Stop Token and Joining Thread, Rev 10

New in R10

— `request_stop()` returns whether the stop state was changed.
— `stop_callback` has type member `callback_type`.
— `stop_callback` constructor supports copying/conversion of callback.
— `stop_callback` deduction guide now deduces to decayed type.
— Class `jthread` is now part of header `<thread>.
— Copy missing definitions from class `std::thread` to class `std::jthread`.
— Extend cross references to `std::thread`.
— Several (other) fixes from LWG multiple reviews.
— Several editorial fixes.

New in R9

— Fixes as requested by LEWG in Kona 2/2019.
  — clarify constness of get `stop_stop_source()` and `get_stop_token()`
— Fixes as requested from wording review by SG1 in Kona 2/2019.
  — clarify concurrency issues
— Fixes of small errors and typos.

New in R8

As requested at the LEWG meeting in San Diego 2018:

— Terminology (especially rename `interrupt_token` to `stop_token`).
— Add a deduction guide for `stop_callback`
— Add `std::nostopstate_t` to create stop tokens that don’t share a stop state
— Make comparisons hidden friends
— Several clarifications in wording

New in R7

— Adopt `www.wg21.link/P1287` as discussed in the SG1 meeting in San Diego 2018, which includes:
  — Add callbacks for interrupt tokens.
  — Split into `interrupt_token` and `interrupt_source`.

New in R6

— Use `condition_variable_any` instead of `condition_variable` to avoid all possible races, deadlocks, and unintended undefined behavior.
— Clarify future binary compatibility for interrupt handling (mention requirements for future callback support and allow `bad_alloc` exceptions on waits.
New in R5

As requested at the SG1 meeting in Seattle 2018:
- Removed exception class `std::interrupted` and the `throw_if_interrupted()` API.
- Removed all TLS extensions and extensions to `std::this_thread`.
- Added support to let `jthread` call a callable that either takes the interrupt token as additional first argument or doesn’t get it (taking just all passed arguments).

New in R4

- Removed interruptible CV waiting members that don’t take a predicate.
- Removed adding a new `cv_status value interrupted`.
- Added CV members for interruptible timed waits.
- Renamed CV members that wait interruptible.
- Several minor fixes (e.g. on `noexcept`) and full proposed wording.

Purpose

This is the proposed wording for a cooperatively interruptible joining thread.

For a full discussion for the motivation, see [www.wg21.link/p0660r0](http://www.wg21.link/p0660r0) and [www.wg21.link/p0660r1](http://www.wg21.link/p0660r1).

A default implementation exists at: [http://github.com/josuttis/jthread](http://github.com/josuttis/jthread). Note that the proposed functionality can be fully implemented on top of the existing C++ standard library without special OS support.

Basis examples

Basis `jthread` examples

- At the end of its lifetime a `jthread` automatically signals a request to stop the started thread (if still joinable) and joins:

  ```cpp
  void testJThreadWithToken()
  {
    std::jthread t([] (std::stop_token stoken) {
      while (!stoken.stop_requested()) {
        //...
      }
    });
    //...
  }
  // jthread destructor signals requests to stop and therefore ends the started thread and joins
  ```

  The stop could also be explicitly requested with `t.request_stop()`.

- If the started thread doesn’t take a stop token, the destructor still has the benefit of calling `join()` (if still joinable):

  ```cpp
  void testJThreadJoining()
  {
    std::jthread t([] { 
      //...
    });
    //...
  }
  // jthread destructor calls join()
  ```

  This is a significant improvement over `std::thread` where you had to program the following to get the same behavior (which is common in many scenarios):

  ```cpp
  void compareWithStdThreadJoining()
  {
    std::thread t([] { 
      //...
    });
    try {
      //...
    } catch (std::thread::error) {
      //...
    }
  }
  ```
catch (...) {
    j.join();
    throw; // rethrow
}
t.join();

— An extended CV API enables to interrupt CV waits using the passed stop token (i.e. interrupting the
CV wait without polling):

```cpp
void testInterruptibleCVWait()
{
    bool ready = false;
    std::mutex readyMutex;
    std::condition_variable_any readyCV;
    std::jthread t([&ready, &readyMutex, &readyCV] (std::stop_token st) {
        while (...) {
            std::unique_lock lg{readyMutex};
            readyCV.wait_until(lg,
                [&ready] {
                    return ready;
                },
                st); // also ends wait on stop request for st
        }
    });
}
```

Basis istop_source/stop_token examples

// create stop_source and stop_token:
std::stop_source ssrc;
std::stop_token stok{ssrc.get_token()};

