Working Draft, Standard for Programming Language C++

Note: this is an early draft. It’s known to be incomplet and incorrekt, and it has lots of bad formatting.
## Contents

1 Scope 1

2 Normative references 2

3 Terms and definitions 3

4 General principles 10

4.1 Implementation compliance 10

4.2 Structure of this document 11

4.3 Syntax notation 11

5 Lexical conventions 13

5.1 Separate translation 13

5.2 Phases of translation 13

5.3 Character sets 14

5.4 Preprocessing tokens 15

5.5 Alternative tokens 16

5.6 Tokens 16

5.7 Comments 16

5.8 Header names 17

5.9 Preprocessing numbers 17

5.10 Identifiers 17

5.11 Keywords 18

5.12 Operators and punctuators 19

5.13 Literals 19

6 Basics 29

6.1 Preamble 29

6.2 Declarations and definitions 30

6.3 One-definition rule 31

6.4 Scope 36

6.5 Name lookup 41

6.6 Program and linkage 53

6.7 Memory and objects 57

6.8 Types 71

6.9 Program execution 78

7 Expressions 90

7.1 Preamble 90

7.2 Properties of expressions 91

7.3 Standard conversions 94

7.4 Usual arithmetic conversions 98

7.5 Primary expressions 99

7.6 Compound expressions 116

7.7 Constant expressions 147

8 Statements 153

8.1 Preamble 153

8.2 Labeled statement 154

8.3 Expression statement 154

8.4 Compound statement or block 154

8.5 Selection statements 154

8.6 Iteration statements 156

8.7 Jump statements 158

1 Scope

This document specifies requirements for implementations of the C++ programming language. The first such requirement is that they implement the language, so this document also defines C++. Other requirements and relaxations of the first requirement appear at various places within this document.

C++ is a general purpose programming language based on the C programming language as described in ISO/IEC 9899:2018 *Programming languages — C* (hereinafter referred to as the *C standard*). C++ provides many facilities beyond those provided by C, including additional data types, classes, templates, exceptions, namespaces, operator overloading, function name overloading, references, free store management operators, and additional library facilities.
2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

(1.1) ISO/IEC 2382, Information technology — Vocabulary
(1.2) ISO 8601:2004, Data elements and interchange formats — Information interchange — Representation of dates and times
(1.3) ISO/IEC 9899:2018, Programming languages — C
(1.4) ISO/IEC/IEEE 9945:2009, Information Technology — Portable Operating System Interface (POSIX)
(1.5) ISO/IEC/IEEE 9945:2009/Cor 1:2013, Information Technology — Portable Operating System Interface (POSIX), Technical Corrigendum 1
(1.6) ISO/IEC/IEEE 9945:2009/Cor 2:2017, Information Technology — Portable Operating System Interface (POSIX), Technical Corrigendum 2
(1.7) ISO/IEC 10646, Information technology — Universal Coded Character Set (UCS)
(1.8) ISO/IEC 10646:2003, Information technology — Universal Multiple-Octet Coded Character Set (UCS)
(1.9) ISO 80000-2:2009, Quantities and units — Part 2: Mathematical signs and symbols to be used in the natural sciences and technology

The library described in ISO/IEC 9899:2018, Clause 7, is hereinafter called the C standard library.

The operating system interface described in ISO/IEC 9945:2003 is hereinafter called POSIX.

The ECMAScript Language Specification described in Standard Ecma-262 is hereinafter called ECMA-262.

[Note 1: References to ISO/IEC 10646:2003 are used only to support deprecated features (D.24). — end note]
3 Terms and definitions

1 For the purposes of this document, the terms and definitions given in ISO/IEC 2382, the terms, definitions, and symbols given in ISO 80000-2:2009, and the following apply.

2 ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- ISO Online browsing platform: available at https://www.iso.org/obp

3 Terms that are used only in a small portion of this document are defined where they are used and italicized where they are defined.

3.1 access

(execution-time action) read or modify the value of an object

[Note 1 to entry: Only objects of scalar type can be accessed. Reads of scalar objects are described in 7.3.2 and modifications of scalar objects are described in 7.6.19, 7.6.1.6, and 7.6.2.3. Attempts to read or modify an object of class type typically invoke a constructor (11.4.5) or assignment operator (11.4.6); such invocations do not themselves constitute accesses, although they may involve accesses of scalar subobjects. — end note]

3.2 arbitrary-positional stream

(library) stream that can seek to any integral position within the length of the stream

[Note 1 to entry: Every arbitrary-positional stream is also a repositionable stream (3.48). — end note]

3.3 argument

(function call expression) expression in the comma-separated list bounded by the parentheses

3.4 argument

(function-like macro) sequence of preprocessing tokens in the comma-separated list bounded by the parentheses

3.5 argument

(throw expression) operand of throw

3.6 argument

(template instantiation) constant-expression, type-id, or id-expression in the comma-separated list bounded by the angle brackets

3.7 block

(execution) wait for some condition (other than for the implementation to execute the execution steps of the thread of execution) to be satisfied before continuing execution past the blocking operation

3.8 block

(statement) compound statement

3.9 character

(library) object which, when treated sequentially, can represent text

[Note 1 to entry: The term does not mean only char, char8_t, char16_t, char32_t, and wchar_t objects (6.8.2), but any value that can be represented by a type that provides the definitions specified in Clause 21, Clause 28, Clause 29, or Clause 30. — end note]

§ 3.9
3.10 character container type
(library) class or a type used to represent a character

[Note 1 to entry: It is used for one of the template parameters of the string, iostream, and regular expression class templates. — end note]

3.11 collating element
sequence of one or more characters within the current locale that collate as if they were a single character

3.12 component
(library) group of library entities directly related as members, parameters, or return types

[Note 1 to entry: For example, the class template basic_string and the non-member function templates that operate on strings are referred to as the string component. — end note]

3.13 conditionally-supported
program construct that an implementation is not required to support

[Note 1 to entry: Each implementation documents all conditionally-supported constructs that it does not support. — end note]

3.14 constant subexpression
expression whose evaluation as subexpression of a conditional-expression CE would not prevent CE from being a core constant expression

3.15 deadlock
(library) situation wherein one or more threads are unable to continue execution because each is blocked waiting for one or more of the others to satisfy some condition

3.16 default behavior
(library implementation) specific behavior provided by the implementation, within the scope of the required behavior

3.17 diagnostic message
message belonging to an implementation-defined subset of the implementation’s output messages

3.18 direct-non-list-initialization
direct-initialization that is not list-initialization

3.19 dynamic type
(glvalue) type of the most derived object to which the glvalue refers

[Example 1: If a pointer (9.3.4.2) p whose static type is “pointer to class B” is pointing to an object of class D, derived from B (11.7), the dynamic type of the expression *p is “D”. References (9.3.4.3) are treated similarly. — end example]

3.20 dynamic type
(prvalue) static type of the prvalue expression
3.21 [defns.expression-equivalent] expression-equivalent
(library) expressions that all have the same effects, either are all potentially-throwing or are all not potentially-throwing, and either are all constant subexpressions or are all not constant subexpressions

[Example 1: For a value x of type int and a function f that accepts integer arguments, the expressions f(x + 2), f(2 + x), and f(1 + x + 1) are expression-equivalent. — end example]

3.22 [defns.regex.finite.state.machine] finite state machine
(regular expression) unspecified data structure that is used to represent a regular expression, and which permits efficient matches against the regular expression to be obtained

3.23 [defns.regex.format.specifier] format specifier
(regular expression) sequence of one or more characters that is to be replaced with some part of a regular expression match

3.24 [defns.handler] handler function
(library) non-reserved function whose definition may be provided by a C++ program

[Note 1 to entry: A C++ program may designate a handler function at various points in its execution by supplying a pointer to the function when calling any of the library functions that install handler functions (Clause 17). — end note]

3.25 [defns.ill-formed] ill-formed program
program that is not well-formed (3.67)

3.26 [defns.impl.defined] implementation-defined behavior
behavior, for a well-formed program construct and correct data, that depends on the implementation and that each implementation documents

3.27 [defns.order.ptr] implementation-defined strict total order over pointers
(library) implementation-defined strict total ordering over all pointer values such that the ordering is consistent with the partial order imposed by the builtin operators <, >, <=, and >=

3.28 [defns.impl.limits] implementation limits
restrictions imposed upon programs by the implementation

3.29 [defns.iostream.templates] iostream class templates
(library) templates that are declared in header <iosfwd> and take two template arguments

[Note 1 to entry: The arguments are named charT and traits. The argument charT is a character container class, and the argument traits is a class which defines additional characteristics and functions of the character type represented by charT necessary to implement the iostream class templates. — end note]

3.30 [defns.locale.specific] locale-specific behavior
behavior that depends on local conventions of nationality, culture, and language that each implementation documents

3.31 [defns.regex.matched] matched
(regular expression) condition when a sequence of zero or more characters correspond to a sequence of characters defined by the pattern
3.32 modifier function
(library) class member function other than a constructor, assignment operator, or destructor that alters the state of an object of the class

3.33 move assignment
(library) assignment of an rvalue of some object type to a modifiable lvalue of the same type

3.34 move construction
(library) direct-initialization of an object of some type with an rvalue of the same type

3.35 multibyte character
sequence of one or more bytes representing a member of the extended character set of either the source or the execution environment

[Note 1 to entry: The extended character set is a superset of the basic character set (5.3). — end note]

3.36 NTCTS
(library) sequence of values that have character type that precede the terminating null character type value charT()

3.37 observer function
(library) class member function that accesses the state of an object of the class but does not alter that state

[Note 1 to entry: Observer functions are specified as const member functions. — end note]

3.38 parameter
(function or catch clause) object or reference declared as part of a function declaration or definition or in the catch clause of an exception handler that acquires a value on entry to the function or handler

3.39 parameter
(function-like macro) identifier from the comma-separated list bounded by the parentheses immediately following the macro name

3.40 parameter
(template) member of a template-parameter-list

3.41 primary equivalence class
(regular expression) set of one or more characters which share the same primary sort key: that is the sort key weighting that depends only upon character shape, and not accents, case, or locale specific tailorings

3.42 program-defined specialization
(library) explicit template specialization or partial specialization that is not part of the C++ standard library and not defined by the implementation

3.43 program-defined type
(library) non-closure class type or enumeration type that is not part of the C++ standard library and not defined by the implementation, or a closure type of a non-implementation-provided lambda expression, or an instantiation of a program-defined specialization

[Note 1 to entry: Types defined by the implementation include extensions (4.1) and internal types used by the library. — end note]
3.44 projection
(library) transformation that an algorithm applies before inspecting the values of elements

[Example 1:]

```c++
std::pair<int, std::string_view> pairs[] = {{2, "foo"}, {1, "bar"}, {0, "baz"}};
std::ranges::sort(pairs, std::ranges::less{}, [] (auto const& p) { return p.first; });
```
sorts the pairs in increasing order of their first members:

```
{{0, "baz"}, {1, "bar"}, {2, "foo"}}
```

—end example

3.45 referenceable type
type that is either an object type, a function type that does not have cv-qualifiers or a ref-qualifier, or a reference type

[Note 1 to entry: The term describes a type to which a reference can be created, including reference types. — end note]

3.46 regular expression
pattern that selects specific strings from a set of character strings

3.47 replacement function
(library) non-reserved function whose definition is provided by a C++ program

[Note 1 to entry: Only one definition for such a function is in effect for the duration of the program’s execution, as the result of creating the program (5.2) and resolving the definitions of all translation units (6.6). — end note]

3.48 repositional stream
(library) stream that can seek to a position that was previously encountered

3.49 required behavior
(library) description of replacement function and handler function semantics applicable to both the behavior provided by the implementation and the behavior of any such function definition in the program

[Note 1 to entry: If such a function defined in a C++ program fails to meet the required behavior when it executes, the behavior is undefined. — end note]

3.50 reserved function
(library) function, specified as part of the C++ standard library, that is defined by the implementation

[Note 1 to entry: If a C++ program provides a definition for any reserved function, the results are undefined. — end note]

3.51 signature
(function) name, parameter-type-list, and enclosing namespace

[Note 1 to entry: Signatures are used as a basis for name mangling and linking. — end note]

3.52 signature
(non-template friend function with trailing requires-clause) name, parameter-type-list, enclosing class, and trailing requires-clause

3.53 signature
(function template) name, parameter-type-list, enclosing namespace, return type, template-head, and trailing requires-clause (if any)
3.54 \[\text{signature} \]
(Friend function template with constraint involving enclosing template parameters) name, parameter-type-list, return type, enclosing class, \textit{template-head}, and trailing \textit{requires-clause} (if any)

3.55 \[\text{signature} \]
(Function template specialization) signature of the template of which it is a specialization and its template arguments (whether explicitly specified or deduced)

3.56 \[\text{signature} \]
(Class member function) name, parameter-type-list, class of which the function is a member, \textit{cv}-qualifiers (if any), \textit{ref-qualifier} (if any), and trailing \textit{requires-clause} (if any)

3.57 \[\text{signature} \]
(Class member function template) name, parameter-type-list, class of which the function is a member, \textit{cv}-qualifiers (if any), \textit{ref-qualifier} (if any), return type (if any), \textit{template-head}, and trailing \textit{requires-clause} (if any)

3.58 \[\text{signature} \]
(Class member function template specialization) signature of the member function template of which it is a specialization and its template arguments (whether explicitly specified or deduced)

3.59 \[\text{stable algorithm} \]
(Library) algorithm that preserves, as appropriate to the particular algorithm, the order of elements

\[\text{Note 1 to entry: Requirements for stable algorithms are given in 16.4.6.8. — end note}\]

3.60 \[\text{static type} \]
Type of an expression resulting from analysis of the program without considering execution semantics

\[\text{Note 1 to entry: The static type of an expression depends only on the form of the program in which the expression appears, and does not change while the program is executing. — end note}\]

3.61 \[\text{sub-expression} \]
(Regular expression) subset of a regular expression that has been marked by parentheses

3.62 \[\text{traits class} \]
(Library) class that encapsulates a set of types and functions necessary for class templates and function templates to manipulate objects of types for which they are instantiated

3.63 \[\text{unblock} \]
Satisfy a condition that one or more blocked threads of execution are waiting for

3.64 \[\text{undefined behavior} \]
Behavior for which this document imposes no requirements

\[\text{Note 1 to entry: Undefined behavior may be expected when this document omits any explicit definition of behavior or when a program uses an erroneous construct or erroneous data. Permissible undefined behavior ranges from ignoring the situation completely with unpredictable results, to behaving during translation or program execution in a documented manner characteristic of the environment (with or without the issuance of a diagnostic message), to terminating a translation or execution (with the issuance of a diagnostic message). Many erroneous program constructs do not engender undefined behavior; they are required to be diagnosed. Evaluation of a constant expression (7.7) never exhibits behavior explicitly specified as undefined in Clause 4 through Clause 15. — end note}\]
3.65 unspecified behavior

behavior, for a well-formed program construct and correct data, that depends on the implementation

[Note 1 to entry: The implementation is not required to document which behavior occurs. The range of possible behaviors is usually delineated by this document. — end note]

3.66 valid but unspecified state

(library) value of an object that is not specified except that the object’s invariants are met and operations on the object behave as specified for its type

[Example 1: If an object \( x \) of type `std::vector<int>` is in a valid but unspecified state, `x.empty()` can be called unconditionally, and `x.front()` can be called only if `x.empty()` returns `false`. — end example]

3.67 well-formed program

C++ program constructed according to the syntax rules, diagnosable semantic rules, and the one-definition rule
4 General principles

4.1 Implementation compliance

4.1.1 General

1 The set of diagnosable rules consists of all syntactic and semantic rules in this document except for those rules containing an explicit notation that “no diagnostic is required” or which are described as resulting in “undefined behavior”.

2 Although this document states only requirements on C++ implementations, those requirements are often easier to understand if they are phrased as requirements on programs, parts of programs, or execution of programs. Such requirements have the following meaning:

(2.1) — If a program contains no violations of the rules in Clause 5 through Clause 32 and Annex D, a conforming implementation shall, within its resource limits as described in Annex B, accept and correctly execute that program.

(2.2) — If a program contains a violation of any diagnosable rule or an occurrence of a construct described in this document as “conditionally-supported” when the implementation does not support that construct, a conforming implementation shall issue at least one diagnostic message.

(2.3) — If a program contains a violation of a rule for which no diagnostic is required, this document places no requirement on implementations with respect to that program.

[Note 1: During template argument deduction and substitution, certain constructs that in other contexts require a diagnostic are treated differently; see 13.10.3. — end note]

3 For classes and class templates, the library Clauses specify partial definitions. Private members (11.8) are not specified, but each implementation shall supply them to complete the definitions according to the description in the library Clauses.

4 For functions, function templates, objects, and values, the library Clauses specify declarations. Implementations shall supply definitions consistent with the descriptions in the library Clauses.

5 A C++ translation unit (5.2) obtains access to the names defined in the library by including the appropriate standard library header or importing the appropriate standard library named header unit (16.4.3.2).

6 The templates, classes, functions, and objects in the library have external linkage (6.6). The implementation provides definitions for standard library entities, as necessary, while combining translation units to form a complete C++ program (5.2).

7 Two kinds of implementations are defined: a hosted implementation and a freestanding implementation. For a hosted implementation, this document defines the set of available libraries. A freestanding implementation is one in which execution may take place without the benefit of an operating system, and has an implementation-defined set of libraries that includes certain language-support libraries (16.4.2.4).

8 A conforming implementation may have extensions (including additional library functions), provided they do not alter the behavior of any well-formed program. Implementations are required to diagnose programs that use such extensions that are ill-formed according to this document. Having done so, however, they can compile and execute such programs.

9 Each implementation shall include documentation that identifies all conditionally-supported constructs that it does not support and defines all locale-specific characteristics.

4.1.2 Abstract machine

1 The semantic descriptions in this document define a parameterized nondeterministic abstract machine. This document places no requirement on the structure of conforming implementations. In particular, they need not copy or emulate the structure of the abstract machine. Rather, conforming implementations are required to emulate (only) the observable behavior of the abstract machine as explained below.

5) “Correct execution” can include undefined behavior, depending on the data being processed; see Clause 3 and 6.9.1.

6) This documentation also defines implementation-defined behavior; see 4.1.2.

7) This provision is sometimes called the “as-if” rule, because an implementation is free to disregard any requirement of this document as long as the result is as if the requirement had been obeyed, as far as can be determined from the observable behavior. This rule is discussed further in 13.10.3.
Certain aspects and operations of the abstract machine are described in this document as implementation-defined (for example, `sizeof(int)`). These constitute the parameters of the abstract machine. Each implementation shall include documentation describing its characteristics and behavior in these respects.\(^8\) Such documentation shall define the instance of the abstract machine that corresponds to that implementation (referred to as the “corresponding instance” below).

Certain other aspects and operations of the abstract machine are described in this document as unspecified (for example, order of evaluation of arguments in a function call (7.6.1.3)). Where possible, this document defines a set of allowable behaviors. These define the nondeterministic aspects of the abstract machine. An instance of the abstract machine can thus have more than one possible execution for a given program and a given input.

Certain other operations are described in this document as undefined (for example, the effect of attempting to modify a const object).

\[\text{Note 1: This document imposes no requirements on the behavior of programs that contain undefined behavior.}\]

A conforming implementation executing a well-formed program shall produce the same observable behavior as one of the possible executions of the corresponding instance of the abstract machine with the same program and the same input. However, if any such execution contains an undefined operation, this document places no requirement on the implementation executing that program with that input (not even with regard to operations preceding the first undefined operation).

The least requirements on a conforming implementation are:

1. Accesses through volatile glvalues are evaluated strictly according to the rules of the abstract machine.
2. At program termination, all data written into files shall be identical to one of the possible results that execution of the program according to the abstract semantics would have produced.
3. The input and output dynamics of interactive devices shall take place in such a fashion that prompting output is actually delivered before a program waits for input. What constitutes an interactive device is implementation-defined.

These collectively are referred to as the observable behavior of the program.

\[\text{Note 2: More stringent correspondences between abstract and actual semantics can be defined by each implementation.}\]

4.2 Structure of this document

Clause 5 through Clause 15 describe the C++ programming language. That description includes detailed syntactic specifications in a form described in 4.3. For convenience, Annex A repeats all such syntactic specifications.

Clause 17 through Clause 32 and Annex D (the library clauses) describe the C++ standard library. That description includes detailed descriptions of the entities and macros that constitute the library, in a form described in Clause 16.

Annex B recommends lower bounds on the capacity of conforming implementations.

Annex C summarizes the evolution of C++ since its first published description, and explains in detail the differences between C++ and C. Certain features of C++ exist solely for compatibility purposes; Annex D describes those features.

4.3 Syntax notation

In the syntax notation used in this document, syntactic categories are indicated by italic type, and literal words and characters in constant width type. Alternatives are listed on separate lines except in a few cases where a long set of alternatives is marked by the phrase “one of”. If the text of an alternative is too long to fit on a line, the text is continued on subsequent lines indented from the first one. An optional terminal or non-terminal symbol is indicated by the subscript “\(^\text{opt}\)”, so

\[
\{ \text{expression}_{\text{opt}} \}
\]

\(\text{§ 4.3}\)
indicates an optional expression enclosed in braces.

Names for syntactic categories have generally been chosen according to the following rules:

1. **X-name** is a use of an identifier in a context that determines its meaning (e.g., class-name, typedef-name).
2. **X-id** is an identifier with no context-dependent meaning (e.g., qualified-id).
3. **X-seq** is one or more X’s without intervening delimiters (e.g., declaration-seq is a sequence of declarations).
4. **X-list** is one or more X’s separated by intervening commas (e.g., identifier-list is a sequence of identifiers separated by commas).
5 Lexical conventions

5.1 Separate translation

The text of the program is kept in units called source files in this document. A source file together with all the headers (16.4.2.3) and source files included (15.3) via the preprocessing directive #include, less any source lines skipped by any of the conditional inclusion (15.2) preprocessing directives, is called a translation unit.

[Note 1: A C++ program need not all be translated at the same time. — end note]

The separate translation units of a program communicate (6.6) by (for example) calls to functions whose identifiers have external or module linkage, manipulation of objects whose identifiers have external or module linkage, or manipulation of data files. Translation units can be separately translated and then later linked to produce an executable program (6.6). — end note]

5.2 Phases of translation

The precedence among the syntax rules of translation is specified by the following phases.

1. Physical source file characters are mapped, in an implementation-defined manner, to the basic source character set (introducing new-line characters for end-of-line indicators) if necessary. The set of physical source file characters accepted is implementation-defined. Any source file character not in the basic source character set (5.3) is replaced by the universal-character-name that designates that character. An implementation may use any internal encoding, so long as an actual extended character encountered in the source file, and the same extended character expressed in the source file as a universal-character-name (e.g., using the \uXXXX notation), are handled equivalently except where this replacement is reverted (5.4) in a raw string literal.

2. Each instance of a backslash character (\) immediately followed by a new-line character is deleted, splicing physical source lines to form logical source lines. Only the last backslash on any physical source line shall be eligible for being part of such a splice. Except for splices reverted in a raw string literal, if a splice results in a character sequence that matches the syntax of a universal-character-name, the behavior is undefined. A source file that is not empty and that does not end in a new-line character, or that ends in a new-line character immediately preceded by a backslash character before any such splicing takes place, shall be processed as if an additional new-line character were appended to the file.

3. The source file is decomposed into preprocessing tokens (5.4) and sequences of whitespace characters (including comments). A source file shall not end in a partial preprocessing token or in a partial comment. Each comment is replaced by one space character. New-line characters are retained. Whether each nonempty sequence of whitespace characters other than new-line is retained or replaced by one space character is unspecified. The process of dividing a source file’s characters into preprocessing tokens is context-dependent.

[Example 1: See the handling of < within a #include preprocessing directive. — end example]

4. Preprocessing directives are executed, macro invocations are expanded, and _Pragma unary operator expressions are executed. If a character sequence that matches the syntax of a universal-character-name is produced by token concatenation (15.6.4), the behavior is undefined. A #include preprocessing directive causes the named header or source file to be processed from phase 1 through phase 4, recursively. All preprocessing directives are then deleted.

5. Each basic-c-char, basic-s-char, and r-char in a character-literal or a string-literal, as well as each escape-sequence and universal-character-name in a character-literal or a non-raw string literal, is encoded in the literal’s associated character encoding as specified in 5.13.3 and 5.13.5.

6. Adjacent string-literals are concatenated and a null character is appended to the result as specified in 5.13.5.

9) Implementations behave as if these separate phases occur, although in practice different phases can be folded together.

10) A partial preprocessing token would arise from a source file ending in the first portion of a multi-character token that requires a terminating sequence of characters, such as a header-name that is missing the closing * or >. A partial comment would arise from a source file ending with an unclosed /* comment.
7. White-space characters separating tokens are no longer significant. Each preprocessing token is converted into a token (5.6). The resulting tokens are syntactically and semantically analyzed and translated as a translation unit.

[Note 1: The process of analyzing and translating the tokens can occasionally result in one token being replaced by a sequence of other tokens (13.3). — end note]

It is implementation-defined whether the sources for module units and header units on which the current translation unit has an interface dependency (10.1, 10.3) are required to be available.

[Note 2: Source files, translation units and translated translation units need not necessarily be stored as files, nor need there be any one-to-one correspondence between these entities and any external representation. The description is conceptual only, and does not specify any particular implementation. — end note]

8. Translated translation units and instantiation units are combined as follows:

[Note 3: Some or all of these can be supplied from a library. — end note]

Each translated translation unit is examined to produce a list of required instantiations.

[Note 4: This can include instantiations which have been explicitly requested (13.9.3). — end note]

The definitions of the required templates are located. It is implementation-defined whether the source of the translation units containing these definitions is required to be available.

[Note 5: An implementation can choose to encode sufficient information into the translated translation unit so as to ensure the source is not required here. — end note]

All the required instantiations are performed to produce instantiation units.

[Note 6: These are similar to translated translation units, but contain no references to uninstantiated templates and no template definitions. — end note]

The program is ill-formed if any instantiation fails.

9. All external entity references are resolved. Library components are linked to satisfy external references to entities not defined in the current translation. All such translator output is collected into a program image which contains information needed for execution in its execution environment.

5.3 Character sets

1 The basic source character set consists of 96 characters: the space character, the control characters representing horizontal tab, vertical tab, form feed, and new-line, plus the following 91 graphical characters:

```
  abcdefghijklmnopqrstuvwxyz
  ABCDEFGHIJKLMNOPQRSTUVWXYZ
  0123456789
  _ { } [ ] # ( ) < > % : ; . * + - / & | ~ ! = , " '
```

2 The universal-character-name construct provides a way to name other characters.

```
  hex-quad:
    hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit
  universal-character-name:
    \u hex-quad
    \U hex-quad hex-quad
```

A universal-character-name designates the character in ISO/IEC 10646 (if any) whose code point is the hexadecimal number represented by the sequence of hexadecimal-digits in the universal-character-name. The program is ill-formed if that number is not a code point or if it is a surrogate code point. Noncharacter code points and reserved code points are considered to designate separate characters distinct from any ISO/IEC 10646 character. If a universal-character-name outside the c-char-sequence, s-char-sequence, or r-char-sequence of a character-literal or string-literal (in either case, including within a user-defined-literal) corresponds to a control character or to a character in the basic source character set, the program is ill-formed.

---

11) The glyphs for the members of the basic source character set are intended to identify characters from the subset of ISO/IEC 10646 which corresponds to the ASCII character set. However, the mapping from source file characters to the source character set (described in translation phase 1) is specified as implementation-defined, and therefore implementations must document how the basic source characters are represented in source files.

12) A sequence of characters resembling a universal-character-name in an r-char-sequence (5.13.5) does not form a universal-character-name.
[Note 1: ISO/IEC 10646 code points are integers in the range \([0, 10FFFF]\) (hexadecimal). A surrogate code point is a value in the range \([D800, DFFF]\) (hexadecimal). A control character is a character whose code point is in either of the ranges \([0, 1F]\) or \([7F, 9F]\) (hexadecimal). — end note]

3 The basic execution character set and the basic execution wide-character set shall each contain all the members of the basic source character set, plus control characters representing alert, backspace, and carriage return, plus a null character (respectively, null wide character), whose value is 0. For each basic execution character set, the values of the members shall be non-negative and distinct from one another. In both the source and execution basic character sets, the value of each character after 0 in the above list of decimal digits shall be one greater than the value of the previous. The execution character set and the execution wide-character set are implementation-defined supersets of the basic execution character set and the basic execution wide-character set, respectively. The values of the members of the execution character sets and the sets of additional members are locale-specific.

5.4 Preprocessing tokens

preprocessing-token:

header-name
import-keyword
module-keyword
export-keyword
identifier
pp-number
character-literal
user-defined-character-literal
string-literal
user-defined-string-literal
preprocessing-op-or-punc
each non-whitespace character that cannot be one of the above

1 Each preprocessing token that is converted to a token (5.6) shall have the lexical form of a keyword, an identifier, a literal, or an operator or punctuator.

2 A preprocessing token is the minimal lexical element of the language in translation phases 3 through 6. The categories of preprocessing token are: header names, placeholder tokens produced by preprocessing import and module directives (import-keyword, module-keyword, and export-keyword), identifiers, preprocessing numbers, character literals (including user-defined character literals), string literals (including user-defined string literals), preprocessing operators and punctuators, and single non-whitespace characters that do not lexically match the other preprocessing token categories. If a ‘\‘ or a ‘" character matches the last category, the behavior is undefined. Preprocessing tokens can be separated by whitespace; this consists of comments (5.7), or whitespace characters (space, horizontal tab, new-line, vertical tab, and form-feed), or both. As described in Clause 15, in certain circumstances during translation phase 4, whitespace (or the absence thereof) serves as more than preprocessing token separation. White space can appear within a preprocessing token only as part of a header name or between the quotation characters in a character literal or string literal.

3 If the input stream has been parsed into preprocessing tokens up to a given character:

(3.1) — If the next character begins a sequence of characters that could be the prefix and initial double quote of a raw string literal, such as R", the next preprocessing token shall be a raw string literal. Between the initial and final double quote characters of the raw string, any transformations performed in phases 1 and 2 (universal-character-names and line splicing) are reverted; this reversion shall apply before any d-char, r-char, or delimiting parenthesis is identified. The raw string literal is defined as the shortest sequence of characters that matches the raw-string pattern

encoding-prefixopt R raw-string

(3.2) — Otherwise, if the next three characters are <:: and the subsequent character is neither : nor >, the < is treated as a preprocessing token by itself and not as the first character of the alternative token <::.

(3.3) — Otherwise, the next preprocessing token is the longest sequence of characters that could constitute a preprocessing token, even if that would cause further lexical analysis to fail, except that a header-name (5.8) is only formed

(3.3.1) — after the include or import preprocessing token in an #include (15.3) or import (15.5) directive, or

(3.3.2) — within a has-include-expression.
4. The \textit{import-keyword} is produced by processing an \textbf{import} directive (15.5), the \textit{module-keyword} is produced by preprocessing a \textbf{module} directive (15.4), and the \textit{export-keyword} is produced by preprocessing either of the previous two directives.

\textit{Note 1}: None has any observable spelling. \textit{—end note}\]

5. \textbf{Example 2}: The program fragment $0xe$+$\text{foo}$ is parsed as a preprocessing number token (one that is not a valid \textit{integer-literal} or \textit{floating-point-literal} token), even though a parse as three preprocessing tokens $0xe$, $+$, and $\text{foo}$ can produce a valid expression (for example, if $\text{foo}$ is a macro defined as 1). Similarly, the program fragment $1E1$ is parsed as a preprocessing number (one that is a valid \textit{floating-point-literal} token), whether or not $E$ is a macro name. \textit{—end example}\]

6. \textbf{Example 3}: The program fragment $x+++++y$ is parsed as $x$ ++ ++ + $y$, which, if $x$ and $y$ have integral types, violates a constraint on increment operators, even though the parse $x$ ++ + ++ $y$ can yield a correct expression. \textit{—end example}\]

5.5 \textbf{Alternative tokens} \textit{[lex.digraph]}\]

Alternative token representations are provided for some operators and punctuators. In all respects of the language, each alternative token behaves the same, respectively, as its primary token, except for its spelling. The set of alternative tokens is defined in Table 1.

\begin{verbatim}
Table 1: Alternative tokens \textit{[tab:lex.digraph]}
\end{verbatim}

<table>
<thead>
<tr>
<th>Alternative</th>
<th>Primary</th>
<th>Alternative</th>
<th>Primary</th>

</tr>
</tbody>
</table>
\end{verbatim}

5.6 \textbf{Tokens} \textit{[lex.token]}\]

\texttt{token:}\n
\texttt{identifier}\n
\texttt{keyword}\n
\texttt{literal}\n
\texttt{operator-or-punctuator}\n
1. There are five kinds of tokens: identifiers, keywords, literals, operators, and other separators. Blanks, horizontal and vertical tabs, newlines, formfeeds, and comments (collectively, “whitespace”), as described below, are ignored except as they serve to separate tokens.

\textit{Note 1}: Some whitespace is required to separate otherwise adjacent identifiers, keywords, numeric literals, and alternative tokens containing alphabetic characters. \textit{—end note}\]

5.7 \textbf{Comments} \textit{[lex.comment]}\]

The characters /* start a comment, which terminates with the characters */. These comments do not nest. The characters // start a comment, which terminates immediately before the next new-line character. If there is a form-feed or a vertical-tab character in such a comment, only whitespace characters shall appear between it and the new-line that terminates the comment; no diagnostic is required.

\textit{Note 13}: These include “digraphs” and additional reserved words. The term “digraph” (token consisting of two characters) is not perfectly descriptive, since one of the alternative preprocessing-tokens is \%: and of course several primary tokens contain two characters. Nonetheless, these alternative tokens that aren’t lexical keywords are colloquially known as “digraphs”.

14. Thus the “stringized” values (15.6.3) of [ and <: will be different, maintaining the source spelling, but the tokens can otherwise be freely interchanged.

15. Literals include strings and character and numeric literals.
[Note 1: The comment characters //, /*, and */ have no special meaning within a // comment and are treated just like other characters. Similarly, the comment characters // and */ have no special meaning within a */ comment. — end note]

5.8 Header names

header-name:
  < h-char-sequence >
  " q-char-sequence "

h-char-sequence:
  h-char
  h-char-sequence h-char

h-char:
  any member of the source character set except new-line and >

q-char-sequence:
  q-char
  q-char-sequence q-char

q-char:
  any member of the source character set except new-line and "

1 [Note 1: Header name preprocessing tokens only appear within a #include preprocessing directive, a __has_include preprocessing expression, or after certain occurrences of an import token (see 5.4). — end note]

The sequences in both forms of header-names are mapped in an implementation-defined manner to headers or to external source file names as specified in 15.3.

2 The appearance of either of the characters ‘ or \ or of either of the character sequences */ or // in a q-char-sequence or an h-char-sequence is conditionally-supported with implementation-defined semantics, as is the appearance of the character " in an h-char-sequence.16

5.9 Preprocessing numbers

pp-number:
  digit
  . digit
  pp-number digit
  pp-number identifier-nondigit
  pp-number ’ digit
  pp-number ’ nondigit
  pp-number e sign
  pp-number E sign
  pp-number p sign
  pp-number P sign
  pp-number .

1 Preprocessing number tokens lexically include all integer-literal tokens (5.13.2) and all floating-point-literal tokens (5.13.4).

2 A preprocessing number does not have a type or a value; it acquires both after a successful conversion to an integer-literal token or a floating-point-literal token.

5.10 Identifiers

identifier:
  identifier-nondigit
  identifier identifier-nondigit
  identifier digit

identifier-nondigit:
  nondigit
  universal-character-name

16) Thus, a sequence of characters that resembles an escape sequence can result in an error, be interpreted as the character corresponding to the escape sequence, or have a completely different meaning, depending on the implementation.
An identifier is an arbitrarily long sequence of letters and digits. Each universal-character-name in an identifier shall designate a character whose encoding in ISO/IEC 10646 falls into one of the ranges specified in Table 2. The initial element shall not be a universal-character-name designating a character whose encoding falls into one of the ranges specified in Table 3. Upper- and lower-case letters are different. All characters are significant.\(^1\)

Table 2: Ranges of characters allowed

| \[00A8-00AD\] | \[00AD-00AF\] | \[00B2-00B5\] | \[00B7-00BA\] | \[00BC-00BE\] | \[00C0-00D6\] | \[00D8-00F6\] | \[00F8-00FF\] |
|\[0100-167F\] | \[1681-180D\] | \[180F-1FFF\] | \[200B-200D\] | \[202A-202E\] | \[203F-2040\] | \[2054\] | \[2060-206F\] |
|\[2070-218F\] | \[2460-24FF\] | \[2776-2793\] | \[2C00-2DFF\] | \[2E80-2FFF\] |
|\[3004-3007\] | \[3021-302F\] | \[3031-D7FF\] | \[F900-FD3D\] | \[FD40-FDCF\] | \[FDF0-FE44\] | \[FE47-FFFD\] |
|\[10000-1FFFD\] | \[20000-2FFFD\] | \[30000-3FFFD\] | \[40000-4FFFD\] | \[50000-5FFFD\] |
|\[60000-6FFFD\] | \[70000-7FFFD\] | \[80000-8FFFD\] | \[90000-9FFFD\] | \[A0000-AFFFD\] |
|\[B0000-BFFFD\] | \[C0000-CFFFD\] | \[D0000-DFFFD\] | \[E0000-EFFFD\] |

Table 3: Ranges of characters disallowed initially (combining characters)

\[0300-036F\] \[1DC0-1DFF\] \[20D0-20FF\] \[FE20-FE2F\]

2 The identifiers in Table 4 have a special meaning when appearing in a certain context. When referred to in the grammar, these identifiers are used explicitly rather than using the identifier grammar production. Unless otherwise specified, any ambiguity as to whether a given identifier has a special meaning is resolved to interpret the token as a regular identifier.

Table 4: Identifiers with special meaning

\[\text{final import module override}\]

3 In addition, some identifiers are reserved for use by C++ implementations and shall not be used otherwise; no diagnostic is required.

\(3.1\) — Each identifier that contains a double underscore \_\_ or begins with an underscore followed by an uppercase letter is reserved to the implementation for any use.

\(3.2\) — Each identifier that begins with an underscore is reserved to the implementation for use as a name in the global namespace.

5.11 Keywords

\(\text{keyword:}\)

\(\text{any identifier listed in Table 5}\)

\(\text{import-keyword}\)

\(\text{module-keyword}\)

\(\text{export-keyword}\)

\(\text{§ 5.11}\) On systems in which linkers cannot accept extended characters, an encoding of the universal-character-name can be used in forming valid external identifiers. For example, some otherwise unused character or sequence of characters can be used to encode the \(\u00a0\) in a universal-character-name. Extended characters can produce a long external identifier, but C++ does not place a translation limit on significant characters for external identifiers. In C++, upper- and lower-case letters are considered different for all identifiers, including external identifiers.
The identifiers shown in Table 5 are reserved for use as keywords (that is, they are unconditionally treated as keywords in phase 7) except in an attribute-token (9.12.1).

[Note 1: The register keyword is unused but is reserved for future use. — end note]

Table 5: Keywords

<table>
<thead>
<tr>
<th>alignas</th>

</thead>
<tbody>
<tr>
<td>not_eq</td>
<td>or</td>
<td>or_eq</td>
<td>xor</td>
<td>xor_eq</td>
<td></td>
</tr>
</tbody>
</table>

5.12 Operators and punctuators

The lexical representation of C++ programs includes a number of preprocessing tokens that are used in the syntax of the preprocessor or are converted into tokens for operators and punctuators:

```
preprocessing-op-or-punctuator:
  preprocessing-operator
  operator-or-punctuator

preprocessing-operator: one of
  #   ##   %   %:   %:%

operator-or-punctuator: one of
  {   }   [   ]   (   )   <   >   <%   %>   %:   %:%
  ?:   ::   .   .*   ->   -*   ~
  !   +=   -=   *=   /=   %=   *=   ^=   &=   |=
  ==   !=   <   >   <=   >=   <=>
  <<=   >>=
  <<=   >>=
  ?:   ::   .   .*   ->   -*   ~
  !   +=   -=   *=   /=   %=   *=   ^=   &=   |=
  ==   !=   <   >   <=   >=   <=>
  <<=   >>=
  <<=   >>=
  and  or  xor  not  bitand  bitor  compl
  and_eq or_eq xor_eq xor_eq
```

Each operator-or-punctuator is converted to a single token in translation phase 7 (5.2).

5.13 Literals

5.13.1 Kinds of literals

There are several kinds of literals.\(^\text{18}\)

\(^\text{18}\) The term “literal” generally designates, in this document, those tokens that are called “constants” in ISO C.
literal:
  integer-literal
  character-literal
  floating-point-literal
  string-literal
  boolean-literal
  pointer-literal
  user-defined-literal

5.13.2 Integer literals

integer-literal:
  binary-literal integer-suffix_{opt}
  octal-literal integer-suffix_{opt}
  decimal-literal integer-suffix_{opt}
  hexadecimal-literal integer-suffix_{opt}

binary-literal:
  0b binary-digit
  0B binary-digit
  binary-literal \'_opt binary-digit

octal-literal:
  0
  octal-literal \'_opt octal-digit

decimal-literal:
  nonzero-digit
  decimal-literal \'_opt digit

hexadecimal-literal:
  hexadecimal-prefix hexadecimal-digit-sequence

binary-digit: one of
  0 1

octal-digit: one of
  0 1 2 3 4 5 6 7

nonzero-digit: one of
  1 2 3 4 5 6 7 8 9

hexadecimal-prefix: one of
  0x 0X

hexadecimal-digit-sequence:
  hexadecimal-digit
  hexadecimal-digit-sequence \'_opt hexadecimal-digit

hexadecimal-digit: one of
  0 1 2 3 4 5 6 7 8 9
  a b c d e f
  A B C D E F

integer-suffix:
  unsigned-suffix long-suffix_{opt}
  unsigned-suffix long-long-suffix_{opt}
  unsigned-suffix size-suffix_{opt}
  long-suffix unsigned-suffix_{opt}
  long-long-suffix unsigned-suffix_{opt}
  size-suffix unsigned-suffix_{opt}

unsigned-suffix: one of
  u U

long-suffix: one of
  l L

long-long-suffix: one of
  ll LL

size-suffix: one of
  z Z
In an integer-literal, the sequence of binary-digits, octal-digits, digits, or hexadecimal-digits is interpreted as a base \( N \) integer as shown in Table 7; the lexically first digit of the sequence of digits is the most significant.

[Note 1: The prefix and any optional separating single quotes are ignored when determining the value. — end note]

Table 7: Base of integer-literals  

<table>
<thead>
<tr>
<th>Kind of integer-literal</th>
<th>base ( N )</th>
</tr>
</thead>
<tbody>
<tr>
<td>binary-literal</td>
<td>2</td>
</tr>
<tr>
<td>octal-literal</td>
<td>8</td>
</tr>
<tr>
<td>decimal-literal</td>
<td>10</td>
</tr>
<tr>
<td>hexadecimal-literal</td>
<td>16</td>
</tr>
</tbody>
</table>

The hexadecimal-digits \( \text{a through f and A through F} \) have decimal values ten through fifteen.

[Example 1: The number twelve can be written 12, 014, 0XC, or \( 0b1100 \). The integer-literals 1048576, \( 1'048'576 \), \( 0X100000 \), \( 0x10'0000 \), and \( 0'004'000'000 \) all have the same value. — end example]

The type of an integer-literal is the first type in the list in Table 8 corresponding to its optional integer-suffix in which its value can be represented. An integer-literal is a prvalue.

Table 8: Types of integer-literals  

<table>
<thead>
<tr>
<th>integer-suffix</th>
<th>decimal-literal</th>
<th>integer-literal other than decimal-literal</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td></td>
<td>long int</td>
<td>unsigned int</td>
</tr>
<tr>
<td></td>
<td>long long int</td>
<td>long int</td>
</tr>
<tr>
<td>u or U</td>
<td>unsigned int</td>
<td>unsigned int</td>
</tr>
<tr>
<td></td>
<td>unsigned long int</td>
<td>unsigned long int</td>
</tr>
<tr>
<td>l or L</td>
<td>long int</td>
<td>long int</td>
</tr>
<tr>
<td></td>
<td>long long int</td>
<td>unsigned long int</td>
</tr>
<tr>
<td>Both u or U and l or L</td>
<td>unsigned long long int</td>
<td>unsigned long long int</td>
</tr>
<tr>
<td>1l or LL</td>
<td>long long int</td>
<td>long long int</td>
</tr>
<tr>
<td>Both u or U and 1l or LL</td>
<td>unsigned long long int</td>
<td>unsigned long long int</td>
</tr>
<tr>
<td>z or Z</td>
<td>the signed integer type corresponding to std::size_t (17.2.4)</td>
<td>the signed integer type corresponding to std::size_t</td>
</tr>
<tr>
<td></td>
<td>std::size_t</td>
<td>std::size_t</td>
</tr>
</tbody>
</table>

If an integer-literal cannot be represented by any type in its list and an extended integer type (6.8.2) can represent its value, it may have that extended integer type. If all of the types in the list for the integer-literal are signed, the extended integer type shall be signed. If all of the types in the list for the integer-literal are unsigned, the extended integer type shall be unsigned. If the list contains both signed and unsigned types, the extended integer type may be signed or unsigned. A program is ill-formed if one of its translation units contains an integer-literal that cannot be represented by any of the allowed types.

5.13.3  Character literals  

character-literal:
encoding-prefixopt \( \text{c-char-sequence} \)
encoding-prefix: one of
   u8  u  U  L

c-char-sequence:
   c-char
   c-char-sequence c-char

c-char:
   basic-c-char
   escape-sequence
   universal-character-name

basic-c-char:
   any member of the basic source character set except the single-quote ', backslash \, or new-line character

escape-sequence:
   simple-escape-sequence
   numeric-escape-sequence
   conditional-escape-sequence

simple-escape-sequence:
   \ simple-escape-sequence-char

simple-escape-sequence-char: one of
   \ " ? \ a b f n r t v

numeric-escape-sequence:
   octal-escape-sequence
   hexadecimal-escape-sequence

octal-escape-sequence:
   \ octal-digit
   \ octal-digit octal-digit
   \ octal-digit octal-digit octal-digit

hexadecimal-escape-sequence:
   \x hexadecimal-digit
   hexadecimal-escape-sequence hexadecimal-digit

conditional-escape-sequence:
   \ conditional-escape-sequence-char

conditional-escape-sequence-char:
   any member of the basic source character set that is not an octal-digit, a simple-escape-sequence-char, or the characters u, U, or x

1 A non-encodable character literal is a character-literal whose c-char-sequence consists of a single c-char that is not a numeric-escape-sequence and that specifies a character that either lacks representation in the literal’s associated character encoding or that cannot be encoded as a single code unit. A multicharacter literal is a character-literal whose c-char-sequence consists of more than one c-char. The encoding-prefix of a non-encodable character literal or a multicharacter literal shall be absent or L. Such character-literals are conditionally-supported.

2 The kind of a character-literal, its type, and its associated character encoding are determined by its encoding-prefix and its c-char-sequence as defined by Table 9. The special cases for non-encodable character literals and multicharacter literals take precedence over their respective base kinds.

[Note 1: The associated character encoding for ordinary and wide character literals determines encodability, but does not determine the value of non-encodable ordinary or wide character literals or ordinary or wide multicharacter literals. The examples in Table 9 for non-encodable ordinary and wide character literals assume that the specified character lacks representation in the execution character set or execution wide-character set, respectively, or that encoding it would require more than one code unit. — end note]

3 In translation phase 4, the value of a character-literal is determined using the range of representable values of the character-literal’s type in translation phase 7. A non-encodable character literal or a multicharacter literal has an implementation-defined value. The value of any other kind of character-literal is determined as follows:

(3.1) — A character-literal with a c-char-sequence consisting of a single basic-c-char, simple-escape-sequence, or universal-character-name is the code unit value of the specified character as encoded in the literal’s associated character encoding.

[Note 2: If the specified character lacks representation in the literal’s associated character encoding or if it cannot be encoded as a single code unit, then the literal is a non-encodable character literal. — end note]
Table 9: Character literals

<table>
<thead>
<tr>
<th>Encoding prefix</th>

<td>UTF-32</td>
<td>U'z'</td>
</tr>
</tbody>
</table>

(3.2) A character-literal with a c-char-sequence consisting of a single numeric-escape-sequence that specifies an integer value $v$ has a value as follows:

(3.2.1) If $v$ does not exceed the range of representable values of the character-literal’s type, then the value is $v$.

(3.2.2) Otherwise, if the character-literal’s encoding-prefix is absent or L, and $v$ does not exceed the range of representable values of the corresponding unsigned type for the underlying type of the character-literal’s type, then the value is the unique value of the character-literal’s type $T$ that is congruent to $v$ modulo $2^N$, where $N$ is the width of $T$.

(3.2.3) Otherwise, the character-literal is ill-formed.

(3.3) A character-literal with a c-char-sequence consisting of a single conditional-escape-sequence is conditionally-supported and has an implementation-defined value.

4 The character specified by a simple-escape-sequence is specified in Table 10.

[Note 3: Using an escape sequence for a question mark is supported for compatibility with ISO C++ 2014 and ISO C. — end note]

<tr>
<td>f or F</td>
<td>float</td>
</tr>
<tr>
<td>l or L</td>
<td>long double</td>
</tr>
</tbody>
</table>

2 The significand of a floating-point literal is the fractional-constant or digit-sequence of a decimal-floating-point literal or the hexadecimal-fractional-constant or hexadecimal-digit-sequence of a hexadecimal-floating-point literal. In the significand, the sequence of digits or hexadecimal-digits and optional period are interpreted as a base $N$ real number $s$, where $N$ is 10 for a decimal-floating-point literal and 16 for a hexadecimal-floating-point literal.

[Note 1: Any optional separating single quotes are ignored when determining the value. — end note]

If an exponent-part or binary-exponent-part is present, the exponent $e$ of the floating-point literal is the result of interpreting the sequence of an optional sign and the digits as a base 10 integer. Otherwise, the exponent $e$ is 0. The scaled value of the literal is $s \times 10^e$ for a decimal-floating-point literal and $s \times 2^e$ for a hexadecimal-floating-point literal.

[Example 1: The floating-point literals 49.625 and 0x2.68p+2 have the same value. The floating-point literals 1.602\textasciitilde 176\textasciitilde 565e\textasciitilde 19 and 1.602176565e\textasciitilde 19 have the same value. — end example]

3 If the scaled value is not in the range of representable values for its type, the program is ill-formed. Otherwise, the value of a floating-point literal is the scaled value if representable, else the larger or smaller representable value nearest the scaled value, chosen in an implementation-defined manner.

5.13.5 String literals

<table>
<thead>
<tr>
<th>string-literal</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoding-prefix\textsubscript{opt} &quot; s-char-sequence\textsubscript{opt} &quot;</td>
</tr>
<tr>
<td>encoding-prefix\textsubscript{opt} R raw-string</td>
</tr>
</tbody>
</table>

s-char-sequence:
  s-char
  s-char-sequence s-char

s-char:
  basic-s-char
  escape-sequence
  universal-character-name

basic-s-char:
  any member of the basic source character set except the double-quote ", backslash \, or new-line character

§ 5.13.5 24
raw-string:
  " d-char-sequence\opt ( r-char-sequence\opt ) d-char-sequence\opt "

r-char-sequence:
  r-char
  r-char-sequence r-char

r-char:
  any member of the source character set, except a right parenthesis \) followed by
  the initial d-char-sequence (which may be empty) followed by a double quote \".

d-char-sequence:
  d-char
  d-char-sequence d-char

d-char:
  any member of the basic source character set except:
    space, the left parenthesis (, the right parenthesis ), the backslash \, and the control characters
    representing horizontal tab, vertical tab, form feed, and newline.

1 The kind of a string-literal, its type, and its associated character encoding are determined by its encoding
prefix and sequence of s-chars or r-chars as defined by Table 12 where n is the number of encoded code units
as described below.

Table 12: String literals [tab:lex.string.literal]

<table>
<thead>
<tr>
<th>Encoding prefix</th>
<th>Kind</th>
<th>Type</th>
<th>Associated character encoding</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>ordinary string literal</td>

<td>UTF-16</td>
<td>u&quot;UTF-16 string&quot; uR&quot;y(UTF-16 raw string)y&quot;</td>
</tr>
<tr>
<td>U</td>
<td>UTF-32 string literal</td>
<td>array of n</td>
<td>UTF-32</td>
<td>U&quot;UTF-32 string&quot; UR&quot;z(UTF-32 raw string)z&quot;</td>
</tr>
</tbody>
</table>

2 A string-literal that has an R in the prefix is a raw string literal. The d-char-sequence serves as a delimiter. The
terminating d-char-sequence of a raw-string is the same sequence of characters as the initial d-char-sequence.
A d-char-sequence shall consist of at most 16 characters.

3 [Note 1: The characters ‘(‘ and ‘)’ are permitted in a raw-string. Thus, R"delimiter((a|b))delimiter" is
equivalent to "(a|b)". — end note]

4 [Note 2: A source-file new-line in a raw string literal results in a new-line in the resulting execution string literal.
Assuming no whitespace at the beginning of lines in the following example, the assert will succeed:

```cpp
const char* p = R"(a\n)\n(a"
assert(std::strcmp(p, "a\\\nb\nc") == 0);
— end note]

5 [Example 1: The raw string

R"a(\n)\n a"

is equivalent to "\na\\\n\n". The raw string
R"(x = "\"y\"")" is equivalent to "x = "\"\"y\"\". — end example

Ordinary string literals and UTF-8 string literals are also referred to as narrow string literals.

In translation phase 6 (5.2), adjacent string-literals are concatenated. If both string-literals have the same encoding-prefix, the resulting concatenated string-literal has that encoding-prefix. If one string-literal has no encoding-prefix, it is treated as a string-literal of the same encoding-prefix as the other operand. If a UTF-8 string literal token is adjacent to a wide string literal token, the program is ill-formed. Any other concatenations are conditionally-supported with implementation-defined behavior.

[Note 3: This concatenation is an interpretation, not a conversion. Because the interpretation happens in translation phase 6 (after the string literal contents have been encoded in the string-literal’s associated character encoding), a string-literal’s initial rawness has no effect on the interpretation or well-formedness of the concatenation. — end note]

Table 13 has some examples of valid concatenations.

<table>
<thead>
<tr>
<th>Source</th>
<th>Means</th>
</tr>
</thead>
<tbody>
<tr>
<td>u&quot;a&quot; u&quot;b&quot; u&quot;ab&quot;</td>
<td>U&quot;a&quot; U&quot;b&quot; U&quot;ab&quot;</td>
</tr>
<tr>
<td>u&quot;a&quot; &quot;b&quot; u&quot;ab&quot;</td>
<td>U&quot;a&quot; &quot;b&quot; U&quot;ab&quot;</td>
</tr>
<tr>
<td>&quot;a&quot; &quot;b&quot; u&quot;ab&quot;</td>
<td>&quot;a&quot; &quot;b&quot; U&quot;ab&quot;</td>
</tr>
</tbody>
</table>

Characters in concatenated strings are kept distinct.

[Example 2:

"\xA" "B" contains the two characters ‘\xA’ and ‘B’ after concatenation (and not the single hexadecimal character ‘\xAB’).
— end example]

Evaluating a string-literal results in a string literal object with static storage duration (6.7.5). Whether all string-literals are distinct (that is, are stored in nonoverlapping objects) and whether successive evaluations of a string-literal yield the same or a different object is unspecified.

[Note 4: The effect of attempting to modify a string-literal is undefined. — end note]

String literal objects are initialized with the sequence of code unit values corresponding to the string-literal’s sequence of s-chars (for a non-raw string literal) and r-chars (for a raw string literal) in order as follows:

(10.1) — The sequence of characters denoted by each contiguous sequence of basic-s-chars, r-chars, simple-escape-sequences (5.13.3), and universal-character-names (5.3) is encoded to a code unit sequence using the string-literal’s associated character encoding. If a character lacks representation in the associated character encoding, then:

(10.1.1) — If the string-literal’s encoding-prefix is absent or L, then the string-literal is conditionally-supported and an implementation-defined code unit sequence is encoded.

(10.1.2) — Otherwise, the string-literal is ill-formed.

When encoding a stateful character encoding, implementations should encode the first such sequence beginning with the initial encoding state and encode subsequent sequences beginning with the final encoding state of the prior sequence.

[Note 5: The encoded code unit sequence can differ from the sequence of code units that would be obtained by encoding each character independently. — end note]

(10.2) — Each numeric-escape-sequence (5.13.3) that specifies an integer value v contributes a single code unit with a value as follows:

(10.2.1) — If v does not exceed the range of representable values of the string-literal’s array element type, then the value is v.

(10.2.2) — Otherwise, if the string-literal’s encoding-prefix is absent or L, and v does not exceed the range of representable values of the corresponding unsigned type for the underlying type of the string-literal’s

§ 5.13.5
array element type, then the value is the unique value of the string-literal’s array element type \( T \) that is congruent to \( v \) modulo \( 2^N \), where \( N \) is the width of \( T \).

(10.2.3) — Otherwise, the string-literal is ill-formed.

When encoding a stateful character encoding, these sequences should have no effect on encoding state.

(10.3) — Each conditional-escape-sequence (5.13.3) contributes an implementation-defined code unit sequence. When encoding a stateful character encoding, it is implementation-defined what effect these sequences have on encoding state.

5.13.6 Boolean literals

boolean-literal:
  false
  true

The Boolean literals are the keywords \texttt{false} and \texttt{true}. Such literals are prvalues and have type \texttt{bool}.

5.13.7 Pointer literals

pointer-literal:
  nullptr

The pointer literal is the keyword \texttt{nullptr}. It is a prvalue of type \texttt{std::nullptr_t}.

[Note 1: \texttt{std::nullptr_t} is a distinct type that is neither a pointer type nor a pointer-to-member type; rather, a prvalue of this type is a null pointer constant and can be converted to a null pointer value or null member pointer value. See 7.3.12 and 7.3.13. — end note]

5.13.8 User-defined literals

user-defined-literal:
  user-defined-integer-literal
  user-defined-floating-point-literal
  user-defined-string-literal
  user-defined-character-literal

user-defined-integer-literal:
  decimal-literal ud-suffix
  octal-literal ud-suffix
  hexadecimal-literal ud-suffix
  binary-literal ud-suffix

user-defined-floating-point-literal:
  fractional-constant exponent-part opt ud-suffix
  digit-sequence exponent-part ud-suffix
  hexadecimal-prefix hexadecimal-fractional-constant binary-exponent-part ud-suffix
  hexadecimal-prefix hexadecimal-digit-sequence binary-exponent-part ud-suffix

user-defined-string-literal:
  string-literal ud-suffix

user-defined-character-literal:
  character-literal ud-suffix

ud-suffix:
  identifier

1 If a token matches both \texttt{user-defined-literal} and another \texttt{literal} kind, it is treated as the latter.

[Example 1: \texttt{123_km} is a \texttt{user-defined-literal}, but \texttt{12LL} is an \texttt{integer-literal}. — end example]

The syntactic non-terminal preceding the \texttt{ud-suffix} in a \texttt{user-defined-literal} is taken to be the longest sequence of characters that could match that non-terminal.

2 A \texttt{user-defined-literal} is treated as a call to a literal operator or literal operator template (12.6). To determine the form of this call for a given \texttt{user-defined-literal} \( L \) with \texttt{ud-suffix} \( X \), first let \( S \) be the set of declarations found by unqualified lookup for the literal-operator-id whose literal suffix identifier is \( X \) (6.5.3). \( S \) shall not be empty.

3 If \( L \) is a \texttt{user-defined-integer-literal}, let \( n \) be the literal without its \texttt{ud-suffix}. If \( S \) contains a literal operator with parameter type \texttt{unsigned long long}, the literal \( L \) is treated as a call of the form

\[
\text{operator } \text{"} X(n \text{ULL}) \text{"
} \]
Otherwise, $S$ shall contain a raw literal operator or a numeric literal operator template (12.6) but not both. If $S$ contains a raw literal operator, the literal $L$ is treated as a call of the form

\[
\text{operator } "X("n")\]

Otherwise ($S$ contains a numeric literal operator template), $L$ is treated as a call of the form

\[
\text{operator } "X<"c_1", 'c_2', \ldots 'c_k">()\]

where $n$ is the source character sequence $c_1c_2\ldots c_k$.

[Note 1: The sequence $c_1c_2\ldots c_k$ can only contain characters from the basic source character set. — end note]

4 If $L$ is a user-defined-floating-point-literal, let $f$ be the literal without its ud-suffix. If $S$ contains a literal operator with parameter type long double, the literal $L$ is treated as a call of the form

\[
\text{operator } "X("fL)\]

Otherwise, $S$ shall contain a raw literal operator or a numeric literal operator template (12.6) but not both. If $S$ contains a raw literal operator, the literal $L$ is treated as a call of the form

\[
\text{operator } "X("f")\]

Otherwise ($S$ contains a numeric literal operator template), $L$ is treated as a call of the form

\[
\text{operator } "X<"c_1", 'c_2', \ldots 'c_k">()\]

where $f$ is the source character sequence $c_1c_2\ldots c_k$.

[Note 2: The sequence $c_1c_2\ldots c_k$ can only contain characters from the basic source character set. — end note]

5 If $L$ is a user-defined-string-literal, let $str$ be the literal without its ud-suffix and let $len$ be the number of code units in $str$ (i.e., its length excluding the terminating null character). If $S$ contains a literal operator template with a non-type template parameter for which $str$ is a well-formed template-argument, the literal $L$ is treated as a call of the form

\[
\text{operator } "X<str>()\]

Otherwise, the literal $L$ is treated as a call of the form

\[
\text{operator } "X(str, len)\]

6 If $L$ is a user-defined-character-literal, let $ch$ be the literal without its ud-suffix. $S$ shall contain a literal operator (12.6) whose only parameter has the type of $ch$ and the literal $L$ is treated as a call of the form

\[
\text{operator } "X(ch)\]

7 [Example 2:

\[
\begin{align*}
\text{long double operator } "\_w(long double);}
\text{std::string operator } "\_w(const char16_t*, std::size_t);}
\text{unsigned operator } "\_w(const char*);}
\text{int main() \{} \text{\{
1.2\_w; \quad // \text{calls operator } "\_w(1.2L)
\text{u"one"\_w; \quad // \text{calls operator } "\_w(u"one", 3)
12\_w; \quad // \text{calls operator } "\_w(12")
\text{"two"\_w; \quad // \text{error: no applicable literal operator}
\text{\}} \text{\} }
\end{align*}
\]

—end example]

8 In translation phase 6 (5.2), adjacent string-literals are concatenated and user-defined-string-literals are considered string-literals for that purpose. During concatenation, ud-suffixes are removed and ignored and the concatenation process occurs as described in 5.13.5. At the end of phase 6, if a string-literal is the result of a concatenation involving at least one user-defined-string-literal, all the participating user-defined-string-literals shall have the same ud-suffix and that suffix is applied to the result of the concatenation.

9 [Example 3:

\[
\begin{align*}
\text{int main() \{} \text{\{
L"A" "B" "C"\_x; \quad // \text{OK: same as L"ABC"\_x}
\text{"P"\_x "Q" "R"\_y; \quad // \text{error: two different ud-suffixes}
\text{\}} \text{\}
\end{align*}
\]

—end example]
6 Basics

6.1 Preamble

[Note 1: This Clause presents the basic concepts of the C++ language. It explains the difference between an object and a name and how they relate to the value categories for expressions. It introduces the concepts of a declaration and a definition and presents C++’s notion of type, scope, linkage, and storage duration. The mechanisms for starting and terminating a program are discussed. Finally, this Clause presents the fundamental types of the language and lists the ways of constructing compound types from these. —end note]

[Note 2: This Clause does not cover concepts that affect only a single part of the language. Such concepts are discussed in the relevant Clauses. —end note]

An entity is a value, object, reference, structured binding, function, enumerator, type, class member, bit-field, template, template specialization, namespace, or pack.

A name is an identifier (5.10), operator-function-id (12.4), literal-operator-id (12.6), or conversion-function-id (11.4.8.3).

Every name is introduced by a declaration, which is a

1. declaration, block-declaration, or member-declaration (9.1, 11.4),
2. init-declarator (9.3),
3. identifier in a structured binding declaration (9.6),
4. init-capture (7.5.5.3),
5. condition with a declarator (8.1),
6. member-declarator (11.4),
7. using-declarator (9.9),
8. parameter-declaration (9.3.4.6),
9. type-parameter (13.2),
10. elaborated-type-specifier that introduces a name (9.2.9.4),
11. class-specifier (11.1),
12. enum-specifier or enumerator-definition (9.7.1),
13. exception-declaration (14.1), or
14. implicit declaration of an injected-class-name (11.1).

[Note 3: The interpretation of a for-range-declaration produces one or more of the above (8.6.5). —end note]

An entity E is denoted by the name (if any) that is introduced by a declaration of E or by a typedef-name introduced by a declaration specifying E.

A variable is introduced by the declaration of a reference other than a non-static data member or of an object. The variable’s name, if any, denotes the reference or object.

A local entity is a variable with automatic storage duration (6.7.5.4), a structured binding (9.6) whose corresponding variable is such an entity, or the *this object (7.5.2).

Some names denote types or templates. In general, whenever a name is encountered it is necessary to determine whether that name denotes one of these entities before continuing to parse the program that contains it. The process that determines this is called name lookup (6.5).

Two names are the same if

1. they are identifiers composed of the same character sequence, or
2. they are operator-function-ids formed with the same operator, or
3. they are conversion-function-ids formed with equivalent (13.7.7.2) types, or
4. they are literal-operator-ids (12.6) formed with the same literal suffix identifier.
A name used in more than one translation unit can potentially refer to the same entity in these translation units depending on the linkage (6.6) of the name specified in each translation unit.

6.2 Declarations and definitions

A declaration (Clause 9) may (re)introduce one or more names and/or entities into a translation unit. If so, the declaration specifies the interpretation and semantic properties of these names. A declaration of an entity or _typedef-name_ X is a redeclaration of X if another declaration of X is reachable from it (10.7). A declaration may also have effects including:

1. A static assertion (9.1),
2. Controlling template instantiation (13.9.3),
3. Guiding template argument deduction for constructors (13.7.2.3),
4. Use of attributes (9.12), and
5. Nothing (in the case of an _empty-declaration_).

Each entity declared by a declaration is also _defined_ by that declaration unless:

1. It declares a function without specifying the function’s body (9.5),
2. It contains the `extern` specifier (9.2.2) or a _linkage-specification_ (9.11) and neither an _initializer_ nor a _function-body_,
3. It declares a non-inline static data member in a class definition (11.4, 11.4.9),
4. It declares a static data member outside a class definition and the variable was defined within the class with the `constexpr` specifier (this usage is deprecated; see D.7),
5. It is an _elaborated-type-specifier_ (11.3),
6. It is an _opaque-enum-declaration_ (9.7.1),
7. It is a _template-parameter_ (13.2),
8. It is a _parameter-declaration_ (9.3.4.6) in a function declarator that is not the _declarator_ of a _function-definition_,
9. It is a _typedef_ declaration (9.2.4),
10. It is an _alias-declaration_ (9.2.4),
11. It is a _using-declaration_ (9.9),
12. It is a _deduction-guide_ (13.7.2.3),
13. It is a _static_assert-declaration_ (9.1),
14. It is an _attribute-declaration_ (9.1),
15. It is an _empty-declaration_ (9.1),
16. It is a _using-directive_ (9.8.4),
17. It is a _using-enum-declaration_ (9.7.2),
18. It is a _template-declaration_ (13.1) whose _template-head_ is not followed by either a _concept-definition_ or a _declaration_ that defines a function, a class, a variable, or a static data member,
19. It is an explicit instantiation declaration (13.9.3), or
20. It is an explicit specialization (13.9.4) whose _declaration_ is not a definition.

A declaration is said to be a _definition_ of each entity that it defines.

_Eg.:_ All but one of the following are definitions:

```c
int a; // defines a
extern const int c = 1; // defines c
int f(int x) { return x+a; } // defines f and defines x
struct S { int a; int b; }; // defines S, S::a, and S::b
struct X { // defines X
    int x; // defines non-static data member x
}
```
static int y;  // declares static data member y
X(): x(0) {}  // defines a constructor of X
;
int X::y = 1;  // defines X::y
enum { up, down };  // defines up and down
namespace N { int d; }  // defines N and N::d
namespace N1 = N;  // defines N1
X anX;  // defines anX

whereas these are just declarations:

extern int a;  // declares a
extern const int c;  // declares c
int f(int);  // declares f
struct S;  // declares S
typedef int Int;  // declares Int
extern X anotherX;  // declares anotherX
using N::d;  // declares d

—end example

[Note 1: In some circumstances, C++ implementations implicitly define the default constructor (11.4.5.2), copy constructor, move constructor (11.4.5.3), copy assignment operator, move assignment operator (11.4.6), or destructor (11.4.7) member functions. —end note]

[Example 2: Given
#include <string>

struct C {
  std::string s;  // std::string is the standard library class (21.3)
};

int main() {
  C a;
  C b = a;
  b = a;
}

the implementation will implicitly define functions to make the definition of C equivalent to

struct C {
  std::string s;
  C() : s() {}  // defines C()
  C(const C& x) : s(x.s) {}  // defines C(const C& x)
  C(C&& x) : s(static_cast<std::string&&>(x.s)) {}  // defines C(C&& x)
    // : s(std::move(x.s)) {}  // defines C(C&& x)
  C& operator=(const C& x) { s = x.s; return *this; }
  C& operator=(C&& x) { s = static_cast<std::string&&>(x.s); return *this; }
    // { s = std::move(x.s); return *this; }
  ~C() {}  // defines ~C()
};

—end example]

[Note 2: A class name can also be implicitly declared by an elaborated-type-specifier (9.2.9.4). —end note]

In the definition of an object, the type of that object shall not be an incomplete type (6.8), an abstract class type (11.7.4), or a (possibly multi-dimensional) array thereof.

6.3 One-definition rule [basic.def.odr]

1 No translation unit shall contain more than one definition of any variable, function, class type, enumeration type, template, default argument for a parameter (for a function in a given scope), or default template argument.

2 An expression or conversion is potentially evaluated unless it is an unevaluated operand (7.2), a subexpression thereof, or a conversion in an initialization or conversion sequence in such a context. The set of potential results of an expression E is defined as follows:

(2.1) — If E is an id-expression (7.5.4), the set contains only E.
If $E$ is a subscripting operation (7.6.1.2) with an array operand, the set contains the potential results of that operand.

If $E$ is a class member access expression (7.6.1.5) of the form $E_1 . \text{template}_{\text{opt}} E_2$ naming a non-static data member, the set contains the potential results of $E_1$.

If $E$ is a class member access expression naming a static data member, the set contains the id-expression designating the data member.

If $E$ is a pointer-to-member expression (7.6.4) of the form $E_1 .* E_2$, the set contains the potential results of $E_1$.

If $E$ has the form ($E_1$), the set contains the potential results of $E_1$.

If $E$ is a glvalue conditional expression (7.6.16), the set is the union of the sets of potential results of the second and third operands.

If $E$ is a comma expression (7.6.20), the set contains the potential results of the right operand.

Otherwise, the set is empty.

[Note 1: This set is a (possibly-empty) set of id-expressions, each of which is either $E$ or a subexpression of $E$.]

Example 1: In the following example, the set of potential results of the initializer of $n$ contains the first $S::x$ subexpression, but not the second $S::x$ subexpression.

```cpp
struct S { static const int x = 0; }
const int &f(const int &r);

int n = b ? (1, S::x) // $S::x$ is not odr-used here
        : f(S::x); // $S::x$ is odr-used here, so a definition is required
```

[End example]

[End note]

A function is named by an expression or conversion as follows:

A function is named by an expression or conversion if it is the selected member of an overload set (6.5, 12.2, 12.3) in an overload resolution performed as part of forming that expression or conversion, unless it is a pure virtual function and either the expression is not an id-expression naming the function with an explicitly qualified name or the expression forms a pointer to member (7.6.2.2).

[Note 2: This covers taking the address of functions (7.3.4, 7.6.2.2), calls to named functions (7.6.1.3), operator overloading (Clause 12), user-defined conversions (11.4.8.3), allocation functions for new-expressions (7.6.2.8), as well as non-default initialization (9.4). A constructor selected to copy or move an object of class type is considered to be named by an expression or conversion even if the call is actually elided by the implementation (11.9.6).]

A deallocation function for a class is named by a new-expression if it is the single matching deallocation function for the allocation function selected by overload resolution, as specified in 7.6.2.8.

A deallocation function for a class is named by a delete-expression if it is the selected usual deallocation function as specified in 7.6.2.9 and 11.11.

A variable is named by an expression if the expression is an id-expression that denotes it. A variable $x$ whose name appears as a potentially-evaluated expression $E$ is odr-used by $E$ unless

- $x$ is a reference that is usable in constant expressions (7.7), or
- $x$ is a variable of non-reference type that is usable in constant expressions and has no mutable subobjects, and $E$ is an element of the set of potential results of an expression of non-volatile-qualified non-class type to which the lvalue-to-rvalue conversion (7.3.2) is applied, or
- $x$ is a variable of non-reference type, and $E$ is an element of the set of potential results of a discarded-value expression (7.2) to which the lvalue-to-rvalue conversion is not applied.

A structured binding is odr-used if it appears as a potentially-evaluated expression.

*this is odr-used if this appears as a potentially-evaluated expression (including as the result of the implicit transformation in the body of a non-static member function (11.4.3)).

A virtual member function is odr-used if it is not pure. A function is odr-used if it is named by a potentially-evaluated expression or conversion. A non-placement allocation or deallocation function for a class is odr-used by the definition of a constructor of that class. A non-placement deallocation function for a class is odr-used...
by the definition of the destructor of that class, or by being selected by the lookup at the point of definition of a virtual destructor (11.4.7).\(^\text{20}\)

8 An assignment operator function in a class is odr-used by an implicitly-defined copy-assignment or move-assignment function for another class as specified in 11.4.6. A constructor for a class is odr-used as specified in 9.4. A destructor for a class is odr-used if it is potentially invoked (11.4.7).

9 A local entity (6.1) is odr-usable in a scope (6.4.1) if:

\[(9.1)\]
- either the local entity is not \*this, or an enclosing class or non-lambda function parameter scope exists and, if the innermost such scope is a function parameter scope, it corresponds to a non-static member function, and

\[(9.2)\]
- for each intervening scope (6.4.1) between the point at which the entity is introduced and the scope (where \*this is considered to be introduced within the innermost enclosing class or non-lambda function definition scope), either:
  \[(9.2.1)\]
  - the intervening scope is a block scope, or
  \[(9.2.2)\]
  - the intervening scope is the function parameter scope of a lambda-expression that has a simple-capture naming the entity or has a capture-default, and the block scope of the lambda-expression is also an intervening scope.

If a local entity is odr-used in a scope in which it is not odr-usable, the program is ill-formed.

[Example 2:]
```cpp
void f(int n) {
 [] { n = 1; };  // error: n is not odr-usable due to intervening lambda-expression
 struct A {
 void f() { n = 2; }  // error: n is not odr-usable due to intervening function definition scope
 };
 void g(int = n);
 [=](int k = n) {};  // error: n is not odr-usable due to intervening function parameter scope
 // outside the block scope of the lambda-expression
 [&] { [n]{ return n; }; };  // OK
 }
```

—end example\]

10 Every program shall contain exactly one definition of every non-inline function or variable that is odr-used in that program outside of a discarded statement (8.5.2); no diagnostic required. The definition can appear explicitly in the program, it can be found in the standard or a user-defined library, or (when appropriate) it is implicitly defined (see 11.4.5.2, 11.4.5.3, 11.4.7, and 11.4.6).

[Example 3:]
```cpp
auto f() {
 struct A {}
 return A();
}
dcltype(f()) g();
auto x = g();
```

A program containing this translation unit is ill-formed because g is odr-used but not defined, and cannot be defined in any other translation unit because the local class A cannot be named outside this translation unit. —end example\]

11 A definition domain is a private-module-fragment or the portion of a translation unit excluding its private-module-fragment (if any). A definition of an inline function or variable shall be reachable from the end of every definition domain in which it is odr-used outside of a discarded statement.

12 A definition of a class shall be reachable in every context in which the class is used in a way that requires the class type to be complete.

[Example 4: The following complete translation unit is well-formed, even though it never defines X:]
```cpp
struct X;
struct X* x1;  // declare X as a struct type
X* x2;  // use X in pointer formation
```

\(\text{20}\) An implementation is not required to call allocation and deallocation functions from constructors or destructors; however, this is a permissible implementation technique.
Note 3: The rules for declarations and expressions describe in which contexts complete class types are required. A class type \( T \) must be complete if:

1. An object of type \( T \) is defined (6.2), or
2. A non-static class data member of type \( T \) is declared (11.4), or
3. \( T \) is used as the allocated type or array element type in a new-expression (7.6.2.8), or
4. An lvalue-to-rvalue conversion is applied to an object of type \( T \) (7.3.2), or
5. An expression is converted (either implicitly or explicitly) to type \( T \) (7.3, 7.6.1.4, 7.6.1.7, 7.6.1.9, 7.6.3), or
6. An expression that is not a null pointer constant, and has type other than \( cv\ void^{*} \), is converted to the type pointer to \( T \) or reference to \( T \) using a standard conversion (7.3), a dynamic_cast (7.6.1.7) or a static_cast (7.6.1.9), or
7. A class member access operator is applied to an expression of type \( T \) (7.6.1.5), or
8. The typeid operator (7.6.1.8) or the sizeof operator (7.6.2.5) is applied to an operand of type \( T \), or
9. A function with a return type or argument type of type \( T \) is defined (6.2) or called (7.6.1.3), or
10. A class with a base class of type \( T \) is defined (11.7), or
11. An lvalue of type \( T \) is assigned to (7.6.19), or
12. The type \( T \) is the subject of an alignof expression (7.6.2.6), or
13. An exception-declaration has type \( T \), reference to \( T \), or pointer to \( T \) (14.4).

There can be more than one definition of a

1. Class type (Clause 11),
2. Enumeration type (9.7.1),
3. Inline function or variable (9.2.8),
4. Templated entity (13.1),
5. Default argument for a parameter (for a function in a given scope) (9.3.4.7), or
6. Default template argument (13.2)

in a program provided that each definition appears in a different translation unit and the definitions satisfy the following requirements. Given such an entity \( D \) defined in more than one translation unit, for all definitions of \( D \), or, if \( D \) is an unnamed enumeration, for all definitions of \( D \) that are reachable at any given program point, the following requirements shall be satisfied.

1. Each such definition shall not be attached to a named module (10.1).
2. Each such definition shall consist of the same sequence of tokens, where the definition of a closure type is considered to consist of the sequence of tokens of the corresponding lambda-expression.
3. In each such definition, corresponding names, looked up according to 6.5, shall refer to the same entity, after overload resolution (12.2) and after matching of partial template specialization (13.10.4), except that a name can refer to
   1. A non-volatile const object with internal or no linkage if the object
      1. Has the same literal type in all definitions of \( D \),
      2. Is initialized with a constant expression (7.7),
      3. Is not odr-used in any definition of \( D \), and
      4. Has the same value in all definitions of \( D \),
   or
   2. A reference with internal or no linkage initialized with a constant expression such that the reference refers to the same entity in all definitions of \( D \).
3. In each such definition, except within the default arguments and default template arguments of \( D \), corresponding lambda-expressions shall have the same closure type (see below).
4. In each such definition, corresponding entities shall have the same language linkage.
— In each such definition, the overloaded operators referred to, the implicit calls to conversion functions, constructors, operator new functions and operator delete functions, shall refer to the same function.

— In each such definition, a default argument used by an (implicit or explicit) function call or a default template argument used by an (implicit or explicit) template-id or simple-template-id is treated as if its token sequence were present in the definition of \( D \); that is, the default argument or default template argument is subject to the requirements described in this paragraph (recursively).

— If \( D \) is a class with an implicitly-declared constructor (11.4.5.2, 11.4.5.3), it is as if the constructor was implicitly defined in every translation unit where it is odr-used, and the implicit definition in every translation unit shall call the same constructor for a subobject of \( D \).

[Example 5:

// translation unit 1:
structure X {
    X(int, int);
    X(int, int, int);
};
X::X(int, int = 0) {
}
structure D {
    X x = 0;
};
D d1; //X(int, int) called by D()

// translation unit 2:
structure X {
    X(int, int);
    X(int, int, int);
};
X::X(int, int = 0, int = 0) {
}
structure D {
    X x = 0;
};
D d2; //X(int, int, int) called by D();
//D()’s implicit definition violates the ODR
— end example]

If \( D \) is a class with a defaulted three-way comparison operator function (11.10.3), it is as if the operator was implicitly defined in every translation unit where it is odr-used, and the implicit definition in every translation unit shall call the same comparison operators for each subobject of \( D \).

If \( D \) is a template and is defined in more than one translation unit, then the preceding requirements shall apply both to names from the template’s enclosing scope used in the template definition, and also to dependent names at the point of instantiation (13.8.3). These requirements also apply to corresponding entities defined within each definition of \( D \) (including the closure types of lambda-expressions, but excluding entities defined within default arguments or default template arguments of either \( D \) or an entity not defined within \( D \)). For each such entity and for \( D \) itself, the behavior is as if there is a single entity with a single definition, including in the application of these requirements to other entities.

[Note 4: The entity is still declared in multiple translation units, and 6.6 still applies to these declarations. In particular, lambda-expressions appearing in the type of \( D \) might result in different declarations having distinct types, and lambda-expressions appearing in a default argument of \( D \) might still denote different types in different translation units. — end note]

If these definitions do not satisfy these requirements, then the program is ill-formed; a diagnostic is required only if the entity is attached to a named module and a prior definition is reachable at the point where a later definition occurs.

[Example 6:

inline void f(bool cond, void (*p)()) {
    if (cond) f(false, []());
}
inline void g(bool cond, void (*p) = []()) {
    if (cond) g(false);
}
struct X {
    void h(bool cond, void (*p)() = []{}) {
        if (cond) h(false);
    }
};

If the definition of f appears in multiple translation units, the behavior of the program is as if there is only one definition of f. If the definition of g appears in multiple translation units, the program is ill-formed (no diagnostic required) because each such definition uses a default argument that refers to a distinct lambda-expression closure type. The definition of X can appear in multiple translation units of a valid program; the lambda-expressions defined within the default argument of X::h within the definition of X denote the same closure type in each translation unit. — end example

17 If, at any point in the program, there is more than one reachable unnamed enumeration definition in the same scope that have the same first enumerator name and do not have typedefd names for linkage purposes (9.7.1), those unnamed enumeration types shall be the same; no diagnostic required.

6.4 Scope

6.4.1 General

The declarations in a program appear in a number of scopes that are in general discontiguous. The global scope contains the entire program; every other scope S is introduced by a declaration, parameter-declaration-clause, statement, or handler (as described in the following subclauses of 6.4) appearing in another scope which thereby contains S. An enclosing scope at a program point is any scope that contains it; the smallest such scope is said to be the immediate scope at that point. A scope intervenes between a program point P and a scope S (that does not contain P) if it is or contains S but does not contain P.

2 Unless otherwise specified:

(2.1) The smallest scope that contains a scope S is the parent scope of S.
(2.2) No two declarations (re)introduce the same entity.
(2.3) A declaration inhabits the immediate scope at its locus (6.4.2).
(2.4) A declaration’s target scope is the scope it inhabits.
(2.5) Any names (re)introduced by a declaration are bound to it in its target scope.

An entity belongs to a scope S if S is the target scope of a declaration of the entity.

[Note 1: Special cases include that:

(2.6) Template parameter scopes are parents only to other template parameter scopes (6.4.8).
(2.7) Corresponding declarations with appropriate linkage declare the same entity (6.6).
(2.8) The declaration in a template-declaration inhabits the same scope as the template-declaration.
(2.9) Friend declarations and declarations of qualified names and template specializations do not bind names (9.3.4); those with qualified names target a specified scope, and other friend declarations and certain elaborated-type-specifiers (9.2.9.4) target a larger enclosing scope.
(2.10) Block-scope extern declarations target a larger enclosing scope but bind a name in their immediate scope.
(2.11) The names of unscoped enumerators are bound in the two innermost enclosing scopes (9.7.1).
(2.12) A class’s name is also bound in its own scope (11.1).
(2.13) The names of the members of an anonymous union are bound in the union’s parent scope (11.5.2).

—end note]

3 Two declarations correspond if they (re)introduce the same name, both declare constructors, or both declare destructors, unless

(3.1) either is a using-declarator, or
(3.2) one declares a type (not a typedef-name) and the other declares a variable, non-static data member other than of an anonymous union (11.5.2), enumerator, function, or function template, or
(3.3) each declares a function or function template, except when

§ 6.4.1
both declare functions with the same parameter-type-list, equivalent (13.7.7.2) trailing requires-clauses (if any, except as specified in 13.7.5), and, if both are non-static members, the same cv-qualifiers (if any) and ref-qualifier (if both have one), or

both declare function templates with equivalent parameter-type-lists, return types (if any), template-heads, and trailing requires-clauses (if any), and, if both are non-static members, the same cv-qualifiers (if any) and ref-qualifier (if both have one).

Note 2: Declarations can correspond even if neither binds a name.

Example 1:
```cpp
struct A {
    friend void f(); // #1
};
struct B {
    friend void f() {} // corresponds to, and defines, #1
};
```
—end example

Example 2:
```cpp
typedef int Int;
enum E : int { a };
void f(int); // #1
void f(Int) {} // defines #1
void f(E) {} // OK: another overload

struct X {
    static void f();
    void f() const; // error: redeclaration
    void g();
    void g() const; // OK
    void g() &; // error: redeclaration
};
```
—end example

Two declarations potentially conflict if they correspond and cause their shared name to denote different entities (6.6). The program is ill-formed if, in any scope, a name is bound to two declarations that potentially conflict and one precedes the other (6.5).

Note 3: Overload resolution can consider potentially conflicting declarations found in multiple scopes (e.g. via using-directives or for operator functions), in which case it is often ambiguous. —end note

Example 3:
```cpp
void f() {
    int x,y;
    void x(); // error: different entity for x
    int y;    // error: redefinition
}
enum { f }; // error: different entity for ::f
namespace A {}
namespace B = A;
namespace B = A; // OK: no effect
namespace B = B; // OK: no effect
namespace A = B; // OK: no effect
namespace B {} // error: different entity for B
```
—end example

A declaration is nominable in a class, class template, or namespace E at a point P if it precedes P, it does not inhabit a block scope, and its target scope is the scope associated with E or, if E is a namespace, any element of the inline namespace set of E (9.8.2).

Example 4:

21) An implicit object parameter (12.2.2) is not part of the parameter-type-list.
namespace A {
    void f() {void g();}
    inline namespace B {
        struct S {
            friend void h();
            static int i;
        };
    }
}

At the end of this example, the declarations of \( f, B, S, \) and \( h \) are nominable in \( A \), but those of \( g \) and \( i \) are not. —end example

When instantiating a templated entity (13.1), any scope \( S \) introduced by any part of the template definition is considered to be introduced by the instantiated entity and to contain the instantiations of any declarations that inhabit \( S \).

### 6.4.2 Point of declaration

The locus of a declaration (6.1) that is a declarator is immediately after the complete declarator (9.3).

[Example 1:

