{ xor} \alpha \).

The sequence \( X \) is initialized with the help of an initialization multiplier \( f \).

The generation algorithm determines the unsigned integer values \( z_1, z_2, z_3, z_4 \) as follows, then delivers \( z_4 \) as its result:

1. Let \( z_1 = X_i \text{ xor} ((X_i \text{ rshift } u) \text{ bitand } d) \).
2. Let \( z_2 = z_1 \text{ xor} ((z_1 \text{ lshift } s) \text{ bitand } b) \).
3. Let \( z_3 = z_2 \text{ xor} ((z_2 \text{ lshift } t) \text{ bitand } c) \).
4. Let \( z_4 = z_3 \text{ xor} (z_3 \text{ rshift } \ell) \).

```cpp
template<class UIntType, size_t w, size_t n, size_t m, size_t r,
UIntType a, size_t u, UIntType d, size_t s,
UIntType b, size_t t,
UIntType c, size_t l, UIntType f>
class mersenne_twister_engine {
public:
  // types
  using result_type = UIntType;

  // engine characteristics
  static constexpr result_type min() { return 0; }
  static constexpr result_type max() { return \(2^w - 1\); }
  static constexptr result_type default_seed = 5489u;
}
```

---

247) The name of this engine refers, in part, to a property of its period: For properly-selected values of the parameters, the period is closely related to a large Mersenne prime number.
The generation algorithm is given by

\[ f \cdot (X_{i-1} \lor (X_{i-1} \ll shift (w-2))) + i \mod n ] \mod 2^w. \]

**Effects:** Constructs a `mersenne_twister_engine` object. Sets \( X_{-n} \) to value \( mod 2^w \). Then, iteratively for \( i = 1 - n, \ldots, -1 \), sets \( X_i \) to

\[ f \cdot (X_{i-1} \lor (X_{i-1} \ll shift (w-2))) + i \mod n \] \mod 2^w.

**Complexity:** \( \Theta(n) \).

**Note:** This algorithm corresponds to a modular linear function of the form \( TA(x_i) = (a \cdot x_i) \mod b \), where \( b \) is of the form \( m^2 - m^1 + 1 \) and \( a = b - (b-1)/m. \) — end note

The state transition is performed as follows:

\( Y = X_{i-n} - X_{i-r} - c. \)

\( X_i \) to \( y = Y \mod m \). Set \( c \) to 1 if \( Y < 0 \), otherwise set \( c \) to 0.

The state \( x_i \) of a `subtract_with_carry_engine` object \( x \) is of size \( \Theta(r) \), and consists of a sequence \( X \) of \( r \) integer values \( 0 \leq X_i < m = 2^w \); all subscripts applied to \( X \) are to be taken modulo \( r \). The state \( x_i \) additionally consists of an integer \( c \) (known as the carry) whose value is either 0 or 1.

The state transition is performed as follows:

\[ Y = X_{i-n} - X_{i-r} - c. \]

\( X_i \) to \( y = Y \mod m \). Set \( c \) to 1 if \( Y < 0 \), otherwise set \( c \) to 0.

[Note: This algorithm corresponds to a modular linear function of the form \( TA(x_i) = (a \cdot x_i) \mod b \), where \( b \) is of the form \( m^2 - m^1 + 1 \) and \( a = b - (b-1)/m. \) — end note]

The generation algorithm is given by \( GA(x_i) = y \), where \( y \) is the value produced as a result of advancing the engine’s state as described above.
// constructors and seeding functions
subtract_with_carry_engine() : subtract_with_carry_engine(default_seed) {}
explicit subtract_with_carry_engine(result_type value);
template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
void seed(result_type value = default_seed);
template<class Sseq> void seed(Sseq& q);

// generating functions
result_type operator()();
void discard(unsigned long long z);

The following relations shall hold: 0u < s, s < r, 0 < w, and w <= numeric_limits<UIntType>::digits.
The textual representation consists of the values of \(X_{i-r}, \ldots, X_{i-1}\), in that order, followed by \(c\).

explicit subtract_with_carry_engine(result_type value);
Effects: Constructs a \(\text{subtract\_with\_carry\_engine}\) object. Sets the values of \(X_{i-r}, \ldots, X_{i-1}\), in that order, as specified below. If \(X_{i-1}\) is then 0, sets \(c\) to 1; otherwise sets \(c\) to 0.

To set the values \(X_k\), first construct \(e\), a \(\text{linear\_congruential\_engine}\) object, as if by the following definition:
\[
\text{linear\_congruential\_engine<result\_type, 40014u,0u,2147483563u> e(value == 0u ? default_seed : value)};
\]
Then, to set each \(X_k\), obtain new values \(z_0, \ldots, z_{n-1}\) from \(n = \lceil w/32 \rceil\) successive invocations of \(e\) taken modulo \(2^{32}\). Set \(X_k\) to \(\left(\sum_{j=0}^{n-1} z_j \cdot 2^{32j}\right) \mod m\).

Complexity: Exactly \(n \cdot r\) invocations of \(e\).

template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
Effects: Constructs a \(\text{subtract\_with\_carry\_engine}\) object. With \(k = \lceil w/32 \rceil\) and \(a\) an array (or equivalent) of length \(r \cdot k\), invokes \(q.generate(a,\ r \cdot k)\) and then, iteratively for \(i = -r, \ldots, -1\), sets \(X_i\) to \(\left(\sum_{j=0}^{k-1} a_{k(i+r)+j} \cdot 2^{32j}\right) \mod m\). If \(X_{-1}\) is then 0, sets \(c\) to 1; otherwise sets \(c\) to 0.

26.6.4 Random number engine adaptor class templates

26.6.4.1 In general
Each type instantiated from a class template specified in this subclause 26.6.4 meets the requirements of a random number engine adaptor (26.6.2.5) type.

Except where specified otherwise, the complexity of each function specified in this subclause 26.6.4 is constant.

Except where specified otherwise, no function described in this subclause 26.6.4 throws an exception.

Every function described in this subclause 26.6.4 that has a function parameter \(q\) of type \(\text{Sseq}\) and a template type parameter named \(\text{Sseq}\) that is different from type \(\text{seed\_seq}\) throws what and when the invocation of \(q.generate\) throws.

Descriptions are provided in this subclause 26.6.4 only for adaptor operations that are not described in subclause 26.6.2.5 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

Each template specified in this subclause 26.6.4 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

26.6.4.2 Class template \(\text{discard\_block\_engine}\)
A \(\text{discard\_block\_engine}\) random number engine adaptor produces random numbers selected from those produced by some base engine \(e\). The state \(x_i\) of a \(\text{discard\_block\_engine}\) engine adaptor object \(x\) consists of the state \(e_i\) of its base engine \(e\) and an additional integer \(n\). The size of the state is the size of \(e\)’s state plus 1.
The transition algorithm discards all but \( r > 0 \) values from each block of \( p \geq r \) values delivered by \( e \). The state transition is performed as follows: If \( n \geq r \), advance the state of \( e \) from \( e_i \) to \( e_{i+p-r} \) and set \( n \) to 0. In any case, then increment \( n \) and advance \( e \)'s then-current state \( e_j \) to \( e_{j+1} \).

The generation algorithm yields the value returned by the last invocation of \( e() \) while advancing \( e \)'s state as described above.

```cpp
template<class Engine, size_t p, size_t r>
class discard_block_engine {
public:
   // types
   using result_type = typename Engine::result_type;

   // engine characteristics
   static constexpr size_t block_size = p;
   static constexpr size_t used_block = r;
   static constexpr result_type min() { return Engine::min(); };
   static constexpr result_type max() { return Engine::max(); };

   // constructors and seeding functions
   discard_block_engine();
   explicit discard_block_engine(const Engine& e);
   explicit discard_block_engine(Engine&& e);
   explicit discard_block_engine(result_type s);
   template<class Sseq> explicit discard_block_engine(Sseq& q);
   void seed();
   void seed(result_type s);
   template<class Sseq> void seed(Sseq& q);

   // generating functions
   result_type operator()();
   void discard(unsigned long long z);

   // property functions
   const Engine& base() const noexcept { return e; };

private:
   Engine e; // exposition only
   int n; // exposition only
};
```

The following relations shall hold: \( 0 < r \) and \( r \leq p \).

The textual representation consists of the textual representation of \( e \) followed by the value of \( n \).

In addition to its behavior pursuant to subclause 26.6.2.5, each constructor that is not a copy constructor sets \( n \) to 0.

### 26.6.4.3 Class template independent_bits_engine

An `independent_bits_engine` random number engine adaptor combines random numbers that are produced by some base engine \( e \), so as to produce random numbers with a specified number of bits \( w \). The state \( x_i \) of an `independent_bits_engine` engine adaptor object \( x \) consists of the state \( e_i \) of its base engine \( e \); the size of the state is the size of \( e \)'s state.

The transition and generation algorithms are described in terms of the following integral constants:

1. Let \( R = e \cdot \max() - e \cdot \min() + 1 \) and \( m = \lceil \log_2 R \rceil \).
2. With \( n \) as determined below, let \( w_0 = \lfloor w/n \rfloor, n_0 = n - w \ mod \ n, y_0 = 2^{w_0} \lfloor R/2^{w_0} \rfloor, \) and \( y_1 = 2^{w_0+1} \lceil R/2^{w_0+1} \rceil \).
3. Let \( n = \lceil w/m \rceil \) if and only if the relation \( R - y_0 \leq \lfloor y_0/n \rfloor \) holds as a result. Otherwise let \( n = 1 + \lceil w/m \rceil \).

[Note: The relation \( w = n w_0 + (n - n_0)(w_0 + 1) \) always holds. — end note]

The transition algorithm is carried out by invoking \( e() \) as often as needed to obtain \( n_0 \) values less than \( y_0 + e \cdot \min() \) and \( n - n_0 \) values less than \( y_1 + e \cdot \min() \).
The generation algorithm uses the values produced while advancing the state as described above to yield a quantity $S$ obtained as if by the following algorithm:

$$S = 0;$$

for ($k = 0; k \neq n_0; k \leftarrow 1$) {
  do $u = e() - e\text{.}\text{min}();$ while ($u \geq y_0$);
  $S = 2^{w_0} \cdot S + u \mod 2^{w_0};$
}

for ($k = n_0; k \neq n; k \leftarrow 1$) {
  do $u = e() - e\text{.}\text{min}();$ while ($u \geq y_1$);
  $S = 2^{w_0+1} \cdot S + u \mod 2^{w_0+1};$
}

```cpp
template<class Engine, size_t w, class UIntType>
class independent_bits_engine {
public:
  // types
  using result_type = UIntType;

  // engine characteristics
  static constexpr result_type min() { return 0; }
  static constexpr result_type max() { return 2^w - 1; }

  // constructors and seeding functions
  independent_bits_engine();
  explicit independent_bits_engine(const Engine& e);
  explicit independent_bits_engine(Engine&& e);
  explicit independent_bits_engine(result_type s);
  template<class Sseq> explicit independent_bits_engine(Sseq& q);
  void seed();
  void seed(result_type s);
  template<class Sseq> void seed(Sseq& q);

  // generating functions
  result_type operator()();
  void discard(unsigned long long z);

  // property functions
  const Engine& base() const noexcept { return e; }
};
```

The following relations shall hold: $0 < w$ and $w \leq \text{numeric\_limits<result\_type>::digits}$.

The textual representation consists of the textual representation of $e$.

26.6.4.4 Class template shuffle_order_engine [rand.adapt.shuf]

A `shuffle_order_engine` random number engine adaptor produces the same random numbers that are produced by some base engine $e$, but delivers them in a different sequence. The state $x_i$ of a `shuffle_order_engine` engine adaptor object $x$ consists of the state $e_i$ of its base engine $e$, an additional value $Y$ of the type delivered by $e$, and an additional sequence $V$ of $k$ values also of the type delivered by $e$. The size of the state is the size of $e$’s state plus $k + 1$.

The transition algorithm permutes the values produced by $e$. The state transition is performed as follows:

(2.1) — Calculate an integer $j = \left\lfloor \frac{k(Y - e\text{.}\text{min})}{e\text{.}\text{max} - e\text{.}\text{min} + 1} \right\rfloor$.

(2.2) — Set $Y$ to $V_j$ and then set $V_j$ to $e()$.

The generation algorithm yields the last value of $Y$ produced while advancing $e$’s state as described above.

```cpp
template<class Engine, size_t k>
class shuffle_order_engine {
public:
  // types
  using result_type = typename Engine::result_type;
};
```
// engine characteristics
static constexpr size_t table_size = k;
static constexpr result_type min() { return Engine::min(); }
static constexpr result_type max() { return Engine::max(); }

// constructors and seeding functions
shuffle_order_engine();
explicit shuffle_order_engine(const Engine& e);
explicit shuffle_order_engine(Engine&& e);
explicit shuffle_order_engine(result_type s);
template<class Sseq> explicit shuffle_order_engine(Sseq& q);
void seed();
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; }
private:
Engine e;  // exposition only
result_type V[k];  // exposition only
result_type Y;  // exposition only
};

The following relation shall hold: 0 < k.
The textual representation consists of the textual representation of e, followed by the k values of V, followed by the value of Y.
In addition to its behavior pursuant to subclause 26.6.2.5, each constructor that is not a copy constructor initializes V[0],...,V[k-1] and Y, in that order, with values returned by successive invocations of e().

26.6.5 Engines and engine adaptors with predefined parameters

using minstd_rand0 =
linear_congruential_engine<uint_fast32_t, 16807, 0, 2147483647>;

1 Required behavior: The 10000th consecutive invocation of a default-constructed object of type minstd_rand0 shall produce the value 1043618065.

using minstd_rand =
linear_congruential_engine<uint_fast32_t, 48271, 0, 2147483647>;

2 Required behavior: The 10000th consecutive invocation of a default-constructed object of type minstd_rand shall produce the value 399268537.

using mt19937 =
mersenne_twister_engine<uint_fast32_t,
32,624,397,31,0x9908b0df,11,0xffffffff,7,0x9d2c5680,.15,0xefc60000,18,1812433253>;

3 Required behavior: The 10000th consecutive invocation of a default-constructed object of type mt19937 shall produce the value 4123659995.

using mt19937_64 =
mersenne_twister_engine<uint_fast64_t,
64,312,156,31,0xb5026f5aa96619e9,29,
0x5555555555555555,17,
0x71d67fffeda60000,37,
0xffffffff00000000,43,
636413622846793005>;

4 Required behavior: The 10000th consecutive invocation of a default-constructed object of type mt19937_64 shall produce the value 9981545732273789042.
using ranlux24_base = subtract_with_carry_engine<uint_fast32_t, 24, 10, 24>;

5 Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux24_base shall produce the value 7937952.

using ranlux48_base = subtract_with_carry_engine<uint_fast64_t, 48, 5, 12>;

6 Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux48_base shall produce the value 61839128582725.

using ranlux24 = discard_block_engine<ranlux24_base, 223, 23>;

7 Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux24 shall produce the value 9901578.

using ranlux48 = discard_block_engine<ranlux48_base, 389, 11>;

8 Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux48 shall produce the value 249142670248501.

using knuth_b = shuffle_order_engine<minstd_rand0,256>;

9 Required behavior: The 10000th consecutive invocation of a default-constructed object of type knuth_b shall produce the value 1112339016.

using default_random_engine = implementation-defined;

10 Remarks: The choice of engine type named by this typedef is implementation-defined. [Note: The implementation may select this type on the basis of performance, size, quality, or any combination of such factors, so as to provide at least acceptable engine behavior for relatively casual, inexpert, and/or lightweight use. Because different implementations may select different underlying engine types, code that uses this typedef need not generate identical sequences across implementations. — end note]

26.6.6 Class random_device [rand.device]

1 A random_device uniform random bit generator produces nondeterministic random numbers.

2 If implementation limitations prevent generating nondeterministic random numbers, the implementation may employ a random number engine.

```cpp
class random_device {
  public:
    // types
    using result_type = unsigned int;

    // generator characteristics
    static constexpr result_type min() { return numeric_limits<result_type>::min(); } 
    static constexpr result_type max() { return numeric_limits<result_type>::max(); }

    // constructors
    random_device() : random_device(implementation-defined) {}
    explicit random_device(const string& token);

    // generating functions
    result_type operator()();

    // property functions
    double entropy() const noexcept;

    // no copy functions
    random_device(const random_device&) = delete;
    void operator=(const random_device&) = delete;
};
```
explicit random_device(const string& token);

3 Effects: Constructs a random_device nondeterministic uniform random bit generator object. The semantics of the token parameter and the token value used by the default constructor are implementation-defined.²⁴⁸

4 Throws: A value of an implementation-defined type derived from exception if the random_device could not be initialized.

double entropy() const noexcept;

5 Returns: If the implementation employs a random number engine, returns 0.0. Otherwise, returns an entropy estimate²⁴⁹ for the random numbers returned by operator(), in the range min() to log₂(max() + 1).

result_type operator()();

6 Returns: A nondeterministic random value, uniformly distributed between min() and max() (inclusive). It is implementation-defined how these values are generated.

7 Throws: A value of an implementation-defined type derived from exception if a random number could not be obtained.

26.6.7 Utilities [rand.util]

26.6.7.1 Class seed_seq [rand.util.seedseq]

class seed_seq {
  public:
    // types
    using result_type = uint_least32_t;

    // constructors
    seed_seq();
    template<class T>
    seed_seq(initializer_list<T> il);
    template<class InputIterator>
    seed_seq(InputIterator begin, InputIterator end);

    // generating functions
    template<class RandomAccessIterator>
    void generate(RandomAccessIterator begin, RandomAccessIterator end);

    // property functions
    size_t size() const noexcept;
    template<class OutputIterator>
    void param(OutputIterator dest) const;

    // no copy functions
    seed_seq(const seed_seq&) = delete;
    void operator=(const seed_seq&) = delete;

    private:
    vector<result_type> v; // exposition only
};

seed_seq();

1 Effects: Constructs a seed_seq object as if by default-constructing its member v.

2.Throws: Nothing.

template<class T>
seed_seq(initializer_list<T> il);

3 Requires: T shall be an integer type.

²⁴⁸ The parameter is intended to allow an implementation to differentiate between different sources of randomness.

²⁴⁹ If a device has n states whose respective probabilities are P₀,...,Pₙ₋₁, the device entropy S is defined as

\[ S = - \sum_{i=0}^{n-1} P_i \cdot \log P_i. \]
Effects: Same as seed_seq(il.begin(), il.end()).

```cpp
template<class InputIterator>
void seed_seq(InputIterator begin, InputIterator end);
```

Requires: InputIterator shall meet the Cpp17InputIterator requirements \((23.3.5.2)\). Moreover, iterator_traits<InputIterator>::value_type shall denote an integer type.

Effects: Constructs a seed_seq object by the following algorithm:

```cpp
for (InputIterator s = begin; s != end; ++s)
    v.push_back((s)\%mod2^{32});
```

```cpp
template<class RandomAccessIterator>
void generate(RandomAccessIterator begin, RandomAccessIterator end);
```

Requires: RandomAccessIterator shall meet the Cpp17RandomAccessIterator requirements \((23.3.5.6)\) and the requirements of a mutable iterator. Moreover, iterator_traits<RandomAccessIterator>::value_type shall denote an unsigned integer type capable of accommodating 32-bit quantities.

Effects: Does nothing if begin == end. Otherwise, with \(s = v.size()\) and \(n = end - begin\), fills the supplied range \([begin, end)\) according to the following algorithm in which each operation is to be carried out modulo \(2^{32}\), each indexing operator applied to begin is to be taken modulo \(n\), and \(T(x)\) is defined as \(x \text{ xor } (x \text{ shift } 27)\):

(8.1) — By way of initialization, set each element of the range to the value 0x8b8b8b8b. Additionally, for use in subsequent steps, let \(p = (n - t)/2\) and let \(q = p + t\), where

\[
t = (n \geq 623) ? 11 : (n \geq 68) \Rightarrow 7 : (n \geq 39) ? 5 : (n \geq 7) \Rightarrow 3 : (n - 1)/2;
\]

(8.2) — With \(m\) as the larger of \(s + 1\) and \(n\), transform the elements of the range: iteratively for \(k = 0, \ldots, m - 1\), calculate values

\[
\begin{align*}
    r_1 &= 1664525 \cdot T(begin[k] \text{ xor } begin[k + p] \text{ xor } begin[k - 1]) \\
    r_2 &= r_1 + \begin{cases} 
        s & , k = 0 \\
        k \mod n + v[k - 1] & , 0 < k \leq s \\
        k \mod n & , s < k
    \end{cases}
\end{align*}
\]

and, in order, increment begin[k+p] by r1, increment begin[k+q] by r2, and set begin[k] to r2.

(8.3) — Transform the elements of the range again, beginning where the previous step ended: iteratively for \(k = m, \ldots, m + n - 1\), calculate values

\[
\begin{align*}
    r_3 &= 1566083941 \cdot T(begin[k] + begin[k + p] + begin[k - 1]) \\
    r_4 &= r_3 - (k \mod n)
\end{align*}
\]

and, in order, update begin[k+p] by xoring it with r3, update begin[k+q] by xoring it with r4, and set begin[k] to r4.

Throws: What and when RandomAccessIterator operations of begin and end throw.

```cpp
size_t size() const noexcept;
```

Returns: The number of 32-bit units that would be returned by a call to param().

Complexity: Constant time.

```cpp
template<class OutputIterator>
void param(OutputIterator dest) const;
```

Requires: OutputIterator shall meet the Cpp17OutputIterator requirements \((23.3.5.3)\). Moreover, the expression \(*dest = rt\) shall be valid for a value rt of type result_type.

Effects: Copies the sequence of prepared 32-bit units to the given destination, as if by executing the following statement:

```cpp
copy(v.begin(), v.end(), dest);
```

Throws: What and when OutputIterator operations of dest throw.
26.6.7.2 Function template generate_canonical

Each function instantiated from the template described in this subclause 26.6.7.2 maps the result of one or more invocations of a supplied uniform random bit generator \( g \) to one member of the specified \( \text{RealType} \), such that, if the values \( g_i \) produced by \( g \) are uniformly distributed, the instantiation’s results \( t_j, 0 \leq t_j < 1 \), are distributed as uniformly as possible as specified below.

[Note: Obtaining a value in this way can be a useful step in the process of transforming a value generated by a uniform random bit generator into a value that can be delivered by a random number distribution. — end note]

```cpp
template<class RealType, size_t bits, class URBG>
RealType generate_canonical(URBG& g);
```

Complexity: Exactly \( k = \max(1, \lceil b/\log_2 R \rceil) \) invocations of \( g \), where \( b^{250} \) is the lesser of \( \text{numeric_limits<RealType>::digits} \) and \( \text{bits} \), and \( R \) is the value of \( g.\text{max}()-g.\text{min}()+1 \).

Effects: Invokes \( g() \) \( k \) times to obtain values \( g_0, \ldots, g_{k-1} \), respectively. Calculates a quantity

\[
S = \sum_{i=0}^{k-1} (g_i - g.\text{min}()) \cdot R^i
\]

using arithmetic of type \( \text{RealType} \).

Returns: \( S/R^k \).

Throws: What and when \( g \) throws.

26.6.8 Random number distribution class templates

26.6.8.1 In general

Each type instantiated from a class template specified in this subclause 26.6.8 meets the requirements of a random number distribution (26.6.2.6) type.

Descriptions are provided in this subclause 26.6.8 only for distribution operations that are not described in 26.6.2.6 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

The algorithms for producing each of the specified distributions are implementation-defined.

The value of each probability density function \( p(z) \) and of each discrete probability function \( P(z_i) \) specified in this subclause is 0 everywhere outside its stated domain.

26.6.8.2 Uniform distributions

26.6.8.2.1 Class template uniform_int_distribution

A \( \text{uniform_int_distribution} \) random number distribution produces random integers \( i, a \leq i \leq b \), distributed according to the constant discrete probability function

\[
P(i|a,b) = 1/(b-a+1).
\]

```cpp
template<class IntType = int>
class uniform_int_distribution {
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructors and reset functions
    uniform_int_distribution() : uniform_int_distribution(0) {}
    explicit uniform_int_distribution(IntType a, IntType b = numeric_limits<IntType>::max());
    explicit uniform_int_distribution(const param_type& parm);
    void reset();
}
```

\( b^{250} \) \( b \) is introduced to avoid any attempt to produce more bits of randomness than can be held in \( \text{RealType} \).

§ 26.6.8.2.1 1123
A \texttt{uniform_int_distribution} random number distribution produces random numbers \( x \), \( a \leq x < b \), distributed according to the constant probability density function

\[ p(x | a,b) = \frac{1}{b - a} . \]

[\text{Note: This implies that } p(x | a, b) \text{ is undefined when } a == b. — end note]

\[
\begin{align*}
\text{template<typename RealType = double>}
\text{class uniform_real_distribution}
\text{ { }
\text{public:}
\text{using result_type = RealType;}
\text{using param_type = unspecified;}
\text{uniform_real_distribution() : uniform_real_distribution(0.0) {}}
\text{explicit uniform_real_distribution(RealType a, RealType b = 1.0);} \\
\text{explicit uniform_real_distribution(const param_type& parm);} \\
\text{void reset();}
\text{}}
\end{align*}
\]
explicit uniform_real_distribution(RealType a, RealType b = 1.0);

Requires: \(a \leq b\) and \(b - a \leq \text{numeric_limits<RealType>::max()}\).
Effects: Constructs a \texttt{uniform_real_distribution} object; \(a\) and \(b\) correspond to the respective parameters of the distribution.

result_type a() const;
Returns: The value of the \(a\) parameter with which the object was constructed.

result_type b() const;
Returns: The value of the \(b\) parameter with which the object was constructed.

26.6.8.3 Bernoulli distributions
26.6.8.3.1 Class bernoulli_distribution

A \texttt{bernoulli_distribution} random number distribution produces \texttt{bool} values \(b\) distributed according to the discrete probability function

\[
P(b | p) = \begin{cases} 
    p & \text{if } b = \text{true}, \\
    1 - p & \text{if } b = \text{false}.
\end{cases}
\]

class bernoulli_distribution {
public:
    // types
    using result_type = bool;
    using param_type = unspecified;

    // constructors and reset functions
    bernoulli_distribution() : bernoulli_distribution(0.5) {} // bernoulli_distribution(0.5) {}
    explicit bernoulli_distribution(double p);
    explicit bernoulli_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    double p() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};

explicit bernoulli_distribution(double p);

Requires: \(0 \leq p \leq 1\).
Effects: Constructs a \texttt{bernoulli_distribution} object; \(p\) corresponds to the parameter of the distribution.

double p() const;
Returns: The value of the \(p\) parameter with which the object was constructed.

26.6.8.3.2 Class template binomial_distribution

A \texttt{binomial_distribution} random number distribution produces integer values \(i \geq 0\) distributed according to the discrete probability function

\[
P(i | t, p) = \binom{t}{i} \cdot p^i \cdot (1 - p)^{t-i}.
\]
template<class IntType = int>
class binomial_distribution {
public:
  // types
  using result_type = IntType;
  using param_type = unspecified;
  // constructors and reset functions
  binomial_distribution() : binomial_distribution(1) {}
  explicit binomial_distribution(IntType t, double p = 0.5);
  explicit binomial_distribution(const param_type& parm);
  void reset();
  // generating functions
  template<class URBG>
  result_type operator()(URBG& g);
  template<class URBG>
  result_type operator()(URBG& g, const param_type& parm);
  // property functions
  IntType t() const;
  double p() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
};

explicit binomial_distribution(IntType t, double p = 0.5);

Requires: $0 \leq p \leq 1$ and $0 \leq t$.

Effects: Constructs a binomial_distribution object; $t$ and $p$ correspond to the respective parameters of the distribution.

IntType t() const;

Returns: The value of the $t$ parameter with which the object was constructed.

double p() const;

Returns: The value of the $p$ parameter with which the object was constructed.

26.6.8.3.3 Class template geometric_distribution

A geometric_distribution random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function

$$P(i \mid p) = p \cdot (1 - p)^i.$$
explicit geometric_distribution(double p);  

2 Requires: 0 < p < 1.
3 Effects: Constructs a geometric_distribution object; p corresponds to the parameter of the distribution.

double p() const;
4 Returns: The value of the p parameter with which the object was constructed.

26.6.8.3.4 Class template negative_binomial_distribution [rand.dist.bern.negbin]

1 A negative_binomial_distribution random number distribution produces random integers i ≥ 0 distributed according to the discrete probability function

\[ P(i | k, p) = \binom{k+i-1}{i} \cdot p^k \cdot (1-p)^i. \]

[Note: This implies that P(i | k, p) is undefined when \( p == 1 \). — end note]

template<class IntType = int>  
class negative_binomial_distribution {
public:
  // types
  using result_type = IntType;
  using param_type = unspecified;

  // constructor and reset functions
  negative_binomial_distribution() : negative_binomial_distribution(1) {}  
  explicit negative_binomial_distribution(IntType k, double p = 0.5);
  explicit negative_binomial_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URBG>
  result_type operator()(URBG& g);
  template<class URBG>
  result_type operator()(URBG& g, const param_type& parm);

  // property functions
  IntType k() const;
  double p() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
};

explicit negative_binomial_distribution(IntType k, double p = 0.5);

2 Requires: 0 < p ≤ 1 and 0 < k.
3 Effects: Constructs a negative_binomial_distribution object; k and p correspond to the respective parameters of the distribution.

IntType k() const;
4 Returns: The value of the k parameter with which the object was constructed.
double p() const;

Returns: The value of the p parameter with which the object was constructed.

26.6.8.4 Poisson distributions

26.6.8.4.1 Class template poisson_distribution

A poisson_distribution random number distribution produces integer values \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i|\mu) = \frac{e^{-\mu} \mu^i}{i!}.
\]

The distribution parameter \( \mu \) is also known as this distribution’s mean.

template<class IntType = int>
class poisson_distribution
{
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructors and reset functions
    poisson_distribution() : poisson_distribution(1.0) {};
    explicit poisson_distribution(double mean);
    explicit poisson_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    double mean() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};

explicit poisson_distribution(double mean);

Requires: \( 0 < \text{mean} \).

Effects: Constructs a poisson_distribution object; mean corresponds to the parameter of the distribution.

double mean() const;

Returns: The value of the mean parameter with which the object was constructed.

26.6.8.4.2 Class template exponential_distribution

An exponential_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x|\lambda) = \lambda e^{-\lambda x}.
\]

template<class RealType = double>
class exponential_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;
}
// constructors and reset functions
exponential_distribution() : exponential_distribution(1.0) {}
explicit exponential_distribution(RealType lambda);
exponential_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType lambda() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

explicit exponential_distribution(RealType lambda);

Requires: 0 < lambda.
Effects: Constructs an exponential_distribution object; lambda corresponds to the parameter of
the distribution.

RealType lambda() const;
Returns: The value of the lambda parameter with which the object was constructed.

26.6.8.4.3 Class template gamma_distribution
A gamma_distribution random number distribution produces random numbers $x > 0$ distributed according
to the probability density function

$$p(x | \alpha, \beta) = \frac{e^{-x/\beta}}{\beta^\alpha \cdot \Gamma(\alpha)} \cdot x^{\alpha - 1}.$$
explicit gamma_distribution(RealType alpha, RealType beta = 1.0);

Requires: \(0 < \alpha\) and \(0 < \beta\).

Effects: Constructs a \texttt{gamma_distribution} object; \(\alpha\) and \(\beta\) correspond to the parameters of the distribution.

RealType alpha() const;

Returns: The value of the \(\alpha\) parameter with which the object was constructed.

RealType beta() const;

Returns: The value of the \(\beta\) parameter with which the object was constructed.

26.6.8.4.4 Class template \texttt{weibull_distribution} \[\texttt{rand.dist.pois.weibull}\]

A \texttt{weibull_distribution} random number distribution produces random numbers \(x \geq 0\) distributed according to the probability density function

\[
p(x | \alpha, \beta) = \frac{\alpha}{\beta} \left( \frac{x}{\beta} \right)^{\alpha-1} \exp \left( -\left( \frac{x}{\beta} \right)^{\alpha} \right).
\]

template<class RealType = double>
class weibull_distribution {
public:
// types
using result_type = RealType;
using param_type = unspecified;

// constructor and reset functions
weibull_distribution(); weibull_distribution(1.0) {};
explicit weibull_distribution(RealType a, RealType b = 1.0);
explicit weibull_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType a() const;
RealType b() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

explicit weibull_distribution(RealType a, RealType b = 1.0);

Requires: \(0 < a\) and \(0 < b\).

Effects: Constructs a \texttt{weibull_distribution} object; \(a\) and \(b\) correspond to the respective parameters of the distribution.

RealType a() const;

Returns: The value of the \(a\) parameter with which the object was constructed.

RealType b() const;

Returns: The value of the \(b\) parameter with which the object was constructed.
26.6.8.4.5 Class template extreme_value_distribution

An extreme_value_distribution random number distribution produces random numbers \( x \) distributed according to the probability density function:

\[
p(x \mid a, b) = \frac{1}{b} \cdot \exp \left( \frac{a - x}{b} - \exp \left( \frac{a - x}{b} \right) \right).
\]

```cpp
// 26.6.8.4.5 1
template<
    class RealType = double
>
class extreme_value_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    extreme_value_distribution() : extreme_value_distribution(0.0) {}
    explicit extreme_value_distribution(RealType a, RealType b = 1.0);
    explicit extreme_value_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType a() const;
    RealType b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

explicit extreme_value_distribution(RealType a, RealType b = 1.0);

2 Requires: \( 0 < b \).
3 Effects: Constructs an extreme_value_distribution object; \( a \) and \( b \) correspond to the respective parameters of the distribution.

RealType a() const;
4 Returns: The value of the \( a \) parameter with which the object was constructed.

RealType b() const;
5 Returns: The value of the \( b \) parameter with which the object was constructed.

26.6.8.5 Normal distributions

26.6.8.5.1 Class template normal_distribution

A normal_distribution random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x \mid \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \cdot \exp \left( -\frac{(x - \mu)^2}{2\sigma^2} \right).
\]

The distribution parameters \( \mu \) and \( \sigma \) are also known as this distribution’s mean and standard deviation.

```cpp
// 26.6.8.5.1 1
template<class RealType = double>
class normal_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    normal_distribution() : normal_distribution(0.0) {}
    explicit normal_distribution(RealType mu, RealType sigma);
    explicit normal_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType mean() const;
    RealType stddev() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

explicit normal_distribution(RealType µ, RealType σ = 1.0);

§ 26.6.8.5.1 1131

251) The distribution corresponding to this probability density function is also known (with a possible change of variable) as the Gumbel Type I, the log-Weibull, or the Fisher-Tippett Type I distribution.
using param_type = unspecified;

// constructors and reset functions
normal_distribution() : normal_distribution(0.0) {}  
explicit normal_distribution(RealType mean, RealType stddev = 1.0);  
explicit normal_distribution(const param_type& parm);  
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType mean() const;
RealType stddev() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

explicit normal_distribution(RealType mean, RealType stddev = 1.0);

Requires: 0 < stddev.
Effects: Constructs a normal_distribution object; mean and stddev correspond to the respective parameters of the distribution.

RealType mean() const;
Returns: The value of the mean parameter with which the object was constructed.

RealType stddev() const;
Returns: The value of the stddev parameter with which the object was constructed.

26.6.8.5.2 Class template lognormal_distribution [rand.dist.norm.lognormal]

A lognormal_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x | m, s) = \frac{1}{sx\sqrt{2\pi}} \cdot \exp \left( -\frac{(\ln x - m)^2}{2s^2} \right).
\]

template<class RealType = double>
class lognormal_distribution {
    public:
        using result_type = RealType;
        using param_type = unspecified;

        // constructors and reset functions
        lognormal_distribution() : lognormal_distribution(0.0) {}  
        explicit lognormal_distribution(RealType m, RealType s = 1.0);  
        explicit lognormal_distribution(const param_type& parm);  
        void reset();

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);
// property functions
RealType m() const;
RealType s() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

explicit lognormal_distribution(RealType m, RealType s = 1.0);

Requires: 0 < s.
Effects: Constructs a lognormal_distribution object; m and s correspond to the respective parameters of the distribution.

RealType m() const;
Returns: The value of the m parameter with which the object was constructed.

RealType s() const;
Returns: The value of the s parameter with which the object was constructed.

26.6.8.5.3 Class template chi_squared_distribution [rand.dist.norm.chisq]
A chi_squared_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x \mid n) = \frac{x^{(n/2) - 1} \cdot e^{-x/2}}{\Gamma(n/2) \cdot 2^{n/2}}.
\]

template<class RealType = double>
class chi_squared_distribution {
  public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    chi_squared_distribution() : chi_squared_distribution(1) {}
    explicit chi_squared_distribution(RealType n);
    explicit chi_squared_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType n() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};

explicit chi_squared_distribution(RealType n);

Requires: 0 < n.
Effects: Constructs a chi_squared_distribution object; n corresponds to the parameter of the distribution.

RealType n() const;
Returns: The value of the n parameter with which the object was constructed.
26.6.8.5.4 Class template cauchy_distribution

A `cauchy_distribution` random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x | a, b) = \left( \pi b \left(1 + \left( \frac{x - a}{b} \right)^2 \right) \right)^{-1}.
\]

```cpp
template<class RealType = double>
class cauchy_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    cauchy_distribution() : cauchy_distribution(0.0) {} // constructor
    explicit cauchy_distribution(RealType a, RealType b = 1.0);
    explicit cauchy_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType a() const;
    RealType b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

2

Requires: \( 0 < b \).

Effects: Constructs a `cauchy_distribution` object; \( a \) and \( b \) correspond to the respective parameters of the distribution.

RealType a() const;

Returns: The value of the \( a \) parameter with which the object was constructed.

RealType b() const;

Returns: The value of the \( b \) parameter with which the object was constructed.

26.6.8.5.5 Class template fisher_f_distribution

A `fisher_f_distribution` random number distribution produces random numbers \( x \geq 0 \) distributed according to the probability density function

\[
p(x | m, n) = \frac{\Gamma((m + n)/2)}{\Gamma(m/2) \Gamma(n/2)} \cdot \left( \frac{m}{n} \right)^{m/2} \cdot x^{(m/2)-1} \cdot \left( 1 + \frac{m x}{n} \right)^{-(m+n)/2}.
\]

```cpp
template<class RealType = double>
class fisher_f_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;
```
1135

// constructor and reset functions
fisher_f_distribution() : fisher_f_distribution(1) {}
explicit fisher_f_distribution(RealType m, RealType n = 1);
explicit fisher_f_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType m() const;
RealType n() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

explicit fisher_f_distribution(RealType m, RealType n = 1);

2 Requires: 0 < m and 0 < n.
3 Effects: Constructs a fisher_f_distribution object; m and n correspond to the respective parameters of the distribution.

RealType m() const;
4 Returns: The value of the m parameter with which the object was constructed.

RealType n() const;
5 Returns: The value of the n parameter with which the object was constructed.

26.6.8.5.6 Class template student_t_distribution [rand.dist.norm.t]
A student_t_distribution random number distribution produces random numbers x distributed according to the probability density function

\[ p(x | n) = \frac{1}{\sqrt{n\pi}} \frac{\Gamma((n + 1)/2)}{\Gamma(n/2)} \left( 1 + \frac{x^2}{n} \right)^{-(n+1)/2} \]

template<class RealType = double>
class student_t_distribution { public:

// types
using result_type = RealType;
using param_type = unspecified;

// constructor and reset functions
student_t_distribution() : student_t_distribution(1) {}
explicit student_t_distribution(RealType n);
explicit student_t_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType n() const;
param_type param() const;
void param(const param_type& parm);
\begin{verbatim}
result_type min() const;
result_type max() const;

explicit student_t_distribution(RealType n);

2 Requires: 0 < n.
3 Effects: Constructs a student_t_distribution object; n corresponds to the parameter of the distribution.

RealType n() const;
4 Returns: The value of the n parameter with which the object was constructed.

26.6.8.6  Sampling distributions  [rand.dist.samp]
26.6.8.6.1  Class template discrete_distribution  [rand.dist.samp.discrete]
1 A discrete_distribution random number distribution produces random integers \(i, 0 \leq i < n\), distributed according to the discrete probability function
\[
P(i | p_0, \ldots, p_{n-1}) = p_i.
\]
2 Unless specified otherwise, the distribution parameters are calculated as: \(p_k = w_k / S\) for \(k = 0, \ldots, n - 1\), in which the values \(w_k\), commonly known as the weights, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: \(0 < S = w_0 + \cdots + w_{n-1}\).

template<class IntType = int>
class discrete_distribution {
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructor and reset functions
    discrete_distribution();
    template<class InputIterator>
        discrete_distribution(InputIterator firstW, InputIterator lastW);
    discrete_distribution(initializer_list<double> wL);
    template<class UnaryOperation>
        discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);
    explicit discrete_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
        result_type operator()(URBG& g);
    template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

    // property functions
    vector<double> probabilities() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};

discrete_distribution();
3 Effects: Constructs a discrete_distribution object with \(n = 1\) and \(p_0 = 1\). [Note: Such an object will always deliver the value 0. — end note]

template<class InputIterator>
    discrete_distribution(InputIterator firstW, InputIterator lastW);
4 Requires: InputIterator shall meet the C++17InputIterator requirements (23.3.5.2). Moreover, iterator_traits<InputIterator>::value_type shall denote a type that is convertible to double.

\end{verbatim}
If firstW == lastW, let n = 1 and w0 = 1. Otherwise, [firstW, lastW) shall form a sequence w of length n > 0.

Effects: Constructs a discrete_distribution object with probabilities given by the formula above.

discrete_distribution(initializer_list<double> wl);

Effects: Same as discrete_distribution(wl.begin(), wl.end()).

template<class UnaryOperation>

discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (20.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation’s sole parameter. If nw = 0, let n = 1, otherwise let n = nw. The relation 0 < δ = (xmax − xmin)/n shall hold.

Effects: Constructs a discrete_distribution object with probabilities given by the formula above, using the following values: If nw = 0, let w0 = 1. Otherwise, let wk = fw(xmin + k · δ + δ/2) for k = 0,...,n − 1.

Complexity: The number of invocations of fw shall not exceed n.

vector<double> probabilities() const;

Returns: A vector<double> whose size member returns n and whose operator[] member returns pk when invoked with argument k for k = 0,...,n − 1.

26.6.8.6.2 Class template piecewise_constant_distribution [rand.dist.samp.pconst]

A piecewise_constant_distribution random number distribution produces random numbers x, b0 ≤ x < bn, uniformly distributed over each subinterval [bi, bi+1) according to the probability density function

\[ p(x | b_0, \ldots, b_n, \rho_0, \ldots, \rho_{n-1}) = \rho_i, \text{ for } b_i \leq x < b_{i+1}, \]

The n + 1 distribution parameters bi, also known as this distribution’s interval boundaries, shall satisfy the relation bi < bi+1 for i = 0,...,n − 1. Unless specified otherwise, the remaining n distribution parameters are calculated as:

\[ \rho_k = \frac{w_k}{S - (b_{k+1} - b_k)} \text{ for } k = 0,...,n - 1, \]

in which the values wk, commonly known as the weights, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: 0 < S = w0 + ··· + wn−1.

template<class RealType = double>

class piecewise_constant_distribution {

public:

// types
using result_type = RealType;
using param_type = unspecified;

// constructor and reset functions
piecewise_constant_distribution();
template<class InputIteratorB, class InputIteratorW>
piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB, InputIteratorW firstW);
template<class UnaryOperation>
piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);
template<class UnaryOperation>
piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
explicit piecewise_constant_distribution(const param_type& parm);
void reset();

// generating functions
template<URBG>
result_type operator()(URBG& g);
template<URBG>
result_type operator()(URBG& g, const param_type& parm);
// property functions
vector<result_type> intervals() const;
vector<result_type> densities() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

piecewise_constant_distribution();

Effects: Constructs a piecewise_constant_distribution object with n = 1, \( \rho_0 = 1 \), \( b_0 = 0 \), and \( b_1 = 1 \).

template<class InputIteratorB, class InputIteratorW>
piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
                               InputIteratorW firstW);

Requires: InputIteratorB and InputIteratorW shall each meet the C++17InputIterator requirements (23.3.5.2). Moreover, the id-expressions iterator_traits<InputIteratorB>::value_type and iterator_traits<InputIteratorW>::value_type shall each denote a type that is convertible to double. If firstB == lastB or ++firstB == lastB, let \( n = 1 \), \( w_0 = 1 \), \( b_0 = 0 \), and \( b_1 = 1 \). Otherwise, \([firstB, lastB)\) shall form a sequence \( b \) of length \( n + 1 \), the length of the sequence \( w \) starting from firstW shall be at least \( n \), and any \( w_k \) for \( k \geq n \) shall be ignored by the distribution.

Effects: Constructs a piecewise_constant_distribution object with parameters as specified above.

template<class UnaryOperation>
piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (20.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation’s sole parameter.

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: If bl.size() < 2, let \( n = 1 \), \( w_0 = 1 \), \( b_0 = 0 \), and \( b_1 = 1 \). Otherwise, let \([bl.begin(), bl.end())\) form a sequence \( b_0, \ldots, b_n \), and let \( w_k = fw((b_{k+1} + b_k)/2) \) for \( k = 0, \ldots, n - 1 \).

Complexity: The number of invocations of \( fw \) shall not exceed \( n \).

template<class UnaryOperation>
.piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (20.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation’s sole parameter. If \( nw = 0 \), let \( n = 1 \), otherwise let \( n = nw \). The relation \( 0 < \delta = (xmax - xmin)/n \) shall hold.

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: Let \( b_k = xmin + k \cdot \delta \) for \( k = 0, \ldots, n \), and \( w_k = fw(b_k + \delta/2) \) for \( k = 0, \ldots, n - 1 \).

Complexity: The number of invocations of \( fw \) shall not exceed \( n \).

vector<result_type> intervals() const;

Returns: A vector<result_type> whose size member returns \( n + 1 \) and whose operator[] member returns \( b_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n \).

vector<result_type> densities() const;

Returns: A vector<result_type> whose size member returns \( n \) and whose operator[] member returns \( \rho_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n - 1 \).

26.6.8.6.3 Class template piecewise_linear_distribution [rand.dist.samp.plinear]

A piecewise_linear_distribution random number distribution produces random numbers \( x, b_0 \leq x < b_n \), distributed over each subinterval \([b_i, b_{i+1})\) according to the probability density function

\[
p(x | b_0, \ldots, b_n, \rho_0, \ldots, \rho_n) = \rho_i \frac{b_{i+1} - x}{b_{i+1} - b_i} + \rho_{i+1} \frac{x - b_i}{b_{i+1} - b_i}, \text{ for } b_i \leq x < b_{i+1}.
\]
The \( n + 1 \) distribution parameters \( b_i \), also known as this distribution's *interval boundaries*, shall satisfy the relation \( b_i < b_{i+1} \) for \( i = 0, \ldots, n - 1 \). Unless specified otherwise, the remaining \( n + 1 \) distribution parameters are calculated as \( \rho_k = w_k / S \) for \( k = 0, \ldots, n \), in which the values \( w_k \), commonly known as the *weights at boundaries*, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold:

\[
0 < S = \frac{1}{2} \sum_{k=0}^{n-1} (w_k + w_{k+1}) \cdot (b_{k+1} - b_k).
\]

### Template Class `piecewise_linear_distribution`

```cpp
template<class RealType = double>
class piecewise_linear_distribution {
  public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    piecewise_linear_distribution();
    template<class InputIteratorB, class InputIteratorW>
      piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
          InputIteratorW firstW);
    template<class UnaryOperation>
      piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);
    template<class UnaryOperation>
      piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
    explicit piecewise_linear_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
      result_type operator()(URBG& g);
    template<class URBG>
      result_type operator()(URBG& g, const param_type& parm);

    // property functions
    vector<result_type> intervals() const;
    vector<result_type> densities() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
  }

piecewise_linear_distribution();
```

### Effects

- **Template Class `piecewise_linear_distribution`**

  - **Constructs a `piecewise_linear_distribution` object with \( n = 1 \), \( \rho_0 = \rho_1 = 1 \), \( b_0 = 0 \), and \( b_1 = 1 \).**

### Requires

- **InputIteratorB** and **InputIteratorW** shall each meet the C++17 `InputIterator` requirements (23.3.5.2). Moreover, the id-expressions `iterator_traits<InputIteratorB>::value_type` and `iterator_traits<InputIteratorW>::value_type` shall each denote a type that is convertible to `double`. If `firstB == lastB` or `++firstB == lastB`, let \( n = 1 \), \( \rho_0 = \rho_1 = 1 \), \( b_0 = 0 \), and \( b_1 = 1 \). Otherwise, \([\text{firstB, lastB}]\) shall form a sequence \( b \) of length \( n + 1 \), the length of the sequence \( w \) starting from \( \text{firstW} \) shall be at least \( n + 1 \), and any \( w_k \) for \( k \geq n + 1 \) shall be ignored by the distribution.

### Effects

- **Constructs a `piecewise_linear_distribution` object with parameters as specified above.**
template<class UnaryOperation>
piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (20.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation’s sole parameter.

Effects: Constructs a piecewise_linear_distribution object with parameters taken or calculated from the following values: Let \( n = nw \), \( \rho_k = xmin + k \cdot \delta \) for \( k = 0, \ldots, n \), and \( w_k = fw(b_k) \) for \( k = 0, \ldots, n \).

Complexity: The number of invocations of \( fw \) shall not exceed \( n + 1 \).

vector<result_type> intervals() const;

Returns: A vector<result_type> whose size member returns \( n + 1 \) and whose operator[] member returns \( b_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n \).

vector<result_type> densities() const;

Returns: A vector<result_type> whose size member returns \( n \) and whose operator[] member returns \( \rho_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n \).

26.6.9 Low-quality random number generation [c.math.rand]

[Note: The header <cstdlib> (17.2.2) declares the functions described in this subclause. — end note]

int rand();
void srand(unsigned int seed);

Effects: The rand and srand functions have the semantics specified in the C standard library.

Remarks: The implementation may specify that particular library functions may call rand. It is implementation-defined whether the rand function may introduce data races (16.5.5.9). [Note: The other random number generation facilities in this document (26.6) are often preferable to rand, because rand’s underlying algorithm is unspecified. Use of rand therefore continues to be non-portable, with unpredictable and oft-questionable quality and performance. — end note]

template<class T> valarray<T> tanh (const valarray<T>&);

template<class T> unspecified1 begin(valarray<T>& v);
template<class T> unspecified2 begin(const valarray<T>& v);
template<class T> unspecified1 end(valarray<T>& v);
template<class T> unspecified2 end(const valarray<T>& v);
}

The header `<valarray>` defines five class templates (`valarray`, `slice_array`, `gslice_array`, `mask_array`, and `indirect_array`), two classes (`slice` and `gslice`), and a series of related function templates for representing and manipulating arrays of values.

The `valarray` array classes are defined to be free of certain forms of aliasing, thus allowing operations on these classes to be optimized.

Any function returning a `valarray<T>` is permitted to return an object of another type, provided all the const member functions of `valarray<T>` are also applicable to this type. This return type shall not add more than two levels of template nesting over the most deeply nested argument type.

Implementations introducing such replacement types shall provide additional functions and operators as follows:

1. For every function taking a `const valarray<T>&` other than `begin` and `end` (26.7.10), identical functions taking the replacement types shall be added;
2. For every function taking two `const valarray<T>&` arguments, identical functions taking every combination of `const valarray<T>&` and replacement types shall be added.

In particular, an implementation shall allow a `valarray<T>` to be constructed from such replacement types and shall allow assignments and compound assignments of such types to `valarray<T>`, `slice_array<T>`, `gslice_array<T>`, `mask_array<T>` and `indirect_array<T>` objects.

These library functions are permitted to throw a `bad_alloc` (17.6.3.1) exception if there are not sufficient resources available to carry out the operation. Note that the exception is not mandated.

26.7.2 Class template `valarray`

26.7.2.1 Overview

namespace std {
    template<class T> class valarray {
        public:
            using value_type = T;

            // 26.7.2.2, construct/destroy
            valarray();
            explicit valarray(size_t);
            valarray(const T&, size_t);
            valarray(const T*, size_t);
            valarray(const valarray&);
            valarray(valarray&&) noexcept;
            valarray(const slice_array<T>&);
            valarray(const gslice_array<T>&);
            valarray(const mask_array<T>&);
            valarray(const indirect_array<T>&);
            valarray(initializer_list<T>);
            ~valarray();

            // 26.7.2.3, assignment
            valarray& operator=(const valarray&);
            valarray& operator=(valarray&&) noexcept;
            valarray& operator=(initializer_list<T>);
            valarray& operator=(const T&);
            valarray& operator=(const slice_array<T>&);

252) Annex B recommends a minimum number of recursively nested template instantiations. This requirement thus indirectly suggests a minimum allowable complexity for valarray expressions.
valarray& operator=(const gslice_array<T>&);
valarray& operator=(const mask_array<T>&);
valarray& operator=(const indirect_array<T>&);

// 26.7.2.4, element access
const T& operator[](size_t) const;
T& operator[](size_t);

// 26.7.2.5, subset operations
valarray operator[](slice) const;
slice_array<T> operator[](slice);
valarray operator[](const gslice&) const;
gslice_array<T> operator[](const gslice&);
valarray operator[](const valarray<bool>&) const;
mask_array<T> operator[](const valarray<bool>&);
valarray operator[](const valarray<size_t>&) const;
indirect_array<T> operator[](const valarray<size_t>&);

// 26.7.2.6, unary operators
valarray operator+(() const;
valarray operator-() const;
valarray operator!() const;

// 26.7.2.7, compound assignment
valarray& operator*=(const T&);
valarray& operator/=(const T&);
valarray& operator%=(const T&);
valarray& operator+=(const T&);
valarray& operator-=(const T&);
valarray& operator^=(const T&);
valarray& operator&=(const T&);
valarray& operator|=(const T&);
valarray& operator<<=(const T&);
valarray& operator>>=(const T&);
valarray& operator*= (const valarray&);
valarray& operator/= (const valarray&);
valarray& operator%= (const valarray&);
valarray& operator+= (const valarray&);
valarray& operator-=(const valarray&);
valarray& operator^= (const valarray&);
valarray& operator|= (const valarray&);
valarray& operator&= (const valarray&);
valarray& operator>>=(const valarray&);

// 26.7.2.8, member functions
void swap(valarray&) noexcept;
size_t size() const;
T sum() const;
T min() const;
T max() const;

valarray shift (int) const;
valarray cshift(int) const;
valarray apply(T func(T)) const;
valarray apply(T func(const T&)) const;
void resize(size_t sz, T c = T());
template<class T, size_t cnt> valarray(const T(&)[cnt], size_t) -> valarray<T>;
}

The class template valarray<T> is a one-dimensional smart array, with elements numbered sequentially from zero. It is a representation of the mathematical concept of an ordered set of values. For convenience, an object of type valarray<T> is referred to as an “array” throughout the remainder of 26.7. The illusion of higher dimensionality may be produced by the familiar idiom of computed indices, together with the powerful subsetting capabilities provided by the generalized subscript operators.\textsuperscript{253}

### 26.7.2.2 Constructors

valarray();\textsuperscript{1}

*Effects:* Constructs a valarray that has zero length.\textsuperscript{254}

explicit valarray(size_t n);\textsuperscript{2}

*Effects:* Constructs a valarray that has length n. Each element of the array is value-initialized (9.3).

valarray(const T& v, size_t n);\textsuperscript{3}

*Effects:* Constructs a valarray that has length n. Each element of the array is initialized with v.

valarray(const T* p, size_t n);\textsuperscript{4}

*Requires:* p points to an array (9.2.3.4) of at least n elements.

*Effects:* Constructs a valarray that has length n. The values of the elements of the array are initialized with the first n values pointed to by the first argument.\textsuperscript{255}

valarray(const valarray& v);\textsuperscript{5}

*Effects:* Constructs a valarray that has the same length as v. The elements are initialized with the values of the corresponding elements of v.\textsuperscript{256}

valarray(valarray&& v) noexcept;\textsuperscript{6}

*Effects:* Constructs a valarray that has the same length as v. The elements are initialized with the values of the corresponding elements of v.

*Complexity:* Constant.

valarray(initializer_list<T> il);\textsuperscript{8}

*Effects:* Equivalent to valarray(il.begin(), il.size()).

valarray(const slice_array<T>&);
valarray(const gslice_array<T>&);
valarray(const mask_array<T>&);
valarray(const indirect_array<T>&);\textsuperscript{9}

These conversion constructors convert one of the four reference templates to a valarray.

valarray();\textsuperscript{10}

*Effects:* The destructor is applied to every element of *this; an implementation may return all allocated memory.

### 26.7.2.3 Assignment

valarray& operator=(const valarray& v);\textsuperscript{1}

*Effects:* Each element of the *this array is assigned the value of the corresponding element of v. If the length of v is not equal to the length of *this, resizing *this to make the two arrays the same length, as if by calling resize(v.size()), before performing the assignment.

\textsuperscript{253} The intent is to specify an array template that has the minimum functionality necessary to address aliasing ambiguities and the proliferation of temporary objects. Thus, the valarray template is neither a matrix class nor a field class. However, it is a very useful building block for designing such classes.

\textsuperscript{254} This default constructor is essential, since arrays of valarray may be useful. After initialization, the length of an empty array can be increased with the resize member function.

\textsuperscript{255} This copy constructor creates a distinct array rather than an alias. Implementations in which arrays share storage are permitted, but they would need to implement a copy-on-reference mechanism to ensure that arrays are conceptually distinct.
Ensures: size() == v.size().
Returns: *this.

valarray& operator=(valarray& v) noexcept;
Effects: *this obtains the value of v. The value of v after the assignment is not specified.
Returns: *this.
Complexity: Linear.

valarray& operator=(initializer_list<T> il);
Effects: Equivalent to: return *this = valarray(il);

valarray& operator=(const T& v);
Effects: Assigns v to each element of *this.
Returns: *this.

valarray& operator=(const slice_array<T>&);
valarray& operator=(const gslice_array<T>&);
valarray& operator=(const mask_array<T>&);
valarray& operator=(const indirect_array<T>&);

Requires: The length of the array to which the argument refers equals size(). The value of an element in the left-hand side of a valarray assignment operator does not depend on the value of another element in that left-hand side.

These operators allow the results of a generalized subscripting operation to be assigned directly to a valarray.

26.7.2.4 Element access
[valarray.access]

const T& operator[](size_t n) const;
T& operator[](size_t n);

Requires: n < size().
Returns: A reference to the corresponding element of the array. [Note: The expression (a[i] = q, a[i]) == q evaluates to true for any non-constant valarray<T> a, any T q, and for any size_t i such that the value of i is less than the length of a. — end note]
Remarks: The expression addressof(a[i+j]) == addressof(a[i]) + j evaluates to true for all size_t i and size_t j such that i+j < a.size().
The expression addressof(a[i]) != addressof(b[j]) evaluates to true for any two arrays a and b and for any size_t i and size_t j such that i < a.size() and j < b.size(). [Note: This property indicates an absence of aliasing and may be used to advantage by optimizing compilers. Compilers may take advantage of inlining, constant propagation, loop fusion, tracking of pointers obtained from operator new, and other techniques to generate efficient valarrays. — end note]
The reference returned by the subscript operator for an array shall be valid until the member function resize(size_t, T) (26.7.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

26.7.2.5 Subset operations
[valarray.sub]
The member operator[] is overloaded to provide several ways to select sequences of elements from among those controlled by *this. Each of these operations returns a subset of the array. The const-qualified versions return this subset as a new valarray object. The non-const versions return a class template object which has reference semantics to the original array, working in conjunction with various overloads of operator= and other assigning operators to allow selective replacement (slicing) of the controlled sequence. In each case the selected element(s) shall exist.

valarray operator[](slice slicearr) const;

Returns: A valarray containing those elements of the controlled sequence designated by slicearr.
[Example:
const valarray<char> v0("abcdefghijkmnop", 16);]
slice_array<T> operator[](slice slicearr);

Returns: An object that holds references to elements of the controlled sequence selected by slicearr.

Example:
  valarray<char> v0("abcdefhijklmnop", 16);
  valarray<char> v1("ABCDE", 5);
  v0[slice(2, 5, 3)] = v1;
  // v0 == valarray<char>("abAdeBghCjkDmnEp", 16);
  
  \[ end example \]

valarray operator[](const gslice& gslicearr) const;

Returns: A valarray containing those elements of the controlled sequence designated by gslicearr.

Example:
  const valarray<char> v0("abcdefghijklmnop", 16);
  const size_t lv[] = { 2, 3 ];
  const size_t dv[] = { 7, 2 ];
  const valarray<size_t> len(lv, 2), str(dv, 2);
  // v0[gslice(3, len, str)] returns
  // valarray<char>("dfhknmo", 6)
  
  \[ end example \]

gslice_array<T> operator[](const gslice& gslicearr);

Returns: An object that holds references to elements of the controlled sequence selected by gslicearr.

Example:
  valarray<char> v0("abcdefhijklmnop", 16);
  valarray<char> v1("ABCDEF", 6);
  const size_t lv[] = { 2, 3 ];
  const size_t dv[] = { 7, 2 ];
  const valarray<size_t> len(lv, 2), str(dv, 2);
  v0[gslice(3, len, str)] = v1;
  // v0 == valarray<char>("abcAeBgCijDlEnFp", 16)
  
  \[ end example \]

valarray operator[](const valarray<bool>& boolarr) const;

Returns: A valarray containing those elements of the controlled sequence designated by boolarr.

Example:
  const valarray<char> v0("abcdefhijklmnop", 16);
  const bool vb[] = { false, false, true, true, false, true };
  // v0[valarray<bool>(vb, 6)] returns
  // valarray<char>("cdf", 3)
  
  \[ end example \]

mask_array<T> operator[](const valarray<bool>& boolarr);

Returns: An object that holds references to elements of the controlled sequence selected by boolarr.

Example:
  valarray<char> v0("abcdefhijklmnop", 16);
  valarray<char> v1("ABC", 3);
  const bool vb[] = { false, false, true, true, false, true };
  v0[valarray<bool>(vb, 6)] = v1;
  // v0 == valarray<char>("abBeGhijklmnop", 16)
  
  \[ end example \]

valarray operator[](const valarray<size_t>& indarr) const;

Returns: A valarray containing those elements of the controlled sequence designated by indarr.

Example:
  valarray<char> v0("abcdefhijklmnop", 16);
  valarray<char> v1("ABC", 3);
  const bool vb[] = { false, false, true, true, false, true };
  v0[valarray<bool>(vb, 6)] = v1;
  // v0 == valarray<char>("abBeGhijklmnop", 16)
  
  \[ end example \]

§ 26.7.2.5
const valarray<char> v0("abcdefghijklmnop", 16);
const size_t vi[] = { 7, 5, 2, 3, 8 };
// v0[valarray<size_t>(vi, 5)] returns
// valarray<char>("hfcdi", 5)

— end example

indirect_array<T> operator[](const valarray<size_t>& indarr);

9 Returns: An object that holds references to elements of the controlled sequence selected by indarr.

[Example:
valarray<char> v0("abcdefghijklmnop", 16);
valarray<char> v1("ABCDE", 5);
const size_t vi[] = { 7, 5, 2, 3, 8 };
v0[valarray<size_t>(vi, 5)] = v1;
// v0 == valarray<char>("abCDeBgAEjklmnop", 16)
— end example]

26.7.2.6 Unary operators

valarray operator+() const;
valarray operator-() const;
valarray operator~() const;
valarray<bool> operator!() const;

1 Requires: Each of these operators may only be instantiated for a type T to which the indicated operator can be applied and for which the indicated operator returns a value which is of type T (bool for operator!) or which may be unambiguously implicitly converted to type T (bool for operator!).

2 Returns: A valarray whose length is size(). Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array.

26.7.2.7 Compound assignment

valarray& operator||(const valarray& v);
valarray& operator||(const valarray& v);
valarray& operator%(const valarray& v);
valarray& operator||(const valarray& v);
valarray& operator||(const valarray& v);
valarray& operator%(const valarray& v);
valarray& operator%(const valarray& v);
valarray& operator%(const valarray& v);
valarray& operator%(const valarray& v);
valarray& operator%(const valarray& v);

1 Requires: size() == v.size(). Each of these operators may only be instantiated for a type T if the indicated operator can be applied to two operands of type T. The value of an element in the left-hand side of a valarray compound assignment operator does not depend on the value of another element in that left hand side.

2 Effects: Each of these operators performs the indicated operation on each of the elements of *this and the corresponding element of v.

3 Returns: *this.

4 Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers.
valarray& operator>>=(const T& v);

5 Requires: Each of these operators may only be instantiated for a type T if the indicated operator can
6 be applied to two operands of type T.
7 Effects: Each of these operators applies the indicated operation to each element of *this and v.
8 Returns: *this
9 Remarks: The appearance of an array on the left-hand side of a compound assignment does not
10 invalidate references or pointers to the elements of the array.

26.7.2.8 Member functions

void swap(valarray& v) noexcept;
1
2 Effects: *this obtains the value of v. v obtains the value of *this.
3 Complexity: Constant.

size_t size() const;
4 Returns: The number of elements in the array.
5 Complexity: Constant time.

6 T sum() const;
7 Requires: size() > 0. This function may only be instantiated for a type T to which operator+= can
8 be applied.
9 Returns: The sum of all the elements of the array. If the array has length 1, returns the value of
10 element 0. Otherwise, the returned value is calculated by applying operator+= to a copy of an element
11 of the array and all other elements of the array in an unspecified order.

T min() const;
12 Requires: size() > 0
13 Returns: The minimum value contained in *this. For an array of length 1, the value of element 0 is
14 returned. For all other array lengths, the determination is made using operator<.

T max() const;
15 Requires: size() > 0.
16 Returns: The maximum value contained in *this. For an array of length 1, the value of element 0 is
17 returned. For all other array lengths, the determination is made using operator<.

valarray shift(int n) const;
18 Returns: A valarray of length size(), each of whose elements I is (*this)[I + n] if I + n is
19 non-negative and less than size(), otherwise T(). [Note: If element zero is taken as the leftmost
20 element, a positive value of n shifts the elements left n places, with zero fill. — end note]
21 [Example: If the argument has the value -2, the first two elements of the result will be value-initialized
22 (9.3); the third element of the result will be assigned the value of the first element of the argument; etc.
23 — end example]

valarray cshift(int n) const;
24 Returns: A valarray of length size() that is a circular shift of *this. If element zero is taken as the
25 leftmost element, a non-negative value of n shifts the elements circularly left n places and a negative
26 value of n shifts the elements circularly right -n places.

valarray apply(T func(T)) const;
valarray apply(T func(const T&)) const;
27 Returns: A valarray whose length is size(). Each element of the returned array is assigned the value
28 returned by applying the argument function to the corresponding element of *this.
void resize(size_t sz, T c = T());

Effects: Changes the length of the *this array to sz and then assigns to each element the value of the second argument. Resizing invalidates all pointers and references to elements in the array.

26.7.3 valarray non-member operations [valarray.nonmembers]

26.7.3.1 Binary operators [valarray.binary]

template<class T> valarray<T> operator* (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator/ (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator% (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator+ (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator- (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator^ (const valarray<T>&, const valarray<T>&);

Requires: Each of these operators may only be instantiated for a type T to which the indicated operator can be applied and for which the indicated operator returns a value which is of type T or which can be unambiguously implicitly converted to type T. The argument arrays have the same length.

Returns: A valarray whose length is equal to the lengths of the argument arrays. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.

template<class T> valarray<T> operator* (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator* (const typename valarray<T>::value_type&, const valarray<T>&);

§ 26.7.3.1 1150
template<class T> valarray<T> operator>>(const typename valarray<T>::value_type&,
  const valarray<T>&);

3 Requires: Each of these operators may only be instantiated for a type T to which the indicated operator
can be applied and for which the indicated operator returns a value which is of type T or which can be
unambiguously implicitly converted to type T.

4 Returns: A valarray whose length is equal to the length of the array argument. Each element of the
returned array is initialized with the result of applying the indicated operator to the corresponding
element of the array argument and the non-array argument.

26.7.3.2 Logical operators [valarray.comparison]

template<class T> valarray<bool> operator==(const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator!=(const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator< (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator> (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator<=(const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator>=(const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator&&(const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator||(const valarray<T>&, const valarray<T>&);

1 Requires: Each of these operators may only be instantiated for a type T to which the indicated operator
can be applied and for which the indicated operator returns a value which is of type bool or which can be
unambiguously implicitly converted to type bool. The two array arguments have the same length.

2 Returns: A valarray<bool> whose length is equal to the length of the array arguments. Each element of
the returned array is initialized with the result of applying the indicated operator to the corresponding
elements of the array arguments.

template<class T> valarray<bool> operator==(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator==(const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<bool> operator!=(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator!=(const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<bool> operator< (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator< (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<bool> operator> (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator> (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<bool> operator<=(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator<=(const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<bool> operator>=(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator>=(const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<bool> operator&&(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator&&(const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<bool> operator||(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator||(const typename valarray<T>::value_type&, const valarray<T>&);

3 Requires: Each of these operators may only be instantiated for a type T to which the indicated operator
can be applied and for which the indicated operator returns a value which is of type bool or which can be
unambiguously implicitly converted to type bool.
Returns: A `valarray<bool>` whose length is equal to the length of the array argument. Each element of
the returned array is initialized with the result of applying the indicated operator to the corresponding
element of the array and the non-array argument.

### 26.7.3.3 Transcendentals

```
template<class T> valarray<T> abs (const valarray<T>&);
template<class T> valarray<T> acos (const valarray<T>&);
template<class T> valarray<T> asin (const valarray<T>&);
template<class T> valarray<T> atan (const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> atan2(const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> cos (const valarray<T>&);
template<class T> valarray<T> cosh (const valarray<T>&);
template<class T> valarray<T> exp (const valarray<T>&);
template<class T> valarray<T> log (const valarray<T>&);
template<class T> valarray<T> log10(const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> pow (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> sin (const valarray<T>&);
template<class T> valarray<T> sinh (const valarray<T>&);
template<class T> valarray<T> sqrt (const valarray<T>&);
template<class T> valarray<T> tan (const valarray<T>&);
template<class T> valarray<T> tanh (const valarray<T>&);
```

**Requires:** Each of these functions may only be instantiated for a type `T` to which a unique function
with the indicated name can be applied (unqualified). This function shall return a value which is of
type `T` or which can be unambiguously implicitly converted to type `T`.

### 26.7.3.4 Specialized algorithms

```
template<class T> void swap(valarray<T>& x, valarray<T>& y) noexcept;
```

**Effects:** Equivalent to `x.swap(y)`.

### 26.7.4 Class `slice`

#### 26.7.4.1 Overview

```
namespace std {

  class slice {
    public:
      slice();
      slice(size_t, size_t, size_t);

      size_t start() const;
      size_t size() const;
      size_t stride() const;
    }

  }
```

The `slice` class represents a BLAS-like slice from an array. Such a slice is specified by a starting index, a
length, and a stride.\(^\text{\footnote{BLAS stands for Basic Linear Algebra Subprograms. C++ programs may instantiate this class. See, for example, Dongarra, Du Croz, Duff, and Hammerling: A set of Level 3 Basic Linear Algebra Subprograms; Technical Report MCS-P1-0888, Argonne National Laboratory (USA), Mathematics and Computer Science Division, August, 1988.}}\)
Example: slice(3, 8, 2) constructs a slice which selects elements 3, 5, 7, ..., 17 from an array. — end example

26.7.4.3 Access functions

size_t start() const;
size_t size() const;
size_t stride() const;

Returns: The start, length, or stride specified by a slice object.

Complexity: Constant time.

26.7.5 Class template slice_array

26.7.5.1 Overview

namespace std {

template<class T> class slice_array {

public:

using value_type = T;

void operator= (const valarray<T>&) const;
void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;
slice_array(const slice_array&);
~slice_array();
const slice_array& operator=(const slice_array&) const;
void operator=(const T&) const;
slice_array() = delete;  // as implied by declaring copy constructor above

slice_array(const slice_array&);
~slice_array();
const slice_array& operator=(const slice_array&) const;
void operator=(const T&) const;
slice_array() = delete;  // as implied by declaring copy constructor above

};
}

1 This template is a helper template used by the slice subscript operator

slice_array<T> valarray<T>::operator[](slice);

2 It has reference semantics to a subset of an array specified by a slice object. [Example: The expression a[slice(1, 5, 3)] = b; has the effect of assigning the elements of b to a slice of the elements in a. For the slice shown, the elements selected from a are 1, 4, ..., 13. — end example]

26.7.5.2 Assignment

void operator=(const valarray<T>&) const;
const slice_array& operator=(const slice_array&) const;

These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the valarray<T> object to which the slice_array object refers.

26.7.5.3 Compound assignment

void operator**= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator<<(const valarray<T>&) const;
void operator>>(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray<T> object to which the slice_array object refers.

26.7.5.4 Fill function [slice.arr.fill]

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the valarray<T> object to which the slice_array object refers.

26.7.6 The gslice class [class.gslice]

26.7.6.1 Overview [class.gslice.overview]

namespace std {
    class gslice {
    public:
        gslice();
        gslice(size_t s, const valarray<size_t>& l, const valarray<size_t>& d);

        size_t start() const;
        valarray<size_t> size() const;
        valarray<size_t> stride() const;
    };
}

1 This class represents a generalized slice out of an array. A gslice is defined by a starting offset (s), a set of lengths (l_j), and a set of strides (d_j). The number of lengths shall equal the number of strides.

2 A gslice represents a mapping from a set of indices (i_j), equal in number to the number of strides, to a single index k. It is useful for building multidimensional array classes using the valarray template, which is one-dimensional. The set of one-dimensional index values specified by a gslice are

\[ k = s + \sum_{j} i_j d_j \]

where the multidimensional indices i_j range in value from 0 to l_{ij} - 1.

3 [Example: The gslice specification

\[
\begin{align*}
\text{start} &= 3 \\
\text{length} &= \{2, 4, 3\} \\
\text{stride} &= \{19, 4, 1\}
\end{align*}
\]

yields the sequence of one-dimensional indices

\[ k = 3 + (0, 1) \times 19 + (0, 1, 2, 3) \times 4 + (0, 1, 2) \times 1 \]

which are ordered as shown in the following table:

\[
\begin{align*}
(i_0, i_1, i_2, k) &= \\
(0, 0, 0, 3), & (0, 0, 1, 4), & (0, 0, 2, 5), & (0, 1, 0, 7), & (0, 1, 1, 8), & (0, 1, 2, 9), & (0, 2, 0, 11), & (0, 2, 1, 12), & (0, 2, 2, 13), & (0, 3, 0, 15), & (0, 3, 1, 16), & (0, 3, 2, 17), & (1, 0, 0, 22),
\end{align*}
\]
That is, the highest-ordered index turns fastest. — end example]

4 It is possible to have degenerate generalized slices in which an address is repeated.

[Example: If the stride parameters in the previous example are changed to \{1, 1, 1\}, the first few elements of the resulting sequence of indices will be

\[
\begin{align*}
(0, & 0, 0, 3), \\
(0, & 0, 1, 4), \\
(0, & 0, 2, 5), \\
(0, & 1, 0, 4), \\
(0, & 1, 1, 5), \\
(0, & 1, 2, 6), \\
\end{align*}
\]

— end example]

6 If a degenerate slice is used as the argument to the non-\texttt{const} version of \texttt{operator[]}\texttt{(const gslice\&)}, the behavior is undefined.

26.7.6.2 Constructors

\texttt{gslice();}

\texttt{gslice(size_t start, const valarray<size_t>& lengths, const valarray<size_t>& strides);}

\texttt{gslice(const gslice\&);}  

1 The default constructor is equivalent to \texttt{gslice(0, valarray<size_t>(), valarray<size_t>())}.

The constructor with arguments builds a \texttt{gslice} based on a specification of start, lengths, and strides, as explained in the previous subclause.

26.7.6.3 Access functions

\texttt{size_t start() const;}

\texttt{valarray<size_t> size() const;}

\texttt{valarray<size_t> stride() const;}

1 Returns: The representation of the start, lengths, or strides specified for the \texttt{gslice}.

2 Complexity: \texttt{start()} is constant time. \texttt{size()} and \texttt{stride()} are linear in the number of strides.

26.7.7 Class template \texttt{gslice\_array}

26.7.7.1 Overview

namespace std {

    template<class T> class gslice\_array {
        public:
            using value\_type = T;

            void operator\=(const valarray<T>&) const;
            void operator\*=(const valarray<T>&) const;
            void operator/=(const valarray<T>&) const;
            void operator\%=const valarray<T>&) const;
            void operator\^=(const valarray<T>&) const;
            void operator&=(const valarray<T>&) const;
            void operator|=(const valarray<T>&) const;
            void operator<<=(const valarray<T>&) const;
            void operator>>=(const valarray<T>&) const;

    };

}
gslice_array(const gslice_array&);
gslice_array();
const gslice_array& operator=(const gslice_array&) const;
void operator=(const T&) const;

gslice_array() = delete;  // as implied by declaring copy constructor above

1 This template is a helper template used by the gslice subscript operator

valarray<T>::operator[](const gslice);

2 It has reference semantics to a subset of an array specified by a gslice object. Thus, the expression

a[gslice(1, length, stride)] = b

has the effect of assigning the elements of b to a generalized slice of the elements in a.

26.7.7.2 Assignment

gslice_array<T> valarray<T>::operator[](const gslice);

1 These assignment operators have reference semantics, assigning the values of the argument array
elements to selected elements of the valarray<T> object to which the gslice_array refers.

26.7.7.3 Compound assignment

void operator==(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements
of the argument array and selected elements of the valarray<T> object to which the gslice_array object refers.

26.7.7.4 Fill function

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the
valarray<T> object to which the gslice_array object refers.

26.7.8 Class template mask_array

26.7.8.1 Overview

namespace std {
template<class T> class mask_array {

1
This template is a helper template used by the mask subscript operator:

```cpp
mask_array<T> valarray<T>::operator[] (const valarray<bool>&).
```

2 It has reference semantics to a subset of an array specified by a boolean mask. Thus, the expression `a[mask] = b;` has the effect of assigning the elements of `b` to the masked elements in `a` (those for which the corresponding element in `mask` is `true`).

### 26.7.8.2 Assignment

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which it refers.

#### 26.7.8.3 Compound assignment

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the mask object refers.

#### 26.7.8.4 Fill function

1 This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `mask_array` object refers.

### 26.7.9 Class template `indirect_array`

#### 26.7.9.1 Overview

```cpp
namespace std {
    template<class T> class indirect_array {
        public:
            using value_type = T;

            void operator= (const valarray<T>&) const;
            void operator/= (const valarray<T>&) const;
            void operator%= (const valarray<T>&) const;
            void operator+= (const valarray<T>&) const;
            void operator-= (const valarray<T>&) const;
            void operator^= (const valarray<T>&) const;
            void operator&= (const valarray<T>&) const;
            void operator|= (const valarray<T>&) const;
            void operator<<=(const valarray<T>&) const;
            void operator>>=(const valarray<T>&) const;
```
indirect_array(const indirect_array&);
~indirect_array();
const indirect_array& operator=(const indirect_array&) const;
void operator=(const T&) const;

indirect_array() = delete;  // as implied by declaring copy constructor above
};
}

1 This template is a helper template used by the indirect subscript operator

indirect_array<T> valarray<T>::operator[] (const valarray<size_t>&).

2 It has reference semantics to a subset of an array specified by an indirect_array. Thus, the expression

    a[indirect] = b;

has the effect of assigning the elements of b to the elements in a whose indices appear in indirect.

26.7.9.2 Assignment

[indirect.array.assign]

void operator=(const valarray<T>&) const;
const indirect_array& operator=(const indirect_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the valarray<T> object to which it refers.

2 If the indirect_array specifies an element in the valarray<T> object to which it refers more than once, the behavior is undefined.

3 [Example:

    int addr[] = {2, 3, 1, 4, 4};
    valarray<size_t> indirect(addr, 5);
    valarray<double> a(0., 10), b(1., 5);
    a[indirect] = b;

    results in undefined behavior since element 4 is specified twice in the indirection. — end example]

26.7.9.3 Compound assignment

[indirect.array.comp.assign]

void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray<T> object to which the indirect_array object refers.

2 If the indirect_array specifies an element in the valarray<T> object to which it refers more than once, the behavior is undefined.

26.7.9.4 Fill function

[indirect.array.fill]

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the valarray<T> object to which the indirect_array object refers.

26.7.10 valarray range access

[valarray.range]

1 In the begin and end function templates that follow, unspecified1 is a type that meets the requirements of a mutable Cpp17RandomAccessIterator (23.3.5.6) and models ContiguousIterator (23.3.4.14), whose value_type is the template parameter T and whose reference type is Tk. unspecified2 is a type that
meets the requirements of a constant `Cpp17RandomAccessIterator` and models `ContiguousIterator`, whose `value_type` is the template parameter `T` and whose `reference` type is `const T&`.

The iterators returned by `begin` and `end` for an array are guaranteed to be valid until the member function `resize(size_t, T)` (26.7.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

```cpp
template<class T> unspecified1 begin(valarray<T>& v);
template<class T> unspecified2 begin(const valarray<T>& v);
```

Returns: An iterator referencing the first value in the array.

```cpp
template<class T> unspecified1 end(valarray<T>& v);
template<class T> unspecified2 end(const valarray<T>& v);
```

Returns: An iterator referencing one past the last value in the array.

### 26.8 Mathematical functions for floating-point types [c.math]

}

1 The contents and meaning of the header `<cmath>` are the same as the C standard library header `<math.h>`, with the addition of a three-dimensional hypotenuse function (26.8.3) and the mathematical special functions described in 26.8.6. [Note: Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (16.2). — end note]

2 For each set of overloaded functions within `<cmath>`, with the exception of `abs`, there shall be additional overloads sufficient to ensure:

1. If any argument of arithmetic type corresponding to a `double` parameter has type `long double`, then all arguments of arithmetic type (6.7.1) corresponding to `double` parameters are effectively cast to `long double`.

2. Otherwise, if any argument of arithmetic type corresponding to a `double` parameter has type `double` or an integer type, then all arguments of arithmetic type corresponding to `double` parameters are effectively cast to `double`. 

§ 26.8.1 1167
3. Otherwise, all arguments of arithmetic type corresponding to `double` parameters have type `float`.

*Note: abs is exempted from these rules in order to stay compatible with C. — end note*

See also: ISO C 7.12

### 26.8.2 Absolute values

- `int abs(int j);`
- `long int abs(long int j);`
- `long long int abs(long long int j);`
- `float abs(float j);`
- `double abs(double j);`
- `long double abs(long double j);`

*Effects: The abs functions have the semantics specified in the C standard library for the functions abs, labs, llabs, fabsf, fabs, and fabsl.*

*Remarks: If abs() is called with an argument of type X for which is_unsigned_v<X> is true and if X cannot be converted to int by integral promotion (7.3.6), the program is ill-formed. [Note: Arguments that can be promoted to int are permitted for compatibility with C. — end note]*

See also: ISO C 7.12.7.2, 7.22.6.1

### 26.8.3 Three-dimensional hypotenuse

- `float hypot(float x, float y, float z);`
- `double hypot(double x, double y, double z);`
- `long double hypot(long double x, long double y, long double z);`

*Returns: √x² + y² + z².*

### 26.8.4 Linear interpolation

- `constexpr float lerp(float a, float b, float t);`
- `constexpr double lerp(double a, double b, double t);`
- `constexpr long double lerp(long double a, long double b, long double t);`

*Returns: a + t(b − a).*

*Remarks: Let r be the value returned. If isfinite(a) && isfinite(b), then:

(2.1) If t == 0, then r == a.
(2.2) If t == 1, then r == b.
(2.3) If t >= 0 && t <= 1, then isfinite(r).
(2.4) If isfinite(t) && a == b, then r == a.
(2.5) If isfinite(t) || !isnan(t) && b-a != 0, then !isnan(r).

Let CMP(x,y) be 1 if x > y, -1 if x < y, and 0 otherwise. For any t1 and t2, the product of CMP(lerp(a, b, t2), lerp(a, b, t1)), CMP(t2, t1), and CMP(b, a) is non-negative.*

### 26.8.5 Classification / comparison functions

The classification / comparison functions behave the same as the C macros with the corresponding names defined in the C standard library. Each function is overloaded for the three floating-point types.

See also: ISO C 7.12.3, 7.12.4

### 26.8.6 Mathematical special functions

If any argument value to any of the functions specified in this subclause is a NaN (Not a Number), the function shall return a NaN but it shall not report a domain error. Otherwise, the function shall report a domain error for just those argument values for which:

(1.1) the function description’s Returns: clause explicitly specifies a domain and those argument values fall outside the specified domain, or
Unless otherwise specified, each function is defined for all finite values, for negative infinity, and for positive infinity.

### 26.8.6.1 Associated Laguerre polynomials

```c
double assoc_laguerre(unsigned n, unsigned m, double x);
float assoc_laguerref(unsigned n, unsigned m, float x);
long double assoc_laguerrel(unsigned n, unsigned m, long double x);
```

1 Effects: These functions compute the associated Laguerre polynomials of their respective arguments m, n, and x.

2 Returns:

\[ L^m_n(x) = (-1)^m \frac{d^m}{dx^m} L_{n+m}(x), \quad \text{for } x \geq 0, \]

where n is n, m is m, and x is x.

3 Remarks: The effect of calling each of these functions is implementation-defined if n >= 128 or if m >= 128.

### 26.8.6.2 Associated Legendre functions

```c
double assoc_legendre(unsigned l, unsigned m, double x);
float assoc_legendref(unsigned l, unsigned m, float x);
long double assoc_legendrel(unsigned l, unsigned m, long double x);
```

1 Effects: These functions compute the associated Legendre functions of their respective arguments l, m, and x.

2 Returns:

\[ P^m_l(x) = (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_l(x), \quad \text{for } |x| \leq 1, \]

where l is l, m is m, and x is x.

3 Remarks: The effect of calling each of these functions is implementation-defined if l >= 128.

### 26.8.6.3 Beta function

```c
double beta(double x, double y);
float betaf(float x, float y);
long double betal(long double x, long double y);
```

1 Effects: These functions compute the beta function of their respective arguments x and y.

2 Returns:

\[ B(x, y) = \frac{\Gamma(x) \Gamma(y)}{\Gamma(x + y)}, \quad \text{for } x > 0, \ y > 0, \]

where x is x and y is y.

### 26.8.6.4 Complete elliptic integral of the first kind

```c
double comp_ellint_1(double k);
float comp_ellint_1f(float k);
long double comp_ellint_1l(long double k);
```

1 Effects: These functions compute the complete elliptic integral of the first kind of their respective arguments k.

2 Returns:

\[ K(k) = F(k, \pi/2), \quad \text{for } |k| \leq 1, \]

where k is k.

3 See also 26.8.6.11.

---

258 A mathematical function is mathematically defined for a given set of argument values (a) if it is explicitly defined for that set of argument values, or (b) if its limiting value exists and does not depend on the direction of approach.
26.8.6.5 Complete elliptic integral of the second kind

\[ \text{double} \quad \text{comp_ellint_2(double k);} \]
\[ \text{float} \quad \text{comp_ellint_2f(float k);} \]
\[ \text{long double} \quad \text{comp_ellint_2l(long double k);} \]

1 Effects: These functions compute the complete elliptic integral of the second kind of their respective arguments \( k \).
2 Returns:
\[ E(k) = E(k, \pi/2), \quad \text{for} \ |k| \leq 1, \]
where \( k \) is \( k \).
3 See also 26.8.6.12.

26.8.6.6 Complete elliptic integral of the third kind

\[ \text{double} \quad \text{comp_ellint_3(double k, double nu);} \]
\[ \text{float} \quad \text{comp_ellint_3f(float k, float nu);} \]
\[ \text{long double} \quad \text{comp_ellint_3l(long double k, long double nu);} \]

1 Effects: These functions compute the complete elliptic integral of the third kind of their respective arguments \( k \) and \( \nu \).
2 Returns:
\[ \Pi(\nu, k) = \Pi(\nu, k, \pi/2), \quad \text{for} \ |k| \leq 1, \]
where \( k \) is \( k \) and \( \nu \) is \( \nu \).
3 See also 26.8.6.13.

26.8.6.7 Regular modified cylindrical Bessel functions

\[ \text{double} \quad \text{cyl_bessel_i(double nu, double x);} \]
\[ \text{float} \quad \text{cyl_bessel_if(float nu, float x);} \]
\[ \text{long double} \quad \text{cyl_bessel_il(long double nu, long double x);} \]

1 Effects: These functions compute the regular modified cylindrical Bessel functions of their respective arguments \( \nu \) and \( x \).
2 Returns:
\[ I_{\nu}(x) = i^{-\nu}J_{\nu}(ix) = \sum_{k=0}^{\infty} \frac{(x/2)^{\nu+2k}}{k! \Gamma(\nu+k+1)}, \quad \text{for} \ x \geq 0, \]
where \( \nu \) is \( \nu \) and \( x \) is \( x \).
3 Remarks: The effect of calling each of these functions is implementation-defined if \( \nu \geq 128 \).
4 See also 26.8.6.8.

26.8.6.8 Cylindrical Bessel functions of the first kind

\[ \text{double} \quad \text{cyl_bessel_j(double nu, double x);} \]
\[ \text{float} \quad \text{cyl_bessel_jf(float nu, float x);} \]
\[ \text{long double} \quad \text{cyl_bessel_jl(long double nu, long double x);} \]

1 Effects: These functions compute the cylindrical Bessel functions of the first kind of their respective arguments \( \nu \) and \( x \).
2 Returns:
\[ J_{\nu}(x) = \sum_{k=0}^{\infty} \frac{(-1)^k(x/2)^{\nu+2k}}{k! \Gamma(\nu+k+1)}, \quad \text{for} \ x \geq 0, \]
where \( \nu \) is \( \nu \) and \( x \) is \( x \).
3 Remarks: The effect of calling each of these functions is implementation-defined if \( \nu \geq 128 \).
26.8.6.9 Irregular modified cylindrical Bessel functions

\texttt{double cyl_bessel_k(double nu, double x);}  
\texttt{float cyl_bessel_kf(float nu, float x);}  
\texttt{long double cyl_bessel_kl(long double nu, long double x);}  

Effects: These functions compute the irregular modified cylindrical Bessel functions of their respective arguments \(\nu\) and \(x\).

Returns:

\[
K_{\nu}(x) = \frac{(\pi/2)i^{\nu+1}(J_{\nu}(ix) + iN_{\nu}(ix))}{\sin\nu\pi}, \quad \text{for } x \geq 0 \text{ and non-integral } \nu
\]

\[
\frac{\pi}{2} \lim_{\mu \to \nu} \frac{1_{-\mu}(x) - 1_{\mu}(x)}{\sin\mu\pi}, \quad \text{for } x \geq 0 \text{ and integral } \nu
\]

where \(\nu\) is \(nu\) and \(x\) is \(x\).

Remarks: The effect of calling each of these functions is implementation-defined if \(nu \geq 128\).

See also 26.8.6.7, 26.8.6.8, 26.8.6.10.

26.8.6.10 Cylindrical Neumann functions

\texttt{double cyl_neumann(double nu, double x);}  
\texttt{float cyl_neumannf(float nu, float x);}  
\texttt{long double cyl_neumannl(long double nu, long double x);}  

Effects: These functions compute the cylindrical Neumann functions, also known as the cylindrical Bessel functions of the second kind, of their respective arguments \(\nu\) and \(x\).

Returns:

\[
N_{\nu}(x) = \begin{cases} 
  \frac{J_{\nu}(x) \cos \nu\pi - J_{-\nu}(x)}{\sin\nu\pi}, & \text{for } x \geq 0 \text{ and non-integral } \nu \\
  \lim_{\mu \to \nu} \frac{J_{\mu}(x) \cos \mu\pi - J_{-\mu}(x)}{\sin\mu\pi}, & \text{for } x \geq 0 \text{ and integral } \nu 
\end{cases}
\]

where \(\nu\) is \(nu\) and \(x\) is \(x\).

Remarks: The effect of calling each of these functions is implementation-defined if \(nu \geq 128\).

See also 26.8.6.8.

26.8.6.11 Incomplete elliptic integral of the first kind

\texttt{double ellint_1(double k, double phi);}  
\texttt{float ellint_1f(float k, float phi);}  
\texttt{long double ellint_1l(long double k, long double phi);}  

Effects: These functions compute the incomplete elliptic integral of the first kind of their respective arguments \(k\) and \(phi\) (\(phi\) measured in radians).

Returns:

\[
F(k, \phi) = \int_{0}^{\phi} \frac{d\theta}{\sqrt{1 - k^2 \sin^2 \theta}}, \quad \text{for } |k| \leq 1,
\]

where \(k\) is \(k\) and \(\phi\) is \(phi\).

26.8.6.12 Incomplete elliptic integral of the second kind

\texttt{double ellint_2(double k, double phi);}  
\texttt{float ellint_2f(float k, float phi);}  
\texttt{long double ellint_2l(long double k, long double phi);}  

Effects: These functions compute the incomplete elliptic integral of the second kind of their respective arguments \(k\) and \(phi\) (\(phi\) measured in radians).

Returns:

\[
E(k, \phi) = \int_{0}^{\phi} \sqrt{1 - k^2 \sin^2 \theta} d\theta, \quad \text{for } |k| \leq 1,
\]

where \(k\) is \(k\) and \(\phi\) is \(phi\).
26.8.6.13 Incomplete elliptic integral of the third kind

```c
double ellint_3(double k, double nu, double phi);
float ellint_3f(float k, float nu, float phi);
long double ellint_3l(long double k, long double nu, long double phi);
```

1 **Effects:** These functions compute the incomplete elliptic integral of the third kind of their respective arguments \(k\), \(nu\), and \(phi\) (\(phi\) measured in radians).

2 **Returns:**

\[
\Pi(\nu, k, \phi) = \int_{0}^{\phi} \frac{d\theta}{(1 - \nu \sin^2 \theta)\sqrt{1 - k^2 \sin^2 \theta}}, \text{ for } |k| \leq 1,
\]

where \(\nu\) is \(nu\), \(k\) is \(k\), and \(\phi\) is \(phi\).

26.8.6.14 Exponential integral

```c
double expint(double x);
float expintf(float x);
long double expintl(long double x);
```

1 **Effects:** These functions compute the exponential integral of their respective arguments \(x\).

2 **Returns:**

\[
Ei(x) = -\int_{-x}^{\infty} \frac{e^{-t}}{t} \, dt
\]

where \(x\) is \(x\).

26.8.6.15 Hermite polynomials

```c
double hermite(unsigned n, double x);
float hermitef(unsigned n, float x);
long double hermitel(unsigned n, long double x);
```

1 **Effects:** These functions compute the Hermite polynomials of their respective arguments \(n\) and \(x\).

2 **Returns:**

\[
H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}
\]

where \(n\) is \(n\) and \(x\) is \(x\).

3 **Remarks:** The effect of calling each of these functions is implementation-defined if \(n >= 128\).

26.8.6.16 Laguerre polynomials

```c
double laguerre(unsigned n, double x);
float laguerref(unsigned n, float x);
long double laguerrel(unsigned n, long double x);
```

1 **Effects:** These functions compute the Laguerre polynomials of their respective arguments \(n\) and \(x\).

2 **Returns:**

\[
L_n(x) = \frac{e^x}{n!} \frac{d^n}{dx^n} (x^n e^{-x}), \text{ for } x \geq 0,
\]

where \(n\) is \(n\) and \(x\) is \(x\).

3 **Remarks:** The effect of calling each of these functions is implementation-defined if \(n >= 128\).

26.8.6.17 Legendre polynomials

```c
double legendre(unsigned l, double x);
float legendref(unsigned l, float x);
long double legendrel(unsigned l, long double x);
```

1 **Effects:** These functions compute the Legendre polynomials of their respective arguments \(l\) and \(x\).

2 **Returns:**

\[
P_l(x) = \frac{1}{2^l l!} \frac{d^l}{dx^l} (x^2 - 1)^l, \text{ for } |x| \leq 1,
\]

where \(l\) is \(l\) and \(x\) is \(x\).

3 **Remarks:** The effect of calling each of these functions is implementation-defined if \(l >= 128\).
26.8.6.18 Riemann zeta function

\[ \zeta(x) = \begin{cases} \sum_{k=1}^{\infty} k^{-x}, & \text{for } x > 1 \\ \frac{1}{2^{1-x}} \sum_{k=1}^{\infty} (-1)^{k-1} k^{-x}, & \text{for } 0 \leq x \leq 1 \\ 2^x \pi^{x-1} \sin\left(\frac{\pi x}{2}\right) \Gamma(1-x) \zeta(1-x), & \text{for } x < 0 \end{cases} \]

where \( x \) is the argument.

26.8.6.19 Spherical Bessel functions of the first kind

\[ j_n(x) = \frac{(\pi/2x)^{1/2} J_n(x)}{1/2} \]

where \( n \) is an integer and \( x \) is the argument.

26.8.6.20 Spherical associated Legendre functions

\[ Y^m_l(\theta, \phi) = (-1)^m \frac{(2l+1)(\ell-m)!}{4\pi (\ell+m)!} P^m_\ell(\cos \theta) e^{im\phi}, \quad \text{for } |m| \leq \ell, \]

where \( l \) is an integer, \( m \) is an integer, and \( \theta \) is the argument in radians.

26.8.6.21 Spherical Neumann functions

\[ n_n(x) = \frac{(\pi/2x)^{1/2} N_{n+1/2}(x)}{1/2} \]

where \( n \) is an integer and \( x \) is the argument.
where \( n \) is \( n \) and \( x \) is \( x \).

\[ \text{Remarks: The effect of calling each of these functions is implementation-defined if } n \geq 128. \]

\[ \text{See also 26.8.6.10.} \]
27 Time library

27.1 General

This Clause describes the chrono library (27.2) and various C functions (27.13) that provide generally useful time utilities, as summarized in Table 85.

Table 85: Time library summary

§ 27.3 Cpp17Clock requirements [time.clock.req]

A clock is a bundle consisting of a duration, a time_point, and a function now() to get the current time_point. The origin of the clock’s time_point is referred to as the clock’s epoch. A clock shall meet the requirements in Table 86.

In Table 86 C1 and C2 denote clock types. t1 and t2 are values returned by C1::now() where the call returning t1 happens before (6.8.2) the call returning t2 and both of these calls occur before C1::time_point::max(). [Note: This means C1 did not wrap around between t1 and t2. — end note]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>C1::rep</td>

<th>Operational semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>C1::now()</td>
<td>C1::time_point</td>
<td>Returns a time_point object representing the current point in time.</td>
</tr>
</tbody>
</table>

3 [Note: The relative difference in durations between those reported by a given clock and the SI definition is a measure of the quality of implementation. — end note]

4 A type TC meets the Cpp17TrivialClock requirements if:
   — TC meets the Cpp17Clock requirements (27.3),
   — the types TC::rep, TC::duration, and TC::time_point meet the Cpp17EqualityComparable (Table 23) and Cpp17LessThanComparable (Table 24) requirements and the requirements of numeric types (26.2).
   [Note: This means, in particular, that operations on these types will not throw exceptions. — end note]
   — values of the types TC::rep, TC::duration, and TC::time_point are swappable (16.5.3.2),
   — the function TC::now() does not throw exceptions, and
   — the type TC::time_point::clock meets the Cpp17TrivialClock requirements, recursively.

27.4 Time-related traits

27.4.1 treat_as_floating_point

template<class Rep> struct treat_as_floating_point : is_floating_point<Rep> { };  
1 The duration template uses the treat_as_floating_point trait to help determine if a duration object can be converted to another duration with a different tick period. If treat_as_floating_point_v<Rep> is true, then implicit conversions are allowed among durations. Otherwise, the implicit convertibility depends on the tick periods of the durations. [Note: The intention of this trait is to indicate whether a given class behaves like a floating-point type, and thus allows division of one value by another with acceptable loss of precision. If treat_as_floating_point_v<Rep> is false, Rep will be treated as if it behaved like an integral type for the purpose of these conversions. — end note]

27.4.2 duration_values

template<class Rep>  
struct duration_values {  
    public:  
        static constexpr Rep zero() noexcept;  
        static constexpr Rep min() noexcept;  
        static constexpr Rep max() noexcept;  
};  
1 The duration template uses the duration_values trait to construct special values of the duration’s representation (Rep). This is done because the representation might be a class type with behavior which requires some other implementation to return these special values. In that case, the author of that class type should specialize duration_values to return the indicated values.

    static constexpr Rep zero() noexcept;  
2    Returns: Rep(0). [Note: Rep(0) is specified instead of Rep() because Rep() may have some other meaning, such as an uninitialized value. — end note]

    Remarks: The value returned shall be the additive identity.

    static constexpr Rep min() noexcept;  
3    Returns: numeric_limits<Rep>::lowest().

    Remarks: The value returned shall compare less than or equal to zero().
static constexpr Rep max() noexcept;

Returns: numeric_limits<Rep>::max().

Remarks: The value returned shall compare greater than zero().

27.4.3 Specializations of common_type

template<class Rep1, class Period1, class Rep2, class Period2>
struct common_type<chrono::duration<Rep1, Period1>, chrono::duration<Rep2, Period2>> {
    using type = chrono::duration<common_type_t<Rep1, Rep2>, see below>;
};

1 The period of the duration indicated by this specialization of common_type shall be the greatest common divisor of Period1 and Period2. [Note: This can be computed by forming a ratio of the greatest common divisor of Period1::num and Period2::num and the least common multiple of Period1::den and Period2::den. —end note]

2 [Note: The typedef name type is a synonym for the duration with the largest tick period possible where both duration arguments will convert to it without requiring a division operation. The representation of this type is intended to be able to hold any value resulting from this conversion with no truncation error, although floating-point durations may have round-off errors. —end note]

template<class Clock, class Duration1, class Duration2>
struct common_type<chrono::time_point<Clock, Duration1>, chrono::time_point<Clock, Duration2>> {
    using type = chrono::time_point<Clock, common_type_t<Duration1, Duration2>>;
};

3 The common type of two time_point types is a time_point with the same clock as the two types and the common type of their two durations.

27.4.4 Class template is_clock

template<class T> struct is_clock;

1 is_clock is a Cpp17UnaryTypeTrait (20.15.1) with a base characteristic of true_type if T meets the Cpp17Clock requirements (27.3), otherwise false_type. For the purposes of the specification of this trait, the extent to which an implementation determines that a type cannot meet the Cpp17Clock requirements is unspecified, except that as a minimum a type T shall not qualify as a Cpp17Clock unless it meets all of the following conditions:

(1.1) — the qualified-ids T::rep, T::period, T::duration, and T::time_point are valid and each denotes a type (13.9.2),

(1.2) — the expression T::is_steady is well-formed when treated as an unevaluated operand,

(1.3) — the expression T::now() is well-formed when treated as an unevaluated operand.

2 The behavior of a program that adds specializations for is_clock is undefined.

27.5 Class template duration

A duration type measures time between two points in time (time_points). A duration has a representation which holds a count of ticks and a tick period. The tick period is the amount of time which occurs from one tick to the next, in units of seconds. It is expressed as a rational constant using the template ratio.

namespace std::chrono {
    template<class Rep, class Period = ratio<1>>
    class duration {
        public:
            using rep = Rep;
            using period = typename Period::type;

            private:
                rep rep_; // exposition only

            public:
                // 27.5.1, construct/copy/destroy
                constexpr duration() = default;

    };

§ 27.5
template<class Rep2>
  constexpr explicit duration(const Rep2& r);

template<class Rep2, class Period2>
  constexpr duration(const duration<Rep2, Period2>& d);

~duration() = default;
duration& operator=(const duration&) = default;

// 27.5.2, observer
constexpr rep count() const;

// 27.5.3, arithmetic
constexpr common_type_t<duration> operator+() const;
constexpr common_type_t<duration> operator-() const;
duration& operator++();
duration operator++(int);
duration& operator--();
duration operator--(int);
duration& operator+=(const duration& d);
duration& operator-=(const duration& d);
duration& operator*=(const rep& rhs);
duration& operator/=(const rep& rhs);
duration& operator%=(const rep& rhs);
duration& operator%=(const duration& rhs);

// 27.5.4, special values
static constexpr duration zero() noexcept;
static constexpr duration min() noexcept;
static constexpr duration max() noexcept;

};

2 Rep shall be an arithmetic type or a class emulating an arithmetic type. If duration is instantiated with a duration type as the argument for the template parameter Rep, the program is ill-formed.

3 If Period is not a specialization of ratio, the program is ill-formed. If Period::num is not positive, the program is ill-formed.

4 Members of duration shall not throw exceptions other than those thrown by the indicated operations on their representations.

5 The defaulted copy constructor of duration shall be a constexpr function if and only if the required initialization of the member rep_ for copy and move, respectively, would satisfy the requirements for a constexpr function.

6 [Example:
   duration<long, ratio<60>> d0; // holds a count of minutes using a long
duration<long long, milli> d1; // holds a count of milliseconds using a long long
duration<double, ratio<1, 30>> d2; // holds a count with a tick period of 1/30 of a second
   // (30 Hz) using a double
   — end example]

27.5.1 Constructors [time.duration.cons]

template<class Rep2>
  constexpr explicit duration(const Rep2& r);

1 Remarks: This constructor shall not participate in overload resolution unless Rep2 is implicitly convertible to rep and

(1.1) — treat_as_floating_point_v<rep> is true or
(1.2) — treat_as_floating_point_v<Rep2> is false.

[Example:
   duration<int, milli> d(3); // OK

§ 27.5.1 1193
```cpp
template<class Rep2, class Period2>
constexpr duration(const duration<Rep2, Period2>& d);
```

**Remarks:** This constructor shall not participate in overload resolution unless no overflow is induced in the conversion and `treat_as_floating_point_v<Rep>` is true or both `ratio_divide<Period2, period>::den` is 1 and `treat_as_floating_point_v<Rep2>` is false. [Note: This requirement prevents implicit truncation error when converting between integral-based `duration` types. Such a construction could easily lead to confusion about the value of the `duration`. —end note] [Example:

```cpp
duration<int, milli> ms(3);
duration<int, micro> us = ms; // OK
duration<int, milli> ms2 = us; // error
```

—end example]

**Effects:** Constructs an object of type `duration`, constructing `rep_` from `duration_cast<duration>(d).count()`.

### § 27.5.3  Arithmetic

**Returns:** `common_type_t<duration>(*this)`.

**Returns:** `common_type_t<duration>(-rep_)`.

```cpp
constexpr duration& operator++();
```

**Effects:** As if by `++rep_`.

**Returns:** `*this`.

```cpp
constexpr duration operator++(int);
```

**Returns:** `duration(rep_++)`.

```cpp
constexpr duration& operator--();
```

**Effects:** As if by `--rep_`.

**Returns:** `*this`.

```cpp
constexpr duration operator--(int);
```

**Returns:** `duration(rep_--)`.

```cpp
constexpr duration& operator+=(const duration& d);
```

**Effects:** As if by: `rep_ += d.count();`

**Returns:** `*this`.

```cpp
constexpr duration& operator-=(const duration& d);
```

**Effects:** As if by: `rep_ -= d.count();`

**Returns:** `*this`.

§ 27.5.3
constexpr duration& operator*=(const rep& rhs);
  Effects: As if by: rep_ *= rhs;
  Returns: *this.

constexpr duration& operator/=(const rep& rhs);
  Effects: As if by: rep_ /= rhs;
  Returns: *this.

constexpr duration& operator%=(const rep& rhs);
  Effects: As if by: rep_ %= rhs;
  Returns: *this.

constexpr duration& operator%=(const duration& rhs);
  Effects: As if by: rep_ %= rhs.count();
  Returns: *this.

27.5.4 Special values  

static constexpr duration zero() noexcept;
  Returns: duration(duration_values<rep>::zero()).

static constexpr duration min() noexcept;
  Returns: duration(duration_values<rep>::min()).

static constexpr duration max() noexcept;
  Returns: duration(duration_values<rep>::max()).

27.5.5 Non-member arithmetic

In the function descriptions that follow, unless stated otherwise, let CD represent the return type of the function.

template<class Rep1, class Period1, class Rep2, class Period2>
  constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
  operator+(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
  Returns: CD(CD(lhs).count() + CD(rhs).count()).

template<class Rep1, class Period1, class Rep2, class Period2>
  constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
  operator-(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
  Returns: CD(CD(lhs).count() - CD(rhs).count()).

template<class Rep1, class Period1, class Rep2>
  constexpr duration<common_type_t<Rep1, Rep2>, Period>
  operator*(const duration<Rep1, Period1>& d, const Rep2& s);
  Remarks: This operator shall not participate in overload resolution unless Rep2 is implicitly convertible to common_type_t<Rep1, Rep2>.
  Returns: CD(d).count() * s).

template<class Rep1, class Period>
  constexpr duration<common_type_t<Rep1, Rep2>, Period>
  operator*(const Rep1& s, const duration<Rep2, Period>& d);
  Remarks: This operator shall not participate in overload resolution unless Rep1 is implicitly convertible to common_type_t<Rep1, Rep2>.
  Returns: d * s.
template<class Rep1, class Period, class Rep2>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator/(const duration<Rep1, Period>& d, const Rep2& s);

Remarks: This operator shall not participate in overload resolution unless Rep2 is implicitly convertible to common_type_t<Rep1, Rep2> and Rep2 is not a specialization of duration.

Returns: CD(CD(d).count() / s).

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<Rep1, Rep2>
operator%(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Let CD be common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>.

Returns: CD(lhs).count() % CD(rhs).count().

27.5.6 Comparisons [time.duration.comparisons]

In the function descriptions that follow, CT represents common_type_t<A, B>, where A and B are the types of the two arguments to the function.

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator==(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: CT(lhs).count() == CT(rhs).count().

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator!=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: !(lhs == rhs).

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: rhs < lhs.

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: !(rhs < lhs).

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: !(lhs < rhs).

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: !(lhs < rhs).
27.5.7 duration_cast

template<class ToDuration, class Rep, class Period>
constexpr ToDuration duration_cast(const duration<Rep, Period>& d);

Remarks: This function shall not participate in overload resolution unless ToDuration is a specialization of duration.

Returns: Let CF be ratio_divide<Period, typename ToDuration::period>, and CR be common_type<typename ToDuration::rep, Rep, intmax_t>::type.
(2.1) If CF::num == 1 and CF::den == 1, returns duration_cast<typename ToDuration::rep>(d.count())
(2.2) otherwise, if CF::num != 1 and CF::den == 1, returns duration_cast<typename ToDuration::rep>(
    static_cast<CR>(d.count()) * static_cast<CR>(CF::num))
(2.3) otherwise, if CF::num == 1 and CF::den != 1, returns duration_cast<typename ToDuration::rep>(
    static_cast<CR>(d.count()) / static_cast<CR>(CF::den))
(2.4) otherwise, returns duration_cast<typename ToDuration::rep>(
    static_cast<CR>(d.count()) * static_cast<CR>(CF::num) / static_cast<CR>(CF::den))

Note: This function does not use any implicit conversions; all conversions are done with static_cast. It avoids multiplications and divisions when it is known at compile time that one or more arguments is 1. Intermediate computations are carried out in the widest representation and only converted to the destination representation at the final step. — end note

27.5.8 Suffixes for duration literals

This subclause describes literal suffixes for constructing duration literals. The suffixes h, min, s, ms, us, ns denote duration values of the corresponding types hours, minutes, seconds, milliseconds, microseconds, and nanoseconds respectively if they are applied to integral literals.

If any of these suffixes are applied to a floating-point literal the result is a chrono::duration literal with an unspecified floating-point representation.

If any of these suffixes are applied to an integer literal and the resulting chrono::duration value cannot be represented in the result type because of overflow, the program is ill-formed.

Example: The following code shows some duration literals.

using namespace std::chrono_literals;
constexpr chrono::hours operator"h(unsigned long long hours);
constexpr chrono::duration<unspecified, ratio<3600, 1>> operator"h(long double hours);

Returns: A duration literal representing hours hours.

constexpr chrono::minutes operator"min(unsigned long long minutes);
constexpr chrono::duration<unspecified, ratio<60, 1>> operator"min(long double minutes);

Returns: A duration literal representing minutes minutes.

constexpr chrono::seconds operator"s(unsigned long long sec);
constexpr chrono::duration<unspecified> operator"s(long double sec);

Returns: A duration literal representing sec seconds.

[Note: The same suffix s is used for basic_string but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. — end note]

constexpr chrono::milliseconds operator"ms(unsigned long long msec);
constexpr chrono::duration<unspecified, milli> operator"ms(long double msec);

Returns: A duration literal representing msec milliseconds.

constexpr chrono::microseconds operator"us(unsigned long long usec);
constexpr chrono::duration<unspecified, micro> operator"us(long double usec);

Returns: A duration literal representing usec microseconds.

constexpr chrono::nanoseconds operator"ns(unsigned long long nsec);
constexpr chrono::duration<unspecified, nano> operator"ns(long double nsec);

Returns: A duration literal representing nsec nanoseconds.

27.5.9 Algorithms  [time.duration.alg]

template<class Rep, class Period>
constexpr duration<Rep, Period> abs(duration<Rep, Period> d);

Remarks: This function shall not participate in overload resolution unless numeric_limits<Rep>::is_signed is true.

Returns: If d >= d.zero(), return d, otherwise return -d.

27.5.10 I/O  [time.duration.io]

template<class charT, class traits, class Rep, class Period>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const duration<Rep, Period>& d);

Requires: Rep is an integral type whose integer conversion rank (6.7.4) is greater than or equal to that of short, or a floating point type. charT is char or wchar_t.

Effects: Forms a basic_string<charT, traits> from d.count() using to_string if charT is char, or to_wstring if charT is wchar_t. Appends the units suffix described below to the basic_string. Inserts the resulting basic_string into os. [Note: This specification ensures that the result of this streaming operation will obey the width and alignment properties of the stream. — end note]

The units suffix depends on the type Period::type as follows:

(3.1) If Period::type is atto, the suffix is "as".
(3.2) Otherwise, if Period::type is femto, the suffix is "fs".
(3.3) Otherwise, if Period::type is pico, the suffix is "ps".
(3.4) Otherwise, if Period::type is nano, the suffix is "ns".
(3.5) Otherwise, if Period::type is micro, the suffix is "µs" ("\u00b5\u0073").
— Otherwise, if `Period::type` is `milli`, the suffix is "ms".
— Otherwise, if `Period::type` is `centi`, the suffix is "cs".
— Otherwise, if `Period::type` is `deci`, the suffix is "ds".
— Otherwise, if `Period::type` is `ratio<1>`, the suffix is "s".
— Otherwise, if `Period::type` is `deca`, the suffix is "das".
— Otherwise, if `Period::type` is `hecto`, the suffix is "hs".
— Otherwise, if `Period::type` is `kilo`, the suffix is "ks".
— Otherwise, if `Period::type` is `mega`, the suffix is "Ms".
— Otherwise, if `Period::type` is `giga`, the suffix is "Gs".
— Otherwise, if `Period::type` is `tera`, the suffix is "Ts".
— Otherwise, if `Period::type` is `peta`, the suffix is "Ps".
— Otherwise, if `Period::type` is `exa`, the suffix is "Es".
— Otherwise, if `Period::type` is `ratio<60>`, the suffix is "min".
— Otherwise, if `Period::type` is `ratio<3600>`, the suffix is "h".
— Otherwise, if `Period::type::den` == 1, the suffix is "[num]s".
— Otherwise, the suffix is "[num/den]s".

In the list above the use of `num` and `den` refer to the static data members of `Period::type`, which are converted to arrays of `charT` using a decimal conversion with no leading zeroes.

4 If `Period::type` is `micro`, but the character U+00B5 cannot be represented in the encoding used for `charT`, the unit suffix "us" is used instead of "µs".

Returns: `os`.

```cpp
template<class charT, class traits, class Rep, class Period>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const duration<Rep, Period>& d);
```

Effects: Streams `d` into `os` using the format specified by the NTCTS `fmt`. `fmt` encoding follows the rules specified in 27.11.

Returns: `os`.

```cpp
template<class charT, class traits, class Rep, class Period, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>&& is, const charT* fmt, duration<Rep, Period>&& d, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream `is` into the duration `d` using the format flags given in the NTCTS `fmt` as specified in 27.12. If the parse parses everything specified by the parsing format flags without error, and yet none of the flags impacts a duration, `d` will be assigned a zero value. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

Returns: `is`.

### 27.6 Class template `time_point`

`namespaces std::chrono {`  
`template<class Clock, class Duration = typename Clock::duration>
class time_point {
    public:
        using clock = Clock;
        using duration = Duration;
        using rep = typename duration::rep;
        using period = typename duration::period;`

§ 27.6 1199
private:
  duration d_; // exposition only

public:
  // 27.6.1, construct
  constexpr time_point(); // has value epoch
  constexpr explicit time_point(const duration& d); // same as time_point() + d
  template<class Duration2>
    constexpr time_point(const time_point<clock, Duration2>& t);

  // 27.6.2, observer
  constexpr duration time_since_epoch() const;

  // 27.6.3, arithmetic
  constexpr time_point& operator++();
  constexpr time_point operator++(int);
  constexpr time_point& operator--();
  constexpr time_point operator--(int);
  constexpr time_point& operator+=(const duration& d);
  constexpr time_point& operator-=(const duration& d);

  // 27.6.4, special values
  static constexpr time_point min() noexcept;
  static constexpr time_point max() noexcept;
};

1 Clock shall either meet the Cpp17Clock requirements (27.3) or be the type local_t.
2 If Duration is not an instance of duration, the program is ill-formed.

27.6.1 Constructors [time.point.cons]

constexpr time_point();
1 Effects: Constructs an object of type time_point, initializing d_ with duration::zero(). Such a time_point object represents the epoch.

constexpr explicit time_point(const duration& d);
2 Effects: Constructs an object of type time_point, initializing d_ with d. Such a time_point object represents the epoch + d.

template<class Duration2>
  constexpr time_point(const time_point<clock, Duration2>& t);
3 Remarks: This constructor shall not participate in overload resolution unless Duration2 is implicitly convertible to duration.
4 Effects: Constructs an object of type time_point, initializing d_ with t.time_since_epoch().

27.6.2 Observer [time.point.observer]

calloperator time_since_epoch() const;
1 Returns: d_.

27.6.3 Arithmetic [time.point.arithmetic]

constexpr time_point& operator++();
1 Effects: ++d_.
2 Returns: *this.

constexpr time_point operator++(int);
3 Returns: time_point(d_++).
constexpr time_point& operator--();

Effects: --d_.
Returns: *this.

castexpr time_point operator--(int);

Returns: time_point(d--).

castexpr time_point& operator+=(const duration& d);

Effects: As if by: d_ += d;
Returns: *this.

castexpr time_point& operator-=(const duration& d);

Effects: As if by: d_ -= d;
Returns: *this.