// register callback
bool cb1called(false);
auto cb1 = [&] { cb1called = true; };
std::stop_callback scb1(stok, cb1); // stop_callback copies cb1
assert(!cb1called);

// request stop
ssrc.request_stop(); // calls all currently registered callbacks
assert(cb1called);

// register another callback
bool cb2called(false);
std::stop_callback scb2(stok,
    [&] { cb2called = true; });
    // immediately calls callback (moved into scb2)
assert(!cb2called);

Feature Test Macro

Update [tab:support.ft] with

```
__cpp_lib_jthread
```

and the corresponding value for the headers <stop_token> and <thread>.
Design Discussion

Problems with "interrupt"

Earlier versions of this paper used the names `interrupt_token`, `interrupt_source` and `interrupt_callback` to refer to the abstraction used to signal interrupt.

However, the term 'interrupt' already has common usage in industry and typically refers to something which can be interrupted and then return back to the non-interrupted state.

For example, hardware interrupts are raised when some event happens and then once the interrupt is handled the system returns back to the non-interrupted state, allowing the interrupt to be raised again.

The boost::thread library also uses the term 'interrupt' to refer to an operation that can be raised many times and when the interrupt is handled the state is reset back to non-interrupted.

This is different from the semantics of the abstraction proposed in this paper which has the semantics that once it has been signalled it never returns to the non-signalled state. Thus the term "interrupt" seems inappropriate and is likely to lead to confusion.

Alternative names

There was some discussion in at LEWG at San Diego about alternative names for `interrupt_token` and there were two candidates: `cancellation_token` and `stop_token`.

The term `cancellation_token` has precedent in other C++ libraries. For example, Microsoft’s PPL uses the names ‘cancellation_token’, ‘cancellation_token_source’ and ‘cancellation_registration’.

The use of the 'cancel' term also has precedent in the Networking TS which defines methods such as `basic_waitable_timer::cancel()` and `basic_socket::cancel()` and makes use of `std::errc::operationCanceled` as an error code in response to a request to cancel the operation.

However, some concerns were raised about the potential for confusion if a `std::jthread::cancel()` method were added as some may confuse this as somehow being related to the semantics of `pthread_cancel()` which is able to cancel a thread at an arbitrary point rather than cooperatively at well-defined cancellation points.

A straw poll was taken in LEWG at San Diego and the group favoured `stop_token`.

A suggestion was also made to introduce the use of the term 'request' to more clearly communicate the asynchronous and cooperative nature of the abstraction. This suggestion has been adopted.

As a result the proposed names for the types and methods are now as follows:

```cpp
class stop_token {
    public:
        [[nodiscard]] bool stop_requested() const noexcept;
        [[nodiscard]] bool stop_possible() const noexcept;
};

class stop_source {
    public:
        ...
        [[nodiscard]] bool stop_requested() const noexcept;
        [[nodiscard]] bool stop_possible() const noexcept;
        bool request_stop() noexcept;
    };

template<Invocable Callback>
class stop_callback {
    public:
        ...
};
```

Callback Registration/Deregistration

An important capability for asynchronous use-cases for `stop_token` is the ability to attach a callback to the `stop_token` that will be called if a request to stop is made. The motivations for this are discussed in more detail in P1287R0.

Registration of a callback is performed by constructing a `stop_callback` object, passing the constructor both a `stop_token` and a `Invocable` object that is invoked if/when a call to `request_stop()` is made.
For example:

```cpp
void cancellable_operation(std::stop_token stoken = {}) {
  auto handle = begin_operation();
  std::stop_callback cb{ stoken, {[&] { cancel_operation(handle); }});
  ...
  auto result = end_operation(handle);
}
```

When a `stop_callback` object is constructed, if the `stop_token` has already received a request to stop then the callback is immediately invoked inside the constructor. Otherwise, the callback is registered with the `stop_token` and is later invoked if/when some thread calls `request_stop()` on an associated `stop_source`. The callback registration is guaranteed to be performed atomically. If there is a concurrent call to `request_stop()` from another thread then either the current thread will see the request to stop and immediately invoke the callback on the current thread or the other thread will see the callback registration and will invoke the callback before returning from `request_stop()`.

When the `stop_callback` object is destructed the callback is deregistered from the list of callbacks associated with the `stop_token`'s shared state the callback is guaranteed not to be called after the `stop_callback` destructor returns.

Note that there is a potential race here between the callback being deregistered and a call to `request_stop()` being made on another thread which could invoke the callback. If the callback has not yet started executing on the other thread then the callback is deregistered and is never called. Otherwise, if the callback has already started executing on another thread then the call to `~stop_callback()` will block the current thread until the callback returns.