```c
unsigned char x = 12;
{ unsigned char x = x; }  
```

Here, the initialization of the second \( x \) has undefined behavior, because the initializer accesses the second \( x \) outside its lifetime (6.7.3). —end example]

[Note 1: A name from an outer scope remains visible up to the locus of the declaration that hides it.]

[Example 2:

```c
const int i = 2;
{ int i[i]; }  
```

declares a block-scope array of two integers. —end example]

—end note]

The locus of a class-specifier is immediately after the identifier or simple-template-id (if any) in its class-head (11.1). The locus of an enum-specifier or opaque-enum-declaration is immediately after the identifier (if any) in it (9.7.1). The locus of an alias-declaration is immediately after it.

The locus of a using-declarator that does not name a constructor is immediately after the using-declarator (9.9).

The locus of an enumerator-definition is immediately after it.

[Example 3:

```c
const int x = 12;
{ enum { x = x }; }  
```

Here, the enumerator \( x \) is initialized with the value of the constant \( x \), namely 12. —end example]

[Note 2: After the declaration of a class member, the member name can be found in the scope of its class even if the class is an incomplete class.]

[Example 4:

```c
struct X {
    enum E { z = 16 };
    int b[X::z];  // OK
};  
```

—end example]

—end note]

The locus of an elaborated-type-specifier that is a declaration (9.2.9.4) is immediately after it.

The locus of an injected-class-name declaration (11.1) is immediately following the opening brace of the class definition.

The locus of the implicit declaration of a function-local predefined variable (9.5.1) is immediately before the function-body of its function’s definition.
The locus of the declaration of a structured binding (9.6) is immediately after the identifier-list of the structured binding declaration.

The locus of a for-range-declaration of a range-based for statement (8.6.5) is immediately after the for-range-initializer.

The locus of a template-parameter is immediately after it.

Example 5:

```c
typedef unsigned char T;
template<class T = T // lookup finds the typedef name of unsigned char
, T // lookup finds the template parameter
N = 0> struct A { }

—end example
```

The locus of a concept-definition is immediately after its concept-name (13.7.9).

Note 3: The constraint-expression cannot use the concept-name. — end note

The locus of a namespace-definition with an identifier is immediately after the identifier.

Note 4: An identifier is invented for an unnamed-namespace-definition (9.8.2.2). — end note

Note 5: Friend declarations can introduce functions or classes that belong to the nearest enclosing namespace or block scope, but they do not bind names anywhere (11.8.4). Function declarations at block scope and variable declarations with the extern specifier at block scope declare entities that belong to the nearest enclosing namespace, but they do not bind names in it. — end note

Note 6: For point of instantiation of a template, see 13.8.4.1. — end note

6.4.3 Block scope [basic.scope.block]

Each

1. selection or iteration statement (8.5, 8.6),
2. substatement of such a statement,
3. handler (14.1), or
4. compound statement (8.4) that is not the compound-statement of a handler introduces a block scope that includes that statement or handler.

Note 1: A substatement that is also a block has only one scope. — end note

A variable that belongs to a block scope is a block variable.

Example 1:

```c
int i = 42;
int a[10];

for (int i = 0; i < 10; i++)
a[i] = i;

int j = i;  // j = 42

—end example
```

2. If a declaration whose target scope is the block scope $S$ of a

1. compound-statement of a lambda-expression, function-body, or function-try-block,
2. substatement of a selection or iteration statement, or
3. handler of a function-try-block

potentially conflicts with a declaration whose target scope is the parent scope of $S$, the program is ill-formed.

Example 2:

```c
if (int x = f()) {
    int x;  // error: redeclaration of x
}
```

§ 6.4.3
else {
    int x;    // error: redeclaration of x
}

—end example]

6.4.4 Function parameter scope 

A parameter-declaration-clause P introduces a function parameter scope that includes P.
[Note 1: A function parameter cannot be used for its value within the parameter-declaration-clause (9.3.4.7). — end note]

(1.1) — If P is associated with a declarator and is preceded by a (possibly-parenthesized) noptr-declarator of the form declarator-id attribute-specifier-seqopt, its scope extends to the end of the nearest enclosing init-declarator, member-declarator, declarator of a parameter-declaration or a nodeclspec-function-declaration, or function-definition, but does not include the locus of the associated declarator.

[Note 2: In this case, P declares the parameters of a function (or a function or template parameter declared with function type). A member function’s parameter scope is nested within its class’s scope. — end note]

(1.2) — If P is associated with a lambda-declarator, its scope extends to the end of the compound-statement in the lambda-expression.

(1.3) — If P is associated with a requirement-parameter-list, its scope extends to the end of the requirement-body of the requires-expression.

(1.4) — If P is associated with a deduction-guide, its scope extends to the end of the deduction-guide.

6.4.5 Namespace scope 

Any namespace-definition for a namespace N introduces a namespace scope that includes the namespace-body for every namespace-definition for N. For each non-friend redeclaration or specialization whose target scope is or is contained by the scope, the portion after the declarator-id, class-head-name, or enum-head-name is also included in the scope. The global scope is the namespace scope of the global namespace (9.8).

[Example 1:
    namespace Q {
        namespace V { void f(); }
        void V::f() { // in the scope of V
            void h();  // declares Q::V::h
        }
    }

    —end example]

6.4.6 Class scope 

Any declaration of a class or class template C introduces a class scope that includes the member-specification of the class-specifier for C (if any). For each non-friend redeclaration or specialization whose target scope is or is contained by the scope, the portion after the declarator-id, class-head-name, or enum-head-name is also included in the scope.

[Note 1: Lookup from a program point before the class-specifier of a class will find no bindings in the class scope.

[Example 1:
    template<class D>
    struct B {
        D::type x;    // #1
    };

    struct A { using type = int; };
    struct C : A, B<C> {};  // error at #1: C::type not found

    —end example]

    —end note]

6.4.7 Enumeration scope 

Any declaration of an enumeration E introduces an enumeration scope that includes the enumerator-list of the enum-specifier for E (if any).
6.4.8 Template parameter scope [basic.scope.temp]

1 Each template template-parameter introduces a template parameter scope that includes the template-head of the template-parameter.

2 Each template-declaration D introduces a template parameter scope that extends from the beginning of its template-parameter-list to the end of the template-declaration. Any declaration outside the template-parameter-list that would inhabit that scope instead inhabits the same scope as D. The parent scope of any scope S that is not a template parameter scope is the smallest scope that contains S and is not a template parameter scope.

[Note 1: Therefore, only template parameters belong to a template parameter scope, and only template parameter scopes have a template parameter scope as a parent scope. — end note]

6.5 Name lookup [basic.lookup]

6.5.1 General [basic.lookup.general]

1 The name lookup rules apply uniformly to all names (including typedef-names (9.2.4), namespace-names (9.8), and class-names (11.3)) wherever the grammar allows such names in the context discussed by a particular rule. Name lookup associates the use of a name with a set of declarations (6.2) of that name. Unless otherwise specified, the program is ill-formed if no declarations are found. If the declarations found by name lookup all denote functions or function templates, the declarations are said to form an overload set. Otherwise, if the declarations found by name lookup do not all denote the same entity, they are ambiguous and the program is ill-formed. Overload resolution (12.2, 12.3) takes place after name lookup has succeeded. The access rules (11.8) are considered only once name lookup and function overload resolution (if applicable) have succeeded. Only after name lookup, function overload resolution (if applicable) and access checking have succeeded are the semantic properties introduced by the declarations used in further processing.

2 A program point P is said to follow any declaration in the same translation unit whose locus (6.4.2) is before P.

[Note 1: The declaration might appear in a scope that does not contain P. — end note]

A declaration X precedes a program point P in a translation unit L if P follows X, X inhabits a class scope and is reachable from P, or else X appears in a translation unit D and

(2.1) — P follows a module-import-declaration or module-declaration that imports D (directly or indirectly), and

(2.2) — X appears after the module-declaration in D (if any) and before the private-module-fragment in D (if any), and

(2.3) — either X is exported or else D and L are part of the same module and X does not inhabit a namespace with internal linkage or declare a name with internal linkage.

[Note 2: Names declared by a using-declaration have no linkage. — end note]

[Note 3: A module-import-declaration imports both the named translation unit(s) and any modules named by exported module-import-declarations within them, recursively.]

[Example 1:

Translation unit #1:
   export module Q;
   export int sq(int i) { return i*i; }

Translation unit #2:
   export module R;
   export import Q;

Translation unit #3:
   import R;
   int main() { return sq(9); } // OK: sq from module Q

— end example]

— end note]

3 A single search in a scope S for a name N from a program point P finds all declarations that precede P to which any name that is the same as N (6.1) is bound in S. If any such declaration is a using-declarator whose terminal name (7.5.4.2) is not dependent (13.8.3.2), it is replaced by the declarations named by the using-declarator (9.9).
In certain contexts, only certain kinds of declarations are included. After any such restriction, any declarations of classes or enumerations are discarded if any other declarations are found.

[Note 4: A type (but not a typedef-name or template) is therefore hidden by any other entity in its scope. — end note]

However, if a lookup is type-only, only declarations of types and templates whose specializations are types are considered; furthermore, if declarations of a typedef-name and of the type to which it refers are found, the declaration of the typedef-name is discarded instead of the type declaration.

### 6.5.2 Member name lookup

A search in a scope $X$ for a name $N$ from a program point $P$ is a single search in $X$ for $N$ from $P$ unless $X$ is the scope of a class or class template $T$, in which case the following steps define the result of the search.

[Note 1: The result differs only if $N$ is a conversion-function-id or if the single search would find nothing. — end note]

The lookup set for $N$ in $C$, called $S(N, C)$, consists of two component sets: the declaration set, a set of members named $N$; and the subobject set, a set of subobjects where declarations of these members were found (possibly via using-declarations). In the declaration set, type declarations (including injected-class-names) are replaced by the types they designate. $S(N, C)$ is calculated as follows:

1. The declaration set is the result of a single search in the scope of $C$ for $N$ from immediately after the class-specifier of $C$ if $P$ is in a complete-class context of $C$ or from $P$ otherwise. If the resulting declaration set is not empty, the subobject set contains $C$ itself, and calculation is complete.

2. Otherwise (i.e., $C$ does not contain a declaration of $N$ or the resulting declaration set is empty), $S(N, C)$ is initially empty. Calculate the lookup set for $N$ in each direct non-dependent (13.8.3.2) base class subobject $B_i$, and merge each such lookup set $S(N, B_i)$ in turn into $S(N, C)$.

[Note 2: If $T$ is incomplete, only base classes whose base-specifier appears before $P$ are considered. If $T$ is an instantiated class, its base classes are not dependent. — end note]

3. The following steps define the result of merging lookup set $S(N, B_i)$ into the intermediate $S(N, C)$:

   - If each of the subobject members of $S(N, B_i)$ is a base class subobject of at least one of the subobject members of $S(N, C)$, or if $S(N, B_i)$ is empty, $S(N, C)$ is unchanged and the merge is complete. Conversely, if each of the subobject members of $S(N, C)$ is a base class subobject of at least one of the subobject members of $S(N, B_i)$, or if $S(N, C)$ is empty, the new $S(N, C)$ is a copy of $S(N, B_i)$.

   - Otherwise, if the declaration sets of $S(N, B_i)$ and $S(N, C)$ differ, the merge is ambiguous: the new $S(N, C)$ is a lookup set with an invalid declaration set and the union of the subobject sets. In subsequent merges, an invalid declaration set is considered different from any other.

   - Otherwise, the new $S(N, C)$ is a lookup set with the shared set of declarations and the union of the subobject sets.

4. The result of the search is the declaration set of $S(N, T)$. If it is an invalid set, the program is ill-formed. If it differs from the result of a search in $T$ for $N$ from immediately after the class-specifier of $T$, the program is ill-formed, no diagnostic required.

**Example 1:**

```c
struct A { int x; };       // S(x,A) = { { A::x }, { A } }
struct B { float x; };    // S(x,B) = { { B::x }, { B } }
struct C: public A, public B { };   // S(x,C) = { invalid, { A in C, B in C } }
struct D: public virtual C { };    // S(x,D) = S(x,C)
struct E: public virtual C { char x; }; // S(x,E) = { { E::x }, { E } }
struct F: public D, public E { };    // S(x,F) = S(x,E)
int main() {
    F f;
    f.x = 0;               // OK, lookup finds E::x
}
```

$S(x,F)$ is unambiguous because the $A$ and $B$ base class subobjects of $D$ are also base class subobjects of $E$, so $S(x,D)$ is discarded in the first merge step. — end example

5. If $N$ is a non-dependent conversion-function-id, conversion function templates that are members of $T$ are considered. For each such template $F$, the lookup set $S(t, T)$ is constructed, considering a function template declaration to have the name $t$ only if it corresponds to a declaration of $F$ (6.4.1). The members of the declaration set of each such lookup set, which shall not be an invalid set, are included in the result.

[Note 3: Overload resolution will discard those that cannot convert to the type specified by $N$ (13.10.4). — end note]
8 [Note 4: A static member, a nested type or an enumerator defined in a base class T can unambiguously be found even if an object has more than one base class subobject of type T. Two base class subobjects share the non-static member subobjects of their common virtual base classes. — end note]

[Example 2:

```c
struct V {
    int v;
};
struct A {
    int a;
    static int s;
    enum { e };
};
struct B : A, virtual V { };
struct C : A, virtual V { };
struct D : B, C { };

void f(D* pd) {
    pd->v++;    // OK: only one v (virtual)
    pd->s++;    // OK: only one s (static)
    int i = pd->e;    // OK: only one e (enumerator)
    pd->a++;    // error: ambiguous: two a in D
}
@end example]

9 [Note 5: When virtual base classes are used, a hidden declaration can be reached along a path through the subobject lattice that does not pass through the hiding declaration. This is not an ambiguity. The identical use with non-virtual base classes is an ambiguity; in that case there is no unique instance of the name that hides all the others. — end note]

[Example 3:

```c
struct V { int f(); int x; };
struct W { int g(); int y; };
struct B : virtual V, W {
    int f(); int x;
    int g(); int y;
};
struct C : virtual V, W { };
struct D : B, C { void glorp(); };

```

As illustrated in Figure 1, the names declared in V and the left-hand instance of W are hidden by those in B, but the names declared in the right-hand instance of W are not hidden at all.

```c
void D::glorp() {
    x++;    // OK: B::x hides V::x
    f();    // OK: B::f() hides V::f()
    y++;    // error: B::y and C’s W::y
    g();    // error: B::g() and C’s W::g()
}
@end example]

figure 1: Name lookup  [fig:class.lookup]
An explicit or implicit conversion from a pointer to or an expression designating an object of a derived class to a pointer or reference to one of its base classes shall unambiguously refer to a unique object representing the base class.

[Example 4:

```c
struct V { }
struct A { }
struct B : A, virtual V { }
struct C : A, virtual V { }
struct D : B, C { }

void g() {
    D d;
    B* pb = &d;
    A* pa = &d;      // error: ambiguous: C's A or B's A?
    V* pv = &d;      // OK: only one V subobject
}
```

—end example]

[Note 6: Even if the result of name lookup is unambiguous, use of a name found in multiple subobjects might still be ambiguous (7.3.13, 7.6.1.5, 11.8.3). —end note]

[Example 5:

```c
struct B1 {
    void f();
    static void f(int);
    int i;
};
struct B2 {
    void f(double);
};
struct I1: B1 { }
struct I2: B1 { }
struct D: I1, I2, B2 {
    using B1::f;
    using B2::f;
    void g() {
        f();        // Ambiguous conversion of this
        f(0);      // Unambiguous (static)
        f(0.0);    // Unambiguous (only one B2)
        int B1::* mpB1 = &D::i;    // Unambiguous
        int D::* mpD = &D::i;      // Ambiguous conversion
    }
}
```

—end example]

6.5.3 Unqualified name lookup [basic.lookup.unqual]

1 A using-directive is active in a scope S at a program point P if it precedes P and inhabits either S or the scope of a namespace nominated by a using-directive that is active in S at P.

[Note 1: A using-directive is exported if and only if it appears in a header unit. —end note]

2 An unqualified search in a scope S from a program point P includes the results of searches from

(2.1) — S, and

(2.2) — for any scope U that contains P and is or is contained by S, each namespace contained by S that is nominated by a using-directive that is active in U at P.

If no declarations are found, the results of the unqualified search are the results of an unqualified search in the parent scope of S, if any, from P.

[Note 2: When a class scope is searched, the scopes of its base classes are also searched (6.5.2). If it inherits from a single base, it is as if the scope of the base immediately contains the scope of the derived class. Template parameter scopes that are associated with one scope in the chain of parents are also considered (13.8.2). —end note]
Unqualified name lookup from a program point performs an unqualified search in its immediate scope.

An unqualified name is a name that does not follow a nested-name-specifier or the . or -> in a class member access expression (7.6.1.5), possibly after a template keyword or -. Unless otherwise specified, such a name undergoes unqualified name lookup from the point where it appears.

An unqualified name that is a component name (7.5.4.2) of a type-specifier or ptr-operator of a conversion-type-id is looked up in the same fashion as the conversion-function-id in which it appears. If that lookup finds nothing, it undergoes unqualified name lookup; in each case, only names that denote types or templates whose specializations are types are considered.

In a friend declaration declarator whose declarator-id is a qualified-id whose lookup context (6.5.5) is a class or namespace S, lookup for an unqualified name that appears after the declarator-id performs a search in the scope associated with S. If that lookup finds nothing, it undergoes unqualified name lookup.

Example 1:
```c
using I = int;
using D = double;
namespace A {
    inline namespace N {using C = char; }
    using F = float;
    void f(I);
    void f(D);
    void f(C);
    void f(F);
}
struct X0 {using F = float; }
struct W {
    using D = void;
    struct X : X0 {
        void g(I);
        void g(::D);
        void g(F);
    };
};
namespace B {
    typedef short I, F;
    class Y {
        friend void A::f(I); // error: no void A::f(short)
        friend void A::f(D); // OK
        friend void A::f(C); // error: A::N::C not found
        friend void A::f(F); // OK
        friend void W::X::g(I); // error: no void W::X::g(short)
        friend void W::X::g(D); // OK
        friend void W::X::g(F); // OK
    };
}
```

6.5.4 Argument-dependent name lookup

When the postfix-expression in a function call (7.6.1.3) is an unqualified-id, and unqualified lookup (6.5.3) for the name in the unqualified-id does not find any

(1.1) — declaration of a class member, or
(1.2) — function declaration inhabiting a block scope, or
(1.3) — declaration not of a function or function template

then lookup for the name also includes the result of argument-dependent lookup in a set of associated namespaces that depends on the types of the arguments (and for template template arguments, the namespace of the template argument), as specified below.

Example 1:
```c
namespace N {
    struct S { }
}
```
```cpp
void f(S);
}

void g() {
    N::S s;
    f(s);        // OK: calls N::f
    (f)(a);     // error: N::f not considered; parentheses prevent argument-dependent lookup
}
```

—end example

2 [Note 1: For purposes of determining (during parsing) whether an expression is a postfix-expression for a function call, the usual name lookup rules apply. In some cases a name followed by < is treated as a template-name even though name lookup did not find a template-name (see 13.3). For example,
```cpp
int h;
void g();
namespace N {
    struct A {
        template <class T> int f(T);
        template <class T> int g(T);
        template <class T> int h(T);
    }

    int x = f<N::A>(N::A());    // OK: lookup of f finds nothing, f treated as template name
    int y = g<N::A>(N::A());    // OK: lookup of g finds a function, g treated as template name
    int z = h<N::A>(N::A());    // error: h< does not begin a template-id
```
The rules have no effect on the syntactic interpretation of an expression. For example,
```cpp
typedef int f;
namespace N {
    struct A {
        friend void f(A &);
        operator int();
        void g(A a) {
            int i = f(a);       // f is the typedef, not the friend function: equivalent to int(a)
        }
    }
};
```
Because the expression is not a function call, argument-dependent name lookup does not apply and the friend function f is not found. —end note]

3 For each argument type T in the function call, there is a set of zero or more associated entities to be considered. The set of entities is determined entirely by the types of the function arguments (and any template template arguments). Typedef names and using-declarations used to specify the types do not contribute to this set. The set of entities is determined in the following way:

(3.1) — If T is a fundamental type, its associated set of entities is empty.

(3.2) — If T is a class type (including unions), its associated entities are: the class itself; the class of which it is a member, if any; and its direct and indirect base classes. Furthermore, if T is a class template specialization, its associated entities also include: the entities associated with the types of the template arguments provided for template type parameters; the templates used as template template arguments; and the classes of which any member templates used as template template arguments are members. [Note 2: Non-type template arguments do not contribute to the set of associated entities. — end note]

(3.3) — If T is an enumeration type, its associated entities are T and, if it is a class member, the member’s class.

(3.4) — If T is a pointer to U or an array of U, its associated entities are those associated with U.

(3.5) — If T is a function type, its associated entities are those associated with the function parameter types and those associated with the return type.

(3.6) — If T is a pointer to a member function of a class X, its associated entities are those associated with the function parameter types and return type, together with those associated with X.

(3.7) — If T is a pointer to a data member of class X, its associated entities are those associated with the member type together with those associated with X.

§ 6.5.4
In addition, if the argument is an overload set or the address of such a set, its associated entities are the union of those associated with each of the members of the set, i.e., the entities associated with its parameter types and return type. Additionally, if the aforementioned overload set is named with a template-id, its associated entities also include its template template-arguments and those associated with its type template-arguments.

The associated namespaces for a call are the innermost enclosing non-inline namespaces for its associated entities as well as every element of the inline namespace set (9.8.2) of those namespaces. Argument-dependent lookup finds all declarations of functions and function templates that

1. are found by a search of any associated namespace, or
2. are declared as a friend (11.8.4) of any class with a reachable definition in the set of associated entities, or
3. are exported, are attached to a named module M (10.2), do not appear in the translation unit containing the point of the lookup, and have the same innermost enclosing non-inline namespace scope as a declaration of an associated entity attached to M (6.6).

If the lookup is for a dependent name (13.8.3, 13.8.4.2), the above lookup is also performed from each point in the instantiation context (10.6) of the lookup, additionally ignoring any declaration that appears in another translation unit, is attached to the global module, and is either discarded (10.4) or has internal linkage.

---

Example 2:

Translation unit #1:
```plaintext
export module M;
namespace R {
    export struct X {};
    export void f(X);
}
namespace S {
    export void f(R::X, R::X);
}
```

Translation unit #2:
```plaintext
export module N;
import M;
export R::X make();
namespace R {
    static int g(X);
}
export template<typename T, typename U> void apply(T t, U u) {
    f(t, u);
    g(t);
}
```

Translation unit #3:
```plaintext
module Q;
import N;
namespace S {
    struct Z { template<typename T> operator T(); }
}
void test() {
    auto x = make(); // OK, decltype(x) is R::X in module M
    R::f(x); // error: R and R::f are not visible here
    f(x); // OK, calls R::f from interface of M
    f(x, S::Z()); // error: S::f in module M not considered
    // even though S is an associated namespace
    apply(x, S::Z()); // error: S::f is visible in instantiation context, but
    // R::g has internal linkage and cannot be used outside TU #2
}
```

---

Example 3:

```plaintext
namespace NS {
    class T {
    }
}
```
void f(T);
void g(T, int);
}
NS::T parm;
void g(NS::T, float);
int main() {
    f(parm); // OK: calls NS::f
    extern void g(NS::T, float);
    g(parm, 1); // OK: calls g(NS::T, float)
}
—end example

6.5.5 Qualified name lookup

6.5.5.1 General

Lookup of an identifier followed by a :: scope resolution operator considers only namespaces, types, and templates whose specializations are types. If a name, template-id, or decltype-specifier is followed by a ::, it shall designate a namespace, class, enumeration, or dependent type, and the :: is never interpreted as a complete nested-name-specifier.

[Example 1:

```cpp
class A {
public:
    static int n;
};
int main() {
    int A;
    A::n = 42; // OK
    A b; // error: A does not name a type
}
template<int> struct B : A {};
namespace N {
    template<int> void B();
in f() {
    return B<0>::n; // error: N::B<0> is not a type
}
}
—end example]

A member-qualified name is the (unique) component name (7.5.4.2), if any, of

(2.1) — an unqualified-id or
(2.2) — a nested-name-specifier of the form type-name :: or namespace-name ::
in the id-expression of a class member access expression (7.6.1.5). A qualified name is

(2.3) — a member-qualified name or
(2.4) — the terminal name of
(2.4.1) — a qualified-id,
(2.4.2) — a using-declarator,
(2.4.3) — a typename-specifier,
(2.4.4) — a qualified-namespace-specifier, or
(2.4.5) — a nested-name-specifier, elaborated-type-specifier, or class-or-decltype that has a nested-name-specifier (7.5.4.3).

The lookup context of a member-qualified name is the type of its associated object expression (considered dependent if the object expression is type-dependent). The lookup context of any other qualified name is the type, template, or namespace nominated by the preceding nested-name-specifier.

[Note 1: When parsing a class member access, the name following the -> or . is a qualified name even though it is not yet known of which kind. — end note]

[Example 2: In

§ 6.5.5.1 48
Qualified name lookup in a class, namespace, or enumeration performs a search of the scope associated with it (6.5.2) except as specified below. Unless otherwise specified, a qualified name undergoes qualified name lookup in its lookup context from the point where it appears unless the lookup context either is dependent and is not the current instantiation (13.8.3.2) or is not a class or class template. If nothing is found by qualified lookup for a member-qualified name that is the terminal name (7.5.4.2) of a nested-name-specifier and is not dependent, it undergoes unqualified lookup.

Example 3:

```
int f();
struct A {
  int B, C;
  template<int> using D = void;
  using T = void;
  void f();
};
using B = A;
template<int> using C = A;
template<int> using D = A;
template<int> using X = A;
template<class T>
void g(T *p) {
  // as instantiated for g<A>:
  p->X<0>::f();  // error: A::X not found in ((p->X) < 0) > ::f()
  p->template X<0>::f();  // OK: ::X found in definition context
  p->B::f();  // OK: non-type A::B ignored
  p->template C<0>::f();  // error: A::C is not a template
  p->template D<0>::f();  // error: A::D<0> is not a class type
  p->T::f();  // error: A::T is not a class type
}
template void g(A*);
```

If a qualified name Q follows a ~:

1. If Q is a member-qualified name, it undergoes unqualified lookup as well as qualified lookup.
2. Otherwise, its nested-name-specifier N shall nominate a type. If N has another nested-name-specifier S, Q is looked up as if its lookup context were that nominated by S.
3. Otherwise, if the terminal name of N is a member-qualified name M, Q is looked up as if ~Q appeared in place of M (as above).
4. Otherwise, Q undergoes unqualified lookup.
5. Each lookup for Q considers only types (if Q is not followed by a <) and templates whose specializations are types. If it finds nothing or is ambiguous, it is discarded.
6. The type-name that is or contains Q shall refer to its (original) lookup context (ignoring cv-qualification) under the interpretation established by at least one (successful) lookup performed.

Example 4:

```
struct C {
  typedef int I;
};
typedef int I1, I2;
extern int* p;
extern int* q;
void f() {
  p->C::I::~I();  // I is looked up in the scope of C
  q->I1::~I2();  // I2 is found by unqualified lookup
}
```
struct A {
    ~A();
};
typedef A AB;
int main() {
    AB* p;
    p->AB::~AB();  // explicitly calls the destructor for A
}
— end example]

6.5.5.2 Class members [class.qual]
1 In a lookup for a qualified name \( N \) whose lookup context is a class \( C \) in which function names are not ignored,\(^{22}\)

(1.1) — if the search finds the injected-class-name of \( C \) (11.1), or

(1.2) — if \( N \) is dependent and is the terminal name of a using-declarator (9.9) that names a constructor, \( N \) is instead considered to name the constructor of class \( C \). Such a constructor name shall be used only in the declarator-id of a (friend) declaration of a constructor or in a using-declaration.

[Example 1:

struct A { A(); };
struct B: public A { B(); };

A::A() { }
B::B() { }

B::A ba; // object of type A
A::A a;  // error: A::A is not a type name
struct A::A a2; // object of type A
— end example]

6.5.5.3 Namespace members [namespace.qual]
1 Qualified name lookup in a namespace \( N \) additionally searches every element of the inline namespace set of \( N \) (9.8.2). If nothing is found, the results of the lookup are the results of qualified name lookup in each namespace nominated by a using-directive that precedes the point of the lookup and inhabits \( N \) or an element of \( N \)'s inline namespace set.

[Note 1: If a using-directive refers to a namespace that has already been considered, it does not affect the result.
— end note]

[Example 1:

int x;
namespace Y {
    void f(float);
    void h(int);
}

namespace Z {
    void h(double);
}

namespace A {
    using namespace Y;
    void f(int);
    void g(int);
    int i;
}

\(^{22}\) Lookups in which function names are ignored include names appearing in a nested-name-specifier, an elaborated-type-specifier, or a base-specifier.
namespace B {
    using namespace Z;
    void f(char);
    int i;
}

namespace AB {
    using namespace A;
    using namespace B;
    void g();
}

void h()
{
    AB::g();  // g is declared directly in AB, therefore S is {AB::g()} and AB::g() is chosen
    AB::f(1);  // f is not declared directly in AB so the rules are applied recursively to A and B;
                // namespace Y is not searched and Y::f(float) is not considered;
                // S is {A::f(int),B::f(char)} and overload resolution chooses A::f(int)
    AB::f('c');  // as above but resolution chooses B::f(char)
    AB::x++;  // x is not declared directly in AB, and is not declared in A or B, so the rules
                // are applied recursively to A and B.
                // S is {} so the use is ambiguous and the program is ill-formed
    AB::i++;  // i is not declared directly in AB so the rules are applied recursively to A and B,
                // S is {A::i,B::i} so the use is ambiguous and the program is ill-formed
    AB::h(16.8);  // h is not declared directly in AB and not declared directly in A or B so the rules
                // are applied recursively to A and B.
                // S is {Y::h(int),Z::h(double)} and
                // overload resolution chooses Z::h(double)
}

—end example

2 [Note 2: The same declaration found more than once is not an ambiguity (because it is still a unique declaration).]

Example 2:
namespace A {
    int a;
}

namespace B {
    using namespace A;
}

namespace C {
    using namespace A;
}

namespace BC {
    using namespace B;
    using namespace C;
}

void f()
{
    BC::a++;  // OK: S is {A::a,A::a}
}

namespace D {
    using A::a;
}

§ 6.5.5.3
namespace BD {
    using namespace B;
    using namespace D;
}

void g()
{
    BD::a++; // OK: S is {A::a, A::a}
}

— end example

— end note

3 [Example 3: Because each referenced namespace is searched at most once, the following is well-defined:

namespace B {
    int b;
}

namespace A {
    using namespace B;
    int a;
}

namespace B {
    using namespace A;
}

void f()
{
    A::a++; // OK: a declared directly in A, S is {A::a}
    B::a++; // OK: both A and B searched (once), S is {A::a}
    A::b++; // OK: both A and B searched (once), S is {B::b}
    B::b++; // OK: b declared directly in B, S is {B::b}
}

— end example

— end note

4 [Note 3: Class and enumeration declarations are not discarded because of other declarations found in other searches. — end note]

[Example 4:]

namespace A {
    struct x { };
    int x;
    int y;
}

namespace B {
    struct y { };
}

namespace C {
    using namespace A;
    using namespace B;
    int i = C::x; // OK, A::x (of type int)
    int j = C::y; // ambiguous, A::y or B::y
}

— end example

6.5.6 Elaborated type specifiers [basic.lookup.elab]

1 If the class-key or enum keyword in an elaborated-type-specifier is followed by an identifier that is not followed by ::, lookup for the identifier is type-only (6.5.1).

[Note 1: In general, the recognition of an elaborated-type-specifier depends on the following tokens. If the identifier is followed by ::, see 6.5.5. — end note]
If the terminal name of the elaborated-type-specifier is a qualified name, lookup for it is type-only. If the name lookup does not find a previously declared type-name, the elaborated-type-specifier is ill-formed.

[Example 1:]

```c
struct Node {
    struct Node* Next; // OK: Refers to injected-class-name Node
    struct Data* Data; // OK: Declares type Data at global scope and member Data
};

struct Data {
    struct Node* Node; // OK: Refers to Node at global scope
    friend struct ::Glob; // error: Glob is not declared, cannot introduce a qualified type (9.2.9.4)
    friend struct Glob; // OK: Refers to (as yet) undeclared Glob at global scope.
    /* ... */
};

struct Base {
    struct Data; // OK: Declares nested Data
    struct Data* thatData; // OK: Refers to ::Data
    struct Base::Data* thisData; // OK: Refers to nested Data
    friend class ::Data; // OK: global Data is a friend
    friend class Data; // OK: nested Data is a friend
    struct Data { /* ... */ }; // Defines nested Data
};

struct Data; // OK: Redeclares Data at global scope
struct ::Data; // error: cannot introduce a qualified type (9.2.9.4)
struct Base::Data; // error: cannot introduce a qualified type (9.2.9.4)
struct Base::Datum; // error: Datum undefined
struct Base::Data* pBase; // OK: refers to nested Data
```

— end example]

### 6.5.7 Using-directives and namespace aliases

In a using-directive or namespace-alias-definition, during the lookup for a namespace-name or for a name in a nested-name-specifier only namespace names are considered.

#### 6.6 Program and linkage

A program consists of one or more translation units (5.1) linked together. A translation unit consists of a sequence of declarations.

```plaintext
translation-unit:
   declaration-seq_opt
global-module-fragment_opt module-declaration declaration-seq_opt private-module-fragment_opt
```

A name is said to have *linkage* when it can denote the same object, reference, function, type, template, namespace or value as a name introduced by a declaration in another scope:

- When a name has external linkage, the entity it denotes can be referred to by names from scopes of other translation units or from other scopes of the same translation unit. (2.1)
- When a name has module linkage, the entity it denotes can be referred to by names from other scopes of the same module unit (10.1) or from scopes of other module units of that same module. (2.2)
- When a name has internal linkage, the entity it denotes can be referred to by names from other scopes in the same translation unit. (2.3)
- When a name has no linkage, the entity it denotes cannot be referred to by names from other scopes. (2.4)

The name of an entity that belongs to a namespace scope (6.4.5) has internal linkage if it is the name of:

- a variable, variable template, function, or function template that is explicitly declared static; or
- a non-template variable of non-volatile const-qualified type, unless
  - it is explicitly declared extern, or
  - it is inline or exported, or
  - it was previously declared and the prior declaration did not have internal linkage; or
(3.3) — a data member of an anonymous union.

[Note 1: An instantiated variable template that has const-qualified type can have external or module linkage, even if not declared extern. — end note]

4 An unnamed namespace or a namespace declared directly or indirectly within an unnamed namespace has internal linkage. All other namespaces have external linkage. The name of an entity that belongs to a namespace scope that has not been given internal linkage above and that is the name of

(4.1) — a variable; or

(4.2) — a function; or

(4.3) — a named class (11.1), or an unnamed class defined in a typedef declaration in which the class has the typedef name for linkage purposes (9.2.4); or

(4.4) — a named enumeration (9.7.1), or an unnamed enumeration defined in a typedef declaration in which the enumeration has the typedef name for linkage purposes (9.2.4); or

(4.5) — an unnamed enumeration that has an enumerator as a name for linkage purposes (9.7.1); or

(4.6) — a template

has its linkage determined as follows:

(4.7) — if the enclosing namespace has internal linkage, the name has internal linkage;

(4.8) — otherwise, if the declaration of the name is attached to a named module (10.1) and is not exported (10.2), the name has module linkage;

(4.9) — otherwise, the name has external linkage.

5 In addition, a member function, a static data member, a named class or enumeration that inhabits a class scope, or an unnamed class or enumeration defined in a typedef declaration that inhabits a class scope such that the class or enumeration has the typedef name for linkage purposes (9.2.4), has the same linkage, if any, as the name of the class of which it is a member.

6 [Example 1:

```c
static void f();
extern "C" void h();
static int i = 0;  // #1
void q() {  
    extern void f(); // internal linkage
    extern void g(); // :g, external linkage
    extern void h(); // C language linkage
    int i;  // #2: i has no linkage
    {  
        extern void f(); // internal linkage
        extern int i;  // #3: internal linkage
    }
}
```]

Even though the declaration at line #2 hides the declaration at line #1, the declaration at line #3 still redeclares #1 and receives internal linkage. — end example]

7 Names not covered by these rules have no linkage. Moreover, except as noted, a name declared at block scope (6.4.3) has no linkage.

8 Two declarations of entities declare the same entity if, considering declarations of unnamed types to introduce their names for linkage purposes, if any (9.2.4, 9.7.1), they correspond (6.4.1), have the same target scope that is not a function or template parameter scope, and either

(8.1) — they appear in the same translation unit, or

(8.2) — they both declare names with module linkage and are attached to the same module, or

(8.3) — they both declare names with external linkage.

[Note 2: There are other circumstances in which declarations declare the same entity (9.11, 13.6, 13.7.6). — end note]

9 If a declaration $H$ that declares a name with internal linkage precedes a declaration $D$ in another translation unit $U$ and would declare the same entity as $D$ if it appeared in $U$, the program is ill-formed.

[Note 3: Such an $H$ can appear only in a header unit. — end note]
If two declarations of an entity are attached to different modules, the program is ill-formed; no diagnostic is required if neither is reachable from the other.

[Example 2:

"decls.h":
```c
int f(); // #1, attached to the global module
int g(); // #2, attached to the global module
```

Module interface of \( M \):
```c
module;
#include "decls.h"
export module M;
export using ::f; // OK: does not declare an entity, exports #1
int g(); // error: matches #2, but attached to \( M \)
export int h(); // #3
export int k(); // #4
```

Other translation unit:
```c
import M;
static int h(); // error: matches #3
int k(); // error: matches #4
```

— end example]

As a consequence of these rules, all declarations of an entity are attached to the same module; the entity is said to be attached to that module.

For any two declarations of an entity \( E \):

(13.1) — If one declares \( E \) to be a variable or function, the other shall declare \( E \) as one of the same type.

(13.2) — If one declares \( E \) to be an enumerator, the other shall do so.

(13.3) — If one declares \( E \) to be a namespace, the other shall do so.

(13.4) — If one declares \( E \) to be a type, the other shall declare \( E \) to be a type of the same kind (9.2.9.4).

(13.5) — If one declares \( E \) to be a class template, the other shall do so with the same kind and an equivalent template-head (13.7.7.2).

[Note 4: The declarations can supply different default template arguments. — end note]

(13.6) — If one declares \( E \) to be a function template or a (partial specialization of a) variable template, the other shall declare \( E \) to be one with an equivalent template-head and type.

(13.7) — If one declares \( E \) to be an alias template, the other shall declare \( E \) to be one with an equivalent template-head and defining-type-id.

(13.8) — If one declares \( E \) to be a concept, the other shall do so.

Types are compared after all adjustments of types (during which typedefs (9.2.4) are replaced by their definitions); declarations for an array object can specify array types that differ by the presence or absence of a major array bound (9.3.4.5). No diagnostic is required if neither declaration is reachable from the other.

[Example 3:

```c
int f(int x, int x); // error: different entities for x
void g(); // #1
void g(int); // OK: different entity from #1
int g(); // error: same entity as #1 with different type
void h(); // #2
namespace h {} // error: same entity as #2, but not a function
```

— end example]

[Note 5: Linkage to non-C++ declarations can be achieved using a linkage-specification (9.11). — end note]

A declaration \( D \) names an entity \( E \) if

(13.1) — \( D \) contains a lambda-expression whose closure type is \( E \),

(13.2) — \( E \) is not a function or function template and \( D \) contains an id-expression, type-specifier, nested-name-specifier, template-name, or concept-name denoting \( E \), or
A declaration is an exposure if it either names a TU-local entity (defined below), ignoring

- the function-body for a non-inline function or function template (but not the deduced return type for a (possibly instantiated) definition of a function with a declared return type that uses a placeholder type (9.2.9.6)),
- the initializer for a variable or variable template (but not the variable’s type),
- friend declarations in a class definition, and
- any reference to a non-volatile const object or reference with internal or no linkage initialized with a constant expression that is not an odr-use (6.3),

or defines a constexpr variable initialized to a TU-local value (defined below).

An entity is TU-local if it is

- a type, function, variable, or template that
  - has a name with internal linkage, or
  - does not have a name with linkage and is declared, or introduced by a lambda-expression, within the definition of a TU-local entity,
- a type with no name that is defined outside a class-specifier, function body, or initializer or is introduced by a defining-type-specifier that is used to declare only TU-local entities,
- a specialization of a TU-local template,
- a specialization of a template with any TU-local template argument, or
- a specialization of a template whose (possibly instantiated) declaration is an exposure.

A value or object is TU-local if either

- it is, or is a pointer to, a TU-local function or the object associated with a TU-local variable, or
- it is an object of class or array type and any of its subobjects or any of the objects or functions to which its non-static data members of reference type refer is TU-local and is usable in constant expressions.

If a (possibly instantiated) declaration of, or a deduction guide for, a non-TU-local entity in a module interface unit (outside the private-module-fragment, if any) or module partition (10.1) is an exposure, the program is ill-formed. Such a declaration in any other context is deprecated (D.8).

If a declaration that appears in one translation unit names a TU-local entity declared in another translation unit that is not a header unit, the program is ill-formed. A declaration instantiated for a template specialization (13.9) appears at the point of instantiation of the specialization (13.8.4.1).

Example 4:

Translation unit #1:
```c
export module A;
static void f() {} // error: is an exposure of f
inline void it() { f(); } // error: is an exposure of f
static inline void its() { f(); } // OK
template<int> void g() { its(); } // OK
template void g<0>();

decaytype(f) *fp; // error: f (though not its type) is TU-local
auto &fr = f; // OK
constexpr auto &fr2 = fr; // error: is an exposure of f
constexpr static auto fp2 = fr; // OK
```
struct S { void (&ref)(); } s{f};  // OK, value is TU-local
constexpr extern struct W { S &s; } wrap{s};  // OK, value is not TU-local

static auto x = []{f();};  // OK
auto x2 = x;  // error: the closure type is TU-local
int y = ([]{f();}(),0);  // error: the closure type is not TU-local
int y2 = (x,0);  // OK

namespace N {
  struct A {};
  void adl(A);
  static void adl(int);
}
void adl(double);

inline void h(auto x) { adl(x); }  // OK, but a specialization might be an exposure

Translation unit #2:
module A;
void other() {
  g<0>();  // OK, specialization is explicitly instantiated
  g<1>();  // error: instantiation uses TU-local its
  h<N::A>();  // error: overload set contains TU-local N::adl(int)
  h<0>();  // OK, calls adl(double)
  adl<N::A>();  // OK; N::adl(int) not found, calls N::adl(N::A)
  fr();  // OK, calls f
  constexpr auto ptr = fr;  // error: fr is not usable in constant expressions here
}

—end example]
contains four separate memory locations: The member a and bit-fields d and e.ee are each separate memory locations, and can be modified concurrently without interfering with each other. The bit-fields b and c together constitute the fourth memory location. The bit-fields b and c cannot be concurrently modified, but b and a, for example, can be.

--- end example

6.7.2 Object model

The constructs in a C++ program create, destroy, refer to, access, and manipulate objects. An object is created by a definition (6.2), by a new-expression (7.6.2.8), by an operation that implicitly creates objects (see below), when implicitly changing the active member of a union (11.5), or when a temporary object is created (7.3.5, 6.7.7). An object occupies a region of storage in its period of construction (11.9.5), throughout its lifetime (6.7.3), and in its period of destruction (11.9.5).

[Note 1: A function is not an object, regardless of whether or not it occupies storage in the way that objects do. —end note]

The properties of an object are determined when the object is created. An object can have a name (6.1). An object has a storage duration (6.7.5) which influences its lifetime (6.7.3). An object has a type (6.8). Some objects are polymorphic (11.7.3); the implementation generates information associated with each such object that makes it possible to determine that object’s type during program execution. For other objects, the interpretation of the values found therein is determined by the type of the expressions (7.6) used to access them.

Objects can contain other objects, called subobjects. A subobject can be a member subobject (11.4), a base class subobject (11.7), or an array element. An object that is not a subobject of any other object is called a complete object. If an object is created in storage associated with a member subobject or array element e (which may or may not be within its lifetime), the created object is a subobject of e’s containing object if:

1. the lifetime of e’s containing object has begun and not ended, and
2. the storage for the new object exactly overlays the storage location associated with e, and
3. the new object is of the same type as e (ignoring cv-qualification).

If a complete object is created (7.6.2.8) in storage associated with another object e of type “array of N unsigned char” or of type “array of N std::byte” (17.2.1), that array provides storage for the created object if:

1. the lifetime of e has begun and not ended, and
2. the storage for the new object fits entirely within e, and
3. there is no array object that satisfies these constraints nested within e.

[Note 2: If that portion of the array previously provided storage for another object, the lifetime of that object ends because its storage was reused (6.7.3). —end note]

[Example 1:]

```cpp
template<
    typename ...T>
struct AlignedUnion {
    alignas(T...) unsigned char data[max(sizeof(T)...)];
};

int f() {
    AlignedUnion<int, char> au;
    int *p = new (au.data) int; // OK, au.data provides storage
    char *c = new (au.data) char(); // OK, ends lifetime of *p
    char *d = new (au.data + 1) char();
    return c + d; // OK
}
```

```cpp
struct A { unsigned char a[32]; };
struct B { unsigned char b[16]; };
A a;
```
An object \( a \) is nested within another object \( b \) if:

1. \( a \) is a subobject of \( b \), or
2. \( b \) provides storage for \( a \), or
3. there exists an object \( c \) where \( a \) is nested within \( c \), and \( c \) is nested within \( b \).

For every object \( x \), there is some object called the complete object of \( x \), determined as follows:

1. If \( x \) is a complete object, then the complete object of \( x \) is itself.
2. Otherwise, the complete object of \( x \) is the complete object of the (unique) object that contains \( x \).

If a complete object, a member subobject, or an array element is of class type, its type is considered the most derived class, to distinguish it from the class type of any base class subobject; an object of a most derived class type or of a non-class type is called a most derived object.

A potentially-overlapping subobject is either:

1. a base class subobject, or
2. a non-static data member declared with the no_unique_address attribute (9.12.10).

An object has nonzero size if it

1. is not a potentially-overlapping subobject, or
2. is not of class type, or
3. is of a class type with virtual member functions or virtual base classes, or
4. has subobjects of nonzero size or unnamed bit-fields of nonzero length.

Otherwise, if the object is a base class subobject of a standard-layout class type with no non-static data members, it has zero size. Otherwise, the circumstances under which the object has zero size are implementation-defined. Unless it is a bit-field (11.4.10), an object with nonzero size shall occupy one or more bytes of storage, including every byte that is occupied in full or in part by any of its subobjects. An object of trivially copyable or standard-layout type (6.8) shall occupy contiguous bytes of storage.

Unless an object is a bit-field or a subobject of zero size, the address of that object is the address of the first byte it occupies. Two objects with overlapping lifetimes that are not bit-fields may have the same address if one is nested within the other, or if at least one is a subobject of zero size and they are of different types; otherwise, they have distinct addresses and occupy disjoint bytes of storage.

Some operations are described as implicitly creating objects within a specified region of storage. For each operation that is specified as implicitly creating objects, that operation implicitly creates and starts the lifetime of zero or more objects of implicit-lifetime types (6.8) in its specified region of storage if doing so would result in the program having defined behavior. If no such set of objects would give the program defined behavior, the behavior of the program is undefined. If multiple such sets of objects would give the program defined behavior, it is unspecified which such set of objects is created.

Note 3: Such operations do not start the lifetimes of subobjects of such objects that are not themselves of implicit-lifetime types. — end note

25 Under the “as-if” rule an implementation is allowed to store two objects at the same machine address or not store an object at all if the program cannot observe the difference (6.9.1).
Further, after implicitly creating objects within a specified region of storage, some operations are described as producing a pointer to a suitable created object. These operations select one of the implicitly-created objects whose address is the address of the start of the region of storage, and produce a pointer value that points to that object, if that value would result in the program having defined behavior. If no such pointer value would give the program defined behavior, the behavior of the program is undefined. If multiple such pointer values would give the program defined behavior, it is unspecified which such pointer value is produced.

Example 3:

```c
#include <cstdlib>
struct X { int a, b; };
X *make_x() {
    // The call to std::malloc implicitly creates an object of type X
    // and its subobjects a and b, and returns a pointer to that X object
    // (or an object that is pointer-interconvertible (6.8.3) with it),
    // in order to give the subsequent class member access operations
    // defined behavior.
    X *p = (X*)std::malloc(sizeof(struct X));
    p->a = 1;
    p->b = 2;
    return p;
}
```

An operation that begins the lifetime of an array of char, unsigned char, or std::byte implicitly creates objects within the region of storage occupied by the array.

Note 4: The array object provides storage for these objects. — end note

Any implicit or explicit invocation of a function named operator new or operator new[] implicitly creates objects in the returned region of storage and returns a pointer to a suitable created object.

Note 5: Some functions in the C++ standard library implicitly create objects (20.10.9.3, 20.10.12, 21.5.3, 26.5.3). — end note

6.7.3 Lifetime

The lifetime of an object or reference is a runtime property of the object or reference. A variable is said to have vacuous initialization if it is default-initialized and, if it is of class type or a (possibly multi-dimensional) array thereof, that class type has a trivial default constructor. The lifetime of an object of type T begins when:

1. storage with the proper alignment and size for type T is obtained, and
2. its initialization (if any) is complete (including vacuous initialization) (9.4), except that if the object is a union member or subobject thereof, its lifetime only begins if that union member is the initialized member in the union (9.4.2, 11.9.3), or as described in 11.5 and 11.4.5.3, and except as described in 20.10.10.2. The lifetime of an object a of type T ends when:
   1. if T is a non-class type, the object is destroyed, or
   2. if T is a class type, the destructor call starts, or
   3. the storage which the object occupies is released, or is reused by an object that is not nested within a (6.7.2).

The lifetime of a reference begins when its initialization is complete. The lifetime of a reference ends as if it were a scalar object requiring storage.

Note 1: 11.9.3 describes the lifetime of base and member subobjects. — end note

The properties ascribed to objects and references throughout this document apply for a given object or reference only during its lifetime.

Note 2: In particular, before the lifetime of an object starts and after its lifetime ends there are significant restrictions on the use of the object, as described below, in 11.9.3 and in 11.9.5. Also, the behavior of an object under construction and destruction can differ from the behavior of an object whose lifetime has started and not ended. 11.9.3 and 11.9.5 describe the behavior of an object during its periods of construction and destruction. — end note

A program may end the lifetime of any object by reusing the storage which the object occupies or by explicitly calling a destructor or pseudo-destructor (7.5.4.4) for the object. For an object of a class type, the program
is not required to call the destructor explicitly before the storage which the object occupies is reused or released; however, if there is no explicit call to the destructor or if a delete-expression (7.6.2.9) is not used to release the storage, the destructor is not implicitly called and any program that depends on the side effects produced by the destructor has undefined behavior.

Before the lifetime of an object has started but after the storage which the object will occupy has been allocated or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any pointer that represents the address of the storage location where the object will be or was located may be used but only in limited ways. For an object under construction or destruction, see 11.9.5. Otherwise, such a pointer refers to allocated storage (6.7.5.5.2), and using the pointer as if the pointer were of type void* is well-defined. Indirection through such a pointer is permitted but the resulting value may only be used in limited ways, as described below. The program has undefined behavior if:

(6.1) — the object will be or was of a class type with a non-trivial destructor and the pointer is used as the operand of a delete-expression,

(6.2) — the pointer is used to access a non-static data member or call a non-static member function of the object, or

(6.3) — the pointer is implicitly converted (7.3.12) to a pointer to a virtual base class, or

(6.4) — the pointer is used as the operand of a static_cast (7.6.1.9), except when the conversion is to pointer to cv void, or to pointer to cv void and subsequently to pointer to cv char, cv unsigned char, or cv std::byte (17.2.1), or

(6.5) — the pointer is used as the operand of a dynamic_cast (7.6.1.7).

[Example 1:]

```cpp
#include <cstdlib>

struct B {
  virtual void f();
  void mutate();
  virtual ~B();
};

struct D1 : B { void f(); };
struct D2 : B { void f(); };

void B::mutate() {
  new (this) D2;  // reuses storage — ends the lifetime of *this
  f();            // undefined behavior
  ... = this;    // OK, this points to valid memory
}

void g() {
  void* p = std::malloc(sizeof(D1) + sizeof(D2));
  B* pb = new (p) D1;
  pb->mutate();
  *pb;            // OK: pb points to valid memory
  void* q = pb;  // OK: pb points to valid memory
  pb->f();       // undefined behavior: lifetime of *pb has ended
}

—end example]
```

Similarly, before the lifetime of an object has started but after the storage which the object will occupy has been allocated or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any glvalue that refers to the original object may be used but only in limited ways. For an object under construction or destruction, see 11.9.5. Otherwise, such a glvalue refers to allocated storage (6.7.5.5.2), and using the properties of the glvalue that do not depend on its value is well-defined. The program has undefined behavior if:

(7.1) — the glvalue is used to access the object, or

(7.2) — the glvalue is used to call a non-static member function of the object, or

26 For example, before the dynamic initialization of an object with static storage duration (6.9.3.3).
(7.3) — the glvalue is bound to a reference to a virtual base class (9.4.4), or

(7.4) — the glvalue is used as the operand of a `dynamic_cast` (7.6.1.7) or as the operand of `typeid`.

8 If, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, a new object is created at the storage location which the original object occupied, a pointer that pointed to the original object, a reference that referred to the original object, or the name of the original object will automatically refer to the new object and, once the lifetime of the new object has started, can be used to manipulate the new object, if the original object is transparently replaceable (see below) by the new object. An object $o_1$ is transparently replaceable by an object $o_2$ if:

(8.1) — the storage that $o_2$ occupies exactly overlays the storage that $o_1$ occupied, and

(8.2) — $o_1$ and $o_2$ are of the same type (ignoring the top-level cv-qualifiers), and

(8.3) — $o_1$ is not a complete const object, and

(8.4) — neither $o_1$ nor $o_2$ is a potentially-overlapping subobject (6.7.2), and

(8.5) — either $o_1$ and $o_2$ are both complete objects, or $o_1$ and $o_2$ are direct subobjects of objects $p_1$ and $p_2$, respectively, and $p_1$ is transparently replaceable by $p_2$.

[Example 2:

```cpp
struct C {
    int i;
    void f();
    const C& operator=( const C& );
};

const C& C::operator=( const C& other) {
    if ( this != &other ) {
        this->~C(); // lifetime of *this ends
        new (this) C(other); // new object of type C created
        f(); // well-defined
    }
    return *this;
}
```

```cpp
c C c1;
c C c2;
c1 = c2; // well-defined
cl.f(); // well-defined; c1 refers to a new object of type C
```

—end example]

[Note 3: If these conditions are not met, a pointer to the new object can be obtained from a pointer that represents the address of its storage by calling `std::launder` (17.6.5). — end note]

9 If a program ends the lifetime of an object of type $T$ with static (6.7.5.2), thread (6.7.5.3), or automatic (6.7.5.4) storage duration and if $T$ has a non-trivial destructor, and another object of the original type does not occupy that same storage location when the implicit destructor call takes place, the behavior of the program is undefined. This is true even if the block is exited with an exception.

[Example 3:

```cpp
class T { };  
struct B {  
    ~B();  
};

void h() {
    B b;
    new (&b) T;  // undefined behavior at block exit
}
```

—end example]
Creating a new object within the storage that a const complete object with static, thread, or automatic storage duration occupies, or within the storage that such a const object used to occupy before its lifetime ended, results in undefined behavior.

[Example 4:]

```
struct B {
    B();
    ~B();
};
const B b;

void h() {
    b.~B();
    new (const_cast<B*>(&b)) const B;  // undefined behavior
}
```

— end example]  

In this subclause, “before” and “after” refer to the “happens before” relation (6.9.2).

[Note 4: Therefore, undefined behavior results if an object that is being constructed in one thread is referenced from another thread without adequate synchronization. — end note]

### 6.7.4 Indeterminate values

When storage for an object with automatic or dynamic storage duration is obtained, the object has an indeterminate value, and if no initialization is performed for the object, that object retains an indeterminate value until that value is replaced (7.6.19).

[Note 1: Objects with static or thread storage duration are zero-initialized, see 6.9.3.2. — end note]

If an indeterminate value is produced by an evaluation, the behavior is undefined except in the following cases:

1. If an indeterminate value of unsigned ordinary character type (6.8.2) or `std::byte` type (17.2.1) is produced by the evaluation of:
   1.1 The second or third operand of a conditional expression (7.6.16),
   1.2 The right operand of a comma expression (7.6.20),
   1.3 The operand of a cast or conversion (7.3.9, 7.6.1.4, 7.6.1.9, 7.6.3) to an unsigned ordinary character type or `std::byte` type (17.2.1), or
   1.4 A discarded-value expression (7.2.3),

   then the result of the operation is an indeterminate value.

2. If an indeterminate value of unsigned ordinary character type or `std::byte` type is produced by the evaluation of the right operand of a simple assignment operator (7.6.19) whose first operand is an lvalue of unsigned ordinary character type or `std::byte` type, an indeterminate value replaces the value of the object referred to by the left operand.

3. If an indeterminate value of unsigned ordinary character type is produced by the evaluation of the initialization expression when initializing an object of unsigned ordinary character type, that object is initialized to an indeterminate value.

4. If an indeterminate value of unsigned ordinary character type or `std::byte` type is produced by the evaluation of the initialization expression when initializing an object of `std::byte` type, that object is initialized to an indeterminate value.

[Example 1:]

```
int f(bool b) {
    unsigned char c;
    unsigned char d = c;  // OK, d has an indeterminate value
    int e = d;            // undefined behavior
    return b ? d : 0;     // undefined behavior if b is true
}
```

— end example]  

§ 6.7.4 63
6.7.5 Storage duration

6.7.5.1 General

The storage duration is the property of an object that defines the minimum potential lifetime of the storage containing the object. The storage duration is determined by the construct used to create the object and is one of the following:

1. static storage duration
2. thread storage duration
3. automatic storage duration
4. dynamic storage duration

Static, thread, and automatic storage durations are associated with objects introduced by declarations (6.2) and implicitly created by the implementation (6.7.7). The dynamic storage duration is associated with objects created by a new-expression (7.6.2.8).

The storage duration categories apply to references as well.

When the end of the duration of a region of storage is reached, the values of all pointers representing the address of any part of that region of storage become invalid pointer values (6.8.3). Indirection through an invalid pointer value and passing an invalid pointer value to a deallocation function have undefined behavior. Any other use of an invalid pointer value has implementation-defined behavior.

6.7.5.2 Static storage duration

All variables which do not have dynamic storage duration, do not have thread storage duration, and are not local have static storage duration. The storage for these entities lasts for the duration of the program (6.9.3.2, 6.9.3.4).

If a variable with static storage duration has initialization or a destructor with side effects, it shall not be eliminated even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in 11.9.6.

The keyword static can be used to declare a block variable (6.4.3) with static storage duration.

Note 1: 8.8 and 6.9.3.4 describe the initialization and destruction of such variables. — end note

6.7.5.3 Thread storage duration

All variables declared with the thread_local keyword have thread storage duration. The storage for these entities lasts for the duration of the thread in which they are created. There is a distinct object or reference per thread, and use of the declared name refers to the entity associated with the current thread.

Note 1: A variable with thread storage duration is initialized as specified in 6.9.3.2, 6.9.3.3, and 8.8 and, if constructed, is destroyed on thread exit (6.9.3.4). — end note

6.7.5.4 Automatic storage duration

Variables that belong to a block or parameter scope and are not explicitly declared static, thread_local, or extern have automatic storage duration. The storage for these entities lasts until the block in which they are created exits.

Note 1: These variables are initialized and destroyed as described in 8.8. — end note

If a variable with automatic storage duration has initialization or a destructor with side effects, an implementation shall not destroy it before the end of its block nor eliminate it as an optimization, even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in 11.9.6.

6.7.5.5 Dynamic storage duration

6.7.5.5.1 General

Objects can be created dynamically during program execution (6.9.1), using new-expressions (7.6.2.8), and destroyed using delete-expressions (7.6.2.9). A C++ implementation provides access to, and management of, dynamic storage via the global allocation functions operator new and operator new[] and the global deallocation functions operator delete and operator delete[].

Some implementations might define that copying an invalid pointer value causes a system-generated runtime fault.
The library provides default definitions for the global allocation and deallocation functions. Some global allocation and deallocation functions are replaceable (17.6.3). A C++ program shall provide at most one definition of a replaceable allocation or deallocation function. Any such function definition replaces the default version provided in the library (16.4.5.6). The following allocation and deallocation functions (17.6) are implicitly declared in global scope in each translation unit of a program.

```cpp
[[nodiscard]] void* operator new(std::size_t);
[[nodiscard]] void* operator new(std::size_t, std::align_val_t);
void operator delete(void*) noexcept;
void operator delete(void*, std::size_t) noexcept;
void operator delete(void*, std::align_val_t) noexcept;
void operator delete(void*, std::size_t, std::align_val_t) noexcept;
[[nodiscard]] void* operator new[](std::size_t);
[[nodiscard]] void* operator new[](std::size_t, std::align_val_t);
void operator delete[](void*) noexcept;
void operator delete[](void*, std::size_t) noexcept;
void operator delete[](void*, std::align_val_t) noexcept;
void operator delete[](void*, std::size_t, std::align_val_t) noexcept;
```

These implicit declarations introduce only the function names `operator new`, `operator new[]`, `operator delete`, and `operator delete[]`.

Allocation and/or deallocation functions may also be declared and defined for any class (11.11).

If the behavior of an allocation or deallocation function does not satisfy the semantic constraints specified in 6.7.5.5.2 and 6.7.5.5.3, the behavior is undefined.

### 6.7.5.5.2 Allocation functions

An allocation function that is not a class member function shall belong to the global scope and not have a name with internal linkage. The return type shall be `void*`. The first parameter shall have type `std::size_t` (17.2). The first parameter shall not have an associated default argument (9.3.4.7). The value of the first parameter is interpreted as the requested size of the allocation. An allocation function can be a function template. Such a template shall declare its return type and first parameter as specified above (that is, template parameter types shall not be used in the return type and first parameter type). Allocation function templates shall have two or more parameters.

An allocation function attempts to allocate the requested amount of storage. If it is successful, it returns the address of storage that is aligned as follows:

- If the allocation function takes an argument of type `std::align_val_t`, the storage will have the alignment specified by the value of this argument.

The intent is to have `operator new()` implementable by calling `std::malloc()` or `std::calloc()`, so the rules are substantially the same. C++ differs from C in requiring a zero request to return a non-null pointer.
Otherwise, if the allocation function is named `operator new[]`, the storage is aligned for any object that does not have new-extended alignment (6.7.6) and is no larger than the requested size.

- Otherwise, the storage is aligned for any object that does not have new-extended alignment and is of the requested size.

An allocation function that fails to allocate storage can invoke the currently installed new-handler function (17.6.4.3), if any.

[Note 1: A program-supplied allocation function can obtain the address of the currently installed `new_handler` using the `std::get_new_handler` function (17.6.4.5). — end note]

An allocation function that has a non-throwing exception specification (14.5) indicates failure by returning a null pointer value. Any other allocation function never returns a null pointer value and indicates failure only by throwing an exception (14.2) of a type that would match a handler (14.4) of type `std::bad_alloc` (17.6.4.1).

5 A global allocation function is only called as the result of a new expression (7.6.2.8), or called directly using the function call syntax (7.6.1.3), or called indirectly to allocate storage for a coroutine state (9.5.4), or called indirectly through calls to the functions in the C++ standard library.

[Note 2: In particular, a global allocation function is not called to allocate storage for objects with static storage duration (6.7.5.2), for objects or references with thread storage duration (6.7.5.3), for objects of type `std::type_info` (7.6.1.8), or for an exception object (14.2). — end note]

6.7.5.5.3 Deallocation functions [basic.stc.dynamic.deallocation]

A deallocation function that is not a class member function shall belong to the global scope and not have a name with internal linkage.

2 A deallocation function is a `destroying operator delete` if it has at least two parameters and its second parameter is of type `std::destroying_delete_t`. A `destroying operator delete` shall be a class member function named `operator delete`.

[Note 1: Array deletion cannot use a `destroying operator delete`. — end note]

3 Each deallocation function shall return `void`. If the function is a destroying operator delete declared in class type `C`, the type of its first parameter shall be `C*`; otherwise, the type of its first parameter shall be `void*`. A deallocation function may have more than one parameter. A usual deallocation function is a deallocation function whose parameters after the first are

- optionally, a parameter of type `std::destroying_delete_t`, then
- optionally, a parameter of type `std::size_t`, then
- optionally, a parameter of type `std::align_val_t`.

A `destroying operator delete` shall be a usual deallocation function. A deallocation function may be an instance of a function template. Neither the first parameter nor the return type shall depend on a template parameter. A deallocation function template shall have two or more function parameters. A template instance is never a usual deallocation function, regardless of its signature.

4 If a deallocation function terminates by throwing an exception, the behavior is undefined. The value of the first argument supplied to a deallocation function may be a null pointer value; if so, and if the deallocation function is one supplied in the standard library, the call has no effect.

5 If the argument given to a deallocation function in the standard library is a pointer that is not the null pointer value (6.8.3), the deallocation function shall deallocate the storage referenced by the pointer, ending the duration of the region of storage.

6.7.5.5.4 Safely-derived pointers [basic.stc.dynamic.safety]

A `traceable pointer object` is

- an object of an object pointer type (6.8.3), or
- an object of an integral type that is at least as large as `std::intptr_t`, or
- a sequence of elements in an array of narrow character type (6.8.2), where the size and alignment of the sequence match those of some object pointer type.

30) The global `operator delete(void*, std::size_t)` precludes use of an allocation function `void operator new(std::size_t, std::size_t)` as a placement allocation function (C.3.3).

§ 6.7.5.4 66
A pointer value is a *safely-derived pointer* to an object with dynamic storage duration only if the pointer value has an object pointer type and is one of the following:

1. The value returned by a call to the C++ standard library implementation of `::operator new(std::size_t)` or `::operator new(std::size_t, std::align_val_t);`\(^{31}\)
2. The result of taking the address of an object (or one of its subobjects) designated by an lvalue resulting from indirection through a safely-derived pointer value;
3. The result of well-defined pointer arithmetic (7.6.6) using a safely-derived pointer value;
4. The result of a well-defined pointer conversion (7.3.12, 7.6.1.4, 7.6.1.9, 7.6.3) of a safely-derived pointer value;
5. The result of a `reinterpret_cast` of a safely-derived pointer value;
6. The result of a `reinterpret_cast` of an integer representation of a safely-derived pointer value;
7. The value of an object whose value was copied from a traceable pointer object, where at the time of the copy the source object contained a copy of a safely-derived pointer value.

An integer value is an *integer representation of a safely-derived pointer* only if its type is at least as large as `std::intptr_t` and it is one of the following:

1. The result of a `reinterpret_cast` of a safely-derived pointer value;
2. The result of a valid conversion of an integer representation of a safely-derived pointer value;
3. The value of an object whose value was copied from a traceable pointer object, where at the time of the copy the source object contained an integer representation of a safely-derived pointer value;
4. The result of an additive or bitwise operation, one of whose operands is an integer representation of a safely-derived pointer value \(P\), if that result converted by `reinterpret_cast<void*>` would compare equal to a safely-derived pointer computable from `reinterpret_cast<void*>(P)`.

An implementation may have *relaxed pointer safety*, in which case the validity of a pointer value does not depend on whether it is a safely-derived pointer value. Alternatively, an implementation may have *strict pointer safety*, in which case a pointer value referring to an object with dynamic storage duration that is not a safely-derived pointer value is an invalid pointer value unless the referenced complete object has previously been declared reachable (20.10.5).

[Note 1: The effect of using an invalid pointer value (including passing it to a deallocation function) is undefined, see 6.7.5. This is true even if the unsafely-derived pointer value would compare equal to some safely-derived pointer value. —end note]

It is implementation-defined whether an implementation has relaxed or strict pointer safety.

### 6.7.5.6 Duration of subobjects

The storage duration of subobjects and reference members is that of their complete object (6.7.2).

### 6.7.6 Alignment

Object types have *alignment requirements* (6.8.2, 6.8.3) which place restrictions on the addresses at which an object of that type may be allocated. An *alignment* is an implementation-defined integer value representing the number of bytes between successive addresses at which a given object can be allocated. An object type imposes an alignment requirement on every object of that type; stricter alignment can be requested using the alignment specifier (9.12.2).

A *fundamental alignment* is represented by an alignment less than or equal to the greatest alignment supported by the implementation in all contexts, which is equal to `alignof(std::max_align_t)` (17.2). The alignment required for a type may be different when it is used as the type of a complete object and when it is used as the type of a subobject.

[Example 1:]

```c
struct B { long double d; }
struct D : virtual B { char c; }
```

\(^{31}\) This subclause does not impose restrictions on indirection through pointers to memory not allocated by `::operator new`. This maintains the ability of many C++ implementations to use binary libraries and components written in other languages. In particular, this applies to C binaries, because indirection through pointers to memory allocated by `std::malloc` is not restricted.
When \( D \) is the type of a complete object, it will have a subobject of type \( B \), so it must be aligned appropriately for a long double. If \( D \) appears as a subobject of another object that also has \( B \) as a virtual base class, the \( B \) subobject might be part of a different subobject, reducing the alignment requirements on the \( D \) subobject. —end example

The result of the `alignof` operator reflects the alignment requirement of the type in the complete-object case.

An extended alignment is represented by an alignment greater than `alignof(std::max_align_t)`. It is implementation-defined whether any extended alignments are supported and the contexts in which they are supported (9.12.2). A type having an extended alignment requirement is an over-aligned type.

[Note 1: Every over-aligned type is or contains a class type to which extended alignment applies (possibly through a non-static data member). — end note]

A new-extended alignment is represented by an alignment greater than `__STDCPP_DEFAULT_NEW_ALIGNMENT_` (15.11).

Alignments are represented as values of the type `std::size_t`. Valid alignments include only those values returned by an `alignof` expression for the fundamental types plus an additional implementation-defined set of values, which may be empty. Every alignment value shall be a non-negative integral power of two.

Alignments have an order from weaker to stronger or stricter alignments. Stricter alignments have larger alignment values. An address that satisfies an alignment requirement also satisfies any weaker valid alignment requirement.

The alignment requirement of a complete type can be queried using an `alignof` expression (7.6.2.6). Furthermore, the narrow character types (6.8.2) shall have the weakest alignment requirement.

[Note 2: This enables the ordinary character types to be used as the underlying type for an aligned memory area (9.12.2). — end note]

Comparing alignments is meaningful and provides the obvious results:

(7.1) Two alignments are equal when their numeric values are equal.

(7.2) Two alignments are different when their numeric values are not equal.

(7.3) When an alignment is larger than another it represents a stricter alignment.

[Note 3: The runtime pointer alignment function (20.10.6) can be used to obtain an aligned pointer within a buffer; the aligned-storage templates in the library (20.15.8.7) can be used to obtain aligned storage. — end note]

If a request for a specific extended alignment in a specific context is not supported by an implementation, the program is ill-formed.

### 6.7.7 Temporary objects

Temporary objects are created

(1.1) when a prvalue is converted to an xvalue (7.3.5),

(1.2) when needed by the implementation to pass or return an object of trivially copyable type (see below), and

(1.3) when throwing an exception (14.2).

[Note 1: The lifetime of exception objects is described in 14.2. — end note]

Even when the creation of the temporary object is unevaluated (7.2), all the semantic restrictions shall be respected as if the temporary object had been created and later destroyed.

[Note 2: This includes accessibility (11.8) and whether it is deleted, for the constructor selected and for the destructor. However, in the special case of the operand of a `decltype-specifier` (9.2.9.5), no temporary is introduced, so the foregoing does not apply to such a prvalue. — end note]

The materialization of a temporary object is generally delayed as long as possible in order to avoid creating unnecessary temporary objects.

[Note 3: Temporary objects are materialized:

(2.1) when binding a reference to a prvalue (9.4.4, 7.6.1.4, 7.6.1.7, 7.6.1.9, 7.6.1.11, 7.6.3),

(2.2) when performing member access on a class prvalue (7.6.1.5, 7.6.4),

(2.3) when performing an array-to-pointer conversion or subscripting on an array prvalue (7.3.3, 7.6.1.2),

(2.4) when initializing an object of type `std::initializer_list<T>` from a `braced-init-list` (9.4.5),

(2.5) for certain unevaluated operands (7.6.1.8, 7.6.2.5), and

§ 6.7.7 68
— when a prvalue that has type other than `cv void` appears as a discarded-value expression (7.2).

— end note

[Example 1: Consider the following code:

class X {
   public:
   X(int);
   X(const X&);
   X& operator=(const X&);
   ~X();
};

class Y {
   public:
   Y(int);
   Y(Y&&);
   ~Y();
};

X f(X);
Y g(Y);

void h() {
   X a(1);
   X b = f(X(2));
   Y c = g(Y(3));
   a = f(a);
}

X(2) is constructed in the space used to hold `f()`’s argument and Y(3) is constructed in the space used to hold `g()`’s argument. Likewise, `f()`’s result is constructed directly in `b` and `g()`’s result is constructed directly in `c`. On the other hand, the expression `a = f(a)` requires a temporary for the result of `f(a)`, which is materialized so that the reference parameter of `X::operator=(const X&)` can bind to it. — end example]

3 When an object of class type X is passed to or returned from a function, if X has at least one eligible copy or move constructor (11.4.4), each such constructor is trivial, and the destructor of X is either trivial or deleted, implementations are permitted to create a temporary object to hold the function parameter or result object. The temporary object is constructed from the function argument or return value, respectively, and the function’s parameter or return object is initialized as if by using the eligible trivial constructor to copy the temporary (even if that constructor is inaccessible or would not be selected by overload resolution to perform a copy or move of the object).

[Note 4: This latitude is granted to allow objects of class type to be passed to or returned from functions in registers. — end note]

4 When an implementation introduces a temporary object of a class that has a non-trivial constructor (11.4.5.2, 11.4.5.3), it shall ensure that a constructor is called for the temporary object. Similarly, the destructor shall be called for a temporary with a non-trivial destructor (11.4.7). Temporary objects are destroyed as the last step in evaluating the full-expression (6.9.1) that (lexically) contains the point where they were created. This is true even if that evaluation ends in throwing an exception. The value computations and side effects of destroying a temporary object are associated only with the full-expression, not with any specific subexpression.

5 There are three contexts in which temporaries are destroyed at a different point than the end of the full-expression. The first context is when a default constructor is called to initialize an element of an array with no corresponding initializer (9.4). The second context is when a copy constructor is called to copy an element of an array while the entire array is copied (7.5.5.3, 11.4.5.3). In either case, if the constructor has one or more default arguments, the destruction of every temporary created in a default argument is sequenced before the construction of the next array element, if any.

6 The third context is when a reference is bound to a temporary object.32 The temporary object to which the reference is bound or the temporary object that is the complete object of a subobject to which the reference

---

32) The same rules apply to initialization of an initializer_list object (9.4.5) with its underlying temporary array.
is bound persists for the lifetime of the reference if the glvalue to which the reference is bound was obtained through one of the following:

1. a temporary materialization conversion (7.3.5),
2. (expression), where expression is one of these expressions,
3. subscripting (7.6.1.2) of an array operand, where that operand is one of these expressions,
4. a class member access (7.6.1.5) using the . operator where the left operand is one of these expressions and the right operand designates a non-static data member of non-reference type,
5. a pointer-to-member operation (7.6.4) using the .* operator where the left operand is one of these expressions and the right operand is a pointer to data member of non-reference type,
6. a
   1. const_cast (7.6.1.11),
   2. static_cast (7.6.1.9),
   3. dynamic_cast (7.6.1.7), or
   4. reinterpret_cast (7.6.1.10)
   converting, without a user-defined conversion, a glvalue operand that is one of these expressions to a glvalue that refers to the object designated by the operand, or to its complete object or a subobject thereof,
7. a conditional expression (7.6.16) that is a glvalue where the second or third operand is one of these expressions, or
8. a comma expression (7.6.20) that is a glvalue where the right operand is one of these expressions.

**Example 2:**
```cpp
template<typename T> using id = T;

int i = 1;
int&& a = id<int[3]>{1, 2, 3}[i];    // temporary array has same lifetime as a
const int& b = static_cast<const int&>(0);    // temporary int has same lifetime as b
int&& c = cond ? id<int[3]>{1, 2, 3}[i] : static_cast<int&&>(0);    // exactly one of the two temporaries is lifetime-extended
```

**Note 5:** An explicit type conversion (7.6.1.4, 7.6.3) is interpreted as a sequence of elementary casts, covered above.

**Example 3:**
```cpp
const int& x = (const int&)1;    // temporary for value 1 has same lifetime as x
```

**end example**

**end note**

**Example 4:**
```cpp
struct S {
    const int& m;
};
const S& s = S{1};    // both S and int temporaries have lifetime of s
```

**end example**

**end note**

The exceptions to this lifetime rule are:

1. A temporary object bound to a reference parameter in a function call (7.6.1.3) persists until the completion of the full-expression containing the call.
2. A temporary object bound to a reference element of an aggregate of class type initialized from a parenthesized expression-list (9.4) persists until the completion of the full-expression containing the expression-list.
— The lifetime of a temporary bound to the returned value in a function return statement (8.7.4) is not extended; the temporary is destroyed at the end of the full-expression in the return statement.

— A temporary bound to a reference in a new-initializer (7.6.2.8) persists until the completion of the full-expression containing the new-initializer.

[Note 7: This might introduce a dangling reference. — end note]

[Example 5:

```cpp
struct S { int mi; const std::pair<int,int>& mp; };
S a { 1, {2,3} };
S* p = new S{ 1, {2,3} }; // creates dangling reference
```
— end example]

7 The destruction of a temporary whose lifetime is not extended by being bound to a reference is sequenced before the destruction of every temporary which is constructed earlier in the same full-expression. If the lifetime of two or more temporaries to which references are bound ends at the same point, these temporaries are destroyed at that point in the reverse order of the completion of their construction. In addition, the destruction of temporaries bound to references shall take into account the ordering of destruction of objects with static, thread, or automatic storage duration (6.7.5.2, 6.7.5.3, 6.7.5.4); that is, if `obj1` is an object with the same storage duration as the temporary and created before the temporary is created the temporary shall be destroyed before `obj1` is destroyed; if `obj2` is an object with the same storage duration as the temporary and created after the temporary is created the temporary shall be destroyed after `obj2` is destroyed.

[Example 6:

```cpp
struct S {
    S();
    S(int);
    friend S operator+(const S&, const S&);
    ~S();
};
S obj1;
const S& cr = S(16)+S(23);
S obj2;
```

The expression `S(16) + S(23)` creates three temporaries: a first temporary `T1` to hold the result of the expression `S(16)`, a second temporary `T2` to hold the result of the expression `S(23)`, and a third temporary `T3` to hold the result of the addition of these two expressions. The temporary `T3` is then bound to the reference `cr`. It is unspecified whether `T1` or `T2` is created first. On an implementation where `T1` is created before `T2`, `T2` shall be destroyed before `T1`. The temporaries `T1` and `T2` are bound to the reference parameters of `operator+`; these temporaries are destroyed at the end of the full-expression containing the call to `operator+`. The temporary `T3` bound to the reference `cr` is destroyed at the end of `cr`'s lifetime, that is, at the end of the program. In addition, the order in which `T3` is destroyed takes into account the destruction order of other objects with static storage duration. That is, because `obj1` is constructed before `T3`, and `T3` is constructed before `obj2`, `obj2` shall be destroyed before `T3`, and `T3` shall be destroyed before `obj1`. — end example]

6.8 Types [basic.types]

6.8.1 General [basic.types.general]

1 [Note 1: 6.8 and the subclauses thereof impose requirements on implementations regarding the representation of types. There are two kinds of types: fundamental types and compound types. Types describe objects (6.7.2), references (9.3.4.3), or functions (9.3.4.6). — end note]

2 For any object (other than a potentially-overlapping subobject) of trivially copyable type `T`, whether or not the object holds a valid value of type `T`, the underlying bytes (6.7.1) making up the object can be copied into an array of `char`, `unsigned char`, or `std::byte` (17.2.1). If the content of that array is copied back into the object, the object shall subsequently hold its original value.

[Example 1:

```cpp
constexpr std::size_t N = sizeof(T);
char buf[N];
T obj;
// obj initialized to its original value
std::memcpy(buf, &obj, N); // between these two calls to memcpy, obj might be modified
std::memcpy(&obj, buf, N); // at this point, each subobject of obj of scalar type holds its original value
```

§ 6.8.1 71
For any trivially copyable type $T$, if two pointers to $T$ point to distinct $T$ objects $obj1$ and $obj2$, where neither $obj1$ nor $obj2$ is a potentially-overlapping subobject, if the underlying bytes (6.7.1) making up $obj1$ are copied into $obj2$, $obj2$ shall subsequently hold the same value as $obj1$.

[Example 2:]

```cpp
T* t1p;
T* t2p;
   // provided that t2p points to an initialized object ...
std::memcpy(t1p, t2p, sizeof(T));
   // at this point, every subobject of trivially copyable type in *t1p contains
   // the same value as the corresponding subobject in *t2p
```

4 The object representation of an object of type $T$ is the sequence of $N$ unsigned char objects taken up by the object of type $T$, where $N$ equals `sizeof(T)`. The value representation of an object of type $T$ is the set of bits that participate in representing a value of type $T$. Bits in the object representation that are not part of the value representation are padding bits. For trivially copyable types, the value representation is a set of bits in the object representation that determines a value, which is one discrete element of an implementation-defined set of values.\(^{35}\)

5 A class that has been declared but not defined, an enumeration type in certain contexts (9.7.1), or an array of unknown bound or of incomplete element type, is an incompletely-defined object type.\(^{36}\) Incompletely-defined object types and cv void are incomplete types (6.8.2).

[Note 2: Objects cannot be defined to have an incomplete type (6.2). — end note]\n
6 A class type (such as “class $X$”) can be incomplete at one point in a translation unit and complete later on; the type “class $X$” is the same type at both points. The declared type of an array object can be an array of incomplete class type and therefore incomplete; if the class type is completed later on in the translation unit, the array type becomes complete; the array type at those two points is the same type. The declared type of an array object can be an array of unknown bound and therefore be incomplete at one point in a translation unit and complete later on; the array types at those two points (“array of unknown bound of $T$” and “array of $N$ $T$”) are different types. The type of a pointer to array of unknown bound, or of a type defined by a typedef declaration to be an array of unknown bound, cannot be completed.

[Example 3:]

```cpp
class X;       // $X$ is an incomplete type
extern X* xp; // $xp$ is a pointer to an incomplete type
extern int arr[]; // the type of $arr$ is incomplete
typeid int UNKA[]; // $UNKA$ is an incomplete type
UNKA* arrp;    // $arrp$ is a pointer to an incomplete type
UNKA** arrpp;

void foo() {
   xp++;          // error: $X$ is incomplete
   arrp++;        // error: incomplete type
   arrpp++;       // OK: sizeof $UNKA*$ is known
}

struct X { int i; }; // now $X$ is a complete type
int arr[10];        // now the type of $arr$ is complete

X x;
void bar() {
   xp = &x;        // OK: type is “pointer to $X$”
   arrp = &arr;    // error: different types
   xp++;           // OK: $X$ is complete
   arrp++;         // error: $UNKA$ can’t be completed
}
```

34) By using, for example, the library functions (16.4.2.3) `std::memcpy` or `std::memmove`.
35) The intent is that the memory model of C++ is compatible with that of ISO/IEC 9899 Programming Language C.
36) The size and layout of an instance of an incompletely-defined object type is unknown.
An object type is a (possibly cv-qualified) type that is not a function type, not a reference type, and not cv void.

Arithmetic types (6.8.2), enumeration types, pointer types, pointer-to-member types (6.8.3), std::nullptr_t, and cv-qualified (6.8.4) versions of these types are collectively called scalar types. Scalar types, trivially copyable class types (11.2), arrays of such types, and cv-qualified versions of these types are collectively called trivially copyable types. Scalar types, trivial class types (11.2), arrays of such types and cv-qualified versions of these types are collectively called trivial types. Scalar types, standard-layout class types (11.2), arrays of such types and cv-qualified versions of these types are collectively called standard-layout types. Scalar types, implicit-lifetime class types (11.2), array types, and cv-qualified versions of these types are collectively called implicit-lifetime types.

