Mandating the Standard Library: 
Clause 28 - Localization library

With the adoption of P0788R3, we have a new way of specifying requirements for the library clauses of the standard. This is one of a series of papers reformulating the requirements into the new format. This effort was strongly influenced by the informational paper P1369R0.

The changes in this series of papers fall into three broad categories.

— Change 'participate in overload resolution' wording into "Constraints' elements
— Change 'Requires' elements into either "Mandates" or "Expects", depending (mostly) on whether or not they can be checked at compile time.
— Drive-by fixes (hopefully very few)

This paper covers Clause 28 (Localization), and is based on N4830.

The entire clause is reproduced here, but the changes are confined to a few sections:

— locale 28.3.1
— locale.cons 28.3.1.2
— locale.members 28.3.1.3
— locale.statics 28.3.1.5
— locale.global.templates 28.3.2
— facet.ctype.char.members 28.4.1.3.2
— locale.codecvt.virtuals 28.4.1.4.2
— locale.codecvt.virtuals 28.4.1.4.2
— locale.time.get.members 28.4.5.1.1
— locale.time.get.virtuals 28.4.5.1.2
— locale.messages 28.4.7.1
— locale.messages.members 28.4.7.1.1
— locale.messages.virtuals 28.4.7.1.2

Drive-by fixes:
— Reworked [facet.ctype.char.members]/2.
— Removed several meaningless paragraphs in [locale.cons].
— Removed a 'shall' from [locale.statics]
— Changed several basic_string<char> types to just string.
— Added 'is' in a few places to make english sentences.

Changes from R0
— Updated to N4830
— Reworked the change in [facet.ctype.char.members]/2 to use 'is a valid range'
— Removed a 'shall' from [locale.statics]
— Incorporated feedback from LWG teleconference 6-Sep-2019.

Thanks to Daniel Krügler for his advice and reviews.

Help for the editors: The changes here can be viewed as latex sources with the following commands
git clone git@github.com:mclow/mandate.git
cd mandate

git diff master..chapter28 locales.tex
28 Localization library

28.1 General

This Clause describes components that C++ programs may use to encapsulate (and therefore be more portable when confronting) cultural differences. The locale facility includes internationalization support for character classification and string collation, numeric, monetary, and date/time formatting and parsing, and message retrieval.

The following subclauses describe components for locales themselves, the standard facets, and facilities from the ISO C library, as summarized in Table 100.

Table 100: Localization library summary

28.2 Header `<locale>` synopsis

```cpp
namespace std {
    // 28.3.1, locale
    class locale;
    template<class Facet> const Facet& use_facet(const locale&);
    template<class Facet> bool has_facet(const locale&) noexcept;

    // 28.3.3, convenience interfaces
    template<class charT> bool isspace (charT c, const locale& loc);
    template<class charT> bool isprint (charT c, const locale& loc);
    template<class charT> bool iscntrl (charT c, const locale& loc);
    template<class charT> bool isupper (charT c, const locale& loc);
    template<class charT> bool islower (charT c, const locale& loc);
    template<class charT> bool isalpha (charT c, const locale& loc);
    template<class charT> bool isdigit (charT c, const locale& loc);
    template<class charT> bool ispunct (charT c, const locale& loc);
    template<class charT> bool isxdigit(charT c, const locale& loc);
    template<class charT> bool isgraph (charT c, const locale& loc);
    template<class charT> bool isblank (charT c, const locale& loc);
    template<class charT> charT toupper(charT c, const locale& loc);
    template<class charT> charT tolower(charT c, const locale& loc);

    // 28.4.1, ctype
    class ctype_base;
    template<class charT> class ctype;
    template<> class ctype<char>;
    template<class charT> class ctype_byname; // specialization
    class codecvt_base;
    template<class internT, class externT, class stateT> class codecvt;
    template<class internT, class externT, class stateT> class codecvt_byname;

    // 28.4.2, numeric
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class num_get;
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class num_put;
    template<class charT> class numpunct;
```
template<class charT>
    class numpunct_byname;

    // 28.4.4, collation
    template<class charT> class collate;
    template<class charT> class collate_byname;

    // 28.4.5, date and time
    class time_base;

    // 28.4.6, money
    class money_base;
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
        class money_get;
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
        class money_put;
    template<class charT, bool Intl = false>
        class moneypunct;
    template<class charT, bool Intl = false>
        class moneypunct_byname;

    // 28.4.7, message retrieval
    class messages_base;
    template<class charT> class messages;
    template<class charT> class messages_byname;
}

1 The header <locale> defines classes and declares functions that encapsulate and manipulate the information peculiar to a locale.257

28.3 Locales

28.3.1 Class locale

namespace std {
    class locale {
    public:
        // types
        class facet;
        class id;
        using category = int; // values assigned here are for exposition only
        static const category none = 0,
            collate = 0x010, ctype = 0x020,
            monetary = 0x040, numeric = 0x080,
            time = 0x100, messages = 0x200,
            all = collate | ctype | monetary | numeric | time | messages;

        // construct/copy/destroy
        locale() noexcept;
        locale(const locale& other) noexcept;
        explicit locale(const char* std_name);
        explicit locale(const string& std_name);
        locale(const locale& other, const char* std_name, category);
        locale(const locale& other, const string& std_name, category);
        template<class Facet> locale(const locale& other, Facet* f);

257) In this subclause, the type name struct tm is an incomplete type that is defined in <ctime>.
locale(const locale& other, const locale& one, category);
~locale(); // not virtual
const locale& operator=(const locale& other) noexcept;
template<class Facet> locale combine(const locale& other) const;

// locale operations
basic_string<char> string name() const;
bool operator==(const locale& other) const;
template<class charT, class traits, class Allocator>
  bool operator()(const basic_string<charT, traits, Allocator>& s1,
                  const basic_string<charT, traits, Allocator>& s2) const;

// global locale objects
static locale global(const locale&);
static const locale& classic();
};

1 Class locale implements a type-safe polymorphic set of facets, indexed by facet type. In other words, a facet has a dual role: in one sense, it’s just a class interface; at the same time, it’s an index into a locale’s set of facets.

2 Access to the facets of a locale is via two function templates, use_facet<> and has_facet<>.

3 [Example: An iostream operator<< might be implemented as:]

```cpp
template<class charT, class traits>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>&& s, Date d) {
    typename basic_ostream<charT, traits>::sentry cerberos(s);
    if (cerberos) {
      ios_base::iostate err = ios_base::iostate::goodbit;
      tm tmbuf; d.extract(tmbuf);
      use_facet<time_put<charT, ostreambuf_iterator<charT, traits>>>(s.getloc()).put(s, err, &tmbuf, 'x');
      s.setstate(err); // might throw
    }
    return s;
  }

— end example
```

4 In the call to use_facet<Facet>(loc), the type argument chooses a facet, making available all members of the named type. If Facet is not present in a locale, it throws the standard exception bad_cast. A C++ program can check if a locale implements a particular facet with the function template has_facet<Facet>(). User-defined facets may be installed in a locale, and used identically as may standard facets.

5 [Note: All locale semantics are accessed via use_facet<> and has_facet<>], except that:

5.1 — A member operator template operator()(const basic_string<C, T, A>&, const basic_string<C, T, A>&) is provided so that a locale may be used as a predicate argument to the standard collections, to collate strings.

5.2 — Convenient global interfaces are provided for traditional ctype functions such as isdigit() and isspace(), so that given a locale object loc a C++ program can call isspace(c, loc). (This eases upgrading existing extractors (??).)

— end note

6 Once a facet reference is obtained from a locale object by calling use_facet<>>, that reference remains usable, and the results from member functions of it may be cached and re-used, as long as some locale object refers to that facet.

7 In successive calls to a locale facet member function on a facet object installed in the same locale, the returned result shall be identical.

---

258) Note that in the call to put the stream is implicitly converted to an ostreambuf_iterator<charT, traits>.
A locale constructed from a name string (such as "POSIX"), or from parts of two named locales, has a name; all others do not. Named locales may be compared for equality; an unnamed locale is equal only to (copies of) itself. For an unnamed locale, `locale::name()` returns the string "*".

Whether there is one global locale object for the entire program or one global locale object per thread is implementation-defined. Implementations should provide one global locale object per thread. If there is a single global locale object for the entire program, implementations are not required to avoid data races on it (??).

28.3.1.1 Types

28.3.1.1.1 Type `locale::category`

```
using category = int;
```

1 Valid category values include the `locale` member bitmask elements `collate`, `ctype`, `monetary`, `numeric`, `time`, and `messages`, each of which represents a single locale category. In addition, `locale` member bitmask constant `none` is defined as zero and represents no category. And `locale` member bitmask constant `all` is defined such that the expression

```
(collate | ctype | monetary | numeric | time | messages | all) == all
```

is `true`, and represents the union of all categories. Further, the expression `(X | Y)`, where `X` and `Y` each represent a single category, represents the union of the two categories.

2 `locale` member functions expecting a category argument require one of the category values defined above, or the union of two or more such values. Such a category value identifies a set of locale categories. Each locale category, in turn, identifies a set of locale facets, including at least those shown in `Table 101`.

```
<table>
<thead>

<td><code>messages&lt;char&gt;</code>, <code>messages&lt;wchar_t&gt;</code></td>
</tr>
</tbody>
</table>
```

3 For any locale `loc` either constructed, or returned by `locale::classic()`, and any facet `Facet` shown in `Table 101`, `has_facet<Facet>(loc)` is `true`. Each `locale` member function which takes a `locale::category` argument operates on the corresponding set of facets.

4 An implementation is required to provide those specializations for facet templates identified as members of a category, and for those shown in `Table 102`.

5 The provided implementation of members of facets `num_get<charT>` and `num_put<charT>` calls `use_facet<F>(l)` only for facet `F` of types `numpunct<charT>` and `ctype<charT>`, and for locale `l` the value obtained by calling member `getloc()` on the `ios_base&` argument to these functions.

6 In declarations of facets, a template parameter with name `InputIterator` or `OutputIterator` indicates the set of all possible specializations on parameters that meet the `Cpp17InputIterator` requirements or `Cpp17OutputIterator` requirements, respectively (??). A template parameter with name `C` represents the set of types containing `char`, `wchar_t`, and any other implementation-defined character types that meet the...

</table>

requirements for a character on which any of the iostream components can be instantiated. A template parameter with name International represents the set of all possible specializations on a bool parameter.

28.3.1.1.2 Class locale::facet  [locale.facet]

namespace std {
    class locale::facet {
        protected:
            explicit facet(size_t refs = 0);
            virtual ~facet();
            facet(const facet&) = delete;
            void operator=(const facet&) = delete;
    };
}

1 Class facet is the base class for locale feature sets. A class is a facet if it is publicly derived from another facet, or if it is a class derived from locale::facet and contains a publicly accessible declaration as follows:

```
static ::std::locale::id id;
```

2 Template parameters in this Clause which are required to be facets are those named Facet in declarations. A program that passes a type that is not a facet, or a type that refers to a volatile-qualified facet, as an (explicit or deduced) template parameter to a locale function expecting a facet, is ill-formed. A const-qualified facet is a valid template argument to any locale function that expects a Facet template parameter.