If the call to the `stop_callback` destructor is made from within the the invocation of the callback on the same thread then the destructor does not block waiting for the callback to return as this would cause a deadlock. Instead, the destructor returns immediately without waiting for the callback to return.

Other Hints

It is intentional that class `std::jthread` supports the full API of `std::thread` (i.e., by supporting to start the thread without taking a stop token as first parameter) to be able to replace any usage of `std::thread` by `std::jthread` without further code changes.

The terminology was carefully selected with the following reasons:

- With a stop token we neither 'interrupt' nor 'cancel' something. We request a stop that cooperatively has to get handled.
- `stop_possible()` helps to avoid adding new callbacks or checking for stop states. The name was selected to have a common and pretty self-explanatory name that is shared by both `stop_sources` and `stop_tokens`.

Initialization of `stop_callbacks`

Class `stop_callback` was carefully designed to be able to accept any callback, whether passed as lvalue or rvalue and whether an implicit conversion to a specified callback type is requested.

The deduction guide for `stop_callbacks` deduces the callback argument type (`callback_type`) such that the constructor performs a decayed copy of the callback argument. Because the constructors are function templates, type conversions are possible.

Given:

```cpp
struct ImplicitArg {};
struct ExplicitArg {};
struct MyCallback {
  MyCallback(ImplicitArg x);
  explicit MyCallback(ExplicitArg x);
  void operator()() const;
};
```

we have the following behavior:

32.2  Requirements

...
32.3 Stop Tokens

32.3.1 Stop Token Introduction

This clause describes components that can be used to asynchronously request that an operation stops execution in a timely manner, typically because the result is no longer required. Such a request is called a stop request.

stop_source, stop_token, and stop_callback implement semantics of shared ownership of a (stop state). Any stop_source, stop_token or stop_callback that shares ownership of the same stop state is an (associated) stop_source, stop_token or stop_callback, respectively. The last remaining owner of the stop state automatically releases the resources associated with the stop state.

A stop_token can be passed to an operation which can either

1. actively poll the token to check if there has been a stop request, or
2. register a callback using the stop_callback class template which will be called in the event that a stop request is made.

A stop request made via a stop_source will be visible to all associated stop_token and stop_source objects. Once a stop request has been made it cannot be withdrawn (a subsequent stop request has no effect).

Callbacks registered via a stop_callback object are called when a stop request is first made by any associated stop_source object.

Calls to the functions request_stop, stop_requested, and stop_possible do not introduce data races. A call to request_stop that returns true synchronizes with a call to stop_requested on an associated stop_token or stop_source object that returns true. Registration of a callback synchronizes with the invocation of that callback.

32.3.2 Header <stop_token> synopsis

namespace std {
    // 32.3.3 class stop_token
    class stop_token;

    // 32.3.4 class stop_source
    class stop_source;

    // no-shared-stop-state indicator
    struct nostopstate_t {
        explicit nostopstate_t() = default;
    };
    inline constexpr nostopstate_t nostopstate{};

    // 32.3.5 class stop_callback
    template<class Callback>
    class stop_callback;
}

32.3.3 Class stop_token

The class stop_token provides an interface for querying whether a stop request has been made (stop_requested) or can ever be made (stop_possible) using an associated stop_source object (32.3.4). A stop_token can also be passed to a stop_callback (32.3.5) constructor to register a callback to be called when a stop request has been made from an associated stop_source.

namespace std {
    class stop_token {
        public:
            // 32.3.3.1 create, copy, destroy:
            stop_token() noexcept;
            stop_token(const stop_token&) noexcept;
            stop_token(stop_token&&) noexcept;
            stop_token& operator=(const stop_token&) noexcept;
            stop_token& operator=(stop_token&&) noexcept;
            ~stop_token();
            void swap(stop_token&) noexcept;
        }
    }
/** 32.3.3.5 stop handling:
[[nodiscard]] bool stop_requested() const noexcept;
[[nodiscard]] bool stop_possible() const noexcept;

[[nodiscard]] friend bool operator==(const stop_token& lhs, const stop_token& rhs) noexcept;
[[nodiscard]] friend bool operator!=(const stop_token& lhs, const stop_token& rhs) noexcept;
friend void swap(stop_token& lhs, stop_token& rhs) noexcept;
*/
}

32.3.3.1 stop_token constructors

stop_token() noexcept;
1
Ensures: stop_possible() is false and stop_requested() is false. [Note: Because the created stop_token object can never receive a stop request, no resources are allocated for a stop state. — end note]

stop_token(const stop_token& rhs) noexcept;
2
Ensures: *this == rhs is true. [Note: *this and rhs share the ownership of the same stop state, if any. — end note]

stop_token(stop_token&& rhs) noexcept;
3
Ensures: *this contains the value of rhs prior to the start of construction and rhs.stop_possible() is false.

