Language support for class layout control

Abstract

The current rules on how layout is created for a class fall between chairs: if the user does not care about the order of members, they prevent optimal placement, while if the user cares, the control is taken away unless all members have the same access control.

This proposal attempts to remedy this situation with an attribute that express the intent and reduce waste or ambiguity.

Changes from R1

Reflect discussion at Cologne meeting.
- "declorder" strategy still discussed as motivation, but it is moved out to P1847 to be the default
- remove "best" strategy
+ refer to Herb's poll on desired papers for C++23

Changes from R0

+ status section
+ wording for bit-fields
+ Q&A to address questions rised on EWGI list
+ example showing visible semantic change from declorder
+ show a possible alternative approach instead of declorder
+ new idea to split "smallest"

Status

R1 was discussed in EWGI in Cologne. Some of the previous decision points got polled. "declorder" is being pursued in separate paper P1847, if passed that will be the default and strategies from this paper will be relaxing that, also removing the attribute-related concerns.

How to tackle the standard-layout related core wording was not decided, a paper dedicated to that part, P1848 is being drafted. Based on reflector feedback it might appear in pre-Belfast mailing.

The discussion also suggested to look for a possible generalized approach through compile time programming. The paper got officially forwarded to SG7 with poll question "Investigate a more general approach through reflection, such as a consteval approach which, allows passing a function which dictates a layout. Then provide "smallest" and other consteval functions in the standard library." I realized only after the meeting that this question in this form does not really make sense in the scope of the paper. At the moment it's unclear how this will be resolved, if new information emerges, it will be reflected in a revision in the pre-Belfast meeting.
Motivation

This proposal is inspired by [Language support for empty objects] (http://open-std.org/JTC1/SC22/WG21/docs/papers/2017/p0840r1.html) that allowed to turn off a layout-creating rule that requires distinct address for all members, including those taking up zero space. Causing wasted performance when the user never looks at member offsets.

We have another rule preventing optimal layout: p19 in [class.mem] stating "Non-static data members of a (non-union) class with the same access control (Clause 14) are allocated so that later members have higher addresses within a class object." (ORDERRULE) In practice that results in plenty of padding when the class has members of different size and alignment. That could be reduced if reordering the members was allowed.

On the other common use case the desired layout is compatible with another language and must have the members in a strict order. This can be achieved only by not using access control.

We have some hard evidence that this feature is wanted. In https://herbsutter.com/2019/07/25/survey-results-your-top-five-iso-c-feature-proposals/ this paper got into top 50 with 7 votes. One of those is mine, but the other six was born in the most natural way, I did not mention the poll to anyone.

Proposal

We propose the addition of an attribute, [[layout(strategy)]] that can be applied to a class definition and indicates that the programmer wants to cancel ORDERRULE and orders the layout created in a certain way indicated by strategy.

[[layout(smallest)]] wants the members reordered to minimize the memory footprint. Minimizing the sum of inter-member padding and maximizing the tail-padding as tie-breaker if multiple variants have the same minimal sizeof(T), that may benefit in a subclass. (Note: see also the "New idea on "smallest" later.)

[[layout(declorder)]] wants the members appear strictly in declaration order regardless access control, thus allowing standard-layout compatibility without interaction of the unrelated ACL functionality. (Note: if P1847 gets accepted then this will be the default state, so dropped as strategy).

We thought about many other sensible strategies that are not proposed at this time, but the implementations can add their own keywords as extension and they can be standardized alter as implementation and usage experience emerges.
### Examples

```cpp
struct cell {
    int idx;
    double fortran_input;
    double fortran_output;
private:
    double f();
public: // should be private but we need this
    // be standard layout!
    // PLEASE do not touch!
    mutable double memoized_f;
};
```

```cpp
struct [[layout(declorder)]] cell {
    int idx;
    double fortran_input;
    double fortran_output;
private:
    double f();
    mutable double memoized_f;
};
```

```cpp
// hand-optimized to save space!
// sorry for the mess
// please remember to re-work if add
// or change a member
struct Dog {
    std::string name;
    std::string bered;
    std::string owner;
    int age;
    bool sex_male;
    bool can_bark;
    bool bark_extra_deep;
    double weight;
    double bark_freq;
};
```

```cpp
struct [[layout(smallest)]] Dog {
    std::string name;
    std::string bered;
    int age;
    bool sex_male;
    double weight;
    std::string owner;
    bool can_bark;
    double bark_freq;
    bool bark_extra_deep;
};
```