3 The refs argument to the constructor is used for lifetime management. For refs == 0, the implementation performs delete static_cast<locale::facet*>(f) (where f is a pointer to the facet) when the last locale object containing the facet is destroyed; for refs == 1, the implementation never destroys the facet.

4 Constructors of all facets defined in this Clause take such an argument and pass it along to their facet base class constructor. All one-argument constructors defined in this Clause are explicit, preventing their participation in automatic conversions.

5 For some standard facets a standard “..._byname” class, derived from it, implements the virtual function semantics equivalent to that facet of the locale constructed by locale(const char*) with the same name.

259) This is a complete list of requirements; there are no other requirements. Thus, a facet class need not have a public copy constructor, assignment, default constructor, destructor, etc.
Each such facet provides a constructor that takes a `const char*` argument, which names the locale, and a `refs` argument, which is passed to the base class constructor. Each such facet also provides a constructor that takes a `string` argument `str` and a `refs` argument, which has the same effect as calling the first constructor with the two arguments `str.c_str()` and `refs`. If there is no “..._byname” version of a facet, the base class implements named locale semantics itself by reference to other facets.

28.3.1.1.3 Class `locale::id`  

```cpp
namespace std {
    class locale::id {
    public:
        id();
        void operator=(const id&) = delete;
        id(const id&) = delete;
    };
}
```

1 The class `locale::id` provides identification of a locale facet interface, used as an index for lookup and to encapsulate initialization.

2 [Note: Because facets are used by iostreams, potentially while static constructors are running, their initialization cannot depend on programmed static initialization. One initialization strategy is for `locale` to initialize each facet’s `id` member the first time an instance of the facet is installed into a locale. This depends only on static storage being zero before constructors run (??). — end note]

28.3.1.2 Constructors and destructor  

```cpp
locale() noexcept;
```

1 Default constructor: a snapshot of the current global locale.

2 Effects: Constructs a copy of the argument last passed to `locale::global(locale&)`, if it has been called; else, the resulting facets have virtual function semantics identical to those of `locale::classic()`.

3 [Note: This constructor yields a copy of the current global locale. It is commonly used as the default value for arguments of functions that take a `const locale&` argument. — end note]

```cpp
locale(const locale& other) noexcept;
```

3 Effects: Constructs a locale which is a copy of `other`.

```cpp
explicit locale(const char* std_name);
```

4 Effects: Constructs a locale using standard C locale names, e.g., "POSIX". The resulting locale implements semantics defined to be associated with that name.

5 Throws: `runtime_error` if the argument is not valid, or is null.

6 Remarks: The set of valid string argument values is "C", ",", and any implementation-defined values.

```cpp
explicit locale(const string& std_name);
```

7 Effects: The same as `locale(std_name.c_str())`.

```cpp
locale(const locale& other, const char* std_name, category);
```

8 Effects: Constructs a locale as a copy of `other` except for the facets identified by the `category` argument, which instead implement the same semantics as `locale(std_name)`.

9 Throws: `runtime_error` if the argument is not valid, or is null.

10 Remarks: The locale has a name if and only if `other` has a name.

```cpp
locale(const locale& other, const string& std_name, category cat);
```

11 Effects: The same as `locale(other, std_name.c_str(), cat)`.

```cpp
template<class Facet> locale(const locale& other, Facet* f);
```

12 Effects: Constructs a locale incorporating all facets from the first argument except that of type `Facet`, and installs the second argument as the remaining facet. If `f` is null, the resulting object is a copy of `other`.

13 Remarks: The resulting locale has no name.
locale(const locale& other, const locale& one, category cats);

Effects: Constructs a locale incorporating all facets from the first argument except those that implement cats, which are instead incorporated from the second argument.

Remarks: The resulting locale has a name if and only if the first two arguments have names.

const locale& operator=(const locale& other) noexcept;

Effects: Creates a copy of other, replacing the current value.

Returns: *this.

~locale();

A non-virtual destructor that throws no exceptions.

28.3.1.3 Members

template<class Facet> locale combine(const locale& other) const;

Effects: Constructs a locale incorporating all facets from *this except for that one facet of other that is identified by Facet.

Returns: The newly created locale.

Throws: runtime_error if has_facet<Facet>(other) is false.

Remarks: The resulting locale has no name.

basic_string<char> string name() const;

Returns: The name of *this, if it has one; otherwise, the string "*".

28.3.1.4 Operators

bool operator==(const locale& other) const;

Returns: true if both arguments are the same locale, or one is a copy of the other, or each has a name and the names are identical; false otherwise.

template<class charT, class traits, class Allocator>
bool operator()(const basic_string<charT, traits, Allocator>& s1,
    const basic_string<charT, traits, Allocator>& s2) const;

Effects: Compares two strings according to the collate<charT> facet.

Remarks: This member operator template (and therefore locale itself) meets the requirements for a comparator predicate template argument (??) applied to strings.

Returns:
use_facet<collate<charT>>(*this).compare(s1.data(), s1.data() + s1.size(),
    s2.data(), s2.data() + s2.size()) < 0

[Example: A vector of strings v can be collated according to collation rules in locale loc simply by (??, ??):
    std::sort(v.begin(), v.end(), loc);
    — end example]

28.3.1.5 Static members

static locale global(const locale& loc);

[Editor’s note: The old P1 gets an Effects: , and the old P2 gets merged into that. P3 split off from the old P2]

Effects: Sets the global locale to its argument.

Effects: Causes future calls to the constructor locale() to return a copy of the argument. If the argument has a name, does
setlocale(LC_ALL, loc.name().c_str());
otherwise, the effect on the C locale, if any, is implementation-defined. No library function other than
locale::global() shall affect the value returned by locale().

3 Remarks: No library function other than locale::global() affects the value returned by locale().

[Note: See 28.5 for data race considerations when setlocale is invoked. — end note]

Returns: The previous value of locale().

static const locale& classic();

The "C" locale.

Returns: A locale that implements the classic "C" locale semantics, equivalent to the value locale("C").

Remarks: This locale, its facets, and their member functions, do not change with time.

28.3.2 locale globals

template<class Facet> const Facet& use_facet(const locale& loc);

1 Requires: Mandates: Facet is a facet class whose definition contains the public static member id as
defined in 28.3.1.1.2.

2 Returns: A reference to the corresponding facet of loc, if present.

3 Throws: bad_cast if has_facet<Facet>(loc) is false.

4 Remarks: The reference returned remains valid at least as long as any copy of loc exists.

template<class Facet> bool has_facet(const locale& loc) noexcept;

5 Returns: true if the facet requested is present in loc; otherwise false.

28.3.3 Convenience interfaces

28.3.3.1 Character classification

template<class charT> bool isspace (charT c, const locale& loc);

1 Each of these functions isF returns the result of the expression:

use_facet<ctype<charT>>(loc).is(ctype_base::F, c)

where F is the ctype_base::mask value corresponding to that function (28.4.1).

28.3.3.2 Conversions

28.3.3.2.1 Character conversions

template<class charT> charT toupper(charT c, const locale& loc);

1 Returns: use_facet<ctype<charT>>(loc).toupper(c).

template<class charT> charT tolower(charT c, const locale& loc);

2 Returns: use_facet<ctype<charT>>(loc).tolower(c).

28.4 Standard locale categories

1 Each of the standard categories includes a family of facets. Some of these implement formatting or parsing of a
datum, for use by standard or users’ iostream operators << and >>, as members put() and get(), respectively.

260) When used in a loop, it is faster to cache the ctype<> facet and use it directly, or use the vector form of ctype<>::is.
Each such member function takes an `ios_base&` argument whose members `flags()`, `precision()`, and `width()` specify the format of the corresponding datum (??). Those functions which need to use other facets call its member `getloc()` to retrieve the locale imbued there. Formatting facets use the character argument `fill` to fill out the specified width where necessary.

2 The `put()` members make no provision for error reporting. (Any failures of the `OutputIterator` argument can be extracted from the returned iterator.) The `get()` members take an `ios_base::iostate&` argument whose value they ignore, but set to `ios_base::failbit` in case of a parse error.

3 Within this clause it is unspecified whether one virtual function calls another virtual function.

### 28.4.1 The `ctype` category

```cpp
namespace std {
    class ctype_base {
        public:
            using mask = see below;

        // numeric values are for exposition only.
        static const mask space = 1 << 0;
        static const mask print = 1 << 1;
        static const mask cntrl = 1 << 2;
        static const mask upper = 1 << 3;
        static const mask lower = 1 << 4;
        static const mask alpha = 1 << 5;
        static const mask digit = 1 << 6;
        static const mask punct = 1 << 7;
        static const mask xdigit = 1 << 8;
        static const mask blank = 1 << 9;
        static const mask alnum = alpha | digit;
        static const mask graph = alnum | punct;
    }
}
```

1 The type `mask` is a bitmask type (??).

### 28.4.1.1 Class template `ctype`

```cpp
namespace std {
    template<class charT>
    class ctype : public locale::facet, public ctype_base {
        public:
            using char_type = charT;

            explicit ctype(size_t refs = 0);

            bool is(mask m, charT c) const;
            const charT* is(const charT* low, const charT* high, mask* vec) const;
            const charT* scan_is(mask m, const charT* low, const charT* high) const;
            const charT* scan_not(mask m, const charT* low, const charT* high) const;
            charT toupper(charT c) const;
            const charT* toupper(charT* low, const charT* high) const;
            charT tolower(charT c) const;
            const charT* tolower(charT* low, const charT* high) const;
            charT widen(char c) const;
            const char* widen(const char* low, const char* high, charT* to) const;
            char narrow(charT c, char dfault) const;
            const charT* narrow(const charT* low, const charT* high, char dfault, char* to) const;

            static locale::id id;

        protected:
            ~ctype();
            virtual bool do_is(mask m, charT c) const;
            virtual const charT* do_is(const charT* low, const charT* high, mask* vec) const;

    }
}
```

§ 28.4.1.1 1305
virtual const charT* do_scan_is(mask m, const charT* low, const charT* high) const;
virtual const charT* do_scan_not(mask m, const charT* low, const charT* high) const;
virtual charT do_toupper(charT) const;
virtual charT do_tolower(charT) const;
virtual const charT* do_toupper(charT* low, const charT* high) const;
virtual const charT* do_tolower(charT* low, const charT* high) const;
virtual charT do_widen(char) const;
virtual charT do_narrow(charT, char dfault) const;
virtual const charT* do_widen(const char char* low, const charT* high, charT* dest) const;
virtual const charT* do_narrow(const charT* low, const charT* high, charT* dest) const;

};

1 Class ctype encapsulates the C library <cctype> features. istream members are required to use ctype<> for character classing during input parsing.

2 The specializations required in Table 101 (28.3.1.1.1), namely ctype<char> and ctype<wchar_t>, implement character classing appropriate to the implementation’s native character set.