27.6.4 Special values

static constexpr time_point min() noexcept;
Returns: time_point(duration::min()).

static constexpr time_point max() noexcept;
Returns: time_point(duration::max()).

27.6.5 Non-member arithmetic

template<class Clock, class Duration1, class Rep2, class Period2>
castexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>>
operator+(const time_point<Clock, duration<Rep2, Period2>>& lhs, const duration<Rep2, Period2>& rhs);
Returns: CT(lhs.time_since_epoch() + rhs), where CT is the type of the return value.

template<class Rep1, class Period1, class Clock, class Duration2>
castexpr time_point<Clock, common_type_t<duration<Rep1, Period1>, Duration2>>
operator+(const duration<Rep1, Period1>& lhs, const time_point<Clock, Duration2>& rhs);
Returns: rhs + lhs.

template<class Clock, class Duration1, class Rep2, class Period2>
castexpr time_point<Clock, common_type_t<duration<Rep2, Period2>, Duration1>>
operator-(const time_point<Clock, duration<Rep2, Period2>>& lhs, const duration<Rep2, Period2>& rhs);
Returns: CT(lhs.time_since_epoch() - rhs), where CT is the type of the return value.

template<class Clock, class Duration1, class Duration2>
castexpr common_type_t<Duration1, Duration2>
operator-(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
Returns: lhs.time_since_epoch() - rhs.time_since_epoch().

27.6.6 Comparisons

template<class Clock, class Duration1, class Duration2>
castexpr bool operator==(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
Returns: lhs.time_since_epoch() == rhs.time_since_epoch().

template<class Clock, class Duration1, class Duration2>
castexpr bool operator!=(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
Returns: !(lhs == rhs).
template<class Clock, class Duration1, class Duration2>
constexpr bool operator<(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: \( \text{lhs.time_since_epoch()} < \text{rhs.time_since_epoch()} \).

template<class Clock, class Duration1, class Duration2>
constexpr bool operator>(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: \( \text{rhs} < \text{lhs} \).

template<class Clock, class Duration1, class Duration2>
constexpr bool operator<=(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: \( \neg (\text{rhs} < \text{lhs}) \).

template<class Clock, class Duration1, class Duration2>
constexpr bool operator>=(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: \( \neg (\text{lhs} < \text{rhs}) \).

27.6.7 time_point_cast

```cpp
template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> time_point_cast(const time_point<Clock, Duration>& t);
```

Remarks: This function shall not participate in overload resolution unless `ToDuration` is a specialization of duration.

Returns:
\( \text{time_point<Clock, ToDuration>(duration_cast<ToDuration>(t.time_since_epoch()))} \).

```cpp
template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> floor(const time_point<Clock, Duration>& tp);
```

Remarks: This function shall not participate in overload resolution unless `ToDuration` is a specialization of duration.

Returns:
\( \text{time_point<Clock, ToDuration>(floor<ToDuration>(tp.time_since_epoch()))} \).

```cpp
template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> ceil(const time_point<Clock, Duration>& tp);
```

Remarks: This function shall not participate in overload resolution unless `ToDuration` is a specialization of duration.

Returns:
\( \text{time_point<Clock, ToDuration>(ceil<ToDuration>(tp.time_since_epoch()))} \).

```cpp
template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> round(const time_point<Clock, Duration>& tp);
```

Remarks: This function shall not participate in overload resolution unless `ToDuration` is a specialization of duration, and `treat_as_floating_point_v<typename ToDuration::rep> is false`.

Returns:
\( \text{time_point<Clock, ToDuration>(round<ToDuration>(tp.time_since_epoch()))} \).

27.7 Clocks

The types defined in this subclause shall meet the `Cpp17TrivialClock` requirements (27.3) unless otherwise specified.

27.7.1 Class system_clock

```cpp
namespace std::chrono {
  class system_clock {
public:
  using rep = see below;
  using period = ratio<unspecfied, unspecfied>;
```
using duration = chrono::duration<rep, period>;
using time_point = chrono::time_point<system_clock>;
static constexpr bool is_steady = unspecified;

static time_point now() noexcept;

// mapping to/from C type time_t
static time_t to_time_t(const time_point& t) noexcept;
static time_point from_time_t(time_t t) noexcept;

1 Objects of type system_clock represent wall clock time from the system-wide realtime clock. Objects of type sys_time<Duration> measure time since (and before) 1970-01-01 00:00:00 UTC excluding leap seconds. This measure is commonly referred to as Unix time. This measure facilitates an efficient mapping between sys_time and calendar types (27.8). [Example:
sys_seconds{sys_days{1970y/January/1}}.time_since_epoch() is 0s.
sys_seconds{sys_days{2000y/January/1}}.time_since_epoch() is 946'684'800s, which is 10'957 * 86'400s.
—end example]

27.7.1.2 Members [time.clock.system.members]

using system_clock::rep = unspecified;

1 Requires: system_clock::duration::min() < system_clock::duration::zero() shall be true.

[Note: This implies that rep is a signed type. — end note]

2 static time_t to_time_t(const time_point& t) noexcept;

2 Returns: A time_t object that represents the same point in time as t when both values are restricted
to the coarser of the precisions of time_t and time_point. It is implementation-defined whether values
are rounded or truncated to the required precision.

3 static time_point from_time_t(time_t t) noexcept;

3 Returns: A time_point object that represents the same point in time as t when both values are
restricted to the coarser of the precisions of time_t and time_point. It is implementation-defined
whether values are rounded or truncated to the required precision.

27.7.1.3 Non-member functions [time.clock.system.nonmembers]

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const sys_time<Duration>& tp);

1 Remarks: This operator shall not participate in overload resolution if treat_as_floating_point_<
typename Duration::rep> is true, or if Duration{1} >= days{1}.

2 Effects:
auto const dp = floor<days>(tp);

2 os << year_month_day(dp) << ' ' << time_of_day(tp-dp);

3 Returns: os.

[Example:
cout << sys_seconds{0s} << '\n'; // 1970-01-01 00:00:00
cout << sys_seconds{946'684'800s} << '\n'; // 2000-01-01 00:00:00
cout << sys_seconds{946'688'523s} << '\n'; // 2000-01-01 01:02:03
—end example]

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const sys_days& dp);

5 Effects: os << year_month_day(dp).

5 Returns: os.
template<class charT, class traits, class Duration>
    basic_ostream<charT, traits>&
    to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const sys_time<Duration>& tp);

Effects: Streams tp into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 27.11. If %Z is used, it will be replaced with "UTC" widened to charT. If %z is used (or a modified variant of %z), an offset of 0min will be formatted.

Returns: os.

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
    basic_istream<charT, traits>&
    from_stream(basic_istream<charT, traits>& is, const charT* fmt, sys_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the sys_time tp using the format flags given in the NTCTS fmt as specified in 27.12. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) shall be called and tp shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

Returns: is.

27.7.2 Class utc_clock

27.7.2.1 Overview

namespace std::chrono {
    class utc_clock {
        public:
            using rep = a signed arithmetic type;
            using period = ratio<unspecified, unspecified>;
            using duration = chrono::duration<rep, period>;
            using time_point = chrono::time_point<utc_clock>;
            static constexpr bool is_steady = unspecified;
        
        static time_point now();
        static sys_time<common_type_t<Duration, seconds>>
            to_sys(const utc_time<Duration>& t);
        static utc_time<common_type_t<Duration, seconds>>
            from_sys(const sys_time<Duration>& t);
    };
}

In contrast to sys_time, which does not take leap seconds into account, utc_clock and its associated time_point, utc_time, count time, including leap seconds, since 1970-01-01 00:00:00 UTC. [Example: clock_cast<utc_clock>(sys_seconds{sys_days{1970y/January/1}}).time_since_epoch() is 0s. clock_cast<utc_clock>(sys_seconds{sys_days{2000y/January/1}}).time_since_epoch() is 946'684'822s, which is 10'957 * 86'400s + 22s. —end example]

utc_clock is not a Cpp17TrivialClock unless the implementation can guarantee that utc_clock::now() does not propagate an exception. [Note: noexcept(from_sys(system_clock::now())) is false. —end note]

27.7.2.2 Member functions

static time_point now();

Returns: from_sys(system_clock::now()), or a more accurate value of utc_time.
template< typename Duration >
static sys_time< common_type_t< Duration, seconds >>
to_sys(const utc_time< Duration >& t);

Returns: A sys_time t, such that from_sys(t) == u if such a mapping exists. Otherwise u represents
a time_point during a leap second insertion and the last representable value of sys_time prior to the
insertion of the leap second is returned.

template< typename Duration >
static utc_time< common_type_t< Duration, seconds >>
from_sys(const sys_time< Duration >& t);

Returns: A utc_time u, such that u.time_since_epoch() - t.time_since_epoch() is equal to the
number of leap seconds that were inserted between t and 1970-01-01. If t is exactly the date of leap
second insertion, then the conversion counts that leap second as inserted.

[Example:
auto t = sys_days{July/1/2015} - 2ns;
auto u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 25s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 25s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 26s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 26s);
— end example]

27.7.2.3 Non-member functions

template< class charT, class traits, class Duration >
basic_ostream< charT, traits >&
operator<<(basic_ostream< charT, traits >& os, const utc_time< Duration >& t);

Effects: Calls to_stream(os, fmt, t), where fmt is a string containing "%F %T" widened to charT.

Returns: os.

template< class charT, class traits, class Duration >
basic_ostream< charT, traits >&
to_stream(basic_ostream< charT, traits >& os, const charT* fmt, const utc_time< Duration >& t);

Effects: Streams tp into os using the format specified by the NTCTS fmt. fmt encoding follows the
rules specified in 27.11. If %Z is used, it will be replaced with "UTC" widened to charT. If %z is used
(or a modified variant of %z), an offset of Omin will be formatted. If tp represents a time during a leap
second insertion, and if a seconds field is formatted, the integral portion of that format shall be "60"
widened to charT.

Returns: os.

[Example:
auto t = sys_days{July/1/2015} - 500ms;
auto u = clock_cast< utc_clock >(t);
for (auto i = 0; i < 8; ++i, u += 250ms)
    cout << u << " UTC\n";  

Produces this output:
2015-06-30 23:59:59.500 UTC
2015-06-30 23:59:59.750 UTC
2015-06-30 23:59:60.000 UTC
2015-06-30 23:59:60.250 UTC
2015-06-30 23:59:60.500 UTC
2015-06-30 23:59:60.750 UTC
2015-07-01 00:00:00.000 UTC

§ 27.7.2.3
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
utc_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the utc_time tp using the format flags given in
the NTCTS fmt as specified in 27.12. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) shall be called and tp shall not be modified. If %Z is used and successfully parsed,
that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used
and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally,
the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that
difference to tp.

Returns: is.

27.7.3 Class tai_clock
[time.clock.tai]
27.7.3.1 Overview
[time.clock.tai.overview]
namespace std::chrono {
class tai_clock {
public:
using rep = a signed arithmetic type;
using period = ratio<unspecified, unspecified>;
using duration = chronon::duration<rep, period>;
using time_point = chronon::time_point<tai_clock>;
static constexpr bool is_steady = unspecified;

static time_point now();

template<class Duration>
static utc_time<common_type_t<Duration, seconds>>
to_utc(const tai_time<Duration>&) noexcept;

static tai_time<common_type_t<Duration, seconds>>
from_utc(const utc_time<Duration>&) noexcept;
};
}

The clock tai_clock measures seconds since 1958-01-01 00:00:00 and is offset 10s ahead of UTC at this date.
That is, 1958-01-01 00:00:00 TAI is equivalent to 1957-12-31 23:59:50 UTC. Leap seconds are not inserted
into TAI. Therefore every time a leap second is inserted into UTC, UTC falls another second behind TAI.
For example by 2000-01-01 there had been 22 leap seconds inserted so 2000-01-01 00:00:00 UTC is equivalent
to 2000-01-01 00:00:32 TAI (22s plus the initial 10s offset).

tai_clock is not a Cpp17TrivialClock unless the implementation can guarantee that tai_clock::now() does not propagate an exception. [Note: noexcept(from_utc(utc_clock::now())) is false. — end note]

27.7.3.2 Member functions
[time.clock.tai.members]
static time_point now();

Returns: from_utc(utc_clock::now()), or a more accurate value of tai_time.

template<class Duration>
static utc_time<common_type_t<Duration, seconds>>
to_utc(const tai_time<Duration>& t) noexcept;

Returns:

utc_time<common_type_t<Duration, seconds>>(t.time_since_epoch()) - 378691210s

[Note:
378691210s == sys_days{1970y/January/1} - sys_days{1958y/January/1} + 10s

§ 27.7.3.2 1206
template<class Duration>
static tai_time<common_type_t<Duration, seconds>>
    from_utc(const utc_time<Duration>& t) noexcept;

Returns:
    tai_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} + 378691210s

[Note:
378691210s == sys_days{1970y/January/1} - sys_days{1958y/January/1} + 10s
—end note]

27.7.3.3 Non-member functions

template<class charT, class traits, class Duration>
    basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>&& os, const tai_time<Duration>&& t);

Effects: Calls to_stream(os, fmt, t), where fmt is a string containing "%F %T" widened to charT.

Returns: os.

template<class charT, class traits, class Duration>
    basic_ostream<charT, traits>&
        to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const tai_time<Duration>& tp);

effects: Streams tp into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 27.11. If %Z is used, it will be replaced with "TAI". If %z is used (or a modified variant of %Z), an offset of 0min will be formatted. The date and time formatted shall be equivalent to that formatted by a sys_time initialized with:

    sys_time<Duration>{t.time_since_epoch()} -
    (sys_days{1970y/January/1} - sys_days{1958y/January/1})

Returns: os.

[Example:
    auto st = sys_days{2000y/January/1};
    auto tt = clock_cast<tai_clock>(st);
    cout << format("%F %T %Z == ", st) << format("%F %T %Z
", tt);

Produces this output:
2000-01-01 00:00:00 UTC == 2000-01-01 00:00:32 TAI
—end example]

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
    basic_istream<charT, traits>&
        from_stream(basic_istream<charT, traits>&& is, const charT* fmt,
                    tai_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
                    minutes* offset = nullptr);

effects: Attempts to parse the input stream is into the tai_time tp using the format flags given in the NTCTS fmt as specified in 27.12. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) shall be called and tp shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

Returns: is.
public:
  using rep = a signed arithmetic type;
  using period = ratio<unspecified, unspecified>;
  using duration = chrono::duration<rep, period>;
  using time_point = chrono::time_point<gps_clock>;
  static constexpr bool is_steady = unspecified;

  static time_point now();

  template<class Duration>
  static utc_time<common_type_t<Duration, seconds>>
  to_utc(const gps_time<Duration>&) noexcept;

  template<class Duration>
  static gps_time<common_type_t<Duration, seconds>>
  from_utc(const utc_time<Duration>&) noexcept;
};

1 The clock gps_clock measures seconds since the first Sunday of January, 1980 00:00:00 UTC. Leap seconds
are not inserted into GPS. Therefore every time a leap second is inserted into UTC, UTC falls another
second behind GPS. Aside from the offset from 1958y/January/1 to 1980y/January/Sunday[1], GPS is
behind TAI by 19s due to the 10s offset between 1958 and 1970 and the additional 9 leap seconds inserted

2 gps_clock is not a Cpp17TrivialClock unless the implementation can guarantee that gps_clock::now()
does not propagate an exception. [Note: noexcept(from_utc(utc_clock::now())) is false. — end note]

27.7.4.2 Member functions [time.clock.gps.members]

static time_point now();
1 Returns: from_utc(utc_clock::now()), or a more accurate value of gps_time.

  template<class Duration>
  static utc_time<common_type_t<Duration, seconds>>
  to_utc(const gps_time<Duration>& t) noexcept;
2 Returns:
  gps_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} + 315964809s
  [Note:
   315964809s == sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1} + 9s
   — end note]

  template<class Duration>
  static gps_time<common_type_t<Duration, seconds>>
  from_utc(const utc_time<Duration>& t) noexcept;
3 Returns:
  gps_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} - 315964809s
  [Note:
   315964809s == sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1} + 9s
   — end note]

27.7.4.3 Non-member functions [time.clock.gps.nonmembers]

  template<class charT, class traits, class Duration>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& os, const gps_time<Duration>& t);
1 Effects: Calls to_stream(os, fmt, t), where fmt is a string containing "%F %T" widened to charT.
2 Returns: os.
template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const gps_time<Duration>& tp);

Effects: Streams tp into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 27.11. If %Z is used, it will be replaced with "GPS". If %z is used (or a modified variant of %z), an offset of 0min will be formatted. The date and time formatted shall be equivalent to that formatted by a sys_time initialized with:

```
sys_time<Duration>(tp.time_since_epoch()) +
(sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1})
```

Returns: os.

Example:
```
auto st = sys_days{2000y/January/1};
auto gt = clock_cast<gps_clock>(st);
cout << format("%F %T %Z == ", st) << format("%F %T %Z\n", gt);
```

Produces this output:
```
2000-01-01 00:00:00 UTC == 2000-01-01 00:00:13 GPS
```

—end example—

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt, gps_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the gps_time tp using the format flags given in the NTCTS fmt as specified in 27.12. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) shall be called and tp shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

Returns: is.

27.7.5 Type file_clock

27.7.5.1 Overview

file_clock is an alias for a type meeting the Cpp17TrivialClock requirements (27.3), and using a signed arithmetic type for file_clock::rep. file_clock is used to create the time_point system used for file_time_type (29.11). Its epoch is unspecified, and noexcept(file_clock::now()) is true. [Note: The type that file_clock denotes may be in a different namespace than std::chrono, such as std::filesystem. —end note—]

27.7.5.2 Member functions

The type denoted by file_clock provides precisely one of the following two sets of static member functions:

```
template<class Duration>
static sys_time<see below>
to_sys(const file_time<Duration>&);
template<class Duration>
static file_time<see below>
from_sys(const sys_time<Duration>&);
```
or:

```
template<class Duration>
static utc_time<see below>
to_utc(const file_time<Duration>&);
```
template<class Duration>
static file_time<see below>
from_utc(const utc_time<Duration>&);

These member functions shall provide time_point conversions consistent with those specified by utc_clock, tai_clock, and gps_clock. The Duration of the resultant time_point is computed from the Duration of the input time_point.

27.7.5.3 Non-member functions

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const file_time<Duration>& t);

Effects: Calls to_stream(os, fmt, t), where fmt is a string containing "%F %T" widened to charT.

Returns: os.

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const file_time<Duration>& tp);

Effects: Streams tp into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 27.11. If %Z is used, it will be replaced with "UTC" widened to charT. If %z is used (or a modified variant of %z), an offset of 0min will be formatted. The date and time formatted shall be equivalent to that formatted by a sys_time initialized with clock_cast<system_clock>(tp), or by a utc_time initialized with clock_cast<utc_clock>(tp).

Returns: os.

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt,
file_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the file_time tp using the format flags given in the NTCTS fmt as specified in 27.12. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) shall be called and tp shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

Returns: is.

27.7.6 Class steady_clock

namespace std::chrono {

class steady_clock {

public:
  using rep = unspecified;
  using period = ratio<unspecified, unspecified>;
  using duration = chrono::duration<rep, period>;
  using time_point = chrono::time_point<unspecified, duration>;
  static constexpr bool is_steady = true;

  static time_point now() noexcept;
};

}

1 Objects of class steady_clock represent clocks for which values of time_point never decrease as physical time advances and for which values of time_point advance at a steady rate relative to real time. That is, the clock may not be adjusted.
27.7.7 Class high_resolution_clock

```cpp
namespace std::chrono {
    class high_resolution_clock {
    public:
        using rep = unspecified;
        using period = ratio<unspecified, unspecified>;
        using duration = chrono::duration<rep, period>;
        using time_point = chrono::time_point<unspecified, duration>;
        static constexpr bool is_steady = unspecified;
        static time_point now() noexcept;
    };
}
```

1 Objects of class `high_resolution_clock` represent clocks with the shortest tick period. `high_resolution_clock` may be a synonym for `system_clock` or `steady_clock`.

27.7.8 Local time

```cpp
template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const local_time<Duration>& lt);
```

2 Effects:

```cpp
os << sys_time<Duration>{lt.time_since_epoch()};
```

3 Returns: os.

```cpp
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt, local_time<Duration>& tp, Alloc* abbrev = nullptr, minutes* offset = nullptr);
```

6 Effects: Attemspt to parse the input stream is into the local_time tp using the format flags given in the NTCTS fmt as specified in 27.12. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) shall be called and tp shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %Z (or a modified variant of %Z) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

7 Returns: is.

27.7.9 time_point conversions

27.7.9.1 Class template clock_time_conversion

```cpp
namespace std::chrono {
    template<class DestClock, class SourceClock> ...
```
struct clock_time_conversion {};
template<class Duration>
utc_time<common_type_t<Duration, seconds>>
operator()(const sys_time<Duration>& t) const;

 template<>
struct clock_time_conversion<system_clock, utc_clock> {
 template<class Duration>
 sys_time<common_type_t<Duration, seconds>>
 operator()(const utc_time<Duration>& t) const;
};

template<class Duration>
 sys_time<common_type_t<Duration, seconds>>
 operator()(const utc_time<Duration>& t) const;

 Returns: utc_clock::from_sys(t).

27.7.9.4 Conversions between system_clock and other clocks

 template<class SourceClock>
 struct clock_time_conversion<system_clock, SourceClock> {
 template<class Duration>
 auto operator()(const time_point<SourceClock, Duration>& t) const
 -> decltype(SourceClock::to_sys(t));
 };
Returns: SourceClock::to_utc(t).

```cpp
template<class DestClock>
struct clock_time_conversion<DestClock, utc_clock> {
    template<class Duration>
    auto operator()(const utc_time<Duration>& t) const
        -> decltype(DestClock::from_utc(t));
};
```

Returns: SourceClock::to_utc(t).

```cpp
template<class Duration>
auto operator()(const utc_time<Duration>& t) const
    -> decltype(DestClock::from_utc(t));
```

Remarks: This function does not participate in overload resolution unless DestClock::from_utc(t) is well-formed. If DestClock::from_utc(t) does not return time_point<DestClock, Duration>, where Duration is a valid chrono::duration specialization, the program is ill-formed.

Returns: DestClock::from_utc(t).

### 27.7.9.6 Function template clock_cast

```cpp
template<class DestClock, class SourceClock, class Duration>
auto clock_cast(const time_point<SourceClock, Duration>& t);
```

Remarks: This function does not participate in overload resolution unless at least one of the following clock time conversion expressions is well-formed:

1. clock_time_conversion<DestClock, SourceClock>{}(t)
2. clock_time_conversion<DestClock, system_clock>{}(clock_time_conversion<system_clock, SourceClock>{}(t))
3. clock_time_conversion<DestClock, utc_clock>{}(clock_time_conversion<utc_clock, SourceClock>{}(t))
4. clock_time_conversion<DestClock, utc_clock>{}(clock_time_conversion<utc_clock, system_clock>{}(clock_time_conversion<system_clock, SourceClock>{}(t)))
5. clock_time_conversion<DestClock, system_clock>{}(clock_time_conversion<system_clock, utc_clock>{}(clock_time_conversion<utc_clock, SourceClock>{}(t)))

A clock time conversion expression is considered better than another clock time conversion expression if it involves fewer operator() calls on clock_time_conversion specializations. If, among the well-formed clock time conversion expressions from the above list, there is not a unique best expression, the clock_cast is ambiguous and the program is ill-formed.

Returns: The best well-formed clock time conversion expression in the above list.

### 27.8 The civil calendar

#### 27.8.1 In general

The types in 27.8 describe the civil (Gregorian) calendar and its relationship to sys_days and local_days.

#### 27.8.2 Class last_spec

```cpp
namespace std::chrono {
    struct last_spec {
        explicit last_spec() = default;
    };
}
```

The type last_spec is used in conjunction with other calendar types to specify the last in a sequence. For example, depending on context, it can represent the last day of a month, or the last day of the week of a month.
27.8.3 Class day [time.cal.day]

27.8.3.1 Overview [time.cal.day.overview]

namespace std::chrono {
    class day {
        unsigned char d_;  // exposition only
    public:
        day() = default;
        constexpr explicit day(unsigned d) noexcept;
        constexpr day& operator++() noexcept;
        constexpr day operator++(int) noexcept;
        constexpr day& operator--() noexcept;
        constexpr day operator--(int) noexcept;
        constexpr day& operator+=(const days& d) noexcept;
        constexpr day& operator-=(const days& d) noexcept;
        constexpr explicit operator unsigned() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

1 day represents a day of a month. It normally holds values in the range 1 to 31, but may hold non-negative values outside this range. It can be constructed with any unsigned value, which will be subsequently truncated to fit into day’s unspecified internal storage. day is Cpp17EqualityComparable (Table 23) and Cpp17LessThanComparable (Table 24), and participates in basic arithmetic with days objects, which represent a difference between two day objects.

2 day is a trivially copyable and standard-layout class type.

27.8.3.2 Member functions [time.cal.day.members]

constexpr explicit day(unsigned d) noexcept;

1 Effects: Constructs an object of type day by initializing d_ with d. The value held is unspecified if d is not in the range [0, 255].

constexpr day& operator++() noexcept;

2 Effects: ++d_.
3 Returns: *this.

constexpr day operator++(int) noexcept;

4 Effects: ++(*this).
5 Returns: A copy of *this as it existed on entry to this member function.

constexpr day& operator--() noexcept;

6 Effects: --d_.
7 Returns: *this.

constexpr day operator--(int) noexcept;

8 Effects: --(*this).
9 Returns: A copy of *this as it existed on entry to this member function.

constexpr day& operator+=(const days& d) noexcept;

10 Effects: *this = *this + d.
11 Returns: *this.

constexpr day& operator-=(const days& d) noexcept;

12 Effects: *this = *this - d.
13 Returns: *this.
constexpr explicit operator unsigned() const noexcept;
14
   Returns: \(d_\).

constexpr bool ok() const noexcept;
15
   Returns: \(1 \leq d_ \&\& d_ < 31\).

27.8.3.3 Non-member functions

constexpr bool operator==(const day& x, const day& y) noexcept;
1
   Returns: \(\text{unsigned}(x) == \text{unsigned}(y)\).

constexpr bool operator<(const day& x, const day& y) noexcept;
2
   Returns: \(\text{unsigned}(x) < \text{unsigned}(y)\).

constexpr day operator+(const day& x, const days& y) noexcept;
3
   Returns: day(\text{unsigned}(x) + y\text{.count()}).

constexpr day operator-(const day& x, const days& y) noexcept;
5
   Returns: \(x + -y\).

constexpr days operator-(const day& x, const day& y) noexcept;
6
   Returns: days{\text{int}(\text{unsigned}(x)) - \text{int}(\text{unsigned}(y))}.

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const day& d);
7
   Effects: Inserts \(\text{format}(\text{fmt}, d)\) where \(\text{fmt}\) is "\%d" widened to \(\text{charT}\). If \(!d\text{.ok()}\), appends with " is not a valid day".

   Returns: \(os\).

template<class charT, class traits>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const day& d);
8
   Effects: Streams \(d\) into \(os\) using the format specified by the NTCTS \(\text{fmt}\). \(\text{fmt}\) encoding follows the rules specified in 27.11.

   Returns: \(os\).

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt, const day& d, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);
9
   Effects: Attempts to parse the input stream \(is\) into the \(\text{day}\ d\) using the format flags given in the NTCTS \(\text{fmt}\) as specified in 27.12. If the parse fails to decode a valid day, \(\text{is}\text{.setstate}(ios_base::failbit)\) shall be called and \(d\) shall not be modified. If \(\%Z\) is used and successfully parsed, that value will be assigned to \(*abbrev\) if \(abbrev\) is non-null. If \(\%z\) (or a modified variant) is used and successfully parsed, that value will be assigned to \(*offset\) if \(offset\) is non-null.

   Returns: \(is\).

constexpr day operator"\"d(unsigned long long d) noexcept;
10
   Returns: day{static_cast<unsigned>(d)}.

27.8.4 Class month

27.8.4.1 Overview

namespace std::chrono {

\[\text{time.cal.month}\]
\[\text{time.cal.month.overview}\]
class month {
    unsigned char m_;  // exposition only
public:
    month() = default;
    constexpr explicit month(unsigned m) noexcept;
    constexpr month& operator++() noexcept;
    constexpr month operator++(int) noexcept;
    constexpr month& operator--() noexcept;
    constexpr month operator--(int) noexcept;
    constexpr month& operator+=(const months& m) noexcept;
    constexpr month& operator-=(const months& m) noexcept;
    constexpr explicit operator unsigned() const noexcept;
    constexpr bool ok() const noexcept;
};

1 month represents a month of a year. It normally holds values in the range 1 to 12, but may hold non-negative values outside this range. It can be constructed with any unsigned value, which will be subsequently truncated to fit into month’s unspecified internal storage. month is Cpp17EqualityComparable (Table 23) and Cpp17LessThanComparable (Table 24), and participates in basic arithmetic with months objects, which represent a difference between two month objects.

2 month is a trivially copyable and standard-layout class type.

27.8.4.2 Member functions

constexpr explicit month(unsigned m) noexcept;
1 Effects: Constructs an object of type month by initializing m_ with m. The value held is unspecified if m is not in the range [0, 255].

customexpr month& month::operator++() noexcept;
2 Effects: *this += months{1}.
3 Returns: *this.

customexpr month operator++(int) noexcept;
4 Effects: ++(*this).
5 Returns: A copy of *this as it existed on entry to this member function.

customexpr month& operator--() noexcept;
6 Effects: *this -= months{1}.
7 Returns: *this.

customexpr month operator--(int) noexcept;
8 Effects: --(*this).
9 Returns: A copy of *this as it existed on entry to this member function.

customexpr month& operator+=(const months& m) noexcept;
10 Effects: *this = *this + m.
11 Returns: *this.

customexpr month& operator-=(const months& m) noexcept;
12 Effects: *this = *this - m.
13 Returns: *this.

customexpr explicit month::operator unsigned() const noexcept;
14 Returns: m_.

§ 27.8.4.2
constexpr bool month::ok() const noexcept;

Returns: 1 <= m_ && m_ <= 12.

27.8.4.3 Non-member functions

constexpr bool operator==(const month& x, const month& y) noexcept;

Returns: unsigned{x} == unsigned{y}.

customexpr month operator+(const month& x, const months& y) noexcept;

Returns:
month(modulo(static_cast<long long>(unsigned{x}) + (y.count() - 1), 12) + 1)
where modulo(n, 12) computes the remainder of n divided by 12 using Euclidean division. [Note: Given a divisor of 12, Euclidean division truncates towards negative infinity and always produces a remainder in the range of [0, 11]. Assuming no overflow in the signed summation, this operation results in a month holding a value in the range [1, 12] even if !x.ok(). —end note] [Example: February + months{11} == January. —end example]

constexpr month operator+(const months& x, const month& y) noexcept;

Returns: y + x.

customexpr month operator-(const month& x, const months& y) noexcept;

Returns: x + -y.

customexpr months operator-(const month& x, const month& y) noexcept;

Returns: If x.ok() == true and y.ok() == true, returns a value m in the range [months{0}, months{11}] satisfying y + m == x. Otherwise the value returned is unspecified. [Example: January - February == months{11}. —end example]

template<class charT, class traits>
operator<<(basic_ostream<charT, traits>& os, const month& m);

Effects: If m.ok() == true inserts format(os.getloc(), fmt, m) where fmt is "%b" widened to charT. Otherwise inserts unsigned{m} << " is not a valid month".

Returns: os.

template<class charT, class traits>
operator<<(basic_ostream<charT, traits>& os, const month& m, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the month m using the format flags given in the NTCTS fmt as specified in 27.12. If the parse fails to decode a valid month, is.setstate(ios_base::failbit) shall be called and m shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.
27.8.5 Class year

27.8.5.1 Overview

namespace std::chrono {
    class year {
        short y_;  // exposition only
    public:
        year() = default;
        constexpr explicit year(int y) noexcept;
        constexpr year& operator++() noexcept;
        constexpr year operator++(int) noexcept;
        constexpr year& operator--() noexcept;
        constexpr year operator--(int) noexcept;
        constexpr year& operator+=(const years& y) noexcept;
        constexpr year& operator-=(const years& y) noexcept;
        constexpr year operator+() const noexcept;
        constexpr year operator-() const noexcept;
        constexpr bool is_leap() const noexcept;
        constexpr explicit operator int() const noexcept;
        constexpr bool ok() const noexcept;
        static constexpr year min() noexcept;
        static constexpr year max() noexcept;
    };
}

1 year represents a year in the civil calendar. It can represent values in the range \([\text{min}(), \text{max}()]\). It can be constructed with any int value, which will be subsequently truncated to fit into year’s unspecified internal storage. year is Cpp17EqualityComparable (Table 23) and Cpp17LessThanComparable (Table 24), and participates in basic arithmetic with years objects, which represent a difference between two year objects.

2 year is a trivially copyable and standard-layout class type.

27.8.5.2 Member functions

constexpr explicit year(int y) noexcept;

1 Effects: Constructs an object of type year by initializing y_ with y. The value held is unspecified if y is not in the range \([-32767, 32767]\).

constexpr year& operator++() noexcept;

2 Effects: ++y_.

3 Returns: *this.

constexpr year operator++(int) noexcept;

4 Effects: ++(*this).

5 Returns: A copy of *this as it existed on entry to this member function.

constexpr year& operator--() noexcept;

6 Effects: --y_.

7 Returns: *this.

constexpr year operator--(int) noexcept;

8 Effects: --(*this).

9 Returns: A copy of *this as it existed on entry to this member function.
constexpr year& operator+=(const years& y) noexcept;  
Effects:  *this = *this + y.  
Returns:  *this.

constexpr year& operator-=(const years& y) noexcept;  
Effects:  *this = *this - y.  
Returns:  *this.

constexpr year operator+() const noexcept;  
Returns:  *this.

constexpr explicit operator int() const noexcept;  
Returns:  y_.  

constexpr year operator-() const noexcept;  
Returns:  year{-y_}.  

castexpr bool is_leap() const noexcept;  
Returns:  y_ % 4 == 0 && (y_ % 100 != 0 || y_ % 400 == 0).

castexpr bool ok() const noexcept;  
Returns:  min() <= y_ && y_ <= max().  

static constexpr year min() noexcept;  
Returns:  year{-32767}.  

static constexpr year max() noexcept;  
Returns:  year{32767}.  

§ 27.8.5.3  Non-member functions  
[time.cal.year.nonmembers]

castexpr bool operator==(const year& x, const year& y) noexcept;  
Returns:  int{x} == int{y}.  

castexpr bool operator<(const year& x, const year& y) noexcept;  
Returns:  int{x} < int{y}.  

castexpr year operator+(const year& x, const years& y) noexcept;  
Returns:  y + x.

castexpr year operator+(const years& x, const year& y) noexcept;  
Returns:  x + -y.

castexpr years operator-(const year& x, const year& y) noexcept;  
Returns:  years{int{x} - int{y}}.

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const year& y);  
Effects:  Inserts format(fmt, y) where fmt is "%Y" widened to charT. If !y.ok(), appends with " is not a valid year".  
Returns:  os.
template<class charT, class traits>  
basic_ostream<charT, traits>&
  to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const year& y);

Effects: Streams y into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 27.11.

Returns: os.

template<class charT, class traits, class Alloc = allocator<charT>>  
basic_istream<charT, traits>&
  from_stream(basic_istream<charT, traits>& is, const charT* fmt,  
              year& y, basic_string<charT, traits, Alloc>* abbrev = nullptr,  
              minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the year y using the format flags given in the NTCTS fmt as specified in 27.12. If the parse fails to decode a valid year, is.setstate(ios_base::failbit) shall be called and y shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

constexpr year operator"y(unsigned long long y) noexcept;

Returns: year{static_cast<int>(y)}.

27.8.6 Class weekday [time.cal.wd]  
27.8.6.1 Overview [time.cal.wd.overview]

class weekday {
  unsigned char wd_;   // exposition only
public:
  weekday() = default;
  constexpr explicit weekday(unsigned wd) noexcept;
  constexpr weekday(const sys_days& dp) noexcept;
  constexpr weekday(const local_days& dp) noexcept;

  constexpr weekday& operator++() noexcept;
  constexpr weekday operator++(int) noexcept;
  constexpr weekday& operator--() noexcept;
  constexpr weekday operator--(int) noexcept;

  constexpr weekday& operator+=(const days& d) noexcept;
  constexpr weekday& operator-=(const days& d) noexcept;

  constexpr explicit operator unsigned() const noexcept;
  constexpr bool ok() const noexcept;

  constexpr weekday_indexed operator[](unsigned index) const noexcept;
  constexpr weekday_last operator[](last_spec) const noexcept;
};

weekday represents a day of the week in the civil calendar. It normally holds values in the range 0 to 6, corresponding to Sunday through Saturday, but it may hold non-negative values outside this range. It can be constructed with any unsigned value, which will be subsequently truncated to fit into weekday's unspecified internal storage. weekday is Cpp17EqualityComparable (Table 23). [Note: weekday is not Cpp17LessThanComparable because there is no universal consensus on which day is the first day of the week. weekday's arithmetic operations treat the days of the week as a circular range, with no beginning and no end. — end note]

weekday is a trivially copyable and standard-layout class type.
27.8.6.2 Member functions

```cpp
constexpr explicit weekday(unsigned wd) noexcept;
Effects: Constructs an object of type weekday by initializing wd_ with wd. The value held is unspecified if wd is not in the range [0, 255].
```

```cpp
constexpr weekday(const sys_days& dp) noexcept;
Effects: Constructs an object of type weekday by computing what day of the week corresponds to the sys_days dp, and representing that day of the week in wd_.
[Example: If dp represents 1970-01-01, the constructed weekday represents Thursday by storing 4 in wd_. — end example]
```

```cpp
constexpr explicit weekday(const local_days& dp) noexcept;
Effects: Constructs an object of type weekday by computing what day of the week corresponds to the local_days dp, and representing that day of the week in wd_.
Remarks: The value after construction is identical to that constructed from sys_days{dp.time_since_epoch()}.
```

```cpp
constexpr weekday& operator++() noexcept;
Effects: *this += days{1}.
Returns: *this.
```

```cpp
constexpr weekday operator++(int) noexcept;
Effects: ++(*this).
Returns: A copy of *this as it existed on entry to this member function.
```

```cpp
constexpr weekday& operator--() noexcept;
Effects: *this -= days{1}.
Returns: *this.
```

```cpp
constexpr weekday operator--(int) noexcept;
Effects: --(*this).
Returns: A copy of *this as it existed on entry to this member function.
```

```cpp
constexpr explicit weekday(const days& d) noexcept;
Effects: *this = *this + d.
Returns: *this.
```

```cpp
constexpr explicit operator unsigned() const noexcept;
Returns: wd_.
```

```cpp
constexpr bool ok() const noexcept;
Returns: wd_ <= 6.
```

```cpp
constexpr weekday_indexed operator[](unsigned index) const noexcept;
Returns: {*this, index}.
```

```cpp
constexpr weekday_last operator[](last_spec) const noexcept;
Returns: weekday_last{*this}.
```
27.8.6.3 Non-member functions

constexpr bool operator==(const weekday& x, const weekday& y) noexcept;
Returns: unsigned{x} == unsigned{y}.

constexpr weekday operator+(const weekday& x, const days& y) noexcept;
Returns:
weekday(modulo(static_cast<long long>(unsigned{x}) + y.count(), 7))
where modulo(n, 7) computes the remainder of n divided by 7 using Euclidean division. [Note: Given a divisor of 7, Euclidean division truncates towards negative infinity and always produces a remainder in the range of \([0, 6]\). Assuming no overflow in the signed summation, this operation results in a weekday holding a value in the range \([0, 6]\) even if \(!x.ok()\). — end note] [Example: Monday + days(6) == Sunday. — end example]

constexpr weekday operator+(const days& x, const weekday& y) noexcept;
Returns: y + x.

constexpr weekday operator-(const weekday& x, const days& y) noexcept;
Returns: x + -y.

constexpr days operator-(const weekday& x, const weekday& y) noexcept;
Returns: If x.ok() == true and y.ok() == true, returns a value d in the range \([days{0}, days{6}]\) satisfying y + d == x. Otherwise the value returned is unspecified. [Example: Sunday - Monday == days{6}. — end example]

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const weekday& wd);
Effects: If wd.ok() == true inserts format(os.getloc(), fmt, wd) where fmt is "%a" widened to charT. Otherwise inserts unsigned{wd} << " is not a valid weekday".
Returns: os.

template<class charT, class traits>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const weekday& wd);
Effects: Streams wd into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 27.11.
Returns: os.

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>&& is, const charT* fmt, const weekday& wd, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);
Effects: Attempts to parse the input stream is into the weekday wd using the format flags given in the NTCTS fmt as specified in 27.12. If the parse fails to decode a valid weekday, is.setstate(ios_base::failbit) shall be called and wd shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.
Returns: is.

27.8.7 Class weekday_indexed

27.8.7.1 Overview

namespace std::chrono {
class weekday_indexed {  
    chrono::weekday wd_;    // exposition only
    unsigned char index_;   // exposition only
}
weekday_indexed represents a weekday and a small index in the range 1 to 5. This class is used to represent the first, second, third, fourth, or fifth weekday of a month.

[Note: A weekday_indexed object can be constructed by indexing a weekday with an unsigned. — end note]

```cpp
constexpr auto wdi = Sunday[2]; // wdi is the second Sunday of an as yet unspecified month
static_assert(wdi.weekday() == Sunday);
static_assert(wdi.index() == 2);
— end example]
```

weekday_indexed is a trivially copyable and standard-layout class type.

### 27.8.7.2 Member functions

```cpp
constexpr weekday_indexed(const chrono::weekday& wd, unsigned index) noexcept;
```

*Effects:* Constructs an object of type `weekday_indexed` by initializing `wd_` with `wd` and `index_` with `index`. The values held are unspecified if `!wd_.ok()` or `index` is not in the range `[1, 5]`.

```cpp
constexpr chrono::weekday weekday() const noexcept;
```

*Returns:* `wd_`.

```cpp
constexpr unsigned index() const noexcept;
```

*Returns:* `index_`.

```cpp
constexpr bool ok() const noexcept;
```

*Returns:* `wd_.ok() && 1 <= index_ && index_ <= 5`.

### 27.8.7.3 Non-member functions

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const weekday_indexed& wdi);
```

*Effects:* `os << wdi.weekday() << '[' << wdi.index(). If `wdi.index()` is in the range `[1, 5]`, appends with ']', otherwise appends with "is not a valid index".

*Returns:* `os`.

### 27.8.8 Class weekday_last

### 27.8.8.1 Overview

```cpp
namespace std::chrono {
    class weekday_last {
    chronos::weekday wd_; // exposition only

    public:
    constexpr explicit weekday_last(const chrono::weekday& wd) noexcept;

    constexpr chrono::weekday weekday() const noexcept;
    constexpr bool ok() const noexcept;
    
    }
}
```
weekday_last represents the last weekday of a month.

[Note: A weekday_last object can be constructed by indexing a weekday with last. — end note] [Example:
constexpr auto wdl = Sunday[last];  // wdl is the last Sunday of an as yet unspecified month
static_assert(wdl.weekday() == Sunday);
—end example]

weekday_last is a trivially copyable and standard-layout class type.

### 27.8.8.2 Member functions

```cpp
constexpr explicit weekday_last(const chrono::weekday& wd) noexcept;
```

Effects: Constructs an object of type weekday_last by initializing wd_ with wd.

```cpp
constexpr chrono::weekday weekday() const noexcept;
```

Returns: wd_.

```cpp
constexpr bool ok() const noexcept;
```

Returns: wd_.ok().

### 27.8.8.3 Non-member functions

```cpp
constexpr bool operator==(const weekday_last& x, const weekday_last& y) noexcept;
```

Returns: x.weekday() == y.weekday().

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const weekday_last& wdl);
```

Returns: os << wdl.weekday() << "[last]".

### 27.8.9 Class month_day

#### 27.8.9.1 Overview

```cpp
namespace std::chrono {
    class month_day {
        chrono::month m_;  // exposition only
        chrono::day d_;    // exposition only

        public:
            month_day() = default;
            constexpr month_day(const chrono::month& m, const chrono::day& d) noexcept;

            constexpr chrono::month month() const noexcept;
            constexpr chrono::day day() const noexcept;
            constexpr bool ok() const noexcept;
    }
}
```

month_day represents a specific day of a specific month, but with an unspecified year. month_day is `cpp17EqualityComparable` (Table 23) and `cpp17LessThanComparable` (Table 24).

month_day is a trivially copyable and standard-layout class type.

#### 27.8.9.2 Member functions

```cpp
constexpr month_day(const chrono::month& m, const chrono::day& d) noexcept;
```

Effects: Constructs an object of type month_day by initializing m_ with m, and d_ with d.

```cpp
constexpr chrono::month month() const noexcept;
```

Returns: m_.

```cpp
constexpr chrono::day day() const noexcept;
```

Returns: d_.
constexpr bool ok() const noexcept;

Returns: true if m_.ok() is true, \(1 \leq d_\), and \(d_\) is less than or equal to the number of days in month m_; otherwise returns false. When m_ == February, the number of days is considered to be 29.

### 27.8.9.3 Non-member functions

```cpp
constexpr bool operator==(const month_day& x, const month_day& y) noexcept;
```

Returns: \(x.month() == y.month() && x.day() == y.day()\).

```cpp
constexpr bool operator<(const month_day& x, const month_day& y) noexcept;
```

Returns: If \(x.month() < y.month()\) returns true. Otherwise, if \(x.month() > y.month()\) returns false. Otherwise, returns \(x.day() < y.day()\).

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const month_day& md);
```

Returns: \(os << md.month() << '/' << md.day()\).

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const month_day& md);
```

Effects: Streams md into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 27.11.

Returns: os.

```cpp
template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt, month_day& md, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream is into the \(month\_day\) md using the format flags given in the NTCTS fmt as specified in 27.12. If the parse fails to decode a valid \(month\_day\), is.setstate(ios_base::failbit) shall be called and md shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

### 27.8.10 Class month_day_last

namespace std::chrono {

```cpp
class month_day_last {
    chrono::month m_; // exposition only

    public:
        constexpr explicit month_day_last(const chrono::month& m) noexcept;

        constexpr chrono::month month() const noexcept;
        constexpr bool ok() const noexcept;
    }
};
```

1 month_day_last represents the last day of a month.

2 **Note:** A `month_day_last` object can be constructed using the expression `m/last` or `last/m`, where `m` is an expression of type `month`. — end note] [Example:

```cpp
constexpr auto mdl = February/last; // mdl is the last day of February of an as yet unspecified year
static_assert(mdl.month() == February);
```

— end example]

3 month_day_last is a trivially copyable and standard-layout class type.
constexpr explicit month_day_last(const chrono::month& m) noexcept;

    Effects: Constructs an object of type month_day_last by initializing m_ with m.

constexpr month month() const noexcept;

    Returns: m_.

constexpr bool ok() const noexcept;

    Returns: m_.ok().

constexpr bool operator==(const month_day_last& x, const month_day_last& y) noexcept;

    Returns: x.month() == y.month().

constexpr bool operator<(const month_day_last& x, const month_day_last& y) noexcept;

    Returns: x.month() < y.month().

template<class charT, class traits>
    basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const month_day_last& mdl);

    Returns: os << mdl.month() << "/last".

27.8.11 Class month_weekday [time.cal.mwd]

27.8.11.1 Overview [time.cal.mwd.overview]

namespace std::chrono {
    class month_weekday {
        chrono::month m_;  // exposition only
        chrono::weekday_indexed wdi_;  // exposition only
    public:
        constexpr month_weekday(const chrono::month& m, const chrono::weekday_indexed& wdi) noexcept;
        constexpr chrono::month month() const noexcept;
        constexpr chrono::weekday_indexed weekday_indexed() const noexcept;
        constexpr bool ok() const noexcept;
    }
};

1 month_weekday represents the n-th weekday of a month, of an as yet unspecified year. To do this the month_weekday stores a month and a weekday_indexed.

2 [Example:
    constexpr auto mwd = February/Tuesday[3];  // mwd is the third Tuesday of February of an as yet unspecified year
    static_assert(mwd.month() == February);
    static_assert(mwd.weekday_indexed() == Tuesday[3]);
    —end example]

3 month_weekday is a trivially copyable and standard-layout class type.

27.8.11.2 Member functions [time.cal.mwd.members]

constexpr month_weekday(const chrono::month& m, const chrono::weekday_indexed& wdi) noexcept;

    Effects: Constructs an object of type month_weekday by initializing m_ with m, and wdi_ with wdi.

constexpr chrono::month month() const noexcept;

    Returns: m_.

constexpr chrono::weekday_indexed weekday_indexed() const noexcept;

    Returns: wdi_.

constexpr bool ok() const noexcept;

    Returns: m_.ok() && wdi_.ok().

§ 27.8.11.2 1227
27.8.11.3 Non-member functions

```cpp
constexpr bool operator==(const month_weekday& x, const month_weekday& y) noexcept;
```

---

1. Returns: `x.month() == y.month() && x.weekday_indexed() == y.weekday_indexed()`.

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const month_weekday& mwd);
```

---

2. Returns: `os << mwd.month() << '/' << mwd.weekday_indexed()`.

27.8.12 Class month_weekday_last

27.8.12.1 Overview

```cpp
namespace std::chrono {
    class month_weekday_last {
        chrono::month m_; // exposition only
        chrono::weekday_last wdl_; // exposition only
    public:
        constexpr month_weekday_last(const chrono::month& m, const chrono::weekday_last& wdl) noexcept;
        constexpr chrono::month month() const noexcept;
        constexpr chrono::weekday_last weekday_last() const noexcept;
        constexpr bool ok() const noexcept;
    };
}
```

---

1. `month_weekday_last` represents the last weekday of a month, of an as yet unspecified year. To do this the `month_weekday_last` stores a `month` and a `weekday_last`.

2. [Example:

```cpp
constexpr auto mwd
    = February/Tuesday[last]; // mwd is the last Tuesday of February of an as yet unspecified year
static_assert(mwd.month() == February);
static_assert(mwd.weekday_last() == Tuesday[last]);
```

---

2. `month_weekday_last` is a trivially copyable and standard-layout class type.

27.8.12.2 Member functions

```cpp
constexpr month_weekday_last(const chrono::month& m, const chrono::weekday_last& wdl) noexcept;
```

---

1. Effects: Constructs an object of type `month_weekday_last` by initializing `m_` with `m`, and `wdl_` with `wdl`.

```cpp
constexpr chrono::month month() const noexcept;
```

---

2. Returns: `m_`.

```cpp
constexpr chrono::weekday_last weekday_last() const noexcept;
```

---

```cpp
constexpr bool ok() const noexcept;
```

---

4. Returns: `m_.ok() && wdl_.ok()`.

27.8.12.3 Non-member functions

```cpp
constexpr bool operator==(const month_weekday_last& x, const month_weekday_last& y) noexcept;
```

---

1. Returns: `x.month() == y.month() && x.weekday_last() == y.weekday_last()`.
template<class charT, class traits>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const month_weekday_last& mwdl);

    Returns: os << mwdl.month() << '/' << mwdl.weekday_last.

27.8.13 Class year_month

27.8.13.1 Overview

namespace std::chrono {

    class year_month {
    chrono::year y_;        // exposition only
    chrono::month m_;        // exposition only

    public:
        year_month() = default;

        constexpr year_month(const chrono::year& y, const chrono::month& m) noexcept;

        constexpr chrono::year year() const noexcept;

        constexpr chrono::month month() const noexcept;

        constexpr year_month& operator+=(const months& dm) noexcept;

        constexpr year_month& operator-=(const months& dm) noexcept;

        constexpr year_month& operator+=(const years& dy) noexcept;

        constexpr year_month& operator-=(const years& dy) noexcept;

        constexpr bool ok() const noexcept;
    };
}

1 year_month represents a specific month of a specific year, but with an unspecified day. year_month is a
field-based time point with a resolution of months. year_month is Cpp17EqualityComparable (Table 23) and
Cpp17LessThanComparable (Table 24).

2 year_month is a trivially copyable and standard-layout class type.

27.8.13.2 Member functions

constexpr year_month(const chrono::year& y, const chrono::month& m) noexcept;

1 Effects: Constructs an object of type year_month by initializing y_ with y, and m_ with m.

constexpr chrono::year year() const noexcept;

2 Returns: y_.

constexpr chrono::month month() const noexcept;

3 Returns: m_.

constexpr year_month& operator+=(const months& dm) noexcept;

4 Effects: *this = *this + dm.

5 Returns: *this.

constexpr year_month& operator-=(const months& dm) noexcept;

6 Effects: *this = *this - dm.

7 Returns: *this.

constexpr year_month& operator+=(const years& dy) noexcept;

8 Effects: *this = *this + dy.

9 Returns: *this.

constexpr year_month& operator-=(const years& dy) noexcept;

10 Effects: *this = *this - dy.

11 Returns: *this.
constexpr bool ok() const noexcept;

Returns: \( y_.\text{ok}() \&\& m_.\text{ok}() \).

27.8.13.3 Non-member functions

```cpp
castexpr bool operator==(const year_month& x, const year_month& y) noexcept;

Returns: \( x.\text{year}() == y.\text{year}() \&\& x.\text{month}() == y.\text{month}() \).
```  

```cpp
castexpr bool operator<(const year_month& x, const year_month& y) noexcept;

Returns: If \( x.\text{year}() < y.\text{year}() \) returns true. Otherwise, if \( x.\text{year}() > y.\text{year}() \) returns false. Otherwise, returns \( x.\text{month}() < y.\text{month}() \).
```  

```cpp
castexpr year_month operator+(const year_month& ym, const months& dm) noexcept;

Returns: A `year_month` value \( z \) such that \( z - ym == dm \).

Complexity: \( O(1) \) with respect to the value of \( dm \).
```  

```cpp
castexpr year_month operator+(const months& dm, const year_month& ym) noexcept;

Returns: \( ym + dm \).
```  

```cpp
castexpr year_month operator-(const year_month& ym, const months& dm) noexcept;

Returns: \( ym + -dm \).
```  

```cpp
castexpr months operator-(const year_month& x, const year_month& y) noexcept;

Returns: \( x.\text{year}() - y.\text{year}() + \text{months}\{\text{static_cast<int>(unsigned{x.month()}) - static_cast<int>(unsigned{y.month()})}\} \).
```  

```cpp
castexpr year_month operator+(const year_month& ym, const years& dy) noexcept;

Returns: \( (ym.\text{year}() + dy) / ym.\text{month}() \).
```  

```cpp
castexpr year_month operator+(const years& dy, const year_month& ym) noexcept;

Returns: \( ym + dy \).
```  

```cpp
castexpr year_month operator-(const year_month& ym, const years& dy) noexcept;

Returns: \( ym + -dy \).
```  

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const year_month& ym);

Returns: \( os << ym.\text{year}() << '/’ << ym.\text{month}() \).
```  

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>& to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const year_month& ym);

Effects: Streams \( ym \) into \( os \) using the format specified by the NTCTS \( \text{fmt} \). \( \text{fmt} \) encoding follows the rules specified in 27.11.

Returns: \( os \).
```  

```cpp
template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>& from_stream(basic_istream<charT, traits>& is, const charT* fmt, year_month& ym, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);

Effects: Attempts to parse the input stream \( \text{is} \) into the `year_month \( \text{ym} \) using the format flags given in the NTCTS \( \text{fmt} \) as specified in 27.12. If the parse fails to decode a valid `year_month`, \( \text{is.setstate}(\text{ios_base::failbit}) \) shall be called and \( \text{ym} \) shall not be modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

\section*{§ 27.8.13.3}
Returns: is.

27.8.14 Class `year_month_day` [time.cal.ymd]

27.8.14.1 Overview [time.cal.ymd.overview]

namespace std::chrono {
    class year_month_day {
        chronno::year y_;         // exposition only
        chronno::month m_;         // exposition only
        chronno::day d_;           // exposition only

    public:
        year_month_day() = default;
        constexpr year_month_day(const chronno::year& y, const chronno::month& m,
                                  const chronno::day& d) noexcept;
        constexpr year_month_day(const year_month_day_last& ymdl) noexcept;
        constexpr year_month_day(const sys_days& dp) noexcept;
        constexpr explicit year_month_day(const local_days& dp) noexcept;

        constexpr year_month_day& operator+=(const months& m) noexcept;
        constexpr year_month_day& operator-=(const months& m) noexcept;
        constexpr year_month_day& operator+=(const years& y) noexcept;
        constexpr year_month_day& operator-=(const years& y) noexcept;

        constexpr chronno::year year() const noexcept;
        constexpr chronno::month month() const noexcept;
        constexpr chronno::day day() const noexcept;
        constexpr operator sys_days() const noexcept;
        constexpr explicit operator local_days() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

1 `year_month_day` represents a specific year, month, and day. `year_month_day` is a field-based time point with a resolution of `days`. [Note: `year_month_day` supports years- and months-oriented arithmetic, but not days-oriented arithmetic. For the latter, there is a conversion to `sys_days`, which efficiently supports days-oriented arithmetic. —end note] `year_month_day` is `Cpp17EqualityComparable` (Table 23) and `Cpp17LessThanComparable` (Table 24).

2 `year_month_day` is a trivially copyable and standard-layout class type.

27.8.14.2 Member functions [time.cal.ymd.members]

constexpr year_month_day(const chronno::year& y, const chronno::month& m,
                         const chronno::day& d) noexcept;

1 Effects: Constructs an object of type `year_month_day` by initializing `y_` with `y`, `m_` with `m`, and `d_` with `d`.

constexpr year_month_day(const year_month_day_last& ymdl) noexcept;

2 Effects: Constructs an object of type `year_month_day` by initializing `y_` with `ymdl.year()`, `m_` with `ymdl.month()`, and `d_` with `ymdl.day()`. [Note: This conversion from `year_month_day_last` to `year_month_day` may be more efficient than converting a `year_month_day_last` to a `sys_days`, and then converting that `sys_days` to a `year_month_day`. —end note]

constexpr year_month_day(const sys_days& dp) noexcept;

3 Effects: Constructs an object of type `year_month_day` that corresponds to the date represented by `dp`.

Remarks: For any value `ymd` of type `year_month_day` for which `ymd.ok()` is true, `ymd == year_month_day(sys_days{ymd})` is true.

constexpr explicit year_month_day(const local_days& dp) noexcept;

4 Effects: Constructs an object of type `year_month_day` that corresponds to the date represented by `dp`.

Remarks: Equivalent to constructing with `sys_days{dp.time_since_epoch()}`.

§ 27.8.14.2
constexpr year_month_day& operator+=(const months& m) noexcept;

Effects: *this = *this + m.
Returns: *this.

constexpr year_month_day& operator-=(const months& m) noexcept;

Effects: *this = *this - m.
Returns: *this.

constexpr year_month_day& year_month_day::operator+=(const years& y) noexcept;

Effects: *this = *this + y.
Returns: *this.

constexpr year_month_day& year_month_day::operator-=(const years& y) noexcept;

Effects: *this = *this - y.
Returns: *this.

constexpr chrono::year year() const noexcept;

Returns: y_.

constexpr chrono::month month() const noexcept;

Returns: m_.

constexpr chrono::day day() const noexcept;

Returns: d_.

constexpr operator sys_days() const noexcept;

Returns: If ok(), returns a sys_days holding a count of days from the sys_days epoch to *this (a negative value if *this represents a date prior to the sys_days epoch). Otherwise, if y_.ok() && m_.ok() is true, returns a sys_days which is offset from sys_days{y_/m_/last}.day() by the number of days d_ is offset from sys_days{y_/m_/last}.day(). Otherwise the value returned is unspecified.

Remarks: A sys_days in the range [days{-12687428}, days{11248737}] which is converted to a year_month_day shall have the same value when converted back to a sys_days.

[Example:
static_assert(year_month_day{sys_days{2017y/January/0}} == 2016y/December/31);
static_assert(year_month_day{sys_days{2017y/January/31}} == 2017y/January/31);
static_assert(year_month_day{sys_days{2017y/January/32}} == 2017y/February/1);
—end example]

constexpr explicit operator local_days() const noexcept;

Returns: local_days{sys_days{*this}.time_since_epoch()}.

constexpr bool ok() const noexcept;

Returns: If y_.ok() is true, and m_.ok() is true, and d_ is in the range [1d, (y_/m_/last).day()], then returns true; otherwise returns false.

27.8.14.3 Non-member functions

constexpr bool operator==(const year_month_day& x, const year_month_day& y) noexcept;

Returns: x.year() == y.year() && x.month() == y.month() && x.day() == y.day().

constexpr bool operator<(const year_month_day& x, const year_month_day& y) noexcept;

Returns: If x.year() < y.year(), returns true. Otherwise, if x.year() > y.year(), returns false. Otherwise, if x.month() < y.month(), returns true. Otherwise, if x.month() > y.month(), returns false. Otherwise, returns x.day() < y.day().
constexpr year_month_day operator+(const year_month_day& ymd, const months& dm) noexcept;
Returns: \((\text{ymd.year() / ymd.month()} + \text{dm}) / \text{ymd.day()})\).

[Note: If \text{ymd.day()} is in the range \([1d, 28d]\), \text{ok()} will return \text{true} for the resultant \text{year_month_day}. — end note]

constexpr year_month_day operator+(const months& dm, const year_month_day& ymd) noexcept;
Returns: \text{ymd} + \text{dm}.

constexpr year_month_day operator-(const year_month_day& ymd, const months& dm) noexcept;
Returns: \text{ymd} + (-\text{dm}).

constexpr year_month_day operator+(const months& dm, const years& dy) noexcept;
Returns: \text{ymd} + \text{dm}.

constexpr year_month_day operator+(const year_month_day& ymd, const years& dy) noexcept;
Returns: \((\text{ymd.year() + dy}) / \text{ymd.month()} / \text{ymd.day()})\).

[Note: If \text{ymd.month()} is February and \text{ymd.day()} is not in the range \([1d, 28d]\), \text{ok()} may return \text{false} for the resultant \text{year_month_day}. — end note]

constexpr year_month_day operator+(const years& dy, const year_month_day& ymd) noexcept;
Returns: \text{ymd} + \text{dy}.

constexpr year_month_day operator+(const year_month_day& ymd, const years& dy) noexcept;
Returns: \text{ymd} + (-\text{dy}).

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const year_month_day& ymd);
Effects: Inserts \text{format(fmt, ymd)} where \text{fmt} is \"%F\" widened to \text{charT}. If \!\text{ymd.ok()}, appends with \"is not a valid date\".
Returns: \text{os}.

template<class charT, class traits>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const year_month_day& ymd);
Effects: Streams \text{ymd} into \text{os} using the format specified by the NTCTS \text{fmt}. \text{fmt} encoding follows the rules specified in \ref{traits}.11.
Returns: \text{os}.

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt, 
year_month_day& ymd, basic_string<charT, traits, Alloc>* abbrev = nullptr, 
minutes* offset = nullptr);
Effects: Attempts to parse the input stream \text{is} into the \text{year_month_day \text{ymd}} using the format flags given in the NTCTS \text{fmt} as specified in \ref{traits}.12. If the parse fails to decode a valid \text{year_month_day}, \text{is.setstate(ios_base::failbit)} shall be called and \text{ymd} shall not be modified. If \%Z is used and successfully parsed, that value will be assigned to \text{*abbrev} if \text{abbrev} is non-null. If \%z (or a modified variant) is used and successfully parsed, that value will be assigned to \text{*offset} if \text{offset} is non-null.
Returns: \text{is}.

\section{Class year_month_day_last}
\subsection{Overview}

namespace std::chrono {
    class year_month_day_last {
        chrono::year \_y; \quad // exposition only
        chrono::month_day_last \_mdl; \quad // exposition only
    }
public:
    constexpr year_month_day_last(const chrono::year& y,
        const chrono::month_day_last& mdl) noexcept;
    constexpr year_month_day_last& operator+=(const months& m) noexcept;
    constexpr year_month_day_last& operator-=(const months& m) noexcept;
    constexpr year_month_day_last& operator+=(const years& y) noexcept;
    constexpr year_month_day_last& operator-=(const years& y) noexcept;
    constexpr chrono::year year() const noexcept;
    constexpr chrono::month month() const noexcept;
    constexpr chrono::month_day_last month_day_last() const noexcept;
    constexpr chrono::day day() const noexcept;
    constexpr operator sys_days() const noexcept;
    constexpr explicit operator local_days() const noexcept;
    constexpr bool ok() const noexcept;
};

year_month_day_last represents the last day of a specific year and month. year_month_day_last is a field-based time point with a resolution of days, except that it is restricted to pointing to the last day of a year and month. [Note: year_month_day_last supports years- and months-oriented arithmetic, but not days-oriented arithmetic. For the latter, there is a conversion to sys_days, which efficiently supports days-oriented arithmetic. — end note] year_month_day_last is Cpp17EqualityComparable (Table 23) and Cpp17LessThanComparable (Table 24),

2 year_month_day_last is a trivially copyable and standard-layout class type.

27.8.15.2 Member functions

    constexpr year_month_day_last(const chrono::year& y,
        const chrono::month_day_last& mdl) noexcept;  
1  Effects: Constructs an object of type year_month_day_last by initializing y_ with y and mdl_ with mdl.
    constexpr year_month_day_last& operator+=(const months& m) noexcept;
2  Effects: *this = *this + m.
3  Returns: *this.
    constexpr year_month_day_last& operator-=(const months& m) noexcept;
4  Effects: *this = *this - m.
5  Returns: *this.
    constexpr year_month_day_last& operator+=(const years& y) noexcept;
6  Effects: *this = *this + y.
7  Returns: *this.
    constexpr year_month_day_last& operator-=(const years& y) noexcept;
8  Effects: *this = *this - y.
9  Returns: *this.
    constexpr chrono::year year() const noexcept;
10  Returns: y_.
    constexpr chrono::month month() const noexcept;
11  Returns: mdl_.month().
    constexpr chrono::month_day_last month_day_last() const noexcept;
12  Returns: mdl_.

§ 27.8.15.2
constexpr chrono::day day() const noexcept;

Returns: A day representing the last day of the (year, month) pair represented by *this.

[Note: This value may be computed on demand. — end note]

constexpr operator sys_days() const noexcept;

Returns: sys_days(year()/month()/day()).

constexpr explicit operator local_days() const noexcept;

Returns: local_days(sys_days(*this).time_since_epoch()).

constexpr bool ok() const noexcept;

Returns: y_.ok() && mdl_.ok().

27.8.15.3 Non-member functions

constexpr bool operator==(const year_month_day_last& x, const year_month_day_last& y) noexcept;

Returns: x.year() == y.year() && x.month_day_last() == y.month_day_last().

constexpr bool operator<(const year_month_day_last& x, const year_month_day_last& y) noexcept;

Returns: If x.year() < y.year(), returns true. Otherwise, if x.year() > y.year(), returns false. Otherwise, returns x.month_day_last() < y.month_day_last().

constexpr year_month_day_last
operator+(const year_month_day_last& ymdl, const months& dm) noexcept;

Returns: (ymdl.year() / ymdl.month() + dm) / last.

constexpr year_month_day_last
operator+(const months& dm, const year_month_day_last& ymdl) noexcept;

Returns: ymdl + dm.

constexpr year_month_day_last
operator-(const year_month_day_last& ymdl, const months& dm) noexcept;

Returns: ymdl + (-dm).

constexpr year_month_day_last
operator+(const years& dy, const year_month_day_last& ymdl) noexcept;

Returns: ymdl + dy.

constexpr year_month_day_last
operator-(const years& dy, const year_month_day_last& ymdl) noexcept;

Returns: ymdl + (-dy).

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const year_month_day_last& ymdl);

Returns: os << ymdl.year() << '/' << ymdl.month_day_last().

27.8.16 Class year_month_weekday

namespace std::chrono {

class year_month_weekday {

chronological::year y_; // exposition only
chronological::month m_; // exposition only
chronological::weekday_indexed wdi_; // exposition only

27.8.16.1 Overview

namespace std::chrono {
year_month_weekday represents a specific year, month, and \( n \)\textsuperscript{th} weekday of the month. \texttt{year_month_weekday} is a field-based time point with a resolution of \texttt{days}. \texttt{Note:} \texttt{year_month_weekday} supports \texttt{years}- and \texttt{months}-oriented arithmetic, but not \texttt{days}-oriented arithmetic. For the latter, there is a conversion to \texttt{sys_days}, which efficiently supports \texttt{days}-oriented arithmetic. — end note \texttt{year_month_weekday} is \texttt{Cpp17EqualityComparable} (Table 23).

\section*{27.8.16.2 Member functions} [time.cal.ymwd.members]

\begin{verbatim}
constexpr year_month_weekday(const chrono::year& y, const chrono::month& m,
    const chrono::weekday_indexed& wdi) noexcept;

constexpr year_month_weekday(const sys_days& dp) noexcept;

template<class charT, class traits>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const year_month_weekday& ymwd);

Returns: os << ymwd.year() << '/' << ymwd.month() << '/' << ymwd.weekday_indexed().

27.8.17 Class year_month_weekday_last

27.8.17.1 Overview

namespace std::chrono {
    class year_month_weekday_last {
        chrono::year y_;       // exposition only
        chrono::month m_;       // exposition only
        chrono::weekday_last wdl_; // exposition only

    public:
        constexpr year_month_weekday_last(const chrono::year& y, const chrono::month& m, const chrono::weekday_last& wdl) noexcept;
        constexpr year_month_weekday_last& operator+=(const months& m) noexcept;
        constexpr year_month_weekday_last& operator-=(const months& m) noexcept;
        constexpr year_month_weekday_last& operator+=(const years& y) noexcept;
        constexpr year_month_weekday_last& operator-=(const years& y) noexcept;

        constexpr chrono::year year() const noexcept;
        constexpr chrono::month month() const noexcept;
        constexpr chrono::weekday weekday() const noexcept;
        constexpr chrono::weekday_last weekday_last() const noexcept;

        constexpr operator sys_days() const noexcept;
        constexpr explicit operator local_days() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

1 year_month_weekday_last represents a specific year, month, and last weekday of the month. year_month_weekday_last is a field-based time point with a resolution of days, except that it is restricted to pointing to the last weekday of a year and month. [Note: year_month_weekday_last supports years- and months-oriented arithmetic, but not days-oriented arithmetic. For the latter, there is a conversion to sys_days, which efficiently supports days-oriented arithmetic. —end note] year_month_weekday_last is Cpp17EqualityComparable (Table 23).

2 year_month_weekday_last is a trivially copyable and standard-layout class type.

27.8.17.2 Member functions

constexpr year_month_weekday_last(const chrono::year& y, const chrono::month& m, const chrono::weekday_last& wdl) noexcept;

Effects: Constructs an object of type year_month_weekday_last by initializing y_ with y, m_ with m, and wdl_ with wdl.

constexpr year_month_weekday_last& operator+=(const months& m) noexcept;

Effects: *this = *this + m.

Returns: *this.

constexpr year_month_weekday_last& operator-=(const months& m) noexcept;

Effects: *this = *this - m.

Returns: *this.

constexpr year_month_weekday_last& operator+=(const years& y) noexcept;

Effects: *this = *this + y.

Returns: *this.
constexpr year_month_weekday_last& operator-=(const years& y) noexcept;
   Effects: *this = *this - y.
   Returns: *this.

constexpr chrono::year year() const noexcept;
   Returns: y_.

constexpr chrono::month month() const noexcept;
   Returns: m_.

constexpr chrono::weekday weekday() const noexcept;
   Returns: wdl_.weekday().

constexpr chrono::weekday_last weekday_last() const noexcept;
   Returns: wdl_.

constexpr operator sys_days() const noexcept;
   Returns: If ok() == true, returns a sys_days that represents the last weekday() of year()/month().
   Otherwise the returned value is unspecified.

constexpr explicit operator local_days() const noexcept;
   Returns: local_days{sys_days{*this}.time_since_epoch()}. 

constexpr bool ok() const noexcept;
   Returns: y_.ok() && m_.ok() && wdl_.ok() .

### 27.8.17.3  Non-member functions

`bool operator==(const year_month_weekday_last& x, 
    const year_month_weekday_last& y) noexcept;
   Returns: x.year() == y.year() && x.month() == y.month() && x.weekday_last() == y.weekday_last().`

`year_month_weekday_last 
operator+(const year_month_weekday_last& ymwdl, const months& dm) noexcept;
   Returns: (ymwdl.year() / ymwdl.month() + dm) / ymwdl.weekday_last().`

`year_month_weekday_last 
operator+(const months& dm, const year_month_weekday_last& ymwdl) noexcept;
   Returns: ymwdl + dm.`

`year_month_weekday_last 
operator-(const year_month_weekday_last& ymwdl, const months& dm) noexcept;
   Returns: ymwdl + (-dm).`

`year_month_weekday_last 
operator+(const year_month_weekday_last& ymwdl, const years& dy) noexcept;
   Returns: {ymwdl.year()+dy, ymwdl.month(), ymwdl.weekday_last()}.`

`year_month_weekday_last 
operator+(const years& dy, const year_month_weekday_last& ymwdl) noexcept;
   Returns: ymwdl + dy. `

`year_month_weekday_last 
operator-(const year_month_weekday_last& ymwdl, const years& dy) noexcept;
   Returns: ymwdl + (-dy).`
template<class charT, class traits>
basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const year_month_weekday_last& ymwl);

Returns: os << ymwl.year() << '//' << ymwl.month() << '//' << ymwl.weekday_last().

27.8.18 Conventional syntax operators [time.cal.operators]

A set of overloaded operator/ functions provides a conventional syntax for the creation of civil calendar dates.

[Note: The year, month, and day are accepted in any of the following 3 orders:

year/month/day
month/day/year
day/month/year

Anywhere a day is required, any of the following can also be specified:

last
weekday[i]
weekday[last]

—end note]

[Note: Partial-date types such as year_month and month_day can be created by not applying the second division operator for any of the three orders. For example:

year_month ym = 2015y/April;
month_day md1 = April/4;
month_day md2 = 4d/April;

—end note]

[Example:

auto a = 2015/4/4;    // a == int(125)
auto b = 2015y/4/4;   // b == year_month_day{year(2015), month(4), day(4)}
auto c = 2015y/4d/April;  // error: no viable operator/ for first /
auto d = 2015/April/4;  // error: no viable operator/ for first /

—end example]

c constexpr year_month
    operator/(const year& y, const month& m) noexcept;

Returns: {y, m}.

c constexpr year_month
    operator/(const year& y, int m) noexcept;

Returns: y / month(m).

c constexpr month_day
    operator/(const month& m, const day& d) noexcept;

Returns: {m, d}.

c constexpr month_day
    operator/(const month& m, int d) noexcept;

Returns: m / day(d).

c constexpr month_day
    operator/(int m, const day& d) noexcept;

Returns: month(m) / d.

c constexpr month_day
    operator/(const day& d, const month& m) noexcept;

Returns: m / d.
constexpr month_day
operator/(const day& d, int m) noexcept;

Returns: month(m) / d.

constexpr month_day_last
operator/(const month& m, last_spec) noexcept;

Returns: month_day_last(m).

constexpr month_day_last
operator/(int m, last_spec) noexcept;

Returns: month(m) / last.

constexpr month_day_last
operator/(last_spec, const month& m) noexcept;

Returns: m / last.

constexpr month_day_last
operator/(last_spec, int m) noexcept;

Returns: month(m) / last.

constexpr month_weekday
operator/(const month& m, const weekday_indexed& wdi) noexcept;

Returns: {m, wdi}.

constexpr month_weekday
operator/(int m, const weekday_indexed& wdi) noexcept;

Returns: month(m) / wdi.

constexpr month_weekday
operator/(const weekday_indexed& wdi, const month& m) noexcept;

Returns: m / wdi.

constexpr month_weekday
operator/(const weekday_indexed& wdi, int m) noexcept;

Returns: month(m) / wdi.

constexpr month_weekday_last
operator/(const month& m, const weekday_last& wdl) noexcept;

Returns: {m, wdl}.

constexpr month_weekday_last
operator/(const month& m, int m) noexcept;

Returns: month(m) / wdl.

constexpr month_weekday_last
operator/(int m, const weekday_last& wdl) noexcept;

Returns: month(m) / wdl.

constexpr month_weekday_last
operator/(const weekday_last& wdl, const month& m) noexcept;

Returns: m / wdl.

constexpr month_weekday_last
operator/(const weekday_last& wdl, int m) noexcept;

Returns: month(m) / wdl.

constexpr year_month_day
operator/(const year_month& ym, const day& d) noexcept;

Returns: {ym.year(), ym.month(), d}.

constexpr year_month_day
operator/(const year_month& ym, int d) noexcept;

Returns: ym / day(d).
constexpr year_month_day
operator/(const year& y, const month_day& md) noexcept;
Returns: y / md.month() / md.day().

constexpr year_month_day
operator/(int y, const month_day& md) noexcept;
Returns: year(y) / md.

constexpr year_month_day
operator/(const month_day& md, const year& y) noexcept;
Returns: y / md.

constexpr year_month_day
operator/(const month_day& md, int y) noexcept;
Returns: year(y) / md.

constexpr year_month_day_last
operator/(const year_month& ym, last_spec) noexcept;
Returns: {ym.year(), month_day_last{ym.month()}}.

constexpr year_month_day_last
operator/(const year& y, const month_day_last& mdl) noexcept;
Returns: {y, mdl}.

constexpr year_month_day_last
operator/(int y, const month_day_last& mdl) noexcept;
Returns: year(y) / mdl.

constexpr year_month_day_last
operator/(const month_day_last& mdl, const year& y) noexcept;
Returns: y / mdl.

constexpr year_month_day_last
operator/(const month_day_last& mdl, int y) noexcept;
Returns: year(y) / mdl.

constexpr year_month_weekday
operator/(const year_month& ym, const weekday_indexed& wdi) noexcept;
Returns: {ym.year(), ym.month(), wdi}.

constexpr year_month_weekday
operator/(const year& y, const month_weekday& mwd) noexcept;
Returns: {y, mwd.month(), mwd.weekday_indexed()}.

constexpr year_month_weekday
operator/(int y, const month_weekday& mwd) noexcept;
Returns: year(y) / mwd.

constexpr year_month_weekday
operator/(const month_weekday& mwd, const year& y) noexcept;
Returns: y / mwd.

constexpr year_month_weekday
operator/(const month_weekday& mwd, int y) noexcept;
Returns: year(y) / mwd.

constexpr year_month_weekday_last
operator/(const year_month& ym, const weekday_last& wdl) noexcept;
Returns: {ym.year(), ym.month(), wdl}.
constexpr year_month_weekday_last
    operator/(const year& y, const month_weekday_last& mwdl) noexcept;
    // Returns: \{y, mwdl.month(), mwdl.weekday_last()\}.

constexpr year_month_weekday_last
    operator/(int y, const month_weekday_last& mwdl) noexcept;
    // Returns: year(y) / mwdl.

constexpr year_month_weekday_last
    operator/(const month_weekday_last& mwdl, const year& y) noexcept;
    // Returns: y / mwdl.

constexpr year_month_weekday_last
    operator/(const month_weekday_last& mwdl, int y) noexcept;
    // Returns: year(y) / mwdl.

27.9 Class template time_of_day [time.tod]

27.9.1 Overview [time.tod.overview]

namespace std::chrono {
    template<class Duration> class time_of_day;
    template<> class time_of_day<hours>;
    template<> class time_of_day<minutes>;
    template<> class time_of_day<seconds>;
    template<class Rep, class Period> class time_of_day<duration<Rep, Period>>;
}

1 The time_of_day class template splits a duration representing the time elapsed since midnight into a 
"broken down" time of day such as hours:minutes:seconds. The Duration template parameter dictates the 
precision to which the time is broken down. [Note: This can vary from a coarse precision of hours to a very 
fine precision of nanoseconds. — end note] A time_of_day object also tracks whether it should be output 
as a 12-hour time format or a 24-hour time format.

2 The primary time_of_day template is not defined. Four specializations are provided to handle four different 
levels of precision.

3 Each specialization of time_of_day is a trivially copyable and standard-layout class type.

27.9.2 Hours precision [time.tod.hours]

namespace std::chrono {
    template<>
    class time_of_day<hours> {
        public:
            using precision = chrono::hours;

            time_of_day() = default;
            constexpr explicit time_of_day(chrono::hours since_midnight) noexcept;

            constexpr chrono::hours hours() const noexcept;
            constexpr explicit operator precision() const noexcept;
            constexpr precision_to_duration() const noexcept;

            constexpr void make24() noexcept;
            constexpr void make12() noexcept;
    };
}

1 [Note: This specialization handles hours since midnight. — end note]

constexpr explicit time_of_day(chrono::hours since_midnight) noexcept;

2 Effects: Constructs an object of type time_of_day in 24-hour format corresponding to since_midnight 
hours after 00:00:00.
Ensures: hours() returns the integral number of hours since_midnight is after 00:00:00.

constexpr chrono::hours hours() const noexcept;

Returns: The stored hour of *this.

constexpr explicit operator precision() const noexcept;

Returns: The number of hours since midnight.

constexpr precision to_duration() const noexcept;

Returns: precision(*this).

constexpr void make24() noexcept;

Effects: If *this is a 12-hour time, converts to a 24-hour time. Otherwise, no effects.

constexpr void make12() noexcept;

Effects: If *this is a 24-hour time, converts to a 12-hour time. Otherwise, no effects.

27.9.3 Minutes precision

namespace std::chrono {
    template<class time_of_day<minutes> { 
public:
    using precision = chrono::minutes;

    time_of_day() = default;
    constexpr time_of_day(chrono::minutes since_midnight) noexcept;

    constexpr chrono::hours hours() const noexcept;
    constexpr chrono::minutes minutes() const noexcept;
    constexpr explicit operator precision() const noexcept;
    constexpr precision to_duration() const noexcept;
    constexpr void make24() noexcept;
    constexpr void make12() noexcept;
};

1 [Note: This specialization handles hours and minutes since midnight. — end note]

constexpr explicit time_of_day(minutes since_midnight) noexcept;

2 Effects: Constructs an object of type time_of_day in 24-hour format corresponding to since_midnight minutes after 00:00:00.

3 Ensures: hours() returns the integral number of hours since_midnight is after 00:00:00. minutes() returns the integral number of minutes since_midnight is after (00:00:00 + hours()).

constexpr chrono::hours hours() const noexcept;

Returns: The stored hour of *this.

constexpr chrono::minutes minutes() const noexcept;

Returns: The stored minute of *this.

constexpr explicit operator precision() const noexcept;

Returns: The number of minutes since midnight.

constexpr precision to_duration() const noexcept;

Returns: precision(*this).

constexpr void make24() noexcept;

Effects: If *this is a 12-hour time, converts to a 24-hour time. Otherwise, no effects.
constexpr void make12() noexcept;

Effects: If *this is a 24-hour time, converts to a 12-hour time. Otherwise, no effects.

27.9.4 Seconds precision

namespace std::chrono {
    template<>
    class time_of_day<seconds> {
    public:
        using precision = chrono::seconds;
        time_of_day() = default;
        constexpr explicit time_of_day(chrono::seconds since_midnight) noexcept;
        constexpr chrono::hours hours() const noexcept;
        constexpr chrono::minutes minutes() const noexcept;
        constexpr chrono::seconds seconds() const noexcept;
        constexpr explicit operator precision() const noexcept;
        constexpr precision to_duration() const noexcept;
        constexpr void make24() noexcept;
        constexpr void make12() noexcept;
    };
}

[Note: This specialization handles hours, minutes, and seconds since midnight. — end note]

constexpr explicit time_of_day(seconds since_midnight) noexcept;

Effects: Constructs an object of type time_of_day in 24-hour format corresponding to since_midnight seconds after 00:00:00.

Ensures: hours() returns the integral number of hours since_midnight is after 00:00:00. minutes() returns the integral number of minutes since_midnight is after (00:00:00 + hours()). seconds() returns the integral number of seconds since_midnight is after (00:00:00 + hours() + minutes()).

constexpr chrono::hours hours() const noexcept;

Returns: The stored hour of *this.

constexpr chrono::minutes minutes() const noexcept;

Returns: The stored minute of *this.

constexpr chrono::seconds seconds() const noexcept;

Returns: The stored second of *this.

constexpr explicit operator precision() const noexcept;

Returns: The number of seconds since midnight.

constexpr precision to_duration() const noexcept;

Returns: precision(*this).

constexpr void make24() noexcept;

Effects: If *this is a 12-hour time, converts to a 24-hour time. Otherwise, no effects.

constexpr void make12() noexcept;

Effects: If *this is a 24-hour time, converts to a 12-hour time. Otherwise, no effects.

27.9.5 Sub-second precision

namespace std::chrono {
    template<class Rep, class Period>
    class time_of_day<duration<Rep, Period>> {
    public:

§ 27.9.5
using precision = duration<Rep, Period>;

time_of_day() = default;
constexpr explicit time_of_day(precision since_midnight) noexcept;

constexpr chrono::hours hours() const noexcept;
constexpr chrono::minutes minutes() const noexcept;
constexpr chrono::seconds seconds() const noexcept;
constexpr precision subseconds() const noexcept;

constexpr explicit operator precision() const noexcept;
constexpr precision to_duration() const noexcept;

constexpr void make24() noexcept;
constexpr void make12() noexcept;
};

This specialization shall not exist unless treat_as_floating_point_v<Rep> is false and duration<Rep, Period> is not convertible to seconds. [Note: This specialization handles hours, minutes, seconds, and fractional seconds since midnight. Typical uses are with milliseconds, microseconds and nanoseconds. — end note]

constexpr explicit time_of_day(precision since_midnight) noexcept;

Effects: Constructs an object of type time_of_day in 24-hour format corresponding to since_midnight fractional seconds after 00:00:00.

Ensures: hours() returns the integral number of hours since_midnight after 00:00:00. minutes() returns the integral number of minutes since_midnight after (00:00:00 + hours()). seconds() returns the integral number of seconds since_midnight after (00:00:00 + hours() + minutes()). subseconds() returns the integral number of fractional seconds since_midnight after (00:00:00 + hours() + minutes() + seconds()).

constexpr chrono::hours hours() const noexcept;

Returns: The stored hour of *this.

constexpr chrono::minutes minutes() const noexcept;

Returns: The stored minute of *this.

constexpr chrono::seconds seconds() const noexcept;

Returns: The stored second of *this.

constexpr duration<Rep, Period> subseconds() const noexcept;

Returns: The stored subsecond of *this.

constexpr explicit operator precision() const noexcept;

Returns: The number of subseconds since midnight.

constexpr precision to_duration() const noexcept;

Returns: precision{*this}.

constexpr void make24() noexcept;

Effects: If *this is a 12-hour time, converts to a 24-hour time. Otherwise, no effects.

constexpr void make12() noexcept;

Effects: If *this is a 24-hour time, converts to a 12-hour time. Otherwise, no effects.
operator<<(basic_ostream<charT, traits>& os, const time_of_day<hours>& t);

Effects: If t is a 24-hour time, outputs to os according to the format "%H00" (27.11). Otherwise outputs to os according to the format "%I%p" (27.11).

Returns: os.

[Example:
  for (hours h : {1h, 18h}) {
    time_of_day<hours> tod(h);
    os << tod << 'n';
    tod.make12();
    os << tod << 'n';
  }

Produces the output:
  0100
  1am
  1800
  6pm

— end example]

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const time_of_day<minutes>& t);

Effects: If t is a 24-hour time, outputs to os according to the format "%H:%M" (27.11). Otherwise outputs to os according to the format "%I:%M%p" (27.11).

Returns: os.

[Example:
  for (minutes m : {68min, 1095min}) {
    time_of_day<minutes> tod(m);
    os << tod << 'n';
    tod.make12();
    os << tod << 'n';
  }

Produces the output:
  01:08
  1:08am
  18:15
  6:15pm

— end example]

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const time_of_day<seconds>& t);

Effects: If t is a 24-hour time, outputs to os according to the format "%T" (27.11). Otherwise outputs to os according to the format "%I:%M:%S%p" (27.11).

Returns: os.

[Example:
  for (seconds s : {4083s, 65745s}) {
    time_of_day<seconds> tod(s);
    os << tod << 'n';
    tod.make12();
    os << tod << 'n';
  }

Produces the output:
  01:08:03
  1:08:03am

§ 27.9.6 1247
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const time_of_day<duration<Rep, Period>>& t);

Effects: If \( t \) is a 24-hour time, outputs to \( os \) according to the format "%T" (27.11). Otherwise outputs to \( os \) according to the format "%I:%M:%S%p" (27.11).

Returns: \( os \).

[Example:
for (milliseconds ms : {4083007ms, 65745123ms}) {
    time_of_day<seconds> tod(ms);
    os << tod << 'n';
    tod.make12();
    os << tod << 'n';
}

Produces the output:
01:08:03.007
1:08:03.007am
18:15:45.123
6:15:45.123pm

—end example]

27.10  Time zones

27.10.1  In general

27.10 describes an interface for accessing the IANA Time Zone database described in RFC 6557, that interoperates with \texttt{sys\_time} and \texttt{local\_time}. This interface provides time zone support to both the civil calendar types (27.8) and to user-defined calendars.

27.10.2  Time zone database

27.10.2.1  Class \texttt{tzdb}

namespace std::chrono {
    struct tzdb {
        string version;
        vector<time_zone> zones;
        vector<link> links;
        vector<leap> leaps;

        const time_zone* locate_zone(string_view tz_name) const;
        const time_zone* current_zone() const;
    };
}

1  Each vector in a \texttt{tzdb} object is sorted to enable fast lookup.

const time_zone* locate_zone(string_view tz_name) const;

2  Returns: If a \texttt{time\_zone} is found for which \texttt{name()} == \texttt{tz\_name}, returns a pointer to that \texttt{time\_zone}. Otherwise if a link is found for which \texttt{tz\_name} == \texttt{link\_name()}, then a pointer is returned to the \texttt{time\_zone} for which \texttt{zone.name()} == \texttt{link.target()}.[Note: A link specifies an alternative name for a \texttt{time\_zone}. —end note]

Throws: If a \texttt{const time\_zone*} cannot be found as described in the Returns: clause, throws a \texttt{runtime\_error}. [Note: On non-exceptional return, the return value is always a pointer to a valid \texttt{time\_zone}. —end note]

const time_zone* current_zone() const;

3  Returns: A pointer to the time zone which the computer has set as its local time zone.
27.10.2.2 Class tzdb_list

namespace std::chrono {
    class tzdb_list {
        public:
            tzdb_list(const tzdb_list&) = delete;
            tzdb_list& operator=(const tzdb_list&) = delete;

            // unspecified additional constructors

            class const_iterator;

            const tzdb& front() const noexcept;
            const_iterator erase_after(const_iterator p);

            const_iterator begin() const noexcept;
            const_iterator end() const noexcept;
            const_iterator cbegin() const noexcept;
            const_iterator cend() const noexcept;
    }
}

1 The tzdb_list database is a singleton; the unique object of type tzdb_list can be accessed via the get_tzdb_list() function. [Note: This access is only needed for those applications that need to have long uptimes and have a need to update the time zone database while running. Other applications can implicitly access the front() of this list via the read-only namespace scope functions get_tzdb(), locate_zone(), and current_zone(). — end note] The tzdb_list object contains a list of tzdb objects.

2 tzdb_list::const_iterator is a constant iterator which meets the Cpp17ForwardIterator requirements and has a value type of tzdb.

    const tzdb& front() const noexcept;

3 Returns: A reference to the first tzdb in the container.

4 Remarks: This operation is thread-safe with respect to reload_tzdb(). [Note: reload_tzdb() pushes a new tzdb onto the front of this container. — end note]

    const_iterator erase_after(const_iterator p);

5 Requires: The iterator following p is dereferenceable.

6 Effects: Erases the tzdb referred to by the iterator following p.

7 Returns: An iterator pointing to the element following the one that was erased, or end() if no such element exists.

8 Remarks: No pointers, references, or iterators are invalidated except those referring to the erased tzdb. [Note: It is not possible to erase the tzdb referred to by begin(). — end note]

9 Throws: Nothing.

    const_iterator begin() const noexcept;

10 Returns: An iterator referring to the first tzdb in the container.

    const_iterator end() const noexcept;

11 Returns: An iterator referring to the position one past the last tzdb in the container.

    const_iterator cbegin() const noexcept;

12 Returns: begin().

    const_iterator cend() const noexcept;

13 Returns: end().
§ 27.10.2.3  Time zone database access

```
tzdb_list& get_tzdb_list();
```

1  **Effects:** If this is the first access to the time zone database, initializes the database. If this call initializes
the database, the resulting database will be a `tzdb_list` holding a single initialized `tzdb`.

2  **Returns:** A reference to the database.

3  **Remarks:** It is safe to call this function from multiple threads at one time.

4  **Throws:** `runtime_error` if for any reason a reference cannot be returned to a valid `tzdb_list` containing
one or more valid `tzdb`.

```
const tzdb& get_tzdb();
```

5  **Returns:** `get_tzdb_list().front()`.

```
const time_zone* locate_zone(string_view tz_name);
```

6  **Returns:** `get_tzdb().locate_zone(tz_name)`.

7  **[Note:]** The time zone database will be initialized if this is the first reference to the database. — *end
note*

```
const time_zone* current_zone();
```

8  **Returns:** `get_tzdb().current_zone()`.

27.10.2.4  Remote time zone database support

The local time zone database is that supplied by the implementation when the program first accesses the
database, for example via `current_zone()`. While the program is running, the implementation may choose
to update the time zone database. This update shall not impact the program in any way unless the program
calls the functions in this subclause. This potentially updated time zone database is referred to as the *remote
time zone database*.

```
const tzdb& reload_tzdb();
```

1  **Effects:** This function first checks the version of the remote time zone database. If the versions of the
local and remote databases are the same, there are no effects. Otherwise the remote database is pushed
to the front of the `tzdb_list` accessed by `get_tzdb_list()`.

2  **Returns:** `get_tzdb_list().front()`.

3  **Remarks:** No pointers, references, or iterators are invalidated.

4  **Remarks:** This function is thread-safe with respect to `get_tzdb_list().front()` and `get_tzdb_list().erase_after()`.

5  **Throws:** `runtime_error` if for any reason a reference cannot be returned to a valid `tzdb`.

```
string remote_version();
```

6  **Returns:** The latest remote database version.

7  **[Note:]** This can be compared with `get_tzdb().version` to discover if the local and remote databases
are equivalent. — *end note*

27.10.3  Exception classes

27.10.3.1  Class nonexistent_local_time

```
namespace std::chrono {
    class nonexistent_local_time : public runtime_error {
public:
        template<class Duration>
        nonexistent_local_time(const local_time<Duration>& tp, const local_info& i);
    };
}
```

1  `nonexistent_local_time` is thrown when an attempt is made to convert a non-existent `local_time` to a
`sys_time` without specifying choose::earliest or choose::latest.
template<class Duration>
nonexistent_local_time(const local_time<Duration>& tp, const local_info& i);

Requires: i.result == local_info::nonexistent.

Effects: Constructs a nonexistent_local_time by initializing the base class with a sequence of char
equivalent to that produced by os.str() initialized as shown below:

```cpp
ostringstream os;
os << tp << " is in a gap between\n" << local_seconds(i.first.end.time_since_epoch()) + i.first.offset << ', '
<< i.first.abbrev << " and\n" << local_seconds(i.second.begin.time_since_epoch()) + i.second.offset << ', '
<< i.second.abbrev
<< " which are both equivalent to\n" << i.first.end << " UTC”;
```

Example:
```cpp
#include <chrono>
#include <iostream>

int main() {
  using namespace std::chrono;
  try {
    auto zt = zoned_time("America/New_York",
                         local_days{Sunday[2]/March/2016} + 2h + 30min);
  } catch (const nonexistent_local_time& e) {
    std::cout << e.what() << '\n';
  }
}
```

Produces the output:

2016-03-13 02:30:00 is in a gap between
2016-03-13 02:00:00 EST and
2016-03-13 03:00:00 EDT which are both equivalent to
2016-03-13 07:00:00 UTC

— end example]

27.10.3.2 Class ambiguous_local_time [time.zone.exception.ambig]

namespace std::chrono {
  class ambiguous_local_time : public runtime_error {
public:
    template<class Duration>
    ambiguous_local_time(const local_time<Duration>& tp, const local_info& i);
  }
}

ambiguous_local_time is thrown when an attempt is made to convert an ambiguous local_time to a
sys_time without specifying choose::earliest or choose::latest.

template<class Duration>
ambiguous_local_time(const local_time<Duration>& tp, const local_info& i);

Requires: i.result == local_info::ambiguous.

Effects: Constructs an ambiguous_local_time by initializing the base class with a sequence of char
equivalent to that produced by os.str() initialized as shown below:

```cpp
ostringstream os;
os << tp << " is ambiguous. It could be\n" << tp << ', ' << i.first.abbrev << " == "
<< tp - i.first.offset << " UTC or\n" << tp << ', ' << i.second.abbrev << " == "
<< tp - i.second.offset << " UTC”;
```

Example:
```cpp
#include <chrono>
#include <iostream>

int main() {
    using namespace std::chrono;
    try {
        auto zt = zoned_time("America/New_York",
            local_days(Sunday[1]/November/2016) + 1h + 30min);
    } catch (const ambiguous_local_time& e) {
        std::cout << e.what() << '\n';
    }
}

Produces the output:
2016-11-06 01:30:00 is ambiguous. It could be
2016-11-06 01:30:00 EDT == 2016-11-06 05:30:00 UTC or
2016-11-06 01:30:00 EST == 2016-11-06 06:30:00 UTC

— end example
```

### 27.10.4 Information classes

#### 27.10.4.1 Class `sys_info`

```cpp
namespace std::chrono {
    struct sys_info {
        sys_seconds begin;
        sys_seconds end;
        seconds offset;
        minutes save;
        string abbrev;
    }
}
```

1. A `sys_info` object can be obtained from the combination of a `time_zone` and either a `sys_time` or `local_time`. It can also be obtained from a `zoned_time`, which is effectively a pair of a `time_zone` and `sys_time`.

2. [Note: This type provides a low-level interface to time zone information. Typical conversions from `sys_time` to `local_time` will use this class implicitly, not explicitly. — end note]

3. The `begin` and `end` data members indicate that, for the associated `time_zone` and `time_point`, the `offset` and `abbrev` are in effect in the range `[begin, end)`. This information can be used to efficiently iterate the transitions of a `time_zone`.

4. The `offset` data member indicates the UTC offset in effect for the associated `time_zone` and `time_point`. The relationship between `local_time` and `sys_time` is:
   
   ```cpp
   offset = local_time - sys_time
   ```

5. The `save` data member is extra information not normally needed for conversion between `local_time` and `sys_time`. If `save` != 0min, this `sys_info` is said to be on “daylight saving” time, and `offset - save` suggests what offset this `time_zone` might use if it were off daylight saving time. However, this information should not be taken as authoritative. The only sure way to get such information is to query the `time_zone` with a `time_point` that returns a `sys_info` where `save` == 0min. There is no guarantee what `time_point` might return such a `sys_info` except that it is guaranteed not to be in the range `[begin, end)` (if `save` != 0min for this `sys_info`).

6. The `abbrev` data member indicates the current abbreviation used for the associated `time_zone` and `time_point`. Abbreviations are not unique among the `time_zones`, and so one cannot reliably map abbreviations back to a `time_zone` and UTC offset.

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const sys_info& r);
```

7. *Effects:* Streams out the `sys_info` object `r` in an unspecified format.

§ 27.10.4.1 1252
27.10.4.2 Class local_info

namespace std::chrono {
    struct local_info {
        static constexpr int unique = 0;
        static constexpr int nonexistent = 1;
        static constexpr int ambiguous = 2;

        int result;
        sys_info first;
        sys_info second;
    }
}

[Note: This type provides a low-level interface to time zone information. Typical conversions from local_time to sys_time will use this class implicitly, not explicitly. — end note]

Describes the result of converting a local_time to a sys_time as follows:

1. When a local_time to sys_time conversion is unique, result == unique, first will be filled out with the correct sys_info, and second will be zero-initialized.
2. If the conversion stems from a nonexistent local_time then result == nonexistent, first will be filled out with the sys_info that ends just prior to the local_time, and second will be filled out with the sys_info that begins just after the local_time.
3. If the conversion stems from an ambiguous local_time, then result == ambiguous, first will be filled out with the sys_info that ends just after the local_time, and second will be filled out with the sys_info that starts just before the local_time.

template<class charT, class traits>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const local_info& r);

Effects: Streams out the local_info object r in an unspecified format.

Returns: os.

27.10.5 Class time_zone

27.10.5.1 Overview

namespace std::chrono {
    class time_zone {
    public:
        time_zone(time_zone&&) = default;
        time_zone& operator=(time_zone&&) = default;

        // unspecified additional constructors

        string_view name() const noexcept;

        template<class Duration> sys_info get_info(const sys_time<Duration>& st) const;
        template<class Duration> local_info get_info(const local_time<Duration>& tp) const;

        template<class Duration>
            sys_time<common_type_t<Duration, seconds>>
            to_sys(const local_time<Duration>& tp) const;

        template<class Duration>
            sys_time<common_type_t<Duration, seconds>>
            to_sys(const local_time<Duration>& tp, choose z) const;

        template<class Duration>
            local_time<common_type_t<Duration, seconds>>
            to_local(const sys_time<Duration>& tp) const;
    }
}
A `time_zone` represents all time zone transitions for a specific geographic area. `time_zone` construction is unspecified, and performed as part of database initialization. [Note: `const time_zone` objects can be accessed via functions such as `locate_zone`. — end note]

### 27.10.5.2 Member functions

#### string_view name() const noexcept;

Returns: The name of the `time_zone`.

[Example: "America/New_York". — end example]

#### template<class Duration>

`sys_info` get_info(const `sys_time<Duration>`& st) const;

Returns: A `sys_info` i for which st is in the range [i.begin, i.end).

#### template<class Duration>

`local_info` get_info(const `local_time<Duration>`& tp) const;

Returns: A `local_info` for `tp`.

#### template<class Duration>

`sys_time<common_type_t<Duration, seconds>>`

`to_sys(const local_time<Duration>& tp)` const;

Returns: A `sys_time` that is at least as fine as `seconds`, and will be finer if the argument `tp` has finer precision. This `sys_time` is the UTC equivalent of `tp` according to the rules of this `time_zone`.

Throws: If the conversion from `tp` to a `sys_time` is ambiguous, throws `ambiguous_local_time`. If the `tp` represents a non-existent time between two UTC `time_points`, throws `nonexistent_local_time`.

#### template<class Duration>

`sys_time<common_type_t<Duration, seconds>>`

`to_sys(const local_time<Duration>& tp, choose z)` const;

Returns: A `sys_time` that is at least as fine as `seconds`, and will be finer if the argument `tp` has finer precision. This `sys_time` is the UTC equivalent of `tp` according to the rules of this `time_zone`. If the conversion from `tp` to a `sys_time` is ambiguous, returns the earlier `sys_time` if `z == choose::earliest`, and returns the later `sys_time` if `z == choose::latest`. If the `tp` represents a non-existent time between two UTC `time_points`, then the two UTC `time_points` will be the same, and that UTC `time_point` will be returned.

#### template<class Duration>

`local_time<common_type_t<Duration, seconds>>`

`to_local(const sys_time<Duration>& tp)` const;

Returns: The `local_time` associated with `tp` and this `time_zone`.

### 27.10.5.3 Non-member functions

#### bool operator==(const `time_zone`& x, const `time_zone`& y) noexcept;

Returns: `x.name()` == `y.name()`.

#### bool operator<(const `time_zone`& x, const `time_zone`& y) noexcept;

Returns: `x.name()` < `y.name()`.

### 27.10.6 Class template `zoned_traits`

```cpp
namespace std::chrono {
    template<class T> struct zoned_traits {};
}
```

`zoned_traits` provides a means for customizing the behavior of `zoned_time<Duration, TimeZonePtr>` for the `zoned_time` default constructor, and constructors taking `string_view`. A specialization for `const time_zone*` is provided by the implementation:

```cpp
namespace std::chrono {
    template<> struct zoned_traits<const time_zone*>
        { static const time_zone* default_zone(); }
}
```
static const time_zone* locate_zone(string_view name);

static const time_zone* default_zone();

Returns: std::chrono::locate_zone("UTC").

static const time_zone* locate_zone(string_view name);

Returns: std::chrono::locate_zone(name).

27.10.7 Class template zoned_time

27.10.7.1 Overview

namespace std::chrono {
    template<class Duration, class TimeZonePtr = const time_zone*>  
    class zoned_time {
        public:
            using duration = common_type_t<Duration, seconds>;
            private:
                TimeZonePtr zone_;  // exposition only
                sys_time<duration> tp_;  // exposition only
                using traits = zoned_traits<TimeZonePtr>;  // exposition only
            public:
                zoned_time();
                zoned_time(const zoned_time&) = default;
                zoned_time& operator=(const zoned_time&) = default;
                zoned_time(const sys_time<Duration>& st);
                explicit zoned_time(TimeZonePtr z);
                explicit zoned_time(string_view name);
                template<class Duration2>
                zoned_time(const zoned_time<Duration2, TimeZonePtr>& zt) noexcept;
                zoned_time(TimeZonePtr z, const sys_time<Duration>& st);
                zoned_time(string_view name, const sys_time<Duration>& st);
                zoned_time(TimeZonePtr z, const local_time<Duration>& tp);
                zoned_time(string_view name, const local_time<Duration>& tp);
                zoned_time(TimeZonePtr z, const local_time<Duration>& tp, choose c);
                zoned_time(string_view name, const local_time<Duration>& tp, choose c);
                template<class Duration2, class TimeZonePtr2>
                zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& zt);
                template<class Duration2, class TimeZonePtr2>
                zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& zt, choose);
                zoned_time(string_view name, const zoned_time<Duration>& zt);
                zoned_time(string_view name, const zoned_time<Duration>& zt, choose);
                zoned_time& operator=(const sys_time<Duration>& st);
                zoned_time& operator=(const local_time<Duration>& ut);
                operator sys_time<duration>() const;
                explicit operator local_time<duration>() const;
                TimeZonePtr get_time_zone() const;
                local_time<duration> get_local_time() const;
                sys_time<duration> get_sys_time() const;
                sys_info get_info() const;
            };

§ 27.10.7.1
zoned_time() \rightarrow \text{zoned\_time}\langle\text{seconds}\rangle;

\text{template}<\text{class Duration}>\:
\begin{align*}
& \text{zoned\_time}(<\text{sys\_time}\langle\text{Duration}\rangle>) \\
& \quad \rightarrow \text{zoned\_time}\langle\text{common\_type\_t}\langle\text{Duration}, \text{seconds}\rangle\rangle;
\end{align*}

\text{template}<\text{class TimeZonePtr}, \text{class Duration}>\:
\begin{align*}
& \text{zoned\_time}(<\text{TimeZonePtr}, <\text{sys\_time}\langle\text{Duration}\rangle>) \\
& \quad \rightarrow \text{zoned\_time}\langle\text{common\_type\_t}\langle\text{Duration}, \text{seconds}\rangle, \text{TimeZonePtr}\rangle;
\end{align*}

\text{template}<\text{class TimeZonePtr}, \text{class Duration}>\:
\begin{align*}
& \text{zoned\_time}(<\text{TimeZonePtr}, <\text{local\_time}\langle\text{Duration}\rangle>, \text{choose} = \text{choose\::\:earliest}) \\
& \quad \rightarrow \text{zoned\_time}\langle\text{common\_type\_t}\langle\text{Duration}, \text{seconds}\rangle, \text{TimeZonePtr}\rangle;
\end{align*}

\text{template}<\text{class TimeZonePtr}, \text{class Duration}>\:
\begin{align*}
& \text{zoned\_time}(<\text{TimeZonePtr}, <\text{zoned\_time}\langle\text{Duration}\rangle>, \text{choose} = \text{choose\::\:earliest}) \\

\end{align*}

\text{zoned\_time}(\text{string\_view}) \rightarrow \text{zoned\_time}\langle\text{seconds}\rangle;

\text{template}<\text{class Duration}>\:
\begin{align*}
& \text{zoned\_time}(<\text{string\_view}, <\text{sys\_time}\langle\text{Duration}\rangle>) \\
& \quad \rightarrow \text{zoned\_time}\langle\text{common\_type\_t}\langle\text{Duration}, \text{seconds}\rangle\rangle;
\end{align*}

\text{template}<\text{class Duration}>\:
\begin{align*}
& \text{zoned\_time}(<\text{string\_view}, <\text{local\_time}\langle\text{Duration}\rangle>, \text{choose} = \text{choose\::\:earliest}) \\
& \quad \rightarrow \text{zoned\_time}\langle\text{common\_type\_t}\langle\text{Duration}, \text{seconds}\rangle\rangle;
\end{align*}

\text{template}<\text{class Duration}, \text{class TimeZonePtr}, \text{class TimeZonePtr2}>\:
\begin{align*}
& \text{zoned\_time}(<\text{TimeZonePtr}, <\text{zoned\_time}\langle\text{Duration}, \text{TimeZonePtr2}\rangle>, \text{choose} = \text{choose\::\:earliest}) \\
& \quad \rightarrow \text{zoned\_time}\langle\text{Duration}, \text{TimeZonePtr}\rangle;
\end{align*}

1 \text{zoned\_time} \text{represents a logical pairing of a time\_zone and a time\_point with precision Duration. zoned\_time<Duration> maintains the invariant that it always refers to a valid time zone and represents a point in time that exists and is not ambiguous in that time zone.}

2 If Duration is not a specialization of std\::\:duration, the program is ill-formed.

### 27.10.7.2 Constructors

#### [time.zone.zonedtime.ctor]

\text{zoned\_time}();

1 \text{Remarks:} This constructor does not participate in overload resolution unless \text{traits\::\:default\_zone()} is a well-formed expression.

2 \text{Effects:} Constructs a \text{zoned\_time} by initializing zone\_ with \text{traits\::\:default\_zone()} and default constructing \text{tp\_}.

\text{zoned\_time}(\text{const sys\_time<Duration>& st});

3 \text{Remarks:} This constructor does not participate in overload resolution unless \text{traits\::\:default\_zone()} is a well-formed expression.

4 \text{Effects:} Constructs a \text{zoned\_time} by initializing zone\_ with \text{traits\::\:default\_zone()} and \text{tp\_} with \text{st}.

\text{explicit zoned\_time(TimeZonePtr z);} 

5 \text{Requires:} \text{z} \text{refers to a time zone.}

6 \text{Effects:} Constructs a \text{zoned\_time} by initializing zone\_ with std\::\:move(\text{z}).

\text{explicit zoned\_time(string\_view name);} 

7 \text{Remarks:} This constructor does not participate in overload resolution unless \text{traits\::\:locate\_zone(string\_view{}) is a well-formed expression and zoned\_time is constructible from the return type of traits\::\:locate\_zone(string\_view{})}. 

§ 27.10.7.2 1256
Effects: Constructs a \texttt{zoned\_time} by initializing \texttt{zone\_} with \texttt{traits::locate\_zone(name)} and default constructing \texttt{tp\_.}

\begin{verbatim}
template<class Duration2>
zoned\_time(const zoned\_time<Duration2, TimeZonePtr>& y) noexcept;
\end{verbatim}

\begin{verbatim}
Remarks: Does not participate in overload resolution unless \texttt{sys\_time<Duration2>} is implicitly convertible to \texttt{sys\_time<Duration>}.  
Effects: Constructs a \texttt{zoned\_time} by initializing \texttt{zone\_} with \texttt{y.zone\_} and \texttt{tp\_} with \texttt{y.tp\_.}
\end{verbatim}

Effects: Constructs a \texttt{zoned\_time} by initializing \texttt{zone\_} with \texttt{std::move(z)} and \texttt{tp\_} with \texttt{st}.

\begin{verbatim}
zoned\_time(TimeZonePtr z, const sys\_time<Duration>& st);
\end{verbatim}

\begin{verbatim}
Requires: \texttt{z} refers to a time zone.
\end{verbatim}

Effects: Constructs a \texttt{zoned\_time} by initializing \texttt{zone\_} with \texttt{std::move(z)} and \texttt{tp\_} with \texttt{zone\_->to\_sys(tp)}.

\begin{verbatim}
zoned\_time(TimeZonePtr z, const local\_time<Duration>& tp);
\end{verbatim}

\begin{verbatim}
Requires: \texttt{z} refers to a valid time zone.
\end{verbatim}

Effects: Equivalent to construction with \{\texttt{traits::locate\_zone(name)}, \texttt{st}\}.

\begin{verbatim}
zoned\_time(TimeZonePtr z, const local\_time<Duration>& tp, choose c);
\end{verbatim}

\begin{verbatim}
Requires: \texttt{z} refers to a valid time zone.
\end{verbatim}

Effects: Constructs a \texttt{zoned\_time} by initializing \texttt{zone\_} with \texttt{std::move(z)} and \texttt{tp\_} with \texttt{zone\_->to\_sys(tp, c)}.

\begin{verbatim}
zoned\_time(TimeZonePtr z, const zoned\_time<Duration2, TimeZonePtr2>& y);
\end{verbatim}

\begin{verbatim}
Remarks: Does not participate in overload resolution unless \texttt{sys\_time<Duration2>} is implicitly convertible to \texttt{sys\_time<Duration>}.  
Requires: \texttt{z} refers to a valid time zone.
\end{verbatim}

Effects: Constructs a \texttt{zoned\_time} by initializing \texttt{zone\_} with \texttt{std::move(z)} and \texttt{tp\_} with \texttt{y.tp\_.}

\begin{verbatim}
template<class Duration2, class TimeZonePtr2>
zoned\_time(TimeZonePtr z, const zoned\_time<Duration2, TimeZonePtr2>& y);
\end{verbatim}

\begin{verbatim}
Requires: \texttt{z} refers to a valid time zone.
\end{verbatim}

Effects: Constructs a \texttt{zoned\_time} by initializing \texttt{zone\_} with \texttt{std::move(z)} and \texttt{tp\_} with \texttt{y.tp\_.}
zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& y, choose);

Remarks: Does not participate in overload resolution unless sys_time<Duration2> is implicitly convertible to sys_time<Duration>.

Requires: z refers to a valid time zone.

Effects: Equivalent to construction with {z, y}.

[Note: The choose parameter has no effect. — end note]

zoned_time(string_view name, const zoned_time<Duration>& y);

Remarks: This constructor does not participate in overload resolution unless zoned_time is constructible from the return type of traits::locate_zone(name) and zoned_time.

Effects: Equivalent to construction with {traits::locate_zone(name), y}.

zoned_time(string_view name, const zoned_time<Duration>& y, choose c);

Remarks: This constructor does not participate in overload resolution unless zoned_time is constructible from the return type of traits::locate_zone(name), zoned_time, and choose.

Effects: Equivalent to construction with {traits::locate_zone(name), y, c}.

[Note: The choose parameter has no effect. — end note]

27.10.7.3 Member functions

zoned_time& operator=(const sys_time<Duration>& st);

Effects: After assignment, get_sys_time() == st. This assignment has no effect on the return value of get_time_zone().

Returns: *this.

zoned_time& operator=(const local_time<Duration>& lt);

Effects: After assignment, get_local_time() == lt. This assignment has no effect on the return value of get_time_zone().

Returns: *this.

operator sys_time<duration>() const;

Returns: get_sys_time().

explicit operator local_time<duration>() const;

Returns: get_local_time().

TimeZonePtr get_time_zone() const;

Returns: zone_.

local_time<duration> get_local_time() const;

Returns: zone_->to_local(tp_).

sys_time<duration> get_sys_time() const;

Returns: tp_.

sys_info get_info() const;

Returns: zone_->get_info(tp_).

27.10.7.4 Non-member functions

template<class Duration1, class Duration2, class TimeZonePtr>
bool operator==(const zoned_time<Duration1, TimeZonePtr>& x,
               const zoned_time<Duration2, TimeZonePtr>& y);

Returns: x.zone_ == y.zone_ && x.tp_ == y.tp_.
template<class Duration1, class Duration2, class TimeZonePtr>
bool operator!=(const zoned_time<Duration1, TimeZonePtr>& x,
const zoned_time<Duration2, TimeZonePtr>& y);  
2
Returns: !(x == y).

template<class charT, class traits, class Duration, class TimeZonePtr>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os,
const zoned_time<Duration, TimeZonePtr>& t);
3
Effects: Streams the value returned from t.get_local_time() to os using the format "%F %T %Z".

Returns: os.

template<class charT, class traits, class Duration, class TimeZonePtr>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt,
const zoned_time<Duration, TimeZonePtr>& tp);
4
Effects: First obtains a sys_info via tp.get_info() which for exposition purposes will be referred to
as info. Then calls to_stream(os, fmt, tp.get_local_time(), &info.abbrev, &info.offset).

Returns: os.

27.10.8 Class leap

27.10.8.1 Overview

namespace std::chrono {
    class leap {
    public:
        leap(const leap&) = default;
        leap& operator=(const leap&) = default;

        // unspecified additional constructors

        constexpr sys_seconds date() const noexcept;
    };
    }

Objects of type leap representing the date of the leap second insertions are constructed and stored in the
time zone database when initialized.

[Example:

    for (auto& l : get_tzdb().leaps)
        if (l <= 2018y/March/17d)
            cout << l.date() << '\n';

Produces the output:

1972-07-01 00:00:00
1973-01-01 00:00:00
1974-01-01 00:00:00
1975-01-01 00:00:00
1976-01-01 00:00:00
1977-01-01 00:00:00
1978-01-01 00:00:00
1979-01-01 00:00:00
1980-01-01 00:00:00
1981-07-01 00:00:00
1982-07-01 00:00:00
1983-07-01 00:00:00
1985-07-01 00:00:00
1988-01-01 00:00:00
1990-01-01 00:00:00
1991-01-01 00:00:00
1992-07-01 00:00:00
1993-07-01 00:00:00
1994-07-01 00:00:00

§ 27.10.8.1
27.10.8.2 Member functions

```cpp
constexpr sys_seconds date() const noexcept;
```

1

Returns: The date and time at which the leap second was inserted.

