This paper combines/integrates/consolidates the wording from its predecessor papers [P0437R1] and [P1370R1]. Each of which papers have been favorably reviewed by SG6 and LEWG. While those papers were originally approved for C++20, we opted to retard their progress due to LWG’s huge backlog at the time. We now submit their combined proposed wording, adjusted per LEWG’s review comments, for LWG review early in the C++23 cycle. Please see those earlier papers for motivation, background information, examples, and other discussion of the present proposal.

2 Proposed wording

2.1 Insert an entry, into Table [tab:support.ft], with the feature-test macro name __cpp_lib_numeric_traits, suitable date value, and header name <numbers>.

2.2 Edit [numerics.general] as shown.

2 The following subclauses describe components for complex number types, random number generation, numeric (n-at-a-time) arrays, generalized numeric algorithms, traits for numeric types, and mathematical constants and functions for floating-point types, as summarized in Table [tab:numerics.summary].

2.3 In Table [tab:numerics.summary], retitle entry “Mathematical constants” to “Mathematical constants and numeric traits”.

2.4 Edit paragraph 1 of [support.limits.general] as shown.

1 The headers <limits> (17.3.2), <climits> (17.3.5), and <cfloat> (17.3.6) supply characteristics of implementation-dependent arithmetic types (6.7.1). In addition, the header <numbers> ([num.traits]) supplies components, collectively known as numeric traits, that provide distinguished values and implementation-dependent characteristics of arithmetic types, and that are extensible to provide analogous values and characteristics for program-defined numeric types.

2.5 Add the following new text to clause [support.limits], positioned at the discretion of the Project Editor. (Much of the wording specifying the individual traits is taken or adapted from the corresponding numeric_limits wording.)

17.3.x Numeric traits

17.3.x.1 General

1 Not all traits are applicable to all numeric types, but where a trait is applicable, its definition provides a value appropriate to the type’s representation. Such values are defined so that they are usable as constant expressions. When a trait is instantiated on a cv-qualified type cv T, the trait’s value shall be equal to the value, if any, provided by the specialization on the unqualified type T.

2 Except for those in [num.traits.util], each trait specified in this subclause [num.traits] is declared as a class template of the following form:

\[
\text{template } \langle \text{class } T \rangle \text{ struct Trait } \{
\}
\]

Each such primary template is explicitly specialized, if and as applicable, for each arithmetic type ([basic.fundamental]). In addition, a program may explicitly specialize each such primary template for any program-defined numeric type ([numeric.requirements]) to which the trait is applicable.

3 Each specialization Trait<T> has no members other than a static inline constexpr T data member named value that is initialized to a value consistent with the trait’s specification.

[Note: If there is no explicit specialization Trait<T> for a given T, there is no member value. — end note]

---

1 Proposed additions (entirely new subclauses are not underlined) and deletions are based on [N4820]. Editorial instructions and drafting notes look like this.

2 The LaTeX source of this wording is available to the Project Editor upon request.
17.3.x.2 Header <numbers> synopsis

template <class T>
inline constexpr auto min_exponent10_v = min_exponent10<T>::value;

template <class T>
inline constexpr auto radix_v = radix<T>::value;

17.3.x.3 Numeric utility traits [num.traits.util]

template <template <class> class Trait, class T>
inline constexpr bool value_exists = see below;

1 Value: true if Trait<T> has a member named value; otherwise false.

template <template <class> class Trait, class T, class R = T>
inline constexpr R value_or(R def = R()) noexcept;

2 Returns: Trait<T>::value if value_exists<Trait,T> is true; otherwise def.

17.3.x.4 Numeric distinguished value traits [num.traits.val]

template <class T> struct denorm_min { see below };

1 Value: T's minimum positive denormalized value, if any; otherwise, the same value as min_normal_v<T>, if any.

template <class T> struct epsilon { see below };

2 Value: e−T(1), where e denotes T's least value greater than 1, if any.

template <class T> struct finite_max { see below };

3 Value: A finite value x, if any, such that T has no other finite value y such that y > x.

template <class T> struct finite_min { see below };

4 Value: A finite value x, if any, such that T has no other finite value y such that y < x.

template <class T> struct infinity { see below };

5 Value: T's positive infinity, if any.

template <class T> struct norm_min { see below };

6 Value: T's minimum positive normalized value, if T supports subnormal numbers; otherwise, T's minimum positive value.

template <class T> struct quiet_NaN { see below };

7 Value: T's quiet “Not a Number” value, if any.
template <class T> struct reciprocal_overflow_threshold { see below };

8 Value: The smallest positive value $x$ of type $T$ such that $T(1)/x$ does not overflow.

template <class T> struct round_error { see below };

9 Value: $T$'s maximum rounding error, if any.

template <class T> struct signaling_NaN { see below };

10 Value: $T$'s signaling “Not a Number” value, if any.

17.3.x.5 Numeric characteristics traits [num.traits.char]

template <class T> struct digits { see below };

1 Value: The number of $\text{radix}_v<T>$ digits that can be represented without change. If is_integer_v<T> is true, this is the number of non-sign bits in the representation; If is_floating_point_v<T> is true, this is the number of $\text{radix}_v<T>$ digits in the mantissa.

template <class T> struct digits10 { see below };

2 Value: The number of base 10 digits that can be represented without change.

template <class T> struct max_digits10 { see below };

3 Value: The number of base 10 digits required to ensure that type $T$ values which differ are always differentiated.

template <class T> struct max_exponent { see below };

4 Value: With $r = \text{radix}_v<T>$, the largest positive integer $i$ such that $r^{i-1}$ is a representable finite value of type $T$.

template <class T> struct max_exponent10 { see below };

5 Value: The largest positive integer $i$ such that $10^i$ is in the range of representable finite type $T$ values.

template <class T> struct min_exponent { see below };

6 Value: With $r = \text{radix}_v<T>$, the minimum negative integer $i$ such that $r^{i-1}$ is a representable, normalized (if applicable), finite value of type $T$.

template <class T> struct min_exponent10 { see below };

7 Value: The minimum negative integer $i$ such that $10^i$ is in the range of representable, normalized (if applicable), finite type $T$ values.

template <class T> struct radix { see below };

8 Value: The base of the representation. If is_floating_point_v<T> is true, this shall refer to the base or radix (often 2) of the exponent representation.

3 Acknowledgments

Many thanks to the readers of early drafts of this paper for their careful proofreading. Special thanks to the authors of [P1370R1], Mark Hoemmen and Damien Lebrun-Grandie, for their support of this proposal and their contributions to it.