### 28.4.1.1.1 ctype members

[locale ctype members]

bool is(mask m, charT c) const;
const charT* scan_is(mask m, const charT* low, const charT* high) const;

1 Returns: do_is(m, c) or do_is(low, high, vec).

const charT* scan_not(mask m, const charT* low, const charT* high) const;

2 Returns: do_scan_not(m, low, high).

charT toupper(charT) const;
const charT* toupper(charT* low, const charT* high) const;

3 Returns: do_toupper(c) or do_toupper(low, high).

charT tolower(charT c) const;
const charT* tolower(charT* low, const charT* high) const;

4 Returns: do_tolower(c) or do_tolower(low, high).

charT widen(char c) const;
const char* widen(const char char* low, const charT* high, charT* to) const;

5 Returns: do_widen(c) or do_widen(low, high, to).

char narrow(charT c, char dfault) const;
const charT* narrow(const charT* low, const charT* high, charT* default, char* dest) const;

6 Returns: do_narrow(c, dfault) or do_narrow(low, high, dfault, to).

### 28.4.1.1.2 ctype virtual functions

[locale ctype virtuals]

bool do_is(mask m, charT c) const;
const charT* do_is(const charT* low, const charT* high, mask* vec) const;

1 Effects: Classifies a character or sequence of characters. For each argument character, identifies a value M of type ctype_base::mask. The second form identifies a value M of type ctype_base::mask for each *p where (low <= p && p < high), and places it into vec[p - low].

2 Returns: The first form returns the result of the expression (M & m) != 0; i.e., true if the character has the characteristics specified. The second form returns high.

const charT* do_scan_is(mask m, const charT* low, const charT* high) const;

3 Effects: Locates a character in a buffer that conforms to a classification m.
Returns: The smallest pointer \( p \) in the range \([\text{low}, \text{high})\) such that \( \text{is}(m, *p) \) would return \text{true}; otherwise, returns \text{high}.

\[
\text{const charT}\* \text{do\_scan\_not}(\text{mask} \ m, \text{const charT}\* \text{low}, \text{const charT}\* \text{high}) \text{ const};
\]

Effects: Locates a character in a buffer that fails to conform to a classification \( m \).

Returns: The smallest pointer \( p \), if any, in the range \([\text{low}, \text{high})\) such that \( \text{is}(m, *p) \) would return \text{false}; otherwise, returns \text{high}.

\[
\text{charT} \quad \text{do\_toupper(charT} \ c) \text{ const};
\]

\[
\text{const charT}\* \text{do\_toupper(charT}\* \text{low}, \text{const charT}\* \text{high}) \text{ const};
\]

Effects: Converts a character or characters to upper case. The second form replaces each character \( *p \) in the range \([\text{low}, \text{high})\) for which a corresponding upper-case character exists, with that character.

Returns: The first form returns the corresponding upper-case character if it is known to exist, or its argument if not. The second form returns \text{high}.

\[
\text{charT} \quad \text{do\_tolower(charT} \ c) \text{ const};
\]

\[
\text{const charT}\* \text{do\_tolower(charT}\* \text{low}, \text{const charT}\* \text{high}) \text{ const};
\]

Effects: Converts a character or characters to lower case. The second form replaces each character \( *p \) in the range \([\text{low}, \text{high})\) and for which a corresponding lower-case character exists, with that character.

Returns: The first form returns the corresponding lower-case character if it is known to exist, or its argument if not. The second form returns \text{high}.

\[
\text{charT} \quad \text{do\_widen(char} \ c) \text{ const};
\]

\[
\text{const char}\* \text{do\_widen(const char}\* \text{low}, \text{const char}\* \text{high}, \text{charT}\* \text{dest}) \text{ const};
\]

Effects: Applies the simplest reasonable transformation from a \text{char} value or sequence of \text{char} values to the corresponding \text{charT} value or values.\(^{261}\) The only characters for which unique transformations are required are those in the basic source character set (??).

For any named \text{ctype} category with a \text{ctype} <\text{charT}> facet \text{ctc} and valid \text{ctype\_base::mask} value \( M \),

\[
(\text{ctc}.\text{is}(M, \ c) \ || \ !\text{is}(M, \ \text{do\_widen}(\ c)) ) \text{ is true}.\(^{262}\)
\]

The second form transforms each character \( *p \) in the range \([\text{low}, \text{high})\), placing the result in \( \text{dest}[p - \text{low}] \).

Returns: The first form returns the transformed value. The second form returns \text{high}.

\[
\text{char} \quad \text{do\_narrow(charT} \ c, \text{char} \ dfault) \text{ const};
\]

\[
\text{const charT}\* \text{do\_narrow(const charT}\* \text{low}, \text{const charT}\* \text{high}, \text{char} \ dfault, \text{char}\* \text{dest}) \text{ const};
\]

Effects: Applies the simplest reasonable transformation from a \text{charT} value or sequence of \text{charT} values to the corresponding \text{char} value or values.

For any character \( c \) in the basic source character set (??) the transformation is such that

\[
\text{do\_widen(do\_narrow}(c, \ dfault)) = c
\]

For any named \text{ctype} category with a \text{ctype<\text{char}>} facet \text{ctc} however, and \text{ctype\_base::mask} value \( M \),

\[
(\text{is}(M, \ c) \ || \ !\text{ctc}.\text{is}(M, \ \text{do\_narrow}(c, \ dfault)) )
\]

is true (unless \text{do\_narrow} returns \text{dfault}). In addition, for any digit character \( c \), the expression \( (\text{do\_narrow}(c, \ \text{dfault}) - '0') \) evaluates to the digit value of the character. The second form transforms each character \( *p \) in the range \([\text{low}, \text{high})\), placing the result (or \text{dfault} if no simple transformation is readily available) in \( \text{dest}[p - \text{low}] \).

Returns: The first form returns the transformed value; or \text{dfault} if no mapping is readily available. The second form returns \text{high}.

---

\(^{261}\) The \text{char} argument of \text{do\_widen} is intended to accept values derived from character literals for conversion to the locale’s encoding.

\(^{262}\) In other words, the transformed character is not a member of any character classification that \( c \) is not also a member of.
28.4.1.2 Class template ctype_byname

namespace std {
    template<class charT>
    class ctype_byname : public ctype<charT> {
        using mask = typename ctype<charT>::mask;
        explicit ctype_byname(const char*, size_t refs = 0);
        explicit ctype_byname(const string&, size_t refs = 0);
    protected:
        ~ctype_byname();
    };
}

28.4.1.3 ctype<char> specialization

namespace std {
    template<>
    class ctype<char> : public locale::facet, public ctype_base {
        using char_type = char;
        explicit ctype(const mask* tab = nullptr, bool del = false, size_t refs = 0);
        bool is(mask m, char c) const;
        const char* is(const char* low, const char* high, mask* vec) const;
        const char* scan_is (mask m, const char* low, const char* high) const;
        const char* scan_not(mask m, const char* low, const char* high) const;
        char toupper(char c) const;
        const char* toupper(char* low, const char* high) const;
        char tolower(char c) const;
        const char* tolower(char* low, const char* high) const;
        char widen(char c) const;
        const char* widen(const char* low, const char* high, char* to) const;
        char narrow(char c, char dfault) const;
        const char* narrow(const char* low, const char* high, char dfault, char* to) const;
        static locale::id id;
        static const size_t table_size = implementation-defined;
        const mask* table() const noexcept;
        static const mask* classic_table() noexcept;
    protected:
        ~ctype();
        virtual char do_toupper(char c) const;
        virtual const char* do_toupper(char* low, const char* high) const;
        virtual char do_tolower(char c) const;
        virtual const char* do_tolower(char* low, const char* high) const;
        virtual char do_widen(char c) const;
        virtual const char* do_widen(const char* low, const char* high, char* to) const;
        virtual char do_narrow(char c, char dfault) const;
        virtual const char* do_narrow(const char* low, const char* high, char dfault, char* to) const;
    };
}

1 A specialization ctype<char> is provided so that the member functions on type char can be implemented inline.\[263\] The implementation-defined value of member table_size is at least 256.

\[263\] Only the char (not unsigned char and signed char) form is provided. The specialization is specified in the standard, and not left as an implementation detail, because it affects the derivation interface for ctype<char>.
28.4.1.3.1 Destructor

~ctype();

1 Effects: If the constructor’s first argument was nonzero, and its second argument was true, does delete [] table().

28.4.1.3.2 Members

In the following member descriptions, for unsigned char values v where v >= table_size, table()[v] is assumed to have an implementation-specific value (possibly different for each such value v) without performing the array lookup.

explicit ctype(const mask* tbl = nullptr, bool del = false, size_t refs = 0);

2 Requires: tbl either 0 or an array of at least table_size elements.

3 Expects: Either tbl == nullptr is true or [tbl, tbl+table_size) is a valid range.

4 Effects: Passes its refs argument to its base class constructor.

bool is(mask m, char c) const;
const char* is(const char* low, const char* high, mask* vec) const;

5 Effects: The second form, for all *p in the range [low, high), assigns into vec[p - low] the value table()[(unsigned char)*p].

6 Returns: The first form returns table()[(unsigned char)c] & m; the second form returns high.

const char* scan_is(mask m, const char* low, const char* high) const;

7 Returns: The smallest p in the range [low, high) such that table()[(unsigned char) *p] & m is true.

const char* scan_not(mask m, const char* low, const char* high) const;

8 Returns: The smallest p in the range [low, high) such that table()[(unsigned char) *p] & m is false.

char toupper(char c) const;
const char* toupper(char* low, const char* high) const;

9 Returns: do_toupper(c) or do_toupper(low, high), respectively.

char tolower(char c) const;
const char* tolower(char* low, const char* high) const;

10 Returns: do_tolower(c) or do_tolower(low, high), respectively.

char widen(char c) const;
const char* widen(const char* low, const char* high, char* to) const;

11 Returns: do_widen(c) or do_widen(low, high, to), respectively.

char narrow(char c, char dfault) const;
const char* narrow(const char* low, const char* high, char dfault, char* to) const;

12 Returns: do_narrow(c, dfault) or do_narrow(low, high, dfault, to), respectively.

Returns: The first constructor argument, if it was nonzero, otherwise classic_table().

28.4.1.3.3 Static members

static const mask* classic_table() noexcept;

1 Returns: A pointer to the initial element of an array of size table_size which represents the classifications of characters in the "C" locale.
28.4.1.3.4 Virtual functions

```
char do_toupper(char) const;
const char* do_toupper(char* low, const char* high) const;
char do_tolower(char) const;
const char* do_tolower(char* low, const char* high) const;

virtual char do_widen(char c) const;
virtual const char* do_widen(const char* low, const char* high, char* to) const;
virtual char do_narrow(char c, char dfault) const;
virtual const char* do_narrow(const char* low, const char* high, char dfault, char* to) const;
```

1 These functions are described identically as those members of the same name in the `ctype` class template (28.4.1.1.1).