27.10.8.3 Non-member functions

```cpp
constexpr bool operator==(const leap& x, const leap& y) noexcept;
```

1

Returns: `x.date() == y.date()`.

```cpp
constexpr bool operator<(const leap& x, const leap& y) noexcept;
```

2

Returns: `x.date() < y.date()`.

```cpp
template<class Duration>
constexpr bool operator==(const leap& x, const sys_time<Duration>& y) noexcept;
```

3

Returns: `x.date() == y`.

```cpp
template<class Duration>
constexpr bool operator==(const leap& x, const sys_time<Duration>& y) noexcept;
```

4

Returns: `y == x`.

```cpp
template<class Duration>
constexpr bool operator!=(const leap& x, const sys_time<Duration>& y) noexcept;
```

5

Returns: `!(x == y)`.

```cpp
template<class Duration>
constexpr bool operator!=(const sys_time<Duration>& x, const leap& y) noexcept;
```

6

Returns: `!(x == y)`.

```cpp
template<class Duration>
constexpr bool operator<(const leap& x, const sys_time<Duration>& y) noexcept;
```

7

Returns: `x.date() < y`.

```cpp
template<class Duration>
constexpr bool operator<(const sys_time<Duration>& x, const leap& y) noexcept;
```

8

Returns: `x < y.date()`.

```cpp
template<class Duration>
constexpr bool operator>(const leap& x, const sys_time<Duration>& y) noexcept;
```

9

Returns: `y < x`.

```cpp
template<class Duration>
constexpr bool operator>(const sys_time<Duration>& x, const leap& y) noexcept;
```

10

Returns: `y < x`.

```cpp
template<class Duration>
constexpr bool operator<=(const leap& x, const sys_time<Duration>& y) noexcept;
```

11

Returns: `!(y < x)`.
template<class Duration>
constexpr bool operator<=(const sys_time<Duration>& x, const leap& y) noexcept;

Returns: !(y < x).

template<class Duration>
constexpr bool operator>=(const leap& x, const sys_time<Duration>& y) noexcept;

Returns: !(x < y).

template<class Duration>
constexpr bool operator>=(const sys_time<Duration>& x, const leap& y) noexcept;

Returns: !(x < y).

### 27.10.9 Class `link`

 namespace std::chrono {
 class link {
 public:
 link(link&&) = default;
 link& operator=(link&&) = default;

 // unspecified additional constructors

 string_view name() const noexcept;
 string_view target() const noexcept;

};
}

A `link` specifies an alternative name for a `time_zone`. `link`s are constructed when the time zone database is initialized.

### 27.10.9.2 Member functions

`string_view name() const noexcept;`  
Returns: The alternative name for the time zone.

`string_view target() const noexcept;`  
Returns: The name of the `time_zone` for which this `link` provides an alternative name.

### 27.10.9.3 Non-member functions

`bool operator==(const link& x, const link& y) noexcept;`  
Returns: `x.name() == y.name()`.

`bool operator<(const link& x, const link& y) noexcept;`  
Returns: `x.name() < y.name()`.

### 27.11 Formatting

Each `format` overload specified in this subclause calls `to_stream` unqualified, so as to enable argument dependent lookup (6.4.2).

`template<class charT, class Streamable>
 basic_string<charT>
 format(const charT* fmt, const Streamable& s);`  
Remarks: This function shall not participate in overload resolution unless `to_stream(decval-basic_ostream<charT>&)()`, `fmt`, `s)` is a valid expression.

Effects: Constructs a local variable of type `basic_ostringstream<charT>` (named `os` for exposition purposes). Executes `os.exceptions(ios::failbit | ios::badbit)`. Then calls `to_stream(os, fmt, s)`.
Returns: os.str().

```cpp
template<class charT, class Streamable>
    basic_string<charT>
    format(const locale& loc, const charT* fmt, const Streamable& s);  
```

Remarks: This function shall not participate in overload resolution unless
to_stream(declval<basic_ostream<charT>&>(), fmt, s)
is a valid expression.

Effects: Constructs a local variable of type basic_ostringstream<charT> (named os for exposition purposes). Executes os.exceptions(ios::failbit | ios::badbit). Then calls os.imbue(loc). Then calls to_stream(os, fmt, s).

Returns: os.str().

```cpp
template<class charT, class traits, class Alloc, class Streamable>
    basic_string<charT, traits, Alloc>
    format(const basic_string<charT, traits, Alloc>& fmt, const Streamable& s);  
```

Remarks: This function shall not participate in overload resolution unless
to_stream(declval<basic_ostringstream<charT, traits, Alloc>&>()(fmt.c_str(), s)
is a valid expression.

Effects: Constructs a local variable of type basic_ostringstream<charT, traits, Alloc> (named os for exposition purposes). Executes os.exceptions(ios::failbit | ios::badbit). Then calls to_stream(os, fmt.c_str(), s).

Returns: os.str().

```cpp
template<class charT, class traits, class Alloc, class Streamable>
    basic_string<charT, traits, Alloc>
    format(const locale& loc, const basic_string<charT, traits, Alloc>& fmt, const Streamable& s);  
```

Remarks: This function shall not participate in overload resolution unless
to_stream(declval<basic_ostringstream<charT, traits, Alloc>&>()(fmt.c_str(), s)
is a valid expression.

Effects: Constructs a local variable of type basic_ostringstream<charT, traits, Alloc> (named os for exposition purposes). Then calls os.imbue(loc). Executes os.exceptions(ios::failbit | ios::badbit). Then calls to_stream(os, fmt.c_str(), s).

Returns: os.str().

The `format` functions call a `to_stream` function with a basic_ostream, a formatting string specifier, and a Streamable argument. Each `to_stream` overload is customized for each Streamable type. However all `to_stream` overloads treat the formatting string specifier according to the following specification:

The `fmt` string consists of zero or more conversion specifiers and ordinary multibyte characters. A conversion specifier consists of a `%` character, possibly followed by an `E` or `O` modifier character (described below), followed by a character that determines the behavior of the conversion specifier. All ordinary multibyte characters (excluding the terminating null character) are streamed unchanged into the basic_ostream.

Each conversion specifier is replaced by appropriate characters as described in Table 87. Some of the conversion specifiers depend on the locale which is imbued to the basic_ostream. If the Streamable object does not contain the information the conversion specifier refers to, the value streamed to the basic_ostream is unspecified.

Unless explicitly specified, Streamable types will not contain time zone abbreviation and time zone offset information. If available, the conversion specifiers `%Z` and `%z` will format this information (respectively). If the information is not available, and `%Z` or `%z` are contained in fmt, os.setstate(ios_base::failbit) shall be called.
Table 87: Meaning of *format* conversion specifiers (continued)

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>%a</code></td>
<td>The locale’s abbreviated weekday name. If the value does not contain a valid weekday, <code>&lt;setstate(ios::failbit)&gt;</code> is called.</td>
</tr>
<tr>
<td><code>%A</code></td>
<td>The locale’s full weekday name. If the value does not contain a valid weekday, <code>&lt;setstate(ios::failbit)&gt;</code> is called.</td>
</tr>
<tr>
<td><code>%b</code></td>
<td>The locale’s abbreviated month name. If the value does not contain a valid month, <code>&lt;setstate(ios::failbit)&gt;</code> is called.</td>
</tr>
<tr>
<td><code>%B</code></td>
<td>The locale’s full month name. If the value does not contain a valid month, <code>&lt;setstate(ios::failbit)&gt;</code> is called.</td>
</tr>
<tr>
<td><code>%c</code></td>
<td>The locale’s date and time representation. The modified command <code>%Ec</code> produces the locale’s alternate date and time representation.</td>
</tr>
<tr>
<td><code>%C</code></td>
<td>The year divided by 100 using floored division. If the result is a single decimal digit, it is prefixed with 0. The modified command <code>%EC</code> produces the locale’s alternative representation of the century.</td>
</tr>
<tr>
<td><code>%d</code></td>
<td>The day of month as a decimal number. If the result is a single decimal digit, it is prefixed with 0. The modified command <code>%Od</code> produces the locale’s alternative representation.</td>
</tr>
<tr>
<td><code>%D</code></td>
<td>Equivalent to <code>%m/%d/%y</code>.</td>
</tr>
<tr>
<td><code>%e</code></td>
<td>The day of month as a decimal number. If the result is a single decimal digit, it is prefixed with a space. The modified command <code>%Oe</code> produces the locale’s alternative representation.</td>
</tr>
<tr>
<td><code>%F</code></td>
<td>Equivalent to <code>%Y-%m-%d</code>.</td>
</tr>
<tr>
<td><code>%g</code></td>
<td>The last two decimal digits of the ISO week-based year. If the result is a single digit it is prefixed by 0.</td>
</tr>
<tr>
<td><code>%G</code></td>
<td>The ISO week-based year as a decimal number. If the result is less than four digits it is left-padded with 0 to four digits.</td>
</tr>
<tr>
<td><code>%h</code></td>
<td>Equivalent to <code>%b</code>.</td>
</tr>
<tr>
<td><code>%H</code></td>
<td>The hour (24-hour clock) as a decimal number. If the result is a single digit, it is prefixed with 0. The modified command <code>%OH</code> produces the locale’s alternative representation.</td>
</tr>
<tr>
<td><code>%I</code></td>
<td>The hour (12-hour clock) as a decimal number. If the result is a single digit, it is prefixed with 0. The modified command <code>%OI</code> produces the locale’s alternative representation.</td>
</tr>
<tr>
<td><code>%j</code></td>
<td>The day of the year as a decimal number. Jan 1 is 001. If the result is less than three digits, it is left-padded with 0 to three digits.</td>
</tr>
<tr>
<td><code>%m</code></td>
<td>The month as a decimal number. Jan is 01. If the result is a single digit, it is prefixed with 0. The modified command <code>%Om</code> produces the locale’s alternative representation.</td>
</tr>
<tr>
<td><code>%M</code></td>
<td>The minute as a decimal number. If the result is a single digit, it is prefixed with 0. The modified command <code>%OM</code> produces the locale’s alternative representation.</td>
</tr>
<tr>
<td><code>%n</code></td>
<td>A new-line character.</td>
</tr>
<tr>
<td><code>%p</code></td>
<td>The locale’s equivalent of the AM/PM designations associated with a 12-hour clock.</td>
</tr>
<tr>
<td><code>%r</code></td>
<td>The locale’s 12-hour clock time.</td>
</tr>
<tr>
<td><code>%R</code></td>
<td>Equivalent to <code>%H:%M</code>.</td>
</tr>
<tr>
<td><code>%S</code></td>
<td>Seconds as a decimal number. If the number of seconds is less than 10, the result is prefixed with 0. If the precision of the input cannot be exactly represented with seconds, then the format is a decimal floating point number with a fixed format and a precision matching that of the precision of the input (or to a microseconds precision if the conversion to floating point decimal seconds cannot be made within 18 fractional digits). The character for the decimal point is localized according to the locale. The modified command <code>%OS</code> produces the locale’s alternative representation.</td>
</tr>
<tr>
<td><code>%t</code></td>
<td>A horizontal-tab character.</td>
</tr>
<tr>
<td><code>%T</code></td>
<td>Equivalent to <code>%H:%M:%S</code>.</td>

27.12 Parsing

Each parse overload specified in this subclause calls from_stream unqualified, so as to enable argument dependent lookup (6.4.2).

```cpp
template<class charT, class traits, class Alloc, class Parsable>
unsized
parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp);
```

Remarks: This function shall not participate in overload resolution unless from_stream(declval<basic_istream<charT, traits>&>(), fmt.c_str(), tp) is a valid expression.

Returns: A manipulator that, when extracted from a basic_istream<charT, traits> is, calls from_stream(is, fmt.c_str(), tp).

```cpp
template<class charT, class traits, class Alloc, class Parsable>
unsized
parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp, basic_string<charT, traits, Alloc>& abbrev);
```

Remarks: This function shall not participate in overload resolution unless from_stream(declval<basic_istream<charT, traits>&>(), fmt.c_str(), tp, addressof(abbrev)) is a valid expression.

Returns: A manipulator that, when extracted from a basic_istream<charT, traits> is, calls from_stream(is, fmt.c_str(), tp, addressof(abbrev)).
template<class charT, class traits, class Alloc, class Parsable>
  unspecified
  parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp, minutes& offset);

6  Remarks: This function shall not participate in overload resolution unless
    from_stream(declval<basic_istream<charT, traits>&>(), fmt.c_str(), tp, nullptr, &offset)
    is a valid expression.

7  Returns: A manipulator that, when extracted from a basic_istream<charT, traits> is,
    calls from_stream(is, fmt.c_str(), tp, nullptr, &offset).

template<class charT, class traits, class Alloc, class Parsable>
  unspecified
  parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp,
        basic_string<charT, traits, Alloc>& abbrev, minutes& offset);

8  Remarks: This function shall not participate in overload resolution unless
    from_stream(declval<basic_istream<charT, traits>&>(), fmt.c_str(), tp, addressof(abbrev), &offset)
    is a valid expression.

9  Returns: A manipulator that, when extracted from a basic_istream<charT, traits> is,
    calls from_stream(is, fmt.c_str(), tp, addressof(abbrev), &offset).

10 All from_stream overloads behave as unformatted input functions, except that they have an unspecified
    effect on the value returned by subsequent calls to basic_istream>::gcount(). Each overload takes a
    format string containing ordinary characters and flags which have special meaning. Each flag begins with a %.
    Some flags can be modified by E or O. During parsing each flag interprets characters as parts of date and time
    types according to the table below. Some flags can be modified by a width parameter given as a positive
    decimal integer called out as N below which governs how many characters are parsed from the stream in
    interpreting the flag. All characters in the format string that are not represented in the table below, except
    for white space, are parsed unchanged from the stream. A white space character matches zero or more white
    space characters in the input stream.

11 If the from_stream overload fails to parse everything specified by the format string, or if insufficient
    information is parsed to specify a complete duration, time point, or calendrical data structure, setstate(ios_base::failbit) is called on the basic_istream.

Table 88: Meaning of parse flags  [tab:time.parse.spec]

27.13 Header `<ctime>` synopsis

```cpp
#define NULL see 17.2.3
#define CLOCKS_PER_SEC see below
#define TIME_UTC see below

namespace std {
    using size_t = see 17.2.4;
    using clock_t = see below;
    using time_t = see below;

    struct timespec;
    struct tm;

clock_t clock();
double difftime(time_t time1, time_t time0);
time_t mktime(struct tm* tm); 
time_t time( time_t* timer);
timespec* timespec_get(timespec* ts, int base);
char* asctime(const struct tm* timeptr);
char* ctime(const time_t* timer);
struct tm* gmtime(const time_t* timer);
struct tm* localtime(const time_t* timer);
size_t strftime(char* s, size_t maxsize, const char* format, const struct tm* timeptr);
}
```

1 The contents of the header `<ctime>` are the same as the C standard library header `<time.h>`.259
2 The functions asctime, ctime, gmtime, and localtime are not required to avoid data races (16.5.5.9).

259) strftime supports the C conversion specifiers C, D, E, F, G, H, d, h, r, t, T, u, v, and z, and the modifiers E and O.

28 Localization library

28.1 General

This Clause describes components that C++ programs may use to encapsulate (and therefore be more portable when confronting) cultural differences. The locale facility includes internationalization support for character classification and string collation, numeric, monetary, and date/time formatting and parsing, and message retrieval.

2 The following subclauses describe components for locales themselves, the standard facets, and facilities from the ISO C library, as summarized in Table 89.

</table>

28.2 Header <locale> synopsis

```cpp
namespace std {
    // 28.3.1, locale
    class locale;
    template<class Facet> const Facet& use_facet(const locale&);
    template<class Facet> bool has_facet(const locale&) noexcept;

    // 28.3.3, convenience interfaces
    template<class charT> bool isspace (charT c, const locale& loc);
    template<class charT> bool isprint (charT c, const locale& loc);
    template<class charT> bool iscntrl (charT c, const locale& loc);
    template<class charT> bool isupper (charT c, const locale& loc);
    template<class charT> bool islower (charT c, const locale& loc);
    template<class charT> bool isalpha (charT c, const locale& loc);
    template<class charT> bool isdigit (charT c, const locale& loc);
    template<class charT> bool ispunct (charT c, const locale& loc);
    template<class charT> bool isxdigit(charT c, const locale& loc);
    template<class charT> bool isgraph (charT c, const locale& loc);
    template<class charT> bool isblank (charT c, const locale& loc);
    template<class charT> charT toupper(charT c, const locale& loc);
    template<class charT> charT tolower(charT c, const locale& loc);

    // 28.4.1, ctype
    class ctype_base;
    template<class charT> class ctype;
    template<> class ctype<char> ; // specialization
    template<class charT> class ctype_byname;
    class codecvt_base;
    template<class internT, class externT, class stateT> class codecvt;
    template<class internT, class externT, class stateT> class codecvt_byname;

    // 28.4.2, numeric
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class num_get;
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class num_put;
    template<class charT>
    class numpunct;
}
```

§ 28.2 1269
1 The header `<locale>` defines classes and declares functions that encapsulate and manipulate the information peculiar to a locale.\[260]\n
28.3 Locales

28.3.1 Class locale

namespace std {
    class locale {
        public:
            // types
            class facet;
            class id;
            using category = int;
            static const category none = 0,
                     collate = 0x010, ctype = 0x020,
                     monetary = 0x040, numeric = 0x080,
                     time = 0x100, messages = 0x200,
                     all = collate | ctype | monetary | numeric | time | messages;

            // construct/copy/destroy
            locale() noexcept;
            locale(const locale& other) noexcept;
            explicit locale(const char* std_name);
            explicit locale(const string& std_name);
            locale(const locale& other, const char* std_name, category);
            locale(const locale& other, const string& std_name, category);
            template<class Facet> locale(const locale& other, Facet* f);
locale(const locale& other, const locale& one, category);
-locale(); // not virtual
const locale& operator=(const locale& other) noexcept;
template<class Facet> locale combine(const locale& other) const;

// locale operations
basic_string<char> name() const;

bool operator==(const locale& other) const;
bool operator!=(const locale& other) const;

template<class charT, class traits, class Allocator>
bool operator()(const basic_string<charT, traits, Allocator>& s1,
    const basic_string<charT, traits, Allocator>& s2) const;

// global locale objects
static locale global(const locale&);
static const locale& classic();
};

Class locale implements a type-safe polymorphic set of facets, indexed by facet type. In other words, a facet has a dual role: in one sense, it’s just a class interface; at the same time, it’s an index into a locale’s set of facets.

Access to the facets of a locale is via two function templates, use_facet<> and has_facet<>.

[Example: An iostream operator<< might be implemented as:

```
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<< (basic_ostream<charT, traits>&& s, Date d) {
    typename basic_ostream<charT, traits>::sentry cerberos(s);
    if (cerberos) {
        ios_base::iostate err = ios_base::iostate::goodbit;
        tm tmbuf; d.extract(tmbuf);
        use_facet<time_put<charT, ostreambuf_iterator<charT, traits>>>(s.getloc()).put(s, s, s.fill(), err, &tmbuf, 'x');
        s.setstate(err); // might throw
    }
    return s;
}
```

—end example]

In the call to use_facet<Facet>(loc), the type argument chooses a facet, making available all members of the named type. If Facet is not present in a locale, it throws the standard exception bad_cast. A C++ program can check if a locale implements a particular facet with the function template has_facet<Facet>(). User-defined facets may be installed in a locale, and used identically as may standard facets.

[Note: All locale semantics are accessed via use_facet<> and has_facet<>], except that:

(5.1) — A member operator template operator()(const basic_string<C, T, A>&, const basic_string<C, T, A>&) is provided so that a locale may be used as a predicate argument to the standard collections, to collate strings.

(5.2) — Convenient global interfaces are provided for traditional ctype functions such as isdigit() and isspace(), so that given a locale object loc a C++ program can call isspace(c, loc). (This eases upgrading existing extractors (29.7.4.2)).

—end note]

Once a facet reference is obtained from a locale object by calling use_facet<>], that reference remains usable, and the results from member functions of it may be cached and re-used, as long as some locale object refers to that facet.

[261] Note that in the call to put the stream is implicitly converted to an ostreambuf_iterator<charT, traits>.

§ 28.3.1
In successive calls to a locale facet member function on a facet object installed in the same locale, the returned result shall be identical.

A `locale` constructed from a name string (such as "POSIX"), or from parts of two named locales, has a name; all others do not. Named locales may be compared for equality; an unnamed locale is equal only to (copies of) itself. For an unnamed locale, `locale::name()` returns the string "*".

Whether there is one global locale object for the entire program or one global locale object per thread is implementation-defined. Implementations should provide one global locale object per thread. If there is a single global locale object for the entire program, implementations are not required to avoid data races on it (16.5.5.9).

### 28.3.1.1 Types

#### [locale.types]

#### 28.3.1.1.1 Type `locale::category` [locale.category]

```cpp
using category = int;
```

1. Valid `category` values include the `locale` member bitmask elements `collate`, `ctype`, `monetary`, `numeric`, `time`, and `messages`, each of which represents a single locale category. In addition, `locale` member bitmask constant `none` is defined as zero and represents no category. And `locale` member bitmask constant `all` is defined such that the expression

   \[(\text{collate} \mid \text{ctype} \mid \text{monetary} \mid \text{numeric} \mid \text{time} \mid \text{messages} \mid \text{all}) == \text{all}\]

   is `true`, and represents the union of all categories. Further, the expression \( (X \mid Y) \), where \( X \) and \( Y \) each represent a single category, represents the union of the two categories.

2. `locale` member functions expecting a `category` argument require one of the `category` values defined above, or the union of two or more such values. Such a `category` value identifies a set of locale categories. Each `locale` category, in turn, identifies a set of locale facets, including at least those shown in Table 90.

#### Table 90: Locale category facets [tab:locale.category.facets]

</tr>
<tr>
<td><code>messages</code></td>
<td><code>messages&lt;char&gt;</code>, <code>messages&lt;wchar_t&gt;</code></td>
</tr>
</tbody>
</table>

3. For any locale `loc` either constructed, or returned by `locale::classic()`, and any facet `Facet` shown in Table 90, `has_facet<Facet>(loc)` is `true`. Each `locale` member function which takes a `locale::category` argument operates on the corresponding set of facets.

4. An implementation is required to provide those specializations for facet templates identified as members of a category, and for those shown in Table 91.

5. The provided implementation of members of facets `num_get<charT>` and `num_put<charT>` calls `use_facet<Facet>(1)` only for facet `F` of types `numpunct<charT>` and `ctype<charT>`, and for locale `l` the value obtained by calling member `getloc()` on the `ios_base` argument to these functions.

6. In declarations of facets, a template parameter with name `InputIterator` or `OutputIterator` indicates the set of all possible specializations on parameters that meet the C++17 `InputIterator` requirements or

|          | `time_put_byname<wchar_t, OutputIterator>` |
| messages | `messages_byname<char>`  
|          | `messages_byname<wchar_t>` |

ClazyOutputIterator requirements, respectively (23.3). A template parameter with name `C` represents the set of types containing `char`, `wchar_t`, and any other implementation-defined character types that meet the requirements for a character on which any of the iostream components can be instantiated. A template parameter with name `International` represents the set of all possible specializations on a bool parameter.

28.3.1.1.2 Class locale::facet  [locale.facet]

```cpp
namespace std {
    class locale::facet {
        protected:
            explicit facet(size_t refs = 0);
            virtual ~facet();
            facet(const facet&) = delete;
            void operator=(const facet&) = delete;
        };
    }
```

1 Class `facet` is the base class for locale feature sets. A class is a `facet` if it is publicly derived from another facet, or if it is a class derived from `locale::facet` and contains a publicly accessible declaration as follows:

```cpp
static ::std::locale::id id;
```

2 Template parameters in this Clause which are required to be facets are those named `Facet` in declarations. A program that passes a type that is not a facet, or a type that refers to a volatile-qualified facet, as an (explicit or deduced) template parameter to a locale function expecting a facet, is ill-formed. A const-qualified facet is a valid template argument to any locale function that expects a `Facet` template parameter.

3 The `refs` argument to the constructor is used for lifetime management. For `refs == 0`, the implementation performs `delete static_cast<locale::facet*>(f)` (where `f` is a pointer to the facet) when the last `locale` object containing the facet is destroyed; for `refs == 1`, the implementation never destroys the facet.

4 Constructors of all facets defined in this Clause take such an argument and pass it along to their `facet` base class constructor. All one-argument constructors defined in this Clause are `explicit`, preventing their participation in automatic conversions.

---

262) This is a complete list of requirements; there are no other requirements. Thus, a facet class need not have a public copy constructor, assignment, default constructor, destructor, etc.
For some standard facets a standard "..._byname" class, derived from it, implements the virtual function semantics equivalent to that facet of the locale constructed by `locale(const char*)` with the same name. Each such facet provides a constructor that takes a `const char*` argument, which names the locale, and a `refs` argument, which is passed to the base class constructor. Each such facet also provides a constructor that takes a `string` argument `str` and a `refs` argument, which has the same effect as calling the first constructor with the two arguments `str.c_str()` and `refs`. If there is no "..._byname" version of a facet, the base class implements named locale semantics itself by reference to other facets.

### 28.3.1.1.3 Class `locale::id`

```cpp
namespace std {
  class locale::id {
    public:
      id();
      void operator=(const id&) = delete;
      id(const id&) = delete;
  };
}
```

The class `locale::id` provides identification of a locale facet interface, used as an index for lookup and to encapsulate initialization.

*[Note: Because facets are used by iostreams, potentially while static constructors are running, their initialization cannot depend on programmed static initialization. One initialization strategy is for `locale` to initialize each facet’s `id` member the first time an instance of the facet is installed into a locale. This depends only on static storage being zero before constructors run (6.8.3.2). — end note]*

### 28.3.1.2 Constructors and destructor

#### `locale()` noexcept;

Default constructor: a snapshot of the current global locale.

*Effects:* Constructs a copy of the argument last passed to `locale::global(locale&)`, if it has been called; else, the resulting facets have virtual function semantics identical to those of `locale::classic()`.

*[Note: This constructor is commonly used as the default value for arguments of functions that take a `const locale&` argument. — end note]*

```cpp
locale(const locale& other) noexcept;
```

*Effects:* Constructs a locale which is a copy of `other`.

#### `explicit locale(const char* std_name)`;

*Effects:* Constructs a locale using standard C locale names, e.g., "POSIX". The resulting locale implements semantics defined to be associated with that name.

*Throws:* `runtime_error` if the argument is not valid, or is null.

*Remarks:* The set of valid string argument values is "C", ",", and any implementation-defined values.

#### `explicit locale(const string& std_name)`;

*Effects:* The same as `locale(std_name.c_str())`.

#### `locale(const locale& other, const char* std_name, category)`;

*Effects:* Constructs a locale as a copy of `other` except for the facets identified by the `category` argument, which instead implement the same semantics as `locale(std_name)`.

*Throws:* `runtime_error` if the argument is not valid, or is null.

*Remarks:* The locale has a name if and only if `other` has a name.

#### `locale(const locale& other, const string& std_name, category cat)`;

*Effects:* The same as `locale(other, std_name.c_str(), cat)`.
template<class Facet> locale(const locale& other, Facet* f);

Effects: Constructs a locale incorporating all facets from the first argument except that of type Facet, and installs the second argument as the remaining facet. If f is null, the resulting object is a copy of other.

Remarks: The resulting locale has no name.

locale(const locale& other, const locale& one, category cats);

Effects: Constructs a locale incorporating all facets from the first argument except those that implement cats, which are instead incorporated from the second argument.

Remarks: The resulting locale has a name if and only if the first two arguments have names.

const locale& operator=(const locale& other) noexcept;

Effects: Creates a copy of other, replacing the current value.

Returns: *this.

~locale();

A non-virtual destructor that throws no exceptions.

28.3.1.3 Members

template<class Facet> locale combine(const locale& other) const;

Effects: Constructs a locale incorporating all facets from *this except for that one facet of other that is identified by Facet.

Returns: The newly created locale.

Throws: runtime_error if has_facet<Facet>(other) is false.

Remarks: The resulting locale has no name.

basic_string<char> name() const;

Returns: The name of *this, if it has one; otherwise, the string "*".

28.3.1.4 Operators

bool operator==(const locale& other) const;

Returns: true if both arguments are the same locale, or one is a copy of the other, or each has a name and the names are identical; false otherwise.

bool operator!=(const locale& other) const;

Returns: !(this == other).

template<class charT, class traits, class Allocator>
bool operator()(const basic_string<charT, traits, Allocator>& s1,
                  const basic_string<charT, traits, Allocator>& s2) const;

Effects: Compares two strings according to the collate<charT> facet.

Remarks: This member operator template (and therefore locale itself) meets the requirements for a comparator predicate template argument (Clause 25) applied to strings.

Returns:

use_facet<collate<charT>>(*this).compare(s1.data(), s1.data() + s1.size(), s2.data(), s2.data() + s2.size()) < 0

[Example: A vector of strings v can be collated according to collation rules in locale loc simply by (25.7.1, 22.3.11):

std::sort(v.begin(), v.end(), loc);

— end example]
**28.3.1.5 Static members**

static locale global(const locale& loc);

Sets the global locale to its argument.

**Effects:** Causes future calls to the constructor locale() to return a copy of the argument. If the argument has a name, does

```
setlocale(LC_ALL, loc.name().c_str());
```

otherwise, the effect on the C locale, if any, is implementation-defined. No library function other than locale::global() shall affect the value returned by locale(). [*Note: See 28.5 for data race considerations when setlocale is invoked. — end note*]

Returns: The previous value of locale().

static const locale& classic();

The "C" locale.

Returns: A locale that implements the classic "C" locale semantics, equivalent to the value locale("C").

Remarks: This locale, its facets, and their member functions, do not change with time.

**28.3.2 locale globals**

```
template<class Facet> const Facet& use_facet(const locale& loc);
```

Requires: Facet is a facet class whose definition contains the public static member id as defined in 28.3.1.1.2.

Returns: A reference to the corresponding facet of loc, if present.

Throws: bad_cast if has_facet<Facet>(loc) is false.

Remarks: The reference returned remains valid at least as long as any copy of loc exists.

```
template<class Facet> bool has_facet(const locale& loc) noexcept;
```

Returns: true if the facet requested is present in loc; otherwise false.

**28.3.3 Convenience interfaces**

**28.3.3.1 Character classification**

```
template<class charT> bool isspace (charT c, const locale& loc);
template<class charT> bool isprint (charT c, const locale& loc);
template<class charT> bool iscntrl (charT c, const locale& loc);
template<class charT> bool isupper (charT c, const locale& loc);
template<class charT> bool islower (charT c, const locale& loc);
template<class charT> bool isalpha (charT c, const locale& loc);
template<class charT> bool isdigit (charT c, const locale& loc);
template<class charT> bool ispunct (charT c, const locale& loc);
template<class charT> bool isxdigit(charT c, const locale& loc);
template<class charT> bool isgraph (charT c, const locale& loc);
template<class charT> bool isblank (charT c, const locale& loc);
```

Each of these functions is\(F\) returns the result of the expression:

```
use_facet<ctype<charT>>(loc).is(ctype_base::F, c)
```

where \(F\) is the \(ctype_base::mask\) value corresponding to that function (28.4.1).\(^{263}\)

**28.3.3.2 Conversions**

**28.3.3.2.1 Character conversions**

```
template<class charT> charT toupper(charT c, const locale& loc);
```

Returns: use_facet<ctype<charT>>(loc).toupper(c).

---

\(^{263}\) When used in a loop, it is faster to cache the \ctype<> facet and use it directly, or use the vector form of \ctype::<is>.
template<class charT> char tolower(charT c, const locale& loc);

Returns: use_facet<ctype<charT>>(loc).tolower(c).

28.4 Standard locale categories

Each of the standard categories includes a family of facets. Some of these implement formatting or parsing of a datum, for use by standard or users’ iostream operators << and >>, as members put() and get(), respectively. Each such member function takes an ios_base& argument whose members flags(), precision(), and width(), specify the format of the corresponding datum (29.5.3). Those functions which need to use other facets call its member getloc() to retrieve the locale imbued there. Formatting facets use the character argument fill to fill out the specified width where necessary.

The put() members make no provision for error reporting. (Any failures of the OutputIterator argument can be extracted from the returned iterator.) The get() members take an ios_base::iostate& argument whose value they ignore, but set to ios_base::failbit in case of a parse error.

Within this clause it is unspecified whether one virtual function calls another virtual function.

28.4.1 The ctype category

namespace std {
    class ctype_base {
        public:
            using mask = see below;

            // numeric values are for exposition only.
            static const mask space = 1 << 0;
            static const mask print = 1 << 1;
            static const mask cntrl = 1 << 2;
            static const mask upper = 1 << 3;
            static const mask lower = 1 << 4;
            static const mask alpha = 1 << 5;
            static const mask digit = 1 << 6;
            static const mask punct = 1 << 7;
            static const mask xdigit = 1 << 8;
            static const mask blank = 1 << 9;
            static const mask alnum = alpha | digit;
            static const mask graph = alnum | punct;
    }
}

1 The type mask is a bitmask type (16.4.2.2.4).

28.4.1.1 Class template ctype

namespace std {
    template<class charT>
    class ctype : public locale::facet, public ctype_base {
        public:
            using char_type = charT;

            explicit ctype(size_t refs = 0);

            bool is(mask m, charT c) const;
            const charT* is(const charT* low, const charT* high, mask* vec) const;
            const charT* scan_is(mask m, const charT* low, const charT* high) const;
            const charT* scan_not(mask m, const charT* low, const charT* high) const;
            charT toupper(charT c) const;
            const charT* toupper(charT* low, const charT* high) const;
            charT tolower(charT c) const;
            const charT* tolower(charT* low, const charT* high) const;
            charT widen(char c) const;
            const char* widen(const char* low, const char* high) const;
            char narrow(charT c, char dfault) const;
            const charT* narrow(const charT* low, const charT* high) const;
    }
}

§ 28.4.1.1 1277
static locale::id id;

protected:
- ctype();
  virtual bool do_is(mask m, charT c) const;
  virtual const charT* do_is(const charT* low, const charT* high, mask* vec) const;
  virtual const charT* do_is(const charT* low, const charT* high, mask m, const charT* low, const charT* high) const;
  virtual const charT* do_is(const charT* low, const charT* high, mask m, const charT* low, const charT* high) const;
  virtual charT do_toupper(charT) const;
  virtual const charT* do_toupper(charT* low, const charT* high) const;
  virtual charT do_toupper(charT) const;
  virtual const charT* do_toupper(charT* low, const charT* high) const;
  virtual charT do_tolower(charT) const;
  virtual const charT* do_tolower(charT* low, const charT* high) const;
  virtual charT do_tolower(charT) const;
  virtual const charT* do_tolower(charT* low, const charT* high) const;
  virtual char* do_widen(char) const;
  virtual const char* do_widen(const char* low, const char* high, charT* dest) const;
  virtual char* do_widen(char) const;
  virtual const char* do_widen(const char* low, const char* high, charT* dest) const;
  virtual const charT* do_narrow(const charT* low, const charT* high, char dfault, char* dest) const;
  virtual const charT* do_narrow(const charT* low, const charT* high, char dfault, char* dest) const;
  virtual const charT* do_narrow(const charT* low, const charT* high, char dfault, char* dest) const;
};

1 Class ctype encapsulates the C library <cctype> features. istream members are required to use ctype<> for character classing during input parsing.

2 The specializations required in Table 90 (28.3.1.1.1), namely ctype<char> and ctype<wchar_t>, implement character classing appropriate to the implementation’s native character set.

28.4.1.1.1 ctype members

   bool is(mask m, charT c) const;
   const charT* is(const charT* low, const charT* high, mask* vec) const;
   Returns: do_is(m, c) or do_is(low, high, vec).

   const charT* scan_is(mask m, const charT* low, const charT* high) const;
   Returns: do_scan_is(m, low, high).

   const charT* scan_not(mask m, const charT* low, const charT* high) const;
   Returns: do_scan_not(m, low, high).

   charT toupper(charT) const;
   const charT* toupper(charT* low, const charT* high) const;
   Returns: do_toupper(c) or do_toupper(low, high).

   charT tolower(charT c) const;
   const charT* tolower(charT* low, const charT* high) const;
   Returns: do_tolower(c) or do_tolower(low, high).

   charT widen(char c) const;
   const char* widen(const char* low, const char* high, charT* to) const;
   Returns: do_widen(c) or do_widen(low, high, to).

   char narrow(charT c, char dfault) const;
   const charT* narrow(const charT* low, const charT* high, char dfault, char* to) const;
   Returns: do_narrow(c, dfault) or do_narrow(low, high, dfault, to).

28.4.1.1.2 ctype virtual functions

   bool do_is(mask m, charT c) const;
   const charT* do_is(const charT* low, const charT* high, mask* vec) const;
   Effects: Classifies a character or sequence of characters. For each argument character, identifies a value M of type ctype_base::mask. The second form identifies a value M of type ctype_base::mask for each *p where (low <= p && p < high), and places it into vec[p - low].
Returns: The first form returns the result of the expression \((M \& m) \neq 0\); i.e., \textit{true} if the character has the characteristics specified. The second form returns \textit{high}.

\[\text{const charT} \text{ do_scan_is} (\text{mask} \ m, \text{const charT*} \ \text{low}, \text{const charT*} \ \text{high}) \text{ const;}\]

\textit{Effects:} Locates a character in a buffer that conforms to a classification \(m\).

\textit{Returns:} The smallest pointer \(p\) in the range \([\text{low}, \text{high})\) such that \(\text{is}(m, *p)\) would return \textit{true}; otherwise, returns \textit{high}.

\[\text{const charT} \text{ do_scan_not} (\text{mask} \ m, \text{const charT*} \ \text{low}, \text{const charT*} \ \text{high}) \text{ const;}\]

\textit{Effects:} Locates a character in a buffer that fails to conform to a classification \(m\).

\textit{Returns:} The smallest pointer \(p\), if any, in the range \([\text{low}, \text{high})\) such that \(\text{is}(m, *p)\) would return \textit{false}; otherwise, returns \textit{high}.

\[\text{charT} \text{ do_toupper} (\text{charT} \ c) \text{ const;}\]
\[\text{const charT} \text{ do_toupper} (\text{charT*} \ \text{low}, \text{const charT*} \ \text{high}) \text{ const;}\]

\textit{Effects:} Converts a character or characters to upper case. The second form replaces each character \(*p\) in the range \([\text{low}, \text{high})\) for which a corresponding upper-case character exists, with that character.

\textit{Returns:} The first form returns the corresponding upper-case character if it is known to exist, or its argument if not. The second form returns \textit{high}.

\[\text{charT} \text{ do_tolower} (\text{charT} \ c) \text{ const;}\]
\[\text{const charT} \text{ do_tolower} (\text{charT*} \ \text{low}, \text{const charT*} \ \text{high}) \text{ const;}\]

\textit{Effects:} Converts a character or characters to lower case. The second form replaces each character \(*p\) in the range \([\text{low}, \text{high})\) and for which a corresponding lower-case character exists, with that character.

\textit{Returns:} The first form returns the corresponding lower-case character if it is known to exist, or its argument if not. The second form returns \textit{high}.

\[\text{charT} \text{ do_widen} (\text{char} \ c) \text{ const;}\]
\[\text{const char*} \text{ do_widen} (\text{const char*} \ \text{low}, \text{const char*} \ \text{high}, \text{charT*} \ \text{dest}) \text{ const;}\]

\textit{Effects:} Applies the simplest reasonable transformation from a \textit{char} value or sequence of \textit{char} values to the corresponding \textit{charT} value or values.\(^{264}\) The only characters for which unique transformations are required are those in the basic source character set (5.3).

For any named \texttt{ctype} category with a \texttt{ctype <charT>} facet \(\texttt{ctc}\) and valid \texttt{ctype_base::mask} value \(M\),
\[\left(\text{\texttt{ctc.is}}(M, \ c) \ || \ !\text{\texttt{is}}(M, \ \text{do_widen}(c)) \right) \text{ is } \textit{true}.\(^{265}\)

The second form transforms each character \(*p\) in the range \([\text{low}, \text{high}),\) placing the result in \(\text{dest}[p - \text{low}]\).

\textit{Returns:} The first form returns the transformed value. The second form returns \textit{high}.

\[\text{char} \text{ do_narrow} (\textit{charT} \ c, \textit{char dfault}) \text{ const;}\]
\[\text{const charT*} \text{ do_narrow} (\text{const charT*} \ \text{low}, \text{const charT*} \ \text{high}, \text{char dfault}, \text{char*} \ \text{dest}) \text{ const;}\]

\textit{Effects:} Applies the simplest reasonable transformation from a \textit{charT} value or sequence of \textit{charT} values to the corresponding \textit{char} value or values.

For any character \(c\) in the basic source character set (5.3) the transformation is such that
\[\text{do_widen(do_narrow(c, 0)) == c}\]

For any named \texttt{ctype} category with a \texttt{ctype<char>} facet \(\texttt{ctc}\) however, and \texttt{ctype_base::mask} value \(M\),
\[\left(\text{\texttt{is}}(M, \ c) \ || \ !\text{\texttt{ctc.is}}(M, \ \text{do_narrow}(c, \ \text{dfault})) \right) \text{ is } \textit{true} \text{ unless } \text{do_narrow} \text{ returns dfault}.\]

In addition, for any digit character \(c\), the expression \((\text{do_-narrow}(c, \ \text{dfault}) - '0')\) evaluates to the digit value of the character. The second form transforms each character \(*p\) in the range \([\text{low}, \text{high}),\) placing the result (or \text{dfault} if no simple transformation is readily available) in \(\text{dest}[p - \text{low}]\).

\[\textit{264}\) The \textit{char} argument of \textit{do_widen} is intended to accept values derived from character literals for conversion to the locale’s encoding.

\[\textit{265}\) In other words, the transformed character is not a member of any character classification that \(c\) is not also a member of.\]
Returns: The first form returns the transformed value; or \texttt{default} if no mapping is readily available. The second form returns \texttt{high}.

### 28.4.1.2 Class template \texttt{ctype\_byname}

```cpp
namespace std {
    template<class charT>
    class ctype\_byname : public ctype<charT> {
        public:
            using mask = typename ctype<charT>::mask;
            explicit ctype\_byname(const char*, size_t refs = 0);
            explicit ctype\_byname(const string&, size_t refs = 0);

            protected:
                ~ctype\_byname();
    };
}
```

### 28.4.1.3 \texttt{ctype\_char} specialization

```cpp
namespace std {
    template <>
    class ctype<char> : public locale::facet, public ctype_base {
        public:
            using char_type = char;

            explicit ctype(const mask* tab = nullptr, bool del = false, size_t refs = 0);

            bool is(mask m, char c) const;
            const char* is(const char* low, const char* high, mask* vec) const;
            const char* scan\_is (mask m, const char* low, const char* high) const;
            const char* scan\_not (mask m, const char* low, const char* high) const;

            char toupper(char c) const;
            const char* toupper(char* low, const char* high) const;
            char tolower(char c) const;
            const char* tolower(char* low, const char* high) const;
            char widen(char c) const;
            const char* widen(const char* low, const char* high, char* to) const;
            char narrow(char c, char dfault) const;
            const char* narrow(const char* low, const char* high, char dfault, char* to) const;

            static locale::id id;
            static const size_t table\_size = implementation\_defined;

            const mask* table() const noexcept;
            static const mask* classic_table() noexcept;

            protected:
                ~ctype();
                virtual char do\_toupper(char c) const;
                virtual const char* do\_toupper(char* low, const char* high) const;
                virtual char do\_tolower(char c) const;
                virtual const char* do\_tolower(char* low, const char* high) const;
                virtual char do\_widen(char c) const;
                virtual const char* do\_widen(const char* low, const char* high, char* to) const;
                virtual char do\_narrow(char c, char dfault) const;
                virtual const char* do\_narrow(const char* low, const char* high, char dfault, char* to) const;
    };
}
```
A specialization `ctype<char>` is provided so that the member functions on type `char` can be implemented inline. The implementation-defined value of member `table_size` is at least 256.

### 28.4.1.3.1 Destructor

```
~ctype();
```

**Effects:** If the constructor’s first argument was nonzero, and its second argument was `true`, does delete [] table().

### 28.4.1.3.2 Members

In the following member descriptions, for `unsigned char` values `v` where `v >= table_size`, `table()[v]` is assumed to have an implementation-specific value (possibly different for each such value `v`) without performing the array lookup.

```
explicit ctype(const mask* tbl = nullptr, bool del = false, size_t refs = 0);
```

**Requires:** `tbl` either 0 or an array of at least `table_size` elements.

**Effects:** Passes its `refs` argument to its base class constructor.

```
bool is(mask m, char c) const;
const char* is(const char* low, const char* high, mask* vec) const;
```

**Effects:** The second form, for all `*p` in the range `[low, high)`, assigns into `vec[p - low]` the value `table()[((unsigned char)*p)]`.

**Returns:** The first form returns `table()[(unsigned char)c] & m`; the second form returns `high`.

```
const char* scan_is(mask m, const char* low, const char* high) const;
const char* scan_not(mask m, const char* low, const char* high) const;
```

**Returns:** The smallest `p` in the range `[low, high)` such that `table()[((unsigned char) *p)] & m` is `true`.

```
char toupper(char c) const;
const char* toupper(char* low, const char* high) const;
```

**Returns:** `do_toupper(c)` or `do_toupper(low, high)`, respectively.

```
tolower(char c) const;
const char* tolower(char* low, const char* high) const;
```

**Returns:** `do_tolower(c)` or `do_tolower(low, high)`, respectively.

```
widen(char c) const;
const char* widen(const char* low, const char* high, char* to) const;
```

**Returns:** `do_widen(c)` or `do_widen(low, high, to)`, respectively.

```
narrow(char c, char dfault) const;
const char* narrow(const char* low, const char* high, char dfault, char* to) const;
```

**Returns:** `do_narrow(c, dfault)` or `do_narrow(low, high, dfault, to)`, respectively.

```
const mask* table() const noexcept;
```

**Returns:** The first constructor argument, if it was nonzero, otherwise `classic_table()`.

---

266) Only the `char` (not `unsigned char` and `signed char`) form is provided. The specialization is specified in the standard, and not left as an implementation detail, because it affects the derivation interface for `ctype<char>`.

§ 28.4.1.3.2
28.4.1.3.3 Static members

\[\text{facet.cctype.char.statics}\]

\begin{verbatim}
static const mask* classic_table() noexcept;
1
\end{verbatim}

\textbf{Returns:} A pointer to the initial element of an array of size \texttt{table_size} which represents the classifications of characters in the "C" locale.

28.4.1.3.4 Virtual functions

\[\text{facet.cctype.char.virtuals}\]

\begin{verbatim}
char do_toupper(char) const;
const char* do_toupper(char* low, const char* high) const;
char do_tolower(char) const;
const char* do_tolower(char* low, const char* high) const;

virtual char do_widen(char c) const;
virtual const char* do_widen(const char* low, const char* high, char* to) const;
virtual char do_narrow(char c, char dfault) const;
virtual const char* do_narrow(const char* low, const char* high, char dfault, char* to) const;
\end{verbatim}

\textbf{1} These functions are described identically as those members of the same name in the \texttt{ctype} class template (28.4.1.1.1).

28.4.1.4 Class template codecvt

\end{verbatim}

\section{28.4.1.4}
The class `codecvt<internT, externT, stateT>` is for use when converting from one character encoding to another, such as from wide characters to multibyte characters or between wide character encodings such as Unicode and EUC.

The `stateT` argument selects the pair of character encodings being mapped between.

The specializations required in Table 90 (28.3.1.1.1) convert the implementation-defined native character set. `codecvt<char, char, mbstate_t>` implements a degenerate conversion; it does not convert at all. The specialization `codecvt<char16_t, char8_t, mbstate_t>` converts between the UTF-16 and UTF-8 encoding forms, and the specialization `codecvt<char32_t, char8_t, mbstate_t>` converts between the UTF-32 and UTF-8 encoding forms. `codecvt<wchar_t, char, mbstate_t>` converts between the native character sets for ordinary and wide characters. Specializations on `mbstate_t` perform conversion between encodings known to the library implementer. Other encodings can be converted by specializing on a program-defined `stateT` type. Objects of type `stateT` can contain any state that is useful to communicate to or from the specialized `do_in` or `do_out` members.

28.4.1.4.1 Members

```cpp
virtual result do_in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;
virtual result do_unshift(
    stateT& state,
    externT* to, externT* to_end, externT*& to_next) const;
virtual int do_encoding() const noexcept;
virtual bool do_always_noconv() const noexcept;
virtual int do_length(stateT&, const externT* from, const externT* end, size_t max) const;
virtual int do_max_length() const noexcept;
```
28.4.1.4.2 Virtual functions

result do_out(
    stateT& state,
    const internT* from, const internT* from_end, const internT*& from_next,
    externT* to, externT* to_end, externT*& to_next) const;

result do_in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;

1 Requires: (from <= from_end && to <= to_end) well-defined and true; state initialized, if at the
beginning of a sequence, or else equal to the result of converting the preceding characters in the
sequence.

2 Effects: Translates characters in the source range [from, from_end), placing the results in sequential
positions starting at destination to. Converts no more than (from_end - from) source elements, and
stores no more than (to_end - to) destination elements.

   Stops if it encounters a character it cannot convert. It always leaves the from_next and to_next pointers
   pointing one beyond the last element successfully converted. If returns noconv, internT and externT
   are the same type and the converted sequence is identical to the input sequence [from, from_next).
   to_next is set equal to to, the value of state is unchanged, and there are no changes to the values in
   [to, to_end).

   A codecvt facet that is used by basic_filebuf (29.9) shall have the property that if
   do_out(state, from, from_end, from_next, to, to_end, to_next)
   would return ok, where from != from_end, then
   do_out(state, from, from + 1, from_next, to, to_end, to_next)
   shall also return ok, and that if
   do_in(state, from, from_end, from_next, to, to_end, to_next)
   would return ok, where to != to_end, then
   do_in(state, from, from_end, from_next, to, to + 1, to_next)
   shall also return ok.267 [Note: As a result of operations on state, it can return ok or partial and set
   from_next == from and to_next != to. — end note]

3 Remarks: Its operations on state are unspecified. [Note: This argument can be used, for example, to
   maintain shift state, to specify conversion options (such as count only), or to identify a cache of seek
   offsets. — end note]

4 Returns: An enumeration value, as summarized in Table 92.

Table 92: do_in/do_out result values

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the conversion</td>
</tr>
<tr>
<td>partial</td>
<td>not all source characters converted</td>
</tr>
<tr>
<td>error</td>
<td>encountered a character in [from, from_end)</td>
</tr>
<tr>
<td></td>
<td>that it could not convert</td>
</tr>
<tr>
<td>noconv</td>
<td>internT and externT are the same type, and</td>
</tr>
<tr>
<td></td>
<td>input sequence is identical to converted</td>
</tr>
<tr>
<td></td>
<td>sequence</td>
</tr>
</tbody>
</table>

A return value of partial, if (from_next == from_end), indicates that either the destination sequence
has not absorbed all the available destination elements, or that additional source elements are needed
before another destination element can be produced.

267 Informally, this means that basic_filebuf assumes that the mappings from internal to external characters is 1 to N: a
codecvt facet that is used by basic_filebuf must be able to translate characters one internal character at a time.

§ 28.4.1.4.2 1284
result do_unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;

Requires: \((to <= to\_end)\) well-defined and \(true\); state initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

Effects: Places characters starting at \(to\) that should be appended to terminate a sequence when the current \(stateT\) is given by \(state\).\(^{268}\) Stores no more than \((to\_end - to)\) destination elements, and leaves the \(to\_next\) pointer pointing one beyond the last element successfully stored.

Returns: An enumeration value, as summarized in Table 93.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the sequence</td>
</tr>
<tr>
<td>partial</td>
<td>space for more than (to_end - to) destination elements was needed to terminate a sequence given the value of state</td>
</tr>
<tr>
<td>error</td>
<td>an unspecified error has occurred</td>
</tr>
<tr>
<td>noconv</td>
<td>no termination is needed for this (state_type)</td>
</tr>
</tbody>
</table>

int do_encoding() const noexcept;

Returns: \(-1\) if the encoding of the \(externT\) sequence is state-dependent; else the constant number of \(externT\) characters needed to produce an internal character; or \(0\) if this number is not a constant.\(^{269}\)

bool do_always_noconv() const noexcept;

Returns: \(true\) if \(do\_in()\) and \(do\_out()\) return \(noconv\) for all valid argument values. \(codecvt<\text{char}, \text{char}, \text{mbstate\_t}>\) returns \(true\).

int do_length(stateT& state, const externT* from, const externT* from_end, size_t max) const;

Requires: \((from <= from\_end)\) well-defined and \(true\); state initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

Effects: The effect on the \(state\) argument is “as if” it called \(do\_in(state, from, from\_end, from, to\_next\_to, to)\) for \(to\) pointing to a buffer of at least \(max\) elements.

Returns: \((from\_next-from)\) where \(from\_next\) is the largest value in the range \([from, from\_end)\] such that the sequence of values in the range \([from, from\_next)\] represents \(max\) or fewer valid complete \(internT\) characters. The specialization \(codecvt<\text{char}, \text{char}, \text{mbstate\_t}>\), returns the lesser of \(max\) and \((from\_end-from)\).

int do_max_length() const noexcept;

Returns: The maximum value that \(do\_length(state, from, from\_end, 1)\) can return for any valid range \([from, from\_end)\] and state value \(state\). The specialization \(codecvt<\text{char}, \text{char}, \text{mbstate\_t}>::do\_max\_length()\) returns \(1\).

28.4.1.5 Class template codecvtbyname

```cpp
namespace std {
    template<class internT, class externT, class stateT>
    class codecvtbyname : public codecvt<internT, externT, stateT> {
        public:
            explicit codecvtbyname(const char*, size_t refs = 0);
            explicit codecvtbyname(const string&, size_t refs = 0);

            protected:
                ~codecvtbyname();
            }
}
```

\(^{268}\) Typically these will be characters to return the state to \(state\_T()\).

\(^{269}\) If \(encoding()\) yields \(-1\), then more than \(max\_length()\) \(externT\) elements may be consumed when producing a single \(internT\) character, and additional \(externT\) elements may appear at the end of a sequence after those that yield the final \(internT\) character.
28.4.2 The numeric category

1 The classes num_get<> and num_put<> handle numeric formatting and parsing. Virtual functions are provided for several numeric types. Implementations may (but are not required to) delegate extraction of smaller types to extractors for larger types.\footnote{Parsing "-1" correctly into, e.g., an unsigned short requires that the corresponding member get() at least extract the sign before delegating.}

2 All specifications of member functions for num_put and num_get in the subclauses of 28.4.2 only apply to the specializations required in Tables 90 and 91 (28.3.1.1.1), namely num_get<char>, num_get<wchar_t>, num_get<C, InputIterator>, num_put<char>, num_put<wchar_t>, and num_put<C, OutputIterator>. These specializations refer to the ios_base& argument for formatting specifications (28.4), and to its imbued locale for the numpunct<> facet to identify all numeric punctuation preferences, and also for the ctype<> facet to perform character classification.

3 Extractor and inserter members of the standard iostreams use num_get<> and num_put<> member functions for formatting and parsing numeric values (29.7.4.2.1, 29.7.5.2.1).

28.4.2.1 Class template num_get

namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class num_get : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = InputIterator;
            explicit num_get(size_t refs = 0);
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, bool& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, long long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned short& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned int& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned long long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, float& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, double& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, long double& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, void*& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, bool& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, long long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, unsigned short& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, unsigned int& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, unsigned long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, unsigned long long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, float& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, double& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, long double& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, void*& v) const;

private:
    static locale::id id;
}

28.4.2.1286
virtual iter_type do_get(iter_type, iter_type, ios_base&,
    ios_base::iostate& err, unsigned int& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
    ios_base::iostate& err, unsigned long& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
    ios_base::iostate& err, unsigned long long& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
    ios_base::iostate& err, float& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
    ios_base::iostate& err, double& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
    ios_base::iostate& err, long double& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
    ios_base::iostate& err, void*& v) const;
}

The facet num_get is used to parse numeric values from an input sequence such as an istream.

iter_type do_get(iter_type in, iter_type end, ios_base& str,
ios_base::iostate& err, void*& val) const;
1

Effects: Reads characters from in, interpreting them according to str.flags(), use_facet<ctype<
charT>>(loc), and use_facet<numpunct<charT>>(loc), where loc is str.getloc().

2

The details of this operation occur in three stages

(2.1)

— Stage 1: Determine a conversion specifier

(2.2)

— Stage 2: Extract characters from in and determine a corresponding char value for the format
expected by the conversion specification determined in stage 1.

(2.3)

— Stage 3: Store results

3

The details of the stages are presented below.
Stage 1: The function initializes local variables via
fmtflags
fmtflags
fmtflags
fmtflags

flags = str.flags();
basefield = (flags & ios_base::basefield);
uppercase = (flags & ios_base::uppercase);
boolalpha = (flags & ios_base::boolalpha);

For conversion to an integral type, the function determines the integral conversion specifier as
indicated in Table 94. The table is ordered. That is, the first line whose condition is true applies.
Table 94: Integer conversions
State
basefield == oct
basefield == hex
basefield == 0
signed integral type
unsigned integral type

[tab:facet.num.get.int]
stdio equivalent
%o
%X
%i
%d
%u

For conversions to a floating-point type the specifier is %g.
For conversions to void* the specifier is %p.
A length modifier is added to the conversion specification, if needed, as indicated in Table 95.
Table 95: Length modifier
Type
short
unsigned short
long
unsigned long
long long
unsigned long long
double
long double

[tab:facet.num.get.length]
Length modifier
h
h
l
l
ll
ll
l
L

Stage 2: If in == end then stage 2 terminates. Otherwise a charT is taken from in and local variables
are initialized as if by
char_type ct = *in;
char c = src[find(atoms, atoms + sizeof(src) - 1, ct) - atoms];
if (ct == use_facet<numpunct<charT>>(loc).decimal_point())
c = ’.’;
bool discard =
ct == use_facet<numpunct<charT>>(loc).thousands_sep()
&& use_facet<numpunct<charT>>(loc).grouping().length() != 0;

where the values src and atoms are defined as if by:
static const char src[] = "0123456789abcdefxABCDEFX+-";
char_type atoms[sizeof(src)];
use_facet<ctype<charT>>(loc).widen(src, src + sizeof(src), atoms);

§ 28.4.2.1.2

1288


for this value of \( \text{loc} \).

If \texttt{discard} is \texttt{true}, then if \texttt{'}.' has not yet been accumulated, then the position of the character is remembered, but the character is otherwise ignored. Otherwise, if \texttt{'}.' has already been accumulated, the character is discarded and Stage 2 terminates. If it is not discarded, then a check is made to determine if \texttt{c} is allowed as the next character of an input field of the conversion specifier returned by Stage 1. If so, it is accumulated.

If the character is either discarded or accumulated then \texttt{in} is advanced by ++\texttt{in} and processing returns to the beginning of stage 2.

**Stage 3:** The sequence of \texttt{chars} accumulated in stage 2 (the field) is converted to a numeric value by the rules of one of the functions declared in the header <\texttt{cstdlib}>:

- For a signed integer value, the function \texttt{strtol}.
- For an unsigned integer value, the function \texttt{strtoul}.
- For a \texttt{float} value, the function \texttt{strtof}.
- For a \texttt{double} value, the function \texttt{strtod}.
- For a \texttt{long double} value, the function \texttt{strtold}.

The numeric value to be stored can be one of:

- zero, if the conversion function does not convert the entire field.
- the most positive (or negative) representable value, if the field to be converted to a signed integer type represents a value too large positive (or negative) to be represented in \texttt{val}.
- the most positive representable value, if the field to be converted to an unsigned integer type represents a value that cannot be represented in \texttt{val}.
- the converted value, otherwise.

The resultant numeric value is stored in \texttt{val}. If the conversion function does not convert the entire field, or if the field represents a value outside the range of representable values, \texttt{ios\_base::failbit} is assigned to \texttt{err}.

Digit grouping is checked. That is, the positions of discarded separators is examined for consistency with \texttt{use\_facet\<numpunct\charT\>(\texttt{loc}).grouping()}. If they are not consistent then \texttt{ios\_base::failbit} is assigned to \texttt{err}.

In any case, if stage 2 processing was terminated by the test for \texttt{in} == \texttt{end} then \texttt{err} |= \texttt{ios\_base::eofbit} is performed.

\[
\text{iter\_type do\_get}(&\text{iter\_type in}, &\text{iter\_type end}, &\text{ios\_base\& str},
\text{ios\_base\& err, bool\& val}) \text{ const};
\]

**Effects:** If \texttt{(str.flags()&ios\_base::boolalpha)} == 0 then input proceeds as it would for a \texttt{long} except that if a value is being stored into \texttt{val}, the value is determined according to the following: If the value to be stored is 0 then \texttt{false} is stored. If the value is 1 then \texttt{true} is stored. Otherwise \texttt{true} is stored and \texttt{ios\_base::failbit} is assigned to \texttt{err}.

Otherwise target sequences are determined “as if” by calling the members \texttt{false\_name()} and \texttt{true\_name()} of the facet obtained by \texttt{use\_facet\<numpunct\charT\>(str.getloc())}. Successive characters in the range \texttt{[in, end]} (see 22.2.3) are obtained and matched against corresponding positions in the target sequences only as necessary to identify a unique match. The input iterator \texttt{in} is compared to \texttt{end} only when necessary to obtain a character. If a target sequence is uniquely matched, \texttt{val} is set to the corresponding value. Otherwise \texttt{false} is stored and \texttt{ios\_base::failbit} is assigned to \texttt{err}.

The \texttt{in} iterator is always left pointing one position beyond the last character successfully matched. If \texttt{val} is set, then \texttt{err} is set to \texttt{str\_goodbit}; or to \texttt{str\_eofbit} if, when seeking another character to match, it is found that \texttt{(in} == \texttt{end}). If \texttt{val} is not set, then \texttt{err} is set to \texttt{str\_failbit}; or to \texttt{(str\_failbit|str\_eofbit)} if the reason for the failure was that \texttt{(in} == \texttt{end)}. [Example: For targets \texttt{true: "a"} and \texttt{false: "abb"}, the input sequence \texttt{"a"} yields \texttt{val} == \texttt{true} and \texttt{err} == \texttt{str\_eofbit}; the input sequence \texttt{"abc"} yields \texttt{err} == \texttt{str\_failbit}, with \texttt{in} ending at the \texttt{'}c'} element. For targets \texttt{true: "1"} and \texttt{false: "0"}, the input sequence \texttt{"1"} yields \texttt{val} == \texttt{true} and \texttt{err} == \texttt{str\_goodbit}. For empty targets ("")", any input sequence yields \texttt{err} == \texttt{str\_failbit}. — end example]

**Returns:** \texttt{in}.
28.4.2.2 Class template num_put

namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class num_put : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;
            explicit num_put(size_t refs = 0);
            iter_type put(iter_type s, ios_base& f, char_type fill, bool v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, unsigned long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, unsigned long long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, double v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long double v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, const void* v) const;
            static locale::id id;
        protected:
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, bool val) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, long val) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, long long val) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, double val) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, long double val) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, const void* val) const;
        }
    }

1 The facet num_put is used to format numeric values to a character sequence such as an ostream.

28.4.2.2.1 Members

iter_type put(iter_type out, ios_base& str, char_type fill, bool val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long double val) const;

1 Returns: do_put(out, str, fill, val).

28.4.2.2.2 Virtual functions

iter_type do_put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long double val) const;

1 Effects: Writes characters to the sequence out, formatting val as desired. In the following description, loc names a local variable initialized as

    locale loc = str.getloc();

2 The details of this operation occur in several stages:

(2.1) — Stage 1: Determine a printf conversion specifier spec and determine the characters that would be printed by printf (29.12) given this conversion specifier for
The first action of stage 1 is to determine a conversion specifier. The tables that describe this determination use the following local variables:

\[
\text{fmtflags flags = str.flags();}
\]
\[
\text{fmtflags basefield = (flags & (ios_base::basefield));}
\]
\[
\text{fmtflags uppercase = (flags & (ios_base::uppercase));}
\]
\[
\text{fmtflags floatfield = (flags & (ios_base::floatfield));}
\]
\[
\text{fmtflags showpos = (flags & (ios_base::showpos));}
\]
\[
\text{fmtflags showbase = (flags & (ios_base::showbase));}
\]
\[
\text{fmtflags showpoint = (flags & (ios_base::showpoint));}
\]

All tables used in describing stage 1 are ordered. That is, the first line whose condition is true applies. A line without a condition is the default behavior when none of the earlier lines apply.

For conversion from an integral type other than a character type, the function determines the integral conversion specifier as indicated in Table 96.

<table>
<thead>
<tr>
<th>State</th>
<th>Stdio Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == ios_base::oct</td>
<td>%o</td>
</tr>
<tr>
<td>(basefield == ios_base::hex) &amp; !uppercase</td>
<td>%x</td>
</tr>
<tr>
<td>(basefield == ios_base::hex)</td>
<td>%X</td>
</tr>
<tr>
<td>for a signed integral type</td>
<td>%d</td>
</tr>
<tr>
<td>for an unsigned integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

For conversion from a floating-point type, the function determines the floating-point conversion specifier as indicated in Table 97.

<table>
<thead>
<tr>
<th>State</th>
<th>Stdio Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>floatfield == ios_base::fixed</td>
<td>%f</td>
</tr>
<tr>
<td>floatfield == ios_base::scientific &amp; !uppercase</td>
<td>%e</td>
</tr>
<tr>
<td>floatfield == ios_base::scientific</td>
<td>%E</td>
</tr>
<tr>
<td>floatfield == (ios_base::fixed</td>
<td>ios_base::scientific) &amp; !uppercase</td>
</tr>
<tr>
<td>floatfield == (ios_base::fixed</td>
<td>ios_base::scientific)</td>
</tr>
<tr>
<td>!uppercase</td>
<td>%g</td>
</tr>
<tr>
<td>otherwise</td>
<td>%G</td>
</tr>
</tbody>
</table>

For conversions from an integral or floating-point type a length modifier is added to the conversion specifier as indicated in Table 98.

The conversion specifier has the following optional additional qualifiers prepended as indicated in Table 99.

For conversion from a floating-point type, if floatfield != (ios_base::fixed | ios_base::scientific), str.precision() is specified as precision in the conversion specification. Otherwise, no precision is specified.

For conversion from void*, the specifier is %p.
Table 98: Length modifier  [tab:facet.num.put.length]

<table>
<thead>
<tr>
<th>Type</th>
<th>Length modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>long</td>
<td>l</td>
</tr>
<tr>
<td>long long</td>
<td>ll</td>
</tr>
<tr>
<td>unsigned long</td>
<td>l</td>
</tr>
<tr>
<td>unsigned long long</td>
<td>ll</td>
</tr>
<tr>
<td>long double</td>
<td>L</td>
</tr>
<tr>
<td>otherwise</td>
<td>none</td>
</tr>
</tbody>
</table>

Table 99: Numeric conversions  [tab:facet.num.put.conv]

<table>
<thead>
<tr>
<th>Type(s)</th>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>an integral type</td>
<td>showpos</td>
<td>+</td>
</tr>
<tr>
<td></td>
<td>showbase</td>
<td>#</td>
</tr>
<tr>
<td>a floating-point type</td>
<td>showpos</td>
<td>+</td>
</tr>
<tr>
<td></td>
<td>showpoint</td>
<td>#</td>
</tr>
</tbody>
</table>

The representations at the end of stage 1 consists of the char’s that would be printed by a call of printf(s, val) where s is the conversion specifier determined above.

Stage 2: Any character c other than a decimal point(.) is converted to a charT via

```
use_facet<ctype<charT>>((loc).widen(c)
```

A local variable punct is initialized via

```
const numpunct<charT>& punct = use_facet<numpunct<charT>>((loc);
```

For arithmetic types, punct.thousands_sep() characters are inserted into the sequence as determined by the value returned by punct.do_grouping() using the method described in 28.4.3.1.2

Decimal point characters(.) are replaced by punct.decimal_point()

Stage 3: A local variable is initialized as

```
fmtflags adjustfield = (flags & (ios_base::adjustfield));
```

The location of any padding\(^{271}\) is determined according to Table 100.

<table>
<thead>
<tr>
<th>State</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>adjustfield == ios_base::left</td>
<td>pad after</td>
</tr>
<tr>
<td>adjustfield == ios_base::right</td>
<td>pad before</td>
</tr>
<tr>
<td>adjustfield == internal and a sign occurs in the representation</td>
<td>pad after the sign</td>
</tr>
<tr>
<td>adjustfield == internal and representation after stage 1 began with 0x or 0X</td>
<td>pad after x or X</td>
</tr>
<tr>
<td>otherwise</td>
<td>pad before</td>
</tr>
</tbody>
</table>

If str.width() is nonzero and the number of charT’s in the sequence after stage 2 is less than str.width(), then enough fill characters are added to the sequence at the position indicated for padding to bring the length of the sequence to str.width().

str.width(0) is called.

Stage 4: The sequence of charT’s at the end of stage 3 are output via

```
*out++ = c
```

\(^{271}\) The conversion specification #o generates a leading 0 which is not a padding character.
Returns: If 
\( (\text{str}.\text{flags()} \& \text{ios}\_\text{base}::\text{boolalpha}) == 0 \) returns \( \text{do\_put}(\text{out}, \text{str}, \text{fill}, \text{(int})\text{val}) \), otherwise obtains a string \( s \) as if by

\[
\text{string\_type } s = \\
\text{val} \ ? \ \text{use\_facet<numpunct<charT>>(loc).truename()} \\
: \ \text{use\_facet<numpunct<charT>>(loc).falsename();}
\]

and then inserts each character \( c \) of \( s \) into \( \text{out} \) via \( *\text{out}++ = c \) and returns \( \text{out} \).

### 28.4.3 The numeric punctuation facet

#### 28.4.3.1 Class template numpunct

```cpp
namespace std {
    template<class charT>
    class numpunct : public locale::facet {
    public:
        using char_type = charT;
        using string_type = basic_string<charT>;

        explicit numpunct(size_t refs = 0);

        char_type decimal_point() const;
        char_type thousands_sep() const;
        string grouping() const;
        string_type truename() const;
        string_type falsename() const;

        static locale::id id;
    protected:
        ~numpunct(); // virtual
        virtual char_type do_decimal_point() const;
        virtual char_type do_thousands_sep() const;
        virtual string do_grouping() const;
        virtual string_type do_truename() const; // for bool
        virtual string_type do_falsename() const; // for bool
    };
```

1. `numpunct<>` specifies numeric punctuation. The specializations required in Table 90 (28.3.1.1.1), namely `numpunct<wchar_t>` and `numpunct<char>`, provide classic "C" numeric formats, i.e., they contain information equivalent to that contained in the "C" locale or their wide character counterparts as if obtained by a call to `widen`.

2. The syntax for number formats is as follows, where `digit` represents the radix set specified by the `fmtflags` argument value, and `thousands-sep` and `decimal-point` are the results of corresponding `numpunct<charT>` members. Integer values have the format:

```
integer ::= [sign] units
sign ::= plusminus
plusminus ::= '+' | '-'
units ::= digits [thousands-sep units]
digits ::= digit [digits]
```

and floating-point values have:

```
floatval ::= [sign] units [decimal-point [digits]] [e [sign] digits] |
           [sign] decimal-point digits [e [sign] digits]
e ::= 'e' | 'E'
```

where the number of digits between `thousands-seps` is as specified by `do_grouping()`. For parsing, if the `digits` portion contains no thousands-separators, no grouping constraint is applied.

#### 28.4.3.1.1 Members

```cpp
char_type decimal_point() const;
```

1. Returns: `do_decimal_point()`.
char_type thousands_sep() const;

Returns: do_thousands_sep().

string grouping() const;

Returns: do_grouping().

string_type truename() const;
string_type falsename() const;

Returns: do_truename() or do_falsename(), respectively.

28.4.3.1.2 Virtual functions

char_type do_decimal_point() const;

Returns: A character for use as the decimal radix separator. The required specializations return "." or L"."

class template numpunct_byname

namespace std {

    template<class charT>
    class numpunct_byname : public numpunct<charT> {
        // this class is specialized for char and wchar_t.
        public:
            using char_type = charT;
            using string_type = basic_string<charT>;

            explicit numpunct_byname(const char*, size_t refs = 0);
            explicit numpunct_byname(const string&, size_t refs = 0);

            protected:
                ~numpunct_byname();
            }
}

28.4.4 The collate category

28.4.4.1 Class template collate

namespace std {

    template<class charT>
    class collate : public locale::facet {
        public:
            using char_type = charT;
            using string_type = basic_string<charT>;

272) Thus, the string "\003" specifies groups of 3 digits each, and "3" probably indicates groups of 51 (!) digits each, because 51 is the ASCII value of "3".
The class `collate<charT>` provides features for use in the collation (comparison) and hashing of strings. A locale member function template, `operator()`, uses the `collate` facet to allow a locale to act directly as the predicate argument for standard algorithms (Clause 25) and containers operating on strings. The specializations required in Table 90 (28.3.1.1.1), namely `collate<char>` and `collate<wchar_t>`, apply lexicographic ordering (25.7.10).

Each function compares a string of characters *p in the range [low, high).

### 28.4.4.1.1 Members

#### int compare(const charT* low1, const charT* high1, const charT* low2, const charT* high2) const;

*Returns:* `do_compare(low1, high1, low2, high2)`.

#### string_type transform(const charT* low, const charT* high) const;

*Returns:* `do_transform(low, high)`.

#### long hash(const charT* low, const charT* high) const;

*Returns:* An integer value equal to the result of calling `hash()` on any other string for which `do_compare()` returns 0 (equal) when passed the two strings. [Note: The probability that the result equals that for another string which does not compare equal should be very small, approaching `(1.0/numeric_limits<unsigned long>::max())`. —end note]

---

273) This function is useful when one string is being compared to many other strings.
28.4.4.2 Class template collate_byname

namespace std {
    template<class charT>
    class collate_byname : public collate<charT> {
        public:
            using string_type = basic_string<charT>;

            explicit collate_byname(const char*, size_t refs = 0);
            explicit collate_byname(const string&, size_t refs = 0);
        protected:
            ~collate_byname();
    };  
}

28.4.5 The time category

Templates time_get<charT, InputIterator> and time_put<charT, OutputIterator> provide date and time formatting and parsing. All specifications of member functions for time_put and time_get in the subclauses of 28.4.5 only apply to the specializations required in Tables 90 and 91 (28.3.1.1.1). Their members use their ios_base&, ios_base::iostate&, and fill arguments as described in 28.4, and the ctype<> facet, to determine formatting details.

28.4.5.1 Class template time_get

namespace std {
    class time_base {
        public:
            enum dateorder { no_order, dmy, mdy, ymd, ydm };
    };

template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class time_get : public locale::facet, public time_base {
        public:
            using char_type = charT;
            using iter_type = InputIterator;

            explicit time_get(size_t refs = 0);

            dateorder date_order() const { return do_date_order(); }
            iter_type get_time(iter_type s, iter_type end, ios_base& f,
                ios_base::iostate& err, tm* t) const;
            iter_type get_date(iter_type s, iter_type end, ios_base& f,
                ios_base::iostate& err, tm* t) const;
            iter_type get_weekday(iter_type s, iter_type end, ios_base& f,
                ios_base::iostate& err, tm* t) const;
            iter_type get_monthname(iter_type s, iter_type end, ios_base& f,
                ios_base::iostate& err, tm* t) const;
            iter_type get_year(iter_type s, iter_type end, ios_base& f,
                ios_base::iostate& err, tm* t) const;
            iter_type get(iter_type s, iter_type end, ios_base& f,
                ios_base::iostate& err, tm* t, char format, char modifier = 0) const;
            iter_type get(iter_type s, iter_type end, ios_base& f,
                ios_base::iostate& err, tm* t, const char_type* fmt,
                const char_type* fmtend) const;

            static locale::id id;
    };

protected:
    ~time_get();
    virtual dateorder do_date_order() const;
    virtual iter_type do_get_time(iter_type s, iter_type end, ios_base&,
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_date(iter_type s, iter_type end, ios_base&,
        ios_base::iostate& err, tm* t) const;

§ 28.4.5.1
virtual iter_type do_get_weekday(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err, tm* t, char format, char modifier) const;
virtual iter_type do_get_monthname(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err, tm* t) const;
virtual iter_type do_get_year(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err, tm* t, char format, char modifier) const;

}  

1 time_get is used to parse a character sequence, extracting components of a time or date into a struct tm object. Each get member parses a format as produced by a corresponding format specifier to time_get<>::put. If the sequence being parsed matches the correct format, the corresponding members of the struct tm argument are set to the values used to produce the sequence; otherwise either an error is reported or unspecified values are assigned.  

2 If the end iterator is reached during parsing by any of the get() member functions, the member sets ios_base::eofbit in err.

28.4.5.1.1 Members

iter_type do_get_time(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;
Returns: do_get_time(s, end, str, err, t).

iter_type do_get_date(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;
Returns: do_get_date(s, end, str, err, t).

iter_type do_get_weekday(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;
iter_type do_get_monthname(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;
Returns: do_get_weekday(s, end, str, err, t) or do_get_monthname(s, end, str, err, t).

iter_type do_get_year(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;
Returns: do_get_year(s, end, str, err, t).

iter_type do_get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err, tm* t, char format, char modifier = 0) const;
Returns: do_get(s, end, f, err, t, format, modifier).

iter_type do_get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err, tm* t, const char_type* fmt, const char_type* fmtend) const;
Requires: [fmt, fmtend) shall be a valid range.
Effects: The function starts by evaluating err = ios_base::goodbit. It then enters a loop, reading zero or more characters from s at each iteration. Unless otherwise specified below, the loop terminates when the first of the following conditions holds:

- The expression fmt == fmtend evaluates to true.
- The expression err == ios_base::goodbit evaluates to false.
- The expression s == end evaluates to true, in which case the function evaluates err = ios_base::eofbit | ios_base::failbit.

274) In other words, user confirmation is required for reliable parsing of user-entered dates and times, but machine-generated formats can be parsed reliably. This allows parsers to be aggressive about interpreting user variations on standard formats.
— The next element of fmt is equal to '%', optionally followed by a modifier character, followed by a conversion specifier character, format, together forming a conversion specification valid for the ISO/IEC 9945 function `strptime`. If the number of elements in the range [fmt, fmtend) is not sufficient to unambiguously determine whether the conversion specification is complete and valid, the function evaluates `err = ios_base::failbit`. Otherwise, the function evaluates `s = do_get(s, end, f, err, t, format, modifier)`, where the value of modifier is '\0' when the optional modifier is absent from the conversion specification. If `err == ios_base::goodbit` holds after the evaluation of the expression, the function increments fmt to point just past the end of the conversion specification and continues looping.

— The expression `isspace(*fmt, f.getloc())` evaluates to true, in which case the function first increments fmt until fmt == fmtend || !isspace(*fmt, f.getloc()) evaluates to true, then advances s until s == end || !isspace(*s, f.getloc()) is true, and finally resumes looping.

— The next character read from s matches the element pointed to by fmt in a case-insensitive comparison, in which case the function evaluates ++fmt, ++s and continues looping. Otherwise, the function evaluates `err = ios_base::failbit`.

[Note: The function uses the `ctype<charT>` facet installed in f's locale to determine valid whitespace characters. It is unspecified by what means the function performs case-insensitive comparison or whether multi-character sequences are considered while doing so. — end note]

Returns: s.

28.4.5.1.2 Virtual functions

`dateorder do_date_order() const;`

Returns: An enumeration value indicating the preferred order of components for those date formats that are composed of day, month, and year. Returns `no_order` if the date format specified by 'x' contains other variable components (e.g., Julian day, week number, week day).

`iter_type do_get_time(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;`

Effects: Reads characters starting at s until it has extracted those struct tm members, and remaining format characters, used by time_put<>::put to produce the format specified by "%H:%M:%S", or until it encounters an error or end of sequence.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid time.

`iter_type do_get_date(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;`

Effects: Reads characters starting at s until it has extracted those struct tm members and remaining format characters used by time_put<>::put to produce one of the following formats, or until it encounters an error. The format depends on the value returned by `date_order()` as shown in Table 101.

Table 101: do_get_date effects

<table>
<thead>
<tr>
<th>date_order()</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>no_order</td>
<td>&quot;%m%d%y&quot;</td>
</tr>
<tr>
<td>dmy</td>
<td>&quot;%d%m%y&quot;</td>
</tr>
<tr>
<td>mdy</td>
<td>&quot;%m%d%y&quot;</td>
</tr>
<tr>
<td>ymd</td>
<td>&quot;%y%m%d&quot;</td>
</tr>
<tr>
<td>ydm</td>
<td>&quot;%y%d%m&quot;</td>
</tr>
</tbody>
</table>

An implementation may also accept additional implementation-defined formats.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid date.

275) This function is intended as a convenience only, for common formats, and may return `no_order` in valid locales.
iter_type do_get_weekday(iter_type s, iter_type end, ios_base& str,  
   ios_base::iostate& err, tm* t) const;

iter_type do_get_monthname(iter_type s, iter_type end, ios_base& str,  
   ios_base::iostate& err, tm* t) const;

Effects: Reads characters starting at \( s \) until it has extracted the (perhaps abbreviated) name of a weekday or month. If it finds an abbreviation that is followed by characters that could match a full name, it continues reading until it matches the full name or fails. It sets the appropriate struct \( \text{tm} \) member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid name.

iter_type do_get_year(iter_type s, iter_type end, ios_base& str,  
   ios_base::iostate& err, tm* t) const;

Effects: Reads characters starting at \( s \) until it has extracted an unambiguous year identifier. It is implementation-defined whether two-digit year numbers are accepted, and (if so) what century they are assumed to lie in. Sets the \( t->\text{tm}_\text{year} \) member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid year identifier.

iter_type do_get(iter_type s, iter_type end, ios_base& f,  
   ios_base::iostate& err, tm* t, char format, char modifier) const;

Requires: \( t \) shall point to an object.

Effects: The function starts by evaluating \( \text{err} = \text{ios_base::goodbit} \). It then reads characters starting at \( s \) until it encounters an error, or until it has extracted and assigned those struct \( \text{tm} \) members, and any remaining format characters, corresponding to a conversion directive appropriate for the ISO/IEC 9945 function \text{strftime}, formed by concatenating ’%’, the \text{modifier} character, when non-NUL, and the \text{format} character. When the concatenation fails to yield a complete valid directive the function leaves the object pointed to by \( t \) unchanged and evaluates \( \text{err} |= \text{ios_base::failbit} \). When \( s == \text{end} \) evaluates to \( \text{true} \) after reading a character the function evaluates \( \text{err} |= \text{ios_base::eofbit} \).

For complex conversion directives such as ’%c’, ’%x’, or ’%X’, or directives that involve the optional modifiers \( \text{E} \) or \( \text{O} \), when the function is unable to unambiguously determine some or all struct \( \text{tm} \) members from the input sequence \( [s, \text{end}) \), it evaluates \( \text{err} |= \text{ios_base::eofbit} \). In such cases the values of those struct \( \text{tm} \) members are unspecified and may be outside their valid range.

Remarks: It is unspecified whether multiple calls to do_get() with the address of the same struct \( \text{tm} \) object will update the current contents of the object or simply overwrite its members. Portable programs should zero out the object before invoking the function.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid input sequence for the given \text{format} and \text{modifier}.

28.4.5.2 Class template time_get_byname
[locale.time.getbyname]

namespace std {
   template<class charT, class InputIterator = istreambuf_iterator<charT>>
   class time_get_byname : public time_get<charT, InputIterator> { 
      public:
         using dateorder = time_base::dateorder;
         using iter_type = InputIterator;

         explicit time_get_byname(const char*, size_t refs = 0);
         explicit time_get_byname(const string&, size_t refs = 0);

      protected:
         ~time_get_byname();
      }
   }

28.4.5.3 Class template time_put
[locale.time.put]

namespace std {
   template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
   class time_put : public locale::facet {

§ 28.4.5.3 1299
public:
    using char_type = charT;
    using iter_type = OutputIterator;

    explicit time_put(size_t refs = 0);

    // the following is implemented in terms of other member functions.
    iter_type put(iter_type s, ios_base& f, char_type fill, const tm* tmb,
                  const charT* pattern, const charT* pat_end) const;
    iter_type put(iter_type s, ios_base& f, char_type fill,
                  const tm* tmb, char format, char modifier = 0) const;

    static locale::id id;

protected:
    ~time_put();
    virtual iter_type do_put(iter_type s, ios_base&, char_type, const tm* t,
                             char format, char modifier) const;

};

28.4.5.3.1 Members

    iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
                  const charT* pattern, const charT* pat_end) const;
    iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
                  char format, char modifier = 0) const;

    Effects: The first form steps through the sequence from pattern to pat_end, identifying characters
    that are part of a format sequence. Each character that is not part of a format sequence is written to
    s immediately, and each format sequence, as it is identified, results in a call to do_put; thus, format
    elements and other characters are interleaved in the output in the order in which they appear in
    the pattern. Format sequences are identified by converting each character c to a char value as if by
    ct.narrow(c, 0), where ct is a reference to ctype<charT> obtained from str.getloc(). The first
    character of each sequence is equal to '%' followed by an optional modifier character mod and a
    format specifier character spec as defined for the function strftime. If no modifier character is present,
    mod is zero. For each valid format sequence identified, calls do_put(s, str, fill, t, spec, mod).
    The second form calls do_put(s, str, fill, t, format, modifier).

    [Note: The fill argument may be used in the implementation-defined formats or by derivations. A
    space character is a reasonable default for this argument. —end note]

    Returns: An iterator pointing immediately after the last character produced.

28.4.5.3.2 Virtual functions

    iter_type do_put(iter_type s, ios_base& str, char_type fill, const tm* t,
                     char format, char modifier) const;

    Effects: Formats the contents of the parameter t into characters placed on the output sequence s.
    Formatting is controlled by the parameters format and modifier, interpreted identically as the format
    specifiers in the string argument to the standard library function strftime, except that the
    sequence of characters produced for those specifiers that are described as depending on the C locale are
    instead implementation-defined.

    Returns: An iterator pointing immediately after the last character produced. [Note: The fill argument
    may be used in the implementation-defined formats or by derivations. A space character is a reasonable
    default for this argument. —end note]
28.4.5.4 Class template `time_put_byname`  

```cpp
class time_put_byname : public time_put<charT, OutputIterator> {
public:
    using char_type = charT;
    using iter_type = OutputIterator;
    explicit time_put_byname(const char*, size_t refs = 0);
    explicit time_put_byname(const string&, size_t refs = 0);

protected:
    ~time_put_byname();
};
```

28.4.6 The monetary category

These templates handle monetary formats. A template parameter indicates whether local or international monetary formats are to be used.

All specifications of member functions for `money_put` and `money_get` in the subclauses of 28.4.6 only apply to the specializations required in Tables 90 and 91 (28.3.1.1.1). Their members use their `ios_base&`, `ios_base::iostate&`, and `fill` arguments as described in 28.4, and the `moneypunct<>` and `ctype<>` facets, to determine formatting details.

28.4.6.1 Class template `money_get`

```cpp
namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class money_get : public locale::facet {
public:
    using char_type = charT;
    using iter_type = InputIterator;
    using string_type = basic_string<charT>;
    explicit money_get(size_t refs = 0);
    iter_type get(iter_type, iter_type, bool, ios_base& f, ios_base::iostate& err, long double& units) const;
    iter_type get(iter_type, iter_type, bool, ios_base& f, ios_base::iostate& err, string_type& digits) const;

    static locale::id id;

protected:
    ~money_get();
    virtual iter_type do_get(iter_type, iter_type, bool, ios_base&, ios_base::iostate& err, long double& units) const;
    virtual iter_type do_get(iter_type, iter_type, bool, ios_base&, ios_base::iostate& err, string_type& digits) const;
};
```

28.4.6.1.1 Members

```cpp
iter_type get(iter_type s, iter_type end, bool intel, ios_base& f, ios_base::iostate& err, long double& quant) const;
iter_type get(iter_type s, iter_type end, bool intel, ios_base& f, ios_base::iostate& err, string_type& quant) const;
```

Returns: `do_get(s, end, intel, f, err, quant)`.  

§ 28.4.6.1.1 1301
28.4.6.1.2 Virtual functions

Iterate do_get(iter_type s, iter_type end, bool intl, ios_base& str,  
ios_base::iostate& err, long double& units) const;
Iterate do_get(iter_type s, iter_type end, bool intl, ios_base& str,  
ios_base::iostate& err, string_type& digits) const;

Effects: Reads characters from s to parse and construct a monetary value according to the format specified by a moneypunct< charT, Intl > facet reference mp and the character mapping specified by a ctype< charT > facet reference ct obtained from the locale returned by str.getloc(), and str.flags(). If a valid sequence is recognized, does not change err; otherwise, sets err to (err|str.failbit), or (err|str.failbit|str.eofbit) if no more characters are available, and does not change units or digits. Uses the pattern returned by mp.neg_format() to parse all values. The result is returned as an integral value stored in units or as a sequence of digits possibly preceded by a minus sign (as produced by ct.widen(c) where c is ‘-’ or in the range from ‘0’ through ‘9’ (inclusive)) stored in digits. [Example: The sequence $1,056.23$ in a common United States locale would yield, for units, 105623, or, for digits, "105623". —end example] If mp.grouping() indicates that no thousands separators are permitted, any such characters are not read, and parsing is terminated at the point where they first appear. Otherwise, thousands separators are optional; if present, they are checked for correct placement only after all format components have been read.

Where money_base::space or money_base::none appears as the last element in the format pattern, no white space is consumed. Otherwise, where money_base::space appears in any of the initial elements of the format pattern, at least one white space character is required. Where money_base::space appears in any of the initial elements of the format pattern, white space is allowed but not required. If (str.flags() & str.showbase) is false, the currency symbol is optional and is consumed only if other characters are needed to complete the format; otherwise, the currency symbol is required.

If the first character (if any) in the string pos returned by mp.positive_sign() or the string neg returned by mp.negative_sign() is recognized in the position indicated by sign in the format pattern, it is consumed and any remaining characters in the string are required after all the other format components. [Example: If showbase is off, then for a neg value of "()" and a currency symbol of "L", in "(100 L)" the "L" is consumed; but if neg is "-", the "L" in "-100 L" is not consumed. —end example] If pos or neg is empty, the sign component is optional, and if no sign is detected, the result is given the sign that corresponds to the source of the empty string. Otherwise, the character in the indicated position must match the first character of pos or neg, and the result is given the corresponding sign. If the first character of pos is equal to the first character of neg, or if both strings are empty, the result is given a positive sign.

Digits in the numeric monetary component are extracted and placed in digits, or into a character buffer buf1 for conversion to produce a value for units, in the order in which they appear, preceded by a minus sign if and only if the result is negative. The value units is produced as if by

```c
for (int i = 0; i < n; ++i)  
    buf2[i] = src[find(atoms, atoms+sizeof(src), buf1[i]) - atoms];  
buf2[n] = 0;  
sscanf(buf2, "%Lf", &units);
```

where n is the number of characters placed in buf1, buf2 is a character buffer, and the values src and atoms are defined as if by

```c
static const char src[] = "0123456789-";  
charT atoms[sizeof(src)];  
ct.widen(src, src + sizeof(src) - 1, atoms);
```

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid monetary quantity.

28.4.6.2 Class template money_put

namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class money_put : public locale::facet {
        public:
            using char_type = charT;

279) The semantics here are different from ct.narrow.
© ISO/IEC

using iter_type = OutputIterator;
using string_type = basic_string<charT>;

explicit money_put(size_t refs = 0);
iter_type put(iter_type s, bool intl, ios_base& f,
char_type fill, long double units) const;
iter_type put(iter_type s, bool intl, ios_base& f,
char_type fill, const string_type& digits) const;

static locale::id id;

protected:
~money_put();
virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill,
long double units) const;
virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill,
const string_type& digits) const;
}

28.4.6.2.1 Members

iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, long double quant) const;
iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, const string_type& quant) const;

Returns: do_put(s, intl, f, loc, quant).

28.4.6.2.2 Virtual functions

iter_type do_put(iter_type s, bool intl, ios_base& str,
char_type fill, long double units) const;
iter_type do_put(iter_type s, bool intl, ios_base& str,
char_type fill, const string_type& digits) const;

Effects: Writes characters to s according to the format specified by a moneypunct<charT, Intl> facet reference mp and the character mapping specified by a ctype<charT> facet reference ct obtained from the locale returned by str.getloc(), and str.flags(). The argument units is transformed into a sequence of wide characters as if by

ct.widen(buf1, buf1 + sprintf(buf1, "%0Lf", units), buf2)

for character buffers buf1 and buf2. If the first character in digits or buf2 is equal to ct.widen('-'), then the pattern used for formatting is the result of mp.neg_format(); otherwise the pattern is the result of mp.pos_format(). Digit characters are written, interspersed with any thousands separators and decimal point specified by the format, in the order they appear (after the optional leading minus sign) in digits or buf2. In digits, only the optional leading minus sign and the immediately subsequent digit characters (as classified according to ct) are used; any trailing characters (including digits appearing after a non-digit character) are ignored. Calls str.width(0).

Remarks: The currency symbol is generated if and only if (str.flags() & str.showbase) is nonzero. If the number of characters generated for the specified format is less than the value returned by str.width() on entry to the function, then copies of fill are inserted as necessary to pad to the specified width. For the value af equal to (str.flags() & str.adjustfield), if (af == str.internal) is true, the fill characters are placed where none or space appears in the formatting pattern; otherwise if (af == str.left) is true, they are placed after the other characters; otherwise, they are placed before the other characters. [Note: It is possible, with some combinations of format patterns and flag values, to produce output that cannot be parsed using num_get<>::get. — end note]

Returns: An iterator pointing immediately after the last character produced.

28.4.6.3 Class template moneypunct

namespace std {
    class money_base {
        public:
            enum part { none, space, symbol, sign, value };
    }
struct pattern { char field[4];
};

template<class charT, bool International = false>
class moneypunct : public locale::facet, public money_base {
public:
    using char_type = charT;
    using string_type = basic_string<charT>;

    explicit moneypunct(size_t refs = 0);
    charT decimal_point() const;
    charT thousands_sep() const;
    string grouping() const;
    string_type curr_symbol() const;
    int frac_digits() const;
    pattern pos_format() const;
    pattern neg_format() const;

    static locale::id id;
    static const bool intl = International;

protected:
    ~moneypunct();
    virtual charT do_decimal_point() const;
    virtual charT do_thousands_sep() const;
    virtual string do_grouping() const;
    virtual string_type do_curr_symbol() const;
    virtual string_type do_positive_sign() const;
    virtual string_type do_negative_sign() const;
    virtual int do_frac_digits() const;
    virtual pattern do_pos_format() const;
    virtual pattern do_neg_format() const;
};

The `moneypunct<>` facet defines monetary formatting parameters used by `money_get<>` and `money_put<>`. A monetary format is a sequence of four components, specified by a `pattern` value `p`, such that the `part` value `static_cast<part>(p.field[i])` determines the `i`th component of the format.

In the `field` member of a `pattern` object, each value `symbol`, `sign`, `value`, and either `space` or `none` appears exactly once. The value `none`, if present, is not first; the value `space`, if present, is neither first nor last.

Where `none` or `space` appears, white space is permitted in the format, except where `none` appears at the end, in which case no white space is permitted. The value `space` indicates that at least one space is required at that position. Where `symbol` appears, the sequence of characters returned by `curr_symbol()` is permitted, and can be required. Where `sign` appears, the first (if any) of the sequence of characters returned by `positive_sign()` or `negative_sign()` (respectively as the monetary value is non-negative or negative) is required. Any remaining characters of the sign sequence are required after all other format components. Where `value` appears, the absolute numeric monetary value is required.

The format of the numeric monetary value is a decimal number:

```
value ::= units [ decimal-point [ digits ] ] |
   decimal-point digits
```

if `frac_digits()` returns a positive value, or

```
value ::= units
```

otherwise. The symbol `decimal-point` indicates the character returned by `decimal_point()`. The other symbols are defined as follows:

```
units ::= digits [ thousands-sep units ]
digits ::= adigit [ digits ]
```

280) An array of `char`, rather than an array of `part`, is specified for `pattern::field` purely for efficiency.
In the syntax specification, the symbol `digit` is any of the values `ct.widen(c)` for `c` in the range ‘0’ through ‘9’ (inclusive) and `ct` is a reference of type `const ctype<charT>&` obtained as described in the definitions of `money_get<>` and `money_put<>`. The symbol `thousands-sep` is the character returned by `thousands_sep()`. The space character used is the value `ct.widen(' ')`. While space characters are those characters `c` for which `ci.is(space, c)` returns true. The number of digits required after the decimal point (if any) is exactly the value returned by `frac_digits()`.

The placement of thousands-separator characters (if any) is determined by the value returned by `grouping()`, defined identically as the member `numpunct<>::do_grouping()`.

### § 28.4.6.3.2 Virtual functions [locale.moneypunct.virtuals]

- `charT do_decimal_point() const;`  
  Returns: The radix separator to use in case `do_frac_digits()` is greater than zero.\(^{281}\)

- `charT do_thousands_sep() const;`  
  Returns: The digit group separator to use in case `do_grouping()` specifies a digit grouping pattern.\(^{282}\)

- `string do_grouping() const;`  
  Returns: A pattern defined identically as, but not necessarily equal to, the result of `numpunct<charT>::do_grouping()`\(^{283}\).

- `string_type do_curr_symbol() const;`  
  Returns: A string to use as the currency identifier symbol. \([Note: \text{For specializations where the second template parameter is} \text{true, this is typically four characters long: a three-letter code as specified by ISO 4217 followed by a space.}]\)\(^{-} \text{end note}\)

- `string_type do_positive_sign() const;`  
  `string_type do_negative_sign() const;`  
  `int do_frac_digits() const;`  
  `pattern do_pos_format() const;`  
  `pattern do_neg_format() const;`  
  Returns: The specializations required in Table 91 (28.3.1.1.1), namely `moneypunct<char>`, `moneypunct<wchar_t>`, `moneypunct<char, true>`, and `moneypunct<wchar_t, true>`, return an object of type `pattern` initialized to `\{ symbol, sign, none, value \}`.\(^{286}\)

\(^{281}\) In common U.S. locales this is ‘.’.

\(^{282}\) In common U.S. locales this is ‘,’.

\(^{283}\) To specify grouping by 3s, the value is “\003” not “3”.

\(^{284}\) This is usually the empty string.

\(^{285}\) In common U.S. locales, this is 2.

\(^{286}\) Note that the international symbol returned by `do_curr_symbol()` usually contains a space, itself, for example, “USD ”.

\(\text{§ 28.4.6.3.2}\)
28.4.6.4 Class template moneypunct_byname

```cpp
namespace std {
    template<class charT, bool Intl = false>
    class moneypunct_byname : public moneypunct<charT, Intl> {
    public:
        using pattern = money_base::pattern;
        using string_type = basic_string<charT>;

        explicit moneypunct_byname(const char*, size_t refs = 0);
        explicit moneypunct_byname(const string&, size_t refs = 0);

    protected:
        ~moneypunct_byname();
    };
}
```

28.4.7 The message retrieval category

Class `messages<charT>` implements retrieval of strings from message catalogs.

28.4.7.1 Class template messages

```cpp
namespace std {
    class messages_base { public:
        using catalog = unspecified signed integer type;
    };

    template<class charT>
    class messages : public locale::facet, public messages_base {
    public:
        using char_type = charT;
        using string_type = basic_string<charT>;

        explicit messages(size_t refs = 0);
        catalog open(const basic_string<char>& fn, const locale&) const;
        string_type get(catalog c, int set, intmsgid, const string_type& dfault) const;
        void close(catalog c) const;
        static locale::id id;

    protected:
        ~messages();
        virtual catalog do_open(const basic_string<char>&, const locale&) const;
        virtual string_type do_get(catalog, int set, int msgid, const string_type& dfault) const;
        virtual void do_close(catalog) const;
    };
}
```

1 Values of type `messages_base::catalog` usable as arguments to members `get` and `close` can be obtained only by calling member `open`.

28.4.7.1.1 Members

```cpp
catalog open(const basic_string<char>& name, const locale& loc) const;
```

1 `Returns: do_open(name, loc).`

```cpp
string_type get(catalog cat, int set, int msgid, const string_type& dfault) const;
```

2 `Returns: do_get(cat, set, msgid, dfault).`

```cpp
void close(catalog cat) const;
```

3 `Effects: Calls do_close(cat).`
28.4.7.1.2 Virtual functions

catalog do_open(const basic_string<char>& name, const locale& loc) const;

1 Returns: A value that may be passed to get() to retrieve a message from the
message catalog identified by the string name according to an implementation-defined
mapping. The result can be used until it is passed to close().
2 Returns a value less than 0 if no such catalog can be opened.
3 Remarks: The locale argument loc is used for character set code conversion when
retrieving messages, if needed.

string_type do_get(catalog cat, int set, intmsgid, const string_type& dfault) const;

4 Requires: cat shall be a catalog obtained from open() and not yet closed.
5 Returns: A message identified by arguments set,msgid, and dfault, according to an implementation-
defined mapping. If no such message can be found, returns dfault.

void do_close(catalog cat) const;

6 Requires: cat shall be a catalog obtained from open() and not yet closed.
7 Effects: Releases unspecified resources associated with cat.
8 Remarks: The limit on such resources, if any, is implementation-defined.

28.4.7.2 Class template messages_byname

namespace std {
    template<class charT>
    class messages_byname : public messages<charT> {
        public:
            using catalog = messages_base::catalog;
            using string_type = basic_string<charT>;

            explicit messages_byname(const char*, size_t refs = 0);
            explicit messages_byname(const string&, size_t refs = 0);

            protected:
                ~messages_byname();
    };
}

28.5 C library locales

28.5.1 Header <clocale> synopsis

namespace std {
    struct lconv;

    char* setlocale(int category, const char* locale);
    lconv* localeconv();
}

#define NULL see 17.2.3
#define LC_ALL see below
#define LC_COLLATE see below
#define LC_CTYPE see below
#define LC_MONETARY see below
#define LC_NUMERIC see below
#define LC_TIME see below

1 The contents and meaning of the header <clocale> are the same as the C standard library header <locale.h>.
2 Calls to the function setlocale may introduce a data race (16.5.5.9) with other calls to setlocale or with
calls to the functions listed in Table 102.

See also: ISO C 7.11

§ 28.5.1
Table 102: Potential `setlocale` data races

| `fprintf` | `isprint` | `iswdigit` | `localeconv` | `tolower` |
| ` fscanf` | `ispunct` | `iswgraph` | `mblen` | `toupper` |
| `isalnum` | `isspace` | `iswlower` | `mbstowcs` | `towlower` |
| `isalpha` | `isupper` | `iswprint` | `mbtowc` | `towupper` |
| `isblank` | `iswalnum` | `iswpunct` | `setlocale` | `wcscoll` |
| `iscntrl` | `iswalpha` | `iswspace` | `strcoll` | `wcstod` |
| `isdigit` | `iswblank` | `iswupper` | `strerror` | `wcstombs` |
| `isgraph` | `iswcntrl` | `isxdigit` | `strtod` | `wcsxfrm` |
| `islower` | `iswctype` | `isxdigit` | `strxfrm` | `wctomb` |
29 Input/output library

29.1 General

This Clause describes components that C++ programs may use to perform input/output operations.

The following subclauses describe requirements for stream parameters, and components for forward declarations of iostreams, predefined iostreams objects, base iostreams classes, stream buffering, stream formatting and manipulators, string streams, and file streams, as summarized in Table 103.

Table 103: Input/output library summary

3 [Note: Figure 7 illustrates relationships among various types described in this clause. A line from A to B indicates that A is an alias (e.g., a typedef) for B or that A is defined in terms of B.]

Figure 7: Stream position, offset, and size types

— end note]

29.2 Iostreams requirements

29.2.1 Imbue limitations

No function described in Clause 29 except for ios_base::imbue and basic_filebuf::pubimbue causes any instance of basic_ios::imbue or basic_streambuf::imbue to be called. If any user function called from a function declared in Clause 29 or as an overriding virtual function of any class declared in Clause 29 calls imbue, the behavior is undefined.
29.2.2 Positioning type limitations

The classes of Clause 29 with template arguments charT and traits behave as described if traits::pos_type and traits::off_type are streampos and streamoff respectively. Except as noted explicitly below, their behavior when traits::pos_type and traits::off_type are other types is implementation-defined.

2 In the classes of Clause 29, a template parameter with name charT represents a member of the set of types containing char, wchar_t, and any other implementation-defined character types that meet the requirements for a character on which any of the iostream components can be instantiated.

29.2.3 Thread safety

Concurrent access to a stream object (29.8, 29.9), stream buffer object (29.6), or C Library stream (29.12) by multiple threads may result in a data race (6.8.2) unless otherwise specified (29.4). [Note: Data races result in undefined behavior (6.8.2). —end note]

2 If one thread makes a library call a that writes a value to a stream and, as a result, another thread reads this value from the stream through a library call b such that this does not result in a data race, then a’s write synchronizes with b’s read.

29.3 Forward declarations

29.3.1 Header <iosfwd> synopsis

namespace std {
    template<class charT> struct char_traits;
    template<> struct char_traits<char>;
    template<> struct char_traits<char8_t>;
    template<> struct char_traits<char16_t>;
    template<> struct char_traits<char32_t>;
    template<> struct char_traits<wchar_t>;

    template<class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>> class basic_ifstream;
    template<class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>> class basic_ofstream;
    template<class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>> class basic_fstream;
}
template<class charT, class traits = char_traits<charT>,
    class Allocator = allocator<charT>>
    class basic_syncbuf;

template<class charT, class traits = char_traits<charT>,
    class Allocator = allocator<charT>>
    class basic_osyncstream;

using ios = basic_ios<char>;
using wios = basic_ios<wchar_t>;

using stringstream = basic_stringstream<char>;
using wstringstream = basic_stringstream<wchar_t>;

§ 29.3.1 1311

1 Default template arguments are described as appearing both in <iosfwd> and in the synopsis of other headers but it is well-formed to include both <iosfwd> and one or more of the other headers.287

287) It is the implementation’s responsibility to implement headers so that including <iosfwd> and other headers does not violate the rules about multiple occurrences of default arguments.
29.3.2 Overview  

The class template specialization `basic_ios<charT, traits>` serves as a virtual base class for the class templates `basic_istream`, `basic_ostream`, and class templates derived from them. `basic_iosstream` is a class template derived from both `basic_istream<charT, traits>` and `basic_ostream<charT, traits>`.

The class template specialization `basic_streambuf<charT, traits>` serves as a base class for class templates `basic_stringbuf`, `basic_filebuf`, and `basic_syncbuf`.

The class template specialization `basic_istream<charT, traits>` serves as a base class for class templates `basic_stringstream` and `basic_filestream`.

The class template specialization `basic_ostream<charT, traits>` serves as a base class for class templates `basic_stringstream` and `basic_filestream`.

[Note: For each of the class templates above, the program is ill-formed if `traits::char_type` is not the same type as `charT`. — end note]

Other `typedef-name`s define instances of class templates specialized for `char` or `wchar_t` types.

Specializations of the class template `fpos` are used for specifying file position information.  
[Example: The types `streampos` and `wstreampos` are used for positioning streams specialized on `char` and `wchar_t` respectively. — end example]

[Note: This synopsis suggests a circularity between `streampos` and `char_traits<char>`. An implementation can avoid this circularity by substituting equivalent types. — end note]

29.4 Standard iostream objects  

29.4.1 Header `<iostream>` synopsis

```cpp
#include <ios>  // see 29.5.1
#include <streambuf>  // see 29.6.1
#include <iostream>  // see 29.7.1
#include <ostream>  // see 29.7.2

namespace std {
    extern std::istream cin;
    extern std::ostream cout;
    extern std::ostream cerr;
    extern std::ostream clog;

    extern std::wistream wcin;
    extern std::wostream wcout;
    extern std::wostream wcerr;
    extern std::wostream wclog;
}
```

29.4.2 Overview

In this Clause, the type name `FILE` refers to the type `FILE` declared in `<cstdio>` (29.12.1).

The header `<iostream>` declares objects that associate objects with the standard C streams provided for by the functions declared in `<cstdio>` (29.12), and includes all the headers necessary to use these objects.

The objects are constructed and the associations are established at some time prior to or during the first time an object of class `ios_base::Init` is constructed, and in any case before the body of `main` (6.8.3.1) begins execution. The objects are not destroyed during program execution. The results of including `<iostream>` in a translation unit shall be as if `<iostream>` defined an instance of `ios_base::Init` with static storage duration.

Mixing operations on corresponding wide- and narrow-character streams follows the same semantics as mixing such operations on `FILE`s, as specified in the C standard library.

---

288) If it is possible for them to do so, implementations should initialize the objects earlier than required.

289) Constructors and destructors for static objects can access these objects to read input from `stdin` or write output to `stdout` or `stderr`.

§ 29.4.2
Concurrent access to a synchronized (29.5.3.4) standard iostream object’s formatted and unformatted input (29.7.4.1) and output (29.7.5.1) functions or a standard C stream by multiple threads shall not result in a data race (6.8.2). [Note: Users must still synchronize concurrent use of these objects and streams by multiple threads if they wish to avoid interleaved characters. — end note]

See also: ISO C 7.21.2

29.4.3 Narrow stream objects

```
istream cin;
```

1. The object `cin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>` (29.12.1).

2. After the object `cin` is initialized, `cin.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (29.5.5.2).

```
ostream cout;
```

3. The object `cout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (29.12.1).

```
ostream cerr;
```

4. The object `cerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (29.12.1).

5. After the object `cerr` is initialized, `cerr.flags() & unitbuf` is nonzero and `cerr.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (29.5.5.2).

```
ostream clog;
```

6. The object `clog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (29.12.1).

29.4.4 Wide stream objects

```
wistream wcin;
```

1. The object `wcin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>` (29.12.1).

2. After the object `wcin` is initialized, `wcin.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (29.5.5.2).

```
wostream wcout;
```

3. The object `wcout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (29.12.1).

```
wostream wcerr;
```

4. The object `wcerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (29.12.1).

5. After the object `wcerr` is initialized, `wcerr.flags() & unitbuf` is nonzero and `wcerr.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (29.5.5.2).

```
wostream wclog;
```

6. The object `wclog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (29.12.1).

29.5 Iostreams base classes

29.5.1 Header `<ios>` synopsis

```
#include <iosfwd>   // see 29.3.1

namespace std {
using streamoff = implementation-defined;
using streamsize = implementation-defined;
```
template<class stateT> class fpos;

class ios_base;

```
// 29.5.6, manipulators
ios_base& boolalpha (ios_base& str);
ios_base& noboolalpha (ios_base& str);
ios_base& showbase (ios_base& str);
ios_base& noshowbase (ios_base& str);
ios_base& showpoint (ios_base& str);
ios_base& noshowpoint (ios_base& str);
ios_base& showpos (ios_base& str);
ios_base& noshowpos (ios_base& str);
ios_base& skipws (ios_base& str);
ios_base& noskipws (ios_base& str);
ios_base& uppercase (ios_base& str);
ios_base& nouppercase (ios_base& str);
ios_base& unitbuf (ios_base& str);
ios_base& nounitbuf (ios_base& str);
```

```
// 29.5.6.2, adjustfield
ios_base& internal (ios_base& str);
ios_base& left (ios_base& str);
ios_base& right (ios_base& str);
```

```
// 29.5.6.3, basefield
ios_base& dec (ios_base& str);
ios_base& hex (ios_base& str);
ios_base& oct (ios_base& str);
```

```
// 29.5.6.4, floatfield
ios_base& fixed (ios_base& str);
ios_base& scientific (ios_base& str);
ios_base& hexfloat (ios_base& str);
ios_base& defaultfloat (ios_base& str);
```

```
// 29.5.7, error reporting
enum class io_errc {
  stream = 1
};
```

```
template<> struct is_error_code_enum<io_errc> : public true_type { };  
error_code make_error_code(io_errc e) noexcept;  
error_condition make_error_condition(io_errc e) noexcept;  
const error_category& iostream_category() noexcept;
```

**29.5.2 Types**

```
using streamoff = implementation-defined;
```

The type `streamoff` is a synonym for one of the signed basic integral types of sufficient size to represent the maximum possible file size for the operating system.  

290) Typically long long.
using streamsize = implementation-defined;

The type streamsize is a synonym for one of the signed basic integral types. It is used to represent the number of characters transferred in an I/O operation, or the size of I/O buffers.\footnote{streamsize is used in most places where ISO C would use size_t.}

29.5.3 Class ios_base

namespace std {
    class ios_base {
    public:
        class failure; // see below

        // 29.5.3.1.2, fmtflags

        using openmode = T3;
        static constexpr openmode app = unspecified;
        static constexpr openmode ate = unspecified;
        static constexpr openmode binary = unspecified;
        static constexpr openmode in = unspecified;
        static constexpr openmode out = unspecified;
        static constexpr openmode trunc = unspecified;

        // 29.5.3.1.5, seekdir
        using seekdir = T4;
        static constexpr seekdir beg = unspecified;
        static constexpr seekdir cur = unspecified;
        static constexpr seekdir end = unspecified;

        class Init;

        // 29.5.3.2, fmtflags state
        fmtflags flags() const;
        fmtflags flags(fmtflags fmtfl);
        fmtflags setf(fmtflags fmtfl);
        fmtflags setf(fmtflags fmtfl, fmtflags mask);
        void unsetf(fmtflags mask);

\footnote{streamsize is used in most places where ISO C would use size_t.}
streamsize precision() const;
streamsize precision(streamsize prec);
streamsize width() const;
streamsize width(streamsize wide);

// 29.5.3.3, locales
locale imbue(const locale& loc);
locale getloc() const;

// 29.5.3.5, storage
static int xalloc();
long& iword(int idx);
void*& pword(int idx);

// destructor
virtual ~ios_base();

// 29.5.3.6, callbacks
enum event { erase_event, imbue_event, copyfmt_event };
using event_callback = void (*)(event, ios_base&, int idx);
void register_callback(event_callback fn, int idx);

ios_base(const ios_base&) = delete;
ios_base& operator=(const ios_base&) = delete;

static bool sync_with_stdio(bool sync = true);

protected:
ios_base();

private:
static int index; // exposition only
long* iarray; // exposition only
void** parray; // exposition only
};

1 ios_base defines several member types:

(1.1) — a type failure, defined as either a class derived from system_error or a synonym for a class derived from system_error;
(1.2) — a class Init;
(1.3) — three bitmask types, fmtflags, iostate, and openmode;
(1.4) — an enumerated type, seekdir.

2 It maintains several kinds of data:

(2.1) — state information that reflects the integrity of the stream buffer;
(2.2) — control information that influences how to interpret (format) input sequences and how to generate (format) output sequences;
(2.3) — additional information that is stored by the program for its private use.

3 [Note: For the sake of exposition, the maintained data is presented here as:

(3.1) — static int index, specifies the next available unique index for the integer or pointer arrays maintained for the private use of the program, initialized to an unspecified value;
(3.2) — long* iarray, points to the first element of an arbitrary-length long array maintained for the private use of the program;
(3.3) — void** parray, points to the first element of an arbitrary-length pointer array maintained for the private use of the program.

— end note]
29.5.3.1 Types

29.5.3.1.1 Class ios_base::failure

namespace std {
    class ios_base::failure : public system_error {
        public:
            explicit failure(const string& msg, const error_code& ec = io_errc::stream);
            explicit failure(const char* msg, const error_code& ec = io_errc::stream);
    };
}

An implementation is permitted to define ios_base::failure as a synonym for a class with equivalent functionality to class ios_base::failure shown in this subclause. [Note: When ios_base::failure is a synonym for another type it shall provide a nested type failure, to emulate the injected class name. — end note] The class failure defines the base class for the types of all objects thrown as exceptions, by functions in the iostreams library, to report errors detected during stream buffer operations.

2 When throwing ios_base::failure exceptions, implementations should provide values of ec that identify the specific reason for the failure. [Note: Errors arising from the operating system would typically be reported as system_category() errors with an error value of the error number reported by the operating system. Errors arising from within the stream library would typically be reported as error_code(io_errc::stream, iostream_category()). — end note]

    explicit failure(const string& msg, const error_code& ec = io_errc::stream);

    explicit failure(const char* msg, const error_code& ec = io_errc::stream);

3 Effects: Constructs an object of class failure by constructing the base class with msg and ec.

    explicit failure(const string& msg, const error_code& ec = io_errc::stream);

    explicit failure(const char* msg, const error_code& ec = io_errc::stream);

4 Effects: Constructs an object of class failure by constructing the base class with msg and ec.

29.5.3.1.2 Type ios_base::fmtflags

using fmtflags = T1;

The type fmtflags is a bitmask type (16.4.2.2.4). Setting its elements has the effects indicated in Table 104.

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolalpha</td>
<td>insert and extract bool type in alphabetic format</td>
</tr>
<tr>
<td>dec</td>
<td>converts integer input or generates integer output in decimal base</td>
</tr>
<tr>
<td>fixed</td>
<td>generate floating-point output in fixed-point notation</td>
</tr>
<tr>
<td>hex</td>
<td>converts integer input or generates integer output in hexadecimal base</td>
</tr>
<tr>
<td>internal</td>
<td>adds fill characters at a designated internal point in certain generated output, or identical to right if no such point is designated</td>
</tr>
<tr>
<td>left</td>
<td>adds fill characters on the right (final positions) of certain generated output</td>
</tr>
<tr>
<td>oct</td>
<td>converts integer input or generates integer output in octal base</td>
</tr>
<tr>
<td>right</td>
<td>adds fill characters on the left (initial positions) of certain generated output</td>
</tr>
<tr>
<td>scientific</td>
<td>generates floating-point output in scientific notation</td>
</tr>
<tr>
<td>showbase</td>
<td>generates a prefix indicating the numeric base of generated integer output</td>
</tr>
<tr>
<td>showpoint</td>
<td>generates a decimal-point character unconditionally in generated floating-point output</td>

<tr>
<td>showpos</td>
<td>generates a + sign in non-negative generated numeric output</td>
</tr>
<tr>
<td>skipws</td>
<td>skips leading whitespace before certain input operations</td>
</tr>
<tr>
<td>unitbuf</td>
<td>flushes output after each output operation</td>
</tr>
<tr>
<td>uppercase</td>
<td>replaces certain lowercase letters with their uppercase equivalents in generated output</td>
</tr>
</tbody>
</table>

2 Type fmtflags also defines the constants indicated in Table 105.
Table 105: fmtflags constants

<table>
<thead>
<tr>
<th>Constant</th>
<th>Allowable values</th>
</tr>
</thead>
<tbody>
<tr>
<td>adjustfield</td>
<td>left</td>
</tr>
<tr>
<td>basefield</td>
<td>dec</td>
</tr>
<tr>
<td>floatfield</td>
<td>scientific</td>
</tr>
</tbody>
</table>

29.5.3.1.3 Type ios_base::iostate

using iostate = T2;

The type iostate is a bitmask type (16.4.2.2.4) that contains the elements indicated in Table 106.

Table 106: iostate effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>badbit</td>
<td>indicates a loss of integrity in an input or output sequence (such as an irrecoverable read error from a file);</td>
</tr>
<tr>
<td>eofbit</td>
<td>indicates that an input operation reached the end of an input sequence;</td>
</tr>
<tr>
<td>failbit</td>
<td>indicates that an input operation failed to read the expected characters, or that an output operation failed to generate the desired characters.</td>
</tr>
</tbody>
</table>

2 Type iostate also defines the constant:

(2.1) — goodbit, the value zero.

29.5.3.1.4 Type ios_base::openmode

using openmode = T3;

The type openmode is a bitmask type (16.4.2.2.4). It contains the elements indicated in Table 107.

