I. Introduction

There are use cases when heap memory allocation should be avoided for the various reasons, which leads to loss of availability guarantees and unpredictable execution time. An example of such a use case is in safety critical applications, where dynamic memory allocation is highly restricted by respective industry standards.

Standard containers allow replacing the default heap-based std::allocator with a custom allocator, which shall fulfill Allocator named requirement, and that custom allocator may replace heap-based allocation with a different allocation source. Although, this mechanism allows replacing the allocator, the information required to calculate the total amount of memory to be consumed by a container and other useful information required to configure custom allocator is hidden within the specific implementation of the container. Users need to apply reverse engineering of the specific implementation to correctly configure their allocator. Furthermore, one implementation of the other standard library might require a different amount of memory than the other one for the same use-case and the problem size.

We propose an additional API that describes container allocation guarantees, in order to enable calculation of total required memory size and provide additional data required to configure specific allocation strategies.

II. Problem description and Scope

Suppose user has use-case with std::deque that is parametrized with some custom allocator:

```cpp
template <typename T, typename Allocator>
void process(const T& t, const Allocator& alloc)
{
    // fill it with 1000 elements
    std::deque<T, Allocator> d(1000, t, alloc);
    // at this point it is using memory blocks.
    for (auto i = 0; i < 100000; ++i)
    {
        d.push_front(t + 3); // make a new element on the front
        d.pop_back(); // pop one off the back.
    }
}
```

User has no idea of how much memory would be required to fulfill std::deque needs for the example above. Thus, user does not know how to configure Allocator instance.

C++17 introduced a pmr namespace with polymorphic_allocator and configurable memory resources that represent different allocation strategies. But user still does not have enough information of
allocation patterns of the particular STL container. Thus, user has no information how to configure the memory resource. The example below shows it:

```cpp
int process()
{
    constexpr std::size_t buffer_size = ?; // how much memory should we pre-allocate;
    std::byte buffer[buffer_size]; // preallocated memory

    std::pmr::monotonic_buffer_resource resource( buffer, buffer_size, std::pmr::null_memory_resource() ); // enough memory assertion

    std::pmr::list<int> list_var(&resource);
    list_var.push_back({});
    list_var.push_back({});
    list_var.push_back({});
}
```

In case of polymorphic allocator the standard does not answer the question how much memory is required to fulfill container memory expectations and how to guarantee that resource will not call upstream as a fallback meaning that the pre-allocated memory is enough.

So, the problem exists for both custom allocators and standardized allocator interfaces.

The current paper focuses on an API to reveal allocation patterns underneath the implementation of any given container, which would provide enough information to configure an allocator.

API changes that would be required to achieve the goal of avoiding heap memory allocation is out of scope for this proposal, but is lightly touched on in this paper.

The main goal of this paper is to get feedback on the approach and critical areas of further generalization.

### III. Describing an allocation pattern

Analysis of typical containers revealed several high-level allocation patterns:

- **List/Map/Set**
  - Many allocations with the same block size

- **Vector/String**
  - Many allocations of increasing size, but no more than 2 blocks will be non-freed at any given time

- **Deque/Unordered_map/Unordered_set**
  - 2 very distinct allocation patterns applied in parallel
    - Many allocation of small block sizes
    - Few allocation of bigger sizes

We developed the following schema in order to be able to describe the variety of patterns:

Allocation pattern can be divided in a set of sub-patterns.

The following structure describes a unit sub-pattern of the allocations:

```cpp
struct memory_config
```
{  
    std::size_t max_block_size;
    std::size_t concurrent_n;
    std::size_t total_n;
    std::size_t alignment
};

max_block_size – container shall guarantee that each allocation is less than or equal to this value
concurrent_n – the number of simultaneously allocated blocks that are not freed
total_n – the number of total block allocations for the whole Container instance lifetime
alignment – alignment of allocated blocks

The set of sub-patterns is described as a tuple: std::tuple<memory_config, ...>. The estimate of the total memory requirements is a combination of requirements described by each tuple element.

IV. Describing container use cases

Most containers have no upper limit for memory allocation if usage is not restricted in some way. At the same time, the allocation pattern may depend on the way by which you limit the usage of a given container.

Here is an example for std::vector:

If we restrict usage of std::vector only by limiting the length, we are unable to predict total_n in the descriptor.

If we additionally ban the shrink_to_fit call, we can estimate total_n, but we should assume the worst case – std::vector was created small and was increased slowly by resizing by one element, thus total_n will be ~ log2(max_length).

If we additionally require a call to reserve() immediately after std::vector default construction, we can estimate total_n = 1 and concurrent_n = 1 (while in other cases concurrent_n = 2).

That difference led us to add a notion of container use cases into the API.