28.4.1.4 Class template codecvt

```
namespace std {
    class codecvt_base {
    public:
        enum result { ok, partial, error, noconv }; 
    };

template<class internT, class externT, class stateT>
    class codecvt : public locale::facet, public codecvt_base {
    public:
        using intern_type = internT;
        using extern_type = externT;
        using state_type = stateT;

        explicit codecvt(size_t refs = 0);

        result out(
            stateT& state,
            const internT* from, const internT* from_end, const internT*& from_next,
            externT* to, externT* to_end, externT*& to_next) const;

        result unshift(
            stateT& state,
            externT* to, externT* to_end, externT*& to_next) const;

        result in(
            stateT& state,
            const externT* from, const externT* from_end, const externT*& from_next,
            internT* to, internT* to_end, internT*& to_next) const;

        int encoding() const noexcept;
        bool always_noconv() const noexcept;
        int length(stateT& state, const externT* from, const externT* end, size_t max) const;
        int max_length() const noexcept;

        static locale::id id;
    protected:
        ~codecvt();
        virtual result do_out(
            stateT& state,
            const internT* from, const internT* from_end, const internT*& from_next,
            externT* to, externT* to_end, externT*& to_next) const;
        virtual result do_in(
            stateT& state,
            const externT* from, const externT* from_end, const externT*& from_next,
            internT* to, internT* to_end, internT*& to_next) const;

```
virtual result do_unshift(
    stateT& state,
    externT* to, externT* to_end, externT*& to_next) const;

virtual int do_encoding() const noexcept;
virtual bool do_always_noconv() const noexcept;
virtual int do_length(stateT& state, externT* from, const externT* end, size_t max) const;
virtual int do_max_length() const noexcept;
};

1 The class `codecvt<internT, externT, stateT>` is for use when converting from one character encoding to another, such as from wide characters to multibyte characters or between wide character encodings such as Unicode and EUC.

2 The `stateT` argument selects the pair of character encodings being mapped between.

3 The specializations required in Table 101 (28.3.1.1.1) convert the implementation-defined native character set. `codecvt<char, char, mbstate_t>` implements a degenerate conversion; it does not convert at all. The specialization `codecvt<char16_t, char8_t, mbstate_t>` converts between the UTF-16 and UTF-8 encoding forms, and the specialization `codecvt<char32_t, char8_t, mbstate_t>` converts between the UTF-32 and UTF-8 encoding forms. `codecvt<wchar_t, char, mbstate_t>` converts between the native character sets for ordinary and wide characters. Specializations on `mbstate_t` perform conversion between encodings known to the library implementer. Other encodings can be converted by specializing on a program-defined `stateT` type. Objects of type `stateT` can contain any state that is useful to communicate to or from the specialized `do_in` or `do_out` members.

### 28.4.1.4.1 Members

result out(
    stateT& state,
    const internT* from, const internT* from_end, const internT*& from_next,
    externT* to, externT* to_end, externT*& to_next) const;

1 Returns: `do_out(state, from, from_end, from_next, to, to_end, to_next)`.

result unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;

2 Returns: `do_unshift(state, to, to_end, to_next)`.

result in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;

3 Returns: `do_in(state, from, from_end, from_next, to, to_end, to_next)`.

int encoding() const noexcept;

4 Returns: `do_encoding()`.

bool always_noconv() const noexcept;

5 Returns: `do_always_noconv()`.

int length(stateT& state, const externT* from, const externT* from_end, size_t max) const;

6 Returns: `do_length(state, from, from_end, max)`.

int max_length() const noexcept;

7 Returns: `do_max_length()`.

### 28.4.1.4.2 Virtual functions

result do_out(
    stateT& state,
    const internT* from, const internT* from_end, const internT*& from_next,
    externT* to, externT* to_end, externT*& to_next) const;

§ 28.4.1.4.2 1311
result do_in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;

1  Requires:  Expects: (from <= from_end && to <= to_end) is well-defined and true; state is initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

2  Effects: Translates characters in the source range [from, from_end), placing the results in sequential positions starting at destination to. Converts no more than (from_end - from) source elements, and stores no more than (to_end - to) destination elements.

    Stops if it encounters a character it cannot convert. It always leaves the from_next and to_next pointers pointing one beyond the last element successfully converted. If returns noconv, internT and externT are the same type and the converted sequence is identical to the input sequence [from, from_next).

    to_next is set equal to to, the value of state is unchanged, and there are no changes to the values in [to, to_end).

3  A codecvt facet that is used by basic_filebuf (??) shall have the property that if
    do_out(state, from, from + 1, from_next, to, to + 1, to_next)
    would return ok, where from != from_end, then
    do_out(state, from, from + 1, from_next, to, to + 1, to_next)
    shall also return ok, and that if
    do_in(state, from, from_end, from_next, to, to_end, to_next)
    would return ok, where to != to_end, then
    do_in(state, from, from_end, from_next, to, to + 1, to_next)
    shall also return ok.264  [Note: As a result of operations on state, it can return ok or partial and set from_next == from and to_next != to. — end note]

4  Remarks: Its operations on state are unspecified. [Note: This argument can be used, for example, to maintain shift state, to specify conversion options (such as count only), or to identify a cache of seek offsets. — end note]

5  Returns: An enumeration value, as summarized in Table 103.

### Table 103: do_in/do_out result values  [tab:locale.codecvt.inout]

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the conversion</td>
</tr>
<tr>
<td>partial</td>
<td>not all source characters converted</td>
</tr>
<tr>
<td>error</td>
<td>encountered a character in [from, from_end) that it could not convert</td>
</tr>
<tr>
<td>noconv</td>
<td>internT and externT are the same type, and input sequence is identical to converted sequence</td>
</tr>
</tbody>
</table>

A return value of partial, if (from_next == from_end), indicates that either the destination sequence has not absorbed all the available destination elements, or that additional source elements are needed before another destination element can be produced.

result do_unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;

6  Requires:  Expects: (to <= to_end) is well-defined and true; state is initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

7  Effects: Places characters starting at to that should be appended to terminate a sequence when the current stateT is given by state.265  Stores no more than (to_end - to) destination elements, and leaves the to_next pointer pointing one beyond the last element successfully stored.

---

264 Informally, this means that basic_filebuf assumes that the mappings from internal to external characters is 1 to N: a codecvt facet that is used by basic_filebuf must be able to translate characters one internal character at a time.

265 Typically these will be characters to return the state to stateT().
Returns: An enumeration value, as summarized in Table 104.

Table 104: do_unshift result values  

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the sequence</td>
</tr>
<tr>
<td>partial</td>
<td>space for more than to_end - to destination elements was needed to terminate a sequence given the value of state</td>
</tr>
<tr>
<td>error</td>
<td>an unspecified error has occurred</td>
</tr>
<tr>
<td>noconv</td>
<td>no termination is needed for this state_type</td>
</tr>
</tbody>
</table>

int do_encoding() const noexcept;

Returns: -1 if the encoding of the externT sequence is state-dependent; else the constant number of externT characters needed to produce an internal character; or 0 if this number is not a constant.\(^\text{266}\)

bool do_always_noconv() const noexcept;

Returns: true if do_in() and do_out() return noconv for all valid argument values. codecvt<char, char, mbstate_t> returns true.

int do_length(stateT& state, const externT* from, const externT* from_end, size_t max) const;

Requires—Expects: (from <= from_end) is well-defined and true; state is initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

Effects: The effect on the state argument is “as if” it called do_in(state, from, from_end, from, to, to+max, to) for to pointing to a buffer of at least max elements.

Returns: (from_next-from) where from_next is the largest value in the range [from, from_end) such that the sequence of values in the range [from, from_next) represents max or fewer valid complete characters of type internT. The specialization codecvt<char, char, mbstate_t>::do_max_length() returns the lesser of max and (from_end-from).

int do_max_length() const noexcept;

Returns: The maximum value that do_length(state, from, from_end, 1) can return for any valid range [from, from_end) and stateT value state. The specialization codecvt<char, char, mbstate_t>::do_max_length() returns 1.

28.4.1.5 Class template codecvt_byname

namespace std {
    template<class internT, class externT, class stateT>
    class codecvt_byname : public codecvt<internT, externT, stateT> {
    public:
        explicit codecvt_byname(const char*, size_t refs = 0);
        explicit codecvt_byname(const string&, size_t refs = 0);

        protected:
            ~codecvt_byname();
    };
}

28.4.2 The numeric category

The classes num_get<> and num_put<> handle numeric formatting and parsing. Virtual functions are provided for several numeric types. Implementations may (but are not required to) delegate extraction of smaller types to extractors for larger types.\(^\text{267}\)

\(^{266}\) If encoding() yields -1, then more than max_length() externT elements may be consumed when producing a single internT character, and additional externT elements may appear at the end of a sequence after those that yield the final internT character.

\(^{267}\) Parsing "-1" correctly into, e.g., an unsigned short requires that the corresponding member get() at least extract the sign before delegating.
All specifications of member functions for `num_put` and `num_get` in the subclauses of 28.4.2 only apply to the specializations required in Tables 101 and 102 (28.3.1.1.1), namely `num_get<char>`, `num_get<wchar_t>`, `num_get<C, InputIterator>`, `num_put<char>`, `num_put<wchar_t>`, and `num_put<C, OutputIterator>`. These specializations refer to the `ios_base&` argument for formatting specifications (28.4), and to its imbedd locale for the `numpunct<>` facet to identify all numeric punctuation preferences, and also for the `ctype<>` facet to perform character classification.

Extractor and inserter members of the standard iostreams use `num_get<>` and `num_put<>` member functions for formatting and parsing numeric values (??, ??).

### 28.4.2.1 Class template `num_get` [locale.num.get]

```cpp
namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class num_get : public locale::facet {
    public:
        using char_type = charT;
        using iter_type = InputIterator;

        explicit num_get(size_t refs = 0);

        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, bool& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, long& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, long long& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, unsigned short& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, unsigned int& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, unsigned long& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, unsigned long long& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, float& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, double& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, long double& v) const;
        iter_type get(iter_type in, iter_type end, ios_base&,
                      ios_base::iostate& err, void*& v) const;

        static locale::id id;

    protected:
        ~num_get();
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, bool& v) const;
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, long& v) const;
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, long long& v) const;
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, unsigned short& v) const;
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, unsigned int& v) const;
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, unsigned long& v) const;
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, unsigned long long& v) const;
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, float& v) const;
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, double& v) const;
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, long double& v) const;
        virtual iter_type do_get(iter_type, iter_type, ios_base&,
                                  ios_base::iostate& err, void*& v) const;
    }
```
virtual iter_type do_get(iter_type, iter_type, ios_base&,
    ios_base::iostate& err, double& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
    ios_base::iostate& err, long double& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
    ios_base::iostate& err, void*& v) const;
}

The facet *num_get* is used to parse numeric values from an input sequence such as an istream.

### 28.4.2.1.1 Members

[facet.num.get.members]

```cpp
definition
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, bool& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, long long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned short& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned int& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned long long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, float& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, long double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, void*& val) const;
```

1 Returns: do_get(in, end, str, err, val).

### 28.4.2.1.2 Virtual functions

[facet.num.get.virtuals]

```cpp
definition
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, long long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned short& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned int& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned long long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, float& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, double& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, long double& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, void*& val) const;
```

1 Effects: Reads characters from *in*, interpreting them according to *str.flags()* and `use_facet<ctype<charT>>(loc)` where *loc* is `str.getloc()`.

The details of this operation occur in three stages:

(2.1)

1 Stage 1: Determine a conversion specifier
Stage 1: The function initializes local variables via

```cpp
    fmtflags flags = str.flags();
    fmtflags basefield = (flags & ios_base::basefield);
    fmtflags uppercase = (flags & ios_base::uppercase);
    fmtflags boolalpha = (flags & ios_base::boolalpha);
```

For conversion to an integral type, the function determines the integral conversion specifier as indicated in Table 105. The table is ordered. That is, the first line whose condition is true applies.