A type is a literal type if it is:

- cv void; or
- a scalar type; or
- a reference type; or
- an array of literal type; or
- a possibly cv-qualified class type (Clause 11) that has all of the following properties:
  - it has a constexpr destructor (9.2.6),
  - it is either a closure type (7.5.5.2), an aggregate type (9.4.2), or has at least one constexpr constructor or constructor template (possibly inherited (9.9) from a base class) that is not a copy or move constructor,
  - if it is a union, at least one of its non-static data members is of non-volatile literal type, and
  - if it is not a union, all of its non-static data members and base classes are of non-volatile literal types.

Two types cv1 T1 and cv2 T2 are layout-compatible types if T1 and T2 are the same type, layout-compatible enumerations (9.7.1), or layout-compatible standard-layout class types (11.4).

6.8.2 Fundamental types

There are five standard signed integer types: “signed char”, “short int”, “int”, “long int”, and “long long int”. In this list, each type provides at least as much storage as those preceding it in the list. There may also be implementation-defined extended signed integer types. The standard and extended signed integer types are collectively called signed integer types. The range of representable values for a signed integer type is \(-2^{N-1} \text{ to } 2^{N-1} - 1\) (inclusive), where N is called the width of the type.

For each of the standard signed integer types, there exists a corresponding (but different) standard unsigned integer type: “unsigned char”, “unsigned short int”, “unsigned int”, “unsigned long int”, and “unsigned long long int”. Likewise, for each of the extended signed integer types, there exists a corresponding extended unsigned integer type. The standard and extended unsigned integer types are collectively called unsigned integer types. An unsigned integer type has the same width N as the corresponding signed integer type. The range of representable values for the unsigned type is 0 to \(2^N - 1\) (inclusive); arithmetic for the unsigned type is performed modulo \(2^N\).

An unsigned integer type has the same object representation, value representation, and alignment requirements (6.7.6) as the corresponding signed integer type. For each value x of a signed integer type, the value of the
corresponding unsigned integer type congruent to \( x \) modulo \( 2^N \) has the same value of corresponding bits in its value representation.\(^{37}\)

[Example 1: The value \(-1\) of a signed integer type has the same representation as the largest value of the corresponding unsigned type. — end example]

Table 14: Minimum width \([\text{tab:basic.fundamental.width}]\)

<table>
<thead>
<tr>
<th>Type</th>
<th>Minimum width ( N )</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed char</td>
<td>8</td>
</tr>
<tr>
<td>short int</td>
<td>16</td>
</tr>
<tr>
<td>int</td>
<td>16</td>
</tr>
<tr>
<td>long int</td>
<td>32</td>
</tr>
<tr>
<td>long long int</td>
<td>64</td>
</tr>
</tbody>
</table>

4 The width of each signed integer type shall not be less than the values specified in Table 14. The value representation of a signed or unsigned integer type comprises \( N \) bits, where \( N \) is the respective width. Each set of values for any padding bits (6.8) in the object representation are alternative representations of the value specified by the value representation.

[Note 3: Padding bits have unspecified value, but cannot cause traps. In contrast, see ISO C 6.2.6.2. — end note]

[Note 4: The signed and unsigned integer types satisfy the constraints given in ISO C 5.2.4.2.1. — end note]

Except as specified above, the width of a signed or unsigned integer type is implementation-defined.

5 Each value \( x \) of an unsigned integer type with width \( N \) has a unique representation \( x = x_02^0 + x_12^1 + \ldots + x_{N-1}2^{N-1} \), where each coefficient \( x_i \) is either 0 or 1; this is called the base-2 representation of \( x \). The base-2 representation of a value of signed integer type is the base-2 representation of the congruent value of the corresponding unsigned integer type. The standard signed integer types and standard unsigned integer types are collectively called the \( \text{standard integer types} \), and the extended signed integer types and extended unsigned integer types are collectively called the \( \text{extended integer types} \).

6 A fundamental type specified to have a signed or unsigned integer type as its \( \text{underlying type} \) has the same object representation, value representation, alignment requirements (6.7.6), and range of representable values as the underlying type. Further, each value has the same representation in both types.

7 Type \( \text{char} \) is a distinct type that has an implementation-defined choice of “\( \text{signed char} \)” or “\( \text{unsigned char} \)” as its underlying type. The values of type \( \text{char} \) can represent distinct codes for all members of the implementation’s basic character set. The three types \( \text{char}, \text{signed char}, \text{and unsigned char} \) are collectively called \( \text{ordinary character types} \). The ordinary character types and \( \text{char8_t} \) are collectively called \( \text{narrow character types} \). For narrow character types, each possible bit pattern of the object representation represents a distinct value.

[Note 5: This requirement does not hold for other types. — end note]

[Note 6: A bit-field of narrow character type whose width is larger than the width of that type has padding bits; see 6.8. — end note]

8 Type \( \text{wchar_t} \) is a distinct type that has an implementation-defined signed or unsigned integer type as its underlying type. The values of type \( \text{wchar_t} \) can represent distinct codes for all members of the largest extended character set specified among the supported locales (28.3.1).

9 Type \( \text{char8_t} \) denotes a distinct type whose underlying type is \( \text{unsigned char} \). Types \( \text{char16_t} \) and \( \text{char32_t} \) denote distinct types whose underlying types are \( \text{uint_least16_t} \) and \( \text{uint_least32_t} \), respectively, in \(<\text{cstdint}>\) (17.4.2).

10 Type \( \text{bool} \) is a distinct type that has the same object representation, value representation, and alignment requirements as an implementation-defined unsigned integer type. The values of type \( \text{bool} \) are \( \text{true} \) and \( \text{false} \).

[Note 7: There are no \( \text{signed}, \text{unsigned}, \text{short}, \) or \( \text{long bool} \) types or values. — end note]

11 Types \( \text{bool}, \text{char}, \text{wchar_t}, \text{char8_t}, \text{char16_t}, \text{char32_t}, \) and the signed and unsigned integer types are collectively called \( \text{integral types} \). A synonym for integral type is \( \text{integer type} \).

\(^{37}\) This is also known as two’s complement representation.

§ 6.8.2
There are three floating-point types: float, double, and long double. The type double provides at least as much precision as float, and the type long double provides at least as much precision as double. The set of values of the type float is a subset of the set of values of the type double; the set of values of the type double is a subset of the set of values of the type long double. The value representation of floating-point types is implementation-defined.

Integral and floating-point types are collectively called arithmetic types. Specializations of the standard library template std::numeric_limits (17.3) shall specify the maximum and minimum values of each arithmetic type for an implementation.

A type cv void is an incomplete type that cannot be completed; such a type has an empty set of values. It is used as the return type for functions that do not return a value. Any expression can be explicitly converted to type cv void (7.6.1.4, 7.6.1.9, 7.6.3). An expression of type cv void shall be used only as an expression statement (8.3), as an operand of a comma expression (7.6.20), as the operand of typeid, noexcept, or decltype, as the expression in a return statement (8.7.4) for a function with the return type cv void, or as the operand of an explicit conversion to type cv void.

A value of type std::nullptr_t is a null pointer constant (7.3.12). Such values participate in the pointer and the pointer-to-member conversions (7.3.12, 7.3.13). sizeof(std::nullptr_t) shall be equal to sizeof(void*).

The types described in this subclause are called fundamental types.

12 Compound types can be constructed in the following ways:

1. arrays of objects of a given type, 9.3.4.5;
2. functions, which have parameters of given types and return void or references or objects of a given type, 9.3.4.6;
3. pointers to cv void or objects or functions (including static members of classes) of a given type, 9.3.4.2;
4. references to objects or functions of a given type, 9.3.4.3. There are two types of references:
   1. lvalue reference
   2. rvalue reference
5. classes containing a sequence of objects of various types (Clause 11), a set of types, enumerations and functions for manipulating these objects (11.4.2), and a set of restrictions on the access to these entities (11.8);
6. unions, which are classes capable of containing objects of different types at different times, 11.5;
7. enumerations, which comprise a set of named constant values. Each distinct enumeration constitutes a different enumerated type, 9.7.1;
8. pointers to non-static class members, which identify members of a given type within objects of a given class, 9.3.4.4. Pointers to data members and pointers to member functions are collectively called pointer-to-member types.

These methods of constructing types can be applied recursively; restrictions are mentioned in 9.3.4. Constructing a type such that the number of bytes in its object representation exceeds the maximum value representable in the type std::size_t (17.2) is ill-formed.

The type of a pointer to cv void or a pointer to an object type is called an object pointer type.

13 A type cv void is an incomplete type that cannot be completed; such a type has an empty set of values. It is used as the return type for functions that do not return a value. Any expression can be explicitly converted to type cv void (7.6.1.4, 7.6.1.9, 7.6.3). An expression of type cv void shall be used only as an expression statement (8.3), as an operand of a comma expression (7.6.20), as a second or third operand of ?: (7.6.16), as the operand of typeid, noexcept, or decltype, as the expression in a return statement (8.7.4) for a function with the return type cv void, or as the operand of an explicit conversion to type cv void.

14 A value of type std::nullptr_t is a null pointer constant (7.3.12). Such values participate in the pointer and the pointer-to-member conversions (7.3.12, 7.3.13). sizeof(std::nullptr_t) shall be equal to sizeof(void*).

15 The types described in this subclause are called fundamental types.

Note 10: Even if the implementation defines two or more fundamental types to have the same value representation, they are nevertheless different types. — end note

§ 6.8.3 Compound types [basic.compound]
The type of a pointer that can designate a function is called a function pointer type. A pointer to an object of type T is referred to as a “pointer to T”.

[Example 1: A pointer to an object of type int is referred to as “pointer to int” and a pointer to an object of class X is called a “pointer to X.” — end example]

Except for pointers to static members, text referring to “pointers” does not apply to pointers to members. Pointers to incomplete types are allowed although there are restrictions on what can be done with them (6.7.6). Every value of pointer type is one of the following:

1. a pointer to an object or function (the pointer is said to point to the object or function), or
2. a pointer past the end of an object (7.6.6), or
3. the null pointer value for that type, or
4. an invalid pointer value.

A value of a pointer type that is a pointer to or past the end of an object represents the address of the first byte in memory (6.7.1) occupied by the object or the first byte in memory after the end of the storage occupied by the object, respectively.

[Note 2: A pointer past the end of an object (7.6.6) is not considered to point to an unrelated object of the object’s type, even if the unrelated object is located at that address. A pointer value becomes invalid when the storage it denotes reaches the end of its storage duration; see 6.7.5. — end note]

For purposes of pointer arithmetic (7.6.6) and comparison (7.6.9, 7.6.10), a pointer past the end of the last element of an array x of n elements is considered to be equivalent to a pointer to a hypothetical array element n of x and an object of type T that is not an array element is considered to belong to an array with one element of type T. The value representation of pointer types is implementation-defined. Pointers to layout-compatible types shall have the same value representation and alignment requirements (6.7.6).

[Note 3: Pointers to over-aligned types (6.7.6) have no special representation, but their range of valid values is restricted by the extended alignment requirement. — end note]

Two objects a and b are pointer-interconvertible if:

1. they are the same object, or
2. one is a union object and the other is a non-static data member of that object (11.5), or
3. one is a standard-layout class object and the other is the first non-static data member of that object, or, if the object has no non-static data members, any base class subobject of that object (11.4), or
4. there exists an object c such that a and c are pointer-interconvertible, and c and b are pointer-interconvertible.

If two objects are pointer-interconvertible, then they have the same address, and it is possible to obtain a pointer to one from a pointer to the other via a reinterpret_cast (7.6.1.10).

[Note 4: An array object and its first element are not pointer-interconvertible, even though they have the same address. — end note]

A pointer to cv void can be used to point to objects of unknown type. Such a pointer shall be able to hold any object pointer. An object of type cv void* shall have the same representation and alignment requirements as cv char*.

6.8.4 CV-qualifiers

A type mentioned in 6.8.2 and 6.8.3 is a cv-unqualified type. Each type which is a cv-unqualified object type or is void (6.8) has three corresponding cv-qualified versions of its type: a const-qualified version, a volatile-qualified version, and a const-volatile-qualified version. The type of an object (6.7.2) includes the cv-qualifiers specified in the decl-specifier-seq (9.2), declarator (9.3), type-id (9.3.2), or new-type-id (7.6.2.8) when the object is created.

1. A const object is an object of type const T or a non-mutable subobject of a const object.
2. A volatile object is an object of type volatile T or a subobject of a volatile object.
3. A const volatile object is an object of type const volatile T, a non-mutable subobject of a const volatile object, a const subobject of a volatile object, or a non-mutable volatile subobject of a const object.

39) For an object that is not within its lifetime, this is the first byte in memory that it will occupy or used to occupy.
The cv-qualified or cv-unqualified versions of a type are distinct types; however, they shall have the same representation and alignment requirements (6.7.6).

Except for array types, a compound type (6.8.3) is not cv-qualified by the cv-qualifiers (if any) of the types from which it is compounded.

An array type whose elements are cv-qualified is also considered to have the same cv-qualifications as its elements.

[Note 1: Cv-qualifiers applied to an array type attach to the underlying element type, so the notation “cv T”, where T is an array type, refers to an array whose elements are so-qualified (9.3.4.5). — end note]

[Example 1:
  
  typedef char CA[5];
  typedef const char CC;
  CC arr1[5] = { 0 };
  const CA arr2 = { 0 };
  
  The type of both arr1 and arr2 is “array of 5 const char”, and the array type is considered to be const-qualified. — end example]

[Note 2: See 9.3.4.6 and 12.2.2 regarding function types that have cv-qualifiers. — end note]

There is a partial ordering on cv-qualifiers, so that a type can be said to be more cv-qualified than another. Table 15 shows the relations that constitute this ordering.

Table 15: Relations on \texttt{const} and \texttt{volatile} [tab:basic.type.qualifier.rel]

<table>
<thead>
<tr>
<th>no cv-qualifier</th>
<th>&lt;</th>
<th>\texttt{const}</th>
</tr>
</thead>
<tbody>
<tr>
<td>no cv-qualifier</td>
<td>&lt;</td>
<td>\texttt{volatile}</td>
</tr>
<tr>
<td>no cv-qualifier</td>
<td>&lt;</td>
<td>\texttt{const volatile}</td>
</tr>
<tr>
<td>\texttt{const}</td>
<td>&lt;</td>
<td>\texttt{const volatile}</td>
</tr>
<tr>
<td>\texttt{volatile}</td>
<td>&lt;</td>
<td>\texttt{const volatile}</td>
</tr>
</tbody>
</table>

In this document, the notation \texttt{cv} (or \texttt{cv1}, \texttt{cv2}, etc.), used in the description of types, represents an arbitrary set of cv-qualifiers, i.e., one of \{\texttt{const}\}, \{\texttt{volatile}\}, \{\texttt{const, volatile}\}, or the empty set. For a type \texttt{cv T}, the top-level cv-qualifiers of that type are those denoted by \texttt{cv}.

[Example 2: The type corresponding to the type-id \texttt{const int} has no top-level cv-qualifiers. The type corresponding to the type-id \texttt{volatile int * const} has the top-level cv-qualifier \texttt{const}. For a class type \texttt{C}, the type corresponding to the type-id \texttt{void (C::* volatile)(int) const} has the top-level cv-qualifier \texttt{volatile}. — end example]

### 6.8.5 Integer conversion rank [conv.rank]

Every integer type has an integer conversion rank defined as follows:

1. (1.1) — No two signed integer types other than \texttt{char} and \texttt{signed char} (if \texttt{char} is signed) have the same rank, even if they have the same representation.

2. (1.2) — The rank of a signed integer type is greater than the rank of any signed integer type with a smaller width.

3. (1.3) — The rank of \texttt{long long int} is greater than the rank of \texttt{long int}, which is greater than the rank of \texttt{int}, which is greater than the rank of \texttt{short int}, which is greater than the rank of \texttt{signed char}.

4. (1.4) — The rank of any unsigned integer type equals the rank of the corresponding signed integer type.

5. (1.5) — The rank of any standard integer type is greater than the rank of any extended integer type with the same width.

6. (1.6) — The rank of \texttt{char} equals the rank of \texttt{signed char} and \texttt{unsigned char}.

7. (1.7) — The rank of \texttt{bool} is less than the rank of all other standard integer types.

8. (1.8) — The ranks of \texttt{char8_t, char16_t, char32_t, and wchar_t} equal the ranks of their underlying types (6.8.2).

---

40) The same representation and alignment requirements are meant to imply interchangeability as arguments to functions, return values from functions, and non-static data members of unions.
The rank of any extended signed integer type relative to another extended signed integer type with the same width is implementation-defined, but still subject to the other rules for determining the integer conversion rank.

For all integer types \( T_1, T_2, \) and \( T_3 \), if \( T_1 \) has greater rank than \( T_2 \) and \( T_2 \) has greater rank than \( T_3 \), then \( T_1 \) has greater rank than \( T_3 \).

[Note 1: The integer conversion rank is used in the definition of the integral promotions (7.3.7) and the usual arithmetic conversions (7.4). — end note]

6.9 Program execution

6.9.1 Sequential execution

An instance of each object with automatic storage duration (6.7.5.4) is associated with each entry into its block. Such an object exists and retains its last-stored value during the execution of the block and while the block is suspended (by a call of a function, suspension of a coroutine (7.6.2.4), or receipt of a signal).

A constituent expression is defined as follows:

1. The constituent expression of an expression is that expression.
2. The constituent expressions of a braced-init-list or of a (possibly parenthesized) expression-list are the constituent expressions of the elements of the respective list.
3. The constituent expressions of a brace-or-equal-initializer of the form \( = \) initializer-clause are the constituent expressions of the initializer-clause.

Example 1:
```c
struct A { int x; }
struct B { int y; struct A a; }
B b = { 5, { 1+1 } };
```
The constituent expressions of the initializer used for the initialization of \( b \) are 5 and 1+1.

The immediate subexpressions of an expression \( E \) are

1. The constituent expressions of \( E \)'s operands (7.2),
2. any function call that \( E \) implicitly invokes,
3. if \( E \) is a lambda-expression (7.5.5), the initialization of the entities captured by copy and the constituent expressions of the initializer of the init-captures,
4. if \( E \) is a function call (7.6.1.3) or implicitly invokes a function, the constituent expressions of each default argument (9.3.4.7) used in the call, or
5. if \( E \) creates an aggregate object (9.4.2), the constituent expressions of each default member initializer (11.4) used in the initialization.

A subexpression of an expression \( E \) is an immediate subexpression of \( E \) or a subexpression of an immediate subexpression of \( E \).

[Note 1: Expressions appearing in the compound-statement of a lambda-expression are not subexpressions of the lambda-expression. — end note]

A full-expression is

1. an unevaluated operand (7.2),
2. a constant-expression (7.7),
3. an immediate invocation (7.7),
4. an init-declarator (9.3) or a mem-initializer (11.9.3), including the constituent expressions of the initializer,
5. an invocation of a destructor generated at the end of the lifetime of an object other than a temporary object (6.7.7) whose lifetime has not been extended, or
6. an expression that is not a subexpression of another expression and that is not otherwise part of a full-expression.

If a language construct is defined to produce an implicit call of a function, a use of the language construct is considered to be an expression for the purposes of this definition. Conversions applied to the result of an expression in order to satisfy the requirements of the language construct in which the expression appears are
also considered to be part of the full-expression. For an initializer, performing the initialization of the entity (including evaluating default member initializers of an aggregate) is also considered part of the full-expression.

[Example 2:

```cpp
struct S {
    S(int i): I(i) {} // full-expression is initialization of I
    int& v() { return I; }
    -S() noexcept(false) {} // full-expression is destruction of s1
    private:
        int I;
};

S s1(1); // full-expression comprises call of S::S(int)
void f() {
    S s2 = 2; // full-expression comprises call of S::S(int)
    if (S(3).v()) // full-expression includes lvalue-to-rvalue and int to bool conversions, // performed before temporary is deleted at end of full-expression
        {}
    bool b = noexcept(S()); // exception specification of destructor of S considered for noexcept
    // full-expression is destruction of s2 at end of block
}
struct B {
    B(S = S(0));
};
B b[2] = { B(), B() }; // full-expression is the entire initialization // including the destruction of temporaries
```

— end example]

6 [Note 2: The evaluation of a full-expression can include the evaluation of subexpressions that are not lexically part of the full-expression. For example, subexpressions involved in evaluating default arguments (9.3.4.7) are considered to be created in the expression that calls the function, not the expression that defines the default argument. — end note]

7 Reading an object designated by a `volatile` glvalue (7.2.1), modifying an object, calling a library I/O function, or calling a function that does any of those operations are all side effects, which are changes in the state of the execution environment. Evaluation of an expression (or a subexpression) in general includes both value computations (including determining the identity of an object for glvalue evaluation and fetching a value previously assigned to an object for prvalue evaluation) and initiation of side effects. When a call to a library I/O function returns or an access through a `volatile` glvalue is evaluated the side effect is considered complete, even though some external actions implied by the call (such as the I/O itself) or by the `volatile` access may not have completed yet.

8 Sequenced before is an asymmetric, transitive, pair-wise relation between evaluations executed by a single thread (6.9.2), which induces a partial order among those evaluations. Given any two evaluations `A` and `B`, if `A` is sequenced before `B` (or, equivalently, `B` is sequenced after `A`), then the execution of `A` shall precede the execution of `B`. If `A` is not sequenced before `B` and `B` is not sequenced before `A`, then `A` and `B` are unsequenced.

[Note 3: The execution of unsequenced evaluations can overlap. — end note]

Evaluations `A` and `B` are indeterminately sequenced when either `A` is sequenced before `B` or `B` is sequenced before `A`, but it is unspecified which.

[Note 4: Indeterminately sequenced evaluations cannot overlap, but either can be executed first. — end note]

An expression `X` is said to be sequenced before an expression `Y` if every value computation and every side effect associated with the expression `X` is sequenced before every value computation and every side effect associated with the expression `Y`.

9 Every value computation and side effect associated with a full-expression is sequenced before every value computation and side effect associated with the next full-expression to be evaluated.\(^{41}\)

10 Except where noted, evaluations of operands of individual operators and of subexpressions of individual expressions are unsequenced.

\(^{41}\) As specified in 6.7.7, after a full-expression is evaluated, a sequence of zero or more invocations of destructor functions for temporary objects takes place, usually in reverse order of the construction of each temporary object.
[Note 5: In an expression that is evaluated more than once during the execution of a program, unsequenced and indeterminately sequenced evaluations of its subexpressions need not be performed consistently in different evaluations. —end note]

The value computations of the operands of an operator are sequenced before the value computation of the result of the operator. If a side effect on a memory location (6.7.1) is unsequenced relative to either another side effect on the same memory location or a value computation using the value of any object in the same memory location, and they are not potentially concurrent (6.9.2), the behavior is undefined.

[Note 6: The next subclause imposes similar, but more complex restrictions on potentially concurrent computations. —end note]

[Example 3:

```c
void g(int i) {
  i = 7, i++, i++;
  // i becomes 9
  i = i++ + 1;       // the value of i is incremented
  i = i++ + i;      // undefined behavior
  i = i + 1;        // the value of i is incremented
}
```

—end example]

When calling a function (whether or not the function is inline), every value computation and side effect associated with any argument expression, or with the postfix expression designating the called function, is sequenced before execution of every expression or statement in the body of the called function. For each function invocation $F$, for every evaluation $A$ that occurs within $F$ and every evaluation $B$ that does not occur within $F$ but is evaluated on the same thread and as part of the same signal handler (if any), either $A$ is sequenced before $B$ or $B$ is sequenced before $A$.

[Note 7: If $A$ and $B$ would not otherwise be sequenced then they are indeterminately sequenced. —end note]

Several contexts in C++ cause evaluation of a function call, even though no corresponding function call syntax appears in the translation unit.

[Example 4: Evaluation of a new-expression invokes one or more allocation and constructor functions; see 7.6.2.8. For another example, invocation of a conversion function (11.4.8.3) can arise in contexts in which no function call syntax appears. —end example]

The sequencing constraints on the execution of the called function (as described above) are features of the function calls as evaluated, regardless of the syntax of the expression that calls the function.

If a signal handler is executed as a result of a call to the `std::raise` function, then the execution of the handler is sequenced after the invocation of the `std::raise` function and before its return.

[Note 8: When a signal is received for another reason, the execution of the signal handler is usually unsequenced with respect to the rest of the program. —end note]

### 6.9.2 Multi-threaded executions and data races [intro.multithread]

#### 6.9.2.1 General [intro.multithread.general]

A thread of execution (also known as a thread) is a single flow of control within a program, including the initial invocation of a specific top-level function, and recursively including every function invocation subsequently executed by the thread.

[Note 1: When one thread creates another, the initial call to the top-level function of the new thread is executed by the new thread, not by the creating thread. —end note]

Every thread in a program can potentially access every object and function in a program. Under a hosted implementation, a C++ program can have more than one thread running concurrently. The execution of each thread proceeds as defined by the remainder of this document. The execution of the entire program consists of an execution of all of its threads.

[Note 2: Usually the execution can be viewed as an interleaving of all its threads. However, some kinds of atomic operations, for example, allow executions inconsistent with a simple interleaving, as described below. —end note]

---

42) In other words, function executions do not interleave with each other.

43) An object with automatic or thread storage duration (6.7.5) is associated with one specific thread, and can be accessed by a different thread only indirectly through a pointer or reference (6.8.3).
Under a freestanding implementation, it is implementation-defined whether a program can have more than one thread of execution.

For a signal handler that is not executed as a result of a call to the `std::raise` function, it is unspecified which thread of execution contains the signal handler invocation.

6.9.2.2 Data races

The value of an object visible to a thread T at a particular point is the initial value of the object, a value assigned to the object by T, or a value assigned to the object by another thread, according to the rules below.

[Note 1: In some cases, there might instead be undefined behavior. Much of this subclause is motivated by the desire to support atomic operations with explicit and detailed visibility constraints. However, it also implicitly supports a simpler view for more restricted programs. — end note]

Two expression evaluations conflict if one of them modifies a memory location (6.7.1) and the other one reads or modifies the same memory location.

The library defines a number of atomic operations (Clause 31) and operations on mutexes (Clause 32) that are specially identified as synchronization operations. These operations play a special role in making assignments in one thread visible to another. A synchronization operation on one or more memory locations is either a consume operation, an acquire operation, a release operation, or both an acquire and release operation. A synchronization operation without an associated memory location is a fence and can be either an acquire fence, a release fence, or both an acquire and release fence. In addition, there are relaxed atomic operations, which are not synchronization operations, and atomic read-modify-write operations, which have special characteristics.

[Note 2: For example, a call that acquires a mutex will perform an acquire operation on the locations comprising the mutex. Correspondingly, a call that releases the same mutex will perform a release operation on those same locations. Informally, performing a release operation on A forces prior side effects on other memory locations to become visible to other threads that later perform a consume or an acquire operation on A. “Relaxed” atomic operations are not synchronization operations even though, like synchronization operations, they cannot contribute to data races. — end note]

All modifications to a particular atomic object M occur in some particular total order, called the modification order of M.

[Note 3: There is a separate order for each atomic object. There is no requirement that these can be combined into a single total order for all objects. In general this will be impossible since different threads can observe modifications to different objects in inconsistent orders. — end note]

A release sequence headed by a release operation A on an atomic object M is a maximal contiguous subsequence of side effects in the modification order of M, where the first operation is A, and every subsequent operation is an atomic read-modify-write operation.

Certain library calls synchronize with other library calls performed by another thread. For example, an atomic store-release synchronizes with a load-acquire that takes its value from the store (31.4).

[Note 4: Except in the specified cases, reading a later value does not necessarily ensure visibility as described below. Such a requirement would sometimes interfere with efficient implementation. — end note]

[Note 5: The specifications of the synchronization operations define when one reads the value written by another. For atomic objects, the definition is clear. All operations on a given mutex occur in a single total order. Each mutex acquisition “reads the value written” by the last mutex release. — end note]

An evaluation A carries a dependency to an evaluation B if

- the value of A is used as an operand of B, unless:
  - B is an invocation of any specialization of `std::kill_dependency` (31.4), or
  - A is the left operand of a built-in logical AND (&&, see 7.6.14) or logical OR (||, see 7.6.15) operator, or
  - A is the left operand of a conditional (?:, see 7.6.16) operator, or
  - A is the left operand of the built-in comma (,) operator (7.6.20); or
  - A writes a scalar object or bit-field M, B reads the value written by A from M, and A is sequenced before B, or
  - for some evaluation X, A carries a dependency to X, and X carries a dependency to B.
8 An evaluation $A$ is dependency-ordered before an evaluation $B$ if

(8.1) $A$ performs a release operation on an atomic object $M$, and, in another thread, $B$ performs a consume operation on $M$ and reads the value written by $A$, or

(8.2) for some evaluation $X$, $A$ is dependency-ordered before $X$ and $X$ carries a dependency to $B$.

[Note 7: The relation “is dependency-ordered before” is analogous to “synchronizes with”, but uses release/consume in place of release/acquire. — end note]

9 An evaluation $A$ inter-thread happens before an evaluation $B$ if

(9.1) $A$ synchronizes with $B$, or

(9.2) $A$ is dependency-ordered before $B$, or

(9.3) for some evaluation $X$

(9.3.1) $A$ synchronizes with $X$ and $X$ is sequenced before $B$, or

(9.3.2) $A$ is sequenced before $X$ and $X$ inter-thread happens before $B$, or

(9.3.3) $A$ inter-thread happens before $X$ and $X$ inter-thread happens before $B$.

[Note 8: The “inter-thread happens before” relation describes arbitrary concatenations of “sequenced before”, “synchronizes with” and “dependency-ordered before” relationships, with two exceptions. The first exception is that a concatenation is not permitted to end with “dependency-ordered before” followed by “sequenced before”. The reason for this limitation is that a consume operation participating in a “dependency-ordered before” relationship provides ordering only with respect to operations to which this consume operation actually carries a dependency. The reason that this limitation applies only to the end of such a concatenation is that any subsequent release operation will provide the required ordering for a prior consume operation. The second exception is that a concatenation is not permitted to consist entirely of “sequenced before”. The reasons for this limitation are (1) to permit “inter-thread happens before” to be transitively closed and (2) the “happens before” relation, defined below, provides for relationships consisting entirely of “sequenced before”. — end note]

10 An evaluation $A$ happens before an evaluation $B$ (or, equivalently, $B$ happens after $A$) if:

(10.1) $A$ is sequenced before $B$, or

(10.2) $A$ inter-thread happens before $B$.

The implementation shall ensure that no program execution demonstrates a cycle in the “happens before” relation.

[Note 9: This cycle would otherwise be possible only through the use of consume operations. — end note]

11 An evaluation $A$ simply happens before an evaluation $B$ if either

(11.1) $A$ is sequenced before $B$, or

(11.2) $A$ synchronizes with $B$, or

(11.3) $A$ simply happens before $X$ and $X$ simply happens before $B$.

[Note 10: In the absence of consume operations, the happens before and simply happens before relations are identical. — end note]

12 An evaluation $A$ strongly happens before an evaluation $D$ if, either

(12.1) $A$ is sequenced before $D$, or

(12.2) $A$ synchronizes with $D$, and both $A$ and $D$ are sequentially consistent atomic operations (31.4), or

(12.3) there are evaluations $B$ and $C$ such that $A$ is sequenced before $B$, $B$ simply happens before $C$, and $C$ is sequenced before $D$, or

(12.4) there is an evaluation $B$ such that $A$ strongly happens before $B$, and $B$ strongly happens before $D$.

[Note 11: Informally, if $A$ strongly happens before $B$, then $A$ appears to be evaluated before $B$ in all contexts. Strongly happens before excludes consume operations. — end note]

13 A visible side effect $A$ on a scalar object or bit-field $M$ with respect to a value computation $B$ of $M$ satisfies the conditions:

(13.1) $A$ happens before $B$ and

(13.2) there is no other side effect $X$ to $M$ such that $A$ happens before $X$ and $X$ happens before $B$. 

§ 6.9.2.2
The value of a non-atomic scalar object or bit-field $M$, as determined by evaluation $B$, shall be the value stored by the visible side effect $A$.

[Note 12: If there is ambiguity about which side effect to a non-atomic object or bit-field is visible, then the behavior is either unspecified or undefined. — end note]

[Note 13: This states that operations on ordinary objects are not visibly reordered. This is not actually detectable without data races, but it is necessary to ensure that data races, as defined below, and with suitable restrictions on the use of atomics, correspond to data races in a simple interleaved (sequentially consistent) execution. — end note]

The value of an atomic object $M$, as determined by evaluation $B$, shall be the value stored by some side effect $A$ that modifies $M$, where $B$ does not happen before $A$.

[Note 14: The set of such side effects is also restricted by the rest of the rules described here, and in particular, by the coherence requirements below. — end note]

If an operation $A$ that modifies an atomic object $M$ happens before an operation $B$ that modifies $M$, then $A$ shall be earlier than $B$ in the modification order of $M$.

[Note 15: This requirement is known as write-write coherence. — end note]

If a value computation $A$ of an atomic object $M$ happens before a value computation $B$ of $M$, and $A$ takes its value from a side effect $X$ on $M$, then the value computed by $B$ shall either be the value stored by $X$ or the value stored by a side effect $Y$ on $M$, where $Y$ follows $X$ in the modification order of $M$.

[Note 16: This requirement is known as read-read coherence. — end note]

If a value computation $A$ of an atomic object $M$ happens before an operation $B$ that modifies $M$, then $A$ shall take its value from a side effect $X$ on $M$, where $X$ precedes $B$ in the modification order of $M$.

[Note 17: This requirement is known as read-write coherence. — end note]

If a side effect $X$ on an atomic object $M$ happens before a value computation $B$ of $M$, then the evaluation $B$ shall take its value from $X$ or from a side effect $Y$ that follows $X$ in the modification order of $M$.

[Note 18: This requirement is known as write-read coherence. — end note]

[Note 19: The four preceding coherence requirements effectively disallow compiler reordering of atomic operations to a single object, even if both operations are relaxed loads. This effectively makes the cache coherence guarantee provided by most hardware available to C++ atomic operations. — end note]

[Note 20: The value observed by a load of an atomic depends on the “happens before” relation, which depends on the values observed by loads of atomics. The intended reading is that there must exist an association of atomic loads with modifications they observe that, together with suitably chosen modification orders and the “happens before” relation derived as described above, satisfy the resulting constraints as imposed here. — end note]

Two actions are potentially concurrent if

(i) they are performed by different threads, or

(ii) they are unsequenced, at least one is performed by a signal handler, and they are not both performed by the same signal handler invocation.

The execution of a program contains a data race if it contains two potentially concurrent conflicting actions, at least one of which is not atomic, and neither happens before the other, except for the special case for signal handlers described below. Any such data race results in undefined behavior.

[Note 21: It can be shown that programs that correctly use mutexes and memory_order::seq_cst operations to prevent all data races and use no other synchronization operations behave as if the operations executed by their constituent threads were simply interleaved, with each value computation of an object being taken from the last side effect on that object in that interleaving. This is normally referred to as “sequential consistency”. However, this applies only to data-race-free programs, and data-race-free programs cannot observe most program transformations that do not change single-threaded program semantics. In fact, most single-threaded program transformations continue to be allowed, since any program that behaves differently as a result has undefined behavior. — end note]

Two accesses to the same object of type volatile std::sig_atomic_t do not result in a data race if both occur in the same thread, even if one or more occurs in a signal handler. For each signal handler invocation, evaluations performed by the thread invoking a signal handler can be divided into two groups $A$ and $B$, such that no evaluations in $B$ happen before evaluations in $A$, and the evaluations of such volatile std::sig_atomic_t objects take values as though all evaluations in $A$ happened before the execution of the signal handler and the execution of the signal handler happened before all evaluations in $B$.

[Note 22: Compiler transformations that introduce assignments to a potentially shared memory location that would not be modified by the abstract machine are generally precluded by this document, since such an assignment might
overwrite another assignment by a different thread in cases in which an abstract machine execution would not have encountered a data race. This includes implementations of data member assignment that overwrite adjacent members in separate memory locations. Reordering of atomic loads in cases in which the atomics in question might alias is also generally precluded, since this could violate the coherence rules. — end note

24 [Note 23: Transformations that introduce a speculative read of a potentially shared memory location might not preserve the semantics of the C++ program as defined in this document, since they potentially introduce a data race. However, they are typically valid in the context of an optimizing compiler that targets a specific machine with well-defined semantics for data races. They would be invalid for a hypothetical machine that is not tolerant of races or provides hardware race detection. — end note]

6.9.2.3 Forward progress

The implementation may assume that any thread will eventually do one of the following:

(1.1) — terminate,
(1.2) — make a call to a library I/O function,
(1.3) — perform an access through a volatile glvalue, or
(1.4) — perform a synchronization operation or an atomic operation.

[Note 1: This is intended to allow compiler transformations such as removal of empty loops, even when termination cannot be proven. — end note]

2 Executions of atomic functions that are either defined to be lock-free (31.10) or indicated as lock-free (31.5) are lock-free executions.

(2.1) — If there is only one thread that is not blocked (3.7) in a standard library function, a lock-free execution in that thread shall complete.

[Note 2: Concurrently executing threads might prevent progress of a lock-free execution. For example, this situation can occur with load-locked store-conditional implementations. This property is sometimes termed obstruction-free. — end note]

(2.2) — When one or more lock-free executions run concurrently, at least one should complete.

[Note 3: It is difficult for some implementations to provide absolute guarantees to this effect, since repeated and particularly inopportune interference from other threads could prevent forward progress, e.g., by repeatedly stealing a cache line for unrelated purposes between load-locked and store-conditional instructions. For implementations that follow this recommendation and ensure that such effects cannot indefinitely delay progress under expected operating conditions, such anomalies can therefore safely be ignored by programmers. Outside this document, this property is sometimes termed lock-free. — end note]

3 During the execution of a thread of execution, each of the following is termed an execution step:

(3.1) — termination of the thread of execution,
(3.2) — performing an access through a volatile glvalue, or
(3.3) — completion of a call to a library I/O function, a synchronization operation, or an atomic operation.

4 An invocation of a standard library function that blocks (3.7) is considered to continuously execute execution steps while waiting for the condition that it blocks on to be satisfied.

[Example 1: A library I/O function that blocks until the I/O operation is complete can be considered to continuously check whether the operation is complete. Each such check consists of one or more execution steps, for example using observable behavior of the abstract machine. — end example]

5 [Note 4: Because of this and the preceding requirement regarding what threads of execution have to perform eventually, it follows that no thread of execution can execute forever without an execution step occurring. — end note]

6 A thread of execution makes progress when an execution step occurs or a lock-free execution does not complete because there are other concurrent threads that are not blocked in a standard library function (see above).

7 For a thread of execution providing concurrent forward progress guarantees, the implementation ensures that the thread will eventually make progress for as long as it has not terminated.

[Note 5: This is required regardless of whether or not other threads of executions (if any) have been or are making progress. To eventually fulfill this requirement means that this will happen in an unspecified but finite amount of time. — end note]

8 It is implementation-defined whether the implementation-created thread of execution that executes main (6.9.3.1) and the threads of execution created by std::thread (32.4.3) or std::jthread (32.4.4) provide concurrent forward progress guarantees. General-purpose implementations should provide these guarantees.
For a thread of execution providing \textit{parallel forward progress guarantees}, the implementation is not required to ensure that the thread will eventually make progress if it has not yet executed any execution step; once this thread has executed a step, it provides concurrent forward progress guarantees.

[Note 6: This does not specify a requirement for when to start this thread of execution, which will typically be specified by the entity that creates this thread of execution. For example, a thread of execution that provides concurrent forward progress guarantees and executes tasks from a set of tasks in an arbitrary order, one after the other, satisfies the requirements of parallel forward progress for these tasks. — end note]

For a thread of execution providing \textit{weakly parallel forward progress guarantees}, the implementation does not ensure that the thread will eventually make progress.

[Note 7: Threads of execution providing weakly parallel forward progress guarantees cannot be expected to make progress regardless of whether other threads make progress or not; however, blocking with forward progress guarantee delegation, as defined below, can be used to ensure that such threads of execution make progress eventually. — end note]

Concurrent forward progress guarantees are stronger than parallel forward progress guarantees, which in turn are stronger than weakly parallel forward progress guarantees.

[Note 8: For example, some kinds of synchronization between threads of execution might only make progress if the respective threads of execution provide parallel forward progress guarantees, but will fail to make progress under weakly parallel guarantees. — end note]

When a thread of execution \( P \) is specified to \textit{block with forward progress guarantee delegation} on the completion of a set \( S \) of threads of execution, then throughout the whole time of \( P \) being blocked on \( S \), the implementation shall ensure that the forward progress guarantees provided by at least one thread of execution in \( S \) is at least as strong as \( P \)'s forward progress guarantees.

[Note 9: It is unspecified which thread or threads of execution in \( S \) are chosen and for which number of execution steps. The strengthening is not permanent and not necessarily in place for the rest of the lifetime of the affected thread of execution. As long as \( P \) is blocked, the implementation has to eventually select and potentially strengthen a thread of execution in \( S \). — end note]

Once a thread of execution in \( S \) terminates, it is removed from \( S \). Once \( S \) is empty, \( P \) is unblocked.

[Note 10: A thread of execution \( B \) thus can temporarily provide an effectively stronger forward progress guarantee for a certain amount of time, due to a second thread of execution \( A \) being blocked on it with forward progress guarantee delegation. In turn, if \( B \) then blocks with forward progress guarantee delegation on \( C \), this can also temporarily provide a stronger forward progress guarantee to \( C \). — end note]

[Note 11: If all threads of execution in \( S \) finish executing (e.g., they terminate and do not use blocking synchronization incorrectly), then \( P \)'s execution of the operation that blocks with forward progress guarantee delegation will not result in \( P \)'s progress guarantee being effectively weakened. — end note]

[Note 12: This does not remove any constraints regarding blocking synchronization for threads of execution providing parallel or weakly parallel forward progress guarantees because the implementation is not required to strengthen a particular thread of execution whose too-weak progress guarantee is preventing overall progress. — end note]

An implementation should ensure that the last value (in modification order) assigned by an atomic or synchronization operation will become visible to all other threads in a finite period of time.

\subsection{Start and termination}[basic.start]

\subsubsection{main function}[basic.start.main]

A program shall contain exactly one function called \texttt{main} that belongs to the global scope. Executing a program starts a main thread of execution (6.9.2, 32.4) in which the \texttt{main} function is invoked. It is implementation-defined whether a program in a freestanding environment is required to define a \texttt{main} function.

[Note 1: In a freestanding environment, startup and termination is implementation-defined; startup contains the execution of constructors for non-local objects with static storage duration; termination contains the execution of destructors for objects with static storage duration. — end note]

An implementation shall not predefine the \texttt{main} function. Its type shall have C++ language linkage and it shall have a declared return type of type \texttt{int}, but otherwise its type is implementation-defined. An implementation shall allow both

\begin{itemize}
  \item a function of \((\)\) returning \texttt{int} and
  \item a function of \((\texttt{int}, \texttt{pointer to pointer to char})\) returning \texttt{int}
\end{itemize}
as the type of `main` (9.3.4.6). In the latter form, for purposes of exposition, the first function parameter is called `argc` and the second function parameter is called `argv`, where `argc` shall be the number of arguments passed to the program from the environment in which the program is run. If `argc` is nonzero these arguments shall be supplied in `argv[0]` through `argv[argc-1]` as pointers to the initial characters of null-terminated multibyte strings (ntmbs) (16.3.3.5.3) and `argv[0]` shall be the pointer to the initial character of a NTMBS that represents the name used to invoke the program or `""`. The value of `argc` shall be non-negative. The value of `argv[argc]` shall be 0.

[Note 2: It is recommended that any further (optional) parameters be added after `argv`. — end note]

3 The function `main` shall not be used within a program. The linkage (6.6) of `main` is implementation-defined. A program that defines `main` as deleted or that declares `main` to be `inline`, `static`, or `constexpr` is ill-formed. The function `main` shall not be a coroutine (9.5.4). The `main` function shall not be declared with a `linkage-specification` (9.11). A program that declares a variable `main` that belongs to the global scope, or that declares a function `main` that belongs to the global scope and is attached to a named module, or that declares an entity named `main` with C language linkage (in any namespace) is ill-formed. The name `main` is not otherwise reserved.

[Example 1: Member functions, classes, and enumerations can be called `main`, as can entities in other namespaces. — end example]

4 Terminating the program without leaving the current block (e.g., by calling the function `std::exit(int)` (17.5)) does not destroy any objects with automatic storage duration (11.4.7). If `std::exit` is called to end a program during the destruction of an object with static or thread storage duration, the program has undefined behavior.

5 A `return` statement (8.7.4) in `main` has the effect of leaving the main function (destroying any objects with automatic storage duration) and calling `std::exit` with the return value as the argument. If control flows off the end of the `compound-statement` of `main`, the effect is equivalent to a `return` with operand 0 (see also 14.4).

### 6.9.3.2 Static initialization

Variables with static storage duration are initialized as a consequence of program initiation. Variables with thread storage duration are initialized as a consequence of thread execution. Within each of these phases of initiation, initialization occurs as follows.

2 Constant initialization is performed if a variable or temporary object with static or thread storage duration is constant-initialized (7.7). If constant initialization is not performed, a variable with static storage duration (6.7.5.2) or thread storage duration (6.7.5.3) is zero-initialized (9.4). Together, zero-initialization and constant initialization are called static initialization; all other initialization is dynamic initialization. All static initialization strongly happens before (6.9.2.2) any dynamic initialization.

[Note 1: The dynamic initialization of non-block variables is described in 6.9.3.3; that of block static variables is described in 8.8. — end note]

3 An implementation is permitted to perform the initialization of a variable with static or thread storage duration as a static initialization even if such initialization is not required to be done statically, provided that

1. the dynamic version of the initialization does not change the value of any other object of static or thread storage duration prior to its initialization, and
2. the static version of the initialization produces the same value in the initialized variable as would be produced by the dynamic initialization if all variables not required to be initialized statically were initialized dynamically.

[Note 2: As a consequence, if the initialization of an object `obj1` refers to an object `obj2` potentially requiring dynamic initialization and defined later in the same translation unit, it is unspecified whether the value of `obj2` used will be the value of the fully initialized `obj2` (because `obj2` was statically initialized) or will be the value of `obj2` merely zero-initialized. For example,

```cpp
inline double fd() { return 1.0; }
extern double d1;
double d2 = d1; // unspecified:
// either statically initialized to 0.0 or
// dynamically initialized to 0.0 if d1 is
// dynamically initialized, or 1.0 otherwise
double d1 = fd(); // either initialized statically or dynamically to 1.0
```
Dynamic initialization of non-block variables

1 Dynamic initialization of a non-block variable with static storage duration is unordered if the variable is an implicitly or explicitly instantiated specialization, is partially-ordered if the variable is an inline variable that is not an implicitly or explicitly instantiated specialization, and otherwise is ordered.

[Note 1: An explicitly specialized non-inline static data member or variable template specialization has ordered initialization. —end note]

2 A declaration \( D \) is appearance-ordered before a declaration \( E \) if

\begin{enumerate}
\item \( D \) appears in the same translation unit as \( E \), or
\item the translation unit containing \( E \) has an interface dependency on the translation unit containing \( D \), in either case prior to \( E \).
\end{enumerate}

3 Dynamic initialization of non-block variables \( V \) and \( W \) with static storage duration are ordered as follows:

\begin{enumerate}
\item If \( V \) and \( W \) have ordered initialization and the definition of \( V \) is appearance-ordered before the definition of \( W \), or if \( V \) has partially-ordered initialization, \( W \) does not have unordered initialization, and for every definition \( E \) of \( W \) there exists a definition \( D \) of \( V \) such that \( D \) is appearance-ordered before \( E \), then

\begin{enumerate}
\item if the program does not start a thread (6.9.2) other than the main thread (6.9.3.1) or \( V \) and \( W \) have ordered initialization and they are defined in the same translation unit, the initialization of \( V \) is sequenced before the initialization of \( W \);
\end{enumerate}

\item otherwise, the initialization of \( V \) strongly happens before the initialization of \( W \).

\end{enumerate}

\begin{enumerate}
\item Otherwise, if the program starts a thread other than the main thread before either \( V \) or \( W \) is initialized, it is unspecified in which threads the initializations of \( V \) and \( W \) occur; the initializations are unsequenced if they occur in the same thread.
\item Otherwise, the initializations of \( V \) and \( W \) are indeterminately sequenced.
\end{enumerate}

[Note 2: This definition permits initialization of a sequence of ordered variables concurrently with another sequence. —end note]

4 A non-initialization odr-use is an odr-use (6.3) not caused directly or indirectly by the initialization of a non-block static or thread storage duration variable.

5 It is implementation-defined whether the dynamic initialization of a non-block non-inline variable with static storage duration is sequenced before the first statement of \texttt{main} or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of any non-inline function or non-inline variable defined in the same translation unit as the variable to be initialized.\footnote{A non-block variable with static storage duration having initialization with side effects is initialized in this case, even if it is not itself odr-used (6.3, 6.7.5.2).} It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

Recommended practice: An implementation should choose such points in a way that allows the programmer to avoid deadlocks.

[Example 1:

\begin{verbatim}
// - File 1 -
#include "a.h"
#include "b.h"
B b;
A::A() {
  b.Use();
}

// - File 2 -
#include "a.h"
A a;

// - File 3 -
#include "a.h"
#include "b.h"
extern A a;
\end{verbatim}
extern B b;

int main()
    { 
    a.Use();
    b.Use();
    }

It is implementation-defined whether either a or b is initialized before main is entered or whether the initializations are delayed until a is first odr-used in main. In particular, if a is initialized before main is entered, it is not guaranteed that b will be initialized before it is odr-used by the initialization of a, that is, before A::A is called. If, however, a is initialized at some point after the first statement of main, b will be initialized prior to its use in A::A. — end example]

6 It is implementation-defined whether the dynamic initialization of a non-block inline variable with static storage duration is sequenced before the first statement of main or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of that variable. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

7 It is implementation-defined whether the dynamic initialization of a non-block non-inline variable with thread storage duration is sequenced before the first statement of the initial function of a thread or is deferred. If it is deferred, the initialization associated with the entity for thread t is sequenced before the first non-initialization odr-use by t of any non-inline variable with thread storage duration defined in the same translation unit as the variable to be initialized. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

8 If the initialization of a non-block variable with static or thread storage duration exits via an exception, the function std::terminate is called (14.6.2).

6.9.3.4 Termination [basic.start.term]

1 Constructed objects (9.4) with static storage duration are destroyed and functions registered with std::atexit are called as part of a call to std::exit (17.5). The call to std::exit is sequenced before the destructions and the registered functions.

[Note 1: Returning from main invokes std::exit (6.9.3.1). — end note]

2 Constructed objects with thread storage duration within a given thread are destroyed as a result of returning from the initial function of that thread and as a result of that thread calling std::exit. The destruction of all constructed objects with thread storage duration within that thread strongly happens before destroying any object with static storage duration.

3 If the completion of the constructor or dynamic initialization of an object with static storage duration strongly happens before that of another, the completion of the destructor of the second is sequenced before the initiation of the destructor of the first. If the completion of the constructor or dynamic initialization of an object with thread storage duration is sequenced before that of another, the completion of the destructor of the second is sequenced before the initiation of the destructor of the first. If an object is initialized statically, the object is destroyed in the same order as if the object was dynamically initialized. For an object of array or class type, all subobjects of that object are destroyed before any block variable with static storage duration initialized during the construction of the subobjects is destroyed. If the destruction of an object with static or thread storage duration exits via an exception, the function std::terminate is called (14.6.2).

4 If a function contains a block variable of static or thread storage duration that has been destroyed and the function is called during the destruction of an object with static or thread storage duration, the program has undefined behavior if the flow of control passes through the definition of the previously destroyed block variable.

[Note 2: Likewise, the behavior is undefined if the block variable is used indirectly (e.g., through a pointer) after its destruction. — end note]

5 If the completion of the initialization of an object with static storage duration strongly happens before a call to std::atexit (see <cstdlib>, 17.5), the call to the function passed to std::atexit is sequenced before the call to the destructor for the object. If a call to std::atexit strongly happens before the completion of the initialization of an object with static storage duration, the call to the destructor for the object is sequenced before the call to the function passed to std::atexit. If a call to std::atexit strongly happens before another call to std::atexit, the call to the function passed to the second std::atexit call is sequenced before the call to the function passed to the first std::atexit call.

§ 6.9.3.4 88
If there is a use of a standard library object or function not permitted within signal handlers (17.13) that does not happen before (6.9.2) completion of destruction of objects with static storage duration and execution of `std::atexit` registered functions (17.5), the program has undefined behavior.

[Note 3: If there is a use of an object with static storage duration that does not happen before the object’s destruction, the program has undefined behavior. Terminating every thread before a call to `std::exit` or the exit from `main` is sufficient, but not necessary, to satisfy these requirements. These requirements permit thread managers as static-storage-duration objects. — end note]

Calling the function `std::abort()` declared in `<cstdlib>` (17.2.2) terminates the program without executing any destructors and without calling the functions passed to `std::atexit()` or `std::at_quick_exit()`.
7 Expressions

7.1 Preamble

[Note 1: Clause 7 defines the syntax, order of evaluation, and meaning of expressions. An expression is a sequence of operators and operands that specifies a computation. An expression can result in a value and can cause side effects. —end note]

[Note 2: Operators can be overloaded, that is, given meaning when applied to expressions of class type (Clause 11) or enumeration type (9.7.1). Uses of overloaded operators are transformed into function calls as described in 12.4. Overloaded operators obey the rules for syntax and evaluation order specified in 7.6, but the requirements of operand type and value category are replaced by the rules for function call. Relations between operators, such as \( \texttt{++a} \) meaning \( a = a + 1 \), are not guaranteed for overloaded operators (12.4). —end note]

Subclause 7.6 defines the effects of operators when applied to types for which they have not been overloaded. Operator overloading shall not modify the rules for the built-in operators, that is, for operators applied to types for which they are defined by this Standard. However, these built-in operators participate in overload resolution, and as part of that process user-defined conversions will be considered where necessary to convert the operands to types appropriate for the built-in operator. If a built-in operator is selected, such conversions will be applied to the operands before the operation is considered further according to the rules in subclause 7.6; see 12.2.2.3, 12.5.

If during the evaluation of an expression, the result is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

[Note 3: Treatment of division by zero, forming a remainder using a zero divisor, and all floating-point exceptions varies among machines, and is sometimes adjustable by a library function. —end note]

[Note 4: The implementation can regroup operators according to the usual mathematical rules only where the operators really are associative or commutative. For example, in the following fragment

```c
int a, b;
/* ... */
    a = a + 32760 + b + 5;
```

the expression statement behaves exactly the same as

```c
    a = (((a + 32760) + b) + 5);
```

due to the associativity and precedence of these operators. Thus, the result of the sum \( a + 32760 \) is next added to \( b \), and that result is then added to 5 which results in the value assigned to \( a \). On a machine in which overflows produce an exception and in which the range of values representable by an int is \([-32768, +32767]\), the implementation cannot rewrite this expression as

```c
    a = ((a + b) + 32765);
```

since if the values for \( a \) and \( b \) were, respectively, -32754 and -15, the sum \( a + b \) would produce an exception while the original expression would not; nor can the expression be rewritten as either

```c
    a = ((a + 32765) + b);
```

or

```c
    a = (a + (b + 32765));
```

since the values for \( a \) and \( b \) might have been, respectively, 4 and -8 or -17 and 12. However on a machine in which overflows do not produce an exception and in which the results of overflows are reversible, the above expression statement can be rewritten by the implementation in any of the above ways because the same result will occur. —end note]

The values of the floating-point operands and the results of floating-point expressions may be represented in greater precision and range than that required by the type; the types are not changed thereby.

45) The precedence of operators is not directly specified, but it can be derived from the syntax.

46) Overloaded operators are never assumed to be associative or commutative.

47) The cast and assignment operators must still perform their specific conversions as described in 7.6.1.4, 7.6.3, 7.6.1.9 and 7.6.19.
7.2 Properties of expressions

7.2.1 Value category

Expressions are categorized according to the taxonomy in Figure 2.

![Expression category taxonomy](fig:basic.lval)

(1.1) — A *glvalue* is an expression whose evaluation determines the identity of an object or function.

(1.2) — A *prvalue* is an expression whose evaluation initializes an object or computes the value of an operand of an operator, as specified by the context in which it appears, or an expression that has type `cv void`.

(1.3) — An *xvalue* is a glvalue that denotes an object whose resources can be reused (usually because it is near the end of its lifetime).

(1.4) — An *lvalue* is a glvalue that is not an xvalue.

(1.5) — An *rvalue* is a prvalue or an xvalue.

Every expression belongs to exactly one of the fundamental classifications in this taxonomy: lvalue, xvalue, or prvalue. This property of an expression is called its *value category*.

[Note 1: The discussion of each built-in operator in 7.6 indicates the category of the value it yields and the value categories of the operands it expects. For example, the built-in assignment operators expect that the left operand is an lvalue and that the right operand is a prvalue and yield an lvalue as the result. User-defined operators are functions, and the categories of values they expect and yield are determined by their parameter and return types. — end note]

[Note 2: Historically, lvalues and rvalues were so-called because they could appear on the left- and right-hand side of an assignment (although this is no longer generally true); glvalues are “generalized” lvalues, prvalues are “pure” rvalues, and xvalues are “eXpiring” lvalues. Despite their names, these terms classify expressions, not values. — end note]

[Note 3: An expression is an xvalue if it is:

(4.1) — the result of calling a function, whether implicitly or explicitly, whose return type is an rvalue reference to object type (7.6.1.3),

(4.2) — a cast to an rvalue reference to object type (7.6.1.4, 7.6.1.7, 7.6.1.9 7.6.1.10, 7.6.1.11, 7.6.3),

(4.3) — a subscripting operation with an xvalue array operand (7.6.1.2),

(4.4) — a class member access expression designating a non-static data member of non-reference type in which the object expression is an xvalue (7.6.1.5), or

(4.5) — a .* pointer-to-member expression in which the first operand is an xvalue and the second operand is a pointer to data member (7.6.4).

In general, the effect of this rule is that named rvalue references are treated as lvalues and unnamed rvalue references to objects are treated as xvalues; rvalue references to functions are treated as lvalues whether named or not. — end note]

[Example 1:

```c
struct A {
    int m;
};
A&& operator+(A, A);
A&& f();
A a;
A&& ar = static_cast<A&&>(a);
```

The expressions `f()`, `f().m`, `static_cast<A&&>(a)`, and `a + a` are xvalues. The expression `ar` is an lvalue. — end example]
The result of a glvalue is the entity denoted by the expression. The result of a prvalue is the value that the expression stores into its context; a prvalue that has type cv void has no result. A prvalue whose result is the value \( V \) is sometimes said to have or name the value \( V \). The result object of a prvalue is the object initialized by the prvalue; a non-discarded prvalue that has type cv void has no result object. [Note 4: Except when the prvalue is the operand of a decltype-specifier, a prvalue of class or array type always has a result object. For a discarded prvalue that has type other than cv void, a temporary object is materialized; see 7.2.3. — end note]

Whenever a glvalue appears as an operand of an operator that expects a prvalue for that operand, the lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), or function-to-pointer (7.3.4) standard conversions are applied to convert the expression to a prvalue. [Note 5: An attempt to bind an rvalue reference to an lvalue is not such a context; see 9.4.4. — end note]

Whenever a prvalue appears as an operand of an operator that expects a glvalue for that operand, the temporary materialization conversion (7.3.5) is applied to convert the expression to an xvalue.

The discussion of reference initialization in 9.4.4 and of temporaries in 6.7.7 indicates the behavior of lvalues and rvalues in other significant contexts.

Unless otherwise indicated (9.2.9.5), a prvalue shall always have complete type or the void type; if it has a class type or (possibly multi-dimensional) array of class type, that class shall not be an abstract class (11.7.4). A glvalue shall not have type cv void.

An lvalue is modifiable unless its type is const-qualified or is a function type. [Note 9: A program that attempts to modify an object through a nonmodifiable lvalue or through an rvalue is ill-formed (7.6.19, 7.6.1.6, 7.6.2.3). — end note]

If a program attempts to access (3.1) the stored value of an object through a glvalue whose type is not similar (7.3.6) to one of the following types the behavior is undefined: 48

(11.1) — the dynamic type of the object,
(11.2) — a type that is the signed or unsigned type corresponding to the dynamic type of the object, or
(11.3) — a char, unsigned char, or std::byte type.

If a program invokes a defaulted copy/move constructor or copy/move assignment operator for a union of type \( U \) with a glvalue argument that does not denote an object of type cv \( U \) within its lifetime, the behavior is undefined. [Note 10: Unlike in C, C++ has no accesses of class type. — end note]

### 7.2.2 Type

If an expression initially has the type “reference to \( T \)” (9.3.4.3, 9.4.4), the type is adjusted to \( T \) prior to any further analysis. The expression designates the object or function denoted by the reference, and the expression is an lvalue or an xvalue, depending on the expression. [Note 1: Before the lifetime of the reference has started or after it has ended, the behavior is undefined (see 6.7.3). — end note]

If a prvalue initially has the type “cv \( T \)”, where \( T \) is a cv-qualified non-class, non-array type, the type of the expression is adjusted to \( T \) prior to any further analysis.

The composite pointer type of two operands \( p1 \) and \( p2 \) having types \( T1 \) and \( T2 \), respectively, where at least one is a pointer or pointer-to-member type or std::nullptr_t, is:

(3.1) — if both \( p1 \) and \( p2 \) are null pointer constants, std::nullptr_t;

48) The intent of this list is to specify those circumstances in which an object can or cannot be aliased.
— if either \( p_1 \) or \( p_2 \) is a null pointer constant, \( T_2 \) or \( T_1 \), respectively;
— if \( T_1 \) or \( T_2 \) is “pointer to \( cv_1 \) \( void \)” and the other type is “pointer to \( cv_2 \) \( T \)”, where \( T \) is an object type or \( void \), “pointer to \( cv_2 \) \( void \)”, where \( cv_2 \) is the union of \( cv_1 \) and \( cv_2 \);
— if \( T_1 \) or \( T_2 \) is “pointer to noexcept function” and the other type is “pointer to function”, where the function types are otherwise the same, “pointer to function”;
— if \( T_1 \) or \( T_2 \) is “pointer to \( cv_1 \) \( C_1 \)” and \( T_2 \) is “pointer to \( cv_2 \) \( C_2 \)”, where \( C_1 \) is reference-related to \( C_2 \) or \( C_2 \) is reference-related to \( C_1 \) (9.4.4), the cv-combined type (7.3.6) of \( T_1 \) and \( T_2 \) or the cv-combined type of \( T_2 \) and \( T_1 \), respectively;
— if \( T_1 \) or \( T_2 \) is “pointer to member of \( C_1 \) of type function”, the other type is “pointer to member of \( C_2 \) of type noexcept function”, and \( C_1 \) is reference-related to \( C_2 \) or \( C_2 \) is reference-related to \( C_1 \) (9.4.4), where the function types are otherwise the same, “pointer to member of \( C_2 \) of type function” or “pointer to member of \( C_1 \) of type function”, respectively;
— if \( T_1 \) is “pointer to member of \( C_1 \) of type \( cv_1 \) \( U \)” and \( T_2 \) is “pointer to member of \( C_2 \) of type \( cv_2 \) \( U \)”, for some non-function type \( U \), where \( C_1 \) is reference-related to \( C_2 \) or \( C_2 \) is reference-related to \( C_1 \) (9.4.4), the cv-combined type of \( T_2 \) and \( T_1 \) or the cv-combined type of \( T_1 \) and \( T_2 \), respectively;
— if \( T_1 \) and \( T_2 \) are similar types (7.3.6), the cv-combined type of \( T_1 \) and \( T_2 \);
— otherwise, a program that necessitates the determination of a composite pointer type is ill-formed.

[Example 1:]
```c
typedef void *p;
typedef const int *q;
typedef int **pi;
typedef const int **pci;
```

The composite pointer type of \( p \) and \( q \) is “pointer to const void”; the composite pointer type of \( pi \) and \( pci \) is “pointer to const pointer to const int”. —end example]

### 7.2.3 Context dependence [expr.context]

1 In some contexts, unevaluated operands appear (7.5.7, 7.6.1.8, 7.6.2.5, 7.6.2.7, 9.2.9.5, 13.1, 13.7.9). An unevaluated operand is not evaluated.

[Note 1: In an unevaluated operand, a non-static class member can be named (7.5.4) and naming of objects or functions does not, by itself, require that a definition be provided (6.3). An unevaluated operand is considered a full-expression (6.9.1). — end note]

2 In some contexts, an expression only appears for its side effects. Such an expression is called a discarded-value expression. The array-to-pointer (7.3.3) and function-to-pointer (7.3.4) standard conversions are not applied. The lvalue-to-rvalue conversion (7.3.2) is applied if and only if the expression is a glvalue of volatile-qualified type and it is one of the following:

- (expression ), where expression is one of these expressions,
- id-expression (7.5.4),
- subscripting (7.6.1.2),
- class member access (7.6.1.5),
- indirection (7.6.2.2),
- pointer-to-member operation (7.6.4),
- conditional expression (7.6.16) where both the second and the third operands are one of these expressions, or
- comma expression (7.6.20) where the right operand is one of these expressions.

[Note 2: Using an overloaded operator causes a function call; the above covers only operators with built-in meaning. — end note]

If the (possibly converted) expression is a prvalue, the temporary materialization conversion (7.3.5) is applied.

[Note 3: If the expression is an lvalue of class type, it must have a volatile copy constructor to initialize the temporary object that is the result object of the lvalue-to-rvalue conversion. — end note]

The glvalue expression is evaluated and its value is discarded.
7.3 Standard conversions [conv]

7.3.1 General [conv.general]

1 Standard conversions are implicit conversions with built-in meaning. 7.3 enumerates the full set of such conversions. A standard conversion sequence is a sequence of standard conversions in the following order:

1.1 — Zero or one conversion from the following set: lvalue-to-rvalue conversion, array-to-pointer conversion, and function-to-pointer conversion.

1.2 — Zero or one conversion from the following set: integral promotions, floating-point promotion, integral conversions, floating-point conversions, floating-integral conversions, pointer conversions, pointer-to-member conversions, and boolean conversions.

1.3 — Zero or one function pointer conversion.

1.4 — Zero or one qualification conversion.

[Note 1: A standard conversion sequence can be empty, i.e., it can consist of no conversions. — end note]

A standard conversion sequence will be applied to an expression if necessary to convert it to a required destination type.

2 [Note 2: Expressions with a given type will be implicitly converted to other types in several contexts:

2.1 — When used as operands of operators. The operator’s requirements for its operands dictate the destination type (7.6).

2.2 — When used in the condition of an if statement (8.5.2) or iteration statement (8.6). The destination type is bool.

2.3 — When used in the expression of a switch statement (8.5.3). The destination type is integral.

2.4 — When used as the source expression for an initialization (which includes use as an argument in a function call and use as the expression in a return statement). The type of the entity being initialized is (generally) the destination type. See 9.4, 9.4.4.

— end note]

3 An expression $E$ can be implicitly converted to a type $T$ if and only if the declaration $T t=E$; is well-formed, for some invented temporary variable $t$ (9.4).

4 Certain language constructs require that an expression be converted to a Boolean value. An expression $E$ appearing in such a context is said to be contextually converted to bool and is well-formed if and only if the declaration bool $t(E)$; is well-formed, for some invented temporary variable $t$ (9.4).

5 Certain language constructs require conversion to a value having one of a specified set of types appropriate to the construct. An expression $E$ of class type $C$ appearing in such a context is said to be contextually implicitly converted to a specified type $T$ and is well-formed if and only if $E$ can be implicitly converted to a type $T$ that is determined as follows: $C$ is searched for non-explicit conversion functions whose return type is $cvT$ or reference to $cvT$ such that $T$ is allowed by the context. There shall be exactly one such $T$.

6 The effect of any implicit conversion is the same as performing the corresponding declaration and initialization and then using the temporary variable as the result of the conversion. The result is an lvalue if $T$ is an lvalue reference type or an rvalue reference to function type (9.3.4.3), an xvalue if $T$ is an rvalue reference to object type, and a prvalue otherwise. The expression $E$ is used as a glvalue if and only if the initialization uses it as a glvalue.

7 [Note 3: For class types, user-defined conversions are considered as well; see 11.4.8. In general, an implicit conversion sequence (12.2.4.2) consists of a standard conversion sequence followed by a user-defined conversion followed by another standard conversion sequence. — end note]

8 [Note 4: There are some contexts where certain conversions are suppressed. For example, the lvalue-to-rvalue conversion is not done on the operand of the unary & operator. Specific exceptions are given in the descriptions of those operators and contexts. — end note]

7.3.2 Lvalue-to-rvalue conversion [conv.lval]

1 A glvalue (7.2.1) of a non-function, non-array type $T$ can be converted to a prvalue. If $T$ is an incomplete type, a program that necessitates this conversion is ill-formed. If $T$ is a non-class type, the type of the prvalue

---

49) For historical reasons, this conversion is called the “lvalue-to-rvalue” conversion, even though that name does not accurately reflect the taxonomy of expressions described in 7.2.1.
is the cv-unqualified version of T. Otherwise, the type of the prvalue is T.\(^{50}\)

2 When an lvalue-to-rvalue conversion is applied to an expression \(E\), and either

(2.1) \(E\) is not potentially evaluated, or

(2.2) the evaluation of \(E\) results in the evaluation of a member \(E_x\) of the set of potential results of \(E\), and \(E_x\) names a variable \(x\) that is not odr-used by \(E_x\) (6.3),

the value contained in the referenced object is not accessed.

\[\text{Example 1:}\]

```c
struct S { int n; }
auto f() {
    S x { 1 }
    constexpr S y { 2 };
    return [&](bool b) { return (b ? y : x).n; }
}
auto g = f();
int m = g(false); // undefined behavior: access of x.n outside its lifetime
int n = g(true); // OK, does not access y.n

@end example\]

3 The result of the conversion is determined according to the following rules:

(3.1) \(T\) is \(cv\ std::nullptr_t\), the result is a null pointer constant (7.3.12).

[Note 1: Since the conversion does not access the object to which the glvalue refers, there is no side effect even if \(T\) is volatile-qualified (6.9.1), and the glvalue can refer to an inactive member of a union (11.5). – end note]

(3.2) Otherwise, if \(T\) has a class type, the conversion copy-initializes the result object from the glvalue.

(3.3) Otherwise, if the object to which the glvalue refers contains an invalid pointer value (6.7.5.5.3, 6.7.5.5.4), the behavior is implementation-defined.

(3.4) Otherwise, the object indicated by the glvalue is read (3.1), and the value contained in the object is the prvalue result.

4 [Note 2: See also 7.2.1. – end note]

7.3.3 Array-to-pointer conversion \([conv.array]\)

1 An lvalue or rvalue of type “array of \(N\ T\)” or “array of unknown bound of \(T\)” can be converted to a prvalue of type “pointer to \(T\)”. The temporary materialization conversion (7.3.5) is applied. The result is a pointer to the first element of the array.

7.3.4 Function-to-pointer conversion \([conv.func]\)

1 An lvalue of function type \(T\) can be converted to a prvalue of type “pointer to \(T\)”. The result is a pointer to the function.\(^{51}\)

7.3.5 Temporary materialization conversion \([conv.rval]\)

1 A prvalue of type \(T\) can be converted to an xvalue of type \(T\). This conversion initializes a temporary object (6.7.7) of type \(T\) from the prvalue by evaluating the prvalue with the temporary object as its result object, and produces an xvalue denoting the temporary object. \(T\) shall be a complete type.

[Note 1: If \(T\) is a class type (or array thereof), it must have an accessible and non-deleted destructor; see 11.4.7. – end note]

[Example 1:]

```c
struct X { int n; }
int k = X().n; // OK, X() prvalue is converted to xvalue

@end example\]

---

50) In C++ class and array prvalues can have cv-qualified types. This differs from ISO C, in which non-lvalues never have cv-qualified types.

51) This conversion never applies to non-static member functions because an lvalue that refers to a non-static member function cannot be obtained.
7.3.6 Qualification conversions

A *cv-decomposition* of a type \( T \) is a sequence of \( cv_i \) and \( P_i \) such that \( T \) is

\[
"cv_0\ P_0\ cv_1\ P_1\ \ldots\ cv_{n-1}\ P_{n-1}\ cv_n\ U"
\]

where each \( cv_i \) is a set of cv-qualifiers (6.8.4), and each \( P_i \) is “pointer to” (9.3.4.2), “pointer to member of class \( C_i \) of type” (9.3.4.4), “array of \( N_i \)”, or “array of unknown bound of” (9.3.4.5). If \( P_i \) designates an array, the cv-qualifiers \( cv_{i+1} \) on the element type are also taken as the cv-qualifiers \( cv_i \) of the array.

Example 1: The type denoted by the type-id `const int **` has three cv-decompositions, taking \( U \) as “int”, as “pointer to `const int`”, and as “pointer to pointer to `const int`”. — end example

The \( n \)-tuple of cv-qualifiers after the first one in the longest cv-decomposition of \( T \), that is, \( cv_1, cv_2, \ldots, cv_n \), is called the *cv-qualification signature* of \( T \).

Two types \( T_1 \) and \( T_2 \) are similar if they have cv-decompositions with the same \( n \) such that corresponding \( P_i \) components are either the same or one is “array of \( N_i \)” and the other is “array of unknown bound of”, and the types denoted by \( U \) are the same.

The *cv-combined type* of two types \( T_1 \) and \( T_2 \) is the type \( T_3 \) similar to \( T_1 \) whose cv-decomposition is such that:

\[
\begin{align*}
(3.1) & \quad \text{for each } i > 0, \ cv^k_i \text{ is the union of } cv^1_i \text{ and } cv^2_i, \\
(3.2) & \quad \text{if either } P^1_i \text{ or } P^2_i \text{ is "array of unknown bound of"}, \ P^3_i \text{ is "array of unknown bound of"}, \text{ otherwise it is } P^i_1, \text{ and} \\
(3.3) & \quad \text{if the resulting } cv^3_i \text{ is different from } cv^1_i \text{ or } cv^2_i, \text{ or the resulting } P^3_i \text{ is different from } P^1_i \text{ or } P^2_i, \text{ then } \text{const is added to every } cv^k_i \text{ for } 0 < k < i, \\
\end{align*}
\]

where \( cv^1_i \) and \( P^1_i \) are the components of the cv-decomposition of \( T_j \). A prvalue of type \( T_1 \) can be converted to type \( T_2 \) if the cv-combined type of \( T_1 \) and \( T_2 \) is \( T_3 \).

Note 1: If a program could assign a pointer of type \( T^{**} \) to a pointer of type `const T^{**}` (that is, if line \#1 below were allowed), a program could inadvertently modify a const object (as it is done on line \#2). For example,

```c
int main() {
  const char c = 'c';
  char* pc;
  const char** pcc = &pc; // #1: not allowed
  *pcc = &c;
  *pc = 'C'; // #2: modifies a const object
}
```

[Note 2: Given similar types \( T_1 \) and \( T_2 \), this construction ensures that both can be converted to the cv-combined type of \( T_1 \) and \( T_2 \). — end note]

4 Note 3: A prvalue of type “pointer to `cv1 T`” can be converted to a prvalue of type “pointer to `cv2 T`” if “`cv2 T`” is more cv-qualified than “`cv1 T`”. A prvalue of type “pointer to member of \( X \) of type `cv1 T`” can be converted to a prvalue of type “pointer to member of \( X \) of type `cv2 T`” if “`cv2 T`” is more cv-qualified than “`cv1 T`”. — end note]

5 Note 4: Function types (including those used in pointer-to-member-function types) are never cv-qualified (9.3.4.6). — end note]

7.3.7 Integral promotions

A prvalue of an integer type other than \( \text{bool, char16_t, char32_t, or wchar_t} \) whose integer conversion rank (6.8.5) is less than the rank of \( \text{int} \) can be converted to a prvalue of type \( \text{int} \) if \( \text{int} \) can represent all the values of the source type; otherwise, the source prvalue can be converted to a prvalue of type \( \text{unsigned int} \).

A prvalue of type \( \text{char16_t, char32_t, or wchar_t} \) can be converted to a prvalue of the first of the following types that can represent all the values of its underlying type: \( \text{int, unsigned int, long int, unsigned long int, long long int, or unsigned long long int} \). If none of the types in that list can represent all the values of its underlying type, a prvalue of type \( \text{char16_t, char32_t, or wchar_t} \) can be converted to a prvalue of its underlying type.

A prvalue of an unscoped enumeration type whose underlying type is not fixed can be converted to a prvalue of the first of the following types that can represent all the values of the enumeration (9.7.1): \( \text{int, unsigned int, long int, unsigned long int, long long int, or unsigned long long int} \). If none of the types in that list can represent all the values of the enumeration, a prvalue of an unscoped enumeration type can be...
converted to a prvalue of the extended integer type with lowest integer conversion rank (6.8.5) greater than
the rank of \texttt{long long} in which all the values of the enumeration can be represented. If there are two such
extended types, the signed one is chosen.

4 A prvalue of an unscoped enumeration type whose underlying type is fixed (9.7.1) can be converted to a
prvalue of its underlying type. Moreover, if integral promotion can be applied to its underlying type, a
prvalue of an unscoped enumeration type whose underlying type is fixed can also be converted to a prvalue
of the promoted underlying type.

5 A prvalue for an integral bit-field (11.4.10) can be converted to a prvalue of type \texttt{int} if \texttt{int} can represent all
the values of the bit-field; otherwise, it can be converted to \texttt{unsigned int} if \texttt{unsigned int} can represent all
the values of the bit-field. If the bit-field is larger yet, no integral promotion applies to it. If the bit-field has
an enumerated type, it is treated as any other value of that type for promotion purposes.

6 A prvalue of type \texttt{bool} can be converted to a prvalue of type \texttt{int}, with \texttt{false} becoming zero and \texttt{true}
becoming one.

7 These conversions are called \textit{integral promotions}.

7.3.8 Floating-point promotion \hfill [conv.fpprom]

1 A prvalue of type \texttt{float} can be converted to a prvalue of type \texttt{double}. The value is unchanged.

2 This conversion is called \textit{floating-point promotion}.

7.3.9 Integral conversions \hfill [conv.integral]

1 A prvalue of an integer type can be converted to a prvalue of another integer type. A prvalue of an unscoped
enumeration type can be converted to a prvalue of an integer type.

2 If the destination type is \texttt{bool}, see 7.3.15. If the source type is \texttt{bool}, the value \texttt{false} is converted to zero
and the value \texttt{true} is converted to one.

3 Otherwise, the result is the unique value of the destination type that is congruent to the source integer
modulo $2^N$, where $N$ is the width of the destination type.

4 The conversions allowed as integral promotions are excluded from the set of integral conversions.

7.3.10 Floating-point conversions \hfill [conv.double]

1 A prvalue of floating-point type can be converted to a prvalue of another floating-point type. If the
source value can be exactly represented in the destination type, the result of the conversion is that exact
representation. If the source value is between two adjacent destination values, the result of the conversion is
an implementation-defined choice of either of those values. Otherwise, the behavior is undefined.

2 The conversions allowed as floating-point promotions are excluded from the set of floating-point conversions.

7.3.11 Floating-integral conversions \hfill [conv.fpint]

1 A prvalue of a floating-point type can be converted to a prvalue of an integer type. The conversion truncates;
that is, the fractional part is discarded. The behavior is undefined if the truncated value cannot be represented
in the destination type.

[\textit{Note 1:} If the destination type is \texttt{bool}, see 7.3.15. — end note]

2 A prvalue of an integer type or of an unscoped enumeration type can be converted to a prvalue of a floating-
point type. The result is exact if possible. If the value being converted is in the range of values that can be
represented but the value cannot be represented exactly, it is an implementation-defined choice of either the
next lower or higher representable value.

[\textit{Note 2:} Loss of precision occurs if the integral value cannot be represented exactly as a value of the floating-point
type. — end note]

If the value being converted is outside the range of values that can be represented, the behavior is undefined.
If the source type is \texttt{bool}, the value \texttt{false} is converted to zero and the value \texttt{true} is converted to one.

7.3.12 Pointer conversions \hfill [conv.ptr]

1 A \textit{null pointer constant} is an integer literal (5.13.2) with value zero or a prvalue of type \texttt{std::nullptr_t}. A
null pointer constant can be converted to a pointer type; the result is the null pointer value of that type (6.8.3)
and is distinguishable from every other value of object pointer or function pointer type. Such a conversion
is called a \textit{null pointer conversion}. Two null pointer values of the same type shall compare equal. The
conversion of a null pointer constant to a pointer to cv-qualified type is a single conversion, and not the sequence of a pointer conversion followed by a qualification conversion (7.3.6). A null pointer constant of integral type can be converted to a prvalue of type `std::nullptr_t`.

[Note 1: The resulting prvalue is not a null pointer value. — end note]

2 A prvalue of type “pointer to cv T”, where T is an object type, can be converted to a prvalue of type “pointer to cv void”. The pointer value (6.8.3) is unchanged by this conversion.

3 A prvalue of type “pointer to cv D”, where D is a complete class type, can be converted to a prvalue of type “pointer to cv B”, where B is a base class (11.7) of D. If B is an inaccessible (11.8) or ambiguous (6.5.2) base class of D, a program that necessitates this conversion is ill-formed. The result of the conversion is a pointer to the base class subobject of the derived class object. The null pointer value is converted to the null pointer value of the destination type.

7.3.13 Pointer-to-member conversions

1 A null pointer constant (7.3.12) can be converted to a pointer-to-member type; the result is the null member pointer value of that type and is distinguishable from any pointer to member not created from a null pointer constant. Such a conversion is called a null member pointer conversion. Two null member pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to member of cv-qualified type is a single conversion, and not the sequence of a pointer-to-member conversion followed by a qualification conversion (7.3.6).

2 A prvalue of type “pointer to member of B of type cv T”, where B is a class type, can be converted to a prvalue of type “pointer to member of cv D”, where D is a complete class derived (11.7) from B. If B is an inaccessible (11.8), ambiguous (6.5.2), or virtual (11.7.2) base class of D, or a base class of a virtual base class of D, a program that necessitates this conversion is ill-formed. The result of the conversion refers to the same member as the pointer to member before the conversion took place, but it refers to the base class member as if it were a member of the derived class. The result refers to the member in D’s instance of B. Since the result has type “pointer to member of D of type cv T”, indirectation through it with a D object is valid. The result is the same as if indirecting through the pointer to member of B with the B subobject of D. The null member pointer value is converted to the null member pointer value of the destination type.52

7.3.14 Function pointer conversions

1 A prvalue of type “pointer to noexcept function” can be converted to a prvalue of type “pointer to function”. The result is a pointer to the function. A prvalue of type “pointer to member of type noexcept function” can be converted to a prvalue of type “pointer to member of type function”. The result designates the member function.

[Example 1:

```c
void (*p)();
void (**pp)() noexcept = &p;  // error: cannot convert to pointer to noexcept function

struct S { typedef void (*p)(); operator p(); float p; }
void (*q)() noexcept = &S();  // error: cannot convert to pointer to noexcept function

— end example]
```

7.3.15 Boolean conversions

1 A prvalue of arithmetic, unscoped enumeration, pointer, or pointer-to-type type can be converted to a prvalue of type `bool`. A zero value, null pointer value, or null member pointer value is converted to `false`; any other value is converted to `true`.

7.4 Usual arithmetic conversions

1 Many binary operators that expect operands of arithmetic or enumeration type cause conversions and yield result types in a similar way. The purpose is to yield a common type, which is also the type of the result. This pattern is called the usual arithmetic conversions, which are defined as follows:

52) The rule for conversion of pointers to members (from pointer to member of base to pointer to member of derived) appears inverted compared to the rule for pointers to objects (from pointer to derived to pointer to base) (7.3.12, 11.7). This inversion is necessary to ensure type safety. Note that a pointer to member is not an object pointer or a function pointer and the rules for conversions of such pointers do not apply to pointers to members. In particular, a pointer to member cannot be converted to a `void*`.
If either operand is of scoped enumeration type (9.7.1), no conversions are performed; if the other operand does not have the same type, the expression is ill-formed.

If either operand is of type `long double`, the other shall be converted to `long double`.

Otherwise, if either operand is `double`, the other shall be converted to `double`.

Otherwise, if either operand is `float`, the other shall be converted to `float`.

Otherwise, the integral promotions (7.3.7) shall be performed on both operands. Then the following rules shall be applied to the promoted operands:

- If both operands have the same type, no further conversion is needed.
- Otherwise, if both operands have signed integer types or both have unsigned integer types, the operand with the type of lesser integer conversion rank shall be converted to the type of the operand with greater rank.
- Otherwise, if the operand that has unsigned integer type has rank greater than or equal to the rank of the type of the other operand, the operand with signed integer type shall be converted to the type of the operand with unsigned integer type.
- Otherwise, if the type of the operand with signed integer type can represent all of the values of the type of the operand with unsigned integer type, the operand with unsigned integer type shall be converted to the type of the operand with signed integer type.
- Otherwise, both operands shall be converted to the unsigned integer type corresponding to the type of the operand with signed integer type.

If one operand is of enumeration type and the other operand is of a different enumeration type or a floating-point type, this behavior is deprecated (D.2).

## 7.5 Primary expressions

A primary expression is a literal or an expression that can be evaluated directly without further computation. The type of a primary expression is determined based on its form as specified in 5.13. A string-literal is an lvalue, a user-defined-literal has the same value category as the corresponding operator call expression described in 5.13.8, and any other literal is a prvalue.

The keyword this names a pointer to the object for which a non-static member function (11.4.3) is invoked or a non-static data member’s initializer (11.4) is evaluated.

The current class at a program point is the class associated with the innermost class scope containing that point.

If a declaration declares a member function or member function template of a class `X`, the expression this is a prvalue of type “pointer to cv-qualifier-seq X” wherever `X` is the current class between the optional cv-qualifier-seq and the end of the function-definition, member-declarator, or declarator. It shall not appear within the declaration of a static member function of the current class (although its type and value category are defined within a static member function as they are within a non-static member function).