### Why language support is required?

Currently we have just one tool to get the best layout: arranging the members in the desired order. That brings in several problems:

- the source will be (way) less readable, the natural thing is to have members arranged by program logic
- the programmer must know the size and alignment of members; including 3rd party and std:: classes (that is next to impossible)
- if some member changed its content, what contains it needs rearrangement (recursively)
- such manual adjustment itself triggers need to rearrange the subsequent classes
- if the source targets several platforms, each may need a different order to be optimal

On top of that, manual rearrangement would cause:

- change in the order of initialization of members
  -- likely trigger warnings on initializer lists
  -- possibly breaking the code if it depended on the order
- need adjusting brace-init lists
- need adjusting structured bindings

What makes the effort extremely infeasible in practice. We can ask the compiler to warn about padding or even dump the realized layout, but then many iterations are needed. And the work redone on a slight change. And we sacrificed much of readability and portability.

Therefore, in practice we mostly just ignore the layout and live with the waste as cost of using the high-level language. Against the design principles of C++. And this is really painful considering that cases
where we use the address of members for anything is really rare. And that the compiler has all the info at hand when it is creating the layout to do the meaningful thing, just it is not allowed.

**Why attribute?**

It passes the "compiling a valid program with all instances of a particular attribute ignored must result in a correct interpretation of the original program" test. This also ensures that existing code will not change its meaning, the programmer must actively apply the attribute. Also this seem the least intrusive way and allows the same source used with non-supporting compiler.

Jens Maurer provided this example:

```cpp
class [[layout(declorder)]] S {
public:
    int x;
private:
    int y;
    void f() { if (!(&x < &y)) abort(); }  // abort() is never called
};
```

```cpp
int main() { S().f(); }
```

Here the program can potentially abort if the attribute is ignored and the implementation did put y before x as it is allowed.

This formally goes against the usual EWG approach on what is suitable as attribute.

Jens offered the idea to make declorder the language default, that would also cure this problem as a side effect. It is pursued in P1847. Supposedly that paper can be processed in short time and if accepted, the attribute route is cleared. If not, we can get back to re-evaluation and alternatives.

**A new idea on "smallest"**

Some of the feedback is concerned on reinterpret_cast and general surprises related the "smallest" that is allowed to move the single base class down to save space. This can be addressed by providing a strategy specifically without that factor. (working name -- suggestions welcome) "minpadd" would require to keep the 0-offset base class at 0 offset if such exists, while beyond that work as "smallest". This might result wasting a handful of bytes, but beyond saving reinterpret_casters, would strictly prevent introducing offset-adjustment. With related potential of performance degradation.

Then "minpadd_full", "minpadd_all", "smallest" would look for really the minimal memory footprint.

**The attribute name**

We considered a simpler approach with just an attribute to disable the ORDRERRULE: [[no_incremental_address]]. That is great for language lawyers, but programmers would benefit more from reflecting the motivation. So next it was [[optimized_layout]] and [[bestlayout]] along with [[smallestlayout]].
But at defining the semantics we (obviously) discovered that "best" is an elusive thing. Smallest was simple to define but in some special cases the size reduction may result loss of performance, not gain (i.e. on modern platforms going from 64 byte to 60).

So we prefer an attribute family \[\text{[layout()]}\] with options already defined and ability to extend with relative ease.

**Other considered strategies (not proposed now)**

"best" allows reordering as the implementation decides optimal on the target platform, without specific preference. This was in the proposal at R1, but EWGI suggested to remove it.

"cacheline" a very powerful strategy for speed optimization aiming to set sizeof(T) be a divisor or multiple of the cacheline size. Not included before gathering experience with implementation and impact, especially for sizes over the cacheline size. Possibly needs additional tuning parameter, i.e. to control maximum extension.

"alpha(N)" sort by the name (or first N letters) combined with smallest where it is tied. This would allow creation of groups of members to keep together (for locality) or apart (to avoid false sharing).