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == oct</td>
<td>%o</td>
</tr>
<tr>
<td>basefield == hex</td>
<td>%X</td>
</tr>
<tr>
<td>basefield == 0</td>
<td>%i</td>
</tr>
<tr>
<td>signed integral type</td>
<td>%d</td>
</tr>
<tr>
<td>unsigned integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

For conversions to a floating-point type the specifier is %g.

For conversions to `void*` the specifier is %p.

A length modifier is added to the conversion specification, if needed, as indicated in Table 106.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>short</td>
<td>h</td>
</tr>
<tr>
<td>unsigned short</td>
<td>h</td>
</tr>
<tr>
<td>long</td>
<td>l</td>
</tr>
<tr>
<td>unsigned long</td>
<td>l</td>
</tr>
<tr>
<td>long long</td>
<td>ll</td>
</tr>
<tr>
<td>unsigned long long</td>
<td>ll</td>
</tr>
<tr>
<td>double</td>
<td>l</td>
</tr>
<tr>
<td>long double</td>
<td>L</td>
</tr>
</tbody>
</table>

Stage 2: If in == end then stage 2 terminates. Otherwise a charT is taken from in and local variables are initialized as if by

```cpp
    char_type ct = *in;
    char c = src[find(atoms, atoms + sizeof(src) - 1, ct) - atoms];
    if (ct == use_facet<numpunct<charT>>(loc).decimal_point())
        c = '.';
    bool discard = ct == use_facet<numpunct<charT>>(loc).thousands_sep() &&
                   use_facet<numpunct<charT>>(loc).grouping().length() != 0;
```

where the values src and atoms are defined as if by:

```cpp
    static const char src[] = "0123456789abcdefxABCDEFX+-"
    char_type atoms[sizeof(src)];
    use_facet<ctype<charT>>(loc).widen(src, src + sizeof(src), atoms);
```

for this value of loc.

If discard is true, then if '.' has not yet been accumulated, then the position of the character is remembered, but the character is otherwise ignored. Otherwise, if '.' has already been accumulated, the character is discarded and Stage 2 terminates. If it is not discarded, then a check is made to determine if c is allowed as the next character of an input field of the conversion specifier returned by Stage 1. If so, it is accumulated.
If the character is either discarded or accumulated then in is advanced by ++in and processing returns to the beginning of stage 2.

**Stage 3:** The sequence of chars accumulated in stage 2 (the field) is converted to a numeric value by the rules of one of the functions declared in the header `<cstdlib>`:

1. For a signed integer value, the function `strtoll`.
2. For an unsigned integer value, the function `strtoull`.
3. For a `float` value, the function `strtof`.
4. For a `double` value, the function `strtod`.
5. For a `long double` value, the function `strtold`.

The numeric value to be stored can be one of:

1. zero, if the conversion function does not convert the entire field.
2. the most positive (or negative) representable value, if the field to be converted to a signed integer type represents a value too large positive (or negative) to be represented in val.
3. the most positive representable value, if the field to be converted to an unsigned integer type represents a value that cannot be represented in val.
4. the converted value, otherwise.

The resultant numeric value is stored in val. If the conversion function does not convert the entire field, or if the field represents a value outside the range of representable values, `ios_base::failbit` is assigned to err.

Digit grouping is checked. That is, the positions of discarded separators is examined for consistency with `use_facet<numpunct<charT>>(loc).grouping()`. If they are not consistent then `ios_base::failbit` is assigned to err.

In any case, if stage 2 processing was terminated by the test for in == end then err |= `ios_base::eofbit` is performed.

```cpp
iter_type do_get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, bool& val) const;
```

**Effects:** If `(str.flags()&ios_base::boolalpha) == 0` then input proceeds as it would for a long except that if a value is being stored into val, the value is determined according to the following: If the value to be stored is 0 then `false` is stored. If the value is 1 then `true` is stored. Otherwise `true` is stored and `ios_base::failbit` is assigned to err.

Otherwise target sequences are determined “as if” by calling the members `falsename()` and `truename()` of the facet obtained by `use_facet<numpunct<charT>>(str.getloc())`. Successive characters in the range [in, end) (see ??) are obtained and matched against corresponding positions in the target sequences only as necessary to identify a unique match. The input iterator in is compared to end only when necessary to obtain a character. If a target sequence is uniquely matched, val is set to the corresponding value. Otherwise false is stored and `ios_base::failbit` is assigned to err.

The in iterator is always left pointing one position beyond the last character successfully matched. If val is set, then err is set to `str.goodbit`; or to `str.eofbit` if, when seeking another character to match, it is found that (in == end). If val is not set, then err is set to `str.failbit`; or to `(str.failbit|str.eofbit)` if the reason for the failure was that (in == end). [Example: For targets `true`: "a" and false: "abb", the input sequence "a" yields val == true and err == `str.eofbit`; the input sequence "abc" yields err = `str.failbit`, with in ending at the 'c' element. For targets `true`: "1" and false: "0", the input sequence "1" yields val == true and err == `str.goodbit`. For empty targets (""), any input sequence yields `err == `str.failbit.` — end example]

**Returns:** in.

### 28.4.2.2 Class template num_put

```cpp
namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class num_put : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;
    }
}
```
The facet `num_put` is used to format numeric values to a character sequence such as an ostream.

### 28.4.2.2.1 Members

```
iter_type put(iter_type out, ios_base& str, char_type fill, bool val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, const void* val) const;
```

1 The facet `num_put` is used to format numeric values to a character sequence such as an ostream.

### 28.4.2.2.2 Virtual functions

```
iter_type do_put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, const void* val) const;
```

1 Returns: `do_put(out, str, fill, val)`.  

1 Effects: Writes characters to the sequence `out`, formatting `val` as desired. In the following description, `loc` names a local variable initialized as

```
locale loc = str.getloc();
```

1 The details of this operation occur in several stages:

1. Stage 1: Determine a printf conversion specifier `spec` and determine the characters that would be printed by `printf` (??) given this conversion specifier for

```
printf(spec, val)
```

assuming that the current locale is the "C" locale.

1. Stage 2: Adjust the representation by converting each `char` determined by stage 1 to a `charT` using a conversion and values returned by members of `use_facet<numpunct<charT>>(loc)`

1. Stage 3: Determine where padding is required.

§ 28.4.2.2.2 1318
— Stage 4: Insert the sequence into the \textit{out}.

Detailed descriptions of each stage follow.

\textit{Returns: out.}

\textbf{Stage 1:} The first action of stage 1 is to determine a conversion specifier. The tables that describe this determination use the following local variables:

\begin{verbatim}
fmtflags flags = str.flags();
fmtflags basefield = (flags & (ios_base::basefield));
fmtflags uppercase = (flags & (ios_base::uppercase));
fmtflags floatfield = (flags & (ios_base::floatfield));
fmtflags showpos = (flags & (ios_base::showpos));
fmtflags showbase = (flags & (ios_base::showbase));
fmtflags showpoint = (flags & (ios_base::showpoint));
\end{verbatim}

All tables used in describing stage 1 are ordered. That is, the first line whose condition is true applies. A line without a condition is the default behavior when none of the earlier lines apply.

For conversion from an integral type other than a character type, the function determines the integral conversion specifier as indicated in Table 107.

Table 107: Integer conversions [tab:facet.num.put.int]

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == ios_base::oct</td>
<td>%o</td>
</tr>
<tr>
<td>(basefield == ios_base::hex) &amp;&amp; !uppercase</td>
<td>%x</td>
</tr>
<tr>
<td>(basefield == ios_base::hex)</td>
<td>%X</td>
</tr>
<tr>
<td>for a \texttt{signed} integral type</td>
<td>%d</td>
</tr>
<tr>
<td>for an \texttt{unsigned} integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

For conversion from a floating-point type, the function determines the floating-point conversion specifier as indicated in Table 108.

Table 108: Floating-point conversions [tab:facet.num.put.fp]

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>floatfield == ios_base::fixed</td>
<td>%f</td>
</tr>
<tr>
<td>floatfield == ios_base::scientific &amp;&amp; !uppercase</td>
<td>%e</td>
</tr>
<tr>
<td>floatfield == ios_base::scientific</td>
<td>%E</td>
</tr>
<tr>
<td>floatfield == (ios_base::fixed</td>
<td>ios_base::scientific) &amp;&amp; !uppercase</td>
</tr>
<tr>
<td>floatfield == (ios_base::fixed</td>
<td>ios_base::scientific)</td>
</tr>
<tr>
<td>!uppercase</td>
<td>%g</td>
</tr>
<tr>
<td>otherwise</td>
<td>%G</td>
</tr>
</tbody>
</table>

For conversions from an integral or floating-point type a length modifier is added to the conversion specifier as indicated in Table 109.

Table 109: Length modifier [tab:facet.num.put.length]

<table>
<thead>
<tr>
<th>Type</th>
<th>Length modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>long</td>
<td>l</td>
</tr>
<tr>
<td>long long</td>
<td>ll</td>
</tr>
<tr>
<td>unsigned long</td>
<td>l</td>
</tr>
<tr>
<td>unsigned long long</td>
<td>ll</td>
</tr>
<tr>
<td>long double</td>
<td>L</td>
</tr>
<tr>
<td>otherwise</td>
<td>none</td>
</tr>
</tbody>
</table>

The conversion specifier has the following optional additional qualifiers prepended as indicated in Table 110.
Table 110: Numeric conversions  [tab:facet.num.put.conv]

<table>
<thead>
<tr>
<th>Type(s)</th>

<td>#</td>
</tr>
<tr>
<td>a floating-point type</td>
<td>showpos</td>
<td>+</td>
</tr>
<tr>
<td></td>
<td>showpoint</td>
<td>#</td>
</tr>
</tbody>
</table>

For conversion from a floating-point type, if floatfield != (ios_base::fixed | ios_base::scientific), str.precision() is specified as precision in the conversion specification. Otherwise, no precision is specified.

For conversion from void* the specifier is %p.

The representations at the end of stage 1 consists of the char’s that would be printed by a call of printf(s, val) where s is the conversion specifier determined above.

Stage 2: Any character c other than a decimal point(.) is converted to a charT via

```c
use_facet<ctype<charT>>(loc).widen(c)
```

A local variable punct is initialized via

```c
const numpunct<charT>& punct = use_facet<numpunct<charT>>(loc);
```

For arithmetic types, punct.thousands_sep() characters are inserted into the sequence as determined by the value returned by punct.do_grouping() using the method described in 28.4.3.1.2

Decimal point characters(;) are replaced by punct.decimal_point()

Stage 3: A local variable is initialized as

```c
fmtflags adjustfield = (flags & (ios_base::adjustfield));
```

The location of any padding268 is determined according to Table 111.

Table 111: Fill padding  [tab:facet.num.put.fill]

<table>
<thead>
<tr>
<th>State</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>adjustfield == ios_base::left</td>
<td>pad after</td>
</tr>
<tr>
<td>adjustfield == ios_base::right</td>
<td>pad before</td>
</tr>
<tr>
<td>adjustfield == internal and a sign occurs in the representation</td>
<td>pad after the sign</td>
</tr>
<tr>
<td>adjustfield == internal and representation after stage 1 began with 0x or 0X</td>
<td>pad after x or X</td>
</tr>
<tr>
<td>otherwise</td>
<td>pad before</td>
</tr>
</tbody>
</table>

If str.width() is nonzero and the number of charT’s in the sequence after stage 2 is less than str.width(), then enough fill characters are added to the sequence at the position indicated for padding to bring the length of the sequence to str.width().

str.width(0) is called.