If a declaration declares a member function or member function template of a class `X`, the expression this is a prvalue of type “pointer to cv-qualifier-seq X” wherever `X` is the current class between the optional cv-qualifier-seq and the end of the function-definition, member-declarator, or declarator. It shall not appear within the declaration of a static member function of the current class (although its type and value category are defined within a static member function as they are within a non-static member function).

[Note 2: This is because declaration matching does not occur until the complete declarator is known. — end note]

[Note 3: In a trailing-return-type, the class being defined is not required to be complete for purposes of class member access (7.6.1.5). Class members declared later are not visible.

---

53) As a consequence, operands of type `bool`, `char8_t`, `char16_t`, `char32_t`, `wchar_t`, or an enumerated type are converted to some integral type.
[Example 1:
struct A {
  char g();
  template<class T> auto f(T t) -> decltype(t + g())
  { return t + g(); }
};
template auto A::f(int t) -> decltype(t + g());
— end example]
— end note]

4 Otherwise, if a member-declarator declares a non-static data member (11.4) of a class X, the expression this is a prvalue of type “pointer to X” wherever X is the current class within the optional default member initializer (11.4).

5 The expression this shall not appear in any other context.

[Example 2:
class Outer {
  int a[sizeof(*this)]; // error: not inside a member function
  unsigned int sz = sizeof(*this); // OK: in default member initializer
  void f() {
    int b[sizeof(*this)]; // OK
    struct Inner {
      int c[sizeof(*this)]; // error: not inside a member function of Inner
    };
  }
};
— end example]

7.5.3 Parentheses 
A parenthesized expression (E) is a primary expression whose type, result, and value category are identical to those of E. The parenthesized expression can be used in exactly the same contexts as those where E can be used, and with the same meaning, except as otherwise indicated.

7.5.4 Names
7.5.4.1 General

id-expression:
  unqualified-id
  qualified-id

1 An id-expression is a restricted form of a primary-expression.
[Note 1: An id-expression can appear after . and -> operators (7.6.1.5). — end note]

2 If an id-expression E denotes a member M of an anonymous union (11.5.2) U:
(2.1) — If U is a non-static data member, E refers to M as a member of the lookup context of the terminal name of E (after any transformation to a class member access expression (11.4.3)).
[Example 1: o.x is interpreted as o.u.x, where u names the anonymous union member. — end example]
(2.2) — Otherwise, E is interpreted as a class member access (7.6.1.5) that designates the member subobject M of the anonymous union variable for U.
[Note 2: Under this interpretation, E no longer denotes a non-static data member. — end note]
[Example 2: N::x is interpreted as N::u.x, where u names the anonymous union variable. — end example]

3 An id-expression that denotes a non-static data member or non-static member function of a class can only be used:
(3.1) — as part of a class member access (7.6.1.5) in which the object expression refers to the member’s class or a class derived from that class, or

54) This also applies when the object expression is an implicit (*this) (11.4.3).
(3.2) — to form a pointer to member (7.6.2.2), or
(3.3) — if that id-expression denotes a non-static data member and it appears in an unevaluated operand.

[Example 3:

```c
struct S {
    int m;
};
int i = sizeof(S::m); // OK
int j = sizeof(S::m + 42); // OK
```
—end example]

A potentially-evaluated id-expression that denotes an immediate function (9.2.6) shall appear only
(4.1) — as a subexpression of an immediate invocation, or
(4.2) — in an immediate function context (7.7).

For an id-expression that denotes an overload set, overload resolution is performed to select a unique function (12.2, 12.3).

[Note 3: A program cannot refer to a function with a trailing requires-clause whose constraint-expression is not satisfied, because such functions are never selected by overload resolution.

[Example 4:

```c
template<typename T> struct A {
    static void f(int) requires false;
};

void g() {
    A<int>::f(0); // error: cannot call f
    void (*p1)(int) = A<int>::f; // error: cannot take the address of f
    decltype(A<int>::f)* p2 = nullptr; // error: the type decltype(A<int>::f) is invalid
}
```
In each case, the constraints of f are not satisfied. In the declaration of p2, those constraints are required to be satisfied even though f is an unevaluated operand (7.2). —end example]
—end note]

7.5.4.2 Unqualified names

unqualified-id:

identifier
operator-function-id
conversion-function-id
literal-operator-id
~ type-name
~ decltype-specifier
template-id

1 An identifier is only an id-expression if it has been suitably declared (Clause 9) or if it appears as part of a declarator-id (9.3). An identifier that names a coroutine parameter refers to the copy of the parameter (9.5.4).

[Note 1: For operator-function-ids, see 12.4; for conversion-function-ids, see 11.4.8.3; for literal-operator-ids, see 12.6; for template-ids, see 13.3. A type-name or decltype-specifier prefixed by ~ denotes the destructor of the type so named; see 7.5.4.4. Within the definition of a non-static member function, an identifier that names a non-static member is transformed to a class member access expression (11.4.3). —end note]

2 A component name of an unqualified-id U is

(2.1) — U if it is a name or
(2.2) — the component name of the template-id or type-name of U, if any.

[Note 2: Other constructs that contain names to look up can have several component names (7.5.4.3, 9.2.9.3, 9.2.9.4, 9.3.4.4, 9.9, 13.2, 13.3, 13.8). —end note]

The terminal name of a construct is the component name of that construct that appears lexically last.

3 The result is the entity denoted by the unqualified-id (6.5.3). If the entity is a local entity and naming it from outside of an unevaluated operand within the scope where the unqualified-id appears would result in some intervening lambda-expression capturing it by copy (7.5.5.3), the type of the expression is the type of a class

§ 7.5.4.2
member access expression (7.6.1.5) naming the non-static data member that would be declared for such a capture in the closure object of the innermost such intervening lambda-expression.

[Note 3: If that lambda-expression is not declared mutable, the type of such an identifier will typically be const qualified. — end note]

Otherwise, the type of the expression is the type of the result.

[Note 4: If the entity is a template parameter object for a template parameter of type T (13.2), the type of the expression is const T. — end note]

The expression is an lvalue if the entity is a function, variable, structured binding (9.6), data member, or template parameter object and a prvalue otherwise (7.2.1); it is a bit-field if the identifier designates a bit-field.

[Example 1:

```c
void f() {
    float x, &r = x;
    [=] {
        decltype(x) y1; // y1 has type float
        decltype((x)) y2 = y1; // y2 has type float const because this lambda
                           // is not mutable and x is an lvalue
        decltype(r) r1 = y1; // r1 has type float
        decltype((r)) r2 = y2; // r2 has type float const
    };
}
@end example]

7.5.4.3 Qualified names

qualified-id:
    nested-name-specifier template_opt unqualified-id

nested-name-specifier:
    ::
      type-name ::
      namespace-name ::
      decltype-specifier ::
      nested-name-specifier identifier ::
      nested-name-specifier template_opt simple-template-id ::

1 The component names of a qualified-id are those of its nested-name-specifier and unqualified-id. The component names of a nested-name-specifier are its identifier (if any) and those of its type-name, namespace-name, simple-template-id, and/or nested-name-specifier.

2 A nested-name-specifier is declarative if it is part of
(2.1) — a class-head-name,
(2.2) — an enum-head-name,
(2.3) — a qualified-id that is the id-expression of a declarator-id, or
(2.4) — a declarative nested-name-specifier.

A declarative nested-name-specifier shall not have a decltype-specifier. A declaration that uses a declarative nested-name-specifier shall be a friend declaration or inhabit a scope that contains the entity being redeclared or specialized.

3 The nested-name-specifier :: nominates the global namespace. A nested-name-specifier with a decltype-specifier nominates the type denoted by the decltype-specifier, which shall be a class or enumeration type. If a nested-name-specifier N is declarative and has a simple-template-id with a template argument list A that involves a template parameter, let T be the template nominated by N without A. T shall be a class template.
(3.1) — If A is the template argument list (13.4) of the corresponding template-head H (13.7.3), N nominates the primary template of T; H shall be equivalent to the template-head of T (13.7.7.2).
(3.2) — Otherwise, N nominates the partial specialization (13.7.6) of T whose template argument list is equivalent to A (13.7.7.2); the program is ill-formed if no such partial specialization exists.
Any other nested-name-specifier nominates the entity denoted by its type-name, namespace-name, identifier, or simple-template-id. If the nested-name-specifier is not declarative, the entity shall not be a template.

A qualified-id shall not be of the form nested-name-specifier templateopt - decltype-specifier nor of the form decltype-specifier :: - type-name.

The result of a qualified-id is the entity it denotes (6.5.5). The type of the expression is the type of the result. The result is an lvalue if the member is a function, a variable, a structured binding (9.6), a static member function, or a data member, and a prvalue otherwise.

7.5.4.4 Destruction

An id-expression that denotes the destructor of a type T names the destructor of T if T is a class type (11.4.7), otherwise the id-expression is said to name a pseudo-destructor.

If the id-expression names a pseudo-destructor, T shall be a scalar type and the id-expression shall appear as the right operand of a class member access (7.6.1.5) that forms the postfix-expression of a function call (7.6.1.3).

[Note 1: Such a call ends the lifetime of the object (7.6.1.3, 6.7.3). — end note]

[Example 1:

```cpp
struct C {
};
void f() {
    C * pc = new C;
    using C2 = C;
    pc->C::~C2(); // OK, destroys *pc
    C().C::~C(); // undefined behavior: temporary of type C destroyed twice
    using T = int;
    0.T::~T();    // OK, no effect
    0.T::~T();    // error: 0.T is a user-defined-floating-point-literal (5.13.8)
}
```
— end example]

7.5.5 Lambda expressions

7.5.5.1 General

A lambda-expression provides a concise way to create a simple function object.

[Example 1:

```cpp
#include <algorithm>
#include <cmath>
void absaort(float* x, unsigned N) {
    std::sort(x, x + N, [](float a, float b) { return std::abs(a) < std::abs(b); });
}
```
— end example]

A lambda-expression is a prvalue whose result object is called the closure object.

[Note 1: A closure object behaves like a function object (20.14). — end note]

In the decl-specifier-seq of the lambda-declarator, each decl-specifier shall be one of mutable, constexpr, or consteval.

[Note 2: The trailing requires-clause is described in 9.3. — end note]
If a lambda-expression includes an empty lambda-declarator, it is as if the lambda-declarator were (). The lambda return type is auto, which is replaced by the type specified by the trailing-return-type if provided and/or deduced from return statements as described in 9.2.9.6.

[Example 2:
  auto x1 = [](int i) { return i; };  // OK: return type is int
  auto x2 = []( { return { 1, 2 }; };  // error: deducing return type from braced-init-list
  int j;
  auto x3 = []( )->auto& { return j; };  // OK: return type is int&
  —end example]

5 A lambda is a generic lambda if the lambda-expression has any generic parameter type placeholders (9.2.9.6), or if the lambda has a template-parameter-list.

[Example 3:
  int i = [](int i, auto a) { return i; }(3, 4);  // OK: a generic lambda
  int j = [](class T>(T t, int i) { return i; }(3, 4);  // OK: a generic lambda
  —end example]

7.5.5.2 Closure types

1 The type of a lambda-expression (which is also the type of the closure object) is a unique, unnamed non-union class type, called the closure type, whose properties are described below.

2 The closure type is declared in the smallest block scope, class scope, or namespace scope that contains the corresponding lambda-expression.

[Note 1: This determines the set of namespaces and classes associated with the closure type (6.5.4). The parameter types of a lambda-declarator do not affect these associated namespaces and classes. —end note]

The closure type is not an aggregate type (9.4.2). An implementation may define the closure type differently from what is described below provided this does not alter the observable behavior of the program other than by changing:

— the size and/or alignment of the closure type,
— whether the closure type is trivially copyable (11.2), or
— whether the closure type is a standard-layout class (11.2).

An implementation shall not add members of rvalue reference type to the closure type.

3 The closure type for a lambda-expression has a public inline function call operator (for a non-generic lambda) or function call operator template (for a generic lambda) (12.4.4) whose parameters and return type are described by the lambda-expression’s parameter-declaration-clause and trailing-return-type respectively, and whose template-parameter-list consists of the specified template-parameter-list, if any. The requires-clause of the function call operator template is the requires-clause immediately following <template-parameter-list>, if any. The trailing requires-clause of the function call operator or operator template is the requires-clause of the lambda-declarator, if any.

[Note 2: The function call operator template for a generic lambda can be an abbreviated function template (9.3.4.6). —end note]

[Example 1:
  auto glambda = [](auto a, auto&& b) { return a < b; };  // OK
  bool b = glambda(3, 3.14);

  auto vglambda = [](auto printer) {
    return [=](auto&& ... ts) {
      // OK: ts is a function parameter pack
      printer(std::forward<decltype(ts)>(ts)...);
      return [=]() {
        printer(ts ...);
      }();
    };
  auto p = vglambda( [](auto v1, auto v2, auto v3) {
    std::cout << v1 << v2 << v3; } );
  auto q = p(1, 'a', 3.14);  // OK: outputs 1a3.14
  —end example]
The function call operator or operator template is declared `const` (11.4.3) if and only if the lambda-expression’s parameter-declaration-clause is not followed by `mutable`. It is neither virtual nor declared `volatile`. Any `noexcept-specifier` specified on a lambda-expression applies to the corresponding function call operator or operator template. An `attribute-specifier-seq` in a lambda-declarator appertains to the type of the corresponding function call operator or operator template. The function call operator or any given operator template specialization is a constexpr function if either the corresponding lambda-expression’s parameter-declaration-clause is followed by `constexpr` or `consteval`, or it satisfies the requirements for a constexpr function (9.2.6). It is an immediate function (9.2.6) if the corresponding lambda-expression’s parameter-declaration-clause is followed by `consteval`.

[Example 2:

```cpp
auto ID = [](auto a) { return a; };
static_assert(ID(3) == 3); // OK

struct NonLiteral {
  NonLiteral(int n) : n(n) {};
  int n;
};
static_assert(ID(NonLiteral{3}).n == 3); // error
```
---

[Example 3:

```cpp
auto monoid = [] (auto v) { return [=] { return v; }; };
auto add = [] (auto m1) constexpr {
  auto ret = m1();
  return [=] (auto m2) mutable {
    auto m1val = m1();
    auto plus = [=] (auto m2val) mutable constexpr {
      return m1val += m2val;
    };
    ret = plus(m2());
    return monoid(ret);
  };
};
constexpr auto zero = monoid(0);
constexpr auto one = monoid(1);
static_assert(add(one)(zero)() == one()); // OK

// Since two below is not declared constexpr, an evaluation of its constexpr member function call operator // cannot perform an lvalue-to-rvalue conversion on one of its subobjects (that represents its capture) // in a constant expression.
auto two = monoid(2);
assert(two() == 2); // OK, not a constant expression.
static_assert(add(one)(one)() == two()); // error: two() is not a constant expression
static_assert(add(one)(one)() == monoid(2)()); // OK
---

[Note 3: The function call operator or operator template can be constrained (13.5.3) by a type-constraint (13.2), a requires-clause (13.1), or a trailing requires-clause (9.3).]

[Example 4:

```cpp
template <typename T> concept C1 = /* ... */;
template <std::size_t N> concept C2 = /* ... */;
template <typename A, typename B> concept C3 = /* ... */;

auto f = []<typename T1, T2> requires C2<sizeof(T1) + sizeof(T2)>
( T1 a1, T1 b1, T2 a2, auto a3, auto a4) requires C3<decltype(a4), T2> {
  // T2 is constrained by a type-constraint.
  // T1 and T2 are constrained by a requires-clause, and
  // T2 and the type of a4 are constrained by a trailing requires-clause.
};
```

The closure type for a non-generic $\text{lambda-expression}$ with no $\text{lambda-capture}$ whose constraints (if any) are satisfied has a conversion function to pointer to function with C++ language linkage (9.11) having the same parameter and return types as the closure type’s function call operator. The conversion is to “pointer to noexcept function” if the function call operator has a non-throwing exception specification. The value returned by this conversion function is the address of a function $F$ that, when invoked, has the same effect as invoking the closure type’s function call operator on a default-constructed instance of the closure type. $F$ is a constexpr function if the function call operator is a constexpr function and is an immediate function if the function call operator is an immediate function.

For a generic lambda with no $\text{lambda-capture}$, the closure type has a conversion function template to pointer to function. The conversion function template has the same invented template parameter list, and the pointer to function has the same parameter types, as the function call operator template. The return type of the function to pointer shall behave as if it were a $\text{decltype-specifier}$ denoting the return type of the corresponding function call operator template specialization.

[Note 4: If the generic lambda has no trailing-return-type or the trailing-return-type contains a placeholder type, return type deduction of the corresponding function call operator template specialization has to be done. The corresponding specialization is that instantiation of the function call operator template with the same template arguments as those deduced for the conversion function template. Consider the following:

```c++
auto glambda = [](auto a) { return a; };
int (*fp)(int) = glambda;
```

The behavior of the conversion function of $\text{glambda}$ above is like that of the following conversion function:

```c++
struct Closure {
  template<class T> auto operator()(T t) const { /* ... */ }
  template<class T> static auto lambda_call_operator_invoker(T a) {
    // forwards execution to operator()(a) and therefore has
    // the same return type deduced
    /* ... */
  }
  template<class T> using fptr_t = decltype(lambda_call_operator_invoker(declval<T>())) (*)(T);

  template<class T> operator fptr_t<T>() const { return &lambda_call_operator_invoker; }
};
```

[Example 5:]

```c++
void f1(int (*)(int)) { }
void f2(char (*)(int)) { }

void g(int (*)(int)) { }  // #1
void g(char (*)(char)) { }  // #2

void h(int (*)(int)) { }  // #3
void h(char (*)(int)) { }  // #4

auto glambda = [](auto a) { return a; };

f1(glambda);               // OK
f2(glambda);                // error: ID is not convertible
g(glambda);                 // error: ambiguous
h(glambda);                 // OK: calls #3 since it is convertible from ID
int* (*fpi)(int*) = [](auto* a) -> auto* { return *a; };     // OK
```

The value returned by any given specialization of this conversion function template is the address of a function $F$ that, when invoked, has the same effect as invoking the generic lambda’s corresponding function call operator template specialization on a default-constructed instance of the closure type. $F$ is a constexpr function.
function if the corresponding specialization is a constexpr function and \(F\) is an immediate function if the
function call operator template specialization is an immediate function.

[Note 5: This will result in the implicit instantiation of the generic lambda's body. The instantiated generic lambda's
return type and parameter types are required to match the return type and parameter types of the pointer to function.
—end note]

[Example 6:]
```cpp
auto GL = [](auto a) { std::cout << a; return a; };
int (*GL_int)(int) = GL;  // OK: through conversion function template
GL_int(3);                // OK: same as GL(3)
```

—end example

11 The conversion function or conversion function template is public, constexpr, non-virtual, non-explicit, const,
and has a non-throwing exception specification (14.5).

[Example 7:]
```cpp
auto Fwd = [](int (*fp)(int), auto a) { return fp(a); };
auto C = [](auto a) { return a; };
static_assert(Fwd(C,3) == 3);  // OK
// No specialization of the function call operator template can be constexpr (due to the local static).
auto NC = [](auto a) { static int s; return a; };
static_assert(Fwd(NC,3) == 3);  // error
```
—end example

12 The lambda-expression's compound-statement yields the function-body (9.5) of the function call operator, but
it is not within the scope of the closure type.

[Example 8:]
```cpp
struct S1 {
  int x, y;
  int operator()(int);
  void f() {  
    [=](int) -> int {  
      return operator()(this->x + y);  // equivalent to S1::operator()(this->x + (*this).y)  
      // this has type S1*
    }
  };
};
```
—end example

Further, a variable `__func__` is implicitly defined at the beginning of the compound-statement of the
lambda-expression, with semantics as described in 9.5.1.

13 The closure type associated with a lambda-expression has no default constructor if the lambda-expression has
a lambda-capture and a defaulted default constructor otherwise. It has a defaulted copy constructor and a
defaulted move constructor (11.4.5.3). It has a deleted copy assignment operator if the lambda-expression has
a lambda-capture and defaulted copy and move assignment operators otherwise (11.4.6).

[Note 6: These special member functions are implicitly defined as usual, which can result in them being defined as
deleted. —end note]

14 The closure type associated with a lambda-expression has an implicitly-declared destructor (11.4.7).
15 A member of a closure type shall not be explicitly instantiated (13.9.3), explicitly specialized (13.9.4), or
named in a friend declaration (11.8.4).

7.5.5.3 Captures

```cpp
lambda-capture:
  capture-default
  capture-list
  capture-default , capture-list
```
The body of a lambda-expression may refer to local entities of enclosing block scopes by capturing those entities, as described below.

If a lambda-capture includes a capture-default that is &, no identifier in a simple-capture of that lambda-capture shall be preceded by &. If a lambda-capture includes a capture-default that is =, each simple-capture of that lambda-capture shall be of the form "& identifier ...opt", "this", or "* this".

Note 1: The form [&, this] is redundant but accepted for compatibility with ISO C++ 2014. —end note

Ignoring appearances in initializers of init-captures, an identifier or this shall not appear more than once in a lambda-capture.

Example 1:

```c++
struct S2 { void f(int i); }

void S2::f(int i) {
    [&, i]{};      // OK
    [&, this, i]{}; // OK, equivalent to [&, i]
    [&, &i]{};     // error: i preceded by & when & is the default
    [=, *this]{};  // OK
    [=, this]{};   // OK, equivalent to [=]
    [i, i]{};      // error: i repeated
    [this, *this]{};  // error: this appears twice
}
```

End example]

A lambda-expression shall not have a capture-default or simple-capture in its lambda-introducer unless its innermost enclosing scope is a block scope (6.4.3) or it appears within a default member initializer and its innermost enclosing scope is the corresponding class scope (6.4.6).

The identifier in a simple-capture shall denote a local entity (6.5.3). The simple-captures this and * this denote the local entity *this. An entity that is designated by a simple-capture is said to be explicitly captured.

If an identifier in a simple-capture appears as the declarator-id of a parameter of the lambda-declarator’s parameter-declaration-clause, the program is ill-formed.

Example 2:

```c++
void f() {
    int x = 0;
    auto g = [x](int x) { return 0; };    // error: parameter and simple-capture have the same name
}
```

End example]

An init-capture inhabits the scope of the lambda-expression’s compound-statement. An init-capture without ellipsis behaves as if it declares and explicitly captures a variable of the form “auto init-capture ;”, except that:
(6.1) — if the capture is by copy (see below), the non-static data member declared for the capture and the variable are treated as two different ways of referring to the same object, which has the lifetime of the non-static data member, and no additional copy and destruction is performed, and

(6.2) — if the capture is by reference, the variable’s lifetime ends when the closure object’s lifetime ends.

[Note 2: This enables an \textit{init-capture} like “\texttt{x = std::move(x)}”; the second “\texttt{x}” must bind to a declaration in the surrounding context. — end note]

\texttt{Example 3:}

\begin{verbatim}
int x = 4;
auto y = [&r = x, x = x+1]()\to int {
  r += 2;
  return x+2;
}(); // Updates \texttt{x} to 6, and initializes \texttt{y} to 7.

auto z = [a = 42](int a) { return 1; }; // error: parameter and local variable have the same name
\end{verbatim}

— end example

7 For the purposes of lambda capture, an expression potentially references local entities as follows:

(7.1) — An id-expression that names a local entity potentially references that entity; an id-expression that names one or more non-static class members and does not form a pointer to member (7.6.2.2) potentially references \texttt{*this}.

[Note 3: This occurs even if overload resolution selects a static member function for the id-expression. — end note]

(7.2) — A this expression potentially references \texttt{*this}.

(7.3) — A lambda-expression potentially references the local entities named by its simple-captures.

If an expression potentially references a local entity within a scope in which it is odr-usable, and the expression would be potentially evaluated if the effect of any enclosing \texttt{typeid} expressions (7.6.1.8) were ignored, the entity is said to be \textit{implicitly captured} by each intervening lambda-expression with an associated capture-default that does not explicitly capture it. The implicit capture of \texttt{*this} is deprecated when the capture-default is \texttt{=}; see D.3.

\texttt{Example 4:}

\begin{verbatim}
void f(int, const int (&)[2] = {}); // #1
void f(const int &k, const int (&)[1]); // #2
void test() {
  const int x = 17;
  auto g = [](auto a) {
    f(x); // OK: calls #1, does not capture x
  };

  auto g1 = [=](auto a) {
    f(x); // OK: calls #1, captures x
  };

  auto g2 = [=](auto a) {
    int selector[sizeof(a) == 1 ? 1 : 2]{};
    f(x, selector); // OK: captures x, can call #1 or #2
  };

  auto g3 = [=](auto a) {
    typeid(a + x); // captures x regardless of whether a + x is an unevaluated operand
  };
}
\end{verbatim}

Within \texttt{g1}, an implementation can optimize away the capture of \texttt{x} as it is not odr-used. — end example

[Note 4: The set of captured entities is determined syntactically, and entities are implicitly captured even if the expression denoting a local entity is within a discarded statement (8.5.2).

\texttt{Example 5:}
template<bool B>
void f(int n) { 
  [=](auto a) { 
    if constexpr (B && sizeof(a) > 4) { 
      (void)n; // captures n regardless of the value of B and sizeof(int) 
    }
  }(0);
}
— end example]
— end note]

8 An entity is captured if it is captured explicitly or implicitly. An entity captured by a lambda-expression is odr-used (6.3) by the lambda-expression.

[Note 5: As a consequence, if a lambda-expression explicitly captures an entity that is not odr-usable, the program is ill-formed (6.3). — end note]

[Example 6:
void f1(int i) {
  int const N = 20;
  auto m1 = [=] {
    int const M = 30;
    auto m2 = [i] {
      int x[N][M];
      x[0][0] = i;
    };
  };  
  struct s1 { 
    int f;
    void work(int n) {
      int m = n*n;
      int j = 40;
      auto m3 = [this, m] { 
        auto m4 = [&j] { 
          int x = n;
          x += m;
          x += i;
          x += f;
        };
      };
    }
  };
  struct s2 { 
    double ohseven = .007;
    auto f() { 
      return [this] { 
        return [*this] { 
          return ohseven;
        };
      }();
    }
    auto g() { 
      return [] { 
        return [*this] { 
          }();
      };
    }
  };
}

— end example]

9 [Note 6: Because local entities are not odr-usable within a default argument (6.3), a lambda-expression appearing in a default argument cannot implicitly or explicitly capture any local entity. Such a lambda-expression can still have

§ 7.5.5.3
an init-capture if any full-expression in its initializer satisfies the constraints of an expression appearing in a default argument (9.3.4.7). — end note]

[Example 7:

```c
void f2() {
    int i = 1;
    void g1(int = (\{i\}{ return i; })()); // error
    void g2(int = (\{return 0;\})()); // error
    void g3(int = (\{i\}{ return i; })()); // error
    void g4(int = (\{return 0;\})()); // OK
    void g5(int = (\{return sizeof i;\})()); // OK
    void g6(int = (\{x=i\}{ return x; })()); // OK
    void g7(int = (\{x=1\}{ return x; })()); // error
}
— end example]

10 An entity is captured by copy if

(10.1) — it is implicitly captured, the capture-default is =, and the captured entity is not *this, or

(10.2) — it is explicitly captured with a capture that is not of the form this, &identifier, or &identifier initializer.

For each entity captured by copy, an unnamed non-static data member is declared in the closure type. The declaration order of these members is unspecified. The type of such a data member is the referenced type if the entity is a reference to an object, an lvalue reference to the referenced function type if the entity is a reference to a function, or the type of the corresponding captured entity otherwise. A member of an anonymous union shall not be captured by copy.

11 Every id-expression within the compound-statement of a lambda-expression that is an odr-use (6.3) of an entity captured by copy is transformed into an access to the corresponding unnamed data member of the closure type.

[Note 7: An id-expression that is not an odr-use refers to the original entity, never to a member of the closure type. However, such an id-expression can still cause the implicit capture of the entity. — end note]

If *this is captured by copy, each expression that odr-uses *this is transformed to instead refer to the corresponding unnamed data member of the closure type.

[Example 8:

```c
void f(const int*);
void g() {
    const int N = 10;
    [=] {
        int arr[N]; // OK: not an odr-use, refers to automatic variable
        f(&N); // OK: causes N to be captured; &N points to
        // the corresponding member of the closure type
    };
}
— end example]

12 An entity is captured by reference if it is implicitly or explicitly captured but not captured by copy. It is unspecified whether additional unnamed non-static data members are declared in the closure type for entities captured by reference. If declared, such non-static data members shall be of literal type.

[Example 9:

```c
// The inner closure type must be a literal type regardless of how reference captures are represented.
static_assert([](int n) { return [&n] { return ++n; }(); })(3) == 4);
— end example]

A bit-field or a member of an anonymous union shall not be captured by reference.

13 An id-expression within the compound-statement of a lambda-expression that is an odr-use of a reference captured by reference refers to the entity to which the captured reference is bound and not to the captured reference.

[Note 8: The validity of such captures is determined by the lifetime of the object to which the reference refers, not by the lifetime of the reference itself. — end note]

[Example 10:
auto h(int &r) {
  return [&] {
    ++r;  // Valid after h returns if the lifetime of the
    // object to which r is bound has not ended
  };
}
—end example]

14 If a lambda-expression \( m_2 \) captures an entity and that entity is captured by an immediately enclosing
lambda-expression \( m_1 \), then \( m_2 \)'s capture is transformed as follows:

(14.1) — if \( m_1 \) captures the entity by copy, \( m_2 \) captures the corresponding non-static data member of \( m_1 \)'s closure
type;

(14.2) — if \( m_1 \) captures the entity by reference, \( m_2 \) captures the same entity captured by
\( m_1 \).

[Example 11: The nested lambda-expressions and invocations below will output 123234.

```cpp
int a = 1, b = 1, c = 1;
auto m1 = [a, &b, &c]() mutable {
  auto m2 = [a, b, &c]() mutable {
    std::cout << a << b << c;
    a = 4; b = 4; c = 4;
  };
  a = 3; b = 3; c = 3;
  m2();
};
a = 2; b = 2; c = 2;
m1();
std::cout << a << b << c;
—end example]

15 When the lambda-expression is evaluated, the entities that are captured by copy are used to direct-initialize
each corresponding non-static data member of the resulting closure object, and the non-static data members
corresponding to the init-captures are initialized as indicated by the corresponding initializer (which may be
copy- or direct-initialization). (For array members, the array elements are direct-initialized in increasing
subscript order.) These initializations are performed in the (unspecified) order in which the non-static data
members are declared.

[Note 9: This ensures that the destructions will occur in the reverse order of the constructions. — end note]

16 [Note 10: If a non-reference entity is implicitly or explicitly captured by reference, invoking the function call operator
of the corresponding lambda-expression after the lifetime of the entity has ended is likely to result in undefined behavior.
— end note]

17 A simple-capture containing an ellipsis is a pack expansion (13.7.4). An init-capture containing an ellipsis is a
pack expansion that declares an init-capture pack (13.7.4).

[Example 12:

```cpp
template<class... Args>
void f(Args... args) {
  auto lm = [&] { return g(args...); };
  lm();

  auto lm2 = [...xs=std::move(args)] { return g(xs...); };
  lm2();
}
—end example]

7.5.6 Fold expressions

1 A fold expression performs a fold of a pack (13.7.4) over a binary operator.

fold-expression:
  ( cast-expression fold-operator ... )
  ( ... fold-operator cast-expression )
  ( cast-expression fold-operator ... fold-operator cast-expression )
fold-operator: one of
+ - * / % ^ & | << >>
+= -= *= /= %= ^= &= |= <<= >>= =
== != < > <= >= && || , .* ->*

An expression of the form \((\ldots \text{op} \ e)\) where \text{op} is a fold-operator is called a \textit{unary left fold}. An expression of the form \((e \text{op} \ldots)\) where \text{op} is a fold-operator is called a \textit{unary right fold}. Unary left folds and unary right folds are collectively called \textit{unary folds}. In a unary fold, the \textit{cast-expression} shall contain an unexpanded pack (13.7.4).

An expression of the form \((e_1 \text{op}_1 \ldots \text{op}_2 e_2)\) where \text{op}_1 and \text{op}_2 are fold-operators is called a \textit{binary fold}. In a binary fold, \text{op}_1 and \text{op}_2 shall be the same fold-operator, and either \(e_1\) shall contain an unexpanded pack or \(e_2\) shall contain an unexpanded pack, but not both. If \(e_2\) contains an unexpanded pack, the expression is called a \textit{binary left fold}. If \(e_1\) contains an unexpanded pack, the expression is called a \textit{binary right fold}.

\[\text{Example 1:}\]
\[
\text{template<typename }...\text{Args}> \\
\text{bool f(Args }...\text{args)} \{ \\
\text{ \ \ \ return (true }&& \ldots \text{ }&& \text{args); // OK} \}
\]
\[
\text{template<typename }...\text{Args}> \\
\text{bool f(Args }...\text{args)} \{ \\
\text{ \ \ \ return (args + }\ldots \text{ + args); // error: both operands contain unexpanded packs} \}
\]
—end example—

7.5.7 Requires expressions [expr.prim.req]
7.5.7.1 General [expr.prim.req.general]

A \textit{requires-expression} provides a concise way to express requirements on template arguments that can be checked by name lookup (6.5) or by checking properties of types and expressions.

\begin{verbatim}
\begin{verbatim}
\textit{requires-expression} : \textit{requires requirement-parameter-list_opt requirement-body}
\textit{requirement-parameter-list} : \{( parameter-declaration-clause )
\textit{requirement-body} : \{
\textit{requirement-seq}
\textit{requirement-seq} : \textit{requirement} \textit{requirement-seq requirement}
\textit{requirement} : \textit{simple(requirement}\textit{type-requirement}\textit{compound-requirement}\textit{nested-requirement}
\end{verbatim}
\end{verbatim}

A \textit{requires-expression} is a prvalue of type \texttt{bool} whose value is described below. Expressions appearing within a \textit{requirement-body} are unevaluated operands (7.2).

\[\text{Example 1:}\] A common use of \textit{requires-expressions} is to define requirements in concepts such as the one below:

\[
\text{template<typename }T\text{>}
\text{concept }R = \text{requires } (T i) \{ \\
\text{ \ \ typedef typename }\text{::type;} \\
\text{ \ \ \ \ }\text{::convertible_to<const typename }T::\text{::type&>>; \\
\text{ \ \ }\};
\]

A \textit{requires-expression} can also be used in a \textit{requires-clause} (13.1) as a way of writing ad hoc constraints on template arguments such as the one below:

\[
\text{template<typename }T\text{>}
\text{requires requires } (T x) \{ x + x; \}
\text{T add(T a, T b) }\{ \text{return a }+ \text{b; }\}
\]
The first `requires` introduces the `requires-clause`, and the second introduces the `requires-expression`. — end example]

A `requires-expression` may introduce local parameters using a `parameter-declaration-clause` (9.3.4.6). A local parameter of a `requires-expression` shall not have a default argument. These parameters have no linkage, storage, or lifetime; they are only used as notation for the purpose of defining `requirements`. The `parameter-declaration-clause` of a `requirement-parameter-list` shall not terminate with an ellipsis.

```cpp
Example 2:

template<typename T>
concept C = requires(T t, ...) { // error: terminates with an ellipsis
t;
};
end example]
```

The substitution of template arguments into a `requires-expression` may result in the formation of invalid types or expressions in its `requirements` or the violation of the semantic constraints of those `requirements`. In such cases, the `requires-expression` evaluates to `false`; it does not cause the program to be ill-formed. The substitution and semantic constraint checking proceeds in lexical order and stops when a condition that determines the result of the `requires-expression` is encountered. If substitution (if any) and semantic constraint checking succeed, the `requires-expression` evaluates to `true`.

[Note 1: If a `requires-expression` contains invalid types or expressions in its `requirements`, and it does not appear within the declaration of a templated entity, then the program is ill-formed. — end note]

If the substitution of template arguments into a `requirement` would always result in a substitution failure, the program is ill-formed; no diagnostic required.

```cpp
Example 3:

template<typename T> concept C =
requires {
new int[-(int)sizeof(T)];   // ill-formed, no diagnostic required
};
end example]
```

### 7.5.7.2 Simple requirements

#### simple-requirement

- expression ;

A `simple-requirement` asserts the validity of an `expression`.

[Note 1: The enclosing `requires-expression` will evaluate to `false` if substitution of template arguments into the `expression` fails. The `expression` is an unevaluated operand (7.2). — end note]

```cpp
Example 1:

template<typename T> concept C =
requires (T a, T b) {
a + b;   // C<T> is true if a + b is a valid expression
};
end example]
```

A `requirement` that starts with a `requires` token is never interpreted as a `simple-requirement`.

[Note 2: This simplifies distinguishing between a `simple-requirement` and a `nested-requirement`. — end note]

### 7.5.7.3 Type requirements

#### type-requirement

- typename nested-name-specifier_opt type-name ;

A `type-requirement` asserts the validity of a type.

[Note 1: The enclosing `requires-expression` will evaluate to `false` if substitution of template arguments fails. — end note]

```cpp
Example 1:

template<typename T, typename T::type = 0> struct S;
template<typename T> using Ref = T&;
```
template<typename T> concept C = requires {
    typename T::inner; // required nested member name
    typename S<T>;     // required valid (13.3) template-id;
    typename Ref<T>;   // required alias template substitution, fails if T is void
};

—end example]

2 A type-requirement that names a class template specialization does not require that type to be complete (6.8).

7.5.7.4 Compound requirements [expr.prim.req.compound]

    compound-requirement:
      { expression } noexcept_opt return-type-requirement_opt;
    return-type-requirement:
      -> type-constraint

1 A compound-requirement asserts properties of the expression E. Substitution of template arguments (if any) and verification of semantic properties proceed in the following order:

(1.1) — Substitution of template arguments (if any) into the expression is performed.

(1.2) — If the noexcept specifier is present, E shall not be a potentially-throwing expression (14.5).

(1.3) — If the return-type-requirement is present, then:

(1.3.1) — Substitution of template arguments (if any) into the return-type-requirement is performed.

(1.3.2) — The immediately-declared constraint (13.2) of the type-constraint for decltype((E)) shall be satisfied.

[Example 1: Given concepts C and D,

    requires {
      { E1 } -> C;
      { E2 } -> D<A1, ⋯, An>;
    };

    is equivalent to

    requires {
      E1; requires C<decltype((E1))>;
      E2; requires D<decltype((E2)), A1, ⋯, An>;
    };

    (including in the case where n is zero). —end example]

2 [Example 2:

    template<typename T> concept C1 = requires(T x) {
      {x++};
    };

    The compound-requirement in C1 requires that x++ is a valid expression. It is equivalent to the simple-requirement x++;

    template<typename T> concept C2 = requires(T x) {
      {*x} -> std::same_as<typename T::inner>;
    };

    The compound-requirement in C2 requires that *x is a valid expression, that typename T::inner is a valid type, and that std::same_as<decltype(*x)), typename T::inner> is satisfied.

    template<typename T> concept C3 =
      requires(T x) {
        {g(x)} noexcept;
      };

    The compound-requirement in C3 requires that g(x) is a valid expression and that g(x) is non-throwing. —end example]

7.5.7.5 Nested requirements [expr.prim.req.nested]

    nested-requirement:
      requires constraint-expression ;
A nested-requirement can be used to specify additional constraints in terms of local parameters. The constraint-expression shall be satisfied (13.5.3) by the substituted template arguments, if any. Substitution of template arguments into a nested-requirement does not result in substitution into the constraint-expression other than as specified in 13.5.2.

[Example 1:

```cpp
template<typename U> concept C = sizeof(U) == 1;

template<typename T> concept D = requires (T t) {
  requires C<decltype (+t)>;
};
```

D<T> is satisfied if sizeof(decltype (+t)) == 1 (13.5.2.3). — end example]

A local parameter shall only appear as an unevaluated operand (7.2) within the constraint-expression.

[Example 2:

```cpp
template<typename T> concept C = requires (T a) {
  requires sizeof(a) == 4; // OK
  requires a == 0; // error: evaluation of a constraint variable
};
```

— end example]

### 7.6 Compound expressions

#### 7.6.1 Postfix expressions

##### 7.6.1.1 General

Postfix expressions group left-to-right.

Note 1: The > token following the type-id in a dynamic_cast, static_cast, reinterpret_cast, or const_cast can be the product of replacing a >> token by two consecutive > tokens (13.3). — end note]

### 7.6.1.2 Subscripting

A postfix expression followed by an expression in square brackets is a postfix expression. One of the expressions shall be a glvalue of type “array of T” or a prvalue of type “pointer to T” and the other shall be a prvalue of unscoped enumeration or integral type. The result is of type “T”. The type “T” shall be a completely-defined object type.55 The expression E1[E2] is identical (by definition) to *(E1)+(E2)), except that in the case of an array operand, the result is an lvalue if that operand is an lvalue and an xvalue otherwise. The expression E1 is sequenced before the expression E2.

A comma expression (7.6.20) appearing as the expr-or-braced-init-list of a subscripting expression is deprecated; see D.4.

55) This is true even if the subscript operator is used in the following common idiom: k[x][0].
A braced-init-list shall not be used with the built-in subscript operator.

### 7.6.1.3 Function call

A function call is a postfix expression followed by parentheses containing a possibly empty, comma-separated list of `initializer-clauses` which constitute the arguments to the function.

[Note 1: If the postfix expression is a function or member function name, the appropriate function and the validity of the call are determined according to the rules in 12.2. — end note]

The postfix expression shall have function type or function pointer type. For a call to a non-member function or to a static member function, the postfix expression shall either be an lvalue that refers to a function (in which case the function-to-pointer standard conversion (7.3.4) is suppressed on the postfix expression), or have function pointer type.

For a call to a non-static member function, the postfix expression shall be an implicit (11.4.3, 11.4.9) or explicit class member access (7.6.1.5) whose `id-expression` is a function member name, or a pointer-to-member expression (7.6.4) selecting a function member; the call is as a member of the class object referred to by the object expression. In the case of an implicit class member access, the implied object is the one pointed to by this.

[Note 2: A member function call of the form `f()` is interpreted as `(*this).f()` (see 11.4.3). — end note]

If the selected function is non-virtual, or if the `id-expression` in the class member access expression is a qualified-id, that function is called. Otherwise, its final overrider (11.7.3) in the dynamic type of the object expression is called; such a call is referred to as a virtual function call.

[Note 3: The dynamic type is the type of the object referred to by the current value of the object expression. 11.9.5 describes the behavior of virtual function calls when the object expression refers to an object under construction or destruction. — end note]

If the `postfix-expression` names a destructor or pseudo-destructor (7.5.4.4), the type of the function call expression is `void`; otherwise, the type of the function call expression is the return type of the statically chosen function (i.e., ignoring the `virtual` keyword), even if the type of the function actually called is different. If the `postfix-expression` names a pseudo-destructor (in which case the `postfix-expression` is a possibly-parenthesized class member access), the function call destroys the object of scalar type denoted by the object expression of the class member access (7.6.1.5, 6.7.3).

Calling a function through an expression whose function type is different from the function type of the called function’s definition results in undefined behavior.

When a function is called, each parameter (9.3.4.6) is initialized (9.4, 11.4.5.3) with its corresponding argument. If there is no corresponding argument, the default argument for the parameter is used.

[Example 1:]
```cpp
template<typename ...T> int f(int n = 0, T ...t);
int x = f<int>();  // error: no argument for second function parameter
```

If the function is a non-static member function, the `this` parameter of the function (7.5.2) is initialized with a pointer to the object of the call, converted as if by an explicit type conversion (7.6.3).

[Note 5: There is no access or ambiguity checking on this conversion; the access checking and disambiguation are done as part of the (possibly implicit) class member access operator. See 6.5.2, 11.8.3, and 7.6.1.5. — end note]

When a function is called, the type of any parameter shall not be a class type that is either incomplete or abstract.

[Note 6: This still allows a parameter to be a pointer or reference to such a type. However, it prevents a passed-by-value parameter to have an incomplete or abstract class type. — end note]

It is implementation-defined whether the lifetime of a parameter ends when the function in which it is defined returns or at the end of the enclosing full-expression. The initialization and destruction of each parameter occurs within the context of the calling function.
The postfix-expression is sequenced before each expression in the expression-list and any default argument. The initialization of a parameter, including every associated value computation and side effect, is indeterminately sequenced with respect to that of any other parameter.

Example 3:
```cpp
void f() {
    std::string s = "but I have heard it works even if you don't believe in it";
    s.replace(0, 4, "") .replace(s.find("even"), 4, "only") .replace(s.find(" don't"), 6, "");
    assert(s == "I have heard it works only if you believe in it");    // OK
}
```
—end example]

Note 7: All side effects of argument evaluations are sequenced before the function is entered (see 6.9.1). — end note]

Example 4:
```cpp
struct S {
    S(int);
};
int operator<<(S, int);
int i, j;
int x = S(i=1) << (i=2);
int y = operator<<(S(j=1), j=2);
```
After performing the initializations, the value of \texttt{i} is 2 (see 7.6.7), but it is unspecified whether the value of \texttt{j} is 1 or 2. — end example]

The result of a function call is the result of the possibly-converted operand of the return statement (8.7.4) that transferred control out of the called function (if any), except in a virtual function call if the return type of the final overrider is different from the return type of the statically chosen function.

Note 9: A function can change the values of its non-const parameters, but these changes cannot affect the values of the arguments except where a parameter is of a reference type (9.3.4.3); if the reference is to a const-qualified type, const_cast is required to be used to cast away the constness in order to modify the argument’s value. Where a parameter is of const reference type a temporary object is introduced if needed (9.2.9, 5.13, 5.13.5, 9.3.4.5, 6.7.7). In addition, it is possible to modify the values of non-constant objects through pointer parameters. — end note]

A function can be declared to accept fewer arguments (by declaring default arguments (9.3.4.7)) or more arguments (by using the ellipsis, ..., or a function parameter pack (9.3.4.6)) than the number of parameters in the function definition (9.5).

Note 10: This implies that, except where the ellipsis (...) or a function parameter pack is used, a parameter is available for each argument. — end note]

When there is no parameter for a given argument, the argument is passed in such a way that the receiving function can obtain the value of the argument by invoking va_arg (17.13).

Note 11: This paragraph does not apply to arguments passed to a function parameter pack. Function parameter packs are expanded during template instantiation (13.7.4), thus each such argument has a corresponding parameter when a function template specialization is actually called. — end note]

The lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the argument expression. An argument that has type cv std::nullptr_t is converted to type void* (7.3.12). After these conversions, if the argument does not have arithmetic, enumeration, pointer, pointer-to-member, or class type, the program is ill-formed. Passing a potentially-evaluated argument of a scoped enumeration type or of a class type (Clause 11) having an eligible non-trivial copy constructor, an eligible non-trivial move constructor, or a non-trivial destructor (11.4.4), with no corresponding parameter, is conditionally-supported with implementation-defined semantics. If the argument has integral or enumeration type that is subject to the integral promotions (7.3.7), or a floating-point type that is subject to the floating-point promotion (7.3.8), the value of the argument is converted to the promoted type before the call. These promotions are referred to as the default argument promotions.
Recursive calls are permitted, except to the `main` function (6.9.3.1).

A function call is an lvalue if the result type is an lvalue reference type or an rvalue reference to function type, an xvalue if the result type is an rvalue reference to object type, and a prvalue otherwise.

### 7.6.1.4 Explicit type conversion (functional notation) [expr.type.conv]

1. A `simple-type-specifier` (9.2.9.3) or `typename-specifier` (13.8) followed by a parenthesized optional `expression-list` or by a `braced-init-list` (the initializer) constructs a value of the specified type given the initializer. If the type is a placeholder for a deduced class type, it is replaced by the return type of the function selected by overload resolution for class template deduction (12.2.2.9) for the remainder of this subclause.

2. If the initializer is a parenthesized single expression, the type conversion expression is equivalent to the corresponding cast expression (7.6.3). Otherwise, if the type is `cv void` and the initializer is `()` or `{}` (after pack expansion, if any), the expression is a prvalue of type `void` that performs no initialization. Otherwise, the expression is a prvalue of the specified type whose result object is direct-initialized (9.4) with the initializer. If the initializer is a parenthesized optional `expression-list`, the specified type shall not be an array type.

### 7.6.1.5 Class member access [expr.ref]

1. A postfix expression followed by a `.` or an arrow `->`, optionally followed by an `id-expression`, is a postfix expression. The postfix expression before the dot or arrow is evaluated.\(^{56}\) The result of that evaluation, together with the `id-expression`, determines the result of the entire postfix expression.

   [Note 1: If the keyword `template` is used, the following unqualified name is considered to refer to a template (13.3). If a `simple-template-id` results and is followed by a `::`, the `id-expression` is a `qualified-id`. — end note]

2. For the first option (dot) the first expression shall be a glvalue. For the second option (arrow) the first expression shall be a prvalue having pointer type. The expression `E1->E2` is evaluated; the expression designates the corresponding member subobject of the object designated by the first expression. If the expression is of scalar type, `E2` shall name the pseudo-destructor of that same type (ignoring cv-qualifications) as `E1`. Otherwise, `E1.E2` is an lvalue of type “function of () returning `void`”.

   [Note 2: This value can only be used for a notional function call (7.5.4.4). — end note]

3. Abbreviating `postfix-expression.id-expression` as `E1.E2`, `E1` is called the `object expression`. If the object expression is of scalar type, `E2` shall name the pseudo-destructor of that same type (ignoring cv-qualifications) and `E1.E2` is an lvalue of type “function of () returning `void`”.

   [Note 3: The program is ill-formed if the result differs from that when the class is complete (6.5.2). — end note]

   [Note 4: 6.5.5 describes how names are looked up after the `.` and `->` operators. — end note]

5. If `E2` is a bit-field, `E1.E2` is a bit-field. The type and value category of `E1.E2` are determined as follows. In the remainder of 7.6.1.5, `cq` represents either `const` or the absence of `const` and `vq` represents either `volatile` or the absence of `volatile`. `cv` represents an arbitrary set of cv-qualifiers, as defined in 6.8.4.

6. If `E2` is declared to have type “reference to `T`”, then `E1.E2` is an lvalue; the type of `E1.E2` is `T`. Otherwise, one of the following rules applies.

   6.1. If `E2` is a static data member and the type of `E2` is `T`, then `E1.E2` is an lvalue; the expression designates the named member of the class. The type of `E1.E2` is `T`.

   6.2. If `E2` is a non-static data member and the type of `E1` is “`cq1 vq1 X`”, and the type of `E2` is “`cq2 vq2 T`”, the expression designates the corresponding member subobject of the object designated by the first expression. If `E1` is an lvalue, then `E1.E2` is an lvalue; otherwise `E1.E2` is an xvalue. Let the notation `vq12` stand for the “union” of `vq1` and `vq2`; that is, if `vq1` or `vq2` is `volatile`, then `vq12` is `volatile`. Similarly, let the notation `cq12` stand for the “union” of `cq1` and `cq2`; that is, if `cq1` or `cq2` is `const`, then `cq12` is `const`. If `E2` is declared to be a `mutable` member, then the type of `E1.E2` is “`vq12 T`”. If `E2` is not declared to be a `mutable` member, then the type of `E1.E2` is “`cq12 vq12 T`”.

   6.3. If `E2` is an overload set, function overload resolution (12.2) is used to select the function to which `E2` refers. The type of `E1.E2` is the type of `E2` and `E1.E2` refers to the function referred to by `E2`.

   6.3.1. If `E2` refers to a static member function, `E1.E2` is an lvalue.

---

\(^{56}\) If the class member access expression is evaluated, the subexpression evaluation happens even if the result is unnecessary to determine the value of the entire postfix expression, for example if the `id-expression` denotes a static member.

\(^{57}\) Note that `(E1)` is an lvalue.
Otherwise (when \( E2 \) refers to a non-static member function), \( E1.E2 \) is a prvalue. The expression can be used only as the left-hand operand of a member function call (11.4.2).

\[ \text{Note 5: Any redundant set of parentheses surrounding the expression is ignored (7.5.3).} \] — end note

If \( E2 \) is a nested type, the expression \( E1.E2 \) is ill-formed.

If \( E2 \) is a member enumerator and the type of \( E2 \) is \( T \), the expression \( E1.E2 \) is a prvalue. The type of \( E1.E2 \) is \( T \).

7. If \( E2 \) is a non-static data member or a non-static member function, the program is ill-formed if the class of which \( E2 \) is directly a member is an ambiguous base (6.5.2) of the naming class (11.8.3) of \( E2 \).

\[ \text{Note 6: The program is also ill-formed if the naming class is an ambiguous base of the class type of the object expression; see 11.8.3.} \] — end note

7.6.1.6 Increment and decrement \[ \text{expr.post.incr} \]

1 The value of a postfix \( ++ \) expression is the value of its operand.

\[ \text{Note 1: The value obtained is a copy of the original value.} \] — end note

The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than \( cv\)\(bool\), or a pointer to a complete object type. An operand with volatile-qualified type is deprecated; see D.6. The value of the operand object is modified (3.1) by adding 1 to it. The value computation of the \( ++ \) expression is sequenced before the modification of the operand object. With respect to an indeterminately-sequenced function call, the operation of postfix \( ++ \) is a single evaluation.

\[ \text{Note 2: Therefore, a function call cannot intervene between the lvalue-to-rvalue conversion and the side effect associated with any single postfix \( ++ \) operator.} \] — end note

The result is a prvalue. The type of the result is the cv-unqualified version of the type of the operand. If the operand is a bit-field that cannot represent the incremented value, the resulting value of the bit-field is implementation-defined. See also 7.6.6 and 7.6.19.

2 The operand of postfix \( -- \) is decremented analogously to the postfix \( ++ \) operator.

\[ \text{Note 3: For prefix increment and decrement, see 7.6.2.3.} \] — end note

7.6.1.7 Dynamic cast \[ \text{expr.dynamic.cast} \]

1 The result of the expression \( \text{dynamic\_cast<T>}(v) \) is the result of converting the expression \( v \) to type \( T \). \( T \) shall be a pointer or reference to a complete class type, or “pointer to \( cv\)\(void\)”. The \( \text{dynamic\_cast} \) operator shall not cast away constness (7.6.1.11).

2 If \( T \) is a pointer type, \( v \) shall be a prvalue of a pointer to complete class type, and the result is a prvalue of type \( T \). If \( T \) is an lvalue reference type, \( v \) shall be an lvalue of a complete class type, and the result is an lvalue of the type referred to by \( T \). If \( T \) is an rvalue reference type, \( v \) shall be a glvalue having a complete class type, and the result is an xvalue of the type referred to by \( T \).

3 If the type of \( v \) is the same as \( T \) (ignoring cv-qualifications), the result is \( v \) (converted if necessary).

4 If \( T \) is “pointer to \( cv1\)\(B\)” and \( v \) has type “pointer to \( cv2\)\(D\)” such that \( B \) is a base class of \( D \), the result is a pointer to the unique \( B \) subobject of the \( D \) object pointed to by \( v \), or a null pointer value if \( v \) is a null pointer value. Similarly, if \( T \) is “reference to \( cv1\)\(B\)” and \( v \) has type “\( cv2\)\(D\)” such that \( B \) is a base class of \( D \), the result is the unique \( B \) subobject of the \( D \) object referred to by \( v \).58 In both the pointer and reference cases, the program is ill-formed if \( B \) is an inaccessible or ambiguous base class of \( D \).

\[ \text{Example 1:} \]

\begin{verbatim}
struct B { }
struct D : B { }
void foo(D* dp) {
    B* bp = dynamic_cast<B*>(dp);  // equivalent to B* bp = dp;
}
\end{verbatim}

— end example

5 Otherwise, \( v \) shall be a pointer to or a glvalue of a polymorphic type (11.7.3).

6 If \( v \) is a null pointer value, the result is a null pointer value.

58) The most derived object (6.7.2) pointed or referred to by \( v \) can contain other \( B \) objects as base classes, but these are ignored.
If \( T \) is “pointer to \( cv \ void \)”, then the result is a pointer to the most derived object pointed to by \( v \). Otherwise, a runtime check is applied to see if the object pointed or referred to by \( v \) can be converted to the type pointed or referred to by \( T \).

If \( C \) is the class type to which \( T \) points or refers, the runtime check logically executes as follows:

(8.1) If, in the most derived object pointed (referred) to by \( v \), \( v \) points (refers) to a public base class subobject of a \( C \) object, and if only one object of type \( C \) is derived from the subobject pointed (referred) to by \( v \) the result points (refers) to that \( C \) object.

(8.2) Otherwise, if \( v \) points (refers) to a public base class subobject of the most derived object, and the type of the most derived object has a base class, of type \( C \), that is unambiguous and public, the result points (refers) to the \( C \) subobject of the most derived object.

(8.3) Otherwise, the runtime check "fails."

The value of a failed cast to pointer type is the null pointer value of the required result type. A failed cast to reference type throws an exception (14.2) of a type that would match a handler (14.4) of type `std::bad_cast` (17.7.4).

**Example 2:**

```cpp
class A { virtual void f(); };  
class B { virtual void g(); };  
class D : public A, private B { };  
void g() {
    D d;  
    B* bp = (B*)&d; // cast needed to break protection  
    A* ap = &d; // public derivation, no cast needed  
    D& dr = dynamic_cast<D&>(*bp); // fails  
    ap = dynamic_cast<A*>(bp); // fails  
    bp = dynamic_cast<B*>(ap); // fails  
    bp = dynamic_cast<B*>(ap); // succeeds  
    bp = dynamic_cast<B*>(ap); // ill-formed (not a runtime check)
}

class E : public D, public B { };  
class F : public E, public D { };  
void h() {
    F f;  
    A* ap = &f; // succeeds: finds unique A  
    D* dp = dynamic_cast<D*>(ap); // fails: yields null; f has two D subobjects  
    E* ep = dynamic_cast<E*>(ap); // error: cast from virtual base  
    E* ep1 = dynamic_cast<E*>(ap); // succeeds  
}
```

--- end example

[Note 1: Subclause 11.9.5 describes the behavior of a `dynamic_cast` applied to an object under construction or destruction. — end note]

### 7.6.1.8 Type identification

The result of a `typeid` expression is an lvalue of static type `const std::type_info` (17.7.3) and dynamic type `const std::type_info` or `const name` where `name` is an implementation-defined class publicly derived from `std::type_info` which preserves the behavior described in 17.7.3. When `typeid` is applied to a glvalue whose type is a polymorphic class type (11.7.3), the result refers to a `std::type_info` object representing the type of the most derived object (6.7.2) (that is, the dynamic type) to which the glvalue refers. If the glvalue is obtained by applying the unary `*` operator to a pointer and the pointer is a null pointer value (6.8.3), the `typeid` expression throws an exception (14.2) of a type that would match a handler of type `std::bad_typeid` exception (17.7.5).

When `typeid` is applied to an expression other than a glvalue of a polymorphic class type, the result refers to a `std::type_info` object representing the static type of the expression. Lvalue-to-value (7.3.2),
array-to-pointer (7.3.3), and function-to-pointer (7.3.4) conversions are not applied to the expression. If the expression is a prvalue, the temporary materialization conversion (7.3.5) is applied. The expression is an unevaluated operand (7.2).

4 When typeid is applied to a type-id, the result refers to a std::type_info object representing the type of the type-id. If the type of the type-id is a reference to a possibly cv-qualified type, the result of the typeid expression refers to a std::type_info object representing the cv-unqualified referenced type. If the type of the type-id is a class type or a reference to a class type, the class shall be completely-defined.

[Note 1: The type-id cannot denote a function type with a cv-qualifier-seq or a ref-qualifier (9.3.4.6). — end note]

5 If the type of the expression or type-id is a cv-qualified type, the result of the typeid expression refers to a std::type_info object representing the cv-unqualified type.

[Example 1:

```cpp
class D { /* ... */ };
D d1;
const D d2;

typeid(d1) == typeid(d2); // yields true
typeid(D) == typeid(const D); // yields true
typeid(D) == typeid(d2); // yields true
typeid(D) == typeid(const D&); // yields true

— end example]

6 If the header <typeinfo> (17.7.3) is not imported or included prior to a use of typeid, the program is ill-formed.

[Note 2: Subclause 11.9.5 describes the behavior of typeid applied to an object under construction or destruction. — end note]

7.6.1.9 Static cast [expr.static.cast]

1 The result of the expression static_cast<T>(v) is the result of converting the expression v to type T. If T is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue. The static_cast operator shall not cast away constness (7.6.1.11).

2 An lvalue of type "cvl B", where B is a class type, can be cast to type “reference to cv2 D”, where D is a class derived (11.7) from B, if cv2 is the same cv-qualification as, or greater cv-qualification than, cvl. If B is a virtual base class of D or a base class of a virtual base class of D, or if no valid standard conversion from “pointer to D” to “pointer to B” exists (7.3.12), the program is ill-formed. An xvalue of type “cvl B” can be cast to type “rvalue reference to cv2 D” with the same constraints as for an lvalue of type “cvl B”. If the object of type “cvl B” is actually a base class subobject of an object of type D, the result refers to the enclosing object of type D. Otherwise, the behavior is undefined.

[Example 1:

```cpp
struct B { };  
struct D : public B { };  
D d;
B &br = d;

static_cast<D&>(br);  // produces lvalue denoting the original d object

— end example]

3 An lvalue of type T1 can be cast to type “rvalue reference to T2” if T2 is reference-compatible with T1 (9.4.4). If the value is not a bit-field, the result refers to the object or the specified base class subobject thereof; otherwise, the lvalue-to-rvalue conversion (7.3.2) is applied to the bit-field and the resulting prvalue is used as the expression of the static_cast for the remainder of this subclause. If T2 is an inaccessible (11.8) or ambiguous (6.5.2) base class of T1, a program that necessitates such a cast is ill-formed.

4 An expression E can be explicitly converted to a type T if there is an implicit conversion sequence (12.2.4.2) from E to T, if overload resolution for a direct-initialization (9.4) of an object or reference of type T from E would find at least one viable function (12.2.3), or if T is an aggregate type (9.4.2) having a first element x and there is an implicit conversion sequence from E to the type of x. If T is a reference type, the effect is the same as performing the declaration and initialization.
for some invented temporary variable \( t \) (9.4) and then using the temporary variable as the result of the conversion. Otherwise, the result object is direct-initialized from \( E \).

[Note 1: The conversion is ill-formed when attempting to convert an expression of class type to an inaccessible or ambiguous base class. —end note]

[Note 2: If \( T \) is “array of unknown bound of \( U \)”, this direct-initialization defines the type of the expression as \( U[1] \). —end note]

Otherwise, the \texttt{static\_cast} shall perform one of the conversions listed below. No other conversion shall be performed explicitly using a \texttt{static\_cast}.

Any expression can be explicitly converted to type \texttt{cv void}, in which case it becomes a discarded-value expression (7.2).

[Note 3: However, if the value is in a temporary object (6.7.7), the destructor for that object is not executed until the usual time, and the value of the object is preserved for the purpose of executing the destructor. —end note]

The inverse of any standard conversion sequence (7.3) not containing an lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), function-to-pointer (7.3.4), null pointer (7.3.12), null member pointer (7.3.13), boolean (7.3.15), or function pointer (7.3.14) conversion, can be performed explicitly using \texttt{static\_cast}. A program is ill-formed if it uses \texttt{static\_cast} to perform the inverse of an ill-formed standard conversion sequence.

\texttt{Example 2:}

```cpp
struct B {};
struct D : private B {};
void f() {
    static_cast<int B::*>((int D::*)0); // error: B is a private base of D
    static_cast<int B::*->((int D::*const)0); // error: B is a private base of D
}
```

—end example]

The lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) conversions are applied to the operand. Such a \texttt{static\_cast} is subject to the restriction that the explicit conversion does not cast away constness (7.6.1.11), and the following additional rules for specific cases:

A value of a scoped enumeration type (9.7.1) can be explicitly converted to an integral type; the result is the same as that of converting to the enumeration’s underlying type and then to the destination type. A value of a scoped enumeration type can also be explicitly converted to a floating-point type; the result is the same as that of converting from the original value to the floating-point type.

A value of integral or enumeration type can be explicitly converted to a complete enumeration type. If the enumeration type has a fixed underlying type, the value is first converted to that type by integral conversion, if necessary, and then to the enumeration type. If the enumeration type does not have a fixed underlying type, the value is unchanged if the original value is within the range of the enumeration values (9.7.1), and otherwise, the behavior is undefined. A value of floating-point type can also be explicitly converted to an enumeration type. The resulting value is the same as converting the original value to the underlying type of the enumeration type (9.3.11), and subsequently to the enumeration type.

A prvalue of type “pointer to \texttt{cv1 B \texttt{cv2}}”, where \( B \) is a class type, can be converted to a prvalue of type “pointer to \texttt{cv2 D \texttt{cv2}}”, where \( D \) is a complete class derived (11.7) from \( B \), if \texttt{cv2} is the same cv-qualification as, or greater cv-qualification than, \texttt{cv1}. If \( B \) is a virtual base class of \( D \) or a base class of a virtual base class of \( D \), or if no valid standard conversion from “pointer to \texttt{D \texttt{cv2}}” to “pointer to \texttt{B \texttt{cv1}}” exists (7.3.12), the program is ill-formed. The null pointer value (6.8.3) is converted to the null pointer value of the destination type. If the prvalue of type “pointer to \texttt{cv1 B \texttt{cv2}}” points to a \( B \) that is actually a subobject of an object of type \( D \), the resulting pointer points to the enclosing object of type \( D \). Otherwise, the behavior is undefined.

A prvalue of type “pointer to member of \( D \) of type \texttt{cv1 T \texttt{cv2}}” can be converted to a prvalue of type “pointer to member of \( B \) of type \texttt{cv2 T \texttt{cv2}}”, where \( D \) is a complete class type and \( B \) is a base class (11.7) of \( D \), if \texttt{cv2} is the same cv-qualification as, or greater cv-qualification than, \texttt{cv1}.

[Note 4: Function types (including those used in pointer-to-member-function types) are never cv-qualified (9.3.4.6). —end note]

If no valid standard conversion from “pointer to member of \( B \) of type \( T \) to “pointer to member of \( D \) of type \( T \) exists (7.3.13), the program is ill-formed. The null member pointer value (7.3.13) is converted to the null member pointer value of the destination type. If class \( B \) contains the original member, or is a base or derived
class of the class containing the original member, the resulting pointer to member points to the original member. Otherwise, the behavior is undefined.

[Note 5: Although class B need not contain the original member, the dynamic type of the object with which indirection through the pointer to member is performed must contain the original member; see 7.6.4. — end note]

A prvalue of type “pointer to cv1 void” can be converted to a prvalue of type “pointer to cv2 T”, where T is an object type and cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If the original pointer value represents the address A of a byte in memory and A does not satisfy the alignment requirement of T, then the resulting pointer value is unspecified. Otherwise, if the original pointer value points to an object a, and there is an object b of type T (ignoring cv-qualification) that is pointer-interconvertible (6.8.3) with a, the result is a pointer to b. Otherwise, the pointer value is unchanged by the conversion.

[Example 3:

```c
T* p1 = new T;
const T* p2 = static_cast<const T*>(static_cast<void*>(p1));
bool b = p1 == p2; // b will have the value true.
```

—end example]

### 7.6.1.10 Reinterpret cast

The result of the expression `reinterpret_cast<T>(v)` is the result of converting the expression v to type T. If T is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue and the lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the expression v. Conversions that can be performed explicitly using `reinterpret_cast` are listed below. No other conversion can be performed explicitly using `reinterpret_cast`.

1. The `reinterpret_cast` operator shall not cast away constness (7.6.1.11). An expression of integral, enumeration, pointer, or pointer-to-member type can be explicitly converted to its own type; such a cast yields the value of its operand.

2. A pointer can be explicitly converted to any integral type large enough to hold all values of its type. The mapping function is implementation-defined.

3. A value of integral type or enumeration type can be explicitly converted to a pointer. A pointer converted to an integer of sufficient size (if any such exists on the implementation) and back to the same pointer type will have its original value; mappings between pointers and integers are otherwise implementation-defined.

4. A function pointer can be explicitly converted to a function pointer of a different type.

5. An object pointer can be explicitly converted to an object pointer of a different type. When a prvalue v of object pointer type is converted to the object pointer type “pointer to cv T”, the result is `static_cast<cv T*>(static_cast<cv void*>(v))`.

---

61 The types can have different cv-qualifiers, subject to the overall restriction that a `reinterpret_cast` cannot cast away constness.
Converting a prvalue of type “pointer to data member of
T1” that points to an object of type T1 to the type “pointer to
T2” (where T2 is an object type and the alignment requirements of T2 are no stricter than those of T1) and back to its
original type yields the original pointer value. — end note]

Converting a function pointer to an object pointer type or vice versa is conditionally-supported. The meaning
of such a conversion is implementation-defined, except that if an implementation supports conversions in both
directions, converting a prvalue of one type to the other type and back, possibly with different cv-qualification,
shall yield the original pointer value.

The null pointer value (6.8.3) is converted to the null pointer value of the destination type.

A prvalue of type “pointer to member function” to a different pointer-to-member-function
a glvalue of type
an lvalue of type

A glvalue of type

The result of the expression

is that of

result is a prvalue and the lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4)
directions, converting a prvalue of one type to the other type and back, possibly with different cv-qualification,
are listed below. No other conversion shall be performed explicitly using
const_cast
— end note

A prvalue of type “pointer to member of X of type T1” can be explicitly converted to a prvalue of a different
type “pointer to member of Y of type T2” if T1 and T2 are both function types or both object types.82 The
null member pointer value (7.3.13) is converted to the null member pointer value of the destination type.
The result of this conversion is unspecified, except in the following cases:

— Converting a prvalue of type “pointer to member function” to a different pointer-to-member-function
type and back to its original type yields the original pointer-to-member value.

— Converting a prvalue of type “pointer to data member of X of type T1” to the type “pointer to data
member of Y of type T2” (where the alignment requirements of T2 are no stricter than those of T1) and
back to its original type yields the original pointer-to-member value.

A glvalue of type T1, designating an object x, can be cast to the type “reference to T2” if an expression
of type “pointer to T1” can be explicitly converted to the type “pointer to T2” using a reinterpret_cast.
The result is that of *reinterpret_cast<T2*>(p) where p is a pointer to x of type “pointer to T1”. No
temporary is created, no copy is made, and no constructors (11.4.5) or conversion functions (11.4.8) are
called.63

7.6.1.11 Const cast

The result of the expression const_cast<T>(v) is of type T. If T is an lvalue reference to object type,
the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the
result is a prvalue and the lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4)
standard conversions are performed on the expression v. Conversions that can be performed explicitly using
const_cast are listed below. No other conversion shall be performed explicitly using const_cast.

[Note 1: Subject to the restrictions in this subclause, an expression can be cast to its own type using a const_cast
operator. — end note]

For two similar types T1 and T2 (7.3.6), a prvalue of type T1 may be explicitly converted to the type T2 using
a const_cast if, considering the cv-decompositions of both types, each P_i \text{ T1} is the same as P_i \text{ T2} for all i. The
result of a const_cast refers to the original entity.

[Example 1:

```cpp
typedef int *A[3]; // array of 3 pointer to int
typedef const int *const CA[3]; // array of 3 const pointer to const int

CA &r = A[0]; // OK, reference binds to temporary array object
// after qualification conversion to type CA
A &r1 = const_cast<A>(CA[0]); // error: temporary array decayed to pointer
A &r2 = const_cast<A&>(CA[0]); // OK
@end example]
```

For two object types T1 and T2, if a pointer to T1 can be explicitly converted to the type “pointer to T2”
using a const_cast, then the following conversions can also be made:

— an lvalue of type T1 can be explicitly converted to an lvalue of type T2 using the cast const_cast<T2&>;
— a glvalue of type T1 can be explicitly converted to an xvalue of type T2 using the cast const_cast<T2&&>;

62) T1 and T2 can have different cv-qualifiers, subject to the overall restriction that a reinterpret_cast cannot cast away
conestness.
63) This is sometimes referred to as a type pun when the result refers to the same object as the source glvalue.
if \( T_1 \) is a class type, a prvalue of type \( T_1 \) can be explicitly converted to an xvalue of type \( T_2 \) using the cast `const_cast<T2&&>`.

The result of a reference `const_cast` refers to the original object if the operand is a glvalue and to the result of applying the temporary materialization conversion (7.3.5) otherwise.

A null pointer value (6.8.3) is converted to the null pointer value of the destination type. The null member pointer value (7.3.13) is converted to the null member pointer value of the destination type.

[Note 2: Depending on the type of the object, a write operation through the pointer, lvalue or pointer to data member resulting from a `const_cast` that casts away a const-qualifier can produce undefined behavior (9.2.9.2). — end note]

A conversion from a type \( T_1 \) to a type \( T_2 \) casts away constness if \( T_1 \) and \( T_2 \) are different, there is a cv-decomposition (7.3.6) of \( T_1 \) yielding \( n \) such that \( T_2 \) has a cv-decomposition of the form

\[
cvP2_0 \ cvP1_0 \ cvP1_1 \cdots \ cvP1_{n-1} \ cvP1_n \ U1_0 \cvP2_n \ U2_0
\]

and there is no qualification conversion that converts \( T_1 \) to

\[
cvP2_0 \ cvP1_0 \ cvP1_1 \cdots \ cvP1_{n-1} \ cvP1_n \ U1_0
\]

Casting from an lvalue of type \( T_1 \) to an lvalue of type \( T_2 \) using an lvalue reference cast or casting from an expression of type \( T_1 \) to an xvalue of type \( T_2 \) using an rvalue reference cast casts away constness if a cast from a prvalue of type “pointer to \( T_1 \)” to the type “pointer to \( T_2 \)” casts away constness.

[Note 3: Some conversions which involve only changes in cv-qualification cannot be done using `const_cast`. For instance, conversions between pointers to functions are not covered because such conversions lead to values whose use causes undefined behavior. For the same reasons, conversions between pointers to member functions, and in particular, the conversion from a pointer to a const member function to a pointer to a non-const member function, are not covered. — end note]

### 7.6.2 Unary expressions

#### 7.6.2.1 General

Expressions with unary operators group right-to-left.

- unary-expression:
  - postfix-expression
  - unary-operator cast-expression
  - `++` cast-expression
  - `--` cast-expression
  - `await-expression`
  - `sizeof unary-expression`
  - `sizeof ( type-id )`
  - `sizeof ... ( identifier )`
  - `alignof ( type-id )`
  - `noexcept-expression`
  - `new-expression`
  - `delete-expression`

- unary-operator: one of
  - `*` & `+` - `!` ~

#### 7.6.2.2 Unary operators

The unary `*` operator performs **indirection**: the expression to which it is applied shall be a pointer to an object type, or a pointer to a function type and the result is an lvalue referring to the object or function to which the expression points. If the type of the expression is “pointer to \( T \)”, the type of the result is “\( T \)”.

[Note 1: Indirection through a pointer to an incomplete type (other than \( cv \) void) is valid. The lvalue thus obtained can be used in limited ways (to initialize a reference, for example); this lvalue must not be converted to a prvalue, see 7.3.2. — end note]

The result of each of the following unary operators is a prvalue.

The result of the unary `&` operator is a pointer to its operand.

- If the operand is a `qualified-id` naming a non-static or variant member \( m \) of some class \( C \) with type \( T \), the result has type “pointer to member of class \( C \) of type \( T \)” and is a prvalue designating \( C::m \).

---

64) `const_cast` is not limited to conversions that cast away a const-qualifier.
Otherwise, if the operand is an lvalue of type \( T \), the resulting expression is a prvalue of type “pointer to \( T \)” whose result is a pointer to the designated object (6.7.1) or function.

[Note 2: In particular, taking the address of a variable of type “\( cv \ T \)” yields a pointer to “\( cv \ T \)”. —end note]

Otherwise, the program is ill-formed.

[Example 1:

```c
struct A { int i; }
struct B : A { }

... &B::i ... // has type int A::*
int a;
int* p1 = &a;
int* p2 = p1 + 1; // defined behavior
bool b = p2 > p1; // defined behavior, with value true
```

—end example]

[Note 3: A pointer to member formed from a `mutable` non-static data member (9.2.2) does not reflect the `mutable` specifier associated with the non-static data member. —end note]

A pointer to member is only formed when an explicit \& is used and its operand is a `qualified-id` not enclosed in parentheses.

[Note 4: That is, the expression \&(qualified-id), where the `qualified-id` is enclosed in parentheses, does not form an expression of type “pointer to member”. Neither does `qualified-id`, because there is no implicit conversion from a `qualified-id` for a non-static member function to the type “pointer to member function” as there is from an lvalue of function type to the type “pointer to function” (7.3.4). Nor is `unqualified-id` a pointer to member, even within the scope of the `unqualified-id`’s class. —end note]

If \& is applied to an lvalue of incomplete class type and the complete type declares `operator&()`, it is unspecified whether the operator has the built-in meaning or the operator function is called. The operand of \& shall not be a bit-field.

[Note 5: The address of an overload set (Clause 12) can be taken only in a context that uniquely determines which function is referred to (see 12.3). Since the context can affect whether the operand is a static or non-static member function, the context can also affect whether the expression has type “pointer to function” or “pointer to member function”. —end note]

The operand of the unary `+` operator shall have arithmetic, unscoped enumeration, or pointer type and the result is the value of the argument. Integral promotion is performed on integral or enumeration operands. The type of the result is the type of the promoted operand.

The operand of the unary `-` operator shall have arithmetic or unscoped enumeration type and the result is the negative of its operand. Integral promotion is performed on integral or enumeration operands. The negative of an unsigned quantity is computed by subtracting its value from \( 2^n \), where \( n \) is the number of bits in the promoted operand. The type of the result is the type of the promoted operand.

The operand of the logical negation operator `!` is contextually converted to `bool` (7.3); its value is `true` if the converted operand is `false` and `false` otherwise. The type of the result is `bool`.

The operand of `~` shall have integral or unscoped enumeration type; the result is the ones’ complement of its operand. Integral promotions are performed. The type of the result is the type of the promoted operand. There is an ambiguity in the grammar when `~` is followed by a `type-name` or `decltype-specifier`. The ambiguity is resolved by treating `~` as the unary complement operator rather than as the start of an `unqualified-id` naming a destructor.

[Note 6: Because the grammar does not permit an operator to follow the .., ->, or :: tokens, a `~` followed by a `type-name` or `decltype-specifier` in a member access expression or `qualified-id` is unambiguously parsed as a destructor name. —end note]

### 7.6.2.3 Increment and decrement [expr.pre.incr]

The operand of prefix `++` is modified (3.1) by adding 1. The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than `cv bool`, or a pointer to a completely-defined object type. An operand with volatile-qualified type is deprecated; see D.6. The result is the updated operand; it is an lvalue, and it is a bit-field if the operand is a bit-field. The expression `++x` is equivalent to `x+=1`.

[Note 1: See the discussions of addition (7.6.6) and assignment operators (7.6.19) for information on conversions. —end note]
The operand of prefix -- is modified (3.1) by subtracting 1. The requirements on the operand of prefix -- and the properties of its result are otherwise the same as those of prefix ++.

[Note 2: For postfix increment and decrement, see 7.6.1.6. — end note]

### 7.6.2.4 Await

The `co_await` expression is used to suspend evaluation of a coroutine (9.5.4) while awaiting completion of the computation represented by the operand expression.