Table 107: openmode effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>app</td>
<td>seek to end before each write</td>
</tr>
<tr>

<tr>
<td>in</td>
<td>open for input</td>
</tr>
<tr>
<td>out</td>
<td>open for output</td>
</tr>
<tr>
<td>trunc</td>
<td>truncate an existing stream when opening</td>
</tr>
</tbody>
</table>

29.5.3.1.5 Type ios_base::seekdir

using seekdir = T4;

The type seekdir is an enumerated type (16.4.2.2.3) that contains the elements indicated in Table 108.

Table 108: seekdir effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>beg</td>
<td>request a seek (for subsequent input or output) relative to the beginning of the stream</td>
</tr>
<tr>
<td>cur</td>
<td>request a seek relative to the current position within the sequence</td>
</tr>
<tr>
<td>end</td>
<td>request a seek relative to the current end of the sequence</td>
</tr>
</tbody>
</table>
The class \texttt{Init} describes an object whose construction ensures the construction of the eight objects declared in \texttt{<iostream>} (29.4) that associate file stream buffers with the standard C streams provided for by the functions declared in \texttt{<cstdio>} (29.12.1).

For the sake of exposition, the maintained data is presented here as:

\begin{verbatim}
static int init_cnt; // exposition only
\end{verbatim}

\begin{itemize}
  \item \texttt{Init();} \hspace{1em} Effects: Constructs an object of class \texttt{Init}. Constructs and initializes the objects \texttt{cin}, \texttt{cout}, \texttt{cerr}, \texttt{clog}, \texttt{wcin}, \texttt{wcout}, \texttt{wcerr}, and \texttt{wclog} if they have not already been constructed and initialized.
  \item \texttt{~Init();} \hspace{1em} Effects: Destroys an object of class \texttt{Init}. If there are no other instances of the class still in existence, calls \texttt{cout.flush()}, \texttt{cerr.flush()}, \texttt{clog.flush()}, \texttt{wcout.flush()}, \texttt{wcerr.flush()}, \texttt{wclog.flush()}.
\end{itemize}

\subsection*{State functions}

\begin{verbatim}
fmtflags flags() const;
\end{verbatim}

\begin{itemize}
  \item \texttt{Returns:} The format control information for both input and output.
  \item \texttt{fmtflags flags(fmtflags fmtfl);} \hspace{1em} \texttt{Ensures:} \texttt{fmtfl == flags().}
  \item \texttt{Returns:} The previous value of \texttt{flags().}
  \item \texttt{fmtflags setf(fmtflags fmtfl);} \hspace{1em} \texttt{Effects:} Sets \texttt{fmtfl} in \texttt{flags().}
  \item \texttt{Returns:} The previous value of \texttt{flags().}
  \item \texttt{fmtflags setf(fmtflags fmtfl, fmtflags mask);} \hspace{1em} \texttt{Effects:} Clears \texttt{mask} in \texttt{flags()}, sets \texttt{fmtfl} & \texttt{mask} in \texttt{flags().}
  \item \texttt{Returns:} The previous value of \texttt{flags().}
  \item \texttt{void unsetf(fmtflags mask);} \hspace{1em} \texttt{Effects:} Clears \texttt{mask} in \texttt{flags().}
  \item \texttt{streamsize precision() const;} \hspace{1em} \texttt{Returns:} The precision to generate on certain output conversions.
  \item \texttt{streamsize precision(streamsize prec);} \hspace{1em} \texttt{Ensures:} \texttt{prec == precision().}
  \item \texttt{Returns:} The previous value of \texttt{precision().}
  \item \texttt{streamsize width() const;} \hspace{1em} \texttt{Returns:} The minimum field width (number of characters) to generate on certain output conversions.
\end{itemize}
streamsize width(streamsize wide);

Ensures: wide == width().
Returns: The previous value of width().

29.5.3.3 Functions

locale imbue(const locale& loc);

Effects: Calls each registered callback pair (fn, idx) (29.5.3.6) as (*fn)(imbue_event, *this, idx) at such a time that a call to ios_base::getloc() from within fn returns the new locale value loc.
Returns: The previous value of getloc().
Ensures: loc == getloc().

locale getloc() const;
Returns: If no locale has been imbued, a copy of the global C++ locale, locale(), in effect at the time of construction. Otherwise, returns the imbued locale, to be used to perform locale-dependent input and output operations.

29.5.3.4 Static members

bool sync_with_stdio(bool sync = true);

Returns: true if the previous state of the standard iostream objects (29.4) was synchronized and otherwise returns false. The first time it is called, the function returns true.
Effects: If any input or output operation has occurred using the standard streams prior to the call, the effect is implementation-defined. Otherwise, called with a false argument, it allows the standard streams to operate independently of the standard C streams.
When a standard iostream object str is synchronized with a standard stdio stream f, the effect of inserting a character c by
    fputc(f, c);
is the same as the effect of
    str.rdbuf()->sputc(c);
for any sequences of characters; the effect of extracting a character c by
    c = fgetc(f);
is the same as the effect of
    c = str.rdbuf()->sbumpc();
for any sequences of characters; and the effect of pushing back a character c by
    ungetc(c, f);
is the same as the effect of
    str.rdbuf()->sputbackc(c);
for any sequence of characters.292

29.5.3.5 Storage functions

static int xalloc();

Returns: index ++.
Remarks: Concurrent access to this function by multiple threads shall not result in a data race (6.8.2).

long& iword(int idx);
Requires: idx is a value obtained by a call to xalloc.
Effects: If iarray is a null pointer, allocates an array of long of unspecified size and stores a pointer to its first element in iarray. The function then extends the array pointed at by iarray as necessary

---

292) This implies that operations on a standard iostream object can be mixed arbitrarily with operations on the corresponding stdio stream. In practical terms, synchronization usually means that a standard iostream object and a standard stdio object share a buffer.
to include the element `iarray[idx]`. Each newly allocated element of the array is initialized to zero. The reference returned is invalid after any other operations on the object. However, the value of the storage referred to is retained, so that until the next call to `copyfmt`, calling `iword` with the same index yields another reference to the same value. If the function fails and `*this` is a base class subobject of a `basic_ios<>` object or subobject, the effect is equivalent to calling `basic_ios<>::setstate(badbit)` on the derived object (which may throw `failure`).

*Returns:* On success `iarray[idx]`. On failure, a valid `long&` initialized to 0.

```cpp
void*& pword(int idx);
```

*Requires:* `idx` is a value obtained by a call to `xalloc`.

*Effects:* If `parray` is a null pointer, allocates an array of pointers to `void` of unspecified size and stores a pointer to its first element in `parray`. The function then extends the array pointed at by `parray` as necessary to include the element `parray[idx]`. Each newly allocated element of the array is initialized to a null pointer. The reference returned is invalid after any other operations on the object. However, the value of the storage referred to is retained, so that until the next call to `copyfmt`, calling `pword` with the same index yields another reference to the same value. If the function fails and `*this` is a base class subobject of a `basic_ios<>` object or subobject, the effect is equivalent to calling `basic_ios<>::setstate(badbit)` on the derived object (which may throw `failure`).

*Returns:* On success `parray[idx]`. On failure a valid `void*&` initialized to 0.

*Remarks:* After a subsequent call to `pword(int)` for the same object, the earlier return value may no longer be valid.

### 29.5.3.6 Callbacks

```cpp
void register_callback(event_callback fn, int idx);
```

*Effects:* Registers the pair `(fn, idx)` such that during calls to `imbue()` (29.5.3.3), `copyfmt()`, or `~ios_base()` (29.5.3.7), the function `fn` is called with argument `idx`. Functions registered are called when an event occurs, in opposite order of registration. Functions registered while a callback function is active are not called until the next event.

*Requires:* The function `fn` shall not throw exceptions.

*Remarks:* Identical pairs are not merged. A function registered twice will be called twice.

### 29.5.3.7 Constructors and destructor

```cpp
ios_base();
```

*Effects:* Each `ios_base` member has an indeterminate value after construction. The object’s members shall be initialized by calling `basic_ios::init` before the object’s first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

```cpp
~ios_base();
```

*Effects:* Destroys an object of class `ios_base`. Calls each registered callback pair `(fn, idx)` (29.5.3.6) as `(*fn)(erase_event, *this, idx)` at such time that any `ios_base` member function called from within `fn` has well-defined results.

### 29.5.4 Class template fpos

```cpp
namespace std {
    template<class stateT> class fpos {
        public:
            // 29.5.4.1, members
            stateT state() const;
            void state(stateT); // exposition only
            private:
                stateT st; // exposition only
    }
}
```

293) An implementation is free to implement both the integer array pointed at by `iarray` and the pointer array pointed at by `parray` as sparse data structures, possibly with a one-element cache for each.

294) For example, because it cannot allocate space.

295) For example, because it cannot allocate space.
29.5.4.1 Members

```cpp
void state(stateT s);
Effects: Assigns s to st.
stateT state() const;
Returns: Current value of st.
```

29.5.4.2 Requirements

An `fpos` type specifies file position information. It holds a state object whose type is equal to the template parameter `stateT`. Type `stateT` shall meet the `Cpp17DefaultConstructible` (Table 25), `Cpp17CopyConstructible` (Table 27), `Cpp17CopyAssignable` (Table 29), and `Cpp17Destructible` (Table 30) requirements. If `is_trivially_copy_constructible_v<stateT>` is true, then `fpos<stateT>` has a trivial copy constructor. If `is_trivially_copy_assignable<stateT>` is true, then `fpos<stateT>` has a trivial copy assignment operator. If `is_trivially_destructible_v<stateT>` is true, then `fpos<stateT>` has a trivial destructor. All specializations of `fpos` meet the `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, `Cpp17CopyAssignable`, `Cpp17Destructible`, and `Cpp17EqualityComparable` (Table 23) requirements. In addition, the expressions shown in Table 109 are valid and have the indicated semantics. In that table,

- (1.1) — `P` refers to an instance of `fpos`,
- (1.2) — `p` and `q` refer to values of type `P` or `const P`,
- (1.3) — `pl` and `ql` refer to modifiable lvalues of type `P`,
- (1.4) — `O` refers to type `streamoff`, and
- (1.5) — `o` refers to a value of type `streamoff` or `const streamoff`.

<td><code>p == q + (p - q)</code></td>
</tr>
</tbody>
</table>

Stream operations that return a value of type `traits::pos_type` return `P(O(-1))` as an invalid value to signal an error. If this value is used as an argument to any `istream`, ` ostream`, or `streambuf` member that accepts a value of type `traits::pos_type` then the behavior of that function is undefined.
29.5.5 Class template basic_ios

29.5.5.1 Overview

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ios : public ios_base {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;

            // 29.5.5.4, flags functions
            explicit operator bool() const;
            bool operator!() const;
            iostate rdstate() const;
            void clear(iostate state = goodbit);
            void setstate(iostate state);
            bool good() const;
            bool eof() const;
            bool fail() const;
            bool bad() const;

            iostate exceptions() const;
            void exceptions(iostate except);

            // 29.5.5.2, constructor/destructor
            explicit basic_ios(basic_streambuf<charT, traits>* sb);
            virtual ~basic_ios();

            // 29.5.5.3, members
            basic_ostream<charT, traits>* tie() const;
            basic_ostream<charT, traits>* tie(basic_ostream<charT, traits>* tiestr);
            basic_streambuf<charT, traits>* rdbuf() const;
            basic_streambuf<charT, traits>* rdbuf(basic_streambuf<charT, traits>* sb);
            basic_ios& copyfmt(const basic_ios& rhs);
            char_type fill() const;
            char_type fill(char_type ch);
            locale imbue(const locale& loc);
            char narrow(char_type c, char dfault) const;
            char_type widen(char c) const;

            basic_ios(const basic_ios&) = delete;
            basic_ios& operator=(const basic_ios&) = delete;

            protected:
                basic_ios();
                void init(basic_streambuf<charT, traits>* sb);
                void move(basic_ios& rhs);
                void move(basic_ios&& rhs);
                void swap(basic_ios& rhs) noexcept;
                void set_rdbuf(basic_streambuf<charT, traits>* sb);
        };
    }
}
### 29.5.5.2 Constructors

**explicit basic_ios(basic_streambuf<charT, traits>* sb);**

*Effects:* Constructs an object of class `basic_ios`, assigning initial values to its member objects by calling `init(sb)`.

*Basic_ios();*

*Effects:* Constructs an object of class `basic_ios (29.5.3.7)` leaving its member objects uninitialized. The object shall be initialized by calling `basic_ios::init` before its first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

~`basic_ios();`

*Remarks:* The destructor does not destroy `rdbuf()`.

**void init(basic_streambuf<charT, traits>* sb);**

*Ensures:* The postconditions of this function are indicated in Table 110.

<table>
<thead>
<tr>
<th>Element</th>

</tbody>
</table>

### 29.5.5.3 Member functions

**basic_ostream<charT, traits>* tie() const;**

*Returns:* An output sequence that is tied to (synchronized with) the sequence controlled by the stream buffer.

**basic_ostream<charT, traits>* tie(basic_ostream<charT, traits>* tiestr);**

*Requires:* If `tiestr` is not null, `tiestr` shall not be reachable by traversing the linked list of tied stream objects starting from `tiestr->tie()`.

*Ensures:* `tiestr == tie()`.

*Returns:* The previous value of `tie()`.

**basic_streambuf<charT, traits>* rdbuf() const;**

*Returns:* A pointer to the `streambuf` associated with the stream.

**basic_streambuf<charT, traits>* rdbuf(basic_streambuf<charT, traits>* sb);**

*Ensures:* `sb == rdbuf()`.

*Effects:* Calls `clear()`.

*Returns:* The previous value of `rdbuf()`.

**locale imbue(const locale& loc);**

*Effects:* Calls `ios_base::imbue(loc)` (29.5.3.3) and if `rdbuf() != 0` then `rdbuf()->pubimbue(loc)` (29.6.3.2.1).
Returns: The prior value of `ios_base::imbue()`.

```cpp
char narrow(char_type c, char dfault) const;
```

*Returns:* `use_facet<ctype<char_type>>((getloc())).narrow(c, dfault)`

```cpp
char_type widen(char c) const;
```

*Returns:* `use_facet<ctype<char_type>>((getloc())).widen(c)`

```cpp
char_type fill() const;
```

*Returns:* The character used to pad (fill) an output conversion to the specified field width.

```cpp
char_type fill(char_type fillch);
```

*Ensures:* `traits::eq(fillch, fill())`.

*Returns:* The previous value of `fill()`.

```cpp
basic_ios& copyfmt(const basic_ios& rhs);
```

*Effects:* If `(this == addressof(rhs))` does nothing. Otherwise assigns to the member objects of `*this` the corresponding member objects of `rhs` as follows:

1. calls each registered callback pair `(fn, idx)` as `(*fn)(erase_event, *this, idx)`;
2. then, assigns to the member objects of `*this` the corresponding member objects of `rhs`, except that
   1. `rdstate()`, `rdbuf()`, and `exceptions()` are left unchanged;
   2. the contents of arrays pointed at by `pword` and `iword` are copied, not the pointers themselves;
   3. if any newly stored pointer values in `*this` point at objects stored outside the object `rhs` and those objects are destroyed when `rhs` is destroyed, the newly stored pointer values are altered to point at newly constructed copies of the objects;
3. then, calls each callback pair that was copied from `rhs` as `(*fn)(copyfmt_event, *this, idx)`;
4. then, calls `exceptions(rhs.exceptions())`.

*Note:* The second pass through the callback pairs permits a copied `pword` value to be zeroed, or to have its referent deep copied or reference counted, or to have other special action taken. —end note*

*Ensures:* The postconditions of this function are indicated in Table 111.

Table 111: `basic_ios::copyfmt()` effects [tab:basic.ios.copyfmt]

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

<td>rhs.fill()</td>
</tr>
<tr>
<td>getloc()</td>
<td>rhs.getloc()</td>
</tr>
</tbody>
</table>

*Returns:* `*this`.

```cpp
void move(basic_ios& rhs);
```

[296] This suggests an infinite amount of copying, but the implementation can keep track of the maximum element of the arrays that is nonzero.
void move(basic_ios&& rhs);

Ensures: \*this shall have the state that rhs had before the function call, except that rdbuf() shall return 0. rhs shall be in a valid but unspecified state, except that rhs.rdbuf() shall return the same value as it returned before the function call, and rhs.tie() shall return 0.

void swap(basic_ios& rhs) noexcept;

Effects: The states of \*this and rhs shall be exchanged, except that rdbuf() shall return the same value as it returned before the function call, and rhs.rdbuf() shall return the same value as it returned before the function call.

void set_rdbuf(basic_streambuf<charT, traits>* sb);

Requires: sb != nullptr.

Effects: Associates the basic_streambuf object pointed to by sb with this stream without calling clear().

Ensures: rdbuf() == sb.

Throws: Nothing.

29.5.5.4 Flags functions [iostate.flags]

explicit operator bool() const;

Returns: !fail().

bool operator!() const;

Returns: fail().

iostate rdstate() const;

Returns: The error state of the stream buffer.

void clear(iostate state = goodbit);

Ensures: If rdbuf() != 0 then state == rdstate(); otherwise rdstate() == (state | ios_base::badbit).

Effects: If ((state | (rdbuf() ? goodbit : badbit) & exceptions()) == 0, returns. Otherwise, the function throws an object of class basic_ios::failure (29.5.3.1.1), constructed with implementation-defined argument values.

void setstate(iostate state);

Effects: Calls clear(rdstate() | state) (which may throw basic_ios::failure (29.5.3.1.1)).

bool good() const;

Returns: rdstate() == 0

bool eof() const;

Returns: true if eofbit is set in rdstate().

bool fail() const;

Returns: true if failbit or badbit is set in rdstate().

bool bad() const;

Returns: true if badbit is set in rdstate().

iostate exceptions() const;

Returns: A mask that determines what elements set in rdstate() cause exceptions to be thrown.

void exceptions(iostate except);

Ensures: except == exceptions().

\(^{207}\) Checking badbit also for fail() is historical practice.
Effects: Calls clear(rdstate()).

29.5.6 ios_base manipulators

29.5.6.1 fmtflags manipulators

Each function specified in this subclause is a designated addressable function (16.5.4.2.1).

ios_base& boolalpha(ios_base& str);
Effects: Calls str.setf(ios_base::boolalpha).
Returns: str.

ios_base& noboolalpha(ios_base& str);
Effects: Calls str.unsetf(ios_base::boolalpha).
Returns: str.

ios_base& showbase(ios_base& str);
Effects: Calls str.setf(ios_base::showbase).
Returns: str.

ios_base& noshowbase(ios_base& str);
Effects: Calls str.unsetf(ios_base::showbase).
Returns: str.

ios_base& showpoint(ios_base& str);
Effects: Calls str.setf(ios_base::showpoint).
Returns: str.

ios_base& noshowpoint(ios_base& str);
Effects: Calls str.unsetf(ios_base::showpoint).
Returns: str.

ios_base& showpos(ios_base& str);
Effects: Calls str.setf(ios_base::showpos).
Returns: str.

ios_base& noshowpos(ios_base& str);
Effects: Calls str.unsetf(ios_base::showpos).
Returns: str.

ios_base& skipws(ios_base& str);
Effects: Calls str.setf(ios_base::skipws).
Returns: str.

ios_base& noskipws(ios_base& str);
Effects: Calls str.unsetf(ios_base::skipws).
Returns: str.

ios_base& uppercase(ios_base& str);
Effects: Calls str.setf(ios_base::uppercase).
Returns: str.

ios_base& nouppercase(ios_base& str);
Effects: Calls str.unsetf(ios_base::uppercase).
Returns: str.
ios_base& unitbuf(ios_base& str);
    Effects: Calls str.setf(ios_base::unitbuf).
    Returns: str.

ios_base& nounitbuf(ios_base& str);
    Effects: Calls str.unsetf(ios_base::unitbuf).
    Returns: str.

29.5.6.2 adjustfield manipulators

Each function specified in this subclause is a designated addressable function (16.5.4.2.1).

ios_base& internal(ios_base& str);
    Effects: Calls str.setf(ios_base::internal, ios_base::adjustfield).
    Returns: str.

ios_base& left(ios_base& str);
    Effects: Calls str.setf(ios_base::left, ios_base::adjustfield).
    Returns: str.

ios_base& right(ios_base& str);
    Effects: Calls str.setf(ios_base::right, ios_base::adjustfield).
    Returns: str.

29.5.6.3 basefield manipulators

Each function specified in this subclause is a designated addressable function (16.5.4.2.1).

ios_base& dec(ios_base& str);
    Effects: Calls str.setf(ios_base::dec, ios_base::basefield).
    Returns: str

ios_base& hex(ios_base& str);
    Effects: Calls str.setf(ios_base::hex, ios_base::basefield).
    Returns: str.

ios_base& oct(ios_base& str);
    Effects: Calls str.setf(ios_base::oct, ios_base::basefield).
    Returns: str.

29.5.6.4 floatfield manipulators

Each function specified in this subclause is a designated addressable function (16.5.4.2.1).

ios_base& fixed(ios_base& str);
    Effects: Calls str.setf(ios_base::fixed, ios_base::floatfield).
    Returns: str.

ios_base& scientific(ios_base& str);
    Effects: Calls str.setf(ios_base::scientific, ios_base::floatfield).
    Returns: str.

ios_base& hexfloat(ios_base& str);
    Effects: Calls str.setf(ios_base::fixed | ios_base::scientific, ios_base::floatfield).
    Returns: str.

298) The function signature dec(ios_base&) can be called by the function signature basic_ostream& stream::operator<<(ios_base&) to permit expressions of the form cout << dec to change the format flags stored in cout.
[Note: The more obvious use of `ios_base::hex` to specify hexadecimal floating-point format would change the meaning of existing well-defined programs. C++ 2003 gives no meaning to the combination of `fixed` and `scientific`. — end note]

```cpp
ios_base& defaultfloat(ios_base& str);
```

Effects: Calls `str.unsetf(ios_base::floatfield)`.

Returns: `str`.

### 29.5.7 Error reporting

```cpp
error_code make_error_code(io_errc e) noexcept;
```

Returns: `error_code(static_cast<int>(e), iostream_category())`.

```cpp
error_condition make_error_condition(io_errc e) noexcept;
```

Returns: `error_condition(static_cast<int>(e), iostream_category())`.

```cpp
const error_category& iostream_category() noexcept;
```

Returns: A reference to an object of a type derived from class `error_category`.

The object’s `default_error_condition` and `equivalent` virtual functions shall behave as specified for the class `error_category`. The object’s `name` virtual function shall return a pointer to the string "iostream".

### 29.6 Stream buffers

#### 29.6.1 Header `<streambuf>` synopsis

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_streambuf;
    using streambuf = basic_streambuf<char>;
    using wstreambuf = basic_streambuf<wchar_t>;
}
```

The header `<streambuf>` defines types that control input from and output to character sequences.

#### 29.6.2 Stream buffer requirements

Stream buffers can impose various constraints on the sequences they control. Some constraints are:

1. The controlled input sequence can be not readable.
2. The controlled output sequence can be not writable.
3. The controlled sequences can be associated with the contents of other representations for character sequences, such as external files.
4. The controlled sequences can support operations directly to or from associated sequences.
5. The controlled sequences can impose limitations on how the program can read characters from a sequence, write characters to a sequence, put characters back into an input sequence, or alter the stream position.

Each sequence is characterized by three pointers which, if non-null, all point into the same `charT` array object. The array object represents, at any moment, a (sub)sequence of characters from the sequence. Operations performed on a sequence alter the values stored in these pointers, perform reads and writes directly to or from associated sequences, and alter “the stream position” and conversion state as needed to maintain this subsequence relationship. The three pointers are:

1. The `beginning pointer`, or lowest element address in the array (called `xbeg` here);
2. The `next pointer`, or next element address that is a current candidate for reading or writing (called `xnext` here);
3. The `end pointer`, or first element address beyond the end of the array (called `xend` here).

The following semantic constraints shall always apply for any set of three pointers for a sequence, using the pointer names given immediately above:
(3.1) If \textit{xnext} is not a null pointer, then \textit{xbeg} and \textit{xend} shall also be non-null pointers into the same \texttt{charT} array, as described above; otherwise, \textit{xbeg} and \textit{xend} shall also be null.

(3.2) If \textit{xnext} is not a null pointer and \textit{xnext} < \textit{xend} for an output sequence, then a \textit{write position} is available. In this case, \texttt{*xnext} shall be assignable as the next element to write (to put, or to store a character value, into the sequence).

(3.3) If \textit{xnext} is not a null pointer and \texttt{xbeg} < \textit{xnext} for an input sequence, then a \textit{putback position} is available. In this case, \texttt{xnext[-1]} shall have a defined value and is the next (preceding) element to store a character that is put back into the input sequence.

(3.4) If \textit{xnext} is not a null pointer and \textit{xnext} < \textit{xend} for an input sequence, then a \textit{read position} is available. In this case, \texttt{*xnext} shall have a defined value and is the next element to read (to get, or to obtain a character value, from the sequence).

29.6.3 Class template basic\_streambuf

namespace std {

template<class charT, class traits = char_traits<charT>>
class basic\_streambuf {

public:
    using char\_type = charT;
    using int\_type = typename traits::int\_type;
    using pos\_type = typename traits::pos\_type;
    using off\_type = typename traits::off\_type;
    using traits\_type = traits;

    virtual ~basic\_streambuf();

    // locales
    locale pubimbue(const locale& loc);
    locale getloc() const;

    // buffer and positioning
    basic\_streambuf* pubsetbuf(char\_type* s, streamsize n);
    pos\_type pubseekoff(off\_type off, ios\_base::seekdir way,
                          ios\_base::openmode which
                          = ios\_base::in | ios\_base::out);
    pos\_type pubseekpos(pos\_type sp,
                         ios\_base::openmode which
                         = ios\_base::in | ios\_base::out);
    int pubsync();

    // get and put areas
    // get area
    streamsize in\_avail();
    int\_type snextc();
    int\_type sbumpc();
    int\_type sgetc();
    streamsize sgetn(char\_type* s, streamsize n);

    // putback
    int\_type sputbackc(char\_type c);
    int\_type sungetc();

    // put area
    int\_type sputc(char\_type c);
    streamsize sputn(const char\_type* s, streamsize n);

protected:
    basic\_streambuf();
    basic\_streambuf(const basic\_streambuf& rhs);
    basic\_streambuf& operator=(const basic\_streambuf& rhs);
    void swap(basic\_streambuf& rhs);
}

§ 29.6.3 1330
// 29.6.3.2, get area access
char_type* eback() const;
char_type* gptr() const;
char_type* egptr() const;
void gbump(int n);
void setg(char_type* gbeg, char_type* gnext, char_type* gend);

// 29.6.3.3, put area access
char_type* pbase() const;
char_type* pptr() const;
char_type* epptr() const;
void pbump(int n);
void setp(char_type* pbeg, char_type* pend);

// 29.6.3.4, virtual functions
// 29.6.3.4.1, locales
virtual void imbue(const locale& loc);

// 29.6.3.4.2, buffer management and positioning
virtual basic_streambuf* setbuf(char_type* s, streamsize n);
virtual pos_type seekoff(off_type off, ios_base::seekdir way,
  ios_base::openmode which = ios_base::in | ios_base::out);
virtual pos_type seekpos(pos_type sp, ios_base::openmode which
  = ios_base::in | ios_base::out);
virtual int sync();

// 29.6.3.4.3, get area
virtual streamsize showmanyc();
virtual streamsize xsgetn(char_type* s, streamsize n);
virtual int_type underflow();
virtual int_type uflow();

// 29.6.3.4.4, putback
virtual int_type pbackfail(int_type c = traits::eof());

// 29.6.3.4.5, put area
virtual streamsize xsputn(const char_type* s, streamsize n);
virtual int_type overflow(int_type c = traits::eof());
};

1 The class template basic_streambuf serves as an abstract base class for deriving various stream buffers whose objects each control two character sequences:

(1.1) — a character input sequence;
(1.2) — a character output sequence.

29.6.3.1 Constructors [streambuf.cons]

basic_streambuf();

1 Effects: Constructs an object of class basic_streambuf<charT, traits> and initializes:299

(1.1) — all its pointer member objects to null pointers,
(1.2) — the getloc() member to a copy the global locale, locale(), at the time of construction.

Remarks: Once the getloc() member is initialized, results of calling locale member functions, and of members of facets so obtained, can safely be cached until the next time the member imbue is called.

299) The default constructor is protected for class basic_streambuf to assure that only objects for classes derived from this class may be constructed.
basic_streambuf(const basic_streambuf& rhs);

Effects: Constructs a copy of rhs.

Ensures:
(4.1) eback() == rhs.eback()
(4.2) gptr() == rhs.gptr()
(4.3) egptr() == rhs.egptr()
(4.4) pbase() == rhs.pbase()
(4.5) pptr() == rhs.pptr()
(4.6) eptr() == rhs.eptr()
(4.7) getloc() == rhs.getloc()

~basic_streambuf();

Effects: None.

29.6.3.2 Public member functions

29.6.3.2.1 Locales

locale pubimbue(const locale& loc);

Ensures: loc == getloc().

Effects: Calls imbue(loc).

Returns: Previous value of getloc().

locale getloc() const;

Returns: If pubimbue() has ever been called, then the last value of loc supplied, otherwise the current
global locale, locale(), in effect at the time of construction. If called after pubimbue() has been called
but before pubimbue has returned (i.e., from within the call of imbue()) then it returns the previous
value.

29.6.3.2.2 Buffer management and positioning

basic_streambuf* pubsetbuf(char_type* s, streamsize n);

Returns: setbuf(s, n).

pos_type pubseekoff(off_type off, ios_base::seekdir way,
ios_base::openmode which
  = ios_base::in | ios_base::out);

Returns: seekoff(off, way, which).

pos_type pubseekpos(pos_type sp,
ios_base::openmode which
  = ios_base::in | ios_base::out);

Returns: seekpos(sp, which).

int pubsync();

Returns: sync().

29.6.3.2.3 Get area

streamsize in_avail();

Returns: If a read position is available, returns egptr() - gptr(). Otherwise returns showmanyc()
(29.6.3.4.3).

int_type snextc();

Effects: Calls sbumpc().

Returns: If that function returns traits::eof(), returns traits::eof(). Otherwise, returns sgetc().
int_type sbumpc();

Returns: If the input sequence read position is not available, returns uflow(). Otherwise, returns traits::to_int_type(*gptr()) and increments the next pointer for the input sequence.

int_type sgetc();

Returns: If the input sequence read position is not available, returns underflow(). Otherwise, returns traits::to_int_type(*gptr()).

streamsize sgetn(char_type* s, streamsize n);

Returns: xsgetn(s, n).

29.6.3.2.4 Putback

int_type sputbackc(char_type c);

Returns: If the input sequence putback position is not available, or if traits::eq(c, gptr()[-1]) is false, returns pbackfail(traits::to_int_type(c)). Otherwise, decrements the next pointer for the input sequence and returns traits::to_int_type(*gptr()).

int_type sungetc();

Returns: If the input sequence putback position is not available, returns pbackfail(). Otherwise, decrements the next pointer for the input sequence and returns traits::to_int_type(*gptr()).

29.6.3.2.5 Put area

int_type sputc(char_type c);

Returns: If the output sequence write position is not available, returns overflow(traits::to_int_type(c)). Otherwise, stores c at the next pointer for the output sequence, increments the pointer, and returns traits::to_int_type(c).

streamsize sputn(const char_type* s, streamsize n);

Returns: xsputn(s, n).

29.6.3.3 Protected member functions

29.6.3.3.1 Assignment

basic_streambuf& operator=(const basic_streambuf& rhs);

Effects: Assigns the data members of rhs to *this.

Ensures:

(2.1) — eback() == rhs.eback()
(2.2) — gptr() == rhs.gptr()
(2.3) — egptr() == rhs.egptr()
(2.4) — pbase() == rhs.pbase()
(2.5) — pptr() == rhs.pptr()
(2.6) — epptr() == rhs.epptr()
(2.7) — getloc() == rhs.getloc()

Returns: *this.

void swap(basic_streambuf& rhs);

Effects: Swaps the data members of rhs and *this.

29.6.3.3.2 Get area access

char_type* eback() const;

Returns: The beginning pointer for the input sequence.
char_type* gptr() const;

Returns: The next pointer for the input sequence.

char_type* egptr() const;

Returns: The end pointer for the input sequence.

void gbump(int n);
Effects: Adds n to the next pointer for the input sequence.

void setg(char_type* gbeg, char_type* gnext, char_type* gend);
Ensures: gbeg == eback(), gnext == gptr(), and gend == egptr().

29.6.3.3 Put area access
[streambuf.put.area]

char_type* pbase() const;
Returns: The beginning pointer for the output sequence.

char_type* pptr() const;
Returns: The next pointer for the output sequence.

char_type* epptr() const;
Returns: The end pointer for the output sequence.

void pbump(int n);
Effects: Adds n to the next pointer for the output sequence.

void setp(char_type* pbeg, char_type* pend);
Ensures: pbeg == pbase(), pbeg == pptr(), and pend == epptr().

29.6.3.4 Virtual functions
[streambuf.virtuals]

29.6.3.4.1 Locales
[streambuf.virt.locales]

void imbue(const locale&);
Effects: Change any translations based on locale.

Remarks: Allows the derived class to be informed of changes in locale at the time they occur. Between invocations of this function a class derived from streambuf can safely cache results of calls to locale functions and to members of facets so obtained.

Default behavior: Does nothing.

29.6.3.4.2 Buffer management and positioning
[streambuf.virt.buffer]

basic_streambuf* setbuf(char_type* s, streamsize n);
Effects: Influences stream buffering in a way that is defined separately for each class derived from basic_streambuf in this Clause (29.8.2, 29.9.2).

Default behavior: Does nothing. Returns this.

pos_type seekoff(off_type off, ios_base::seekdir way,
ios_base::openmode which
= ios_base::in | ios_base::out);
Effects: Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from basic_streambuf in this Clause (29.8.2.4, 29.9.2.4).

Default behavior: Returns pos_type(off_type(-1)).

pos_type seekpos(pos_type sp,
ios_base::openmode which
= ios_base::in | ios_base::out);
Effects: Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from basic_streambuf in this Clause (29.8.2, 29.9).
Default behavior: Returns `pos_type(off_type(-1))`.

```cpp
int sync();
```

Effects: Synchronizes the controlled sequences with the arrays. That is, if `pbase()` is non-null the characters between `pbase()` and `pptr()` are written to the controlled sequence. The pointers may then be reset as appropriate.

Returns: -1 on failure. What constitutes failure is determined by each derived class (29.9.2.4).

Default behavior: Returns zero.

29.6.3.4.3 Get area

```cpp
streamsize showmanyc();
```

Returns: An estimate of the number of characters available in the sequence, or -1. If it returns a positive value, then successive calls to `underflow()` will not return `traits::eof()` until at least that number of characters have been extracted from the stream. If `showmanyc()` returns -1, then calls to `underflow()` or `uflow()` will fail.

Default behavior: Returns zero.

Remarks: Uses `traits::eof()`.

```cpp
streamsize xsgetn(char_type* s, streamsize n);
```

Effects: Assigns up to `n` characters to successive elements of the array whose first element is designated by `s`. The characters assigned are read from the input sequence as if by repeated calls to `sbumpc()`. Assigning stops when either `n` characters have been assigned or a call to `sbumpc()` would return `traits::eof()`.

Returns: The number of characters assigned.

Remarks: Uses `traits::eof()`.

```cpp
int_type underflow();
```

Remarks: The public members of `basic_streambuf` call this virtual function only if `gptr()` is null or `gptr() >= egptr()`.

Returns: `traits::to_int_type(c)`, where `c` is the first character of the pending sequence, without moving the input sequence position past it. If the pending sequence is null then the function returns `traits::eof()` to indicate failure.

The pending sequence of characters is defined as the concatenation of

- the empty sequence if `gptr()` is null, otherwise the characters in `[gptr(), egptr())`, followed by
- some (possibly empty) sequence of characters read from the input sequence.

The result character is the first character of the pending sequence if it is non-empty, otherwise the next character that would be read from the input sequence.

The backup sequence is the empty sequence if `eback()` is null, otherwise the characters in `[eback(), gptr())`.

Effects: The function sets up the `gptr()` and `egptr()` such that if the pending sequence is non-empty, then `egptr()` is non-null and the characters in `[gptr(), egptr())` are the characters in the pending sequence, otherwise either `gptr()` is null or `gptr() == egptr()`.

If `eback()` and `gptr()` are non-null then the function is not constrained as to their contents, but the “usual backup condition” is that either

- the backup sequence contains at least `gptr() - eback()` characters, in which case the characters in `[eback(), gptr())` agree with the last `gptr() - eback()` characters of the backup sequence, or

300) The morphemes of `showmanyc` are “es-how-many-see”, not “show-manic”.

301) `underflow` or `uflow` might fail by throwing an exception prematurely. The intention is not only that the calls will not return `eof()` but that they will return “immediately”.

302) Classes derived from `basic_streambuf` can provide more efficient ways to implement `xsgetn()` and `xsputn()` by overriding these definitions from the base class.
— the characters in \([\text{gptr()} - n, \text{gptr()}]\) agree with the backup sequence (where \(n\) is the length of the backup sequence).

**Default behavior:** Returns \(\text{traits}::\text{eof}()\).

```cpp
int_type uflow();
```

**Requires:** The constraints are the same as for \(\text{underflow()}\), except that the result character shall be transferred from the pending sequence to the backup sequence, and the pending sequence shall not be empty before the transfer.

**Default behavior:** Calls \(\text{underflow()}\). If \(\text{underflow()}\) returns \(\text{traits}::\text{eof}()\), returns \(\text{traits}::\text{eof}()\). Otherwise, returns the value of \(\text{traits}::\text{to_int_type}(*\text{gptr()}\) and increment the value of the next pointer for the input sequence.

**Returns:** \(\text{traits}::\text{eof}()\) to indicate failure.

### 29.6.3.4.4 Putback

**[streambuf.virt.pback]**

```cpp
int_type pbackfail(int_type c = \text{traits}::\text{eof}());
```

**Remarks:** The public functions of \(\text{basic_streambuf}\) call this virtual function only when \(\text{gptr()}\) is null, \(\text{gptr()} == \text{eback}()\), or \(\text{traits}::\text{eq}(\text{traits}::\text{to_char_type}(c), \text{gptr()}[-1])\) returns \(\text{false}\). Other calls shall also satisfy that constraint.

The **pending sequence** is defined as for \(\text{underflow()}\), with the modifications that

- If \(\text{traits}::\text{eq_int_type}(c, \text{traits}::\text{eof}())\) returns \(\text{true}\), then the input sequence is backed up one character before the pending sequence is determined.

- If \(\text{traits}::\text{eq_int_type}(c, \text{traits}::\text{eof}())\) returns \(\text{false}\), then \(c\) is prepended. Whether the input sequence is backed up or modified in any other way is unspecified.

**Ensures:** On return, the constraints of \(\text{gptr()}, \text{eback}(), \) and \(\text{pptr}()\) are the same as for \(\text{underflow()}\).

**Returns:** \(\text{traits}::\text{eof}()\) to indicate failure. Failure may occur because the input sequence could not be backed up, or if for some other reason the pointers could not be set consistent with the constraints. \(\text{pbackfail()}\) is called only when put back has really failed.

Returns some value other than \(\text{traits}::\text{eof}()\) to indicate success.

**Default behavior:** Returns \(\text{traits}::\text{eof}()\).

### 29.6.3.4.5 Put area

**[streambuf.virt.put]**

```cpp
streamsize xsputn(const char_type* s, streamsize n);
```

**Effects:** Writes up to \(n\) characters to the output sequence as if by repeated calls to \(\text{sputc}(c)\). The characters written are obtained from successive elements of the array whose first element is designated by \(s\). Writing stops when either \(n\) characters have been written or a call to \(\text{sputc}(c)\) would return \(\text{traits}::\text{eof}()\). It is unspecified whether the function calls \(\text{overflow()}\) when \(\text{pptr()} == \text{epptr}()\) becomes \(\text{true}\) or whether it achieves the same effects by other means.

**Returns:** The number of characters written.

```cpp
int_type overflow(int_type c = \text{traits}::\text{eof}());
```

**Effects:** Consumes some initial subsequence of the characters of the **pending sequence**. The pending sequence is defined as the concatenation of

- the empty sequence if \(\text{pbase}()\) is null, otherwise the \(\text{pptr()} - \text{pbase}()\) characters beginning at \(\text{pbase}()\), followed by

- the empty sequence if \(\text{traits}::\text{eq_int_type}(c, \text{traits}::\text{eof}())\) returns \(\text{true}\), otherwise the sequence consisting of \(c\).

**Remarks:** The member functions \(\text{sputc}()\) and \(\text{sputn}()\) call this function in case that no room can be found in the put buffer enough to accommodate the argument character sequence.

**Requires:** Every overriding definition of this virtual function shall obey the following constraints:
The effect of consuming a character on the associated output sequence is specified.\[5.1\]

Let \( r \) be the number of characters in the pending sequence not consumed. If \( r \) is nonzero then \( \text{pbase()} \) and \( \text{pptr()} \) shall be set so that: \( \text{pptr()} - \text{pbase()} = r \) and the \( r \) characters starting at \( \text{pbase()} \) are the associated output stream. In case \( r \) is zero (all characters of the pending sequence have been consumed) then either \( \text{pbase()} \) is set to `nullptr`, or \( \text{pbase()} \) and \( \text{pptr()} \) are both set to the same non-null value.\[5.2\]

The function may fail if either appending some character to the associated output stream fails or if it is unable to establish \( \text{pbase()} \) and \( \text{pptr()} \) according to the above rules.\[5.3\]

Returns: \( \text{traits::eof()} \) or throws an exception if the function fails. Otherwise, returns some value other than \( \text{traits::eof()} \) to indicate success.\[6\]

Default behavior: Returns \( \text{traits::eof()} \).

29.7 Formatting and manipulators

29.7.1 Header `<istream>` synopsis

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_istream;

template<class charT, class traits = char_traits<charT>>
    using istream = basic_istream<char>;

template<class charT, class traits = char_traits<charT>>
    using wistream = basic_istream<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
    class basic_iostream;

template<class charT, class traits = char_traits<charT>>
    using iostream = basic_iostream<char>;

template<class charT, class traits = char_traits<charT>>
    using wiostream = basic_iostream<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
    basic_istream<charT, traits>& ws(basic_istream<charT, traits>& is);

    template<class charT, class traits = char_traits<charT>, class T>
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&& is, T&& x);
}
```

29.7.2 Header `<ostream>` synopsis

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ostream;

template<class charT, class traits = char_traits<charT>>
    using ostream = basic_ostream<char>;

template<class charT, class traits = char_traits<charT>>
    using wostream = basic_ostream<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
    basic_ostream<charT, traits>& endl(basic_ostream<charT, traits>& os);

    template<class charT, class traits = char_traits<charT>>
    basic_ostream<charT, traits>& ends(basic_ostream<charT, traits>& os);

    template<class charT, class traits = char_traits<charT>>
    basic_ostream<charT, traits>& flush(basic_ostream<charT, traits>& os);

    template<class charT, class traits = char_traits<charT>>
    basic_ostream<charT, traits>& emit_on_flush(basic_ostream<charT, traits>& os);

    template<class charT, class traits = char_traits<charT>>
    basic_ostream<charT, traits>& noemit_on_flush(basic_ostream<charT, traits>& os);

    template<class charT, class traits = char_traits<charT>>
    basic_ostream<charT, traits>& flush_emit(basic_ostream<charT, traits>& os);
}
```

303) That is, for each class derived from an instance of `basic_streambuf` in this Clause (29.8.2, 29.9.2), a specification of how consuming a character effects the associated output sequence is given. There is no requirement on a program-defined class.

304) Typically, `overflow` returns \( c \) to indicate success, except when \( \text{traits::eq_int_type(c, traits::eof())} \) returns `true`, in which case it returns \( \text{traits::not_eof(c)} \).
template<class charT, class traits, class T>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&& os, const T& x);
}

29.7.3 Header `<iomanip>` synopsis

namespace std {

    // types T1, T2, ... are unspecified implementation types
    T1 resetiosflags(ios_base::fmtflags mask);
    T2 setiosflags (ios_base::fmtflags mask);
    T3 setbase(int base);
    template<class charT> T4 setfill(charT c);

    template<class charT, class traits, class Allocator>
    T13 quoted(basic_string<charT, traits, Allocator>& s,
               charT delim = charT('"'), charT escape = charT('\'));
    template<class charT, class traits>
    T14 quoted(basic_string_view<charT, traits> s,
               charT delim = charT('"'), charT escape = charT('\'));
}

29.7.4 Input streams

1 The header `<istream>` defines two types and a function signature that control input from a stream buffer along with a function template that extracts from stream rvalues.

29.7.4.1 Class template basic_istream

namespace std {

    template<class charT, class traits = char_traits<charT>>
    class basic_istream : virtual public basic_ios<charT, traits> { public:
        // types (inherited from basic_ios (29.5.5))
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        // 29.7.4.1.1, constructor/destructor
        explicit basic_istream(basic_streambuf<charT, traits>* sb);
        virtual ~basic_istream();

        // 29.7.4.1.3, prefix/suffix
        class sentry;

        // 29.7.4.2, formatted input
        basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>&& (*pf)(basic_istream<charT, traits>&&));
        basic_istream<charT, traits>&
        operator>>(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&));

    } // end class basic_istream

§ 29.7.4.1
basic_istream<charT, traits>&
   operator>>(ios_base& (*pf)(ios_base&));

basic_istream<charT, traits>& operator>>(bool& n);
basic_istream<charT, traits>& operator>>(short& n);

basic_istream<charT, traits>& getline(char_type* s, streamsize n, char_type delim);

basic_istream<charT, traits>& ignore(streamsize n = 1, int_type delim = traits::eof());
int_type peek();
basic_istream<charT, traits>& read (char_type* s, streamsize n);
streamsize readsome(char_type* s, streamsize n);

basic_istream<charT, traits>& putback(char_type c);
basic_istream<charT, traits>& unget();
int sync();
pos_type tellg();
basic_istream<charT, traits>& seekg(pos_type);
basic_istream<charT, traits>& seekg(off_type, ios_base::seekdir);

protected:
   // 29.7.4.1.1, copy/move constructor
basic_istream(const basic_istream& rhs) = delete;
basic_istream(basic_istream&& rhs);

   // 29.7.4.1.2, assign and swap
basic_istream& operator=(const basic_istream& rhs) = delete;
basic_istream& operator=(basic_istream&& rhs);
void swap(basic_istream& rhs);
};

   // 29.7.4.2.3, character extraction templates
template<class charT, class traits>
   basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&, charT&);
template<class traits>
   basic_istream<char, traits>& operator>>(basic_istream<char, traits>&, unsigned char&);
template<class traits>
   basic_istream<char, traits>& operator>>(basic_istream<char, traits>&, signed char&);
The class template basic_istream defines a number of member function signatures that assist in reading and interpreting input from sequences controlled by a stream buffer.

Two groups of member function signatures share common properties: the formatted input functions (or extractors) and the unformatted input functions. Both groups of input functions are described as if they obtain (or extract) input characters by calling rdbuf()->sbumpc() or rdbuf()->sgetc(). They may use other public members of istream.

If rdbuf()->sbumpc() or rdbuf()->sgetc() returns traits::eof(), then the input function, except as explicitly noted otherwise, completes its actions and does setstate(eofbit), which may throw ios_base::failure (29.5.5.4), before returning.

If one of these called functions throws an exception, then unless explicitly noted otherwise, the input function sets badbit in error state. If badbit is on in exceptions(), the input function rethrows the exception without completing its actions, otherwise it does not throw anything and proceeds as if the called function had returned a failure indication.

### 29.7.4.1.1 Constructors

**explicit basic_istream(basic_streambuf<charT, traits>* sb);**

*Effects:* Constructs an object of class basic_istream, initializing the base class subobject with basic_ios::init(sb) (29.5.5.2).

*Ensures:* gcount() == 0.

**basic_istream(basic_istream&& rhs);**

*Effects:* Move constructs from the rvalue rhs. This is accomplished by default constructing the base class, copying the gcount() from rhs, calling basic_ios<charT, traits>::move(rhs) to initialize the base class, and setting the gcount() for rhs to 0.

### 29.7.4.1.2 Assignment and swap

**basic_istream& operator=(basic_istream&& rhs);**

*Effects:* As if by swap(rhs).

*Returns:* *this.

**void swap(basic_istream& rhs);**

*Effects:* Calls basic_ios<charT, traits>::swap(rhs). Exchanges the values returned by gcount() and rhs.gcount().

### 29.7.4.1.3 Class basic_istream::sentry

```cpp
template<class charT, class traits, size_t N>
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&, charT(&)[N]);

template<class char, size_t N>
    basic_istream<char, traits>& operator>>(basic_istream<char, traits>&, unsigned char(&)[N]);

template<class char, size_t N>
    basic_istream<char, traits>& operator>>(basic_istream<char, traits>&, signed char(&)[N]);
```
The class `sentry` defines a class that is responsible for doing exception safe prefix and suffix operations.

```cpp
explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false);
```

**Effects:** If `is.good()` is false, calls `is.setstate(failbit)`. Otherwise, prepares for formatted or unformatted input. First, if `is.tie()` is not a null pointer, the function calls `is.tie()->flush()` to synchronize the output sequence with any associated external C stream. Except that this call can be suppressed if the put area of `is.tie()` is empty. Further an implementation is allowed to defer the call to `flush` until a call of `is.rdbuf()->underflow()` occurs. If no such call occurs before the `sentry` object is destroyed, the call to `flush` may be eliminated entirely. If `noskipws` is zero and `is.flags() & ios_base::skipws` is nonzero, the function extracts and discards each character as long as the next available input character `c` is a whitespace character. If `is.rdbuf()->sbumpc()` or `is.rdbuf()->sgetc()` returns `traits::eof()`, the function calls `setstate(failbit | eofbit)` (which may throw `ios_base::failure`).

**Remarks:** The constructor

```cpp
explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false)
```

uses the currently imbued locale in `is`, to determine whether the next input character is whitespace or not.

To decide if the character `c` is a whitespace character, the constructor performs as if it executes the following code fragment:

```cpp
const ctype<charT>& ctype = use_facet<ctype<charT>>(is.getloc());
if (ctype.is(ctype.space, c) != 0)
    // c is a whitespace character.
```

If, after any preparation is completed, `is.good()` is true, `ok_` != false otherwise, `ok_` == false. During preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure`) (29.5.5.4)

```cpp
~sentry();
```

**Effects:** None.

```cpp
explicit operator bool() const;
```

**Effects:** Returns `ok_`.

### 29.7.4.2 Formatted input functions

#### 29.7.4.2.1 Common requirements

Each formatted input function begins execution by constructing an object of class `sentry` with the `noskipws` (second) argument false. If the `sentry` object returns true, when converted to a value of type bool, the function endeavors to obtain the requested input. If an exception is thrown during input then `ios::badbit` is turned on in *this’s error state. If `(exceptions()&badbit) != 0` then the exception is rethrown. In any case, the formatted input function destroys the `sentry` object. If no exception has been thrown, it returns *this.

#### 29.7.4.2.2 Arithmetic extractors

```cpp
operator>>(unsigned short& val);
operator>>(unsigned int& val);
operator>>(long& val);
operator>>(unsigned long& val);
operator>>(long long& val);
operator>>(unsigned long long& val);
operator>>(float& val);
operator>>(double& val);
operator>>(long double& val);
```

---

305) This will be possible only in functions that are part of the library. The semantics of the constructor used in user code is as specified.

306) The `sentry` constructor and destructor can also perform additional implementation-dependent operations.

307) This is done without causing an `ios::failure` to be thrown.
operator>>(bool& val);
operator>>(void*& val);

1. As in the case of the inserters, these extractors depend on the locale’s num_get<> (28.4.2.1) object to perform parsing the input stream data. These extractors behave as formatted input functions (as described in 29.7.4.2.1). After a sentry object is constructed, the conversion occurs as if performed by the following code fragment:

   using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
   iostate err = iostate::goodbit;
   use_facet<numget>(loc).get(*this, 0, *this, err, val);
   setstate(err);

   In the above fragment, loc stands for the private member of the basic_ios class. [Note: The first argument provides an object of the istreambuf_iterator class which is an iterator pointed to an input stream. It bypasses istreams and uses streambufs directly. — end note] Class locale relies on this type as its interface to istream, so that it does not need to depend directly on istream.

operator>>(short& val);

2. The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

   using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
   iostate err = iostate::goodbit;
   long lval;
   use_facet<numget>(loc).get(*this, 0, *this, err, lval);
   if (lval < numeric_limits<short>::min()) {
       err |= ios_base::failbit;
       val = numeric_limits<short>::min();
   } else if (numeric_limits<short>::max() < lval) {
       err |= ios_base::failbit;
       val = numeric_limits<short>::max();
   } else
       val = static_cast<short>(lval);
   setstate(err);

operator>>(int& val);

3. The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

   using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
   iostate err = iostate::goodbit;
   long lval;
   use_facet<numget>(loc).get(*this, 0, *this, err, lval);
   if (lval < numeric_limits<int>::min()) {
       err |= ios_base::failbit;
       val = numeric_limits<int>::min();
   } else if (numeric_limits<int>::max() < lval) {
       err |= ios_base::failbit;
       val = numeric_limits<int>::max();
   } else
       val = static_cast<int>(lval);
   setstate(err);

29.7.4.2.3 basic_istream::operator>>

basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& (*pf)(basic_istream<charT, traits>&));

1. Effects: None. This extractor does not behave as a formatted input function (as described in 29.7.4.2.1).

2. Returns: pf(*this).308

308) See, for example, the function signature ws(basic_istream&) (29.7.4.4).
basic_istream<charT, traits>&
   operator>>(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&&));

3 Effects: Calls pf(*this). This extractor does not behave as a formatted input function (as described in 29.7.4.2.1).
   Returns: *this.

basic_istream<charT, traits>& operator>>(ios_base& (*pf)(ios_base&));

4 Effects: Calls pf(*this). This extractor does not behave as a formatted input function (as described in 29.7.4.2.1).
   Returns: *this.

template<class charT, class traits, size_t N>
   basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& in, charT (&s)[N]);
template<class traits, size_t N>
   basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, unsigned char (&s)[N]);
template<class traits, size_t N>
   basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, signed char (&s)[N]);

7 Effects: Behaves like a formatted input member (as described in 29.7.4.2.1) of in. After a sentry object is constructed, operator>> extracts characters and stores them into s. If width() is greater than zero, n is min(size_t(width()), N). Otherwise n is N. n is the maximum number of characters stored.

Characters are extracted and stored until any of the following occurs:

(8.1) — n-1 characters are stored;
(8.2) — end of file occurs on the input sequence;
(8.3) — letting ct be use_facet<ctype<charT>>(in.getloc()), ct.is(ct.space, c) is true.

operator>> then stores a null byte (char[0]) in the next position, which may be the first position if no characters were extracted. operator>> then calls width(0).

If the function extracted no characters, it calls setstate(failbit), which may throw ios_base::failure (29.5.5.4).
   Returns: in.

template<class charT, class traits>
   basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& in, charT& c);
template<class traits>
   basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, unsigned char& c);
template<class traits>
   basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, signed char& c);

12 Effects: Behaves like a formatted input member (as described in 29.7.4.2.1) of in. After a sentry object is constructed a character is extracted from in, if one is available, and stored in c. Otherwise, the function calls in.setstate(failbit).
   Returns: in.

basic_istream<charT, traits>& operator>>(basic_streambuf<charT, traits>* sb);

14 Effects: Behaves as an unformatted input function (29.7.4.3). If sb is null, calls setstate(failbit), which may throw ios_base::failure (29.5.5.4). After a sentry object is constructed, extracts characters from *this and inserts them in the output sequence controlled by sb. Characters are extracted and inserted until any of the following occurs:

(14.1) — end-of-file occurs on the input sequence;
(14.2) — inserting in the output sequence fails (in which case the character to be inserted is not extracted);
(14.3) — an exception occurs (in which case the exception is caught).

If the function inserts no characters, it calls setstate(failbit), which may throw ios_base::failure (29.5.5.4). If it inserted no characters because it caught an exception thrown while extracting

309) See, for example, the function signature dec(ios_base&) (29.5.6.3).
characters from \*this and failbit is on in exceptions() (29.5.5.4), then the caught exception is rethrown.

\textbf{Returns:} \*this.

### 29.7.4.3 Unformatted input functions [istream.unformatted]

Each unformatted input function begins execution by constructing an object of class \texttt{sentry} with the default argument \texttt{nospw} (second) argument \texttt{true}. If the \texttt{sentry} object returns \texttt{true}, when converted to a value of type \texttt{bool}, the function endeavors to obtain the requested input. Otherwise, if the \texttt{sentry} constructor exits by throwing an exception or if the \texttt{sentry} object returns \texttt{false}, when converted to a value of type \texttt{bool}, the function returns without attempting to obtain any input. In either case the number of extracted characters is set to 0; unformatted input functions taking a character array of nonzero size as an argument shall also store a null character (using \texttt{charT()}) in the first location of the array. If an exception is thrown during input then \texttt{ios::badbit} is turned on in \*this’s error state. (Exceptions thrown from \texttt{basic_ios<>::clear()} are not caught or rethrown.) If \((\text{exceptions()&badbit}) \neq 0\) then the exception is rethrown. It also counts the number of characters extracted. If no exception has been thrown it ends by storing the count in a member object and returning the value specified. In any event the \texttt{sentry} object is destroyed before leaving the unformatted input function.

\begin{verbatim}
streamsize gcount() const;

\textbf{Effects:} None. This member function does not behave as an unformatted input function (as described above).

\textbf{Returns:} The number of characters extracted by the last unformatted input member function called for the object.
\end{verbatim}

\begin{verbatim}
int_type get();

\textbf{Effects:} Behaves as an unformatted input function (as described above). After constructing a \texttt{sentry} object, extracts a character \(c\), if one is available. Otherwise, the function calls \texttt{setstate(failbit)} (which may throw \texttt{ios_base::failure (29.5.5.4)}), \texttt{Returns:} \(c\) if available, otherwise \texttt{traits::eof()}.
\end{verbatim}

\begin{verbatim}
basic_istream<charT, traits>& get(char_type& c);

\textbf{Effects:} Behaves as an unformatted input function (as described above). After constructing a \texttt{sentry} object, extracts a character, if one is available, and assigns it to \(c\). Otherwise, the function calls \texttt{setstate(failbit)} (which may throw \texttt{ios_base::failure (29.5.5.4)}).

\textbf{Returns:} \*this.
\end{verbatim}

\begin{verbatim}
basic_istream<charT, traits>& get(char_type* s, streamsize n, char_type delim);

\textbf{Effects:} Behaves as an unformatted input function (as described above). After constructing a \texttt{sentry} object, extracts characters and stores them into successive locations of an array whose first element is designated by \(s\). Characters are extracted and stored until any of the following occurs:

\begin{enumerate}
\item \(n\) is less than one or \((n - 1)\) characters are stored;
\item end-of-file occurs on the input sequence (in which case the function calls \texttt{setstate(eofbit)});
\item \texttt{traits::eq(c, delim)} for the next available input character \(c\) (in which case \(c\) is not extracted).
\end{enumerate}

If the function stores no characters, it calls \texttt{setstate(failbit)} (which may throw \texttt{ios_base::failure (29.5.5.4)}). In any case, if \(n\) is greater than zero it then stores a null character into the next successive location of the array.

\textbf{Returns:} \*this.
\end{verbatim}

\begin{verbatim}
basic_istream<charT, traits>& get(char_type* s, streamsize n);

\textbf{Effects:} Calls \texttt{get(s, n, \texttt{widen(\texttt{\"n\")})}}.

\textbf{Returns:} Value returned by the call.
\end{verbatim}

---

310) This is done without causing an \texttt{ios::failure} to be thrown.

311) Note that this function is not overloaded on types \texttt{signed char} and \texttt{unsigned char}.

312) Note that this function is not overloaded on types \texttt{signed char} and \texttt{unsigned char}.
basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb, char_type delim);

**Effects:** Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts characters and inserts them in the output sequence controlled by sb. Characters are extracted and inserted until any of the following occurs:

1. end-of-file occurs on the input sequence;
2. inserting in the output sequence fails (in which case the character to be inserted is not extracted);
3. traits::eq(c, delim) for the next available input character c (in which case c is not extracted);
4. an exception occurs (in which case, the exception is caught but not rethrown).

If the function inserts no characters, it calls setstate(failbit), which may throw ios_base::failure (29.5.5.4).

**Returns:** *this.

basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb);

**Effects:** Calls get(sb, widen('\n')).

**Returns:** Value returned by the call.

basic_istream<charT, traits>& getline(char_type* s, streamsize n, char_type delim);

**Effects:** Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts characters and stores them into successive locations of an array whose first element is designated by s. Characters are extracted and stored until one of the following occurs:

1. end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit));
2. traits::eq(c, delim) for the next available input character c (in which case the input character is extracted but not stored);\(^{314}\)
3. n is less than one or n - 1 characters are stored (in which case the function calls setstate(failbit)).

These conditions are tested in the order shown.\(^{315}\)

If the function extracts no characters, it calls setstate(failbit) (which may throw ios_base::failure (29.5.5.4)).\(^{316}\)

In any case, if n is greater than zero, it then stores a null character (using charT()) into the next successive location of the array.

**Returns:** *this.

**Example:**

```cpp
#include <iostream>

int main() {
    using namespace std;
    const int line_buffer_size = 100;

    char buffer[line_buffer_size];
    int line_number = 0;
    while (cin.getline(buffer, line_buffer_size, '\n') || cin.gcount()) {
        int count = cin.gcount();
        if (cin.eof())
            cout << "Partial final line"; // cin.fail() is false
        else if (cin.fail()) {
            cout << "Partial long line";
            cin.clear(cin.rdstate() & ~ios_base::failbit);
        } else {
            count--;
            // Don’t include newline in count
        }
    }
}
```

Note that this function is not overloaded on types signed char and unsigned char.

Since the final input character is “extracted”, it is counted in the gcount(), even though it is not stored.

This allows an input line which exactly fills the buffer, without setting failbit. This is different behavior than the historical AT&T implementation.

This implies an empty input line will not cause failbit to be set.
cout << "Line " << ++line_number;
}
cout << " (" << count << " chars): " << buffer << endl;
} — end example]

basic_istream<charT, traits>& getline(char_type* s, streamsize n);
24 Returns: getline(s, n, widen('\n'))

basic_istream<charT, traits>& ignore(streamsize n = 1, int_type delim = traits::eof());
25 Effects: Behaves as an unformatted input function (as described above). After constructing a sentry
object, extracts characters and discards them. Characters are extracted until any of the following
occurs:

(25.1) n != numeric_limits<streamsize>::max() (17.3.4) and n characters have been extracted so
far
(25.2) end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit),
which may throw ios_base::failure (29.5.5.4));
(25.3) traits::eq_int_type(traits::to_int_type(c), delim) for the next available input character
 c (in which case c is extracted).

26 Remarks: The last condition will never occur if traits::eq_int_type(delim, traits::eof()).
27 Returns: *this.

int_type peek();
28 Effects: Behaves as an unformatted input function (as described above). After constructing a sentry
object, reads but does not extract the current input character.
29 Returns: traits::eof() if good() is false. Otherwise, returns rdbuf()->sgetc().

basic_istream<charT, traits>& read(char_type* s, streamsize n);
30 Effects: Behaves as an unformatted input function (as described above). After constructing a sentry
object, if !good() calls setstate(failbit) which may throw an exception, and return. Otherwise
extracts characters and stores them into successive locations of an array whose first element is designated
by s.317 Characters are extracted and stored until either of the following occurs:

(30.1) n characters are stored;
(30.2) end-of-file occurs on the input sequence (in which case the function calls setstate(failbit |
eofbit), which may throw ios_base::failure (29.5.5.4)).

31 Returns: *this.

streamsize readsome(char_type* s, streamsize n);
32 Effects: Behaves as an unformatted input function (as described above). After constructing a sentry
object, if !good() calls setstate(failbit) which may throw an exception, and return. Other-
wise extracts characters and stores them into successive locations of an array whose first element is designated
by s. If rdbuf()->in_avail() == -1, calls setstate(eofbit) (which may throw ios_base::failure (29.5.5.4)), and extracts no characters;

(32.1) If rdbuf()->in_avail() == 0, extracts no characters
(32.2) If rdbuf()->in_avail() > 0, extracts min(rdbuf()->in_avail(), n)).

33 Returns: The number of characters extracted.

basic_istream<charT, traits>& putback(char_type c);  
34 Effects: Behaves as an unformatted input function (as described above), except that the function first
clears eofbit. After constructing a sentry object, if !good() calls setstate(failbit) which may
throw an exception, and return. If rdbuf() is not null, calls rdbuf()->sputbackc(c). If rdbuf()

317) Note that this function is not overloaded on types signed char and unsigned char.
is null, or if sputbackc returns traits::eof(), calls setstate(badbit) (which may throw ios_base::failure (29.5.5.4)). [Note: This function extracts no characters, so the value returned by the next call to gcount() is 0. — end note]

Returns: *this.

basic_istream<charT, traits>& unget();

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit. After constructing a sentry object, if !good() calls setstate(failbit) which may throw an exception, and return. If rdbuf() is not null, calls rdbuf()->sungetc(). If rdbuf() is null, or if sungetc returns traits::eof(), calls setstate(badbit) (which may throw ios_base::failure (29.5.5.4)). [Note: This function extracts no characters, so the value returned by the next call to gcount() is 0. — end note]

Returns: *this.

int sync();

Effects: Behaves as an unformatted input function (as described above), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to gcount(). After constructing a sentry object, if rdbuf() is a null pointer, returns -1. Otherwise, calls rdbuf()->pubsync() and, if that function returns -1 calls setstate(badbit) (which may throw ios_base::failure (29.5.5.4), and returns -1. Otherwise, returns zero.

pos_type tellg();

Effects: Behaves as an unformatted input function (as described above), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to gcount().

Returns: After constructing a sentry object, if fail() != false, returns pos_type(-1) to indicate failure. Otherwise, returns rdbuf()->pubseekoff(0, cur, in).

basic_istream<charT, traits>& seekg(pos_type pos);

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit, it does not count the number of characters extracted, and it does not affect the value returned by subsequent calls to gcount(). After constructing a sentry object, if fail() != true, executes rdbuf()->pubseekpos(pos, ios_base::in). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).

Returns: *this.

basic_istream<charT, traits>& seekg(off_type off, ios_base::seekdir dir);

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit, does not count the number of characters extracted, and does not affect the value returned by subsequent calls to gcount(). After constructing a sentry object, if fail() != true, executes rdbuf()->pubseekoff(off, dir, ios_base::in). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).

Returns: *this.

29.7.4.4 Standard basic_istream manipulators [istream.manip]

1 Each instantiation of the function template specified in this subclause is a designated addressable function (16.5.4.2.1).

template<class charT, class traits>
  basic_istream<charT, traits>& ws(basic_istream<charT, traits>& is);

2 Effects: Behaves as an unformatted input function (29.7.4.3), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to is.gcount(). After constructing a sentry object extracts characters as long as the next available character c is whitespace or until there are no more characters in the sequence. Whitespace characters are distinguished with the same criterion as used by sentry::sentry (29.7.4.1.3). If ws stops extracting characters because there are no more available it sets eofbit, but not failbit.

3 Returns: is.
29.7.4.5 Rvalue stream extraction

\[
\text{template<class charT, class traits, class T>}
\text{basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&& is, T&& x);} \\
\]

1 Effects: Equivalent to:
\[
is >> \text{std::forward<T>>(x);} \\
\text{return is;} \\
\]

2 Remarks: This function shall not participate in overload resolution unless the expression \( is >> \text{std::forward<T>>(x) } \) is well-formed.

29.7.4.6 Class template basic_iostream

namespace std {
\[
\text{template<class charT, class traits = char_traits<charT>>} \\
\text{class basic_iostream} \\
\text{: public basic_istream<charT, traits>,} \\
\text{ public basic_ostream<charT, traits> { \\
\text{ public:} \\
\text{ \hspace{1em} using char_type = charT;} \\
\text{ \hspace{1em} using int_type = typename traits::int_type;} \\
\text{ \hspace{1em} using pos_type = typename traits::pos_type;} \\
\text{ \hspace{1em} using off_type = typename traits::off_type;} \\
\text{ \hspace{1em} using traits_type = traits; } \\
\]
\]
\[
// 29.7.4.6.1, constructor
\text{explicit basic_iostream(basic_streambuf<charT, traits>** sb);} \\
\]
\[
// 29.7.4.6.2, destructor
\text{virtual ~basic_iostream();} \\
\]
\[
\text{protected:} \\
\]
\[
// 29.7.4.6.1, constructor
\text{basic_iostream(const basic_iostream& rhs) = delete;} \\
\text{basic_iostream(basic_iostream&& rhs);} \\
\]
\[
// 29.7.4.6.3, assign and swap
\text{basic_iostream& operator=(const basic_iostream& rhs) = delete;} \\
\text{basic_iostream& operator=(basic_iostream&& rhs);} \\
\text{void swap(basic_iostream& rhs);} \\
\] 
}

1 The class template basic_iostream inherits a number of functions that allow reading input and writing output to sequences controlled by a stream buffer.

29.7.4.6.1 Constructors

\[
\text{explicit basic_iostream(basic_streambuf<charT, traits>** sb);} \\
\]

1 Effects: Constructs an object of class basic_iostream, initializing the base class subobjects with basic_istream<charT, traits>(sb) (29.7.4.1) and basic_ostream<charT, traits>(sb) (29.7.5.1).

2 Ensures: rdbuf() == sb and gcount() == 0.

\[
\text{basic_iostream(basic_iostream&& rhs);} \\
\]

1 Effects: Move constructs from the rvalue rhs by constructing the basic_istream base class with move(rhs).

29.7.4.6.2 Destructor

\[
\text{virtual ~basic_iostream();} \\
\]

1 Effects: Destroys an object of class basic_iostream.

2 Remarks: Does not perform any operations on rdbuf().
29.7.4.6.3 Assignment and swap

basic_iostream& operator=(basic_iostream&& rhs);

Effects: As if by swap(rhs).

void swap(basic_iostream& rhs);

Effects: Calls basic_istream<charT, traits>::swap(rhs).

29.7.5 Output streams

The header <ostream> defines a type and several function signatures that control output to a stream buffer along with a function template that inserts into stream rvalues.

29.7.5.1 Class template basic_ostream

namespace std {
  template<class charT, class traits = char_traits<charT>>
  class basic_ostream : virtual public basic_ios<charT, traits> {
    public:
      // types (inherited from basic_ios (29.5.5))
      using char_type = charT;
      using int_type = typename traits::int_type;
      using pos_type = typename traits::pos_type;
      using off_type = typename traits::off_type;
      using traits_type = traits;

      // 29.7.5.1.1, constructor/destructor
      explicit basic_ostream(basic_streambuf<char_type, traits>* sb);
      virtual ~basic_ostream();

      // 29.7.5.1.3, prefix/suffix
      class sentry;

      // 29.7.5.2, formatted output
      basic_ostream<charT, traits>&
      operator<<(basic_ostream<charT, traits>& (*pf)(basic_ostream<charT, traits>&&));
      basic_ostream<charT, traits>&
      operator<<(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&&));
      basic_ostream<charT, traits>&
      operator<<(ios_base& (*pf)(ios_base&));
      basic_ostream<charT, traits>&
      operator<<(bool n);
      basic_ostream<charT, traits>&
      operator<<(short n);
      basic_ostream<charT, traits>&
      operator<<(unsigned short n);
      basic_ostream<charT, traits>&
      operator<<(int n);
      basic_ostream<charT, traits>&
      operator<<(unsigned int n);
      basic_ostream<charT, traits>&
      operator<<(long n);
      basic_ostream<charT, traits>&
      operator<<(unsigned long n);
      basic_ostream<charT, traits>&
      operator<<(long long n);
      basic_ostream<charT, traits>&
      operator<<(unsigned long long n);
      basic_ostream<charT, traits>&
      operator<<(float f);
      basic_ostream<charT, traits>&
      operator<<(double f);
      basic_ostream<charT, traits>&
      operator<<(const void* p);
      basic_ostream<charT, traits>&
      operator<<(nullptr_t);
      basic_ostream<charT, traits>&
      operator<<(basic_streambuf<char_type, traits>* sb);

      // 29.7.5.3, unformatted output
      basic_ostream<charT, traits>&
      put(char_type c);
      basic_ostream<charT, traits>&
      write(const char_type* s, streamsize n);
      basic_ostream<charT, traits>&
      flush();
The class template `basic_ostream` defines a number of member function signatures that assist in formatting and writing output to output sequences controlled by a stream buffer.

Two groups of member function signatures share common properties: the *formatted output functions* (or *inserters*) and the *unformatted output functions*. Both groups of output functions generate (or *insert*) output characters by actions equivalent to calling `rdbuf()->sputc(int_type)`. They may use other public members of `basic_ostream` except that they shall not invoke any virtual members of `rdbuf()` except `overflow()`, `xputn()`, and `sync()`.

If one of these called functions throws an exception, then unless explicitly noted otherwise the output function sets `badbit` in error state. If `badbit` is on in `exceptions()`, the output function rethrows the exception without completing its actions, otherwise it does not throw anything and treat as an error.

### 29.7.5.1.1 Constructors

```cpp
explicit basic_ostream(basic_streambuf<charT, traits>* sb);
```

1. **Effects**: Constructs an object of class `basic_ostream`, initializing the base class subobject with `basic_ios<charT, traits>::init(sb)` (29.5.5.2).
2. **Ensures**: `rdbuf() == sb`.

---

1. The class template `basic_ostream` defines a number of member function signatures that assist in formatting and writing output to output sequences controlled by a stream buffer.
2. Two groups of member function signatures share common properties: the *formatted output functions* (or *inserters*) and the *unformatted output functions*. Both groups of output functions generate (or *insert*) output characters by actions equivalent to calling `rdbuf()->sputc(int_type)`. They may use other public members of `basic_ostream` except that they shall not invoke any virtual members of `rdbuf()` except `overflow()`, `xputn()`, and `sync()`.
3. If one of these called functions throws an exception, then unless explicitly noted otherwise the output function sets `badbit` in error state. If `badbit` is on in `exceptions()`, the output function rethrows the exception without completing its actions, otherwise it does not throw anything and treat as an error.
basic_ostream(basic_ostream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by default constructing the base class and calling `basic_ios<charT, traits>::move(rhs)` to initialize the base class.

virtual ~basic_ostream();

Effects: Destroys an object of class `basic_ostream`.

Remarks: Does not perform any operations on `rdbuf()`.

### 29.7.5.1.2 Assignment and swap

```cpp
basic_ostream& operator=(basic_ostream&& rhs);
```

Effects: As if by `swap(rhs)`.

Returns: *this.

```cpp
void swap(basic_ostream& rhs);
```

Effects: Calls `basic_ios<charT, traits>::swap(rhs)`.

### 29.7.5.1.3 Class `basic_ostream::sentry`

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ostream<charT, traits>::sentry {
        bool ok_; // exposition only
        public:
            explicit sentry(basic_ostream<charT, traits>& os);
            ~sentry();
            explicit operator bool() const { return ok_; }
            sentry(const sentry&) = delete;
            sentry& operator=(const sentry&) = delete;
    };
}
```

The class `sentry` defines a class that is responsible for doing exception safe prefix and suffix operations.

```cpp
explicit sentry(basic_ostream<charT, traits>& os);
```

If `os.good()` is nonzero, prepares for formatted or unformatted output. If `os.tie()` is not a null pointer, calls `os.tie()->flush()`.

If, after any preparation is completed, `os.good()` is `true`, `ok_ == true` otherwise, `ok_ == false`. During preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure (29.5.5.4)`) during preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure (29.5.5.4)`)

```cpp
~sentry();
```

If `(!os.flags() & ios_base::unitbuf) && !uncaught_exceptions() && os.good()` is true, calls `os.rdbuf()->pubsync()`. If that function returns -1, sets `badbit` in `os.rdstate()` without propagating an exception.

```cpp
explicit operator bool() const;
```

Effects: Returns `ok_`.

### 29.7.5.1.4 Seek members

```cpp
pos_type tellp();
```

Returns: If `fail() != false`, returns `pos_type(-1)` to indicate failure. Otherwise, returns `rdbuf()->pubseekoff(0, cur, out)`.

---

318) The call `os.tie()->flush()` does not necessarily occur if the function can determine that no synchronization is necessary.

319) The `sentry` constructor and destructor can also perform additional implementation-dependent operations.
basic_ostream<charT, traits>& seekp(pos_type pos);

3 Effects: If fail() \(!=\) true, executes rdbuf() \(\rightarrow\)pubseekpos(pos, ios_base::out). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).

4 Returns: \*this.

basic_ostream<charT, traits>& seekp(off_type off, ios_base::seekdir dir);

5 Effects: If fail() \(!=\) true, executes rdbuf() \(\rightarrow\)pubseekoff(off, dir, ios_base::out). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).

6 Returns: \*this.

29.7.5.2 Formatted output functions [ostream.formatted]

29.7.5.2.1 Common requirements [ostream.formatted.reqnts]

1 Each formatted output function begins execution by constructing an object of class sentry. If this object returns \textbf{true} when converted to a value of type bool, the function endeavors to generate the requested output. If the generation fails, then the formatted output function does setstate(ios_base::failbit), which might throw an exception. If an exception is thrown during output, then ios::badbit is turned on\(^\text{320}\) in \*this’s error state. If (exceptions()&badbit) \(!=\) 0 then the exception is rethrown. Whether or not an exception is thrown, the sentry object is destroyed before leaving the formatted output function. If no exception is thrown, the result of the formatted output function is \*this.

2 The descriptions of the individual formatted output functions describe how they perform output and do not mention the sentry object.

3 If a formatted output function of a stream os determines padding, it does so as follows. Given a charT character sequence seq where charT is the character type of the stream, if the length of seq is less than os.width(), then enough copies of os.fill() are added to this sequence as necessary to pad to a width of os.width() characters. If (os.flags() & ios_base::adjustfield) == ios_base::left is \textbf{true}, the fill characters are placed after the character sequence; otherwise, they are placed before the character sequence.

29.7.5.2.2 Arithmetic inserters [ostream.inserters.arithmetic]

operator<<(bool val);
operator<<(short val);
operator<<(unsigned short val);
operator<<(int val);
operator<<(long val);
operator<<(unsigned long val);
operator<<(long long val);
operator<<(unsigned long long val);
operator<<(float val);
operator<<(double val);
operator<<(long double val);
operator<<(const void* val);

1 Effects: The classes num_get<> and num_put<> handle locale-dependent numeric formatting and parsing. These inserter functions use the imbued locale value to perform numeric formatting. When val is of type bool, long, unsigned long, long, unsigned long, long double, long double, or const void*, the formatting conversion occurs as if it performed the following code fragment:

\[
\text{bool failed = use_facet<}
\text{num_put<charT, ostreambuf_iterator<charT, traits>>}
\text{>(getloc()).put(*this, *this, fill(), val).failed();}
\]

When val is of type short the formatting conversion occurs as if it performed the following code fragment:

\[
\text{ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;}
\]

\(^\text{320}\) without causing an ios::failure to be thrown.
When `val` is of type `int` the formatting conversion occurs as if it performed the following code fragment:

```cpp
ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
bool failed = use_facet<num_put<charT, ostreambuf_iterator<charT, traits>>>(getloc()).put(*this, *this, fill(),
  baseflags == ios_base::oct || baseflags == ios_base::hex
  ? static_cast<long>(static_cast<unsigned short>(val))
  : static_cast<long>(val)).failed();
```

When `val` is of type `unsigned short` or `unsigned int` the formatting conversion occurs as if it performed the following code fragment:

```cpp
bool failed = use_facet<num_put<charT, ostreambuf_iterator<charT, traits>>>(getloc()).put(*this, *this, fill(),
  static_cast<unsigned long>(val)).failed();
```

When `val` is of type `float` the formatting conversion occurs as if it performed the following code fragment:

```cpp
bool failed = use_facet<num_put<charT, ostreambuf_iterator<charT, traits>>>(getloc()).put(*this, *this, fill(),
  static_cast<double>(val)).failed();
```

The first argument provides an object of the `ostreambuf_iterator<>` class which is an iterator for class `basic_ostream<>`. It bypasses `ostreams` and uses `streambufs` directly. Class `locale` relies on these types as its interface to `iostreams`, since for flexibility it has been abstracted away from direct dependence on `ostream`. The second parameter is a reference to the base class subobject of type `ios_base`. It provides formatting specifications such as field width, and a locale from which to obtain other facets. If `failed` is `true` then does `setstate(badbit)`, which may throw an exception, and returns.

**Returns:** `*this`.

### § 29.7.5.2.3 basic_ostream::operator<<

```cpp
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& (*pf)(basic_ostream<charT, traits>&&));
```

1 **Effects:** None. Does not behave as a formatted output function (as described in § 29.7.5.2.1).

3 **Returns:** `pf(*this)`.321

```cpp
basic_ostream<charT, traits>&
operator<<(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&&));
```

3 **Effects:** Calls `pf(*this)`. This inserter does not behave as a formatted output function (as described in § 29.7.5.2.1).

5 **Returns:** `*this`.322

```cpp
basic_ostream<charT, traits>& operator<<(ios_base& (*pf)(ios_base&));
```

5 **Effects:** Calls `pf(*this)`. This inserter does not behave as a formatted output function (as described in § 29.7.5.2.1).

6 **Returns:** `*this`.

---

321) See, for example, the function signature `endl(basic_ostream&)` (§ 29.7.5.4).
322) See, for example, the function signature `dec(ios_base&)` (§ 29.5.6.3).
basic_ostream<charT, traits>& operator<<(basic_streambuf<charT, traits>* sb);

Effects: Behaves as an unformatted output function (29.7.5.3). After the sentry object is constructed, if sb is null calls setstate(badbit) (which may throw ios_base::failure).

Gets characters from sb and inserts them in *this. Characters are read from sb and inserted until any of the following occurs:

- end-of-file occurs on the input sequence;
- inserting in the output sequence fails (in which case the character to be inserted is not extracted);
- an exception occurs while getting a character from sb.

If the function inserts no characters, it calls setstate(failbit) (which may throw ios_base::failure (29.5.5.4)). If an exception was thrown while extracting a character, the function sets failbit in error state, and if failbit is on in exceptions() the caught exception is rethrown.

Returns: *this.

basic_ostream<charT, traits>& operator<<(nullptr_t);

Effects: Equivalent to:

return *this << s;

where s is an implementation-defined NTCTS (16.3.17).

29.7.5.2.4 Character inserter function templates

[ostream.inserters.character]

template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, charT c);

template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, char c);

// specialization

template<class traits>
basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, char c);

// signed and unsigned

template<class traits>
basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, signed char c);

template<class traits>
basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, unsigned char c);

Effects: Behaves as a formatted output function (29.7.5.2.1) of out. Constructs a character sequence seq. If c has type char and the character type of the stream is not char, then seq consists of out.widen(c); otherwise seq consists of c. Determines padding for seq as described in 29.7.5.2.1. Inserts seq into out. Calls os.width(0).

Returns: out.

template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, const charT* s);

template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, const char* s);

template<class traits>
basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const signed char* s);

template<class traits>
basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const unsigned char* s);

Requires: s shall not be a null pointer.

Effects: Behaves like a formatted inserter (as described in 29.7.5.2.1) of out. Creates a character sequence seq of \( n \) characters starting at s, each widened using out.widen() (29.5.5.3), where \( n \) is the number that would be computed as if by:

- \( \text{traits}.\text{length}(s) \) for the overload where the first argument is of type basic_ostream<charT, traits>\& and the second is of type const charT*, and also for the overload where the first argument is of type basic_ostream<char, traits>\& and the second is of type const char*,

\( \section{29.7.5.2.4} \) 1354
Determines padding for seq as described in §29.7.5.2.1. Inserts seq into out. Calls width(0).

Returns: out.

29.7.5.3 Unformatted output functions

Each unformatted output function begins execution by constructing an object of class sentry. If this object returns true, while converting to a value of type bool, the function endeavors to generate the requested output. If an exception is thrown during output, then ios::badbit is turned on\(^{323}\) in *this’s error state. If (exceptions() & badbit) ! = 0 then the exception is rethrown. In any case, the unformatted output function ends by destroying the sentry object, then, if no exception was thrown, returning the value specified for the unformatted output function.

```
basic_ostream<charT, traits>& put(char_type c);
```

Effects: Behaves as an unformatted output function (as described above). After constructing a sentry object, inserts the character c, if possible.\(^{324}\)

Otherwise, calls setstate(badbit) (which may throw ios_base::failure (29.5.5.4)).

Returns: *this.

```
basic_ostream& write(const char_type* s, streamsize n);
```

Effects: Behaves as an unformatted output function (as described above). After constructing a sentry object, obtains characters to insert from successive locations of an array whose first element is designated by s.\(^{325}\) Characters are inserted until either of the following occurs:

- n characters are inserted;
- inserting in the output sequence fails (in which case the function calls setstate(badbit), which may throw ios_base::failure (29.5.5.4)).

Returns: *this.

```
basic_ostream& flush();
```

Effects: Behaves as an unformatted output function (as described above). If rdbuf() is not a null pointer, constructs a sentry object. If this object returns true when converted to a value of type bool the function calls rdbuf()->pubsync(). If that function returns -1 calls setstate(badbit) (which may throw ios_base::failure (29.5.5.4)). Otherwise, if the sentry object returns false, does nothing.

Returns: *this.

29.7.5.4 Standard manipulators

Each instantiation of any of the function templates specified in this subclause is a designated addressable function (16.5.4.2.1).

```
template<class charT, class traits>
    basic_ostream<charT, traits>& endl(basic_ostream<charT, traits>& os);
```

Effects: Calls os.put(os.widen(’\n’)), then os.flush().

Returns: os.

```
template<class charT, class traits>
    basic_ostream<charT, traits>& ends(basic_ostream<charT, traits>& os);
```

Effects: Inserts a null character into the output sequence: calls os.put(charT()).

Returns: os.

\(^{323}\) without causing an ios::failure to be thrown.

\(^{324}\) Note that this function is not overloaded on types signed char and unsigned char.

\(^{325}\) Note that this function is not overloaded on types signed char and unsigned char.
template<class charT, class traits>
    basic_ostream<charT, traits>& flush(basic_ostream<charT, traits>& os);

Effects: Calls os.flush().

Returns: os.

template<class charT, class traits>
    basic_ostream<charT, traits>& emit_on_flush(basic_ostream<charT, traits>& os);

Effects: If os.rdbuf() is a basic_syncbuf<charT, traits, Allocator>*, called buf for the purpose of exposition, calls buf->set_emit_on_sync(true). Otherwise this manipulator has no effect. [Note: To work around the issue that the Allocator template argument cannot be deduced, implementations can introduce an intermediate base class to basic_syncbuf that manages its emit_on_sync flag. — end note]

Returns: os.

template<class charT, class traits>
    basic_ostream<charT, traits>& noemit_on_flush(basic_ostream<charT, traits>& os);

Effects: If os.rdbuf() is a basic_syncbuf<charT, traits, Allocator>*, called buf for the purpose of exposition, calls buf->set_emit_on_sync(false). Otherwise this manipulator has no effect.

Returns: os.

template<class charT, class traits>
    basic_ostream<charT, traits>& flush_emit(basic_ostream<charT, traits>& os);

Effects: Calls os.flush(). Then, if os.rdbuf() is a basic_syncbuf<charT, traits, Allocator>*, called buf for the purpose of exposition, calls buf->emit().

Returns: os.

29.7.5.5 Rvalue stream insertion

[ostream.rvalue]

template<class charT, class traits, class T>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&& os, const T& x);

Effects: As if by: os << x;

Returns: os.

Remarks: This function shall not participate in overload resolution unless the expression os << x is well-formed.

29.7.6 Standard manipulators

[std.manip]

The header <iomanip> defines several functions that support extractors and inserters that alter information maintained by class ios_base and its derived classes.

unspeccified resetiosflags(ios_base::fmtflags mask);

Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> then the expression out << resetiosflags(mask) behaves as if it called f(out, mask), or if in is an object of type basic_istream<charT, traits> then the expression in >> resetiosflags(mask) behaves as if it called f(in, mask), where the function f is defined as:326

    void f(ios_base& str, ios_base::fmtflags mask) {
        // reset specified flags
        str.setf(ios_base::fmtflags(0), mask);
    }

The expression out << resetiosflags(mask) shall have type basic_ostream<charT, traits>& and value out. The expression in >> resetiosflags(mask) shall have type basic_istream<charT, traits>& and value in.

326 The expression cin >> resetiosflags(ios_base::skipws) clears ios_base::skipws in the format flags stored in the basic_istream<charT, traits> object cin (the same as cin >> noskipws), and the expression cout << resetiosflags(ios_base::showbase) clears ios_base::showbase in the format flags stored in the basic_ostream<charT, traits> object cout (the same as cout << noshowbase).

§ 29.7.6
unspecified setiosflags(ios_base::fmtflags mask);

Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> then the expression out << setiosflags(mask) behaves as if it called f(out, mask), or if in is an object of type basic_istream<charT, traits> then the expression in >> setiosflags(mask) behaves as if it called f(in, mask), where the function f is defined as:

```cpp
void f(ios_base& str, ios_base::fmtflags mask) {
    // set specified flags
    str.setf(mask);
}
```

The expression out << setiosflags(mask) shall have type basic_ostream<charT, traits>& and value out. The expression in >> setiosflags(mask) shall have type basic_istream<charT, traits>& and value in.

unspecified setbase(int base);

Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> then the expression out << setbase(base) behaves as if it called f(out, base), or if in is an object of type basic_istream<charT, traits> then the expression in >> setbase(base) behaves as if it called f(in, base), where the function f is defined as:

```cpp
void f(ios_base& str, int base) {
    // set basefield
    str.setf(base == 8 ? ios_base::oct :
                base == 10 ? ios_base::dec :
                base == 16 ? ios_base::hex :
                ios_base::fmtflags(0), ios_base::basefield);
}
```

The expression out << setbase(base) shall have type basic_ostream<charT, traits>& and value out. The expression in >> setbase(base) shall have type basic_istream<charT, traits>& and value in.

unspecified setfill(char_type c);

Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> and c has type charT then the expression out << setfill(c) behaves as if it called f(out, c), where the function f is defined as:

```cpp
template<class charT, class traits>
void f(basic_ios<charT, traits>& str, charT c) {
    // set fill character
    str.fill(c);
}
```

The expression out << setfill(c) shall have type basic_ostream<charT, traits>& and value out.

unspecified setprecision(int n);

Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> then the expression out << setprecision(n) behaves as if it called f(out, n), or if in is an object of type basic_istream<charT, traits> then the expression in >> setprecision(n) behaves as if it called f(in, n), where the function f is defined as:

```cpp
void f(ios_base& str, int n) {
    // set precision
    str.precision(n);
}
```

The expression out << setprecision(n) shall have type basic_ostream<charT, traits>& and value out. The expression in >> setprecision(n) shall have type basic_istream<charT, traits>& and value in.

unspecified setw(int n);

Returns: An object of unspecified type such that if out is an instance of basic_ostream<charT, traits> then the expression out << setw(n) behaves as if it called f(out, n), or if in is an object
of type `basic_istream<charT, traits>` then the expression `in >> setw(n)` behaves as if it called `f(in, n)`, where the function `f` is defined as:
```cpp
void f(ios_base& str, int n) {
    // set width
    str.width(n);
}
```

The expression `out << setw(n)` shall have type `basic_ostream<charT, traits>&` and value `out`. The expression `in >> setw(n)` shall have type `basic_istream<charT, traits>&` and value `in`.

### 29.7.7 Extended manipulators

The header `<iomanip>` defines several functions that support extractors and inserters that allow for the parsing and formatting of sequences and values for money and time.

```cpp
template<class moneyT> unspecified get_money(moneyT& mon, bool intl = false);
```

**Requires:** The type `moneyT` shall be either `long double` or a specialization of the `basic_string` template (Clause 21).

**Effects:** The expression `in >> get_money(mon, intl)` described below behaves as a formatted input function (29.7.4.2.1).

**Returns:** An object of unspecified type such that if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> get_money(mon, intl)` behaves as if it called `f(in, mon, intl)`, where the function `f` is defined as:
```cpp
template<class charT, class traits, class moneyT>
void f(basic_ios<charT, traits>& str, moneyT& mon, bool intl) {
    using Iter = istreambuf_iterator<charT, traits>;
    using MoneyGet = money_get<charT, Iter>;
    ios_base::iostate err = ios_base::goodbit;
    const MoneyGet& mg = use_facet<MoneyGet>(str.getloc());
    mg.get(Iter(str.rdbuf()), Iter(), intl, str, err, mon);
    if (ios_base::goodbit != err)
        str.setstate(err);
}
```

The expression `in >> get_money(mon, intl)` shall have type `basic_istream<charT, traits>&` and value `in`.

```cpp
template<class moneyT> unspecified put_money(const moneyT& mon, bool intl = false);
```

**Requires:** The type `moneyT` shall be either `long double` or a specialization of the `basic_string` template (Clause 21).

**Returns:** An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << put_money(mon, intl)` behaves as a formatted output function (29.7.5.2.1) that calls `f(out, mon, intl)`, where the function `f` is defined as:
```cpp
template<class charT, class traits, class moneyT>
void f(basic_ios<charT, traits>& str, const moneyT& mon, bool intl) {
    using Iter = ostreambuf_iterator<charT, traits>;
    using MoneyPut = money_put<charT, Iter>;
    const MoneyPut& mp = use_facet<MoneyPut>(str.getloc());
    const Iter end = mp.put(Iter(str.rdbuf()), Intl(), Intl, str, str.fill(), mon);
    if (end.failed())
        str.setstate(ios::badbit);
}
```

The expression `out << put_money(mon, intl)` shall have type `basic_ostream<charT, traits>&` and value `out`. 

§ 29.7.7 1358
template<class charT> unspecified get_time(struct tm* tmb, const charT* fmt);

Requirements: The argument tmb shall be a valid pointer to an object of type struct tm. The argument fmt shall be a valid pointer to an array of objects of type charT with char_traits<charT>::length(fmt) elements.

Returns: An object of unspecified type such that if in is an object of type basic_istream<charT, traits> then the expression in >> get_time(tmb, fmt) behaves as if it called f(in, tmb, fmt), where the function f is defined as:

```cpp
template<class charT, class traits>
void f(basic_istream<charT, traits>& str, struct tm* tmb, const charT* fmt) {
  using Iter = istreambuf_iterator<charT, traits>;
  using TimeGet = time_get<charT, Iter>;

  ios_base::iostate err = ios_base::goodbit;
  const TimeGet& tg = use_facet<TimeGet>(str.getloc());

  tg.get(Iter(str.rdbuf()), Iter(), str, err, tmb,
        fmt, fmt + traits::length(fmt));
  if (err != ios_base::goodbit)
    str.setstate(err);
}
```

The expression in >> get_time(tmb, fmt) shall have type basic_istream<charT, traits>& and value in.

template<class charT> unspecified put_time(const struct tm* tmb, const charT* fmt);

Requirements: The argument tmb shall be a valid pointer to an object of type struct tm, and the argument fmt shall be a valid pointer to an array of objects of type charT with char_traits<charT>::length(fmt) elements.

Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> then the expression out << put_time(tmb, fmt) behaves as if it called f(out, tmb, fmt), where the function f is defined as:

```cpp
template<class charT, class traits>
void f(basic_ostream<charT, traits>& str, const struct tm* tmb, const charT* fmt) {
  using Iter = ostreambuf_iterator<charT, traits>;
  using TimePut = time_put<charT, Iter>;

  const TimePut& tp = use_facet<TimePut>(str.getloc());
  const Iter end = tp.put(Iter(str.rdbuf()), str, str.fill(), tmb,
                         fmt, fmt + traits::length(fmt));
  if (end.failed())
    str.setstate(ios_base::badbit);
}
```

The expression out << put_time(tmb, fmt) shall have type basic_ostream<charT, traits>& and value out.

29.7.8 Quoted manipulators [quoted.manip]

Note: Quoted manipulators provide string insertion and extraction of quoted strings (for example, XML and CSV formats). Quoted manipulators are useful in ensuring that the content of a string with embedded spaces remains unchanged if inserted and then extracted via stream I/O.

```cpp
template<class charT>
unspecified quoted(const charT* s, charT delim = charT('"'), charT escape = charT('\\'));
```

```cpp
template<class charT, class traits, class Allocator>
unspecified quoted(const basic_string<charT, traits, Allocator>& s, charT delim = charT('"'), charT escape = charT('\\'));
```
template<class charT, class traits>
   unspecified quoted(basic_string_view<charT, traits> s,
   charT delim = charT('<''), charT escape = charT('"'));

Returns: An object of unspecified type such that if out is an instance of basic_ostream with member type char_type the same as charT and with member type traits_type, which in the second and third forms is the same as traits, then the expression out << quoted(s, delim, escape) behaves as a formatted output function (29.7.5.2.1) of out. This forms a character sequence seq, initially consisting of the following elements:

(2.1) — delim.
(2.2) — Each character in s. If the character to be output is equal to escape or delim, as determined by traits_type::eq, first output escape.
(2.3) — delim.

Let x be the number of elements initially in seq. Then padding is determined for seq as described in 29.7.5.2.1, seq is inserted as if by calling out.rdbuf()->sputn(seq, n), where n is the larger of out.width() and x, and out.width(0) is called. The expression out << quoted(s, delim, escape) shall have type basic_ostream<charT, traits>& and value out.

template<class charT, class traits, class Allocator>
   unspecified quoted(basic_string<charT, traits, Allocator>& s,
   charT delim = charT('<''), charT escape = charT('"'));

Returns: An object of unspecified type such that:

(3.1) — If in is an instance of basic_istream with member types char_type and traits_type the same as charT and traits, respectively, then the expression in >> quoted(s, delim, escape) behaves as if it extracts the following characters from in using operator>>(basic_istream<charT, traits>&, charT&) (29.7.4.2.3) which may throw ios_base::failure (29.5.3.1.1):

(3.1.1) — If the first character extracted is equal to delim, as determined by traits_type::eq, then:
   — Turn off the skipws flag.
   — s.clear()
   — Until an unescaped delim character is reached or !in, extract characters from in and append them to s, except that if an escape is reached, ignore it and append the next character to s.
   — Discard the final delim character.
   — Restore the skipws flag to its original value.
(3.1.2) — Otherwise, in >> s.
(3.2) — If out is an instance of basic_ostream with member types char_type and traits_type the same as charT and traits, respectively, then the expression out << quoted(s, delim, escape) behaves as specified for the const basic_string<charT, traits, Allocator>& overload of the quoted function.

The expression in >> quoted(s, delim, escape) shall have type basic_istream<charT, traits>& and value in. The expression out << quoted(s, delim, escape) shall have type basic_ostream<charT, traits>& and value out.

29.8 String-based streams

29.8.1 Header <sstream> synopsis
The header `<sstream>` defines four class templates and eight types that associate stream buffers with objects of class `basic_string`, as described in 21.3.

### 29.8.2 Class template `basic_stringbuf`

```
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_stringbuf : public basic_streambuf<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;
            using allocator_type = Allocator;

        // 29.8.2.1, constructors
        basic_stringbuf() : basic_stringbuf(ios_base::in | ios_base::out) {} // basic_stringbuf
        explicit basic_stringbuf(ios_base::openmode which); // explicit basic_stringbuf
        explicit basic_stringbuf(
            const basic_string<charT, traits, Allocator>& str,
            ios_base::openmode which = ios_base::in | ios_base::out);
        basic_stringbuf(const basic_stringbuf& rhs) = delete;
        basic_stringbuf(basic_stringbuf&& rhs);

        // 29.8.2.2, assign and swap
        basic_stringbuf& operator=(const basic_stringbuf& rhs) = delete;
        basic_stringbuf& operator=(basic_stringbuf&& rhs);
        void swap(basic_stringbuf& rhs);

        // 29.8.2.3, get and set
        basic_string<charT, traits, Allocator>& str() const;
        void str(const basic_string<charT, traits, Allocator>& s);

        protected:
            // 29.8.2.4, overridden virtual functions
            int_type underflow() override;
            int_type pbackfail(int_type c = traits::eof()) override;
            int_type overflow (int_type c = traits::eof()) override;
            basic_streambuf<charT, traits>* setbuf(charT*, streamsize) override;

            pos_type seekoff(off_type off, ios_base::seekdir way,
                             ios_base::openmode which
                             = ios_base::in | ios_base::out) override;
```
The class `basic_stringbuf` is derived from `basic_streambuf` to associate possibly the input sequence and possibly the output sequence with a sequence of arbitrary characters. The sequence can be initialized from, or made available as, an object of class `basic_string`.

For the sake of exposition, the maintained data is presented here as:

(2.1) — `ios_base::openmode mode`, has `in` set if the input sequence can be read, and `out` set if the output sequence can be written.

### 29.8.2.1 Constructors

#### [stringbuf.cons]

**explicit basic_stringbuf(ios_base::openmode which);**

**Effects:** Constructs an object of class `basic_stringbuf`, initializing the base class with `basic_streambuf()` (29.6.3.1), and initializing `mode` with `which`. It is implementation-defined whether the sequence pointers (`eback()`, `gptr()`, `egptr()`, `pbase()`, `pptr()`, `epptr()`) are initialized to null pointers.

**Ensures:** `str() == ""`. [stringbuf.str]

**explicit basic_stringbuf(const basic_string<charT, traits, Allocator>& s, ios_base::openmode which = ios_base::in | ios_base::out);**

**Effects:** Constructs an object of class `basic_stringbuf`, initializing the base class with `basic_streambuf()` (29.6.3.1), and initializing `mode` with `which`. Then calls `str(s)`.

**basic_stringbuf(basic_stringbuf&& rhs);**

**Effects:** Move constructs from the rvalue `rhs`. It is implementation-defined whether the sequence pointers in `*this` (`eback()`, `gptr()`, `egptr()`, `pbase()`, `pptr()`, `epptr()`) obtain the values which `rhs` had. Whether they do or not, `*this` and `rhs` reference separate buffers (if any at all) after the construction. The openmode, locale and any other state of `rhs` is also copied.

**Ensures:** Let `rhs_p` refer to the state of `rhs` just prior to this construction and let `rhs_a` refer to the state of `rhs` just after this construction.

1. `str() == rhs_p.str()`
2. `gptr() - eback() == rhs_p.gptr() - rhs_p.eback()`
3. `egptr() - eback() == rhs_p.egptr() - rhs_p.eback()`
4. `pptr() - pbase() == rhs_p.pptr() - rhs_p.pbase()`
5. `epptr() - pbase() == rhs_p.epptr() - rhs_p.pbase()`
6. `if (eback()) eback() != rhs_a.eback()`
7. `if (gptr()) gptr() != rhs_a.gptr()`
8. `if (egptr()) egptr() != rhs_a.egptr()`
9. `if (pbase()) pbase() != rhs_a.pbase()`
10. `if (pptr()) pptr() != rhs_a.pptr()`
11. `if (epptr()) epptr() != rhs_a.epptr()`
29.8.2.2 Assignment and swap

basic_stringbuf\& operator=(basic_stringbuf\&\& rhs);

Effects: After the move assignment \*this has the observable state it would have had if it had been
move constructed from rhs (see 29.8.2.1).

Returns: \*this.

void swap(basic_stringbuf\& rhs);

Effects: Exchanges the state of \*this and rhs.

template<class charT, class traits, class Allocator>
void swap(basic_stringbuf<charT, traits, Allocator>\& x,
          basic_stringbuf<charT, traits, Allocator>\& y);

Effects: As if by x.swap(y).

29.8.2.3 Member functions

basic_string<charT, traits, Allocator> str() const;

Returns: A basic_string object whose content is equal to the basic_stringbuf underlying character
sequence. If the basic_stringbuf was created only in input mode, the resultant basic_string
contains the character sequence in the range [eback(), egptr()). If the basic_stringbuf was
created with which \& ios_base::out being nonzero then the resultant basic_string contains the
character sequence in the range [pbase(), high_mark), where high_mark represents the position one
past the highest initialized character in the buffer. Characters can be initialized by writing to the stream,
by constructing the basic_stringbuf with a basic_string, or by calling the str(basic_string)
member function. In the case of calling the str(basic_string) member function, all characters
initialized prior to the call are now considered uninitialized (except for those characters re-initialized
by the new basic_string). Otherwise the basic_stringbuf has been created in neither input nor
output mode and a zero length basic_string is returned.

void str(const basic_string<charT, traits, Allocator>& s);

Effects: Copies the content of s into the basic_stringbuf underlying character sequence and initializes
the input and output sequences according to mode.

Ensures: If mode \& ios_base::out is nonzero, pbase() points to the first underlying character and
egptr() >= pbase() + s.size() holds; in addition, if mode \& ios_base::ate is nonzero, pptr()
== pbase() + s.size() holds, otherwise pptr() == pbase() is true. If mode \& ios_base::in is
nonzero, eback() points to the first underlying character, and both gptr() == eback() and egptr()
== eback() + s.size() hold.

29.8.2.4 Overridden virtual functions

int_type underflow() override;

Returns: If the input sequence has a read position available, returns traits::to_int_type(*gptr()).
Otherwise, returns traits::eof(). Any character in the underlying buffer which has been initialized
is considered to be part of the input sequence.

int_type pbackfail(int_type c = traits::eof()) override;

Effects: Puts back the character designated by c to the input sequence, if possible, in one of three ways:

(2.1) If traits::eq_int_type(c, traits::eof()) returns false and if the input sequence has a
putback position available, and if traits::eq(to_char_type(c), gptr()[-1]) returns true,
assigns gptr() - 1 to gptr().

Returns: c.

(2.2) If traits::eq_int_type(c, traits::eof()) returns false and if the input sequence has a
putback position available, and if mode \& ios_base::out is nonzero, assigns c to \*--gptr().

Returns: c.

(2.3) If traits::eq_int_type(c, traits::eof()) returns true and if the input sequence has a
putback position available, assigns gptr() - 1 to gptr().
Returns: \texttt{traits::not\_eof(c)}.

\textbf{Returns:} As specified above, or \texttt{traits::eof()} to indicate failure.

\textbf{Remarks:} If the function can succeed in more than one of these ways, it is unspecified which way is chosen.

\begin{verbatim}
int_type overflow(int_type c = traits::eof()) override;
\end{verbatim}

\textbf{Effects:} Appends the character designated by \texttt{c} to the output sequence, if possible, in one of two ways:

\begin{enumerate}
\item If \texttt{traits::eq\_int\_type(c, traits::eof())} returns \texttt{false} and if either the output sequence has a write position available or the function makes a write position available (as described below), the function calls \texttt{sputc(c)}.
\item Signals success by returning \texttt{c}.
\end{enumerate}

\begin{enumerate}
\item If \texttt{traits::eq\_int\_type(c, traits::eof())} returns \texttt{true}, there is no character to append.
\item Signals success by returning a value other than \texttt{traits::eof()}.
\end{enumerate}

\textbf{Remarks:} The function can alter the number of write positions available as a result of any call.

\textbf{Returns:} As specified above, or \texttt{traits::eof()} to indicate failure.

The function can make a write position available only if \texttt{(mode & ios\_base::out) != 0}. To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements to hold the current array object (if any), plus at least one additional write position. If \texttt{(mode & ios\_base::in) != 0}, the function alters the read end pointer \texttt{egptr()} to point just past the new write position.

\begin{verbatim}
pos_type seekoff(off_type off, ios_base::seekdir way, 
    ios_base::openmode which = ios_base::in | ios_base::out) override;
\end{verbatim}

\textbf{Effects:} Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 112.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
Conditions & Result \\
\hline
\texttt{(which & ios\_base::in) == ios\_base::in} & positions the input sequence \\
\texttt{(which & ios\_base::out) == ios\_base::out} & positions the output sequence \\
\texttt{(which & (ios\_base::in | ios\_base::out)) == (ios\_base::in | ios\_base::out)} & positions both the input and the output sequences if \texttt{which & ios\_base::in} or \texttt{which & ios\_base::out} and either \texttt{way == ios\_base::beg} or \texttt{way == ios\_base::end} \\
Otherwise & the positioning operation fails. \\
\hline
\end{tabular}
\caption{seekoff positioning}
\end{table}

\textbf{Conditions}

\textbf{Returns:} \texttt{pos\_type(newoff)}, constructed from the resultant offset \texttt{newoff} (of type \texttt{off\_type}), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is \texttt{pos\_type(off\_type(-1))}.

\section*{§ 29.8.2.4}

\texttt{N4820}
Table 113: newoff values

<table>
<thead>
<tr>
<th>Condition</th>
<th>newoff Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>way == ios_base::beg</td>
<td>0</td>
</tr>
<tr>
<td>way == ios_base::cur</td>
<td>the next pointer minus the beginning pointer (xnext - xbeg).</td>
</tr>
<tr>
<td>way == ios_base::end</td>
<td>the high mark pointer minus the beginning pointer (high_mark - xbeg).</td>
</tr>
</tbody>
</table>

```cpp
pos_type seekpos(pos_type sp,
    ios_base::openmode which = ios_base::in | ios_base::out) override;
```

**Effects:** Equivalent to `seekoff(off_type(sp), ios_base::beg, which)`.

**Returns:** `sp` to indicate success, or `pos_type(off_type(-1))` to indicate failure.

```cpp
basic_streambuf<charT, traits>* setbuf(charT* s, streamsize n);
```

**Effects:** implementation-defined, except that `setbuf(0, 0)` has no effect.

**Returns:** `this`.

### 29.8.3 Class template basic_istringstream

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_istringstream : public basic_istream<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;
            using allocator_type = Allocator;

            // 29.8.3.1, constructors
            basic_istringstream() : basic_istringstream(ios_base::in) {}
            explicit basic_istringstream(ios_base::openmode which);
            explicit basic_istringstream(  
                const basic_string<charT, traits, Allocator>& str,
                ios_base::openmode which = ios_base::in);
            basic_istringstream(const basic_istringstream& rhs) = delete;
            basic_istringstream(basic_istringstream&& rhs);

            // 29.8.3.2, assign and swap
            basic_istringstream& operator=(const basic_istringstream& rhs) = delete;
            basic_istringstream& operator=(basic_istringstream&& rhs);
            void swap(basic_istringstream& rhs);

            // 29.8.3.3, members
            basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

            basic_string<charT, traits, Allocator> str() const;
            void str(const basic_string<charT, traits, Allocator>& s);
        private:
            basic_stringbuf<charT, traits, Allocator> sb; // exposition only
        }
    }
}
```
template<class charT, class traits, class Allocator>
  void swap(basic_istringstream<charT, traits, Allocator>& x,
            basic_istringstream<charT, traits, Allocator>& y);
}

The class basic_istringstream<charT, traits, Allocator> supports reading objects of class basic_string<charT, traits, Allocator>. It uses a basic_stringbuf<charT, traits, Allocator> object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

— sb, the stringbuf object.

### 29.8.3.1 Constructors

**[istringstream.cons]**

```
explicit basic_istringstream(ios_base::openmode which);
```

**Effects:** Constructs an object of class `basic_istringstream<charT, traits>`, initializing the base class with `basic_istream<charT, traits>(addressof(sb))` (29.7.4.1) and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(which | ios_base::in)` (29.8.2.1).

```
explicit basic_istringstream(const basic_string<charT, traits, Allocator>& str,
                            ios_base::openmode which = ios_base::in);
```

**Effects:** Constructs an object of class `basic_istringstream<charT, traits>`, initializing the base class with `basic_istream<charT, traits>(addressof(sb))` (29.7.4.1) and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(str, which | ios_base::in)` (29.8.2.1).

```
basic_istringstream(basic_istringstream&& rhs);
```

**Effects:** Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Next `basic_istream<charT, traits>::set_rdbuf(addressof(sb))` is called to install the contained `basic_stringbuf`.

### 29.8.3.2 Assignment and swap

**[istringstream.assign]**

```
basic_istringstream& operator=(basic_istringstream&& rhs);
```

**Effects:** Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

```
void swap(basic_istringstream& rhs);
```

**Effects:** Exchanges the state of `*this` and `rhs` by calling `basic_istream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template<class charT, class traits, class Allocator>
  void swap(basic_istringstream<charT, traits, Allocator>& x,
            basic_istringstream<charT, traits, Allocator>& y);
```

**Effects:** As if by `x.swap(y)`.

### 29.8.3.3 Member functions

**[istringstream.members]**

```
basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
```

**Returns:** `const_cast<basic_stringbuf<charT, traits, Allocator>*>(addressof(sb))`.

```
basic_string<charT, traits, Allocator> str() const;
```

**Returns:** `rdbuf()->str()`.

```
void str(const basic_string<charT, traits, Allocator>& s);
```

**Effects:** Calls `rdbuf()->str(s)`.
29.8.4 Class template basic_ostringstream

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_ostringstream : public basic_ostream<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;
            using allocator_type = Allocator;

            // 29.8.4.1, constructors
            basic_ostringstream() : basic_ostringstream(ios_base::out) {};
            explicit basic_ostringstream(ios_base::openmode which);
            explicit basic_ostringstream(
                const basic_string<charT, traits, Allocator>& str,
                ios_base::openmode which = ios_base::out);
            basic_ostringstream(const basic_ostringstream& rhs) = delete;
            basic_ostringstream(basic_ostringstream&& rhs);

            // 29.8.4.2, assign and swap
            basic_ostringstream& operator=(const basic_ostringstream& rhs) = delete;
            basic_ostringstream& operator=(basic_ostringstream&& rhs);
            void swap(basic_ostringstream& rhs);

            // 29.8.4.3, members
            basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
            basic_string<charT, traits, Allocator> str() const;
            void str(const basic_string<charT, traits, Allocator>& s);
            private:
                basic_stringbuf<charT, traits, Allocator> sb; // exposition only
            }
    }
}
```

1 The class `basic_ostringstream<charT, traits, Allocator>` supports writing objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf` object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

(1.1) — `sb`, the `stringbuf` object.

29.8.4.1 Constructors

```cpp
explicit basic_ostringstream(ios_base::openmode which);
```

1 **Effects:** Constructs an object of class `basic_ostringstream<charT, traits>`, initializing the base class with `basic_ostream<charT, traits>>(addressof(sb))` (29.7.5.1) and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(which | ios_base::out)` (29.8.2.1).