"pack(N)" would invoke the effect of \#pragma pack(N) finally bring this omnipresent facility in the standard. Not included because this proposal aims only at reordering members, not interacting with alignment.

"compact" would imply "smallest" "pack(1)" and implicit \[\text{[no_unique_address]}\] removing all possible waste.

**Interaction with standard layout**

The following thoughts are not completely tied to the core of this proposal. So they might be better handled in a separate paper. I allocated P1848 for that purpose. EWGI did not get to poll this question, so it is not yet submitted.

A major clash point is with 'standard-layout'. Rearranging the members shall render the class not standard-layout. The ambiguous point is when the \[\text{[layout(smallest)]}\] is present on a standard-layout class and no rearrangement actually happened. But that may change just due to size change of members later.

We believe that the spirit of standard-layout lies in the actual layout arrangement. The requirement on no mixed access was put in only as reflection of ORDERRULE. bullet (7.3) can be changed to this original intent stating it depends on all its members laid out in declaration order.

Going this route would create a behavior change on existing code without using the attribute (the only such change): \text{is-standard-layout} for a class with mixed access always reported false and now can report true if the implementation did not use the license of reordering (likely). We consider preserving the way of such code has less value than the change that moves toward the original intent and give more clarity.

Full compatibility, if desired, can be achieved by an extra bullet in wording, that keeps mixed-access implying not standard-layout. If that way is chosen we suggest to mark that condition as deprecated.
Interaction with library

The specification method of the library allows the implementation to use or not use the attribute without the user could detect it. The few cases where it is not evident are classes with public members, like std::pair.

Simplest and safest way is to explicitly state that the implementation is allowed to use [[layout(*)]] except where multiple public data members are specified. Or state that library classes' layout is unspecified. so users can not rely on member positions at all. A clear published decision is preferred.

Risks

This proposal does not create new kind of risk, as impact is similar to [[no_unique_address]]: if we mix code compiled with versions that implement it differently, the program will not work. (Similar mess can be created by inconsistent control of alignment through #pragma pack and related default packing control compiler switches.) But we add an extra item to those potential problems. For practice we consider these problems as an aspect of ODR violation.

The implementation of the attribute in general and a stable approach for "best" in particular, must become part of the ABI.

Summary of decision points

- bikeshed the strategy names
- add/remove some of the strategies

in scope of P1848:
- tie standard-layoutness to actual created layout (yes) or consider potential reorder as breaker
- preserve not standard-layoutness of mixed-access classes without attribute? (no; if choice is yes, consider to keep mark this condition as deprecated)

Wording illustration

(The wording reflect earlier version of the proposal; delta against N4778
"best" strategy is no longer proposed, the related wording will be scrapped, but till then serves as illustration;
)

Add a new subclause [dcl.attr.layout] after last attribute

9.11.12 Layout control attribute

| The attribute-token layout specifies special rules regarding nonstatic member placement when the memory layout for a class is created. This attribute may appertain to struct or class definition. It shall appear at most once in each attribute-list.
| It shall have an attribute-argument-clause of the following form:
2 The attribute allows placing members in layout according to the indicated strategy, removing requirement set in (10.3 p19). [Note: The order of the members can be changed compared to how they would appear without the attribute. – end note]

3 For bit-fields, each field shall remain in its allocation unit. [Note: Moving fields within the allocation unit and moving the allocation unit is allowed but not moving fields to a different unit or joining allocation units. – end note]

4 The declorder strategy requires members appear in the layout strictly in the order of declaration. [Note: Members are allocated so that later members have higher addresses within a class object or same if [[no_unique_address]] was used. – end note]

5 The smallest strategy aims for a layout with the smallest memory size. The size is considered smaller if sizeof(T) is smaller or sizeof(T) is equal and the amount of tail padding is greater. The implementation shall consider possible orders of the members and use one of the layouts with the smallest size. If the layout that is created by ignoring the layout attribute has the smallest size, that must be used. [Note: Gratuitous reordering without gain is not allowed. – end note]

6 The best strategy aims for a layout that the implementation considers ideal using its knowledge about the target platform. Any reordering is allowed. [Note: The result is up to quality of implementation. It can be identical to what the smallest strategy produces. It can leave the layout as if it had no layout attribute. It can increase the size if that is likely to increase the runtime performance. Quality is not considered good if it makes the performance worse without a chance to be better. – end note]

7 The reordering shall be deterministic, so multiple translation units use the same layout from identical member definition and strategy.