```cpp
await-expression:
    co_await cast-expression
```

An `await-expression` shall appear only in a potentially-evaluated expression within the `compound-statement` of a `function-body` outside of a `handler` (14.1). In a `declaration-statement` or in the `simple-declaration` (if any) of an `init-statement`, an `await-expression` shall appear only in an `initializer` of that `declaration-statement` or `simple-declaration`. An `await-expression` shall not appear in a default argument (9.3.4.7). An `await-expression` shall not appear in the initializer of a block variable with static or thread storage duration. A context within a function where an `await-expression` can appear is called a `suspension context` of the function.

Evaluation of an `await-expression` involves the following auxiliary types, expressions, and objects:

1. **p** is an lvalue naming the promise object (9.5.4) of the enclosing coroutine and **P** is the type of that object.
2. Unless the `await-expression` was implicitly produced by a `yield-expression` (7.6.17), an initial suspend point, or a final suspend point (9.5.4), a search is performed for the name `await_transform` in the scope of **P** (6.5.2). If this search is performed and finds at least one declaration, then **a** is `p.await_transform`(`cast-expression`); otherwise, **a** is the `cast-expression`.
3. **o** is determined by enumerating the applicable `operator co_await` functions for an argument **a** (12.2.2.3), and choosing the best one through overload resolution (12.2). If overload resolution is ambiguous, the program is ill-formed. If no viable functions are found, **o** is **a**. Otherwise, **o** is a call to the selected function with the argument **a**. If **o** would be a prvalue, the temporary materialization conversion (7.3.5) is applied.
4. **e** is an lvalue referring to the result of evaluating the (possibly-converted) **o**.
5. **h** is an object of type `std::coroutine_handle<**P**>` referring to the enclosing coroutine.
6. `await-ready` is the expression `e.await_ready()`, contextually converted to `bool`.
7. `await-suspend` is the expression `e.await_suspend(**h**)`, which shall be a prvalue of type `void, bool, or std::coroutine_handle<**Z**>` for some type **Z**.
8. `await-resume` is the expression `e.await_resume()`.

The `await-expression` has the same type and value category as the `await-resume` expression.

The `await-expression` evaluates the (possibly-converted) **o** expression and the `await-ready` expression, then:

1. If the result of `await-ready` is `false`, the coroutine is considered suspended. Then:
   1.1. If the type of `await-suspend` is `std::coroutine_handle<**Z**>`, `await-suspend.resume()` is evaluated.
      [Note 1: This resumes the coroutine referred to by the result of `await-suspend`. Any number of coroutines can be successively resumed in this fashion, eventually returning control flow to the current coroutine caller or resumer (9.5.4). — end note]
   1.2. Otherwise, if the type of `await-suspend` is `bool`, `await-suspend` is evaluated, and the coroutine is resumed if the result is `false`.
   1.3. Otherwise, `await-suspend` is evaluated.

   If the evaluation of `await-suspend` exits via an exception, the exception is caught, the coroutine is resumed, and the exception is immediately re-thrown (14.2). Otherwise, control flow returns to the current coroutine caller or resumer (9.5.4) without exiting any scopes (8.7).

2. If the result of `await-ready` is `true`, or when the coroutine is resumed, the `await-resume` expression is evaluated, and its result is the result of the `await-expression`.

[Example 1:]
template <typename T>
struct my_future {
    /* ... */
    bool await_ready();
    void await_suspend(std::coroutine_handle<>);
    T await_resume();
};

template <class Rep, class Period>
auto operator co_await(std::chrono::duration<Rep, Period> d) {
    struct awaiter {
        std::chrono::system_clock::duration duration;
        /* ... */
        awaiter(std::chrono::system_clock::duration d) : duration(d) {}
        bool await_ready() const { return duration.count() <= 0; }
        void await_resume() {}
        void await_suspend(std::coroutine_handle<> h) { /* ... */ }
    };
    return awaiter{d};
}

using namespace std::chrono;

my_future<int> h();

my_future<void> g() {
    std::cout << "just about go to sleep...\n";
    co_await 10ms;
    std::cout << "resumed\n";
    co_await h();
}

auto f(int x = co_await h());  // error: await-expression outside of function suspension context
int a[] = { co_await h() };  // error: await-expression outside of function suspension context

— end example

7.6.2.5 SIZEOF [expr.sizeof]

1 The sizeof operator yields the number of bytes occupied by a non-potentially-overlapping object of the type of its operand. The operand is either an expression, which is an unevaluated operand (7.2), or a parenthesized type-id. The sizeof operator shall not be applied to an expression that has function or incomplete type, to the parenthesized name of such types, or to a glvalue that designates a bit-field. The result of sizeof applied to any of the narrow character types is 1. The result of sizeof applied to any other fundamental type (6.8.2) is implementation-defined.

[Note 1: In particular, the values of sizeof(bool), sizeof(char16_t), sizeof(char32_t), and sizeof(wchar_t) are implementation-defined. — end note]

[Note 2: See 6.7.1 for the definition of byte and 6.8 for the definition of object representation. — end note]

2 When applied to a reference type, the result is the size of the referenced type. When applied to a class, the result is the number of bytes in an object of that class including any padding required for placing objects of that type in an array. The result of applying sizeof to a potentially-overlapping subobject is the size of the type, not the size of the subobject. When applied to an array, the result is the total number of bytes in the array. This implies that the size of an array of n elements is n times the size of an element.

3 The lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are not applied to the operand of sizeof. If the operand is a prvalue, the temporary materialization conversion (7.3.5) is applied.

4 The identifier in a sizeof... expression shall name a pack. The sizeof... operator yields the number of elements in the pack (13.7.4). A sizeof... expression is a pack expansion (13.7.4).
The result of \texttt{sizeof} and \texttt{sizeof...} is a prvalue of type \texttt{std::size_t}.

\begin{itemize}
\item [Note 3] A \texttt{sizeof} expression is an integral constant expression (7.7). The type \texttt{std::size_t} is defined in the standard header \texttt{<cstdint>} (17.2.1, 17.2.4). — end note
\end{itemize}

\subsection*{7.6.2.6 Alignof \hfill \texttt{[expr.alignof]}}

An \texttt{alignof} expression yields the alignment requirement of its operand type. The operand shall be a \texttt{type-id} representing a complete object type, or an array thereof, or a reference to one of those types.

The result is a prvalue of type \texttt{std::size_t}.

\begin{itemize}
\item [Note 1] An \texttt{alignof} expression is an integral constant expression (7.7). The type \texttt{std::size_t} is defined in the standard header \texttt{<cstdint>} (17.2.1, 17.2.4). — end note
\end{itemize}

When \texttt{alignof} is applied to a reference type, the result is the alignment of the referenced type. When \texttt{alignof} is applied to an array type, the result is the alignment of the element type.

\subsection*{7.6.2.7 \texttt{noexcept} operator \hfill \texttt{[expr.unary.noexcept]}}

The \texttt{noexcept} operator determines whether the evaluation of its operand, which is an unevaluated operand (7.2), can throw an exception (14.2).

\begin{itemize}
\item [Note 1] A \texttt{noexcept-expression} is an integral constant expression (7.7). — end note
\end{itemize}

The result of the \texttt{noexcept} operator is \texttt{true} unless the \texttt{expression} is potentially-throwing (14.5).

\subsection*{7.6.2.8 \texttt{new} \hfill \texttt{[expr.new]}}

The \texttt{new-expression} attempts to create an object of the \texttt{type-id} (9.3.2) or \texttt{new-type-id} to which it is applied. The type of that object is the \texttt{allocated type}. This type shall be a complete object type, but not an abstract class type or array thereof (6.7.2, 6.8, 11.7.4).

\begin{itemize}
\item [Note 1] Because references are not objects, references cannot be created by \texttt{new-expressions}. — end note
\item [Note 2] The \texttt{type-id} can be a cv-qualified type, in which case the object created by the \texttt{new-expression} has a cv-qualified type. — end note
\end{itemize}

The \texttt{new-expression} has the following form:

\begin{itemize}
\item [Note 2] If a placeholder type (9.2.9.6) appears in the \texttt{type-specifier-seq} of a \texttt{new-type-id} or \texttt{type-id} of a \texttt{new-expression}, the allocated type is deduced as follows: Let \texttt{init} be the \texttt{new-initializer}, if any, and \texttt{T} be the \texttt{new-type-id} or
\end{itemize}
type-id of the new-expression, then the allocated type is the type deduced for the variable \(x\) in the invented declaration (9.2.9.6):

\[
T \ x \ init; \\
[Example 1:
new\ auto(1); \quad //\ allocated\ type\ is\ int\ 
auto\ x = new\ auto('a'); \quad //\ allocated\ type\ is\ char,\ x\ is\ of\ type\ char* 
\]

\[
\text{template<class } T > \text{ struct A } \{ A(T, T); \}; \\
auto\ y = new\ A(1, 2); \quad //\ allocated\ type\ is\ A<int> 
\]

--- end example]

3 The new-type-id in a new-expression is the longest possible sequence of new-declarators.

[Note 3: This prevents ambiguities between the declarator operators \&, \&\&, *, and [] and their expression counterparts. — end note]

[Example 2:
new\ int * i; \quad // syntax error: parsed as (new int*) i, not as (new int)*i
The * is the pointer declarator and not the multiplication operator. — end example]

4 [Note 4: Parentheses in a new-type-id of a new-expression can have surprising effects.

[Example 3:
new\ int(*[10])(); \quad // error
is ill-formed because the binding is
(new int) (*[10])(); \quad // error
Instead, the explicitly parenthesized version of the new operator can be used to create objects of compound types (6.8.3):
new\ (int (*[10])());
allocates an array of 10 pointers to functions (taking no argument and returning int). — end example]

— end note]

5 Objects created by a new-expression have dynamic storage duration (6.7.5.5).

[Note 5: The lifetime of such an object is not necessarily restricted to the scope in which it is created. — end note]

When the allocated object is not an array, the result of the new-expression is a pointer to the object created.

6 When the allocated object is an array (that is, the noptr-new-declarator syntax is used or the new-type-id or type-id denotes an array type), the new-expression yields a pointer to the initial element (if any) of the array.

[Note 6: Both new int and new int[10] have type int* and the type of new int[i][10] is int (*)[10] — end note]

The attribute-specifier-seq in a noptr-new-declarator appertains to the associated array type.

7 Every constant-expression in a noptr-new-declarator shall be a converted constant expression (7.7) of type std::size_t and its value shall be greater than zero.

[Example 4: Given the definition int\ n = 42, new float[n][5] is well-formed (because n is the expression of a noptr-new-declarator), but new float[5][n] is ill-formed (because n is not a constant expression). — end example]

8 If the type-id or new-type-id denotes an array type of unknown bound (9.3.4.5), the new-initializer shall not be omitted; the allocated object is an array with n elements, where n is determined from the number of initial elements supplied in the new-initializer (9.4.2, 9.4.3).

9 If the expression in a noptr-new-declarator is present, it is implicitly converted to std::size_t. The expression is erroneous if:

- the expression is of non-class type and its value before converting to std::size_t is less than zero;
- the expression is of class type and its value before application of the second standard conversion (12.2.4.2.3)\(^67\) is less than zero;
- its value is such that the size of the allocated object would exceed the implementation-defined limit (Annex B); or

\(^67\) If the conversion function returns a signed integer type, the second standard conversion converts to the unsigned type std::size_t and thus thwarts any attempt to detect a negative value afterwards.
(9.4) the new-initializer is a braced-init-list and the number of array elements for which initializers are provided (including the terminating ‘\0’ in a string-literal (5.13.5)) exceeds the number of elements to initialize.

If the expression is erroneous after converting to std::size_t:
(9.5) if the expression is a core constant expression, the program is ill-formed;
(9.6) otherwise, an allocation function is not called; instead
(9.6.1) if the allocation function that would have been called has a non-throwing exception specification (14.5), the value of the new-expression is the null pointer value of the required result type;
(9.6.2) otherwise, the new-expression terminates by throwing an exception of a type that would match a handler (14.4) of type std::bad_array_new_length (17.6.4.2).

When the value of the expression is zero, the allocation function is called to allocate an array with no elements.

A new-expression may obtain storage for the object by calling an allocation function (6.7.5.5.2). If the new-expression terminates by throwing an exception, it may release storage by calling a deallocation function (6.7.5.5.3). If the allocated type is a non-array type, the allocation function’s name is operator new and the deallocation function’s name is operator delete. If the allocated type is an array type, the allocation function’s name is operator new[] and the deallocation function’s name is operator delete[].

[Note 7: An implementation is required to provide default definitions for the global allocation functions (6.7.5.5, 17.6.3.2, 17.6.3.3). A C++ program can provide alternative definitions of these functions (16.4.5.6) and/or class-specific versions (11.11). The set of allocation and deallocation functions that can be called by a new-expression can include functions that do not perform allocation or deallocation; for example, see 17.6.3.4. — end note]

If the new-expression does not begin with a unary :: operator and the allocated type is a class type T or array thereof, a search is performed for the allocation function’s name in the scope of T (6.5.2). Otherwise, or if nothing is found, the allocation function’s name is looked up by searching for it in the global scope.

An implementation is allowed to omit a call to a replaceable global allocation function (17.6.3.2, 17.6.3.3). When it does so, the storage is instead provided by the implementation or provided by extending the allocation of another new-expression.

During an evaluation of a constant expression, a call to an allocation function is always omitted.

[Note 8: Only new-expressions that would otherwise result in a call to a replaceable global allocation function can be evaluated in constant expressions (7.7). — end note]

The implementation may extend the allocation of a new-expression e1 to provide storage for a new-expression e2 if the following would be true were the allocation not extended:
(14.1) the evaluation of e1 is sequenced before the evaluation of e2, and
(14.2) e2 is evaluated whenever e1 obtains storage, and
(14.3) both e1 and e2 invoke the same replaceable global allocation function, and
(14.4) if the allocation function invoked by e1 and e2 is throwing, any exceptions thrown in the evaluation of either e1 or e2 would be first caught in the same handler, and
(14.5) the pointer values produced by e1 and e2 are operands to evaluated delete-expressions, and
(14.6) the evaluation of e2 is sequenced before the evaluation of the delete-expression whose operand is the pointer value produced by e1.

[Example 5:]

```c++
void can_merge(int x) {
  // These allocations are safe for merging:
  std::unique_ptr<char[]> a{new (std::nothrow) char[8]};
  std::unique_ptr<char[]> b{new (std::nothrow) char[8]};
  std::unique_ptr<char[]> c{new (std::nothrow) char[x]};

  g(a.get(), b.get(), c.get());
}

void cannot_merge(int x) {
  std::unique_ptr<char[]> a{new char[8]};
  try {
    // Merging this allocation would change its catch handler.
    std::unique_ptr<char[]> b{new char[x]};
  }

  // If the b allocation is lost, then the exception from the next line would be lost.
  // But there is no way to figure out that this new allocation was safe.
}
```

§ 7.6.2.8
When a `new-expression` calls an allocation function and that allocation has not been extended, the `new-expression` passes the amount of space requested to the allocation function as the first argument of type `std::size_t`. That argument shall be no less than the size of the object being created; it may be greater than the size of the object if the object is an array and the allocation function is not a non-allocating form (17.6.3.4). For arrays of `char`, `unsigned char`, and `std::byte`, the difference between the result of the `new-expression` and the address returned by the allocation function shall be an integral multiple of the strictest fundamental alignment requirement (6.7.6) of any object type whose size is no greater than the size of the array being created.

[Note 9: Because allocation functions are assumed to return pointers to storage that is appropriately aligned for objects of any type with fundamental alignment, this constraint on array allocation overhead permits the common idiom of allocating character arrays into which objects of other types will later be placed. — end note]

When a `new-expression` calls an allocation function and that allocation has been extended, the size argument to the allocation call shall be no greater than the sum of the sizes for the omitted calls as specified above, plus the size for the extended call had it not been extended, plus any padding necessary to align the allocated objects within the allocated memory.

The `new-placement` syntax is used to supply additional arguments to an allocation function; such an expression is called a `placement new-expression`.

Overload resolution is performed on a function call created by assembling an argument list. The first argument is the amount of space requested, and has type `std::size_t`. If the type of the allocated object has new-extended alignment, the next argument is the type’s alignment, and has type `std::align_val_t`. If the `new-placement` syntax is used, the `initializer-clause`s in its `expression-list` are the succeeding arguments. If no matching function is found then

1. if the allocated object type has new-extended alignment, the alignment argument is removed from the argument list;
2. otherwise, an argument that is the type’s alignment and has type `std::align_val_t` is added into the argument list immediately after the first argument;

and then overload resolution is performed again.

[Example 6:]

- `new T` results in one of the following calls:
  - `operator new(sizeof(T))`
  - `operator new(sizeof(T), std::align_val_t(alignof(T)))`

- `new(2,f) T` results in one of the following calls:
  - `operator new(sizeof(T), 2, f)`
  - `operator new(sizeof(T), std::align_val_t(alignof(T)), 2, f)`

- `new T[5]` results in one of the following calls:
  - `operator new[](sizeof(T) * 5 + x)`
  - `operator new[](sizeof(T) * 5 + x, std::align_val_t(alignof(T)))`

- `new(2,f) T[5]` results in one of the following calls:
  - `operator new[](sizeof(T) * 5 + x, 2, f)`
  - `operator new[](sizeof(T) * 5 + x, std::align_val_t(alignof(T)), 2, f)`

Here, each instance of `x` is a non-negative unspecified value representing array allocation overhead; the result of the `new-expression` will be offset by this amount from the value returned by `operator new[]`. This overhead may be applied in all array `new-expressions`, including those referencing a placement allocation function, except when referencing the library function `operator new[](std::size_t, void*)`. The amount of overhead may vary from one invocation of `new` to another. — end example]

[Note 10: Unless an allocation function has a non-throwing exception specification (14.5), it indicates failure to allocate storage by throwing a `std::bad_alloc` exception (6.7.5.5.2, Clause 14, 17.6.4.1); it returns a non-null pointer
otherwise. If the allocation function has a non-throwing exception specification, it returns null to indicate failure to allocate storage and a non-null pointer otherwise. — end note]

If the allocation function is a non-allocating form (17.6.3.4) that returns null, the behavior is undefined. Otherwise, if the allocation function returns null, initialization shall not be done, the deallocation function shall not be called, and the value of the new-expression shall be null.

[Note 11: When the allocation function returns a value other than null, it must be a pointer to a block of storage in which space for the object has been reserved. The block of storage is assumed to be appropriately aligned and of the requested size. The address of the created object will not necessarily be the same as that of the block if the object is an array. — end note]

A new-expression that creates an object of type T initializes that object as follows:

— (22.1) If the new-initializer is omitted, the object is default-initialized (9.4).

[Note 12: If no initialization is performed, the object has an indeterminate value. — end note]

— (22.2) Otherwise, the new-initializer is interpreted according to the initialization rules of 9.4 for direct-initialization.

The invocation of the allocation function is sequenced before the evaluations of expressions in the new-initializer. Initialization of the allocated object is sequenced before the value computation of the new-expression.

If the new-expression creates an object or an array of objects of class type, access and ambiguity control are done for the allocation function, the deallocation function (6.7.5.5.3), and the constructor (11.4.5) selected for the initialization (if any). If the new-expression creates an array of objects of class type, the destructor is potentially invoked (11.4.7).

If any part of the object initialization described above68 terminates by throwing an exception and a suitable deallocation function can be found, the deallocation function is called to free the memory in which the object was being constructed, after which the exception continues to propagate in the context of the new-expression. If no unambiguous matching deallocation function can be found, propagating the exception does not cause the object’s memory to be freed.

[Note 13: This is appropriate when the called allocation function does not allocate memory; otherwise, it is likely to result in a memory leak. — end note]

If the new-expression does not begin with a unary :: operator and the allocated type is a class type T or an array thereof, a search is performed for the deallocation function’s name in the scope of T. Otherwise, or if nothing is found, the deallocation function’s name is looked up by searching for it in the global scope.

A declaration of a placement deallocation function matches the declaration of a placement allocation function if it has the same number of parameters and, after parameter transformations (9.3.4.6), all parameter types except the first are identical. If the lookup finds a single matching deallocation function, that function will be called; otherwise, no deallocation function will be called. If the lookup finds a usual deallocation function and that function, considered as a placement deallocation function, would have been selected as a match for the allocation function, the program is ill-formed. For a non-placement allocation function, the normal deallocation function lookup is used to find the matching deallocation function (7.6.2.9).

[Example 7:

```cpp
struct S {
    // Placement allocation function:
    static void* operator new(std::size_t, std::size_t);

    // Usual (non-placement) deallocation function:
    static void operator delete(void*, std::size_t);
};

S* p = new (0) S; // error: non-placement deallocation function matches
                  // placement allocation function
```

If a new-expression calls a deallocation function, it passes the value returned from the allocation function call as the first argument of type void*. If a placement deallocation function is called, it is passed the same additional arguments as were passed to the placement allocation function, that is, the same arguments as those specified with the new-placement syntax. If the implementation is allowed to introduce a temporary

68) This can include evaluating a new-initializer and/or calling a constructor.
object or make a copy of any argument as part of the call to the allocation function, it is unspecified whether
the same object is used in the call to both the allocation and deallocation functions.

7.6.2.9 Delete

The delete-expression operator destroys a most derived object (6.7.2) or array created by a new-expression.

delete-expression:
::opt delete cast-expression
::opt delete [ ] cast-expression

The first alternative is a single-object delete expression, and the second is an array delete expression. Whenever
the delete keyword is immediately followed by empty square brackets, it shall be interpreted as the second
alternative.

If the object being deleted has incomplete class type at the point of deletion and the complete class has a
non-trivial destructor or a deallocation function, the behavior is undefined. In an array delete expression, if the dynamic type of the object to be
deleted differs from its static type, the behavior is undefined.

[Note 1: This means that the syntax of the delete-expression must match the type of the object allocated by new, not
the syntax of the new-expression. — end note]

[Note 2: A pointer to a const type can be the operand of a delete-expression; it is not necessary to cast away the
constness (7.6.1.11) of the pointer expression before it is used as the operand of the delete-expression. — end note]

In a single-object delete expression, if the static type of the object to be deleted is different from its dynamic
type and the selected deallocation function (see below) is not a destroying operator delete, the static type
shall be a base class of the dynamic type of the object to be deleted and the static type shall have a virtual
destructor or the behavior is undefined. In an array delete expression, if the dynamic type of the object to be
deleted differs from its static type, the behavior is undefined.

The cast-expression in a delete-expression shall be evaluated exactly once.

If the object being deleted has incomplete class type at the point of deletion and the complete class has a
non-trivial destructor or a deallocation function, the behavior is undefined.

If the value of the operand of the delete-expression is not a null pointer value and the selected deallocation
function (see below) is not a destroying operator delete, the delete-expression will invoke the destructor (if any)
for the object or the elements of the array being deleted. In the case of an array, the elements will be
destroyed in order of decreasing address (that is, in reverse order of the completion of their constructor; see
11.9.3).

If the value of the operand of the delete-expression is not a null pointer value, then:

7.1 If the allocation call for the new-expression for the object to be deleted was not omitted and the
allocation was not extended (7.6.2.8), the delete-expression shall call a deallocation function (6.7.5.5.3).
The value returned from the allocation call of the new-expression shall be passed as the first argument
to the deallocation function.

7.2 Otherwise, if the allocation was extended or was provided by extending the allocation of another
new-expression, and the delete-expression for every other pointer value produced by a new-expression that
had storage provided by the extended new-expression has been evaluated, the delete-expression shall call
a deallocation function. The value returned from the allocation call of the extended new-expression
shall be passed as the first argument to the deallocation function.

7.3 Otherwise, the delete-expression will not call a deallocation function.

69) A lambda-expression with a lambda-introducer that consists of empty square brackets can follow the delete keyword if the
lambda-expression is enclosed in parentheses.

70) This implies that an object cannot be deleted using a pointer of type void* because void is not an object type.

71) For nonzero-length arrays, this is the same as a pointer to the first element of the array created by that new-expression.
Zero-length arrays do not have a first element.
[Note 3: The deallocation function is called regardless of whether the destructor for the object or some element of the array throws an exception. — end note]

If the value of the operand of the delete-expression is a null pointer value, it is unspecified whether a deallocation function will be called as described above.

If a deallocation function is called, it is operator delete for a single-object delete expression or operator delete[] for an array delete expression.

[Note 4: An implementation provides default definitions of the global deallocation functions (17.6.3.2, 17.6.3.3). A C++ program can provide alternative definitions of these functions (16.4.5.6), and/or class-specific versions (11.11). — end note]

If the keyword delete in a delete-expression is not preceded by the unary :: operator and the type of the operand is a pointer to a (possibly cv-qualified) class type T:

- If T has a virtual destructor, the deallocation function is the one selected at the point of definition of the dynamic type’s virtual destructor (11.4.7).
- Otherwise, a search is performed for the deallocation function’s name in the scope of T.

Otherwise, or if nothing is found, the deallocation function’s name is looked up by searching for it in the global scope. In any case, any declarations other than of usual deallocation functions (6.7.5.5.3) are discarded.

[Note 5: If only a placement deallocation function is found in a class, the program is ill-formed because the lookup set is empty (6.5). — end note]

If more than one deallocation function is found, the function to be called is selected as follows:

1. If any of the deallocation functions is a destroying operator delete, all deallocation functions that are not destroying operator deletes are eliminated from further consideration.
2. If the type has new-extended alignment, a function with a parameter of type std::align_val_t is preferred; otherwise a function without such a parameter is preferred. If any preferred functions are found, all non-preferred functions are eliminated from further consideration.
3. If exactly one function remains, that function is selected and the selection process terminates.
4. If the deallocation functions belong to a class scope, the one without a parameter of type std::size_t is selected.
5. If the type is complete and if, for an array delete expression only, the operand is a pointer to a class type with a non-trivial destructor or a (possibly multi-dimensional) array thereof, the function with a parameter of type std::size_t is selected.
6. Otherwise, it is unspecified whether a deallocation function with a parameter of type std::size_t is selected.

For a single-object delete expression, the deleted object is the object denoted by the operand if its static type does not have a virtual destructor, and its most-derived object otherwise.

[Note 6: If the deallocation function is not a destroying operator delete and the deleted object is not the most derived object in the former case, the behavior is undefined, as stated above. — end note]

For an array delete expression, the deleted object is the array object. When a delete-expression is executed, the selected deallocation function shall be called with the address of the deleted object in a single-object delete expression, or the address of the deleted object suitably adjusted for the array allocation overhead (7.6.2.8) in an array delete expression, as its first argument.

[Note 7: Any cv-qualifiers in the type of the deleted object are ignored when forming this argument. — end note]

If a destroying operator delete is used, an unspecified value is passed as the argument corresponding to the parameter of type std::destroying_delete_t. If a deallocation function with a parameter of type std::align_val_t is used, the alignment of the type of the deleted object is passed as the corresponding argument. If a deallocation function with a parameter of type std::size_t is used, the size of the deleted object in a single-object delete expression, or of the array plus allocation overhead in an array delete expression, is passed as the corresponding argument.

[Note 8: If this results in a call to a replaceable deallocation function, and either the first argument was not the result of a prior call to a replaceable allocation function or the second or third argument was not the corresponding argument in said call, the behavior is undefined (17.6.3.2, 17.6.3.3). — end note]

Access and ambiguity control are done for both the deallocation function and the destructor (11.4.7, 11.11).
7.6.3 Explicit type conversion (cast notation) \[expr.cast\]

1 The result of the expression \((T)\) \textit{cast-expression} is of type \(T\). The result is an lvalue if \(T\) is an lvalue reference type or an rvalue reference to function type and an xvalue if \(T\) is an rvalue reference to object type; otherwise the result is a prvalue.

[Note 1: If \(T\) is a non-class type that is cv-qualified, the \textit{cv-qualifiers} are discarded when determining the type of the resulting prvalue; see 7.2. — end note]

2 An explicit type conversion can be expressed using functional notation (7.6.1.4), a type conversion operator (\texttt{dynamic_cast}, \texttt{static_cast}, \texttt{reinterpret_cast}, \texttt{const_cast}), or the \textit{cast} notation.

\begin{verbatim}
  cast-expression:
    unary-expression
    ( type-id ) cast-expression
\end{verbatim}

3 Any type conversion not mentioned below and not explicitly defined by the user (11.4.8) is ill-formed.

4 The conversions performed by

\begin{verbatim}
(4.1) — a \texttt{const_cast} (7.6.1.11),
(4.2) — a \texttt{static_cast} (7.6.1.9),
(4.3) — a \texttt{static_cast} followed by a \texttt{const_cast},
(4.4) — a \texttt{reinterpret_cast} (7.6.1.10), or
(4.5) — a \texttt{reinterpret_cast} followed by a \texttt{const_cast},
\end{verbatim}

can be performed using the cast notation of explicit type conversion. The same semantic restrictions and behaviors apply, with the exception that in performing a \texttt{static_cast} in the following situations the conversion is valid even if the base class is inaccessible:

\begin{verbatim}
(4.6) — a pointer to an object of derived class type or an lvalue or rvalue of derived class type may be explicitly converted to a pointer or reference to an unambiguous base class type, respectively;
(4.7) — a pointer to member of derived class type may be explicitly converted to a pointer to member of an unambiguous non-virtual base class type;
(4.8) — a pointer to an object of an unambiguous non-virtual base class type, a glvalue of an unambiguous non-virtual base class type, or a pointer to member of an unambiguous non-virtual base class type may be explicitly converted to a pointer, a reference, or a pointer to member of a derived class type, respectively.
\end{verbatim}

If a conversion can be interpreted in more than one of the ways listed above, the interpretation that appears first in the list is used, even if a cast resulting from that interpretation is ill-formed. If a conversion can be interpreted in more than one way as a \texttt{static_cast} followed by a \texttt{const_cast}, the conversion is ill-formed.

[Example 1:

\begin{verbatim}
struct A { }
struct I1 : A { }
struct I2 : A { }
struct D : I1, I2 { }
A* foo( D* p ) { 
  return (A*)( p ); // ill-formed \texttt{static_cast} interpretation
}
\end{verbatim}

— end example]

5 The operand of a cast using the cast notation can be a prvalue of type “pointer to incomplete class type”. The destination type of a cast using the cast notation can be “pointer to incomplete class type”. If both the operand and destination types are class types and one or both are incomplete, it is unspecified whether the \texttt{static_cast} or the \texttt{reinterpret_cast} interpretation is used, even if there is an inheritance relationship between the two classes.

[Note 2: For example, if the classes were defined later in the translation unit, a multi-pass compiler would be permitted to interpret a cast between pointers to the classes as if the class types were complete at the point of the cast. — end note]

7.6.4 Pointer-to-member operators \[expr.mptr.oper\]

1 The pointer-to-member operators \(\Rightarrow\) and \(\Rightarrow\) group left-to-right.
pm-expression:
cast-expression
pm-expression .* cast-expression
pm-expression ->* cast-expression

2 The binary operator .* binds its second operand, which shall be of type “pointer to member of T” to its first operand, which shall be a glvalue of class T or of a class of which T is an unambiguous and accessible base class. The result is an object or a function of the type specified by the second operand.

3 The binary operator ->* binds its second operand, which shall be of type “pointer to member of T” to its first operand, which shall be of type “pointer to U” where U is either T or a class of which T is an unambiguous and accessible base class. The expression E1->*E2 is converted into the equivalent form (*((E1)).*E2.

4 Abbreviating pm-expression .*cast-expression as E1.*E2, E1 is called the object expression. If the dynamic type of E1 does not contain the member to which E2 refers, the behavior is undefined. Otherwise, the expression E1 is sequenced before the expression E2.

5 The restrictions on cv-qualification, and the manner in which the cv-qualifiers of the operands are combined to produce the cv-qualifiers of the result, are the same as the rules for E1.E2 given in 7.6.1.5.

[Note 1: It is not possible to use a pointer to member that refers to a mutable member to modify a const class object. For example,

```c
struct S {
    S() : i(0) { }
    mutable int i;
};
void f()
{
    const S cs;
    int S::* pm = &S::i; // pm refers to mutable member S::i
    cs.*pm = 88; // error: cs is a const object
}
```

—end note]

6 If the result of .* or ->* is a function, then that result can be used only as the operand for the function call operator ()..

[Example 1:

```c
(ptr_to_obj->*ptr_to_mfct)(10);
```
calls the member function denoted by ptr_to_mfct for the object pointed to by ptr_to_obj. — end example]

In a .* expression whose object expression is an rvalue, the program is ill-formed if the second operand is a pointer to member function whose ref-qualifier is &, unless its cv-qualifier-seq is const. In a .* expression whose object expression is an lvalue, the program is ill-formed if the second operand is a pointer to member function whose ref-qualifier is &k. The result of a .* expression whose second operand is a pointer to a data member is an lvalue if the first operand is an lvalue and an xvalue otherwise. The result of a .* expression whose second operand is a pointer to a member function is a prvalue. If the second operand is the null member pointer value (7.3.13), the behavior is undefined.

7.6.5 Multiplicative operators [expr.mul]

1 The multiplicative operators *, /, and % group left-to-right.

```
multiplicative-expression:
    pm-expression
    pm-expression * pm-expression
    pm-expression / pm-expression
    pm-expression % pm-expression
```

2 The operands of * and / shall have arithmetic or unscoped enumeration type; the operands of % shall have integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed on the operands and determine the type of the result.

3 The binary * operator indicates multiplication.

4 The binary / operator yields the quotient, and the binary % operator yields the remainder from the division of the first expression by the second. If the second operand of / or % is zero the behavior is undefined. For
integral operands the \( / \) operator yields the algebraic quotient with any fractional part discarded;\textsuperscript{72} if the quotient \( a/b \) is representable in the type of the result, \( (a/b) \cdot b + a \% b \) is equal to \( a \); otherwise, the behavior of both \( a/b \) and \( a \% b \) is undefined.

### 7.6.6 Additive operators

The additive operators \( + \) and \( - \) group left-to-right. The usual arithmetic conversions (7.4) are performed for operands of arithmetic or enumeration type.

\[
\text{additive-expression} : \\
\quad \text{multiplicative-expression} \\
\quad \text{additive-expression} + \text{multiplicative-expression} \\
\quad \text{additive-expression} - \text{multiplicative-expression}
\]

For addition, either both operands shall have arithmetic or unscoped enumeration type, or one operand shall be a pointer to a completely-defined object type and the other shall have integral or unscoped enumeration type.

\textbf{2} For subtraction, one of the following shall hold:

(2.1) — both operands have arithmetic or unscoped enumeration type; or

(2.2) — both operands are pointers to cv-qualified or cv-unqualified versions of the same completely-defined object type; or

(2.3) — the left operand is a pointer to a completely-defined object type and the right operand has integral or unscoped enumeration type.

The result of the binary \( + \) operator is the sum of the operands. The result of the binary \( - \) operator is the difference resulting from the subtraction of the second operand from the first.

\textbf{4} When an expression \( J \) that has integral type is added to or subtracted from an expression \( P \) of pointer type, the result has the type of \( P \).

\textbf{4.1} — If \( P \) evaluates to a null pointer value and \( J \) evaluates to 0, the result is a null pointer value.

\textbf{4.2} — Otherwise, if \( P \) points to an array element \( i \) of an array object \( x \) with \( n \) elements (9.3.4.5), the expressions \( P + J \) and \( J + P \) (where \( J \) has the value \( j \)) point to the (possibly-hypothetical) array element \( i + j \) of \( x \) if \( 0 \leq i + j \leq n \) and the expression \( P - J \) points to the (possibly-hypothetical) array element \( i - j \) of \( x \) if \( 0 \leq i - j \leq n \).

\textbf{4.3} — Otherwise, the behavior is undefined.

\textbf{5} When two pointer expressions \( P \) and \( Q \) are subtracted, the type of the result is an implementation-defined signed integral type; this type shall be the same type that is defined as \texttt{std::ptrdiff_t} in the \textless stddef \textgreater header (17.2.4).

\textbf{5.1} — If \( P \) and \( Q \) both evaluate to null pointer values, the result is 0.

\textbf{5.2} — Otherwise, if \( P \) and \( Q \) point to, respectively, array elements \( i \) and \( j \) of the same array object \( x \), the expression \( P - Q \) has the value \( i - j \).

\textbf{5.3} — Otherwise, the behavior is undefined.

\begin{itemize}
  \item [Note 1:] If the value \( i - j \) is not in the range of representable values of type \texttt{std::ptrdiff_t}, the behavior is undefined. \textit{— end note}\end{itemize}

\textbf{6} For addition or subtraction, if the expressions \( P \) or \( Q \) have type “pointer to \( cv \) \( T \)”, where \( T \) and the array element type are not similar (7.3.6), the behavior is undefined.

\begin{itemize}
  \item [Note 2:] In particular, a pointer to a base class cannot be used for pointer arithmetic when the array contains objects of a derived class type. \textit{— end note}\end{itemize}

### 7.6.7 Shift operators

The shift operators \( << \) and \( >> \) group left-to-right.

\textsuperscript{72} This is often called truncation towards zero.

\textsuperscript{73} As specified in 6.8.3, an object that is not an array element is considered to belong to a single-element array for this purpose and a pointer past the last element of an array of \( n \) elements is considered to be equivalent to a pointer to a hypothetical array element \( n \) for this purpose.
The operands shall be of integral or unscoped enumeration type and integral promotions are performed. The type of the result is that of the promoted left operand. The behavior is undefined if the right operand is negative, or greater than or equal to the width of the promoted left operand.

The value of \( E_1 \ll E_2 \) is the unique value congruent to \( E_1 \times 2^{E_2} \) modulo \( 2^N \), where \( N \) is the width of the type of the result.

[Note 1: \( E_1 \) is left-shifted \( E_2 \) bit positions; vacated bits are zero-filled. — end note]

The value of \( E_1 \gg E_2 \) is \( E_1 / 2^{E_2} \), rounded down.

[Note 2: \( E_1 \) is right-shifted \( E_2 \) bit positions. Right-shift on signed integral types is an arithmetic right shift, which performs sign-extension. — end note]

The expression \( E_1 \) is sequenced before the expression \( E_2 \).

### 7.6.8 Three-way comparison operator

The three-way comparison operator groups left-to-right.

\[
\text{compare-expression}:
\begin{align*}
\text{shift-expression} \\
\text{additive-expression} \\
\text{shift-expression} \ll \text{additive-expression} \\
\text{shift-expression} \gg \text{additive-expression}
\end{align*}
\]

2 The expression \( p \llq q \) is a prvalue indicating whether \( p \) is less than, equal to, greater than, or incomparable with \( q \).

3 If one of the operands is of type \texttt{bool} and the other is not, the program is ill-formed.

4 If both operands have arithmetic types, or one operand has integral type and the other operand has unscoped enumeration type, the usual arithmetic conversions (7.4) are applied to the operands. Then:

(4.1) — If a narrowing conversion (9.4.5) is required, other than from an integral type to a floating-point type, the program is ill-formed.

(4.2) — Otherwise, if the operands have integral type, the result is of type \texttt{std::strong\_ordering}. The result is \texttt{std::strong\_ordering::equal} if both operands are arithmetically equal, \texttt{std::strong\_ordering::less} if the first operand is arithmetically less than the second operand, and \texttt{std::strong\_ordering::greater} otherwise.

(4.3) — Otherwise, the operands have floating-point type, and the result is of type \texttt{std::partial\_ordering}. The expression \( a \llq b \) yields \texttt{std::partial\_ordering::less} if \( a \) is less than \( b \), \texttt{std::partial\_ordering::greater} if \( a \) is greater than \( b \), \texttt{std::partial\_ordering::equivalent} if \( a \) is equivalent to \( b \), and \texttt{std::partial\_ordering::unordered} otherwise.

5 If both operands have the same enumeration type \( E \), the operator yields the result of converting the operands to the underlying type of \( E \) and applying \( \llq \) to the converted operands.

6 If at least one of the operands is of object pointer type and the other operand is of object pointer or array type, array-to-pointer conversions (7.3.3), pointer conversions (7.3.12), and qualification conversions (7.3.6) are performed on both operands to bring them to their composite pointer type (7.2.2). After the conversions, the operands shall have the same type.

[Note 1: If both of the operands are arrays, array-to-pointer conversions (7.3.3) are not applied. — end note]

In this case, \( p \llq q \) is of type \texttt{std::strong\_ordering} and the result is defined by the following rules:

(6.1) — If two pointer operands \( p \) and \( q \) compare equal (7.6.10), \( p \llq q \) yields \texttt{std::strong\_ordering::equal};

(6.2) — otherwise, if \( p \) and \( q \) compare unequal, \( p \llq q \) yields \texttt{std::strong\_ordering::less} if \( q \) compares greater than \( p \) and \texttt{std::strong\_ordering::greater} if \( p \) compares greater than \( q \) (7.6.9);

(6.3) — otherwise, the result is unspecified.

7 Otherwise, the program is ill-formed.

8 The three comparison category types (17.11.2) (the types \texttt{std::strong\_ordering}, \texttt{std::weak\_ordering}, and \texttt{std::partial\_ordering}) are not predefined; if the header \texttt{<compare>} (17.11.1) is not imported or included prior to a use of such a class type – even an implicit use in which the type is not named (e.g., via

§ 7.6.8
the auto specifier (9.2.9.6) in a defaulted three-way comparison (11.10.3) or use of the built-in operator – the program is ill-formed.

7.6.9 Relational operators

The relational operators group left-to-right.

[Example 1: a<b<c means (a<b)<c and not (a<b)&& (b<c). — end example]

The lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the operands. The comparison is deprecated if both operands were of array type prior to these conversions (D.5).

The converted operands shall have arithmetic, enumeration, or pointer type. The operators < (less than), > (greater than), <= (less than or equal to), and => (greater than or equal to) all yield false or true. The type of the result is bool.

The usual arithmetic conversions (7.4) are performed on operands of arithmetic or enumeration type. If both operands are pointers, pointer conversions (7.3.12) and qualification conversions (7.3.6) are performed to bring them to their composite pointer type (7.2.2). After conversions, the operands shall have the same type.

The result of comparing unequal pointers to objects74 is defined in terms of a partial order consistent with the following rules:

(4.1) — If two pointers point to different elements of the same array, or to subobjects thereof, the pointer to the element with the higher subscript is required to compare greater.

(4.2) — If two pointers point to different non-static data members of the same object, or to subobjects of such members, recursively, the pointer to the later declared member is required to compare greater provided the two members have the same access control (11.8), neither member is a subobject of zero size, and their class is not a union.

(4.3) — Otherwise, neither pointer is required to compare greater than the other.

If two operands p and q compare equal (7.6.10), p<=q and p>=q both yield true and p<q and p>q both yield false. Otherwise, if a pointer p compares greater than a pointer q, p=>q, p>q, q<=p, and q<p all yield true and p<q, p<q, q>=p, and q>p all yield false. Otherwise, the result of each of the operators is unspecified.

If both operands (after conversions) are of arithmetic or enumeration type, each of the operators shall yield true if the specified relationship is true and false if it is false.

7.6.10 Equality operators

The == (equal to) and the != (not equal to) operators group left-to-right. The lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the operands. The comparison is deprecated if both operands were of array type prior to these conversions (D.5).

The converted operands shall have arithmetic, enumeration, pointer, or pointer-to-member type, or type std::nullptr_t. The operators == and != both yield true or false, i.e., a result of type bool. In each case below, the operands shall have the same type after the specified conversions have been applied.

If at least one of the operands is a pointer, pointer conversions (7.3.12), function pointer conversions (7.3.14), and qualification conversions (7.3.6) are performed on both operands to bring them to their composite pointer type (7.2.2). Comparing pointers is defined as follows:

74) As specified in 6.8.3, an object that is not an array element is considered to belong to a single-element array for this purpose and a pointer past the last element of an array of n elements is considered to be equivalent to a pointer to a hypothetical array element n for this purpose.
— If one pointer represents the address of a complete object, and another pointer represents the address one past the last element of a different complete object,\(^{75}\) the result of the comparison is unspecified.

— Otherwise, if the pointers are both null, both point to the same function, or both represent the same address (6.8.3), they compare equal.

— Otherwise, the pointers compare unequal.

If at least one of the operands is a pointer to member, pointer-to-member conversions (7.3.13), function pointer conversions (7.3.14), and qualification conversions (7.3.6) are performed on both operands to bring them to their composite pointer type (7.2.2). Comparing pointers to members is defined as follows:

— If two pointers to members are both the null member pointer value, they compare equal.

— If only one of two pointers to members is the null member pointer value, they compare unequal.

— If either is a pointer to a virtual member function, the result is unspecified.

— If one refers to a member of class \(C_1\) and the other refers to a member of a different class \(C_2\), where neither is a base class of the other, the result is unspecified.

\[\text{Example 1:}\]

```cpp
struct A {};
struct B : A { int x; };
struct C : A { int x; };

int A::*bx = (int(A::*))&B::x;
int A::*cx = (int(A::*))&C::x;

bool b1 = (bx == cx); // unspecified
```

— end example\]

— If both refer to (possibly different) members of the same union (11.5), they compare equal.

— Otherwise, two pointers to members compare equal if they would refer to the same member of the same most derived object (6.7.2) or the same subobject if indirection with a hypothetical object of the associated class type were performed, otherwise they compare unequal.

\[\text{Example 2:}\]

```cpp
struct B {
    int f();
};
struct L : B {
};
struct R : B {
};
struct D : L, R {
};

int (B::*pb)() = &B::f;
int (L::*pl)() = pb;
int (R::*pr)() = pb;
int (D::*pdl)() = pl;
int (D::*pdr)() = pr;
bool x = (pdl == pdr); // false
bool y = (pb == pl); // true
```

— end example\]

Two operands of type `std::nullptr_t` or one operand of type `std::nullptr_t` and the other a null pointer constant compare equal.

If two operands compare equal, the result is `true` for the `==` operator and `false` for the `!=` operator. If two operands compare unequal, the result is `false` for the `==` operator and `true` for the `!=` operator. Otherwise, the result of each of the operators is unspecified.

If both operands are of arithmetic or enumeration type, the usual arithmetic conversions (7.4) are performed on both operands; each of the operators shall yield `true` if the specified relationship is true and `false` if it is false.

\(^{75}\) As specified in 6.8.3, an object that is not an array element is considered to belong to a single-element array for this purpose.
7.6.11 Bitwise AND operator

```
and-expression:
    equality-expression
    and-expression & equality-expression
```

The `&` operator groups left-to-right. The operands shall be of integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed. Given the coefficients \( x_i \) and \( y_i \) of the base-2 representation (6.8.2) of the converted operands \( x \) and \( y \), the coefficient \( r_i \) of the base-2 representation of the result \( r \) is 1 if both \( x_i \) and \( y_i \) are 1, and 0 otherwise.

[Note 1: The result is the bitwise AND function of the operands. — end note]

7.6.12 Bitwise exclusive OR operator

```
exclusive-or-expression:
    and-expression ^ exclusive-or-expression
```

The `^` operator groups left-to-right. The operands shall be of integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed. Given the coefficients \( x_i \) and \( y_i \) of the base-2 representation (6.8.2) of the converted operands \( x \) and \( y \), the coefficient \( r_i \) of the base-2 representation of the result \( r \) is 1 if either (but not both) of \( x_i \) and \( y_i \) are 1, and 0 otherwise.

[Note 1: The result is the bitwise exclusive OR function of the operands. — end note]

7.6.13 Bitwise inclusive OR operator

```
inclusive-or-expression:
    exclusive-or-expression
    inclusive-or-expression | exclusive-or-expression
```

The `|` operator groups left-to-right. The operands shall be of integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed. Given the coefficients \( x_i \) and \( y_i \) of the base-2 representation (6.8.2) of the converted operands \( x \) and \( y \), the coefficient \( r_i \) of the base-2 representation of the result \( r \) is 1 if at least one of \( x_i \) and \( y_i \) are 1, and 0 otherwise.

[Note 1: The result is the bitwise inclusive OR function of the operands. — end note]

7.6.14 Logical AND operator

```
logical-and-expression:
    inclusive-or-expression
    logical-and-expression && inclusive-or-expression
```

The `&&` operator groups left-to-right. The operands are both contextually converted to `bool` (7.3). The result is `true` if both operands are `true` and `false` otherwise. Unlike `&`, `&&` guarantees left-to-right evaluation: the second operand is not evaluated if the first operand is `false`. The result is a `bool`. If the second expression is evaluated, the first expression is sequenced before the second expression (6.9.1).

7.6.15 Logical OR operator

```
logical-or-expression:
    logical-and-expression
    logical-or-expression || logical-and-expression
```

The `||` operator groups left-to-right. The operands are both contextually converted to `bool` (7.3). The result is `true` if either of its operands is `true`, and `false` otherwise. Unlike `|`, `||` guarantees left-to-right evaluation; moreover, the second operand is not evaluated if the first operand evaluates to `true`. The result is a `bool`. If the second expression is evaluated, the first expression is sequenced before the second expression (6.9.1).

7.6.16 Conditional operator

```
conditional-expression:
    logical-or-expression
    logical-or-expression ? expression : assignment-expression
```

§ 7.6.16
Conditional expressions group right-to-left. The first expression is contextually converted to `bool` (7.3). It is evaluated and if it is `true`, the result of the conditional expression is the value of the second expression, otherwise that of the third expression. Only one of the second and third expressions is evaluated. The first expression is sequenced before the second or third expression (6.9.1).

If either the second or the third operand has type `void`, one of the following shall hold:

1. The second or the third operand (but not both) is a (possibly parenthesized) throw-expression (7.6.18); the result is of the type and value category of the other. The conditional-expression is a bit-field if that operand is a bit-field.

2. Both the second and the third operands have type `void`; the result is of type `void` and is a prvalue.

    [Note 1: This includes the case where both operands are throw-expressions. — end note]

Otherwise, if the second and third operand are glvalue bit-fields of the same value category and of types `cv1 T` and `cv2 T`, respectively, the operands are considered to be of type `cv T` for the remainder of this subclause, where `cv` is the union of `cv1` and `cv2`.

Otherwise, if the second and third operand have different types and either has (possibly cv-qualified) class type, or if both are glvalues of the same value category and the same type except for cv-qualification, an attempt is made to form an implicit conversion sequence (12.2.4.2) from each of those operands to the type of the other.

    [Note 2: Properties such as access, whether an operand is a bit-field, or whether a conversion function is deleted are ignored for that determination. — end note]

Attempts are made to form an implicit conversion sequence from an operand expression `E1` of type `T1` to a target type related to the type `T2` of the operand expression `E2` as follows:

1. If `E2` is an lvalue, the target type is “lvalue reference to `T2`”, but an implicit conversion sequence can only be formed if the reference would bind directly (9.4.4) to a glvalue.

2. If `E2` is an xvalue, the target type is “rvalue reference to `T2`”, but an implicit conversion sequence can only be formed if the reference would bind directly.

3. If `E2` is a prvalue or if neither of the conversion sequences above can be formed and at least one of the operands has (possibly cv-qualified) class type:
   
   1. if `T1` and `T2` are the same class type (ignoring cv-qualification) and `T2` is at least as cv-qualified as `T1`, the target type is `T2`.
   2. otherwise, if `T2` is a base class of `T1`, the target type is `cv1 T2`, where `cv1` denotes the cv-qualifiers of `T1`.
   3. otherwise, the target type is the type that `E2` would have after applying the lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions.

Using this process, it is determined whether an implicit conversion sequence can be formed from the second operand to the target type determined for the third operand, and vice versa. If both sequences can be formed, or one can be formed but it is the ambiguous conversion sequence, the program is ill-formed. If no conversion sequence can be formed, the operands are left unchanged and further checking is performed as described below. Otherwise, if exactly one conversion sequence can be formed, that conversion is applied to the chosen operand and the converted operand is used in place of the original operand for the remainder of this subclause.

    [Note 3: The conversion might be ill-formed even if an implicit conversion sequence could be formed. — end note]

If the second and third operands are glvalues of the same value category and have the same type, the result is of that type and value category and it is a bit-field if the second or the third operand is a bit-field, or if both are bit-fields.

Otherwise, the result is a prvalue. If the second and third operands do not have the same type, and either has (possibly cv-qualified) class type, overload resolution is used to determine the conversions (if any) to be applied to the operands (12.2.2.3, 12.5). If the overload resolution fails, the program is ill-formed. Otherwise, the conversions thus determined are applied, and the converted operands are used in place of the original operands for the remainder of this subclause.

Lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the second and third operands. After those conversions, one of the following shall hold:
(7.1) — The second and third operands have the same type; the result is of that type and the result object is initialized using the selected operand.

(7.2) — The second and third operands have arithmetic or enumeration type; the usual arithmetic conversions (7.4) are performed to bring them to a common type, and the result is of that type.

(7.3) — One or both of the second and third operands have pointer type; pointer conversions (7.3.12), function pointer conversions (7.3.14), and qualification conversions (7.3.6) are performed to bring them to their composite pointer type (7.2.2). The result is of the composite pointer type.

(7.4) — One or both of the second and third operands have pointer-to-member type; pointer to member conversions (7.3.13), function pointer conversions (7.3.14), and qualification conversions (7.3.6) are performed to bring them to their composite pointer type (7.2.2). The result is of the composite pointer type.

(7.5) — Both the second and third operands have type std::nullptr_t or one has that type and the other is a null pointer constant. The result is of type std::nullptr_t.

### 7.6.17 Yielding a value

**yield-expression**:

co_yield assignment-expression

co_yield braced-init-list

A **yield-expression** shall appear only within a suspension context of a function (7.6.2.4). Let \( e \) be the operand of the **yield-expression** and \( p \) be an lvalue naming the promise object of the enclosing coroutine (9.5.4), then the **yield-expression** is equivalent to the expression `co_await p.yield_value(e)`.

**Example 1**:

```cpp
template <typename T>
struct my_generator {
    struct promise_type {
        T current_value;
        /\* ... */\*
        auto yield_value(T v) {
            current_value = std::move(v);
            return std::suspend_always{};
        }
    };
    struct iterator { /\* ... */ }; // error: yield-expression outside of function suspension context
    iterator begin();
    iterator end();
};

my_generator<pair<int,int>> g1() {
    for (int i = 0; i < 10; ++i) co_yield {i,i};
}

my_generator<pair<int,int>> g2() {
    for (int i = 0; i < 10; ++i) co_yield make_pair(i,i);
}

auto f(int x = co_yield 5); // error: yield-expression outside of function suspension context
int a[] = { co_yield 1 }; // error: yield-expression outside of function suspension context

int main() {
    auto r1 = g1();
    auto r2 = g2();
    assert(std::equal(r1.begin(), r1.end(), r2.begin(), r2.end()));
}
```

### 7.6.18 Throwing an exception

**throw-expression**:

throw assignment-expression<opt>

A **throw-expression** is of type void.
Evaluating a throw-expression with an operand throws an exception (14.2); the type of the exception object is determined by removing any top-level cv-qualifiers from the static type of the operand and adjusting the type from “array of T” or function type T to “pointer to T”.

A throw-expression with no operand rethrows the currently handled exception (14.4). The exception is reactivated with the existing exception object; no new exception object is created. The exception is no longer considered to be caught.

[Example 1: An exception handler that cannot completely handle the exception itself can be written like this:

```cpp
try {
    // ...
} catch (...) {
    // catch all exceptions
    // respond (partially) to exception
    throw;
                // pass the exception to some other handler
}
```

—end example]

If no exception is presently being handled, evaluating a throw-expression with no operand calls std::terminate() (14.6.2).

### 7.6.19 Assignment and compound assignment operators

The assignment operator (=) and the compound assignment operators all group right-to-left. All require a modifiable lvalue as their left operand; their result is an lvalue referring to the left operand. The result in all cases is a bit-field if the left operand is a bit-field. In all cases, the assignment is sequenced after the value computation of the right and left operands, and before the value computation of the assignment expression. The right operand is sequenced before the left operand. With respect to an indeterminately-sequenced function call, the operation of a compound assignment is a single evaluation.

[Note 1: Therefore, a function call cannot intervene between the lvalue-to-rvalue conversion and the side effect associated with any single compound assignment operator. — end note]

The right operand is implicitly converted (7.3) to the cv-unqualified type of the left operand.

When the left operand of an assignment operator is a bit-field that cannot represent the value of the expression, the resulting value of the bit-field is implementation-defined.

A simple assignment whose left operand is of a volatile-qualified type is deprecated (D.6) unless the (possibly parenthesized) assignment is a discarded-value expression or an unevaluated operand.

The behavior of an expression of the form $E_1 op = E_2$ is equivalent to $E_1 = E_1 op E_2$ except that $E_1$ is evaluated only once. Such expressions are deprecated if $E_1$ has volatile-qualified type; see D.6. For $+= -$ and $-=-$, $E_1$ shall either have arithmetic type or be a pointer to a possibly cv-qualified completely-defined object type. In all other cases, $E_1$ shall have arithmetic type.

If the value being stored in an object is read via another object that overlaps in any way the storage of the first object, then the overlap shall be exact and the two objects shall have the same type, otherwise the behavior is undefined.

[Note 2: This restriction applies to the relationship between the left and right sides of the assignment operation; it is not a statement about how the target of the assignment can be aliased in general. See 7.2.1. — end note]

A braced-init-list may appear on the right-hand side of

(8.1) — an assignment to a scalar, in which case the initializer list shall have at most a single element. The meaning of $x = \{v\}$, where $T$ is the scalar type of the expression $x$, is that of $x = T\{v\}$. The meaning of $x = \{\}$ is $x = T\{\}$.  

§ 7.6.19 146
an assignment to an object of class type, in which case the initializer list is passed as the argument to
the assignment operator function selected by overload resolution (12.4.3.2, 12.2).

[Example 1:
complex<double> z;
z = { 1,2 }; // meaning z.operator={1,2}
z += { 1, 2 }; // meaning z.operator+=({1,2})
int a, b;
a = b = { 1 }; // meaning a=b=1;
a = { 1 } = b; // syntax error
— end example]

7.6.20 Comma operator

The comma operator groups left-to-right.

expression:
  assignment-expression
  expression , assignment-expression

A pair of expressions separated by a comma is evaluated left-to-right; the left expression is a discarded-value
expression (7.2). The left expression is sequenced before the right expression (6.9.1). The type and value of
the result are the type and value of the right operand; the result is of the same value category as its right
operand, and is a bit-field if its right operand is a bit-field.

[Note 1: In contexts where the comma token is given special meaning (e.g. function calls (7.6.1.3), lists of initializers
(9.4), or template-argument-lists (13.3)), the comma operator as described in this subclause can appear only in
parentheses.
[Example 1: f(a, (t=3, t+2), c);
has three arguments, the second of which has the value 5. — end example]
— end note]

[Note 2: A comma expression appearing as the expr-braced-init-list of a subscripting expression (7.6.1.2) is deprecated;
see D.4. — end note]

7.7 Constant expressions

Certain contexts require expressions that satisfy additional requirements as detailed in this subclause; other
contexts have different semantics depending on whether or not an expression satisfies these requirements.
Expressions that satisfy these requirements, assuming that copy elision (11.9.6) is not performed, are called
constant expressions.

[Note 1: Constant expressions can be evaluated during translation. — end note]

constant-expression:
  conditional-expression

2 A variable or temporary object o is constant-initialized if

(2.1) — either it has an initializer or its default-initialization results in some initialization being performed, and

(2.2) — the full-expression of its initialization is a constant expression when interpreted as a constant-expression,
except that if o is an object, that full-expression may also invoke constexpr constructors for o and its
subobjects even if those objects are of non-literal class types.

[Note 2: Such a class can have a non-trivial destructor. Within this evaluation, std::is_constant_evaluated() (20.15.11) returns true. — end note]

3 A variable is potentially-constant if it is constexpr or it has reference or const-qualified integral or enumeration
type.

4 A constant-initialized potentially-constant variable V is usable in constant expressions at a point P if V’s
initializing declaration D is reachable from P and

(4.1) — V is constexpr,

(4.2) — V is not initialized to a TU-local value, or

(4.3) — P is in the same translation unit as D.
An object or reference is *usable in constant expressions* if it is

- a variable that is usable in constant expressions, or
- a template parameter object (13.2), or
- a string literal object (5.13.5), or
- a temporary object of non-volatile const-qualified literal type whose lifetime is extended (6.7.7) to that of a variable that is usable in constant expressions, or
- a non-mutable subobject or reference member of any of the above.

An expression \( E \) is a *core constant expression* unless the evaluation of \( E \), following the rules of the abstract machine (6.9.1), would evaluate one of the following:

- this (7.5.2), except in a constexpr function (9.2.6) that is being evaluated as part of \( E \);
- an invocation of a non-constexpr function;
- an invocation of an undefined constexpr function;
- an invocation of an instantiated constexpr function that fails to satisfy the requirements for a constexpr function;
- an invocation of a virtual function (11.7.3) for an object unless
  - the object is usable in constant expressions or
  - its lifetime began within the evaluation of \( E \);
- an expression that would exceed the implementation-defined limits (see Annex B);
- an operation that would have undefined behavior as specified in Clause 4 through Clause 15;
- an lvalue-to-rvalue conversion (7.3.2) unless it is applied to
  - a non-volatile glvalue that refers to an object that is usable in constant expressions, or
  - a non-volatile glvalue of literal type that refers to a non-volatile object whose lifetime began within the evaluation of \( E \);
- an lvalue-to-rvalue conversion that is applied to a glvalue that refers to a non-active member of a union or a subobject thereof;
- an lvalue-to-rvalue conversion that is applied to an object with an indeterminate value (6.7.4);
- an invocation of an implicitly-defined copy/move constructor or copy/move assignment operator for a union whose active member (if any) is mutable, unless the lifetime of the union object began within the evaluation of \( E \);
- an *id-expression* that refers to a variable or data member of reference type unless the reference has a preceding initialization and either
  - it is usable in constant expressions or
  - its lifetime began within the evaluation of \( E \);
- in a *lambda-expression*, a reference to this or to a variable with automatic storage duration defined outside that *lambda-expression*, where the reference would be an odr-use (6.3, 7.5.5):

[Example 1:]

```c
c
void g() {
    const int n = 0;
    [=] {
        constexpr int i = n; // OK, n is not odr-used here
        constexpr int j = *n; // error: &n would be an odr-use of n
    };
}
```

---

76) Overload resolution (12.2) is applied as usual.

77) This includes, for example, signed integer overflow (7.2), certain pointer arithmetic (7.6.6), division by zero (7.6.5), or certain shift operations (7.6.7).
[Note 3: If the odr-use occurs in an invocation of a function call operator of a closure type, it no longer refers to this or to an enclosing automatic variable due to the transformation (7.5.5.3) of the id-expression into an access of the corresponding data member.

[Example 2:
```cpp
auto monad = [] (auto v) { return [=] { return v; }; }; 
auto bind = [] (auto m) {
    return [=] (auto fvm) { return fvm(m()); }; 
};
// OK to capture objects with automatic storage duration created during constant expression evaluation.
static_assert(bind(monad(2))(monad)() == monad(2)());
```

— end example]

— end note]

(5.14) — a conversion from type cv void* to a pointer-to-object type;

(5.15) — a reinterpret_cast (7.6.1.10);

(5.16) — a modification of an object (7.6.19, 7.6.1.6, 7.6.2.3) unless it is applied to a non-volatile lvalue of literal type that refers to a non-volatile object whose lifetime began within the evaluation of E;

(5.17) — a new-expression (7.6.2.8), unless the selected allocation function is a replaceable global allocation function (17.6.3.2, 17.6.3.3) and the allocated storage is deallocated within the evaluation of E;

(5.18) — a delete-expression (7.6.2.9), unless it deallocates a region of storage allocated within the evaluation of E;

(5.19) — a call to an instance of std::allocator<T>::allocate (20.10.10.2), unless the allocated storage is deallocated within the evaluation of E;

(5.20) — a call to an instance of std::allocator<T>::deallocate (20.10.10.2), unless it deallocates a region of storage allocated within the evaluation of E;

(5.21) — an await-expression (7.6.2.4);

(5.22) — a yield-expression (7.6.17);

(5.23) — a three-way comparison (7.6.8), relational (7.6.9), or equality (7.6.10) operator where the result is unspecified;

(5.24) — a throw-expression (7.6.18);

(5.25) — a dynamic_cast (7.6.1.7) or typeid (7.6.1.8) expression that would throw an exception;

(5.26) — an asm-declaration (9.10); or

(5.27) — an invocation of the va_arg macro (17.13.2).

If E satisfies the constraints of a core constant expression, but evaluation of E would evaluate an operation that has undefined behavior as specified in Clause 16 through Clause 32, or an invocation of the va_start macro (17.13.2), it is unspecified whether E is a core constant expression.

[Example 3:
```cpp
int x;
// not constant

struct A {
    constexpr A(bool b) : m(b?42:x) { }
    int m;
};
constexpr int v = A(true).m; // OK: constructor call initializes m with the value 42
constexpr int w = A(false).m; // error: initializer for m is x, which is non-constant

constexpr int f1(int k) {
    constexpr int x = k; // error: x is not initialized by a constant expression
    return x;
}
constexpr int f2(int k) {
    int x = k; // OK: not required to be a constant expression
```
constexpr int incr(int &n) {
  return ++n;
}

constexpr int g(int k) {
  constexpr int x = incr(k);  // error: incr(k) is not a core constant expression
  return x;
}

constexpr int h(int k) {  // OK: incr(k) is not required to be a core constant expression
  int x = incr(k);
  return x;
}

constexpr int y = h(1);  // OK: initializes y with the value 2  // h(1) is a core constant expression because // the lifetime of k begins inside h(1)

—end example]
A **converted constant expression** of type $T$ is an expression, implicitly converted to type $T$, where the converted expression is a constant expression and the implicit conversion sequence contains only

- user-defined conversions,
- lvalue-to-rvalue conversions (7.3.2),
- array-to-pointer conversions (7.3.3),
- function-to-pointer conversions (7.3.4),
- qualification conversions (7.3.6),
- integral promotions (7.3.7),
- integral conversions (7.3.9) other than narrowing conversions (9.4.5),
- null pointer conversions (7.3.12) from `std::nullptr_t`,
- null member pointer conversions (7.3.13) from `std::nullptr_t`, and
- function pointer conversions (7.3.14),

and where the reference binding (if any) binds directly.

[Note 5: Such expressions can be used in `new` expressions (7.6.2.8), as case expressions (8.5.3), as enumerator initializers if the underlying type is fixed (9.7.1), as array bounds (9.3.4.5), and as non-type template arguments (13.4). — end note]

A **contextually converted constant expression of type** `bool` is an expression, contextually converted to `bool` (7.3), where the converted expression is a constant expression and the conversion sequence contains only the conversions above.

A **constant expression** is either a glvalue core constant expression that refers to an entity that is a permitted result of a constant expression (as defined below), or a prvalue core constant expression whose value satisfies the following constraints:

- if the value is an object of class type, each non-static data member of reference type refers to an entity that is a permitted result of a constant expression,
- if the value is of pointer type, it contains the address of an object with static storage duration, the address past the end of such an object (7.6.6), the address of a non-immediate function, or a null pointer value,
- if the value is of pointer-to-member-function type, it does not designate an immediate function, and
- if the value is an object of class or array type, each subobject satisfies these constraints for the value.

An entity is a **permitted result of a constant expression** if it is an object with static storage duration that either is not a temporary object or is a temporary object whose value satisfies the above constraints, or if it is a non-immediate function.

[Example 5:]
```cpp
consteval int f() { return 42; }
consteval auto g() { return f; }
consteval int h(int (*p)() = g()) { return p(); }
constexpr int r = h();  // OK
constexpr auto e = g();  // error: a pointer to an immediate function is
                         // not a permitted result of a constant expression
```

---

Recommended practice: Implementations should provide consistent results of floating-point evaluations, irrespective of whether the evaluation is performed during translation or during program execution.

[Note 6: Since this document imposes no restrictions on the accuracy of floating-point operations, it is unspecified whether the evaluation of a floating-point expression during translation yields the same result as the evaluation of the same expression (or the same operations on the same values) during program execution.]

[Example 6:]
```cpp
bool f() {
    char array[1 + int(1 + 0.2 - 0.1 - 0.1)];  // Must be evaluated during translation
```
int size = 1 + int(1 + 0.2 - 0.1 - 0.1); // May be evaluated at runtime
return sizeof(array) == size;
}

It is unspecified whether the value of f() will be true or false. — end example]
— end note]

An expression or conversion is in an immediate function context if it is potentially evaluated and its innermost enclosing non-block scope is a function parameter scope of an immediate function. An expression or conversion is an immediate invocation if it is a potentially-evaluated explicit or implicit invocation of an immediate function and is not in an immediate function context. An immediate invocation shall be a constant expression.

An expression or conversion is manifestly constant-evaluated if it is:

1. a constant-expression, or
2. the condition of a constexpr if statement (8.5.2), or
3. an immediate invocation, or
4. the result of substitution into an atomic constraint expression to determine whether it is satisfied (13.5.2.3), or
5. the initializer of a variable that is usable in constant expressions or has constant initialization (6.9.3.2).

Example 7:

```cpp
template<bool> struct X {}
X<std::is_constant_evaluated()> x; // type X<true>
int y;
const int a = std::is_constant_evaluated() ? y : 1; // dynamic initialization to 1
double z[a]; // error: a is not usable
const int b = std::is_constant_evaluated() ? 2 : y; // static initialization to 2
int c = y + (std::is_constant_evaluated() ? 2 : y); // dynamic initialization to y+y

constexpr int f() {
    const int n = std::is_constant_evaluated() ? 13 : 17; // m is 13
    int m = std::is_constant_evaluated() ? 13 : 17; // m can be 13 or 17 (see below)
    char arr[n] = {}; // char[13]
    return m + sizeof(arr);
}
int p = f(); // m is 13; initialized to 26
int q = p + f(); // m is 17 for this call; initialized to 56

— end example]
[Note 7: A manifestly constant-evaluated expression is evaluated even in an unevaluated operand. — end note]

An expression or conversion is potentially constant evaluated if it is:

1. a manifestly constant-evaluated expression,
2. a potentially-evaluated expression (6.3),
3. an immediate subexpression of a braced-init-list,
4. an expression of the form & cast-expression that occurs within a templated entity, or
5. a subexpression of one of the above that is not a subexpression of a nested unevaluated operand.

A function or variable is needed for constant evaluation if it is:

1. a constexpr function that is named by an expression (6.3) that is potentially constant evaluated, or
2. a variable named by a potentially constant evaluated expression that is either a constexpr variable or is of non-volatile const-qualified integral type or of reference type.

78) Testing this condition can involve a trial evaluation of its initializer as described above.
79) In some cases, constant evaluation is needed to determine whether a narrowing conversion is performed (9.4.5).
80) In some cases, constant evaluation is needed to determine whether such an expression is value-dependent (13.8.3.4).
8 Statements

8.1 Preamble

Except as indicated, statements are executed in sequence.

statement:
   labeled-statement
   attribute-specifier-seq_opt expression-statement
   attribute-specifier-seq_opt compound-statement
   attribute-specifier-seq_opt selection-statement
   attribute-specifier-seq_opt iteration-statement
   attribute-specifier-seq_opt jump-statement
   declaration-statement
   attribute-specifier-seq_opt try-block

init-statement:
   expression-statement
   simple-declaration

condition:
   expression
   attribute-specifier-seq_opt decl-specifier-seq declarator brace-or-equal-initializer

The optional attribute-specifier-seq appertains to the respective statement.

2 A substatement of a statement is one of the following:

(2.1) — for a labeled-statement, its statement,

(2.2) — for a compound-statement, any statement of its statement-seq,

(2.3) — for a selection-statement, any of its statements (but not its init-statement), or

(2.4) — for an iteration-statement, its statement (but not an init-statement).

[Note 1: The compound-statement of a lambda-expression is not a substatement of the statement (if any) in which the lambda-expression lexically appears. — end note]

3 A statement \(S_1\) encloses a statement \(S_2\) if

(3.1) — \(S_2\) is a substatement of \(S_1\) (Clause 9),

(3.2) — \(S_1\) is a selection-statement or iteration-statement and \(S_2\) is the init-statement of \(S_1\),

(3.3) — \(S_1\) is a try-block and \(S_2\) is its compound-statement or any of the compound-statements of its handlers, or

(3.4) — \(S_1\) encloses a statement \(S_3\) and \(S_3\) encloses \(S_2\).

4 The rules for conditions apply both to selection-statements and to the for and while statements (8.6). A condition that is not an expression is a declaration (Clause 9). The declarator shall not specify a function or an array. The decl-specifier-seq shall not define a class or enumeration. If the auto type-specifier appears in the decl-specifier-seq, the type of the identifier being declared is deduced from the initializer as described in 9.2.9.6.

5 The value of a condition that is an initialized declaration in a statement other than a switch statement is the value of the declared variable contextually converted to bool (7.3). If that conversion is ill-formed, the program is ill-formed. The value of a condition that is an initialized declaration in a switch statement is the value of the declared variable if it has integral or enumeration type, or of that variable implicitly converted to integral or enumeration type otherwise. The value of a condition that is an expression is the value of the expression, contextually converted to bool for statements other than switch; if that conversion is ill-formed, the program is ill-formed. The value of the condition will be referred to as simply “the condition” where the usage is unambiguous.

6 If a condition can be syntactically resolved as either an expression or a declaration, it is interpreted as the latter.

7 In the decl-specifier-seq of a condition, each decl-specifier shall be either a type-specifier or constexpr.
8.2 Labeled statement

A statement can be labeled.

labeled-statement:
  attribute-specifier-seqopt identifier : statement
  attribute-specifier-seqopt case constant-expression : statement
  attribute-specifier-seqopt default : statement

The optional attribute-specifier-seq appertains to the label. The only use of a label with an identifier is as the target of a goto. No two labels in a function shall have the same identifier. A label can be used in a goto statement before its introduction by a labeled-statement.

2 Case labels and default labels shall occur only in switch statements.

8.3 Expression statement

Expression statements have the form

expression-statement:
  expressionopt ;

The expression is a discarded-value expression (7.2.3). All side effects from an expression statement are completed before the next statement is executed. An expression statement with the expression missing is called a null statement.

[Note 1: Most statements are expression statements — usually assignments or function calls. A null statement is useful to carry a label just before the ) of a compound statement and to supply a null body to an iteration statement such as a while statement (8.6.2). — end note]

8.4 Compound statement or block

A compound statement (also known as a block) groups a sequence of statements into a single statement.

compound-statement:
  { statement-seqopt }

statement-seq:
  statement
  statement-seq statement

[Note 1: A compound statement defines a block scope (6.4). A declaration is a statement (8.8). — end note]

8.5 Selection statements

8.5.1 General

Selection statements choose one of several flows of control.

selection-statement:
  if constexpropt ( init-statementopt condition ) statement
  if constexpropt ( init-statementopt condition ) statement else statement
  switch ( init-statementopt condition ) statement

See 9.3.4 for the optional attribute-specifier-seq in a condition.

[Note 1: An init-statement ends with a semicolon. — end note]

2 [Note 2: Each selection-statement and each substatement of a selection-statement has a block scope (6.4.3). — end note]

8.5.2 The if statement

If the condition (8.5) yields true the first substatement is executed. If the else part of the selection statement is present and the condition yields false, the second substatement is executed. If the first substatement is reached via a label, the condition is not evaluated and the second substatement is not executed. In the second form of if statement (the one including else), if the first substatement is also an if statement then that inner if statement shall contain an else part.\textsuperscript{81}

2 If the if statement is of the form if constexpr, the value of the condition shall be a contextually converted constant expression of type bool (7.7); this form is called a constexpr if statement. If the value of the converted condition is false, the first substatement is a discarded statement, otherwise the second substatement, if

\textsuperscript{81} In other words, the else is associated with the nearest un-elsed if.
present, is a discarded statement. During the instantiation of an enclosing templated entity (13.1), if the
condition is not value-dependent after its instantiation, the discarded substatement (if any) is not instantiated.

[Note 1: Odr-uses (6.3) in a discarded statement do not require an entity to be defined. — end note]

A case or default label appearing within such an if statement shall be associated with a switch statement
(8.5.3) within the same if statement. A label (8.2) declared in a substatement of a constexpr if statement
shall only be referred to by a statement (8.7.6) in the same substatement.

[Example 1:]

```cpp
template<
typename T, 
typename ... Rest>
void g(T&& p, Rest&& ...rs) {
    // ... handle p
    if constexpr (sizeof...(rs) > 0)
        g(rs...); // never instantiated with an empty argument list
}
extern int x; // no definition of x required
int f() {
    if constexpr (true)
        return 0;
    else if (x)
        return x;
    else
        return -x;
}
@end example]
```

An if statement of the form

```cpp
if constexpr (init-statement condition) statement
```

is equivalent to

```cpp
{
    init-statement
    if constexpr (condition) statement
}
```

and an if statement of the form

```cpp
if constexpr (init-statement condition) statement else statement
```

is equivalent to

```cpp
{
    init-statement
    if constexpr (condition) statement else statement
}
```

except that the init-statement is in the same scope as the condition.

### 8.5.3 The switch statement

The switch statement causes control to be transferred to one of several statements depending on the value
of a condition.

The condition shall be of integral type, enumeration type, or class type. If of class type, the condition is
contextually implicitly converted (7.3) to an integral or enumeration type. If the (possibly converted) type
is subject to integral promotions (7.3.7), the condition is converted to the promoted type. Any statement
within the switch statement can be labeled with one or more case labels as follows:

```cpp
case constant-expression :
```

where the constant-expression shall be a converted constant expression (7.7) of the adjusted type of the switch
condition. No two of the case constants in the same switch shall have the same value after conversion.

There shall be at most one label of the form

```cpp
default :
```

within a switch statement.
Switch statements can be nested; a case or default label is associated with the smallest switch enclosing it.

When the switch statement is executed, its condition is evaluated. If one of the case constants has the same value as the condition, control is passed to the statement following the matched case label. If no case constant matches the condition, and if there is a default label, control passes to the statement labeled by the default label. If no case matches and if there is no default then none of the statements in the switch is executed.

case and default labels in themselves do not alter the flow of control, which continues unimpeded across such labels. To exit from a switch, see break, 8.7.2.

[A switch statement of the form]

```c
switch ( init-statement condition ) statement
```

is equivalent to

```c
{ 
  init-statement
  switch ( condition ) statement
}
```

except that the init-statement is in the same scope as the condition.

### 8.6 Iteration statements [stmt.iter]
#### 8.6.1 General [stmt.iter.general]

Iteration statements specify looping.

**iteration-statement:**

- while ( condition ) statement
- do statement while ( expression )
- for ( init-statement condition opt ; expression opt ) statement
- for ( init-statement opt for-range-declaration : for-range-initializer ) statement

**for-range-declaration:**

```c
attribute-specifier-seq opt decl-specifier-seq declarator
attribute-specifier-seq opt decl-specifier-seq ref-qualifier opt [ identifier-list ]
```

**for-range-initializer:**

```c
expr-or-braced-init-list
```

See 9.3.4 for the optional attribute-specifier-seq in a for-range-declaration.

[Note 1: An init-statement ends with a semicolon. — end note]

The substatement in an iteration-statement implicitly defines a block scope (6.4) which is entered and exited each time through the loop. If the substatement in an iteration-statement is a single statement and not a compound-statement, it is as if it was rewritten to be a compound-statement containing the original statement.

**Example 1:**

```c
while (--x >= 0)
  int i;
```

can be equivalently rewritten as

```c
while (--x >= 0) {
  int i;
}
```

Thus after the while statement, i is no longer in scope. — end example]

#### 8.6.2 The while statement [stmt.while]

In the while statement the substatement is executed repeatedly until the value of the condition (8.5) becomes false. The test takes place before each execution of the substatement.

A while statement is equivalent to
label:
{
  if ( condition ) {
    statement
    goto label;
  }
}

[Note 1: The variable created in the condition is destroyed and created with each iteration of the loop.]

[Example 1:
struct A {
  int val;
  A(int i) : val(i) { }
  ~A() { }
  operator bool() { return val != 0; }
};
int i = 1;
while (A a = i) {
  // ...
  i = 0;
}
In the while-loop, the constructor and destructor are each called twice, once for the condition that succeeds and once for the condition that fails. — end example]
— end note]

8.6.3 The do statement
[stmt.do]
1 The expression is contextually converted to bool (7.3); if that conversion is ill-formed, the program is ill-formed.
2 In the do statement the substatement is executed repeatedly until the value of the expression becomes false. The test takes place after each execution of the statement.

8.6.4 The for statement
[stmt.for]
1 The for statement
   for ( init-statement condition_opt ; expression_opt ) statement
is equivalent to
   {
      init-statement
      while ( condition ) {
        statement
        expression;
      }
   }
except that the init-statement is in the same scope as the condition, and except that a continue in statement (not enclosed in another iteration statement) will execute expression before re-evaluating condition.
[Note 1: Thus the first statement specifies initialization for the loop; the condition (8.5) specifies a test, sequenced before each iteration, such that the loop is exited when the condition becomes false; the expression often specifies incrementing that is sequenced after each iteration. — end note]
2 Either or both of the condition and the expression can be omitted. A missing condition makes the implied while clause equivalent to while(true).

8.6.5 The range-based for statement
[stmt.ranged]
1 The range-based for statement
   for ( init-statement_opt for-range-declaration : for-range-initializer ) statement
is equivalent to
where

(1.1) — if the for-range-initializer is an expression, it is regarded as if it were surrounded by parentheses (so that
a comma operator cannot be reinterpreted as delimiting two init-declarators);

(1.2) — range, begin, and end are variables defined for exposition only; and

(1.3) — begin-expr and end-expr are determined as follows:

(1.3.1) — if the for-range-initializer is an expression of array type \( R \), begin-expr and end-expr are \( \text{range} \) and \( \text{range} + N \), respectively, where \( N \) is the array bound. If \( R \) is an array of unknown bound or an
array of incomplete type, the program is ill-formed;

(1.3.2) — if the for-range-initializer is an expression of class type \( C \), and searches in the scope of \( C \) (6.5.2)
for the names begin and end each find at least one declaration, begin-expr and end-expr are
\( \text{range}.\text{begin}() \) and \( \text{range}.\text{end}() \), respectively;

(1.3.3) — otherwise, begin-expr and end-expr are \( \text{begin}() \) and \( \text{end}() \), respectively, where
begin and end undergo argument-dependent lookup (6.5.4).

[Note 1: Ordinary unqualified lookup (6.5.3) is not performed. — end note]

Example 1:
```c
int array[5] = { 1, 2, 3, 4, 5 };
for (int& x : array)
  x *= 2;
```

—end example]

2 In the decl-specifier-seq of a for-range-declaration, each decl-specifier shall be either a type-specifier or constexpr.
The decl-specifier-seq shall not define a class or enumeration.

8.7 Jump statements [stmt.jump]

8.7.1 General [stmt.jump.general]

1 Jump statements unconditionally transfer control.

```
jump-statement:
  break;
  continue;
  return expr-or-braced-init-listopt;
  coroutine-return-statement
goto identifier;
```

2 [Note 1: On exit from a scope (however accomplished), objects with automatic storage duration (6.7.5.4) that have
been constructed in that scope are destroyed in the reverse order of their construction. For temporaries, see 6.7.7.
However, the program can be terminated (by calling std::exit() or std::abort() (17.5), for example) without
destroying objects with automatic storage duration. — end note]

[Note 2: A suspension of a coroutine (7.6.2.4) is not considered to be an exit from a scope. — end note]

8.7.2 The break statement [stmt.break]

1 The break statement shall occur only in an iteration-statement or a switch statement and causes termination
of the smallest enclosing iteration-statement or switch statement; control passes to the statement following the
terminated statement, if any.
8.7.3 The continue statement

The continue statement shall occur only in an iteration-statement and causes control to pass to the loop-continuation portion of the smallest enclosing iteration-statement, that is, to the end of the loop. More precisely, in each of the statements

```c
while (foo) {
    // ...
    contin: ;
}
```

```c
do {
    // ...
    contin: ;
} while (foo);
```

```c
for (;;) {
    // ...
    contin: ;
} while (foo);
```
a continue not contained in an enclosed iteration statement is equivalent to goto contin.

8.7.4 The return statement

A function returns to its caller by the return statement.

The expr-or-braced-init-list of a return statement is called its operand. A return statement with no operand shall be used only in a function whose return type is cv void, a constructor (11.4.5), or a destructor (11.4.7). A return statement with an operand of type void shall be used only in a function whose return type is cv void. A return statement with any other operand shall be used only in a function whose return type is not cv void; the return statement initializes the glvalue result or prvalue result object of the (explicit or implicit) function call by copy-initialization (9.4) from the operand.

[Note 1: A return statement can involve an invocation of a constructor to perform a copy or move of the operand if it is not a prvalue or if its type differs from the return type of the function. A copy operation associated with a return statement can be elided or converted to a move operation if an automatic storage duration variable is returned (11.9.6). —end note]

The destructor for the result object is potentially invoked (11.4.7, 14.3).

[Example 1]

```c
class A {
    ~A() {}
};
A f() { return A(); } // error: destructor of A is private (even though it is never invoked)
```

—end example

Flowing off the end of a constructor, a destructor, or a non-coroutine function with a cv void return type is equivalent to a return with no operand. Otherwise, flowing off the end of a function other than main (6.9.3.1) or a coroutine (9.5.4) results in undefined behavior.

The copy-initialization of the result of the call is sequenced before the destruction of temporaries at the end of the full-expression established by the operand of the return statement, which, in turn, is sequenced before the destruction of local variables (8.7) of the block enclosing the return statement.

8.7.5 The co_return statement

A coroutine returns to its caller or resumer (9.5.4) by the co_return statement or when suspended (7.6.2.4). A coroutine shall not enclose a return statement (8.7.4).

[Note 1: For this determination, it is irrelevant whether the return statement is enclosed by a discarded statement (8.5.2). —end note]

The expr-or-braced-init-list of a co_return statement is called its operand. Let p be an lvalue naming the coroutine promise object (9.5.4). A co_return statement is equivalent to:

```c
{ S; goto final-suspend; }
```

where final-suspend is the exposition-only label defined in 9.5.4 and S is defined as follows:

1. If the operand is a braced-init-list or an expression of non-void type, S is p.return_value(expr-or-braced-init-list). The expression S shall be a prvalue of type void.

2. Otherwise, S is the compound-statement { expression_opt ; p.return_void(); }. The expression p.return_void() shall be a prvalue of type void.
If \( p \).return_void() is a valid expression, flowing off the end of a coroutine’s function-body is equivalent to a \texttt{co_return} with no operand; otherwise flowing off the end of a coroutine’s function-body results in undefined behavior.

### 8.7.6 The \texttt{goto} statement

The \texttt{goto} statement unconditionally transfers control to the statement labeled by the identifier. The identifier shall be a label (8.2) located in the current function.

### 8.8 Declaration statement

A declaration statement introduces one or more new names into a block; it has the form

```
declaration-statement:
   block-declaration
```

\[\text{Note 1: If an identifier introduced by a declaration was previously declared in an outer block, the outer declaration is hidden for the remainder of the block (6.5.3), after which it resumes its force. —end note}\]

A variable with automatic storage duration (6.7.5.4) is active everywhere in the scope to which it belongs after its \textit{init-declarator}.

Upon each transfer of control (including sequential execution of statements) within a function from point \( P \) to point \( Q \), all variables that are active at \( P \) and not at \( Q \) are destroyed in the reverse order of their construction. Then, all variables that are active at \( Q \) but not at \( P \) are initialized in declaration order; unless all such variables have vacuous initialization (6.7.3), the transfer of control shall not be a jump.\(^{82}\) When a \textit{declaration-statement} is executed, \( P \) and \( Q \) are the points immediately before and after it; when a function returns, \( Q \) is after its body.

\[\text{Example 1:}\]
```
void f() {
   // ...
   goto lx;     // error: jump into scope of a
   // ...
   ly:
      X a = 1;
   // ...
   lx:
      goto ly;     // OK, jump implies destructor call for a followed by
      // construction again immediately following label ly
}
```

\[\text{—end example}\]

Dynamic initialization of a block variable with static storage duration (6.7.5.2) or thread storage duration (6.7.5.3) is performed the first time control passes through its declaration; such a variable is considered initialized upon the completion of its initialization. If the initialization exits by throwing an exception, the initialization is not complete, so it will be tried again the next time control enters the declaration. If control enters the declaration concurrently while the variable is being initialized, the concurrent execution shall wait for completion of the initialization.

\[\text{Note 2: A conforming implementation cannot introduce any deadlock around execution of the initializer. Deadlocks might still be caused by the program logic; the implementation need only avoid deadlocks due to its own synchronization operations. —end note}\]

If control re-enters the declaration recursively while the variable is being initialized, the behavior is undefined.

\[\text{Example 2:}\]
```
int foo(int i) {
   static int s = foo(2*i);    // undefined behavior: recursive call
   return i+1;
}
```

\[\text{—end example}\]

An object associated with a block variable with static or thread storage duration will be destroyed if and only if it was constructed.

\[\text{Note 3: 6.9.3.4 describes the order in which such objects are destroyed. —end note}\]

\footnote{82} The transfer from the condition of a \texttt{switch} statement to a \texttt{case} label is considered a jump in this respect.
8.9 Ambiguity resolution

There is an ambiguity in the grammar involving expression-statements and declarations: An expression-statement with a function-style explicit type conversion (7.6.1.4) as its leftmost subexpression can be indistinguishable from a declaration where the first declarator starts with a `. In those cases the statement is a declaration.

[Note 1: If the statement cannot syntactically be a declaration, there is no ambiguity, so this rule does not apply. In some cases, the whole statement needs to be examined to determine whether this is the case. This resolves the meaning of many examples.]

Example 1: Assuming T is a simple-type-specifier (9.2.9),

```c
T(a)->m = 7;  // expression-statement
T(a)++;        // expression-statement
T(a,5)<<c;    // expression-statement

T(*d)(int);    // declaration
T(e)[5];       // declaration
T(f) = { 1, 2 }; // declaration
T(*g)(double(3)); // declaration
```

In the last example above, g, which is a pointer to T, is initialized to double(3). This is of course ill-formed for semantic reasons, but that does not affect the syntactic analysis. — end example]

The remaining cases are declarations.

Example 2:

```c
class T {

public:
    T();        // declaration
    T(int);     // declaration
    T(int, int); // declaration
};

T(a);        // declaration
T(*b)();     // declaration
T(c)=7;      // declaration
T(d),e,f=3;  // declaration
extern int h;
T(g)(h,2);   // declaration
```

—end example[—end note]

The disambiguation is purely syntactic; that is, the meaning of the names occurring in such a statement, beyond whether they are type-names or not, is not generally used in or changed by the disambiguation. Class templates are instantiated as necessary to determine if a qualified name is a type-name. Disambiguation precedes parsing, and a statement disambiguated as a declaration may be an ill-formed declaration. If, during parsing, lookup finds that a name in a template argument is bound to (part of) the declaration being parsed, the program is ill-formed. No diagnostic is required.

Example 3:

```c
struct T1 {
    T1 operator() (int x) { return T1(x); }  
    int operator=(int x) { return x; }  
    T1(int) { }  
};

struct T2 { T2(int) { } };  

int a, (*(*b)(T2))(int), c, d;

void f() {
    // disambiguation requires this to be parsed as a declaration:
    T1(a) = 3, T2(4), (*(*b)(T2(c)))(int(d));  // T2 will be declared as a variable of type T1, but this will not allow the last part of the declaration to parse properly, since it depends on T2 being a type-name
    }
```

—end example]
9 Declarations

9.1 Preamble

Declarations generally specify how names are to be interpreted. Declarations have the form

\[
\text{declaration-seq:}
\text{declaration}
\text{declaration-seq declaration}
\]

\[
\text{declaration:}
\text{block-declaration}
\text{nodelclspec-function-declaration}
\text{function-definition}
\text{template-declaration}
\text{deduction-guide}
\text{explicit-instantiation}
\text{explicit-specialization}
\text{export-declaration}
\text{linkage-specification}
\text{namespace-definition}
\text{empty-declaration}
\text{attribute-declaration}
\text{module-import-declaration}
\]

\[
\text{block-declaration:}
\text{simple-declaration}
\text{asm-declaration}
\text{namespace-alias-definition}
\text{using-declaration}
\text{using-enum-declaration}
\text{using-directive}
\text{static_assert-declaration}
\text{alias-declaration}
\text{opaque-enum-declaration}
\]

\[
\text{nodelclspec-function-declaration:}
\text{attribute-specifier-seq_{opt} declarator ;}
\]

\[
\text{alias-declaration:}
\text{using identifier attribute-specifier-seq_{opt} = defining-type-id ;}
\]

\[
\text{simple-declaration:}
\text{decl-specifier-seq init-declarator-list_{opt} ;}
\text{attribute-specifier-seq decl-specifier-seq init-declarator-list ;}
\text{attribute-specifier-seq_{opt} decl-specifier-seq ref-qualifier_{opt} [ identifier-list ] initializer ;}
\]

\[
\text{static_assert-declaration:}
\text{static_assert ( constant-expression ) ;}
\text{static_assert ( constant-expression , string-literal ) ;}
\]

\[
\text{empty-declaration:}
\text{;}
\text{attribute-declaration:}
\text{attribute-specifier-seq ;}
\]

[Note 1: \text{asm-declarations} are described in 9.10, and \text{linkage-specifications} are described in 9.11; \text{function-definitions} are described in 9.5 and \text{template-declarations} and \text{deduction-guides} are described in 13.7.2.3; \text{namespace-definitions} are described in 9.8.2, \text{using-declarations} are described in 9.9 and \text{using-directives} are described in 9.8.4. – end note]

Certain declarations contain one or more scopes (6.4.1). Unless otherwise stated, utterances in Clause 9 about components in, of, or contained by a declaration or subcomponent thereof refer only to those components of the declaration that are not nested within scopes nested within the declaration.