32.3.3.2 stop_token destructor

~stop_token();
1
Effects: Releases ownership of the stop state, if any.

32.3.3.3 stop_token assignment

stop_token& operator=(const stop_token& rhs) noexcept;
1
Effects: Equivalent to: stop_token(rhs).swap(*this).

stop_token& operator=(stop_token&& rhs) noexcept;
2
Returns: *this.

Effects: Equivalent to: stop_token(std::move(rhs)).swap(*this).

4
Returns: *this.

32.3.3.4 stop_token swap

void swap(stop_token& rhs) noexcept;
1
Effects: Exchanges the values of *this and rhs.
32.3.3.5 stop_token members

[[nodiscard]] bool stop_requested() const noexcept;
1
   Returns: true if *this has ownership of a stop state that has received a stop request; otherwise, false.

[[nodiscard]] bool stop_possible() const noexcept;
2
   Returns: false if:
   — *this does not have ownership of a stop state, or
   — a stop request was not made and there are no associated stop_source objects; otherwise, true.

32.3.3.6 stop_token comparisons

[[nodiscard]] bool operator==(const stop_token& lhs, const stop_token& rhs) noexcept;
1
   Returns: true if lhs and rhs have ownership of the same stop state or if both lhs and rhs do not have ownership of a stop state; otherwise false.

[[nodiscard]] bool operator!=(const stop_token& lhs, const stop_token& rhs) noexcept;
2
   Returns: !(lhs==rhs).

32.3.3.7 Specialized algorithms

friend void swap(stop_token& x, stop_token& y) noexcept;
1
   Effects: Equivalent to: x.swap(y).

32.3.4 Class stop_source

The class stop_source implements the semantics of making a stop request. A stop request made on a stop_source object is visible to all associated stop_source and stop_token (32.3.3) objects. Once a stop request has been made it cannot be withdrawn (a subsequent stop request has no effect).

namespace std {
   // no-shared-stop-state indicator
   struct nostopstate_t {
      explicit nostopstate_t() = default;
   };
   inline constexpr nostopstate_t nostopstate{};

   class stop_source {
      public:
         // 32.3.4.1 create, copy, destroy:
         stop_source();
         explicit stop_source(nostopstate_t) noexcept;
         stop_source(const stop_source&) noexcept;
         stop_source(stop_source&&) noexcept;
         stop_source& operator=(const stop_source&) noexcept;
         stop_source& operator=(stop_source&&) noexcept;
         ~stop_source();
         void swap(stop_source&) noexcept;

         // 32.3.4.5 stop handling:
         [[nodiscard]] stop_token get_token() const noexcept;
         [[nodiscard]] bool stop_possible() const noexcept;
         [[nodiscard]] bool stop_requested() const noexcept;
         bool request_stop() noexcept;
         [[nodiscard]] friend bool operator==(const stop_source& lhs, const stop_source& rhs) noexcept;
         [[nodiscard]] friend bool operator!=(const stop_source& lhs, const stop_source& rhs) noexcept;
         friend void swap(stop_source& lhs, stop_source& rhs) noexcept;
   };
};
32.3.4.1 stop_source constructors

```
stop_source();
```

1. **Effects:** Initialises *this to have ownership of a new stop state.

2. **Ensures:** `stop_possible()` is true and `stop_requested()` is false.

3. **Throws:** `bad_alloc` if memory could not be allocated for the stop state.

```
explicit stop_source(nostopstate_t) noexcept;
```

4. **Ensures:** `stop_possible()` is false and `stop_requested()` is false. [Note: No resources are allocated for the state. — end note]

```
stop_source(const stop_source& rhs) noexcept;
```

5. **Ensures:** *this == rhs is true. [Note: *this and rhs share the ownership of the same stop state, if any. — end note]

```
stop_source(stop_source&& rhs) noexcept;
```

6. **Ensures:** *this contains the value of rhs prior to the start of construction and rhs.stop_possible() is false.

32.3.4.2 stop_source destructor

```
~stop_source();
```

1. **Effects:** Releases ownership of the stop state, if any.

32.3.4.3 stop_source assignment

```
stop_source& operator=(const stop_source& rhs) noexcept;
```

1. **Effects:** Equivalent to: `stop_source(rhs).swap(*this)`.

32.3.4.4 stop_source swap

```
void swap(stop_source& rhs) noexcept;
```

1. **Effects:** Exchanges the values of *this and rhs.