```cpp
explicit basic_ostringstream(
    const basic_string<charT, traits, Allocator>& str,
    ios_base::openmode which = ios_base::out);
```

2 **Effects:** Constructs an object of class `basic_ostringstream<charT, traits>`, initializing the base class with `basic_ostream<charT, traits>>(addressof(sb))` (29.7.5.1) and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(str, which | ios_base::out)` (29.8.2.1).
basic_ostringstream(basic_ostringstream&& rhs);

   Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_stringbuf. Next basic_ostream<charT, traits>::set_rdbuf(addressof(sb)) is called to install the contained basic_stringbuf.

29.8.4.2 Assignment and swap [ostringstream.assign]

basic_ostringstream& operator=(basic_ostringstream&& rhs);

   Effects: Move assigns the base and members of *this from the base and corresponding members of rhs.

Returns: *this.

void swap(basic_ostringstream& rhs);

   Effects: Exchanges the state of *this and rhs by calling basic_ostream<charT, traits>::swap(rhs) and sb.swap(rhs.sb).

template<class charT, class traits, class Allocator>
void swap(basic_ostringstream<charT, traits, Allocator>& x,
          basic_ostringstream<charT, traits, Allocator>& y);

   Effects: As if by x.swap(y).

29.8.4.3 Member functions [ostringstream.members]

basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

   Returns: const_cast<basic_stringbuf<charT, traits, Allocator>*>(addressof(sb)).

basic_string<charT, traits, Allocator> str() const;

   Returns: rdbuf()->str().

void str(const basic_string<charT, traits, Allocator>& s);

   Effects: Calls rdbuf()->str(s).

29.8.5 Class template basic_stringstream [stringstream]

namespace std {
   template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>
   class basic_stringstream : public basic_iostream<charT, traits> {
   public:
      using char_type = charT;
      using int_type = typename traits::int_type;
      using pos_type = typename traits::pos_type;
      using off_type = typename traits::off_type;
      using traits_type = traits;
      using allocator_type = Allocator;

      // 29.8.5.1, constructors
      basic_stringstream() : basic_stringstream(ios_base::out | ios_base::in) {}
      explicit basic_stringstream(ios_base::openmode which);
      explicit basic_stringstream(
           const basic_string<charT, traits, Allocator>& str,
           ios_base::openmode which = ios_base::out | ios_base::in);
      basic_stringstream(const basic_stringstream& rhs) = delete;
      basic_stringstream(basic_stringstream&& rhs);

      // 29.8.5.2, assign and swap
      basic_stringstream& operator=(const basic_stringstream& rhs) = delete;
      basic_stringstream& operator=(basic_stringstream&& rhs);
      void swap(basic_stringstream& rhs);

   }

§ 29.8.5 1368
The class template `basic_stringstream<charT, traits>` supports reading and writing from objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf<charT, traits, Allocator>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as

(1.1) \( sb \), the stringbuf object.

### 29.8.5.1 Constructors

#### [stringstream.cons]

**explicit basic_stringstream(ios_base::openmode which);**

*Effects:* Constructs an object of class `basic_stringstream<charT, traits>`, initializing the base class with `basic_iostream<charT, traits>(addressof(sb))` (29.7.4.6.1) and initializing \( sb \) with `basic_stringbuf<charT, traits, Allocator>(which)`. 

**explicit basic_stringstream(const basic_string<charT, traits, Allocator>& str, ios_base::openmode which = ios_base::out | ios_base::in);**

*Effects:* Constructs an object of class `basic_stringstream<charT, traits>`, initializing the base class with `basic_iostream<charT, traits>(addressof(sb))` (29.7.4.6.1) and initializing \( sb \) with `basic_stringbuf<charT, traits, Allocator>(str, which)`. 

**basic_stringstream(basic_stringstream&& rhs);**

*Effects:* Move constructs from the rvalue \( rhs \). This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Next `basic_istream<charT, traits>::set_rdbuf(addressof(sb))` is called to install the contained `basic_stringbuf`. 

### 29.8.5.2 Assignment and swap

#### [stringstream.assign]

**basic_stringstream& operator=(basic_stringstream&& rhs);**

*Effects:* Move assigns the base and members of \*this from the base and corresponding members of \( rhs \). 

*Returns:* \*this.

**void swap(basic_stringstream& rhs);**

*Effects:* Exchanges the state of \*this and \( rhs \) by calling `basic_istream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`. 

**template<class charT, class traits, class Allocator>**

**void swap(basic_stringstream<charT, traits, Allocator>& x, basic_stringstream<charT, traits, Allocator>& y);**

*Effects:* As if by \( x\).swap(y). 

### 29.8.5.3 Member functions

#### [stringstream.members]

**basic_stringbuf<charT, traits, Allocator>* rdbuf() const;**

*Returns:* `const_cast<basic_stringbuf<charT, traits, Allocator>*>(addressof(sb))`. 

---

1 The class template `basic_stringstream<charT, traits>` supports reading and writing from objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf<charT, traits, Allocator>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as (1.1) \( sb \), the stringbuf object.
basic_string<charT, traits, Allocator> str() const;

Returns: rdbuf()->str().

void str(const basic_string<charT, traits, Allocator>& str);

Effects: Calls rdbuf()->str(str).

29.9 File-based streams

29.9.1 Header <fstream> synopsis

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_filebuf;
    using filebuf = basic_filebuf<char>;
    using wfilebuf = basic_filebuf<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
    class basic_ifstream;
    using ifstream = basic_ifstream<char>;
    using wifstream = basic_ifstream<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
    class basic_ofstream;
    using ofstream = basic_ofstream<char>;
    using wofstream = basic_ofstream<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
    class basic_fstream;
    using fstream = basic_fstream<char>;
    using wfstream = basic_fstream<wchar_t>;
}

The header <fstream> defines four class templates and eight types that associate stream buffers with files and assist reading and writing files.

[Note: The class template basic_filebuf treats a file as a source or sink of bytes. In an environment that uses a large character set, the file typically holds multibyte character sequences and the basic_filebuf object converts those multibyte sequences into wide character sequences. —end note]

2 In this subclause, member functions taking arguments of const filesystem::path::value_type* are only be provided on systems where filesystem::path::value_type (29.11.7) is not char. [Note: These functions enable class path support for systems with a wide native path character type, such as wchar_t. —end note]

29.9.2 Class template basic_filebuf

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_filebuf : public basic_streambuf<charT, traits> {

    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        // 29.9.2.1, constructors/destructor
        basic_filebuf();
        basic_filebuf(const basic_filebuf& rhs) = delete;
        basic_filebuf(basic_filebuf&& rhs);
        virtual ~basic_filebuf();

        // 29.9.2.2, assign and swap
        basic_filebuf& operator=(const basic_filebuf& rhs) = delete;
        basic_filebuf& operator=(basic_filebuf&& rhs);
        void swap(basic_filebuf& rhs);
    }

§ 29.9.2 1370
The class `basic_filebuf<charT, traits>` associates both the input sequence and the output sequence with a file.

The restrictions on reading and writing a sequence controlled by an object of class `basic_filebuf<charT, traits>` are the same as for reading and writing with the C standard library `FILE`s.

In particular:

1. If the file is not open for reading the input sequence cannot be read.
2. If the file is not open for writing the output sequence cannot be written.
3. A joint file position is maintained for both the input sequence and the output sequence.

An instance of `basic_filebuf` behaves as described in 29.9.2 provided `traits::pos_type` is `fpos<traits::state_type>`. Otherwise the behavior is undefined.

In order to support file I/O and multibyte/wide character conversion, conversions are performed using members of a facet, referred to as `a_codecvt` in following subclauses, obtained as if by

```c++
const codecvt<charT, char, typename traits::state_type>& a_codecvt = use_facet<codecvt<charT, char, typename traits::state_type>>(getloc());
```

### 29.9.2.1 Constructors

```c++
basic_filebuf();
```  
1. **Effects:** Constructs an object of class `basic_filebuf<charT, traits>`, initializing the base class with `basic_streambuf<charT, traits>()` (29.6.3.1).
2. **Ensures:** `is_open() == false`.  

§ 29.9.2.1 1371
basic_filebuf(basic_filebuf&& rhs);

**Effects:** Move constructs from the rvalue rhs. It is implementation-defined whether the sequence pointers in *this (eback(), gptr(), egptr(), pbase(), pptr(), epptr()) obtain the values which rhs had. Whether they do or not, *this and rhs reference separate buffers (if any at all) after the construction. Additionally *this references the file which rhs did before the construction, and rhs references no file after the construction. The openmode, locale and any other state of rhs is also copied.

**Ensures:** Let rhs_p refer to the state of rhs just prior to this construction and let rhs_a refer to the state of rhs just after this construction.

![List of assertions](4.1) - ![List of assertions](4.2) - ![List of assertions](4.3) - ![List of assertions](4.4) - ![List of assertions](4.5) - ![List of assertions](4.6) - ![List of assertions](4.7) - ![List of assertions](4.8) - ![List of assertions](4.9) - ![List of assertions](4.10) - ![List of assertions](4.11) - ![List of assertions](4.12)

virtual ~basic_filebuf();

**Effects:** Destroys an object of class basic_filebuf<CharT, traits>. Calls close(). If an exception occurs during the destruction of the object, including the call to close(), the exception is caught but not rethrown (see 16.5.5.12).

### 29.9.2.2 Assignment and swap

basic_filebuf& operator=(basic_filebuf&& rhs);

**Effects:** Calls close() then move assigns from rhs. After the move assignment *this has the observable state it would have had if it had been move constructed from rhs (see 29.9.2.1).

**Returns:** *this.

void swap(basic_filebuf& rhs);

**Effects:** Exchanges the state of *this and rhs.

template<class CharT, class Traits>
void swap(basic_filebuf<CharT, Traits>& x, basic_filebuf<CharT, Traits>& y);

**Effects:** As if by x.swap(y).

### 29.9.2.3 Member functions

bool is_open() const;

**Returns:** true if a previous call to open succeeded (returned a non-null value) and there has been no intervening call to close.

basic_filebuf* open(const CharT* s, ios_base::openmode mode);
basic_filebuf* open(const filesystem::path::value_type* s, ios_base::openmode mode); // wide systems only; see 29.9.1

**Expects:** s shall point to a NTCTS (16.3.17).

**Effects:** If is_open() != false, returns a null pointer. Otherwise, initializes the filebuf as required. It then opens the file to which s resolves, if possible, as if by a call to fopen with the second argument
determined from `mode & ~ios_base::ate` as indicated in Table 114. If `mode` is not some combination of flags shown in the table then the open fails.

Table 114: File open modes

</tbody>
</table>

If the open operation succeeds and (`mode & ios_base::ate`) != 0, positions the file to the end (as if by calling `fseek(file, 0, SEEK_END)`), where `file` is the pointer returned by calling `fopen`).327

If the repositioning operation fails, calls `close()` and returns a null pointer to indicate failure.

Returns: `this` if successful, a null pointer otherwise.

```cpp
basic_filebuf* open(const string& s, ios_base::openmode mode);
```

Returns: `open(s.c_str(), mode);`

```cpp
basic_filebuf* close();
```

Effects: If `is_open() == false`, returns a null pointer. If a put area exists, calls `overflow(traits::eof())` to flush characters. If the last virtual member function called on `*this` (between `underflow, overflow, seekoff, and seekpos`) was `overflow` then calls `a_codecvt.unshift` (possibly several times) to determine a termination sequence, inserts those characters and calls `overflow(traits::eof())` again. Finally, regardless of whether any of the preceding calls fails or throws an exception, the function closes the file (as if by calling `fclose(file)`). If any of the calls made by the function, including `fclose`, fails, `close` fails by returning a null pointer. If one of these calls throws an exception, the exception is caught and rethrown after closing the file.

Returns: `this` on success, a null pointer otherwise.

Ensures: `is_open() == false`.

29.9.2.4 Overridden virtual functions

```cpp
streamsize showmanyc() override;
```

Effects: Behaves the same as `basic_streambuf::showmanyc()` (29.6.3.4).

Remarks: An implementation might well provide an overriding definition for this function signature if it can determine that more characters can be read from the input sequence.

327) The macro `SEEK_END` is defined, and the function signatures `fopen(const char*, const char*)` and `fseek(FILE*, long, int)` are declared, in `<cstdio>` (29.12.1).
int_type underflow() override;

Effects: Behaves according to the description of basic_streambuf<charT, traits>::underflow(), with the specialization that a sequence of characters is read from the input sequence as if by reading from the associated file into an internal buffer (extern_buf) and then as if by doing:

char  extern_buf[XSIZE];
char*  extern_end;
charT intern_buf[ISIZE];
charT* intern_end;
ccodecvt_base::result r =
a Codecvt.in(state, extern_buf, extern_buf+XSIZE, extern_end,  
  intern_buf, intern_buf+ISIZE, intern_end);

This shall be done in such a way that the class can recover the position (fpos_t) corresponding to each character between intern_buf and intern_end. If the value of r indicates that a Codecvt.in() ran out of space in intern_buf, retry with a larger intern_buf.

int_type uflow() override;

Effects: Behaves according to the description of basic_streambuf<charT, traits>::uflow(), with the specialization that a sequence of characters is read from the input with the same method as used by underflow.

int_type pbackfail(int_type c = traits::eof()) override;

Effects: Puts back the character designated by c to the input sequence, if possible, in one of three ways:

(5.1) If traits::eq_int_type(c, traits::eof()) returns false and if the function makes a putback position available and if traits::eq(to_char_type(c), gptr()[−1]) returns true, decrements the next pointer for the input sequence, gptr().

Returns: c.

(5.2) If traits::eq_int_type(c, traits::eof()) returns false and if the function makes a putback position available and if the function is permitted to assign to the putback position, decrements the next pointer for the input sequence, and stores c there.

Returns: c.

(5.3) If traits::eq_int_type(c, traits::eof()) returns true, and if either the input sequence has a putback position available or the function makes a putback position available, decrements the next pointer for the input sequence, gptr().

Returns: traits::not_eof(c).

Returns: As specified above, or traits::eof() to indicate failure.

Remarks: If is_open() == false, the function always fails.

The function does not put back a character directly to the input sequence.

If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

int_type overflow(int_type c = traits::eof()) override;

Effects: Behaves according to the description of basic_streambuf<charT, traits>::overflow(c), except that the behavior of “consuming characters” is performed by first converting as if by:

char  b = pbase();
charT p = pptr();
charT end;
char  xbuf[XSIZE];
char* xbuf_end;
ccodecvt_base::result r =
a Codecvt.out(state, b, p, end, xbuf, xbuf+XSIZE, xbuf_end);

and then

(10.1) If r == codecvt_base::error then fail.

(10.2) If r == codecvt_base::noconv then output characters from b up to (and not including) p.
basic_streambuf* setbuf(char_type* s, streamsize n) override;

Effects: If setbuf(0, 0) is called on a stream before any I/O has occurred on that stream, the stream becomes unbuffered. Otherwise the results are implementation-defined. “Unbuffered” means that pbase() and pptr() always return null and output to the file should appear as soon as possible.

pos_type seekoff(off_type off, ios_base::seekdir way, ios_base::openmode which = ios_base::in | ios_base::out) override;

Effects: Let width denote a_codecvt.encoding(). If is_open() == false, or off != 0 && width <= 0, then the positioning operation fails. Otherwise, if way != basic_ios::cur or off != 0, and if the last operation was output, then update the output sequence and write any unshift sequence. Next, seek to the new position: if width > 0, call fseek(file, width * off, whence), otherwise call fseek(file, 0, whence).

Remarks: “The last operation was output” means either the last virtual operation was overflow or the put buffer is non-empty. “Write any unshift sequence” means, if width if less than zero then call a_codecvt.unshift(state, xbuf, xbuf+XSIZE, xbuf_end) and output the resulting unshift sequence. The function determines one of three values for the argument whence, of type int, as indicated in Table 115.

Table 115: seekoff effects

<table>
<thead>
<tr>
<th>way</th>
<th>stdio Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basic_ios::beg</td>
<td>SEEK_SET</td>
</tr>
<tr>
<td>basic_ios::cur</td>
<td>SEEK_CUR</td>
</tr>
<tr>
<td>basic_ios::end</td>
<td>SEEK_END</td>
</tr>
</tbody>
</table>

Returns: A newly constructed pos_type object that stores the resultant stream position, if possible. If the positioning operation fails, or if the object cannot represent the resultant stream position, returns pos_type(off_type(-1)).

pos_type seekpos(pos_type sp, ios_base::openmode which = ios_base::in | ios_base::out) override;

Alters the file position, if possible, to correspond to the position stored in sp (as described below). Altering the file position performs as follows:

1. if (om & ios_base::out) != 0, then update the output sequence and write any unshift sequence;
2. set the file position to sp as if by a call to fsetpos;
3. if (om & ios_base::in) != 0, then update the input sequence;

where om is the open mode passed to the last call to open(). The operation fails if is_open() returns false.

If sp is an invalid stream position, or if the function positions neither sequence, the positioning operation fails. If sp has not been obtained by a previous successful call to one of the positioning functions (seekoff or seekpos) on the same file the effects are undefined.

Returns: sp on success. Otherwise returns pos_type(off_type(-1)).

int sync() override;

Effects: If a put area exists, calls filebuf::overflow to write the characters to the file, then flushes the file as if by calling fflush(file). If a get area exists, the effect is implementation-defined.
void imbue(const locale& loc) override;

20  Requires: If the file is not positioned at its beginning and the encoding of the current locale as determined by a_codecvt.encoding() is state-dependent (28.4.1.4.2) then that facet is the same as the corresponding facet of loc.

21  Effects: Causes characters inserted or extracted after this call to be converted according to loc until another call of imbue.

22  Remarks: This may require reconversion of previously converted characters. This in turn may require the implementation to be able to reconstruct the original contents of the file.

29.9.3  Class template basic_ifstream

namespace std {

template<class charT, class traits = char_traits<charT>>
class basic_ifstream : public basic_istream<charT, traits> { public:
  using char_type = charT;
  using int_type = typename traits::int_type;
  using pos_type = typename traits::pos_type;
  using off_type = typename traits::off_type;
  using traits_type = traits;

  // 29.9.3.1, constructors
  basic_ifstream();
  explicit basic_ifstream(const char* s,
                          ios_base::openmode mode = ios_base::in);
  explicit basic_ifstream(const filesystem::path::value_type* s,
                          ios_base::openmode mode = ios_base::in); // wide systems only; see 29.9.1
  explicit basic_ifstream(const string& s,
                          ios_base::openmode mode = ios_base::in);
  explicit basic_ifstream(const filesystem::path& s,
                          ios_base::openmode mode = ios_base::in);
  basic_ifstream(const basic_ifstream& rhs) = delete;
  basic_ifstream(basic_ifstream&& rhs);

  // 29.9.3.2, assign and swap
  basic_ifstream& operator=(const basic_ifstream& rhs) = delete;
  basic_ifstream& operator=(basic_ifstream&& rhs);

  void swap(basic_ifstream& rhs);

  // 29.9.3.3, members
  basic_filebuf<charT, traits>* rdbuf() const;

  bool is_open() const;
  void open(const char* s, ios_base::openmode mode = ios_base::in);
  void open(const filesystem::path::value_type* s,
            ios_base::openmode mode = ios_base::in); // wide systems only; see 29.9.1
  void open(const string& s, ios_base::openmode mode = ios_base::in);
  void open(const filesystem::path& s, ios_base::openmode mode = ios_base::in);
  void close();

  private:
    basic_filebuf<charT, traits> sb; // exposition only
  };

};

template<class charT, class traits>
void swap(basic_ifstream<charT, traits>& x,
          basic_ifstream<charT, traits>& y);
}

1 The class basic_ifstream<charT, traits> supports reading from named files. It uses a basic_filebuf<charT, traits> object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

(1.1) — sb, the filebuf object.
29.9.3.1 Constructors

basic_ifstream();

Effects: Constructs an object of class basic_ifstream<charT, traits>, initializing the base class with basic_istream<charT, traits>(addressof(sb)) (29.7.4.1.1) and initializing sb with basic_filebuf<charT, traits>() (29.9.2.1).

explicit basic_ifstream(const char* s, ios_base::openmode mode = ios_base::in);
explicit basic_ifstream(const filesystem::path::value_type* s, ios_base::openmode mode = ios_base::in); // wide systems only; see 29.9.1

Effects: Constructs an object of class basic_ifstream<charT, traits>, initializing the base class with basic_istream<charT, traits>(addressof(sb)) (29.7.4.1.1) and initializing sb with basic_filebuf<charT, traits>() (29.9.2.1), then calls rdbuf()->open(s, mode | ios_base::in). If that function returns a null pointer, calls setstate(failbit).

explicit basic_ifstream(const string& s, ios_base::openmode mode = ios_base::in);

Effects: The same as basic_ifstream(s.c_str(), mode).

basic_ifstream(basic_ifstream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_filebuf. Next basic_istream<charT, traits>::set_rdbuf(addressof(sb)) is called to install the contained basic_filebuf.

29.9.3.2 Assignment and swap

basic_ifstream& operator=(basic_ifstream&& rhs);

Effects: Move assigns the base and members of *this from the base and corresponding members of rhs.

Returns: *this.

void swap(basic_ifstream& rhs);

Effects: Exchanges the state of *this and rhs by calling basic_istream<charT, traits>::swap(rhs) and sb.swap(rhs.sb).

template<class charT, class traits>
void swap(basic_ifstream<charT, traits>& x, basic_ifstream<charT, traits>& y);

Effects: As if by x.swap(y).

29.9.3.3 Member functions

basic_filebuf<charT, traits>* rdbuf() const;

Returns: const_cast<basic_filebuf<charT, traits>*>(addressof(sb)).

bool is_open() const;

Returns: rdbuf()->is_open().

void open(const char* s, ios_base::openmode mode = ios_base::in);
void open(const filesystem::path::value_type* s, ios_base::openmode mode = ios_base::in); // wide systems only; see 29.9.1

Effects: Calls rdbuf()->open(s, mode | ios_base::in). If that function does not return a null pointer calls clear(), otherwise calls setstate(failbit) (which may throw ios_base::failure) (29.5.5.4).
void open(const string& s, ios_base::openmode mode = ios_base::in);
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::in);

Effects: Calls open(s.c_str(), mode).

void close();

Effects: Calls rdbuf()->close() and, if that function returns a null pointer, calls setstate(failbit)
(which may throw ios_base::failure) (29.5.5.4).

29.9.4 Class template basic_ofstream

namespace std {

template<class charT, class traits = char_traits<charT>>
class basic_ofstream : public basic_ostream<charT, traits> {
public:
using char_type = charT;
using int_type = typename traits::int_type;
using pos_type = typename traits::pos_type;
using off_type = typename traits::off_type;
using traits_type = traits;

// 29.9.4.1, constructors
basic_ofstream();
explicit basic_ofstream(const char* s,
   ios_base::openmode mode = ios_base::out);
explicit basic_ofstream(const filesystem::path::value_type* s,
   ios_base::openmode mode = ios_base::out); // wide systems only; see 29.9.1
explicit basic_ofstream(const string& s,
   ios_base::openmode mode = ios_base::out);
explicit basic_ofstream(const filesystem::path& s,
   ios_base::openmode mode = ios_base::out);
basic_ofstream(const basic_ofstream& rhs) = delete;
basic_ofstream(basic_ofstream&& rhs);

// 29.9.4.2, assign and swap
basic_ofstream& operator=(const basic_ofstream& rhs) = delete;
basic_ofstream& operator=(basic_ofstream&& rhs);
void swap(basic_ofstream& rhs);

// 29.9.4.3, members
basic_filebuf<charT, traits>* rdbuf() const;

bool is_open() const;
void open(const char* s, ios_base::openmode mode = ios_base::out);
void open(const filesystem::path::value_type* s,
   ios_base::openmode mode = ios_base::out); // wide systems only; see 29.9.1
void open(const string& s, ios_base::openmode mode = ios_base::out);
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::out);
void close();
private:
   basic_filebuf<charT, traits> sb; // exposition only
};

template<class charT, class traits>
void swap(basic_ofstream<charT, traits>& x,
   basic_ofstream<charT, traits>& y);
}

1 The class basic_ofstream<charT, traits> supports writing to named files. It uses a basic_filebuf<charT, traits> object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

— sb, the filebuf object.
29.9.4.1 Constructors

basic_ofstream();

Effects: Constructs an object of class basic_ofstream<charT, traits>, initializing the base class with basic_ostream<charT, traits>(addressof(sb)) (29.7.5.1.1) and initializing sb with basic_filebuf<charT, traits>() (29.9.2.1).

explicit basic_ofstream(const char* s,
    ios_base::openmode mode = ios_base::out);
explicit basic_ofstream(const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::out); // wide systems only; see 29.9.1

Effects: Constructs an object of class basic_ofstream<charT, traits>, initializing the base class with basic_ostream<charT, traits>(addressof(sb)) (29.7.5.1.1) and initializing sb with basic_filebuf<charT, traits>() (29.9.2.1), then calls rdbuf()->open(s, mode | ios_base::out). If that function returns a null pointer, calls setstate(failbit).

explicit basic_ofstream(const string& s,
    ios_base::openmode mode = ios_base::out);
explicit basic_ofstream(const filesystem::path& s,
    ios_base::openmode mode = ios_base::out);

Effects: The same as basic_ofstream(s.c_str(), mode).

basic_ofstream(basic_ofstream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_filebuf. Next basic_ostream<charT, traits>::set_rdbuf(addressof(sb)) is called to install the contained basic_filebuf.

29.9.4.2 Assignment and swap

basic_ofstream& operator=(basic_ofstream&& rhs);

Effects: Move assigns the base and members of *this from the base and corresponding members of rhs.

Returns: *this.

void swap(basic_ofstream& rhs);

Effects: Exchanges the state of *this and rhs by calling basic_ostream<charT, traits>::swap(rhs) and sb.swap(rhs.sb).

template<class charT, class traits>
void swap(basic_ofstream<charT, traits>& x,
    basic_ofstream<charT, traits>& y);

Effects: As if by x.swap(y).

29.9.4.3 Member functions

basic_filebuf<charT, traits>* rdbuf() const;

Returns: const_cast<basic_filebuf<charT, traits>* >(addressof(sb)).

bool is_open() const;

Returns: rdbuf()->is_open().

void open(const char* s, ios_base::openmode mode = ios_base::out);
void open(const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::out); // wide systems only; see 29.9.1

Effects: Calls rdbuf()->open(s, mode | ios_base::out). If that function does not return a null pointer calls clear(), otherwise calls setstate(failbit) (which may throw ios_base::failure) (29.5.5.4).
void close();

4 Effects: Calls rdbuf()->close() and, if that function fails (returns a null pointer), calls setstate(
failbit) (which may throw ios_base::failure) (29.5.5.4).

void open(const string& s, ios_base::openmode mode = ios_base::out);
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::out);

5 Effects: Calls open(s.c_str(), mode).

29.9.5 Class template basic_fstream

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_fstream : public basic_iostream<charT, traits> {
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        // 29.9.5.1, constructors
        basic_fstream();
        explicit basic_fstream(
            const char* s,
            ios_base::openmode mode = ios_base::in | ios_base::out);
        explicit basic_fstream(
            const filesystem::path::value_type* s,
            ios_base::openmode mode = ios_base::in | ios_base::out); // wide systems only; see 29.9.1
        explicit basic_fstream(
            const string& s,
            ios_base::openmode mode = ios_base::in | ios_base::out);
        explicit basic_fstream(
            const filesystem::path& s,
            ios_base::openmode mode = ios_base::in | ios_base::out);
        basic_fstream(const basic_fstream& rhs) = delete;
        basic_fstream(basic_fstream&& rhs);

        // 29.9.5.2, assign and swap
        basic_fstream& operator=(const basic_fstream& rhs) = delete;
        basic_fstream& operator=(basic_fstream&& rhs);
        void swap(basic_fstream& rhs);

        // 29.9.5.3, members
        basic_filebuf<charT, traits>* rdbuf() const;
        bool is_open() const;
        void open(
            const char* s,
            ios_base::openmode mode = ios_base::in | ios_base::out);
        void open(
            const filesystem::path::value_type* s,
            ios_base::openmode mode = ios_base::in | ios_base::out); // wide systems only; see 29.9.1
        void open(
            const string& s,
            ios_base::openmode mode = ios_base::in | ios_base::out);
        void open(
            const filesystem::path& s,
            ios_base::openmode mode = ios_base::in | ios_base::out);
        void close();

        private:
            basic_filebuf<charT, traits> sb; // exposition only
    };

§ 29.9.5 1380
The class template `basic_fstream<charT, traits>` supports reading and writing from named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequences. For the sake of exposition, the maintained data is presented here as:

\[ (1.1) \quad \text{sb}, \text{ the basic_filebuf object.} \]

### 29.9.5.1 Constructors

```
basic_fstream();
```

**Effects:** Constructs an object of class `basic_fstream<charT, traits>`, initializing the base class with `basic_iostream<charT, traits>(addressof(sb))` (29.7.4.6.1) and initializing `sb` with `basic_filebuf<charT, traits>()`.

```
explicit basic_fstream(const char* s,
                       ios_base::openmode mode = ios_base::in | ios_base::out);
explicit basic_fstream(const filesystem::path::value_type* s,
                       ios_base::openmode mode = ios_base::in | ios_base::out);
// wide systems only; see 29.9.1
```

**Effects:** Constructs an object of class `basic_fstream<charT, traits>`, initializing the base class with `basic_iostream<charT, traits>(addressof(sb))` (29.7.4.6.1) and initializing `sb` with `basic_filebuf<charT, traits>()`. Then calls `rdbuf()->open(s, mode)`. If that function returns a null pointer, calls `setstate(failbit)`.

```
explicit basic_fstream(const string& s,
                       ios_base::openmode mode = ios_base::in | ios_base::out);
explicit basic_fstream(const filesystem::path& s,
                       ios_base::openmode mode = ios_base::in | ios_base::out);
```

**Effects:** The same as `basic_fstream(s.c_str(), mode)`.

```
basic_fstream(basic_fstream&& rhs);
```

**Effects:** Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_filebuf`. Next `basic_istream<charT, traits>::set_rdbuf(addressof(sb))` is called to install the contained `basic_filebuf`.

### 29.9.5.2 Assignment and swap

```
basic_fstream& operator=(basic_fstream&& rhs);
```

**Effects:** Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

**Returns:** `*this`.

```
void swap(basic_fstream& rhs);
```

**Effects:** Exchanges the state of `*this` and `rhs` by calling `basic_iostream<charT,traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```
template<class charT, class traits>
void swap(basic_fstream<charT, traits>& x,
          basic_fstream<charT, traits>& y);
```

**Effects:** As if by `x.swap(y)`.

### 29.9.5.3 Member functions

```
basic_filebuf<charT, traits>* rdbuf() const;
```

**Returns:** `const_cast<basic_filebuf<charT, traits>*>(addressof(sb))`. 

§ 29.9.5.3
bool is_open() const;

2 Returns: rdbuf()->is_open().

void open(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);

void open(
    const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);  // wide systems only; see 29.9.1

3 Effects: Calls rdbuf() -> open(s, mode). If that function does not return a null pointer calls clear(),
otherwise calls setstate(failbit) (which may throw ios_base::failure) (29.5.5.4).

void open(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);

void open(
    const filesystem::path& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);

4 Effects: Calls open(s.c_str(), mode).

void close();

5 Effects: Calls rdbuf() -> close() and, if that function returns a null pointer, calls setstate(failbit)
(which may throw ios_base::failure) (29.5.5.4).

29.10 Synchronized output streams

29.10.1 Header <syncstream> synopsis

#include <ostream>  // see 29.7.2

namespace std {
    template<class charT, class traits, class Allocator>
    class basic_syncbuf;

    using syncbuf = basic_syncbuf<char>;
    using wsyncbuf = basic_syncbuf<wchar_t>;

    template<class charT, class traits, class Allocator>
    class basic_osyncstream;

    using osyncstream = basic_osyncstream<char>;
    using wosyncstream = basic_osyncstream<wchar_t>;
}

1 The header <syncstream> provides a mechanism to synchronize execution agents writing to the same stream.

29.10.2 Class template basic_syncbuf

29.10.2.1 Overview

namespace std {
    template<class charT, class traits, class Allocator>
    class basic_syncbuf : public basic_streambuf<charT, traits> {
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;
        using allocator_type = Allocator;

        using streambuf_type = basic_streambuf<charT, traits>;
    }
// 29.10.2.2, construction and destruction
explicit basic_syncbuf(streambuf_type* obuf = nullptr)
    : basic_syncbuf(obuf, Allocator()) {}
    basic_syncbuf(streambuf_type*, const Allocator&);
    basic_syncbuf(basic_syncbuf&&);
    ~basic_syncbuf();

// 29.10.2.3, assignment and swap
basic_syncbuf& operator=(basic_syncbuf&&);
void swap(basic_syncbuf&);

// 29.10.2.4, member functions
bool emit();
streambuf_type* get_wrapped() const noexcept;
allocator_type get_allocator() const noexcept;
void set_emit_on_sync(bool) noexcept;

protected:
    // 29.10.2.5, overridden virtual functions
    int sync() override;

private:
    streambuf_type* wrapped;    // exposition only
    bool emit_on_sync();    // exposition only
};

// 29.10.2.6, specialized algorithms
template<class charT, class traits, class Allocator>
void swap(basic_syncbuf<charT, traits, Allocator>&,
    basic_syncbuf<charT, traits, Allocator>&);

1 Class template basic_syncbuf stores character data written to it, known as the associated output, into
internal buffers allocated using the object’s allocator. The associated output is transferred to the wrapped
stream buffer object *wrapped when emit() is called or when the basic_syncbuf object is destroyed. Such
transfers are atomic with respect to transfers by other basic_syncbuf objects with the same wrapped stream
buffer object.

29.10.2.2 Construction and destruction [syncstream.syncbuf.cons]
basic_syncbuf(streambuf_type* obuf, const Allocator& allocator);

1 Effects: Constructs the basic_syncbuf object and sets wrapped to obuf.

2 Remarks: A copy of allocator is used to allocate memory for internal buffers holding the associated
output.

3 Throws: Nothing unless an exception is thrown by the construction of a mutex or by memory allocation.

4 Ensures: get_wrapped() == obuf and get_allocator() == allocator are true.

basic_syncbuf(basic_syncbuf&& other);

5 Effects: Move constructs from other (Table 26).

6 Ensures: The value returned by this->get_wrapped() is the value returned by other.get_wrapped()
prior to calling this constructor. Output stored in other prior to calling this constructor will be
stored in this afterwards. other.rdbuf()->pbase() == other.rdbuf()->pptr() and other.get_wrapped() == nullptr are true.

7 Remarks: This constructor disassociates other from its wrapped stream buffer, ensuring destruction of
other produces no output.

~basic_syncbuf();

8 Effects: Calls emit().

9 Throws: Nothing. If an exception is thrown from emit(), the destructor catches and ignores that
exception.
29.10.2.3 Assignment and swap

basic_syncbuf& operator=(basic_syncbuf&& rhs) noexcept;

Effects: Calls emit() then move assigns from rhs. After the move assignment *this has the observable state it would have had if it had been move constructed from rhs (29.10.2.2).

Returns: *this.

Ensures:

1. rhs.get_wrapped() == nullptr is true.
2. this->get_allocator() == rhs.get_allocator() is true when
   allocator_traits<Allocator>::propagate_on_container_move_assignment::value is true; otherwise, the allocator is unchanged.

Remarks: This assignment operator disassociates rhs from its wrapped stream buffer, ensuring destruction of rhs produces no output.

void swap(basic_syncbuf& other) noexcept;

Requires: Either allocator_traits<Allocator>::propagate_on_container_swap::value is true or this->get_allocator() == other.get_allocator() is true.

Effects: Exchanges the state of *this and other.

29.10.2.4 Member functions

bool emit();

Effects: Atomically transfers the associated output of *this to the stream buffer *wrapped, so that it appears in the output stream as a contiguous sequence of characters. wrapped->pubsync() is called if and only if a call was made to sync() since the most recent call to emit(), if any.

Returns: true if all of the following conditions hold; otherwise false:
1. wrapped == nullptr is false.
2. All of the characters in the associated output were successfully transferred.
3. The call to wrapped->pubsync() (if any) succeeded.

Ensures: On success, the associated output is empty.

Synchronization: All emit() calls transferring characters to the same stream buffer object appear to execute in a total order consistent with the “happens before” relation (6.8.2.1), where each emit() call synchronizes with subsequent emit() calls in that total order.

Remarks: May call member functions of wrapped while holding a lock uniquely associated with wrapped.

streambuf_type* get_wrapped() const noexcept;

Returns: wrapped.

allocator_type get_allocator() const noexcept;

Returns: A copy of the allocator that was set in the constructor or assignment operator.

void set_emit_on_sync(bool b) noexcept;

Effects: emit_on_sync = b.

29.10.2.5 Overridden virtual functions

int sync() override;

Effects: Records that the wrapped stream buffer is to be flushed. Then, if emit_on_sync is true, calls emit(). [Note: If emit_on_sync is false, the actual flush is delayed until a call to emit(). — end note]

Returns: If emit() was called and returned false, returns -1; otherwise 0.
29.10.2.6 Specialized algorithms

```cpp
template<class charT, class traits, class Allocator>
void swap(basic_syncbuf<charT, traits, Allocator>& a, basic_syncbuf<charT, traits, Allocator>& b) noexcept;
```

Effects: Equivalent to `a.swap(b)`.

29.10.3 Class template `basic_osyncstream`

29.10.3.1 Overview

```cpp
namespace std {
    template<class charT, class traits, class Allocator>
    class basic_osyncstream : public basic_ostream<charT, traits> {
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;
        using allocator_type = Allocator;
        using streambuf_type = basic_streambuf<charT, traits>;
        using syncbuf_type = basic_syncbuf<charT, traits, Allocator>;
        // 29.10.3.2, construction and destruction
        basic_osyncstream(streambuf_type*, const Allocator&);
        explicit basic_osyncstream(streambuf_type* obuf) :
            basic_osyncstream(obuf, Allocator()) {}
        basic_osyncstream(basic_osyncstream<charT, traits>&& os, const Allocator& allocator) :
            basic_osyncstream(os.rdbuf(), allocator) {}
        explicit basic_osyncstream(basic_osyncstream<charT, traits>&& os) :
            basic_osyncstream(os, Allocator()) {}
        basic_osyncstream(basic_osyncstream<>&) noexcept;
        basic_osyncstream();
        // 29.10.3.3, assignment
        basic_osyncstream& operator=(basic_osyncstream<>&) noexcept;
        // 29.10.3.4, member functions
        void emit();
        streambuf_type* get_wrapped() const noexcept;
        syncbuf_type* rdbuf() const noexcept {
            return const_cast<syncbuf_type*>((addressof(sb))); }
        private:
            syncbuf_type sb; // exposition only
    };
}
```

1 `Allocator` shall meet the `Cpp17Allocator` requirements (Table 34).

2 [Example: A named variable can be used within a block statement for streaming.]

```cpp
{
    osyncstream bout(cout);
    bout << "Hello, ";
    bout << "World!";
    bout << endl; // flush is noted
    bout << "and more!\n";
} // characters are transferred and cout is flushed
```

— end example

3 [Example: A temporary object can be used for streaming within a single statement.]

```cpp
osyncstream(cout) << "Hello, " << "World!" << '\n';
```

In this example, `cout` is not flushed. — end example
29.10.3.2 Construction and destruction

`basic_osyncstream(streambuf_type* buf, const Allocator& allocator);`

**Effects:** Initializes `sb` from `buf` and `allocator`. Initializes the base class with `basic_ostream<charT, traits>(addressof(sb))`.

**Note:** The member functions of the provided stream buffer might be called from `emit()` while a lock is held. Care should be taken to ensure that this does not result in deadlock. — end note

**Ensures:** `get_wrapped() == buf` is true.

`basic_osyncstream(basic_osyncstream&& other) noexcept;`

**Effects:** Move constructs the base class and `sb` from the corresponding subobjects of `other`, and calls `basic_ostream<charT, traits>::set_rdbuf(addressof(sb))`.

**Ensures:** The value returned by `get_wrapped()` is the value returned by `os.get_wrapped()` prior to calling this constructor. `nullptr == other.get_wrapped()` is true.

`~basic_osyncstream();`

**Effects:** Calls `emit()`. If an exception is thrown from `emit()`, that exception is caught and ignored.

29.10.3.3 Assignment

`basic_osyncstream& operator=(basic_osyncstream&& rhs) noexcept;`

**Effects:** First, calls `emit()`. If an exception is thrown from `emit()`, that exception is caught and ignored. Move assigns `sb` from `rhs.sb`. [Note: This disassociates `rhs` from its wrapped stream buffer ensuring destruction of `rhs` produces no output. — end note]

**Ensures:** `nullptr == rhs.get_wrapped()` is true. `get_wrapped()` returns the value previously returned by `rhs.get_wrapped()`.

29.10.3.4 Member functions

`void emit();`

**Effects:** Calls `sb.emit()`. If that call returns `false`, calls `setstate(ios::badbit)`.

[Example: A flush on a `basic_osyncstream` does not flush immediately:

```cpp
{ 
    osyncstream bout(cout);
    bout << "Hello," << '
';  // no flush
    bout.emit();                // characters transferred; cout not flushed
    bout << "World!" << endl;   // flush noted; cout not flushed
    bout.emit();                // characters transferred; cout flushed
    bout << "Greetings."
    bout << '
';               // no flush
}  // characters transferred; cout not flushed
```

— end example]

[Example: The function `emit()` can be used to handle exceptions from operations on the underlying stream.

```cpp
{ 
    osyncstream bout(cout);
    bout << "Hello, " << "World!" << '
';
    try {
        bout.emit();
    } catch (...) {
        // handle exception
    }
}  // characters transferred; cout not flushed
```

— end example]

`streambuf_type* get_wrapped() const noexcept;`

**Returns:** `sb.get_wrapped()`.
Example: Obtaining the wrapped stream buffer with `get_wrapped()` allows wrapping it again with an `osyncstream`. For example,

```cpp
{ osyncstream bout1(cout);
  bout1 << "Hello, ";
  { osyncstream(bout1.get_wrapped()) << "Goodbye, " << "Planet!" << '\n';
  }
  bout1 << "World!" << '\n';
}
```

produces the *uninterleaved* output

```
Goodbye, Planet!
Hello, World!
```

— end example

29.11 File systems

29.11.1 General

This subclause describes operations on file systems and their components, such as paths, regular files, and directories.

A **file system** is a collection of files and their attributes.

A **file** is an object within a file system that holds user or system data. Files can be written to, or read from, or both. A file has certain attributes, including type. File types include regular files and directories. Other types of files, such as symbolic links, may be supported by the implementation.

A **directory** is a file within a file system that acts as a container of directory entries that contain information about other files, possibly including other directory files. The **parent directory** of a directory is the directory that both contains a directory entry for the given directory and is represented by the dot-dot filename (29.11.7.1) in the given directory. The **parent directory** of other types of files is a directory containing a directory entry for the file under discussion.

A **link** is an object that associates a filename with a file. Several links can associate names with the same file. A **hard link** is a link to an existing file. Some file systems support multiple hard links to a file. If the last hard link to a file is removed, the file itself is removed. [Note: A hard link can be thought of as a shared-ownership smart pointer to a file. — end note] A **symbolic link** is a type of file with the property that when the file is encountered during pathname resolution (29.11.7), a string stored by the file is used to modify the pathname resolution. [Note: Symbolic links are often called symlinks. A symbolic link can be thought of as a raw pointer to a file. If the file pointed to does not exist, the symbolic link is said to be a “dangling” symbolic link. — end note]

29.11.2 Conformance

Conformance is specified in terms of behavior. Ideal behavior is not always implementable, so the conformance subclauses take that into account.

29.11.2.1 POSIX conformance

Some behavior is specified by reference to POSIX (29.11.3). How such behavior is actually implemented is unspecified. [Note: This constitutes an “as if” rule allowing implementations to call native operating system or other APIs. — end note]

Implementations should provide such behavior as it is defined by POSIX. Implementations shall document any behavior that differs from the behavior defined by POSIX. Implementations that do not support exact POSIX behavior should provide behavior as close to POSIX behavior as is reasonable given the limitations of actual operating systems and file systems. If an implementation cannot provide any reasonable behavior, the implementation shall report an error as specified in 29.11.6. [Note: This allows users to rely on an exception being thrown or an error code being set when an implementation cannot provide any reasonable behavior. — end note]

Implementations are not required to provide behavior that is not supported by a particular file system. [Example: The FAT file system used by some memory cards, camera memory, and floppy disks does not support hard links, symlinks, and many other features of more capable file systems, so implementations are
not required to support those features on the FAT file system but instead are required to report an error as described above. —end example]

29.11.2.2 Operating system dependent behavior conformance \[fs.conform.os\]
1 Behavior that is specified as being operating system dependent is dependent upon the behavior and characteristics of an operating system. The operating system an implementation is dependent upon is implementation-defined.
2 It is permissible for an implementation to be dependent upon an operating system emulator rather than the actual underlying operating system.

29.11.2.3 File system race behavior \[fs.race.behavior\]
1 A file system race is the condition that occurs when multiple threads, processes, or computers interleave access and modification of the same object within a file system. Behavior is undefined if calls to functions provided by this subclause introduce a file system race.
2 If the possibility of a file system race would make it unreliable for a program to test for a precondition before calling a function described herein, Requires: is not specified for the function. [Note: As a design practice, preconditions are not specified when it is unreasonable for a program to detect them prior to calling the function. —end note]

29.11.3 Normative references \[fs.norm.ref\]
1 This subclause mentions commercially available operating systems for purposes of exposition.^[328]

29.11.4 Requirements \[fs.req\]
1 Throughout this subclause, char, wchar_t, char8_t, char16_t, and char32_t are collectively called encoded character types.
2 Functions with template parameters named EcharT shall not participate in overload resolution unless EcharT is one of the encoded character types.
3 Template parameters named InputIterator shall meet the Cpp17InputIterator requirements (23.3.5.2) and shall have a value type that is one of the encoded character types.
4 [Note: Use of an encoded character type implies an associated character set and encoding. Since signed char and unsigned char have no implied character set and encoding, they are not included as permitted types. —end note]
5 Template parameters named Allocator shall meet the Cpp17Allocator requirements (Table 34).

29.11.4.1 Namespaces and headers \[fs.req.namespace\]
1 Unless otherwise specified, references to entities described in this subclause are assumed to be qualified with ::std::filesystem:::

29.11.5 Header <filesystem> synopsis \[fs.filesystem.syn\]
namespace std::filesystem {
    // 29.11.7, paths
    class path;
    // 29.11.7, path non-member functions
    void swap(path& lhs, path& rhs) noexcept;
    size_t hash_value(const path& p) noexcept;
    // 29.11.8, filesystem errors
    class filesystem_error;

bool is_symlink(file_status s) noexcept;
bool is_symlink(const path& p);
bool is_symlink(const path& p, error_code& ec) noexcept;
1 Implementations should ensure that the resolution and range of \texttt{file\_time\_type} reflect the operating system dependent resolution and range of file time values.

### 29.11.6 Error reporting

Filesystem library functions often provide two overloads, one that throws an exception to report file system errors, and another that sets an \texttt{error\_code}. [Note: This supports two common use cases:

1. Uses where file system errors are truly exceptional and indicate a serious failure. Throwing an exception is an appropriate response.
2. Uses where file system errors are routine and do not necessarily represent failure. Returning an error code is the most appropriate response. This allows application specific error handling, including simply ignoring the error.

\section*{§ 29.11.6}
Functions not having an argument of type `error_code&` handle errors as follows, unless otherwise specified:

(2.1) When a call by the implementation to an operating system or other underlying API results in an error that prevents the function from meeting its specifications, an exception of type `filesystem_error` shall be thrown. For functions with a single path argument, that argument shall be passed to the `filesystem_error` constructor with a single path argument. For functions with two path arguments, the first of these arguments shall be passed to the `filesystem_error` constructor as the `path1` argument, and the second shall be passed as the `path2` argument. The `filesystem_error` constructor’s `error_code` argument is set as appropriate for the specific operating system dependent error.

(2.2) Failure to allocate storage is reported by throwing an exception as described in 16.5.5.12.

(2.3) Destructors throw nothing.

Functions having an argument of type `error_code&` handle errors as follows, unless otherwise specified:

(3.1) If a call by the implementation to an operating system or other underlying API results in an error that prevents the function from meeting its specifications, the `error_code&` argument is set as appropriate for the specific operating system dependent error. Otherwise, `clear()` is called on the `error_code&` argument.

### 29.11.7 Class `path`

An object of class `path` represents a path and contains a pathname. Such an object is concerned only with the lexical and syntactic aspects of a path. The path does not necessarily exist in external storage, and the pathname is not necessarily valid for the current operating system or for a particular file system.

[Note: Class `path` is used to support the differences between the string types used by different operating systems to represent pathnames, and to perform conversions between encodings when necessary. — end note]

A `path` is a sequence of elements that identify the location of a file within a filesystem. The elements are the `root-name_opt`, `root-directory_opt`, and an optional sequence of `filenames` (29.11.7.1). The maximum number of elements in the sequence is operating system dependent (29.11.2.2).

An `absolute path` is a path that unambiguously identifies the location of a file without reference to an additional starting location. The elements of a path that determine if it is absolute are operating system dependent. An `relative path` is a path that is not absolute, and as such, only unambiguously identifies the location of a file when resolved relative to an implied starting location. The elements of a path that determine if it is relative are operating system dependent. [Note: Pathnames `"."` and `".."` are relative paths. — end note]

A `pathname` is a character string that represents the name of a path. Pathnames are formatted according to the generic pathname format grammar (29.11.7.1) or according to an operating system dependent `native pathname format` accepted by the host operating system.

Pathname resolution is the operating system dependent mechanism for resolving a pathname to a particular file in a file hierarchy. There may be multiple pathnames that resolve to the same file. [Example: POSIX specifies the mechanism in section 4.11, Pathname resolution. — end example]

```cpp
namespace std::filesystem {
    class path {
        using value_type = see below;
        using string_type = basic_string<value_type>;
        static constexpr value_type preferred_separator = see below;

        // 29.11.9.1, enumeration format
        enum format;

        // 29.11.7.4.1, constructors and destructor
        path() noexcept;
        path(const path& p);
        path(path&& p) noexcept;
        path(string_type&& source, format fmt = auto_format);
    }
}
```
template<class Source>
path(const Source& source, format fmt = auto_format);
template<class InputIterator>
path(InputIterator first, InputIterator last, format fmt = auto_format);
template<class Source>
path(const Source& source, const locale& loc, format fmt = auto_format);
template<class InputIterator>
path(InputIterator first, InputIterator last, const locale& loc, format fmt = auto_format);
~path();

// 29.11.7.4.2, assignments

};

value_type is a typedef for the operating system dependent encoded character type used to represent pathnames.

The value of the preferred_separator member is the operating system dependent preferred-separator character (29.11.7.1).

[Example: For POSIX-based operating systems, value_type is char and preferred_separator is the slash character (’/’). For Windows-based operating systems, value_type is wchar_t and preferred_separator is the backslash character (L’\’). —end example]

29.11.7.1 Generic pathname format

pathname:
  root-name_opt root-directory_opt relative-path

root-name:
  operating system dependent sequences of characters
  implementation-defined sequences of characters

root-directory:
  directory-separator

relative-path:
  filename
  filename directory-separator relative-path
  an empty path

filename:
  non-empty sequence of characters other than directory-separator characters

directory-separator:
  preferred-separator directory-separator_opt
  fallback-separator directory-separator_opt

preferred-separator:
  operating system dependent directory separator character

fallback-separator:
  /, if preferred-separator is not /

A filename is the name of a file. The dot and dot-dot filenames, consisting solely of one and two period characters respectively, have special meaning. The following characteristics of filenames are operating system dependent:

(1.1) — The permitted characters. [Example: Some operating systems prohibit the ASCII control characters (0x00 – 0x1F) in filenames. —end example] [Note: For wide portability, users may wish to limit filename characters to the POSIX Portable Filename Character Set: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z a b c d e f g h i j k l m n o p q r s t u v w x y z 0 1 2 3 4 5 6 7 8 9 . _ — end note]

(1.2) — The maximum permitted length.

(1.3) — Filenames that are not permitted.

(1.4) — Filenames that have special meaning.

(1.5) — Case awareness and sensitivity during path resolution.

(1.6) — Special rules that may apply to file types other than regular files, such as directories.
Except in a root-name, multiple successive directory-separator characters are considered to be the same as one directory-separator character.

The dot filename is treated as a reference to the current directory. The dot-dot filename is treated as a reference to the parent directory. What the dot-dot filename refers to relative to root-directory is implementation-defined. Specific filenames may have special meanings for a particular operating system.

A root-name identifies the starting location for pathname resolution (29.11.7). If there are no operating system dependent root-names, at least one implementation-defined root-name is required. [Note: Many operating systems define a name beginning with two directory-separator characters as a root-name that identifies network or other resource locations. Some operating systems define a single letter followed by a colon as a drive specifier – a root-name identifying a specific device such as a disk drive. — end note]

If a root-name is otherwise ambiguous, the possibility with the longest sequence of characters is chosen. [Note: On a POSIX-like operating system, it is impossible to have a root-name and a relative-path without an intervening root-directory element. — end note]

Normalization of a generic format pathname means:

1. If the path is empty, stop.
2. Replace each slash character in the root-name with a preferred-separator.
3. Replace each directory-separator with a preferred-separator. [Note: The generic pathname grammar (29.11.7.1) defines directory-separator as one or more slashes and preferred-separators. — end note]
4. Remove each dot filename and any immediately following directory-separator.
5. As long as any appear, remove a non-dot-dot filename immediately followed by a directory-separator and a dot-dot filename, along with any immediately following directory-separator.
6. If there is a root-directory, remove all dot-dot filenames and any directory-separators immediately following them. [Note: These dot-dot filenames attempt to refer to nonexistent parent directories. — end note]
7. If the last filename is dot-dot, remove any trailing directory-separator.
8. If the path is empty, add a dot.

The result of normalization is a path in normal form, which is said to be normalized.

29.11.7.2 Conversions

29.11.7.2.1 Argument format conversions

[Note: The format conversions described in this subclause are not applied on POSIX-based operating systems because on these systems:

(1.1) — The generic format is acceptable as a native path.
(1.2) — There is no need to distinguish between native format and generic format in function arguments.
(1.3) — Paths for regular files and paths for directories share the same syntax.
— end note]

Several functions are defined to accept detected-format arguments, which are character sequences. A detected-format argument represents a path using either a pathname in the generic format (29.11.7.1) or a pathname in the native format (29.11.7). Such an argument is taken to be in the generic format if and only if it matches the generic format and is not acceptable to the operating system as a native path.

[Note: Some operating systems may have no unambiguous way to distinguish between native format and generic format arguments. This is by design as it simplifies use for operating systems that do not require disambiguation. An implementation for an operating system where disambiguation is required is permitted to distinguish between the formats. — end note]

Pathnames are converted as needed between the generic and native formats in an operating-system-dependent manner. Let \( G(n) \) and \( N(g) \) in a mathematical sense be the implementation’s functions that convert native-to-generic and generic-to-native formats respectively. If \( g = G(n) \) for some \( n \), then \( G(N(g)) = g \); if \( n = N(g) \) for some \( g \), then \( N(G(n)) = n \). [Note: Neither \( G \) nor \( N \) need be invertible. — end note]

If the native format requires paths for regular files to be formatted differently from paths for directories, the path shall be treated as a directory path if its last element is a directory-separator, otherwise it shall be treated as a path to a regular file.
[Note: A path stores a native format pathname (29.11.7.4.6) and acts as if it also stores a generic format pathname, related as given below. The implementation may generate the generic format pathname based on the native format pathname (and possibly other information) when requested. — end note]

When a path is constructed from or is assigned a single representation separate from any path, the other representation is selected by the appropriate conversion function (G or N).

When the (new) value \( p \) of one representation of a path is derived from the representation of that or another path, a value \( q \) is chosen for the other representation. The value \( q \) converts to \( p \) (by G or N as appropriate) if any such value does so; \( q \) is otherwise unspecified. [Note: If \( q \) is the result of converting any path at all, it is the result of converting \( p \). — end note]

### 29.11.7.2.2 Type and encoding conversions

The native encoding of an ordinary character string is the operating system dependent current encoding for pathnames (29.11.7). The native encoding for wide character strings is the implementation-defined execution wide-character set encoding (5.3).

For member function arguments that take character sequences representing paths and for member functions returning strings, value type and encoding conversion is performed if the value type of the argument or return value differs from `path::value_type`. For the argument or return value, the method of conversion and the encoding to be converted to is determined by its value type:

- **char**: The encoding is the native ordinary encoding. The method of conversion, if any, is operating system dependent. [Note: For POSIX-based operating systems `path::value_type` is char so no conversion from char value type arguments or to char value type return values is performed. For Windows-based operating systems, the native ordinary encoding is determined by calling a Windows API function. — end note] [Note: This results in behavior identical to other C and C++ standard library functions that perform file operations using ordinary character strings to identify paths. Changing this behavior would be surprising and error prone. — end note]

- **wchar_t**: The encoding is the native wide encoding. The method of conversion is unspecified. [Note: For Windows-based operating systems `path::value_type` is wchar_t so no conversion from wchar_t value type arguments or to wchar_t value type return values is performed. — end note]

- **char8_t**: The encoding is UTF-8. The method of conversion is unspecified.

- **char16_t**: The encoding is UTF-16. The method of conversion is unspecified.

- **char32_t**: The encoding is UTF-32. The method of conversion is unspecified.

If the encoding being converted to has no representation for source characters, the resulting converted characters, if any, are unspecified. Implementations should not modify member function arguments if already of type `path::value_type`.

### 29.11.7.3 Requirements

In addition to the requirements (29.11.4), function template parameters named `Source` shall be one of:

- A function argument `const Source& source` shall have an effective range `[source.begin(), source.end())`.

- A type meeting the `Cpp17InputIterator` requirements that iterates over a NTCTS. The value type shall be an encoded character type. A function argument `const Source& source` shall have an effective range `[source, end)` where `end` is the first iterator value with an element value equal to `iterator_traits<Source>::value_type()`.

- A character array that after array-to-pointer decay results in a pointer to the start of a NTCTS. The value type shall be an encoded character type. A function argument `const Source& source` shall have an effective range `[source, end)` where `end` is the first iterator value with an element value equal to `iterator_traits<decay_t<Source>>::value_type()`.

Functions taking template parameters named `Source` shall not participate in overload resolution unless either

- `Source` is a specialization of `basic_string` or `basic_string_view`, or

- the `qualified-id iterator_traits<decay_t<Source>>::value_type` is valid and denotes a possibly `const` encoded character type (13.9.2).
[Note: See path conversions (29.11.7.2) for how the value types above and their encodings convert to path::value_type and its encoding. —end note]

Arguments of type Source shall not be null pointers.

29.11.7.4 Members

29.11.7.4.1 Constructors

path() noexcept;

Effects: Constructs an object of class path.

Ensure: empty() == true.

path(const path& p);

Effects: Constructs an object of class path having the same pathname in the native and generic formats, respectively, as the original value of p. In the second form, p is left in a valid but unspecified state.

path(std::string&& source, format fmt = auto_format);

Effects: Constructs an object of class path for which the pathname in the detected-format of source has the original value of source (29.11.7.2.1), converting format if required (29.11.7.2.1). source is left in a valid but unspecified state.

template<class Source>
path(const Source& source, format fmt = auto_format);

Effects: Let s be the effective range of source (29.11.7.3) or the range [first, last), after converting the encoding as follows:

— If value_type is wchar_t, converts to the native wide encoding (29.11.7.2.2) using the codecvt<wchar_t, char, mbstate_t> facet of loc.

— Otherwise a conversion is performed using the codecvt<wchar_t, char, mbstate_t> facet of loc, and then a second conversion to the current ordinary encoding.

Finds the detected-format of s (29.11.7.2.1) and constructs an object of class path for which the pathname in that format is s.

[Example: A string is to be read from a database that is encoded in ISO/IEC 8859-1, and used to create a directory:]

```cpp
namespace fs = std::filesystem;
std::string latin1_string = read_latin1_data();
codecvt_8859_1<wchar_t> latin1_facet;
std::locale latin1_locale(std::locale(), latin1_facet);
fs::create_directory(fs::path(latin1_string, latin1_locale));
```

For POSIX-based operating systems, the path is constructed by first using latin1_facet to convert ISO/IEC 8859-1 encoded latin1_string to a wide character string in the native wide encoding (29.11.7.2.2). The resulting wide string is then converted to an ordinary character pathname string in the current native ordinary encoding. If the native wide encoding is UTF-16 or UTF-32, and the current native ordinary encoding is UTF-8, all of the characters in the ISO/IEC 8859-1 character set will be converted to their Unicode representation, but for other native ordinary encodings some characters may have no representation.
For Windows-based operating systems, the path is constructed by using \texttt{latin1\_facet} to convert ISO/IEC 8859-1 encoded \texttt{latin1\_string} to a UTF-16 encoded wide character pathname string. All of the characters in the ISO/IEC 8859-1 character set will be converted to their Unicode representation.

\textit{—end example}\n
\section*{29.11.7.4.2 Assignments} \hspace{3cm} \texttt{[fs.path.assign]} \n
\begin{verbatim}
    path& operator=(const path& p);

    \textbf{Effects:} If \texttt{*this} and \texttt{p} are the same object, has no effect. Otherwise, sets both respective pathnames of \texttt{*this} to the respective pathnames of \texttt{p}.

    \textbf{Returns:} \texttt{*this}.

    path& operator=(path&& p) noexcept;

    \textbf{Effects:} If \texttt{*this} and \texttt{p} are the same object, has no effect. Otherwise, sets both respective pathnames of \texttt{*this} to the respective pathnames of \texttt{p}. \texttt{p} is left in a valid but unspecified state. \texttt{[Note: A valid implementation is \texttt{swap(p)}. —end note]} \n
    \textbf{Returns:} \texttt{*this}.

    path& operator=(string_type&& source);

    \textbf{Effects:} Sets the pathname in the detected-format of \texttt{source} to the original value of \texttt{source}. \texttt{source} is left in a valid but unspecified state.

    \textbf{Returns:} \texttt{*this}.

    template<class Source>
        path& operator=(const Source& source);
    template<class Source>
        path& assign(const Source& source);
    template<class InputIterator>
        path& assign(InputIterator first, InputIterator last);

    \textbf{Effects:} Let \texttt{s} be the effective range of \texttt{source} (29.11.7.3) or the range [\texttt{first}, \texttt{last}), with the encoding converted if required (29.11.7.2). Finds the detected-format of \texttt{s} (29.11.7.2.1) and sets the pathname in that format to \texttt{s}.

    \textbf{Returns:} \texttt{*this}.
\end{verbatim}

\section*{29.11.7.4.3 Appends} \hspace{3cm} \texttt{[fs.path.append]} \n
\begin{verbatim}
    path& operator/=(const path& p);

    \textbf{Effects:} If \texttt{p.is_absolute()} \texttt{|| (p.has_root_name() \&\& p.root_name() != root_name())}, then \texttt{operator=\(p\)}.

    Otherwise, modifies \texttt{*this} as if by these steps:

    (3.1) \texttt{— If p.has_root_directory()}, then removes any root directory and relative path from the generic format pathname. Otherwise, if \texttt{!has_root_directory()} \texttt{&& is_absolute()} is \texttt{true} or if \texttt{has_filename()} is \texttt{true}, then appends \texttt{path::preferred_separator} to the generic format pathname.

    (3.2) \texttt{— Then appends the native format pathname of p, omitting any root-name from its generic format pathname, to the native format pathname.}

    \texttt{[Example: Even if //host is interpreted as a root-name, both of the paths path("//host")/"foo" and path("//host")/"foo" equal "/host/foo" (although the former might use backslash as the preferred separator).}

    Expression examples:

    // On POSIX,
    path("foo") /= path(""); \hspace{1cm} // yields path("foo")
    path("foo") /= path("/bar"); \hspace{1cm} // yields path("/bar")
\end{verbatim}
On Windows,

```cpp
path("foo") /= path("");  // yields path("foo\")
path("foo") /= path("/bar");  // yields path("bar")
path("foo") /= path("c:/bar");  // yields path("c:/bar")
path("foo") /= path("c:");  // yields path("c:")
path("c:") /= path("");  // yields path("c:")
path("c:foo") /= path("/bar");  // yields path("c:/bar")
path("c:foo") /= path("c:bar");  // yields path("c:foo\bar")
```

— end example

Returns: `*this`.

```cpp
template<class Source>
path& operator/(const Source& source);
template<class Source>
path& append(const Source& source);
```

Effects: Equivalent to: `return operator/(path(source));`

```cpp
template<class InputIterator>
path& append(InputIterator first, InputIterator last);
```

Effects: Equivalent to: `return operator/(path(first, last));`

### 29.11.7.4.4 Concatenation

```cpp
path& operator+=(const path& x);
path& operator+=(const string_type& x);
path& operator+=(basic_string_view<value_type> x);
path& operator+=(const value_type* x);
path& operator+=(value_type x);
template<class Source>
path& operator+=(const Source& x);
template<class EcharT>
path& operator+=(EcharT x);
template<class Source>
path& concat(const Source& x);
```

Effects: Appends `path(x).native()` to the pathname in the native format. [Note: This directly manipulates the value of `native()` and may not be portable between operating systems. —end note]

Returns: `*this`.

```cpp
template<class InputIterator>
path& concat(InputIterator first, InputIterator last);
```

Effects: Equivalent to: `return *this += path(first, last);`

### 29.11.7.4.5 Modifiers

```cpp
void clear() noexcept;
```

Ensures: `empty() == true`.

```cpp
path& make_preferred();
```

Effects: Each `directory-separator` of the pathname in the generic format is converted to `preferred-separator`.

Returns: `*this`.

[Example:

```cpp
path p("foo/bar");
std::cout << p << '\n';
p.make_preferred();
std::cout << p << '\n';
```

On an operating system where `preferred-separator` is a slash, the output is:

"foo/bar"
"foo/bar"]
On an operating system where preferred-separator is a backslash, the output is:

"foo/bar"
"foo\bar"
— end example]

path& remove_filename();

Ensures: !has_filename().
Effects: Remove the generic format pathname of filename() from the generic format pathname.
Returns: *this.

[Example:
path("foo/bar").remove_filename(); // yields "foo/
path("foo/").remove_filename(); // yields "foo/
p{} /foo").remove_filename(); // yields "/
p" /foo").remove_filename(); // yields "/
— end example]

path& replace_filename(const path& replacement);

Effects: Equivalent to:
remove_filename();
operator/=(replacement);
Returns: *this.

[Example:
path("/foo").replace_filename("bar"); // yields "/bar" on POSIX
path("/").replace_filename("bar"); // yields "/bar" on POSIX
— end example]

path& replace_extension(const path& replacement = path());

Effects:
(12.1) Any existing extension() (29.11.4.9) is removed from the pathname in the generic format, then
(12.2) If replacement is not empty and does not begin with a dot character, a dot character is appended
        to the pathname in the generic format, then
(12.3) operator+=(replacement);
Returns: *this.
void swap(path& rhs) noexcept;
Effects: Swaps the contents (in all formats) of the two paths.
Complexity: Constant time.

29.11.7.4.6 Native format observers [fs.path.native.obs]
The string returned by all native format observers is in the native pathname format (29.11.7).

const string_type& native() const noexcept;
Returns: The pathname in the native format.

const value_type* c_str() const noexcept;
Effects: Equivalent to: return native().c_str();

operator string_type() const;
Returns: native().
[Note: Conversion to string_type is provided so that an object of class path can be given as an
argument to existing standard library file stream constructors and open functions. — end note]
§ 29.11.7.4.7 Generic format observers

Generic format observer functions return strings formatted according to the generic pathname format (29.11.7.1). A single slash (‘/’) character is used as the directory-separator.

[Example: On an operating system that uses backslash as its preferred-separator,
   path("foo\bar").generic_string()
returns "foo/bar". — end example]

29.11.7.4.8 Compare

int compare(const path& p) const noexcept;

(1.1) — Let rootNameComparison be the result of this->root_name().native().compare(p.root_name().native()). If rootNameComparison is not 0, rootNameComparison.

(1.2) — Otherwise, if !this->has_root_directory() and p.has_root_directory(), a value less than 0.

(1.3) — Otherwise, if this->has_root_directory() and !p.has_root_directory(), a value greater than 0.

(1.4) — Otherwise, if native() for the elements of this->relative_path() are lexicographically less than native() for the elements of p.relative_path(), a value less than 0.

(1.5) — Otherwise, if native() for the elements of this->relative_path() are lexicographically greater than native() for the elements of p.relative_path(), a value greater than 0.

(1.6) — Otherwise, 0.
int compare(const string_type& s) const
int compare(basic_string_view<value_type> s) const;
int compare(const value_type* s) const

Effects: Equivalent to: return compare(path(s));

29.11.7.4.9 Decomposition [fs.path.decompose]

path root_name() const;
Returns: root-name, if the pathname in the generic format includes root-name, otherwise path().

path root_directory() const;
Returns: root-directory, if the pathname in the generic format includes root-directory, otherwise path().

path root_path() const;
Returns: root_name() / root_directory().

path relative_path() const;
Returns: A path composed from the pathname in the generic format, if empty() is false, beginning with the first filename after root_path(). Otherwise, path().

path parent_path() const;
Returns: *this if has_relative_path() is false, otherwise a path whose generic format pathname is the longest prefix of the generic format pathname of *this that produces one fewer element in its iteration.

path filename() const;
Returns: relative_path().empty() ? path() : *--end().

[Example:
  path("/foo/bar.txt").filename(); // yields "bar.txt"
  path("/foo/bar").filename(); // yields "bar"
  path("/foo/bar/").filename(); // yields ""
  path("/").filename(); // yields ""
  path("//host").filename(); // yields ""
  path(".").filename(); // yields "."
  path("..").filename(); // yields ".."
— end example]

path stem() const;
Returns: Let \textit{f} be the generic format pathname of filename(). Returns a path whose pathname in the generic format is

- \textit{f}, if it contains no periods other than a leading period or consists solely of one or two periods;
- otherwise, the prefix of \textit{f} ending before its last period.

[Example:
  std::cout << path("/foo/bar.txt").stem(); // outputs "bar"
  path p = "foo.bar.baz.tar";
  for (; !p.extension().empty(); p = p.stem())
    std::cout << p.extension() << '\n';
    // outputs: .tar
    // .baz
    // .bar
— end example]

path extension() const;
Returns: A path whose pathname in the generic format is the suffix of filename() not included in stem().

[Example:
path("/foo/bar.txt").extension(); // yields ".txt" and stem() is "bar"
path("/foo/bar").extension(); // yields "" and stem() is "bar"
path("/foo/.profile").extension(); // yields "" and stem() is ".profile"
path("./bar").extension(); // yields "" and stem() is ".bar"
path("..bar").extension(); // yields ".bar" and stem() is "."

— end example]

[Note: The period is included in the return value so that it is possible to distinguish between no extension and an empty extension. — end note]

[Note: On non-POSIX operating systems, for a path p, it may not be the case that p.stem() + p.extension() == p.filename(), even though the generic format pathnames are the same. — end note]

29.11.7.4.10 Query [fs.path.query]

[nodiscard] bool empty() const noexcept;

Returns: true if the pathname in the generic format is empty, otherwise false.

bool has_root_path() const;
Returns: !root_path().empty().

bool has_root_name() const;
Returns: !root_name().empty().

bool has_root_directory() const;
Returns: !root_directory().empty().

bool has_relative_path() const;
Returns: !relative_path().empty().

bool has_parent_path() const;
Returns: !parent_path().empty().

bool has_filename() const;
Returns: !filename().empty().

bool has_stem() const;
Returns: !stem().empty().

bool has_extension() const;
Returns: !extension().empty().

bool is_absolute() const;
Returns: true if the pathname in the native format contains an absolute path (29.11.7), otherwise false.

[Example: path("/").is_absolute() is true for POSIX-based operating systems, and false for Windows-based operating systems. — end example]

bool is_relative() const;
Returns: !is_absolute().

29.11.7.4.11 Generation [fs.path.gen]

path lexically_normal() const;

Returns: A path whose pathname in the generic format is the normal form (29.11.7.1) of the pathname in the generic format of *this.

[Example:
assert(path("foo/./bar/..").lexically_normal() == "foo/");
assert(path("foo/:///bar/..").lexically_normal() == "foo/");]
The above assertions will succeed. On Windows, the returned path’s directory-separator characters will be backslashes rather than slashes, but that does not affect path equality. — end example]

path lexically_relative(const path& base) const;

Returns: *this made relative to base. Does not resolve (29.11.7) symlinks. Does not first normalize (29.11.7.1) *this or base.

Effects: If root_name() != base.root_name() is true or is_absolute() != base.is_absolute() is true or !has_root_directory() && base.has_root_directory() is true, returns path(). Determines the first mismatched element of *this and base as if by:

auto [a, b] = mismatch(begin(), end(), base.begin(), base.end());

Then,

(4.1) — if a == end() and b == base.end(), returns path("."); otherwise
(4.2) — let n be the number of filename elements in [b, base.end()) that are not dot or dot-dot or empty, minus the number that are dot-dot. If n<0, returns path(); otherwise
(4.3) — if n == 0 and (a == end() || a->empty()), returns path("."); otherwise
(4.4) — returns an object of class path that is default-constructed, followed by
(4.4.1) — application of operator/=(path(".")) n times, and then
(4.4.2) — application of operator/= for each element in [a, end()).

[Example:
assert(path("/a/d").lexically_relative("/a/b/c") == "../../d");
assert(path("/a/b/c").lexically_relative("/a/d") == ".../b/c");
assert(path("a/b/c").lexically_relative("a") == "b/c");
assert(path("a/b/c").lexically_relative("a/b/c/z/y") == ".../..");
assert(path("a/b/c").lexically_relative("a/b/c") == ".");
assert(path("a/b/c").lexically_relative("c/d") == ".../a/b");

The above assertions will succeed. On Windows, the returned path’s directory-separator characters will be backslashes rather than slashes, but that does not affect path equality. — end example]

[Note: If symlink following semantics are desired, use the operational function relative(). — end note]

path lexically_proximate(const path& base) const;

Returns: If the value of lexically_relative(base) is not an empty path, return it. Otherwise return *this.

[Note: If symlink following semantics are desired, use the operational function proximate(). — end note]

[Note: If normalization (29.11.7.1) is needed to ensure consistent matching of elements, apply lexically_normal() to *this, base, or both. — end note]
(4.3) — Each successive *filename* element, if present.
(4.4) — An empty element, if a trailing non-root *directory-separator* is present.

The backward traversal order is the reverse of forward traversal.

```
iterator begin() const;
```

*Returns:* An iterator for the first present element in the traversal list above. If no elements are present, the end iterator.

```
iterator end() const;
```

*Returns:* The end iterator.

### 29.11.7.6 Inserter and extractor

[fs.path.io]

```
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const path& p);
```

*Effects:* Equivalent to `os << quoted(p.string<charT, traits>())`. [*Note:* The `quoted` function is described in 29.7.8. — end note]

*Returns:* `os`.

```
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, path& p);
```

*Effects:* Equivalent to:

```
basic_string<charT, traits> tmp;
is >> quoted(tmp);
p = tmp;
```

*Returns:* `is`.

### 29.11.7.7 Non-member functions

[fs.path.nonmember]

```
void swap(path& lhs, path& rhs) noexcept;
```

*Effects:* Equivalent to `lhs.swap(rhs)`.

```
size_t hash_value (const path& p) noexcept;
```

*Returns:* A hash value for the path `p`. If for two paths, `p1 == p2` then `hash_value(p1) == hash_value(p2)`.

```
friend bool operator==(const path& lhs, const path& rhs) noexcept;
```

*Returns:* `!(lhs < rhs) && !(rhs < lhs)`.

*Note:* Path equality and path equivalence have different semantics.

(4.1) — Equality is determined by the `path` non-member `operator==`, which considers the two paths’ lexical representations only. [*Example:* `path("foo") == "bar"` is never `true`. — end example]

(4.2) — Equivalence is determined by the `equivalent()` non-member function, which determines if two paths resolve (29.11.7) to the same file system entity. [*Example:* `equivalent("foo", "bar")` will be `true` when both paths resolve to the same file. — end example]

Programmers wishing to determine if two paths are “the same” must decide if “the same” means “the same representation” or “resolve to the same actual file”, and choose the appropriate function accordingly. — end note

```
friend bool operator!=(const path& lhs, const path& rhs) noexcept;
```

*Returns:* `!(lhs == rhs)`.

```
friend bool operator< (const path& lhs, const path& rhs) noexcept;
```

*Returns:* `lhs.compare(rhs) < 0`.

§ 29.11.7 1406
friend bool operator<=(const path& lhs, const path& rhs) noexcept;

Returns: !(rhs < lhs).

friend bool operator>(const path& lhs, const path& rhs) noexcept;

Returns: rhs < lhs.

friend bool operator>=(const path& lhs, const path& rhs) noexcept;

Returns: !(lhs < rhs).

friend path operator/ (const path& lhs, const path& rhs);

Effects: Equivalent to: return path(lhs) /= rhs;

29.11.8 Class filesystem_error

namespace std::filesystem {
    class filesystem_error : public system_error {
        public:
            filesystem_error(const string& what_arg, error_code ec);
            filesystem_error(const string& what_arg, const path& p1, error_code ec);
            filesystem_error(const string& what_arg, const path& p1, const path& p2, error_code ec);

            const path& path1() const noexcept;
            const path& path2() const noexcept;
            const char* what() const noexcept override;
    };
}

1 The class filesystem_error defines the type of objects thrown as exceptions to report file system errors from functions described in this subclause.

29.11.8.1 Members

Constructor are provided that store zero, one, or two paths associated with an error.

filesystem_error(const string& what_arg, error_code ec);

Ensures:

(2.1) code() == ec,
(2.2) path1().empty() == true,
(2.3) path2().empty() == true, and
(2.4) string_view(what()).find(what_arg.c_str()) != string_view::npos.

filesystem_error(const string& what_arg, const path& p1, error_code ec);

Ensures:

(3.1) code() == ec,
(3.2) path1() returns a reference to the stored copy of p1,
(3.3) path2().empty() == true, and
(3.4) string_view(what()).find(what_arg.c_str()) != string_view::npos.

filesystem_error(const string& what_arg, const path& p1, const path& p2, error_code ec);

Ensures:

(4.1) code() == ec,
(4.2) path1() returns a reference to the stored copy of p1,
(4.3) path2() returns a reference to the stored copy of p2, and
(4.4) string_view(what()).find(what_arg.c_str()) != string_view::npos.
const path& path1() const noexcept;
5  Returns: A reference to the copy of p1 stored by the constructor, or, if none, an empty path.

const path& path2() const noexcept;
6  Returns: A reference to the copy of p2 stored by the constructor, or, if none, an empty path.

const char* what() const noexcept override;
7  Returns: An nttbs that incorporates the what_arg argument supplied to the constructor. The exact format is unspecified. Implementations should include the system_error::what() string and the pathnames of path1 and path2 in the native format in the returned string.

29.11.9 Enumerations [fs.enum]
29.11.9.1 Enum path::format [fs.enum.path.format]
1 This enum specifies constants used to identify the format of the character sequence, with the meanings listed in Table 116.

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>native_format</td>
<td>The native pathname format.</td>
</tr>
<tr>
<td>generic_format</td>
<td>The generic pathname format.</td>
</tr>
<tr>
<td>auto_format</td>
<td>The interpretation of the format of the character sequence is implementation-defined. The implementation may inspect the content of the character sequence to determine the format. [Note: For POSIX-based systems, native and generic formats are equivalent and the character sequence should always be interpreted in the same way. — end note]</td>
</tr>
</tbody>
</table>

29.11.9.2 Enum class file_type [fs.enum.file.type]
1 This enum class specifies constants used to identify file types, with the meanings listed in Table 117. The values of the constants are distinct.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>The type of the file has not been determined or an error occurred while trying to determine the type.</td>
</tr>
<tr>
<td>not_found</td>
<td>Pseudo-type indicating the file was not found. [Note: The file not being found is not considered an error while determining the type of a file. — end note]</td>
</tr>
<tr>
<td>regular</td>
<td>Regular file</td>
</tr>
<tr>
<td>directory</td>
<td>Directory file</td>
</tr>
<tr>
<td>symlink</td>
<td>Symbolic link file</td>
</tr>
<tr>
<td>block</td>
<td>Block special file</td>
</tr>
<tr>
<td>character</td>
<td>Character special file</td>
</tr>
<tr>
<td>fifo</td>
<td>FIFO or pipe file</td>
</tr>
<tr>
<td>socket</td>
<td>Socket file</td>
</tr>
<tr>
<td>implementation-defined</td>
<td>Implementations that support file systems having file types in addition to the above file_type types shall supply implementation-defined file_type constants to separately identify each of those additional file types</td>
</tr>
<tr>
<td>unknown</td>
<td>The file exists but the type could not be determined</td>
</tr>
</tbody>
</table>
29.11.9.3  Enum class copy_options

The enum class type copy_options is a bitmask type (16.4.2.2.4) that specifies bitmask constants used to control the semantics of copy operations. The constants are specified in option groups with the meanings listed in Table 118. The constant none represents the empty bitmask, and is shown in each option group for purposes of exposition; implementations shall provide only a single definition. Every other constant in the table represents a distinct bitmask element.

Table 118: Enum class copy_options

<table>
<thead>
<tr>
<th>Option group controlling copy_file function effects for existing target files</th>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>(Default)</td>
<td>Error; file already exists.</td>
</tr>
<tr>
<td>skip_existing</td>
<td>Do not overwrite existing file, do not report an error.</td>
<td></td>
</tr>
<tr>
<td>overwrite_existing</td>
<td>Overwrite the existing file.</td>
<td></td>
</tr>
<tr>
<td>update_existing</td>
<td>Overwrite the existing file if it is older than the replacement file.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option group controlling copy function effects for sub-directories</th>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>(Default)</td>
<td>Do not copy sub-directories.</td>
</tr>
<tr>
<td>recursive</td>
<td>Recursively copy sub-directories and their contents.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option group controlling copy function effects for symbolic links</th>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>(Default)</td>
<td>Follow symbolic links.</td>
</tr>
<tr>
<td>copy_symlinks</td>
<td>Copy symbolic links as symbolic links rather than copying the files that they point to.</td>
<td></td>
</tr>
<tr>
<td>skip_symlinks</td>
<td>Ignore symbolic links.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option group controlling copy function effects for choosing the form of copying</th>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>(Default)</td>
<td>Copy content.</td>
</tr>
<tr>
<td>directories_only</td>
<td>Copy directory structure only, do not copy non-directory files.</td>
<td></td>
</tr>
<tr>
<td>create_symlinks</td>
<td>Make symbolic links instead of copies of files. The source path shall be an absolute path unless the destination path is in the current directory.</td>
<td></td>
</tr>
<tr>
<td>create_hard_links</td>
<td>Make hard links instead of copies of files.</td>
<td></td>
</tr>
</tbody>
</table>

29.11.9.4  Enum class perms

The enum class type perms is a bitmask type (16.4.2.2.4) that specifies bitmask constants used to identify file permissions, with the meanings listed in Table 119.

29.11.9.5  Enum class perm_options

The enum class type perm_options is a bitmask type (16.4.2.2.4) that specifies bitmask constants used to control the semantics of permissions operations, with the meanings listed in Table 120. The bitmask constants are bitmask elements. In Table 120 perm denotes a value of type perms passed to permissions.

29.11.9.6  Enum class directory_options

The enum class type directory_options is a bitmask type (16.4.2.2.4) that specifies bitmask constants used to identify directory traversal options, with the meanings listed in Table 121. The constant none represents the empty bitmask; every other constant in the table represents a distinct bitmask element.

29.11.10  Class file_status

namespace std::filesystem {
    class file_status {
        public:
            // 29.11.10.1, constructors and destructor
            file_status() noexcept : file_status(file_type::none) {} 
            explicit file_status(file_type ft, 
                perms prms = perms::unknown) noexcept;
### Table 119: Enum class `perms`  
[tab:fs.enum perms]

</table>

### Table 120: Enum class `perm_options`  
[tab:fs.enum.perm.opts]

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>replace</td>
<td>permissions shall replace the file’s permission bits with <code>perm</code></td>
</tr>
<tr>
<td>add</td>
<td>permissions shall replace the file’s permission bits with the bitwise OR of <code>perm</code> and the file’s current permission bits.</td>
</tr>
<tr>
<td>remove</td>
<td>permissions shall replace the file’s permission bits with the bitwise AND of the complement of <code>perm</code> and the file’s current permission bits.</td>
</tr>
<tr>
<td>nofollow</td>
<td>permissions shall change the permissions of a symbolic link itself rather than the permissions of the file the link resolves to.</td>
</tr>
</tbody>
</table>

### Table 121: Enum class `directory_options`  
[tab:fs.enum.dir.opts]

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>(Default) Skip directory symlinks, permission denied is an error.</td>
</tr>
<tr>
<td>follow_directory_symlink</td>
<td>Follow rather than skip directory symlinks.</td>
</tr>
<tr>
<td>skip_permission_denied</td>
<td>Skip directories that would otherwise result in permission denied.</td>
</tr>
</tbody>
</table>
An object of type `file_status` stores information about the type and permissions of a file.

### 29.11.10.1 Constructors

```cpp
explicit file_status(file_type ft, perms prms = perms::unknown) noexcept;
```

**Ensures:** `type() == ft` and `permissions() == prms`.

### 29.11.10.2 Observers

```cpp
file_type type() const noexcept;
perms permissions() const noexcept;
```

**Returns:** The value of `type()` specified by the postconditions of the most recent call to a constructor, `operator=`, or `type(file_type)` function.

**Returns:** The value of `permissions()` specified by the postconditions of the most recent call to a constructor, `operator=`, or `permissions(perms)` function.

### 29.11.10.3 Modifiers

```cpp
void type(file_type ft) noexcept;
```

**Ensures:** `type() == ft`.

```cpp
void permissions(perms prms) noexcept;
```

**Ensures:** `permissions() == prms`.

### 29.11.11 Class `directory_entry`

```cpp
namespace std::filesystem {
    class directory_entry {
        public:
            // 29.11.11.1, constructors and destructor
            directory_entry() noexcept = default;
            directory_entry(const directory_entry&) = default;
            directory_entry(directory_entry&) noexcept = default;
            explicit directory_entry(const filesystem::path& p);
            directory_entry(const filesystem::path& p, error_code& ec);
            ~directory_entry();

            // assignments
            directory_entry& operator=(const directory_entry&) = default;
            directory_entry& operator=(directory_entry&) noexcept = default;

            // 29.11.11.2, modifiers
            void assign(const filesystem::path& p);
            void assign(const filesystem::path& p, error_code& ec);
            void replace_filename(const filesystem::path& p);
        }
    }
}
```
void replace_filename(const filesystem::path& p, error_code& ec);
void refresh();
void refresh(error_code ec) noexcept;

// 29.11.11.3, observers
const filesystem::path& path() const noexcept;
operator const filesystem::path&() const noexcept;
bool exists() const;
bool exists(error_code& ec) const noexcept;
bool is_block_file() const;
bool is_block_file(error_code& ec) const noexcept;
bool is_character_file() const;
bool is_character_file(error_code& ec) const noexcept;
bool is_directory() const;
bool is_directory(error_code& ec) const noexcept;
bool is_fifo() const;
bool is_fifo(error_code& ec) const noexcept;
bool is_other() const;
bool is_other(error_code& ec) const noexcept;
bool is_regular_file() const;
bool is_regular_file(error_code& ec) const noexcept;
bool is_socket() const;
bool is_socket(error_code& ec) const noexcept;
bool is_symlink() const;
bool is_symlink(error_code& ec) const noexcept;
uintmax_t file_size() const;
uintmax_t file_size(error_code& ec) const noexcept;
uintmax_t hard_link_count() const;
uintmax_t hard_link_count(error_code& ec) const noexcept;
file_time_type last_write_time() const;
file_time_type last_write_time(error_code& ec) const noexcept;
file_status status() const;
file_status status(error_code& ec) const noexcept;
file_status symlink_status() const;
file_status symlink_status(error_code& ec) const noexcept;

bool operator==(const directory_entry& rhs) const noexcept;
bool operator!=(const directory_entry& rhs) const noexcept;
bool operator<(const directory_entry& rhs) const noexcept;
bool operator>(const directory_entry& rhs) const noexcept;
bool operator<=(const directory_entry& rhs) const noexcept;
bool operator>=(const directory_entry& rhs) const noexcept;

private:
filesystem::path pathobject;  // exposition only
friend class directory_iterator;  // exposition only
};

1 A directory_entry object stores a path object and may store additional objects for file attributes such as hard link count, status, symlink status, file size, and last write time.

2 Implementations should store such additional file attributes during directory iteration if their values are available and storing the values would allow the implementation to eliminate file system accesses by directory_entry observer functions (29.11.14). Such stored file attribute values are said to be cached.

3 [Note: For purposes of exposition, class directory_iterator (29.11.12) is shown above as a friend of class directory_entry. Friendship allows the directory_iterator implementation to cache already available attribute values directly into a directory_entry object without the cost of an unneeded call to refresh(). —end note]

4 [Example:
using namespace std::filesystem;

§ 29.11.11
// use possibly cached last write time to minimize disk accesses
for (auto& x : directory_iterator("."))
{
    std::cout << x.path() << " " << x.last_write_time() << std::endl;
}

// call refresh() to refresh a stale cache
for (auto& x : directory_iterator("."))
{
    lengthy_function(x.path()); // cache becomes stale
    x.refresh();
    std::cout << x.path() << " " << x.last_write_time() << std::endl;
}

On implementations that do not cache the last write time, both loops will result in a potentially expensive call to the `std::filesystem::last_write_time` function. On implementations that do cache the last write time, the first loop will use the cached value and so will not result in a potentially expensive call to the `std::filesystem::last_write_time` function. The code is portable to any implementation, regardless of whether or not it employs caching. — end example]

29.11.11.1 Constructors

```cpp
explicit directory_entry(const filesystem::path& p);
directory_entry(const filesystem::path& p, error_code& ec);
```

1 Effects: Constructs an object of type `directory_entry`, then `refresh()` or `refresh(ec)`, respectively.
2 Ensures: `path() == p` if no error occurs, otherwise `path() == filesystem::path()`.
3 Throws: As specified in 29.11.6.

29.11.11.2 Modifiers

```cpp
void assign(const filesystem::path& p);
void assign(const filesystem::path& p, error_code& ec);
```

1 Effects: Equivalent to `pathobject = p`, then `refresh()` or `refresh(ec)`, respectively. If an error occurs, the values of any cached attributes are unspecified.
2 Throws: As specified in 29.11.6.

```cpp
void replace_filename(const filesystem::path& p);
void replace_filename(const filesystem::path& p, error_code& ec);
```

3 Effects: Equivalent to `pathobject.replace_filename(p)`, then `refresh()` or `refresh(ec)`, respectively. If an error occurs, the values of any cached attributes are unspecified.
4 Throws: As specified in 29.11.6.

```cpp
void refresh();
void refresh(error_code& ec) noexcept;
```

4 Effects: Stores the current values of any cached attributes of the file `p` resolves to. If an error occurs, an error is reported (29.11.6) and the values of any cached attributes are unspecified.
5 Throws: As specified in 29.11.6.
6 [Note: Implementations of `directory_iterator` (29.11.12) are prohibited from directly or indirectly calling the `refresh` function since it must access the external file system, and the objective of caching is to avoid unnecessary file system accesses. — end note]

29.11.11.3 Observers

Unqualified function names in the `Returns: elements of the directory_entry observers described below refer to members of the std::filesystem namespace.

```cpp
const filesystem::path& path() const noexcept;
operator const filesystem::path&() const noexcept;
```

2 Returns: `pathobject`. 

§ 29.11.3
bool exists() const;
bool exists(error_code& ec) const noexcept;

3   Returns: exists(this->status()) or exists(this->status(ec)), respectively.

4   Throws: As specified in 29.11.6.

bool is_block_file() const;
bool is_block_file(error_code& ec) const noexcept;

5   Returns: is_block_file(this->status()) or is_block_file(this->status(ec)), respectively.

6   Throws: As specified in 29.11.6.

bool is_character_file() const;
bool is_character_file(error_code& ec) const noexcept;

7   Returns: is_character_file(this->status()) or is_character_file(this->status(ec)), respectively.

8   Throws: As specified in 29.11.6.

bool is_directory() const;
bool is_directory(error_code& ec) const noexcept;

9   Returns: is_directory(this->status()) or is_directory(this->status(ec)), respectively.

10  Throws: As specified in 29.11.6.

bool is_fifo() const;
bool is_fifo(error_code& ec) const noexcept;

11  Returns: is_fifo(this->status()) or is_fifo(this->status(ec)), respectively.

12  Throws: As specified in 29.11.6.

bool is_other() const;
bool is_other(error_code& ec) const noexcept;

13  Returns: is_other(this->status()) or is_other(this->status(ec)), respectively.

14  Throws: As specified in 29.11.6.

bool is_regular_file() const;
bool is_regular_file(error_code& ec) const noexcept;

15  Returns: is_regular_file(this->status()) or is_regular_file(this->status(ec)), respectively.

16  Throws: As specified in 29.11.6.

bool is_socket() const;
bool is_socket(error_code& ec) const noexcept;

17  Returns: is_socket(this->status()) or is_socket(this->status(ec)), respectively.

18  Throws: As specified in 29.11.6.

bool is_symlink() const;
bool is_symlink(error_code& ec) const noexcept;

19  Returns: is_symlink(this->symlink_status()) or is_symlink(this->symlink_status(ec)), respectively.

20  Throws: As specified in 29.11.6.

uintmax_t file_size() const;
uintmax_t file_size(error_code& ec) const noexcept;

21  Returns: If cached, the file size attribute value. Otherwise, file_size(path()) or file_size(path(),

22  ec), respectively.

23  Throws: As specified in 29.11.6.

uintmax_t hard_link_count() const;
uintmax_t hard_link_count(error_code& ec) const noexcept;

Returns: If cached, the hard link count attribute value. Otherwise, hard_link_count(path()) or hard_link_count(path(), ec), respectively.

Throws: As specified in 29.11.6.

file_time_type last_write_time() const;
file_time_type last_write_time(error_code& ec) const noexcept;

Returns: If cached, the last write time attribute value. Otherwise, last_write_time(path()) or last_write_time(path(), ec), respectively.

Throws: As specified in 29.11.6.

file_status status() const;
file_status status(error_code& ec) const noexcept;

Returns: If cached, the status attribute value. Otherwise, status(path()) or status(path(), ec), respectively.

Throws: As specified in 29.11.6.

file_status symlink_status() const;
file_status symlink_status(error_code& ec) const noexcept;

Returns: If cached, the symlink status attribute value. Otherwise, symlink_status(path()) or symlink_status(path(), ec), respectively.

Throws: As specified in 29.11.6.

bool operator==(const directory_entry& rhs) const noexcept;

Returns: pathobject == rhs.pathobject.

bool operator!=(const directory_entry& rhs) const noexcept;

Returns: pathobject != rhs.pathobject.

bool operator< (const directory_entry& rhs) const noexcept;

Returns: pathobject < rhs.pathobject.

bool operator> (const directory_entry& rhs) const noexcept;

Returns: pathobject > rhs.pathobject.

bool operator<=(const directory_entry& rhs) const noexcept;

Returns: pathobject <= rhs.pathobject.

bool operator>=(const directory_entry& rhs) const noexcept;

Returns: pathobject >= rhs.pathobject.

29.11.12 Class directory_iterator

An object of type directory_iterator provides an iterator for a sequence of directory_entry elements representing the path and any cached attribute values (29.11.11) for each file in a directory or in an implementation-defined directory-like file type. [Note: For iteration into sub-directories, see class recursive_directory_iterator (29.11.13). – end note]
directory_iterator(const path& p, directory_options options);
directory_iterator(const path& p, error_code& ec);
directory_iterator(const path& p, directory_options options,
                    error_code& ec);
directory_iterator(const directory_iterator& rhs);
directory_iterator(directory_iterator&& rhs) noexcept;
~directory_iterator();
directory_iterator& operator=(const directory_iterator& rhs);
directory_iterator& operator=(directory_iterator&& rhs) noexcept;
const directory_entry& operator*() const;
const directory_entry* operator->() const;
directory_iterator& operator++();
directory_iterator& increment(error_code& ec);

// other members as required by 23.3.5.2, input iterators
};  

directory_iterator meets the Cpp17InputIterator requirements (23.3.5.2).

If an iterator of type directory_iterator reports an error or is advanced past the last directory element,
that iterator shall become equal to the end iterator value. The directory_iterator default constructor
shall create an iterator equal to the end iterator value, and this shall be the only valid iterator for the end
condition.

The end iterator is not dereferenceable.

Two end iterators are always equal. An end iterator shall not be equal to a non-end iterator.

The result of calling the path() member of the directory_entry object obtained by dereferencing a
directory_iterator is a reference to a path object composed of the directory argument from which the
iterator was constructed with filename of the directory entry appended as if by operator/=

Directory iteration shall not yield directory entries for the current (dot) and parent (dot-dot) directories.

The order of directory entries obtained by dereferencing successive increments of a directory_iterator is
unspecified.

Constructors and non-const directory_iterator member functions store the values of any cached at-
tributes (29.11.11) in the directory_entry element returned by operator*(). directory_iterator member
functions shall not directly or indirectly call any directory_entry refresh function. [Note: The exact
mechanism for storing cached attribute values is not exposed to users. For exposition, class directory_it-
terator is shown in 29.11.11 as a friend of class directory_entry. — end note]

[Note: Programs performing directory iteration may wish to test if the path obtained by dereferencing a
directory iterator actually exists. It could be a symbolic link to a non-existent file. Programs recursively
walking directory trees for purposes of removing and renaming entries may wish to avoid following symbolic
links. — end note]

[Note: If a file is removed from or added to a directory after the construction of a directory_iterator for
the directory, it is unspecified whether or not subsequently incrementing the iterator will ever result in an
iterator referencing the removed or added directory entry. See POSIX readdir_r. — end note]

29.11.12.1 Members [fs.dir.itr.members]
directory_iterator() noexcept;

Effects: Constructs the end iterator.

explicit directory_iterator(const path& p);
directory_iterator(const path& p, directory_options options);
directory_iterator(const path& p, error_code& ec);
directory_iterator(const path& p, directory_options options, error_code& ec);

Effects: For the directory that p resolves to, constructs an iterator for the first element in a sequence of
directory_entry elements representing the files in the directory, if any; otherwise the end iterator. However, if
and construction encounters an error indicating that permission to access p is denied, constructs the end iterator and does not report an error.

**Throws:** As specified in 29.11.6.

[Note: To iterate over the current directory, use `directory_iterator(".")` rather than `directory_iterator("\""). — end note]

directory_iterator(const directory_iterator& rhs);
directory_iterator(directory_iterator&& rhs) noexcept;

**Effects:** Constructs an object of class `directory_iterator`.

**Ensures:** *this has the original value of rhs.

directory_iterator& operator=(const directory_iterator& rhs);
directory_iterator& operator=(directory_iterator&& rhs) noexcept;

**Effects:** If *this and rhs are the same object, the member has no effect.

**Ensures:** *this has the original value of rhs.

**Returns:** *this.

directory_iterator& operator++();
directory_iterator& increment(error_code& ec);

**Effects:** As specified for the prefix increment operation of Input iterators (23.3.5.2).

**Returns:** *this.

**Throws:** As specified in 29.11.6.

29.11.12.2 Non-member functions

These functions enable range access for `directory_iterator`.

directory_iterator begin(directory_iterator iter) noexcept;

**Returns:** iter.

directory_iterator end(const directory_iterator&) noexcept;

**Returns:** directory_iterator().

29.11.13 Class recursive_directory_iterator

An object of type `recursive_directory_iterator` provides an iterator for a sequence of `directory_entry` elements representing the files in a directory or in an implementation-defined directory-like file type, and its sub-directories.

```cpp
namespace std::filesystem {
    class recursive_directory_iterator {
        public:
            using iterator_category = input_iterator_tag;
            using value_type = directory_entry;
            using difference_type = ptrdiff_t;
            using pointer = const directory_entry*;
            using reference = const directory_entry&;

            recursive_directory_iterator() noexcept;
            explicit recursive_directory_iterator(const path& p);
            recursive_directory_iterator(const path& p, directory_options options);
            recursive_directory_iterator(const path& p, directory_options options,
                                          error_code& ec);
            recursive_directory_iterator(const path& p, error_code& ec);
            recursive_directory_iterator(const recursive_directory_iterator& rhs);
            recursive_directory_iterator(recursive_directory_iterator&& rhs) noexcept;
            ~recursive_directory_iterator();

    } // 29.11.13.1, constructors and destructor

§ 29.11.13
// 29.11.13.1, observers
directory_options options() const;
int depth() const;
bool recursion_pending() const;

const directory_entry& operator*() const;
const directory_entry* operator->() const;

// 29.11.13.1, modifiers
recursive_directory_iterator&
     operator=(const recursive_directory_iterator& rhs);
recursive_directory_iterator&
     operator=(recursive_directory_iterator&& rhs) noexcept;
recursive_directory_iterator& operator++();
recursive_directory_iterator& increment(error_code& ec);
void pop();
void pop(error_code& ec);
void disable_recursion_pending();

// other members as required by 23.3.5.2, input iterators
};

Calling options, depth, recursion_pending, pop or disable_recursion_pending on an iterator that is not dereferenceable results in undefined behavior.

3 The behavior of a recursive_directory_iterator is the same as a directory_iterator unless otherwise specified.

4 [Note: If the directory structure being iterated over contains cycles then the end iterator may be unreachable. — end note]

29.11.13.1 Members

recursive_directory_iterator() noexcept;

Effects: Constructs the end iterator.

explicit recursive_directory_iterator(const path& p);
recursive_directory_iterator(const path& p, directory_options options);
recursive_directory_iterator(const path& p, directory_options options, error_code& ec);
recursive_directory_iterator(const path& p, error_code& ec);

Effects: Constructs an iterator representing the first entry in the directory to which p resolves, if any; otherwise, the end iterator. However, if
(options & directory_options::skip_permission_denied) != directory_options::none
and construction encounters an error indicating that permission to access p is denied, constructs the end iterator and does not report an error.

Ensures: options() == options for the signatures with a directory_options argument, otherwise options() == directory_options::none.

Throws: As specified in 29.11.6.

[Note: To iterate over the current directory, use recursive_directory_iterator(".") rather than recursive_directory_iterator("""). — end note]

[Note: By default, recursive_directory_iterator does not follow directory symlinks. To follow directory symlinks, specify options as directory_options::follow_directory_symlink — end note]

recursive_directory_iterator(const recursive_directory_iterator& rhs);

Effects: Constructs an object of class recursive_directory_iterator.

Ensures:

(8.1) — options() == rhs.options()
recursive_directory_iterator(recursive_directory_iterator&& rhs) noexcept;

Effects: Constructs an object of class recursive_directory_iterator.

Ensures: options(), depth(), and recursion_pending() have the values that rhs.options(), rhs.depth(), and rhs.recursion_pending(), respectively, had before the function call.

recursive_directory_iterator& operator=(const recursive_directory_iterator& rhs);

Effects: If *this and rhs are the same object, the member has no effect.

Ensures:

(12.1) options() == rhs.options()
(12.2) depth() == rhs.depth()
(12.3) recursion_pending() == rhs.recursion_pending()

Returns: *this.

recursive_directory_iterator& operator=(recursive_directory_iterator&& rhs) noexcept;

Effects: If *this and rhs are the same object, the member has no effect.

Ensures: options(), depth(), and recursion_pending() have the values that rhs.options(), rhs.depth(), and rhs.recursion_pending(), respectively, had before the function call.

Returns: *this.

directory_options options() const;

Returns: The value of the argument passed to the constructor for the options parameter, if present, otherwise directory_options::none.

Throws: Nothing.

int depth() const;

Returns: The current depth of the directory tree being traversed. [Note: The initial directory is depth 0, its immediate subdirectories are depth 1, and so forth. — end note]

Throws: Nothing.

bool recursion_pending() const;

Returns: true if disable_recursion_pending() has not been called subsequent to the prior construction or increment operation, otherwise false.

Throws: Nothing.

recursive_directory_iterator& operator++();
recursive_directory_iterator& increment(error_code& ec);

Effects: As specified for the prefix increment operation of Input iterators (23.3.5.2), except that:

(23.1) If there are no more entries at the current depth, then if depth() != 0 iteration over the parent directory resumes; otherwise *this = recursive_directory_iterator().

(23.2) Otherwise if

    recursion_pending() && is_directory(*this)->status()) &&
    (!is_symlink(*this)->symlink_status()) ||
    (options() & directory_options::follow_directory_symlink) != directory_options::none)

then either directory (*this)->path() is recursively iterated into or, if

    (options() & directory_options::skip_permission_denied) != directory_options::none

and an error occurs indicating that permission to access directory (*this)->path() is denied, then directory (*this)->path() is treated as an empty directory and no error is reported.

Returns: *this.

Throws: As specified in 29.11.6.
void pop();
void pop(error_code& ec);

Effects: If depth() == 0, set *this to recursive_directory_iterator(). Otherwise, cease iteration of the directory currently being iterated over, and continue iteration over the parent directory.

Throws: As specified in 29.11.6.

Remarks: Any copies of the previous value of *this are no longer required to be dereferenceable nor to be in the domain of ==.

void disable_recursion_pending();

Ensures: recursion_pending() == false.

[Note: disable_recursion_pending() is used to prevent unwanted recursion into a directory. — end note]

29.11.13.2 Non-member functions

These functions enable use of recursive_directory_iterator with range-based for statements.

recursive_directory_iterator begin(recursive_directory_iterator iter) noexcept;

Returns: iter.

recursive_directory_iterator end(const recursive_directory_iterator&) noexcept;

Returns: recursive_directory_iterator().

29.11.14 Filesystem operation functions

Filesystem operation functions query or modify files, including directories, in external storage.

[Note: Because hardware failures, network failures, file system races (29.11.2.3), and many other kinds of errors occur frequently in file system operations, users should be aware that any filesystem operation function, no matter how apparently innocuous, may encounter an error; see 29.11.6. — end note]

29.11.14.1 Absolute

path absolute(const path& p);
path absolute(const path& p, error_code& ec);

Effects: Composes an absolute path referencing the same file system location as p according to the operating system (29.11.2.2).

Returns: The composed path. The signature with argument ec returns path() if an error occurs.

[Note: For the returned path, rp, rp.is_absolute() is true unless an error occurs. — end note]

Throws: As specified in 29.11.6.

[Note: To resolve symlinks, or perform other sanitization which might require queries to secondary storage, such as hard disks, consider canonical (29.11.14.2). — end note]

[Note: Implementations are strongly encouraged to not query secondary storage, and not consider !exists(p) an error. — end note]

[Example: For POSIX-based operating systems, absolute(p) is simply current_path()/p. For Windows-based operating systems, absolute might have the same semantics as GetFullPathNameW. — end example]

29.11.14.2 Canonical

path canonical(const path& p);
path canonical(const path& p, error_code& ec);

Effects: Converts p to an absolute path that has no symbolic link, dot, or dot-dot elements in its pathname in the generic format.

Returns: A path that refers to the same file system object as absolute(p). The signature with argument ec returns path() if an error occurs.

Throws: As specified in 29.11.6.

Remarks: !exists(p) is an error.
29.11.14.3 Copy

void copy(const path& from, const path& to);

Effects: Equivalent to copy(from, to, copy_options::none).

void copy(const path& from, const path& to, error_code& ec);

Effects: Equivalent to copy(from, to, copy_options::none, ec).

void copy(const path& from, const path& to, copy_options options);
void copy(const path& from, const path& to, copy_options options,
          error_code& ec);

Requires: At most one element from each option group (29.11.9.3) is set in options.

Effects: Before the first use of f and t:

(4.1) If

  (options & copy_options::create_symlinks) != copy_options::none ||
  (options & copy_options::skip_symlinks) != copy_options::none

then auto f = symlink_status(from) and if needed auto t = symlink_status(to).

(4.2) Otherwise, if

  (options & copy_options::copy_symlinks) != copy_options::none

then auto f = symlink_status(from) and if needed auto t = status(to).

(4.3) Otherwise, auto f = status(from) and if needed auto t = status(to).

Effects are then as follows:

(4.4) If f.type() or t.type() is an implementation-defined file type (29.11.9.2), then the effects are implementation-defined.

(4.5) Otherwise, an error is reported as specified in 29.11.6 if:

(4.5.1) exists(f) is false, or

(4.5.2) equivalent(from, to) is true, or

(4.5.3) is_other(f) || is_other(t) is true, or

(4.5.4) is_directory(f) && is_regular_file(t) is true.

(4.6) Otherwise, if is_symlink(f), then:

(4.6.1) If (options & copy_options::skip_symlinks) != copy_options::none then return.

(4.6.2) Otherwise if

  !exists(t) && (options & copy_options::copy_symlinks) != copy_options::none

then copy_symlink(from, to).

(4.6.3) Otherwise report an error as specified in 29.11.6.

(4.7) Otherwise, if is_regular_file(f), then:

(4.7.1) If (options & copy_options::directories_only) != copy_options::none, then return.

(4.7.2) Otherwise, if (options & copy_options::create_symlinks) != copy_options::none, then create a symbolic link to the source file.

(4.7.3) Otherwise, if (options & copy_options::create_hard_links) != copy_options::none, then create a hard link to the source file.

(4.7.4) Otherwise, if is_directory(t), then copy_file(from, to/from.filename(), options).

(4.7.5) Otherwise, copy_file(from, to, options).

(4.7.6) Otherwise, if

  is_directory(f) &&
  (options & copy_options::create_symlinks) != copy_options::none

then report an error with an error_code argument equal to make_error_code(errc::is_a_directory).
Otherwise, if
\[ \text{is\_directory}(f) \land (options \& \text{copy\_options::recursive}) \neq \text{copy\_options::none} \mid\mid options == \text{copy\_options::none} \]
then:
- If \( \text{exists}(t) \) is false, then \( \text{create\_directory}(to, from) \).
- Then, iterate over the files in \( from \), as if by
  \[
  \text{for (const directory\_entry& x : directory\_iterator(from))}
  \]
  \[
  \text{copy(x.path()), to/x.path().filename(),}
  \]
  \[
  \text{options | copy\_options::in\_recursive\_copy};
  \]
where \text{in\_recursive\_copy} is a bitmask element of \text{copy\_options} that is not one of the elements in 29.11.9.3.

Otherwise, for the signature with argument \text{ec}, \text{ec.clear()}.

Otherwise, no effects.

\textbf{Throws:} As specified in 29.11.6.

\textbf{Remarks:} For the signature with argument \text{ec}, any library functions called by the implementation shall have an \text{error\_code} argument if applicable.

\textbf{Example:} Given this directory structure:

```
/dir1
  file1
  file2
  dir2
    file3
```

Calling \text{copy("/dir1", "/dir3")} would result in:

```
/dir1
  file1
  file2
  dir2
    file3
/dir3
  file1
  file2
```

Alternatively, calling \text{copy("/dir1", "/dir3", copy\_options::recursive)} would result in:

```
/dir1
  file1
  file2
  dir2
    file3
/dir3
  file1
  file2
  dir2
    file3
```

\textit{— end example}\]

### 29.11.14.4 Copy file

\textbf{bool copy\_file(const path& from, const path& to);}  
\textbf{bool copy\_file(const path& from, const path& to, error\_code& ec);}  

\textbf{Returns:} \text{copy\_file(from, to, copy\_options::none)} or \text{copy\_file(from, to, copy\_options::none, ec)}, respectively.

\textbf{Throws:} As specified in 29.11.6.

\textbf{bool copy\_file(const path& from, const path& to, copy\_options options);}
bool copy_file(const path& from, const path& to, copy_options options, 
    error_code& ec);

Requires: At most one element from each option group (29.11.9.3) is set in options.

Effects: As follows:

(4.1)
  — Report an error as specified in 29.11.6 if:

(4.1.1)
  — is_regular_file(from) is false, or

(4.1.2)
  — exists(to) is true and is_regular_file(to) is false, or

(4.1.3)
  — exists(to) is true and equivalent(from, to) is true, or

(4.1.4)
  — exists(to) is true and

  (options & (copy_options::skip_existing | 
    copy_options::overwrite_existing | 
    copy_options::update_existing)) == copy_options::none

(4.2)
  — Otherwise, copy the contents and attributes of the file from resolves to, to the file to resolves to, if:

(4.2.1)
  — exists(to) is false, or

(4.2.2)
  — (options & copy_options::overwrite_existing) != copy_options::none, or

(4.2.3)
  — (options & copy_options::update_existing) != copy_options::none and from is more recent than to, determined as if by use of the last_write_time function (29.11.14.25).

(4.3)
  — Otherwise, no effects.

Returns: true if the from file was copied, otherwise false. The signature with argument ec returns false if an error occurs.

Throws: As specified in 29.11.6.

Complexity: At most one direct or indirect invocation of status(to).

29.11.14.5 Copy symlink

void copy_symlink(const path& existing_symlink, const path& new_symlink);
void copy_symlink(const path& existing_symlink, const path& new_symlink, 
    error_code& ec) noexcept;

Effects: Equivalent to function(read_symlink(existing_symlink), new_symlink) or 
        function(read_symlink(existing_symlink, ec), new_symlink, ec), respectively, where in each 
        case function is create_symlink or create_directory_symlink as appropriate.

Throws: As specified in 29.11.6.

29.11.14.6 Create directories

bool create_directories(const path& p);
bool create_directories(const path& p, error_code& ec);

Effects: Calls create_directory() for each element of p that does not exist.

Returns: true if a new directory was created for the directory p resolves to, otherwise false.

Throws: As specified in 29.11.6.

Complexity: O(n) where n is the number of elements of p.

29.11.14.7 Create directory

bool create_directory(const path& p);
bool create_directory(const path& p, error_code& ec) noexcept;

Effects: Creates the directory p resolves to, as if by POSIX mkdir with a second argument of static_cast<int>(perms::all). If mkdir fails because p resolves to an existing directory, no error is reported. Otherwise on failure an error is reported.

Returns: true if a new directory was created, otherwise false.

Throws: As specified in 29.11.6.
bool create_directory(const path& p, const path& existing_p);
bool create_directory(const path& p, const path& existing_p, error_code& ec) noexcept;

**Effects:** Creates the directory `p` resolves to, with attributes copied from directory `existing_p`. The set of attributes copied is operating system dependent. If `mkdir` fails because `p` resolves to an existing directory, no error is reported. Otherwise on failure an error is reported. [Note: For POSIX-based operating systems, the attributes are those copied by native API `stat(existing_p.c_str(), &attributes_stat)` followed by `mkdir(p.c_str(), attributes_stat.st_mode)`. For Windows-based operating systems, the attributes are those copied by native API `CreateDirectoryExW(existing_p.c_str(), p.c_str(), 0)`. —end note]

**Returns:** `true` if a new directory was created with attributes copied from directory `existing_p`, otherwise `false`.

**Throws:** As specified in 29.11.6.

### 29.11.14.8 Create directory symlink

void create_directory_symlink(const path& to, const path& new_symlink);
void create_directory_symlink(const path& to, const path& new_symlink, error_code& ec) noexcept;

**Effects:** Establishes the postcondition, as if by POSIX `symlink()`.

**Ensures:** `new_symlink` resolves to a symbolic link file that contains an unspecified representation of `to`.

**Throws:** As specified in 29.11.6.

[Note: Some operating systems require symlink creation to identify that the link is to a directory. Portable code should use `create_directory_symlink()` to create directory symlinks rather than `create_symlink()` —end note]

### 29.11.14.9 Create hard link

void create_hard_link(const path& to, const path& new_hard_link);
void create_hard_link(const path& to, const path& new_hard_link, error_code& ec) noexcept;

**Effects:** Establishes the postcondition, as if by POSIX `link()`.

**Ensures:**

(2.1) `exists(to) && exists(new_hard_link) && equivalent(to, new_hard_link)`

(2.2) The contents of the file or directory `to` resolves to are unchanged.

**Throws:** As specified in 29.11.6.

[Note: Some operating systems do not support hard links at all or support them only for regular files. Some file systems (such as the FAT file system) do not support hard links regardless of the operating system. —end note]

### 29.11.14.10 Create symlink

void create_symlink(const path& to, const path& new_symlink);
void create_symlink(const path& to, const path& new_symlink, error_code& ec) noexcept;

**Effects:** Establishes the postcondition, as if by POSIX `symlink()`.

**Ensures:** `new_symlink` resolves to a symbolic link file that contains an unspecified representation of `to`.

**Throws:** As specified in 29.11.6.

[Note: Some operating systems do not support symbolic links at all or support them only for regular files. Some file systems (such as the FAT file system) do not support symbolic links regardless of the operating system. —end note]
29.11.14.11 Current path

path current_path();
path current_path(error_code& ec);

Returns: The absolute path of the current working directory, whose pathname in the native format is obtained as if by POSIX `getcwd()`. The signature with argument `ec` returns `path()` if an error occurs.

Throws: As specified in 29.11.6.

Remarks: The current working directory is the directory, associated with the process, that is used as the starting location in pathname resolution for relative paths.

[Note: The `current_path()` name was chosen to emphasize that the returned value is a path, not just a single directory name. — end note]

[Note: The current path as returned by many operating systems is a dangerous global variable. It may be changed unexpectedly by third-party or system library functions, or by another thread. — end note]

void current_path(const path& p);
void current_path(const path& p, error_code& ec) noexcept;

Effects: Establishes the postcondition, as if by POSIX `chdir()`.

Ensures: equivalent(p, current_path()).

Throws: As specified in 29.11.6.

[Note: The current path for many operating systems is a dangerous global state. It may be changed unexpectedly by a third-party or system library functions, or by another thread. — end note]

29.11.14.12 Equivalent

bool equivalent(const path& p1, const path& p2);
bool equivalent(const path& p1, const path& p2, error_code& ec) noexcept;

Returns: true, if p1 and p2 resolve to the same file system entity, otherwise false. The signature with argument `ec` returns false if an error occurs.

Two paths are considered to resolve to the same file system entity if two candidate entities reside on the same device at the same location. [Note: On POSIX platforms, this is determined as if by the values of the POSIX `stat` class, obtained as if by `stat()` for the two paths, having equal `st_dev` values and equal `st_ino` values. — end note]

Remarks: !exists(p1) || !exists(p2) is an error.

Throws: As specified in 29.11.6.

29.11.14.13 Exists

bool exists(file_status s) noexcept;

Returns: `status_known(s) && s.type() != file_type::not_found`.

bool exists(const path& p);
bool exists(const path& p, error_code& ec) noexcept;

Let s be a file_status, determined as if by `status(p)` or `status(p, ec)`, respectively.

Effects: The signature with argument `ec` calls `ec.clear()` if `status_known(s)`.

Returns: `exists(s)`.

Throws: As specified in 29.11.6.

29.11.14.14 File size

uintmax_t file_size(const path& p);
uintmax_t file_size(const path& p, error_code& ec) noexcept;

Effects: If `exists(p)` is false, an error is reported (29.11.6).

Returns:
— If is_regular_file(p), the size in bytes of the file p resolves to, determined as if by the value of the POSIX stat class member st_size obtained as if by POSIX stat().

— Otherwise, the result is implementation-defined.

The signature with argument ec returns static_cast<uintmax_t>(-1) if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.15 Hard link count

uintmax_t hard_link_count(const path& p);
uintmax_t hard_link_count(const path& p, error_code& ec) noexcept;

Returns: The number of hard links for p. The signature with argument ec returns static_cast<uintmax_t>(-1) if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.16 Is block file

bool is_block_file(file_status s) noexcept;

Returns: s.type() == file_type::block.

bool is_block_file(const path& p);
bool is_block_file(const path& p, error_code& ec) noexcept;

Returns: is_block_file(status(p)) or is_block_file(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.17 Is character file

bool is_character_file(file_status s) noexcept;

Returns: s.type() == file_type::character.

bool is_character_file(const path& p);
bool is_character_file(const path& p, error_code& ec) noexcept;

Returns: is_character_file(status(p)) or is_character_file(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.18 Is directory

bool is_directory(file_status s) noexcept;

Returns: s.type() == file_type::directory.

bool is_directory(const path& p);
bool is_directory(const path& p, error_code& ec) noexcept;

Returns: is_directory(status(p)) or is_directory(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.19 Is empty

bool is_empty(const path& p);
bool is_empty(const path& p, error_code& ec);

Effects:

(1.1) — Determine file_status s, as if by status(p) or status(p, ec), respectively.
(1.2) — For the signature with argument ec, return false if an error occurred.
(1.3) — Otherwise, if is_directory(s):
(1.3.1) — Create a variable itr, as if by directory_iterator itr(p) or directory_iterator itr(p, ec), respectively.
For the signature with argument `ec`, return `false` if an error occurred.

Otherwise, return `itr == directory_iterator()`.

Determine `uintmax_t sz`, as if by `file_size(p)` or `file_size(p, ec)`, respectively.

For the signature with argument `ec`, return `false` if an error occurred.

Otherwise, return `sz == 0`.

Throws: As specified in 29.11.6.

29.11.14.20  Is fifo

```cpp
bool is_fifo(file_status s) noexcept;
```

Returns: `s.type() == file_type::fifo`.

```cpp
bool is_fifo(const path& p);
bool is_fifo(const path& p, error_code& ec) noexcept;
```

Returns: `is_fifo(status(p))` or `is_fifo(status(p, ec))`, respectively. The signature with argument `ec` returns `false` if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.21  Is other

```cpp
bool is_other(file_status s) noexcept;
```

Returns: `exists(s) && !is_regular_file(s) && !is_directory(s) && !is_symlink(s)`.

```cpp
bool is_other(const path& p);
bool is_other(const path& p, error_code& ec) noexcept;
```

Returns: `is_other(status(p))` or `is_other(status(p, ec))`, respectively. The signature with argument `ec` returns `false` if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.22  Is regular file

```cpp
bool is_regular_file(file_status s) noexcept;
```

Returns: `s.type() == file_type::regular`.

```cpp
bool is_regular_file(const path& p);
```

Returns: `is_regular_file(status(p))`.

Throws: filesystem_error if `status(p)` would throw filesystem_error.

```cpp
bool is_regular_file(const path& p, error_code& ec) noexcept;
```

Effects: Sets `ec` as if by `status(p, ec)`. [Note: `file_type::none`, `file_type::not_found` and `file_type::unknown` cases set `ec` to error values. To distinguish between cases, call the `status` function directly. —end note]

Returns: `is_regular_file(status(p, ec))`. Returns `false` if an error occurs.

29.11.14.23  Is socket

```cpp
bool is_socket(file_status s) noexcept;
```

Returns: `s.type() == file_type::socket`.