A \text{simple-declaration} or \text{nodelclspec-function-declaration} of the form

\[
\text{attribute-specifier-seq_{opt} decl-specifier-seq_{opt} init-declarator-list_{opt} ;}
\]
is divided into three parts. Attributes are described in §9.12. decl-specifiers, the principal components of a decl-specifier-seq, are described in §9.2. declarators, the components of an init-declarator-list, are described in §9.3. The attribute-specifier-seq appertains to each of the entities declared by the declarators of the init-declarator-list.

[Note 2: In the declaration for an entity, attributes appertaining to that entity can appear at the start of the declaration and after the declarator-id for that declaration. —end note]

[Example 1:

```c
int [[noreturn]] void f [[noreturn]] () ;  // OK
```
—end example]

4 If a declarator-id is a name, the init-declarator and (hence) the declaration introduce that name.

[Note 3: Otherwise, the declarator-id is a qualified-id or names a destructor or its unqualified-id is a template-id and no name is introduced. —end note]

The defining-type-specifiers (§9.2.9) in the decl-specifier-seq and the recursive declarator structure describe a type (§9.3.4), which is then associated with the declarator-id.

5 In a simple-declaration, the optional init-declarator-list can be omitted only when declaring a class (§11.1) or enumeration (§9.7.1), that is, when the decl-specifier-seq contains either a class-specifier, an elaborated-type-specifier with a class-key (§11.3), or an enum-specifier. In these cases and whenever a class-specifier or enum-specifier is present in the decl-specifier-seq, the identifiers in these specifiers are also declared (as class-names, enum-names, or enumerators, depending on the syntax). In such cases, the decl-specifier-seq shall (re)introduce one or more names into the program.

[Example 2:

```c
enum { } ;  // error
typedef class { } ;  // error
```
—end example]

6 A simple-declaration with an identifier-list is called a structured binding declaration (§9.6). If the decl-specifier-seq contains any decl-specifier other than static, thread_local, auto (§9.2.9.6), or cv-qualifiers, the program is ill-formed. The initializer shall be of the form “= assignment-expression”, of the form “{ assignment-expression }”, or of the form “( assignment-expression )”, where the assignment-expression is of array or non-union class type.

7 If the decl-specifier-seq contains the typedef specifier, the declaration is called a typedef declaration and each declarator-id is declared to be a typedef-name, synonymous with its associated type (§9.2.4).

[Note 4: Such a declarator-id is an identifier (§11.4.8.3). —end note]

If the decl-specifier-seq contains no typedef specifier, the declaration is called a function declaration if the type associated with a declarator-id is a function type (§9.3.4.6) and an object declaration otherwise.

8 Syntactic components beyond those found in the general form of simple-declaration are added to a function declaration to make a function-definition. An object declaration, however, is also a definition unless it contains the extern specifier and has no initializer (§6.2). An object definition causes storage of appropriate size and alignment to be reserved and any appropriate initialization (§9.4) to be done.

9 A nodeclspec-function-declaration shall declare a constructor, destructor, or conversion function.

[Note 5: A nodeclspec-function-declaration can only be used in a template-declaration (§13.1), explicit-instantiation (§13.9.3), or explicit-specialization (§13.9.4). —end note]

10 In a static_assert-declaration, the constant-expression shall be a contextually converted constant expression of type bool (§7.7). If the value of the expression when so converted is true, the declaration has no effect. Otherwise, the program is ill-formed, and the resulting diagnostic message (§4.1) shall include the text of the string-literal, if one is supplied, except that characters not in the basic source character set (§5.3) are not required to appear in the diagnostic message.

[Example 3:

```c
static_assert(sizeof(int) == sizeof(void*), "wrong pointer size");
```
—end example]

11 An empty-declaration has no effect.

12 Except where otherwise specified, the meaning of an attribute-declaration is implementation-defined.
9.2 Specifiers \[dcl.spec\]

9.2.1 General \[dcl.spec.general\]

1 The specifiers that can be used in a declaration are

```plaintext
decl-specifier:
  storage-class-specifier
  defining-type-specifier
  function-specifier
  friend
typedef
constexpr
consteval
constinit
inline
dcl-specifier-seq:
  decl-specifier attribute-specifier-seq_opt
dcl-specifier decl-specifier-seq
```

The optional attribute-specifier-seq in a decl-specifier-seq appertains to the type determined by the preceding decl-specifiers (9.3.4). The attribute-specifier-seq affects the type only for the declaration it appears in, not other declarations involving the same type.

2 Each decl-specifier shall appear at most once in a complete decl-specifier-seq, except that long may appear twice. At most one of the constexpr, consteval, and constinit keywords shall appear in a decl-specifier-seq.

3 If a type-name is encountered while parsing a decl-specifier-seq, it is interpreted as part of the decl-specifier-seq if and only if there is no previous defining-type-specifier other than a cv-qualifier in the decl-specifier-seq. The sequence shall be self-consistent as described below.

[Example 1:]
```plaintext
typedef char* Pc;
static Pc; // error: name missing
```

Here, the declaration static Pc is ill-formed because no name was specified for the static variable of type Pc. To get a variable called Pc, a type-specifier (other than const or volatile) has to be present to indicate that the typedef-name Pc is the name being (re)declared, rather than being part of the decl-specifier-sequence. For another example,

```plaintext
void f(const Pc); // void f(char* const) (not const char*)
void g(const int Pc); // void g(const int)
```

—end example]

[Note 1: Since signed, unsigned, long, and short by default imply int, a type-name appearing after one of those specifiers is treated as the name being (re)declared.]

[Example 2:]
```plaintext
void h(unsigned Pc); // void h(unsigned int)
void k(unsigned int Pc); // void k(unsigned int)
```

—end example]

—end note]

9.2.2 Storage class specifiers \[dcl.stc\]

1 The storage class specifiers are

```plaintext
storage-class-specifier:
  static
thread_local
extern
mutable
```

At most one storage-class-specifier shall appear in a given decl-specifier-seq, except that thread_local may appear with static or extern. If thread_local appears in any declaration of a variable it shall be present in all declarations of that entity. If a storage-class-specifier appears in a decl-specifier-seq, there can be no typedef specifier in the same decl-specifier-seq and the init-declarator-list or member-declarator-list of the declaration shall not be empty (except for an anonymous union declared in a namespace scope (11.5.2)). The storage-class-specifier applies to the name declared by each init-declarator in the list and not to any names declared by other specifiers.

§ 9.2.2
1 [Note 1: See 13.9.4 and 13.9.3 for restrictions in explicit specializations and explicit instantiations, respectively. —end note]

2 [Note 2: A variable declared without a storage-class-specifier at block scope or declared as a function parameter has automatic storage duration by default (6.7.5.4). —end note]

3 The thread_local specifier indicates that the named entity has thread storage duration (6.7.5.3). It shall be applied only to the declaration of a variable of namespace or block scope, to a structured binding declaration (9.6), or to the declaration of a static data member. When thread_local is applied to a variable of block scope the storage-class-specifier static is implied if no other storage-class-specifier appears in the decl-specifier-seq.

4 The static specifier shall be applied only to the declaration of a variable or function, to a structured binding declaration (9.6), or to the declaration of an anonymous union (11.5.2). There can be no static function declarations within a block, nor any static function parameters. A static specifier used in the declaration of a variable declares the variable to have static storage duration (6.7.5.2), unless accompanied by the thread_local specifier, which declares the variable to have thread storage duration (6.7.5.3). A static specifier can be used in declarations of class members; 11.4.9 describes its effect. For the linkage of a name declared with a static specifier, see 6.6.

5 The extern specifier shall be applied only to the declaration of a variable or function. The extern specifier shall not be used in the declaration of a class member or function parameter. For the linkage of a name declared with an extern specifier, see 6.6.

[Note 3: The extern keyword can also be used in explicit-instantiations and linkage-specifications, but it is not a storage-class-specifier in such contexts. —end note]

6 All declarations for a given entity shall give its name the same linkage.

[Note 4: The linkage given by some declarations is affected by previous declarations. Overloads are distinct entities. —end note]

[Example 1: The linkage given by some declarations is affected by previous declarations. Overloads are distinct entities. —end example]

```
static char* f(); // f() has internal linkage
char* f();       // f() still has internal linkage
{ /* ... */ }   

char* g();      // g() has external linkage
static char* g() // error: inconsistent linkage
{ /* ... */ }   

void h();       // external linkage
inline void h(); // external linkage
inline void l(); // external linkage
void l();       // external linkage
inline void m(); // external linkage
extern void m(); // external linkage
static void n(); // internal linkage
inline void n(); // internal linkage

static int a;  // a has internal linkage
int a;         // error: two definitions
static int b;  // b has internal linkage
extern int b;  // b still has internal linkage
int c;         // c has external linkage
static int c;  // error: inconsistent linkage
extern int d;  // d has external linkage
static int d;  // error: inconsistent linkage
```

§ 9.2.2 165
The name of a declared but undefined class can be used in an `extern` declaration. Such a declaration can only be used in ways that do not require a complete class type.

```
Example 2:
struct S;
extern S a;
extern S f();
extern void g(S);
void h() {
    g(a); // error: S is incomplete
    f(); // error: S is incomplete
}
—end example
```

The `mutable` specifier shall appear only in the declaration of a non-static data member (11.4) whose type is neither const-qualified nor a reference type.

```
Example 3:
class X {
    mutable const int* p; // OK
    mutable int* const q; // error
};
—end example
```

[Note 5: The `mutable` specifier on a class data member nullifies a `const` specifier applied to the containing class object and permits modification of the mutable class member even though the rest of the object is const (6.8.4, 9.2.9.2). —end note]

### 9.2.3 Function specifiers

A `function-specifier` can be used only in a function declaration.

```
function-specifier:
    virtual
    explicit-specifier

explicit-specifier:
    explicit ( constant-expression )
    explicit
```

The `virtual` specifier shall be used only in the initial declaration of a non-static member function; see 11.7.3.

An `explicit-specifier` shall be used only in the declaration of a constructor or conversion function within its class definition; see 11.4.8.2 and 11.4.8.3.

In an `explicit-specifier`, the `constant-expression`, if supplied, shall be a contextually converted constant expression of type `bool` (7.7). The `explicit-specifier explicit` without a `constant-expression` is equivalent to the `explicit-specifier explicit(true)`. If the constant expression evaluates to `true`, the function is explicit. Otherwise, the function is not explicit. A `( token that follows `explicit` is parsed as part of the `explicit-specifier`.

### 9.2.4 The typedef specifier

Declarations containing the `decl-specifier typedef` declare identifiers that can be used later for naming fundamental (6.8.2) or compound (6.8.3) types. The `typedef` specifier shall not be combined in a `decl-specifier-seq with any other kind of specifier except a defining-type-specifier, and it shall not be used in the `decl-specifier-seq of a parameter-declaration (9.3.4.6) or in the `decl-specifier-seq of a function-definition (9.5). If a `typedef` specifier appears in a declaration without a `declarator, the program is ill-formed.

```
typedef-name:
    identifier
    simple-template-id
```

A name declared with the `typedef` specifier becomes a `typedef-name`. A `typedef-name` names the type associated with the `identifier` (9.3) or `simple-template-id` (13.1); a `typedef-name` is thus a synonym for another type. A `typedef-name` does not introduce a new type the way a class declaration (11.3) or enum declaration (9.7.1) does.

```
Example 1: After
```
typedef int MILES, *KLICKSP;
the constructions

MILES distance;
extern KLICKSP metricp;

are all correct declarations; the type of distance is int and that of metricp is “pointer to int”. — end example

2 A typedef-name can also be introduced by an alias-declaration. The identifier following the using keyword is not looked up; it becomes a typedef-name and the optional attribute-specifier-seq following the identifier appertains to that typedef-name. Such a typedef-name has the same semantics as if it were introduced by the typedef specifier. In particular, it does not define a new type.

[Example 2:
using handler_t = void (*)(int);
extern handler_t ignore;
extern void (*ignore)(int); // redeclare ignore
using cell = pair<void*, cell*>; // error
— end example]

The defining-type-specifier-seq of the defining-type-id shall not define a class or enumeration if the alias-declaration is the declaration of a template-declaration.

3 A simple-template-id is only a typedef-name if its template-name names an alias template or a template template-parameter.

[Note 1: A simple-template-id that names a class template specialization is a class-name (11.3). If a typedef-name is used to identify the subject of an elaborated-type-specifier (9.2.9.4), a class definition (Clause 11), a constructor declaration (11.4.5), or a destructor declaration (11.4.7), the program is ill-formed. — end note]

[Example 3:
struct S {
    S();
    ~S();
};
typedef struct S T;
S a = T(); // OK
struct T * p; // error
— end example]

4 If the typedef declaration defines an unnamed class or enumeration, the first typedef-name declared by the declaration to be that type is used to denote the type for linkage purposes only (6.6).

[Note 2: A typedef declaration involving a lambda-expression does not itself define the associated closure type, and so the closure type is not given a name for linkage purposes. — end note]

[Example 4:
typedef struct { } *ps, S; // S is the class name for linkage purposes
typedef decltype([]{}()) C; // the closure type has no name for linkage purposes
— end example]

5 An unnamed class with a typedef name for linkage purposes shall not

(5.1) — declare any members other than non-static data members, member enumerations, or member classes,
(5.2) — have any base classes or default member initializers, or
(5.3) — contain a lambda-expression,
and all member classes shall also satisfy these requirements (recursively).

[Example 5:
typedef struct {
    int f() {}
} X; // error: struct with typedef name for linkage has member functions
— end example]
9.2.5 The friend specifier

The friend specifier is used to specify access to class members; see 11.8.4.

9.2.6 The constexpr and consteval specifiers

The constexpr specifier shall be applied only to the definition of a variable or variable template or the declaration of a function or function template. The consteval specifier shall be applied only to the declaration of a function or function template. A function or static data member declared with the constexpr or consteval specifier is implicitly an inline function or variable (9.2.8). If any declaration of a function or function template has a constexpr or consteval specifier, then all its declarations shall contain the same specifier.

[Note 1: An explicit specialization can differ from the template declaration with respect to the constexpr or consteval specifier. — end note]

[Note 2: Function parameters cannot be declared constexpr. — end note]

[Example 1:

```cpp
class pixel {
   int x;
   int y;
   constexpr pixel(int); // error: pixel is a type
};
constexpr pixel pixel::pixel(int a) : x(a), y(x) { // OK: definition
   square(x); }
constexpr pixel pixel small(2); // error: square not defined, so small(2) // not constant (7.7) so constexpr not satisfied
```]

```cpp
constexpr void square(int &x); // OK: declaration
constexpr int bufsz = 1024; // OK: definition
constexpr struct pixel { // error: pixel is a type
   int x;
   int y;
   constexpr pixel(int); // OK: declaration
};
constexpr pixel::pixel(int a) : x(a), y(x) // OK: definition
   { square(x); }
constexpr pixel large(4); // OK: square defined
int next(constexpr int x) { // error: not for parameters
   return x + 1;
}
extern constexpr int memsz; // error: not a definition
```

2 A constexpr or consteval specifier used in the declaration of a function declares that function to be a constexpr function. A function or constructor declared with the consteval specifier is called an immediate function. A destructor, an allocation function, or a deallocation function shall not be declared with the consteval specifier.

3 The definition of a constexpr function shall satisfy the following requirements:

- its return type (if any) shall be a literal type;
- each of its parameter types shall be a literal type;
- it shall not be a coroutine (9.5.4);
- if the function is a constructor or destructor, its class shall not have any virtual base classes;
- its function-body shall not enclose (8.1)
  - a goto statement,
  - a label with an identifier (8.2),
  - a definition of a variable of non-literal type or of static or thread storage duration.

[Note 3: A function-body that is = delete or = default encloses none of the above. — end note]

[Example 2:

```cpp
constexpr int square(int x)
   { return x * x; } // OK
```]
The definition of a constexpr constructor whose function-body is not \texttt{= delete} shall additionally satisfy the following requirements:

\begin{enumerate}
\item[(4.1)] for a non-delegating constructor, every constructor selected to initialize non-static data members and base class subobjects shall be a constexpr constructor;
\item[(4.2)] for a delegating constructor, the target constructor shall be a constexpr constructor.
\end{enumerate}

\begin{example}
\begin{verbatim}
struct Length {
  constexpr explicit Length(int i = 0) : val(i) { }
private:
  int val;
};
\end{verbatim}
\end{example}

The definition of a constexpr destructor whose function-body is not \texttt{= delete} shall additionally satisfy the following requirement:

\begin{enumerate}
\item[(5.1)] for every subobject of class type or (possibly multi-dimensional) array thereof, that class type shall have a constexpr destructor.
\end{enumerate}

For a constexpr function or constexpr constructor that is neither defaulted nor a template, if no argument values exist such that an invocation of the function or constructor could be an evaluated subexpression of a core constant expression (7.7), or, for a constructor, an evaluated subexpression of the initialization full-expression of some constant-initialized object (6.9.3.2), the program is ill-formed, no diagnostic required.

\begin{example}
\begin{verbatim}
constexpr int f(bool b)
 { return b ? throw 0 : 0; }            \comment{OK}
constexpr int f() { return f(true); }  \comment{ill-formed, no diagnostic required}
\end{verbatim}
\end{example}
If the instantiated template specialization of a constexpr function template or member function of a class template would fail to satisfy the requirements for a constexpr function, that specialization is still a constexpr function, even though a call to such a function cannot appear in a constant expression. If no specialization of the template would satisfy the requirements for a constexpr function when considered as a non-template function, the template is ill-formed, no diagnostic required.

An invocation of a constexpr function in a given context produces the same result as an invocation of an equivalent non-constexpr function in the same context in all respects except that

(8.1) — an invocation of a constexpr function can appear in a constant expression (7.7) and
(8.2) — copy elision is not performed in a constant expression (11.9.6).

Note 4: Declaring a function constexpr can change whether an expression is a constant expression. This can indirectly cause calls to std::is_constant_evaluated within an invocation of the function to produce a different value. — end note

The constexpr and consteval specifiers have no effect on the type of a constexpr function.

Example 5:

```cpp
constexpr int bar(int x, int y) // OK
{ return x + y + x*y; }

int bar(int x, int y) // error: redefinition of bar
{ return x * 2 + 3 * y; }
```

— end example

A constexpr specifier used in an object declaration declares the object as const. Such an object shall have literal type and shall be initialized. In any constexpr variable declaration, the full-expression of the initialization shall be a constant expression (7.7). A constexpr variable shall have constant destruction.

Example 6:

```cpp
struct pixel {
    int x, y;
};
constexpr pixel ur = { 1294, 1024 }; // OK
constexpr pixel origin; // error: initializer missing
```

— end example

9.2.7 The constinit specifier [dcl.constinit]

The constinit specifier shall be applied only to a declaration of a variable with static or thread storage duration. If the specifier is applied to any declaration of a variable, it shall be applied to the initializing declaration. No diagnostic is required if no constinit declaration is reachable at the point of the initializing declaration.

If a variable declared with the constinit specifier has dynamic initialization (6.9.3.3), the program is ill-formed.

Note 1: The constinit specifier ensures that the variable is initialized during static initialization (6.9.3.2). — end note

Example 1:

```cpp
const char * g() { return "dynamic initialization"; }
constexpr const char * f(bool p) { return p ? "constant initializer" : g(); }
constinit const char * c = f(true); // OK
constinit const char * d = f(false); // error
```

— end example

9.2.8 The inline specifier [dcl.inline]

The inline specifier shall be applied only to the declaration of a variable or function.
A function declaration (9.3.4.6, 11.4.2, 11.8.4) with an `inline` specifier declares an *inline function*. The `inline` specifier indicates to the implementation that inline substitution of the function body at the point of call is to be preferred to the usual function call mechanism. An implementation is not required to perform this inline substitution at the point of call; however, even if this inline substitution is omitted, the other rules for inline functions specified in this subclause shall still be respected.

[Note 1: The `inline` keyword has no effect on the linkage of a function. In certain cases, an inline function cannot use names with internal linkage; see 6.6. — end note]

A variable declaration with an `inline` specifier declares an *inline variable*.

The `inline` specifier shall not appear on a block scope declaration or on the declaration of a function parameter. If the `inline` specifier is used in a friend function declaration, that declaration shall be a definition or the function shall have previously been declared inline.

If a definition of a function or variable is reachable at the point of its first declaration as inline, the program is ill-formed. If a function or variable with external or module linkage is declared inline in one definition domain, an inline declaration of it shall be reachable from the end of every definition domain in which it is declared; no diagnostic is required.

[Note 2: A call to an inline function or a use of an inline variable can be encountered before its definition becomes reachable in a translation unit. — end note]

[Note 3: An inline function or variable with external or module linkage can be defined in multiple translation units (6.3), but is one entity with one address. A type or `static` variable defined in the body of such a function is therefore a single entity. — end note]

If an inline function or variable that is attached to a named module is declared in a definition domain, it shall be defined in that domain.

[Note 4: A constexpr function (9.2.6) is implicitly inline. In the global module, a function defined within a class definition is implicitly inline (11.4.2, 11.8.4. — end note]

### 9.2.9 Type specifiers

#### 9.2.9.1 General

The type-specifiers are

- `type-specifier`
  - `simple-type-specifier`
  - `elaborated-type-specifier`
  - `typename-specifier`
  - `cv-qualifier`
- `type-specifier-seq`
  - `type-specifier attribute-specifier-seq_opt`
  - `type-specifier type-specifier-seq`
- `defining-type-specifier`
  - `type-specifier`
  - `class-specifier`
  - `enum-specifier`
- `defining-type-specifier-seq`
  - `defining-type-specifier attribute-specifier-seq_opt`
  - `defining-type-specifier defining-type-specifier-seq`

The optional `attribute-specifier-seq` in a `type-specifier-seq` or a `defining-type-specifier-seq` appertains to the type denoted by the preceding `type-specifiers` or `defining-type-specifiers` (9.3.4). The `attribute-specifier-seq` affects the type only for the declaration it appears in, not other declarations involving the same type.

As a general rule, at most one `defining-type-specifier` is allowed in the complete `decl-specifier-seq` of a `declaration` or in a `defining-type-specifier-seq`, and at most one `type-specifier` is allowed in a `type-specifier-seq`. The only exceptions to this rule are the following:

- `const` can be combined with any type specifier except itself.
- `volatile` can be combined with any type specifier except itself.
- `signed` or `unsigned` can be combined with `char`, `long`, `short`, or `int`.
- `short` or `long` can be combined with `int`. 

§ 9.2.9.1
Except in a declaration of a constructor, destructor, or conversion function, at least one defining-type-specifier that is not a cv-qualifier shall appear in a complete type-specifier-seq or a complete decl-specifier-seq.\(^83\)

3 [Note 1: enum-specifiers, class-specifiers, and typename-specifiers are discussed in 9.7.1, Clause 11, and 13.8, respectively. The remaining type-specifiers are discussed in the rest of 9.2.9. — end note]

### 9.2.9.2 The cv-qualifiers

There are two cv-qualifiers, const and volatile. Each cv-qualifier shall appear at most once in a cv-qualifier-seq. If a cv-qualifier appears in a decl-specifier-seq, the init-declarator-list or member-declarator-list of the declaration shall not be empty.

[Note 1: 6.8.4 and 9.3.4.6 describe how cv-qualifiers affect object and function types. — end note]

Redundant cv-qualifications are ignored.

[Note 2: For example, these could be introduced by typedefs. — end note]

[Note 3: Declaring a variable const can affect its linkage (9.2.2) and its usability in constant expressions (7.7). As described in 9.4, the definition of an object or subobject of const-qualified type must specify an initializer or be subject to default-initialization. — end note]

A pointer or reference to a cv-qualified type need not actually point or refer to a cv-qualified object, but it is treated as if it does; a const-qualified access path cannot be used to modify an object even if the object referenced is a non-const object and can be modified through some other access path.

[Note 4: Cv-qualifiers are supported by the type system so that they cannot be subverted without casting (7.6.1.11). — end note]

Any attempt to modify (7.6.19, 7.6.1.6, 7.6.2.3) a const object (6.8.4) during its lifetime (6.7.3) results in undefined behavior.

**Example 1:**

```plaintext
const int ci = 3; // cv-qualified (initialized as required)
    ci = 4; // error: attempt to modify const

int i = 2; // not cv-qualified
const int* cip; // pointer to const int
cip = &i; // OK: cv-qualified access path to unqualified
    *cip = 4; // error: attempt to modify through ptr to const

int* ip;
ip = const_cast<int*>(cip); // cast needed to convert const int* to int*
    *ip = 4; // defined: *ip points to i, a non-const object

const int* ciq = new const int(3); // initialized as required
int* iq = const_cast<int*>(ciq); // cast required
    *iq = 4; // undefined behavior: modifies a const object
```

For another example,

```plaintext
struct X {
    mutable int i;
    int j;
};
struct Y {
    X x;
    Y();
};

const Y y;
y.x.++; // well-formed: mutable member can be modified
y.x.++; // error: const-qualified member modified
Y* p = const_cast<Y*>(&y); // cast away const-ness of y
```

---

\(^83\) There is no special provision for a decl-specifier-seq that lacks a type-specifier or that has a type-specifier that only specifies cv-qualifiers. The “implicit int” rule of C is no longer supported.
The semantics of an access through a volatile glvalue are implementation-defined. If an attempt is made to access an object defined with a volatile-qualified type through the use of a non-volatile glvalue, the behavior is undefined.

5  [Note 5: volatile is a hint to the implementation to avoid aggressive optimization involving the object because the value of the object might be changed by means undetectable by an implementation. Furthermore, for some implementations, volatile might indicate that special hardware instructions are required to access the object. See 6.9.1 for detailed semantics. In general, the semantics of volatile are intended to be the same in C++ as they are in C. — end note]

9.2.9.3  Simple type specifiers

The simple type specifiers are

\[ \text{simple-type-specifier:} \]
\[ \text{nested-name-specifier opt type-name} \]
\[ \text{nested-name-specifier template simple-template-id} \]
\[ \text{decltype-specifier} \]
\[ \text{placeholder-type-specifier} \]
\[ \text{nested-name-specifier opt template-name} \]
\[ \text{char} \]
\[ \text{char8_t} \]
\[ \text{char16_t} \]
\[ \text{char32_t} \]
\[ \text{wchar_t} \]
\[ \text{bool} \]
\[ \text{short} \]
\[ \text{int} \]
\[ \text{long} \]
\[ \text{signed} \]
\[ \text{unsigned} \]
\[ \text{float} \]
\[ \text{double} \]
\[ \text{void} \]

\[ \text{type-name:} \]
\[ \text{class-name} \]
\[ \text{enum-name} \]
\[ \text{typedef-name} \]

2  The component names of a simple-type-specifier are those of its nested-name-specifier, type-name, simple-template-id, template-name, and/or type-constraint (if it is a placeholder-type-specifier). The component name of a type-name is the first name in it.

3  A placeholder-type-specifier is a placeholder for a type to be deduced (9.2.9.6). A type-specifier of the form typename_opt nested-name-specifier_opt template-name is a placeholder for a deduced class type (9.2.9.7). The nested-name-specifier, if any, shall be non-dependent and the template-name shall name a deducible template. A deducible template is either a class template or is an alias template whose defining-type-id is of the form

\[ \text{typename opt nested-name-specifier opt template opt simple-template-id} \]

where the nested-name-specifier (if any) is non-dependent and the template-name of the simple-template-id names a deducible template.

[Note 1: An injected-class-name is never interpreted as a template-name in contexts where class template argument deduction would be performed (13.8.2). — end note]

The other simple-type-specifiers specify either a previously-declared type, a type determined from an expression, or one of the fundamental types (6.8.2). Table 16 summarizes the valid combinations of simple-type-specifiers and the types they specify.

4  When multiple simple-type-specifiers are allowed, they can be freely intermixed with other decl-specifiers in any order.

[Note 2: It is implementation-defined whether objects of char type are represented as signed or unsigned quantities. The signed specifier forces char objects to be signed; it is redundant in other contexts. — end note]
Table 16: *simple-type-specifiers* and the types they specify

| signed short int     | “short int”                    |
| signed short         | “short int”                    |
| short int            | “short int”                    |
| short                | “short int”                    |
| wchar_t              | “wchar_t”                      |
| float                | “float”                        |
| double               | “double”                       |
| long double          | “long double”                  |
| void                 | “void”                         |

9.2.9.4 Elaborated type specifiers

elaborated-type-specifier:

```
class-key attribute-specifier-seq_{opt} nested-name-specifier_{opt} identifier
class-key simple-template-id
class-key nested-name-specifier template_{opt} simple-template-id elaborated-enum-specifier
```

elaborated-enum-specifier:

```
enum nested-name-specifier_{opt} identifier
```

1 The component names of an elaborated-type-specifier are its identifier (if any) and those of its nested-name-specifier and simple-template-id (if any).

2 If an elaborated-type-specifier is the sole constituent of a declaration, the declaration is ill-formed unless it is an explicit specialization (13.9.4), an explicit instantiation (13.9.3) or it has one of the following forms:

§ 9.2.9.4
class-key attribute-specifier-seq_opt identifier;
class-key attribute-specifier-seq_opt simple-template-id;

In the first case, the elaborated-type-specifier declares the identifier as a class-name. The second case shall appear only in an explicit-specialization (13.9.4) or in a template-declaration (where it declares a partial specialization (13.7)). The attribute-specifier-seq, if any, appertains to the class or template being declared.

Otherwise, an elaborated-type-specifier E shall not have an attribute-specifier-seq. If E contains an identifier but no nested-name-specifier and (unqualified) lookup for the identifier finds nothing, E shall not be introduced by the enum keyword and declares the identifier as a class-name. The target scope of E is the nearest enclosing namespace or block scope.

If an elaborated-type-specifier appears with the friend specifier as an entire member-declaration, the member-declaration shall have one of the following forms:

friend class-key nested-name-specifier_opt identifier;
friend class-key simple-template-id;
friend class-key nested-name-specifier template_opt simple-template-id;

Any unqualified lookup for the identifier (in the first case) does not consider scopes that contain the target scope; no name is bound.

[Note 1: A using-directive in the target scope is ignored if it refers to a namespace not contained by that scope. 6.5.6 describes how name lookup proceeds in an elaborated-type-specifier. —end note]

If the identifier or simple-template-id resolves to a class-name or enum-name, the elaborated-type-specifier introduces it into the declaration the same way a simple-type-specifier introduces its type-name (9.2.9.3). If the identifier or simple-template-id resolves to a typedef-name (9.2.4, 13.3), the elaborated-type-specifier is ill-formed.

[Note 3: This implies that, within a class template with a template type-parameter T, the declaration
friend class T;
is ill-formed. However, the similar declaration friend T; is allowed (11.8.4). —end note]

The class-key or enum keyword present in the elaborated-type-specifier shall agree in kind with the declaration to which the name in the elaborated-type-specifier refers. This rule also applies to the form of elaborated-type-specifier that declares a class-name or friend class since it can be construed as referring to the definition of the class. Thus, in any elaborated-type-specifier, the enum keyword shall be used to refer to an enumeration (9.7.1), the union class-key shall be used to refer to a union (11.5), and either the class or struct class-key shall be used to refer to a non-union class (11.1).

[Example 1:
enum class E { a, b };
enum E x = E::a; // OK
struct S { } s;
    class S* p = &s; // OK
—end example]

9.2.9.5 Decltype specifiers

decltype-specifier:
    decltype ( expression )

1 For an expression E, the type denoted by decltype(E) is defined as follows:

(1.1) — if E is an unparenthesized id-expression naming a structured binding (9.6), decltype(E) is the referenced type as given in the specification of the structured binding declaration;

(1.2) — otherwise, if E is an unparenthesized id-expression naming a non-type template-parameter (13.2), decltype(E) is the type of the template-parameter after performing any necessary type deduction (9.2.9.6, 9.2.9.7);

(1.3) — otherwise, if E is an unparenthesized id-expression or an unparenthesized class member access (7.6.1.5), decltype(E) is the type of the entity named by E. If there is no such entity, the program is ill-formed;

(1.4) — otherwise, if E is an xvalue, decltype(E) is T&&, where T is the type of E;

(1.5) — otherwise, if E is an lvalue, decltype(E) is T&, where T is the type of E;
otherwise, `decltype(E)` is the type of `E`.

The operand of the `decltype` specifier is an unevaluated operand (7.2).

**Example 1:**

```cpp
cost int&& foo();
int i;
struct A { double x; };
const A* a = new A();
decltype(foo()) x1 = 17; // type is `const int&&`
decltype(i) x2; // type is `int`
decltype(a->x) x3; // type is `double`
decltype((a->x)) x4 = x3; // type is const double&
```

**Note 1:** The rules for determining types involving `decltype(auto)` are specified in 9.2.9.6. **— end note**

If the operand of a `decltype-specifier` is a prvalue and is not a (possibly parenthesized) immediate invocation (7.7), the temporary materialization conversion is not applied (7.3.5) and no result object is provided for the prvalue. The type of the prvalue may be incomplete or an abstract class type.

**Note 2:** As a result, storage is not allocated for the prvalue and it is not destroyed. Thus, a class type is not instantiated as a result of being the type of a function call in this context. In this context, the common purpose of writing the expression is merely to refer to its type. In that sense, a `decltype-specifier` is analogous to a use of a `typedef-name`, so the usual reasons for requiring a complete type do not apply. In particular, it is not necessary to allocate storage for a temporary object or to enforce the semantic constraints associated with invoking the type’s destructor. **— end note**

**Note 3:** Unlike the preceding rule, parentheses have no special meaning in this context. **— end note**

**Example 2:**

```cpp
template<class T> struct A { ~A() = delete; };
template<class T> auto h() -> A<T>;
template<class T> auto i(T) // identity
  -> T;
template<class T> auto f(T) // #1
  -> decltype(i(h<T>()));
  // forces completion of `A<T>` and implicitly uses `A<T>::~A()`
  // for the temporary introduced by the use of `h()`.
  // (A temporary is not introduced as a result of the use of `i()`.)
template<class T> auto f(T) // #2
  -> void;
auto g() -> void {
  f(42); // OK: calls #2. (#1 is not a viable candidate: type deduction
  // fails (13.10.3) because `A<int>::~A()` is implicitly used in its
  // decltype-specifier)
}
template<class T> auto q(T) // does not force completion of `A<T>; A<T>::~A()` is not implicitly
  -> decltype((h<T>()));
  // used within the context of this decltype-specifier
void r() {
  q(42); // error: deduction against `q` succeeds, so overload resolution selects
  // the specialization "q(T) -> decltype((h<T>()))" with T=int;
  // the return type is `A<int>`, so a temporary is introduced and its
  // destructor is used, so the program is ill-formed
}
```

**9.2.9.6 Placeholder type specifiers**

**9.2.9.6.1 General**

A `placeholder-type-specifier` designates a placeholder type that will be replaced later by deduction from an initializer.

§ 9.2.9.6.1 176
A placeholder-type-specifier of the form type-constraint_{pt} auto can be used as a decl-specifier of the decl-specifier-seq of a parameter-declaration of a function declaration or lambda-expression and, if it is not the auto type-specifier introducing a trailing-return-type (see below), is a generic parameter type placeholder of the function declaration or lambda-expression.

[Note 1: Having a generic parameter type placeholder signifies that the function is an abbreviated function template (9.3.4.6) or the lambda is a generic lambda (7.5.5). — end note]

The placeholder type can appear with a function declarator in the decl-specifier-seq, type-specifier-seq, conversion-function-id, or trailing-return-type, in any context where such a declarator is valid. If the function declarator includes a trailing-return-type (9.3.4.6), that trailing-return-type specifies the declared return type of the function. Otherwise, the function declarator shall declare a function. If the declared return type of the function contains a placeholder type, the return type of the function is deduced from non-discarded return statements, if any, in the body of the function (8.5.2).

The type of a variable declared using a placeholder type is deduced from its initializer. This use is allowed in an initializing declaration (9.4) of a variable. The placeholder type shall appear as one of the decl-specifiers in the decl-specifier-seq and the decl-specifier-seq shall be followed by one or more declarators, each of which shall be followed by a non-empty initializer. If the initializer is a parenthesized expression-list, the expression-list shall be a single assignment-expression.

Example 1:

```cpp
auto x = 5;
const auto *v = &x, u = 6;
static auto y = 0.0;
auto int r;
auto f() -> int;
auto g() { return 0.0; }
auto h();
```

// OK: x has type int
// OK: v has type const int*, u has type const int
// OK: y has type double
// error: auto is not a storage-class-specifier
// OK: f returns int
// OK: g returns double
// OK: h’s return type will be deduced when it is defined

The auto type-specifier can also be used to introduce a structured binding declaration (9.6).

A placeholder type can also be used in the type-specifier-seq in the new-type-id or type-id of a new-expression (7.6.2.8) and as a decl-specifier of the parameter-declaration’s decl-specifier-seq in a template-parameter (13.2).

A program that uses a placeholder type in a context not explicitly allowed in 9.2.9.6 is ill-formed.

If the init-declarator-list contains more than one init-declarator, they shall all form declarations of variables. The type of each declared variable is determined by placeholder type deduction (9.2.9.6.2), and if the type that replaces the placeholder type is not the same in each deduction, the program is ill-formed.

Example 2:

```cpp
auto x = 5, *y = &x;
auto a = 5, b = { 1, 2 };
```

// OK: auto is int
// error: different types for auto

If a function with a declared return type that contains a placeholder type has multiple non-discarded return statements, the return type is deduced for each such return statement. If the type deduced is not the same in each deduction, the program is ill-formed.

If a function with a declared return type that uses a placeholder type has no non-discarded return statements, the return type is deduced as though from a return statement with no operand at the closing brace of the function body.

Example 3:

```cpp
auto f() { }
auto* g() { }
```

// OK, return type is void
// error: cannot deduce auto* from void()

An exported function with a declared return type that uses a placeholder type shall be defined in the translation unit containing its exported declaration, outside the private-module-fragment (if any).

[Note 2: The deduced return type cannot have a name with internal linkage (6.6). — end note]

If a variable or function with an undeduced placeholder type is named by an expression (6.3), the program is ill-formed. Once a non-discarded return statement has been seen in a function, however, the return type deduced from that statement can be used in the rest of the function, including in other return statements.
Example 4:

```c
auto n = n; // error: n's initializer refers to n
auto f(); // error: f's return type is unknown
void g() { &f; }
auto sum(int i) {
    if (i == 1)
        return i;
    else
        return sum(i-1)+i; // OK, sum's return type has been deduced
}
```

—end example—

Return type deduction for a templated entity that is a function or function template with a placeholder in its declared type occurs when the definition is instantiated even if the function body contains a return statement with a non-type-dependent operand.

[Note 3: Therefore, any use of a specialization of the function template will cause an implicit instantiation. Any errors that arise from this instantiation are not in the immediate context of the function type and can result in the program being ill-formed (13.10.3). —end note]

Example 5:

```c
template <class T> auto f(T t) { return t; } // return type deduced at instantiation time
deftype decltype(f(1)) int_t; // instantiates f<int> to deduce return type
template<class T> auto f(T* t) { return *t; } // instantiates both fs to determine return types, // chooses second
```

—end example—

If a function or function template \(F\) has a declared return type that uses a placeholder type, redeclarations or specializations of \(F\) shall use that placeholder type, not a deduced type; otherwise, they shall not use a placeholder type.

Example 6:

```c
auto f();
auto f() { return 42; } // return type is int
auto f(); // OK
int f(); // error: auto and int don't match
decltype(auto) f(); // error: auto and decltype(auto) don't match

template <typename T> auto g(T t) { return t; } // #1
template auto g(int); // OK, return type is int
template char g(char); // error: no matching template
template<> auto g(double); // OK, forward declaration with unknown return type

template <class T> T g(T t) { return t; } // OK, not functionally equivalent to #1
template char g(char); // OK, now there is a matching template
template auto g(float); // still matches #1

void h() { return g(42); } // error: ambiguous

template <typename T> struct A {
    friend T frf(T);
};
auto frf(int i) { return i; } // not a friend of A<int>
extern int v;
auto v = 17; // OK, redeclares v
struct S {
    static int i;
};
auto S::i = 23; // OK
```

—end example—

A function declared with a return type that uses a placeholder type shall not be virtual (11.7.3).

A function declared with a return type that uses a placeholder type shall not be a coroutine (9.5.4).
An explicit instantiation declaration (13.9.3) does not cause the instantiation of an entity declared using a placeholder type, but it also does not prevent that entity from being instantiated as needed to determine its type.

[Example 7:

```c++
template <typename T> auto f(T t) { return t; }
extern template auto f(int);
int (*p)(int) = f;  // does not instantiate f<int>
// instantiates f<int> to determine its return type, but an explicit instantiation definition is still required somewhere in the program
```

— end example]

### 9.2.9.6.2 Placeholder type deduction [dcl.type.auto.deduct]

**Placeholder type deduction** is the process by which a type containing a placeholder type is replaced by a deduced type.

1 A type $T$ containing a placeholder type, and a corresponding initializer $E$, are determined as follows:

- **(2.1)** for a non-discarded `return` statement that occurs in a function declared with a return type that contains a placeholder type, $T$ is the declared return type and $E$ is the operand of the `return` statement. If the `return` statement has no operand, then $E$ is `void();`
- **(2.2)** for a variable declared with a type that contains a placeholder type, $T$ is the declared type of the variable and $E$ is the initializer. If the initialization is direct-list-initialization, the initializer shall be a `braced-init-list` containing only a single `assignment-expression` and $E$ is the `assignment-expression`;
- **(2.3)** for a non-type template parameter declared with a type that contains a placeholder type, $T$ is the declared type of the non-type template parameter and $E$ is the corresponding template argument.

In the case of a `return` statement with no operand or with an operand of type `void`, $T$ shall be either `type-constraint` and `decltype(auto)` or `cv` `type-constraint` `auto`.

3 If the deduction is for a `return` statement and $E$ is a `braced-init-list` (9.4.5), the program is ill-formed.

4 If the `placeholder-type-specifier` is of the form `type-constraint` `auto`, the deduced type $T'$ replacing $T$ is determined using the rules for template argument deduction. Obtain $P$ from $T$ by replacing the occurrences of `type-constraint` `auto` either with a new invented type template parameter $U$ or, if the initialization is `copy-list-initialization`, with `std::initializer_list<U>`. Deduce a value for $U$ using the rules of template argument deduction from a function call (13.10.3.2), where $P$ is a function template parameter type and the corresponding argument is $E$. If the deduction fails, the declaration is ill-formed. Otherwise, $T'$ is obtained by substituting the deduced $U$ into $P$.

[Example 1:

```c++
auto x1 = { 1, 2 };  // decltype(x1) is std::initializer_list<int>
auto x2 = { 1, 2.0 };  // error: cannot deduce element type
auto x3{ 1, 2 };  // error: not a single element
auto x4 = { 3 };  // decltype(x4) is std::initializer_list<int>
auto x5{ 3 };  // decltype(x5) is int

— end example]

[Example 2:

```c++
const auto &i = expr;
```

The type of $i$ is the deduced type of the parameter $u$ in the call $f(expr)$ of the following invented function template:

```c++
template <class U> void f(const U& u);
```

— end example]

5 If the `placeholder-type-specifier` is of the form `type-constraint` `decltype(auto)`, $T$ shall be the placeholder alone. The type deduced for $T$ is determined as described in 9.2.9.5, as though $E$ had been the operand of the `decltype`.

[Example 3:

```c++
int i;
int& f();
auto x2a(i);  // decltype(x2a) is int
decatype(auto) x2d(i);  // decltype(x2d) is int
auto x3a = i;  // decltype(x3a) is int
```

§ 9.2.9.6.2
For a placeholder-type-specifier with a type-constraint, the immediately-declared constraint (13.2) of the type-constraint for the type deduced for the placeholder shall be satisfied.

9.2.9.7 Deduced class template specialization types

If a placeholder for a deduced class type appears as a decl-specifier in the decl-specifier-seq of an initializing declaration (9.4) of a variable, the declared type of the variable shall be cv T, where T is the placeholder.

Example 1:
```cpp
template <class ...T> struct A {
    A(T...) {};
};
A x[29]{}; // error: no declarator operators allowed
const & A y{}; // error: no declarator operators allowed
```

The placeholder is replaced by the return type of the function selected by overload resolution for class template deduction (12.2.2.9). If the decl-specifier-seq is followed by an init-declarator-list or member-declarator-list containing more than one declarator, the type that replaces the placeholder shall be the same in each deduction.

A placeholder for a deduced class type can also be used in the type-specifier-seq in the new-type-id or type-id of a new-expression (7.6.2.8), as the simple-type-specifier in an explicit type conversion (functional notation) (7.6.1.4), or as the type-specifier in the parameter-declaration of a template-parameter (13.2). A placeholder for a deduced class type shall not appear in any other context.

Example 2:
```cpp
template<class T> struct container {
    container(T t) {}
    template<class Iter> container(Iter beg, Iter end);
};
template<class Iter>
container(Iter b, Iter e) -> container<typename std::iterator_traits<Iter>::value_type>;
std::vector<double> v = { /* ... */ }; // OK, deduces int for T
auto d = container(v.begin(), v.end()); // OK, deduces double for T
container e{5, 6}; // error: int is not an iterator
```

9.3 Declarators

A declarator declares a single variable, function, or type, within a declaration. The init-declarator-list appearing in a simple-declaration is a comma-separated sequence of declarators, each of which can have an initializer.

### § 9.3.1 General

- init-declarator-list:
  - init-declarator
  - init-declarator-list , init-declarator

- init-declarator:
  - declarator initializer_opt
  - declarator requires-qualifiers
  - declarator requires-qualifiers , declarator requires-qualifiers
In all contexts, a declarator is interpreted as given below. Where an abstract-declarator can be used (or omitted) in place of a declarator (9.3.4.6, 14.1), it is as if a unique identifier were included in the appropriate place (9.3.2). The preceding specifiers indicate the type, storage class or other properties of the entity or entities being declared. Each declarator specifies one entity and (optionally) names it and/or modifies the type of the specifiers with operators such as * (pointer to) and () (function returning).

[Note 1: An init-declarator can also specify an initializer (9.4). — end note]

Each init-declarator or member-declarator in a declaration is analyzed separately as if it were in a declaration by itself.

[Note 2: A declaration with several declarators is usually equivalent to the corresponding sequence of declarations each with a single declarator. That is,

T D1, D2, ... Dn;

is usually equivalent to

T D1; T D2; ... T Dn;

where T is a decl-specifier-seq and each Di is an init-declarator or member-declarator. One exception is when a name introduced by one of the declarators hides a type name used by the decl-specifiers, so that when the same decl-specifiers are used in a subsequent declaration, they do not have the same meaning, as in

struct S { /* ... */ };  // declare two instances of struct S
S S, T;                  // error

Another exception is when T is auto (9.2.9.6), for example:

auto i = 1, j = 2.0;     // error: deduced types for i and j do not match
as opposed to

auto i = 1;              // OK: i deduced to have type int
auto j = 2.0;            // OK: j deduced to have type double
— end note]

The optional requires-clause (13.1) in an init-declarator or member-declarator shall be present only if the declarator declares a templated function (9.3.4.6). When present after a declarator, the requires-clause is called the trailing requires-clause. The trailing requires-clause introduces the constraint-expression that results from interpreting its constraint-logical-or-expression as a constraint-expression.

[Example 1:

void f1(int a) requires true; // error: non-templated function

template<typename T>
  auto f2(T a) -> bool requires true; // OK

template<typename T>
  auto f3(T a) requires true -> bool; // error: requires-clause precedes trailing-return-type

void g(int (*)(char) requires true); // error: constraint on a parameter-declaration

  void* p = new void (*)(char) requires true; // error: not a function declaration
— end example]

Declarators have the syntax

declarator:
  ptr-declarator
  noptr-declarator parameters-and-qualifiers trailing-return-type

ptr-declarator:
  noptr-declarator
  ptr-operator ptr-declarator
noptr-declarator:
  declarator-id attribute-specifier-seq_opt
  noptr-declarator parameters-and-qualifiers
  noptr-declarator [ constant-expression_opt ] attribute-specifier-seq_opt
  ( ptr-declarator )

parameters-and-qualifiers:
  ( parameter-declaration-clause ) cv-qualifier-seq_opt
  ref-qualifier_opt noexcept-specifier_opt attribute-specifier-seq_opt

trailing-return-type:
  -> type-id

ptr-operator:
  * attribute-specifier-seq_opt cv-qualifier-seq_opt
  & attribute-specifier-seq_opt
  && attribute-specifier-seq_opt
  nested-name-specifier * attribute-specifier-seq_opt cv-qualifier-seq_opt

cv-qualifier-seq:
  cv-qualifier cv-qualifier-seq_opt

cv-qualifier:
  const
  volatile

ref-qualifier:
  &
  &&

declarator-id:
  . . . opt id-expression

9.3.2 Type names

To specify type conversions explicitly, and as an argument of sizeof, alignof, new, or typeid, the name of a type shall be specified. This can be done with a type-id, which is syntactically a declaration for a variable or function of that type that omits the name of the entity.

type-id:
  type-specifier-seq abstract-declarator_opt

defining-type-id:
  defining-type-specifier-seq abstract-declarator_opt

abstract-declarator:
  ptr-abstract-declarator
  noptr-abstract-declarator_opt parameters-and-qualifiers trailing-return-type
  abstract-pack-declarator

ptr-abstract-declarator:
  noptr-abstract-declarator
  ptr-operator ptr-abstract-declarator_opt

noptr-abstract-declarator:
  noptr-abstract-declarator_opt parameters-and-qualifiers
  noptr-abstract-declarator_opt [ constant-expression_opt ] attribute-specifier-seq_opt
  ( ptr-abstract-declarator )

abstract-pack-declarator:
  noptr-abstract-pack-declarator
  ptr-operator abstract-pack-declarator

noptr-abstract-pack-declarator:
  noptr-abstract-pack-declarator parameters-and-qualifiers
  noptr-abstract-pack-declarator_opt [ constant-expression_opt ] attribute-specifier-seq_opt

It is possible to identify uniquely the location in the abstract-declarator where the identifier would appear if the construction were a declarator in a declaration. The named type is then the same as the type of the hypothetical identifier.

Example 1:
int
// int i
int *
// int *pi
int *[3]
// int *p[3]
int (*)(int)[3]
// int (*pi)[3]
int *
// int *f()
int (*)[3]
// int (*p3i)[3]
int *()
// int *f()
int (*)(double)
// int (*pf)(double)

name respectively the types “int”, “pointer to int”, “array of 3 pointers to int”, “pointer to array of 3 int”, “function of (no parameters) returning pointer to int”, and “pointer to a function of (double) returning int”. — end example

A type can also be named (often more easily) by using a typedef (9.2.4).

9.3.3 Ambiguity resolution

dcl.ambig.res

1 The ambiguity arising from the similarity between a function-style cast and a declaration mentioned in 8.9 can also occur in the context of a declaration. In that context, the choice is between a function declaration with a redundant set of parentheses around a parameter name and an object declaration with a function-style cast as the initializer. Just as for the ambiguities mentioned in 8.9, the resolution is to consider any construct that could possibly be a declaration a declaration.

[Note 1: A declaration can be explicitly disambiguated by adding parentheses around the argument. The ambiguity can be avoided by use of copy-initialization or list-initialization syntax, or by use of a non-function-style cast. — end note]

[Example 1:

struct S {
  S(int);
};

void foo(double a) {
  S w(int(a));     // function declaration
  S x(int());      // function declaration
  S y((int(a)));   // object declaration
  S y((int)a);     // object declaration
  S z = int(a);    // object declaration
}
— end example]

2 An ambiguity can arise from the similarity between a function-style cast and a type-id. The resolution is that any construct that could possibly be a type-id in its syntactic context shall be considered a type-id.

[Example 2:

template <class T> struct X {}
template <int N> struct Y {}
X<int()> a;             // type-id
X<int(1)> b;            // expression (ill-formed)
Y<int()> c;             // type-id (ill-formed)
Y<int(1)> d;            // expression

void foo(signed char a) {
  sizeof(int());          // type-id (ill-formed)
  sizeof(int(a));         // expression
  sizeof(int(unsigned(a))); // type-id (ill-formed)
  (int())+1;              // type-id (ill-formed)
  (int(a))+1;             // expression
  (int(unsigned(a)))+1;    // type-id (ill-formed)
}
— end example]

3 Another ambiguity arises in a parameter-declaration-clause when a type-name is nested in parentheses. In this case, the choice is between the declaration of a parameter of type pointer to function and the declaration of a parameter with redundant parentheses around the declarator-id. The resolution is to consider the type-name as a simple-type-specifier rather than a declarator-id.

[Example 3:

§ 9.3.3 183

183
9.3.4 Meaning of declarators

9.3.4.1 General

A declarator contains exactly one declarator-id; it names the entity that is declared. If the unqualified-id occurring in a declarator-id is a template-id, the declarator shall appear in the declaration of a template-declaration (13.7), explicit-specialization (13.9.4), or explicit-instantiation (13.9.3).

[Note 1: An unqualified-id that is not an identifier is used to declare certain functions (11.4.8.3, 11.4.7, 12.4, 12.6). —end note]

The optional attribute-specifier-seq following a declarator-id appertains to the entity that is declared.

2 If the declaration is a friend declaration:

(2.1) — The declarator does not bind a name.

(2.2) — If the id-expression E in the declarator-id of the declarator is a qualified-id or a template-id:

(2.2.1) — If the friend declaration is not a template declaration, then in the lookup for the terminal name of E:

(2.2.1.1) — if the unqualified-id in E is a template-id, all function declarations are discarded;

(2.2.1.2) — otherwise, if the declarator corresponds (6.4.1) to any declaration found of a non-template function, all function template declarations are discarded;

(2.2.1.3) — each remaining function template is replaced with the specialization chosen by deduction from the friend declaration (13.10.3.7) or discarded if deduction fails.

(2.2.2) — The declarator shall correspond to one or more declarations found by the lookup; they shall all have the same target scope, and the target scope of the declarator is that scope.

(2.3) — Otherwise, the terminal name of E is not looked up. The declaration’s target scope is the innermost enclosing namespace scope; if the declaration is contained by a block scope, the declaration shall correspond to a declaration that inhabits the innermost block scope.

3 Otherwise:

(3.1) — If the id-expression in the declarator-id of the declarator is a qualified-id Q, let S be its lookup context (6.5.5); the declaration shall inhabit a namespace scope.

(3.2) — Otherwise, let S be the entity associated with the scope inhabited by the declarator.

(3.3) — If the declarator declares an explicit instantiation or a partial or explicit specialization, the declarator does not bind a name. If it declares a class member, the terminal name of the declarator-id is not looked up; otherwise, only those lookup results that are nominable in S are considered when identifying any function template specialization being declared (13.10.3.7).

[Example 1:

```cpp
namespace N {
    inline namespace O {
        template<class T> void f(T); // #1
        template<class T> void g(T) {}
    }
```
namespace P {
    template<class T> void f(T*); // #2, more specialized than #1
    template<class> int g;
}
using P::f,P::g;

namespace P {
    template<> void N::f(int*) {} // OK: #2 is not nominable
    template void N::g(int); // error: lookup is ambiguous
— end example

(3.4) — Otherwise, the terminal name of the declarator-id is not looked up. If it is a qualified name, the declarator shall correspond to one or more declarations nominable in S; all the declarations shall have the same target scope and the target scope of the declarator is that scope.

[Example 2]:

namespace Q {
    namespace V {
        void f();
    }
    void V::f() { /* ... */ } // OK
    void V::g() { /* ... */ } // error: g() is not yet a member of V
    namespace V {
        void g();
    }
}

namespace R {
    void Q::V::g() { /* ... */ } // error: R doesn't enclose Q
}
— end example

(3.5) — If the declaration inhabits a block scope S and declares a function (9.3.4.6) or uses the extern specifier, the declaration shall not be attached to a named module (10.1); its target scope is the innermost enclosing namespace scope, but the name is bound in S.

[Example 3]:

namespace X {
    void p() {
        q(); // error: q not yet declared
        extern void q(); // q is a member of namespace X
        extern void r(); // r is a member of namespace X
    }
    void middle() {
        q(); // error: q not found
    }
    void q() { /* ... */ } // definition of X::q
    void q() { /* ... */ } // some other, unrelated q
    void X::r() { /* ... */ } // error: r cannot be declared by qualified-id
— end example

4 A static, thread_local, extern, mutable, friend, inline, virtual, constexpr, or typedef specifier or an explicit-specifier applies directly to each declarator-id in a declaration; the type specified for each declarator-id depends on both the decl-specifier-seq and its declarator.

5 Thus, (for each declarator) a declaration has the form

T D

where T is of the form attribute-specifier-seq, opt decl-specifier-seq and D is a declarator. Following is a recursive procedure for determining the type specified for the contained declarator-id by such a declaration.

6 First, the decl-specifier-seq determines a type. In a declaration

§ 9.3.4.1
the \text{decl-specifier-seq} \ T \ D \the type \ T. 

\text{Example 4:} In the declaration 
\begin{verbatim}
    int unsigned i;
\end{verbatim}
the type specifiers \text{int unsigned} determine the type “\text{unsigned int}” (9.2.9.3). —end example] 
\[ \text{Example 4:} \]

In a declaration \text{attribute-specifier-seq}\_\text{opt} \ T \ D \ where \ D \ is an unadorned name, the type of the declared entity is “\text{?}”.

In a declaration \ T \ D \ where \ D \ has the form
\begin{verbatim}
    ( D1 )
\end{verbatim}
the type of the contained \text{declarator-id} is the same as that of the contained \text{declarator-id} in the declaration \ T \ D1 

Parentheses do not alter the type of the embedded \text{declarator-id}, but they can alter the binding of complex declarators.

\subsubsection*{9.3.4.2 Pointers} [decl.ptr]

In a declaration \ T \ D \ where \ D \ has the form
\begin{verbatim}
    * attribute-specifier-seq\_\text{opt} cv-qualifier-seq\_\text{opt} \ D1
\end{verbatim}
and the type of the contained \text{declarator-id} in the declaration \ T \ D1 is “\text{derived-declarator-type-list} \ T\text{’}, the type of the \text{declarator-id} in \ D \ is “\text{derived-declarator-type-list} cv-qualifier-seq \text{pointer to} \ T\text{’}. The \text{cv-qualifiers} apply to the pointer and not to the object pointed to. Similarly, the optional \text{attribute-specifier-seq} (9.12.1) appertains to the pointer and not to the object pointed to.

\text{Example 1:} The declarations
\begin{verbatim}
    const int ci = 10, *pc = &ci, *const cpc = pc, **ppc;
    int i, *p, *const cp = &i;
\end{verbatim}
declare \text{ci}, a constant integer; \text{pc}, a pointer to a constant integer; \text{cpc}, a constant pointer to a constant integer; \text{ppc}, a pointer to a pointer to a constant integer; \text{i}, an integer; \text{p}, a pointer to integer; and \text{cp}, a constant pointer to integer. The value of \text{ci}, \text{cpc}, and \text{cp} cannot be changed after initialization. The value of \text{pc} can be changed, and so can the object pointed to by \text{cp}. Examples of some correct operations are
\begin{verbatim}
    i = ci;        // \text{error}
    *cp = ci;     // \text{error}
    pc++;         // \text{error}
    pc = cpc;     // \text{error}
    pc = p;       // \text{error}
    ppc = &pc;    // \text{error}
\end{verbatim}
Examples of ill-formed operations are
\begin{verbatim}
    ci = 1;        // \text{error}
    ci++;         // \text{error}
    *pc = 2;      // \text{error}
    cp = &ci;     // \text{error}
    cpc++;        // \text{error}
    p = pc;       // \text{error}
    ppc = &p;     // \text{error}
\end{verbatim}
Each is unacceptable because it would either change the value of an object declared \text{const} or allow it to be changed through a \text{cv-unqualified} pointer later, for example:
\begin{verbatim}
    *ppc = &ci;    // OK, but would make \text{p} point to \text{ci} because of previous error
    *p = 5;       // clobber \text{ci}
\end{verbatim}

—end \text{example}]

\text{Note 1:} Forming a pointer to reference type is ill-formed; see 9.3.4.3. Forming a function pointer type is ill-formed if the function type has \text{cv-qualifiers} or a \text{ref-qualifier}; see 9.3.4.6. Since the address of a bit-field (11.4.10) cannot be taken, a pointer can never point to a bit-field. —end \text{note}]

\subsubsection*{9.3.4.3 References} [decl.ref]

In a declaration \ T \ D \ where \ D \ has either of the forms
\begin{verbatim}
\end{verbatim}

\section*{§ 9.3.4.3}
and the type of the contained declarator-id in the declaration \( T \ D_1 \) is “\( \text{derived-declarator-type-list} \ T \)”, the type of the declarator-id in \( D \) is “\( \text{derived-declarator-type-list} \ \text{reference to} \ T \)”. The optional attribute-specifier-seq appertains to the reference type. Cv-qualified references are ill-formed except when the cv-qualifiers are introduced through the use of a typedef-name (9.2.4, 13.2) or decltype-specifier (9.2.9.5), in which case the cv-qualifiers are ignored.

Example 1:

```c
typedef int& A;
const A aref = 3;  // error: lvalue reference to non-const initialized with rvalue
```

The type of `aref` is “lvalue reference to int”, not “lvalue reference to const int”. — end example

Note 1: A reference can be thought of as a name of an object. — end note

A declarator that specifies the type “reference to cv void” is ill-formed.

Example 2:

```c
void f(double& a) { a += 3.14; }
// ...
double d = 0;
f(d);
```

declares `a` to be a reference parameter of `f` so the call `f(d)` will add 3.14 to `d`.

```c
int v[20];
// ...
int& g(int i) { return v[i]; }
// ...
g(3) = 7;
```

declares the function `g()` to return a reference to an integer so `g(3)=7` will assign 7 to the fourth element of the array `v`. For another example,

```c
struct link {
    link* next;
};
link* first;
void h(link*& p) {
    // p is a reference to pointer
    p->next = first;
    first = p;
    p = 0;
}
void k() {
    link* q = new link;
    h(q);
}
```

declares `p` to be a reference to a pointer to `link` so `h(q)` will leave `q` with the value zero. See also 9.4.4. — end example

It is unspecified whether or not a reference requires storage (6.7.5).

There shall be no references to references, no arrays of references, and no pointers to references. The declaration of a reference shall contain an initializer (9.4.4) except when the declaration contains an explicit extern specifier (9.2.2), is a class member (11.4) declaration within a class definition, or is the declaration of a parameter or a return type (9.3.4.6); see 6.2. A reference shall be initialized to refer to a valid object or function.

Note 2: In particular, a null reference cannot exist in a well-defined program, because the only way to create such a reference would be to bind it to the “object” obtained by indirection through a null pointer, which causes undefined behavior. As described in 11.4.10, a reference cannot be bound directly to a bit-field. — end note
If a **typedef-name** (9.2.4, 13.2) or a **decltype-specifier** (9.2.9.5) denotes a type TR that is a reference to a type T, an attempt to create the type “lvalue reference to **cv** TR” creates the type “lvalue reference to T”, while an attempt to create the type “rvalue reference to **cv** TR” creates the type TR.

[Note 3: This rule is known as reference collapsing. — end note]

[Example 3:

```cpp
int i;
typedef int& LRI;
typedef int&& RRI;
LRI& r1 = i; // r1 has the type int
const LRI& r2 = i; // r2 has the type int
const LRI&& r3 = i; // r3 has the type int&&
RRI& r4 = i; // r4 has the type int&&
RRI&& r5 = 5; // r5 has the type int&&
decatype(r2)&& r6 = i; // r6 has the type int&&
decatype(r2)& r7 = i; // r7 has the type int&&
```

—end example]

7 [Note 4: Forming a reference to function type is ill-formed if the function type has **cv-qualifiers** or a **ref-qualifier**; see 9.3.4.6. — end note]

### 9.3.4.4 Pointers to members

[decl.mpstr]

1 The component names of a **ptr-operator** are those of its **nested-name-specifier**, if any.

2 In a declaration T D where D has the form

```cpp
nested-name-specifier * attribute-specifier-seq_opt cv-qualifier-seq_opt D1
```

and the **nested-name-specifier** denotes a class, and the type of the contained **declarator-id** in the declaration T D1 is “derived-declarator-type-list T”, the type of the **declarator-id** in D is “derived-declarator-type-list cv-qualifier-seq pointer to member of class nested-name-specifier of type T”. The optional attribute-specifier-seq (9.12.1) appertains to the pointer-to-member.

3 [Example 1:

```cpp
struct X {
    void f(int);
    int a;
};
struct Y;

int X::* pmi = &X::a;
void (X::* pmf)(int) = &X::f;
double X::* pmd;
char Y::* pmc;
```

declares pmi, pmf, pmd and pmc to be a pointer to a member of X of type int, a pointer to a member of X of type void(int), a pointer to a member of X of type double and a pointer to a member of Y of type char respectively. The declaration of pmd is well-formed even though X has no members of type double. Similarly, the declaration of pmc is well-formed even though Y is an incomplete type. pmi and pmf can be used like this:

```cpp
X obj; // ...
obj.*pmi = 7; // assign 7 to an integer member of obj
(obj.*pmf)(7); // call a function member of obj with the argument 7
```

—end example]

4 A pointer to member shall not point to a static member of a class (11.4.9), a member with reference type, or “**cv** void”.

5 [Note 1: See also 7.6.2 and 7.6.4. The type “pointer to member” is distinct from the type “pointer”, that is, a pointer to member is declared only by the pointer-to-member declarator syntax, and never by the pointer declarator syntax. There is no “reference-to-member” type in C++. — end note]
9.3.4.5 Arrays

1 In a declaration `T D` where `D` has the form
   
   \[ D1 [ \text{constant-expression}_{\text{opt}} \] \text{attribute-specifier-seq}_{\text{opt}} \]
   
   and the type of the contained declarator-id in the declaration `T D1` is “derived-declarator-type-list `T`”, the type of the declarator-id in `D` is “derived-declarator-type-list array of `N` `T`”. The constant-expression shall be a converted constant expression of type `std::size_t (7.7)`. Its value `N` specifies the array bound, i.e., the number of elements in the array; `N` shall be greater than zero.

2 In a declaration `T D` where `D` has the form
   
   \[ D1 [ \] \text{attribute-specifier-seq}_{\text{opt}} \]
   
   and the type of the contained declarator-id in the declaration `T D1` is “derived-declarator-type-list `T`”, the type of the declarator-id in `D` is “derived-declarator-type-list array of unknown bound of `T`”, except as specified below.

3 A type of the form “array of `N` `U`” or “array of unknown bound of `U`” is an array type. The optional attribute-specifier-seq appertains to the array type.

4 `U` is called the array element type; this type shall not be a placeholder type (9.2.9.6), a reference type, a function type, an array of unknown bound, or `cv void`.

[Note 1: An array can be constructed from one of the fundamental types (except void), from a pointer, from a pointer to member, from a class, or from an array of known bound. — end note]

[Example 1:]
   
   ```c
   float fa[17], *afp[17];
   ```
   
   declares an array of float numbers and an array of pointers to float numbers. — end example]

5 Any type of the form “cv-qualifier-seq array of `N` `U`” is adjusted to “array of `N` cv-qualifier-seq `U`”, and similarly for “array of unknown bound of `U`”.

[Example 2:]
   
   ```c
   typedef int A[5], AA[2][3];
   typedef const A CA;
   typedef const AA CAA;
   ```
   
   — type is “array of 5 const int”
   
   — type is “array of 2 array of 3 const int”

[Note 2: An “array of `N` cv-qualifier-seq `U`” has cv-qualified type; see 6.8.4. — end note]

6 An object of type “array of `N` `U`” consists of a contiguously allocated non-empty set of `N` subobjects of type `U`, known as the elements of the array, and numbered 0 to `N-1`.

7 In addition to declarations in which an incomplete object type is allowed, an array bound may be omitted in some cases in the declaration of a function parameter (9.3.4.6). An array bound may also be omitted when an object (but not a non-static data member) of array type is initialized and the declarator is followed by an initializer (9.4, 11.4, 7.6.1.4, 7.6.2.8). In these cases, the array bound is calculated from the number of initial elements (say, `N`) supplied (9.4.2), and the type of the array is “array of `N` `U`”.

8 Furthermore, if there is a reachable declaration of the entity that inhabits the same scope in which the bound was specified, an omitted array bound is taken to be the same as in that earlier declaration, and similarly for the definition of a static data member of a class.

[Example 3:]
   
   ```c
   extern int x[10];
   struct S {
       static int y[10];
   };
   int x[]; // OK: bound is 10
   int S::y[]; // OK: bound is 10
   void f() {
       extern int x[];
       int i = sizeof(x); // error: incomplete object type
   }
   ```

— end example]
[Note 3: When several “array of” specifications are adjacent, a multidimensional array type is created; only the first of the constant expressions that specify the bounds of the arrays can be omitted.

Example 4:

```c
int x3d[3] [5] [7];
```

declares an array of three elements, each of which is an array of five elements, each of which is an array of seven integers. The overall array can be viewed as a three-dimensional array of integers, with rank $3 \times 5 \times 7$. Any of the expressions $x3d$, $x3d[1][j]$, $x3d[1][j][k]$ can reasonably appear in an expression. The expression $x3d[1]$ is equivalent to $(x3d + i)$; in that expression, $x3d$ is subject to the array-to-pointer conversion (7.3.3) and is first converted to a pointer to a 2-dimensional array with rank $5 \times 7$ that points to the first element of $x3d$. Then $i$ is added, which on typical implementations involves multiplying $i$ by the length of the object to which the pointer points, which is $\text{sizeof}(\text{int}) \times 5 \times 7$. The result of the addition and indirect is an lvalue denoting the $i$th array element of $x3d$ (an array of five arrays of seven integers). If there is another subscript, the same argument applies again, so $x3d[1][j]$ is an lvalue denoting the $j$th array element of the $i$th array element of $x3d$ (an array of seven integers), and $x3d[1][j][k]$ is an lvalue denoting the $k$th array element of the $j$th array element of the $i$th array element of $x3d$ (an integer). — end example]

The first subscript in the declaration helps determine the amount of storage consumed by an array but plays no other part in subscript calculations. — end note]

[Note 4: Conversions affecting expressions of array type are described in 7.3.3. — end note]

[Note 5: The subscript operator can be overloaded for a class (12.4.5). For the operator’s built-in meaning, see 7.6.1.2. — end note]

### 9.3.4.6 Functions

In a declaration $T D$ where $D$ has the form

```c
D1 ( parameter-declaration-clause ) cv-qualifier-seq
    ref-qualifier_opt noexcept-specifier_opt attribute-specifier-seq_opt
and the type of the contained declarator-id in the declaration $T D1$ is “derived-declarator-type-list $T$”, the type of the declarator-id in $D$ is “derived-declarator-type-list noexcept_opt function of parameter-type-list cv-qualifier-seq ref-qualifier_opt returning $T$”, where

(1.1) — the parameter-type-list is derived from the parameter-declaration-clause as described below and

(1.2) — the optional noexcept is present if and only if the exception specification (14.5) is non-throwing.

The optional attribute-specifier-seq appertains to the function type.

In a declaration $T D$ where $D$ has the form

```c
D1 ( parameter-declaration-clause ) cv-qualifier-seq
    ref-qualifier_opt noexcept-specifier_opt attribute-specifier-seq_opt trailing-return-type
and the type of the contained declarator-id in the declaration $T D1$ is “derived-declarator-type-list $T$”, $T$ shall be the single type-specifier auto. The type of the declarator-id in $D$ is “derived-declarator-type-list noexcept_opt function of parameter-type-list cv-qualifier-seq ref-qualifier_opt returning $U$”, where

(2.1) — the parameter-type-list is derived from the parameter-declaration-clause as described below,

(2.2) — $U$ is the type specified by the trailing-return-type, and

(2.3) — the optional noexcept is present if and only if the exception specification is non-throwing.

The optional attribute-specifier-seq appertains to the function type.

A type of either form is a function type.

```
```

[84] As indicated by syntax, cv-qualifiers are a significant component in function return types.

§ 9.3.4.6
parameter-declaration:
    attribute-specifier-seqopt decl-specifier-seq declarator
    attribute-specifier-seqopt decl-specifier-seq declarator = initializer-clause
    attribute-specifier-seqopt decl-specifier-seq abstract-declaratoropt
    attribute-specifier-seqopt decl-specifier-seq abstract-declaratoropt = initializer-clause

The optional attribute-specifier-seq in a parameter-declaration appertains to the parameter.

4 The parameter-declaration-clause determines the arguments that can be specified, and their processing, when the function is called.

[Note 1: The parameter-declaration-clause is used to convert the arguments specified on the function call; see 7.6.1.3. — end note]

If the parameter-declaration-clause is empty, the function takes no arguments. A parameter list consisting of a single unnamed parameter of non-dependent type void is equivalent to an empty parameter list. Except for this special case, a parameter shall not have type cv void. A parameter with volatile-qualified type is deprecated; see D.6. If the parameter-declaration-clause terminates with an ellipsis or a function parameter pack (13.7.4), the number of arguments shall be equal to or greater than the number of parameters that do not have a default argument and are not function parameter packs. Where syntactically correct and where “...” is not part of an abstract-declarator, “, ...” is synonymous with “...”.

[Example 1: The declaration
   
   int printf(const char*, ...);

declarates a function that can be called with varying numbers and types of arguments.

   printf("hello world");
   printf("a=%ld b=%ld", a, b);

However, the first argument must be of a type that can be converted to a const char*. — end example]

[Note 2: The standard header <stdarg> (17.13.2) contains a mechanism for accessing arguments passed using the ellipsis (see 7.6.1.3 and 17.13). — end note]

5 The type of a function is determined using the following rules. The type of each parameter (including function parameter packs) is determined from its own parameter-declaration (9.3). After determining the type of each parameter, any parameter of type “array of T” or of function type T is adjusted to be “pointer to T”. After producing the list of parameter types, any top-level cv-qualifiers modifying a parameter type are deleted when forming the function type. The resulting list of transformed parameter types and the presence or absence of the ellipsis or a function parameter pack is the function’s parameter-type-list.

[Note 3: This transformation does not affect the types of the parameters. For example, int(*)(const int, decltype(p)*) and int(*)(int, const int*) are identical types. — end note]

[Example 2:
   
   void f(char*);
   // #1
   void f(char[]) {}
   // defines #1
   void f(const char*) {}
   // OK: another overload
   void f(char *const) {}
   // error: redefines #1

   void g(char*)([2]);
   // #2
   void g(char*[2]) {}
   // defines #2
   void g(char[[3]] [2]) {}
   // OK: another overload

   void h(int x(const int));
   // #3
   void h(int (*)(int)) {}
   // defines #3

   — end example]

6 A function type with a cv-qualifier-seq or a ref-qualifier (including a type named by typedef-name (9.2.4, 13.2)) shall appear only as:

   (6.1) — the function type for a non-static member function,
   (6.2) — the function type to which a pointer to member refers,
   (6.3) — the top-level function type of a function typedef declaration or alias-declaration,
   (6.4) — the type-id in the default argument of a type-parameter (13.2), or
   (6.5) — the type-id of a template-argument for a type-parameter (13.4.2).
Example 3:

```c
typedef int FIC(int) const;

FIC f;       // error: does not declare a member function
struct S {
  FIC f;      // OK
};
FIC S::*pm = &S::f; // OK
```

The effect of a `cv-qualifier-seq` in a function declarator is not the same as adding `cv`-qualification on top of the function type. In the latter case, the `cv`-qualifiers are ignored.

Note 4: A function type that has a `cv-qualifier-seq` is not a `cv`-qualified type; there are no `cv`-qualified function types.

Example 4:

```c
typedef void F();
struct S {
  const F f;       // OK: equivalent to: void f();
};
```

Example 5: The declaration

```c
int fseek(FILE*, long, int);
```

declares a function taking three arguments of the specified types, and returning `int` (9.2.9).

Note 5: Function types are checked during the assignments and initializations of pointers to functions, references to functions, and pointers to member functions.

Example 6:

```c
typedef void F();
F fv;       // OK: equivalent to void fv();
F fv {}     // error
void fv() {} // OK: definition of fv
```

An identifier can optionally be provided as a parameter name; if present in a function definition (9.5), it names a parameter.

Note 7: In particular, parameter names are also optional in function definitions and names used for a parameter in different declarations and the definition of a function need not be the same.

Example 7: The declaration

```c
int i,
  *pi,
  f(),
  *fpi(int),
  (*fpi)(const char*, const char*),
  (*fpi(int))(int);
```

declares an integer `i`, a pointer `pi` to an integer, a function `f` taking no arguments and returning an integer, a function `fpi` taking an integer argument and returning a pointer to an integer, a pointer `pif` to a function which takes two pointers to constant characters and returns an integer, a function `fpif` taking an integer argument and returning a pointer to a function that takes an integer argument and returns an integer. It is especially useful to compare `fpi` and `pif`. The binding of `*fpi(int)` is `*(fpi(int))`, so the declaration suggests, and the same construction in an
expression requires, the calling of a function \texttt{fpi}, and then using indirection through the (pointer) result to yield an integer. In the declarator \texttt{(*pif)(const char*, const char*)}, the extra parentheses are necessary to indicate that indirection through a pointer to a function yields a function, which is then called. — end example

[Note 8: Typedefs and trailing-return-types are sometimes convenient when the return type of a function is complex. For example, the function \texttt{fpif} above can be declared

\begin{verbatim}
typedef int IFUNC(int);
IFUNC* fpif(int);
\end{verbatim}

or

\begin{verbatim}
auto fpif(int)->int(*)(int);
\end{verbatim}

A trailing-return-type is most useful for a type that would be more complicated to specify before the declarator-id:

\begin{verbatim}
template <class T, class U> auto add(T t, U u) -> decltype(t + u);
\end{verbatim}

rather than

\begin{verbatim}
template <class T, class U> decltype((*(T*)0) + (*(U*)0)) add(T t, U u);
\end{verbatim}

— end note]

17 A \textit{non-template function} is a function that is not a function template specialization.

[Note 9: A function template is not a function. — end note]

18 An \textit{abbreviated function template} is a function declaration that has one or more generic parameter type placeholders (9.2.9.6). An abbreviated function template is equivalent to a function template (13.7.7) whose template-parameter-list includes one invented type template-parameter for each generic parameter type placeholder of the function declaration, in order of appearance. For a placeholder-type-specifier of the form auto, the invented parameter is an unconstrained type-parameter. For a placeholder-type-specifier of the form type-constraint auto, the invented parameter is a type-parameter with that type-constraint. The invented type template-parameter is a template parameter pack if the corresponding parameter-declaration declares a function parameter pack. If the placeholder contains \texttt{decltype(auto)}, the program is ill-formed. The adjusted function parameters of an abbreviated function template are derived from the parameter-declaration-clause by replacing each occurrence of a placeholder with the name of the corresponding invented template-parameter.

[Example 8:]

\begin{verbatim}
template<typename T> concept C1 = /* ... */;
template<typename T> concept C2 = /* ... */;
template<typename... Ts> concept C3 = /* ... */;
void g1(const C1 auto*, C2 auto&);
void g2(C1 auto&...);
void g3(C3 auto...);
void g4(C3 auto);
\end{verbatim}

These declarations are functionally equivalent (but not equivalent) to the following declarations.

\begin{verbatim}
template<C1 T, C2 U> void g1(const T*, U&);
template<C1... Ts> void g2(Ts&...);
template<C3... Ts> void g3(Ts...);
template<C3 T> void g4(T);
\end{verbatim}

Abbreviated function templates can be specialized like all function templates.

\begin{verbatim}
template<> void g1<int>(const int*, const double&); // OK, specialization of g1<int, const double>
\end{verbatim}

— end example]

19 An abbreviated function template can have a template-head. The invented template-parameters are appended to the template-parameter-list after the explicitly declared template-parameters.

[Example 9:]

\begin{verbatim}
template<typename> concept C = /* ... */;
template <typename T, C U>
void g(T x, U y, C auto z);
\end{verbatim}

This is functionally equivalent to each of the following two declarations.

\begin{verbatim}
template<typename T, C U, C W>
void g(T x, U y, W z);
\end{verbatim}
A function declaration at block scope shall not declare an abbreviated function template.

A declarator-id or abstract-declarator containing an ellipsis shall only be used in a parameter-declaration. When it is part of a parameter-declaration-clause, the parameter-declaration declares a function parameter pack (13.7.4). Otherwise, the parameter-declaration is part of a template-parameter-list and declares a template parameter pack; see 13.2. A function parameter pack is a pack expansion (13.7.4).

Example 10:

```cpp
template<typename... T> void f(T (* ...t)(int, int));
int add(int, int);
float subtract(int, int);
void g() {
f(add, subtract);
}
```

There is a syntactic ambiguity when an ellipsis occurs at the end of a parameter-declaration-clause without a preceding comma. In this case, the ellipsis is parsed as part of the abstract-declarator if the type of the parameter either names a template parameter pack that has not been expanded or contains auto; otherwise, it is parsed as part of the parameter-declaration-clause.85

9.3.4.7 Default arguments

1 If an initializer-clause is specified in a parameter-declaration this initializer-clause is used as a default argument. [Note 1: Default arguments will be used in calls where trailing arguments are missing (7.6.1.3). — end note]

2 [Example 1: The declaration

```cpp
void point(int = 3, int = 4);
```

declares a function that can be called with zero, one, or two arguments of type int. It can be called in any of these ways:

```cpp
point(1,2); point(1); point();
```
The last two calls are equivalent to point(1,4) and point(3,4), respectively. [end example]

3 A default argument shall be specified only in the parameter-declaration-clause of a function declaration or lambda-declarator or in a template-parameter (13.2); in the latter case, the initializer-clause shall be an assignment-expression. A default argument shall not be specified for a template parameter pack or a function parameter pack. If it is specified in a parameter-declaration-clause, it shall not occur within a declarator or abstract-declarator of a parameter-declaration.86

For non-template functions, default arguments can be added in later declarations of a function that inhabit the same scope. Declarations that inhabit different scopes have completely distinct sets of default arguments. That is, declarations in inner scopes do not acquire default arguments from declarations in outer scopes, and vice versa. In a given function declaration, each parameter subsequent to a parameter with a default argument shall have a default argument supplied in this or a previous declaration, unless the parameter was expanded from a parameter pack, or shall be a function parameter pack.

[Note 2: A default argument cannot be redefined by a later declaration (not even to the same value) (6.3). — end note]

Example 2:

```cpp
void g(int = 0, ...); // OK, ellipsis is not a parameter so it can follow
void f(int, int);    // a parameter with a default argument
```

85) One can explicitly disambiguate the parse either by introducing a comma (so the ellipsis will be parsed as part of the parameter-declaration-clause) or by introducing a name for the parameter (so the ellipsis will be parsed as part of the declarator-id).

86) This means that default arguments cannot appear, for example, in declarations of pointers to functions, references to functions, or typedef declarations.
For a given inline function defined in different translation units, the accumulated sets of default arguments at the end of the translation units shall be the same; no diagnostic is required. If a friend declaration \( D \) specifies a default argument expression, that declaration shall be a definition and there shall be no other declaration of the function or function template which is reachable from \( D \) or from which \( D \) is reachable.

The default argument has the same semantic constraints as the initializer in a declaration of a variable of the parameter type, using the copy-initialization semantics (9.4). The names in the default argument are looked up, and the semantic constraints are checked, at the point where the default argument appears. Name lookup and checking of semantic constraints for default arguments of templated functions are performed as described in 13.9.2.

[Example 3: In the following code, \( g \) will be called with the value \( f(2) \):

```c
int a = 1;
int f(int);
int g(int x = f(a));  // default argument: f(::a)

void h() {
  a = 2;
  {
    int a = 3;
    g();  // g(f(::a))
  }
}
```

—end example]

[Note 3: A default argument is a complete-class context (11.4). Access checking applies to names in default arguments as described in 11.8. — end note]

Except for member functions of class templates, the default arguments in a member function definition that appears outside of the class definition are added to the set of default arguments provided by the member function declaration in the class definition; the program is ill-formed if a default constructor (11.4.5.2), copy or move constructor (11.4.5.3), or copy or move assignment operator (11.4.6) is so declared. Default arguments for a member function of a class template shall be specified on the initial declaration of the member function within the class template.

[Example 4:

```c
class C {
  void f(int i = 3);
  void g(int i, int j = 99);
};

void C::f(int i = 3) {}  // error: default argument already specified in class scope
void C::g(int i = 88, int j) {}  // in this translation unit, C::g can be called with no argument
```
Note 4: A local variable cannot be odr-used (6.3) in a default argument. —end note

Example 5:

```c
void f() {
    int i;
    extern void g(int x = i); // error
    extern void h(int x = sizeof(i)); // OK
    // ...
}
```

—end example

Note 5: The keyword this cannot appear in a default argument of a member function; see 7.5.2.

Example 6:

```c
class A {
    void f(A* p = this) {} // error
};
```

—end example

—end note

A default argument is evaluated each time the function is called with no argument for the corresponding parameter. A parameter shall not appear as a potentially-evaluated expression in a default argument.

Note 6: Parameters of a function declared before a default argument are in scope and can hide namespace and class member names. —end note

Example 7:

```c
int a;
int f(int a, int b = a); // error: parameter a used as default argument
typedef int I;
int g(float I, int b = I(2)); // error: parameter I found
int h(int a, int b = sizeof(a)); // OK, unevaluated operand
```

—end example

A non-static member shall not appear in a default argument unless it appears as the id-expression of a class member access expression (7.6.1.5) or unless it is used to form a pointer to member (7.6.2.2).

Example 8: The declaration of X::mem1() in the following example is ill-formed because no object is supplied for the non-static member X::a used as an initializer.