Stage 4: The sequence of charT’s at the end of stage 3 are output via

```c
*out++ = c
```

iter_type do_put(iter_type out, ios_base& str, char_type fill, bool val) const;

6 Returns: If (str.flags() & ios_base::boolalpha) == 0 returns do_put(out, str, fill, (int)val), otherwise obtains a string s as if by

```c
string_type s =
val ? use_facet<numpunct<charT>>(loc).truename()
    : use_facet<numpunct<charT>>(loc).falsename();
```

and then inserts each character c of s into out via *out++ = c and returns out.

---

268) The conversion specification #o generates a leading 0 which is not a padding character.
28.4.3 The numeric punctuation facet

28.4.3.1 Class template numpunct

```cpp
namespace std {
    template<class charT>
    class numpunct : public locale::facet {
        public:
            using char_type = charT;
            using string_type = basic_string<charT>;

            explicit numpunct(size_t refs = 0);

            char_type decimal_point() const;
            char_type thousands_sep() const;
            string grouping() const;
            string_type truename() const;
            string_type falsename() const;

            static locale::id id;
        protected:
            ~numpunct();
            // virtual
            virtual char_type do_decimal_point() const;
            virtual char_type do_thousands_sep() const;
            virtual string do_grouping() const;
            virtual string_type do_truename() const; // for bool
            virtual string_type do_falsename() const; // for bool
    }
}
```

1 numpunct<> specifies numeric punctuation. The specializations required in Table 101 (28.3.1.1.1), namely numpunct<wchar_t> and numpunct<char>, provide classic "C" numeric formats, i.e., they contain information equivalent to that contained in the "C" locale or their wide character counterparts as if obtained by a call to widen.

2 The syntax for number formats is as follows, where digit represents the radix set specified by the fmtflags argument value, and thousands-sep and decimal-point are the results of corresponding numpunct<charT> members. Integer values have the format:

```
integer ::= [sign] units
sign ::= plusminus
plusminus ::= '+' | '-'
units ::= digits [thousands-sep units]
digits ::= digit [digits]
```

and floating-point values have:

```
floatval ::= [sign] units [decimal-point [digits]] [e [sign] digits] |
           [sign] decimal-point digits [e [sign] digits]
e ::= 'e' | 'E'
```

where the number of digits between thousands-seps is as specified by do_grouping(). For parsing, if the digits portion contains no thousands-separators, no grouping constraint is applied.

28.4.3.1.1 Members

```cpp
char_type decimal_point() const;

Returns: do_decimal_point().
```

```cpp
char_type thousands_sep() const;

Returns: do_thousands_sep().
```

```cpp
string grouping() const;

Returns: do_grouping().
```
28.4.3.1.2 Virtual functions

```
4

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string_type truename() const;</td>
<td>Returns: do_truename() or do_falsename(), respectively.</td>
</tr>
<tr>
<td>string_type falsename() const;</td>
<td></td>
</tr>
</tbody>
</table>

28.4.3.2 Class template numpunct_byname

```

```
269
Thus, the string "\003" specifies groups of 3 digits each, and "3" probably indicates groups of 51 (!) digits each, because 51 is the ASCII value of "3".

§ 28.4.4.1 1322
The class `collate<charT>` provides features for use in the collation (comparison) and hashing of strings. A locale member function template, `operator()`, uses the collate facet to allow a locale to act directly as the predicate argument for standard algorithms (??) and containers operating on strings. The specializations required in Table 101 (28.3.1.1.1), namely `collate<char>` and `collate<wchar_t>`, apply lexicographic ordering (??).

Each function compares a string of characters `*p` in the range `[low, high)`.

### 28.4.4.1.1 Members

**int compare(const charT* low1, const charT* high1,**

**const charT* low2, const charT* high2) const;**

- **Returns:** `do_compare(low1, high1, low2, high2)`.

**string_type transform(const charT* low, const charT* high) const;**

- **Returns:** `do_transform(low, high)`.

**long hash(const charT* low, const charT* high) const;**

- **Returns:** `do_hash(low, high)`.

### 28.4.4.1.2 Virtual functions

**int do_compare(const charT* low1, const charT* high1,**

**const charT* low2, const charT* high2) const;**

- **Returns:** 1 if the first string is greater than the second, -1 if less, zero otherwise. The specializations required in Table 101 (28.3.1.1.1), namely `collate<char>` and `collate<wchar_t>`, implement a lexicographical comparison (??).

**string_type do_transform(const charT* low, const charT* high) const;**

- **Returns:** A `basic_string<charT>` value that, compared lexicographically with the result of calling `transform()` on another string, yields the same result as calling `do_compare()` on the same two strings.\footnote{This function is useful when one string is being compared to many other strings.}

**long do_hash(const charT* low, const charT* high) const;**

- **Returns:** An integer value equal to the result of calling `hash()` on any other string for which `do_compare()` returns 0 (equal) when passed the two strings. \[Note: The probability that the result equals that for another string which does not compare equal should be very small, approaching $(1.0/\text{numeric\_limits<unsigned\_long>::max()}). \] —end note

### 28.4.4.2 Class template `collate_byname`

```cpp
namespace std {
    template<class charT>
    class collate_byname : public collate<charT> {
    public:
        using string_type = basic_string<charT>;

        explicit collate_byname(const char*, size_t refs = 0);
        explicit collate_byname(const string&, size_t refs = 0);
    }
}
```
protected:
  ~collate_byname();
};

28.4.5 The time category

Templates `time_get<charT, InputIterator>` and `time_put<charT, OutputIterator>` provide date and time formatting and parsing. All specifications of member functions for `time_put` and `time_get` in the subclauses of 28.4.5 only apply to the specializations required in Tables 101 and 102 (28.3.1.1.1). Their members use their `ios_base&`, `ios_base::iostate&`, and `fill` arguments as described in 28.4, and the `ctype<>` facet, to determine formatting details.

28.4.5.1 Class template `time_get`

```cpp
namespace std {
    class time_base {
        public:
            enum dateorder { no_order, dmy, mdy, ymd, ydm };
    };

template<class charT, class InputIterator = istreambuf_iterator<charT>>
class time_get : public locale::facet, public time_base {
    public:
        using char_type = charT;
        using iter_type = InputIterator;

        explicit time_get(size_t refs = 0);

        dateorder date_order() const { return do_date_order(); } const
        iter_type get_time(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t) const;
        iter_type get_date(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t) const;
        iter_type get_weekday(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t) const;
        iter_type get_monthname(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t) const;
        iter_type get_year(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t) const;
        iter_type get(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t, char format, char modifier = 0) const;
        iter_type get(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t, const char_type* fmt,
            const char_type* fmtend) const;

        static locale::id id;
    protected:
        ~time_get();
        virtual dateorder do_date_order() const;
        virtual iter_type do_get_time(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t) const;
        virtual iter_type do_get_date(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t) const;
        virtual iter_type do_get_weekday(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t) const;
        virtual iter_type do_get_monthname(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t) const;
        virtual iter_type do_get_year(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t) const;
        virtual iter_type do_get(iter_type s, iter_type end, ios_base& f,
            ios_base::iostate& err, tm* t, char format, char modifier) const;
    }
}
```
time_get is used to parse a character sequence, extracting components of a time or date into a struct tm object. Each get member parses a format as produced by a corresponding format specifier to time_get<>::put. If the sequence being parsed matches the correct format, the corresponding members of the struct tm argument are set to the values used to produce the sequence; otherwise either an error is reported or unspecified values are assigned.\footnote{In other words, user confirmation is required for reliable parsing of user-entered dates and times, but machine-generated formats can be parsed reliably. This allows parsers to be aggressive about interpreting user variations on standard formats.}

If the end iterator is reached during parsing by any of the get() member functions, the member sets ios_base::eofbit in err.

28.4.5.1.1 Members

```cpp
dateorder date_order() const;

Returns: do_date_order().
```

```cpp
iter_type get_time(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;

Returns: do_get_time(s, end, str, err, t).
```

```cpp
iter_type get_date(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;

Returns: do_get_date(s, end, str, err, t).
```

```cpp
iter_type get_weekday(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;
iter_type get_monthname(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;

Returns: do_get_weekday(s, end, str, err, t) or do_get_monthname(s, end, str, err, t).
```

```cpp
iter_type get_year(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;

Returns: do_get_year(s, end, str, err, t).
```

```cpp
iter_type get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err, tm* t, char format, char modifier = 0) const;

Returns: do_get(s, end, f, err, t, format, modifier).
```

```cpp
iter_type get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err, tm* t, const char_type* fmt, const char_type* fmtend) const;

Requires: Expects: [fmt, fmtend) shall be is a valid range.

Effects: The function starts by evaluating err = ios_base::goodbit. It then enters a loop, reading zero or more characters from s at each iteration. Unless otherwise specified below, the loop terminates when the first of the following conditions holds:

(8.1) The expression fmt == fmtend evaluates to true.

(8.2) The expression err == ios_base::goodbit evaluates to false.

(8.3) The expression s == end evaluates to true, in which case the function evaluates err = ios_base::eofbit | ios_base::failbit.

(8.4) The next element of fmt is equal to '%', optionally followed by a modifier character, followed by a conversion specifier character, format, together forming a conversion specification valid for the ISO/IEC 9945 function strptime. If the number of elements in the range [fmt, fmtend) is not sufficient to unambiguously determine whether the conversion specification is complete and valid, the function evaluates err = ios_base::failbit. Otherwise, the function evaluates s = do_get(s, end, f, err, t, format, modifier), where the value of modifier is '0' when the optional modifier is absent from the conversion specification. If err == ios_base::goodbit holds after the evaluation of the expression, the function increments fmt to point just past the end of the conversion specification and continues looping.
```
— The expression `isspace(*fmt, f.getloc())` evaluates to `true`, in which case the function first increments `fmt` until `fmt == fmtend || !isspace(*fmt, f.getloc())` evaluates to `true`, then advances `s` until `s == end || !isspace(*s, f.getloc())` is `true`, and finally resumes looping.

— The next character read from `s` matches the element pointed to by `fmt` in a case-insensitive comparison, in which case the function evaluates `++fmt, ++s` and continues looping. Otherwise, the function evaluates `err = ios_base::failbit.`

[Note: The function uses the `ctype<char>` facet installed in `f`’s locale to determine valid whitespace characters. It is unspecified by what means the function performs case-insensitive comparison or whether multi-character sequences are considered while doing so. — end note]

Returns: `s`.

### 28.4.5.1.2 Virtual functions

```cpp
dateorder do_date_order() const;
```

Returns: An enumeration value indicating the preferred order of components for those date formats that are composed of day, month, and year. Returns `no_order` if the date format specified by ‘x’ contains other variable components (e.g., Julian day, week number, week day).

```cpp
iter_type do_get_time(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;
```

Effects: Reads characters starting at `s` until it has extracted those `struct tm` members, and remaining format characters, used by `time_put<>::put` to produce the format specified by "%H:%M:%S", or until it encounters an error or end of sequence.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid time.