```cpp
bool is_socket(const path& p);
bool is_socket(const path& p, error_code& ec) noexcept;
```

Returns: `is_socket(status(p))` or `is_socket(status(p, ec))`, respectively. The signature with argument `ec` returns `false` if an error occurs.

Throws: As specified in 29.11.6.
29.11.14.24 Is symlink

bool is_symlink(file_status s) noexcept;
1
Returns: s.type() == file_type::symlink.

bool is_symlink(const path& p);
bool is_symlink(const path& p, error_code& ec) noexcept;
2
Returns: is_symlink(symlink_status(p)) or is_symlink(symlink_status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 29.11.6.

29.11.14.25 Last write time

file_time_type last_write_time(const path& p);
file_time_type last_write_time(const path& p, error_code& ec) noexcept;
1
Returns: The time of last data modification of p, determined as if by the value of the POSIX stat class member st_mtime obtained as if by POSIX stat(). The signature with argument ec returns file_time_type::min() if an error occurs.

Throws: As specified in 29.11.6.

void last_write_time(const path& p, file_time_type new_time);
void last_write_time(const path& p, file_time_type new_time, error_code& ec) noexcept;
3
Effects: Sets the time of last data modification of the file resolved to by p to new_time, as if by POSIX futimens().

Throws: As specified in 29.11.6.

[Note: A postcondition of last_write_time(p) == new_time is not specified since it might not hold for file systems with coarse time granularity. —end note]

29.11.14.26 Permissions

void permissions(const path& p, perms prms, perm_options opts=perm_options::replace);
void permissions(const path& p, perms prms, error_code& ec) noexcept;
void permissions(const path& p, perms prms, perm_options opts, error_code& ec);
1
Requires: Exactly one of the perm_options constants replace, add, or remove is present in opts.

Remarks: The second signature behaves as if it had an additional parameter perm_options opts with an argument of perm_options::replace.

Effects: Applies the action specified by opts to the file p resolves to, or to file p itself if p is a symbolic link and perm_options::nofollow is set in opts. The action is applied as if by POSIX fchmodat().

[Note: Conceptually permissions are viewed as bits, but the actual implementation may use some other mechanism. —end note]

Throws: As specified in 29.11.6.

29.11.14.27 Proximate

path proximate(const path& p, error_code& ec);
1
Returns: proximate(p, current_path(), ec).

Throws: As specified in 29.11.6.

path proximate(const path& p, const path& base = current_path());
path proximate(const path& p, const path& base, error_code& ec);
3
Returns: For the first form:
weakly_canonical(p).lexically_proximate(weakly_canonical(base));

For the second form:
weakly_canonical(p, ec).lexically_proximate(weakly_canonical(base, ec));
or `path()` at the first error occurrence, if any.

**Throws**: As specified in 29.11.6.

### 29.11.14.28 Read symlink

```cpp
path read_symlink(const path& p);
path read_symlink(const path& p, error_code& ec);
```

**Returns**: If `p` resolves to a symbolic link, a `path` object containing the contents of that symbolic link. The signature with argument `ec` returns `path()` if an error occurs.

**Throws**: As specified in 29.11.6. [Note: It is an error if `p` does not resolve to a symbolic link. — end note]

### 29.11.14.29 Relative

```cpp
path relative(const path& p, error_code& ec);
```

**Returns**: `relative(p, current_path(), ec)`.

**Throws**: As specified in 29.11.6.

### 29.11.14.30 Remove

```cpp
bool remove(const path& p);
bool remove(const path& p, error_code& ec) noexcept;
```

**Effects**: If `exists(symlink_status(p, ec))`, the file `p` is removed as if by POSIX `remove()`. [Note: A symbolic link is itself removed, rather than the file it resolves to. — end note]

**Ensures**: `exists(symlink_status(p))` is false.

**Returns**: `false` if `p` did not exist, otherwise `true`. The signature with argument `ec` returns `false` if an error occurs.

**Throws**: As specified in 29.11.6.

### 29.11.14.31 Remove all

```cpp
uintmax_t remove_all(const path& p);
uintmax_t remove_all(const path& p, error_code& ec);
```

**Effects**: Recursively deletes the contents of `p` if it exists, then deletes file `p` itself, as if by POSIX `remove()`. [Note: A symbolic link is itself removed, rather than the file it resolves to. — end note]

**Ensures**: `exists(symlink_status(p))` is false.

**Returns**: The number of files removed. The signature with argument `ec` returns `static_cast<
uintmax_t>(-1)` if an error occurs.

**Throws**: As specified in 29.11.6.

### 29.11.14.32 Rename

```cpp
void rename(const path& old_p, const path& new_p);
void rename(const path& old_p, const path& new_p, error_code& ec) noexcept;
```

**Effects**: Renames `old_p` to `new_p`, as if by POSIX `rename()`.

[Note:
— If old_p and new_p resolve to the same existing file, no action is taken.
— Otherwise, the rename may include the following effects:
  — if new_p resolves to an existing non-directory file, new_p is removed; otherwise,
  — if new_p resolves to an existing directory, new_p is removed if empty on POSIX compliant
    operating systems but may be an error on other operating systems.

A symbolic link is itself renamed, rather than the file it resolves to. — end note]

2

29.11.14.33  Resize file  

void resize_file(const path& p, uintmax_t new_size);
void resize_file(const path& p, uintmax_t new_size, error_code& ec) noexcept;

1

Effects: Causes the size that would be returned by file_size(p) to be equal to new_size, as if by
POSIX truncate().

2

Throws: As specified in 29.11.6.

29.11.14.34  Space  

space_info space(const path& p);
space_info space(const path& p, error_code& ec) noexcept;

1

Returns: An object of type space_info. The value of the space_info object is determined as if
by using POSIX statvfs to obtain a POSIX struct statvfs, and then multiplying its f_blocks,
free, and available members respectively. Any members for which the value cannot be determined
shall be set to static_cast<uintmax_t>(-1). For the signature with argument ec, all members are
set to static_cast<uintmax_t>(-1) if an error occurs.

2

Throws: As specified in 29.11.6.

3

Remarks: The value of member space_info::available is operating system dependent. [Note:
available may be less than free. — end note]

29.11.14.35  Status  

file_status status(const path& p);

1

Effects: As if:

error_code ec;
file_status result = status(p, ec);
if (result.type() == file_type::none)
  throw filesystem_error(implementation-supplied-message, p, ec);
return result;

2

Returns: See above.

3

Throws: filesystem_error. [Note: result values of file_status(file_type::not_found) and
file_status(file_type::unknown) are not considered failures and do not cause an exception to be
thrown. — end note]

file_status status(const path& p, error_code& ec) noexcept;

4

Effects: If possible, determines the attributes of the file p resolves to, as if by using POSIX stat()
to obtain a POSIX struct stat. If, during attribute determination, the underlying file system API
reports an error, sets ec to indicate the specific error reported. Otherwise, ec.clear(). [Note: This
allows users to inspect the specifics of underlying API errors even when the value returned by status() is
not file_status(file_type::none). — end note]

5

Let prms denote the result of (m & perms::mask), where m is determined as if by converting the
st_mode member of the obtained struct stat to the type perms.

6

Returns:

(6.1) — If ec != error_code():
If the specific error indicates that \( p \) cannot be resolved because some element of the path does not exist, returns \( \text{file_status(file_type::not_found)} \).

Otherwise, if the specific error indicates that \( p \) can be resolved but the attributes cannot be determined, returns \( \text{file_status(file_type::unknown)} \).

Otherwise, returns \( \text{file_status(file_type::none)} \).

[Note: These semantics distinguish between \( p \) being known not to exist, \( p \) existing but not being able to determine its attributes, and there being an error that prevents even knowing if \( p \) exists. These distinctions are important to some use cases. — end note]

Otherwise,

— If the attributes indicate a regular file, as if by POSIX \( S_ISREG \), returns \( \text{file_status(file_type::regular, prms)} \). [Note: file_type::regular implies appropriate \(<\text{fstream}>\) operations would succeed, assuming no hardware, permission, access, or file system race errors. Lack of file_type::regular does not necessarily imply \(<\text{fstream}>\) operations would fail on a directory. — end note]

— Otherwise, if the attributes indicate a directory, as if by POSIX \( S_ISDIR \), returns \( \text{file_status(file_type::directory, prms)} \). [Note: file_type::directory implies that calling \( \text{directory_iterator(p)} \) would succeed. — end note]

— Otherwise, if the attributes indicate a block special file, as if by POSIX \( S_ISBLK \), returns \( \text{file_status(file_type::block, prms)} \).

— Otherwise, if the attributes indicate a character special file, as if by POSIX \( S_ISCHR \), returns \( \text{file_status(file_type::character, prms)} \).

— Otherwise, if the attributes indicate a fifo or pipe file, as if by POSIX \( S_ISFIFO \), returns \( \text{file_status(file_type::fifo, prms)} \).

— Otherwise, if the attributes indicate a socket, as if by POSIX \( S_ISSOCK \), returns \( \text{file_status(file_type::socket, prms)} \).

— Otherwise, if the attributes indicate an implementation-defined file type (29.11.9.2), returns \( \text{file_status(file_type::A, prms)} \), where \( A \) is the constant for the implementation-defined file type.

— Otherwise, returns \( \text{file_status(file_type::unknown, prms)} \).

Remarks: If a symbolic link is encountered during pathname resolution, pathname resolution continues using the contents of the symbolic link.

### 29.11.14.36 Status known

bool status_known(file_status s) noexcept;

Returns: \( s.\text{type()} \neq \text{file_type::none} \).

### 29.11.14.37 Symlink status

file_status symlink_status(const path& p);

file_status symlink_status(const path& p, error_code& ec) noexcept;

Effects: Same as \( \text{status()} \), above, except that the attributes of \( p \) are determined as if by using POSIX \( \text{lstat()} \) to obtain a POSIX struct \( \text{stat} \).

Let \( \text{prms} \) denote the result of \( (m \& \text{perms}::\text{mask}) \), where \( m \) is determined as if by converting the \( \text{st_mode} \) member of the obtained struct \( \text{stat} \) to the type \( \text{perms} \).

Returns: Same as \( \text{status()} \), above, except that if the attributes indicate a symbolic link, as if by POSIX \( S_ISLINK \), returns \( \text{file_status(file_type::symlink, prms)} \). The signature with argument \( \text{ec} \) returns \( \text{file_status(file_type::none)} \) if an error occurs.

Remarks: Pathname resolution terminates if \( p \) names a symbolic link.

Throws: As specified in 29.11.6.

### 29.11.14.38 Temporary directory path

path temp_directory_path();
path temp_directory_path(error_code& ec);

1. Let p be an unspecified directory path suitable for temporary files.

Effects: If exists(p) is false or is_directory(p) is false, an error is reported (29.11.6).

Returns: The path p. The signature with argument ec returns path() if an error occurs.

Throws: As specified in 29.11.6.

[Example: For POSIX-based operating systems, an implementation might return the path supplied by the first environment variable found in the list TMPDIR, TMP, TEMP, TEMPDIR, or if none of these are found, "/tmp".
For Windows-based operating systems, an implementation might return the path reported by the Windows GetTempPath API function. — end example]

29.11.14.39 Weakly canonical

path weakly_canonical(const path& p);
path weakly_canonical(const path& p, error_code& ec);

1. Returns: p with symlinks resolved and the result normalized (29.11.7.1).

Effects: Using status(p) or status(p, ec), respectively, to determine existence, return a path composed by operator/= from the result of calling canonical() with a path argument composed of the leading elements of p that exist, if any, followed by the elements of p that do not exist, if any: For the first form, canonical() is called without an error_code argument. For the second form, canonical() is called with ec as an error_code argument, and path() is returned at the first error occurrence, if any.

Ensures: The returned path is in normal form (29.11.7.1).

Remarks: Implementations should avoid unnecessary normalization such as when canonical has already been called on the entirety of p.

Throws: As specified in 29.11.6.

The contents and meaning of the header <cinttypes> are the same as the C standard library header <inttypes.h>, with the following changes:

— The header <cinttypes> includes the header <cstdint> instead of <stdint.h>, and
if and only if the type `intmax_t` designates an extended integer type (6.7.1), the following function signatures are added:

```c
intmax_t abs(intmax_t);
imaxdiv_t div(intmax_t, intmax_t);
```

which shall have the same semantics as the function signatures `intmax_t imaxabs(intmax_t)` and `imaxdiv_t imaxdiv(intmax_t, intmax_t)`, respectively.

30 Regular expressions library [re]

30.1 General [re.general]

1 This Clause describes components that C++ programs may use to perform operations involving regular expression matching and searching.

2 The following subclauses describe a basic regular expression class template and its traits that can handle char-like (21.1) template arguments, two specializations of this class template that handle sequences of char and wchar_t, a class template that holds the result of a regular expression match, a series of algorithms that allow a character sequence to be operated upon by a regular expression, and two iterator types for enumerating regular expression matches, as summarized in Table 122.

30.2 Definitions [re.def]

1 The following definitions shall apply to this Clause:

30.2.1 [defns.regex.collating.element]
collating element
a sequence of one or more characters within the current locale that collate as if they were a single character.

30.2.2 [defns.regex.finite.state.machine]
finite state machine
an unspecified data structure that is used to represent a regular expression, and which permits efficient matches against the regular expression to be obtained.

30.2.3 [defns.regex.format.specifier]
format specifier
a sequence of one or more characters that is to be replaced with some part of a regular expression match.

30.2.4 [defns.regex.matched]
matched
a sequence of zero or more characters is matched by a regular expression when the characters in the sequence correspond to a sequence of characters defined by the pattern.

30.2.5 [defns.regex.primary.equivalence.class]
primary equivalence class
a set of one or more characters which share the same primary sort key: that is the sort key weighting that depends only upon character shape, and not accents, case, or locale specific tailorings.
30.2.6 [defns.regex.regular.expression]

regular expression
a pattern that selects specific strings from a set of character strings.

30.2.7 [defns.regex.subexpression]

sub-expression
a subset of a regular expression that has been marked by parenthesis.

30.3 Requirements [re.req]

1 This subclause defines requirements on classes representing regular expression traits. [Note: The class template regex_traits, defined in 30.7, meets these requirements. — end note]

2 The class template basic_regex, defined in 30.8, needs a set of related types and functions to complete the definition of its semantics. These types and functions are provided as a set of member typedef-names and functions in the template parameter traits used by the basic_regex class template. This subclause defines the semantics of these members.

3 To specialize class template basic_regex for a character container CharT and its related regular expression traits class Traits, use basic_regex<CharT, Traits>.

4 In Table 123 X denotes a traits class defining types and functions for the character container type charT; u is an object of type X; v is an object of type const X; p is a value of type const charT*; I1 and I2 are input iterators (23.3.5.2); F1 and F2 are forward iterators (23.3.5.4); c is a value of type const charT; s is an object of type X::string_type; cs is an object of type const X::string_type; b is a value of type bool; I is a value of type int; cl is an object of type X::char_class_type, and loc is an object of type X::locale_type.

Table 123: Regular expression traits class requirements [tab:re.req]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>X::char_type</td>
<td>charT</td>
<td>The character container type used in the implementation of class template basic_regex.</td>
</tr>
<tr>
<td>X::string_type</td>
<td>basic_string&lt;CharT&gt;</td>
<td></td>
</tr>
<tr>
<td>X::locale_type</td>
<td>A copy constructible type</td>
<td>A type that represents the locale used by the traits class.</td>
</tr>
<tr>
<td>X::char_class_type</td>
<td>A bitmask type (16.4.2.2.4).</td>
<td>A bitmask type representing a particular character classification.</td>
</tr>
<tr>
<td>X::length(p)</td>
<td>size_t</td>
<td>Yields the smallest i such that p[i] == 0. Complexity is linear in i.</td>
</tr>
<tr>
<td>v.translate(c)</td>
<td>X::char_type</td>
<td>Returns a character such that for any character d that is to be considered equivalent to c then v.translate(c) == v.translate(d).</td>
</tr>
<tr>
<td>v.translate_nocase(c)</td>
<td>X::char_type</td>
<td>For all characters C that are to be considered equivalent to c when comparisons are to be performed without regard to case, then v.translate_nocase(c) == v.translate_nocase(C).</td>
</tr>
<tr>
<td>v.transform(F1, F2)</td>
<td>X::string_type</td>
<td>Returns a sort key for the character sequence designated by the iterator range [F1, F2) such that if the character sequence [G1, G2) sorts before the character sequence [H1, H2) then v.transform(G1, G2) &lt; v.transform(H1, H2).</td>
</tr>
</tbody>
</table>
Table 123: Regular expression traits class requirements (continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>v.transform_primary(F1, F2)</td>
<td>X::string_type</td>
<td>Returns a sort key for the character sequence designated by the iterator range [F1, F2) such that if the character sequence [G1, G2) sorts before the character sequence [H1, H2) when character case is not considered then v.transform_primary(G1, G2) &lt; v.transform_primary(H1, H2).</td>
</tr>
<tr>
<td>v.lookup_collatename(F1, F2)</td>
<td>X::string_type</td>
<td>Returns a sequence of characters that represents the collating element consisting of the character sequence designated by the iterator range [F1, F2). Returns an empty string if the character sequence is not a valid collating element.</td>
</tr>
<tr>
<td>v.lookup_classname(F1, F2, b)</td>
<td>X::char_class_type</td>
<td>Converts the character sequence designated by the iterator range [F1, F2) into a value of a bitmask type that can subsequently be passed to isctype. Values returned from lookup_classname can be bitwise OR’ed together; the resulting value represents membership in either of the corresponding character classes. If b is true, the returned bitmask is suitable for matching characters without regard to their case. Returns 0 if the character sequence is not the name of a character class recognized by X. The value returned shall be independent of the case of the characters in the sequence.</td>
</tr>
<tr>
<td>v.isctype(c, cl)</td>
<td>bool</td>
<td>Returns true if character c is a member of one of the character classes designated by cl, false otherwise.</td>
</tr>
<tr>
<td>v.value(c, I)</td>
<td>int</td>
<td>Returns the value represented by the digit c in base I if the character c is a valid digit in base I; otherwise returns -1. [Note: The value of I will only be 8, 10, or 16. —end note]</td>
</tr>
<tr>
<td>u.imbue(loc)</td>
<td>X::locale_type</td>
<td>Imbues u with the locale loc and returns the previous locale used by u if any.</td>
</tr>
<tr>
<td>v.getloc()</td>
<td>X::locale_type</td>
<td>Returns the current locale used by v, if any.</td>
</tr>
</tbody>
</table>

5 [Note: Class template regex_traits meets the requirements for a regular expression traits class when it is specialized for char or wchar_t. This class template is described in the header <regex>, and is described in 30.7. —end note]

        std::match_results<BidirectionalIterator, polymorphic_allocator<sub_match<BidirectionalIterator>>>;

    using cmatch = match_results<const char*>;
    using wcmatch = match_results<const wchar_t*>;
    using smatch = match_results<string::const_iterator>;
    using wsmatch = match_results<wstring::const_iterator>;
}

30.5 Namespace std::regex_constants

The namespace std::regex_constants holds symbolic constants used by the regular expression library. This namespace provides three types, syntax_option_type, match_flag_type, and error_type, along with several constants of these types.

30.5.1 Bitmask type syntax_option_type

namespace std::regex_constants {
    using syntax_option_type = T1;
    inline constexpr syntax_option_type icase = unspecified;
    inline constexpr syntax_option_type nosubs = unspecified;
    inline constexpr syntax_option_type optimize = unspecified;
    inline constexpr syntax_option_type collate = unspecified;
    inline constexpr syntax_option_type ECMAScript = unspecified;
    inline constexpr syntax_option_type basic = unspecified;
    inline constexpr syntax_option_type extended = unspecified;
    inline constexpr syntax_option_type awk = unspecified;
    inline constexpr syntax_option_type grep = unspecified;
    inline constexpr syntax_option_type egrep = unspecified;
    inline constexpr syntax_option_type multiline = unspecified;
}

The type syntax_option_type is an implementation-defined bitmask type (16.4.2.2.4). Setting its elements has the effects listed in Table 124. A valid value of type syntax_option_type shall have at most one of the grammar elements ECMAScript, basic, extended, awk, grep, egrep, set. If no grammar element is set, the default grammar is ECMAScript.

30.5.2 Bitmask type match_flag_type

namespace std::regex_constants {
    using match_flag_type = T2;
    inline constexpr match_flag_type match_default = {};
    inline constexpr match_flag_type match_not_bol = unspecified;
    inline constexpr match_flag_type match_not_bow = unspecified;
    inline constexpr match_flag_type match_not_eol = unspecified;
    inline constexpr match_flag_type match_not_eow = unspecified;
    inline constexpr match_flag_type match_any = unspecified;
    inline constexpr match_flag_type match_not_null = unspecified;
    inline constexpr match_flag_type match_continuous = unspecified;
    inline constexpr match_flag_type match_prev_avail = unspecified;
    inline constexpr match_flag_type format_default = {};
    inline constexpr match_flag_type format_sed = unspecified;
    inline constexpr match_flag_type format_no_copy = unspecified;
    inline constexpr match_flag_type format_first_only = unspecified;
}
### Table 124: `syntax_option_type` effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>icase</td>
<td>Specifies that matching of regular expressions against a character container sequence shall be performed without regard to case.</td>
</tr>
<tr>
<td>nosubs</td>
<td>Specifies that no sub-expressions shall be considered to be marked, so that when a regular expression is matched against a character container sequence, no sub-expression matches shall be stored in the supplied <code>match_results</code> object.</td>
</tr>
<tr>
<td>optimize</td>
<td>Specifies that the regular expression engine should pay more attention to the speed at which regular expressions are matched, and less to the speed with which regular expression objects are constructed. Otherwise it has no detectable effect on the program output.</td>
</tr>
<tr>
<td>collate</td>
<td>Specifies that character ranges of the form &quot;[a-b]&quot; shall be locale sensitive.</td>
</tr>
<tr>
<td>ECMAScript</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by ECMAScript in ECMA-262, as modified in 30.13. See also: ECMA-262 15.10</td>
</tr>
<tr>
<td>basic</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by basic regular expressions in POSIX. See also: POSIX, Base Definitions and Headers, Section 9.3</td>
</tr>
<tr>
<td>extended</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by extended regular expressions in POSIX. See also: POSIX, Base Definitions and Headers, Section 9.4</td>
</tr>
<tr>
<td>awk</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by the utility awk in POSIX.</td>
</tr>
<tr>
<td>grep</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by the utility grep in POSIX.</td>
</tr>
<tr>
<td>egrep</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by the utility grep when given the -E option in POSIX.</td>
</tr>
<tr>
<td>multiline</td>
<td>Specifies that ^ shall match the beginning of a line and $ shall match the end of a line, if the ECMAScript engine is selected.</td>
</tr>
</tbody>
</table>

---

1 The type `match_flag_type` is an implementation-defined bitmask type (16.4.2.2.4). The constants of that type, except for `match_default` and `format_default`, are bitmask elements. The `match_default` and `format_default` constants are empty bitmasks. Matching a regular expression against a sequence of characters `[first, last)` proceeds according to the rules of the grammar specified for the regular expression object, modified according to the effects listed in Table 125 for any bitmask elements set.

### Table 125: `regex_constants::match_flag_type` effects when obtaining a match against a character container sequence `[first, last)`.  

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>match_not_bol</td>
<td>The first character in the sequence <code>[first, last)</code> shall be treated as though it is not at the beginning of a line, so the character ^ in the regular expression shall not match <code>[first, first)</code>.</td>
</tr>
<tr>
<td>match_not_eol</td>
<td>The last character in the sequence <code>[first, last)</code> shall be treated as though it is not at the end of a line, so the character &quot;$&quot; in the regular expression shall not match <code>[last, last)</code>.</td>
</tr>
</tbody>
</table>
| match_not_bow      | The expression "\b" shall not match the sub-sequence `[first, first)`.
| match_not_eow      | The expression "\b" shall not match the sub-sequence `[last, last)`. |
| match_any          | If more than one match is possible then any match is an acceptable result. |
| match_not_null     | The expression shall not match an empty sequence. |
| match_continuous   | The expression shall only match a sub-sequence that begins at `first`. |
| match_prev_avail   | --`first` is a valid iterator position. When this flag is set the flags `match_not_bol` and `match_not_bow` shall be ignored by the regular expression algorithms (30.11) and iterators (30.12). |
Table 125: regex_constants::match_flag_type effects when obtaining a match against a character container sequence [first, last). (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>format_default</td>
<td>When a regular expression match is to be replaced by a new string, the new string shall be constructed using the rules used by the ECMAScript replace function in ECMA-262, part 15.5.4.11 String.prototype.replace. In addition, during search and replace operations all non-overlapping occurrences of the regular expression shall be located and replaced, and sections of the input that did not match the expression shall be copied unchanged to the output string.</td>
</tr>
<tr>
<td>format_sed</td>
<td>When a regular expression match is to be replaced by a new string, the new string shall be constructed using the rules used by the sed utility in POSIX.</td>
</tr>
<tr>
<td>format_no_copy</td>
<td>During a search and replace operation, sections of the character container sequence being searched that do not match the regular expression shall not be copied to the output string.</td>
</tr>
<tr>
<td>format_first_only</td>
<td>When specified during a search and replace operation, only the first occurrence of the regular expression shall be replaced.</td>
</tr>
</tbody>
</table>

30.5.3 Implementation-defined error_type

namespace std::regex_constants {
    using error_type = T3;
    inline constexpr error_type error_collate = unspecified;
    inline constexpr error_type error_ctype = unspecified;
    inline constexpr error_type error_escape = unspecified;
    inline constexpr error_type error_backref = unspecified;
    inline constexpr error_type error_brack = unspecified;
    inline constexpr error_type error_paren = unspecified;
    inline constexpr error_type error_brace = unspecified;
    inline constexpr error_type error_badbrace = unspecified;
    inline constexpr error_type error_range = unspecified;
    inline constexpr error_type error_space = unspecified;
    inline constexpr error_type error_badrepeat = unspecified;
    inline constexpr error_type error_complexity = unspecified;
    inline constexpr error_type error_stack = unspecified;
}

1 The type error_type is an implementation-defined enumerated type (16.4.2.2.3). Values of type error_type represent the error conditions described in Table 126:

Table 126: error_type values in the C locale

<table>
<thead>
<tr>
<th>Value</th>
<th>Error condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_collate</td>
<td>The expression contained an invalid collating element name.</td>
</tr>
<tr>
<td>error_ctype</td>
<td>The expression contained an invalid character class name.</td>
</tr>
<tr>
<td>error_escape</td>
<td>The expression contained an invalid escaped character, or a trailing escape.</td>
</tr>
<tr>
<td>error_backref</td>
<td>The expression contained an invalid back reference.</td>
</tr>
<tr>
<td>error_brack</td>
<td>The expression contained mismatched [ and ].</td>
</tr>
<tr>
<td>error_paren</td>
<td>The expression contained mismatched { and }.</td>
</tr>
<tr>
<td>error_brace</td>
<td>The expression contained mismatched { and }.</td>
</tr>
<tr>
<td>error_badbrace</td>
<td>The expression contained an invalid range in a {} expression.</td>
</tr>
<tr>
<td>error_range</td>
<td>The expression contained an invalid character range, such as [b-a] in most encodings.</td>
</tr>
<tr>
<td>error_space</td>
<td>There was insufficient memory to convert the expression into a finite state machine.</td>
</tr>
<tr>
<td>error_badrepeat</td>
<td>One of *+{ was not preceded by a valid regular expression.</td>
</tr>
<tr>
<td>error_complexity</td>
<td>The complexity of an attempted match against a regular expression exceeded a pre-set level.</td>
</tr>
<tr>
<td>error_stack</td>
<td>There was insufficient memory to determine whether the regular expression could match the specified character sequence.</td>
</tr>
</tbody>
</table>
30.6 Class regex_error

```cpp
class regex_error : public runtime_error {
public:
    explicit regex_error(regex_constants::error_type ecode);
    regex_constants::error_type code() const;
};
```

The class `regex_error` defines the type of objects thrown as exceptions to report errors from the regular expression library.

```cpp
regex_error(regex_constants::error_type ecode);
```

**Effects:** Constructs an object of class `regex_error`.

```cpp
regex_constants::error_type code() const;
```

**Returns:** The error code that was passed to the constructor.

30.7 Class template regex_traits

```cpp
namespace std {
    template<class charT>
    struct regex_traits {
        using char_type = charT;
        using string_type = basic_string<char_type>;
        using locale_type = locale;
        using char_class_type = bitmask_type;

        regex_traits();
        static size_t length(const char_type* p);
        charT translate(charT c) const;
        charT translate_nocase(charT c) const;
        template<class ForwardIterator>
        string_type transform(ForwardIterator first, ForwardIterator last) const;
        template<class ForwardIterator>
        string_type transform_primary(ForwardIterator first, ForwardIterator last) const;
        template<class ForwardIterator>
        string_type lookup_collatename(ForwardIterator first, ForwardIterator last) const;
        template<class ForwardIterator>
        char_class_type lookup_classname(ForwardIterator first, ForwardIterator last, bool icase = false) const;
        bool isctype(charT c, char_class_type f) const;
        int value(charT ch, int radix) const;
        locale_type imbue(locale_type l);
        locale_type getloc() const;
    };
}
```

The specializations `regex_traits<char>` and `regex_traits<wchar_t>` shall be valid and shall meet the requirements for a regular expression traits class (30.3).

```cpp
using char_class_type = bitmask_type;
```

The type `char_class_type` is used to represent a character classification and is capable of holding an implementation specific set returned by `lookup_classname`.

```cpp
static size_t length(const char_type* p);
```

**Returns:** `char_traits<charT>::length(p)`.

```cpp
charT translate(charT c) const;
```

**Returns:** `c`.

§ 30.7
charT translate_nocase(charT c) const;
   
   Returns: use_facet<ctype<charT>>(getloc()).tolower(c).

template<class ForwardIterator>
string_type transform(ForwardIterator first, ForwardIterator last) const;
   
   Effects: As if by:
   
   string_type str(first, last);
   return use_facet<collate<charT>>(getloc()).transform(str.data(), str.data() + str.length());

template<class ForwardIterator>
string_type transform_primary(ForwardIterator first, ForwardIterator last) const;
   
   Effects: If typeid(use_facet<collate<charT>>) == typeid(collate_byname<charT>)
   and the form of the sort key returned by collate_byname<charT>::transform(first, last) is
   known and can be converted into a primary sort key then returns that key, otherwise returns an empty
   string.

template<class ForwardIterator>
string_type lookup_collatename(ForwardIterator first, ForwardIterator last) const;
   
   Returns: A sequence of one or more characters that represents the collating element consisting of the
   character sequence designated by the iterator range [first, last). Returns an empty string if the
   character sequence is not a valid collating element.

template<class ForwardIterator>
char_class_type lookup_classname(
   ForwardIterator first, ForwardIterator last, bool icase = false) const;
   
   Returns: An unspecified value that represents the character classification named by the character
   sequence designated by the iterator range [first, last). If the parameter icase is true then the
   returned mask identifies the character classification without regard to the case of the characters being
   matched, otherwise it does honor the case of the characters being matched. The value returned shall
   be independent of the case of the characters in the character sequence. If the name is not recognized
   then returns char_class_type().

Remarks: For regex_traits<char>, at least the narrow character names in Table 127 shall be
recognized. For regex_traits<wchar_t>, at least the wide character names in Table 127 shall be
recognized.

bool isctype(charT c, char_class_type f) const;
   
   Effects: Determines if the character c is a member of the character classification represented by f.

   Returns: Given the following function declaration:
   
   // for exposition only
   template<class C>
   ctype_base::mask convert(typename regex_traits<C>::char_class_type f);
   
   that returns a value in which each ctype_base::mask value corresponding to a value in f named in
   Table 127 is set, then the result is determined as if by:
   
   ctype_base::mask m = convert<charT>(f);
   const ctype<charT>& ct = use_facet<ctype<charT>>(getloc());
   if (ct.is(m, c)) {
      return true;
   } else if (c == ct.widen('_')) {
      charT w[1] = { ct.widen('w') };
      char_class_type x = lookup_classname(w, w+1);
      return (f&x) == x;
   } else {
      return false;
   }

329) For example, if the parameter icase is true then [[:lower:]] is the same as [[:alpha:]].
Example:
```cpp
regex_traits<char> t;
string d("d");
string u("upper");
regex_traits<char>::char_class_type f;
f = t.lookup_classname(d.begin(), d.end());
f |= t.lookup_classname(u.begin(), u.end());
ctype_base::mask m = convert<char>(f); // m == ctype_base::digit|ctype_base::upper
```
— end example

```cpp
regex_traits<char> t;
string w("w");
regex_traits<char>::char_class_type f;
f = t.lookup_classname(w.begin(), w.end());
t.isctype('A', f); // returns true
t.isctype('_', f); // returns true
t.isctype(' ', f); // returns false
```
— end example

int value(charT ch, int radix) const;
13 Requires: The value of radix shall be 8, 10, or 16.
14 Returns: The value represented by the digit ch in base radix if the character ch is a valid digit in base radix; otherwise returns -1.

locale_type imbue(locale_type loc);
15 Effects: Imbues this with a copy of the locale loc. [Note: Calling imbue with a different locale than the one currently in use invalidates all cached data held by *this. — end note]
16 Returns: If no locale has been previously imbued then a copy of the global locale in effect at the time of construction of *this, otherwise a copy of the last argument passed to imbue.
17 Ensures: getloc() == loc.

locale_type getloc() const;
18 Returns: If no locale has been imbued then a copy of the global locale in effect at the time of construction of *this, otherwise a copy of the last argument passed to imbue.

30.8 Class template basic_regex

1 For a char-like type charT, specializations of class template basic_regex represent regular expressions constructed from character sequences of charT characters. In the rest of 30.8, charT denotes a given char-like
type. Storage for a regular expression is allocated and freed as necessary by the member functions of class basic_regex.

2 Objects of type specialization of basic_regex are responsible for converting the sequence of charT objects to an internal representation. It is not specified what form this representation takes, nor how it is accessed by algorithms that operate on regular expressions. [Note: Implementations will typically declare some function templates as friends of basic_regex to achieve this — end note]

3 The functions described in this Clause report errors by throwing exceptions of type regex_error.

namespace std {
  template<class charT, class traits = regex_traits<charT>>
  class basic_regex {
  public:
    // types
    using value_type = charT;
    using traits_type = traits;
    using string_type = typename traits::string_type;
    using flag_type = regex_constants::syntax_option_type;
    using locale_type = typename traits::locale_type;

    // 30.5.1, constants
    static constexpr flag_type icase = regex_constants::icase;
    static constexpr flag_type nosubs = regex_constants::nosubs;
    static constexpr flag_type optimize = regex_constants::optimize;
    static constexpr flag_type collate = regex_constants::collate;
    static constexpr flag_type ECMAScript = regex_constants::ECMAScript;
    static constexpr flag_type basic = regex_constants::basic;
    static constexpr flag_type extended = regex_constants::extended;
    static constexpr flag_type awk = regex_constants::awk;
    static constexpr flag_type grep = regex_constants::grep;
    static constexpr flag_type egrep = regex_constants::egrep;
    static constexpr flag_type multiline = regex_constants::multiline;

    // 30.8.1, construct/copy/destroy
    explicit basic_regex();
    explicit basic_regex(const charT* p, flag_type f = regex_constants::ECMAScript);
    basic_regex(const charT* p, size_t len, flag_type f = regex_constants::ECMAScript);
    basic_regex(const basic_regex&);
    basic_regex(basic_regex&&) noexcept;
    template<class ST, class SA>
    explicit basic_regex(const basic_string<charT, ST, SA>& p,
                         flag_type f = regex_constants::ECMAScript);
    template<class ForwardIterator>
    basic_regex(ForwardIterator first, ForwardIterator last,
                flag_type f = regex_constants::ECMAScript);
    basic_regex(initializer_list<charT>, flag_type = regex_constants::ECMAScript);
    ~basic_regex();
    basic_regex& operator=(const basic_regex& that);
    basic_regex& operator=(basic_regex&& that) noexcept;
    basic_regex& operator=(const charT* ptr);
    basic_regex& operator=(initializer_list<charT> il);
    template<class ST, class SA>
    basic_regex& operator=(const basic_string<charT, ST, SA>& s,
                          flag_type f = regex_constants::ECMAScript);

    // 30.8.2, assign
    basic_regex& assign(const basic_regex& that);
    basic_regex& assign(basic_regex&& that) noexcept;
    basic_regex& assign(const charT* ptr, flag_type f = regex_constants::ECMAScript);
    basic_regex& assign(const charT* p, size_t len, flag_type f);
    template<class string_traits, class A>
    basic_regex& assign(const basic_string<charT, string_traits, A>& s,
                        flag_type f = regex_constants::ECMAScript);
  }
30.8.1 Constructors

basic_regex();

Effects: Constructs an object of class basic_regex that does not match any character sequence.

explicit basic_regex(const charT* p, flag_type f = regex_constants::ECMAScript);

Requires: p shall not be a null pointer.

Throws: regex_error if p is not a valid regular expression.

Effects: Constructs an object of class basic_regex; the object’s internal finite state machine is constructed from the regular expression contained in the array of charT of length char_traits<charT>::length(p) whose first element is designated by p, and interpreted according to the flags specified in f.

Ensures: flags() returns f. mark_count() returns the number of marked sub-expressions within the expression.

basic_regex(const charT* p, size_t len, flag_type f = regex_constants::ECMAScript);

Requires: p shall not be a null pointer.

Throws: regex_error if p is not a valid regular expression.

Effects: Constructs an object of class basic_regex; the object’s internal finite state machine is constructed from the regular expression contained in the sequence of characters [p, p+len), and interpreted according to the flags specified in f.

Ensures: flags() returns f. mark_count() returns the number of marked sub-expressions within the expression.

basic_regex(const basic_regex& e);

Effects: Constructs an object of class basic_regex as a copy of the object e.

Ensures: flags() and mark_count() return e.flags() and e.mark_count(), respectively.

basic_regex(basic_regex&& e) noexcept;

Effects: Move constructs an object of class basic_regex from e.

Ensures: flags() and mark_count() return the values that e.flags() and e.mark_count(), respectively, had before construction. e is in a valid state with unspecified value.
template<class ST, class SA>
    explicit basic_regex(const basic_string<charT, ST, SA>& s,
        flag_type f = regex_constants::ECMAScript);

    Throws: regex_error if s is not a valid regular expression.

    Effects: Constructs an object of class basic_regex: the object’s internal finite state machine
              is constructed from the regular expression contained in the string s, and interpreted
              according to the flags specified in f.

    Ensures: flags() returns f. mark_count() returns the number of marked sub-expressions within the
             expression.

template<class ForwardIterator>
    basic_regex(ForwardIterator first, ForwardIterator last,
        flag_type f = regex_constants::ECMAScript);

    Throws: regex_error if the sequence [first, last) is not a valid regular expression.

    Effects: Constructs an object of class basic_regex: the object’s internal finite state machine
              is constructed from the regular expression contained in the sequence of characters [first, last),
              and interpreted according to the flags specified in f.

    Ensures: flags() returns f. mark_count() returns the number of marked sub-expressions within the
             expression.

basic_regex(initializer_list<charT> il, flag_type f = regex_constants::ECMAScript);

    Effects: Same as basic_regex(il.begin(), il.end(), f).

30.8.2 Assignment

    basic_regex& operator=(const basic_regex& e);

    Effects: Copies e into *this and returns *this.

    Ensures: flags() and mark_count() return e.flags() and e.mark_count(), respectively.

    basic_regex& operator=(basic_regex&& e) noexcept;

    Effects: Move assigns from e into *this and returns *this.

    Ensures: flags() and mark_count() return the values that e.flags() and e.mark_count(), re-
             spectively, had before assignment. e is in a valid state with unspecified value.

    basic_regex& operator=(const charT* ptr);

    Requires: ptr shall not be a null pointer.

    Effects: Returns assign(ptr).

    basic_regex& operator=(initializer_list<charT> il);

    Effects: Returns assign(il.begin(), il.end()).

    template<class ST, class SA>
    basic_regex& operator=(const basic_string<charT, ST, SA>& p);

    Effects: Returns assign(p).

    basic_regex& assign(const basic_regex& that);

    Effects: Equivalent to: return *this = that;

    basic_regex& assign(basic_regex&& that) noexcept;

    Effects: Equivalent to: return *this = std::move(that);

    basic_regex& assign(const charT* ptr, flag_type f = regex_constants::ECMAScript);

    Returns: assign(string_type(ptr), f).

    basic_regex& assign(const charT* ptr, size_t len, flag_type f = regex_constants::ECMAScript);

    Returns: assign(string_type(ptr, len), f).
template<class string_traits, class A>
basic_regex& assign(const basic_string<charT, string_traits, A>& s, flag_type f = regex_constants::ECMAScript);

Throws: regex_error if s is not a valid regular expression.
Returns: *this.
Effects: Assigns the regular expression contained in the string s, interpreted according the flags specified in f. If an exception is thrown, *this is unchanged.
Ensures: If no exception is thrown, flags() returns f and mark_count() returns the number of marked sub-expressions within the expression.

template<class InputIterator>
basic_regex& assign(InputIterator first, InputIterator last, flag_type f = regex_constants::ECMAScript);

Requires: InputIterator shall meet the Cpp17InputIterator requirements (23.3.5.2).
Returns: assign(string_type(first, last), f).

basic_regex& assign(initializer_list<charT> il, flag_type f = regex_constants::ECMAScript);
Effects: Same as assign(il.begin(), il.end(), f).
Returns: *this.

30.8.3 Constant operations [re.regex.operations]

unsigned mark_count() const;

Effects: Returns the number of marked sub-expressions within the regular expression.

flag_type flags() const;

Effects: Returns a copy of the regular expression syntax flags that were passed to the object’s constructor or to the last call to assign.

30.8.4 Locale [re.regex.locale]

locale_type imbue(locale_type loc);

Effects: Returns the result of traits_inst.imbue(loc) where traits_inst is a (default-initialized) instance of the template type argument traits stored within the object. After a call to imbue the basic_regex object does not match any character sequence.

locale_type getloc() const;

Effects: Returns the result of traits_inst.getloc() where traits_inst is a (default-initialized) instance of the template parameter traits stored within the object.

30.8.5 Swap [re.regex.swap]

void swap(basic_regex& e);

Effects: Swaps the contents of the two regular expressions.
Ensures: *this contains the regular expression that was in e, e contains the regular expression that was in *this.
Complexity: Constant time.

30.8.6 Non-member functions [re.regex.nonmemb]

template<class charT, class traits>
void swap(basic_regex<charT, traits>& lhs, basic_regex<charT, traits>& rhs);

Effects: Calls lhs.swap(rhs).
30.9 Class template sub_match

Class template `sub_match` denotes the sequence of characters matched by a particular marked sub-expression.

```cpp
namespace std {
    template<class BidirectionalIterator>
    class sub_match : public pair<BidirectionalIterator, BidirectionalIterator> {
        public:
            using value_type = typename iterator_traits<BidirectionalIterator>::value_type;
            using difference_type = typename iterator_traits<BidirectionalIterator>::difference_type;
            using iterator = BidirectionalIterator;
            using string_type = basic_string<value_type>;
            bool matched;

            constexpr sub_match();
            difference_type length() const;
            operator string_type() const;
            string_type str() const;
            int compare(const sub_match& s) const;
            int compare(const string_type& s) const;
            int compare(const value_type* s) const;
    };
}
```

30.9.1 Members

```cpp
constexpr sub_match();
Effects: Value-initializes the pair base class subobject and the member matched.

difference_type length() const;
Returns: matched ? distance(first, second) : 0.

operator string_type() const;
Returns: matched ? string_type(first, second) : string_type().

string_type str() const;
Returns: matched ? string_type(first, second) : string_type().

int compare(const sub_match& s) const;
Returns: str().compare(s.str()).

int compare(const string_type& s) const;
Returns: str().compare(s).

int compare(const value_type* s) const;
Returns: str().compare(s).
```

30.9.2 Non-member operators

```cpp
template<class BiIter>
bool operator==(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
Returns: lhs.compare(rhs) == 0.

template<class BiIter>
bool operator!=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
Returns: lhs.compare(rhs) != 0.
```
template<class BiIter>
bool operator<(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);

Returns: \( \text{lhs.compare(rhs)} < 0 \).

template<class BiIter>
bool operator>(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);

Returns: \( \text{lhs.compare(rhs)} > 0 \).

template<class BiIter>
bool operator<=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);

Returns: \( \text{lhs.compare(rhs)} \leq 0 \).

template<class BiIter>
bool operator>=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);

Returns: \( \text{lhs.compare(rhs)} \geq 0 \).

template<class BiIter, class ST, class SA>
bool operator==(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, const sub_match<BiIter>& rhs);

Returns:
\[ \text{rhs.compare(typename sub_match<BiIter>::string_type(lhs.data(), lhs.size())) == 0} \]

template<class BiIter, class ST, class SA>
bool operator!=(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, const sub_match<BiIter>& rhs);

Returns: \( \neg (\text{lhs} == \text{rhs}) \).

template<class BiIter, class ST, class SA>
bool operator<(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, const sub_match<BiIter>& rhs);

Returns:
\[ \text{rhs.compare(typename sub_match<BiIter>::string_type(lhs.data(), lhs.size())) > 0} \]

template<class BiIter, class ST, class SA>
bool operator<=(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, const sub_match<BiIter>& rhs);

Returns: \( \text{rhs} \leq \text{lhs} \).

template<class BiIter, class ST, class SA>
bool operator>=(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, const sub_match<BiIter>& rhs);

Returns: \( \neg (\text{rhs} \leq \text{lhs}) \).

template<class BiIter, class ST, class SA>
bool operator==(const sub_match<BiIter>& lhs, const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);

Returns:
lhs.compare(typename sub_match<BiIter>::string_type(rhs.data(), rhs.size())) == 0

template<class BiIter, class ST, class SA>
bool operator!=(
    const sub_match<BiIter>& lhs,
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);

Returns: !(lhs == rhs).

template<class BiIter, class ST, class SA>
bool operator<(const typename iterator_traits<BiIter>::value_type* lhs,
    const sub_match<BiIter>& rhs);

Returns: rhs.compare(lhs) > 0.
const sub_match<BiIter>& rhs);

Returns: !(lhs < rhs).

template<class BiIter>
bool operator==(const sub_match<BiIter>& lhs,
               const typename iterator_traits<BiIter>::value_type* rhs);

Returns: lhs.compare(rhs) == 0.

template<class BiIter>
bool operator==(const sub_match<BiIter>& lhs,
               const typename iterator_traits<BiIter>::value_type* rhs);

Returns: !(lhs == rhs).

template<class BiIter>
bool operator<(const sub_match<BiIter>& lhs,
               const typename iterator_traits<BiIter>::value_type* rhs);

Returns: lhs.compare(rhs) < 0.

template<class BiIter>
bool operator<(const sub_match<BiIter>& lhs,
               const typename iterator_traits<BiIter>::value_type* rhs);

Returns: !(lhs < rhs).

template<class BiIter>
bool operator==(const typename iterator_traits<BiIter>::value_type& lhs,
               const sub_match<BiIter>& rhs);

Returns: rhs.compare(typename sub_match<BiIter>::string_type(1, lhs)) == 0.

template<class BiIter>
bool operator<(const typename iterator_traits<BiIter>::value_type& lhs,
               const sub_match<BiIter>& rhs);

Returns: rhs.compare(typename sub_match<BiIter>::string_type(1, lhs)) > 0.

template<class BiIter>
bool operator<(const typename iterator_traits<BiIter>::value_type& lhs,
               const sub_match<BiIter>& rhs);

Returns: rhs < lhs.

template<class BiIter>
bool operator==(const typename iterator_traits<BiIter>::value_type& lhs,
               const sub_match<BiIter>& rhs);

Returns: rhs < lhs.
template<class BiIter>
bool operator==(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);
37
Returns: lhs.compare(typename sub_match<BiIter>::string_type(1, rhs)) == 0.

template<class BiIter>
bool operator!=(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);
38
Returns: !(lhs == rhs).

template<class BiIter>
bool operator<(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);
39
Returns: rhs < lhs.

template<class BiIter>
bool operator<=(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);
40
Returns: !(rhs < lhs).

template<class BiIter>
bool operator>(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);
41
Returns: !(lhs < rhs).

template<class BiIter>
bool operator>=(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);
42
Returns: !(lhs < rhs).

template<class charT, class ST, class BiIter>
basic_ostream<charT, ST>&
operator<<(basic_ostream<charT, ST>& os, const sub_match<BiIter>& m);
43
Returns: os << m.str().

30.10 Class template match_results

Class template match_results denotes a collection of character sequences representing the result of a regular
expression match. Storage for the collection is allocated and freed as necessary by the member functions of
class template match_results.

The class template match_results meets the requirements of an allocator-aware container and of a sequence
container (22.2.1, 22.2.3) except that only copy assignment, move assignment, and operations defined for
const-qualified sequence containers are supported and that the semantics of comparison functions are different
from those required for a container.

A default-constructed match_results object has no fully established result state. A match result is ready
when, as a consequence of a completed regular expression match modifying such an object, its result state
becomes fully established. The effects of calling most member functions from a match_results object that
is not ready are undefined.

The sub_match object stored at index 0 represents sub-expression 0, i.e., the whole match. In this case the
sub_match member matched is always true. The sub_match object stored at index n denotes what matched
the marked sub-expression n within the matched expression. If the sub-expression n participated in a regular
expression match then the sub_match member matched evaluates to true, and members first and second
denote the range of characters [first, second) which formed that match. Otherwise matched is false,
and members first and second point to the end of the sequence that was searched. [Note: The sub_match
objects representing different sub-expressions that did not participate in a regular expression match need not
be distinct. — end note]
namespace std {
  template<class BidirectionalIterator,  
          class Allocator = allocator<sub_match<BidirectionalIterator>>>  
    class match_results {
  public:
    using value_type = sub_match<BidirectionalIterator>;  
    using const_reference = const value_type&;  
    using reference = value_type&;  
    using const_iterator = implementation-defined;  
    using iterator = const_iterator;  
    using difference_type = 
        typename iterator_traits<BidirectionalIterator>::difference_type;  
    using size_type = typename allocator_traits<Allocator>::size_type;  
    using char_type = 
        typename iterator_traits<BidirectionalIterator>::value_type;  
    using string_type = basic_string<char_type>;  

    // 30.10.1, construct/copy/destroy  
    match_results() : match_results(Allocator()) {}  
    explicit match_results(const Allocator&);  
    match_results(const match_results& m);  
    match_results(match_results&& m) noexcept;  
    match_results& operator=(const match_results& m);  
    match_results& operator=(match_results&& m);  
    ~match_results();

    // 30.10.2, state  
    bool ready() const;  
    size_type size() const;  
    size_type max_size() const;  
    [[nodiscard]] bool empty() const;

    // 30.10.3, size  
    difference_type length(size_type sub = 0) const;  
    difference_type position(size_type sub = 0) const;  
    string_type str(size_type sub = 0) const;  
    const_reference operator[](size_type n) const;  
    const_reference prefix() const;  
    const_reference suffix() const;  
    const_iterator begin() const;  
    const_iterator end() const;  
    const_iterator cbegin() const;  
    const_iterator cend() const;

    // 30.10.4, element access  
    template<class OutputIter>  
    OutputIter format(OutputIter out,  
                      const char_type* fmt_first, const char_type* fmt_last,  
                      regex_constants::match_flag_type flags = regex_constants::format_default) const;

    template<class OutputIter, class ST, class SA>  
    OutputIter format(OutputIter out,  
                      const basic_string<char_type, ST, SA>& fmt,  
                      regex_constants::match_flag_type flags = regex_constants::format_default) const;

    template<class ST, class SA>  
    basic_string<char_type, ST, SA> format(const basic_string<char_type, ST, SA>& fmt,  
                                          regex_constants::match_flag_type flags = regex_constants::format_default) const;

§ 30.10
string_type
  format(const char_type* fmt,
          regex_constants::match_flag_type flags = regex_constants::format_default) const;

  // 30.10.6, allocator
  allocator_type get_allocator() const;

  // 30.10.7, swap
  void swap(match_results& that);
};

30.10.1 Constructors

explicit match_results(const Allocator& a);

  Effects: Constructs an object of class match_results.
  Ensures: ready() returns false. size() returns 0.

match_results(const match_results& m);

  Effects: Constructs an object of class match_results, as a copy of m.

match_results(match_results&& m) noexcept;

  Effects: Move constructs an object of class match_results from m satisfying the same postconditions as Table 128. Additionally, the stored Allocator value is move constructed from m.get_allocator().
  Throws: Nothing.

match_results& operator=(const match_results& m);

  Effects: Assigns m to *this. The postconditions of this function are indicated in Table 128.

match_results& operator=(match_results&& m);

  Effects: Move-assigns m to *this. The postconditions of this function are indicated in Table 128.

Table 128: match_results assignment operator effects

<table>

<td>m.position(n) for all integers n &lt; m.size()</td>
</tr>
</tbody>
</table>

30.10.2 State

bool ready() const;

  Returns: true if *this has a fully established result state, otherwise false.

30.10.3 Size

size_type size() const;

  Returns: One plus the number of marked sub-expressions in the regular expression that was matched if *this represents the result of a successful match. Otherwise returns 0. [Note: The state of a match_results object can be modified only by passing that object to regex_match or regex_search. Subclauses 30.11.2 and 30.11.3 specify the effects of those algorithms on their match_results arguments. —end note]
size_type max_size() const;

Returns: The maximum number of sub_match elements that can be stored in *this.

[[nodiscard]] bool empty() const;

Returns: size() == 0.

### 30.10.4 Element access

**difference_type** length(size_type sub = 0) const;

Requires: ready() == true.

Returns: (*this)[sub].length().

difference_type position(size_type sub = 0) const;

Requires: ready() == true.

Returns: The distance from the start of the target sequence to (*this)[sub].first.

**string_type** str(size_type sub = 0) const;

Requires: ready() == true.

Returns: string_type((*this)[sub]).

**const_reference** operator[](size_type n) const;

Requires: ready() == true.

Returns: A reference to the sub_match object representing the character sequence that matched marked sub-expression n. If n == 0 then returns a reference to a sub_match object representing the character sequence that matched the whole regular expression. If n >= size() then returns a sub_match object representing an unmatched sub-expression.

**const_reference** prefix() const;

Requires: ready() == true.

Returns: A reference to the sub_match object representing the character sequence from the start of the string being matched/searched to the start of the match found.

**const_reference** suffix() const;

Requires: ready() == true.

Returns: A reference to the sub_match object representing the character sequence from the end of the match found to the end of the string being matched/searched.

**const_iterator** begin() const;
**const_iterator** cbegin() const;

Returns: A starting iterator that enumerates over all the sub-expressions stored in *this.

**const_iterator** end() const;
**const_iterator** cend() const;

Returns: A terminating iterator that enumerates over all the sub-expressions stored in *this.

### 30.10.5 Formatting

**template<class OutputIter>**

OutputIter format(
    OutputIter out,
    const char_type* fmt_first, const char_type* fmt_last,
    regex_constants::match_flag_type flags = regex_constants::format_default) const;

Requires: ready() == true and OutputIter shall meet the requirements for a Cpp17OutputIterator (23.3.5.3).

Effects: Copies the character sequence [fmt_first, fmt_last) to OutputIter out. Replaces each format specifier or escape sequence in the copied range with either the character(s) it represents or
the sequence of characters within \*this to which it refers. The bitmasks specified in flags determine which format specifiers and escape sequences are recognized.

\textbf{Returns:} out.

\begin{verbatim}
3 template<class OutputIter, class ST, class SA>
    OutputIter format(
        OutputIter out,
        const basic_string< char_type, ST, SA >& fmt,
        regex_constants::match_flag_type flags = regex_constants::format_default) const;
\end{verbatim}

\textbf{Effects:} Equivalent to:

\begin{verbatim}
return format(out, fmt.data(), fmt.data() + fmt.size(), flags);
\end{verbatim}

\begin{verbatim}
4 template<class ST, class SA>
    basic_string< char_type, ST, SA > format(
        const basic_string< char_type, ST, SA >& fmt,
        regex_constants::match_flag_type flags = regex_constants::format_default) const;
\end{verbatim}

\textbf{Requires:} ready() == true.

\textbf{Effects:} Constructs an empty string result of type basic_string< char_type, ST, SA > and calls:

\begin{verbatim}
format(back_inserter(result), fmt, flags);
\end{verbatim}

\textbf{Returns:} result.

\begin{verbatim}
5 string_type format(
    const char_type* fmt,
    regex_constants::match_flag_type flags = regex_constants::format_default) const;
\end{verbatim}

\textbf{Requires:} ready() == true.

\textbf{Effects:} Constructs an empty string result of type string_type and calls:

\begin{verbatim}
format(back_inserter(result), fmt, fmt + char_traits<char_type>::length(fmt), flags);
\end{verbatim}

\textbf{Returns:} result.

\subsection{30.10.6 Allocator \[re.results.all\]}

\begin{verbatim}
allocator_type get_allocator() const;
\end{verbatim}

\textbf{Returns:} A copy of the Allocator that was passed to the object’s constructor or, if that allocator has been replaced, a copy of the most recent replacement.

\subsection{30.10.7 Swap \[re.results.swap\]}

\begin{verbatim}
void swap(match_results& that);
\end{verbatim}

\textbf{Effects:} Swaps the contents of the two sequences.

\textbf{Ensures:} \*this contains the sequence of matched sub-expressions that were in \texttt{that}, \texttt{that} contains the sequence of matched sub-expressions that were in \*this.

\textbf{Complexity:} Constant time.

\begin{verbatim}
template<class BidirectionalIterator, class Allocator>
    void swap(match_results<BidirectionalIterator, Allocator>& m1,
            match_results<BidirectionalIterator, Allocator>& m2);
\end{verbatim}

\textbf{Effects:} As if by \texttt{m1.swap(m2)}.

\subsection{30.10.8 Non-member functions \[re.results.nonmember\]}

\begin{verbatim}
template<class BidirectionalIterator, class Allocator>
    bool operator==(const match_results<BidirectionalIterator, Allocator>& m1,
                    const match_results<BidirectionalIterator, Allocator>& m2);
\end{verbatim}

\textbf{Returns:} \texttt{true} if neither match result is ready, \texttt{false} if one match result is ready and the other is not. If both match results are ready, returns \texttt{true} only if:

\begin{enumerate}
\item \texttt{m1.empty() \&\& m2.empty()}, or
\end{enumerate}
The following conditions are satisfied:

- \( m_1.\text{empty()} \) \&\& \( m_2.\text{empty()} \), and
- \( m_1.\text{prefix()} == m_2.\text{prefix()} \),
- \( m_1.\text{size()} == m_2.\text{size()} \) \&\& \( \text{equal}(m_1.\text{begin()}, m_1.\text{end()}, m_2.\text{begin()}) \), and
- \( m_1.\text{suffix()} == m_2.\text{suffix()} \).

[Note: The algorithm \text{equal} is defined in Clause 25. — end note]

```cpp
template<class BidirectionalIterator, class Allocator>
bool operator!= (const match_results<BidirectionalIterator, Allocator>& m1,
                const match_results<BidirectionalIterator, Allocator>& m2);
```

Returns: \(! (m1 == m2) \).

### 30.11 Regular expression algorithms

#### § 30.11.2 1463

**Table 129:** Effects of \text{regex_match} algorithm

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>( m.\text{size()} )</td>
<td>( 1 + e.\text{mark_count()} )</td>
</tr>
<tr>
<td>( m.\text{empty()} )</td>
<td>\text{false}</td>
</tr>
<tr>
<td>( m.\text{prefix().first} )</td>
<td>\text{first}</td>
</tr>
<tr>
<td>( m.\text{prefix().second} )</td>
<td>\text{first}</td>
</tr>
<tr>
<td>( m.\text{prefix().matched} )</td>
<td>\text{false}</td>
</tr>
<tr>
<td>( m.\text{suffix().first} )</td>
<td>\text{last}</td>
</tr>
<tr>
<td>( m.\text{suffix().second} )</td>
<td>\text{last}</td>
</tr>
<tr>
<td>( m.\text{suffix().matched} )</td>
<td>\text{false}</td>
</tr>
<tr>
<td>( m[0].\text{first} )</td>
<td>\text{first}</td>
</tr>
<tr>
<td>( m[0].\text{second} )</td>
<td>\text{last}</td>
</tr>
<tr>
<td>( m[0].\text{matched} )</td>
<td>\text{true}</td>
</tr>
</tbody>
</table>
Table 129: Effects of regex_match algorithm (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>m[n].first</td>
<td>For all integers 0 &lt; n &lt; m.size(), the start of the sequence that matched sub-expression n. Alternatively, if sub-expression n did not participate in the match, then last.</td>
</tr>
<tr>
<td>m[n].second</td>
<td>For all integers 0 &lt; n &lt; m.size(), the end of the sequence that matched sub-expression n. Alternatively, if sub-expression n did not participate in the match, then last.</td>
</tr>
<tr>
<td>m[n].matched</td>
<td>For all integers 0 &lt; n &lt; m.size(), true if sub-expression n participated in the match, false otherwise.</td>
</tr>
</tbody>
</table>

4. Effects: Behaves “as if” by constructing an instance of match_results<BidirectionalIterator> what, and then returning the result of regex_match(first, last, what, e, flags).

5. Returns: regex_match(str, str + char_traits<charT>::length(str), m, e, flags).

6. Returns: regex_match(s.begin(), s.end(), m, e, flags).

7. Returns: regex_match(str, str + char_traits<charT>::length(str), e, flags).

8. Returns: regex_match(s.begin(), s.end(), e, flags).

30.11.3 regex_search [re.alg.search]

template<class BidirectionalIterator, class Allocator, class charT, class traits>
bool regex_search(BidirectionalIterator first, BidirectionalIterator last,
                 match_results<BidirectionalIterator, Allocator>& m,
                 const basic_regex<charT, traits>& e,
                 regex_constants::match_flag_type flags = regex_constants::match_default);  

1. Requires: Type BidirectionalIterator shall meet the Cpp17BidirectionalIterator requirements (23.3.5.5).
2. Effects: Determines whether there is some sub-sequence within [first, last) that matches the regular expression e. The parameter flags is used to control how the expression is matched against the character sequence. Returns true if such a sequence exists, false otherwise.
Ensures: \( m.\text{ready()} == \text{true} \) in all cases. If the function returns \( \text{false} \), then the effect on parameter \( m \) is unspecified except that \( m.\text{size()} \) returns 0 and \( m.\text{empty()} \) returns \( \text{true} \). Otherwise the effects on parameter \( m \) are given in Table 130.

Table 130: Effects of `regex_search` algorithm  

<table>
<thead>

</tr>
<tr>
<td>( m[n].\text{matched} )</td>
<td>For all integers ( 0 &lt; n &lt; m.\text{size()} ), ( \text{true} ) if sub-expression ( n ) participated in the match, ( \text{false} ) otherwise.</td>
</tr>
</tbody>
</table>

template<class charT, class Allocator, class traits>
bool regex_search(const charT* str, match_results<const charT*, Allocator>& m,
                 const basic_regex<charT, traits>& e,
                 regex_constants::match_flag_type flags = regex_constants::match_default);

Returns: `regex_search(str, str + char_traits<charT>::length(str), m, e, flags)`.

template<class ST, class SA, class Allocator, class charT, class traits>
bool regex_search(const basic_string<charT, ST, SA>& s,
                  match_results<typename basic_string<charT, ST, SA>::const_iterator,
                  Allocator>& m,
                  const basic_regex<charT, traits>& e,
                  regex_constants::match_flag_type flags = regex_constants::match_default);

Returns: `regex_search(s.begin(), s.end(), m, e, flags)`.

template<class BidirectionalIterator, class charT, class traits>
bool regex_search(BidirectionalIterator first, BidirectionalIterator last,
                 const basic_regex<charT, traits>& e,
                 regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Behaves “as if” by constructing an object `what` of type `match_results<BidirectionalIterator>` and returning `regex_search(first, last, what, e, flags)`.

template<class charT, class traits>
bool regex_search(const charT* str,
                  const basic_regex<charT, traits>& e,
                  regex_constants::match_flag_type flags = regex_constants::match_default);

Returns: `regex_search(str, str + char_traits<charT>::length(str), e, flags)`.
template<class ST, class SA, class charT, class traits>
bool regex_search(const basic_string<charT, ST, SA>& s,
    const basic_regex<charT, traits>& e,
    regex_constants::match_flag_type flags = regex_constants::match_default);

Returns: regex_search(s.begin(), s.end(), e, flags).

30.11.4 regex_replace  
[re.alg.replace]

template<class OutputIterator, class BidirectionalIterator, 
    class traits, class charT, class ST, class SA>
OutputIterator
regex_replace(OutputIterator out,
    BidirectionalIterator first, BidirectionalIterator last,
    const basic_regex<charT, traits>& e,
    const basic_string<charT, ST, SA>& fmt,
    regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Constructs a regex_iterator object i as if by
regex_iterator<BidirectionalIterator, charT, traits> i(first, last, e, flags)
and uses i to enumerate through all of the matches m of type match_results<BidirectionalIterator>
that occur within the sequence [first, last). If no such matches are found and !(flags & regex_-
constants::format_no_copy), then calls
out = copy(first, last, out)
If any matches are found then, for each such match:

(1.1) — If !(flags & regex_constants::format_no_copy), calls
    out = copy(m.prefix().first, m.prefix().second, out)
(1.2) — Then calls
    out = m.format(out, fmt, flags)
    for the first form of the function and
    out = m.format(out, fmt, fmt + char_traits<charT>::length(fmt), flags)
    for the second.

Finally, if such a match is found and !(flags & regex_constants::format_no_copy), calls
out = copy(last_m.suffix().first, last_m.suffix().second, out)
where last_m is a copy of the last match found. If flags & regex_constants::format_first_only
is nonzero, then only the first match found is replaced.

Returns: out.

template<class traits, class charT, class ST, class SA, class FST, class FSA>
basic_string<charT, ST, SA>
regex_replace(const basic_string<charT, ST, SA>& s,
    const basic_regex<charT, traits>& e,
    const basic_string<charT, FST, FSA>& fmt,
    regex_constants::match_flag_type flags = regex_constants::match_default);

template<class traits, class charT, class ST, class SA>
basic_string<charT, ST, SA>
regex_replace(const basic_string<charT, ST, SA>& s,
    const basic_regex<charT, traits>& e,
    const charT* fmt,
    regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Constructs an empty string result of type basic_string<charT, ST, SA> and calls:
regex_replace(back_inserter(result), s.begin(), s.end(), e, fmt, flags);

Returns: result.

template<class traits, class charT, class ST, class SA>
basic_string<charT>
regex_replace(const charT* s,
const basic_regex<charT, traits>& e,
const basic_string<charT, ST, SA>& fmt,
regex_constants::match_flag_type flags = regex_constants::match_default);

template<class traits, class charT>
regex_replace(const charT* s,
const basic_regex<charT, traits>& e,
const charT* fmt,
regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Constructs an empty string result of type basic_string<charT> and calls:
regex_replace(back_inserter(result), s, s + char_traits<charT>::length(s), e, fmt, flags);

Returns: result.

30.12 Regular expression iterators

30.12.1 Class template regex_iterator

The class template regex_iterator is an iterator adaptor. It represents a new view of an existing iterator sequence, by enumerating all the occurrences of a regular expression within that sequence. A regex_iterator uses regex_search to find successive regular expression matches within the sequence from which it was constructed. After the iterator is constructed, and every time operator++ is used, the iterator finds and stores a value of match_results<BidirectionalIterator>. If the end of the sequence is reached (regex_search returns false), the iterator becomes equal to the end-of-sequence iterator value. The default constructor constructs an end-of-sequence iterator object, which is the only legitimate iterator to be used for the end condition. The result of operator* on an end-of-sequence iterator is not defined. For any other iterator value a const match_results<BidirectionalIterator>& is returned. The result of operator-> on an end-of-sequence iterator is not defined. For any other iterator value a const match_results<BidirectionalIterator>* is returned. It is impossible to store things into regex_iterators. Two end-of-sequence iterators are always equal. An end-of-sequence iterator is not equal to a non-end-of-sequence iterator. Two non-end-of-sequence iterators are equal when they are constructed from the same arguments.

namespace std {

template<class BidirectionalIterator,
         class charT = typename iterator_traits<BidirectionalIterator>::value_type,
         class traits = regex_traits<charT>>
class regex_iterator {
public:
  using regex_type = basic_regex<charT, traits>;
  using iterator_category = forward_iterator_tag;
  using value_type = match_results<BidirectionalIterator>;
  using difference_type = ptrdiff_t;
  using pointer = const value_type*;
  using reference = const value_type&;

  regex_iterator();
  regex_iterator(BidirectionalIterator a, BidirectionalIterator b,
    const regex_type& re,
    regex_constants::match_flag_type m = regex_constants::match_default);
  regex_iterator(BidirectionalIterator a, BidirectionalIterator b,
    const regex_type&,
    regex_constants::match_flag_type m);
  regex_iterator(const regex_iterator&);  // copy constructor
  regex_iterator(const regex_iterator&) = delete;

  bool operator==(const regex_iterator&) const;
  bool operator!=(const regex_iterator&) const;

  const value_type* operator*() const;
  const value_type* operator->() const;
};

§ 30.12.1 1467
An object of type `regex_iterator` that is not an end-of-sequence iterator holds a zero-length match if `match[0].matched == true` and `match[0].first == match[0].second`. [Note: For example, this can occur when the part of the regular expression that matched consists only of an assertion (such as `'^'`, `'$'`, `'\b'`, `'\B'`). — end note]

### 30.12.1.1 Constructors

`regex_iterator();`

**Effects:** Constructs an end-of-sequence iterator.

`regex_iterator(BidirectionalIterator a, BidirectionalIterator b, const regex_type& re, regex_constants::match_flag_type m = regex_constants::match_default);`

**Effects:** Initializes `begin` and `end` to `a` and `b`, respectively, sets `pregex` to `addressof(re)`, sets `flags` to `m`, then calls `regex_search(begin, end, match, *pregex, flags)`. If this call returns `false` the constructor sets `*this` to the end-of-sequence iterator.

### 30.12.1.2 Comparisons

`bool operator==(const regex_iterator& right) const;`

**Returns:** `true` if `*this` and `right` are both end-of-sequence iterators or if the following conditions all hold:

1. `begin == right.begin`.
2. `end == right.end`.
3. `pregex == right.pregex`.
4. `flags == right.flags`.
5. `match[0] == right.match[0]`.

Otherwise `false`.

`bool operator!=(const regex_iterator& right) const;`

**Returns:** `!(*this == right)`.

### 30.12.1.3 Indirection

`const value_type& operator*() const;`

**Returns:** `match`.

`const value_type* operator->() const;`

**Returns:** `addressof(match)`.

### 30.12.1.4 Increment

`regex_iterator& operator++();`

**Effects:** Constructs a local variable `start` of type `BidirectionalIterator` and initializes it with the value of `match[0].second`.

2. If the iterator holds a zero-length match and `start == end` the operator sets `*this` to the end-of-sequence iterator and returns `*this`. 

§ 30.12.1.4

1468
Otherwise, if the iterator holds a zero-length match, the operator calls:

```cpp
regex_search(start, end, match, *pregex,
flags | regex_constants::match_not_null | regex_constants::match_continuous)
```

If the call returns `true` the operator returns `*this`. Otherwise the operator increments `start` and
continues as if the most recent match was not a zero-length match.

If the most recent match was not a zero-length match, the operator sets `flags` to `flags | regex_-
constants::match_prev_avail` and calls `regex_search(start, end, match, *pregex, flags)`. If
the call returns `false` the iterator sets `*this` to the end-of-sequence iterator. The iterator then returns
`*this`.

In all cases in which the call to `regex_search` returns `true`, `match.prefix().first` shall be equal to
the previous value of `match[0].second`, and for each index `i` in the half-open range `[0, match.size())`
for which `match[i].matched` is `true`, `match.position(i)` shall return `distance(begin, match[i].
first)`.

[Note: This means that `match.position(i)` gives the offset from the beginning of the target sequence,
which is often not the same as the offset from the sequence passed in the call to `regex_search`. — end
note]

It is unspecified how the implementation makes these adjustments.

[Note: This means that a compiler may call an implementation-specific search function, in which case a
program-defined specialization of `regex_search` will not be called. — end note]

```cpp
regex_iterator operator++(int);
```

**Effects:** As if by:

```cpp
regex_iterator tmp = *this;
++(*this);
return tmp;
```

### 30.12.2 Class template `regex_token_iterator`  

The class template `regex_token_iterator` is an iterator adaptor; that is to say it represents a new view of
an existing iterator sequence, by enumerating all the occurrences of a regular expression within that sequence,
and presenting one or more sub-expressions for each match found. Each position enumerated by the iterator
is a `sub_match` class template instance that represents what matched a particular sub-expression within the
regular expression.

When class `regex_token_iterator` is used to enumerate a single sub-expression with index `-1` the iterator
performs field splitting: that is to say it enumerates one sub-expression for each section of the character
container sequence that does not match the regular expression specified.

After it is constructed, the iterator finds and stores a value `regex_iterator<BidirectionalIterator>`
`position` and sets the internal count `N` to zero. It also maintains a sequence `subs` which contains a list of
the sub-expressions which will be enumerated. Every time `operator++` is used the count `N` is incremented; if
`N` exceeds or equals `subs.size()`, then the iterator increments member `position` and sets count `N` to zero.

If the end of sequence is reached (`position` is equal to the end of sequence iterator), the iterator becomes
equal to the end-of-sequence iterator value, unless the sub-expression being enumerated has index `-1`, in
which case the iterator enumerates one last sub-expression that contains all the characters from the end of
the last regular expression match to the end of the input sequence being enumerated, provided that this
would not be an empty sub-expression.

The default constructor constructs an end-of-sequence iterator object, which is the only legitimate iterator
to be used for the end condition. The result of `operator*` on an end-of-sequence iterator is not defined.
For any other iterator value a `const sub_match<BidirectionalIterator>&` is returned. The result of
`operator->` on an end-of-sequence iterator is not defined. For any other iterator value a `const sub_-
match<BidirectionalIterator>**` is returned.

It is impossible to store things into `regex_token_iterators`. Two end-of-sequence iterators are always equal.
An end-of-sequence iterator is not equal to a non-end-of-sequence iterator. Two non-end-of-sequence iterators
are equal when they are constructed from the same arguments.
namespace std {

template<class BidirectionalIterator,
    class charT = typename iterator_traits<BidirectionalIterator>::value_type,
    class traits = regex_traits<charT>>
class regex_token_iterator {
public:
    using regex_type = basic_regex<charT, traits>;
    using iterator_category = forward_iterator_tag;
    using value_type = sub_match<BidirectionalIterator>;
    using difference_type = ptrdiff_t;
    using pointer = const value_type*;
    using reference = const value_type&;

    regex_token_iterator();
    regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                        const regex_type& re,
                        int submatch = 0,
                        regex_constants::match_flag_type m =
                        regex_constants::match_default);
    regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                        const regex_type& re,
                        const vector<int>& submatches,

                        regex_constants::match_flag_type m =
                        regex_constants::match_default) = delete;
    regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                        const regex_type& re,
                        initializer_list<int> submatches,
                        regex_constants::match_flag_type m =
                        regex_constants::match_default) = delete;
    template<size_t N>
    regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                        const regex_type& re,
                        const int (&submatches)[N],
                        regex_constants::match_flag_type m =
                        regex_constants::match_default) = delete;

    bool operator==(const regex_token_iterator&) const;
    bool operator!=(const regex_token_iterator&) const;
    value_type& operator*() const;
    value_type* operator->() const;
    regex_token_iterator& operator++();
    regex_token_iterator operator++(int);

};
A suffix iterator is a regex_token_iterator object that points to a final sequence of characters at the end of the target sequence. In a suffix iterator the member result holds a pointer to the data member suffix, the value of the member suffix.match is true, suffix.first points to the beginning of the final sequence, and suffix.second points to the end of the final sequence.

[Note: For a suffix iterator, data member suffix.first is the same as the end of the last match found, and suffix.second is the same as the end of the target sequence — end note]

The current match is (*position).prefix() if subs[N] == -1, or (*position)[subs[N]] for any other value of subs[N].

30.12.2.1 Constructors

regex_token_iterator();

Effects: Constructs the end-of-sequence iterator.

regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b, const regex_type& re, int submatch = 0, regex_constants::match_flag_type m = regex_constants::match_default);

regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b, const regex_type& re, const vector<int>& submatches, regex_constants::match_flag_type m = regex_constants::match_default);

regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b, const regex_type& re, initializer_list<int> submatches, regex_constants::match_flag_type m = regex_constants::match_default);

template<size_t N>
regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b, const regex_type& re, const int (&submatches)[N], regex_constants::match_flag_type m = regex_constants::match_default);

Requires: Each of the initialization values of submatches shall be >= -1.

Effects: The first constructor initializes the member subs to hold the single value submatch. The second, third, and fourth constructors initialize the member subs to hold a copy of the sequence of integer values pointed to by the iterator range [begin(submatches), end(submatches)].

Each constructor then sets N to 0, and position to position_iterator(a, b, re, m). If position is not an end-of-sequence iterator the constructor sets result to the address of the current match. Otherwise if any of the values stored in subs is equal to -1 the constructor sets *this to a suffix iterator that points to the range [a, b), otherwise the constructor sets *this to an end-of-sequence iterator.

30.12.2.2 Comparisons

bool operator==(const regex_token_iterator& right) const;

Returns: true if *this and right are both end-of-sequence iterators, or if *this and right are both suffix iterators and suffix == right.suffix; otherwise returns false if *this or right is an end-of-sequence iterator or a suffix iterator. Otherwise returns true if position == right.position, N == right.N, and subs == right.subs. Otherwise returns false.
bool operator!=(const regex_token_iterator& right) const;

Returns: !(\*this == right).

30.12.2.3 Indirection [re tokiter deref]

const value_type& operator*() const;
Returns: result.

const value_type* operator->() const;
Returns: result.

30.12.2.4 Increment [re tokiter incr]

regex_token_iterator& operator++();
Effects: Constructs a local variable prev of type position_iterator, initialized with the value of position.
If \*this is a suffix iterator, sets \*this to an end-of-sequence iterator.
Otherwise, if N + 1 < subs.size(), increments N and sets result to the address of the current match.
Otherwise, sets N to 0 and increments position. If position is not an end-of-sequence iterator the operator sets result to the address of the current match.
Otherwise, if any of the values stored in subs is equal to -1 and prev->suffix().length() is not 0 the operator sets \*this to a suffix iterator that points to the range [prev->suffix().first, prev->suffix().second).
Otherwise, sets \*this to an end-of-sequence iterator.
Returns: \*this

regex_token_iterator& operator++(int);
Effects: Constructs a copy tmp of \*this, then calls ++(*this).
Returns: tmp.

30.13 Modified ECMAScript regular expression grammar [re grammar]

The regular expression grammar recognized by basic_regex objects constructed with the ECMAScript flag is that specified by ECMA-262, except as specified below.

Objects of type specialization of basic_regex store within themselves a default-constructed instance of their traits template parameter, henceforth referred to as traits_inst. This traits_inst object is used to support localization of the regular expression; basic_regex member functions shall not call any locale dependent C or C++ API, including the formatted string input functions. Instead they shall call the appropriate traits member function to achieve the required effect.

The following productions within the ECMAScript grammar are modified as follows:

ClassAtom :
  -
ClassAtomNoDash
ClassAtomExClass
ClassAtomCollatingElement
ClassAtomEquivalence
IdentityEscape :
  SourceCharacter but not c

The following new productions are then added:

ClassAtomExClass :
  [: ClassName :]

ClassAtomCollatingElement :
  [. ClassName .]
ClassAtomEquivalence ::
[= ClassName =]

ClassName ::
ClassNameCharacter
ClassNameCharacter ClassName

ClassNameCharacter ::
SourceCharacter but not one of "." ":" ":=

The productions ClassAtomExClass, ClassAtomCollatingElement and ClassAtomEquivalence provide functionality equivalent to that of the same features in regular expressions in POSIX.

The regular expression grammar may be modified by any regex_constants::syntax_option_type flags specified when constructing an object of type specialization of basic_regex according to the rules in Table 124.

A ClassName production, when used in ClassAtomExClass, is not valid if traits_inst.lookup_classname returns zero for that name. The names recognized as valid ClassNames are determined by the type of the traits class, but at least the following names shall be recognized: alnum, alpha, blank, cntrl, digit, graph, lower, print, punct, space, upper, xdigit, d, s, w. In addition the following expressions shall be equivalent:

\d and [[[:digit:]]]
\D and [\^[[:digit:]]]
\s and [[[:space:]]]

A ClassName production when used in a ClassAtomCollatingElement production is not valid if the value returned by traits_inst.lookup_collatename for that name is an empty string.

The results from multiple calls to traits_inst.lookup_classname can be bitwise OR’ed together and subsequently passed to traits_inst.isctype.

A ClassName production when used in a ClassAtomEquivalence production is not valid if the value returned by traits_inst.lookup_collatename for that name is an empty string or if the value returned by traits_inst.transform_primary for the result of the call to traits_inst.lookup_collatename is an empty string.

When the sequence of characters being transformed to a finite state machine contains an invalid class name the translator shall throw an exception object of type regex_error.

If the CV of a UnicodeEscapeSequence is greater than the largest value that can be held in an object of type charT the translator shall throw an exception object of type regex_error. [Note: This means that values of the form "uxxxx" that do not fit in a character are invalid. —end note]

Where the regular expression grammar requires the conversion of a sequence of characters to an integral value, this is accomplished by calling traits_inst.value.

The behavior of the internal finite state machine representation when used to match a sequence of characters is as described in ECMA-262. The behavior is modified according to any match_flag_type flags (30.5.2) specified when using the regular expression object in one of the regular expression algorithms (30.11). The behavior is also localized by interaction with the traits class template parameter as follows:

During matching of a regular expression finite state machine against a sequence of characters, two characters c and d are compared object using the following rules:

- if (flags() & regex_constants::icase) the two characters are equal if traits_inst.translate_nocase(c) == traits_inst.translate_nocase(d);
- otherwise, if flags() & regex_constants::collate the two characters are equal if traits_inst.translate(c) == traits_inst.translate(d);
- otherwise, the two characters are equal if c == d.
During matching of a regular expression finite state machine against a sequence of characters, comparison of a collating element range \( c_1-c_2 \) against a character \( c \) is conducted as follows: if \( \text{flags}() \) & \text{regex-constants::collate} \) is false then the character \( c \) is matched if \( c_1 \leq c \land c \leq c_2 \), otherwise \( c \) is matched in accordance with the following algorithm:

```cpp
string_type str1 = string_type(1,
   flags() & icase ?
   traits_inst.translate_nocase(c1) : traits_inst.translate(c1));
string_type str2 = string_type(1,
   flags() & icase ?
   traits_inst.translate_nocase(c2) : traits_inst.translate(c2));
string_type str = string_type(1,
   flags() & icase ?
   traits_inst.translate_nocase(c) : traits_inst.translate(c));
return traits_inst.transform(str1.begin(), str1.end())
   <= traits_inst.transform(str.begin(), str.end())
   && traits_inst.transform(str.begin(), str.end())
   <= traits_inst.transform(str2.begin(), str2.end());
```

During matching of a regular expression finite state machine against a sequence of characters, testing whether a collating element is a member of a primary equivalence class is conducted by first converting the collating element and the equivalence class to sort keys using `traits::transform_primary`, and then comparing the sort keys for equality.

During matching of a regular expression finite state machine against a sequence of characters, a character \( c \) is a member of a character class designated by an iterator range \([\text{first}, \text{last})\) if \( \text{traits-inst.isctype}(c, \text{traits_inst.lookup_classname(first, last, flags() & icase}) \) is true.

31 Atomic operations library

31.1 General

This Clause describes components for fine-grained atomic access. This access is provided via operations on atomic objects.

The following subclauses describe atomics requirements and components for types and operations, as summarized in Table 131.

Table 131: Atomics library summary

}
31.3 Type aliases

The type aliases `atomic_intN_t`, `atomic_uintN_t`, `atomic_intptr_t`, and `atomic_uintptr_t` are defined if and only if `intN_t`, `uintN_t`, `intptr_t`, and `uintptr_t` are defined, respectively.

31.4 Order and consistency

namespace std {
    enum class memory_order : unspecified {
        unspecified, relaxed, consume, acquire, release, acq_rel, seq_cst
    };
    inline constexpr memory_order memory_order_relaxed = memory_order::relaxed;
    inline constexpr memory_order memory_order_consume = memory_order::consume;
    inline constexpr memory_order memory_order_acquire = memory_order::acquire;
    inline constexpr memory_order memory_order_release = memory_order::release;
    inline constexpr memory_order memory_order_acq_rel = memory_order::acq_rel;
    inline constexpr memory_order memory_order_seq_cst = memory_order::seq_cst;
}

The enumeration `memory_order` specifies the detailed regular (non-atomic) memory synchronization order as defined in 6.8.2 and may provide for operation ordering. Its enumerated values and their meanings are as follows:

1. `memory_order::relaxed`: no operation orders memory.
2. `memory_order::release`, `memory_order::acq_rel`, and `memory_order::seq_cst`: a store operation performs a release operation on the affected memory location.
3. `memory_order::consume`: a load operation performs a consume operation on the affected memory location. [Note: Prefer `memory_order::acquire`, which provides stronger guarantees than `memory_order::consume`. Implementations have found it infeasible to provide performance better than that of `memory_order::acquire`. Specification revisions are under consideration. — end note]
4. `memory_order::acquire`, `memory_order::acq_rel`, and `memory_order::seq_cst`: a load operation performs an acquire operation on the affected memory location.

[Note: Atomic operations specifying `memory_order::relaxed` are relaxed with respect to memory ordering. Implementations must still guarantee that any given atomic access to a particular atomic object be indivisible with respect to all other atomic accesses to that object. — end note]

An atomic operation `A` that performs a release operation on an atomic object `M` synchronizes with an atomic operation `B` that performs an acquire operation on `M` and takes its value from any side effect in the release sequence headed by `A`.

An atomic operation `A` on some atomic object `M` is coherence-ordered before another atomic operation `B` on `M` if

1. `A` is a modification, and `B` reads the value stored by `A`, or
2. `A` precedes `B` in the modification order of `M`, or
3. `A` and `B` are not the same atomic read-modify-write operation, and there exists an atomic modification `X` of `M` such that `A` reads the value stored by `X` and `X` precedes `B` in the modification order of `M`, or
4. `A` and `B` are both `memory_order::seq_cst` operations, then `A` precedes `B` in `S`; and
5. `A` is a `memory_order::seq_cst` operation and `B` happens before a `memory_order::seq_cst` fence `Y`, then `A` precedes `Y` in `S`; and
6. `A` is a `memory_order::seq_cst` fence `X` happens before `A` and `B` is a `memory_order::seq_cst` operation, then `X` precedes `B` in `S`; and
7. `A` is a `memory_order::seq_cst` fence `X` happens before `A` and `B` happens before a `memory_order::seq_cst` fence `Y`, then `X` precedes `Y` in `S`.

§ 31.4 1479
5 [Note: This definition ensures that $S$ is consistent with the modification order of any atomic object $M$. It also ensures that a $\text{memory\_order::seq\_cst}$ load $A$ of $M$ gets its value either from the last modification of $M$ that precedes $A$ in $S$ or from some non-$\text{memory\_order::seq\_cst}$ modification of $M$ that does not happen before any modification of $M$ that precedes $A$ in $S$. —end note]

6 [Note: We do not require that $S$ be consistent with “happens before” (6.8.2.1). This allows more efficient implementation of $\text{memory\_order::acquire}$ and $\text{memory\_order::release}$ on some machine architectures. It can produce surprising results when these are mixed with $\text{memory\_order::seq\_cst}$ accesses. —end note]

7 [Note: $\text{memory\_order::seq\_cst}$ ensures sequential consistency only for a program that is free of data races and uses exclusively $\text{memory\_order::seq\_cst}$ atomic operations. Any use of weaker ordering will invalidate this guarantee unless extreme care is used. In many cases, $\text{memory\_order::seq\_cst}$ atomic operations are reorderable with respect to other atomic operations performed by the same thread. —end note]

8 Implementations should ensure that no “out-of-thin-air” values are computed that circularly depend on their own computation.

[Note: For example, with $x$ and $y$ initially zero,

// Thread 1:
r1 = y.load($\text{memory\_order::relaxed}$);
x.store(r1, $\text{memory\_order::relaxed}$);
// Thread 2:
r2 = x.load($\text{memory\_order::relaxed}$);
y.store(r2, $\text{memory\_order::relaxed}$);
should not produce $r1 == r2 == 42$, since the store of 42 to $y$ is only possible if the store to $x$ stores 42, which circularly depends on the store to $y$ storing 42. Note that without this restriction, such an execution is possible. —end note]

9 [Note: The recommendation similarly disallows $r1 == r2 == 42$ in the following example, with $x$ and $y$ again initially zero:

// Thread 1:
r1 = x.load($\text{memory\_order::relaxed}$);
if (r1 == 42) y.store(42, $\text{memory\_order::relaxed}$);
// Thread 2:
r2 = y.load($\text{memory\_order::relaxed}$);
if (r2 == 42) x.store(42, $\text{memory\_order::relaxed}$);
—end note]

Atomic read-modify-write operations shall always read the last value (in the modification order) written before the write associated with the read-modify-write operation.

Implementations should make atomic stores visible to atomic loads within a reasonable amount of time.

template<class T>
T kill_dependency(T y) noexcept;

Effects: The argument does not carry a dependency to the return value (6.8.2).

Returns: $y$.

31.5 Lock-free property [atomics.lockfree]

#define ATOMIC_BOOL_LOCK_FREE unspecified
#define ATOMIC_CHAR_LOCK_FREE unspecified
#define ATOMIC_CHAR8_T_LOCK_FREE unspecified
#define ATOMIC_CHAR16_T_LOCK_FREE unspecified
#define ATOMIC_CHAR32_T_LOCK_FREE unspecified
#define ATOMIC_WCHAR_T_LOCK_FREE unspecified
#define ATOMIC_SHORT_LOCK_FREE unspecified
#define ATOMIC_INT_LOCK_FREE unspecified
#define ATOMIC_LONG_LOCK_FREE unspecified
#define ATOMIC_LLONG_LOCK_FREE unspecified
#define ATOMIC_POINTER_LOCK_FREE unspecified

The ATOMIC_..._LOCK_FREE macros indicate the lock-free property of the corresponding atomic types, with the signed and unsigned variants grouped together. The properties also apply to the corresponding (partial)
specializations of the atomic template. A value of 0 indicates that the types are never lock-free. A value of 1 indicates that the types are sometimes lock-free. A value of 2 indicates that the types are always lock-free.

The function atomic_is_lock_free (31.7.1) indicates whether the object is lock-free. In any given program execution, the result of the lock-free query shall be consistent for all pointers of the same type.

Atomic operations that are not lock-free are considered to potentially block (6.8.2.2).

[Note: Operations that are lock-free should also be address-free. That is, atomic operations on the same memory location via two different addresses will communicate atomically. The implementation should not depend on any per-process state. This restriction enables communication by memory that is mapped into a process more than once and by memory that is shared between two processes. — end note]

31.6 Class template atomic_ref

namespace std {
  template<class T> struct atomic_ref {
    private:
      T* ptr; // exposition only
    public:
      using value_type = T;
      static constexpr bool is_always_lock_free = implementation-defined;
      static constexpr size_t required_alignment = implementation-defined;

      atomic_ref& operator=(const atomic_ref&) = delete;

      explicit atomic_ref(T&);
      atomic_ref(const atomic_ref&) noexcept;
      T operator=(T) const noexcept;
      operator T() const noexcept;
      bool is_lock_free() const noexcept;
      void store(T, memory_order = memory_order_seq_cst) const noexcept;
      T load(memory_order = memory_order_seq_cst) const noexcept;
      T exchange(T, memory_order = memory_order_seq_cst) const noexcept;
      bool compare_exchange_weak(T&, T,
        memory_order, memory_order) const noexcept;
      bool compare_exchange_strong(T&, T,
        memory_order, memory_order) const noexcept;
      bool compare_exchange_weak(T&, T,
        memory_order = memory_order_seq_cst) const noexcept;
      bool compare_exchange_strong(T&, T,
        memory_order = memory_order_seq_cst) const noexcept;
  };
}

1 An atomic_ref object applies atomic operations (31.1) to the object referenced by *ptr such that, for the lifetime (6.6.3) of the atomic_ref object, the object referenced by *ptr is an atomic object (6.8.2.1).

2 The template argument for T shall be trivially copyable (6.7).

3 The lifetime (6.6.3) of an object referenced by *ptr shall exceed the lifetime of all atomic_ref objects that reference the object. While any atomic_ref instances exist that reference the *ptr object, all accesses to that object shall exclusively occur through those atomic_ref instances. No subobject of the object referenced by atomic_ref shall be concurrently referenced by any other atomic_ref object.

4 Atomic operations applied to an object through a referencing atomic_ref are atomic with respect to atomic operations applied through any other atomic_ref referencing the same object. [Note: Atomic operations or the atomic_ref constructor could acquire a shared resource, such as a lock associated with the referenced object, to enable atomic operations to be applied to the referenced object. — end note]

31.6.1 Operations

static constexpr bool is_always_lock_free;

1 The static data member is_always_lock_free is true if the atomic_ref type’s operations are always lock-free, and false otherwise.
static constexpr size_t required_alignment;

The alignment required for an object to be referenced by an atomic reference, which is at least `alignof(T)`.

[Note: Hardware could require an object referenced by an atomic_ref to have stricter alignment (6.6.6) than other objects of type T. Further, whether operations on an atomic_ref are lock-free could depend on the alignment of the referenced object. For example, lock-free operations on `std::complex<double>` could be supported only if aligned to `2*alignof(double)`. — end note]

`atomic_ref(T& obj);`

Requires: The referenced object shall be aligned to `required_alignment`.
Effects: Constructs an atomic reference that references the object.
Throws: Nothing.

`atomic_ref(const atomic_ref& ref) noexcept;`
Effects: Constructs an atomic reference that references the object referenced by `ref`.

T operator=(T desired) const noexcept;
Effects: Equivalent to:
```cpp
store(desired);
return desired;
```
operator T() const noexcept;
Effects: Equivalent to: `return load();`

bool is_lock_free() const noexcept;
Returns: true if the object’s operations are lock-free, false otherwise.

void store(T desired, memory_order order = memory_order_seq_cst) const noexcept;
Requires: The order argument shall not be `memory_order_consume`, `memory_order_acquire`, nor `memory_order_acq_rel`.
Effects: Atomically replaces the value referenced by *ptr with the value of desired. Memory is affected according to the value of order.

T load(memory_order order = memory_order_seq_cst) const noexcept;
Requires: The order argument shall not be `memory_order_release` nor `memory_order_acq_rel`.
Effects: Memory is affected according to the value of order.
Returns: Atomically returns the value referenced by *ptr.

T exchange(T desired, memory_order order = memory_order_seq_cst) const noexcept;
Effects: Atomically replaces the value referenced by *ptr with desired. Memory is affected according to the value of order. This operation is an atomic read-modify-write operation (6.8.2).
Returns: Atomically returns the value referenced by *ptr immediately before the effects.

bool compare_exchange_weak(T& expected, T desired, memory_order success, memory_order failure) const noexcept;

bool compare_exchange_strong(T& expected, T desired, memory_order success, memory_order failure) const noexcept;

bool compare_exchange_weak(T& expected, T desired, memory_order order = memory_order_seq_cst) const noexcept;

bool compare_exchange_strong(T& expected, T desired, memory_order order = memory_order_seq_cst) const noexcept;

Requires: The failure argument shall not be `memory_order_release` nor `memory_order_acq_rel`. 

§ 31.6.1 1482
Effects: Retrieves the value in `expected`. It then atomically compares the value representation of the value referenced by `*ptr` for equality with that previously retrieved from `expected`, and if true, replaces the value referenced by `*ptr` with that in `desired`. If and only if the comparison is true, memory is affected according to the value of `success`, and if the comparison is false, memory is affected according to the value of `failure`. When only one `memory_order` argument is supplied, the value of `success` is `order`, and the value of `failure` is `order` except that a value of `memory_order_acq_rel` shall be replaced by the value `memory_order_acquire` and a value of `memory_order_release` shall be replaced by the value `memory_order_relaxed`. If and only if the comparison is false then, after the atomic operation, the value in `expected` is replaced by the value read from the value referenced by `*ptr` during the atomic comparison. If the operation returns true, these operations are atomic read-modify-write operations (6.8.2.1) on the value referenced by `*ptr`. Otherwise, these operations are atomic load operations on that memory.

Returns: The result of the comparison.

Remarks: A weak compare-and-exchange operation may fail spuriously. That is, even when the contents of memory referred to by `expected` and `ptr` are equal, it may return false and store back to `expected` the same memory contents that were originally there. [Note: This spurious failure enables implementation of compare-and-exchange on a broader class of machines, e.g., load-locked store-conditional machines. A consequence of spurious failure is that nearly all uses of weak compare-and-exchange will be in a loop. When a compare-and-exchange is in a loop, the weak version will yield better performance on some platforms. When a weak compare-and-exchange would require a loop and a strong one would not, the strong one is preferable. — end note]

31.6.2 Specializations for integral types

There are specializations of the `atomic_ref` class template for the integral types `char`, `signed char`, `unsigned char`, `short`, `unsigned short`, `int`, `unsigned int`, `long`, `unsigned long`, `long long`, `unsigned long long`, `char8_t`, `char16_t`, `char32_t`, `wchar_t`, and any other types needed by the typedefs in the header `<cstdint>`. For each such type `integral`, the specialization `atomic_ref<integral>` provides additional atomic operations appropriate to integral types. [Note: For the specialization `atomic_ref<bool>`, see 31.6. — end note]

```cpp
namespace std {
    template<> struct atomic_ref<integral> {
        private:
            integral* ptr; // exposition only
        public:
            using value_type = integral;
            using difference_type = value_type;
            static constexpr bool is_always_lock_free = implementation-defined;
            static constexpr size_t required_alignment = implementation-defined;
            atomic_ref& operator=(const atomic_ref&) = delete;
            explicit atomic_ref(integral&);
            atomic_ref(const atomic_ref&) noexcept;
            integral operator=(integral) const noexcept;
            operator integral() const noexcept;
            bool is_lock_free() const noexcept;
            void store(integral, memory_order = memory_order_seq_cst) const noexcept;
            integral load(memory_order = memory_order_seq_cst) const noexcept;
            integral exchange(integral,
                memory_order = memory_order_seq_cst) const noexcept;
            bool compare_exchange_weak(integral&, integral,
                memory_order, memory_order) const noexcept;
            bool compare_exchange_strong(integral&, integral,
                memory_order, memory_order) const noexcept;
            bool compare_exchange_weak(integral&, integral,
                memory_order = memory_order_seq_cst) const noexcept;
            bool compare_exchange_strong(integral&, integral,
                memory_order = memory_order_seq_cst) const noexcept;
    }
}
```
integral fetch_add(integral,
        memory_order = memory_order_seq_cst) const noexcept;
integral fetch_sub(integral,
        memory_order = memory_order_seq_cst) const noexcept;
integral fetch_and(integral,
        memory_order = memory_order_seq_cst) const noexcept;
integral fetch_or(integral,
        memory_order = memory_order_seq_cst) const noexcept;
integral fetch_xor(integral,
        memory_order = memory_order_seq_cst) const noexcept;
integral operator++(int) const noexcept;
integral operator--(int) const noexcept;
integral operator++() const noexcept;
integral operator--() const noexcept;
integral operator+=(integral) const noexcept;
integral operator-=(integral) const noexcept;
integral operator&=(integral) const noexcept;
integral operator|=(integral) const noexcept;
integral operator^=(integral) const noexcept;

integral fetch_key(integral operand, memory_order order = memory_order_seq_cst) const noexcept;

**Effects:** Atomically replaces the value referenced by `*ptr` with the result of the computation applied to the value referenced by `*ptr` and the given operand. Memory is affected according to the value of `order`. These operations are atomic read-modify-write operations (6.8.2.1).

**Returns:** Atomically, the value referenced by `*ptr` immediately before the effects.

**Remarks:** For signed integer types, the result is as if the object value and parameters were converted to their corresponding unsigned types, the computation performed on those types, and the result converted back to the signed type. [Note: There are no undefined results arising from the computation. — end note]

integral operator op=(integral operand) const noexcept;

**Effects:** Equivalent to: return `fetch_key(operand) op operand`;

### 31.6.3 Specializations for floating-point types

There are specializations of the `atomic_ref` class template for the floating-point types `float`, `double`, and `long double`. For each such type `floating-point`, the specialization `atomic_ref<floating-point>` provides additional atomic operations appropriate to floating-point types.

```cpp
namespace std {
    template<> struct atomic_ref<floating-point> {
        private:
            floating-point* ptr; // exposition only
        public:
            using value_type = floating-point;
            using difference_type = value_type;
            static constexpr bool is_always_lock_free = implementation-defined;
            static constexpr size_t required_alignment = implementation-defined;

            atomic_ref& operator=(const atomic_ref&) = delete;
            explicit atomic_ref(floating-point&);        // exposition only
            atomic_ref(const atomic_ref&) noexcept;
            floating-point operator=(floating-point) noexcept;
            operator floating-point() const noexcept;
    };
}

§ 31.6.3
bool is_lock_free() const noexcept;
void store(floating-point, memory_order = memory_order_seq_cst) const noexcept;
floating-point load(memory_order = memory_order_seq_cst) const noexcept;
floating-point exchange(floating-point,
memory_order = memory_order_seq_cst) const noexcept;
bool compare_exchange_weak(floating-pointk, floating-point,
memory_order, memory_order) const noexcept;
bool compare_exchange_strong(floating-pointk, floating-point,
memory_order, memory_order) const noexcept;
bool compare_exchange_weak(floating-pointk, floating-point,
memory_order, memory_order) const noexcept;
bool compare_exchange_strong(floating-pointk, floating-point,
memory_order = memory_order_seq_cst) const noexcept;
}
}

2 Descriptions are provided below only for members that differ from the primary template.
3 The following operations perform arithmetic computations. The key, operator, and computation correspondence are identified in Table 132.

floating-point fetch_key(floating-point operand,
memory_order order = memory_order_seq_cst) const noexcept;

4 Effects: Atomically replaces the value referenced by *ptr with the result of the computation applied to the value referenced by *ptr and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2.1).

5 Returns: Atomically, the value referenced by *ptr immediately before the effects.

6 Remarks: If the result is not a representable value for its type (7.1), the result is unspecified, but the operations otherwise have no undefined behavior. Atomic arithmetic operations on floating-point should conform to the std::numeric_limits<floating-point> traits associated with the floating-point type (17.3.2). The floating-point environment (26.3) for atomic arithmetic operations on floating-point may be different than the calling thread’s floating-point environment.

floating-point operator==(floating-point operand) const noexcept;

Effects: Equivalent to: return fetch_key(operand) op operand;

31.6.4 Partial specialization for pointers [atomics.ref.pointer]

namespace std {
  template<class T> struct atomic_ref<T*> {
    private:
      T** ptr; // exposition only
    public:
      using value_type = T*;
      using difference_type = ptrdiff_t;
      static constexpr bool is_always_lock_free = implementation-defined;
      static constexpr size_t required_alignment = implementation-defined;
      atomic_ref& operator=(const atomic_ref&) = delete;
      explicit atomic_ref(T*&) noexcept;
      atomic_ref(const atomic_ref&) noexcept;
      T* operator=(T*) const noexcept;
      operator T*() const noexcept;

    § 31.6.4 1485
bool is_lock_free() const noexcept;
void store(T*, memory_order = memory_order_seq_cst) const noexcept;
T* load(memory_order = memory_order_seq_cst) const noexcept;
T* exchange(T*, memory_order = memory_order_seq_cst) const noexcept;
bool compare_exchange_weak(T*, T*,
    memory_order, memory_order) const noexcept;
bool compare_exchange_strong(T*, T*,
    memory_order, memory_order) const noexcept;
T* compare_exchange_weak(T*, T*,
    memory_order = memory_order_seq_cst) const noexcept;
T* compare_exchange_strong(T*, T*,
    memory_order = memory_order_seq_cst) const noexcept;
T* fetch_add(difference_type, memory_order = memory_order_seq_cst) const noexcept;
T* fetch_sub(difference_type, memory_order = memory_order_seq_cst) const noexcept;
T* operator++(int) const noexcept;
T* operator--(int) const noexcept;
T* operator++() const noexcept;
T* operator--() const noexcept;
T* operator+=(difference_type) const noexcept;
T* operator-=(difference_type) const noexcept;
};

1 Descriptions are provided below only for members that differ from the primary template.
2 The following operations perform arithmetic computations. The key, operator, and computation correspondence is identified in Table 133.

T* fetch_key(difference_type operand, memory_order_order = memory_order_seq_cst) const noexcept;

3 Requires: T shall be an object type, otherwise the program is ill-formed.
4 Effects: Atomically replaces the value referenced by *ptr with the result of the computation applied to the value referenced by *ptr and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2.1).
5 Returns: Atomically, the value referenced by *ptr immediately before the effects.
6 Remarks: The result may be an undefined address, but the operations otherwise have no undefined behavior.

T* operator op=(difference_type operand) const noexcept;

7 Effects: Equivalent to: return fetch_key(operand) op operand;

31.6.5 Member operators common to integers and pointers to objects
[atomics.ref.memop]

T* operator++(int) const noexcept;
1 Effects: Equivalent to: return fetch_add(1);
T* operator--(int) const noexcept;
2 Effects: Equivalent to: return fetch_sub(1);
T* operator++() const noexcept;
3 Effects: Equivalent to: return fetch_add(1) + 1;
T* operator--() const noexcept;
4 Effects: Equivalent to: return fetch_sub(1) - 1;

31.7 Class template atomic
[atomics.types.generic]

namespace std {
    template<class T> struct atomic {
        using value_type = T;

§ 31.7 1486
static constexpr bool is_always_lock_free = implementation-defined;
bool is_lock_free() const volatile noexcept;
bool is_lock_free() const noexcept;
void store(T, memory_order = memory_order::seq_cst) volatile noexcept;
void store(T, memory_order = memory_order::seq_cst) noexcept;
T load(memory_order = memory_order::seq_cst) const volatile noexcept;
T load(memory_order = memory_order::seq_cst) const noexcept;
operator T() const volatile noexcept;
operator T() const noexcept;
void store(T, memory_order = memory_order::seq_cst) volatile noexcept;
void store(T, memory_order = memory_order::seq_cst) noexcept;
T load(memory_order = memory_order::seq_cst) const volatile noexcept;
T load(memory_order = memory_order::seq_cst) const noexcept;
operator T() const volatile noexcept;
operator T() const noexcept;
T exchange(T, memory_order = memory_order::seq_cst) volatile noexcept;
T exchange(T, memory_order = memory_order::seq_cst) noexcept;
T exchange(T, memory_order = memory_order::seq_cst) volatile noexcept;
T exchange(T, memory_order = memory_order::seq_cst) noexcept;
bool compare_exchange_weak(T&, T, memory_order, memory_order) volatile noexcept;
bool compare_exchange_weak(T&, T, memory_order, memory_order) noexcept;
bool compare_exchange_strong(T&, T, memory_order, memory_order) volatile noexcept;
bool compare_exchange_strong(T&, T, memory_order, memory_order) noexcept;
bool compare_exchange_weak(T&, T, memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_weak(T&, T, memory_order = memory_order::seq_cst) noexcept;
bool compare_exchange_strong(T&, T, memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_strong(T&, T, memory_order = memory_order::seq_cst) noexcept;
T operator=(T) volatile noexcept;
T operator=(T) noexcept;
T operator=(T) volatile noexcept;
T operator=(T) noexcept;
atomic() noexcept = default;
constexpr atomic(T) noexcept;
atomic(const atomic&) = delete;
atomic& operator=(const atomic&) = delete;
atomic& operator=(const atomic&) volatile = delete;
atomic(T desired) = default;
const expr atomic(T desired) noexcept;
Effects: Leaves the atomic object in an uninitialized state. [Note: These semantics ensure compatibility with C. — end note]

31.7.1 Operations on atomic types

[atomics.types.operations]
1 [Note: Many operations are volatile-qualified. The “volatile as device register” semantics have not changed in the standard. This qualification means that volatility is preserved when applying these operations to volatile objects. It does not mean that operations on non-volatile objects become volatile. — end note]

atomic() noexcept = default;

cast expr atomic(T desired) noexcept;
Effects: Initializes the object with the value desired. Initialization is not an atomic operation (6.8.2). [Note: It is possible to have an access to an atomic object A race with its construction, for example by communicating the address of the just-constructed object A to another thread via memory_order::relaxed operations on a suitable atomic pointer variable, and then immediately accessing A in the receiving thread. This results in undefined behavior. — end note]
The macro expands to a token sequence suitable for constant initialization of an atomic variable of static storage duration of a type that is initialization-compatible with value. [Note: This operation may need to initialize locks. — end note] Concurrent access to the variable being initialized, even via an atomic operation, constitutes a data race. [Example:

```
atomic<int> v = ATOMIC_VAR_INIT(5);
```
—end example]

```c
static constexpr bool is_always_lock_free = implementation-defined;
```

The static data member is_always_lock_free is true if the atomic type’s operations are always lock-free, and false otherwise. [Note: The value of is_always_lock_free is consistent with the value of the corresponding ATOMIC_..._LOCK_FREE macro, if defined. — end note]

```c
bool is_lock_free() const volatile noexcept;
bool is_lock_free() const noexcept;
```

Returns: true if the object’s operations are lock-free, false otherwise. [Note: The return value of the is_lock_free member function is consistent with the value of is_always_lock_free for the same type. — end note]

```c
void store(T desired, memory_order order = memory_order::seq_cst) volatile noexcept;
void store(T desired, memory_order order = memory_order::seq_cst) noexcept;
```

Requires: The order argument shall not be memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.

Effects: Atomically replaces the value pointed to by this with the value of desired. Memory is affected according to the value of order.

```c
T operator=(T desired) volatile noexcept;
T operator=(T desired) noexcept;
```

Effects: Equivalent to store(desired).

```c
T load(memory_order order = memory_order::seq_cst) const volatile noexcept;
T load(memory_order order = memory_order::seq_cst) const noexcept;
```

Requires: The order argument shall not be memory_order::release nor memory_order::acq_rel.

Effects: Memory is affected according to the value of order.

Returns: Atomically returns the value pointed to by this.

operator T() const volatile noexcept;
operator T() const noexcept;

Effects: Equivalent to: return load();

```c
T exchange(T desired, memory_order order = memory_order::seq_cst) volatile noexcept;
T exchange(T desired, memory_order order = memory_order::seq_cst) noexcept;
```

Effects: Atomically replaces the value pointed to by this with desired. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2).

Returns: Atomically returns the value pointed to by this immediately before the effects.

```c
bool compare_exchange_weak(T& expected, T desired,
memory_order success, memory_order failure) volatile noexcept;
bool compare_exchange_weak(T& expected, T desired,
memory_order success, memory_order failure) noexcept;
bool compare_exchange_strong(T& expected, T desired,
memory_order success, memory_order failure) volatile noexcept;
bool compare_exchange_strong(T& expected, T desired,
memory_order success, memory_order failure) noexcept;
bool compare_exchange_weak(T& expected, T desired,
memory_order order = memory_order::seq_cst) volatile noexcept;
```

§ 31.7.1
bool compare_exchange_weak(T& expected, T desired,  
    memory_order order = memory_order::seq_cst) noexcept;

bool compare_exchange_strong(T& expected, T desired,  
    memory_order order = memory_order::seq_cst) volatile noexcept;

bool compare_exchange_strong(T& expected, T desired,  
    memory_order order = memory_order::seq_cst) noexcept;

Requires: The failure argument shall not be memory_order::release nor memory_order::acq_rel.

Effects: Retrieves the value in expected. It then atomically compares the value representation of  
the value pointed to by this for equality with that previously retrieved from expected, and if true,  
replaces the value pointed to by this with that in desired. If and only if the comparison is true,  
memory is affected according to the value of success, and if the comparison is false, memory is affected  
according to the value of failure. When only one memory_order argument is supplied, the value of  
success is order, and the value of failure is order except that a value of memory_order::acq_rel  
shall be replaced by the value memory_order::acquire and a value of memory_order::release shall  
be replaced by the value memory_order::relaxed. If and only if the comparison is false then, after  
the atomic operation, the value in expected is replaced by the value pointed to by this during the  
atomic comparison. If the operation returns true, these operations are atomic read-modify-write  
operations (6.8.2) on the memory pointed to by this. Otherwise, these operations are atomic load  
operations on that memory.

Returns: The result of the comparison.

[Note: For example, the effect of compare_exchange_strong on objects without padding bits (6.7) is  
if (memcmp(this, &expected, sizeof(*this)) == 0)  
    memcpy(this, &desired, sizeof(*this));  
else  
    memcpy(expected, this, sizeof(*this));  
— end note] [Example: The expected use of the compare-and-exchange operations is as follows. The  
compare-and-exchange operations will update expected when another iteration of the loop is needed.  
expected = current.load();  
do {  
    desired = function(expected);  
} while (!current.compare_exchange_weak(expected, desired));  
— end example] [Example: Because the expected value is updated only on failure, code releasing the  
memory containing the expected value on success will work. For example, list head insertion will act  
atomically and would not introduce a data race in the following code:  
do {  
    p->next = head; // make new list node point to the current head  
} while (!head.compare_exchange_weak(p->next, p)); // try to insert  
— end example]

Implementations should ensure that weak compare-and-exchange operations do not consistently return  
false unless either the atomic object has value different from expected or there are concurrent  
modifications to the atomic object.

Remarks: A weak compare-and-exchange operation may fail spuriously. That is, even when the  
contents of memory referred to by expected and this are equal, it may return false and store back to  
expected the same memory contents that were originally there. [Note: This spurious failure  
enables implementation of compare-and-exchange on a broader class of machines, e.g., load-locked  
store-conditional machines. A consequence of spurious failure is that nearly all uses of weak compare-  
and-exchange will be in a loop. When a compare-and-exchange is in a loop, the weak version will yield  
better performance on some platforms. When a weak compare-and-exchange would require a loop and  
a strong one would not, the strong one is preferable. — end note]

[Note: Under cases where the memcpy and memcmp semantics of the compare-and-exchange operations  
apply, the outcome might be failed comparisons for values that compare equal with operator== if  
the value representation has trap bits or alternate representations of the same value. Notably, on  
implementations conforming to ISO/IEC/IEEE 60559, floating-point -0.0 and +0.0 will not compare  
equal with memcmp but will compare equal with operator==, and NaNs with the same payload will  
compare equal with memcmp but will not compare equal with operator==. — end note] [Note: Because
compare-and-exchange acts on an object’s value representation, padding bits that never participate in the object’s value representation are ignored. As a consequence, the following code is guaranteed to avoid spurious failure:

```c
struct padded {
    char clank = 0x42;
    // Padding here.
    unsigned biff = 0xC0DEFEFE;
};
atomic<padded> pad = ATOMIC_VAR_INIT({});

bool zap() {
    padded expected, desired{0, 0};
    return pad.compare_exchange_strong(expected, desired);
}
```

— end note] [Note: For a union with bits that participate in the value representation of some members but not others, compare-and-exchange might always fail. This is because such padding bits have an indeterminate value when they do not participate in the value representation of the active member. As a consequence, the following code is not guaranteed to ever succeed:

```c
union pony {
    double celestia = 0.;
    short luna; // padded
};
atomic<pony> princesses = ATOMIC_VAR_INIT({});

bool party(pony desired) {
    pony expected;
    return princesses.compare_exchange_strong(expected, desired);
}
```

— end note]

### 31.7.2 Specializations for integers [atomics.types.int]

There are specializations of the `atomic` class template for the integral types `char`, `signed char`, `unsigned char`, `short`, `unsigned short`, `int`, `unsigned int`, `long`, `unsigned long`, `long long`, `char8_t`, `char16_t`, `char32_t`, `wchar_t`, and any other types needed by the typedefs in the header `<cstdint>`. For each such type `integral`, the specialization `atomic<integral>` provides additional atomic operations appropriate to integral types. [Note: For the specialization `atomic<bool>`, see 31.7. — end note]

```c
namespace std {

template<> struct atomic<integral> {
    using value_type = integral;
    using difference_type = value_type;
    static constexpr bool is_always_lock_free = implementation-defined;
    bool is_lock_free() const volatile noexcept;
    bool is_lock_free() const noexcept;
    void store(integral, memory_order = memory_order::seq_cst) volatile noexcept;
    void store(integral, memory_order = memory_order::seq_cst) noexcept;
    integral load(memory_order = memory_order::seq_cst) const volatile noexcept;
    integral load(memory_order = memory_order::seq_cst) const noexcept;
    operator integral() const volatile noexcept;
    operator integral() const noexcept;
    integral exchange(integral, memory_order = memory_order::seq_cst) volatile noexcept;
    integral exchange(integral, memory_order = memory_order::seq_cst) noexcept;
    bool compare_exchange_weak(integral&, integral,
        memory_order, memory_order) volatile noexcept;
    bool compare_exchange_weak(integral&, integral,
        memory_order, memory_order) noexcept;
    bool compare_exchange_strong(integral&, integral,
        memory_order, memory_order) volatile noexcept;
    bool compare_exchange_strong(integral&, integral,
        memory_order, memory_order) noexcept;

```
bool compare_exchange_weak(integral&, integral,
    memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_weak(integral&, integral,
    memory_order = memory_order::seq_cst) noexcept;
bool compare_exchange_strong(integral&, integral,
    memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_strong(integral&, integral,
    memory_order = memory_order::seq_cst) noexcept;

integral fetch_add(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_add(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_sub(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_sub(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_and(integral, memory_order = memory_order::seq_cst) volatile noexcep;
integral fetch_and(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_or(integral, memory_order = memory_order::seq_cst) volatile noexcep;
integral fetch_or(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_xor(integral, memory_order = memory_order::seq_cst) volatile noexcep;
integral fetch_xor(integral, memory_order = memory_order::seq_cst) noexcept;

atomic() noexcept = default;
constexpr atomic(integral) noexcept;
atomic(const atomic&) = delete;
atomic& operator=(const atomic&) = delete;
atomic& operator=(const atomic&) volatile = delete;

integral operator=(integral) volatile noexcept;
integral operator=(integral) noexcept;
integral operator++(int) volatile noexcept;
integral operator++(int) noexcept;
integral operator--(int) volatile noexcept;
integral operator--(int) noexcept;
integral operator++() volatile noexcept;
integral operator++() noexcept;
integral operator--() volatile noexcept;
integral operator--() noexcept;
integral operator+=(integral) volatile noexcept;
integral operator+=(integral) noexcept;
integral operator-=(integral) volatile noexcept;
integral operator-=(integral) noexcept;
integral operator&=(integral) volatile noexcept;
integral operator&=(integral) noexcept;
integral operator|=(integral) volatile noexcept;
integral operator|=(integral) noexcept;
integral operator^=(integral) volatile noexcept;
integral operator^=(integral) noexcept;

2 The atomic integral specializations are standard-layout structs. They each have a trivial default constructor
and a trivial destructor.
3 Descriptions are provided below only for members that differ from the primary template.
4 The following operations perform arithmetic computations. The key, operator, and computation correspondence is:

<table>
<thead>
<tr>
<th>key</th>
<th>Op</th>
<th>Computation</th>
<th>key</th>
<th>Op</th>
<th>Computation</th>
</tr>
</thead>
<tbody>
<tr>
<td>add</td>
<td>+</td>
<td>addition</td>
<td>sub</td>
<td>-</td>
<td>subtraction</td>
</tr>
<tr>
<td>or</td>
<td></td>
<td>bitwise inclusive or</td>
<td>xor</td>
<td>^</td>
<td>bitwise exclusive or</td>
</tr>
<tr>
<td>and</td>
<td>&amp;</td>
<td>bitwise and</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

T fetch_key(T operand, memory_order order = memory_order::seq_cst) volatile noexcep;
T fetch_key(T operand, memory_order order = memory_order::seq_cst) noexcept;

Effects: Atomically replaces the value pointed to by this with the result of the computation applied to the value pointed to by this and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2).