```c
int b;
class X {
    int a;
    int mem1(int i = a); // error: non-static member a used as default argument
    int mem2(int i = b); // OK; use X::b
    static int b;
};
```

The declaration of X::mem2() is meaningful, however, since no object is needed to access the static member X::b. Classes, objects, and members are described in Clause 11. —end example

A default argument is not part of the type of a function.

Example 9:

```c
int f(int = 0);
void h() {
    int j = f(1);
    int k = f(); // OK, means f(0)
}
int (*p1)(int) = &f;
int (*p2)() = &f; // error: type mismatch
```

§ 9.3.4.7 196
When an overload set contains a declaration of a function that inhabits a scope \( S \), any default argument associated with any reachable declaration that inhabits \( S \) is available to the call.

[Note 7: The candidate might have been found through a using-declarator from which the declaration that provides the default argument is not reachable. — end note]

A virtual function call (11.7.3) uses the default arguments in the declaration of the virtual function determined by the static type of the pointer or reference denoting the object. An overriding function in a derived class does not acquire default arguments from the function it overrides.

[Example 10:

```c
struct A {
    virtual void f(int a = 7);
};
struct B : public A {
    void f(int a);
};
void m() {
    B* pb = new B;
    A* pa = pb;
    pa->f(); // OK, calls pa->B::f(7)
    pb->f(); // error: wrong number of arguments for B::f()
}
```
—end example]

9.4 Initializers [dcl.init]

9.4.1 General [dcl.init.general]

The process of initialization described in 9.4 applies to all initializations regardless of syntactic context, including the initialization of a function parameter (7.6.1.3), the initialization of a return value (8.7.4), or when an initializer follows a declarator.

```
initializer:
    brace-or-equal-initializer
    ( expression-list )
brace-or-equal-initializer:
    = initializer-clause
    braced-init-list
initializer-clause:
    assignment-expression
    braced-init-list
braced-init-list:
    { initializer-list ,opt }
    { designated-initializer-list ,opt }
    { }
initializer-list:
    initializer-clause ...opt
    initializer-list , initializer-clause ...opt
designated-initializer-list:
    designated-initializer-clause
    designated-initializer-list , designated-initializer-clause
designated-initializer-clause:
    designator brace-or-equal-initializer
designator:
    . identifier
expr-or-braced-init-list:
    expression
    braced-init-list
```

[Note 1: The rules in 9.4 apply even if the grammar permits only the brace-or-equal-initializer form of initializer in a given context. — end note]
Except for objects declared with the `constexpr` specifier, for which see 9.2.6, an initializer in the definition of a variable can consist of arbitrary expressions involving literals and previously declared variables and functions, regardless of the variable’s storage duration.

[Example 1:

```c
int f(int);
int a = 2;
int b = f(a);
int c(b);
```

—end example]

3 [Note 2: Default arguments are more restricted; see 9.3.4.7. — end note]

4 [Note 3: The order of initialization of variables with static storage duration is described in 6.9.3 and 8.8. — end note]

A declaration D of a variable with linkage shall not have an initializer if D inhabits a block scope.

To zero-initialize an object or reference of type T means:

1. If T is a scalar type (6.8), the object is initialized to the value obtained by converting the integer literal 0 (zero) to T.87
2. If T is a (possibly cv-qualified) non-union class type, its padding bits (6.8) are initialized to zero bits and each non-static data member, each non-virtual base class subobject, and, if the object is not a base class subobject, each virtual base class subobject is zero-initialized;
3. If T is a (possibly cv-qualified) union type, its padding bits (6.8) are initialized to zero bits and the object’s first non-static named data member is zero-initialized;
4. If T is an array type, each element is zero-initialized;
5. If T is a reference type, no initialization is performed.

7 To default-initialize an object of type T means:

1. If T is a (possibly cv-qualified) class type (Clause 11), constructors are considered. The applicable constructors are enumerated (12.2.2.4), and the best one for the initializer () is chosen through overload resolution (12.2). The constructor thus selected is called, with an empty argument list, to initialize the object.
2. If T is an array type, each element is default-initialized.
3. Otherwise, no initialization is performed.

A class type T is const-default-constructible if default-initialization of T would invoke a user-provided constructor of T (not inherited from a base class) or if

1. Each direct non-variant non-static data member M of T has a default member initializer or, if M is of class type X (or array thereof), X is const-default-constructible,
2. If T is a union with at least one non-static data member, exactly one variant member has a default member initializer,
3. If T is not a union, for each anonymous union member with at least one non-static data member (if any), exactly one non-static data member has a default member initializer, and
4. Each potentially constructed base class of T is const-default-constructible.

If a program calls for the default-initialization of an object of a const-qualified type T, T shall be a const-default-constructible class type or array thereof.

8 To value-initialize an object of type T means:

1. If T is a (possibly cv-qualified) class type (Clause 11), then
   1. If T has either no default constructor (11.4.5.2) or a default constructor that is user-provided or deleted, then the object is default-initialized;
   2. Otherwise, the object is zero-initialized and the semantic constraints for default-initialization are checked, and if T has a non-trivial default constructor, the object is default-initialized;
2. If T is an array type, then each element is value-initialized;
3. Otherwise, the object is zero-initialized.

87) As specified in 7.3.12, converting an integer literal whose value is 0 to a pointer type results in a null pointer value.
A program that calls for default-initialization or value-initialization of an entity of reference type is ill-formed.

[Note 4: For every object of static storage duration, static initialization (6.9.3.2) is performed at program startup before any other initialization takes place. In some cases, additional initialization is done later. — end note]

If no initializer is specified for an object, the object is default-initialized.

If the entity being initialized does not have class type, the expression-list in a parenthesized initializer shall be a single expression.

The initialization that occurs in the = form of a brace-or-equal-initializer or condition (8.5), as well as in argument passing, function return, throwing an exception (14.2), handling an exception (14.4), and aggregate member initialization (9.4.2), is called copy-initialization.

[Note 5: Copy-initialization can invoke a move (11.4.5.3). — end note]

The initialization that occurs

- for an initializer that is a parenthesized expression-list or a braced-init-list,
- for a new-initializer (7.6.2.8),
- in a static_cast expression (7.6.1.9),
- in a functional notation type conversion (7.6.1.4), and
- in the braced-init-list form of a condition

is called direct-initialization.

The semantics of initializers are as follows. The destination type is the type of the object or reference being initialized and the source type is the type of the initializer expression. If the initializer is not a single (possibly parenthesized) expression, the source type is not defined.

- If the initializer is a (non-parenthesized) braced-init-list or is = braced-init-list, the object or reference is list-initialized (9.4.5).
- If the destination type is a reference type, see 9.4.4.
- If the destination type is an array of characters, an array of char8_t, an array of char16_t, an array of char32_t, or an array of wchar_t, and the initializer is a string-literal, see 9.4.3.
- If the initializer is (), the object is value-initialized.

[Note 6: Since () is not permitted by the syntax for initializer, 

\[
\text{X a();}
\]

is not the declaration of an object of class X, but the declaration of a function taking no argument and returning an X. The form () is permitted in certain other initialization contexts (7.6.2.8, 7.6.1.4, 11.9.3). — end note]

- Otherwise, if the destination type is an array, the object is initialized as follows. Let \( x_1, \ldots, x_k \) be the elements of the expression-list. If the destination type is an array of unknown bound, it is defined as having \( k \) elements. Let \( n \) denote the array size after this potential adjustment. If \( k \) is greater than \( n \), the program is ill-formed. Otherwise, the \( i \)th array element is copy-initialized with \( x_i \) for each \( 1 \leq i \leq k \), and value-initialized for each \( k < i \leq n \). For each \( 1 \leq i < j \leq n \), every value computation and side effect associated with the initialization of the \( i \)th element of the array is sequenced before those associated with the initialization of the \( j \)th element.

- Otherwise, if the destination type is a (possibly cv-qualified) class type:

  - If the initializer expression is a prvalue and the cv-unqualified version of the source type is the same class as the class of the destination, the initializer expression is used to initialize the destination object.

  [Example 2: \( \text{T x = T(T(T()));} \) calls the T default constructor to initialize \( x \). — end example]

  - Otherwise, if the initialization is direct-initialization, or if it is copy-initialization where the cv-unqualified version of the source type is the same class as, or a derived class of, the class of the destination, constructors are considered. The applicable constructors are enumerated (12.2.2.4), and the best one is chosen through overload resolution (12.2). Then:

    - If overload resolution is successful, the selected constructor is called to initialize the object, with the initializer expression or expression-list as its argument(s).
Otherwise, if no constructor is viable, the destination type is an aggregate class, and the initialized is a parenthesized expression-list, the object is initialized as follows. Let $e_1, \ldots, e_n$ be the elements of the aggregate (9.4.2). Let $x_1, \ldots, x_k$ be the elements of the expression-list. If $k$ is greater than $n$, the program is ill-formed. The element $e_i$ is copy-initialized with $x_i$ for $1 \leq i \leq k$. The remaining elements are initialized with their default member initializers, if any, and otherwise are value-initialized. For each $1 \leq i < j \leq n$, every value computation and side effect associated with the initialization of $e_i$ is sequenced before those associated with the initialization of $e_j$.

[Note 7: By contrast with direct-list-initialization, narrowing conversions (9.4.5) are permitted, designators are not permitted, a temporary object bound to a reference does not have its lifetime extended (6.7.7), and there is no brace elision.]

[Example 3:

```cpp
struct A {
  int a;
  int&& r;
};

int f();
int n = 10;

A a1{1, f()};  // OK, lifetime is extended
A a2{1, f()};  // well-formed, but dangling reference
A a3{1.0, 1};  // error: narrowing conversion
A a4{1.0, 1};  // well-formed, but dangling reference
A a5{1.0, std::move(n)};  // OK

— end example]

— end note]

(15.6.2.3)

Otherwise, the initialization is ill-formed.

(15.6.3)

Otherwise (i.e., for the remaining copy-initialization cases), user-defined conversions that can convert from the source type to the destination type or (when a conversion function is used) to a derived class thereof are enumerated as described in 12.2.2.5, and the best one is chosen through overload resolution (12.2). If the conversion cannot be done or is ambiguous, the initialization is ill-formed. The function selected is called with the initializer expression as its argument; if the function is a constructor, the call is a prvalue of the cv-unqualified version of the destination type whose result object is initialized by the constructor. The call is used to direct-initialize, according to the rules above, the object that is the destination of the copy-initialization.

(15.7)

Otherwise, if the source type is a (possibly cv-qualified) class type, conversion functions are considered. The applicable conversion functions are enumerated (12.2.2.6), and the best one is chosen through overload resolution (12.2). The user-defined conversion so selected is called to convert the initializer expression into the object being initialized. If the conversion cannot be done or is ambiguous, the initialization is ill-formed.

(15.8)

Otherwise, if the initialization is direct-initialization, the source type is `std::nullptr_t`, and the destination type is `bool`, the initial value of the object being initialized is `false`.

(15.9)

Otherwise, the initial value of the object being initialized is the (possibly converted) value of the initializer expression. A standard conversion sequence (7.3) will be used, if necessary, to convert the initializer expression to the cv-unqualified version of the destination type; no user-defined conversions are considered. If the conversion cannot be done, the initialization is ill-formed. When initializing a bit-field with a value that it cannot represent, the resulting value of the bit-field is implementation-defined.

[Note 8: An expression of type “cv1 T” can initialize an object of type “cv2 T” independently of the cv-qualifiers cv1 and cv2.

```cpp
int a;
const int b = a;
int c = b;

— end note]

16 An initializer-clause followed by an ellipsis is a pack expansion (13.7.4).
If the initializer is a parenthesized expression-list, the expressions are evaluated in the order specified for function calls (7.6.1.3).

The same identifier shall not appear in multiple designators of a designated-initializer-list.

An object whose initialization has completed is deemed to be constructed, even if the object is of non-class type or no constructor of the object’s class is invoked for the initialization.

[Note 9: Such an object might have been value-initialized or initialized by aggregate initialization (9.4.2) or by an inherited constructor (11.9.4). — end note]

Destroying an object of class type invokes the destructor of the class. Destroying a scalar type has no effect other than ending the lifetime of the object (6.7.3). Destroying an array destroys each element in reverse subscript order.

A declaration that specifies the initialization of a variable, whether from an explicit initializer or by default-initialization, is called the initializing declaration of that variable.

[Note 10: In most cases this is the defining declaration (6.2) of the variable, but the initializing declaration of a non-inline static data member (11.4.9.3) can be the declaration within the class definition and not the definition (if any) outside it. — end note]

9.4.2 Aggregates

An aggregate is an array or a class (Clause 11) with

- no user-declared or inherited constructors (11.4.5),
- no private or protected direct non-static data members (11.8),
- no virtual functions (11.7.3), and
- no virtual, private, or protected base classes (11.7.2).

[Note 1: Aggregate initialization does not allow accessing protected and private base class’ members or constructors. — end note]

The elements of an aggregate are:

- for an array, the array elements in increasing subscript order, or
- for a class, the direct base classes in declaration order, followed by the direct non-static data members (11.4) that are not members of an anonymous union, in declaration order.

When an aggregate is initialized by an initializer list as specified in 9.4.5, the elements of the initializer list are taken as initializers for the elements of the aggregate. The explicitly initialized elements of the aggregate are determined as follows:

- If the initializer list is a designated-initializer-list, the aggregate shall be of class type, the identifier in each designator shall name a direct non-static data member of the class, and the explicitly initialized elements of the aggregate are the elements that are, or contain, those members.

- If the initializer list is an initializer-list, the explicitly initialized elements of the aggregate are the first \( n \) elements of the aggregate, where \( n \) is the number of elements in the initializer list.

- Otherwise, the initializer list must be \( \{ \} \), and there are no explicitly initialized elements.

For each explicitly initialized element:

- If the element is an anonymous union member and the initializer list is a designated-initializer-list, the element is initialized by the designated-initializer-list \( \{ D \} \), where \( D \) is the designated-initializer-clause naming a member of the anonymous union member. There shall be only one such designated-initializer-clause.

[Example 1:

```c
struct C {
    union {
        int a;
        const char* p;
    };
    int x;
} c = { .a = 1, .x = 3 };
initializes c.a with 1 and c.x with 3. — end example]
```
Otherwise, the element is copy-initialized from the corresponding *initializer-clause* or is initialized with the *brace-or-equal-initializer* of the corresponding *designated-initializer-clause*. If that initializer is of the form *assignment-expression* or \( = \) *assignment-expression* and a narrowing conversion (9.4.5) is required to convert the expression, the program is ill-formed.

[Note 2: If an initializer is itself an initializer list, the element is list-initialized, which will result in a recursive application of the rules in this subclause if the element is an aggregate. — end note]

**Example 2:**

```c
struct A {
    int x;
    struct B {
        int i;
        int j;
    } b;
} a = { 1, { 2, 3 } };
```

initializes `a.x` with 1, `a.b.i` with 2, `a.b.j` with 3.

```c
struct base1 { int b1, b2 = 42; };
struct base2 {
    base2() {
        b3 = 42;
    }
    int b3;
};
struct derived : base1, base2 {
    int d;
};
```

```c
derived d1{{1, 2}, {}, 4};
derived d2{{}, {}, 4};
```

initializes `d1.b1` with 1, `d1.b2` with 2, `d1.b3` with 42, `d1.d` with 4, and `d2.b1` with 0, `d2.b2` with 42, `d2.b3` with 42, `d2.d` with 4. — end example]

For a non-union aggregate, each element that is not an explicitly initialized element is initialized as follows:

- If the element has a default member initializer (11.4), the element is initialized from that initializer.
- Otherwise, if the element is not a reference, the element is copy-initialized from an empty initializer list (9.4.5).
- Otherwise, the program is ill-formed.

If the aggregate is a union and the initializer list is empty, then

- if any variant member has a default member initializer, that member is initialized from its default member initializer;
- otherwise, the first member of the union (if any) is copy-initialized from an empty initializer list.

**Example 3:**

```c
struct S { int a; const char* b; int c; int d = b[a]; };
S ss = { 1, "asdf" };
```

initializes `ss.a` with 1, `ss.b` with "asdf", `ss.c` with the value of an expression of the form `int{}` (that is, 0), and `ss.d` with the value of `ss.b[ss.a]` (that is, 's'), and in

```c
struct X { int i, j, k = 42; };
X a[] = { 1, 2, 3, 4, 5, 6 };
X b[2] = { { 1, 2, 3 }, { 4, 5, 6 } };
```

`a` and `b` have the same value

```c
struct A {
    string a;
    int b = 42;
    int c = -1;
};
A{.c=21} has the following steps:
```
6 The initializations of the elements of the aggregate are evaluated in the element order. That is, all value computations and side effects associated with a given element are sequenced before those of any element that follows it in order.

7 An aggregate that is a class can also be initialized with a single expression not enclosed in braces, as described in 9.4.

8 The destructor for each element of class type is potentially invoked (11.4.7) from the context where the aggregate initialization occurs.

[Note 3: This provision ensures that destructors can be called for fully-constructed subobjects in case an exception is thrown (14.3). — end note]

9 An array of unknown bound initialized with a brace-enclosed *initializer-list* containing \( n \) *initializer-clauses* is defined as having \( n \) elements (9.3.4.5).

[Example 4:

```c
int x[] = { 1, 3, 5 };
```

declares and initializes \( x \) as a one-dimensional array that has three elements since no size was specified and there are three initializers. — end example]

An array of unknown bound shall not be initialized with an empty *braced-init-list* `{}`.

[Note 4: A default member initializer does not determine the bound for a member array of unknown bound. Since the default member initializer is ignored if a suitable *mem-initializer* is present (11.9.3), the default member initializer is not considered to initialize the array of unknown bound.

[Example 5:

```c
struct S {
    int y[] = { 0 }; // error: non-static data member of incomplete type
};
```

— end example]

— end note]

10 [Note 5: Static data members, non-static data members of anonymous union members, and unnamed bit-fields are not considered elements of the aggregate.

[Example 6:

```c
struct A {
    int i;
    static int s;
    int j;
    int :17;
    int k;
} a = { 1, 2, 3 };
```

Here, the second initializer 2 initializes \( a.j \) and not the static data member \( A::s \), and the third initializer 3 initializes \( a.k \) and not the unnamed bit-field before it. — end example]

— end note]

11 An *initializer-list* is ill-formed if the number of *initializer-clauses* exceeds the number of elements of the aggregate.

[Example 7:

```c
char cv[4] = { 'a', 's', 'd', 'f', 0 }; // error
```

is ill-formed. — end example]

12 If a member has a default member initializer and a potentially-evaluated subexpression thereof is an aggregate initialization that would use that default member initializer, the program is ill-formed.

[Example 8:

88) The syntax provides for empty *braced-init-lists*, but nonetheless C++ does not have zero length arrays.
struct A;
extern A a;

struct A {
    const A& a1 { A{a,a} };  // OK
    const A& a2 { A{} };    // error
};
A a{a,a};                         // OK

struct B {
    int n = B{}.n;                      // error
};

—end example]

13 If an aggregate class C contains a subaggregate element e with no elements, the initializer-clause for e shall not be omitted from an initializer-list for an object of type C unless the initializer-clauses for all elements of C following e are also omitted.

[Example 9:
struct S { } s;
struct A {
    S s1;
    int i1;
    S s2;
    int i2;
    S s3;
    int i3;
} a = {
    { },  // Required initialization
    0,
    s,    // Required initialization
    0
};     // Initialization not required for A::s3 because A::i3 is also not initialized
—end example]

14 When initializing a multi-dimensional array, the initializer-clauses initialize the elements with the last (rightmost) index of the array varying the fastest (9.3.4.5).

[Example 10:
int x[2][2] = { 3, 1, 4, 2 }; initializes x[0][0] to 3, x[0][1] to 1, x[1][0] to 4, and x[1][1] to 2. On the other hand,
float y[4][3] = {
    { 1 }, { 2 }, { 3 }, { 4 }
};
initializes the first column of y (regarded as a two-dimensional array) and leaves the rest zero. —end example]

15 Braces can be elided in an initializer-list as follows. If the initializer-list begins with a left brace, then the succeeding comma-separated list of initializer-clauses initializes the elements of a subaggregate; it is erroneous for there to be more initializer-clauses than elements. If, however, the initializer-list for a subaggregate does not begin with a left brace, then only enough initializer-clauses from the list are taken to initialize the elements of the subaggregate; any remaining initializer-clauses are left to initialize the next element of the aggregate of which the current subaggregate is an element.

[Example 11:
float y[4][3] = {
    { 1, 3, 5 },
    { 2, 4, 6 },
    { 3, 5, 7 },
};
is a completely-braced initialization: 1, 3, and 5 initialize the first row of the array y[0], namely y[0][0], y[0][1], and y[0][2]. Likewise the next two lines initialize y[1] and y[2]. The initializer ends early and therefore y[3]s elements are initialized as if explicitly initialized with an expression of the form float(), that is, are initialized with 0.0. In the following example, braces in the initializer-list are elided; however the initializer-list has the same effect as the completely-braced initializer-list of the above example,
float y[4][3] = {
    1, 3, 5, 2, 4, 6, 3, 5, 7
};

The initializer for y begins with a left brace, but the one for y[0] does not, therefore three elements from the list are used. Likewise the next three are taken successively for y[1] and y[2]. — end example

All implicit type conversions (7.3) are considered when initializing the element with an assignment-expression. If the assignment-expression can initialize an element, the element is initialized. Otherwise, if the element is itself a subaggregate, brace elision is assumed and the assignment-expression is considered for the initialization of the first element of the subaggregate.

[Note 6: As specified above, brace elision cannot apply to subaggregates with no elements; an initializer-clause for the entire subobject is required. — end note]

[Example 12:
struct A {
    int i;
    operator int();
};
struct B {
    A a1, a2;
    int z;
};
A a;
B b = { 4, a, a };

Braces are elided around the initializer-clause for b.a1.i. b.a1.i is initialized with 4, b.a2 is initialized with a, b.z is initialized with whatever a.operator int() returns. — end example]

[Note 7: An aggregate array or an aggregate class can contain elements of a class type with a user-declared constructor (11.4.5). Initialization of these aggregate objects is described in 11.9.2. — end note]

[Note 8: Whether the initialization of aggregates with static storage duration is static or dynamic is specified in 6.9.3.2, 6.9.3.3, and 8.8. — end note]

When a union is initialized with an initializer list, there shall not be more than one explicitly initialized element.

[Example 13:
union u { int a; const char* b; }; u a = { 1 }; u b = a; u c = 1; // error u d = { 0, "asdf" }; // error u e = { "asdf" }; // error u f = { .b = "asdf" }; // error u g = { .a = 1, .b = "asdf" }; // error — end example]

[Note 9: As described above, the braces around the initializer-clause for a union member can be omitted if the union is a member of another aggregate. — end note]

9.4.3 Character arrays

An array of ordinary character type (6.8.2), char8_t array, char16_t array, char32_t array, or wchar_t array can be initialized by an ordinary string literal, UTF-8 string literal, UTF-16 string literal, UTF-32 string literal, or wide string literal, respectively, or by an appropriately-typed string-literal enclosed in braces (5.13.5). Successive characters of the value of the string-literal initialize the elements of the array.

[Example 1:
char msg[] = "Syntax error on line %s\n";
shows a character array whose members are initialized with a string-literal. Note that because ‘\n’ is a single character and because a trailing ‘\0’ is appended, sizeof(msg) is 25. — end example]

There shall not be more initializers than there are array elements.

[Example 2:
char cv[4] = "asdf"; // error

§ 9.4.3 205
is ill-formed since there is no space for the implied trailing ‘\0’. —end example]

3 If there are fewer initializers than there are array elements, each element not explicitly initialized shall be zero-initialized (9.4).

9.4.4 References

1 A variable whose declared type is “reference to T” (9.3.4.3) shall be initialized.

[Example 1:

```c
int g(int) noexcept;
void f() {
  int i;
  int& r = i;  // r refers to i
  r = 1;       // the value of i becomes 1
  int* p = &r; // p points to i
  int& rr = r; // rr refers to what r refers to, that is, to i
  int (&rg)(int) = g; // rg refers to the function g
  rg(i);
  // calls function g
  int a[3];
  int (&ra)[3] = a; // ra refers to the array a
  ra[1] = i;       // modifies a[1]
}
—end example]

2 A reference cannot be changed to refer to another object after initialization.

[Note 1: Assignment to a reference assigns to the object referred to by the reference (7.6.19). —end note]

Argument passing (7.6.1.3) and function value return (8.7.4) are initializations.

3 The initializer can be omitted for a reference only in a parameter declaration (9.3.4.6), in the declaration of a function return type, in the declaration of a class member within its class definition (11.4), and where the extern specifier is explicitly used.

[Example 2:

```c
int& r1; // error: initializer missing
extern int& r2; // OK
—end example]

4 Given types “cv1 T1” and “cv2 T2”, “cv1 T1” is reference-related to “cv2 T2” if T1 is similar (7.3.6) to T2, or T1 is a base class of T2. “cv1 T1” is reference-compatible with “cv2 T2” if a prvalue of type “pointer to cv2 T2” can be converted to the type “pointer to cv1 T1” via a standard conversion sequence (7.3). In all cases where the reference-compatible relationship of two types is used to establish the validity of a reference binding and the standard conversion sequence would be ill-formed, a program that necessitates such a binding is ill-formed.

5 A reference to type “cv1 T1” is initialized by an expression of type “cv2 T2” as follows:

(5.1) — If the reference is an lvalue reference and the initializer expression

(5.1.1) — is an lvalue (but is not a bit-field), and “cv1 T1” is reference-compatible with “cv2 T2”, or

(5.1.2) — has a class type (i.e., T2 is a class type), where T1 is not reference-related to T2, and can be converted to an lvalue of type “cv3 T3”, where “cv1 T1” is reference-compatible with “cv3 T3”89

(this conversion is selected by enumerating the applicable conversion functions (12.2.2.7) and choosing the best one through overload resolution (12.2)),

then the reference is bound to the initializer expression lvalue in the first case and to the lvalue result of the conversion in the second case (or, in either case, to the appropriate base class subobject of the object).

[Note 2: The usual lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are not needed, and therefore are suppressed, when such direct bindings to lvalues are done. —end note]

[Example 3:

```c
double d = 2.0;
```

89) This requires a conversion function (11.4.8.3) returning a reference type.
© ISO/IEC N4885

double& rd = d;  // rd refers to d
const double& rcd = d;  // rcd refers to d

struct A { }
struct B : A { operator int&(); } b;
A& ra = b;  // ra refers to A subobject in b
const A& rca = b;  // rca refers to A subobject in b
int& ir = B();  // ir refers to the result of B::operator int

— end example [5.2]

— Otherwise, if the reference is an lvalue reference to a type that is not const-qualified or is volatile-qualified, the program is ill-formed.

[Example 4:]
double& rd2 = 2.0;  // error: not an lvalue and reference not const
int i = 2;
double& rd3 = i;  // error: type mismatch and reference not const
— end example [5.3]

— Otherwise, if the initializer expression

(5.3.1) is an rvalue (but not a bit-field) or function lvalue and “cv1 T1” is reference-compatible with “cv2 T2”, or

(5.3.2) has a class type (i.e., T2 is a class type), where T1 is not reference-related to T2, and can be converted to an rvalue or function value type of value “cv3 T3”, where “cv1 T1” is reference-compatible with “cv3 T3” (see 12.2.2.7),

then the value of the initializer expression in the first case and the result of the conversion in the second case is called the converted initializer. If the converted initializer is a prvalue, its type T4 is adjusted to type “cv1 T4” (7.3.6) and the temporary materialization conversion (7.3.5) is applied. In any case, the reference is bound to the resulting glvalue (or to an appropriate base class subobject).

[Example 5:]
struct A { }
struct B : A { } b;
extern B f();
const A& rca2 = f();  // bound to the A subobject of the B rvalue.
A&& rra = f();  // same as above
struct X {
    operator B();
    operator int&();
} x;
const A& r = x;  // bound to the A subobject of the result of the conversion
int i2 = 42;
int&& rri = static_cast<int&&>(i2);  // bound directly to i2
B&& rrb = x;  // bound directly to the result of operator B
— end example [5.4]

— Otherwise:

(5.4.1) If T1 or T2 is a class type and T1 is not reference-related to T2, user-defined conversions are considered using the rules for copy-initialization of an object of type “cv1 T1” by user-defined conversion (9.4.122.2.5, 12.2.2.6); the program is ill-formed if the corresponding non-reference copy-initialization would be ill-formed. The result of the call to the conversion function, as described for the non-reference copy-initialization, is then used to direct-initialize the reference. For this direct-initialization, user-defined conversions are not considered.

(5.4.2) Otherwise, the initializer expression is implicitly converted to a prvalue of type “cv1 T1”. The temporary materialization conversion is applied and the reference is bound to the result.

If T1 is reference-related to T2:

(5.4.3) “cv1” shall be the same cv-qualification as, or greater cv-qualification than, “cv2”; and

(5.4.4) if the reference is an rvalue reference, the initializer expression shall not be an lvalue.

[Example 6:]

§ 9.4.4 207
struct Banana { };  
struct Enigma { operator const Banana(); };  
struct Alaska { operator Banana&(); };  

void enigmatic() {  
   typedef const Banana ConstBanana;  
   Banana &&banana1 = ConstBanana(); // error  
   Banana &&banana2 = Enigma(); // error  
   Banana &&banana3 = Alaska(); // error  
}

const double& rcd2 = 2;  
// error: from result of conversion function  
double&& rrd = 2;  
// error: initializer is lvalue of related type  
const volatile int cvi = 1;  
const int& r2 = cvi;  
// error: cv-qualifier dropped  
struct A { operator volatile int&(); } a;  
const int& r3 = a;  
// error: cv-qualifier dropped  

double d2 = 1.0;  
double&& rrd2 = d2;  
// error: initializer is lvalue of related type  
struct X { operator int&(); };  
int&& rri2 = X();  
// error: result of conversion function is lvalue of related type  
i3 = 2;  
double&& rrd3 = i3;  
// error: initializer is lvalue of related type

In all cases except the last (i.e., implicitly converting the initializer expression to the referenced type),
the reference is said to bind directly to the initializer expression.

[Note 3: 6.7.7 describes the lifetime of temporaries bound to references. — end note]

### 9.4.5 List-initialization

List-initialization is initialization of an object or reference from a **braced-init-list**. Such an initializer is called an **initializer list**, and the comma-separated **initializer-clauses** of the **initializer-list** or **designated-initializer-clauses** of the **designated-initializer-list** are called the **elements** of the initializer list. An initializer list may be empty.

List-initialization can occur in direct-initialization or copy-initialization contexts; list-initialization in a direct-initialization context is called **direct-list-initialization** and list-initialization in a copy-initialization context is called **copy-list-initialization**.

[Note 1: List-initialization can be used

1. as the initializer in a variable definition (9.4)
2. as the initializer in a **new-expression** (7.6.2.8)
3. in a **return** statement (8.7.4)
4. as a **for-range-initializer** (8.6)
5. as a function argument (7.6.1.3)
6. as a subscript (7.6.1.2)
7. as an argument to a constructor invocation (9.4, 7.6.1.4)
8. as an initializer for a non-static data member (11.4)
9. in a **mem-initializer** (11.9.3)
10. on the right-hand side of an assignment (7.6.19)

[Example 1:]

```cpp
int a = {1};
std::complex<double> z{1,2};
new std::vector<std::string>"once", "upon", "a", "time"; // 4 string elements
f( {"Nicholas","Annemarie"} ); // pass list of two elements
return "Norah"; // return list of one element
int* e {}; // initialization to zero / null pointer
x = double(1); // explicitly construct a double
std::map<std::string,int> anim = { {"bear",4}, {"cassowary",2}, {"tiger",7} };
```

—end example]

§ 9.4.5
A constructor is an *initializer-list constructor* if its first parameter is of type `std::initializer_list<E>` or reference to `cv std::initializer_list<E>` for some type E, and either there are no other parameters or else all other parameters have default arguments (9.3.4.7).

*Note 2:* Initializer-list constructors are favored over other constructors in list-initialization (12.2.2.8). Passing an initializer list as the argument to the constructor template `template<class T> C(T)` of a class C does not create an initializer-list constructor, because an initializer list argument causes the corresponding parameter to be a non-deduced context (13.10.3.2). — *end note*

The template `std::initializer_list` is not predefined; if the header `<initializer_list>` is not imported or included prior to a use of `std::initializer_list` — even an implicit use in which the type is not named (9.2.9.6) — the program is ill-formed.

List-initialization of an object or reference of type T is defined as follows:

1. If the braced-init-list contains a designated-initializer-list, T shall be an aggregate class. The ordered identifiers in the designators of the designated-initializer-list shall form a subsequence of the ordered identifiers in the direct non-static data members of T. Aggregate initialization is performed (9.4.2).

   *Example 2:*
   ```
   struct A { int x; int y; int z; }
   A a, b; // error: designator order does not match declaration order
   A b; // OK, b.y initialized to 0
   ```
   — *end example*

2. If T is an aggregate class and the initializer list has a single element of type `cv U`, where U is T or a class derived from T, the object is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization).

3. Otherwise, if T is a character array and the initializer list has a single element that is an appropriately-typed string-literal (9.4.3), initialization is performed as described in that subclause.

4. Otherwise, if T is an aggregate, aggregate initialization is performed (9.4.2).

   *Example 3:*
   ```
   double ad[] = { 1, 2.0 }; // OK
   int ai[] = { 1, 2.0 }; // error: narrowing
   struct S2 {
     int m1;
     double m2, m3;
   }
   S2 s21 = { 1, 2, 3.0 }; // OK
   S2 s22 { 1.0, 2, 3 }; // error: narrowing
   S2 s23 { }; // OK: default to 0,0,0
   ```
   — *end example*

5. Otherwise, if the initializer list has no elements and T is a class type with a default constructor, the object is value-initialized.

6. Otherwise, if T is a specialization of `std::initializer_list<E>`, the object is constructed as described below.

7. Otherwise, if T is a class type, constructors are considered. The applicable constructors are enumerated and the best one is chosen through overload resolution (12.2, 12.2.2.8). If a narrowing conversion (see below) is required to convert any of the arguments, the program is ill-formed.

   *Example 4:*
   ```
   struct S {
     S(const std::initializer_list<double>&); // #1
     S(const std::initializer_list<int>&); // #2
     S(); // #3
     // ...
   }
   S s1 = { 1.0, 2.0, 3.0 }; // invoke #1
   S s2 = { 1, 2, 3 }; // invoke #2
   ```
Example 5:

```cpp
struct Map {
    Map(std::initializer_list<std::pair<std::string, int>>);
};
Map ship = {{"Sophie",14}, {"Surprise",28}};
```

Example 6:

```cpp
struct S {
    S(int, double, double);    // #1
    S();                      // #2
    // ...
};
S s1 = { 1, 2, 3.0 };       // OK: invoke #1
S s2 { 1.0, 2, 3 };         // error: narrowing
S s3 { };                  // OK: invoke #2
```

Example 7:

```cpp
enum byte : unsigned char { };  // OK
byte b { 42 };                 // OK
byte c = { 42 };              // error
byte d = byte( 42 );          // OK; same value as b
byte e { -1 };                // error
```

Example 8:

```cpp
int x1 {2};                   // OK
int x2 {2.0};                 // error: narrowing
```

Example 9:
```cpp
struct S {
    S(std::initializer_list<double>); // #1
    S(const std::string&); // #2
    // ...
};

const S& r1 = { 1, 2, 3.0 }; // OK: invoke #1
const S& r2 = { "Spinach" }; // OK: invoke #2
S& r3 = { 1, 2, 3 }; // error: initializer is not an lvalue
const int& i1 = { 1 }; // OK
const int& i2 = { 1.1 }; // error: narrowing
const int (&iar)[2] = { 1, 2 }; // OK: iar is bound to temporary array
struct A { }; a;
struct B { explicit B(const A&); }; const B& b2{a}; // error: cannot copy-list-initialize B temporary from A

(3.11) Otherwise, if the initializer list has no elements, the object is value-initialized.

[Example 10:
int** pp {}; // initialized to null pointer
— end example]

(3.12) Otherwise, the program is ill-formed.

[Example 11:
struct A { int i; int j; }; A a1 { 1, 2 }; // aggregate initialization A a2 { 1.2 }; // error: narrowing struct B {
    B(std::initializer_list<int>);
}; B b1 { 1, 2 }; // creates initializer_list<int> and calls constructor B b2 { 1, 2.0 }; // error: narrowing struct C {
    C(int i, double j);
}; C c1 = { 1, 2.2 }; // calls constructor with arguments (1, 2.2) C c2 = { 1.1, 2 }; // error: narrowing
int j { 1 }; // initialize to 1
int k { }; // initialize to 0
— end example]

4 Within the initializer-list of a braced-init-list, the initializer-clauses, including any that result from pack expansions (13.7.4), are evaluated in the order in which they appear. That is, every value computation and side effect associated with a given initializer-clause is sequenced before every value computation and side effect associated with any initializer-clause that follows it in the comma-separated list of the initializer-list.

[Note 4: This evaluation ordering holds regardless of the semantics of the initialization; for example, it applies when the elements of the initializer-list are interpreted as arguments of a constructor call, even though ordinarily there are no sequencing constraints on the arguments of a call. — end note]

5 An object of type std::initializer_list<E> is constructed from an initializer list as if the implementation generated and materialized (7.3.5) a prvalue of type "array of N const E", where N is the number of elements in the initializer list. Each element of that array is copy-initialized with the corresponding element of the initializer list, and the std::initializer_list<E> object is constructed to refer to that array.

[Note 5: A constructor or conversion function selected for the copy is required to be accessible (11.8) in the context of the initializer list. — end note]

If a narrowing conversion is required to initialize any of the elements, the program is ill-formed.

[Example 12:
struct X {
    X(std::initializer_list<double> v);
};

§ 9.4.5
The initialization will be implemented in a way roughly equivalent to this:

```cpp
const double __a[3] = {double{1}, double{2}, double{3}};
X x(std::initializer_list<double>(__a, __a+3));
```

assuming that the implementation can construct an `initializer_list` object with a pair of pointers. — end example

The array has the same lifetime as any other temporary object (6.7.7), except that initializing an `initializer_list` object from the array extends the lifetime of the array exactly like binding a reference to a temporary.

```cpp
Example 13:

typedef std::complex<double> cmplx;
std::vector<cmplx> v1 = {1, 2, 3};

void f() {
    std::vector<cmplx> v2{1, 2, 3};
    std::initializer_list<int> i3 = {1, 2, 3};
}

struct A {
    std::initializer_list<int> i4;
    A() : i4({1, 2, 3}) {} // ill-formed, would create a dangling reference
};
```

For `v1` and `v2`, the `initializer_list` object is a parameter in a function call, so the array created for `{1, 2, 3}` has full-expression lifetime. For `i3`, the `initializer_list` object is a variable, so the array persists for the lifetime of the variable. For `i4`, the `initializer_list` object is initialized in the constructor’s ctor-initializer as if by binding a temporary array to a reference member, so the program is ill-formed (11.9.3). — end example

- Note 6: The implementation is free to allocate the array in read-only memory if an explicit array with the same `initializer_list` object from the array extends the lifetime of the array exactly like binding a reference to a temporary.

- Note 7: As indicated above, such conversions are not allowed at the top level in list-initializations. — end note

A narrowing conversion is an implicit conversion

- from a floating-point type to an integer type, or
- from `long` `double` to `double` or `float`, or from `double` to `float`, except where the source is a constant expression and the actual value after conversion is within the range of values that can be represented (even if it cannot be represented exactly), or
- from an integer type or unscoped enumeration type to a floating-point type, except where the source is a constant expression and the actual value after conversion will fit into the target type and will produce the original value when converted back to the original type, or
- from an integer type or unscoped enumeration type to an integer type that cannot represent all the values of the original type, except where the source is a constant expression whose value after integral promotions will fit into the target type, or
- from a pointer type or a pointer-to-member type to `bool`.

[Note 6: The implementation is free to allocate the array in read-only memory if an explicit array with the same `initializer_list` can be so allocated. — end note]

```cpp
Example 14:

int x = 999; // x is not a constant expression
const int y = 999;
const int z = 99;
char c1 = x; // OK, though it potentially narrows (in this case, it does narrow)
char c2(x);
char c3(y); // error: potentially narrows
char c4(z);
// error: narrows (assuming char is 8 bits)
unsigned char uc1 = {5}; // OK: no narrowing needed
unsigned char uc2 = {-1}; // error: narrows
unsigned int ui1 = {-1}; // error: narrows
signed int si1 = {unsigned int{-1}}; // error: narrows
int ii = (2.0); // error: narrows
float f1 { x }; // error: potentially narrows
float f2 { 7 }; // OK: 7 can be exactly represented as a float
```
bool b = {"meow");       // error: narrows
int f(int);
int a[]} = { 2, f(2), f(2.0) };  // OK: the double-to-int conversion is not at the top level
—end example]

9.5 Function definitions

9.5.1 In general

1 Function definitions have the form

```
function-definition:
  attribute-specifier-seq_opt decl-specifier-seq_opt declarator virt-specifier-seq_opt function-body
attribute-specifier-seq_opt decl-specifier-seq_opt declarator requires-clause function-body
```

function-body:
```
ctor_initializer_opt compound-statement
function-try-block
  = default;
  = delete;
```

Any informal reference to the body of a function should be interpreted as a reference to the non-terminal `function-body`. The optional `attribute-specifier-seq` in a `function-definition` appertains to the function. A `virt-specifier-seq` can be part of a `function-definition` only if it is a `member-declaration` (11.4).

2 In a `function-definition`, either `void declarator`; or `declarator`; shall be a well-formed function declaration as described in 9.3.4.6. A function shall be defined only in namespace or class scope. The type of a parameter or the return type for a function definition shall not be a (possibly cv-qualified) class type that is incomplete or abstract within the function body unless the function is deleted (9.5.3).

3 [Example 1: A simple example of a complete function definition is
```
int max(int a, int b, int c) {
  int m = (a > b) ? a : b;
  return (m > c) ? m : c;
}
```
Here `int` is the `decl-specifier-seq`; `max(int a, int b, int c)` is the `declarator`; `{ /* ... */ }` is the `function-body`. —end example]

4 A `ctor-initializer` is used only in a constructor; see 11.4.5 and 11.9.

5 [Note 1: A `cv-qualifier-seq` affects the type of `this` in the body of a member function; see 7.5.2. —end note]

6 [Note 2: Unused parameters need not be named. For example,
```
void printf(int a, int) {
  std::printf("a = %d\n",a);
}
```
—end note]

7 A `function-local predefined variable` is a variable with static storage duration that is implicitly defined in a function parameter scope.

8 The `function-local predefined variable` `__func__` is defined as if a definition of the form
```
static const char __func__[ ] = "function-name";
```
had been provided, where `function-name` is an implementation-defined string. It is unspecified whether such a variable has an address distinct from that of any other object in the program.\(^{90}\)

[Example 2:
```
struct S {
  S(): s(__func__) { }       // OK
  const char* s;
};
void f(const char* s = __func__);   // error: __func__ is undeclared
—end example]

\(^{90}\) Implementations are permitted to provide additional predefined variables with names that are reserved to the implementation (5.10). If a predefined variable is not odr-used (6.3), its string value need not be present in the program image.
9.5.2 Explicitly-defaulted functions

A function definition whose function-body is of the form = default ; is called an explicitly-defaulted definition. A function that is explicitly defaulted shall

1. be a special member function or a comparison operator function (12.4.3), and
2. not have default arguments.

The type $T_1$ of an explicitly defaulted special member function $F$ is allowed to differ from the type $T_2$ it would have had if it were implicitly declared, as follows:

1. $T_1$ and $T_2$ may have differing ref-qualifiers;
2. $T_1$ and $T_2$ may have differing exception specifications; and
3. if $T_2$ has a parameter of type const $C&$, the corresponding parameter of $T_1$ may be of type $C&$.

If $T_1$ differs from $T_2$ in any other way, then:

1. if $F$ is an assignment operator, and the return type of $T_1$ differs from the return type of $T_2$ or $T_1$’s parameter type is not a reference, the program is ill-formed;
2. otherwise, if $F$ is explicitly defaulted on its first declaration, it is defined as deleted;
3. otherwise, the program is ill-formed.

An explicitly-defaulted function that is not defined as deleted may be declared constexpr or consteval only if it is constexpr-compatible (11.4.4, 11.10.1). A function explicitly defaulted on its first declaration is implicitly inline (9.2.8), and is implicitly constexpr (9.2.6) if it is constexpr-compatible.

Example 1:

```cpp
struct S {
    constexpr S() = default; // error: implicit S() is not constexpr
    S(int a = 0) = default;   // error: default argument
    void operator=(const S&) = default; // error: non-matching return type
    -S() noexcept(false) = default; // OK, despite mismatched exception specification
private:
    int i;
    S(S&);                 // OK: private copy constructor
};
S::S(S&) = default; // OK: defines copy constructor

struct T {
    T();
    T(T&&) noexcept(false);
};
struct U {
    T t;
    U();
    U(U&&) noexcept = default;
};
U u1;
U u2 = static_cast<U&&>(u1); // OK, calls std::terminate if T::T(T&&) throws
```

Example 2:

Explicitly-defaulted functions and implicitly-declared functions are collectively called defaulted functions, and the implementation shall provide implicit definitions for them (11.4.5, 11.4.7, 11.4.5.3, 11.4.6), including possibly defining them as deleted. A defaulted prospective destructor (11.4.7) that is not a destructor is defined as deleted. A defaulted special member function that is neither a prospective destructor nor an eligible special member function (11.4.4) is defined as deleted. A function is user-provided if it is user-declared and not explicitly defaulted or deleted on its first declaration. A user-provided explicitly-defaulted function (i.e., explicitly defaulted after its first declaration) is defined at the point where it is explicitly defaulted; if such a function is implicitly defined as deleted, the program is ill-formed.

Note 1: Declaring a function as defaulted after its first declaration can provide efficient execution and concise definition while enabling a stable binary interface to an evolving code base. — end note

Example 2:
struct trivial {
    trivial() = default;
    trivial(const trivial&) = default;
    trivial(trivial&&) = default;
    trivial& operator=(const trivial&) = default;
    trivial& operator=(trivial&&) = default;
    ~trivial() = default;
};

struct nontrivial1 {
    nontrivial1();
};

nontrivial1::nontrivial1() = default;
// not first declaration

9.5.3 Deleted definitions

A deleted definition of a function is a function definition whose function-body is of the form = delete; or an explicitly-defaulted definition of the function where the function is defined as deleted. A deleted function is a function with a deleted definition or a function that is implicitly defined as deleted.

A program that refers to a deleted function implicitly or explicitly, other than to declare it, is ill-formed.

[Note 1: This includes calling the function implicitly or explicitly and forming a pointer or pointer-to-member to the function. It applies even for references in expressions that are not potentially-evaluated. For an overload set, only the function selected by overload resolution is referenced. The implicit odr-use (6.3) of a virtual function does not, by itself, constitute a reference. — end note]

[Example 1: One can prevent default initialization and initialization by non-doubles with

struct onlydouble {
    onlydouble() = delete; // OK, but redundant
    template<class T>
    onlydouble(T) = delete;
    onlydouble(double);
};

—end example]

[Example 2: One can prevent use of a class in certain new-expressions by using deleted definitions of a user-declared operator new for that class.

struct sometype {
    void* operator new(std::size_t) = delete;
    void* operator new[](std::size_t) = delete;
};

sometype* p = new sometype; // error: deleted class operator new
sometype* q = new sometype[3]; // error: deleted class operator new[]

—end example]

[Example 3: One can make a class uncopiable, i.e., move-only, by using deleted definitions of the copy constructor and copy assignment operator, and then providing defaulted definitions of the move constructor and move assignment operator.

struct moveonly {
    moveonly() = default;
    moveonly(const moveonly&) = delete;
    moveonly(moveonly&&) = default;
    moveonly& operator=(const moveonly&) = delete;
    moveonly& operator=(moveonly&&) = default;
    ~moveonly() = default;
};

moveonly* p;
moveonly q(*p); // error: deleted copy constructor

—end example]

A deleted function is implicitly an inline function (9.2.8).

[Note 2: The one-definition rule (6.3) applies to deleted definitions. — end note]
A deleted definition of a function shall be the first declaration of the function or, for an explicit specialization of a function template, the first declaration of that specialization. An implicitly declared allocation or deallocation function (6.7.5.5) shall not be defined as deleted.

[Example 4:]

```cpp
struct sometype {
    sometype();
};
sometype::sometype() = delete; // error: not first declaration
```

— end example]

### 9.5.4 Coroutine definitions

A function is a coroutine if its function-body encloses a coroutine-return-statement (8.7.5), an await-expression (7.6.2.4), or a yield-expression (7.6.17). The parameter-declaration-clause of the coroutine shall not terminate with an ellipsis that is not part of a parameter-declaration.

[Example 1:]

```cpp
task<int> f();

task<void> g1() {
    int i = co_await f();
    std::cout << "f() => " << i << std::endl;
}

template <typename... Args>
task<void> g2(Args&&...){ // OK, ellipsis is a pack expansion
    int i = co_await f();
    std::cout << "f() => " << i << std::endl;
}

task<void> g3(int a, ...) { // error: variable parameter list not allowed
    int i = co_await f();
    std::cout << "f() => " << i << std::endl;
}
```

— end example]

3 The promise type of a coroutine is `std::coroutine_traits<R, P_1, ..., P_n>::promise_type`, where `R` is the return type of the function, and `P_1...P_n` are the sequence of types of the function parameters, preceded by the type of the implicit object parameter (12.2.2) if the coroutine is a non-static member function. The promise type shall be a class type.

4 In the following, `p_i` is an lvalue of type `P_i`, where `p_0` denotes `*this` and `p_{i+1}` denotes the `i`th function parameter for a non-static member function, and `p_i` denotes the `i`th function parameter otherwise.

A coroutine behaves as if its function-body were replaced by:

```cpp
{
    promise-type promise; promise-constructor-arguments
    try {
        co_await promise . initial_suspend();
        function-body
    } catch (...) {
        if (!initial-await-resume-called)
            throw;
        promise . unhandled_exception();
    }
    final-suspend:
    co_await promise . final_suspend();
}
```

where

(5.1) — the await-expression containing the call to `initial_suspend` is the initial suspend point, and

(5.2) — the await-expression containing the call to `final_suspend` is the final suspend point, and
— initial-await-resume-called is initially `false` and is set to `true` immediately before the evaluation of the `await-resume` expression (7.6.2.4) of the initial suspend point, and

— promise-type denotes the promise type, and

— the object denoted by the exposition-only name `promise` is the promise object of the coroutine, and

— the label denoted by the name `final-suspend` is defined for exposition only (8.7.5), and

— promise-constructor-arguments is determined as follows: overload resolution is performed on a promise constructor call created by assembling an argument list with lvalues `p_1`...`p_n`. If a viable constructor is found (12.2.3), then `promise-constructor-arguments` is `(p_1, ..., p_n)`, otherwise `promise-constructor-arguments` is empty.

6 If searches for the names `return_void` and `return_value` in the scope of the promise type each find any declarations, the program is ill-formed.

[Note 1: If `return_void` is found, flowing off the end of a coroutine is equivalent to a `co_return` with no operand. Otherwise, flowing off the end of a coroutine results in undefined behavior (8.7.5). — end note]

7 The expression `promise.get_return_object()` is used to initialize the glvalue result or prvalue result object of a call to a coroutine. The call to `get_return_object` is sequenced before the call to `initial_suspend` and is invoked at most once.

8 A suspended coroutine can be resumed to continue execution by invoking a resumption member function (17.12.4.6) of a coroutine handle (17.12.4) that refers to the coroutine. The function that invoked a resumption member function is called the `resumer`. Invoking a resumption member function for a coroutine that is not suspended results in undefined behavior.

9 An implementation may need to allocate additional storage for a coroutine. This storage is known as the coroutine state and is obtained by calling a non-array allocation function (6.7.5.5.2). The allocation function’s name is looked up by searching for it in the scope of the promise type.

9.1 — If any declarations are found, overload resolution is performed on a function call created by assembling an argument list. The first argument is the amount of space requested, and has type `std::size_t`. The lvalues `p_1`...`p_n` are the succeeding arguments.

9.2 — Otherwise, a search is performed in the global scope.

If no viable function is found (12.2.3), overload resolution is performed again on a function call created by passing just the amount of space required as an argument of type `std::size_t`.

10 If a search for the name `get_return_object_on_allocation_failure` in the scope of the promise type (6.5.2) finds any declarations, then the result of a call to an allocation function used to obtain storage for the coroutine state is assumed to return `nullptr` if it fails to obtain storage, and if a global allocation function is selected, the `::operator new(size_t, nothrow_t)` form is used. The allocation function used in this case shall have a non-throwing `noexcept-specifier`. If the allocation function returns `nullptr`, the coroutine returns control to the caller of the coroutine and the return value is obtained by a call to `T::get_return_object_on_allocation_failure()`, where `T` is the promise type.

[Example 2:]

```cpp
#include <iostream>
#include <coroutine>

using ::operator new(size_t, nothrow_t) will be used if allocation is needed

struct generator {
    using promise_type;
    using handle = std::coroutine_handle<promise_type>;
}

struct promise_type {
    int current_value;
    static auto get_return_object_on_allocation_failure() { return generator(nullptr); }
    auto get_return_object() { return generator(handle::from_promise(*this)); }
    auto initial_suspend() { return std::suspend_always{}; }
    auto final_suspend() noexcept { return std::suspend_always{}; }
    void unhandled_exception() { std::terminate(); }
    void return_void() {}
    auto yield_value(int value) {
        current_value = value;
        return std::suspend_always();
    }
};
```
```cpp
bool move_next() { return coro ? (coro.resume(), !coro.done()) : false; }
int current_value() { return coro.promise().current_value; }
generator(generator const&) = delete;
generator(generator && rhs) : coro(rhs.coro) { rhs.coro = nullptr; }
~generator() { if (coro) coro.destroy(); }
private:
generator(handle h) : coro(h) {}  
handle coro;
};
generator f() { co_yield 1; co_yield 2; }
int main() {
  auto g = f();
  while (g.move_next()) std::cout << g.current_value() << std::endl;
}
```

11 The coroutine state is destroyed when control flows off the end of the coroutine or the `destroy` member function (17.12.4.6) of a coroutine handle (17.12.4) that refers to the coroutine is invoked. In the latter case, control in the coroutine is considered to be transferred out of the function (8.8). The storage for the coroutine state is released by calling a non-array deallocation function (6.7.5.5.3). If `destroy` is called for a coroutine that is not suspended, the program has undefined behavior.

12 The deallocation function’s name is looked up by searching for it in the scope of the promise type. If nothing is found, a search is performed in the global scope. If both a usual deallocation function with only a pointer parameter and a usual deallocation function with both a pointer parameter and a size parameter are found, then the selected deallocation function shall be the one with two parameters. Otherwise, the selected deallocation function shall be the function with one parameter. If no usual deallocation function is found, the program is ill-formed. The selected deallocation function shall be called with the address of the block of storage to be reclaimed as its first argument. If a deallocation function with a parameter of type `std::size_t` is used, the size of the block is passed as the corresponding argument.

13 When a coroutine is invoked, after initializing its parameters (7.6.1.3), a copy is created for each coroutine parameter. For a parameter of type `cv T`, the copy is a variable of type `cv T` with automatic storage duration that is direct-initialized from an xvalue of type `T` referring to the parameter.

[Note 2: An original parameter object is never a const or volatile object (6.8.4). — end note]

The initialization and destruction of each parameter copy occurs in the context of the called coroutine. Initializations of parameter copies are sequenced before the call to the coroutine promise constructor and indeterminately sequenced with respect to each other. The lifetime of parameter copies ends immediately after the lifetime of the coroutine promise object ends.

[Note 3: If a coroutine has a parameter passed by reference, resuming the coroutine after the lifetime of the entity referred to by that parameter has ended is likely to result in undefined behavior. — end note]

14 If the evaluation of the expression `promise.unhandled_exception()` exits via an exception, the coroutine is considered suspended at the final suspend point.

15 The expression `co_await promise.final_suspend()` shall not be potentially-throwing (14.5).

### 9.6 Structured binding declarations

1 A structured binding declaration introduces the identifiers `v_0`, `v_1`, `v_2`,… of the identifier-list as names of structured bindings. Let `cv` denote the cv-qualifiers in the decl-specifier-seq and `S` consist of the storage-class-specifiers of the decl-specifier-seq (if any). A `cv` that includes `volatile` is deprecated; see D.6. First, a variable with a unique name `e` is introduced. If the assignment-expression in the initializer has array type `A` and no ref-qualifier is present, `e` is defined by

```
attribute-specifier-seqopt S cv & e;
```

and each element is copy-initialized or direct-initialized from the corresponding element of the assignment-expression as specified by the form of the initializer. Otherwise, `e` is defined as-if by

```
attribute-specifier-seqopt decl-specifier-seq ref-qualifieropt e initializer;
```
where the declaration is never interpreted as a function declaration and the parts of the declaration other than the declaration is never interpreted as a function declaration and the parts of the declaration other than the 

declarator-id are taken from the corresponding structured binding declaration. The type of the 
id-expression e is called E.

[Note 1: E is never a reference type (7.2). — end note]

2 If the initializer refers to one of the names introduced by the structured binding declaration, the program is 
il-formed.

3 If E is an array type with element type T, the number of elements in the identifier-list shall be equal to the 

type of the declared type of E. Each vi is the name of an lvalue that refers to the element i of the array and whose 

type is T; the referenced type is T.

[Note 2: The top-level cv-qualifiers of T are cv. — end note]

[Example 1: 
\[
\begin{align*}
&\text{auto } f() \to \text{int(&)[2];} \\
&\text{auto } [x, y] = f(); \\
&\text{auto &} [xr, yr] = f();
\end{align*}
\]
// x and y refer to elements in a copy of the array return value  
// xr and yr refer to elements in the array referred to by f's return value

— end example]

4 Otherwise, if the qualified-id std::tuple_size<E> names a complete class type with a member named value, 
the expression std::tuple_size<E>::value shall be a well-formed integral constant expression and the 
number of elements in the identifier-list shall be equal to the value of that expression. Let i be an index prvalue 
of type std::size_t corresponding to vi. If a search for the name get in the scope of E (6.5.2) finds at least 
one declaration that is a function template whose first template parameter is a non-type parameter, the 
initializer is e.get<i>(). Otherwise, the initializer is get<i>(e), where get undergoes argument-dependent 
lookup (6.5.4). In either case, get<i> is interpreted as a template-id.

[Note 3: Ordinary unqualified lookup (6.5.3) is not performed. — end note]

In either case, e is an lvalue if the type of the entity e is an lvalue reference and an xvalue otherwise. Given 
the type Ti designated by std::tuple_element<i, E>::type and the type U, designated by either T&, & or 
T&&, where U is an lvalue reference if the initializer is an lvalue and an rvalue reference otherwise, variables 
are introduced with unique names ri as follows:

\[
S 
U, 
ri
= 
initializer;
\]

Each vi is the name of an lvalue of type Ti that refers to the object bound to ri; the referenced type is Ti.

5 Otherwise, all of E's non-static data members shall be direct members of E or of the same base class of E, 
well-formed when named as e.name in the context of the structured binding. E shall not have an anonymous 
union member, and the number of elements in the identifier-list shall be equal to the number of non-static 
data members of E. Designating the non-static data members of E as m0, m1, m2, ... (in declaration order), 
each vi is the name of an lvalue that refers to the member mi of e and whose type is that of e.mi (7.6.1.5); 
the referenced type is the declared type of mi if that type is a reference type, or the type of e.m, otherwise. 
The lvalue is a bit-field if that member is a bit-field.

[Example 2: 
\[
\begin{align*}
&\text{struct S } \{ \text{mutable int x1 : 2; volatile double y1; } \}; \\
&\text{S f();} \\
&\text{const auto } [x, y] = f();
\end{align*}
\]
The type of the id-expression x is "int", the type of the id-expression y is "const volatile double". — end example]

9.7 Enumerations

9.7.1 Enumeration declarations

An enumeration is a distinct type (6.8.3) with named constants. Its name becomes an enum-name within its 
scope.

\[
\begin{align*}
\text{enum-name:} \\
\text{identifier} \\
\text{enum-specifier:} \\
\text{enum-head } \{ \text{enumerator-list}_{opt} \} \\
\text{enum-head } \{ \text{enumerator-list} , \} \\
\text{enum-head:} \\
\text{enum-key attribute-specifier-seq}_{opt} \text{enum-head-name}_{opt} \text{enum-base}_{opt}
\end{align*}
\]

§ 9.7.1 219
enum-head-name:
    nested-name-specifier_opt identifier

opaque-enum-declaration:
    enum-key attribute-specifier-seq_opt enum-head-name enum-base_opt ;

enum-key:
    enum
    enum class
    enum struct

enum-base:
    : type-specifier-seq

enumerator-list:
    enumerator-definition
    enumerator-list , enumerator-definition

enumerator-definition:
    enumerator
    enumerator = constant-expression

enumerator:
    identifier attribute-specifier-seq_opt

The optional attribute-specifier-seq in the enum-head and the opaque-enum-declaration appertains to the enumeration; the attributes in that attribute-specifier-seq are thereafter considered attributes of the enumeration whenever it is named. A : following “enum nested-name-specifier_opt identifier” within the decl-specifier-seq of a member-declaration is parsed as part of an enum-base.

[Note 1: This resolves a potential ambiguity between the declaration of an enumeration with an enum-base and the declaration of an unnamed bit-field of enumeration type.

[Example 1:
    struct S {
      enum E : int {};
      enum E : int {};          // error: redeclaration of enumeration
    };
    —end example]
    —end note]

The identifier in an enum-head-name is not looked up and is introduced by the enum-specifier or opaque-enum-declaration. If the enum-head-name of an opaque-enum-declaration contains a nested-name-specifier, the declaration shall be an explicit specialization (13.9.4).

2 The enumeration type declared with an enum-key of only enum is an unscooped enumeration, and its enumerators are unscooped enumerators. The enum-keys enum class and enum struct are semantically equivalent; an enumeration type declared with one of these is a scoped enumeration, and its enumerators are scoped enumerators. The optional enum-head-name shall not be omitted in the declaration of a scoped enumeration. The type-specifier-seq of an enum-base shall name an integral type; any cv-qualification is ignored. An opaque-enum-declaration declaring an unscooped enumeration shall not omit the enum-base. The identifiers in an enumerator-list are declared as constants, and can appear wherever constants are required. An enumerator-definition with = gives the associated enumerator the value indicated by the constant-expression. If the first enumerator has no initializer, the value of the corresponding constant is zero. An enumerator-definition without an initializer gives the enumerator the value obtained by increasing the value of the previous enumerator by one.

[Example 2:
    enum { a, b, c=0 };
    enum { d, e, f=e+2 };

defines a, c, and d to be zero, b and e to be 1, and f to be 3. —end example]

The optional attribute-specifier-seq in an enumerator appertains to that enumerator.

3 An opaque-enum-declaration is either a redeclaration of an enumeration in the current scope or a declaration of a new enumeration.

[Note 2: An enumeration declared by an opaque-enum-declaration has a fixed underlying type and is a complete type. The list of enumerators can be provided in a later redeclaration with an enum-specifier. —end note]
A scoped enumeration shall not be later redeclared as unscoped or with a different underlying type. An unscoped enumeration shall not be later redeclared as scoped and each redeclaration shall include an enum-base specifying the same underlying type as in the original declaration.

4 If an enum-head-name contains a nested-name-specifier, the enclosing enum-specifier or opaque-enum-declaration D shall not inherit a class scope and shall correspond to one or more declarations nominable in the class, class template, or namespace to which the nested-name-specifier refers (6.4.1). All those declarations shall have the same target scope; the target scope of D is that scope.

5 Each enumeration defines a type that is different from all other types. Each enumeration also has an underlying type. The underlying type can be explicitly specified using an enum-base. For a scoped enumeration type, the underlying type is int if it is not explicitly specified. In both of these cases, the underlying type is said to be fixed. Following the closing brace of an enum-specifier, each enumerator has the type of its enumeration. If the underlying type is fixed, the type of each enumerator prior to the closing brace is the underlying type and the constant-expression in the enumerator-definition shall be a converted constant expression of the underlying type (7.7). If the underlying type is not fixed, the type of each enumerator prior to the closing brace is determined as follows:

(5.1) If an initializer is specified for an enumerator, the constant-expression shall be an integral constant expression (7.7). If the expression has unscoped enumeration type, the enumerator has the underlying type of that enumeration type, otherwise it has the same type as the expression.

(5.2) If no initializer is specified for the first enumerator, its type is an unspecified signed integral type.

(5.3) Otherwise the type of the enumerator is the same as that of the preceding enumerator unless the incremented value is not representable in that type, in which case the type is an unspecified integral type sufficient to contain the incremented value. If no such type exists, the program is ill-formed.

6 An enumeration whose underlying type is fixed is an incomplete type until immediately after its enum-base (if any), at which point it becomes a complete type. An enumeration whose underlying type is not fixed is an incomplete type until the closing } of its enum-specifier, at which point it becomes a complete type.

7 For an enumeration whose underlying type is not fixed, the underlying type is an integral type that can represent all the enumerator values defined in the enumeration. If no integral type can represent all the enumerator values, the enumeration is ill-formed. It is implementation-defined which integral type is used as the underlying type except that the underlying type shall not be larger than int unless the value of an enumerator cannot fit in an int or unsigned int. If the enumerator-list is empty, the underlying type is as if the enumeration had a single enumerator with value 0.

8 For an enumeration whose underlying type is fixed, the values of the enumeration are the values of the underlying type. Otherwise, the values of the enumeration are the values representable by a hypothetical integer type with minimal width M such that all enumerators can be represented. The width of the smallest bit-field large enough to hold all the values of the enumeration type is M. It is possible to define an enumeration that has values not defined by any of its enumerators. If the enumerator-list is empty, the values of the enumeration are as if the enumeration had a single enumerator with value 0.\footnote{This set of values is used to define promotion and conversion semantics for the enumeration type. It does not preclude an expression of enumeration type from having a value that falls outside this range.}

9 Two enumeration types are layout-compatible enumerations if they have the same underlying type.

10 The value of an enumerator or an object of an unscoped enumeration type is converted to an integer by integral promotion (7.3.7).

[Example 3:

enum color { red, yellow, green=20, blue };  
color col = red;  
color* cp = &col;  
if (*cp == blue)  
// ...

makes color a type describing various colors, and then declares col as an object of that type, and cp as a pointer to an object of that type. The possible values of an object of type color are red, yellow, green, blue; these values can be converted to the integral values 0, 1, 20, and 21. Since enumerations are distinct types, objects of type color can be assigned only values of type color.

    color c = 1;  
    // error: type mismatch, no conversion from int to color
    int i = yellow;  
    // OK: yellow converted to integral value 1, integral promotion

\footnote{This set of values is used to define promotion and conversion semantics for the enumeration type. It does not preclude an expression of enumeration type from having a value that falls outside this range.}
Note that this implicit `enum` to `int` conversion is not provided for a scoped enumeration:

```cpp
enum class Col { red, yellow, green);
int x = Col::red; // error: no Col to int conversion
Col y = Col::red);
if (y) {} // error: no Col to bool conversion
```

The name of each unscoped enumerator is also bound in the scope that immediately contains the `enum-specifier`. An unnamed enumeration that does not have a typedef name for linkage purposes (9.2.4) and that has a first enumerator is denoted, for linkage purposes (6.6), by its underlying type and its first enumerator; such an enumeration is said to have an enumerator as a name for linkage purposes.

[Note 3: Each unnamed enumeration with no enumerators is a distinct type. — end note]

[Example 4:]
```cpp
enum direction { left='l', right='r'};

void g() {
  direction d; // OK
  d = left; // OK
  d = direction::right; // OK
}

enum class altitude { high='h', low='l'};

void h() {
  altitude a; // OK
  a = high; // error: high not in scope
  a = altitude::low; // OK
}
```

---

9.7.2 The `using enum` declaration

[enum.udecl]

1 The `elaborated-enum-specifier` shall not name a dependent type and the type shall have a reachable `enum-specifier`.

2 A `using enum-declaration` is equivalent to a `using-declaration` for each enumerator.

3 [Note 1: A `using enum-declaration` in class scope makes the enumerators of the named enumeration available via member lookup.

[Example 1:]
```cpp
enum class fruit { orange, apple);
struct S {
  using enum fruit; // OK, introduces orange and apple into S
};
void f() {
  S s;
  s.orange; // OK, names fruit::orange
  S::orange; // OK, names fruit::orange
}
```

— end example]

— end note]

4 [Note 2: Two `using enum-declarations` that introduce two enumerators of the same name conflict.

[Example 2:]
```cpp
enum class fruit { orange, apple};
enum class color { red, orange};
void f() {
  using enum fruit; // OK
```
using enum color;  // error: color::orange and fruit::orange conflict
}
—end example]
—end note]

9.8 Namespaces

9.8.1 General

A namespace is an optionally-named entity whose scope can contain declarations of any kind of entity. The name of a namespace can be used to access entities that belong to that namespace; that is, the members of the namespace. Unlike other entities, the definition of a namespace can be split over several parts of one or more translation units and modules.

[Note 1: A namespace-definition is exported if it contains any export-declarations (10.2). A namespace is never attached to a named module and never has a name with module linkage. — end note]

Example 1:

```c
export module M;
namespace N1 {}  // N1 is not exported
export namespace N2 {}  // N2 is exported
namespace N3 { export int n; }  // N3 is exported
—end example]
```

There is a global namespace with no declaration; see 6.4.5. The global namespace belongs to the global scope; it is not an unnamed namespace (9.8.2.2).

[Note 2: Lacking a declaration, it cannot be found by name lookup. — end note]

9.8.2 Namespace definition

9.8.2.1 General

Every namespace-definition shall inhabit a namespace scope (6.4.5).

In a named-name-definition $D$, the identifier is the name of the namespace. The identifier is looked up by searching for it in the scopes of the namespace $A$ in which $D$ appears and of every element of the inline namespace set of $A$. If the lookup finds a namespace-definition for a namespace $N$, $D$ extends $N$, and the target scope of $D$ is the scope to which $N$ belongs. If the lookup finds nothing, the identifier is introduced as a namespace-name into $A$.

Because a namespace-definition contains declarations in its namespace-body and a namespace-definition is itself a declaration, it follows that namespace-definitions can be nested.

Example 1:

```c
namespace Outer {
  int i;
```

§ 9.8.2.1
4 If the optional initial `inline` keyword appears in a `namespace-definition` for a particular namespace, that namespace is declared to be an `inline namespace`. The `inline` keyword may be used on a `namespace-definition` that extends a namespace only if it was previously used on the `namespace-definition` that initially declared the `namespace-name` for that namespace.

5 The optional `attribute-specifier-seq` in a `named-namespace-definition` app pertains to the namespace being defined or extended.

6 Members of an inline namespace can be used in most respects as though they were members of the enclosing namespace. Specifically, the inline namespace and its enclosing namespace are both added to the set of associated namespaces used in argument-dependent lookup (6.5.4) whenever one of them is, and a `using-directive` (9.8.4) that names the inline namespace is implicitly inserted into the enclosing namespace as for an unnamed namespace (9.8.2.2). Furthermore, each member of the inline namespace can subsequently be partially specialized (13.7.6), explicitly instantiated (13.9.3), or explicitly specialized (13.9.4) as though it were a member of the enclosing namespace. Finally, looking up a name in the enclosing namespace via explicit qualification (6.5.5.3) will include members of the inline namespace even if there are declarations of that name in the enclosing namespace.

7 These properties are transitive: if a namespace N contains an inline namespace M, which in turn contains an inline namespace O, then the members of O can be used as though they were members of M or N. The `inline namespace set` of N is the transitive closure of all inline namespaces in N.

8 A `nested-namespace-definition` with an `enclosing-namespace-specifier` E, `identifier` I and `namespace-body` B is equivalent to

```
namespace E { inline_opt namespace I { B } }
```

where the optional `inline` appears if and only if it appears in the `unnamed-namespace-definition` and all occurrences of `unique` in a translation unit are replaced by the same identifier, and this identifier differs from all other identifiers in the translation unit. The optional `attribute-specifier-seq` in the `unnamed-namespace-definition` app pertains to `unique`.

[Example 2:]

```
namespace { int i; } // unique::i
void f() { i++; } // unique::i++
```

9.8.2.2 Unnamed namespaces

1 An `unnamed-namespace-definition` behaves as if it were replaced by

```
inline_opt namespace unique { /* empty body */ }
```

```
using namespace unique;
```

```
namespace unique { namespace-body }
```

where `inline` appears if and only if it appears in the `unnamed-namespace-definition` and all occurrences of `unique` in a translation unit are replaced by the same identifier, and this identifier differs from all other identifiers in the translation unit. The optional `attribute-specifier-seq` in the `unnamed-namespace-definition` app pertains to `unique`.

[Example 1:]

```
namespace { int i; } // unique::i
void f() { i++; } // unique::i++
```
namespace A {
    namespace {
        int i;  // A::unique::i
        int j;  // A::unique::j
    }
    void g() { i++; }  // A::unique::i++
}

using namespace A;
void h() {
    i++;  // A::unique::i
    A::i++;  // error: unique::i or A::unique::i
    j++;  // A::unique::j
}
—end example]

9.8.3 Namespace alias

A namespace-alias-definition declares an alternate name for a namespace according to the following grammar:

namespace-alias-definition:
    identifier  

qualified-name-specifier:
    namespace-identifier = qualified-name-specifier ;

namespace-identifier:
    nested-name-specifier opt namespace-name

The identifier in a namespace-alias-definition becomes a namespace-alias and denotes the namespace denoted by the qualified-name-specifier.

[Note 1: When looking up a namespace-name in a namespace-alias-definition, only namespace names are considered, see 6.5.7. — end note]

9.8.4 Using namespace directive

A using-directive shall not appear in class scope, but may appear in namespace scope or in block scope.

[Note 1: When looking up a namespace-name in a using-directive, only namespace names are considered, see 6.5.7. — end note]

The optional attribute-specifier-seq opt appertains to the using-directive.

[Note 2: A using-directive makes the names in the nominated namespace usable in the scope in which the using-directive appears after the using-directive (6.5.3, 6.5.5.3). During unqualified name lookup, the names appear as if they were declared in the nearest enclosing namespace which contains both the using-directive and the nominated namespace. — end note]

[Note 3: A using-directive does not introduce any names. — end note]

[Example 1:]

namespace A {
    int i;
    namespace B {
        namespace C {
            int i;
        }
        using namespace A::B::C;
        void f1() {
            i = 5;  // OK, C::i visible in B and hides A::i
        }
    }
    namespace D {
        using namespace B;
        using namespace C;
        void f2() {
            i = 5;  // ambiguous, B::C::i or A::i?
```cpp
void f3() {
  i = 5;   // uses A::i
}
void f4() {
  i = 5;   // error: neither i is visible
}
```

---end example---

4 [Note 4: A using-directive is transitive: if a scope contains a using-directive that nominates a namespace that itself contains using-directives, the namespaces nominated by those using-directives are also eligible to be considered. — end note]

[Example 2:]
```cpp
namespace M {
  int i;
}
namespace N {
  int i;
  using namespace M;
}
void f() {
  using namespace N;
  i = 7;   // error: both M::i and N::i are visible
}
```

For another example,
```cpp
namespace A {
  int i;
}
namespace B {
  int i;
  int j;
}
namespace C {
  namespace D {
    using namespace A;
    int j;
    int k;
    int a = i;   // B::i hides A::i
  }
  using namespace D;
  int k = 89;   // no problem yet
  int l = k;   // ambiguous: C::k or D::k
  int m = i;   // B::i hides A::i
  int n = j;   // D::j hides B::j
}
```

---end example---

5 [Note 5: Declarations in a namespace that appear after a using-directive for that namespace can be found through that using-directive after they appear. — end note]

6 [Note 6: If name lookup finds a declaration for a name in two different namespaces, and the declarations do not declare the same entity and do not declare functions or function templates, the use of the name is ill-formed (6.5). In particular, the name of a variable, function or enumerator does not hide the name of a class or enumeration declared in a different namespace. For example,

```cpp
namespace A {
  class X { };extern "C" int g();extern "C++" int h();
```
namespace B {
    void X(int);
    extern "C" int g();
    extern "C++" int h(int);
}
using namespace A;
using namespace B;

void f() {
    X(1); // error: name X found in two namespaces
    g(); // OK: name g refers to the same entity
    h(); // OK: overload resolution selects A::h
}

— end note }

[Note 7: The order in which namespaces are considered and the relationships among the namespaces implied by the using-directives do not affect overload resolution. Neither is any function excluded because another has the same signature, even if one is in a namespace reachable through using-directives in the namespace of the other.92 — end note]

[Example 3:]
namespace D {
    int d1;
    void f(char);
}
using namespace D;
int d1; // OK: no conflict with D::d1

namespace E {
    int e;
    void f(int);
}

namespace D { // namespace extension
    int d2;
    using namespace E;
    void f(int);
}

void f() {
    d1++;
    ::d1++; // error: ambiguous ::d1 or D::d1?
    ::d1++;
    D::d1++; // OK
    d2++;
    // OK: D::d2
e++;
    // OK: E::e
    f(1);
    // error: ambiguous: D::f(int) or E::f(int)?
    f('a'); // OK: D::f(char)
}
— end example]

## 9.9 The using declaration

```
using-declaration:
    using using-declarator-list ;
using-declarator-list:
    using-declarator 
    using-declarator-list , using-declarator 

using-declarator:
    typename opt nested-name-specifier unqualified-id
```

92) During name lookup in a class hierarchy, some ambiguities can be resolved by considering whether one member hides the other along some paths (6.5.2). There is no such disambiguation when considering the set of names found as a result of following using-directives.

§ 9.9
The component names of a using-declarator are those of its nested-name-specifier and unqualified-id. Each using-declarator in a using-declaration\(^{93}\) names the set of declarations found by lookup (6.5.5) for the using-declarator, except that class and enumeration declarations that would be discarded are merely ignored when checking for ambiguity (6.5), conversion function templates with a dependent return type are ignored, and certain functions are hidden as described below. If the terminal name of the using-declarator is dependent (13.8.3.2), the using-declarator is considered to name a constructor if and only if the nested-name-specifier has a terminal name that is the same as the unqualified-id. If the lookup in any instantiation finds that a using-declarator that is not considered to name a constructor does do so, or that a using-declarator that is considered to name a constructor does not, the program is ill-formed.

If the using-declarator names a constructor, it declares that the class inherits the named set of constructor declarations from the nominated base class.

[Note 1: Otherwise, the unqualified-id in the using-declarator is bound to the using-declarator, which is replaced during name lookup with the declarations it names (6.5). If such a declaration is of an enumeration, the names of its enumerators are not bound. For the keyword typename, see 13.8. end note]

In a using-declaration used as a member-declaration, each using-declarator shall either name an enumerator or have a nested-name-specifier naming a base class of the current class (7.5.2).

[Example 1:

```c
enum class button { up, down };
struct S {
    using button::up;
    button b = up; // OK
};

—end example]
```

If a using-declarator names a constructor, its nested-name-specifier shall name a direct base class of the current class. If the immediate (class) scope is associated with a class template, it shall derive from the specified base class or have at least one dependent base class.

[Example 2:

```c
struct B {
    void f(char);
    enum E { e };
    union { int x; };
};

struct C {
    int f();
};

struct D : B {
    using B::f; // OK: B is a base of D
    using B::e; // OK: e is an enumerator of base B
    using B::x; // OK: x is a union member of base B
    void f(int) { f('c'); } // calls B::f(char)
    void g(int) { g('c'); } // recursively calls D::g(int)
};

template <typename... bases>
struct X : bases... {
    using bases::f...;
};

X<B, C> x; // OK: B::f and C::f named

—end example]
```

[Note 2: Since destructors do not have names, a using-declaration cannot refer to a destructor for a base class. end note]

If a constructor or assignment operator brought from a base class into a derived class has the signature of a copy/move constructor or assignment operator for the derived class (11.4.5.3, 11.4.6), the using-declaration

\(^{93}\) A using-declaration with more than one using-declarator is equivalent to a corresponding sequence of using-declarations with one using-declarator each.
does not by itself suppress the implicit declaration of the derived class member; the member from the base class is hidden or overridden by the implicitly-declared copy/move constructor or assignment operator of the derived class, as described below.

5 A using-declaration shall not name a template-id.

[Example 3:

```cpp
struct A {
    template <class T> void f(T);
    template <class T> struct X { }; // error
};
struct B : A {
    using A::f<double>; // error
    using A::X<int>; // error
};

—end example]
```

6 A using-declaration shall not name a namespace.

7 A using-declaration that names a class member other than an enumerator shall be a member-declaration.

[Example 4:

```cpp
struct X {
    int i;
    static int s;
};

void f() {
    using X::i; // error: X::i is a class member and this is not a member declaration.
    using X::s; // error: X::s is a class member and this is not a member declaration.
}

—end example]
```

8 If a declaration is named by two using-declarators that inhabit the same class scope, the program is ill-formed.

9 [Note 3: A using-declarator whose nested-name-specifier names a namespace does not name declarations added to the namespace after it. Thus, additional overloads added after the using-declaration are ignored, but default function arguments (9.3.4.7), default template arguments (13.2), and template specializations (13.7.6, 13.9.4) are considered. —end note]

[Example 5:

```cpp
namespace A {
    void f(int);
}

using A::f; // f is a synonym for A::f; that is, for A::f(int).
namespace A {
    void f(char);
}

void foo() {
    f('a'); // calls f(int), even though f(char) exists.
}

void bar() {
    using A::f; // f is a synonym for A::f; that is, for A::f(int) and A::f(char).
    f('a'); // calls f(char)
}

—end example]
```

10 If a declaration named by a using-declaration that inhabits the target scope of another declaration potentially conflicts with it (6.4.1), and either is reachable from the other, the program is ill-formed. If two declarations named by using-declarations that inhabit the same scope potentially conflict, either is reachable from the other, and they do not both declare functions or function templates, the program is ill-formed.

[Note 4: Overload resolution possibly cannot distinguish between conflicting function declarations. —end note]
Example 6:

```cpp
namespace A {
  int x;
  int f(int);
  int g;
  void h();
}

namespace B {
  int i;
  struct g {};
  struct x {};
  void f(int);
  void f(double);
  void g(char);
  // OK: hides struct g
}

void func() {
  int i;
  using B::i; // error: conflicts
  void f(char);
  using B::f; // OK: f is a function
  using A::f;
  f(i);
  // error: ambiguous
  static_cast<int(*)>(f)(i); // OK: calls A::f
  f(3.5); // calls B::f(double)
  using B::g;
  g('a'); // calls B::g(char)
  struct g g1; // g1 has class type B::g
  using A::g;
  // error: conflicts with B::g
  void h();
  using A::h;
  using B::x;
  using A::x;
  // OK: hides struct B::x
  x = 99; // assigns to A::x
  struct x x1; // x1 has class type B::x
}

—end example
```

The set of declarations named by a using-declarator that inhabits a class C does not include member functions and member function templates of a base class that correspond to (and thus would conflict with) a declaration of a function or function template in C.

Example 7:

```cpp
struct B {
  virtual void f(int);
  virtual void f(char);
  void g(int);
  void h(int);
};

struct D : B {
  using B::f;
  void f(int); // OK: D::f(int) overrides B::f(int);
  using B::g;
  void g(char); // OK
  using B::h;
  void h(int); // OK: D::h(int) hides B::h(int)
};
```

§ 9.9
void k(D* p)
{
    p->f(1); // calls D::f(int)
    p->f('a'); // calls B::f(char)
    p->g(1); // calls B::g(int)
    p->g('a'); // calls D::g(char)
}

struct B1 {
    B1(int);
};

struct B2 {
    B2(int);
};

struct D1 : B1, B2 {
    using B1::B1;
    using B2::B2;
};
D1 d1(0); // error: ambiguous

struct D2 : B1, B2 {
    using B1::B1;
    using B2::B2;
    D2(int); // OK: D2::D2(int) hides B1::B1(int) and B2::B2(int)
};
D2 d2(0); // calls D2::D2(int)

— end example]

12 [Note 5: For the purpose of forming a set of candidates during overload resolution, the functions named by a using-declaration in a derived class are treated as though they were direct members of the derived class. In particular, the implicit object parameter is treated as if it were a reference to the derived class rather than to the base class (12.2.2). This has no effect on the type of the function, and in all other respects the function remains part of the base class. — end note]

13 Constructors that are named by a using-declaration are treated as though they were constructors of the derived class when looking up the constructors of the derived class (6.5.5.2) or forming a set of overload candidates (12.2.2.4, 12.2.2.5, 12.2.2.8).

[Note 6: If such a constructor is selected to perform the initialization of an object of class type, all subobjects other than the base class from which the constructor originated are implicitly initialized (11.9.4). A constructor of a derived class is sometimes preferred to a constructor of a base class if they would otherwise be ambiguous (12.2.4). — end note]

14 In a using-declarator that does not name a constructor, every declaration named shall be accessible. In a using-declarator that names a constructor, no access check is performed.

15 [Note 7: Because a using-declarator designates a base class member (and not a member subobject or a member function of a base class subobject), a using-declarator cannot be used to resolve inherited member ambiguities.

[Example 8:

struct A { int x(); };  
struct B : A {};  
struct C : A {
    using A::x;
    int x(int);
};  

struct D : B, C {
    using C::x;
    int x(double);
};  

int f(D* d) {
    return d->x(); // error: overload resolution selects A::x, but A is an ambiguous base class
}  

§ 9.9 231
A *using-declaration* has the usual accessibility for a *member-declaration*. Base-class constructors considered because of a *using-declarator* are accessible if they would be accessible when used to construct an object of the base class; the accessibility of the *using-declaration* is ignored.

**Example 9:**
```cpp
class A {
    private:
        void f(char);
    public:
        void f(int);
    protected:
        void g();
};

class B : public A {
    using A::f; // error: A::f(char) is inaccessible
    public:
        using A::g; // B::g is a public synonym for A::g
};
```

---

**9.10 The *asm* declaration**

An *asm* declaration has the form

```
asm-declaration:
    attribute-specifier-seq_opt asm (string-literal) ;
```

The *asm* declaration is conditionally-supported; its meaning is implementation-defined. The optional *attribute-specifier-seq* in an *asm-declaration* appertains to the *asm* declaration.

*Note 1:* Typically it is used to pass information through the implementation to an assembler. — end note

**9.11 Linkage specifications**

All functions and variables whose names have external linkage and all function types have a *language linkage*.

*Note 1:* Some of the properties associated with an entity with language linkage are specific to each implementation and are not described here. For example, a particular language linkage might be associated with a particular form of representing names of objects and functions with external linkage, or with a particular calling convention, etc. — end note

The default language linkage of all function types, functions, and variables is C++ language linkage. Two function types with different language linkages are distinct types even if they are otherwise identical.

**Linkage (6.6)** between C++ and non-C++ code fragments can be achieved using a *linkage-specification*:

```
linkage-specification:
    extern string-literal { declaration-seq_opt }
```

The *string-literal* indicates the required language linkage. This document specifies the semantics for the *string-literals* "C" and "C++". Use of a *string-literal* other than "C" or "C++" is conditionally-supported, with implementation-defined semantics.

*Note 2:* Therefore, a linkage-specification with a *string-literal* that is unknown to the implementation requires a diagnostic. — end note

*Note 3:* It is recommended that the spelling of the *string-literal* be taken from the document defining that language. For example, Ada (not ADA) and Fortran or FORTRAN, depending on the vintage. — end note

Every implementation shall provide for linkage to the C programming language, "C", and C++, "C++".

**Example 1:**
```cpp
complex sqrt(complex); // C++ language linkage by default
extern "C" {
    double sqrt(double); // C language linkage
}
```
A module-import-declaration shall not be directly contained in a linkage-specification. A module-import-declaration appearing in a linkage specification with other than C++ language linkage is conditionally-supported with implementation-defined semantics.

Linkage specifications nest. When linkage specifications nest, the innermost one determines the language linkage.

[Note 4: A linkage specification does not establish a scope. — end note]

A linkage-specification shall inhabit a namespace scope. In a linkage-specification, the specified language linkage applies to the function types of all function declarators and to all functions and variables.

Example 2:

```c
extern "C"
    // f1 and its function type have C language linkage;
    void f1(void(*pf)(int));  // pf is a pointer to a C function

extern "C" typedef void FUNC();
FUNC f2;
    // f2 has C++ language linkage and
    // its type has C language linkage

extern "C" FUNC f3;
    // f3 and its type have C language linkage

void (*pf2)(FUNC*);
    // the variable pf2 has C++ language linkage; its type
    // is “pointer to C++ function that takes one parameter of type
    // pointer to C function”

extern "C" {
    static void f4();
        // the name of the function f4 has internal linkage,
        // so f4 has no language linkage; its type has C language linkage
}

extern "C" void f5() {
    extern void f4();  // OK: Name linkage (internal) and function type linkage (C language linkage)
        // obtained from previous declaration.
}

extern void f4();  // OK: Name linkage (internal) and function type linkage (C language linkage)

void f6() {
    extern void f4();  // OK: Name linkage (internal) and function type linkage (C language linkage)
        // obtained from previous declaration.
}

--- end example ---
```

A C language linkage is ignored in determining the language linkage of class members, friend functions with a trailing requires-clause, and the function type of class member functions.

Example 3:

```c
extern "C" typedef void FUNC_c();

class C {
    void mf1(FUNC_c*);
        // the function mf1 and its type have C++ language linkage;
        // the parameter has type “pointer to C function”
    FUNC_c mf2;
        // the function mf2 and its type have C++ language linkage
    static FUNC_c* q;
        // the data member q has C++ language linkage;
        // its type is “pointer to C function”
};

extern "C" {
    class X {
        void mf();
            // the function mf and its type have C++ language linkage
        void mf2(void(*)(void*));  // the function mf2 has C++ language linkage;
    }
}
```
If two declarations of an entity give it different language linkages, the program is ill-formed; no diagnostic is required if neither declaration is reachable from the other. A redeclaration of an entity without a linkage specification inherits the language linkage of the entity and (if applicable) its type.

Two declarations declare the same entity if they (re)introduce the same name, one declares a function or variable with C language linkage, and the other declares such an entity or declares a variable that belongs to the global scope.

Example 4:

```c
int x;
namespace A {
    extern "C" int f();
    extern "C" int g() { return 1; }
    extern "C" int h();
    extern "C" int x(); // error: same name as global-space object x
}
namespace B {
    extern "C" int f(); // A::f and B::f refer to the same function
    extern "C" int g() { return 1; } // error: the function g with C language linkage has two definitions
}
int A::f() { return 98; } // definition for the function f with C language linkage
extern "C" int h() { return 97; } // definition for the function h with C language linkage
// A::h and ::h refer to the same function
```

A declaration directly contained in a linkage-specification is treated as if it contains the `extern` specifier (9.2.2) for the purpose of determining the linkage of the declared name and whether it is a definition. Such a declaration shall not specify a storage class.

Example 5:

```c
extern "C" double f();
static double f(); // error
extern "C" int i; // declaration
extern "C" {
    int i;
    // definition
}
extern "C" static void g(); // error
```

Because the language linkage is part of a function type, when indirection through a pointer to C function, the function to which the resulting lvalue refers is considered a C function. — end note]

Linkage from C++ to objects defined in other languages and to objects defined in C++ from other languages is implementation-defined and language-dependent. Only where the object layout strategies of two language implementations are similar enough can such linkage be achieved.

9.12 Attributes [dcl.attr]

9.12.1 Attribute syntax and semantics [dcl.attr.grammar]

Attributes specify additional information for various source constructs such as types, variables, names, blocks, or translation units.