```cpp
iter_type do_get_date(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;
```

Effects: Reads characters starting at `s` until it has extracted those `struct tm` members and remaining format characters used by `time_put<>::put` to produce one of the following formats, or until it encounters an error. The format depends on the value returned by `date_order()` as shown in Table 112.

<table>
<thead>
<tr>
<th><code>date_order()</code></th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>no_order</td>
<td>&quot;%m%d%y&quot;</td>
</tr>
<tr>
<td>dmy</td>
<td>&quot;%d%m%y&quot;</td>
</tr>
<tr>
<td>mdy</td>
<td>&quot;%m%d%y&quot;</td>
</tr>
<tr>
<td>ymd</td>
<td>&quot;%y%m%d&quot;</td>
</tr>
<tr>
<td>ydm</td>
<td>&quot;%y%d%m&quot;</td>
</tr>
</tbody>
</table>

An implementation may also accept additional implementation-defined formats.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid date.

```cpp
iter_type do_get_weekday(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;
iter_type do_get_monthname(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;
```

Effects: Reads characters starting at `s` until it has extracted the (perhaps abbreviated) name of a weekday or month. If it finds an abbreviation that is followed by characters that could match a full name, it continues reading until it matches the full name or fails. It sets the appropriate `struct tm` member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid name.

---

²⁷² This function is intended as a convenience only, for common formats, and may return `no_order` in valid locales.
iter_type do_get_year(iter_type s, iter_type end, ios_base& str,  
    ios_base::iostate& err, tm* t) const;

Effects: Reads characters starting at s until it has extracted an unambiguous year identifier. It is implementation-defined whether two-digit year numbers are accepted, and (if so) what century they are assumed to lie in. Sets the t->tm_year member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid year identifier.

iter_type do_get(iter_type s, iter_type end, ios_base& f,  
    ios_base::iostate& err, tm* t, char format, char modifier) const;

Requires: Expects: t shall points to an object.

Effects: The function starts by evaluating err = ios_base::goodbit. It then reads characters starting at s until it encounters an error, or until it has extracted and assigned those struct tm members, and any remaining format characters, corresponding to a conversion directive appropriate for the ISO/IEC 9945 function strftime, formed by concatenating '%', the modifier character, when non-NUL, and the format character. When the concatenation fails to yield a complete valid directive the function leaves the object pointed to by t unchanged and evaluates err |= ios_base::failbit. When s == end evaluates to true after reading a character the function evaluates err |= ios_base::eofbit. When

For complex conversion directives such as %c, %x, or %X, or directives that involve the optional modifiers E or O, when the function is unable to unambiguously determine some or all struct tm members from the input sequence [s, end], it evaluates err |= ios_base::eofbit. In such cases the values of those struct tm members are unspecified and may be outside their valid range.

Remarks: It is unspecified whether multiple calls to do_get() with the address of the same struct tm object will update the current contents of the object or simply overwrite its members. Portable programs should zero out the object before invoking the function.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid input sequence for the given format and modifier.

28.4.5.2 Class template time_getbyname

namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class time_getbyname : public time_get<charT, InputIterator> {
    public:
        using dateorder = time_base::dateorder;
        using iter_type = InputIterator;

        explicit time_getbyname(const char*, size_t refs = 0);
        explicit time_getbyname(const string&, size_t refs = 0);

        protected:
            ~time_getbyname();
            
    };
}

28.4.5.3 Class template time_put

namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class time_put : public locale::facet {
    public:
        using char_type = charT;
        using iter_type = OutputIterator;

        explicit time_put(size_t refs = 0);

        // the following is implemented in terms of other member functions.
        iter_type put(iter_type s, ios_base& f, char_type fill, const tm* tmb,  
            const charT* pattern, const charT* pat_end) const;
        iter_type put(iter_type s, ios_base& f, char_type fill,  
            const tm* tmb, char format, char modifier = 0) const;
}

§ 28.4.5.3 1327
static locale::id id;

protected:
- ~time_put();
  virtual iter_type do_put(iter_type s, ios_base& str, char_type fill, const tm* t,
      char format, char modifier) const;
};

28.4.5.3.1 Members

iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
    const charT* pattern, const charT* pat_end) const;
iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
    char format, char modifier = 0) const;

Effects: The first form steps through the sequence from pattern to pat_end, identifying characters
that are part of a format sequence. Each character that is not part of a format sequence is written to
s immediately, and each format sequence, as it is identified, results in a call to do_put; thus, format
elements and other characters are interleaved in the output in the order in which they appear in the
pattern. Format sequences are identified by converting each character c to a char value as if by
ct.narrow(c, 0), where ct is a reference to ctype<charT> obtained from str.getloc(). The first
character of each sequence is equal to ‘%’, followed by an optional modifier character mod273 and a
format specifier character spec as defined for the function strftime. If no modifier character is present,
mod is zero. For each valid format sequence identified, calls do_put(s, str, fill, t, spec, mod).

The second form calls do_put(s, str, fill, t, format, modifier).

[Note: The fill argument may be used in the implementation-defined formats or by derivations. A
space character is a reasonable default for this argument. —end note]

Returns: An iterator pointing immediately after the last character produced.

28.4.5.3.2 Virtual functions

iter_type do_put(iter_type s, ios_base& str, char_type fill, const tm* t,
    char format, char modifier) const;

Effects: Formats the contents of the parameter t into characters placed on the output sequence s.
Formatting is controlled by the parameters format and modifier, interpreted identically as the format
specifiers in the string argument to the standard library function strftime()274, except that the
sequence of characters produced for those specifiers that are described as depending on the C locale are
instead implementation-defined.275

Returns: An iterator pointing immediately after the last character produced. [Note: The fill argument
may be used in the implementation-defined formats or by derivations. A space character is a reasonable
default for this argument. —end note]

28.4.5.4 Class template time_put_byname

namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class time_put_byname : public time_put<charT, OutputIterator> {
    public:
    using char_type = charT;
    using iter_type = OutputIterator;

    explicit time_put_byname(const char*, size_t refs = 0);
    explicit time_put_byname(const string&, size_t refs = 0);

    protected:
    - ~time_put_byname();
    
    }
}
28.4.6 The monetary category

These templates handle monetary formats. A template parameter indicates whether local or international monetary formats are to be used.

All specifications of member functions for `money_put` and `money_get` in the subclauses of 28.4.6 only apply to the specializations required in Tables 101 and 102 (28.3.1.1.1). Their members use their `ios_base` and `ios_base::iostate` and `fill` arguments as described in 28.4, and the `moneypunct<>` and `ctype<>` facets, to determine formatting details.

28.4.6.1 Class template money_get

```cpp
namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class money_get : public locale::facet {
    public:
        using char_type = charT;
        using iter_type = InputIterator;
        using string_type = basic_string<charT>;

        explicit money_get(size_t refs = 0);

        iter_type get(iter_type s, iter_type end, bool intl, ios_base& f, ios_base::iostate& err, long double& units) const;
        iter_type get(iter_type s, iter_type end, bool intl, ios_base& f, ios_base::iostate& err, string_type& digits) const;

        static locale::id id;
    protected:
        ~money_get();
        virtual iter_type do_get(iter_type, iter_type, bool, ios_base&, ios_base::iostate& err, long double& units) const;
        virtual iter_type do_get(iter_type, iter_type, bool, ios_base&, ios_base::iostate& err, string_type& digits) const;
    }
}
```

28.4.6.1.1 Members

```cpp
iter_type get(iter_type s, iter_type end, bool intl, ios_base& f, ios_base::iostate& err, long double& quant) const;
iter_type get(iter_type s, iter_type end, bool intl, ios_base& f, ios_base::iostate& err, string_type& quant) const;
```

Returns: do_get(s, end, intl, f, err, quant).

28.4.6.1.2 Virtual functions

```cpp
iter_type do_get(iter_type s, iter_type end, bool intl, ios_base& str, ios_base::iostate& err, long double& units) const;
iter_type do_get(iter_type s, iter_type end, bool intl, ios_base& str, ios_base::iostate& err, string_type& digits) const;
```

Effects: Reads characters from s to parse and construct a monetary value according to the format specified by a `moneypunct<charT, Intl>` facet reference `mp` and the character mapping specified by a `ctype<charT>` facet reference `ct` obtained from the locale returned by `str.getloc()` and `str.flags()`.

If a valid sequence is recognized, does not change `err`; otherwise, sets `err` to `(err|str.failbit)`, or `(err|str.failbit|str.eofbit)` if no more characters are available, and does not change `units` or `digits`. Uses the pattern returned by `mp.neg_format()` to parse all values. The result is returned as an integral value stored in `units` or as a sequence of digits possibly preceded by a minus sign (as produced by `ct.widen(c)` where `c` is `-` or in the range from ’0’ through ’9’ (inclusive)) stored in `digits`. [Example: The sequence $1,056.23$ in a common United States locale would yield, for `units`, 105623, or, for `digits`, "105623". — end example] If `mp.grouping()` indicates that no thousands
separators are permitted, any such characters are not read, and parsing is terminated at the point
where they first appear. Otherwise, thousands separators are optional; if present, they are checked for
correct placement only after all format components have been read.

Where `money_base::space` or `money_base::none` appears as the last element in the format pattern, no
white space is consumed. Otherwise, where `money_base::space` appears in any of the initial elements
of the format pattern, at least one white space character is required. Where `money_base::none`
appears in any of the initial elements of the format pattern, white space is allowed but not required.
If `(str.flags() & str.showbase)` is false, the currency symbol is optional and is consumed only if
other characters are needed to complete the format; otherwise, the currency symbol is required.

If the first character (if any) in the string `pos` returned by `mp.positive_sign()` or the string `neg`
returned by `mp.negative_sign()` is recognized in the position indicated by `sign` in the format pattern,
it is consumed and any remaining characters in the string are required after all the other format
components. [Example: If `showbase` is off, then for a `neg` value of "(" and a currency symbol of
"L", in "(100 L)" the "L" is consumed; but if `neg` is "-", the "L" in "-100 L" is not consumed.
—end example] If `pos` or `neg` is empty, the sign component is optional, and if no sign is detected, the
result is given the sign that corresponds to the source of the empty string. Otherwise, the character
in the indicated position must match the first character of `pos` or `neg`, and the result is given the
corresponding sign. If the first character of `pos` is equal to the first character of `neg`, or if both strings
are empty, the result is given a positive sign.

Digits in the numeric monetary component are extracted and placed in `digits`, or into a character
buffer `buf1` for conversion to produce a value for `units`, in the order in which they appear, preceded
by a minus sign if and only if the result is negative. The value `units` is produced as if by:

```c
for (int i = 0; i < n; ++i)
    buf2[i] = src[find(atoms, atoms+sizeof(src), buf1[i]) - atoms];
buf2[n] = 0;
sscanf(buf2, "%Lf", &units);
```

where `n` is the number of characters placed in `buf1`, `buf2` is a character buffer, and the values `src` and
`atoms` are defined as if by:

```c
static const char src[] = "0123456789-";
charT atoms[sizeof(src)];
ct.widen(src, src + sizeof(src) - 1, atoms);
```

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid
monetary quantity.

§ 28.4.6.2 Class template `money_put`

```c
namespace std {

    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class money_put : public locale::facet {
    public:
        using char_type = charT;
        using iter_type = OutputIterator;
        using string_type = basic_string<charT>;

        explicit money_put(size_t refs = 0);

        iter_type put(iter_type s, bool intl, ios_base& f,
        char_type fill, long double units) const;
        iter_type put(iter_type s, bool intl, ios_base& f,
        char_type fill, const string_type& digits) const;

        static locale::id id;

        protected:
            =money_put();
            virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill,
            long double units) const;

    } // class money_put

276} The semantics here are different from `ct.narrow`.

