Abstract

In [P1110][3] Jeffrey Yesskin and JF Bastien explore the design space of placeholders with the goal of not naming entities for which a name would provide no additional information. In this paper, we propose a concrete solution for the use of _ (U+005F _ LOW LINE) as such placeholder for variable declarations and pattern matching text in a fully backward compatible manner.

Revisions

Revision 1

- Specify that placeholders can appear as class members
- Make use of _ ill-formed once a placeholder has been declared in the same scope

Motivation

Both [P1110][3], [P1469][2] and [P0577][4] go over the motivation both for a placeholder syntax in general and the single underscore _:
• Some variable, like locks, `scope_guard` and other RAII objects are only used for their side
effects.
```cpp
std::lock_guard lock(mutex);
```
• Some structured bindings may not be used, and we would like a syntax to specify that
this is the case. Introducing names for variables that are not used to convey less meaning
than `_`, which convey the "I don't care meaning". It is furthermore not possible to apply
attributes to structured bindings and as such, it is not possible to carry the developer's
intent to the compiler. The current wording advises:

```
Recommended practice: For an entity marked `[[maybe_unused]]`, implementa-
tions should not emit a warning that the entity or its structured
bindings (if any) are used or unused. For a structured binding declaration
not marked `[[maybe_unused]]`, implementations should not emit such a
warning unless all of its structured bindings are unused.
```

• We need a wildcard token for pattern matching. The proposed `_` is, as explained by
[P1469][2] an industry wide-standard and we believe having a single token `_` for both
wildcards and placeholders contribute to make C++ more consistent with itself and with
other languages (making easier to teach, etc)

### Design considerations

The design as presented in this paper takes the following design parameters into consideration

• `_` is recognized as some kind of placeholder in many existing languages, including `go`,
`python`, `rust`, `C#`.
• `_` is used in existing code and popular frameworks.
• `_` might be defined as a macro function in some files depending on the `gettext` library.
• `_` already carries the meaning of "I don't want to use this variable". Variables that
developers care about have more meaningful names.
• `_` unnamed variables cannot have linkage.
• `_` and `__` are similar enough that we should not give meaning to both.
• Tokens are rare, using a different token for placeholder may needlessly restrict the
design space for more important features.
• For consistency, we would like to use the same token as the pattern matching place-
holder.

### Proposal

We propose that when `_` is used as the identifier for the declaration of a variable, non static
class member variable, function parameter name, lambda capture or structured binding. the
introduced name is implicitly given the [[maybe_unused]] attribute.

[Example:
auto _ = foo(); // equivalent to [[maybe_unused]] auto _ = f();
— end example]

When a variable, function parameter, non-static class member variablem, structured binding or lambda capture is introduced by the identifier _ at function scope, or at namespace scope within the purview of a module implementation unit, it can redefine an existing declaration, [basic.scope.declarative] in the same scope. After redeclaration, if the variable is used, the program is ill-formed.

[Example:
namespace a {
    auto _ = f(); // Ok, declare a variable "_"
    auto _ = f(); // error: "_" is already defined in this namespace scope
}
void f() {
    auto _ = 42; // Ok, declare a variable "_"
    auto _ = 0; // Ok, re-declare a variable "_"
    {
        auto _ = 1; // Ok, shadowing
        assert(_ == 1); // Ok
    }
    assert(_ == 42); // ill-formed: Use of a redeclared placeholder variables
}
— end example]

In contexts where the grammar expects a pattern matching pattern, _ represents the wildcard pattern.

inspect(i) {
    0 => 0;
    _ => 1; // wildcard pattern
};

Should declaring variables called _ be deprecated?

This paper does not propose to deprecate variables called _, as a few frameworks have legitimate and widely deployed usages of it (see the section about google mock), and a depreciation is not necessary for the well-behaving of this proposal. We do however think that such depreciation may be useful to consider in a longer time frame.