Example:

```c
[[layout(smallest)]] struct S {
    double d1;
    bool b1;
    double d2;
    bool b2;
    double d3;
    bool b3;
};
```

If double is aligned on 8 bytes, without the attribute the struct has 7 bytes padding after b1, b2 and b3, having size 48 bytes. With the attribute it can be reordered by moving the three bools next to each other and have 5 byte padding, size 32 bytes. The bools must be placed last for the maximum tail padding. – end example.

In 10.1 [class.prop] p3 change bullet (3.3)

(3.3) — has the same access control (10.8) for all non-static data members.
(3.3) — has such layout, that all non-static data members are allocated in the order of their declaration.
Add at end of first sentence of 10.3 Class members [class.mem] p19

Non-static data members of a (non-union) class with the same access control (10.8) are allocated so that later members have higher addresses within a class object, unless the class has the layout attribute [9.10.12]. The order ...

Add new section after 15.5.5.15 in 15.5.5 [conforming]

15.5.5.16 Layout control [lib.layoutcontrol]

The C++ library classes where multiple public data members are specified (like std::pair) must ensure a layout where these members appear in declaration order.

Add layout to table 15 in 14.1 [cpp.cond]

Acknowledgements

Many thanks to Richard Smith for championing this proposal.
To James Dennett, Daniel J. Garcia and Roger Orr for reviewing the initial draft.
To Jens Maurer for clarification on "attribute" and the related source example.

Appendix

Possible improvements in the future

(Not part of the proposal at this time.)

Bulk specification

The programmers who want to use this attribute will likely want it on majority of their classes. So, a simple form that could add it to many places with little source change would be good. Like with extern "C" that can be applied to make a {} block that will apply it to all relevant elements inside.

We considered the attribute applicable to the extern "" {} block and namespace {} block with the semantics that it would be used on any class definition within the block without a layout attribute. Neither felt good enough.

The implementation could likely add a facility like current #pragma pack along with push and pop, but pragmas that is not fit for the standard.
Q&A

Does it change the initialization order of members?

Absolutely not! The only change is the offset of the members within the memory. Any other semantic is unchanged. One of the major motivations of this paper is that manual rearrangement changes things that we want to avoid.

Is there implementation experience?

No. I still plan to create an implementation in Clang but it is already overdue by a year. Might still happen. I also stumbled on a problem with "smallest". It is trivial for the usual case when size is multiple of alignment. But over-aligned members or base class with tail padding adds extra space that might be used to host some of the members. For my method of using that, but some space remains, I have no formal evidence that a tighter fill could not exist. Ideas welcome.

Implementability (with relative ease) was key element in design of this proposal. Many interesting ideas were dropped due to being unclear how to implement across variety of platforms or expected to collide with known compiler extensions.

Is there usage experience?

No

Why does this need to be an attribute? C++ attributes traditionally don't change semantics, and this changes offset in a manner that is observable in C++. "Why attribute?" tries to address this, but it's not really true. To be fair, neither is it true for [[no_unique_address]]. Could this be done with something else than an attribute?

It does not "need" to be an attribute, but that is the framework that is least intrusive and easiest for implementations. Also the proposal was directly inspired by [[no_unique_address]] thinking "this has the very same global impact".

If not attribute, then it leaves us with a keyword, that is way more intrusive. Even if it could be context-sensitive, looks like much heavier. That would also make the code hostile to cross-compile. The code written with this attribute passes the old compiler that does not support it, and the client will still get a working program. Except for one corner case, but there the user actively relies on the support so could not expect good results without.