§ 28.4.6.2 1330
virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill, const string_type& digits) const;
};

28.4.6.2.1 Members

iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, long double quant) const;
iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, const string_type& quant) const;
1
Returns: do_put(s, intl, f, loc, quant).

28.4.6.2.2 Virtual functions

iter_type do_put(iter_type s, bool intl, ios_base& str, char_type fill, long double units) const;
iter_type do_put(iter_type s, bool intl, ios_base& str, char_type fill, const string_type& digits) const;
1
Effects: Writes characters to s according to the format specified by a moneypunct<
charT, Intl> facet reference mp and the character mapping specified by a ctype<
ccharT> facet reference ct obtained from the locale returned by str.getloc(), and str.flags(). The argument units is transformed into a sequence of wide characters as if by

ct.widen(buf1, buf1 + sprintf(buf1, "%.0Lf", units), buf2) for character buffers buf1 and buf2. If the first character in digits or buf2 is equal to ct.widen('-'), then the pattern used for formatting is the result of mp.neg_format(); otherwise the pattern is the result of mp.pos_format(). Digit characters are written, interspersed with any thousands separators and decimal point specified by the format, in the order they appear (after the optional leading minus sign) in digits or buf2. In digits, only the optional leading minus sign and the immediately subsequent digit characters (as classified according to ct) are used; any trailing characters (including digits appearing after a non-digit character) are ignored. Calls str.width(0).

2
Remarks: The currency symbol is generated if and only if (str.flags() & str.showbase) is nonzero. If the number of characters generated for the specified format is less than the value returned by str.width() on entry to the function, then copies of fill are inserted as necessary to pad to the specified width. For the value af equal to (str.flags() & str.adjustfield), if (af == str.internal) is true, the fill characters are placed where none or space appears in the formatting pattern; otherwise if (af == str.left) is true, they are placed after the other characters; otherwise, they are placed before the other characters. [Note: It is possible, with some combinations of format patterns and flag values, to produce output that cannot be parsed using num_get<>::get. — end note]

3
Returns: An iterator pointing immediately after the last character produced.

28.4.6.3 Class template moneypunct

namespace std {
    class money_base {
    public:
        enum part { none, space, symbol, sign, value };
        struct pattern { char field[4]; }; 
    };

template<class charT, bool International = false>
    class moneypunct : public locale::facet, public money_base {
    public:
        using char_type = charT;
        using string_type = basic_string<charT>;

        explicit moneypunct(size_t refs = 0);

        charT decimal_point() const;
        charT thousands_sep() const;
        string grouping() const;
        string_type curr_symbol() const;
        string_type positive_sign() const;
    };
The `moneypunct<>` facet defines monetary formatting parameters used by `money_get<>` and `money_put<>`. A monetary format is a sequence of four components, specified by a `pattern` value `p`, such that the `part` value `static_cast<part>(p.field[i])` determines the `i`th component of the format. In the `field` member of a `pattern` object, each value `symbol`, `sign`, `value`, and either `space` or `none` appears exactly once. The value `none`, if present, is not first; the value `space`, if present, is neither first nor last.

Where `none` or `space` appears, white space is permitted in the format, except where `none` appears at the end, in which case no white space is permitted. The value `space` indicates that at least one space is required at that position. Where `symbol` appears, the sequence of characters returned by `curr_symbol()` is permitted, and can be required. Where `sign` appears, the first (if any) of the sequence of characters returned by `positive_sign()` or `negative_sign()` (respectively as the monetary value is non-negative or negative) is required. Any remaining characters of the sign sequence are required after all other format components. Where `value` appears, the absolute numeric monetary value is required.

The format of the numeric monetary value is a decimal number:

```
value ::= units [ decimal-point [ digits ] ]
```

if `frac_digits()` returns a positive value, or

```
value ::= units
```

otherwise. The symbol `decimal-point` indicates the character returned by `decimal_point()`. The other symbols are defined as follows:

```
units ::= digits [ thousands-sep units ]
digits ::= adigit [ digits ]
```

In the syntax specification, the symbol `adigit` is any of the values `ct.widen(c)` for `c` in the range `'0'` through `'9'` (inclusive) and `ct` is a reference of type `const ctype<charT>&` obtained as described in the definitions of `money_get<>` and `money_put<>`. The symbol `thousands-sep` is the character returned by `thousands_sep()`. The space character used is the value `ct.widen(' ')`. White space characters are those characters `c` for which `ci.is(space, c)` returns `true`. The number of digits required after the decimal point (if any) is exactly the value returned by `frac_digits()`.

The placement of thousands-separator characters (if any) is determined by the value returned by `grouping()`, defined identically as the member `numpunct<>::do_grouping()`.

### 28.4.6.3.1 Members

277) An array of `char`, rather than an array of `part`, is specified for `pattern::field` purely for efficiency.
Each of these functions \( F \) returns the result of calling the corresponding virtual member function \( \text{do}_F() \).

### 28.4.6.3.2 Virtual functions

CharT \( \text{do}_\text{decimal_point}() \) const;

---

1. Returns: The radix separator to use in case \( \text{do}_\text{frac_digits}() \) is greater than zero.\(^{278}\)

CharT \( \text{do}_\text{thousands_sep}() \) const;

2. Returns: The digit group separator to use in case \( \text{do}_\text{grouping}() \) specifies a digit grouping pattern.\(^{279}\)

String \( \text{do}_\text{grouping}() \) const;

3. Returns: A pattern defined identically as, but not necessarily equal to, the result of \( \text{numpunct<CharT>::do}_\text{grouping}() \).\(^{280}\)

StringType \( \text{do}_\text{curr_symbol}() \) const;

4. Returns: A string to use as the currency identifier symbol. [Note: For specializations where the second template parameter is true, this is typically four characters long: a three-letter code as specified by ISO 4217 followed by a space. — end note] \(^{281}\)

StringType \( \text{do}_\text{positive_sign}() \) const;

5. Returns: \( \text{do}_\text{positive_sign}() \) returns the string to use to indicate a positive monetary value; \( \text{do}_\text{negative_sign}() \) returns the string to use to indicate a negative value.

Int \( \text{do}_\text{frac_digits}() \) const;

6. Returns: The number of digits after the decimal radix separator, if any.\(^{282}\)

Pattern \( \text{do}_\text{pos_format}() \) const;

7. Pattern \( \text{do}_\text{neg_format}() \) const;

---

1. Returns: The specializations required in Table 102 (28.3.1.1.1), namely

\[ \begin{align*}
(7.1) & \quad \text{moneypunct<CharT>} \\
(7.2) & \quad \text{moneypunct<wchar_t>} \\
(7.3) & \quad \text{moneypunct<CharT, true>} \\
(7.4) & \quad \text{moneypunct<wchar_t, true>}
\end{align*} \]

return an object of type \( \text{pattern} \) initialized to \( \{ \text{symbol, sign, none, value} \} \).\(^{283}\)

### 28.4.6.4 Class template moneypunct_byname

namespace std {

```cpp
    template<class CharT, bool Intl = false>
    class moneypunct_byname : public moneypunct<CharT, Intl> { 

    public:
        using pattern = money_base::pattern;
        using string_type = basic_string<CharT>;

        explicit moneypunct_byname(const char*, size_t refs = 0);
        explicit moneypunct_byname(const string&, size_t refs = 0);
    
    };
```
protected:
  ~moneypunct_byname();
};

28.4.7 The message retrieval category

Class messages<charT> implements retrieval of strings from message catalogs.

28.4.7.1 Class template messages

namespace std {
  class messages_base {
    public:
      using catalog = unspecified signed integer type;
    }

template<class charT>
  class messages : public locale::facet, public messages_base {
    public:
      using char_type = charT;
      using string_type = basic_string<charT>;
      explicit messages(size_t refs = 0);
      catalog open(const basic_string<char> string& fn, const locale&) const;
      string_type get(catalog c, int set, int msgid, const string_type& dfault) const;
      void close(catalog c) const;
      static locale::id id;
    protected:
      ~messages();
      virtual catalog do_open(const basic_string<char> string& name, const locale& loc) const;
      virtual string_type do_get(catalog, int set, int msgid, const string_type& dfault) const;
      virtual void do_close(catalog) const;
    }
  }

1 Values of type messages_base::catalog usable as arguments to members get and close can be obtained only by calling member open.

28.4.7.1.1 Members

catalog open(const basic_string<char> string& name, const locale& loc) const;
1 Returns: do_open(name, loc).

string_type get(catalog cat, int set, int msgid, const string_type& dfault) const;
2 Returns: do_get(cat, set, msgid, dfault).

void close(catalog cat) const;
3 Effects: Calls do_close(cat).

28.4.7.1.2 Virtual functions

catalog do_open(const basic_string<char> string& name, const locale& loc) const;
1 Returns: A value that may be passed to get() to retrieve a message from the message catalog identified by the string name according to an implementation-defined mapping. The result can be used until it is passed to close().

2 Returns a value less than 0 if no such catalog can be opened.

3 Remarks: The locale argument loc is used for character set code conversion when retrieving messages, if needed.
string_type do_get(catalog cat, int set, intmsgid, const string_type& dfault) const;

 Requires—Expects: cat shall be a catalog obtained from open() and not yet closed. Returns: A message identified by arguments set, msgid, and dfault, according to an implementation-defined mapping. If no such message can be found, returns dfault.

 void do_close(catalog cat) const;

 Requires—Expects: cat shall be a catalog obtained from open() and not yet closed. Effects: Releases unspecified resources associated with cat. Remarks: The limit on such resources, if any, is implementation-defined.

 28.4.7.2 Class template messages_byname

 namespace std {
  template<class charT>
  class messages_byname : public messages<charT> { public:
    using catalog = messages_base::catalog;
    using string_type = basic_string<charT>;

    explicit messages_byname(const char*, size_t refs = 0);
    explicit messages_byname(const string&, size_t refs = 0);

    protected:
      ~messages_byname();
  };
}

 28.5 C library locales

 28.5.1 Header <clocale> synopsis

 namespace std {
  struct lconv {
    char* setlocale(int category, const char* locale);
    lconv* localeconv();
  }

  #define NULL see ??
  #define LC_ALL see below
  #define LC_COLLATE see below
  #define LC_CTYPE see below
  #define LC_MONETARY see below
  #define LC_NUMERIC see below
  #define LC_TIME see below

 1 The contents and meaning of the header <clocale> are the same as the C standard library header <locale.h>.
 2 Calls to the function setlocale may introduce a data race (??) with other calls to setlocale or with calls to the functions listed in Table 113.

 See also: ISO C 7.11
Table 113: Potential `setlocale` data races