32.3.4.5 stop_source members

```
[[nodiscard]] stop_token get_token() const noexcept;
```

1. **Returns:** `stop_token()` if `stop_possible()` is false; otherwise a new associated `stop_token` object.

```
[[nodiscard]] bool stop_possible() const noexcept;
```

2. **Returns:** true if *this has ownership of a stop state; otherwise, false.

```
[[nodiscard]] bool stop_requested() const noexcept;
```

3. **Returns:** true if *this has ownership of a stop state that has received a stop request; otherwise, false.

```
bool request_stop() noexcept;
```

4. **Effects:** If *this does not have ownership of a stop state, returns false. Otherwise, atomically determines whether the owned stop state has received a stop request, and if not, makes a stop request. The determination and making of the stop request are an atomic read-modify-write operation (??). If the request was made, the callbacks registered by associated `stop_callback` objects are synchronously called. If an invocation of a callback exits via an exception then `terminate()` is called. [Note: A stop request includes notifying all condition variables of type `condition_variable_any` temporarily registered during an interruptible wait (32.6.4.2). — end note]
Ensures: stop_possible() is false or stop_requested() is true.

Returns: true if this call made a stop request; otherwise false.

32.3.4.6 stop_source comparisons

[[nodiscard]] bool operator==(const stop_source& lhs, const stop_source& rhs) noexcept;

Returns: true if lhs and rhs have ownership of the same stop state or if both lhs and rhs do not have ownership of a stop state; otherwise false.

[[nodiscard]] bool operator!=(const stop_source& lhs, const stop_source& rhs) noexcept;

Returns: !(lhs==rhs).

32.3.4.7 Specialized algorithms

friend void swap(stop_source& x, stop_source& y) noexcept;

Effects: Equivalent to: x.swap(y).

32.3.5 Class Template stop_callback

namespace std {

    template<class Callback>
    class stop_callback {

        public:
            using callback_type = Callback;

        // 32.3.5.1 create, destroy:
            template<class C>
            explicit stop_callback(const stop_token& st, C&& cb)
                noexcept(is_nothrow_constructible_v<Callback, C>);
            template<class C>
            explicit stop_callback(stop_token&& st, C&& cb)
                noexcept(is_nothrow_constructible_v<Callback, C>);
            ~stop_callback();

            stop_callback(const stop_callback&) = delete;
            stop_callback(stop_callback&&) = delete;
            stop_callback& operator=(const stop_callback&) = delete;
            stop_callback& operator=(stop_callback&&) = delete;

        private:
            Callback callback;  // exposition only
    };

    template<class Callback>
    stop_callback(stop_token, Callback) -> stop_callback<Callback>;
}

Mandates: stop_callback is instantiated with an argument for the template parameter Callback that satisfies both Invocable and Destructible.

Expects: stop_callback is instantiated with an argument for the template parameter Callback that models both Invocable and Destructible.

32.3.5.1 stop_callback constructors and destructor

template<class C>
    explicit stop_callback(const stop_token& st, C&& cb)
        noexcept(is_nothrow_constructible_v<Callback, C>);

template<class C>
    explicit stop_callback(stop_token&& st, C&& cb)
        noexcept(is_nothrow_constructible_v<Callback, C>);

Constraints: Callback and C satisfy Constructible<Callback, C>.
2 Expects: Callback and C model Constructible<Callback, C>.

3 Effects: Initializes callback with static_cast<C&&>(cb). If st.stopRequested() is true, static_cast<Callback&&>(callback)() is evaluated in the current thread before the constructor returns. Otherwise, if st has ownership of a stop state, acquires shared ownership of that stop state and registers the callback with that stop state such that static_cast<Callback&&>(callback)() is evaluated by the first call to request_stop() on an associated stop_source.

4 Remarks: If evaluating static_cast<Callback&&>(callback)() exits via an exception, then terminate() is called.

5 Throws: Any exception thrown by the initialization of callback.

~stop_callback();

6 Effects: Unregisters the callback from the owned stop state, if any. The destructor does not block waiting for the execution of another callback registered by an associated stop_callback. If callback is concurrently executing on another thread, then the return from the invocation of callback strongly happens before (??) callback is destroyed. If callback is executing on the current thread, then the destructor does not block (??) waiting for the return from the invocation of callback. Releases ownership of the stop state, if any.
32.4 Threads

... 

32.4.1 Header <thread> synopsis

namespace std {
    class thread;

    void swap(thread& x, thread& y) noexcept;
    // 32.4.3 class jthread
    class jthread;
}

32.4.2 Class thread

...

32.4.3 Class jthread

The class jthread provides a mechanism to create a new thread of execution. The functionality is the same as for class thread (32.4.2) with the additional ability to request that the thread stops and then joins the started thread.