Possible set of use-cases for the standard containers is on the table below:
<table>
<thead>
<tr>
<th>Container</th>
<th>Use case</th>
<th>Restrictions</th>
<th>total_n</th>
<th>concurrent_n</th>
<th>max_block_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>vector string</td>
<td>max_size</td>
<td>size &amp; reserve &lt;= MAX_N</td>
<td>?</td>
<td>2</td>
<td>O(sizeof(value_type) * MAX_N)</td>
</tr>
<tr>
<td></td>
<td>max_size_no_shrink</td>
<td>max_size plus: no shrink_to_fit</td>
<td>O(MAX_N)</td>
<td>2</td>
<td>O(sizeof(value_type) * MAX_N)</td>
</tr>
<tr>
<td></td>
<td>max_size_no_resize</td>
<td>max_size_no_shrink plus: no more than 1 resize/reserve</td>
<td>O(log2(MAX_N))</td>
<td>2</td>
<td>O(sizeof(value_type) * MAX_N)</td>
</tr>
<tr>
<td></td>
<td>max_size_reserve</td>
<td>max_size_no_shrink plus: one reserve() after construction</td>
<td>1</td>
<td>1</td>
<td>O(sizeof(value_type) * MAX_N)</td>
</tr>
<tr>
<td>[multi]map, [multi]set,</td>
<td>max_size</td>
<td>size &lt;= MAX_N</td>
<td>?</td>
<td>MAX_N</td>
<td>O(sizeof(node_type&lt;value_type&gt;))</td>
</tr>
<tr>
<td>forward_list, list</td>
<td>max_element_insertions</td>
<td>no more element insertions</td>
<td>MAX_N</td>
<td>MAX_N</td>
<td>O(sizeof(node_type&lt;value_type&gt;))</td>
</tr>
<tr>
<td>deque</td>
<td>max_size</td>
<td>size &lt;= MAX_N</td>
<td>? (Possible for some cases)</td>
<td>O(MAX_N) + C</td>
<td>max(sizeof(void*) * O(MAX_N), internal_calc(sizeof(T)))</td>
</tr>
<tr>
<td>unordered_[multi]set,</td>
<td>max_size*</td>
<td>size &amp; reserve &lt; MAX_n &amp;&amp; max_load_factor &gt;= passed_load_factor &amp;&amp; rehash &lt;= MAX_n / passed_load_factor</td>
<td>?</td>
<td>O(MAX_N / load_factor) + C</td>
<td>max(sizeof(void*) * O(MAX_N / load_factor), O(sizeof(T)))</td>
</tr>
<tr>
<td>unordered_[multi]map</td>
<td>max_element_insertions</td>
<td>no more element insertions</td>
<td>TBD</td>
<td>TBD</td>
<td>TBD</td>
</tr>
<tr>
<td></td>
<td>max_element_insertions_reserve</td>
<td>no more element insertions plus: one reserve() after construction</td>
<td>TBD</td>
<td>TBD</td>
<td>TBD</td>
</tr>
</tbody>
</table>
V. Proposed API approaches to query allocation pattern

The main idea is to be able to query how much memory is required for a particular container with a particular use-case and problem size using a specific memory allocation strategy. The API should be constexpr to allow getting the required memory size at compilation time if all of the parameters are known.

Proposed API

The proposal is to introduce the new class template in namespace std named memory_helper with two template parameters. memory_helper shall provide a std::tuple of memory_config’s for the specified container and use-case:

\[
\text{template <typename UseCase, typename Container> struct memory_helper}
\]

UseCase - a tag that describes the use-case for the container

Container - container type

Use-case is a tag (empty class) representing the use-case for the container. All use cases would be introduced in std::usecase namespace.

memory_helper should have specialization for each container and applicable use-case for that container. For example:

\[
\text{template <typename T, typename Alloc> struct memory_helper<typename T::usecase::max_element_insertions, std::list<T, Alloc>>}
\]

Each specialization of memory_helper must provide the following members:

config - public data member that has std::tuple<memory_config,...> type.

memory_helper( /* each specialization specific args */ ) - constructor initializing the config member.

Example:

\[
\text{template <typename T, typename Alloc> struct memory_helper<typename T::usecase::max_element_insertions, std::list<T, Alloc>>}
\]

\{
    constexpr memory_helper(std::size_t N) : config(memory_config{
            get_maxsizeof_chunk_for_list<T>(), N, N})
    \}

    const std::tuple<memory_config> config;
\}
VI. Usage examples

Let us look at the solution for std::deque example:

```cpp
constexpr std::size_t allocator_overhead = //allocator specific overhead;
constexpr auto max_size = 1001;
constexpr std::memory_helper<std::usecase::max_size, std::deque<T>>
    helper{max_size};
constexpr auto config = std::get<0>(helper.config);
constexpr auto memory_size = config.concurrent_n * config.max_block_size
    + allocator_overhead;
const auto memory = std::make_unique<std::byte[]>(memory_size);
//allocator specific code
mem::memory_pool<config.concurrent_n, config.max_block_size,
    config.alignment> pool(memory.get(), memory_size);
mem::custom_allocator<T, decltype(pool)> alloc(pool);
std::deque<T, decltype(alloc)> d(max_size - 1, t, alloc); // some type T
for (int i = 0; i < 100000; ++i)
{
    d.push_front(T(t)); // make a new element on the front
    d.pop_back(); // pop one off the back.
}
```

The solution works for std::pmr::monotonic_buffer_resource problem as well:

```cpp
constexpr memory_helper< std::usecase::max_element_insertions, std::list<int>> h{3};
constexpr memory_config mc{std::get<0>(h.config)};
constexpr std::size_t buffer_size = mc.max_block_size *
    mc.total_n;
std::byte buffer[buffer_size]{};
auto& null_resource = std::pmr::null_memory_resource();
std::pmr::monotonic_buffer_resource resource(buffer, buffer_size,
    null_resource);
std::pmr::list<int> list_var(&resource);
list_var.push_back({});
list_var.push_back({});
list_var.push_back({});
list_var.push_back({}); // Out of memory
VII. Further investigation in plans

a) Nested containers API
The case of `std::list<std::string>` implies allocation on several levels, which would require additional information to configure the `memory_resource`. Early internal investigation showed potential for generalization of the API to recurrent level. Details are targeted to the next iteration of the paper.

b) Allocators contact API
Need to define an API that could tell the user the allocation strategy overhead if any (e.g. strategy of pool replenishment from the upstream), but that should be a separate paper.