Returns: Atomically, the value pointed to by this immediately before the effects.

Remarks: For signed integer types, the result is as if the object value and parameters were converted to their corresponding unsigned types, the computation performed on those types, and the result converted back to the signed type. [Note: There are no undefined results arising from the computation. — end note]

T operator op=(T operand) volatile noexcept;
T operator op=(T operand) noexcept;

Effects: Equivalent to: return fetch_key(operand) op operand;

31.7.3 Specializations for floating-point types

There are specializations of the atomic class template for the floating-point types float, double, and long double. For each such type floating-point, the specialization atomic<floating-point> provides additional atomic operations appropriate to floating-point types.

namespace std {
  template<> struct atomic<floating-point> {
    using value_type = floating-point;
    using difference_type = value_type;
    static constexpr bool is_always_lock_free = implementation-defined;
    bool is_lock_free() const volatile noexcept;
    bool is_lock_free() const noexcept;
    void store(floating-point, memory_order = memory_order_seq_cst) volatile noexcept;
    void store(floating-point, memory_order = memory_order_seq_cst) noexcept;
    floating-point load(memory_order = memory_order_seq_cst) volatile noexcept;
    floating-point load(memory_order = memory_order_seq_cst) noexcept;
    operator floating-point() volatile noexcept;
    operator floating-point() noexcept;
    floating-point exchange(floating-point, memory_order = memory_order_seq_cst) volatile noexcept;
    floating-point exchange(floating-point, memory_order = memory_order_seq_cst) noexcept;
    bool compare_exchange_weak(floating-point&, floating-point, memory_order, memory_order) volatile noexcept;
    bool compare_exchange_weak(floating-point&, floating-point, memory_order, memory_order) noexcept;
    bool compare_exchange_strong(floating-point&, floating-point, memory_order, memory_order) volatile noexcept;
    bool compare_exchange_strong(floating-point&, floating-point, memory_order, memory_order) noexcept;
    bool compare_exchange_weak(floating-point&, floating-point, memory_order = memory_order_seq_cst) volatile noexcept;
    bool compare_exchange_weak(floating-point&, floating-point, memory_order = memory_order_seq_cst) noexcept;
    bool compare_exchange_strong(floating-point&, floating-point, memory_order = memory_order_seq_cst) volatile noexcept;
    bool compare_exchange_strong(floating-point&, floating-point, memory_order = memory_order_seq_cst) noexcept;
    floating-point fetch_add(floating-point, memory_order = memory_order_seq_cst) volatile noexcept;
    floating-point fetch_add(floating-point, memory_order = memory_order_seq_cst) noexcept;
    floating-point fetch_sub(floating-point, memory_order = memory_order_seq_cst) volatile noexcept;
    floating-point fetch_sub(floating-point, memory_order = memory_order_seq_cst) noexcept;
  }
}

§ 31.7.3 1492
atomic() noexcept = default;
constexpr atomic(floating-point) noexcept;
atomic(const atomic&) = delete;
atomic& operator=(const atomic&) = delete;
atomic& operator=(const atomic&) volatile = delete;
floating-point operator=(floating-point) volatile noexcept;
floating-point operator=(floating-point) noexcept;
floating-point operator+= (floating-point) volatile noexcept;
floating-point operator+= (floating-point) noexcept;
floating-point operator-= (floating-point) volatile noexcept;
floating-point operator-= (floating-point) noexcept;
};

2 The atomic floating-point specializations are standard-layout structs. They each have a trivial default
constructor and a trivial destructor.

3 Descriptions are provided below only for members that differ from the primary template.

4 The following operations perform arithmetic addition and subtraction computations. The key, operator, and
computation correspondence are identified in Table 132.

T A::fetch_key(T operand, memory_order order = memory_order_seq_cst) volatile noexcept;
T A::fetch_key(T operand, memory_order order = memory_order_seq_cst) noexcept;

5 Effects: Atomically replaces the value pointed to by this with the result of the computation applied
to the value pointed to by this and the given operand. Memory is affected according to the value of
order. These operations are atomic read-modify-write operations (6.8.2).

6 Returns: Atomically, the value pointed to by this immediately before the effects.

7 Remarks: If the result is not a representable value for its type (7.1) the result is unspecified, but the
operations otherwise have no undefined behavior. Atomic arithmetic operations on floating-point
should conform to the std::numeric_limits<floating-point> traits associated with the floating-
point type (17.3.2). The floating-point environment (26.3) for atomic arithmetic operations on
floating-point may be different than the calling thread’s floating-point environment.

T operator op=(T operand) volatile noexcept;
T operator op=(T operand) noexcept;

8 Effects: Equivalent to: return fetch_key(operand) op operand;

9 Remarks: If the result is not a representable value for its type (7.1) the result is unspecified, but the
operations otherwise have no undefined behavior. Atomic arithmetic operations on floating-point
should conform to the std::numeric_limits<floating-point> traits associated with the floating-
point type (17.3.2). The floating-point environment (26.3) for atomic arithmetic operations on
floating-point may be different than the calling thread’s floating-point environment.

31.7.4 Partial specialization for pointers

namespace std {
    template<class T> struct atomic<T*> {
        using value_type = T*;
        using difference_type = ptrdiff_t;
        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const volatile noexcept;
        bool is_lock_free() const noexcept;
        void store(T*, memory_order = memory_order::seq_cst) volatile noexcept;
        void store(T*, memory_order = memory_order::seq_cst) noexcept;
        T* load(memory_order = memory_order::seq_cst) const volatile noexcept;
        T* load(memory_order = memory_order::seq_cst) const noexcept;
        operator T*() const volatile noexcept;
        operator T*() const noexcept;
        T* exchange(T*, memory_order = memory_order::seq_cst) volatile noexcept;
        T* exchange(T*, memory_order = memory_order::seq_cst) noexcept;
        bool compare_exchange_weak(T*&, T*, memory_order, memory_order) volatile noexcept;
        bool compare_exchange_weak(T*&, T*, memory_order, memory_order) noexcept;
    };
};
bool compare_exchange_strong(T*&, T*, memory_order, memory_order) volatile noexcept;
bool compare_exchange_strong(T*&, T*, memory_order, memory_order) noexcept;
bool compare_exchange_weak(T*&, T*, memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_weak(T*&, T*, memory_order = memory_order::seq_cst) noexcept;
bool compare_exchange_strong(T*&, T*, memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_strong(T*&, T*, memory_order = memory_order::seq_cst) noexcept;
T* fetch_add(ptrdiff_t, memory_order = memory_order::seq_cst) volatile noexcept;
T* fetch_add(ptrdiff_t, memory_order = memory_order::seq_cst) noexcept;
T* fetch_sub(ptrdiff_t, memory_order = memory_order::seq_cst) volatile noexcept;
T* fetch_sub(ptrdiff_t, memory_order = memory_order::seq_cst) noexcept;
atomic() noexcept = default;
constexpr atomic(T*) noexcept;
atomic(const atomic&) = delete;
atomic& operator=(const atomic&) = delete;
atomic& operator=(const atomic&) volatile = delete;
T* operator=(T*) volatile noexcept;
T* operator=(T*) noexcept;
T* operator++(int) volatile noexcept;
T* operator++(int) noexcept;
T* operator--(int) volatile noexcept;
T* operator--(int) noexcept;
T* operator++() volatile noexcept;
T* operator++() noexcept;
T* operator--() volatile noexcept;
T* operator--() noexcept;
T* operator+=(ptrdiff_t) volatile noexcept;
T* operator+=(ptrdiff_t) noexcept;
T* operator-=(ptrdiff_t) volatile noexcept;
T* operator-=(ptrdiff_t) noexcept;

1 There is a partial specialization of the atomic class template for pointers. Specializations of this partial specialization are standard-layout structs. They each have a trivial default constructor and a trivial destructor.
2 Descriptions are provided below only for members that differ from the primary template.
3 The following operations perform pointer arithmetic. The key, operator, and computation correspondence is:

<table>
<thead>
<tr>
<th>Key</th>
<th>Op</th>
<th>Computation</th>
</tr>
</thead>
<tbody>
<tr>
<td>add</td>
<td>+</td>
<td>addition</td>
</tr>
<tr>
<td>T* fetch_key(ptrdiff_t operand, memory_order order = memory_order::seq_cst) volatile noexcept;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>T* fetch_key(ptrdiff_t operand, memory_order order = memory_order::seq_cst) noexcept;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

4 Requires: T shall be an object type, otherwise the program is ill-formed. [Note: Pointer arithmetic on void* or function pointers is ill-formed. —end note]
5 Effects: Atomically replaces the value pointed to by this with the result of the computation applied to the value pointed to by this and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2).
6 Returns: Atomically, the value pointed to by this immediately before the effects.
7 Remarks: The result may be an undefined address, but the operations otherwise have no undefined behavior.
T* operator op=(ptrdiff_t operand) volatile noexcept;
T* operator op=(ptrdiff_t operand) noexcept;

Effects: Equivalent to: return fetch_key(operand) op operand;

31.7.5 Member operators common to integers and pointers to objects

Effects: Equivalent to: return fetch_add(1);

Effects: Equivalent to: return fetch_sub(1);

Effects: Equivalent to: return fetch_add(1) + 1;

Effects: Equivalent to: return fetch_sub(1) - 1;

31.8 Non-member functions

Effects: Non-atomically initializes *object with value desired. This function shall only be applied
to objects that have been default constructed, and then only once. [Note: These semantics ensure
compatibility with C. — end note] [Note: Concurrent access from another thread, even via an atomic
operation, constitutes a data race. — end note]

[Note: The non-member functions enable programmers to write code that can be compiled as either C or
C++, for example in a shared header file. — end note]

31.9 Flag type and operations

namespace std {

    struct atomic_flag {

        bool test_and_set(memory_order = memory_order::seq_cst) volatile noexcept;
        bool test_and_set(memory_order = memory_order::seq_cst) noexcept;
        void clear(memory_order = memory_order::seq_cst) volatile noexcept;
        void clear(memory_order = memory_order::seq_cst) noexcept;

        atomic_flag() noexcept = default;
        atomic_flag(const atomic_flag&) = delete;
        atomic_flag& operator=(const atomic_flag&) = delete;
        atomic_flag& operator=(const atomic_flag&) volatile = delete;
    };

    bool atomic_flag::test_and_set(volatile atomic_flag*) noexcept;
    bool atomic_flag::test_and_set(atomic_flag*) noexcept;
    bool atomic_flag::test_and_set(volatile atomic_flag*, memory_order) noexcept;
    bool atomic_flag::test_and_set(atomic_flag*, memory_order) noexcept;
    void atomic_flag::clear(volatile atomic_flag*) noexcept;

};

§ 31.9
The `atomic_flag` type provides the classic test-and-set functionality. It has two states, set and clear. Operations on an object of type `atomic_flag` shall be lock-free. [Note: Hence the operations should also be address-free. — end note] The `atomic_flag` type is a standard-layout struct. It has a trivial default constructor and a trivial destructor.

The macro `ATOMIC_FLAG_INIT` shall be defined in such a way that it can be used to initialize an object of type `atomic_flag` to the clear state. The macro can be used in the form:

```c
atomic_flag guard = ATOMIC_FLAG_INIT;
```

It is unspecified whether the macro can be used in other initialization contexts. For a complete static-duration object, that initialization shall be static. Unless initialized with `ATOMIC_FLAG_INIT`, it is unspecified whether an `atomic_flag` object has an initial state of set or clear.

```c
void atomic_flag_clear(volatile atomic_flag* object) noexcept;
void atomic_flag_clear_explicit(volatile atomic_flag*, memory_order) noexcept;
void atomic_flag_clear_explicit(atomic_flag*, memory_order) noexcept;
```

### 31.10 Fences [atomics.fences]

This subclause introduces synchronization primitives called fences. Fences can have acquire semantics, release semantics, or both. A fence with acquire semantics is called an *acquire fence*. A fence with release semantics is called a *release fence*.

A release fence `A` synchronizes with an acquire fence `B` if there exist atomic operations `X` and `Y`, both operating on some atomic object `M`, such that `A` is sequenced before `X`, `X` modifies `M`, `Y` is sequenced before `B`, and `Y` reads the value written by `X` or a value written by any side effect in the hypothetical release sequence `X` would head if it were a release operation.

A release fence `A` synchronizes with an atomic operation `B` that performs an acquire operation on an atomic object `M` if there exists an atomic operation `X` such that `A` is sequenced before `X`, `X` modifies `M`, and `B` reads the value written by `X` or a value written by any side effect in the hypothetical release sequence `X` would head if it were a release operation.

An atomic operation `A` that is a release operation on an atomic object `M` synchronizes with an acquire fence `B` if there exists some atomic operation `X` on `M` such that `X` is sequenced before `B` and reads the value written by `A` or a value written by any side effect in the release sequence headed by `A`.

```c
extern "C" void atomic_thread_fence(memory_order order) noexcept;
```
(5.1) has no effects, if order == memory_order::relaxed;
(5.2) is an acquire fence, if order == memory_order::acquire or order == memory_order::consume;
(5.3) is a release fence, if order == memory_order::release;
(5.4) is both an acquire fence and a release fence, if order == memory_order::acq_rel;
(5.5) is a sequentially consistent acquire and release fence, if order == memory_order::seq_cst.

extern "C" void atomic_signal_fence(memory_order order) noexcept;

Effects: Equivalent to atomic_thread_fence(order), except that the resulting ordering constraints are established only between a thread and a signal handler executed in the same thread.

[Note: atomic_signal_fence can be used to specify the order in which actions performed by the thread become visible to the signal handler. Compiler optimizations and reorderings of loads and stores are inhibited in the same way as with atomic_thread_fence, but the hardware fence instructions that atomic_thread_fence would have inserted are not emitted. — end note]
32 Thread support library

32.1 General

The following subclauses describe components to create and manage threads (6.8.2), perform mutual exclusion, and communicate conditions and values between threads, as summarized in Table 134.

Table 134: Thread support library summary

<table>
<thead>
<tr>
<th>Subclause</th>

<td>Futures &lt;future&gt;</td>
</tr>
</tbody>
</table>

32.2 Requirements

32.2.1 Template parameter names

Throughout this Clause, the names of template parameters are used to express type requirements. If a template parameter is named `Predicate`, `operator()` applied to the template argument shall return a value that is convertible to `bool`. If a template parameter is named `Clock`, the corresponding template argument shall be a type `C` for which `is_clock_v<C>` is `true`; otherwise the program is ill-formed.

32.2.2 Exceptions

Some functions described in this Clause are specified to throw exceptions of type `system_error` (19.5.7). Such exceptions shall be thrown if any of the function’s error conditions is detected or a call to an operating system or other underlying API results in an error that prevents the library function from meeting its specifications. Failure to allocate storage shall be reported as described in 16.5.5.12.

[Example: Consider a function in this clause that is specified to throw exceptions of type `system_error` and specifies error conditions that include `operation_not_permitted` for a thread that does not have the privilege to perform the operation. Assume that, during the execution of this function, an `errno` of `EPERM` is reported by a POSIX API call used by the implementation. Since POSIX specifies an `errno` of `EPERM` when “the caller does not have the privilege to perform the operation”, the implementation maps `EPERM` to an `error_condition` of `operation_not_permitted` (19.5) and an exception of type `system_error` is thrown. — end example]

The `error_code` reported by such an exception’s `code()` member function shall compare equal to one of the conditions specified in the function’s error condition element.

32.2.3 Native handles

Several classes described in this Clause have members `native_handle_type` and `native_handle`. The presence of these members and their semantics is implementation-defined. [Note: These members allow implementations to provide access to implementation details. Their names are specified to facilitate portable compile-time detection. Actual use of these members is inherently non-portable. — end note]

32.2.4 Timing specifications

Several functions described in this Clause take an argument to specify a timeout. These timeouts are specified as either a `duration` or a `time_point` type as specified in Clause 27.

Implementations necessarily have some delay in returning from a timeout. Any overhead in interrupt response, function return, and scheduling induces a “quality of implementation” delay, expressed as duration $D_i$. Ideally, this delay would be zero. Further, any contention for processor and memory resources induces a “quality of management” delay, expressed as duration $D_m$. The delay durations may vary from timeout to timeout, but in all cases shorter is better.
The functions whose names end in `_for` take an argument that specifies a duration. These functions produce relative timeouts. implementations should use a steady clock to measure time for these functions. ③ Given a duration argument \( D_i \), the real-time duration of the timeout is \( D_i + D_i + D_m \).

The functions whose names end in `_until` take an argument that specifies a time point. These functions produce absolute timeouts. implementations should use the clock specified in the time point to measure time for these functions. Given a clock time point argument \( C_t \), the clock time point of the return from timeout should be \( C_t + D_i + D_m \) when the clock is not adjusted during the timeout. If the clock is adjusted to the time \( C_a \) during the timeout, the behavior should be as follows:

1. \( C_a > C_t \), the waiting function should wake as soon as possible, i.e., \( C_a + D_i + D_m \), since the timeout is already satisfied. [Note: This specification may result in the total duration of the wait decreasing when measured against a steady clock. — end note]
2. \( C_a \leq C_t \), the waiting function should not time out until \( \text{Clock}::\text{now()} \) returns a time \( C_n \geq C_t \), i.e., waking at \( C_t + D_i + D_m \). [Note: When the clock is adjusted backwards, this specification may result in the total duration of the wait increasing when measured against a steady clock. When the clock is adjusted forwards, this specification may result in the total duration of the wait decreasing when measured against a steady clock. — end note]

An implementation shall return from such a timeout at any point from the time specified above to the time it would return from a steady-clock relative timeout on the difference between \( C_t \) and the time point of the call to the `_until` function. [Note: Implementations should decrease the duration of the wait when the clock is adjusted forwards. — end note]

[Note: If the clock is not synchronized with a steady clock, e.g., a CPU time clock, these timeouts might not provide useful functionality. — end note]

The resolution of timing provided by an implementation depends on both operating system and hardware. The finest resolution provided by an implementation is called the `native resolution`.

Implementation-provided clocks that are used for these functions shall meet the `Cpp17TrivialClock` requirements (27.3).

A function that takes an argument which specifies a timeout will throw if, during its execution, a clock, time point, or time duration throws an exception. Such exceptions are referred to as `timeout-related exceptions`. [Note: Instantiations of clock, time point and duration types supplied by the implementation as specified in 27.7 do not throw exceptions. — end note]

### 32.2.5 Requirements for `Cpp17Lockable` types

#### 32.2.5.1 In general

An `execution agent` is an entity such as a thread that may perform work in parallel with other execution agents. [Note: Implementations or users may introduce other kinds of agents such as processes or thread-pool tasks. — end note] The calling agent is determined by context, e.g., the calling thread that contains the call, and so on.

[Note: Some lockable objects are “agent oblivious” in that they work for any execution agent model because they do not determine or store the agent’s ID (e.g., an ordinary spin lock). — end note]

The standard library templates `unique_lock` (32.4.4.3), `shared_lock` (32.4.4.4), `scoped_lock` (32.4.4.2), `lock_guard` (32.4.4.1), `lock`, `try_lock` (32.4.5), and `condition_variable_any` (32.5.4) all operate on user-supplied lockable objects. The `Cpp17BasicLockable` requirements, the `Cpp17Lockable` requirements, and the `Cpp17TimedLockable` requirements list the requirements imposed by these library types in order to acquire or release ownership of a `lock` by a given execution agent. [Note: The nature of any lock ownership and any synchronization it may entail are not part of these requirements. — end note]

#### 32.2.5.2 `Cpp17BasicLockable` requirements

A type \( L \) meets the `Cpp17BasicLockable` requirements if the following expressions are well-formed and have the specified semantics (\( \text{n} \) denotes a value of type \( L \)).

---

③ All implementations for which standard time units are meaningful must necessarily have a steady clock within their hardware implementation.
m.lock()

Effects: Blocks until a lock can be acquired for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

m.unlock()

Requires: The current execution agent shall hold a lock on m.

Effects: Releases a lock on m held by the current execution agent.

Throws: Nothing.

32.2.5.3 Cpp17Lockable requirements

A type \( L \) meets the Cpp17Lockable requirements if it meets the Cpp17BasicLockable requirements and the following expressions are well-formed and have the specified semantics (\( m \) denotes a value of type \( L \)).

m.try_lock()

Effects: Attempts to acquire a lock for the current execution agent without blocking. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

Return type: bool.

Returns: true if the lock was acquired, false otherwise.

32.2.5.4 Cpp17TimedLockable requirements

A type \( L \) meets the Cpp17TimedLockable requirements if it meets the Cpp17Lockable requirements and the following expressions are well-formed and have the specified semantics (\( m \) denotes a value of type \( L \), \( \text{rel\_time} \) denotes a value of an instantiation of duration (27.5), and \( \text{abs\_time} \) denotes a value of an instantiation of time_point (27.6)).

m.try_lock_for(\( \text{rel\_time} \))

Effects: Attempts to acquire a lock for the current execution agent within the relative timeout (32.2.4) specified by \( \text{rel\_time} \). The function shall not return within the timeout specified by \( \text{rel\_time} \) unless it has obtained a lock on \( m \) for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

Return type: bool.

Returns: true if the lock was acquired, false otherwise.

m.try_lock_until(\( \text{abs\_time} \))

Effects: Attempts to acquire a lock for the current execution agent before the absolute timeout (32.2.4) specified by \( \text{abs\_time} \). The function shall not return before the timeout specified by \( \text{abs\_time} \) unless it has obtained a lock on \( m \) for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

Return type: bool.

Returns: true if the lock was acquired, false otherwise.

32.3 Threads

32.3 describes components that can be used to create and manage threads. [Note: These threads are intended to map one-to-one with operating system threads. — end note]

32.3.1 Header <thread> synopsis

namespace std {
    class thread;

    void swap(thread& x, thread& y) noexcept;

    namespace this_thread {
        thread::id get_id() noexcept;
    }

§ 32.3.1
The class `thread` provides a mechanism to create a new thread of execution, to join with a thread (i.e., wait for a thread to complete), and to perform other operations that manage and query the state of a thread. A `thread` object uniquely represents a particular thread of execution. That representation may be transferred to other `thread` objects in such a way that no two `thread` objects simultaneously represent the same thread of execution. A thread of execution is `detached` when no `thread` object represents that thread. Objects of class `thread` can be in a state that does not represent a thread of execution. [Note: A `thread` object does not represent a thread of execution after default construction, after being moved from, or after a successful call to `detach` or `join`. — end note]
An object of type `thread::id` provides a unique identifier for each thread of execution and a single distinct value for all `thread` objects that do not represent a thread of execution (32.3.2). Each thread of execution has an associated `thread::id` object that is not equal to the `thread::id` object of any other thread of execution and that is not equal to the `thread::id` object of any `thread` object that does not represent threads of execution.

`thread::id` is a trivially copyable class (11.1). The library may reuse the value of a `thread::id` of a terminated thread that can no longer be joined.

[Note: Relational operators allow `thread::id` objects to be used as keys in associative containers. — end note]

```cpp
thread::id id() noexcept;
```

**Effects:** Constructs an object of type `id`.

**Ensures:** The constructed object does not represent a thread of execution.

```cpp
bool operator==(thread::id x, thread::id y) noexcept;
```

**Returns:** `true` only if `x` and `y` represent the same thread of execution or neither `x` nor `y` represents a thread of execution.

```cpp
bool operator!=(thread::id x, thread::id y) noexcept;
```

**Returns:** `!(x == y)`

```cpp
bool operator<(thread::id x, thread::id y) noexcept;
```

**Returns:** A value such that `operator<` is a total ordering as described in 25.7.

```cpp
bool operator>(thread::id x, thread::id y) noexcept;
```

**Returns:** `y < x`.

```cpp
bool operator<=(thread::id x, thread::id y) noexcept;
```

**Returns:** `!(y < x)`.

```cpp
bool operator>=(thread::id x, thread::id y) noexcept;
```

**Returns:** `!(x < y)`.

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& out, thread::id id);
```

**Effects:** Inserts an unspecified text representation of `id` into `out`. For two objects of type `thread::id` `x` and `y`, if `x == y` the `thread::id` objects have the same text representation and if `x != y` the `thread::id` objects have distinct text representations.

**Returns:** `out`.

```cpp
template<> struct hash<thread::id>;
```

The specialization is enabled (20.14.18).

### 32.3.2.2 Constructors

```cpp
thread() noexcept;
```

**Effects:** Constructs a `thread` object that does not represent a thread of execution.

**Ensures:** `get_id() == id()`.
template<class F, class... Args> explicit thread(F&& f, Args&&... args);

Requires: F and each T_i in Args shall meet the Cpp17MoveConstructible requirements. \( \text{INVOKER}(\text{decay-copy}(\text{std::forward<F>}(f)), \text{decay-copy}(\text{std::forward<Args>}(\text{args}))) \ldots \) (20.14.3) shall be a valid expression.

Remarks: This constructor shall not participate in overload resolution if remove_cvref_t<F> is the same type as std::thread.

Effects: Constructs an object of type thread. The new thread of execution executes \( \text{INVOKER}(\text{decay-copy}(\text{std::forward<F>}(f)), \text{decay-copy}(\text{std::forward<Args>}(\text{args}))) \ldots \) with the calls to decay-copy being evaluated in the constructing thread. Any return value from this invocation is ignored. [Note: This implies that any exceptions not thrown from the invocation of the copy of f will be thrown in the constructing thread, not the new thread. —end note] If the invocation of \( \text{INVOKER}(\text{decay-copy}(\text{std::forward<F>}(f)), \text{decay-copy}(\text{std::forward<Args>}(\text{args}))) \ldots \) terminates with an uncaught exception, terminate shall be called.

Synchronization: The completion of the invocation of the constructor synchronizes with the beginning of the invocation of the copy of f.

Ensures: get_id() \(!=\) id(). *this represents the newly started thread.

Throws: system_error if unable to start the new thread.

Error conditions:

— resource_unavailable_try_again — the system lacked the necessary resources to create another thread, or the system-imposed limit on the number of threads in a process would be exceeded.

thread(thread&& x) noexcept;

Effects: Constructs an object of type thread from x, and sets x to a default constructed state.

Ensures: x.get_id() == id() and get_id() returns the value of x.get_id() prior to the start of construction.

32.3.2.3 Destructor

~thread();

If joinable(), calls terminate(). Otherwise, has no effects. [Note: Either implicitly detaching or joining a joinable() thread in its destructor could result in difficult to debug correctness (for detach) or performance (for join) bugs encountered only when an exception is thrown. Thus the programmer must ensure that the destructor is never executed while the thread is still joinable. —end note]

32.3.2.4 Assignment

thread& operator=(thread&& x) noexcept;

Effects: If joinable(), calls terminate(). Otherwise, assigns the state of x to *this and sets x to a default constructed state.

Ensures: x.get_id() == id() and get_id() returns the value of x.get_id() prior to the assignment.

Returns: *this.

32.3.2.5 Members

void swap(thread& x) noexcept;

Effects: Swaps the state of *this and x.

bool joinable() const noexcept;

Returns: get_id() \(!=\) id().

void join();

Effects: Blocks until the thread represented by *this has completed.

Synchronization: The completion of the thread represented by *this synchronizes with (6.8.2) the corresponding successful join() return. [Note: Operations on *this are not synchronized. —end note]
Ensures: The thread represented by *this has completed. get_id() == id().

Throws: system_error when an exception is required (32.2.2).

Error conditions:
(7.1) — resource_deadlock_would_occur — if deadlock is detected or get_id() == this_thread::get_id().
(7.2) — no_such_process — if the thread is not valid.
(7.3) — invalid_argument — if the thread is not joinable.

void detach();

Effects: The thread represented by *this continues execution without the calling thread blocking. When detach() returns, *this no longer represents the possibly continuing thread of execution. When the thread previously represented by *this ends execution, the implementation shall release any owned resources.

Ensures: get_id() == id().

Throws: system_error when an exception is required (32.2.2).

Error conditions:
(11.1) — no_such_process — if the thread is not valid.
(11.2) — invalid_argument — if the thread is not joinable.

id get_id() const noexcept;

Returns: A default constructed id object if *this does not represent a thread, otherwise this_thread::get_id() for the thread of execution represented by *this.

32.3.2.6 Static members

unsigned hardware_concurrency() noexcept;

Returns: The number of hardware thread contexts. [Note: This value should only be considered to be a hint. — end note] If this value is not computable or well-defined, an implementation should return 0.

32.3.2.7 Specialized algorithms

void swap(thread& x, thread& y) noexcept;

Effects: As if by x.swap(y).

32.3.3 Namespace this_thread

namespace std::this_thread {
    thread::id get_id() noexcept;

    void yield() noexcept;
    template<class Clock, class Duration>
        void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);
    template<class Rep, class Period>
        void sleep_for(const chrono::duration<Rep, Period>& rel_time);
}

thread::id this_thread::get_id() noexcept;

Returns: An object of type thread::id that uniquely identifies the current thread of execution. No other thread of execution shall have this id and this thread of execution shall always have this id. The object returned shall not compare equal to a default constructed thread::id.

void this_thread::yield() noexcept;

Effects: Offers the implementation the opportunity to reschedule.

Synchronization: None.
template<class Clock, class Duration>
void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);

Effects: Blocks the calling thread for the absolute timeout (32.2.4) specified by abs_time.
Synchronization: None.
Throws: Timeout-related exceptions (32.2.4).

template<class Rep, class Period>
void sleep_for(const chrono::duration<Rep, Period>& rel_time);

Effects: Blocks the calling thread for the relative timeout (32.2.4) specified by rel_time.
Synchronization: None.
Throws: Timeout-related exceptions (32.2.4).

32.4 Mutual exclusion [thread.mutex]

This subclause provides mechanisms for mutual exclusion: mutexes, locks, and call once. These mechanisms ease the production of race-free programs (6.8.2).

32.4.1 Header <mutex> synopsis [mutex.syn]
namespace std {
  class mutex;
  class recursive_mutex;
  class timed_mutex;
  class recursive_timed_mutex;

  struct defer_lock_t { explicit defer_lock_t() = default; };
  struct try_to_lock_t { explicit try_to_lock_t() = default; };
  struct adopt_lock_t { explicit adopt_lock_t() = default; };

  inline constexpr defer_lock_t defer_lock { };
  inline constexpr try_to_lock_t try_to_lock { };
  inline constexpr adopt_lock_t adopt_lock { };

  template<class Mutex> class lock_guard;
  template<class... MutexTypes> class scoped_lock;
  template<class Mutex> class unique_lock;

  template<class L1, class L2, class... L3> int try_lock(L1&, L2&, L3&...);
  template<class L1, class L2, class... L3> void lock(L1&, L2&, L3&...);

  struct once_flag;
  template<class Callable, class... Args>
  void call_once(once_flag& flag, Callable&& func, Args&&... args);
}

32.4.2 Header <shared_mutex> synopsis [shared.mutex.syn]
namespace std {
  class shared_mutex;
  class shared_timed_mutex;
  template<class Mutex> class shared_lock;
  template<class Mutex>
  void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
}
32.4.3 Mutex requirements

32.4.3.1 In general

1 A mutex object facilitates protection against data races and allows safe synchronization of data between execution agents (32.2.5). An execution agent owns a mutex from the time it successfully calls one of the lock functions until it calls unlock. Mutexes can be either recursive or non-recursive, and can grant simultaneous ownership to one or many execution agents. Both recursive and non-recursive mutexes are supplied.

32.4.3.2 Mutex types

1 The mutex types are the standard library types mutex, recursive_mutex, timed_mutex, recursive_timed_mutex, shared_mutex, and shared_timed_mutex. They shall meet the requirements set out in this subclause. In this description, m denotes an object of a mutex type.

2 The mutex types shall meet the Cpp17Lockable requirements (32.2.5.3).

3 The mutex types shall be Cpp17DefaultConstructible and Cpp17Destructible. If initialization of an object of a mutex type fails, an exception of type system_error shall be thrown. The mutex types shall not be copyable or movable.

4 The error conditions for error codes, if any, reported by member functions of the mutex types shall be:

   (4.1) — resource_unavailable_try_again — if any native handle type manipulated is not available.
   (4.2) — operation_not_permitted — if the thread does not have the privilege to perform the operation.
   (4.3) — invalid_argument — if any native handle type manipulated as part of mutex construction is incorrect.

5 The implementation shall provide lock and unlock operations, as described below. For purposes of determining the existence of a data race, these behave as atomic operations (6.8.2). The lock and unlock operations on a single mutex shall appear to occur in a single total order. [Note: This can be viewed as the modification order (6.8.2) of the mutex. — end note] [Note: Construction and destruction of an object of a mutex type need not be thread-safe; other synchronization should be used to ensure that mutex objects are initialized and visible to other threads. — end note]

6 The expression m.lock() shall be well-formed and have the following semantics:

   Requires: If m is of type mutex, timed_mutex, shared_mutex, or shared_timed_mutex, the calling thread does not own the mutex.

   Effects: Blocks the calling thread until ownership of the mutex can be obtained for the calling thread.

   Ensures: The calling thread owns the mutex.

   Return type: void.

   Synchronization: Prior unlock() operations on the same object shall synchronize with (6.8.2) this operation.

   Throws: system_error when an exception is required (32.2.2).

   Error conditions:

   (13.1) — operation_not_permitted — if the thread does not have the privilege to perform the operation.
   (13.2) — resource_deadlock_would_occur — if the implementation detects that a deadlock would occur.

14 The expression m.try_lock() shall be well-formed and have the following semantics:

   Requires: If m is of type mutex, timed_mutex, shared_mutex, or shared_timed_mutex, the calling thread does not own the mutex.

   Effects: Attempts to obtain ownership of the mutex for the calling thread without blocking. If ownership is not obtained, there is no effect and try_lock() immediately returns. An implementation may fail to obtain the lock even if it is not held by any other thread. [Note: This spurious failure is normally uncommon, but allows interesting implementations based on a simple compare and exchange (Clause 31). — end note] An implementation should ensure that try_lock() does not consistently return false in the absence of contending mutex acquisitions.

   Return type: bool.

   Returns: true if ownership of the mutex was obtained for the calling thread, otherwise false.

   Synchronization: If try_lock() returns true, prior unlock() operations on the same object synchronize with (6.8.2) this operation. [Note: Since lock() does not synchronize with a failed subsequent try_-
lock(), the visibility rules are weak enough that little would be known about the state after a failure, even in the absence of spurious failures. — end note]

20 Throws: Nothing.
21 The expression m.unlock() shall be well-formed and have the following semantics:
22 Requires: The calling thread shall own the mutex.
23 Effects: Releases the calling thread's ownership of the mutex.
24 Return type: void.
25 Synchronization: This operation synchronizes with (6.8.2) subsequent lock operations that obtain ownership on the same object.
26 Throws: Nothing.

32.4.3.2.1 Class mutex

namespace std {
    class mutex {
    public:
        constexpr mutex() noexcept;
        ~mutex();
        mutex(const mutex&) = delete;
        mutex& operator=(const mutex&) = delete;
        void lock();
        bool try_lock();
        void unlock();

        using native_handle_type = implementation-defined;    // see 32.2.3
        native_handle_type native_handle();                  // see 32.2.3
    }
};

1 The class mutex provides a non-recursive mutex with exclusive ownership semantics. If one thread owns a mutex object, attempts by another thread to acquire ownership of that object will fail (for try_lock()) or block (for lock()) until the owning thread has released ownership with a call to unlock().
2 [Note: After a thread A has called unlock(), releasing a mutex, it is possible for another thread B to lock the same mutex, observe that it is no longer in use, unlock it, and destroy it, before thread A appears to have returned from its unlock call. Implementations are required to handle such scenarios correctly, as long as thread A doesn’t access the mutex after the unlock call returns. These cases typically occur when a reference-counted object contains a mutex that is used to protect the reference count. — end note]
3 The class mutex shall meet all of the mutex requirements (32.4.3). It shall be a standard-layout class (11.1).
4 [Note: A program may deadlock if the thread that owns a mutex object calls lock() on that object. If the implementation can detect the deadlock, a resource_deadlock_would_occur error condition may be observed. — end note]
5 The behavior of a program is undefined if it destroys a mutex object owned by any thread or a thread terminates while owning a mutex object.

32.4.3.2.2 Class recursive_mutex

namespace std {
    class recursive_mutex {
    public:
        recursive_mutex();
        ~recursive_mutex();
        recursive_mutex(const recursive_mutex&) = delete;
        recursive_mutex& operator=(const recursive_mutex&) = delete;

        void lock();
        bool try_lock() noexcept;
        void unlock();

        using native_handle_type = implementation-defined;
        native_handle_type native_handle();
    }
};
using native_handle_type = implementation-defined; // see 32.2.3
native_handle_type native_handle(); // see 32.2.3
};

The class recursive_mutex provides a recursive mutex with exclusive ownership semantics. If one thread owns a recursive_mutex object, attempts by another thread to acquire ownership of that object will fail (for try_lock()) or block (for lock()) until the first thread has completely released ownership.

The class recursive_mutex shall meet all of the mutex requirements (32.4.3). It shall be a standard-layout class (11.1).

A thread that owns a recursive_mutex object may acquire additional levels of ownership by calling lock() or try_lock() on that object. It is unspecified how many levels of ownership may be acquired by a single thread. If a thread has already acquired the maximum level of ownership for a recursive_mutex object, additional calls to try_lock() shall fail, and additional calls to lock() shall throw an exception of type system_error. A thread shall call unlock() once for each level of ownership acquired by calls to lock() and try_lock(). Only when all levels of ownership have been released may ownership be acquired by another thread.

The behavior of a program is undefined if:

1. it destroys a recursive_mutex object owned by any thread or
2. a thread terminates while owning a recursive_mutex object.

32.4.3.3 Timed mutex types [thread.timedmutex.requirements]
The timed mutex types are the standard library types timed_mutex, recursive_timed_mutex, and shared_timed_mutex. They shall meet the requirements set out below. In this description, m denotes an object of a mutex type, rel_time denotes an object of an instantiation of duration (27.5), and abs_time denotes an object of an instantiation of time_point (27.6).

The timed mutex types shall meet the Cpp17TimedLockable requirements (32.2.5.4).

The expression m.try_lock_for(rel_time) shall be well-formed and have the following semantics:

Requires: If m is of type timed_mutex or shared_timed_mutex, the calling thread does not own the mutex.

Effects: The function attempts to obtain ownership of the mutex within the relative timeout (32.2.4) specified by rel_time. If the time specified by rel_time is less than or equal to rel_time.zero(), the function attempts to obtain ownership without blocking (as if by calling try_lock()). The function shall return within the timeout specified by rel_time only if it has obtained ownership of the mutex object. [Note: As with try_lock(), there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note]

Return type: bool.

Returns: true if ownership was obtained, otherwise false.

Synchronization: If try_lock_for() returns true, prior unlock() operations on the same object synchronize with (6.8.2) this operation.

Throws: Timeout-related exceptions (32.2.4).

The expression m.try_lock_until(abs_time) shall be well-formed and have the following semantics:

Requires: If m is of type timed_mutex or shared_timed_mutex, the calling thread does not own the mutex.

Effects: The function attempts to obtain ownership of the mutex. If abs_time has already passed, the function attempts to obtain ownership without blocking (as if by calling try_lock()). The function shall return before the absolute timeout (32.2.4) specified by abs_time only if it has obtained ownership of the mutex object. [Note: As with try_lock(), there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note]

Return type: bool.

Returns: true if ownership was obtained, otherwise false.

Synchronization: If try_lock_until() returns true, prior unlock() operations on the same object synchronize with (6.8.2) this operation.
§ 32.4.3.3.1 Class timed_mutex
namespace std {
  class timed_mutex {
    public:
      timed_mutex();
      ~timed_mutex();

      timed_mutex(const timed_mutex&) = delete;
      timed_mutex& operator=(const timed_mutex&) = delete;

      void lock();  // blocking
      bool try_lock();
      template<class Rep, class Period>  
        bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
      template<class Clock, class Duration>  
        bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
      void unlock();

      using native_handle_type = implementation-defined;  // see 32.2.3
      native_handle_type native_handle();  // see 32.2.3
  };
}

The class timed_mutex provides a non-recursive mutex with exclusive ownership semantics. If one thread owns a timed_mutex object, attempts by another thread to acquire ownership of that object will fail (for try_lock() or block (for lock(), try_lock_for(), and try_lock_until()) until the owning thread has released ownership with a call to unlock() or the call to try_lock_for() or try_lock_until() times out (having failed to obtain ownership).

The class timed_mutex shall meet all of the timed mutex requirements (32.4.3.3). It shall be a standard-layout class (11.1).

The behavior of a program is undefined if:

1. — it destroys a timed_mutex object owned by any thread,
2. — a thread that owns a timed_mutex object calls lock(), try_lock(), try_lock_for(), or try_lock_until() on that object, or
3. — a thread terminates while owning a timed_mutex object.

§ 32.4.3.3.2 Class recursive_timed_mutex
namespace std {
  class recursive_timed_mutex {
    public:
      recursive_timed_mutex();
      ~recursive_timed_mutex();

      recursive_timed_mutex(const recursive_timed_mutex&) = delete;
      recursive_timed_mutex& operator=(const recursive_timed_mutex&) = delete;

      void lock();  // blocking
      bool try_lock() noexcept;
      template<class Rep, class Period>  
        bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
      template<class Clock, class Duration>  
        bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
      void unlock();

      using native_handle_type = implementation-defined;  // see 32.2.3
      native_handle_type native_handle();  // see 32.2.3
  };
}
1 The class `recursive_timed_mutex` provides a recursive mutex with exclusive ownership semantics. If one thread owns a `recursive_timed_mutex` object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()`) or block (for `lock()`, `try_lock_for()`, and `try_lock_until()`) until the owning thread has completely released ownership or the call to `try_lock_for()` or `try_lock_until()` times out (having failed to obtain ownership).

2 The class `recursive_timed_mutex` shall meet all of the timed mutex requirements (32.4.3.3). It shall be a standard-layout class (11.1).

3 A thread that owns a `recursive_timed_mutex` object may acquire additional levels of ownership by calling `lock()`, `try_lock()`, `try_lock_for()`, or `try_lock_until()` on that object. It is unspecified how many levels of ownership may be acquired by a single thread. If a thread has already acquired the maximum level of ownership for a `recursive_timed_mutex` object, additional calls to `try_lock()`, `try_lock_for()`, or `try_lock_until()` shall fail, and additional calls to `lock()` shall throw an exception of type `system_error`. A thread shall call `unlock()` once for each level of ownership acquired by calls to `lock()`, `try_lock()`, `try_lock_for()`, and `try_lock_until()`. Only when all levels of ownership have been released may ownership of the object be acquired by another thread.

4 The behavior of a program is undefined if:

- it destroys a `recursive_timed_mutex` object owned by any thread, or
- a thread terminates while owning a `recursive_timed_mutex` object.

32.4.3.4 Shared mutex types

1 The standard library types `shared_mutex` and `shared_timed_mutex` are shared mutex types. Shared mutex types shall meet the requirements of mutex types (32.4.3.2), and additionally shall meet the requirements set out below. In this description, \( m \) denotes an object of a shared mutex type.

2 In addition to the exclusive lock ownership mode specified in 32.4.3.2, shared mutex types provide a shared lock ownership mode. Multiple execution agents can simultaneously hold a shared lock ownership of a shared mutex type. But no execution agent shall hold a shared lock while another execution agent holds an exclusive lock on the same shared mutex type, and vice-versa. The maximum number of execution agents which can share a shared lock on a single shared mutex type is unspecified, but shall be at least 10000. If more than the maximum number of execution agents attempt to obtain a shared lock, the excess execution agents shall block until the number of shared locks are reduced below the maximum amount by other execution agents releasing their shared lock.

3 The expression \( m.lock_shared() \) shall be well-formed and have the following semantics:

- Requires: The calling thread has no ownership of the mutex.
- Effects: Blocks the calling thread until shared ownership of the mutex can be obtained for the calling thread. If an exception is thrown then a shared lock shall not have been acquired for the current thread.
- Ensures: The calling thread has a shared lock on the mutex.
- Return type: void.
- Synchronization: Prior `unlock()` operations on the same object shall synchronize with (6.8.2) this operation.
- Throws: `system_error` when an exception is required (32.2.2).

4 Error conditions:

- operation_not_permitted — if the thread does not have the privilege to perform the operation.
- resource_deadlock_would_occur — if the implementation detects that a deadlock would occur.

5 The expression \( m.unlock_shared() \) shall be well-formed and have the following semantics:

- Requires: The calling thread shall hold a shared lock on the mutex.
- Effects: Releases a shared lock on the mutex held by the calling thread.
- Return type: void.
- Synchronization: This operation synchronizes with (6.8.2) subsequent `lock()` operations that obtain ownership on the same object.
- Throws: Nothing.
The expression `m.try_lock_shared()` shall be well-formed and have the following semantics:

**Requires:** The calling thread has no ownership of the mutex.

**Effects:** Attempts to obtain shared ownership of the mutex for the calling thread without blocking. If shared ownership is not obtained, there is no effect and `try_lock_shared()` immediately returns. An implementation may fail to obtain the lock even if it is not held by any other thread.

**Return type:** `bool`.

**Returns:** `true` if the shared ownership lock was acquired, `false` otherwise.

**Synchronization:** If `try_lock_shared()` returns `true`, prior `unlock()` operations on the same object synchronize with (6.8.2) this operation.

**Throws:** Nothing.

### 32.4.3.4.1 Class `shared_mutex`

```cpp
namespace std {
    class shared_mutex {
    public:
        shared_mutex();
        ~shared_mutex();

        shared_mutex(const shared_mutex&) = delete;
        shared_mutex& operator=(const shared_mutex&) = delete;

        // exclusive ownership
        void lock(); // blocking
        bool try_lock();
        void unlock();

        // shared ownership
        void lock_shared(); // blocking
        bool try_lock_shared();
        void unlock_shared();

        using native_handle_type = implementation-defined; // see 32.2.3
        native_handle_type native_handle(); // see 32.2.3
    };
}
```

1. The class `shared_mutex` provides a non-recursive mutex with shared ownership semantics.
2. The class `shared_mutex` shall meet all of the shared mutex requirements (32.4.3.4). It shall be a standard-layout class (11.1).
3. The behavior of a program is undefined if:
   - (3.1) it destroys a `shared_mutex` object owned by any thread,
   - (3.2) a thread attempts to recursively gain any ownership of a `shared_mutex`, or
   - (3.3) a thread terminates while possessing any ownership of a `shared_mutex`.
4. `shared_mutex` may be a synonym for `shared_timed_mutex`.

### 32.4.3.5 Shared timed mutex types

The standard library type `shared_timed_mutex` is a `shared timed mutex type`. Shared timed mutex types shall meet the requirements of timed mutex types (32.4.3.3), shared mutex types (32.4.3.4), and additionally shall meet the requirements set out below. In this description, `m` denotes an object of a shared timed mutex type, `rel_type` denotes an object of an instantiation of `duration` (27.5), and `abs_time` denotes an object of an instantiation of `time_point` (27.6).

1. The expression `m.try_lock_shared_for(rel_time)` shall be well-formed and have the following semantics:
   **Requires:** The calling thread has no ownership of the mutex.

   **Effects:** Attempts to obtain shared lock ownership for the calling thread within the relative timeout (32.2.4) specified by `rel_time`. If the time specified by `rel_time` is less than or equal to `rel_time.zero()`, the function attempts to obtain ownership without blocking (as if by calling `try_lock_...`.)
The class `shared_timed_mutex` provides a non-recursive mutex with shared ownership semantics.

```cpp
namespace std {
    class shared_timed_mutex {
        public:
            shared_timed_mutex();
            ~shared_timed_mutex();
            shared_timed_mutex(const shared_timed_mutex&) = delete;
            shared_timed_mutex& operator=(const shared_timed_mutex&) = delete;

            // exclusive ownership
            void lock(); // blocking
            bool try_lock();
            template<class Rep, class Period>
                bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
            template<class Clock, class Duration>
                bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
            void unlock();

            // shared ownership
            void lock_shared(); // blocking
            bool try_lock_shared();
            template<class Rep, class Period>
                bool try_lock_shared_for(const chrono::duration<Rep, Period>& rel_time);
            template<class Clock, class Duration>
                bool try_lock_shared_until(const chrono::time_point<Clock, Duration>& abs_time);
            void unlock_shared();
    };
}
```

The expression `m.try_lock_shared_until(abs_time)` shall be well-formed and have the following semantics:

**Requires:** The calling thread has no ownership of the mutex.

**Effects:** The function attempts to obtain shared ownership of the mutex. If `abs_time` has already passed, the function attempts to obtain shared ownership without blocking (as if by calling `try_lock_shared()`). The function shall return before the absolute timeout (32.2.4) specified by `abs_time` only if it has obtained shared ownership of the mutex object. [Note: As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note] If an exception is thrown then a shared lock shall not have been acquired for the current thread.

**Return type:** `bool`.

**Returns:** `true` if the shared lock was acquired, `false` otherwise.

**Synchronization:** If `try_lock_shared_for()` returns `true`, prior `unlock()` operations on the same object synchronize with (6.8.2) this operation.

**Throws:** Timeout-related exceptions (32.2.4).

§ 32.4.3.5.1
The class \texttt{shared\_timed\_mutex} shall meet all of the shared timed mutex requirements (32.4.3.5). It shall be a standard-layout class (11.1).

The behavior of a program is undefined if:

1. it destroys a \texttt{shared\_timed\_mutex} object owned by any thread,
2. a thread attempts to recursively gain any ownership of a \texttt{shared\_timed\_mutex}, or
3. a thread terminates while possessing any ownership of a \texttt{shared\_timed\_mutex}.

32.4.4 Locks

A \textit{lock} is an object that holds a reference to a lockable object and may unlock the lockable object during the lock’s destruction (such as when leaving block scope). An execution agent may use a lock to aid in managing ownership of a lockable object in an exception safe manner. A lock is said to \textit{own} a lockable object if it is currently managing the ownership of that lockable object for an execution agent. A lock does not manage the lifetime of the lockable object it references. [Note: Locks are intended to ease the burden of unlocking the lockable object under both normal and exceptional circumstances. —end note]

Some lock constructors take tag types which describe what should be done with the lockable object during the lock’s construction.

```cpp
namespace std {
    struct defer_lock_t { }; // do not acquire ownership of the mutex
    struct try_to_lock_t { }; // try to acquire ownership of the mutex
        // without blocking
    struct adopt_lock_t { }; // assume the calling thread has already
        // obtained mutex ownership and manage it

    inline constexpr defer_lock_t defer_lock { };  
    inline constexpr try_to_lock_t try_to_lock { }; 
    inline constexpr adopt_lock_t adopt_lock { };
}
```

32.4.4.1 Class template \texttt{lock\_guard}

An object of type \texttt{lock\_guard} controls the ownership of a lockable object within a scope. A \texttt{lock\_guard} object maintains ownership of a lockable object throughout the \texttt{lock\_guard} object’s lifetime (6.6.3). The behavior of a program is undefined if the lockable object referenced by \texttt{pm} does not exist for the entire lifetime of the \texttt{lock\_guard} object. The supplied \texttt{Mutex} type shall meet the \texttt{Cpp17BasicLockable} requirements (32.2.5.2).

```cpp
namespace std {
    template<class Mutex>
    class lock_guard {
        public:
            using mutex_type = Mutex;

            explicit lock_guard(mutex_type& m);
            lock_guard(mutex_type& m, adopt_lock_t);
            ~lock_guard();

            lock_guard(const lock_guard&) = delete;
            lock_guard& operator=(const lock_guard&) = delete;

        private:
            mutex_type& pm; // exposition only
        };
    }
```

An object of type \texttt{lock\_guard} controls the ownership of a lockable object within a scope. A \texttt{lock\_guard} object maintains ownership of a lockable object throughout the \texttt{lock\_guard} object’s lifetime (6.6.3). The behavior of a program is undefined if the lockable object referenced by \texttt{pm} does not exist for the entire lifetime of the \texttt{lock\_guard} object. The supplied \texttt{Mutex} type shall meet the \texttt{Cpp17BasicLockable} requirements (32.2.5.2).

```cpp
explicit lock_guard(mutex_type& m);
```

\textbf{Requires:} If \texttt{mutex\_type} is not a recursive mutex, the calling thread does not own the mutex \texttt{m}.

\textbf{Effects:} Initializes \texttt{pm} with \texttt{m}. Calls \texttt{m.lock()}.

```cpp
lock_guard(mutex_type& m, adopt_lock_t);
```

\textbf{Requires:} The calling thread owns the mutex \texttt{m}.

\textbf{Effects:} Initializes \texttt{pm} with \texttt{m}.
32.4.4.2 Class template scoped_lock

namespace std {
    template<class... MutexTypes>
    class scoped_lock {
    public:
        using mutex_type = Mutex; // If MutexTypes... consists of the single type Mutex
        explicit scoped_lock(MutexTypes&... m);
        explicit scoped_lock(adopt_lock_t, MutexTypes&... m);
        ~scoped_lock();
        scoped_lock(const scoped_lock&) = delete;
        scoped_lock& operator=(const scoped_lock&) = delete;
    private:
        tuple<MutexTypes&...> pm; // exposition only
    };
}

An object of type scoped_lock controls the ownership of lockable objects within a scope. A scoped_lock object maintains ownership of lockable objects throughout the scoped_lock object’s lifetime (6.6.3). The behavior of a program is undefined if the lockable objects referenced by pm do not exist for the entire lifetime of the scoped_lock object. When sizeof...(MutexTypes) is 1, the supplied Mutex type shall meet the Cpp17BasicLockable requirements (32.2.5.2). Otherwise, each of the mutex types shall meet the Cpp17Lockable requirements (32.2.5.3).

explicit scoped_lock(MutexTypes&... m);

Requires: If a MutexTypes type is not a recursive mutex, the calling thread does not own the corresponding mutex element of m.

Effects: Initializes pm with tie(m...). Then if sizeof...(MutexTypes) is 0, no effects. Otherwise if sizeof...(MutexTypes) is 1, then m.lock(). Otherwise, lock(m...).

explicit scoped_lock(adopt_lock_t, MutexTypes&... m);

Requires: The calling thread owns all the mutexes in m.

Effects: Initializes pm with tie(m...).

Throws: Nothing.

~scoped_lock();

Effects: For all i in [0, sizeof...(MutexTypes)), get<i>(pm).unlock().
template<class Rep, class Period>
    unique_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);
-unique_lock();

unique_lock(const unique_lock&) = delete;
unique_lock& operator=(const unique_lock&) = delete;
unique_lock(unique_lock&& u) noexcept;
unique_lock& operator=(unique_lock&& u);

// 32.4.4.3.2, locking
void lock();
bool try_lock();

template<class Rep, class Period>
    bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
template<class Clock, class Duration>
    bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
void unlock();

// 32.4.4.3.3, modifiers
void swap(unique_lock& x, unique_lock& y) noexcept;
mutex_type* release() noexcept;

// 32.4.4.3.4, observers
bool owns_lock() const noexcept;
explicit operator bool () const noexcept;
mutex_type* mutex() const noexcept;

private:
    mutex_type* pm;       // exposition only
    bool owns;            // exposition only
};

template<class Mutex>
    void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;

1 An object of type unique_lock controls the ownership of a lockable object within a scope. Ownership of the lockable object may be acquired at construction or after construction, and may be transferred, after acquisition, to another unique_lock object. Objects of type unique_lock are not copyable but are movable. The behavior of a program is undefined if the contained pointer pm is not null and the lockable object pointed to by pm does not exist for the entire remaining lifetime (6.6.3) of the unique_lock object. The supplied Mutex type shall meet the Cpp17BasicLockable requirements (32.2.5.2).

2 [Note: unique_lock<Mutex> meets the Cpp17BasicLockable requirements. If Mutex meets the Cpp17Lockable requirements (32.2.5.3), unique_lock<Mutex> also meets the Cpp17Lockable requirements; if Mutex meets the Cpp17TimedLockable requirements (32.2.5.4), unique_lock<Mutex> also meets the Cpp17TimedLockable requirements. — end note]

32.4.4.3.1 Constructors, destructor, and assignment

unique_lock() noexcept;

1 Effects: Constructs an object of type unique_lock.

2 Ensures: pm == 0 and owns == false.

explicit unique_lock(mutex_type& m);

3 Requires: If mutex_type is not a recursive mutex the calling thread does not own the mutex.

4 Effects: Constructs an object of type unique_lock and calls m.lock().

5 Ensures: pm == addressof(m) and owns == true.
unique_lock(mutex_type& m, defer_lock_t) noexcept;
   Effects: Constructs an object of type unique_lock.
   Ensures: pm == addressof(m) and owns == false.

unique_lock(mutex_type& m, try_to_lock_t);
   Requires: The supplied Mutex type shall meet the Cpp17Lockable requirements (32.2.5.3). If mutex_type is not a recursive mutex the calling thread does not own the mutex.
   Effects: Constructs an object of type unique_lock and calls m.try_lock().
   Ensures: pm == addressof(m) and owns == res, where res is the value returned by the call to m.try_lock().

unique_lock(mutex_type& m, adopt_lock_t);
   Requires: The calling thread owns the mutex.
   Effects: Constructs an object of type unique_lock.
   Ensures: pm == addressof(m) and owns == true.
   Throws: Nothing.

template<class Clock, class Duration>
unique_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);
   Requires: If mutex_type is not a recursive mutex the calling thread does not own the mutex. The supplied Mutex type shall meet the Cpp17TimedLockable requirements (32.2.5.4).
   Effects: Constructs an object of type unique_lock and calls m.try_lock_until(abs_time).
   Ensures: pm == addressof(m) and owns == res, where res is the value returned by the call to m.try_lock_until(abs_time).

template<class Rep, class Period>
unique_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);
   Requires: If mutex_type is not a recursive mutex the calling thread does not own the mutex. The supplied Mutex type shall meet the Cpp17TimedLockable requirements (32.2.5.4).
   Effects: Constructs an object of type unique_lock and calls m.try_lock_for(rel_time).
   Ensures: pm == addressof(m) and owns == res, where res is the value returned by the call to m.try_lock_for(rel_time).

unique_lock(unique_lock&& u) noexcept;
   Ensures: pm == u_p.pm and owns == u_p.owns (where u_p is the state of u just prior to this construction), u.pm == 0 and u.owns == false.

unique_lock& operator=(unique_lock&& u);
   Effects: If owns calls pm->unlock().
   Ensures: pm == u_p.pm and owns == u_p.owns (where u_p is the state of u just prior to this construction), u.pm == 0 and u.owns == false.
   [Note: With a recursive mutex it is possible for both *this and u to own the same mutex before the assignment. In this case, *this will own the mutex after the assignment and u will not. —end note]
   Throws: Nothing.

~unique_lock();
   Effects: If owns calls pm->unlock().

32.4.4.3.2 Locking
   [thread.lock.unique.locking]

void lock();
   Effects: As if by pm->lock().
   Ensures: owns == true.
Throws: Any exception thrown by \texttt{pm->lock(). system_error} when an exception is required (32.2.2).

Error conditions:

(4.1) operation_not_permitted — if \texttt{pm} is null ptr.

(4.2) resource_deadlock_would_occur — if on entry owns is true.

bool try_lock();

Requires: The supplied Mutex shall meet the \textit{Cpp17Lockable} requirements (32.2.5.3).

Effects: As if by \texttt{pm->try_lock()}. 

Returns: The value returned by the call to try_lock().

Ensures: owns == res, where res is the value returned by the call to try_lock().

Throws: Any exception thrown by \texttt{pm->try_lock(). system_error} when an exception is required (32.2.2).

Error conditions:

(10.1) operation_not_permitted — if \texttt{pm} is null ptr.

(10.2) resource_deadlock_would_occur — if on entry owns is true.

\textbf{template}<\textit{class Clock, class Duration}>

bool try_lock_until(const \texttt{chrono::time_point<Clock, Duration}> & abs_time);

Requires: The supplied Mutex type shall meet the \textit{Cpp17TimedLockable} requirements (32.2.5.4).

Effects: As if by \texttt{pm->try_lock_until(abs_time)}.

Returns: The value returned by the call to try_lock_until(abs_time).

Ensures: owns == res, where res is the value returned by the call to try_lock_until(abs_time).

Throws: Any exception thrown by \texttt{pm->try_lock_until(). system_error} when an exception is required (32.2.2).

Error conditions:

(16.1) operation_not_permitted — if \texttt{pm} is null ptr.

(16.2) resource_deadlock_would_occur — if on entry owns is true.

\textbf{template}<\textit{class Rep, class Period}>

bool try_lock_for(const \texttt{chrono::duration<Rep, Period>} & rel_time);

Requires: The supplied Mutex type shall meet the \textit{Cpp17TimedLockable} requirements (32.2.5.4).

Effects: As if by \texttt{pm->try_lock_for(rel_time)}.

Returns: The value returned by the call to try_lock_until(rel_time).

Ensures: owns == res, where res is the value returned by the call to try_lock_for(rel_time).

Throws: Any exception thrown by \texttt{pm->try_lock_for(). system_error} when an exception is required (32.2.2).

Error conditions:

(22.1) operation_not_permitted — if \texttt{pm} is null ptr.

(22.2) resource_deadlock_would_occur — if on entry owns is true.

void unlock();

Effects: As if by \texttt{pm->unlock()}. 

Ensures: owns == false.

Throws: system_error when an exception is required (32.2.2).

Error conditions:

(26.1) operation_not_permitted — if on entry owns is false.
32.4.4.3.3 Modifiers

```cpp
void swap(unique_lock& u) noexcept;
```

*Effects:* Swaps the data members of `*this` and `u`.

```cpp
mutex_type* release() noexcept;
```

*Returns:* The previous value of `pm`.

*Ensures:* `pm == 0` and `owns == false`.

```cpp
template<class Mutex>
void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;
```

*Effects:* As if by `x.swap(y)`.

32.4.4.3.4 Observers

```cpp
bool owns_lock() const noexcept;
```

*Returns:* `owns`.

```cpp
explicit operator bool() const noexcept;
```

*Returns:* `owns`.

```cpp
mutex_type* mutex() const noexcept;
```

*Returns:* `pm`.

32.4.4.4 Class template shared_lock

```cpp
namespace std {

class shared_lock {

public:
    using mutex_type = Mutex;

    // 32.4.4.4.1, construct/copy/destroy
    shared_lock() noexcept;
    explicit shared_lock(mutex_type& m);
    shared_lock(mutex_type& m, defer_lock_t) noexcept;
    shared_lock(mutex_type& m, try_to_lock_t);
    shared_lock(mutex_type& m, adopt_lock_t);
    template<class Clock, class Duration>
    shared_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);
    template<class Rep, class Period>
    shared_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);
    ~shared_lock();

    shared_lock(const shared_lock&) = delete;
    shared_lock& operator=(const shared_lock&) = delete;
    shared_lock(shared_lock&& u) noexcept;
    shared_lock& operator=(shared_lock&& u) noexcept;

    // 32.4.4.4.2, locking
    void lock();
    bool try_lock();
    template<class Rep, class Period>
    bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
    template<class Clock, class Duration>
    bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
    void unlock();

    // 32.4.4.4.3, modifiers
    void swap(shared_lock& u) noexcept;
    mutex_type* release() noexcept;

}
```
// 32.4.4.4.4, observers
bool owns_lock() const noexcept;
explicit operator bool () const noexcept;
mutex_type* mutex() const noexcept;

private:
  mutex_type* pm;  // exposition only
  bool owns;      // exposition only
};

template<class Mutex>
void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;

1 An object of type shared_lock controls the shared ownership of a lockable object within a scope. Shared ownership of the lockable object may be acquired at construction or after construction, and may be transferred, after acquisition, to another shared_lock object. Objects of type shared_lock are not copyable but are movable. The behavior of a program is undefined if the contained pointer pm is not null and the lockable object pointed to by pm does not exist for the entire remaining lifetime (6.6.3) of the shared_lock object. The supplied Mutex type shall meet the shared mutex requirements (32.4.3.5).

2 [Note: shared_lock<Mutex> meets the Cpp17TimedLockable requirements (32.2.5.4). — end note]

32.4.4.4.4.1 Constructors, destructor, and assignment [thread.lock.shared.cons]

shared_lock() noexcept;
Effects: Constructs an object of type shared_lock.
Ensures: pm == nullptr and owns == false.

explicit shared_lock(mutex_type& m);
Requires: The calling thread does not own the mutex for any ownership mode.
Effects: Constructs an object of type shared_lock and calls m.lock_shared().
Ensures: pm == addressof(m) and owns == true.

shared_lock(mutex_type& m, defer_lock_t) noexcept;
Effects: Constructs an object of type shared_lock.
Ensures: pm == addressof(m) and owns == false.

shared_lock(mutex_type& m, try_to_lock_t);
Requires: The calling thread does not own the mutex for any ownership mode.
Effects: Constructs an object of type shared_lock and calls m.try_lock_shared().
Ensures: pm == addressof(m) and owns == res where res is the value returned by the call to m.try_lock_shared().

shared_lock(mutex_type& m, adopt_lock_t);
Requires: The calling thread has shared ownership of the mutex.
Effects: Constructs an object of type shared_lock.
Ensures: pm == addressof(m) and owns == true.

template<class Clock, class Duration>
shared_lock(mutex_type& m,
            const chrono::time_point<Clock, Duration>& abs_time);
Requires: The calling thread does not own the mutex for any ownership mode.
Effects: Constructs an object of type shared_lock and calls m.try_lock_shared_until(abs_time).
Ensures: pm == addressof(m) and owns == res where res is the value returned by the call to m.try_lock_shared_until(abs_time).
template<class Rep, class Period>
  shared_lock(mutex_type& m,
              const chrono::duration<Rep, Period>& rel_time);

  Requires: The calling thread does not own the mutex for any ownership mode.
  Effects: Constructs an object of type shared_lock and calls m.try_lock_shared_for(rel_time).
  Ensures: pm == addressof(m) and owns == res where res is the value returned by the call to
           m.try_lock_shared_for(rel_time).

  ~shared_lock();
  Effects: If owns calls pm->unlock_shared().

  shared_lock(shared_lock&& sl) noexcept;
  Ensures: pm == sl_p.pm and owns == sl_p.owns (where sl_p is the state of sl just prior to this
           construction), sl.pm == nullptr and sl.owns == false.

  shared_lock& operator=(shared_lock&& sl) noexcept;
  Effects: If owns calls pm->unlock_shared().
  Ensures: pm == sl_p.pm and owns == sl_p.owns (where sl_p is the state of sl just prior to this
           assignment), sl.pm == nullptr and sl.owns == false.

32.4.4.4.2 Locking [thread.lock.shared.locking]

void lock();
  Effects: As if by pm->lock_shared().
  Ensures: owns == true.
  Throws: Any exception thrown by pm->lock_shared(). system_error when an exception is required
          (32.2.2).
  Error conditions:
    (4.1) — operation_not_permitted — if pm is nullptr.
    (4.2) — resource_deadlock_would_occur — if on entry owns is true.

bool try_lock();
  Effects: As if by pm->try_lock_shared().
  Returns: The value returned by the call to pm->try_lock_shared().
  Ensures: owns == res, where res is the value returned by the call to pm->try_lock_shared().
  Throws: Any exception thrown by pm->try_lock_shared(). system_error when an exception is required
          (32.2.2).
  Error conditions:
    (9.1) — operation_not_permitted — if pm is nullptr.
    (9.2) — resource_deadlock_would_occur — if on entry owns is true.

template<class Clock, class Duration>
  bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
  Effects: As if by pm->try_lock_shared_until(abs_time).
  Returns: The value returned by the call to pm->try_lock_shared_until(abs_time).
  Ensures: owns == res, where res is the value returned by the call to pm->try_lock_shared_until(abs_time).
  Throws: Any exception thrown by pm->try_lock_shared_until(abs_time). system_error when an exception is required
          (32.2.2).
  Error conditions:
    (14.1) — operation_not_permitted — if pm is nullptr.
    (14.2) — resource_deadlock_would_occur — if on entry owns is true.
template<class Rep, class Period>
bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);

Effects: As if by pm->try_lock_shared_for(rel_time).
Returns: The value returned by the call to pm->try_lock_shared_for(rel_time).
Ensures: owns == res, where res is the value returned by the call to pm->try_lock_shared_for(rel_time).
Throws: Any exception thrown by pm->try_lock_shared_for(rel_time), system_error when an exception is required (32.2.2).
Error conditions:

void unlock();
Effects: As if by pm->unlock_shared().
Ensures: owns == false.
Throws: system_error when an exception is required (32.2.2).
Error conditions:

(19.1) — operation_not_permitted — if pm is nullptr.
(19.2) — resource_deadlock_would_occur — if on entry owns is true.

32.4.4.4.3 Modifiers [thread.lock.shared.mod]

void swap(shared_lock& sl) noexcept;
Effects: Swaps the data members of *this and sl.
mutex_type* release() noexcept;
Returns: The previous value of pm.
Ensures: pm == nullptr and owns == false.

template<class Mutex>
void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
Effects: As if by x.swap(y).

32.4.4.4.4 Observers [thread.lock.shared.obs]

bool owns_lock() const noexcept;
Returns: owns.
explicit operator bool() const noexcept;
Returns: owns.
mutex_type* mutex() const noexcept;
Returns: pm.

32.4.5 Generic locking algorithms [thread.lock.algorithm]

template<class L1, class L2, class... L3> int try_lock(L1&, L2&, L3&...);
Requires: Each template parameter type shall meet the Cpp17Lockable requirements. [Note: The unique_lock class template meets these requirements when suitably instantiated. — end note]
Effects: Calls try_lock() for each argument in order beginning with the first until all arguments have been processed or a call to try_lock() fails, either by returning false or by throwing an exception. If a call to try_lock() fails, unlock() is called for all prior arguments with no further calls to try_lock().
Returns: -1 if all calls to try_lock() returned true, otherwise a zero-based index value that indicates the argument for which try_lock() returned false.
template<class L1, class L2, class... L3> void lock(L1&, L2&, L3&...);

Requires: Each template parameter type shall meet the Cpp17Lockable requirements, [Note: The unique_lock class template meets these requirements when suitably instantiated. —end note]

Effects: All arguments are locked via a sequence of calls to lock(), try_lock(), or unlock() on each argument. The sequence of calls does not result in deadlock, but is otherwise unspecified. [Note: A deadlock avoidance algorithm such as try-and-back-off must be used, but the specific algorithm is not specified to avoid over-constraining implementations. —end note] If a call to lock() or try_lock() throws an exception, unlock() is called for any argument that had been locked by a call to lock() or try_lock().

32.4.6 Call once

32.4.6.1 Struct once_flag

namespace std {
struct once_flag {
   constexpr once_flag() noexcept;
   once_flag(const once_flag&) = delete;
   once_flag& operator=(const once_flag&) = delete;
};
}

The class once_flag is an opaque data structure that call_once uses to initialize data without causing a data race or deadlock.

call_once

1 The class once_flag is an opaque data structure that call_once uses to initialize data without causing a data race or deadlock.

call_once

2 The class once_flag is an opaque data structure that call_once uses to initialize data without causing a data race or deadlock.

call_once

3 The class once_flag is an opaque data structure that call_once uses to initialize data without causing a data race or deadlock.

call_once

4 The class once_flag is an opaque data structure that call_once uses to initialize data without causing a data race or deadlock.

call_once

5 The class once_flag is an opaque data structure that call_once uses to initialize data without causing a data race or deadlock.

32.4.6.2 Function call_once

template<class Callable, class... Args>
void call_once(once_flag& flag, Callable&& func, Args&&... args);

Requires: 

(INVOKE(std::forward<Callable>(func), std::forward<Args>(args)...)

(see 20.14.3) shall be a valid expression.

2 Effects: An execution of call_once that does not call its func is a passive execution. An execution of call_once that calls its func is an active execution. An active execution shall call INVOKE( std::forward<Callable>(func), std::forward<Args>(args)...). If such a call to func throws an exception the execution is exceptional, otherwise it is returning. An exceptional execution shall propagate the exception to the caller of call_once. Among all executions of call_once for any given once_flag, at most one shall be a returning execution; if there is a returning execution, it shall be the last active execution; and there are passive executions only if there is a returning execution. [Note: Passive executions allow other threads to reliably observe the results produced by the earlier returning execution. —end note]

3 Synchronization: For any given once_flag: all active executions occur in a total order; completion of an active execution synchronizes with (6.8.2) the start of the next one in this total order; and the returning execution synchronizes with the return from all passive executions.

4 Throws: system_error when an exception is required (32.2.2), or any exception thrown by func.

5 [Example:

// global flag, regular function
void init();
std::once_flag flag;
void f() {
    std::call_once(flag, init);
}

// function static flag, function object
struct initializer {
    void operator()();
};

void g() {
    static std::once_flag flag2;
    std::call_once(flag2, initializer());
}

// object flag, member function
class information {
    std::once_flag verified;
    void verifier();
    public:
        void verify() { std::call_once(verified, &information::verifier, *this); }
    }
    — end example

32.5 Condition variables

Condition variables provide synchronization primitives used to block a thread until notified by some other
thread that some condition is met or until a system time is reached. Class condition_variable provides a
condition variable that can only wait on an object of type unique_lock<mutex>, allowing the implementation
to be more efficient. Class condition_variable_any provides a general condition variable that can wait on
objects of user-supplied lock types.

Condition variables permit concurrent invocation of the wait, wait_for, wait_until, notify_one and
notify_all member functions.

The execution of notify_one and notify_all shall be atomic. The execution of wait, wait_for, and
wait_until shall be performed in three atomic parts:
1. the release of the mutex and entry into the waiting state;
2. the unblocking of the wait; and
3. the reacquisition of the lock.

The implementation shall behave as if all executions of notify_one, notify_all, and each part of the wait,
wait_for, and wait_until executions are executed in a single unspecified total order consistent with the
'happens before' order.

Condition variable construction and destruction need not be synchronized.

32.5.1 Header <condition_variable> synopsis

namespace std {
    class condition_variable;
    class condition_variable_any;
    void notify_all_at_thread_exit(condition_variable& cond, unique_lock<mutex> lk);
    enum class cv_status { no_timeout, timeout };
}

32.5.2 Non-member functions

void notify_all_at_thread_exit(condition_variable& cond, unique_lock<mutex> lk);

Requires: lk is locked by the calling thread and either

— no other thread is waiting on cond, or
lk.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

**Effects:** Transfers ownership of the lock associated with lk into internal storage and schedules cond to be notified when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed. This notification shall be as if:

```cpp
lk.unlock();
cond.notify_all();
```

**Synchronization:** The implied lk.unlock() call is sequenced after the destruction of all objects with thread storage duration associated with the current thread.

**[Note:** The supplied lock will be held until the thread exits, and care should be taken to ensure that this does not cause deadlock due to lock ordering issues. After calling notify_all_at_thread_exit it is recommended that the thread should be exited as soon as possible, and that no blocking or time-consuming tasks are run on that thread. — end note]**

**[Note:** It is the user’s responsibility to ensure that waiting threads do not erroneously assume that the thread has finished if they experience spurious wakeups. This typically requires that the condition being waited for is satisfied while holding the lock on lk, and that this lock is not released and reacquired prior to calling notify_all_at_thread_exit. — end note]**

### 32.5.3 Class condition_variable

```cpp
namespace std {
    class condition_variable {
        public:
            condition_variable();
            ~condition_variable();
            condition_variable(const condition_variable&) = delete;
            condition_variable& operator=(const condition_variable&) = delete;
            void notify_one() noexcept;
            void notify_all() noexcept;
            void wait(unique_lock<mutex>& lock);
            template<class Predicate>
                void wait(unique_lock<mutex>& lock, Predicate pred);
            template<class Clock, class Duration>
                cv_status wait_until(unique_lock<mutex>& lock,
                    const chrono::time_point<Clock, Duration>& abs_time);
            template<class Clock, class Duration, class Predicate>
                bool wait_until(unique_lock<mutex>& lock,
                    const chrono::time_point<Clock, Duration>& abs_time,
                    Predicate pred);
            template<class Rep, class Period>
                cv_status wait_for(unique_lock<mutex>& lock,
                    const chrono::duration<Rep, Period>& rel_time);
            template<class Rep, class Period, class Predicate>
                bool wait_for(unique_lock<mutex>& lock,
                    const chrono::duration<Rep, Period>& rel_time,
                    Predicate pred);
            using native_handle_type = implementation-defined; // see 32.2.3
            native_handle_type native_handle(); // see 32.2.3
    };
}
```

1. The class `condition_variable` shall be a standard-layout class (11.1).

```cpp
condition_variable();
```

**Effects:** Constructs an object of type `condition_variable`.

**Throws:** `system_error` when an exception is required (32.2.2).

**Error conditions:**
— resourceUnavailableTryAgain — if some non-memory resource limitation prevents initialization.

~condition_variable();

5 Requires: There shall be no thread blocked on *this. [Note: That is, all threads shall have been notified; they may subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait needs to happen before destruction. The user should take care to ensure that no threads wait on *this once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of wait, wait_for, or wait_until that take a predicate. — end note]

Effects: Destroys the object.

6 void notify_one() noexcept;

7 Effects: If any threads are blocked waiting for *this, unblocks one of those threads.

8 void notify_all() noexcept;

9 Effects: Unblocks all threads that are blocked waiting for *this.

10 void wait(unique_lock<mutex>& lock);

11 Requires: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
11.1 — no other thread is waiting on this condition_variable object or
11.2 — lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

12 Effects:
12.1 — Atomically calls lock.unlock() and blocks on *this.
12.2 — When unblocked, calls lock.lock() (possibly blocking on the lock), then returns.
12.3 — The function will unblock when signaled by a call to notify_one() or a call to notify_all(), or spuriously.

Remarks: If the function fails to meet the postcondition, terminate() shall be called (14.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

13 Ensures: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

14 template<class Predicate>
15 void wait(unique_lock<mutex>& lock, Predicate pred);

16 Requires: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
16.1 — no other thread is waiting on this condition_variable object or
16.2 — lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

17 Effects: Equivalent to:
17.1 while (!pred())
17.2 wait(lock);

Remarks: If the function fails to meet the postcondition, terminate() shall be called (14.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

18 Ensures: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

19 template<class Clock, class Duration>
20 cv_status wait_until(unique_lock<mutex>& lock,
20.1 const chrono::time_point<Clock, Duration>& abs_time);

21 Requires: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
21.1 — no other thread is waiting on this condition_variable object or

§ 32.5.3
— \texttt{lock.mutex()} returns the same value for each of the \texttt{lock} arguments supplied by all concurrently waiting (via \texttt{wait}, \texttt{wait\_for}, or \texttt{wait\_until}) threads.

\textbf{Effects:}
- Atomically calls \texttt{lock.unlock()} and blocks on \texttt{*this}.
- When unblocked, calls \texttt{lock.lock()} (possibly blocking on the lock), then returns.
- The function will unblock when signaled by a call to \texttt{notify\_one()}, a call to \texttt{notify\_all()}, expiration of the absolute timeout (32.2.4) specified by \texttt{abs\_time}, or spuriously.
- If the function exits via an exception, \texttt{lock.lock()} shall be called prior to exiting the function.

\textbf{Remarks:} If the function fails to meet the postcondition, \texttt{terminate()} shall be called (14.5.1). \[Note: This can happen if the re-locking of the mutex throws an exception. — end note\]

\textbf{Ensures:} \texttt{lock.owns\_lock()} is \texttt{true} and \texttt{lock.mutex()} is locked by the calling thread.

\textbf{Returns:} \texttt{cv\_status::timeout} if the absolute timeout (32.2.4) specified by \texttt{abs\_time} expired, otherwise \texttt{cv\_status::no\_timeout}.

\textbf{Throws:} Timeout-related exceptions (32.2.4).

\begin{verbatim}
template<class Rep, class Period>
  cv\_status wait\_for(unique\_lock<mutex>& lock,
               const chron\_::duration<Rep, Period>& rel\_time);
\end{verbatim}

\textbf{Requires:} \texttt{lock.owns\_lock()} is \texttt{true} and \texttt{lock.mutex()} is locked by the calling thread, and either
- no other thread is waiting on this \texttt{condition\_variable} object or
- \texttt{lock.mutex()} returns the same value for each of the \texttt{lock} arguments supplied by all concurrently waiting (via \texttt{wait}, \texttt{wait\_for}, or \texttt{wait\_until}) threads.

\textbf{Effects:} Equivalent to:
\begin{verbatim}
return wait\_until(lock, chron\_::steady\_clock\::now() + rel\_time);
\end{verbatim}

\textbf{Returns:} \texttt{cv\_status::timeout} if the relative timeout (32.2.4) specified by \texttt{rel\_time} expired, otherwise \texttt{cv\_status::no\_timeout}.

\textbf{Remarks:} If the function fails to meet the postcondition, \texttt{terminate()} shall be called (14.5.1). \[Note: This can happen if the re-locking of the mutex throws an exception. — end note\]

\textbf{Ensures:} \texttt{lock.owns\_lock()} is \texttt{true} and \texttt{lock.mutex()} is locked by the calling thread.

\textbf{Throws:} Timeout-related exceptions (32.2.4).

\begin{verbatim}
template<class Clock, class Duration, class Predicate>
  bool wait\_until(unique\_lock<mutex>& lock,
                const chron\_::time\_point<Clock, Duration>& abs\_time,
                Predicate pred);
\end{verbatim}

\textbf{Requires:} \texttt{lock.owns\_lock()} is \texttt{true} and \texttt{lock.mutex()} is locked by the calling thread, and either
- no other thread is waiting on this \texttt{condition\_variable} object or
- \texttt{lock.mutex()} returns the same value for each of the \texttt{lock} arguments supplied by all concurrently waiting (via \texttt{wait}, \texttt{wait\_for}, or \texttt{wait\_until}) threads.

\textbf{Effects:} Equivalent to:
\begin{verbatim}
while (!pred())
  if (wait\_until(lock, abs\_time) == cv\_status::timeout)
    return pred();
return true;
\end{verbatim}

\textbf{Remarks:} If the function fails to meet the postcondition, \texttt{terminate()} shall be called (14.5.1). \[Note: This can happen if the re-locking of the mutex throws an exception. — end note\]

\textbf{Ensures:} \texttt{lock.owns\_lock()} is \texttt{true} and \texttt{lock.mutex()} is locked by the calling thread.

\textbf{[Note:} The returned value indicates whether the predicate evaluated to \texttt{true} regardless of whether the timeout was triggered. — end note\]

\textbf{Throws:} Timeout-related exceptions (32.2.4) or any exception thrown by \texttt{pred}.
template<class Rep, class Period, class Predicate>
bool wait_for(unique_lock<mutex>& lock,
    const chrono::duration<Rep, Period>& rel_time,
    Predicate pred);

**Requires:** lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
— no other thread is waiting on this condition_variable object or
— lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

**Effects:** Equivalent to:
return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));

[Note: There is no blocking if pred() is initially true, even if the timeout has already expired. — end note]

**Remarks:** If the function fails to meet the postcondition, terminate() shall be called (14.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

**Ensures:** lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

[Note: The returned value indicates whether the predicate evaluates to true regardless of whether the timeout was triggered. — end note]

**Throws:** Timeout-related exceptions (32.2.4) or any exception thrown by pred.

### 32.5.4 Class condition_variable_any

A Lock type shall meet the Cpp17BasicLockable requirements (32.2.5.2). [Note: All of the standard mutex types meet this requirement. If a Lock type other than one of the standard mutex types or a unique_lock wrapper for a standard mutex type is used with condition_variable_any, the user should ensure that any necessary synchronization is in place with respect to the predicate associated with the condition_variable_any instance. — end note]

```cpp
namespace std {
    class condition_variable_any {
    public:
    condition_variable_any();
    ~condition_variable_any();

    condition_variable_any(const condition_variable_any&) = delete;
    condition_variable_any& operator=(const condition_variable_any&) = delete;

    void notify_one() noexcept;
    void notify_all() noexcept;
    template<class Lock>
    void wait(Lock& lock);
    template<class Lock, class Predicate>
    void wait(Lock& lock, Predicate pred);

    template<class Lock, class Clock, class Duration>
    cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);
    template<class Lock, class Clock, class Duration, class Predicate>
    bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time,
                    Predicate pred);
    template<class Lock, class Rep, class Period>
    cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);
    template<class Lock, class Rep, class Period, class Predicate>
    bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time, Predicate pred);
    }
}
```

**Effects:** Constructs an object of type condition_variable_any.

**Throws:** bad_alloc or system_error when an exception is required (32.2.2).
Error conditions:

— `resource_unavailable_try_again` — if some non-memory resource limitation prevents initialization.

— `operation_not_permitted` — if the thread does not have the privilege to perform the operation.

~`condition_variable_any();`

Requires: There shall be no thread blocked on `*this`. [Note: That is, all threads shall have been notified; they may subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait needs to happen before destruction. The user should take care to ensure that no threads wait on `*this` once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of `wait`, `wait_for`, or `wait_until` that take a predicate. — end note]

Effects: Destroys the object.

`void notify_one() noexcept;`

Effects: If any threads are blocked waiting for `*this`, unblocks one of those threads.

`void notify_all() noexcept;`

Effects: Unblocks all threads that are blocked waiting for `*this`.

`template<class Lock>
void wait(Lock& lock);`

Effects:

(9.1) — Atomically calls `lock.unlock()` and blocks on `*this`.

(9.2) — When unblocked, calls `lock.lock()` (possibly blocking on the lock) and returns.

(9.3) — The function will unblock when signaled by a call to `notify_one()`, a call to `notify_all()`, or spuriously.

Remarks: If the function fails to meet the postcondition, `terminate()` shall be called (14.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

Ensures: `lock` is locked by the calling thread.

Throws: Nothing.

`template<class Lock, class Predicate>
void wait(Lock& lock, Predicate pred);`

Effects: Equivalent to:

```c
while (!pred())
    wait(lock);
```

`template<class Lock, class Clock, class Duration>
cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);`

Effects:

(14.1) — Atomically calls `lock.unlock()` and blocks on `*this`.

(14.2) — When unblocked, calls `lock.lock()` (possibly blocking on the lock) and returns.

(14.3) — The function will unblock when signaled by a call to `notify_one()`, a call to `notify_all()`, expiration of the absolute timeout (32.2.4) specified by `abs_time`, or spuriously.

(14.4) — If the function exits via an exception, `lock.lock()` shall be called prior to exiting the function.

Remarks: If the function fails to meet the postcondition, `terminate()` shall be called (14.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

Ensures: `lock` is locked by the calling thread.

Returns: `cv_status::timeout` if the absolute timeout (32.2.4) specified by `abs_time` expired, otherwise `cv_status::no_timeout`.

Throws: Timeout-related exceptions (32.2.4).
template<class Lock, class Rep, class Period>
    cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);

Effects: Equivalent to:
        return wait_until(lock, chrono::steady_clock::now() + rel_time);

Returns: cv_status::timeout if the relative timeout (32.2.4) specified by rel_time expired, otherwise cv_status::no_timeout.

Remarks: If the function fails to meet the postcondition, terminate() shall be called (14.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

Ensures: lock is locked by the calling thread.

Throws: Timeout-related exceptions (32.2.4).

template<class Lock, class Clock, class Duration, class Predicate>
    bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time, Predicate pred);

Effects: Equivalent to:
        while (!pred())
            if (wait_until(lock, abs_time) == cv_status::timeout)
                return pred();
        return true;

[Note: There is no blocking if pred() is initially true, or if the timeout has already expired. — end note]

[Note: The returned value indicates whether the predicate evaluates to true regardless of whether the timeout was triggered. — end note]

template<class Lock, class Rep, class Period, class Predicate>
    bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time, Predicate pred);

Effects: Equivalent to:
        return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));

32.6 Futures

32.6.1 Overview

32.6 describes components that a C++ program can use to retrieve in one thread the result (value or exception) from a function that has run in the same thread or another thread. [Note: These components are not restricted to multi-threaded programs but can be useful in single-threaded programs as well. — end note]

32.6.2 Header <future> synopsis

namespace std {
    enum class future_errc {
        broken_promise = implementation-defined,
        future_already_retrieved = implementation-defined,
        promise_already_satisfied = implementation-defined,
        no_state = implementation-defined
    };

    enum class launch : unspecified {
        async = unspecified,
        deferred = unspecified,
        implementation-defined
    };

    enum class future_status {
        ready,
        timeout,
        deferred
    };
}
```cpp
template<> struct is_error_code_enum<future_errc> : public true_type { 
};
error_code make_error_code(future_errc e) noexcept;
error_condition make_error_condition(future_errc e) noexcept;

const error_category& future_category() noexcept;

class future_error;

template<class R> class promise;
template<class R> class promise<R&>;
template<> class promise<void>;

template<class R>
void swap(promise<R>& x, promise<R>& y) noexcept;

template<class R, class Alloc>
struct uses_allocator<promise<R>, Alloc>;

template<class R> class future;
template<class R> class future<R&>;
template<> class future<void>;

template<class R> class shared_future;
template<class R> class shared_future<R&>;
template<> class shared_future<void>;

template<class> class packaged_task;
// not defined

template<class R, class... ArgTypes>
class packaged_task<R(ArgTypes...)>

template<class R, class... ArgTypes>
void swap(packaged_task<R(ArgTypes...)>&, packaged_task<R(ArgTypes...)>&) noexcept;

template<class F, class... Args>

[[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
async(F&& f, Args&&... args);

template<class F, class... Args>
[[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
async(launch policy, F&& f, Args&&... args);
```
32.6.4 Class future_error

namespace std {
    class future_error : public logic_error {
        public:
            explicit future_error(future_errc e);

            const error_code& code() const noexcept;
            const char* what() const noexcept;

        private:
            error_code ec_;          // exposition only
        };
    }

    explicit future_error(future_errc e);

    Effects: Constructs an object of class future_error and initializes ec_ with make_error_code(e).

    const error_code& code() const noexcept;

    Returns: ec_.

    const char* what() const noexcept;

    Returns: An NTBS incorporating code().message().

32.6.5 Shared state

Many of the classes introduced in this subclause use some state to communicate results. This shared state consists of some state information and some (possibly not yet evaluated) result, which can be a (possibly void) value or an exception. [Note: Futures, promises, and tasks defined in this clause reference such shared state. — end note]

[Note: The result can be any kind of object including a function to compute that result, as used by async when policy is launch::deferred. — end note]

An asynchronous return object is an object that reads results from a shared state. A waiting function of an asynchronous return object is one that potentially blocks to wait for the shared state to be made ready. If a waiting function can return before the state is made ready because of a timeout (32.2.5), then it is a timed waiting function, otherwise it is a non-timed waiting function.

An asynchronous provider is an object that provides a result to a shared state. The result of a shared state is set by respective functions on the asynchronous provider. [Note: Such as promises or tasks. — end note] The means of setting the result of a shared state is specified in the description of those classes and functions that create such a state object.

When an asynchronous return object or an asynchronous provider is said to release its shared state, it means:

(5.1) — if the return object or provider holds the last reference to its shared state, the shared state is destroyed; and
(5.2) — the return object or provider gives up its reference to its shared state; and
(5.3) — these actions will not block for the shared state to become ready, except that it may block if all of the following are true: the shared state was created by a call to std::async, the shared state is not yet ready, and this was the last reference to the shared state.

When an asynchronous provider is said to make its shared state ready, it means:

(6.1) — first, the provider marks its shared state as ready; and
(6.2) — second, the provider unblocks any execution agents waiting for its shared state to become ready.

When an asynchronous provider is said to abandon its shared state, it means:

(7.1) — first, if that state is not ready, the provider
(7.1.1) — stores an exception object of type future_error with an error condition of broken_promise within its shared state; and then
(7.1.2) — makes its shared state ready;
(7.2) — second, the provider releases its shared state.
A shared state is ready only if it holds a value or an exception ready for retrieval. Waiting for a shared state to become ready may invoke code to compute the result on the waiting thread if so specified in the description of the class or function that creates the state object.

Calls to functions that successfully set the stored result of a shared state synchronize with (6.8.2) calls to functions successfully detecting the ready state resulting from that setting. The storage of the result (whether normal or exceptional) into the shared state synchronizes with (6.8.2) the successful return from a call to a waiting function on the shared state.

Some functions (e.g., promise::set_value_at_thread_exit) delay making the shared state ready until the calling thread exits. The destruction of each of that thread’s objects with thread storage duration (6.6.5.2) is sequenced before making that shared state ready.

Access to the result of the same shared state may conflict (6.8.2). [Note: This explicitly specifies that the result of the shared state is visible in the objects that reference this state in the sense of data race avoidance (16.5.5.9). For example, concurrent accesses through references returned by shared_future::get() (32.6.8) must either use read-only operations or provide additional synchronization. — end note]

32.6.6 Class template promise

```cpp
namespace std {
    template<class R>
    class promise {
    public:
        promise();
        template<class Allocator>
        promise(allocator_arg_t, const Allocator& a);
        promise(promise&& rhs) noexcept;
        promise(const promise& rhs) = delete;
        ~promise();

        // assignment
        promise& operator=(promise&& rhs) noexcept;
        promise& operator=(const promise& rhs) = delete;
        void swap(promise& other) noexcept;

        // retrieving the result
        future<R> get_future();

        // setting the result
        void set_value(see below);
        void set_exception(exception_ptr p);

        // setting the result with deferred notification
        void set_value_at_thread_exit(see below);
        void set_exception_at_thread_exit(exception_ptr p);
    };

    template<class R>
    void swap(promise<R>& x, promise<R>& y) noexcept;

    template<class R, class Alloc>
    struct uses_allocator<promise<R>, Alloc> {
    }
}
```

1 The implementation shall provide the template promise and two specializations, promise<R&> and promise<void>. These differ only in the argument type of the member functions set_value and set_value_at_thread_exit, as set out in their descriptions, below.

2 The set_value, set_exception, set_value_at_thread_exit, and set_exception_at_thread_exit member functions behave as though they acquire a single mutex associated with the promise object while updating the promise object.
true_type { };  

Requires: Alloc shall meet the Cpp17Allocator requirements (Table 34).

promise();

template<class Allocator>
promise(allocator_arg_t, const Allocator& a);

Effects: Constructs a promise object and a shared state. The second constructor uses the allocator a to allocate memory for the shared state.

promise(promise&& rhs) noexcept;

Effects: Constructs a new promise object and transfers ownership of the shared state of rhs (if any) to the newly-constructed object.

Ensures: rhs has no shared state.

~promise();

Effects: Abandons any shared state (32.6.5).

promise& operator=(promise&& rhs) noexcept;

Effects: Abandons any shared state (32.6.5) and then as if promise(std::move(rhs)).swap(*this).

Returns: *this.

void swap(promise& other) noexcept;

Effects: Exchanges the shared state of *this and other.

Ensures: *this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that *this had prior to the call to swap.

future<R> get_future();

Returns: A future<R> object with the same shared state as *this.

Synchronization: Calls to this function do not introduce data races (6.8.2) with calls to set_value, set_exception, set_value_at_thread_exit, or set_exception_at_thread_exit. [Note: Such calls need not synchronize with each other. — end note]

Throws: future_error if *this has no shared state or if get_future has already been called on a promise with the same shared state as *this.

Error conditions:

— future_already_retrieved if get_future has already been called on a promise with the same shared state as *this.

— no_state if *this has no shared state.

void promise::set_value(const R& r);
void promise::set_value(R&& r);
void promise<R&>::set_value(R& r);
void promise<void>::set_value();

Effects: Atomically stores the value r in the shared state and makes that state ready (32.6.5).

Throws:

— future_error if its shared state already has a stored value or exception, or

— for the first version, any exception thrown by the constructor selected to copy an object of R, or

— for the second version, any exception thrown by the constructor selected to move an object of R.

Error conditions:

— promise_already_satisfied if its shared state already has a stored value or exception.

— no_state if *this has no shared state.

void set_exception(exception_ptr p);

Requires: p is not null.
Effects: Atomically stores the exception pointer `p` in the shared state and makes that state ready (32.6.5).

Throws: `future_error` if its shared state already has a stored value or exception.

Error conditions:

1. `promise_already_satisfied` if its shared state already has a stored value or exception.
2. `no_state` if `*this` has no shared state.

```cpp
void promise::set_value_at_thread_exit(const R& r);
void promise::set_value_at_thread_exit(R&& r);
void promise<R&>::set_value_at_thread_exit(R& r);
void promise<void>::set_value_at_thread_exit();
```

Effects: Stores the value `r` in the shared state without making that state ready immediately. Schedules that state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

Throws:

1. `future_error` if its shared state already has a stored value or exception, or
2. for the first version, any exception thrown by the constructor selected to copy an object of `R`, or
3. for the second version, any exception thrown by the constructor selected to move an object of `R`.

Error conditions:

1. `promise_already_satisfied` if its shared state already has a stored value or exception.
2. `no_state` if `*this` has no shared state.

```cpp
void set_exception_at_thread_exit(exception_ptr p);
```

Requires: `p` is not null.

Effects: Stores the exception pointer `p` in the shared state without making that state ready immediately. Schedules that state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

Throws: `future_error` if an error condition occurs.

Error conditions:

1. `promise_already_satisfied` if its shared state already has a stored value or exception.
2. `no_state` if `*this` has no shared state.

```cpp
template<class R>
void swap(promise<R>& x, promise<R>& y) noexcept;
```

Effects: As if by `x.swap(y)`.

### 32.6.7 Class template `future`

The class template `future` defines a type for asynchronous return objects which do not share their shared state with other asynchronous return objects. A default-constructed `future` object has no shared state. A `future` object with shared state can be created by functions on asynchronous providers (32.6.5) or by the move constructor and shares its shared state with the original asynchronous provider. The result (value or exception) of a `future` object can be set by calling a respective function on an object that shares the same shared state.

1. [Note: Member functions of `future` do not synchronize with themselves or with member functions of `shared_future`. — end note]

The effect of calling any member function other than the destructor, the move-assignment operator, `share`, or `valid` on a `future` object for which `valid() == false` is undefined. [Note: It is valid to move from a `future` object for which `valid() == false`. — end note] [Note: Implementations should detect this case and throw an object of type `future_error` with an error condition of `future_error::no_state`. — end note]

```cpp
namespace std {
    template<class R>
    class future {
```

§ 32.6.7 1534
public:
  future() noexcept;
  future(future&&) noexcept;
  future(const future& rhs) = delete;
  ~future();
  future& operator=(const future& rhs) = delete;
  future& operator=(future&&) noexcept;
  shared_future<R> share() noexcept;

  // retrieving the value
  see below get();

  // functions to check state
  bool valid() const noexcept;

  void wait() const;
  template<class Rep, class Period>
    future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
  template<class Clock, class Duration>
    future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
};

The implementation shall provide the template future and two specializations, future<R&> and future<void>. These differ only in the return type and return value of the member function get, as set out in its description, below.

future() noexcept;

Effects: Constructs an empty future object that does not refer to a shared state.

Ensures: valid() == false.
uture(future&& rhs) noexcept;

Effects: Move constructs a future object that refers to the shared state that was originally referred to by rhs (if any).

Ensures:
  (8.1) -- valid() returns the same value as rhs.valid() prior to the constructor invocation.
  (8.2) -- rhs.valid() == false.

~future();

Effects:
  (9.1) -- Releases any shared state (32.6.5);
  (9.2) -- destroys *this.

future& operator=(future&& rhs) noexcept;

Effects:
  (10.1) -- Releases any shared state (32.6.5).
  (10.2) -- move assigns the contents of rhs to *this.

Ensures:
  (11.1) -- valid() returns the same value as rhs.valid() prior to the assignment.
  (11.2) -- rhs.valid() == false.

shared_future<R> share() noexcept;

Returns: shared_future<R>(std::move(*this)).

Ensures: valid() == false.

R future::get();
R& future<R&>::get();
void future<void>::get();

[Note: As described above, the template and its two required specializations differ only in the return type and return value of the member function get. — end note]

Effects:

(15.1) — wait()s until the shared state is ready, then retrieves the value stored in the shared state;
(15.2) — releases any shared state (32.6.5).

Returns:

(16.1) — future::get() returns the value v stored in the object’s shared state as std::move(v).
(16.2) — future<R&>::get() returns the reference stored as value in the object’s shared state.
(16.3) — future<void>::get() returns nothing.

Throws: The stored exception, if an exception was stored in the shared state.

Ensures: valid() == false.

bool valid() const noexcept;

Returns: true only if *this refers to a shared state.

void wait() const;

Effects: Blocks until the shared state is ready.

template<class Rep, class Period>
future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;

Effects: None if the shared state contains a deferred function (32.6.9), otherwise blocks until the shared state is ready or until the relative timeout (32.2.4) specified by rel_time has expired.

Returns:

(22.1) — future_status::deferred if the shared state contains a deferred function.
(22.2) — future_status::ready if the shared state is ready.
(22.3) — future_status::timeout if the function is returning because the relative timeout (32.2.4) specified by rel_time has expired.

Throws: timeout-related exceptions (32.2.4).

template<class Clock, class Duration>
future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;

Effects: None if the shared state contains a deferred function (32.6.9), otherwise blocks until the shared state is ready or until the absolute timeout (32.2.4) specified by abs_time has expired.

Returns:

(25.1) — future_status::deferred if the shared state contains a deferred function.
(25.2) — future_status::ready if the shared state is ready.
(25.3) — future_status::timeout if the function is returning because the absolute timeout (32.2.4) specified by abs_time has expired.

Throws: timeout-related exceptions (32.2.4).

32.6.8 Class template shared_future

The class template shared_future defines a type for asynchronous return objects which may share their shared state with other asynchronous return objects. A default-constructed shared_future object has no shared state. A shared_future object with shared state can be created by conversion from a future object and shares its shared state with the original asynchronous provider (32.6.5) of the shared state. The result (value or exception) of a shared_future object can be set by calling a respective function on an object that shares the same shared state.

[Note: Member functions of shared_future do not synchronize with themselves, but they synchronize with the shared state. — end note]
The effect of calling any member function other than the destructor, the move-assignment operator, the copy-assignment operator, or valid() on a shared_future object for which valid() == false is undefined. [Note: It is valid to copy or move from a shared_future object for which valid() is false. — end note]

[Note: Implementations should detect this case and throw an object of type future_error with an error condition of future_errc::no_state. — end note]

namespace std {
    template<class R>
    class shared_future {
        public:
            shared_future() noexcept;
            shared_future(const shared_future& rhs) noexcept;
            shared_future(future<R>&& rhs) noexcept;
            shared_future(shared_future&& rhs) noexcept;
            ~shared_future();
            shared_future& operator=(const shared_future& rhs) noexcept;
            shared_future& operator=(shared_future&& rhs) noexcept;

            // retrieving the value
            see below get() const;

            // functions to check state
            bool valid() const noexcept;
            void wait() const;
            template<class Rep, class Period>
                future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
            template<class Clock, class Duration>
                future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
        }
    }
}

The implementation shall provide the template shared_future and two specializations, shared_future<R&> and shared_future<void>. These differ only in the return type and return value of the member function get, as set out in its description, below.

shared_future() noexcept;

Effects: Constructs an empty shared_future object that does not refer to a shared state.

Ensures: valid() == false.

shared_future(const shared_future& rhs) noexcept;

Effects: Constructs a shared_future object that refers to the same shared state as rhs (if any).

Ensures: valid() returns the same value as rhs.valid().

shared_future(future<R>&& rhs) noexcept;

Effects: Move constructs a shared_future object that refers to the shared state that was originally referred to by rhs (if any).

Ensures:

(10.1) valid() returns the same value as rhs.valid() returned prior to the constructor invocation.

(10.2) rhs.valid() == false.

shared_future(shared_future&& rhs) noexcept;

Effects: Move constructs a shared_future object that refers to the shared state that was originally referred to by rhs (if any).

(11.1) Releases any shared state (32.6.5);

(11.2) destroys *this.

shared_future& operator=(shared_future&& rhs) noexcept;

Effects:
© ISO/IEC

§ 32.6.8 1538

(12.1) — Releases any shared state (32.6.5);
(12.2) — move assigns the contents of \( \text{rhs} \) to \(*\text{this}\).

\textbf{Ensures:}

(13.1) — valid() returns the same value as rhs.valid() returned prior to the assignment.
(13.2) — rhs.valid() == false.

\textbf{shared_future& operator\= (const shared_future& rhs) noexcept;}

\textbf{Effects:}

(14.1) — Releases any shared state (32.6.5);
(14.2) — assigns the contents of \( \text{rhs} \) to \(*\text{this}\). \textbf{[Note: As a result, \(*\text{this}\) refers to the same shared state as \( \text{rhs} \) (if any). — end note]}

\textbf{Ensures: valid() == rhs.valid().}

\textbf{const R& shared_future::get() const;}
\textbf{R& shared_future<R&>::get() const;}
\textbf{void shared_future<void>::get() const;}

\textbf{[Note: As described above, the template and its two required specializations differ only in the return type and return value of the member function get. — end note]}

\textbf{[Note: Access to a value object stored in the shared state is unsynchronized, so programmers should apply only those operations on R that do not introduce a data race (6.8.2). — end note]}

\textbf{Effects: wait()} until the shared state is ready, then retrieves the value stored in the shared state.

\textbf{Returns:}

(19.1) — shared_future::get() returns a const reference to the value stored in the object’s shared state. \textbf{[Note: Access through that reference after the shared state has been destroyed produces undefined behavior; this can be avoided by not storing the reference in any storage with a greater lifetime than the shared_future object that returned the reference. — end note]}
(19.2) — shared_future<R&>::get() returns the reference stored as value in the object’s shared state.
(19.3) — shared_future<void>::get() returns nothing.

\textbf{Throws:} The stored exception, if an exception was stored in the shared state.

\textbf{bool valid() const noexcept;}

\textbf{Returns:} \texttt{true} only if \(*\text{this}\) refers to a shared state.

\textbf{void wait() const;}

\textbf{Effects:} Blocks until the shared state is ready.

\textbf{template<class Rep, class Period>}
\textbf{future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;}

\textbf{Effects:} None if the shared state contains a deferred function (32.6.9), otherwise blocks until the shared state is ready or until the relative timeout (32.2.4) specified by \texttt{rel_time} has expired.

\textbf{Returns:}

(24.1) — future_status::deferred if the shared state contains a deferred function.
(24.2) — future_status::ready if the shared state is ready.
(24.3) — future_status::timeout if the function is returning because the relative timeout (32.2.4) specified by \texttt{rel_time} has expired.

\textbf{Throws:} timeout-related exceptions (32.2.4).

\textbf{template<class Clock, class Duration>}
\textbf{future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;}

\textbf{Effects:} None if the shared state contains a deferred function (32.6.9), otherwise blocks until the shared state is ready or until the absolute timeout (32.2.4) specified by \texttt{abs_time} has expired.

\textbf{Returns:}
future_status::deferred if the shared state contains a deferred function.

future_status::ready if the shared state is ready.

future_status::timeout if the function is returning because the absolute timeout (32.2.4) specified by abs_time has expired.

## 32.6.9 Function template async

The function template async provides a mechanism to launch a function potentially in a new thread and provides the result of the function in a future object with which it shares a shared state.

template<class F, class... Args>
  [[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
  async(F&& f, Args&&... args);

template<class F, class... Args>
  [[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
  async(launch policy, F&& f, Args&&... args);

Requires: F and each Ti in Args shall meet the Cpp17MoveConstructible requirements, and

\[
\text{INVOKE}(\text{decay-copy}((\text{forward}<F>(f))),
  \text{decay-copy}((\text{forward}<\text{Args}>(\text{args})))...) \quad // \text{see 20.14.3, 32.3.2.2}
\]

shall be a valid expression.

Effects: The first function behaves the same as a call to the second function with a policy argument of launch::async | launch::deferred and the same arguments for F and Args. The second function creates a shared state that is associated with the returned future object. The further behavior of the second function depends on the policy argument as follows (if more than one of these conditions applies, the implementation may choose any of the corresponding policies):

1. If launch::async is set in policy, calls

\[
\text{INVOKE}(\text{decay-copy}((\text{forward}<F>(f))),
  \text{decay-copy}((\text{forward}<\text{Args}>(\text{args})))...) \quad (20.14.3, 32.3.2.2)
\]

as if in a new thread of execution represented by a thread object with the calls to decay-copy being evaluated in the thread that called async. Any return value is stored as the result in the shared state. Any exception propagated from the execution of

\[
\text{INVOKE}(\text{decay-copy}((\text{forward}<F>(f))),
  \text{decay-copy}((\text{forward}<\text{Args}>(\text{args})))...) \quad // \text{see 20.14.3, 32.3.2.2}
\]

is stored as the exceptional result in the shared state. The thread object is stored in the shared state and affects the behavior of any asynchronous return objects that reference that state.

2. If launch::deferred is set in policy, stores

\[
\text{decay-copy}((\text{forward}<F>(f))) \quad \text{and} \quad \text{decay-copy}((\text{forward}<\text{Args}>(\text{args})))...
\]

in the shared state. These copies of f and args constitute a deferred function. Invocation of the deferred function evaluates

\[
\text{INVOKE}(\text{std::move}(g),
  \text{std::move}(\text{xyz})) \quad \text{where} \quad g \text{ is the stored value of} \quad \text{decay-copy}((\text{forward}<F>(f))) \quad \text{and} \quad \text{xyz is the stored copy of} \quad \text{decay-copy}((\text{forward}<\text{Args}>(\text{args})))...
\]

Any return value is stored as the result in the shared state. Any exception propagated from the execution of the deferred function is stored as the exceptional result in the shared state. The shared state is not made ready until the function has completed. The first call to a non-timed waiting function (32.6.5) on an asynchronous return object referring to this shared state shall invoke the deferred function in the thread that called the waiting function. Once evaluation of

\[
\text{INVOKE}(\text{std::move}(g),
  \text{std::move}(\text{xyz})) \quad \text{begins, the function is no longer considered deferred.} \quad \text{[Note: If this policy is specified together with other policies, such as when using a policy value of launch::async | launch::deferred, implementations should defer invocation or the selection of the policy when no more concurrency can be effectively exploited. — end note]}
\]

3. If no value is set in the launch policy, or a value is set that is neither specified in this document nor by the implementation, the behavior is undefined.

Returns: An object of type future<invoke_result_t<decay_t<F>, decay_t<Args>...>> that refers to the shared state created by this call to async. [Note: If a future obtained from async is moved outside the local scope, other code that uses the future should be aware that the future’s destructor may block for the shared state to become ready. — end note]

Synchronization: Regardless of the provided policy argument,
the invocation of \texttt{async} synchronizes with (6.8.2) the invocation of \texttt{f}. \textit{[Note: This statement applies even when the corresponding \texttt{future} object is moved to another thread. — end note]}

and

the completion of the function \texttt{f} is sequenced before (6.8.2) the shared state is made ready. \textit{[Note: \texttt{f} might not be called at all, so its completion might never happen. — end note]}

If the implementation chooses the \texttt{launch::async} policy,

a call to a waiting function on an asynchronous return object that shares the shared state created by this \texttt{async} call shall block until the associated thread has completed, as if joined, or else time out (32.3.2.5);

the associated thread completion synchronizes with (6.8.2) the return from the first function that successfully detects the ready status of the shared state or with the return from the last function that releases the shared state, whichever happens first.

\textit{Throws: system\_error} if \texttt{policy == launch::async} and the implementation is unable to start a new thread, or \texttt{std::bad\_alloc} if memory for the internal data structures could not be allocated.

\textit{Error conditions:}

\textit{— resource\_unavailable\_try\_again} — if \texttt{policy == launch::async} and the system is unable to start a new thread.

\textit{[Example:]}

\begin{verbatim}
int work1(int value);
int work2(int value);
int work(int value) {
  auto handle = std::async([=]{ return work2(value); });
  int tmp = work1(value);
  return tmp + handle.get(); // #1
}
\end{verbatim}

\textit{[Note: Line #1 might not result in concurrency because the \texttt{async} call uses the default policy, which may use \texttt{launch::deferred}, in which case the lambda might not be invoked until the \texttt{get()} call; in that case, \texttt{work1} and \texttt{work2} are called on the same thread and there is no concurrency. — end note]}

32.6.10 Class template \texttt{packaged\_task} \texttt{[futures.task]}

The class template \texttt{packaged\_task} defines a type for wrapping a function or callable object so that the return value of the function or callable object is stored in a future when it is invoked.

When the \texttt{packaged\_task} object is invoked, its stored task is invoked and the result (whether normal or exceptional) stored in the shared state. Any futures that share the shared state will then be able to access the stored result.

\begin{verbatim}
namespace std {
  template<class> class packaged_task; // not defined

  template<class R, class... ArgTypes>
  class packaged_task<R(ArgTypes...)> {
    public:
      // construction and destruction
      packaged_task() noexcept;
      template<class F>
      explicit packaged_task(F&& f);
      ~packaged_task();

      // no copy
      packaged_task(const packaged_task&) = delete;
      packaged_task& operator=(const packaged_task&) = delete;

      // move support
      packaged_task(packaged_task&& rhs) noexcept;
      packaged_task& operator=(packaged_task&& rhs) noexcept;
      void swap(packaged_task& other) noexcept;

      bool valid() const noexcept;
  }

\end{verbatim}
// result retrieval
future<R> get_future();

// execution
void operator()(ArgTypes...);
void make_ready_at_thread_exit(ArgTypes...);
void reset();

};

template<class R, class... ArgTypes>
void swap(packaged_task<R(ArgTypes...)>& x, packaged_task<R(ArgTypes...)>& y) noexcept;

32.6.10.1 Member functions

packaged_task() noexcept;

Effects: Constructs a packaged_task object with no shared state and no stored task.

template<class F>
packaged_task(F&& f);

Requires: INVOKE<R>(f, t1, t2, ..., tN) (20.14.3), where t1, t2, ..., tN are values of the corresponding types in ArgTypes..., shall be a valid expression. Invoking a copy of f shall behave the same as invoking f.

Remarks: This constructor shall not participate in overload resolution if remove_cvref_t<F> is the same type as packaged_task<R(ArgTypes...)>. Effects: Constructs a new packaged_task object with a shared state and initializes the object’s stored task with std::forward<F>(f).

Throws: Any exceptions thrown by the copy or move constructor of f, or bad_alloc if memory for the internal data structures could not be allocated.

packaged_task(packaged_task&& rhs) noexcept;

Effects: Constructs a new packaged_task object and transfers ownership of rhs’s shared state to *this, leaving rhs with no shared state. Moves the stored task from rhs to *this.

Ensures: rhs has no shared state.

packaged_task& operator=(packaged_task&& rhs) noexcept;

Effects:
(8.1) — Releases any shared state (32.6.5);
(8.2) — calls packaged_task(std::move(rhs)).swap(*this).

~packaged_task();

Effects: Abandons any shared state (32.6.5).

void swap(packaged_task& other) noexcept;

Effects: Exchanges the shared states and stored tasks of *this and other.

Ensures: *this has the same shared state and stored task (if any) as other prior to the call to swap. other has the same shared state and stored task (if any) as *this prior to the call to swap.

bool valid() const noexcept;

Returns: true only if *this has a shared state.

future<R> get_future();

Returns: A future object that shares the same shared state as *this.

Synchronization: Calls to this function do not introduce data races (6.8.2) with calls to operator() or make_ready_at_thread_exit. [Note: Such calls need not synchronize with each other. — end note]

Throws: A future_error object if an error occurs.
Error conditions:

— future_already_retrieved if get_future has already been called on a packaged_task object with the same shared state as *this.

— no_state if *this has no shared state.

void operator()(ArgTypes... args);

Effects: As if by \texttt{INVOKE}\texttt{<R>(f, t_1, t_2, ..., t_N)} (20.14.3), where \( f \) is the stored task of *this and \( t_1, t_2, ..., t_N \) are the values in \texttt{args}... If the task returns normally, the return value is stored as the asynchronous result in the shared state of *this, otherwise the exception thrown by the task is stored. The shared state of *this is made ready, and any threads blocked in a function waiting for the shared state of *this to become ready are unblocked.

Throws: A future_error exception object if there is no shared state or the stored task has already been invoked.

Error conditions:

— promise_already_satisfied if the stored task has already been invoked.

— no_state if *this has no shared state.

void make_ready_at_thread_exit(ArgTypes... args);

Effects: As if by \texttt{INVOKE}\texttt{<R>(f, t_1, t_2, ..., t_N)} (20.14.3), where \( f \) is the stored task and \( t_1, t_2, ..., t_N \) are the values in \texttt{args}... If the task returns normally, the return value is stored as the asynchronous result in the shared state of *this, otherwise the exception thrown by the task is stored. In either case, this shall be done without making that state ready (32.6.5) immediately. Schedules the shared state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

Throws: future_error if an error condition occurs.

Error conditions:

— promise_already_satisfied if the stored task has already been invoked.

— no_state if *this has no shared state.

void reset();

Effects: As if *this = packaged_task(std::move(f)), where \( f \) is the task stored in *this. [Note: This constructs a new shared state for *this. The old state is abandoned (32.6.5). — end note]

Throws:

— bad_alloc if memory for the new shared state could not be allocated.

— any exception thrown by the move constructor of the task stored in the shared state.

— future_error with an error condition of no_state if *this has no shared state.

32.6.10.2 Globals

\[
\text{template<class R, class... ArgTypes>}
\]
void swap(packaged_task<R(ArgTypes...)>& x, packaged_task<R(ArgTypes...)>& y) noexcept;

Effects: As if by \( x.\text{swap}(y) \).
Annex A  (informative)
Grammar summary  [gram]

1 This summary of C++ grammar is intended to be an aid to comprehension. It is not an exact statement of the language. In particular, the grammar described here accepts a superset of valid C++ constructs. Disambiguation rules (8.8, 9.1, 11.7) must be applied to distinguish expressions from declarations. Further, access control, ambiguity, and type rules must be used to weed out syntactically valid but meaningless constructs.

A.1 Keywords  [gram.key]
1 New context-dependent keywords are introduced into a program by typedef (9.1.3), namespace (9.7.1), class (Clause 11), enumeration (9.6), and template (Clause 13) declarations.

typedef-name:
  identifier
  simple-template-id

namespace-name:
  identifier
  namespace-alias

namespace-alias:
  identifier

class-name:
  identifier
  simple-template-id

enum-name:
  identifier

template-name:
  identifier

A.2 Lexical conventions  [gram.lex]

hex-quad:
  hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit

universal-character-name:
  \u hex-quad
  \U hex-quad hex-quad

preprocessing-token:
  header-name
  identifier
  pp-number
  character-literal
  user-defined-character-literal
  string-literal
  user-defined-string-literal
  preprocessing-op-or-punc
  each non-white-space character that cannot be one of the above

token:
  identifier
  keyword
  literal
  operator
  punctuator

header-name:
  < h-char-sequence >
  " q-char-sequence "

§ A.2
h-char-sequence:
h-char
  h-char-sequence h-char

h-char:
  any member of the source character set except new-line and >

q-char-sequence:
q-char
  q-char-sequence q-char

q-char:
  any member of the source character set except new-line and "

pp-number:
digit
  . digit
  pp-number digit
  pp-number identifier-nondigit
  pp-number ' digit
  pp-number ' nondigit
  pp-number e sign
  pp-number E sign
  pp-number p sign
  pp-number P sign
  pp-number .

Annex B  (informative)
Implementation quantities

1 Because computers are finite, C++ implementations are inevitably limited in the size of the programs they can successfully process. Every implementation shall document those limitations where known. This documentation may cite fixed limits where they exist, say how to compute variable limits as a function of available resources, or say that fixed limits do not exist or are unknown.

2 The limits may constrain quantities that include those described below or others. The bracketed number following each quantity is recommended as the minimum for that quantity. However, these quantities are only guidelines and do not determine compliance.

   (2.1) Nesting levels of compound statements (8.3), iteration control structures (8.5), and selection control structures (8.4) [256].
   (2.2) Nesting levels of conditional inclusion (15.1) [256].
   (2.3) Pointer (9.2.3.1), array (9.2.3.4), and function (9.2.3.5) declarators (in any combination) modifying a class, arithmetic, or incomplete type in a declaration [256].
   (2.4) Nesting levels of parenthesized expressions (7.5.3) within a full-expression [256].
   (2.5) Number of characters in an internal identifier (5.10) or macro name (15.5) [1024].
   (2.6) Number of characters in an external identifier (5.10, 6.5) [1024].
   (2.7) External identifiers (6.5) in one translation unit [65536].
   (2.8) Identifiers with block scope declared in one block (6.3.3) [1024].
   (2.9) Structured bindings (9.5) introduced in one declaration [256].
   (2.10) Macro identifiers (15.5) simultaneously defined in one translation unit [65536].
   (2.11) Parameters in one function definition (9.4.1) [256].
   (2.12) Arguments in one function call (7.6.1.2) [256].
   (2.13) Parameters in one macro definition (15.5) [256].
   (2.14) Arguments in one macro invocation (15.5) [256].
   (2.15) Characters in one logical source line (5.2) [65536].
   (2.16) Characters in a string literal (5.13.5) (after concatenation (5.2)) [65536].
   (2.17) Size of an object (6.6.2) [262144].
   (2.18) Nesting levels for #include files (15.2) [256].
   (2.19) Case labels for a switch statement (8.4.2) (excluding those for any nested switch statements) [16384].
   (2.20) Non-static data members (including inherited ones) in a single class (11.3) [16384].
   (2.21) Lambda-captures in one lambda-expression (7.5.5.2) [256].
   (2.22) Enumeration constants in a single enumeration (9.6) [4096].
   (2.23) Levels of nested class definitions (11.3.10) in a single member-specification [256].
   (2.24) Functions registered by atexit() (17.5) [32].
   (2.25) Functions registered by at_quick_exit() (17.5) [32].
   (2.26) Direct and indirect base classes (11.6) [16384].
   (2.27) Direct base classes for a single class (11.6) [1024].
   (2.28) Class members declared in a single member-specification (including member functions) (11.3) [4096].
   (2.29) Final overriding virtual functions in a class, accessible or not (11.6.2) [16384].
   (2.30) Direct and indirect virtual bases of a class (11.6.1) [1024].
(2.31) — Static data members of a class (11.3.8.2) [1024].
(2.32) — Friend declarations in a class (11.8.3) [4096].
(2.33) — Access control declarations in a class (11.8.1) [4096].
(2.34) — Member initializers in a constructor definition (11.9.2) [6144].
(2.35) — initializer-clauses in one braced-init-list (9.3) [16384].
(2.36) — Scope qualifications of one identifier (7.5.4.2) [256].
(2.37) — Nested linkage-specifications (9.10) [1024].
(2.38) — Recursive constexpr function invocations (9.1.5) [512].
(2.39) — Full-expressions evaluated within a core constant expression (7.7) [1048576].
(2.40) — Template parameters in a template declaration (13.1) [1024].
(2.41) — Recursively nested template instantiations (13.8.1), including substitution during template argument deduction (13.9.2) [1024].
(2.42) — Handlers per try block (14.3) [256].
(2.43) — Number of placeholders (20.14.14.4) [10].
Annex C  (informative)
Compatibility

C.1  C++ and ISO C

This subclause lists the differences between C++ and ISO C, by the chapters of this document.

C.1.1  Clause 5: lexical conventions

Affected subclause: 5.11
Change: New Keywords
New keywords are added to C++; see 5.11.
Rationale: These keywords were added in order to implement the new semantics of C++.
Effect on original feature: Change to semantics of well-defined feature. Any ISO C programs that used any of these keywords as identifiers are not valid C++ programs.
Difficulty of converting: Syntactic transformation. Converting one specific program is easy. Converting a large collection of related programs takes more work.
How widely used: Common.

Affected subclause: 5.13.3
Change: Type of character literal is changed from int to char.
Rationale: This is needed for improved overloaded function argument type matching. For example:

```c
int function( int i );
int function( char c );

function( 'x' );
```

It is preferable that this call match the second version of function rather than the first.
Effect on original feature: Change to semantics of well-defined feature. ISO C programs which depend on `sizeof('x') == sizeof(int)` will not work the same as C++ programs.
Difficulty of converting: Simple.
How widely used: Programs which depend upon `sizeof('x')` are probably rare.

Affected subclause: 5.13.5
Change: String literals made const.
The type of a string literal is changed from “array of char” to “array of const char”. The type of a UTF-8 string literal is changed from “array of char” to “array of const char8_t”. The type of a UTF-16 string literal is changed from “array of some-integer-type” to “array of const char16_t”. The type of a UTF-32 string literal is changed from “array of some-integer-type” to “array of const char32_t”. The type of a wide string literal is changed from “array of wchar_t” to “array of const wchar_t”.
Rationale: This avoids calling an inappropriate overloaded function, which might expect to be able to modify its argument.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Syntactic transformation. The fix is to add a cast:

```c
char* p = "abc";  // valid in C, invalid in C++
void f(char*) {
    char* p = (char*)"abc";  // OK: cast added
    f(p);
    f((char*)"def");  // OK: cast added
}
```

How widely used: Programs that have a legitimate reason to treat string literals as pointers to potentially modifiable memory are probably rare.
C.1.2 Clause 6: basics

1 Affected subclause: 6.1
Change: C++ does not have “tentative definitions” as in C.
E.g., at file scope,

```
int i;
```

is valid in C, invalid in C++. This makes it impossible to define mutually referential file-local static objects, if initializers are restricted to the syntactic forms of C. For example,
```
struct X { int i; struct X* next; };
```
```
static struct X a;
static struct X b = { 0, &a };
static struct X a = { 1, &b };
```

Rationale: This avoids having different initialization rules for fundamental types and user-defined types.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. In C++, the initializer for one of a set of mutually-referential file-local static objects must invoke a function call to achieve the initialization.
How widely used: Seldom.

2 Affected subclause: 6.3
Change: A struct is a scope in C++, not in C.
Rationale: Class scope is crucial to C++, and a struct is a class.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: C programs use struct extremely frequently, but the change is only noticeable when struct, enumeration, or enumerator names are referred to outside the struct. The latter is probably rare.

3 Affected subclause: 6.5 [also 9.1.7]
Change: A name of file scope that is explicitly declared const, and not explicitly declared extern, has internal linkage, while in C it would have external linkage.
Rationale: Because const objects may be used as values during translation in C++, this feature urges programmers to provide an explicit initializer for each const object. This feature allows the user to put const objects in source files that are included in more than one translation unit.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Seldom.

4 Affected subclause: 6.8.3.1
Change: The main function cannot be called recursively and cannot have its address taken.
Rationale: The main function may require special actions.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Trivial: create an intermediary function such as mymain(argc, argv).
How widely used: Seldom.

5 Affected subclause: 6.7
Change: C allows “compatible types” in several places, C++ does not.
For example, otherwise-identical struct types with different tag names are “compatible” in C but are distinctly different types in C++.
Rationale: Stricter type checking is essential for C++.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. The “typesafe linkage” mechanism will find many, but not all, of such problems. Those problems not found by typesafe linkage will continue to function properly, according to the “layout compatibility rules” of this document.
How widely used: Common.

C.1.3 Clause 7: expressions

1 Affected subclause: 7.3.11
Change: Converting void* to a pointer-to-object type requires casting.
```
char a[10];
```
void* b = a;
void foo() {
    char* c = b;
}

ISO C will accept this usage of pointer to void being assigned to a pointer to object type. C++ will not.

Rationale: C++ tries harder than C to enforce compile-time type safety.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Could be automated. Violations will be diagnosed by the C++ translator. The fix is to add a cast. For example:

```c
char* c = (char*) b;
```

How widely used: This is fairly widely used but it is good programming practice to add the cast when assigning pointer-to-void to pointer-to-object. Some ISO C translators will give a warning if the cast is not used.

2 Affected subclause: 7.6.1.2
Change: Implicit declaration of functions is not allowed.
Rationale: The type-safe nature of C++.

Effect on original feature: Deletion of semantically well-defined feature. Note: the original feature was labeled as “obsolete” in ISO C.

Difficulty of converting: Syntactic transformation. Facilities for producing explicit function declarations are fairly widespread commercially.

How widely used: Common.

3 Affected subclauses: 7.6.1.5 and 7.6.2.2
Change: Decrement operator is not allowed with bool operand.
Rationale: Feature with surprising semantics.

Effect on original feature: A valid ISO C expression utilizing the decrement operator on a bool lvalue (for instance, via the C typedef in <stdbool.h>) is ill-formed in this International Standard.

4 Affected subclauses: 7.6.2.4 and 7.6.3
Change: Types must be defined in declarations, not in expressions.
In C, a sizeof expression or cast expression may define a new type. For example,

```c
p = (void*)(struct x {int i;} *)0;
```

defines a new type, struct x.

Rationale: This prohibition helps to clarify the location of definitions in the source code.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Seldom.

5 Affected subclauses: 7.6.16, 7.6.19, and 7.6.20
Change: The result of a conditional expression, an assignment expression, or a comma expression may be an lvalue.

Rationale: C++ is an object-oriented language, placing relatively more emphasis on lvalues. For example, function calls may yield lvalues.

Effect on original feature: Change to semantics of well-defined feature. Some C expressions that implicitly rely on lvalue-to-rvalue conversions will yield different results. For example,

```c
char arr[100];
sizeof(0, arr)
```
yields 100 in C++ and sizeof(char*) in C.

Difficulty of converting: Programs must add explicit casts to the appropriate rvalue.

How widely used: Rare.

C.1.4 Clause 8: statements

1 Affected subclauses: 8.4.2 and 8.6.5
Change: It is now invalid to jump past a declaration with explicit or implicit initializer (except across entire block not entered).

Rationale: Constructors used in initializers may allocate resources which need to be de-allocated upon leaving the block. Allowing jump past initializers would require complicated runtime determination of
allocation. Furthermore, any use of the uninitialized object could be a disaster. With this simple compile-time rule, C++ assures that if an initialized variable is in scope, then it has assuredly been initialized.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation.

**How widely used:** Seldom.

2. **Affected subclause:** 8.6.3

**Change:** It is now invalid to return (explicitly or implicitly) from a function which is declared to return a value without actually returning a value.

**Rationale:** The caller and callee may assume fairly elaborate return-value mechanisms for the return of class objects. If some flow paths execute a return without specifying any value, the implementation must embody many more complications. Besides, promising to return a value of a given type, and then not returning such a value, has always been recognized to be a questionable practice, tolerated only because very-old C had no distinction between void functions and int functions.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. Add an appropriate return value to the source code, such as zero.

**How widely used:** Seldom. For several years, many existing C implementations have produced warnings in this case.

**C.1.5 Clause 9: declarations**

1. **Affected subclause:** 9.1.1

**Change:** In C++, the `static` or `extern` specifiers can only be applied to names of objects or functions. Using these specifiers with type declarations is illegal in C++. In C, these specifiers are ignored when used on type declarations.

Example:

```c
static struct S { // valid C, invalid in C++
  int i;
};
```

**Rationale:** Storage class specifiers don’t have any meaning when associated with a type. In C++, class members can be declared with the `static` storage class specifier. Allowing storage class specifiers on type declarations could render the code confusing for users.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Syntactic transformation.

**How widely used:** Seldom.

2. **Affected subclause:** 9.1.1

**Change:** In C++, `register` is not a storage class specifier.

**Rationale:** The storage class specifier had no effect in C++.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Syntactic transformation.

**How widely used:** Common.

3. **Affected subclause:** 9.1.3

**Change:** A C++ typedef name must be different from any class type name declared in the same scope (except if the typedef is a synonym of the class name with the same name). In C, a typedef name and a struct tag name declared in the same scope can have the same name (because they have different name spaces).

Example:

```c
typedef struct name1 { /* ... */ } name1; // valid C and C++
struct name { /* ... */ }; // valid C, invalid C++
typedef int name; // valid C, invalid C++
```

**Rationale:** For ease of use, C++ doesn’t require that a type name be prefixed with the keywords `class`, `struct` or `union` when used in object declarations or type casts.

Example:

```c
class name { /* ... */ };
name i; // i has type class name
```
Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. One of the 2 types has to be renamed.

How widely used: Seldom.

4 Affected subclause: 9.1.7 [see also 6.5]
Change: Const objects must be initialized in C++ but can be left uninitialized in C.

Rationale: A const object cannot be assigned to so it must be initialized to hold a useful value.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation.

How widely used: Seldom.

5 Affected subclause: 9.1.7
Change: Banning implicit int.

In C++ a decl-specifier-seq must contain a type-specifier, unless it is followed by a declarator for a constructor, a destructor, or a conversion function. In the following example, the left-hand column presents valid C; the right-hand column presents equivalent C++:

```c
void f(const parm);
const n = 3;
main()
    int main()
    /* ... */
```

```c++
void f(const int parm);
const int n = 3;
int main()
    /* ... */
```

Rationale: In C++, implicit int creates several opportunities for ambiguity between expressions involving function-like casts and declarations. Explicit declaration is increasingly considered to be proper style. Liaison with WG14 (C) indicated support for (at least) deprecating implicit int in the next revision of C.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation. Could be automated.

How widely used: Common.

6 Affected subclause: 9.1.7.5
Change: The keyword auto cannot be used as a storage class specifier.