Layout “smallest” is close to “packed” attributes. Please cite prior experience in various toolchains. Is there uniformity in implementations of “packed”? Why don't you propose that semantic? (example at https://godbolt.org/z/3wyjrn)

The packed "attribute" in the previous example changes the alignment of int. This proposal is about reordering within the layout and treats the alignment as given. It was considered and dropped due to the current standard has no direct control on the alignment (only cloning unspecified one.) While most compilers have several methods for alignment control (compiler switch, #pragma pack, __declspec(align)
to name a few). And the control is already dependent on their interaction plus the requirements of the target platform. Moving that into the standard would be more than desirable, but did not happen in the last 20 years, probably due to all the interactions and major risk.

The control of the alignment is an orthogonal issue, and reordering is helpful exactly in the cases where alignment is mandatory (i.e. the SPARC and many other RISC architectures) or desired to avoid performance penalty.

Meanwhile, the infrastructure of this attribute allows easy addition of strategies and vendors can (and we hope will) provide such in a way that is fit in their environment. And eventually those can get into the standard as the established, working practice.

**Layout “smallest” is not really smallest as above packed example shows**

It is smallest within constraints imposed by the platform and the programmer through alignment control. But alternative names are considered like "minpadd".

**Layout “best” is pretty handwavy. I absolutely expect implementation and usage experience before this can move forward. I want to see that there's an actionable benefit to the compiler when this attribute is used.**

"best" has the weakest specification, that allows to do nothing or mirror "smallest", so there can not be problem with implementability. However it allows the implementation to provide some much better. It serves clients who know that they are not interested in any specific placement and allow full freedom for the implementation. And it can improve for them over time without a need to change the source code.

Benefit from manual rearrangement of class members was presented in many articles and talks. This proposal opens the way to save human effort and allow the compiler to take over.

If where compiling all the client using a struct is not a problem, it could be used in profile-based optimizations instead of simple heuristics. I really see no reason to doubt the compiler could do any better than it can now burdened with an ancient restriction.

**I'd like a discussion of ABI issues this paper can cause, and how users can avoid them (potentially with tooling help).**

The ABI issues are the same as caused by [[no_unique_address]]. And usage of #pragma pack (+ alternatives). The latter is a thing we live together from the beginning of the C language. And the "tooling" is pretty weak on several major platforms. I.e. one can try to compile with MSVC switch setting the structure alignment to 1 instead of the default 4/8. And include <windows.h> and use something. The build is clean and the result will crash. As many structs will have a different layout in the program than in the system DLLs. (Because the source uses #pragma pack for control and pack(N) does not increase the alignment to N if it more than what comes from the switch...)

But tooling is certainly possible if the vendor provides it, i.e. on the same platform different values for ITERATOR_DEBUG_LEVEL, that cause different content in the standard classes has a chance to get an alert in linking.

The implementation can emit information on what attribute was used and in what way and internal identifier for strategy implementation and can check it too. Or an offset table. A related example https://docs.microsoft.com/en-us/previous-versions/visualstudio/visual-studio-2012/k3349xx(v=vs.110) is MSVC’s warning C4742 that remembers alignment used for structure members. While the implementation is not open, the best guess is that the layout table is emitted to the .obj file as comment and is checked. The very same information can point out discrepancy on the member offsets. However this method is limited to cases where linking is involved. For a DLL+header there is probably no way to discover that the client
compiled the header with incompatible options. (This latter problem is nothing new, just try to build a WIN32 API application with the "default packing" option set to 1 and enjoy the crash related to system calls.)

This proposal does create an additional case, as the concrete algorithm even for "smallest" could suffer an incompatible change.

But the user who starts the project with arranging a solid build system that ensures everything compiled with same version and flags is protected from these problems too. While doing less is ill-advised. The libraries that ship as header+binary will probably stick to just the conservative layout control.

How does the proposal affect bit-field members (including zero-width bit-fields)?
See p3 in wording. The allocation units created from the original source are preserved, but the units are allowed to be moved around, so are fields within a unit. Constrained by the strategy semantics.

How can I keep certain members on the same cache line, or keep them in different cache lines?
This proposal only works on full structure, no mark for individual members. I have implementation plan for the cacheline strategy mentioned above that works well when the total (smallest) size is <= CL size.

For finer control a later proposal could add attribute to mark individual members and the strategy work on them. Or a strategy can describe some naming convention it use for guidance.

I added a simple "alpha" strategy to the non-proposed but interesting strategies that could gelp this use case. It may be considered for inclusion.