[Editorial note: This color signals differences in behavior compared to class std::thread ]

namespace std {
    class jthread {
    public:
        // types
        using id = thread::id;
        using native_handle_type = thread::native_handle_type;

        // construct/copy/destroy
        jthread() noexcept;
        template<class F, class... Args> explicit jthread(F&& f, Args&&... args);
        ~jthread();
        jthread(const jthread&) = delete;
        jthread(jthread&&) noexcept;
        jthread& operator=(const jthread&) = delete;
        jthread& operator=(jthread&&) noexcept;

        // members
        void swap(jthread&) noexcept;
        [[nodiscard]] bool joinable() const noexcept;
        void join();
        void detach();
        [[nodiscard]] id get_id() const noexcept;
        [[nodiscard]] native_handle_type native_handle(); // see ??

        // stop token handling
        [[nodiscard]] stop_source get_stop_source() noexcept;
        [[nodiscard]] stop_token get_stop_token() const noexcept;
        bool request_stop() noexcept;

        friend void swap(jthread& lhs, jthread& rhs) noexcept;

        // static members
        [[nodiscard]] static unsigned int hardware_concurrency() noexcept;

    private:
        stop_source ssource; // exposition only
    }
}
### 32.4.3.1 jthread constructors

```cpp
jthread() noexcept;
```

**Effects:** Constructs a `jthread` object that does not represent a thread of execution.

**Ensures:** `get_id() == id()` is true and `ssource.stop_possible()` is false.

```cpp
template<class F, class... Args> explicit jthread(F&& f, Args&&... args);
```

**Requires:** `F` and each `T_i` in `Args` shall satisfy the Cpp17MoveConstructible requirements. `INVOKE(decay-copy(std::forward<F>(f)), ssource.get_token(), decay-copy(std::forward<Args>(args)))...` or `INVOKE(decay-copy(std::forward<F>(f)), decay-copy(std::forward<Args>(args)))...` are valid expressions.

**Remarks:** This constructor shall not participate in overload resolution if `remove_cvref_t<F>` is the same type as `jthread`.

**Effects:** Initializes `ssource` and constructs an object of type `jthread`. The new thread of execution executes `INVOKE(decay-copy(std::forward<F>(f)), ssource.get_token(), decay-copy(std::forward<Args>(args)))...` if that expression is well-formed, otherwise `INVOKE(decay-copy(std::forward<F>(f)), decay-copy(std::forward<Args>(args)))...` with the calls to `decay-copy` being evaluated in the constructing thread. Any return value from this invocation is ignored. [Note: This implies that any exceptions not thrown from the invocation of the copy of `f` will be thrown in the constructing thread, not the new thread. — end note] If the `INVOKE` expression exits via an exception, `terminate()` is called.

**Synchronization:** The completion of the invocation of the constructor synchronizes with the beginning of the invocation of the copy of `f`.

**Ensures:** `get_id() != id()` is true and `ssource.stop_possible()` is true and `*this` represents the newly started thread. [Note: The calling thread can make a stop request only once, because it cannot replace this stop token. — end note]

**Throws:** `system_error` if unable to start the new thread.

**Error conditions:**

9.1 **— resource_unavailable_try_again** — the system lacked the necessary resources to create another thread, or the system-imposed limit on the number of threads in a process would be exceeded.

```cpp
jthread(jthread&& x) noexcept;
```

**Effects:** Constructs an object of type `jthread` from `x`, and sets `x` to a default constructed state.

**Ensures:** `x.get_id() == id()` and `get_id()` returns the value of `x.get_id()` prior to the start of construction. `ssource` has the value of `x.ssource` prior to the start of construction and `x.ssource.stop_possible()` is false.

### 32.4.3.2 jthread destructor

```cpp
~jthread();
```

**Effects:** If `joinable()` is true, calls `request_stop()` and then `join()`. [Note: Operations on `*this` are not synchronized. — end note]

### 32.4.3.3 jthread assignment

```cpp
jthread& operator=(jthread&& x) noexcept;
```

**Effects:** If `joinable()` is true, calls `request_stop()` and then `join()`. Assigns the state of `x` to `*this` and sets `x` to a default constructed state.

**Ensures:** `x.get_id() == id()` and `get_id()` returns the value of `x.get_id()` prior to the assignment. `ssource` has the value of `x.ssource` prior to the assignment and `x.ssource.stop_possible()` is false.

**Returns:** `*this`.
32.4.3.4 Members

```cpp
void swap(jthread& x) noexcept;
```

*Effects:* Exchanges the values of `*this` and `x`.

```cpp
[[nodiscard]] bool joinable() const noexcept;
```

*Returns:* `get_id() != id()`.

```cpp
void join();
```

*Effects:* Blocks until the thread represented by `*this` has completed.