Alternative Design

A previous version of this proposal suggested that _ should refer to the first declaration in scope, but many prefered the approach in this current revision.
Pattern matching

Citing [P1371R0][1], _ can be used as a pattern matching wildcard without ambiguities

Even though _ is a valid identifier, it does not introduce a name as doing so would result in redeclaration errors in the case where multiple wildcard _ identifiers are used. It is possible for users to have already introduced _ as a type or variable name in the same scope where an inspect statement is used. As a highly-visible example, the authors are aware of the use of _ as a name in the popular “Google Mock” library. Idiomatically this is accessed by introducing _ into the current namespace or block scope with a using declaration. Using the wildcard pattern in cases like this is unambiguous since the expression pattern requires a ^ introducer for primary expressions. _ will always match against an existing name and _ will always represent the wildcard pattern. An existing _ name can be used without ambiguity in the matched statement to which control is passed. Naturally, the impact of defining _ in the pre-processor cannot be predicted or controlled by this paper and is thus liable to result in an ill-formed program.

Impact on P2011 and other pipeline rewrite musing

Placeholders in pipeline rewrite have a “Bind to this” semantic rather than a “I don’t care” semantic. As such, these proposals could use a different syntax.

It might also be possible to have _ and _1, ... contextually be used as bind placeholders in pipeline require contexts.

Impact on existing code

Google Mock

Google Mock appear to constitute the most common use of the identifier. With this proposal, Google Mock continues to work. Variables named _ may shadow the testing::_ global variable introduced by google mock:

```cpp
namespace testing {
  const internal::AnythingMatcher _ = {};
}
```

Because the proposal limits the use of placeholder to function scope (because of linker considerations), there is little risk that increased use of _ causes shadowing issues for users of this framework.

It is possible to use the feature proposed in this paper along with google mock as long as the using namespace testing; appears before any declaration of _ in that code.

Compiler explorer link
Gettext

Some projects using Gettext define `_` as a function-like macro.

```
#define _(msgid) gettext (msgid)
```

It is important to know that this is not provided in any gettext header. It is also technically undefined as the `_` is reserved at global scope. But, regardless, defining this macro would not prevent the use of the proposed syntax, as `_` is only expanded by the preprocessor in this case if followed by parentheses:

```
constexpr const char* gettext(int) { return nullptr;}
#define _(msgid) gettext (msgid)
```

```
int main() {
    constexpr auto _ = _(42);
    auto _ = 42;
    static_assert(_ == nullptr);
}
```

Implementation

R0 of this proposal has been implemented in Clang and the implementation is available on Compiler Explorer.

The implementation consists of ignoring existing `_` variables in the same scope when declaring placeholder variables. Note that name lookup is not affected by this proposal, some variables are simply skipped over based on their name. The variables otherwise conserve their name for diagnostics purposes.

The current version of this proposal can be emulated with the `-Werror` flag Compiler Explorer.

// TODO

Rebuttal some wilder ideas explored by P1110

[P1110] explores the different places where a placeholder may be used.

Enums

The code on the left (P1110) can be written in standard C++ in a way that expresses the intent as clearly, if not more.
Concept-constrained declarations

The following example from P1110 is a historical artifact as C++20 uniformizes auto for this purpose.

```cpp
template<Integral __ N> class integral_constant { ... };
Numeric multiplyAdd(Numeric __ x, Numeric __ y, Numeric __ z) {
    Numeric __ multiplied = x * y;
    return multiplied + z;
}
```

Here is the C++20 equivalent

```cpp
template<Integral auto N> class integral_constant { ... };
Numeric multiplyAdd(Numeric auto x, Numeric auto y, Numeric auto z) {
    Numeric auto multiplied = x * y;
    return multiplied + z;
}
```

Other explored areas, including placeholders for function names, type declaration, using and concepts are not useful, either because C++ does already provide the desired facilities such as anonymous type, or because the entity needs a name (concepts, functions and using declarations without a name cannot be used)