```c
void f() {
    auto int x;  // valid C, invalid C++
}
```

Rationale: Allowing the use of auto to deduce the type of a variable from its initializer results in undesired interpretations of auto as a storage class specifier in certain contexts.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Rare.

7 Affected subclause: 9.2.3.5
Change: In C++, a function declared with an empty parameter list takes no arguments. In C, an empty parameter list means that the number and type of the function arguments are unknown.

Example:

```c
int f();  // means int f(void) in C++
```

Rationale: This is to avoid erroneous function calls (i.e., function calls with the wrong number or type of arguments).

Effect on original feature: Change to semantics of well-defined feature. This feature was marked as “obsolete” in C.

Difficulty of converting: Syntactic transformation. The function declarations using C incomplete declaration style must be completed to become full prototype declarations. A program may need to be updated further if different calls to the same (non-prototype) function have different numbers of arguments or if the type of corresponding arguments differed.

How widely used: Common.
Affected subclause: 9.2.3.5 [see 7.6.2.4]
Change: In C++, types may not be defined in return or parameter types. In C, these type definitions are allowed.
Example:
```c
void f(struct S { int a; } arg) {} // valid C, invalid C++
enum E { A, B, C } f() {} // valid C, invalid C++
```

Rationale: When comparing types in different translation units, C++ relies on name equivalence when C relies on structural equivalence. Regarding parameter types: since the type defined in a parameter list would be in the scope of the function, the only legal calls in C++ would be from within the function itself.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. The type definitions must be moved to file scope, or in header files.

How widely used: Seldom. This style of type definition is seen as poor coding style.

Affected subclause: 9.4
Change: In C++, the syntax for function definition excludes the “old-style” C function. In C, “old-style” syntax is allowed, but deprecated as “obsolescent”.

Rationale: Prototypes are essential to type safety.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Common in old programs, but already known to be obsolescent.

Affected subclause: 9.3.1
Change: In C++, designated initialization support is restricted compared to the corresponding functionality in C. In C++, designators for non-static data members must be specified in declaration order, designators for array elements and nested designators are not supported, and designated and non-designated initializers cannot be mixed in the same initializer list.

Example:
```c
struct A { int x, y; };
struct B { struct A a; };
struct A a = {.y = 1, .x = 2}; // valid C, invalid C++
int arr[3] = {{1} = 5}; // valid C, invalid C++
struct B b = {.a.x = 0}; // valid C, invalid C++
struct A c = {.x = 1, 2}; // valid C, invalid C++
```

Rationale: In C++, members are destroyed in reverse construction order and the elements of an initializer list are evaluated in lexical order, so field initializers must be specified in order. Array designators conflict with lambda-expression syntax. Nested designators are seldom used.

Effect on original feature: Deletion of feature that is incompatible with C++.

Difficulty of converting: Syntactic transformation.

How widely used: Out-of-order initializers are common. The other features are seldom used.

Affected subclause: 9.3.2
Change: In C++, when initializing an array of character with a string, the number of characters in the string (including the terminating ‘\0’) must not exceed the number of elements in the array. In C, an array can be initialized with a string even if the array is not large enough to contain the string-terminating ‘\0’.

Example:
```c
char array[4] = "abcd"; // valid C, invalid C++
```

Rationale: When these non-terminated arrays are manipulated by standard string functions, there is potential for major catastrophe.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. The arrays must be declared one element bigger to contain the string terminating ‘\0’.

How widely used: Seldom. This style of array initialization is seen as poor coding style.
12 Affected subclause: 9.6
Change: C++ objects of enumeration type can only be assigned values of the same enumeration type. In C, objects of enumeration type can be assigned values of any integral type.

Example:
```
enum color { red, blue, green};
enum color c = 1;  // valid C, invalid C++
```

Rationale: The type-safe nature of C++.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation. (The type error produced by the assignment can be automatically corrected by applying an explicit cast.)
How widely used: Common.

13 Affected subclause: 9.6
Change: In C++, the type of an enumerator is its enumeration. In C, the type of an enumerator is int.

Example:
```
enum e { A };
sizeof(A) == sizeof(int)  // in C
sizeof(A) == sizeof(e)   // in C++
/* and sizeof(int) is not necessarily equal to sizeof(e) */
```

Rationale: In C++, an enumeration is a distinct type.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Seldom. The only time this affects existing C code is when the size of an enumerator is taken. Taking the size of an enumerator is not a common C coding practice.

C.1.6 Clause 11: classes

1 Affected subclause: 11.2 [see also 9.1.3]
Change: In C++, a class declaration introduces the class name into the scope where it is declared and hides any object, function or other declaration of that name in an enclosing scope. In C, an inner scope declaration of a struct tag name never hides the name of an object or function in an outer scope.

Example:
```
int x[99];
void f() {
    struct x { int a; };
    sizeof(x);  // size of the array in C */
    /* size of the struct in C++ */
}
```

Rationale: This is one of the few incompatibilities between C and C++ that can be attributed to the new C++ name space definition where a name can be declared as a type and as a non-type in a single scope causing the non-type name to hide the type name and requiring that the keywords class, struct, union or enum be used to refer to the type name. This new name space definition provides important notational conveniences to C++ programmers and helps making the use of the user-defined types as similar as possible to the use of fundamental types. The advantages of the new name space definition were judged to outweigh by far the incompatibility with C described above.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation. If the hidden name that needs to be accessed is at global scope, the :: C++ operator can be used. If the hidden name is at block scope, either the type or the struct tag has to be renamed.
How widely used: Seldom.

2 Affected subclause: 11.3.4.2
Change: Copying volatile objects.
The implicitly-declared copy constructor and implicitly-declared copy assignment operator cannot make a copy of a volatile lvalue. For example, the following is valid in ISO C:
struct X { int i; };
volatile struct X x1 = {0};
struct X x2 = x1; // invalid C++
struct X x3;
x3 = x1; // also invalid C++

Rationale: Several alternatives were debated at length. Changing the parameter to volatile const X& would greatly complicate the generation of efficient code for class objects. Discussion of providing two alternative signatures for these implicitly-defined operations raised unanswered concerns about creating ambiguities and complicating the rules that specify the formation of these operators according to the bases and members.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. If volatile semantics are required for the copy, a user-declared constructor or assignment must be provided. If non-volatile semantics are required, an explicit const_cast can be used.

How widely used: Seldom.

Affected subclause: 11.3.9
Change: Bit-fields of type plain int are signed.
Rationale: Leaving the choice of signedness to implementations could lead to inconsistent definitions of template specializations. For consistency, the implementation freedom was eliminated for non-dependent types, too.

Effect on original feature: The choice is implementation-defined in C, but not so in C++.

Difficulty of converting: Syntactic transformation.

How widely used: Seldom.

Affected subclause: 11.3.10
Change: In C++, the name of a nested class is local to its enclosing class. In C the name of the nested class belongs to the same scope as the name of the outermost enclosing class.

Example:
```c
struct X {
    struct Y { /* ... */ } y;
};
struct Y yy; // valid C, invalid C++
```

Rationale: C++ classes have member functions which require that classes establish scopes. The C rule would leave classes as an incomplete scope mechanism which would prevent C++ programmers from maintaining locality within a class. A coherent set of scope rules for C++ based on the C rule would be very complicated and C++ programmers would be unable to predict reliably the meanings of nontrivial examples involving nested or local functions.

Effect on original feature: Change to semantics of well-defined feature.

Difficulty of converting: Semantic transformation. To make the struct type name visible in the scope of the enclosing struct, the struct tag could be declared in the scope of the enclosing struct, before the enclosing struct is defined. Example:
```c
struct Y; // struct Y and struct X are at the same scope
struct X {
    struct Y { /* ... */ } y;
};
```

All the definitions of C struct types enclosed in other struct definitions and accessed outside the scope of the enclosing struct could be exported to the scope of the enclosing struct. Note: this is a consequence of the difference in scope rules, which is documented in 6.3.

How widely used: Seldom.

Affected subclause: 11.3.11
Change: In C++, a typedef name may not be redeclared in a class definition after being used in that definition.

Example:
```c
typedef int I;
```
struct S {
    I i;
    int I;    // valid C, invalid C++
};

Rationale: When classes become complicated, allowing such a redefinition after the type has been used can create confusion for C++ programmers as to what the meaning of I really is.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. Either the type or the struct member has to be renamed.

How widely used: Seldom.

C.1.7 Clause 15: preprocessing directives
[diff.cpp]

- Affected subclause: 15.10
- Change: Whether `__STDC__` is defined and if so, what its value is, are implementation-defined.
- Rationale: C++ is not identical to ISO C. Mandating that `__STDC__` be defined would require that translators make an incorrect claim. Each implementation must choose the behavior that will be most useful to its marketplace.
- Effect on original feature: Change to semantics of well-defined feature.
- Difficulty of converting: Semantic transformation.
- How widely used: Programs and headers that reference `__STDC__` are quite common.

C.2 C++ and ISO C++ 2003
[diff.cpp03]

- This subclause lists the differences between C++ and ISO C++ 2003 (ISO/IEC 14882:2003, Programming Languages — C++), by the chapters of this document.

C.2.1 Clause 5: lexical conventions
[diff.cpp03.lex]

- Affected subclause: 5.4
- Change: New kinds of string literals.
- Rationale: Required for new features.
- Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. Specifically, macros named R, u8, u8R, u, uR, U, UR, or LR will not be expanded when adjacent to a string literal but will be interpreted as part of the string literal. For example:

```
#define u8 "abc"
const char* s = u8"def";    // Previously "abcdef", now "def"
```

- Affected subclause: 5.4
- Change: User-defined literal string support.
- Rationale: Required for new features.
- Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. For example:

```
#define _x "there"
"hello"_x    // #1
```

Previously, #1 would have consisted of two separate preprocessing tokens and the macro _x would have been expanded. In this International Standard, #1 consists of a single preprocessing token, so the macro is not expanded.

- Affected subclause: 5.11
- Change: New keywords.
- Rationale: Required for new features.
- Effect on original feature: Added to Table 5, the following identifiers are new keywords: alignas, alignof, char16_t, char32_t, constexpr, decltype, noexcept, nullptr, static_assert, and thread_local. Valid C++ 2003 code using these identifiers is invalid in this International Standard.

- Affected subclause: 5.13.2
- Change: Type of integer literals.
- Rationale: C99 compatibility.
- Effect on original feature: Certain integer literals larger than can be represented by long could change from an unsigned integer type to signed long long.
C.2.2 Clause 7: expressions

1 Affected subclause: 7.3.11
   Change: Only literals are integer null pointer constants.
   Rationale: Removing surprising interactions with templates and constant expressions.
   Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. For example:
   ```
   void f(void *); // #1
   void f(...); // #2
   template<int N> void g() {
     f(0*N); // calls #2; used to call #1
   }
   ```

2 Affected subclause: 7.6.5
   Change: Specify rounding for results of integer / and %.
   Rationale: Increase portability, C99 compatibility.
   Effect on original feature: Valid C++ 2003 code that uses integer division rounds the result toward 0 or toward negative infinity, whereas this International Standard always rounds the result toward 0.

3 Affected subclause: 7.6.14
   Change: && is valid in a type-name.
   Rationale: Required for new features.
   Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. For example:
   ```
   bool b1 = new int && false; // previously false, now ill-formed
   struct S { operator int(); }; // previously ill-formed
   bool b2 = &S::operator int && false; // previously false, now ill-formed
   ```

C.2.3 Clause 9: declarations

1 Affected subclause: 9.1
   Change: Remove auto as a storage class specifier.
   Rationale: New feature.
   Effect on original feature: Valid C++ 2003 code that uses the keyword auto as a storage class specifier may be invalid in this International Standard. In this International Standard, auto indicates that the type of a variable is to be deduced from its initializer expression.

2 Affected subclause: 9.3.4
   Change: Narrowing restrictions in aggregate initializers.
   Rationale: Catches bugs.
   Effect on original feature: Valid C++ 2003 code may fail to compile in this International Standard. For example, the following code is valid in C++ 2003 but invalid in this International Standard because double to int is a narrowing conversion:
   ```
   int x[] = { 2.0 }; // previously ill-formed
   ```

C.2.4 Clause 11: classes

1 Affected subclauses: 11.3.4.1, 11.3.6, 11.3.4.2, and 11.3.5
   Change: Implicitly-declared special member functions are defined as deleted when the implicit definition would have been ill-formed.
   Rationale: Improves template argument deduction failure.
   Effect on original feature: A valid C++ 2003 program that uses one of these special member functions in a context where the definition is not required (e.g., in an expression that is not potentially evaluated) becomes ill-formed.

2 Affected subclause: 11.3.6
   Change: User-declared destructors have an implicit exception specification.
   Rationale: Clarification of destructor requirements.
   Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard. In particular, destructors that throw exceptions will call std::terminate (without calling std::unexpected) if their exception specification is non-throwing.
C.2.5 Clause 13: templates

1. **Affected subclause:** 13.1
   **Change:** Remove `export`.
   **Rationale:** No implementation consensus.
   **Effect on original feature:** A valid C++ 2003 declaration containing `export` is ill-formed in this International Standard.

2. **Affected subclause:** 13.3
   **Change:** Remove whitespace requirement for nested closing template right angle brackets.
   **Rationale:** Considered a persistent but minor annoyance. Template aliases representing non-class types would exacerbate whitespace issues.
   **Effect on original feature:** Change to semantics of well-defined expression. A valid C++ 2003 expression containing a right angle bracket (“>”) followed immediately by another right angle bracket may now be treated as closing two templates. For example, the following code is valid in C++ 2003 because “>>>” is a right-shift operator, but invalid in this International Standard because “>>>” closes two templates.

   ```cpp
   template <class T> struct X { };
   template <int N> struct Y { };
   X< Y< 1 >> 2 > x;
   ```

3. **Affected subclause:** 13.7.4.2
   **Change:** Allow dependent calls of functions with internal linkage.
   **Rationale:** Overly constrained, simplify overload resolution rules.
   **Effect on original feature:** A valid C++ 2003 program could get a different result than this International Standard.

C.2.6 Clause 16: library introduction

1. **Affected:** Clause 16 – Clause 32
   **Change:** New reserved identifiers.
   **Rationale:** Required by new features.
   **Effect on original feature:** Valid C++ 2003 code that uses any identifiers added to the C++ standard library by this International Standard may fail to compile or produce different results in this International Standard. A comprehensive list of identifiers used by the C++ standard library can be found in the Index of Library Names in this International Standard.

2. **Affected subclause:** 16.5.1.2
   **Change:** New headers.
   **Rationale:** New functionality.
   **Effect on original feature:** The following C++ headers are new: `<array>`, `<atomic>`, `<chrono>`, `<codecvt>`, `<condition_variable>`, `<forward_list>`, `<future>`, `<initializer_list>`, `<mutex>`, `<random>`, `<ratio>`, `<regex>`, `<scoped_allocator>`, `<system_error>`, `<thread>`, `<tuple>`, `<typeindex>`, `<type_traits>`, `<unordered_map>`, and `<unordered_set>`. In addition the following C compatibility headers are new: `<cfenv>`, `<cinttypes>`, `<cstdint>`, and `<cuchar>`. Valid C++ 2003 code that includes headers with these names may be invalid in this International Standard.

3. **Affected subclause:** 16.5.3.2
   **Effect on original feature:** Function `swap` moved to a different header
   **Rationale:** Remove dependency on `<algorithm>` for `swap`.
   **Effect on original feature:** Valid C++ 2003 code that has been compiled expecting swap to be in `<algorithm>` may have to instead include `<utility>`.

4. **Affected subclause:** 16.5.4.2.2
   **Change:** New reserved namespace.
   **Rationale:** New functionality.
   **Effect on original feature:** The global namespace `posix` is now reserved for standardization. Valid C++ 2003 code that uses a top-level namespace `posix` may be invalid in this International Standard.

5. **Affected subclause:** 16.5.5.3
   **Change:** Additional restrictions on macro names.
   **Rationale:** Avoid hard to diagnose or non-portable constructs.
   **Effect on original feature:** Names of attribute identifiers may not be used as macro names. Valid C++ 2003 code that defines `override`, `final`, `carries_dependency`, or `noreturn` as macros is invalid in this International Standard.
C.2.7 Clause 17: language support library

1 Affected subclause: 17.6.2.1
Change: `operator new` may throw exceptions other than `std::bad_alloc`.
Rationale: Consistent application of `noexcept`.
Effect on original feature: Valid C++ 2003 code that assumes that global `operator new` only throws `std::bad_alloc` may execute differently in this International Standard. Valid C++ 2003 code that replaces the global replaceable `operator new` is ill-formed in this International Standard, because the exception specification of `throw(std::bad_alloc)` was removed.

C.2.8 Clause 19: diagnostics library

1 Affected subclause: 19.4
Change: Thread-local error numbers.
Rationale: Support for new thread facilities.
Effect on original feature: Valid but implementation-specific C++ 2003 code that relies on `errno` being the same across threads may change behavior in this International Standard.

C.2.9 Clause 20: general utilities library

1 Affected subclause: 20.10.5
Change: Minimal support for garbage-collected regions.
Rationale: Required by new feature.
Effect on original feature: Valid C++ 2003 code, compiled without traceable pointer support, that interacts with newer C++ code using regions declared reachable may have different runtime behavior.

Change: Standard function object types no longer derived from `std::unary_function` or `std::binary_function`.
Rationale: Superseded by new feature; `unary_function` and `binary_function` are no longer defined.
Effect on original feature: Valid C++ 2003 code that depends on function object types being derived from `unary_function` or `binary_function` may fail to compile in this International Standard.

C.2.10 Clause 21: strings library

1 Affected subclause: 21.3
Change: `basic_string` requirements no longer allow reference-counted strings.
Rationale: Invalidation is subtly different with reference-counted strings. This change regularizes behavior for this International Standard.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard.

2 Affected subclause: 21.3.2.1
Change: Loosen `basic_string` invalidation rules.
Rationale: Allow small-string optimization.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard. Some `const` member functions, such as `data` and `c_str`, no longer invalidate iterators.

C.2.11 Clause 22: containers library

1 Affected subclause: 22.2
Change: Complexity of `size()` member functions now constant.
Rationale: Lack of specification of complexity of `size()` resulted in divergent implementations with inconsistent performance characteristics.
Effect on original feature: Some container implementations that conform to C++ 2003 may not conform to the specified `size()` requirements in this International Standard. Adjusting containers such as `std::list` to the stricter requirements may require incompatible changes.

2 Affected subclause: 22.2
Change: Requirements change: relaxation.
Rationale: Clarification.
Effect on original feature: Valid C++ 2003 code that attempts to meet the specified container requirements may now be over-specified. Code that attempted to be portable across containers may need to be adjusted as follows:

(2.1) not all containers provide `size()`; use `empty()` instead of `size() == 0`;

§ C.2.11 1577
(2.2) — not all containers are empty after construction (array);
(2.3) — not all containers have constant complexity for swap() (array).

3 **Affected subclause:** 22.2

**Change:** Requirements change: default constructible.

**Rationale:** Clarification of container requirements.

**Effect on original feature:** Valid C++ 2003 code that attempts to explicitly instantiate a container using a user-defined type with no default constructor may fail to compile.

4 **Affected subclauses:** 22.2.3 and 22.2.6

**Change:** Signature changes: from void return types.

**Rationale:** Old signature threw away useful information that may be expensive to recalculate.

**Effect on original feature:** The following member functions have changed:

- (4.1) — erase(iter) for set, multiset, map, multimap
- (4.2) — erase(begin, end) for set, multiset, map, multimap
- (4.3) — insert(pos, num, val) for vector, deque, list, forward_list
- (4.4) — insert(pos, beg, end) for vector, deque, list, forward_list

Valid C++ 2003 code that relies on these functions returning void (e.g., code that creates a pointer to member function that points to one of these functions) will fail to compile with this International Standard.

5 **Affected subclauses:** 22.2.3 and 22.2.6

**Change:** Signature changes: from iterator to const_iterator parameters.

**Rationale:** Overspecification.

**Effect on original feature:** The signatures of the following member functions changed from taking an iterator to taking a const_iterator:

- (5.1) — insert(iter, val) for vector, deque, list, set, multiset, map, multimap
- (5.2) — insert(pos, beg, end) for vector, deque, list, forward_list
- (5.3) — erase(begin, end) for set, multiset, map, multimap
- (5.4) — all forms of list::splice
- (5.5) — all forms of list::merge

Valid C++ 2003 code that uses these functions may fail to compile with this International Standard.

6 **Affected subclauses:** 22.2.3 and 22.2.6

**Change:** Signature changes: resize.

**Rationale:** Performance, compatibility with move semantics.

**Effect on original feature:** For vector, deque, and list the fill value passed to resize is now passed by reference instead of by value, and an additional overload of resize has been added. Valid C++ 2003 code that uses this function may fail to compile with this International Standard.

C.2.12 **Clause 25:** algorithms library

1 **Affected subclause:** 25.1

**Change:** Result state of inputs after application of some algorithms.

**Rationale:** Required by new feature.

**Effect on original feature:** A valid C++ 2003 program may detect that an object with a valid but unspecified state has a different valid but unspecified state with this International Standard. For example, std::remove and std::remove_if may leave the tail of the input sequence with a different set of values than previously.

C.2.13 **Clause 26:** numerics library

1 **Affected subclause:** 26.4

**Change:** Specified representation of complex numbers.

**Rationale:** Compatibility with C99.

**Effect on original feature:** Valid C++ 2003 code that uses implementation-specific knowledge about the binary representation of the required template specializations of std::complex may not be compatible with this International Standard.
C.2.14 Clause 29: input/output library

Affected subclauses: 29.7.4.1.3, 29.7.5.1.3, and 29.5.5.4

Change: Specify use of explicit in existing boolean conversion functions.

Rationale: Clarify intentions, avoid workarounds.

Effect on original feature: Valid C++ 2003 code that relies on implicit boolean conversions will fail to compile with this International Standard. Such conversions occur in the following conditions:

1. passing a value to a function that takes an argument of type bool;
2. using operator== to compare to false or true;
3. returning a value from a function with a return type of bool;
4. initializing members of type bool via aggregate initialization;
5. initializing a const bool& which would bind to a temporary object.

1.2 Affected subclause: 29.5.3.1.1

Change: Change base class of std::ios_base::failure.

Rationale: More detailed error messages.

Effect on original feature: std::ios_base::failure is no longer derived directly from std::exception, but is now derived from std::system_error, which in turn is derived from std::runtime_error. Valid C++ 2003 code that assumes that std::ios_base::failure is derived directly from std::exception may execute differently in this International Standard.

1.3 Affected subclause: 29.5.3

Change: Flag types in std::ios_base are now bitmasks with values defined asconstexpr static members.

Rationale: Required for new features.

Effect on original feature: Valid C++ 2003 code that relies on std::ios_base flag types being represented as std::bitset or as an integer type may fail to compile with this International Standard. For example:

```cpp
#include <iostream>

int main() {
    int flag = std::ios_base::hex;
    std::cout.setf(flag); // error: setf does not take argument of type int
}
```

C.3 C++ and ISO C++ 2011

This subclause lists the differences between C++ and ISO C++ 2011 (ISO/IEC 14882:2011, Programming Languages — C++), by the chapters of this document.

C.3.1 Clause 5: lexical conventions

Affected subclause: 5.9

Change: pp-number can contain one or more single quotes.

Rationale: Necessary to enable single quotes as digit separators.

Effect on original feature: Valid C++ 2011 code may fail to compile or may change meaning in this International Standard. For example, the following code is valid both in C++ 2011 and in this International Standard, but the macro invocation produces different outcomes because the single quotes delimit a character literal in C++ 2011, whereas they are digit separators in this International Standard:

```cpp
#define M(x, ...) __VA_ARGS__
int x[2] = { M(1'2,3'4, 5) };
// int x[2] = { 3'4, 5 }; — this International Standard
```

C.3.2 Clause 6: basics

Affected subclause: 6.6.5.4.2

Change: New usual (non-placement) deallocator.

Rationale: Required for sized deallocation.

Effect on original feature: Valid C++ 2011 code could declare a global placement allocation function and deallocation function as follows:

```cpp
void* operator new(std::size_t, std::size_t);
void operator delete(void*, std::size_t) noexcept;
```
N4820

© ISO/IEC

In this International Standard, however, the declaration of operator delete might match a predefined usual
(non-placement) operator delete (6.6.5.4). If so, the program is ill-formed, as it was for class member
allocation functions and deallocation functions (7.6.2.7).

C.3.3
1

Clause 7: expressions

[diff.cpp11.expr]

Affected subclause: 7.6.16
Change: A conditional expression with a throw expression as its second or third operand keeps the type
and value category of the other operand.
Rationale: Formerly mandated conversions (lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and functionto-pointer (7.3.3) standard conversions), especially the creation of the temporary due to lvalue-to-rvalue
conversion, were considered gratuitous and surprising.
Effect on original feature: Valid C++ 2011 code that relies on the conversions may behave differently in
this International Standard:
struct S {
int x = 1;
void mf() { x = 2; }
};
int f(bool cond) {
S s;
(cond ? s : throw 0).mf();
return s.x;
}

In C++ 2011, f(true) returns 1. In this International Standard, it returns 2.
sizeof(true ? "" : throw 0)

In C++ 2011, the expression yields sizeof(const char*).
sizeof(const char[1]).

C.3.4
1

In this International Standard, it yields

Clause 9: declarations

[diff.cpp11.dcl.dcl]

Affected subclause: 9.1.5
Change: constexpr non-static member functions are not implicitly const member functions.
Rationale: Necessary to allow constexpr member functions to mutate the object.
Effect on original feature: Valid C++ 2011 code may fail to compile in this International Standard. For
example, the following code is valid in C++ 2011 but invalid in this International Standard because it declares
the same member function twice with different return types:
struct S {
constexpr const int &f();
int &f();
};

2

Affected subclause: 9.3.1
Change: Classes with default member initializers can be aggregates.
Rationale: Necessary to allow default member initializers to be used by aggregate initialization.
Effect on original feature: Valid C++ 2011 code may fail to compile or may change meaning in this
International Standard. For example:
struct S { // Aggregate in C++ 2014 onwards.
int m = 1;
};
struct X {
operator int();
operator S();
};
X a{};
S b{a}; // uses copy constructor in C++ 2011,
// performs aggregate initialization in this International Standard

C.3.5
1

Clause 16: library introduction

[diff.cpp11.library]

Affected subclause: 16.5.1.2
Change: New header.
Rationale: New functionality.
§ C.3.5

1580


Effect on original feature: The C++ header `<shared_mutex>` is new. Valid C++ 2011 code that includes a header with that name may be invalid in this International Standard.

C.3.6 Clause 29: input/output library

1 Affected subclause: 29.12
   Change: `gets` is not defined.
   Rationale: Use of `gets` is considered dangerous.
   Effect on original feature: Valid C++ 2011 code that uses the `gets` function may fail to compile in this International Standard.

C.4 C++ and ISO C++ 2014

1 This subclause lists the differences between C++ and ISO C++ 2014 (ISO/IEC 14882:2014, Programming Languages — C++), by the chapters of this document.

C.4.1 Clause 5: lexical conventions

1 Affected subclause: 5.2
   Change: Removal of trigraph support as a required feature.
   Rationale: Prevents accidental uses of trigraphs in non-raw string literals and comments.
   Effect on original feature: Valid C++ 2014 code that uses trigraphs may not be valid or may have different semantics in this International Standard. Implementations may choose to translate trigraphs as specified in C++ 2014 if they appear outside of a raw string literal, as part of the implementation-defined mapping from physical source file characters to the basic source character set.

2 Affected subclause: 5.9
   Change: `pp-number` can contain `p` sign and `P` sign.
   Rationale: Necessary to enable hexadecimal floating literals.
   Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard. Specifically, character sequences like `0p+0` and `0e1_p+0` are three separate tokens each in C++ 2014, but one single token in this International Standard. For example:

   ```cpp
   #define F(a) b ## a
   int b0p = F(0p+0);
   // ill-formed; equivalent to “int b0p = b0p + 0;” in C++ 2014
   ```

C.4.2 Clause 7: expressions

1 Affected subclauses: 7.6.1.5 and 7.6.2.2
   Change: Remove increment operator with `bool` operand.
   Rationale: Obsolete feature with occasionally surprising semantics.
   Effect on original feature: A valid C++ 2014 expression utilizing the increment operator on a `bool` lvalue is ill-formed in this International Standard. Note that this might occur when the lvalue has a type given by a template parameter.

2 Affected subclauses: 7.6.2.7 and 7.6.2.8
   Change: Dynamic allocation mechanism for over-aligned types.
   Rationale: Simplify use of over-aligned types.
   Effect on original feature: In C++ 2014 code that uses a `new-expression` to allocate an object with an over-aligned class type, where that class has no allocation functions of its own, `::operator new(std::size_t)` is used to allocate the memory. In this International Standard, `::operator new(std::size_t, std::align_val_t)` is used instead.

C.4.3 Clause 9: declarations

1 Affected subclause: 9.1.1
   Change: Removal of `register` `storage-class-specifier`.
   Rationale: Enable repurposing of deprecated keyword in future revisions of this International Standard.
   Effect on original feature: A valid C++ 2014 declaration utilizing the `register` `storage-class-specifier` is ill-formed in this International Standard. The specifier can simply be removed to retain the original meaning.

2 Affected subclause: 9.1.7.5
   Change: `auto` deduction from `braced-init-list`.
   Rationale: More intuitive deduction behavior.
   Effect on original feature: Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. For example:
Affected subclause: 9.2.3.5
Change: Make exception specifications be part of the type system.
Rationale: Improve type-safety.
Effect on original feature: Valid C++ 2014 code may fail to compile or change meaning in this International Standard. For example:

```cpp
void g1() noexcept;
void g2();
template<class T> int f(T *, T *);
int x = f(g1, g2); // ill-formed; previously well-formed
```

Affected subclause: 9.3.1
Change: Definition of an aggregate is extended to apply to user-defined types with base classes.
Rationale: To increase convenience of aggregate initialization.
Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard; initialization from an empty initializer list will perform aggregate initialization instead of invoking a default constructor for the affected types. For example:

```cpp
struct derived;
struct base {
    friend struct derived;
private:
    base();
};
struct derived : base {};

derived d1{}; // error; the code was well-formed in C++ 2014
derived d2; // still OK
```

C.4.4 Clause 11: classes

Affected subclause: 11.9.3
Change: Inheriting a constructor no longer injects a constructor into the derived class.
Rationale: Better interaction with other language features.
Effect on original feature: Valid C++ 2014 code that uses inheriting constructors may not be valid or may have different semantics. A `using-declaration` that names a constructor now makes the corresponding base class constructors visible to initializations of the derived class rather than declaring additional derived class constructors.

```cpp
struct A {
    template<typename T> A(T, typename T::type = 0);
    A(int);
};
struct B : A {
    using A::A;
    B(int);
};
B b(42L); // now calls B(int), used to call B<long>(long),
// which called A(int) due to substitution failure
// in A<long>(long).
```

C.4.5 Clause 13: templates

Affected subclause: 13.9.2.5
Change: Allowance to deduce from the type of a non-type template argument.
Rationale: In combination with the ability to declare non-type template arguments with placeholder types, allows partial specializations to decompose from the type deduced for the non-type template argument.
Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard. For example:

```cpp
template <int N> struct A;
template <typename T, T N> int foo(A<N>*) = delete;
void foo(void *);
```
void bar(A<0> *p) {
    foo(p); // ill-formed; previously well-formed
}

C.4.6 Clause 14: exception handling

Affected subclause: 14.4
Change: Remove dynamic exception specifications.
Rationale: Dynamic exception specifications were a deprecated feature that was complex and brittle in use. They interacted badly with the type system, which became a more significant issue in this International Standard where (non-dynamic) exception specifications are part of the function type.
Effect on original feature: A valid C++ 2014 function declaration, member function declaration, function pointer declaration, or function reference declaration, if it has a potentially throwing dynamic exception specification, will be rejected as ill-formed in this International Standard. Violating a non-throwing dynamic exception specification will call `terminate` rather than `unexpected` and might not perform stack unwinding prior to such a call.

C.4.7 Clause 16: library introduction

Affected subclause: 16.5.1.2
Change: New headers.
Rationale: New functionality.
Effect on original feature: The following C++ headers are new: `<any>`, `<charconv>`, `<execution>`, `<filesystem>`, `<memory_resource>`, `<optional>`, `<string_view>`, and `<variant>`. Valid C++ 2014 code that `#include`s headers with these names may be invalid in this International Standard.

Affected subclause: 16.5.4.2.3
Change: New reserved namespaces.
Rationale: Reserve namespaces for future revisions of the standard library that might otherwise be incompatible with existing programs.
Effect on original feature: The global namespaces `std` followed by an arbitrary sequence of digits is reserved for future standardization. Valid C++ 2014 code that uses such a top-level namespace, e.g., `std2`, may be invalid in this International Standard.

C.4.8 Clause 20: general utilities library

Affected subclause: 20.14.16
Change: Constructors taking allocators removed.
Rationale: No implementation consensus.
Effect on original feature: Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. Specifically, constructing a `std::function` with an allocator is ill-formed and uses-allocator construction will not pass an allocator to `std::function` constructors in this International Standard.

Affected subclause: 20.11.3
Change: Different constraint on conversions from `unique_ptr`.
Rationale: Adding array support to `shared_ptr`, via the syntax `shared_ptr<T[]>` and `shared_ptr<T[N]>`,
Effect on original feature: Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. For example:

```cpp
#include <memory>
std::unique_ptr<int[]> arr(new int[1]);
std::shared_ptr<int> ptr(std::move(arr)); // error: int(*)[] is not compatible with int*
```

C.4.9 Clause 21: strings library

Affected subclause: 21.3.2
Change: Non-const `.data()` member added.
Rationale: The lack of a non-const `.data()` differed from the similar member of `std::vector`. This change regularizes behavior for this International Standard.
Effect on original feature: Overloaded functions which have differing code paths for `char*` and `const char*` arguments will execute differently when called with a non-const string’s `.data()` member in this International Standard.

```cpp
int f(char *) = delete;
```
```cpp
int f(const char *);  
string s;  
int x = f(s.data()); // ill-formed; previously well-formed
```

### C.4.10 Clause 22: containers library

**Affected subclause:** 22.2.6  
**Change:** Requirements change:  
Rationale: Increase portability, clarification of associative container requirements.  
**Effect on original feature:** Valid C++ 2014 code that attempts to use associative containers having a comparison object with non-const function call operator may fail to compile in this International Standard:
```
#include <set>
struct compare
{
    bool operator()(int a, int b)
    {
        return a < b;
    }
};
int main() {
    const std::set<int, compare> s;
    s.find(0);
}
```

### C.4.11 Annex D: compatibility features

**Change:** The class templates `auto_ptr`, `unary_function`, and `binary_function`, the function templates `random_shuffle`, and the function templates (and their return types) `ptr_fun`, `mem_fun`, `mem_fun_ref`, `bind1st`, and `bind2nd` are not defined.  
Rationale: Superseded by new features.  
**Effect on original feature:** Valid C++ 2014 code that uses these class templates and function templates may fail to compile in this International Standard.

**Change:** Remove old iostreams members [depr.ios.members].  
Rationale: Redundant feature for compatibility with pre-standard code has served its time.  
**Effect on original feature:** A valid C++ 2014 program using these identifiers may be ill-formed in this International Standard.

### C.5 C++ and ISO C++ 2017

**Affected subclause:** 5.8  
**Change:** `header-name` tokens are formed in more contexts.  
Rationale: Required for new features.  
**Effect on original feature:** When the identifier `import` is followed by a `<` character, a `header-name` token may be formed.  
```
template<typename> class import {};
import<int> f(); // ill-formed; previously well-formed
::import<int> g(); // OK
```

**Affected subclause:** 5.11  
**Change:** New keywords.  
Rationale: Required for new features.

- The `char8_t` keyword is added to differentiate the types of ordinary and UTF-8 literals (5.13.5).
- The `concept` keyword is added to enable the definition of concepts (13.6.8).
- The `constexpr` keyword is added to declare immediate functions (9.1.5).

§ C.5.1
The `co_await`, `co_yield`, and `co_return` keywords are added to enable the definition of coroutines (9.4.4).

The `requires` keyword is added to introduce constraints through a `requires-clause` or a `requires-expression`.

**Effect on original feature:** Valid ISO C++ 2017 code using `char8_t`, `concept`, `consteval`, `co_await`, `co_yield`, `co_return`, or `requires` as an identifier is not valid in this International Standard.

**Affected subclause:** 5.12

**Change:** New operator `<=>

**Rationale:** Necessary for new functionality.

**Effect on original feature:** Valid C++ 2017 code that contains a `<=` token immediately followed by a `>` token may be ill-formed or have different semantics in this International Standard:

```cpp
namespace N {
    struct X {}
    bool operator<=(X, X);
    template<bool(X, X)> struct Y {}
    Y(operator<= y);          // ill-formed; previously well-formed
}
```

**Affected subclause:** 5.13

**Change:** Type of UTF-8 string and character literals.

**Rationale:** Required for new features. The changed types enable function overloading, template specialization, and type deduction to distinguish ordinary and UTF-8 string and character literals.

**Effect on original feature:** Valid ISO C++ 2017 code that depends on UTF-8 string literals having type “array of const char” and UTF-8 character literals having type “char” is not valid in this International Standard.

```cpp
const auto *u8s = u8"text";       // u8s previously deduced as const char*; now deduced as const char8_t*
const char *ps = u8s;             // ill-formed; previously well-formed

auto u8c = u8'c';                 // u8c previously deduced as char; now deduced as char8_t
char *pc = &u8c;                  // ill-formed; previously well-formed

std::string s = u8"text";        // ill-formed; previously well-formed

void f(const char *s);
f(u8"text");                // ill-formed; previously well-formed

template<typename> struct ct;
template<> struct ct<char> {
    using type = char;
};
ct<decltype(u8'c')>::type x;     // ill-formed; previously well-formed.
```

### C.5.2 Clause 6: basics

**Affected subclauses:** 6.5, 10.1, and 10.3

**Change:** New identifiers with special meaning.

**Rationale:** Required for new features.

**Effect on original feature:** Top-level declarations beginning with `module` or `import` may be either ill-formed or interpreted differently in this International Standard. [Example:

```cpp
class module;
module *m1;          // ill-formed; previously well-formed
::module *m2;        // OK

class import {};
import j1;           // was variable declaration; now import-declaration
::import j2;         // variable declaration
=end example]
```

**Affected subclause:** 6.8.2.1

**Change:** Except for the initial release operation, a release sequence consists solely of atomic read-modify-write operations.

§ C.5.2
Rationale: Removal of rarely used and confusing feature.
Effect on original feature: If a `memory_order_release` atomic store is followed by a `memory_order_relaxed` store to the same variable by the same thread, then reading the latter value with a `memory_order_acquire` load no longer provides any “happens before” guarantees, even in the absence of intervening stores by another thread.

C.5.3 Clause 7: expressions [diff.cpp17.expr]

Affected subclause: 7.5.5.2
Change: Implicit lambda capture may capture additional entities.
Rationale: Rule simplification, necessary to resolve interactions with constexpr if.
Effect on original feature: Lambdas with a `capture-default` may capture local entities that were not captured in C++ 2017 if those entities are only referenced in contexts that do not result in an odr-use.

C.5.4 Clause 9: declarations [diff.cpp17.dcl.dcl]

Affected subclause: 9.3.1
Change: A class that has user-declared constructors is never an aggregate.
Rationale: Remove potentially error-prone aggregate initialization which may apply notwithstanding the declared constructors of a class.
Effect on original feature: Valid C++ 2017 code that aggregate-initializes a type with a user-declared constructor may be ill-formed or have different semantics in this International Standard.

```cpp
struct A {
    A() = delete;
};// not an aggregate; previously an aggregate

struct B {
    B() = default;
    int i = 0;
};// not an aggregate; previously an aggregate

struct C {
    C(C&&) = default;
    int a, b;
};// not an aggregate; previously an aggregate

A a{}; // ill-formed; previously well-formed
B b = {1}; // ill-formed; previously well-formed
auto* c = new C{2, 3}; // ill-formed; previously well-formed

struct Y;

struct X {
    operator Y();
};

struct Y {
    Y(const Y&) = default;
    X x;
};// not an aggregate; previously an aggregate

Y y(x()); // copy constructor call; previously aggregate-initialization
```

C.5.5 Clause 11: classes [diff.cpp17.class]

Affected subclauses: 11.3.4 and 11.3.7.2
Change: The class name can no longer be used parenthesized immediately after an `explicit decl-specifier` in a constructor declaration. The `conversion-function-id` can no longer be used parenthesized immediately after an `explicit decl-specifier` in a conversion function declaration.
Rationale: Necessary for new functionality.
Effect on original feature: Valid C++ 2017 code may fail to compile in this International Standard. For example:

§ C.5.5
ISO/IEC N4820

struct S {
    explicit (S)(const S&); // ill-formed; previously well-formed
    explicit (operator int)(); // ill-formed; previously well-formed
    explicit(true) (S)(int); // OK
};

2 Affected subclauses: 11.3.4 and 11.3.6
Change: A *simple-template-id* is no longer valid as the *declarator-id* of a constructor or destructor.
Rationale: Remove potentially error-prone option for redundancy.
Effect on original feature: Valid C++ 2017 code may fail to compile in this International Standard. For example:

```cpp
template<class T>
struct A {
    A<T>();       // error: simple-template-id not allowed for constructor
    A(int);       // OK, injected-class-name used
    ~A<T>();     // error: simple-template-id not allowed for destructor
};
```

C.5.6 Clause 13: templates

1 Affected subclause: 13.2
Change: An *unqualified-id* that is followed by a `<` and for which name lookup finds nothing or finds a function will be treated as a *template-name* in order to potentially cause argument dependent lookup to be performed.
Rationale: It was problematic to call a function template with an explicit template argument list via argument dependent lookup because of the need to have a template with the same name visible via normal lookup.
Effect on original feature: Previously valid code that uses a function name as the left operand of a `<` operator would become ill-formed.

```cpp
struct A {}
bool operator<(void (*)(void), A);
void f() {
    int main() {
        A a;
        f < a;     // ill-formed; previously well-formed
        (f) < a;   // still well formed
    }
}
```

C.5.7 Clause 14: exception handling

1 Affected subclause: 14.4
Change: Remove `throw()` exception specification.
Rationale: Removal of obsolete feature that has been replaced by `noexcept`.
Effect on original feature: A valid C++ 2017 function declaration, member function declaration, function pointer declaration, or function reference declaration that uses `throw()` for its exception specification will be rejected as ill-formed in this International Standard. It should simply be replaced with `noexcept` for no change of meaning since C++ 2017. [Note: There is no way to write a function declaration that is non-throwing in this International Standard and is also non-throwing in C++ 2003 except by using the preprocessor to generate a different token sequence in each case. —end note]

C.5.8 Clause 16: library introduction

1 Affected subclause: 16.5.1.2
Change: New headers.
Rationale: New functionality.
Effect on original feature: The following C++ headers are new: `<bit>`, `<compare>`, `<concepts>`, `<contract>`, `<coroutine>`, `<ranges>`, `<span>`, `<syncstream>`, and `<version>`. Valid C++ 2017 code that #includes headers with these names may be invalid in this International Standard.

2 Affected subclause: 16.5.1.2
Change: Remove vacuous C++ header files.
Rationale: The empty headers implied a false requirement to achieve C compatibility with the C++ headers.
Effect on original feature: A valid C++ 2017 program that #includes any of the following headers may
fail to compile: `<ccomplex>`, `<ciso646>`, `<cstdalign>`, `<cstdbool>`, and `<ctgmath>`. To retain the same behavior:

(2.1) — a `#include` of `<ccomplex>` can be replaced by a `#include` of `<complex>` (26.4.1),
(2.2) — a `#include` of `<ctgmath>` can be replaced by a `#include` of `<cmath>` (26.8.1) and a `#include` of `<complex>`, and
(2.3) — a `#include` of `<ciso646>`, `<cstdalign>`, or `<cstdbool>` can simply be removed.

C.5.9 Clause 22: containers library  
[Affected subclauses: 22.3.9 and 22.3.10]  
[Change: Return types of `remove`, `remove_if`, and `unique` changed from `void` to `container::size_type`.  
Rationale: Improve efficiency and convenience of finding number of removed elements.  
Effect on original feature: Code that depends on the return types might have different semantics in this International Standard. Translation units compiled against this version of C++ may be incompatible with translation units compiled against C++ 2017, either failing to link or having undefined behavior.]

C.5.10 Clause 25: algorithms library  
[Affected subclause: 25.2]  
[Change: The number and order of deducible template parameters for algorithm declarations is now unspecified, instead of being as-declared.  
Rationale: Increase implementor freedom and allow some function templates to be implemented as function objects with templated call operators.  
Effect on original feature: A valid C++ 2017 program that passes explicit template arguments to algorithms not explicitly specified to allow such in this version of C++ may fail to compile or have undefined behavior.]

C.5.11 Clause 29: input/output library  
[Affected subclauses: 29.7.4.2.3 and 29.7.5.2.4]  
[Change: Character array extraction only takes array types.  
Rationale: Increase safety via preventing buffer overflow at compile time.  
Effect on original feature: Valid C++ 2017 code may fail to compile in this International Standard:  
```c++
auto p = new char[100];
char q[100];
std::cin >> std::setw(20) >> p;  // ill-formed; previously well-formed
std::cin >> std::setw(20) >> q;  // OK
```  
2 [Affected subclause: 29.7.5.2.4]  
[Change: Overload resolution for ostream inserters used with UTF-8 literals.  
Rationale: Required for new features.  
Effect on original feature: Valid ISO C++ 2017 code that passes UTF-8 literals to `basic_ostream::operator<<` no longer calls character-related overloads.  
```c++
std::cout << u8"text";  // previously called operator<<(const char*) and printed a string;
```
```c++
// now calls operator<<(const void*) and prints a pointer value
std::cout << u8'X';  // previously called operator<<(char) and printed a character;
```
```c++
// now calls operator<<(int) and prints an integer value
```  
3 [Affected subclause: 29.11.7]  
[Change: Return type of filesystem path format observer member functions.  
Rationale: Required for new features.  
Effect on original feature: Valid ISO C++ 2017 code that depends on the `u8string()` and `generic_u8string()` member functions of `std::filesystem::path` returning `std::string` is not valid in this International Standard.  
```c++
std::filesystem::path p;
std::string s1 = p.u8string();  // ill-formed; previously well-formed
std::string s2 = p.generic_u8string();  // ill-formed; previously well-formed
```]

C.5.12 Annex D: compatibility features  
[Affected subclause: 22.3.9 and 22.3.10]  
[Change: Remove `uncaught_exception`.  
Rationale: The function did not have a clear specification when multiple exceptions were active, and has been superseded by `uncaught_exceptions`.]

§ C.5.12 1588
Effect on original feature: A valid C++ 2017 program that calls `std::uncaught_exception` may fail to compile. It might be revised to use `std::uncaught_exceptions` instead, for clear and portable semantics.

2 Change: Remove support for adaptable function API.
Rationale: The deprecated support relied on a limited convention that could not be extended to support the general case or new language features. It has been superseded by direct language support with `decltype`, and by the `std::bind` and `std::not_fn` function templates.

Effect on original feature: A valid C++ 2017 program that relies on the presence of `result_type`, `argument_type`, `first_argument_type`, or `second_argument_type` in a standard library class may fail to compile. A valid C++ 2017 program that calls `not1` or `not2`, or uses the class templates `unary_negate` or `binary_negate`, may fail to compile.

3 Change: Remove redundant members from `std::allocator`.
Rationale: `std::allocator` was overspecified, encouraging direct usage in user containers rather than relying on `std::allocator_traits`, leading to poor containers.

Effect on original feature: A valid C++ 2017 program that directly makes use of the `pointer`, `const_pointer`, `reference`, `const_reference`, `rebind`, `address`, `construct`, `destroy`, or `max_size` members of `std::allocator`, or that directly calls `allocate` with an additional hint argument, may fail to compile.

4 Change: Remove redundant members from `std::allocator`.
Rationale: The iterator encouraged use of algorithms that might throw exceptions, but did not return the number of elements successfully constructed that might need to be destroyed in order to avoid leaks.

Effect on original feature: A valid C++ 2017 program that uses this iterator class may fail to compile.

5 Change: Remove temporary buffers API.
Rationale: The temporary buffer facility was intended to provide an efficient optimization for small memory requests, but there is little evidence this was achieved in practice, while requiring the user to provide their own exception-safe wrappers to guard use of the facility in many cases.

Effect on original feature: A valid C++ 2017 program that calls `get_temporary_buffer` or `return_temporary_buffer` may fail to compile.

6 Change: Remove `shared_ptr::unique`.
Rationale: The result of a call to this member function is not reliable in the presence of multiple threads and weak pointers. The member function `use_count` is similarly unreliable, but has a clearer contract in such cases, and remains available for well defined use in single-threaded cases.

Effect on original feature: A valid C++ 2017 program that calls `unique` on a `shared_ptr` object may fail to compile.

7 Affected subclause: D.9
Change: Remove deprecated type traits.
Rationale: The traits had unreliable or awkward interfaces. The `is_literal_type` trait provided no way to detect which subset of constructors and member functions of a type were declared `constexpr`. The `result_of` trait had a surprising syntax that could not report the result of a regular function type. It has been superseded by the `invoke_result` trait.

Effect on original feature: A valid C++ 2017 program that relies on the `is_literal_type` or `result_of` type traits, on the `is_literal_type_v` variable template, or on the `result_of_t` alias template may fail to compile.

C.6 C standard library

This subclause summarizes the explicit changes in headers, definitions, declarations, or behavior between the C standard library in the C standard and the parts of the C++ standard library that were included from the C standard library.

C.6.1 Modifications to headers

For compatibility with the C standard library, the C++ standard library provides the C headers enumerated in D.6, but their use is deprecated in C++. There are no C++ headers for the C standard library’s headers `<stdatomic.h>`, `<stdnoreturn.h>`, and `<threads.h>`, nor are these headers from the C standard library headers themselves part of C++.

The C headers `<complex.h>` and `<tgmath.h>` do not contain any of the content from the C standard library and instead merely include other headers from the C++ standard library.
C.6.2 Modifications to definitions

C.6.2.1 Types char16_t and char32_t

The types `char16_t` and `char32_t` are distinct types rather than typedefs to existing integral types. The tokens `char16_t` and `char32_t` are keywords in this International Standard (5.11). They do not appear as macro names defined in `<cuchar>` (21.5.5).

C.6.2.2 Type wchar_t

The type `wchar_t` is a distinct type rather than a typedef to an existing integral type. The token `wchar_t` is a keyword in this International Standard (5.11). It does not appear as a type name defined in any of `<cassert>` (19.3.1), `<cstddef>` (17.2.1), `<cstdlib>` (17.2.2), or `<cwchar>` (21.5.4).

C.6.2.3 Header <assert.h>

The token `static_assert` is a keyword in this International Standard (5.11). It does not appear as a macro name defined in `<cassert>` (19.3.1).

C.6.2.4 Header <iso646.h>

The tokens `and`, `and_eq`, `bitand`, `bitor`, `compl`, `not_eq`, `not`, `or`, `or_eq`, `xor`, and `xor_eq` are keywords in this International Standard (5.11), and are not introduced as macros by `<iso646.h>` (D.6.2).

C.6.2.5 Header <stdalign.h>

The token `alignas` is a keyword in this International Standard (5.11), and is not introduced as a macro by `<stdalign.h>` (D.6.3).

C.6.2.6 Header <stdbool.h>

The tokens `bool`, `true`, and `false` are keywords in this International Standard (5.11), and are not introduced as macros by `<stdbool.h>` (D.6.4).

C.6.2.7 Macro NULL

The macro `NULL`, defined in any of `<locale>` (28.5), `<cstdlib>` (17.2.1), `<stdio>` (29.12.1), `<cstdlib>` (17.2.2), `<cstring>` (21.5.3), `<ctime>` (27.13), or `<cwchar>` (21.5.4), is an implementation-defined C++ null pointer constant in this International Standard (17.2).

C.6.3 Modifications to declarations

1 Header `<cstring>` (21.5.3): The following functions have different declarations:

   (1.1) — `strchr`
   (1.2) — `strpbrk`
   (1.3) — `strrchr`
   (1.4) — `strstr`
   (1.5) — `memchr`

   Subclause 21.5.3 describes the changes.

2 Header `<cwchar>` (21.5.4): The following functions have different declarations:

   (2.1) — `wcschr`
   (2.2) — `wcschrpbrk`
   (2.3) — `wcsrchr`
   (2.4) — `wcsstr`
   (2.5) — `wmemchr`

   Subclause 21.5.4 describes the changes.

3 Header `<cstdlib>` (17.2.1) declares the name `nullptr_t` in addition to the names declared in `<stddef.h>` in the C standard library.
C.6.4 Modifications to behavior

1 Header `<cstdlib>` (17.2.2): The following functions have different behavior:
   (1.1) — `atexit`
   (1.2) — `exit`
   (1.3) — `abort`
   Subclause 17.5 describes the changes.

2 Header `<csetjmp>` (17.13.2): The following functions have different behavior:
   (2.1) — `longjmp`
   Subclause 17.13.2 describes the changes.

C.6.4.1 Macro `offsetof(type, member-designator)`

1 The macro `offsetof`, defined in `<cstddef>` (17.2.1), accepts a restricted set of `type` arguments in this International Standard. Subclause 17.2.4 describes the change.

C.6.4.2 Memory allocation functions

1 The functions `aligned_alloc`, `calloc`, `malloc`, and `realloc` are restricted in this International Standard. Subclause 20.10.12 describes the changes.
Annex D  (normative)  
Compatibility features  

1 This Clause describes features of the C++ Standard that are specified for compatibility with existing implementations.

2 These are deprecated features, where deprecated is defined as: Normative for the current edition of this International Standard, but having been identified as a candidate for removal from future revisions. An implementation may declare library names and entities described in this Clause with the deprecated attribute (9.11.5).

D.1 Arithmetic conversion on enumerations  

The ability to apply the usual arithmetic conversions (7.4) on operands where one is of enumeration type and the other is of a different enumeration type or a floating-point type is deprecated. [Note: Three-way comparisons (7.6.8) between such operands are ill-formed. — end note]  [Example:

```cpp
enum E1 { e };
enum E2 { f };
bool b = e <= 3.7; // deprecated
int k = f - e;     // deprecated
auto cmp = e <=> f; // ill-formed
```

— end example]

D.2 Implicit capture of *this by reference  

For compatibility with prior C++ International Standards, a lambda-expression with capture-default = (7.5.5.2) may implicitly capture *this by reference. [Example:

```cpp
struct X {
    int x;
    void foo(int n) {
        auto f = [=]() { x = n; }; // deprecated: x means this->x, not a copy thereof
        auto g = [=, this]() { x = n; }; // recommended replacement
    }
};
```

— end example]

D.3 Array comparisons  

Equality and relational comparisons (7.6.10, 7.6.9) between two operands of array type are deprecated. [Note: Three-way comparisons (7.6.8) between such operands are ill-formed. — end note]  [Example:

```cpp
int arr1[5];
int arr2[5];
bool same = arr1 == arr2; // deprecated, same as &arr1[0] == &arr2[0],
auto cmp = arr1 <=> arr2; // ill-formed
```

— end example]

D.4 Redeclaration of static constexpr data members  

For compatibility with prior C++ International Standards, a constexpr static data member may be redundantly redeclared outside the class with no initializer. This usage is deprecated. [Example:

```cpp
struct A {
    static constexpr int n = 5; // definition (declaration in C++ 2014)
};
constexpr int A::n; // redundant declaration (definition in C++ 2014)
```

— end example]
D.5 Implicit declaration of copy functions

The implicit definition of a copy constructor (11.3.4.2) as defaulted is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor (11.3.6). The implicit definition of a copy assignment operator (11.3.5) as defaulted is deprecated if the class has a user-declared copy constructor or a user-declared destructor. In a future revision of this International Standard, these implicit definitions could become deleted (9.4).

D.6 C standard library headers

For compatibility with the C standard library, the C++ standard library provides the C headers shown in Table 135.

| <assert.h> | <inttypes.h> | <signal.h> | <stdio.h> | <wchar.h> |
| <complex.h> | <iso646.h> | <stdalign.h> | <stdlib.h> | <wctype.h> |
| <ctype.h> | <limits.h> | <stdarg.h> | <stdbool.h> | <stddef.h> |
| <errno.h> | <locale.h> | <stdbool.h> | <stddef.h> | <stdio.h> |
| <errno.h> | <locale.h> | <stdbool.h> | <stddef.h> | <string.h> |
| <fenv.h> | <math.h> | <setjmp.h> | <uchar.h> |
| <float.h> | <setjmp.h> | <uchar.h> | <uchar.h> |

D.6.1 Header <complex.h> synopsis

The header <complex.h> behaves as if it simply includes the header <complex> (26.4.1).

D.6.2 Header <iso646.h> synopsis

The C++ header <iso646.h> is empty. [Note: and, and_eq, bitand, bitor, compl, not_eq, not, or, or_eq, xor, and xor_eq are keywords in this International Standard (5.11). —end note]

D.6.3 Header <stdalign.h> synopsis

The contents of the C++ header <stdalign.h> are the same as the C standard library header <stdalign.h>, with the following changes: The header <stdalign.h> does not define a macro named alignas.

SEE ALSO: ISO C 7.15

D.6.4 Header <stdbool.h> synopsis

The contents of the C++ header <stdbool.h> are the same as the C standard library header <stdbool.h>, with the following changes: The header <stdbool.h> does not define macros named bool, true, or false.

SEE ALSO: ISO C 7.18

D.6.5 Header <tgmath.h> synopsis

The header <tgmath.h> behaves as if it simply includes the headers <cmath> (26.8.1) and <complex> (26.4.1).

[Note: The overloads provided in C by type-generic macros are already provided in <complex> and <cmath> by “sufficient” additional overloads. —end note]

[Note: Names introduced by <cmath> or <complex> in namespace std are not placed into the global namespace scope by <tgmath.h>. —end note]
D.6.6 Other C headers

Every C header other than <complex.h>, <iso646.h>, <stdalign.h>, <stdbool.h>, and <tgmath.h>, each of which has a name of the form <name.h>, behaves as if each name placed in the standard library namespace by the corresponding <name> header is placed within the global namespace scope, except for the functions described in 26.8.6, the declaration of std::byte (17.2.1), and the functions and function templates described in 17.2.5. It is unspecified whether these names are first declared or defined within namespace scope (6.3.6) of the namespace std and are then injected into the global namespace scope by explicit using-declarations (9.8).

[Example: The header <cstdlib> assuredly provides its declarations and definitions within the namespace std. It may also provide these names within the global namespace. The header <stdlib.h> assuredly provides the same declarations and definitions within the global namespace, much as in the C Standard. It may also provide these names within the namespace std. — end example]

D.7 Relational operators

The header <utility> has the following additions:

```cpp
namespace std::rel_ops {
    template<class T> bool operator!=(const T&, const T&);
    template<class T> bool operator>(const T&, const T&);
    template<class T> bool operator<=(const T&, const T&);
    template<class T> bool operator>=(const T&, const T&);
}
```

To avoid redundant definitions of operator!= out of operator== and operators >, <=, and >= out of operator<, the library provides the following:

```cpp
template<class T> bool operator!=(const T& x, const T& y);

Requires: Type T is Cpp17EqualityComparable (Table 23).

Returns: ! (x == y).
```

```cpp
template<class T> bool operator>(const T& x, const T& y);

Requires: Type T is Cpp17LessThanComparable (Table 24).

Returns: y < x.
```

```cpp
template<class T> bool operator<=(const T& x, const T& y);

Requires: Type T is Cpp17LessThanComparable (Table 24).

Returns: !(y < x).
```

```cpp
template<class T> bool operator>=(const T& x, const T& y);

Requires: Type T is Cpp17LessThanComparable (Table 24).

Returns: !(x < y).
```

D.8 char* streams

D.8.1 Header <strstream> synopsis

The header <strstream> defines types that associate stream buffers with character array objects and assist reading and writing such objects.

```cpp
namespace std {
    class strstreambuf;
    class istrstream;
    class ostrstream;
    class strstream;
}
```

D.8.2 Class strstreambuf

```cpp
namespace std {
    class strstreambuf : public basic_streambuf<char> {
        public:
            strstreambuf() : strstreambuf(0) {} // explicit strstreambuf(streamsize alsize_arg);
    }
```
The class `strstreambuf` associates the input sequence, and possibly the output sequence, with an object of some character array type, whose elements store arbitrary values. The array object has several attributes.

[Note: For the sake of exposition, these are represented as elements of a bitmask type (indicated here as `T1`) called `strstate`. The elements are:

1. **allocated**, set when a dynamic array object has been allocated, and hence should be freed by the destructor for the `strstreambuf` object;
2. **constant**, set when the array object has `const` elements, so the output sequence cannot be written;
3. **dynamic**, set when the array object is allocated (or reallocated) as necessary to hold a character sequence that can change in length;
4. **frozen**, set when the program has requested that the array object not be altered, reallocated, or freed.

—end note]

[Note: For the sake of exposition, the maintained data is presented here as:

1. `strstate strmode`, the attributes of the array object associated with the `strstreambuf` object;
2. `int alsize`, the suggested minimum size for a dynamic array object;
3. `void* (*palloc)(size_t)`, points to the function to call to allocate a dynamic array object;
4. `void (*pfree)(void*)`, points to the function to call to free a dynamic array object.]
Each object of class `strstreambuf` has a *seekable area*, delimited by the pointers `seeklow` and `seekhigh`. If `gnext` is a null pointer, the seekable area is undefined. Otherwise, `seeklow` equals `gbeg` and `seekhigh` is either `pend`, if `pend` is not a null pointer, or `gend`.

### D.8.2.1 `strstreambuf` constructors

#### explicit `strstreambuf(streamsize alsizet);`

**Effects:** Constructs an object of class `strstreambuf`, initializing the base class with `streambuf()`. The postconditions of this function are indicated in Table 136.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>strmode</code></td>
<td>dynamic</td>
</tr>
<tr>
<td><code>alsize</code></td>
<td><code>alsizet</code></td>
</tr>
<tr>
<td><code>palloc</code></td>
<td>a null pointer</td>
</tr>
<tr>
<td><code>pfree</code></td>
<td>a null pointer</td>
</tr>
</tbody>
</table>

#### `strstreambuf(void* (*palloc_arg)(size_t), void (*pfree_arg)(void*));`

**Effects:** Constructs an object of class `strstreambuf`, initializing the base class with `streambuf()`. The postconditions of this function are indicated in Table 137.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>strmode</code></td>
<td>dynamic</td>
</tr>
<tr>
<td><code>alsize</code></td>
<td>an unspecified value</td>
</tr>
<tr>
<td><code>palloc</code></td>
<td><code>palloc_arg</code></td>
</tr>
<tr>
<td><code>pfree</code></td>
<td><code>pfree_arg</code></td>
</tr>
</tbody>
</table>

#### `strstreambuf(char* gnext_arg, streamsize n, char* pbeg_arg = nullptr);`

1. `strstreambuf(signed char* gnext_arg, streamsize n,`
2. `signed char* pbeg_arg = nullptr);`
3. `strstreambuf(unsigned char* gnext_arg, streamsize n,`
4. `unsigned char* pbeg_arg = nullptr);`

**Effects:** Constructs an object of class `strstreambuf`, initializing the base class with `streambuf()`. The postconditions of this function are indicated in Table 138.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>strmode</code></td>
<td>0</td>
</tr>
<tr>
<td><code>alsize</code></td>
<td>an unspecified value</td>
</tr>
<tr>
<td><code>palloc</code></td>
<td>a null pointer</td>
</tr>
<tr>
<td><code>pfree</code></td>
<td>a null pointer</td>
</tr>
</tbody>
</table>

---

`gnext_arg` shall point to the first element of an array object whose number of elements $N$ is determined as follows:

1. If $n > 0$, $N = n$.
2. If $n == 0$, $N$ is `std::strlen(gnext_arg)`.
3. If $n < 0$, $N$ is `INT_MAX`.\(^{331}\)

\(^{331}\) The function signature `strlen(const char*)` is declared in `<cstring>` (21.5.3). The macro `INT_MAX` is defined in `<climits>` (17.3.5).
If pbeg_arg is a null pointer, the function executes:

```c
    setg(gnext_arg, gnext_arg, gnext_arg + N);
```

Otherwise, the function executes:

```c
    setg(gnext_arg, gnext_arg, pbeg_arg);
    setp(pbeg_arg, pbeg_arg + N);
```

**strstreambuf**

```c
strstreambuf(const char* gnext_arg, streamsize n);
strstreambuf(const signed char* gnext_arg, streamsize n);
strstreambuf(const unsigned char* gnext_arg, streamsize n);
```

**Effects:** Behaves the same as **strstreambuf((char*)gnext_arg,n)**, except that the constructor also sets constant in strmode.

**virtual ~strstreambuf();**

**Effects:** Destroys an object of class **strstreambuf**. The function frees the dynamically allocated array object only if `(strmode & allocated) != 0` and `(strmode & frozen) == 0`. (D.8.2.3 describes how a dynamically allocated array object is freed.)

### D.8.2.2 Member functions

**void freeze(bool freezefl = true);**

**Effects:** If strmode & dynamic is nonzero, alters the freeze status of the dynamic array object as follows:

1. If freezefl is true, the function sets frozen in strmode.
2. Otherwise, it clears frozen in strmode.

**char* str();**

**Effects:** Calls freeze(), then returns the beginning pointer for the input sequence, gbeg.

**Remarks:** The return value can be a null pointer.

**int pcount() const;**

**Effects:** If the next pointer for the output sequence, pnext, is a null pointer, returns zero. Otherwise, returns the current effective length of the array object as the next pointer minus the beginning pointer for the output sequence, `pnext - pbeg`.

### D.8.2.3 strstreambuf overridden virtual functions

**int_type overflow(int_type c = EOF) override;**

**Effects:** Appends the character designated by c to the output sequence, if possible, in one of two ways:

1. If c != EOF and if either the output sequence has a write position available or the function makes a write position available (as described below), assigns c to *pnext++.
   
   Returns (unsigned char)c.

2. If c == EOF, there is no character to append.
   
   Returns a value other than EOF.

**Remarks:** The function can alter the number of write positions available as a result of any call.

To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements n to hold the current array object (if any), plus at least one additional write position. How many additional write positions are made available is otherwise unspecified. If palloc is not a null pointer, the function calls (palloc)(n) to allocate the new dynamic array object. Otherwise, it evaluates the expression new charT[n]. In either case, if the allocation fails, the function returns EOF. Otherwise, it sets allocated in strmode.

To free a previously existing dynamic array object whose first element address is p: If pfree is not a null pointer, the function calls (pfree)(p). Otherwise, it evaluates the expression delete[]p.

---

332) An implementation should consider alsizel in making this decision.
If `(strmode & dynamic) == 0`, or if `(strmode & frozen) != 0`, the function cannot extend the array (reallocate it with greater length) to make a write position available.

```cpp
int_type pbackfail(int_type c = EOF) override;
```

Puts back the character designated by `c` to the input sequence, if possible, in one of three ways:

1. If `c != EOF`, if the input sequence has a putback position available, and if `(char)c == gnext[-1]`, assigns `gnext - 1` to `gnext`. Returns `c`.
2. If `c != EOF`, if the input sequence has a putback position available, and if `strmode & constant` is zero, assigns `c` to `*--gnext`. Returns `c`.
3. If `c == EOF` and if the input sequence has a putback position available, assigns `gnext - 1` to `gnext`. Returns a value other than `EOF`.

Returns `EOF` to indicate failure.

Remarks: If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

```cpp
int_type underflow() override;
```

Effects: Reads a character from the input sequence, if possible, without moving the stream position past it, as follows:

1. If the input sequence has a read position available, the function signals success by returning `(unsigned char)*gnext`.
2. Otherwise, if the current write next pointer `pnext` is not a null pointer and is greater than the current read end pointer `gend`, makes a read position available by assigning to `gend` a value greater than `gnext` and no greater than `pnext`. Returns `(unsigned char)*gnext`.

Returns `EOF` to indicate failure.

Remarks: The function can alter the number of read positions available as a result of any call.

```cpp
pos_type seekoff(off_type off, seekdir way, openmode which = in | out) override;
```

Effects: Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 139.

Table 139: `seekoff` positioning

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>(which &amp; ios::in) != 0</code></td>
<td>positions the input sequence</td>
</tr>
<tr>
<td><code>(which &amp; ios::out) != 0</code></td>
<td>positions the output sequence</td>
</tr>
<tr>
<td>`(which &amp; (ios::in</td>
<td>ios::out)) == (ios::in</td>
</tr>
<tr>
<td>Otherwise</td>
<td>the positioning operation fails.</td>
</tr>
</tbody>
</table>

For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines `newoff` as indicated in Table 140.

If `(newoff + off) < (seeklow - xbeg)` or `(seekhigh - xbeg) < (newoff + off)`, the positioning operation fails. Otherwise, the function assigns `xbeg + newoff + off` to the next pointer `xnext`.

Returns: `pos_type(newoff)`, constructed from the resultant offset `newoff` (of type `off_type`), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is `pos_type(off_type(-1))`. 

§ D.8.2.3
Table 140: newoff values

<table>
<thead>
<tr>
<th>Condition</th>
<th>newoff Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>way == ios::beg</td>
<td>0</td>
</tr>
<tr>
<td>way == ios::cur</td>
<td>the next pointer minus the beginning pointer (xnext - xbeg).</td>
</tr>
<tr>
<td>way == ios::end</td>
<td>seekhigh minus the beginning pointer (seekhigh - xbeg).</td>
</tr>
</tbody>
</table>

pos_type seekpos(pos_type sp, ios_base::openmode which = ios_base::in | ios_base::out) override;

17 Effects: Alters the stream position within one of the controlled sequences, if possible, to correspond to the stream position stored in sp (as described below).

(17.1) — If (which & ios::in) != 0, positions the input sequence.
(17.2) — If (which & ios::out) != 0, positions the output sequence.
(17.3) — If the function positions neither sequence, the positioning operation fails.

For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines newoff from sp.offset():

(18.1) — If newoff is an invalid stream position, has a negative value, or has a value greater than (seekhigh - seeklow), the positioning operation fails
(18.2) — Otherwise, the function adds newoff to the beginning pointer xbeg and stores the result in the next pointer xnext.

19 Returns: pos_type(newoff), constructed from the resultant offset newoff (of type off_type), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is pos_type(off_type(-1)).

streambuf<char>* setbuf(char* s, streamsize n) override;

20 Effects: Behavior is implementation-defined, except that setbuf(0, 0) has no effect.

D.8.3 Class istrstream

namespace std {

class istrstream : public basic_istream<char> {

public:
    explicit istrstream(const char* s);
    explicit istrstream(char* s);
    istrstream(const char* s, streamsize n);
    istrstream(char* s, streamsize n);
    virtual ~istrstream();

    strstreambuf* rdbuf() const;
    char* str();
private:
    strstreambuf sb; // exposition only
};

1 The class istrstream supports the reading of objects of class strstreambuf. It supplies a strstreambuf object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

(1.1) — sb, the strstreambuf object.

D.8.3.1 istrstream constructors

explicit istrstream(const char* s);
explicit istrstream(char* s);

1  Effects: Constructs an object of class istrstream, initializing the base class with istream(&sb) and initializing sb with strstreambuf(s,0). s shall designate the first element of an NTBS.

istrstream(const char* s, streamsize n);

2  Effects: Constructs an object of class istrstream, initializing the base class with istream(&sb) and initializing sb with strstreambuf(s,n). s shall designate the first element of an array whose length is n elements, and n shall be greater than zero.

D.8.3.2 Member functions

strstreambuf* rdbuf() const;

1  Returns: const_cast<strstreambuf*>(&sb).

char* str();

2  Returns: rdbuf()->str().

D.8.4 Class ostrstream

namespace std {

class ostrstream : public basic_ostream<char> { [depr.ostrstream]

   public:
      ostrstream();
      ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);
      virtual ~ostrstream();

      strstreambuf* rdbuf() const;
      void freeze(bool freezefl = true);
      char* str();
      int pcount() const;

   private:
      strstreambuf sb;  // exposition only
};

1  The class ostrstream supports the writing of objects of class strstreambuf. It supplies a strstreambuf object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

(1.1) — sb, the strstreambuf object.

D.8.4.1 ostrstream constructors

ostrstream();

1  Effects: Constructs an object of class ostrstream, initializing the base class with ostream(&sb) and initializing sb with strstreambuf().

ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);

2  Effects: Constructs an object of class ostrstream, initializing the base class with ostream(&sb), and initializing sb with one of two constructors:

(2.1) — If (mode & app) == 0, then s shall designate the first element of an array of n elements. The constructor is strstreambuf(s, n, s).

(2.2) — If (mode & app) != 0, then s shall designate the first element of an array of n elements that contains an NTBS whose first element is designated by s. The constructor is strstreambuf(s, n, s + std::strlen(s)).333

333) The function signature strlen(const char*) is declared in <cstring> (21.5.3).
D.8.4.2 Member functions

strstreambuf* rdbuf() const;

Returns: \((\text{strstreambuf*})&sb\).

void freeze(bool freezefl = true);

Effects: Calls rdbuf()\(\rightarrow\)freeze(freezefl).

char* str();

Returns: rdbuf()\(\rightarrow\)str().

int pcount() const;

Returns: rdbuf()\(\rightarrow\)pcount().

D.8.5 Class strstream

namespace std {

class strstream : public basic_iostream<char> {

public:

// types
using char_type = char;
using int_type = char_traits<char>::int_type;
using pos_type = char_traits<char>::pos_type;
using off_type = char_traits<char>::off_type;

// constructors/destructor
strstream();
strstream(char* s, int n, 
    ios_base::openmode mode = ios_base::in|ios_base::out);
virtual ~strstream();

// members
strstreambuf* rdbuf() const;
void freeze(bool freezefl = true);
int pcount() const;
char* str();

private:
    strstreambuf sb; // exposition only
};

} // namespace std

1 The class \textit{strstream} supports reading and writing from objects of class \textit{strstreambuf}. It supplies a \textit{strstreambuf} object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

\((1.1)\) — \(sb\), the \textit{strstreambuf} object.

D.8.5.1 \textit{strstream} constructors

strstream();

Effects: Constructs an object of class \textit{strstream}, initializing the base class with \textit{iostream(&sb)}.

strstream(char* s, int n, 
    ios_base::openmode mode = ios_base::in|ios_base::out);

Effects: Constructs an object of class \textit{strstream}, initializing the base class with \textit{iostream(&sb)} and initializing \(sb\) with one of the two constructors:

\((2.1)\) — If \((\text{mode} \& \text{app}) == 0\), then \(s\) shall designate the first element of an array of \(n\) elements. The constructor is \textit{strstreambuf} \((s,n,s)\).

\((2.2)\) — If \((\text{mode} \& \text{app}) != 0\), then \(s\) shall designate the first element of an array of \(n\) elements that contains an \textit{NTBS} whose first element is designated by \(s\). The constructor is \textit{strstreambuf} \((s,n,s + \text{std::strlen}(s))\).
D.8.5.2  *strstrm* stream destructor

virtual ~*strstrm*();

*Effects:* Destroys an object of class *strstrm*.

D.8.5.3  *strstrm* stream operations

strstrmbuf* rdbuf() const;

*Returns:* `const_cast<strstrmbuf*>(sbb)`.

void freeze(bool freezefl = true);

*Effects:* Calls `rdbuf()`->freeze(freezefl).

char* str();

*Returns:* `rdbuf()`->str().

int pcount() const;

*Returns:* `rdbuf()`->pcount().

D.9  Deprecated type traits

The header `<type_traits>` has the following addition:

```cpp
namespace std {
    template<class T> struct is_pod;
    template<class T> inline constexpr bool is_pod_v = is_pod<T>::value;
}
```

*Requires:* `remove_all_extents_t<T>` shall be a complete type or `cv void`.

*is_pod<T>* is a Cpp17UnaryTypeTrait (20.15.1) with a base characteristic of `true_type` if `T` is a POD type, and `false_type` otherwise. A POD class is a class that is both a trivial class and a standard-layout class, and has no non-static data members of type non-POD class (or array thereof). A POD type is a scalar type, a POD class, an array of such a type, or a cv-qualified version of one of these types.

*Note:* It is unspecified whether a closure type (7.5.5.1) is a POD type. —end note

D.10  Deprecated iterator primitives

D.10.1  Basic iterator

The header `<iterator>` has the following addition:

```cpp
namespace std {
    template<class Category, class T, class Distance = ptrdiff_t, class Pointer = T*, class Reference = T&>
    struct iterator {
        using iterator_category = Category;
        using value_type = T;
        using difference_type = Distance;
        using pointer = Pointer;
        using reference = Reference;
    };
}
```

*The iterator* template may be used as a base class to ease the definition of required types for new iterators.

*Note:* If the new iterator type is a class template, then these aliases will not be visible from within the iterator class's template definition, but only to callers of that class. —end note

*Example:* If a C++ program wants to define a bidirectional iterator for some data structure containing `double` and such that it works on a large memory model of the implementation, it can do so with:
class MyIterator :
    public iterator<bidirectional_iterator_tag, double, long, T*, T&> {
        // code implementing ++, etc.
    };

—end example

D.11 Deprecated move_iterator access [depr.move.iter.elem]

The following member is declared in addition to those members specified in 23.5.3.5:

```cpp
namespace std {
    template<class Iterator>
    class move_iterator {
        public:
            constexpr pointer operator->() const;
        }
    }
```

conconstexpr pointer operator->() const;

Returns: current.

D.12 Deprecated shared_ptr atomic access [depr.util.smartptr.shared.atomic]

The header <memory> has the following additions:

```cpp
namespace std {
    template<class T>
    bool atomic_is_lock_free(const shared_ptr<T>* p);

    template<class T>
    shared_ptr<T> atomic_load(const shared_ptr<T>* p);
    template<class T>
    shared_ptr<T> atomic_load_explicit(const shared_ptr<T>* p, memory_order mo);

    template<class T>
    void atomic_store(shared_ptr<T>* p, shared_ptr<T> r);
    template<class T>
    void atomic_store_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

    template<class T>
    shared_ptr<T> atomic_exchange(shared_ptr<T>* p, shared_ptr<T> r);
    template<class T>
    shared_ptr<T> atomic_exchange_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

    template<class T>
    bool atomic_compare_exchange_weak(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);
    template<class T>
    bool atomic_compare_exchange_strong(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);
    template<class T>
    bool atomic_compare_exchange_weak_explicit(  
        shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,  
        memory_order success, memory_order failure);
    template<class T>
    bool atomic_compare_exchange_strong_explicit(  
        shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,  
        memory_order success, memory_order failure);
}
```

Concurrent access to a shared_ptr object from multiple threads does not introduce a data race if the access is done exclusively via the functions in this subclause and the instance is passed as their first argument.

The meaning of the arguments of type memory_order is explained in 31.4.

```cpp
template<class T> bool atomic_is_lock_free(const shared_ptr<T>* p);
```

Requires: p shall not be null.

Returns: true if atomic access to *p is lock-free, false otherwise.
template<class T> shared_ptr<T> atomic_load(const shared_ptr<T>* p);

Requires: p shall not be null.

Returns: atomic_load_explicit(p, memory_order_seq_cst).

Throws: Nothing.

template<class T> shared_ptr<T> atomic_load_explicit(const shared_ptr<T>* p, memory_order mo);

Requires: p shall not be null.

Requires: mo shall not be memory_order_release or memory_order_acq_rel.

Returns: *p.

Throws: Nothing.

template<class T> void atomic_store(shared_ptr<T>* p, shared_ptr<T> r);

Requires: p shall not be null.

Effects: As if by atomic_store_explicit(p, r, memory_order_seq_cst).

Throws: Nothing.

template<class T> void atomic_store_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

Requires: p shall not be null.

Requires: mo shall not be memory_order_acquire or memory_order_acq_rel.

Effects: As if by p->swap(r).

Throws: Nothing.

template<class T> shared_ptr<T> atomic_exchange(shared_ptr<T>* p, shared_ptr<T> r);

Requires: p shall not be null.

Returns: atomic_exchange_explicit(p, r, memory_order_seq_cst).

Throws: Nothing.

template<class T>
shared_ptr<T> atomic_exchange_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

Requires: p shall not be null.

Effects: As if by p->swap(r).

Returns: The previous value of *p.

Throws: Nothing.

template<class T>
bool atomic_compare_exchange_weak(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);

Requires: p shall not be null and v shall not be null.

Returns:
    atomic_compare_exchange_weak_explicit(p, v, w, memory_order_seq_cst, memory_order_seq_cst)

Throws: Nothing.

template<class T>
bool atomic_compare_exchange_strong(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);

Returns:
    atomic_compare_exchange_strong_explicit(p, v, w, memory_order_seq_cst, memory_order_seq_cst)

template<class T>
bool atomic_compare_exchange_weak_explicit(
    shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
    memory_order success, memory_order failure);
template<class T>
    bool atomic_compare_exchange_strong_explicit(
        shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
        memory_order success, memory_order failure);

Requires: p shall not be null and v shall not be null. The failure argument shall not be memory_order_release nor memory_order_acq_rel.

Effects: If *p is equivalent to *v, assigns w to *p and has synchronization semantics corresponding to the value of success, otherwise assigns *p to *v and has synchronization semantics corresponding to the value of failure.

Returns: true if *p was equivalent to *v, false otherwise.

Throws: Nothing.

Remarks: Two shared_ptr objects are equivalent if they store the same pointer value and share ownership. The weak form may fail spuriously. See 31.7.1.

D.13 Deprecated basic_string capacity

The following member is declared in addition to those members specified in 21.3.2.4:

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_string {
    public:
        void reserve();
    }
}
```

Effects: After this call, capacity() has an unspecified value greater than or equal to size(). [Note: This is a non-binding shrink to fit request. —end note]

D.14 Deprecated standard code conversion facets

The header `<codecvt>` provides code conversion facets for various character encodings.

D.14.1 Header `<codecvt>` synopsis

```cpp
namespace std {
    enum codecvt_mode {
        consume_header = 4,
        generate_header = 2,
        little_endian = 1
    };

    template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
    class codecvt_utf8 : public codecvt<Elem, char, mbstate_t> {
    public:
        explicit codecvt_utf8(size_t refs = 0);
        ~codecvt_utf8();
    }

    template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
    class codecvt_utf16 : public codecvt<Elem, char, mbstate_t> {
    public:
        explicit codecvt_utf16(size_t refs = 0);
        ~codecvt_utf16();
    }

    template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
    class codecvt_utf8_utf16 : public codecvt<Elem, char, mbstate_t> {
    public:
        explicit codecvt_utf8_utf16(size_t refs = 0);
        ~codecvt_utf8_utf16();
    }
}
D.14.2 Requirements

1 For each of the three code conversion facets \texttt{codecvt\_utf8}, \texttt{codecvt\_utf16}, and \texttt{codecvt\_utf8\_utf16}:

1.1 — \texttt{Elem} is the wide-character type, such as \texttt{wchar\_t}, \texttt{char16\_t}, or \texttt{char32\_t}.

1.2 — \texttt{Maxcode} is the largest wide-character code that the facet will read or write without reporting a conversion error.

1.3 — If \texttt{(Mode \& consume\_header)}, the facet shall consume an initial header sequence, if present, when reading a multibyte sequence to determine the endianness of the subsequent multibyte sequence to be read.

1.4 — If \texttt{(Mode \& generate\_header)}, the facet shall generate an initial header sequence when writing a multibyte sequence to advertise the endianness of the subsequent multibyte sequence to be written.

1.5 — If \texttt{(Mode \& little\_endian)}, the facet shall generate a multibyte sequence in little-endian order, as opposed to the default big-endian order.

2 For the facet \texttt{codecvt\_utf8}:

2.1 — The facet shall convert between UTF-8 multibyte sequences and UCS-2 or UTF-32 (depending on the size of \texttt{Elem}) within the program.

2.2 — Endianness shall not affect how multibyte sequences are read or written.

2.3 — The multibyte sequences may be written as either a text or a binary file.

3 For the facet \texttt{codecvt\_utf16}:

3.1 — The facet shall convert between UTF-16 multibyte sequences and UCS-2 or UTF-32 (depending on the size of \texttt{Elem}) within the program.

3.2 — Multibyte sequences shall be read or written according to the \texttt{Mode} flag, as set out above.

3.3 — The multibyte sequences may be written only as a binary file. Attempting to write to a text file produces undefined behavior.

4 For the facet \texttt{codecvt\_utf8\_utf16}:

4.1 — The facet shall convert between UTF-8 multibyte sequences and UTF-16 (one or two 16-bit codes) within the program.

4.2 — Endianness shall not affect how multibyte sequences are read or written.

4.3 — The multibyte sequences may be written as either a text or a binary file.

5 The encoding forms UTF-8, UTF-16, and UTF-32 are specified in ISO/IEC 10646. The encoding form UCS-2 is specified in ISO/IEC 10646-1:1993.

D.15 Deprecated convenience conversion interfaces

The header \texttt{<locale>} has the following additions:

```cpp
namespace std {
    template<class Codecvt, class Elem = wchar_t,
             class Wide_alloc = allocator<Elem>,
             class Byte_alloc = allocator<char>>
    class wstring_convert;

    template<class Codecvt, class Elem = wchar_t,
             class Tr = char_traits<Elem>>
    class wbuffer_convert;
}
```

D.15.1 Class template \texttt{wstring\_convert}

Class template \texttt{wstring\_convert} performs conversions between a wide string and a byte string. It lets you specify a code conversion facet (like class template \texttt{codecvt}) to perform the conversions, without affecting any streams or locales. [*Example:* If you want to use the code conversion facet \texttt{codecvt\_utf8} to output to
cout a UTF-8 multibyte sequence corresponding to a wide string, but you don’t want to alter the locale for cout, you can write something like:

```cpp
wstring_convert<std::codecvt_utf8<wchar_t>> myconv;
std::string mbstring = myconv.to_bytes(L"Hello
");
std::cout << mbstring;
```

— end example

namespace std {

```cpp
template<class Codecvt, class Elem = wchar_t,
class Wide_alloc = allocator<Elem>,
class Byte_alloc = allocator<char>>
class wstring_convert {
public:
  using byte_string = basic_string<char, char_traits<char>, Byte_alloc>;
  using wide_string = basic_string<Elem, char_traits<Elem>, Wide_alloc>;
  using state_type = typename Codecvt::state_type;
  using int_type = typename wide_string::traits_type::int_type;

  wstring_convert() : wstring_convert(new Codecvt) {} 
  explicit wstring_convert(Codecvt* pcvt);
  wstring_convert(Codecvt* pcvt, state_type state);
  explicit wstring_convert(const byte_string& byte_err,
      const wide_string& wide_err = wide_string());
  ~wstring_convert();
  wstring_convert(const wstring_convert&) = delete;
  wstring_convert& operator=(const wstring_convert&) = delete;

  wide_string from_bytes(char byte);
  wide_string from_bytes(const char* ptr);
  wide_string from_bytes(const byte_string& str);
  wide_string from_bytes(const char* first, const char* last);

  byte_string to_bytes(Elem wchar);
  byte_string to_bytes(const Elem* wptr);
  byte_string to_bytes(const wide_string& wstr);
  byte_string to_bytes(const Elem* first, const Elem* last);

  size_t converted() const noexcept;
  state_type state() const;

private:
  byte_string byte_err_string; // exposition only
  wide_string wide_err_string; // exposition only
  Codecvt* cvtptr; // exposition only
  state_type cvtstate; // exposition only
  size_t cvtcount; // exposition only
};
```

The class template describes an object that controls conversions between wide string objects of class `basic_string<Elem, char_traits<Elem>, Wide_alloc>` and byte string objects of class `basic_string<char, char_traits<char>, Byte_alloc>`. The class template defines the types `wide_string` and `byte_string` as synonyms for these two types. Conversion between a sequence of `Elem` values (stored in a `wide_string` object) and multibyte sequences (stored in a `byte_string` object) is performed by an object of class `Codecvt`, which meets the requirements of the standard code-conversion facet `codecvt<Elem, char, mbstate_t>`.

An object of this class template stores:

1. `byte_err_string` — a byte string to display on errors
2. `wide_err_string` — a wide string to display on errors
3. `cvtptr` — a pointer to the allocated conversion object (which is freed when the `wstring_convert` object is destroyed)
---

(3.4) — cvtstate — a conversion state object

(3.5) — cvtcount — a conversion count

using byte_string = basic_string<char, char_traits<char>, Byte_alloc>;

The type shall be a synonym for basic_string<char, char_traits<char>, Byte_alloc>.

size_t converted() const noexcept;

Returns: cvtcount.

wide_string from_bytes(char byte);
wide_string from_bytes(const char* ptr);
wide_string from_bytes(const byte_string& str);
wide_string from_bytes(const char* first, const char* last);

Effects: The first member function shall convert the single-element sequence byte to a wide string. The second member function shall convert the null-terminated sequence beginning at ptr to a wide string. The third member function shall convert the sequence stored in str to a wide string. The fourth member function shall convert the sequence defined by the range [first, last) to a wide string.

In all cases:

(7.1) — If the cvtstate object was not constructed with an explicit value, it shall be set to its default value (the initial conversion state) before the conversion begins. Otherwise it shall be left unchanged.

(7.2) — The number of input elements successfully converted shall be stored in cvtcount.

Returns: If no conversion error occurs, the member function shall return the converted wide string. Otherwise, if the object was constructed with a wide-error string, the member function shall return the wide-error string. Otherwise, the member function throws an object of class range_error.

using int_type = typename wide_string::traits_type::int_type;

The type shall be a synonym for wide_string::traits_type::int_type.

state_type state() const;
returns cvtstate.

using state_type = typename Codecvt::state_type;

The type shall be a synonym for Codecvt::state_type.

byte_string to_bytes(Elem wchar);
byte_string to_bytes(const Elem* wptr);
byte_string to_bytes(const wide_string& wstr);
byte_string to_bytes(const Elem* first, const Elem* last);

Effects: The first member function shall convert the single-element sequence wchar to a byte string. The second member function shall convert the null-terminated sequence beginning at wptr to a byte string. The third member function shall convert the sequence stored in wstr to a byte string. The fourth member function shall convert the sequence defined by the range [first, last) to a byte string.

In all cases:

(13.1) — If the cvtstate object was not constructed with an explicit value, it shall be set to its default value (the initial conversion state) before the conversion begins. Otherwise it shall be left unchanged.

(13.2) — The number of input elements successfully converted shall be stored in cvtcount.

Returns: If no conversion error occurs, the member function shall return the converted byte string. Otherwise, if the object was constructed with a byte-error string, the member function shall return the byte-error string. Otherwise, the member function shall throw an object of class range_error.

using wide_string = basic_string<Elem, char_traits<Elem>, Wide_alloc>;

The type shall be a synonym for basic_string<Elem, char_traits<Elem>, Wide_alloc>.

explicit wstring_convert(Codecvt* pcvt);
wstring_convert(Codecvt* pcvt, state_type state);
explicit wstring_convert(const byte_string& byte_err,
    const wide_string& wide_err = wide_string());

Requires: For the first and second constructors, pcvt != nullptr.

Effects: The first constructor shall store pcvt in cvtptr and default values in cvtstate, byte_err_string, and wide_err_string. The second constructor shall store pcvt in cvtptr, state in cvtstate, and default values in byte_err_string and wide_err_string; moreover the stored state shall be retained between calls to from_bytes and to_bytes. The third constructor shall store new Codecvt in cvtptr, state_type() in cvtstate, byte_err in byte_err_string, and wide_err in wide_err_string.

~wstring_convert();

Effects: The destructor shall delete cvtptr.

D.15.2 Class template wbuffer_convert

[depr.conversions.buffer]

1 Class template wbuffer_convert looks like a wide stream buffer, but performs all its I/O through an underlying byte stream buffer that you specify when you construct it. Like class template wstring_convert, it lets you specify a code conversion facet to perform the conversions, without affecting any streams or locales.

namespace std {
    template<class Codecvt, class Elem = wchar_t, class Tr = char_traits<Elem>>
    class wbuffer_convert : public basic_streambuf<Elem, Tr> {
        public:
            using state_type = typename Codecvt::state_type;

            wbuffer_convert() : wbuffer_convert(nullptr) {}
            explicit wbuffer_convert(streambuf* bytebuf,
                Codecvt* pcvt = new Codecvt,
                state_type state = state_type());

            ~wbuffer_convert();

            wbuffer_convert(const wbuffer_convert&) = delete;
            wbuffer_convert& operator=(const wbuffer_convert&) = delete;

            streambuf* rdbuf() const;
            streambuf* rdbuf(streambuf* bytebuf);

            state_type state() const;

        private:
            streambuf* bufptr; // exposition only
            Codecvt* cvtptr; // exposition only
            state_type cvtstate; // exposition only
    };
}

2 The class template describes a stream buffer that controls the transmission of elements of type Elem, whose character traits are described by the class Tr, to and from a byte stream buffer of type streambuf. Conversion between a sequence of Elem values and multibyte sequences is performed by an object of class Codecvt, which shall meet the requirements of the standard code-conversion facet codecvt<Elem, char, mbstate_t>.

3 An object of this class template stores:

(3.1) — bufptr — a pointer to its underlying byte stream buffer
(3.2) — cvtptr — a pointer to the allocated conversion object (which is freed when the wbuffer_convert object is destroyed)
(3.3) — cvtstate — a conversion state object

state_type state() const;

Returns: cvtstate.
streambuf* rdbuf() const;
Returns: bufptr.

streambuf* rdbuf(streambuf* bytebuf);
Effects: Stores bytebuf in bufptr.
Returns: The previous value of bufptr.

using state_type = typename Codecvt::state_type;
The type shall be a synonym for Codecvt::state_type.

explicit wbuffer_convert(
    streambuf* bytebuf,
    Codecvt* pcvt = new Codecvt,
    state_type state = state_type());
Requires: pcvt != nullptr.
Effects: The constructor constructs a stream buffer object, initializes bufptr to bytebuf, initializes cvtptr to pcvt, and initializes cvtstate to state.

~wbuffer_convert();
Effects: The destructor shall delete cvtptr.

D.16 Deprecated locale category facets

1 The ctype locale category includes the following facets as if they were specified in Table 90 of 28.3.1.1.1.
   codecvt<char16_t, char, mbstate_t>
   codecvt<char32_t, char, mbstate_t>

2 The ctype locale category includes the following facets as if they were specified in Table 91 of 28.3.1.1.1.
   codecvt_byname<char16_t, char, mbstate_t>
   codecvt_byname<char32_t, char, mbstate_t>

3 The following class template specializations are required in addition to those specified in 28.4.1.4. The specialization codecvt<char16_t, char, mbstate_t> converts between the UTF-16 and UTF-8 encoding forms, and the specialization codecvt<char32_t, char, mbstate_t> converts between the UTF-32 and UTF-8 encoding forms.

D.17 Deprecated filesystem path factory functions

template<class Source>
path u8path(const Source& source);

template<class InputIterator>
path u8path(InputIterator first, InputIterator last);
Requires: The source and [first, last) sequences are UTF-8 encoded. The value type of Source and InputIterator is char. Source meets the requirements specified in 29.11.7.3.

Returns:

(2.1) — If value_type is char and the current native narrow encoding (29.11.7.2.2) is UTF-8, return path(source) or path(first, last); otherwise,

(2.2) — if value_type is wchar_t and the native wide encoding is UTF-16, or if value_type is char16_t or char32_t, convert source or [first, last) to a temporary, tmp, of type string_type and return path(tmp); otherwise,

(2.3) — convert source or [first, last) to a temporary, tmp, of type u32string and return path(tmp).

Remarks: Argument format conversion (29.11.7.2.1) applies to the arguments for these functions. How Unicode encoding conversions are performed is unspecified.

[Example: A string is to be read from a database that is encoded in UTF-8, and used to create a directory using the native encoding for filenames:

namespace fs = std::filesystem;
std::string utf8_string = read_utf8_data();
fs::create_directory(fs::u8path(utf8_string));]
For POSIX-based operating systems with the native narrow encoding set to UTF-8, no encoding or type conversion occurs.

For POSIX-based operating systems with the native narrow encoding not set to UTF-8, a conversion to UTF-32 occurs, followed by a conversion to the current native narrow encoding. Some Unicode characters may have no native character set representation.

For Windows-based operating systems a conversion from UTF-8 to UTF-16 occurs. — end example]
The following documents are cited informatively in this document.

— ISO 4217:2015, Codes for the representation of currencies

The arithmetic specification described in ISO/IEC 10967-1:2012 is called LIA-1 in this document.

### Index of grammar productions

The first bold page number for each entry is the page in the general text where the grammar production is defined. The second bold page number is the corresponding page in the Grammar summary (Annex A). Other page numbers refer to pages where the grammar production is mentioned in the general text.

Index of implementation-defined behavior

The entries in this index are rough descriptions; exact specifications are at the indicated page in the general text.

#pragma, 439
additional execution policies supported by parallel algorithms, 710, 988
additional file_type enumerators for file systems supporting additional types of file, 1408
additional formats for time_get::do_get_date, 1298
additional supported forms of preprocessing directive, 428
algorithms for producing the standard random number distributions, 1123
alignment, 60
alignment additional values, 60
allocation of bit-fields within a class object, 265
any use of an invalid pointer other than to perform indirection or deallocate, 56
argument values to construct basic_ios::failure, 1326
assignability of placeholder objects, 674
behavior of iostream classes when traits::pos_type is not streampos or when traits::off_type is not streamoff, 1310
behavior of non-standard attributes, 223
behavior of strstreambuf::setbuf, 1599
bits in a byte, 50
choice of larger or smaller value of floating literal, 19
concatenation of some types of string literals, 21
consistency of build level and violation continuation mode, 29
conversions between pointers and integers, 113
converting characters from source character set to execution character set, 9
converting function pointer to object pointer and vice versa, 114
default configuration of a pool, 652
default next_buffer_size for a monotonic_buffer_resource, 654
default number of buckets in unordered_map, 846
default number of buckets in unordered_multimap, 852
default number of buckets in unordered_multiset, 861, 862
default number of buckets in unordered_set, 857
defining main in freestanding environment, 77
definition and meaning of __STDC__, 441, 1574
definition and meaning of __STDC_VERSION__, 441
definition of NULL, 475, 1590
derived type for typeid, 111
diagnostic message, 3
dynamic initialization of static inline variables before main, 79
dynamic initialization of static variables before main, 79
dynamic initialization of thread-local variables before entry, 79
effect of calling associated Laguerre polynomials with n >= 128 or m >= 128, 1169
effect of calling associated Legendre polynomials with l >= 128, 1169
effect of calling basic_filebuf::setbuf with nonzero arguments, 1375
effect of calling basic_filebuf::sync when a get area exists, 1375
effect of calling basic_streambuf::setbuf with nonzero arguments, 1365
effect of calling cylindrical Bessel functions of the first kind with nu >= 128, 1170
effect of calling cylindrical Neumann functions with nu >= 128, 1171
effect of calling Hermite polynomials with n >= 128, 1172
effect of calling filesystem::copy, 1421
effect on C locale of calling locale::global, 1276
encoding of universal character name not in execution character set, 18
error_category for errors originating outside the operating system, 472
establishing of and argument for violation handler, 228
except type when random_device constructor fails, 1121
except type when random_device::operator() fails, 1121
except type when shared_ptr constructor fails, 629, 630
excepts thrown by standard library functions that have a potentially-throwing exception specification, 472
execution character set and execution wide-character set, 11
exit status, 489
extended signed integer types, 65
file type of the file argument of filesystem::status, 1431
formatted character sequence generated by time_put::do_put in C locale, 1300
forward progress guarantees for implicit threads of parallel algorithms (if not defined for thread), 987
growth factor for monotonic_buffer_resource, 654
headers for freestanding implementation, 455
how random_device::operator() generates values, 1121
how the set of importable headers is determined, 236
interactive device, 7
interpretation of the path character sequence with format path::auto_format, 1408
largest supported value to configure the largest allocation satisfied directly by a pool, 652
largest supported value to configure the maximum number of blocks to replenish a pool, 652
linkage of main, 77
linkage of names from C standard library, 456
linkage of objects between C++ and other languages, 222
locale names, 1274
lvalue-to-rvalue conversion of an invalid pointer value, 86
manner of search for included source file, 431
mapping from name to catalog when calling messages::do_open, 1307
mapping from physical source file characters to basic source character set, 10, 1581
mapping header name to header or external source file, 13
mapping of pointer to integer, 113
mapping physical source file characters to basic source character set, 9
mapping to message when calling messages::do_get, 1307
maximum depth of recursive template instantiations, 391
maximum size of an allocated object, 120, 495
meaning of ' ', \, /, or / in a q-char-sequence or an h-char-sequence, 13
meaning of asm declaration, 219
meaning of attribute declaration, 152
meaning of dot-dot in root-directory, 1396
mechanism for selecting the build level, 228
negative value of character literal in preprocessor, 430
nesting limit for #include directives, 431
NTCTS in basic_ostream<charT, traits>& operator<<(nullptr_t), 1354
number of placeholders for bind expressions, 659, 674
number of threads in a program under a freestanding implementation, 72
numeric values of character literals in #if directives, 430
operating system on which implementation depends, 1388
parameters to main, 77
passing argument of class type through ellipsis, 108
physical source file characters, 9
presence and meaning of native_handle_type and native_handle, 1498
range defined for character literals, 18
rank of extended signed integer type, 65
required alignment for atomic_ref type's operations, 1481, 1483–1485
required libraries for freestanding implementation, 6
resource limits on a message catalog, 1307
result of filesystem::file_size, 1426
result of inexact floating-point conversion, 88
return value of bad_alloc::what, 495
return value of bad_any_cast::what, 586
return value of bad_array_new_length::what, 495
return value of bad_cast::what, 497
return value of bad_exception::what, 500
return value of bad_function_call::what, 674
return value of bad_optional_access::what, 572
return value of bad_typeid::what, 498
return value of bad_variant_access::what, 585
return value of bad_weak_ptr::what, 627
return value of char_traits<char16_t>::eof, 718

type of vector::const_iterator, 815
type of vector::iterator, 815
type of vector<bool>::const_iterator, 819
type of vector<bool>::iterator, 819

underlying type for enumeration, 206
underlying type of bool, 66
underlying type of char, 66
underlying type of wchar_t, 66

value of bit-field that cannot represent
assigned value, 135
incremented value, 109
initializer, 186
value of character literal outside range of
corresponding type, 18

Index of implementation-defined behavior
value of `ctype<char>::table_size`, 1281
value of `has-attribute-expression` for non-standard attributes, 429
value of multicharacter literal, 17
value of `pow(0,0)`, 1100
value of result of inexact integer to floating-point conversion, 88
value of wide-character literal containing multiple characters, 18
value of wide-character literal with single c-char that is not in execution wide-character set, 18
value representation of floating-point types, 67
value representation of pointer types, 68
values of a trivially copyable type, 64
values of various `ATOMIC_..._LOCK_FREE` macros, 1480
whether `<cfenv>` functions can be used to manage floating-point status, 1093
whether a given `atomic` type’s operations are always lock free, 642, 644, 1487, 1488, 1490, 1492, 1493
whether a given `atomic_ref` type’s operations are always lock free, 1481, 1483–1485
whether an implementation has relaxed or strict pointer safety, 60
whether functions from Annex K of the C standard library are declared when C++ headers are included, 454
whether `get_pointer_safety` returns `pointer_safety::relaxed` or `pointer_safety::preferred` if the implementation has relaxed pointer safety, 606
whether locale object is global or per-thread, 1272
whether pragma `FENV_ACCESS` is supported, 1093
whether `rand` may introduce a data race, 1140
whether sequence pointers are copied by `basic_filebuf` move constructor, 1372
whether sequence pointers are copied by `basic_stringbuf` move constructor, 1362
whether sequence pointers are initialized to null pointers, 1362
whether source of translation units must be available to locate template definitions, 10
whether stack is unwound before calling the function `std::terminate` when a `noexcept` specification is violated, 426
whether the implementation is hosted or freestanding, 455
whether the lifetime of a parameter ends when the callee returns or at the end of the enclosing full-expression, 107
whether the sources for module units and header units on which the current translation unit has an interface dependency are required to be available during translation, 10
whether the thread that executes `main` and the threads created by `std::thread` provide concurrent forward progress guarantees, 76
whether `time_get::do_get_year` accepts two-digit year numbers, 1299
whether values are rounded or truncated to the required precision when converting between `time_t` values and `time_point` objects, 1203
which functions in the C++ standard library may be recursively reentered, 471
which non-standard-layout objects containing no data are considered empty, 52
which scalar types have unique object representations, 696
width of integral type, 66