*Synchronization:* The completion of the thread represented by `*this` synchronizes with (`??`) the corresponding successful `join()` return. [Note: Operations on `*this` are not synchronized. — end note]

*Ensures:* The thread represented by `*this` has completed. `get_id() == id()`.

*Throws:* `system_error` when an exception is required (`??`).

```cpp
(7.1) — resource_deadlock_would_occur — if deadlock is detected or `get_id() == this_thread::get_id()`.
(7.2) — no_such_process — if the thread is not valid.
(7.3) — invalid_argument — if the thread is not joinable.
```

```cpp
void detach();
```

*Effects:* The thread represented by `*this` continues execution without the calling thread blocking. When `detach()` returns, `*this` no longer represents the possibly continuing thread of execution. When the thread previously represented by `*this` ends execution, the implementation shall release any owned resources.

*Ensures:* `get_id() == id()`.

*Throws:* `system_error` when an exception is required (`??`).

*Error conditions:

```cpp
(11.1) — no_such_process — if the thread is not valid.
(11.2) — invalid_argument — if the thread is not joinable.
```

```cpp
id get_id() const noexcept;
```

*Returns:* A default constructed `id` object if `*this` does not represent a thread, otherwise `this_thread::get_id()` for the thread of execution represented by `*this`.

32.4.3.5 jthread stop members

```cpp
[[nodiscard]] stop_source get_stop_source() noexcept
```

*Effects:* Equivalent to: `return ssource;`

```cpp
[[nodiscard]] stop_token get_stop_token() const noexcept
```

*Effects:* Equivalent to: `return ssource.get_token();`

```cpp
bool request_stop() noexcept;
```

32.4.3.6 Specialized algorithms

```cpp
friend void swap(jthread& x, jthread& y) noexcept;
```

*Effects:* Equivalent to: `x.swap(y)`.

32.4.3.7 Static members

```cpp
unsigned hardware_concurrency() noexcept;
```

*Returns:* `thread::hardware_concurrency()`.

            bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time,
             Predicate pred);
        template<class Lock, class Rep, class Period>
            cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);
        template<class Lock, class Rep, class Period, class Predicate>
            bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time, Predicate pred);

        // 32.6.4.2 interruptible waits:
        template<class Lock, class Predicate>
            bool wait_until(Lock& lock, Predicate pred, stop_token stoken);
        template<class Lock, class Clock, class Duration, class Predicate>
            bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time
             Predicate pred, stop_token stoken);
        template<class Lock, class Rep, class Period, class Predicate>
            bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time,
             Predicate pred, stop_token stoken);
    }
}
```

§ 32.6.4
condition_variable_any();

Effects: Constructs an object of type condition_variable_any.

Throws: bad_alloc or system_error when an exception is required (??).

Error conditions:

1. resource_unavailable_try_again — if some non-memory resource limitation prevents initialization.

2. operation_not_permitted — if the thread does not have the privilege to perform the operation.

- condition_variable_any();

Requires: There shall be no thread blocked on *this. [Note: That is, all threads shall have been notified; they may subsequently lock on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait needs to happen before destruction. The user should take care to ensure that no threads wait on *this once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of wait, wait_for, or wait_until that take a predicate. —end note]

Effects: Destroys the object.

void notify_one() noexcept;

Effects: If any threads are blocked waiting for *this, unblocks one of those threads.

void notify_all() noexcept;

Effects: Unblocks all threads that are blocked waiting for *this.

32.6.4.1 Noninterruptible waits [thread.condvarany.wait]

template<class Lock>
void wait(Lock& lock);

Effects:

1. Atomics calls lock.unlock() and blocks on *this.

2. When unblocked, calls lock.lock() (possibly blocking on the lock) and returns.

3. The function will unblock when requested by a call to notify_one(), a call to notify_all(), or spuriously.

Remarks: If the function fails to meet the postcondition, terminate() is called (??). [Note: This can happen if the re-locking of the mutex throws an exception. —end note]

Ensures: lock is locked by the calling thread.

Throws: Nothing.

template<class Lock, class Predicate>
void wait(Lock& lock, Predicate pred);

Effects: Equivalent to:

while (!pred())
    wait(lock);

template<class Lock, class Clock, class Duration>
cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);

Effects:

1. Atomics calls lock.unlock() and blocks on *this.

2. When unblocked, calls lock.lock() (possibly blocking on the lock) and returns.

3. The function will unblock when requested by a call to notify_one(), a call to notify_all(), expiration of the absolute timeout (??) specified by abs_time, or spuriously.

4. If the function exits via an exception, lock.lock() shall be called prior to exiting the function.
Remarks: If the function fails to meet the postcondition, terminate() is called (??). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

Ensures: lock is locked by the calling thread.

Returns: cv_status::timeout if the absolute timeout (??) specified by abs_time expired, otherwise cv_status::no_timeout.

Throws: Timeout-related exceptions (??).

```
template<class Lock, class Rep, class Period>
    cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);
```

Effects: Equivalent to:
```
    return wait_until(lock, chrono::steady_clock::now() + rel_time);
```

Returns: cv_status::timeout if the relative timeout (??) specified by rel_time expired, otherwise cv_status::no_timeout.

Remarks: If the function fails to meet the postcondition, terminate() is called (??). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

Ensures: lock is locked by the calling thread.

Throws: Timeout-related exceptions (??).

```
template<class Lock, class Rep, class Period, class Predicate>
    bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time, Predicate pred);
```

Effects: Equivalent to:
```
    return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));
```

§ 32.6.4.1
32.6.4.2 Interruptible waits

The following wait functions will be notified when there is a stop request on the passed stop_token. In that case the functions return immediately, returning false if the predicate evaluates to false.

```cpp
template<class Lock, class Predicate>
bool wait_until(Lock& lock,
             Predicate pred,
             stop_token stoken);
```

**Effects:** Registers for the duration of this call *this to get notified on a stop request on stoken during this call and then equivalent to:

```cpp
while (!stoken.stop_requested()) {
    if (pred())
        return true;
    wait(lock);
}
return pred();
```

*Note: The returned value indicates whether the predicate evaluated to true regardless of whether there was a stop request. — end note*

**Ensures:** lock is locked by the calling thread.

**Remarks:** If the function fails to meet the postcondition, terminate() is called (??). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

**Throws:** Any exception thrown by pred.

```cpp
template<class Lock, class Clock, class Duration, class Predicate>
bool wait_until(Lock& lock,
                const chrono::time_point<Clock, Duration>& abs_time
             Predicate pred,
             stop_token stoken);
```

**Effects:** Registers for the duration of this call *this to get notified on a stop request on stoken during this call and then equivalent to:

```cpp
while (!stoken.stop_requested()) {
    if (pred())
        return true;
    if (cv.wait_until(lock, abs_time) == cv_status::timeout)
        return pred();
}
return pred();
```

*Note: There is no blocking if pred() is initially true, stoken.stop_requested() was already true or the timeout has already expired. — end note*

*Note: The returned value indicates whether the predicate determination to true regardless of whether the timeout was triggered or a stop request was made. — end note*

**Ensures:** lock is locked by the calling thread.

**Remarks:** If the function fails to meet the postcondition, terminate() is called (??). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

**Throws:** Timeout-related exceptions (??), or any exception thrown by pred.

```cpp
template<class Lock, class Rep, class Period, class Predicate>
bool wait_for(Lock& lock,
              const chrono::duration<Rep, Period>& rel_time,
             Predicate pred,
             stop_token stoken);
```

**Effects:** Equivalent to:

```cpp
return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred), std::move(stoken));
```
32.7 Other Fixes

In 6.8.2.2 Forward progress [intro.progress]/8:

It is implementation-defined whether the implementation-created thread of execution that executes main (6.8.3.1) and the threads of execution created by `std::thread` (32.3.2) or `std::jthread` (32.4.3) provide concurrent forward progress guarantees.

In 16.5.1.2 Headers [headers] in tab:headers.cpp add:

```cpp
<stop_token>
```

In 17.12.3.4 Resumption [coroutine.handle.resumption]/1:

Resuming a coroutine via `resume`, `operator()`, or `destroy` on an execution agent other than the one on which it was suspended has implementation-defined behavior unless each execution agent either is an instance of `std::thread` or `std::jthread`, or is the thread that executes `main`.

In 25.3.3 Effect of execution policies on algorithm execution [algorithms.parallel.exec]/6:

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::parallel_policy` are permitted to execute either in the invoking thread of execution or in a thread of execution implicitly created by the library to support parallel algorithm execution. If the threads of execution created by `thread` (32.3.2) or `jthread` (32.4.3) provide concurrent forward progress guarantees (6.8.2.2), then a thread of execution implicitly created by the library will provide parallel forward progress guarantees; otherwise, the provided forward progress guarantee is implementation-defined.

In 26.3.1 Header `<cfenv>` synopsis [cfenv.syn]/2:

The floating-point environment has thread storage duration (6.6.5.2). The initial state for a thread's floating-point environment is the state of the floating-point environment of the thread that constructs the corresponding `thread` object (32.3.2) or `jthread` object (32.4.3) at the time it constructed the object.