```c
attribute-specifier-seq:
    attribute-specifier-seq_opt attribute-specifier
attribute-specifier:
    [ [ attribute-using-prefix_opt attribute-list ] ]
    alignment-specifier
```

§ 9.12.1
alignment-specifier:
  alignas ( type-id ...opt )
  alignas ( constant-expression ...opt )

attribute-using-prefix:
  using attribute-namespaces

attribute-list:
  attribute_opt
  attribute-list , attribute_opt
  attribute ...
  attribute-list , attribute ...

attribute:
  attribute-token attribute-argument-clause_opt

attribute-token:
  identifier
  attribute-scoped-token

attribute-scoped-token:
  attribute-namespaces :: identifier

attribute-namespaces:
  identifier

attribute-argument-clause:
  ( balanced-token-seq_opt )

balanced-token-seq:
  balanced-token
  balanced-token-seq balanced-token

balanced-token:
  ( balanced-token-seq_opt )
  [ balanced-token-seq_opt ]
  { balanced-token-seq_opt }
any token other than a parenthesis, a bracket, or a brace

2 If an attribute-specifier contains an attribute-using-prefix, the attribute-list following that attribute-using-prefix shall not contain an attribute-scoped-token and every attribute-token in that attribute-list is treated as if its identifier were prefixed with N::, where N is the attribute-namespaces specified in the attribute-using-prefix.

[Note 1: This rule imposes no constraints on how an attribute-using-prefix affects the tokens in an attribute-argument-clause. —end note]

[Example 1:

```
[[using CC: opt(1), debug]] // same as [[CC::opt(1), CC::debug]]
void f() {}  
[[using CC: opt(1)]] [[CC::debug]] // same as [[CC::opt(1)]] [[CC::debug]]
void g() {}  
[[using CC: CC::opt(1)]] // error: cannot combine using and scoped attribute token
void h() {}  
```

—end example]

3 [Note 2: For each individual attribute, the form of the balanced-token-seq will be specified. —end note]

4 In an attribute-list, an ellipsis may appear only if that attribute’s specification permits it. An attribute followed by an ellipsis is a pack expansion (13.7.4). An attribute-specifier that contains no attributes has no effect. The order in which the attribute-tokens appear in an attribute-list is not significant. If a keyword (5.11) or an alternative token (5.5) that satisfies the syntactic requirements of an identifier (5.10) is contained in an attribute-token, it is considered an identifier. No name lookup (6.5) is performed on any of the identifiers contained in an attribute-token. The attribute-token determines additional requirements on the attribute-argument-clause (if any).

5 Each attribute-specifier-seq is said to appertain to some entity or statement, identified by the syntactic context where it appears (Clause 8, Clause 9, 9.3). If an attribute-specifier-seq that appertains to some entity or statement contains an attribute or alignment-specifier that is not allowed to apply to that entity or statement, the program is ill-formed. If an attribute-specifier-seq appertains to a friend declaration (11.8.4), that declaration shall be a definition.
Note 3: An attribute-specifier-seq cannot appear to an explicit instantiation (13.9.3). — end note

For an attribute-token (including an attribute-scoped-token) not specified in this document, the behavior is implementation-defined. Any attribute-token that is not recognized by the implementation is ignored. An attribute-token is reserved for future standardization if

(6.1) — it is not an attribute-scoped-token and is not specified in this document, or
(6.2) — it is an attribute-scoped-token and its attribute-namespace is std followed by zero or more digits.

Each implementation should choose a distinctive name for the attribute-namespace in an attribute-scoped-token.

Two consecutive left square bracket tokens shall appear only when introducing an attribute-specifier or within the balanced-token-seq of an attribute-argument-clause.

Note 4: If two consecutive left square brackets appear where an attribute-specifier is not allowed, the program is ill-formed even if the brackets match an alternative grammar production. — end note

Example 2:

```c
int p[10];
void f() {
    int x = 42, y[5];
    int(p[x]) { return x; }(); // error: invalid attribute on a nested declarator-id and
    y[] { return 2; }(); = 2; // error even though attributes are not allowed in this context.
    int i [{vendor::attr([])}]; // well-formed implementation-defined attribute.
}
```
—end example

9.12.2 Alignment specifier

An alignmentSpecifier may be applied to a variable or to a class data member, but it shall not be applied to a bit-field, a function parameter, or an exception-declaration (14.4). An alignmentSpecifier may also be applied to the declaration of a class (in an elaborated-typeSpecifier (9.2.9.4) or class-head (Clause 11), respectively). An alignmentSpecifier with an ellipsis is a pack expansion (13.7.4).

When the alignmentSpecifier is of the form alignas(constant-expression):

(2.1) — the constant-expression shall be an integral constant expression
(2.2) — if the constant expression does not evaluate to an alignment value (6.7.6), or evaluates to an extended alignment and the implementation does not support that alignment in the context of the declaration, the program is ill-formed.

An alignmentSpecifier of the form alignas(type-id) has the same effect as alignas(alignof(type-id)) (7.6.2.6).

The alignment requirement of an entity is the strictest nonzero alignment specified by its alignmentSpecifiers, if any; otherwise, the alignmentSpecifiers have no effect.

The combined effect of all alignmentSpecifiers in a declaration shall not specify an alignment that is less strict than the alignment that would be required for the entity being declared if all alignmentSpecifiers appertaining to that entity were omitted.

Example 1:

```c
struct alignas(8) S {};
struct alignas(1) U {
    S s;
}; // error: U specifies an alignment that is less strict than if the alignas(1) were omitted.
```
—end example

If the defining declaration of an entity has an alignmentSpecifier, any non-defining declaration of that entity shall either specify equivalent alignment or have no alignmentSpecifier. Conversely, if any declaration of an entity has an alignmentSpecifier, every defining declaration of that entity shall specify an equivalent alignment. No diagnostic is required if declarations of an entity have different alignmentSpecifiers in different translation units.

Example 2:

```c
// Translation unit #1:
struct S { int x; } s, *p = &s;
```
// Translation unit #2:
struct alignas(16) S; // ill-formed, no diagnostic required: definition of S lacks alignment
extern S* p;
— end example]

[Example 3: An aligned buffer with an alignment requirement of A and holding N elements of type T can be declared as:
alignas(T) alignas(A) T buffer[N];
Specifying alignas(T) ensures that the final requested alignment will not be weaker than alignof(T), and therefore the program will not be ill-formed. — end example]

alignas(double) void f(); // error: alignment applied to function
alignas(double) unsigned char c[sizeof(double)]; // array of characters, suitably aligned for a double
extern unsigned char c[sizeof(double)]; // no alignas necessary
alignas(float)
extern unsigned char c[sizeof(double)]; // error: different alignment in declaration
— end example]

9.12.3 Carries dependency attribute [dcl.attr.depend]
The attribute-token carries_dependency specifies dependency propagation into and out of functions. It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute may be applied to the declarator-id of a parameter-declaration in a function declaration or lambda, in which case it specifies that the initialization of the parameter carries a dependency to (6.9.2) each lvalue-to-rvalue conversion (7.3.2) of that object. The attribute may also be applied to the declarator-id of a function declaration, in which case it specifies that the return value, if any, carries a dependency to the evaluation of the function call expression.

The first declaration of a function shall specify the carries_dependency attribute for its declarator-id if any declaration of the function specifies the carries_dependency attribute. Furthermore, the first declaration of a function shall specify the carries_dependency attribute for a parameter if any declaration of that function specifies the carries_dependency attribute for that parameter. If a function or one of its parameters is declared with the carries_dependency attribute in its first declaration in one translation unit and the same function or one of its parameters is declared without the carries_dependency attribute in its first declaration in another translation unit, the program is ill-formed, no diagnostic required.

[Note 1: The carries_dependency attribute does not change the meaning of the program, but might result in generation of more efficient code. — end note]

[Example 1:
/* Translation unit A. */
struct foo { int* a; int* b; };  
std::atomic<struct foo *> foo_head[10];
int foo_array[10][10];
[[carries_dependency]] struct foo* f(int i) {
  return foo_head[i].load(memory_order::consume);
}
int g(int* x, int* y [[carries_dependency]]) {
  return kill_dependency(foo_array[*x][*y]);
}
/* Translation unit B. */
[[carries_dependency]] struct foo* f(int i);
int g(int* x, int* y [[carries_dependency]]);
int c = 3;
void h(int i) {
  struct foo* p;
p = f(i);
    do_something_with(g(&c, p->a));
    do_something_with(g(p->a, &c));
}

The carries_dependency attribute on function f means that the return value carries a dependency out of f, so that the implementation need not constrain ordering upon return from f. Implementations of f and its caller may choose to preserve dependencies instead of emitting hardware memory ordering instructions (a.k.a. fences). Function g’s second parameter has a carries_dependency attribute, but its first parameter does not. Therefore, function h’s first call to g carries a dependency into g, but its second call does not. The implementation might need to insert a fence prior to the second call to g. — end example]

9.12.4 Deprecated attribute [dcl.attr.deprecated]

The attribute-token deprecated can be used to mark names and entities whose use is still allowed, but is discouraged for some reason.

[Note 1: In particular, deprecated is appropriate for names and entities that are deemed obsolescent or unsafe. — end note]

It shall appear at most once in each attribute-list. An attribute-argument-clause may be present and, if present, it shall have the form:

( string-literal )

[Note 2: The string-literal in the attribute-argument-clause can be used to explain the rationale for deprecation and/or to suggest a replacing entity. — end note]

The attribute may be applied to the declaration of a class, a typedef-name, a variable, a non-static data member, a function, a namespace, an enumeration, an enumerator, or a template specialization.

An entity declared without the deprecated attribute can later be redeclared with the attribute and vice-versa.

[Note 3: Thus, an entity initially declared without the attribute can be marked as deprecated by a subsequent redeclaration. However, after an entity is marked as deprecated, later redeclarations do not un-deprecate the entity. — end note]

Redeclarations using different forms of the attribute (with or without the attribute-argument-clause or with different attribute-argument-clauses) are allowed.

Recommended practice: Implementations should use the deprecated attribute to produce a diagnostic message in case the program refers to a name or entity other than to declare it, after a declaration that specifies the attribute. The diagnostic message should include the text provided within the attribute-argument-clause of any deprecated attribute applied to the name or entity.

9.12.5 Fallthrough attribute [dcl.attr.fallthrough]

The attribute-token fallthrough may be applied to a null statement (8.3); such a statement is a fallthrough statement. The attribute-token fallthrough shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. A fallthrough statement may only appear within an enclosing switch statement (8.5.3). The next statement that would be executed after a fallthrough statement shall be a labeled statement whose label is a case label or default label for the same switch statement and, if the fallthrough statement is contained in an iteration statement, the next statement shall be part of the same execution of the substatement of the innermost enclosing iteration statement. The program is ill-formed if there is no such statement.

Recommended practice: The use of a fallthrough statement should suppress a warning that an implementation might otherwise issue for a case or default label that is reachable from another case or default label along some path of execution. Implementations should issue a warning if a fallthrough statement is not dynamically reachable.

[Example 1:

    void f(int n) {
        void g(), h(), i();
        switch (n) {
            case 1:
            case 2:
                g();
        }}}}
case 3: // warning on fallthrough discouraged
    do {
        // error: next statement is not part of the same substatement execution
        [[fallthrough]];
    } while (false);
case 6:
    do {
        // error: next statement is not part of the same substatement execution
        [[fallthrough]];
    } while (n--);
case 7:
    while (false) {
        // error: next statement is not part of the same substatement execution
        [[fallthrough]];
    }
case 5:
    h();
case 4: // implementation may warn on fallthrough
    i();
        // error
    [[fallthrough]];
}
—end example

9.12.6 Likelihood attributes [dcl.attr.likelihood]

1 The attribute-tokens likely and unlikely may be applied to labels or statements. The attribute-tokens likely and unlikely shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute-token likely shall not appear in an attribute-specifier-seq that contains the attribute-token unlikely.

2 Recommended practice: The use of the likely attribute is intended to allow implementations to optimize for the case where paths of execution including it are arbitrarily more likely than any alternative path of execution that does not include such an attribute on a statement or label. The use of the unlikely attribute is intended to allow implementations to optimize for the case where paths of execution including it are arbitrarily more unlikely than any alternative path of execution that does not include such an attribute on a statement or label. A path of execution includes a label if and only if it contains a jump to that label.

[Note 1: Excessive usage of either of these attributes is liable to result in performance degradation. —end note]

3 [Example 1:]

    void g(int);
    int f(int n) {
        if (n > 5) [[unlikely]] { // n > 5 is considered to be arbitrarily unlikely
            g(0);
            return n * 2 + 1;
        }

        switch (n) {
        case 1: g(1); // n == 2 is considered to be arbitrarily more
            [[fallthrough]]; // likely than any other value of n
        [[likely]] case 2:
            g(2);
            break;
        }
        return 3;
    }
—end example

9.12.7 Maybe unused attribute [dcl.attr.unused]

1 The attribute-token maybe_unused indicates that a name or entity is possibly intentionally unused. It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present.

2 The attribute may be applied to the declaration of a class, a typedef-name, a variable (including a structured binding declaration), a non-static data member, a function, an enumeration, or an enumerator.
A name or entity declared without the `maybe_unused` attribute can later be redeclared with the attribute and vice versa. An entity is considered marked after the first declaration that marks it.

**Recommended practice:** For an entity marked `maybe_unused`, implementations should not emit a warning that the entity or its structured bindings (if any) are used or unused. For a structured binding declaration not marked `maybe_unused`, implementations should not emit such a warning unless all of its structured bindings are unused.

**Example 1:**
```c
[[maybe_unused]] void f([[maybe_unused]] bool thing1,
   [[maybe_unused]] bool thing2) {
   [[maybe_unused]] bool b = thing1 && thing2;
   assert(b);
}
```
Implementations should not warn that `b` is unused, whether or not `NDEBUG` is defined. — end example

### 9.12.8 Nodiscard attribute

The attribute-token `nodiscard` may be applied to the declarator-id in a function declaration or to the declaration of a class or enumeration. It shall appear at most once in each attribute-list. An attribute-argument-clause may be present and, if present, shall have the form:

```c
  ( string-literal )
```

A name or entity declared without the `nodiscard` attribute can later be redeclared with the attribute and vice-versa.

**Note 1:** Thus, an entity initially declared without the attribute can be marked as `nodiscard` by a subsequent redeclaration. However, after an entity is marked as `nodiscard`, later redeclarations do not remove the `nodiscard` from the entity. — end note

Redeclarations using different forms of the attribute (with or without the attribute-argument-clause or with different attribute-argument-clauses) are allowed.

A **nodocard type** is a (possibly cv-qualified) class or enumeration type marked `nodocard` in a reachable declaration. A **nodocard call** is either

1. A function call expression (7.6.1.3) that calls a function declared `nodocard` in a reachable declaration or whose return type is a nodiscard type, or
2. An explicit type conversion (7.6.1.4, 7.6.1.9, 7.6.3) that constructs an object through a constructor declared `nodocard` in a reachable declaration, or that initializes an object of a nodiscard type.

**Recommended practice:** Appearance of a nodiscard call as a potentially-evaluated discarded-value expression (7.2) is discouraged unless explicitly cast to `void`. Implementations should issue a warning in such cases.

**Note 2:** This is typically because discarding the return value of a nodiscard call has surprising consequences. — end note

The `string-literal` in a `nodocard` attribute-argument-clause should be used in the message of the warning as the rationale for why the result should not be discarded.

**Example 1:**
```c
struct [[nodiscard]] my_scopeguard { /* ... */ };   // does not acquire resource
struct my_unique {
  my_unique() = default;
  [[nodiscard]] my_unique(int fd) { /* ... */ }   // acquires resource
  ~my_unique() noexcept { /* ... */ }            // releases resource, if any
};
struct [[nodiscard]] error_info { /* ... */ };   // warning encouraged
error_info enable_missile_safety_mode();   // warning not encouraged, cast to void
void launch_missiles();   // warning encouraged
void test_missiles() {
  my_scopeguard();   // warning not encouraged, comma operator, statement continues
  void)my_scopeguard(),
  launch_missiles();   // warning encouraged
  my_unique(42);
  my_unique();   // warning not encouraged
```
9.12.9 Noreturn attribute

The attribute-token **noreturn** specifies that a function does not return. It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute may be applied to the declarator-id in a function declaration. The first declaration of a function shall specify the **noreturn** attribute if any declaration of that function specifies the **noreturn** attribute. If a function is declared with the **noreturn** attribute in one translation unit and the same function is declared without the **noreturn** attribute in another translation unit, the program is ill-formed, no diagnostic required.

1. If a function \( f \) is called where \( f \) was previously declared with the **noreturn** attribute and \( f \) eventually returns, the behavior is undefined.

2. **Recommended practice:** Implementations should issue a warning if a function marked [[noreturn]] might return.

   **Example 1:**
   ```cpp
   [[noreturn]] void f() {
     throw "error";
     // OK
   }
   
   [[noreturn]] void q(int i) {
     // behavior is undefined if called with an argument <= 0
     if (i > 0)
       throw "positive";
   }
   -- end example
   ```

9.12.10 No unique address attribute

The attribute-token **no_unique_address** specifies that a non-static data member is a potentially-overlapping subobject (6.7.2). It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute may appertain to a non-static data member other than a bit-field.

1. **Recommended practice:** The non-static data member can share the address of another non-static data member or that of a base class, and any padding that would normally be inserted at the end of the object can be reused as storage for other members.

   **Example 1:**
   ```cpp
   template<typename Key, typename Value,
            typename Hash, typename Pred, typename Allocator>
   class hash_map {
     [[no_unique_address]] Hash hasher;
     [[no_unique_address]] Pred pred;
     [[no_unique_address]] Allocator alloc;
     Bucket *buckets;
     // ...
   public:
     // ...
   }
   ```

   Here, hasher, pred, and alloc could have the same address as buckets if their respective types are all empty. **end example**
10 Modules

10.1 Module units and purviews

A module unit is a translation unit that contains a module-declaration. A named module is the collection of module units with the same module-name. The identifiers module and import shall not appear as identifiers in a module-name or module-partition. All module-names either beginning with an identifier consisting of std followed by zero or more digits or containing a reserved identifier (5.10) are reserved and shall not be specified in a module-declaration; no diagnostic is required. If any identifier in a reserved module-name is a reserved identifier, the module name is reserved for use by C++ implementations; otherwise it is reserved for future standardization. The optional attribute-specifier-seq appertains to the module-declaration.

A module interface unit is a module unit whose module-declaration starts with export-keyword; any other module unit is a module implementation unit. A named module shall contain exactly one module interface unit with no module-partition, known as the primary module interface unit of the module; no diagnostic is required.

A module partition is a module unit whose module-declaration contains a module-partition. A named module shall not contain multiple module partitions with the same module-partition. All module partitions of a module that are module interface units shall be directly or indirectly exported by the primary module interface unit (10.3). No diagnostic is required for a violation of these rules.

[Note 1: Module partitions can be imported only by other module units in the same module. The division of a module into module units is not visible outside the module. — end note]

[Example 1:]
Translation unit #1:
export module A;
export import :Foo;
export int baz();

Translation unit #2:
export module A:Foo;
import :Internals;
export int foo() { return 2 * (bar() + 1); }

Translation unit #3:
module A:Internals;
int bar();

Translation unit #4:
module A;
import :Internals;
int bar() { return baz() - 10; }
int baz() { return 30; }

Module A contains four translation units:

(4.1) — a primary module interface unit,
(4.2) — a module partition A:Foo, which is a module interface unit forming part of the interface of module A,
(4.3) — a module partition A:Internals, which does not contribute to the external interface of module A, and
— a module implementation unit providing a definition of \texttt{bar} and \texttt{baz}, which cannot be imported because it does not have a partition name.

— end example

5 A module unit purview is the sequence of tokens starting at the module-declaration and extending to the end of the translation unit. The purview of a named module \texttt{M} is the set of module unit purviews of \texttt{M}'s module units.

6 The global module is the collection of all global-module-fragments and all translation units that are not module units. Declarations appearing in such a context are said to be in the purview of the global module.

[Note 2: The global module has no name, no module interface unit, and is not introduced by any module-declaration. — end note]

7 A module is either a named module or the global module. A declaration is attached to a module as follows:

(7.1) If the declaration is a non-dependent friend declaration that nominates a function with a \texttt{declarator-id} that is a \texttt{qualified-id} or \texttt{template-id} or that nominates a class other than with an \texttt{elaborated-type-specifier} with neither a \texttt{nested-name-specifier} nor a \texttt{simple-template-id}, it is attached to the module to which the friend is attached (6.6).

(7.2) Otherwise, if the declaration

(7.2.1) is a replaceable global allocation or deallocation function (17.6.3.2, 17.6.3.3), or

(7.2.2) is a \texttt{namespace-definition} with external linkage, or

(7.2.3) appears within a \texttt{linkage-specification}, it is attached to the global module.

(7.3) Otherwise, the declaration is attached to the module in whose purview it appears.

8 A module-declaration that contains neither an \texttt{export-keyword} nor a \texttt{module-partition} implicitly imports the primary module interface unit of the module as if by a \texttt{module-import-declaration}.

[Example 2:

Translation unit #1:

\begin{verbatim}
module B:Y;
int y();
\end{verbatim}

// does not implicitly import B

Translation unit #2:

\begin{verbatim}
export module B;
import :Y;
int n = y();
\end{verbatim}

// OK, does not create interface dependency cycle

Translation unit #3:

\begin{verbatim}
module B:X1;
int &a = n;
\end{verbatim}

// error: n not visible here

Translation unit #4:

\begin{verbatim}
module B:X2;
import B;
int &b = n;
\end{verbatim}

// OK

Translation unit #5:

\begin{verbatim}
module B;
int &c = n;
\end{verbatim}

// implicitly imports B

// OK

— end example]

10.2 Export declaration

\begin{verbatim}
export-declaration:
    export declaration
    export { declaration-seq }
    export-keyword module-import-declaration
\end{verbatim}

1 An export-declaration shall inhabit a namespace scope and appear in the purview of a module interface unit. An export-declaration shall not appear directly or indirectly within an unnamed namespace or a
private-module-fragment. An export-declaration has the declarative effects of its declaration, declaration-seq (if any), or module-import-declaration. The declaration or declaration-seq of an export-declaration shall not contain an export-declaration or module-import-declaration.

[Note 1: An export-declaration does not establish a scope. — end note]

2 A declaration is exported if it is declared within an export-declaration and inhabits a namespace scope or it is

(2.1) — a namespace-definition that contains an exported declaration, or
(2.2) — a declaration within a header unit (10.3) that introduces at least one name.

3 An exported declaration that is not a module-import-declaration shall declare at least one name. If the declaration is not within a header unit, it shall not declare a name with internal linkage.

4 [Example 1:
Source file "a.h":
   export int x;

Translation unit #1:
   module;
   #include "a.h" // error: declaration of x is not in the
   // purview of a module interface unit
   export module M;
   export namespace {} // error: does not introduce any names
   export namespace {
      int a1; // error: export of name with internal linkage
   }
   namespace {
      export int a2; // error: export of name with internal linkage
   }
   export static int b; // error: b explicitly declared static
   export int f(); // OK
   export namespace N { } // OK
   export using namespace N; // error: does not declare a name
   — end example]

5 If the declaration is a using-declaration (9.9) and is not within a header unit, all entities to which all of the using-declarators ultimately refer (if any) shall have been introduced with a name having external linkage.

[Example 2:
Source file "b.h":
   int f();

Importable header "c.h":
   int g();

Translation unit #1:
   export module X;
   export int h();

Translation unit #2:
   module;
   #include "b.h"
   export module M;
   import "c.h";
   import X;
   export using ::f, ::g, ::h; // OK
   struct S;
   export using ::S; // error: S has module linkage
   namespace N {
      export int h();
      static int h(int); // #1
   }
   export using N::h; // error: #1 has internal linkage

§ 10.2
— end example]

[Note 2: These constraints do not apply to type names introduced by typedef declarations and alias-declarations.]

[Example 3:

```c
export module M;
struct S;
export using T = S; // OK, exports name T denoting type S
— end example]

— end note]

6 A redeclaration of an entity or typedef-name X is implicitly exported if X was introduced by an exported declaration; otherwise it shall not be exported.

[Example 4:

```c
export module M;
struct S { int n; };
typedef S S;
export typedef S S; // OK, does not redeclare an entity
export struct S; // error: exported declaration follows non-exported declaration
— end example]

[Note 3: Names introduced by exported declarations have either external linkage or no linkage; see 6.6. Namespace-scoped declarations exported by a module can be found by name lookup in any translation unit importing that module (6.5). Class and enumeration member names can be found by name lookup in any context in which a definition of the type is reachable. — end note]

[Example 5:

Interface unit of M:
```c
export module M;
export struct X {
    static void f();
    struct Y { };
};

namespace {
    struct S { };
}
export void f(S); // OK
struct T { };
export T id(T); // OK
export struct A; // & exported as incomplete

export auto rootFinder(double a) {
    return [=](double x) { return (x + a/x)/2; };
}
export const int n = 5; // OK, n has external linkage
```

Implementation unit of M:
```c
module M;
struct A {
    int value;
};

Main program:
```c
import M;
int main() {
    X::f(); // OK, X is exported and definition of X is reachable
    X::Y y; // OK, X::Y is exported as a complete type
    auto f = rootFinder(2); // OK
    return A{45}.value; // error: A is incomplete
}
8 [Note 4: Declarations in an exported namespace-definition or in an exported linkage-specification (9.11) are exported and subject to the rules of exported declarations.

[Example 6:

```c
export module M;
export namespace N {
    int x;     // OK
    static_assert(1 == 1);    // error: does not declare a name
}
```

—end example]

10.3 Import declaration

module-import-declaration:

- import-keyword module-name attribute-specifier-seq_opt ;
- import-keyword module-partition attribute-specifier-seq_opt ;
- import-keyword header-name attribute-specifier-seq_opt ;

A module-import-declaration shall inhabit the global namespace scope. In a module unit, all module-import-declarations and export-declarations exporting module-import-declarations shall appear before all other declarations in the declaration-seq of the translation-unit and of the private-module-fragment (if any). The optional attribute-specifier-seq appertains to the module-import-declaration.

A module-import-declaration imports a set of translation units determined as described below.

[Note 1: Namespace-scope declarations exported by the imported translation units can be found by name lookup (6.5) in the importing translation unit and declarations within the imported translation units become reachable (10.7) in the importing translation unit after the import declaration. —end note]

A module-import-declaration that specifies a module-name M imports all module interface units of M.

A module-import-declaration that specifies a module-partition shall only appear after the module-declaration in a module unit of some module M. Such a declaration imports the so-named module partition of M.

A module-import-declaration that specifies a header-name H imports a synthesized header unit, which is a translation unit formed by applying phases 1 to 7 of translation (5.2) to the source file or header nominated by H, which shall not contain a module-declaration.

[Note 2: All declarations within a header unit are implicitly exported (10.2), and are attached to the global module (10.1). —end note]

An importable header is a member of an implementation-defined set of headers that includes all importable C++ library headers (16.4.2.3). H shall identify an importable header. Given two such module-import-declarations:

- if their header-names identify different headers or source files (15.3), they import distinct header units;
- otherwise, if they appear in the same translation unit, they import the same header unit;
- otherwise, it is unspecified whether they import the same header unit.

[Note 3: It is therefore possible that multiple copies exist of entities declared with internal linkage in an importable header. —end note]

[Note 4: A module-import-declaration nominating a header-name is also recognized by the preprocessor, and results in macros defined at the end of phase 4 of translation of the header unit being made visible as described in 15.5. Any other module-import-declaration does not make macros visible. —end note]

A declaration of a name with internal linkage is permitted within a header unit despite all declarations being implicitly exported (10.2).

[Note 5: A definition that appears in multiple translation units cannot in general refer to such names (6.3). —end note]

A header unit shall not contain a definition of a non-inline function or variable whose name has external linkage.

7 When a module-import-declaration imports a translation unit T, it also imports all translation units imported by exported module-import-declarations in T; such translation units are said to be exported by T. Additionally, when a module-import-declaration in a module unit of some module M imports another module unit U of M,
it also imports all translation units imported by non-exported *module-import-declarations* in the module unit purview of $U$.  These rules can in turn lead to the importation of yet more translation units.

8 A module implementation unit shall not be exported.

[Example 1:
Translation unit #1:
  module M:Part;
Translation unit #2:
  export module M;
  export import :Part;  // error: exported partition :Part is an implementation unit
  — end example]

9 A module implementation unit of a module $M$ that is not a module partition shall not contain a *module-import-declaration* nominating $M$.

[Example 2:
  module M;
  import M;  // error: cannot import $M$ in its own unit
  — end example]

10 A translation unit has an *interface dependency* on a translation unit $U$ if it contains a declaration (possibly a *module-declaration*) that imports $U$ or if it has an interface dependency on a translation unit that has an interface dependency on $U$. A translation unit shall not have an interface dependency on itself.

[Example 3:
Interface unit of $M_1$:
  export module $M_1$;
  import $M_2$;
Interface unit of $M_2$:
  export module $M_2$;
  import $M_3$;
Interface unit of $M_3$:
  export module $M_3$;
  import $M_1$;  // error: cyclic interface dependency $M_3 \rightarrow M_1 \rightarrow M_2 \rightarrow M_3$
  — end example]

10.4 **Global module fragment**

[module.global.frag]

---

1. Prior to phase 4 of translation, only preprocessing directives can appear in the *declaration-seq* (15.1).  — end note

2. A *global-module-fragment* specifies the contents of the *global module fragment* for a module unit. The global module fragment can be used to provide declarations that are attached to the global module and usable within the module unit.

3. A declaration $D$ is *decl-reachable* from a declaration $S$ in the same translation unit if:

(3.1) $D$ does not declare a function or function template and $S$ contains an *id-expression*, *namespace-name*, *type-name*, *template-name*, or *concept-name* naming $D$, or

(3.2) $D$ declares a function or function template that is named by an expression (6.3) appearing in $S$, or

(3.3) $S$ contains a dependent call $E$ (13.8.3) and $D$ is found by name lookup for the dependent name in an expression synthesized from $E$ by replacing each type-dependent argument or operand with a value of a placeholder type with no associated namespaces or entities, or

(3.4) $S$ contains an expression that takes the address of an overload set (12.3) that contains $D$ and for which the target type is dependent, or

94) This is consistent with the lookup rules for imported names (6.5).
— there exists a declaration $M$ that is not a namespace-definition for which $M$ is decl-reachable from $S$ and either

- $D$ is decl-reachable from $M$, or
- $D$ redeclares the entity declared by $M$ or $M$ redeclares the entity declared by $D$, and $D$ neither is a friend declaration nor inhabits a block scope, or
- $D$ declares a namespace $N$ and $M$ is a member of $N$, or
- one of $M$ and $D$ declares a class or class template $C$ and the other declares a member or friend of $C$, or
- one of $D$ and $M$ declares an enumeration $E$ and the other declares an enumerator of $E$, or
- $D$ declares a function or variable and $M$ is declared in $D$, or
- one of $M$ and $D$ declares a template and the other declares a partial or explicit specialization or an implicit or explicit instantiation of that template, or
- one of $M$ and $D$ declares a class or enumeration type and the other introduces a typedef name for linkage purposes for that type.

In this determination, it is unspecified

- whether a reference to an alias-declaration, typedef declaration, using-declaration, or namespace-alias-definition is replaced by the declarations they name prior to this determination,
- whether a simple-template-id that does not denote a dependent type and whose template-name names an alias template is replaced by its denoted type prior to this determination,
- whether a decltype-specifier that does not denote a dependent type is replaced by its denoted type prior to this determination, and
- whether a non-value-dependent constant expression is replaced by the result of constant evaluation prior to this determination.

4 A declaration $D$ in a global module fragment of a module unit is discarded if $D$ is not decl-reachable from any declaration in the declaration-seq of the translation-unit.

[Note 2: A discarded declaration is neither reachable nor visible to name lookup outside the module unit, nor in template instantiations whose points of instantiation (13.8.4.1) are outside the module unit, even when the instantiation context (10.6) includes the module unit. — end note]

5 [Example 1:

```c
const int size = 2;
int ary1[size]; // unspecified whether size is decl-reachable from ary1
constexpr int identity(int x) { return x; }
int ary2[identity(2)]; // unspecified whether identity is decl-reachable from ary2

template<typename> struct S;
template<typename, int> struct S2;
constexpr int g(int);

template<typename T, int N>
t S<S2<T, g(N)>> f(); // S, S2, g, and :: are decl-reachable from f

template<int N>
void h() noexcept(g(N) == N); // g and :: are decl-reachable from h
```

— end example]

6 [Example 2:

Source file "foo.h":

```c
namespace N {
    struct X {}
    int d();
    int e();
    inline int f(X, int = d()) { return e(); }
}```

95) A declaration can appear within a lambda-expression in the initializer of a variable.
```c
int g(X);
int h(X);
}

Module M interface:
module;
#include "foo.h"
export module M;
template<typename T> int use_f() {
    N::X x;
    return f(x, 123);
}

template<typename T> int use_g() {
    N::X x;
    return g((T(), x));
}

template<typename T> int use_h() {
    N::X x;
    return h((T(), x));
}

int k = use_h<int>();
```

Module M implementation:
```c
module M;
int a = use_f<int>(); // OK
int b = use_g<int>(); // error: no viable function for call to g;
    // g is not decl-reachable from purview of
    // module M's interface, so is discarded
int c = use_h<int>(); // OK
```

### 10.5 Private module fragment

A private-module-fragment shall appear only in a primary module interface unit (10.1). A module unit with a private-module-fragment shall be the only module unit of its module; no diagnostic is required.

1 A private-module-fragment shall appear only in a primary module interface unit (10.1). A module unit with a private-module-fragment shall be the only module unit of its module; no diagnostic is required.

2 [Note 1: A private-module-fragment ends the portion of the module interface unit that can affect the behavior of other translation units. A private-module-fragment allows a module to be represented as a single translation unit without making all of the contents of the module reachable to importers. The presence of a private-module-fragment affects:

- (2.1) the point by which the definition of an exported inline function is required (9.2.8),
- (2.2) the point by which the definition of an exported function with a placeholder return type is required (9.2.9.6),
- (2.3) whether a declaration is required not to be an exposure (6.6),
- (2.4) where definitions for inline functions and templates must appear (6.3, 9.2.8, 13.1),
- (2.5) the instantiation contexts of templates instantiated before it (10.6), and
- (2.6) the reachability of declarations within it (10.7).

—end note]

3 [Example 1:

```c
export module A;
export inline void fn_e(); // error: exported inline function fn_e not defined
inline void fn_m(); // OK, module-linkage inline function
```
static void fn_s();
export struct X;
export void g(X *x) {
    fn_s();          // OK, call to static function in same translation unit
    fn_m();          // OK, call to module-linkage inline function
}
export X *factory();  // OK
module :private;
struct X {};
    // definition not reachable from importers of A
X *factory() {
    return new X();
}
void fn_e() {}
void fn_m() {}
void fn_s() {}
—end example

10.6 Instantiation context

The instantiation context is a set of points within the program that determines which declarations are found by argument-dependent name lookup (6.5.4) and which are reachable (10.7) in the context of a particular declaration or template instantiation.

During the implicit definition of a defaulted function (11.4.4, 11.10.1), the instantiation context is the union of the instantiation context from the definition of the class and the instantiation context of the program construct that resulted in the implicit definition of the defaulted function.

During the implicit instantiation of a template whose point of instantiation is specified as that of an enclosing specialization (13.8.4.1), the instantiation context is the union of the instantiation context of the enclosing specialization and, if the template is defined in a module interface unit of a module M and the point of instantiation is not in a module interface unit of M, the point at the end of the declaration-seq of the primary module interface unit of M (prior to the private-module-fragment, if any).

During the implicit instantiation of a template that is implicitly instantiated because it is referenced from within the implicit definition of a defaulted function, the instantiation context is the instantiation context of the defaulted function.

During the instantiation of any other template specialization, the instantiation context comprises the point of instantiation of the template.

In any other case, the instantiation context at a point within the program comprises that point.

[Example 1:
Translation unit #1:
    export module stuff;
    export template<typename T, typename U> void foo(T, U u) { auto v = u; }
    export template<typename T> void bar(T, U u) { auto v = *u; }

Translation unit #2:
    export module M1;
    import "defn.h";        // provides struct X {}
    import stuff;
    export template<typename T> void f(T t) {
        X x;
        foo(t, x);
    }

Translation unit #3:
    export module M2;
    import "decl.h";        // provides struct X; (not a definition)
    import stuff;
    export template<typename T> void g(T t) {
        X *x;
        bar(t, x);
    }

§ 10.6 250
Translation unit #4:

```c
import M1;
import M2;
void test() {
    f(0);
    g(0);
}
```

The call to `f(0)` is valid; the instantiation context of `foo<int, X>` comprises

1. the point at the end of translation unit #1,
2. the point at the end of translation unit #2, and
3. the point of the call to `f(0)`,

so the definition of `X` is reachable (10.7).

It is unspecified whether the call to `g(0)` is valid: the instantiation context of `bar<int, X>` comprises

1. the point at the end of translation unit #1,
2. the point at the end of translation unit #3, and
3. the point of the call to `g(0)`.

so the definition of `X` need not be reachable, as described in 10.7. — end example

### 10.7 Reachability

A translation unit `U` is necessarily reachable from a point `P` if `U` is a module interface unit on which the translation unit containing `P` has an interface dependency, or the translation unit containing `P` imports `U`, in either case prior to `P` (10.3).

[Note 1: While module interface units are reachable even when they are only transitively imported via a non-exported import declaration, namespace-scope names from such module interface units are not found by name lookup (6.5). — end note]

All translation units that are necessarily reachable are reachable. Additional translation units on which the point within the program has an interface dependency may be considered reachable, but it is unspecified which are and under what circumstances.96

[Note 2: It is advisable to avoid depending on the reachability of any additional translation units in programs intending to be portable. — end note]

A declaration `D` is reachable from a point `P` if

1. `D` appears prior to `P` in the same translation unit, or
2. `D` is not discarded (10.4), appears in a translation unit that is reachable from `P`, and does not appear within a private-module-fragment.

A declaration is reachable if it is reachable from any point in the instantiation context (10.6).

[Note 3: Whether a declaration is exported has no bearing on whether it is reachable. — end note]

The accumulated properties of all reachable declarations of an entity within a context determine the behavior of the entity within that context.

[Note 4: These reachable semantic properties include type completeness, type definitions, initializers, default arguments of functions or template declarations, attributes, names bound, etc. Since default arguments are evaluated in the context of the call expression, the reachable semantic properties of the corresponding parameter types apply in that context.

[Example 1:

Translation unit #1:
```
export module M:A;
export struct B;
```

Translation unit #2:
```
module M:B;
```
struct B {
    operator int();
};

Translation unit #3:
module M:C;
import :A;
B b1;       // error: no reachable definition of struct B

Translation unit #4:
export module M;
export import :A;
import :B;
B b2;
export void f(B b = B());

Translation unit #5:
module X;
import M;
B b3;       // error: no reachable definition of struct B
void g() { f(); }       // error: no reachable definition of struct B

[Note 5: Declarations of an entity can be reachable even where they cannot be found by name lookup. — end note]

Example 2:

Translation unit #1:
export module A;
struct X {};
export using Y = X;

Translation unit #2:
module B;
import A;
Y y;       // OK, definition of X is reachable
X x;       // error: X not visible to unqualified lookup

— end example]
11 Classes

11.1 Preamble

A class is a type. Its name becomes a class-name within its scope.

```
class-name:
    identifier
    simple-template-id
```

A class-specifier or an elaborated-type-specifier is used to make a class-name. An object of a class consists of a (possibly empty) sequence of members and base class objects.

```
class-specifier:
    class-head { member-specification_opt }

class-head:
    class-key attribute-specifier-seq_opt class-head-name class-virt-specifier_opt base-clause_opt
    class-key attribute-specifier-seq_opt base-clause_opt

class-head-name:
    nested-name-specifier_opt class-name

class-virt-specifier:
    final

class-key:
    class
    struct
    union
```

A class declaration where the class-name in the class-head-name is a simple-template-id shall be an explicit specialization (13.9.4) or a partial specialization (13.7.6). A class-specifier whose class-head omits the class-head-name defines an unnamed class.

[Note 1: An unnamed class thus can’t be final. — end note]

Otherwise, the class-name is an identifier; it is not looked up, and the class-specifier introduces it.

2 The class-name is also bound in the scope of the class (template) itself; this is known as the injected-class-name. For purposes of access checking, the injected-class-name is treated as if it were a public member name. A class-specifier is commonly referred to as a class definition. A class is considered defined after the closing brace of its class-specifier has been seen even though its member functions are in general not yet defined. The optional attribute-specifier-seq appertains to the class; the attributes in the attribute-specifier-seq are thereafter considered attributes of the class whenever it is named.

If a class-head-name contains a nested-name-specifier, the class-specifier shall not inhabit a class scope. If its class-name is an identifier, the class-specifier shall correspond to one or more declarations nominable in the class, class template, or namespace to which the nested-name-specifier refers; they shall all have the same target scope, and the target scope of the class-specifier is that scope.

[Example 1:
```
namespace N {
    template<class>
    struct A {
        struct B;
    };
}
using N::A;
template<class T> struct A<T>::B {}; // OK
template<> struct A<void> {}; // error: A not nominable in ::
```
— end example]

[Note 2: The class-key determines whether the class is a union (11.5) and whether access is public or private by default (11.8). A union holds the value of at most one data member at a time. — end note]
A class is marked with the class-virt-specifier `final` and it appears as a class-or-decltype in a base-clause (11.7), the program is ill-formed. Whenever a class-key is followed by a class-head-name, the identifier `final`, and a colon or left brace, `final` is interpreted as a class-virt-specifier.

**Example 2:**
```cpp
class A;
class A final {};  // OK: definition of class A,
class C { constexpr operator int() { return 5; } };
class B final : C{};  // OK: definition of nested class B,
class X {  // not declaration of a bit-field member final
  class Y { constexpr operator int() { return 5; } };
};
```

Note 3: Complete objects of class type have nonzero size. Base class subobjects and members declared with the no_unique_address attribute (9.12.10) are not so constrained. — end note

Note 4: Class objects can be assigned (12.4.3.2, 11.4.6), passed as arguments to functions (9.4, 11.4.5.3), and returned by functions (except objects of classes for which copying or moving has been restricted; see 9.5.3 and 11.8). Other plausible operators, such as equality comparison, can be defined by the user; see 12.4. — end note

### 11.2 Properties of classes

A trivially copyable class is a class:

1. A trivially copyable class is a class:
   0. has at least one eligible copy constructor, move constructor, copy assignment operator, or move assignment operator (11.4.4, 11.4.5.3, 11.4.6),
   1. where each eligible copy constructor, move constructor, copy assignment operator, and move assignment operator is trivial, and
   2. has a trivial, non-deleted destructor (11.4.7).

2. A trivial class is a class that is trivially copyable and has one or more eligible default constructors (11.4.5.2), all of which are trivial.

Note 1: In particular, a trivially copyable or trivial class does not have virtual functions or virtual base classes. — end note

A class S is a standard-layout class if it:

1. has no non-static data members of type non-standard-layout class (or array of such types) or reference,
2. has no virtual functions (11.7.3) and no virtual base classes (11.7.2),
3. has the same access control (11.8) for all non-static data members,
4. has no non-standard-layout base classes,
5. has at most one base class subobject of any given type,
6. has all non-static data members and bit-fields in the class and its base classes first declared in the same class, and
7. has no element of the set $M(S)$ of types as a base class, where for any type X, $M(X)$ is defined as follows.

Note 2: $M(X)$ is the set of the types of all non-base-class subobjects that can be at a zero offset in X. — end note

- If X is a non-union class type with no non-static data members, the set $M(X)$ is empty.
- If X is a non-union class type with a non-static data member of type $X_0$ that is either of zero size or is the first non-static data member of $X$ (where said member may be an anonymous union), the set $M(X)$ consists of $X_0$ and the elements of $M(X_0)$.
- If X is a union type, the set $M(X)$ is the union of all $M(U_i)$ and the set containing all $U_i$, where each $U_i$ is the type of the $i^{th}$ non-static data member of $X$.

97 This ensures that two subobjects that have the same class type and that belong to the same most derived object are not allocated at the same address (7.6.10).
If X is an array type with element type X_e, the set M(X) consists of X_e and the elements of M(X_e).

If X is a non-class, non-array type, the set M(X) is empty.

Example 1:

```c
struct B { int i; }; // standard-layout class
struct C : B { }; // standard-layout class
struct D : C { }; // standard-layout class
struct E : D { char : 4; }; // not a standard-layout class
struct Q {};
struct S : Q { };
struct T : Q { };
struct U : S, T { }; // not a standard-layout class
```

Example 2:

```c
struct N { // neither trivial nor standard-layout
    int i;
    int j;
    virtual ~N();
};
struct T { // trivial but not standard-layout
    int i;
    private:
        int j;
};
struct SL { // standard-layout but not trivial
    int i;
    int j;
    ~SL();
};
struct POD { // both trivial and standard-layout
    int i;
    int j;
};
```

Note 3: Standard-layout classes are useful for communicating with code written in other programming languages. Their layout is specified in 11.4.

Note 4: Aggregates of class type are described in 9.4.2.

A class S is an implicit-lifetime class if it is an aggregate or has at least one trivial eligible constructor and a trivial, non-deleted destructor.

11.3 Class names

A class definition introduces a new type.

Example 1:

```c
struct X { int a; };
struct Y { int a; };
X a1;
Y a2;
int a3;
```
declares three variables of three different types. This implies that

```c
a1 = a2; // error: Y assigned to X
a1 = a3; // error: int assigned to X
```
are type mismatches, and that

```c
int f(X);
int f(Y);
```
declare overloads (Clause 12) named f and not simply a single function f twice. For the same reason,

```c
struct S { int a; };  // error: double definition
struct S { int a; };  // error: double definition
```
is ill-formed because it defines S twice. —end example]

[Note 1: It can be necessary to use an elaborated-type-specifier to refer to a class that belongs to a scope in which its name is also bound to a variable, function, or enumerator (6.5.6).

[Example 2:

```c
struct stat {
  // ...
};

stat gstat;  // use plain stat to define variable
int stat(struct stat*);  // stat now also names a function

void f() {
  struct stat* ps;  // struct prefix needed to name struct stat
  stat(ps);  // call stat function
}
```
—end example]

An elaborated-type-specifier can also be used to declare an identifier as a class-name.

[Example 3:

```c
struct s { int a; }

void g() {
  struct s;  // hide global struct s with a block-scope declaration
  s* p;  // refer to local struct s
  struct s { char* p; };  // define local struct s
  struct s;  // redeclaration, has no effect
}
```
—end example]

Such declarations allow definition of classes that refer to each other.

[Example 4:

```c
class Vector;

class Matrix {
  // ...
  friend Vector operator*(const Matrix&, const Vector&);
};
class Vector {
  // ...
  friend Vector operator*(const Matrix&, const Vector&);
};
```
Declaration of friends is described in 11.8.4, operator functions in 12.4. —end example]

—end note]

[Note 2: An elaborated-type-specifier (9.2.9.4) can also be used as a type-specifier as part of a declaration. It differs from a class declaration in that it can refer to an existing class of the given name. —end note]

[Example 5:

```c
struct s { int a; }

void g(int s) {
  struct s* p = new struct s;  // global s
```
\[ p->a = s; \quad // \text{parameter } s \]

—end example

[Note 3: The declaration of a class name takes effect immediately after the \textit{identifier} is seen in the class definition or \textit{elaborated-type-specifier}. For example,

\begin{verbatim}
class A * A;
\end{verbatim}

first specifies A to be the name of a class and then redefines it as the name of a pointer to an object of that class. This means that the elaborated form \texttt{class A} must be used to refer to the class. Such artistry with names can be confusing and is best avoided. —end note]

A \textit{simple-template-id} is only a \textit{class-name} if its \textit{template-name} names a class template.

11.4 Class members

11.4.1 General

\begin{verbatim}
member-specification:
    member-declaration member-specification_opt
    access-specifier : member-specification_opt

member-declaration:
    attribute-specifier-seq_opt declspec-seq_opt member-declarator-list_opt ;
    function-definition
    using-declaration
    using-enum-declaration
    static_assert-declaration
    template-declaration
    explicit-specialization
    deduction-guide
    alias-declaration
    opaque-enum-declaration
    empty-declaration

member-declarator-list:
    member-declarator
    member-declarator-list , member-declarator

member-declarator:
    declarator virt-specifier-seq_opt pure-specifier_opt
    declarator requires-clause
    declarator brace-or-equal-initializer_opt
    identifier_opt attribute-specifier-seq_opt : constant-expression brace-or-equal-initializer_opt

virt-specifier-seq:
    virt-specifier
    virt-specifier-seq virt-specifier

virt-specifier:
    override
    final

pure-specifier:
    = 0
\end{verbatim}

The \textit{member-specification} in a class definition declares the full set of members of the class; no member can be added elsewhere. A \textit{direct member} of a class X is a member of X that was first declared within the \textit{member-specification} of X, including anonymous union members (11.5.2) and direct members thereof. Members of a class are data members, member functions (11.4.2), nested types, enumerators, and member templates (13.7.3) and specializations thereof.

[Note 1: A specialization of a static data member template is a static data member. A specialization of a member function template is a member function. A specialization of a member class template is a nested class. —end note]

A \texttt{member-declaration} does not declare new members of the class if it is

\begin{enumerate}
\item[(2.1)] a friend declaration (11.8.4),
\item[(2.2)] a \textit{deduction-guide} (13.7.2.3),
\item[(2.3)] a \textit{template-declaration} whose \textit{declaration} is one of the above,
\end{enumerate}
For any other member-declaration, each declared entity that is not an unnamed bit-field (11.4.10) is a member of the class, and each such member-declaration shall either declare at least one member name of the class or declare at least one unnamed bit-field.

3 A data member is a non-function member introduced by a member-declarator. A member function is a member that is a function. Nested types are classes (11.3, 11.4.11) and enumerations (9.7.1) declared in the class and arbitrary types declared as members by use of a typedef declaration (9.2.4) or alias-declaration. The enumerators of an unscoped enumeration (9.7.1) defined in the class are members of the class.

4 A data member or member function may be declared static in its member-declaration, in which case it is a static member (see 11.4.9) (a static data member (11.4.9.3) or static member function (11.4.9.2), respectively) of the class. Any other data member or member function is a non-static member (a non-static data member or non-static member function (11.4.3), respectively).

[Note 2: A non-static data member of non-reference type is a member subobject of a class object (6.7.2). — end note]

5 A member shall not be declared twice in the member-specification, except that

(5.1) — a nested class or member class template can be declared and then later defined, and

(5.2) — an enumeration can be introduced with an opaque_enum-declaration and later redeclared with an enum-specifier.

[Note 3: A single name can denote several member functions provided their types are sufficiently different (6.4.1). — end note]

6 A redeclaration of a class member outside its class definition shall be a definition, an explicit specialization, or an explicit instantiation (13.9.4, 13.9.3). The member shall not be a non-static data member.

7 A complete-class context of a class (template) is a

(7.1) — function body (9.5.1),

(7.2) — default argument (9.3.4.7),

(7.3) — default template argument (13.2),

(7.4) — noexcept-specifier (14.5), or

(7.5) — default member initializer

within the member-specification of the class or class template.

[Note 4: A complete-class context of a nested class is also a complete-class context of any enclosing class, if the nested class is defined within the member-specification of the enclosing class. — end note]

8 A class is considered a completely-defined object type (6.8) (or complete type) at the closing } of the class-specifier. The class is regarded as complete within its complete-class contexts; otherwise it is regarded as incomplete within its own class member-specification.

9 In a member-declarator, an = immediately following the declarator is interpreted as introducing a pure-specifier if the declarator-id has function type, otherwise it is interpreted as introducing a brace-or-equal-initializer.

[Example 1:

```c
struct S {
  using T = void();
  T * p = 0; // OK: brace-or-equal-initializer
  virtual T f = 0; // OK: pure-specifier
};
```

— end example]

10 In a member-declarator for a bit-field, the constant_expression is parsed as the longest sequence of tokens that could syntactically form a constant_expression.
struct S {
    int x1 : 8 = 42;  // OK, "= 42" is brace-or-equal-initializer
    int x2 : 8 { 42 };  // OK, "{ 42 }", is brace-or-equal-initializer
    int y1 : true ? 8 : a = 42;  // OK, brace-or-equal-initializer is absent
    int y2 : true ? 8 : b = 42;  // error: cannot assign to const int
    int y3 : (true ? 8 : b) = 42;  // OK, "= 42", is brace-or-equal-initializer
    int z : 1 || new int { 0 };  // OK, brace-or-equal-initializer is absent
};

A brace-or-equal-initializer shall appear only in the declaration of a data member. (For static data members, see 11.4.9.3; for non-static data members, see 11.9.3 and 9.4.2). A brace-or-equal-initializer for a non-static data member specifies a default member initializer for the member, and shall not directly or indirectly cause the implicit definition of a defaulted default constructor for the enclosing class or the exception specification of that constructor.

A member shall not be declared with the extern storage-class-specifier. Within a class definition, a member shall not be declared with the thread_local storage-class-specifier unless also declared static.

The decl-specifier-seq may be omitted in constructor, destructor, and conversion function declarations only; when declaring another kind of member the decl-specifier-seq shall contain a type-specifier that is not a cv-qualifier. The member-declarator-list can be omitted only after a class-specifier or an enum-specifier or in a friend declaration (11.8.4). A pure-specifier shall be used only in the declaration of a virtual function (11.7.3) that is not a friend declaration.

The optional attribute-specifier-seq in a member-declaration appertains to each of the entities declared by the member-declarators; it shall not appear if the optional member-declarator-list is omitted.

A virt-specifier-seq shall contain at most one of each virt-specifier. A virt-specifier-seq shall appear only in the first declaration of a virtual member function (11.7.3).

The type of a non-static data member shall not be an incomplete type (6.8), an abstract class type (11.7.4), or a (possibly multi-dimensional) array thereof.

[Note 5: In particular, a class C cannot contain a non-static member of class C, but it can contain a pointer or reference to an object of class C. — end note]

[Note 6: See 7.5.4 for restrictions on the use of non-static data members and non-static member functions. — end note]

[Note 7: The type of a non-static member function is an ordinary function type, and the type of a non-static data member is an ordinary object type. There are no special member function types or data member types. — end note]

[Example 3: A simple example of a class definition is]

```cpp
struct tnode {
   char tword[20];
   int count;
   tnode* left;
   tnode* right;
};
```

which contains an array of twenty characters, an integer, and two pointers to objects of the same type. Once this definition has been given, the declaration

tnode s, *sp;

declares s to be a tnode and sp to be a pointer to a tnode. With these declarations, sp->count refers to the count member of the object to which sp points; s.left refers to the left subtree pointer of the object s; and s.right->tword[0] refers to the initial character of the tword member of the right subtree of s. — end example]

[Note 8: Non-static data members of a (non-union) class with the same access control (11.8) and non-zero size (6.7.2) are allocated so that later members have higher addresses within a class object (7.6.9). The order of allocation of non-static data members with different access control is unspecified. Implementation alignment requirements can cause two adjacent members not to be allocated immediately after each other; so can requirements for space for managing virtual functions (11.7.3) and virtual base classes (11.7.2). — end note]

If T is the name of a class, then each of the following shall have a name different from T:

(21.1) every static data member of class T;

(21.2) every member function of class T;
[Note 9: This restriction does not apply to constructors, which do not have names (11.4.5) — end note]

(21.3) — every member of class \( T \) that is itself a type;
(21.4) — every member template of class \( T \);
(21.5) — every enumerator of every member of class \( T \) that is an unscoped enumerated type; and
(21.6) — every member of every anonymous union that is a member of class \( T \).

22 In addition, if class \( T \) has a user-declared constructor (11.4.5), every non-static data member of class \( T \) shall have a name different from \( T \).

23 The common initial sequence of two standard-layout struct (11.2) types is the longest sequence of non-static data members and bit-fields in declaration order, starting with the first such entity in each of the structs, such that corresponding entities have layout-compatible types, either both entities are declared with the no_unique_address attribute (9.12.10) or neither is, and either both entities are bit-fields with the same width or neither is a bit-field.

[Example 4:

```c
struct A { int a; char b; }
struct B { const int b1; volatile char b2; }
struct C { int c; unsigned : 0; char b; }
struct D { int d; char b : 4; }
struct E { unsigned int e; char b; }
```

The common initial sequence of \( A \) and \( B \) comprises all members of either class. The common initial sequence of \( A \) and \( C \) and of \( A \) and \( D \) comprises the first member in each case. The common initial sequence of \( A \) and \( E \) is empty. — end example]

24 Two standard-layout struct (11.2) types are layout-compatible classes if their common initial sequence comprises all members and bit-fields of both classes (6.8).

25 Two standard-layout unions are layout-compatible if they have the same number of non-static data members and corresponding non-static data members (in any order) have layout-compatible types (6.8).

26 In a standard-layout union with an active member (11.5) of struct type \( T_1 \), it is permitted to read a non-static data member \( m \) of another union member of struct type \( T_2 \) provided \( m \) is part of the common initial sequence of \( T_1 \) and \( T_2 \); the behavior is as if the corresponding member of \( T_1 \) were nominated.

[Example 5:

```c
struct T1 { int a, b; }
struct T2 { int c; double d; }
union U { T1 t1; T2 t2; }
int f() {
    U u = { { 1, 2 } }; // active member is t1
    return u.t2.c; // OK, as if u.t1.a were nominated
}
```

— end example]

[Note 10: Reading a volatile object through a glvalue of non-volatile type has undefined behavior (9.2.9.2). — end note]

27 If a standard-layout class object has any non-static data members, its address is the same as the address of its first non-static data member if that member is not a bit-field. Its address is also the same as the address of each of its base class subobjects.

[Note 11: There can therefore be unnamed padding within a standard-layout struct object inserted by an implementation, but not at its beginning, as necessary to achieve appropriate alignment. — end note]

[Note 12: The object and its first subobject are pointer-interconvertible (6.8.3, 7.6.1.9). — end note]

11.4.2 Member functions [class.mfct]

1 If a member function is attached to the global module and is defined (9.5) in its class definition, it is inline (9.2.8).

[Note 1: A member function is also inline if it is declared inline, constexpr, or consteval. — end note]

2 [Example 1:

```c
struct X {
    typedef int T;
```
The definition of the member function \( f \) of class \( X \) inhabits the global scope; the notation \( X::f \) indicates that the function \( f \) is a member of class \( X \) and in the scope of class \( X \). In the function definition, the parameter type \( T \) refers to the typedef member \( T \) declared in class \( X \) and the default argument \( \text{count} \) refers to the static data member \( \text{count} \) declared in class \( X \). —end example

Member functions of a local class shall be defined inline in their class definition, if they are defined at all.

[Note 2: A member function can be declared (but not defined) using a typedef for a function type. The resulting member function has exactly the same type as it would have if the function declarator were provided explicitly, see 9.3.4.6. For example,

\[
\begin{align*}
\text{typedef void } & \text{fv();} \\
\text{typedef void } & \text{fvc() const;}
\end{align*}
\]

\[
\begin{align*}
\text{struct } & \text{S} \\
& \{ \\
& \quad \text{fv memfunc1;} \quad \text{// equivalent to: void memfunc1();} \\
& \quad \text{void memfunc2();} \\
& \quad \text{fvc memfunc3;} \quad \text{// equivalent to: void memfunc3() const;}
& \}; \\
& \text{fv } S::* \text{pmfv1} = &S::\text{memfunc1;} \\
& \text{fv } S::* \text{pmfv2} = &S::\text{memfunc2;} \\
& \text{fv } S::* \text{pmfv3} = &S::\text{memfunc3;}
\end{align*}
\]

Also see 13.4. —end note]
n2.set("def",0,0);
}

In the body of the member function `tnode::set`, the member names `tword`, `count`, `left`, and `right` refer to members of the object for which the function is called. Thus, in the call `n1.set("abc",&n2,0)`, `tword` refers to `n1.tword`, and in the call `n2.set("def",0,0)`, it refers to `n2.tword`. The functions `strlen`, `perror`, and `strcpy` are not members of the class `tnode` and should be declared elsewhere. [Note 2: A non-static member function can be declared with `cv-qualifiers`, which affect the type of the `this` pointer (7.5.2), and/or a `ref-qualifier` (9.3.4.6); both affect overload resolution (12.2.2). — end note]

A non-static member function may be declared virtual (11.7.3) or pure virtual (11.7.4).

### 11.4.4 Special member functions

Default constructors (11.4.5.2), copy constructors, move constructors (11.4.5.3), copy assignment operators, move assignment operators (11.4.6), and prospective destructors (11.4.7) are special member functions. [Note 1: The implementation will implicitly declare these member functions for some class types when the program does not explicitly declare them. The implementation will implicitly define them if they are odr-used (6.3) or needed for constant evaluation (7.7). — end note]

An implicitly-declared special member function is declared at the closing `}` of the class-specifier. Programs shall not define implicitly-declared special member functions.

Programs may explicitly refer to implicitly-declared special member functions.

**Example 1**: A program may explicitly call or form a pointer to member to an implicitly-declared special member function.

```c
struct A {:
struct B : A {
  B & operator=(const B &);
};
B & B::operator=(const B & a) {
  this->A::operator=(a); // well-formed
  return *this;
}
```

[Note 2: The special member functions affect the way objects of class type are created, copied, moved, and destroyed, and how values can be converted to values of other types. Often such special member functions are called implicitly. — end note]

Special member functions obey the usual access rules (11.8).

**Example 2**: Declaring a constructor protected ensures that only derived classes and friends can create objects using it. — end example]

Two special member functions are of the same kind if:

- they are both default constructors,
- they are both copy or move constructors with the same first parameter type, or
- they are both copy or move assignment operators with the same first parameter type and the same `cv-qualifiers` and `ref-qualifier`, if any.

An eligible special member function is a special member function for which:

- the function is not deleted,
- the associated constraints (13.5), if any, are satisfied, and
- no special member function of the same kind is more constrained (13.5.5).

For a class, its non-static data members, its non-virtual direct base classes, and, if the class is not abstract (11.7.4), its virtual base classes are called its potentially constructed subobjects.

A defaulted special member function is `constexpr-compatible` if the corresponding implicitly-declared special member function would be a `constexpr` function.

---

98) See, for example, `<cstring>` (21.5.3).
11.4.5 Constructors

11.4.5.1 General

A declarator declares a constructor if it is a function declarator (9.3.4.6) of the form

\[ \text{ptr-declarator \ ( parameter-declaration-clause \ )\ noexcept-specifier_{opt}\ attribute-specifier-seq_{opt}} \]

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

1. in a friend declaration (11.8.4), the id-expression is a qualified-id that names a constructor (6.5.5.2);
2. otherwise, in a member-declaration that belongs to the member-specification of a class or class template, the id-expression is the injected-class-name (11.1) of the immediately-enclosing entity;
3. otherwise, the id-expression is a qualified-id whose unqualified-id is the injected-class-name of its lookup context.

Constructors do not have names. In a constructor declaration, each decl-specifier in the optional decl-specifier-seq shall be friend, inline, constexpr, or an explicit-specifier.

[Example 1:

```cpp
struct S {
    S(); // declares the constructor
};
S::S() { } // defines the constructor
–end example]
```

A constructor is used to initialize objects of its class type.

[Note 1: Because constructors do not have names, they are never found during unqualified name lookup; however an explicit type conversion using the functional notation (7.6.1.4) will cause a constructor to be called to initialize an object. The syntax looks like an explicit call of the constructor. – end note]

[Example 2:

```cpp
complex zz = complex(1,2.3);
cprint( complex(7.8,1.2) );
–end example]
```

[Note 2: For initialization of objects of class type see 11.9. – end note]

An object created in this way is unnamed.

[Note 3: 6.7.7 describes the lifetime of temporary objects. – end note]

[Note 4: Explicit constructor calls do not yield lvalues, see 7.2.1. – end note]

A constructor can be invoked for a const, volatile or const volatile object. const and volatile semantics (9.2.9.2) are not applied on an object under construction. They come into effect when the constructor for the most derived object (6.7.2) ends.

A return statement in the body of a constructor shall not specify a return value. The address of a constructor shall not be taken.

A constructor shall not be a coroutine.

11.4.5.2 Default constructors

A default constructor for a class X is a constructor of class X for which each parameter that is not a function parameter pack has a default argument (including the case of a constructor with no parameters). If there is no user-declared constructor for class X, a non-explicit constructor having no parameters is implicitly declared as defaulted (9.5). An implicitly-declared default constructor is an inline public member of its class.

A defaulted default constructor for class X is defined as deleted if:

1. X is a union that has a variant member with a non-trivial default constructor and no variant member of X has a default member initializer,
2. X is a non-union class that has a variant member M with a non-trivial default constructor and no variant member of the anonymous union containing M has a default member initializer,
— any non-static data member with no default member initializer (11.4) is of reference type,

— any non-variant non-static data member of const-qualified type (or array thereof) with no brace-or-equal-initializer is not const-default-constructible (9.4),

— X is a union and all of its variant members are of const-qualified type (or array thereof),

— X is a non-union class and all members of any anonymous union member are of const-qualified type (or array thereof),

— any potentially constructed subobject, except for a non-static data member with a brace-or-equal-initializer, has class type M (or array thereof) and either M has no default constructor or overload resolution (12.2) as applied to find M's corresponding constructor results in an ambiguity or in a function that is deleted or inaccessible from the defaulted default constructor, or

— any potentially constructed subobject has a type with a destructor that is deleted or inaccessible from the defaulted default constructor.

A default constructor is trivial if it is not user-provided and if:

— its class has no virtual functions (11.7.3) and no virtual base classes (11.7.2), and

— no non-static data member of its class has a default member initializer (11.4), and

— all the direct base classes of its class have trivial default constructors, and

— for all the non-static data members of its class that are of class type (or array thereof), each such class has a trivial default constructor.

Otherwise, the default constructor is non-trivial.

A default constructor that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.3) to create an object of its class type (6.7.2), when it is needed for constant evaluation (7.7), or when it is explicitly defaulted after its first declaration. The implicitly-defined default constructor performs the set of initializations of the class that would be performed by a user-written default constructor for that class with no ctor-initializer (11.9.3) and an empty compound-statement. If that user-written default constructor would be ill-formed, the program is ill-formed. If that user-written default constructor would satisfy the requirements of a constexpr constructor (9.2.6), the implicitly-defined default constructor is constexpr. Before the defaulted default constructor for a class is implicitly defined, all the non-user-provided default constructors for its base classes and its non-static data members are implicitly defined.

Default constructors are called implicitly to create class objects of static, thread, or automatic storage duration (6.7.5.2, 6.7.5.3, 6.7.5.4) defined without an initializer (9.4), are called to create class objects of dynamic storage duration (6.7.5.5) created by a new-expression in which the new-initializer is omitted (7.6.2.8), or are called when the explicit type conversion syntax (7.6.1.4) is used. A program is ill-formed if the default constructor for an object is implicitly used and the constructor is not accessible (11.8).

11.4.5.3 Copy/move constructors

A non-template constructor for class X is a copy constructor if its first parameter is of type X&, const X&, volatile X&, or const volatile X&, and either there are no other parameters or else all other parameters have default arguments (9.3.4.7).

[Example 1: X::X(const X&) and X::X(X&, int=1) are copy constructors.

```c++
struct X {
    X(int);
    X(const X&, int = 1);
};
X a1();   // calls X(int);
X b(a, 0); // calls X(const X&, int);
X c = b;  // calls X(const X&, int);
```
2 A non-template constructor for class X is a move constructor if its first parameter is of type X&&, const X&&, volatile X&&, or const volatile X&&, and either there are no other parameters or else all other parameters have default arguments (9.3.4.7).

[Example 2: Y::Y(Y&&) is a move constructor.]

```cpp
struct Y {
    Y(const Y&);
    Y(Y&&);
};
```

3 [Note 1: All forms of copy/move constructor can be declared for a class.]

[Example 3:]

```cpp
struct X {
    X(const X&);
    X(X&);            // OK
    X(X&&);          // OK, but possibly not sensible
};
```

[End example]

[End note]

4 [Note 2: If a class X only has a copy constructor with a parameter of type X&, an initializer of type const X or volatile X cannot initialize an object of type cv X.]

[Example 4:]

```cpp
struct X {
    X();               // default constructor
    X(X&);            // copy constructor with a non-const parameter
};
```

```cpp
const X cx;
X x = cx;        // error: X::X(X&) cannot copy cx into x
```

[End example]

[End note]

5 A declaration of a constructor for a class X is ill-formed if its first parameter is of type cv X and either there are no other parameters or else all other parameters have default arguments. A member function template is never instantiated to produce such a constructor signature.

[Example 5:]

```cpp
struct S {
    template<typename T> S(T);
    S();
};
```

```cpp
S g;
```

```cpp
void h() {
    S a(g);        // does not instantiate the member template to produce S::S<S>(S);
    // uses the implicitly declared copy constructor
}
```

[End example]

6 If the class definition does not explicitly declare a copy constructor, a non-explicit one is declared implicitly. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy constructor is defined as deleted; otherwise, it is defined as defaulted (9.5). The latter case is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor (D.9).

7 The implicitly-declared copy constructor for a class X will have the form

```
X::X(const X&)
```
if each potentially constructed subobject of a class type $M$ (or array thereof) has a copy constructor whose first parameter is of type $\text{const } M\&$ or $\text{const volatile } M\&$.\(^{99}\) Otherwise, the implicitly-declared copy constructor will have the form

$$X::X(X&)$$

If the definition of a class $X$ does not explicitly declare a move constructor, a non-explicit one will be implicitly declared as defaulted if and only if

1. $X$ does not have a user-declared copy constructor,
2. $X$ does not have a user-declared copy assignment operator,
3. $X$ does not have a user-declared move assignment operator, and
4. $X$ does not have a user-declared destructor.

[Note 3: When the move constructor is not implicitly declared or explicitly supplied, expressions that otherwise would have invoked the move constructor might instead invoke a copy constructor. — end note]

The implicitly-declared move constructor for class $X$ will have the form

$$X::X(X&&)$$

An implicitly-declared copy/move constructor is an inline public member of its class. A defaulted copy/move constructor for a class $X$ is defined as deleted (9.5.3) if $X$ has:

1. a potentially constructed subobject type $M$ (or array thereof) that cannot be copied/moved because overload resolution (12.2), as applied to find $M$'s corresponding constructor, results in an ambiguity or a function that is deleted or inaccessible from the defaulted constructor,
2. a variant member whose corresponding constructor as selected by overload resolution is non-trivial,
3. any potentially constructed subobject of a type with a destructor that is deleted or inaccessible from the defaulted constructor, or,
4. for the copy constructor, a non-static data member of rvalue reference type.

[Note 4: A defaulted move constructor that is defined as deleted is ignored by overload resolution (12.2, 12.3). Such a constructor would otherwise interfere with initialization from an rvalue which can use the copy constructor instead. — end note]

A copy/move constructor for class $X$ is trivial if it is not user-provided and if:

1. class $X$ has no virtual functions (11.7.3) and no virtual base classes (11.7.2), and
2. the constructor selected to copy/move each direct base class subobject is trivial, and
3. for each non-static data member of $X$ that is of class type (or array thereof), the constructor selected to copy/move that member is trivial;
   otherwise the copy/move constructor is non-trivial.

A copy/move constructor that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.3), when it is needed for constant evaluation (7.7), or when it is explicitly defaulted after its first declaration.

[Note 5: The copy/move constructor is implicitly defined even if the implementation elided its odr-use (6.3, 6.7.7). — end note]

If the implicitly-defined constructor would satisfy the requirements of a constexpr constructor (9.2.6), the implicitly-defined constructor is constexpr.

Before the defaulted copy/move constructor for a class is implicitly defined, all non-user-provided copy/move constructors for its potentially constructed subobjects are implicitly defined.

[Note 6: An implicitly-declared copy/move constructor has an implied exception specification (14.5). — end note]

The implicitly-defined copy/move constructor for a non-union class $X$ performs a memberwise copy/move of its bases and members.

[Note 7: Default member initializers of non-static data members are ignored. See also the example in 11.9.3. — end note]

\(^{99}\) This implies that the reference parameter of the implicitly-declared copy constructor cannot bind to a volatile lvalue; see C.5.7.
The order of initialization is the same as the order of initialization of bases and members in a user-defined constructor (see 11.9.3). Let \( x \) be either the parameter of the constructor or, for the move constructor, an \( x \)value referring to the parameter. Each base or non-static data member is copied/moved in the manner appropriate to its type:

- (14.1) if the member is an array, each element is direct-initialized with the corresponding subobject of \( x \);
- (14.2) if a member \( m \) has rvalue reference type \( T&& \), it is direct-initialized with \( \text{static
cast}<T&&>(x.m) \);
- (14.3) otherwise, the base or member is direct-initialized with the corresponding base or member of \( x \).

Virtual base class subobjects shall be initialized only once by the implicitly-defined copy/move constructor (see 11.9.3).

The implicitly-defined copy/move constructor for a union \( X \) copies the object representation (6.8) of \( X \). For each object nested within (6.7.2) the object that is the source of the copy, a corresponding object \( o \) nested within the destination is identified (if the object is a subobject) or created (otherwise), and the lifetime of \( o \) begins before the copy is performed.

11.4.6 Copy/move assignment operator

A user-declared copy assignment operator \( X::operator= \) is a non-static non-template member function of class \( X \) with exactly one parameter of type \( X, \) \( X&, \) \( \text{const } X& \), \( \text{volatile } X& \), or \( \text{const volatile } X& \).

[Note 1: An overloaded assignment operator must be declared to have only one parameter; see 12.4.3.2. — end note]

[Note 2: More than one form of copy assignment operator can be declared for a class. — end note]

[Note 3: If a class \( X \) only has a copy assignment operator with a parameter of type \( X& \), an expression of type \( \text{const } X \) cannot be assigned to an object of type \( X \).]

[Example 1:

```c++
struct X {
    X();
    X& operator=(X&);
};
const X cx;
X x;
void f() {
    x = cx; // error: X::operator=(X&) cannot assign cx into x
}
```
— end example]
— end note]

If the class definition does not explicitly declare a copy assignment operator, one is declared implicitly. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy assignment operator is defined as deleted; otherwise, it is defined as defaulted (9.5). The latter case is deprecated if the class has a user-declared copy constructor or a user-declared destructor (D.9). The implicitly-declared copy assignment operator for a class \( X \) will have the form

\( X& X::operator=(\text{const } X&) \)

if

- (2.1) each direct base class \( B \) of \( X \) has a copy assignment operator whose parameter is of type \( \text{const } B&, \) \( \text{const volatile } B&, \) or \( B, \) and
- (2.2) for all the non-static data members of \( X \) that are of a class type \( M \) (or array thereof), each such class type has a copy assignment operator whose parameter is of type \( \text{const } M&, \) \( \text{const volatile } M&, \) or \( M \).

Otherwise, the implicitly-declared copy assignment operator will have the form

\( X& X::operator=(X&) \)

100) Because a template assignment operator or an assignment operator taking an rvalue reference parameter is never a copy assignment operator, the presence of such an assignment operator does not suppress the implicit declaration of a copy assignment operator. Such assignment operators participate in overload resolution with other assignment operators, including copy assignment operators, and, if selected, will be used to assign an object.

101) This implies that the reference parameter of the implicitly-declared copy assignment operator cannot bind to a \( \text{volatile} \) lvalue; see C.5.7.
A user-declared move assignment operator \( X::\text{operator=} \) is a non-static non-template member function of class \( X \) with exactly one parameter of type \( X&& \), \( \text{const } X&& \), \( \text{volatile } X&& \), or \( \text{const volatile } X&& \).

[Note 4: An overloaded assignment operator must be declared to have only one parameter; see 12.4.3.2. — end note]

[Note 5: More than one form of move assignment operator can be declared for a class. — end note]

If the definition of a class \( X \) does not explicitly declare a move assignment operator, one will be implicitly declared as defaulted if and only if

1. \( X \) does not have a user-declared copy constructor,
2. \( X \) does not have a user-declared move constructor,
3. \( X \) does not have a user-declared copy assignment operator, and
4. \( X \) does not have a user-declared destructor.

[Example 2: The class definition

\[
\text{struct } S \{
    \text{int } a;
    S& \text{ operator=}(\text{const } S&) = \text{default};
\};
\]

will not have a default move assignment operator implicitly declared because the copy assignment operator has been user-declared. The move assignment operator may be explicitly defaulted.

\[
\text{struct } S \{
    \text{int } a;
    S& \text{ operator=}(S&&) = \text{default};
    S& \text{ operator=(S&&)} = \text{default};
\};
\]

—end example]

The implicitly-declared move assignment operator for a class \( X \) will have the form

\[
X& X::\text{operator=} (X&&)
\]

The implicitly-declared copy/move assignment operator for class \( X \) has the return type \( X& \); it returns the object for which the assignment operator is invoked, that is, the object assigned to. An implicitly-declared copy/move assignment operator is an inline public member of its class.

A defaulted copy/move assignment operator for class \( X \) is defined as deleted if \( X \) has:

1. a variant member with a non-trivial corresponding assignment operator and \( X \) is a union-like class, or
2. a non-static data member of \( \text{const} \) non-class type (or array thereof), or
3. a non-static data member of reference type, or
4. a direct non-static data member of class type \( M \) (or array thereof) or a direct base class \( M \) that cannot be copied/moved because overload resolution (12.2), as applied to find \( M \)'s corresponding assignment operator, results in an ambiguity or a function that is deleted or inaccessible from the defaulted assignment operator.

[Note 6: A defaulted move assignment operator that is defined as deleted is ignored by overload resolution (12.2, 12.3). — end note]

Because a copy/move assignment operator is implicitly declared for a class if not declared by the user, a base class copy/move assignment operator is always hidden by the corresponding assignment operator of a derived class (12.4.3.2).

[Note 7: A using-declaration that names an assignment operator with a parameter type that could be that of a copy/move assignment operator for a derived class does not suppress the implicit declaration of the derived class operator (9.9). — end note]

A copy/move assignment operator for class \( X \) is trivial if it is not user-provided and if:

1. class \( X \) has no virtual functions (11.7.3) and no virtual base classes (11.7.2), and
2. the assignment operator selected to copy/move each direct base class subobject is trivial, and
3. for each non-static data member of \( X \) that is of class type (or array thereof), the assignment operator selected to copy/move that member is trivial;

otherwise the copy/move assignment operator is non-trivial.
A copy/move assignment operator for a class X that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.3) (e.g., when it is selected by overload resolution to assign to an object of its class type), when it is needed for constant evaluation (7.7), or when it is explicitly defaulted after its first declaration. The implicitly-defined copy/move assignment operator is constexpr if

- X is a literal type, and
- the assignment operator selected to copy/move each direct base class subobject is a constexpr function, and
- for each non-static data member of X that is of class type (or array thereof), the assignment operator selected to copy/move that member is a constexpr function.

Before the defaulted copy/move assignment operator for a class is implicitly defined, all non-user-provided copy/move assignment operators for its direct base classes and its non-static data members are implicitly defined.

[Note 8: An implicitly-declared copy/move assignment operator has an implied exception specification (14.5). — end note]

The implicitly-defined copy/move assignment operator for a non-union class X performs memberwise copy/move assignment of its subobjects. The direct base classes of X are assigned first, in the order of their declaration in the base-specifier-list, and then the immediate non-static data members of X are assigned, in the order in which they were declared in the class definition. Let x be either the parameter of the function or, for the move operator, an xvalue referring to the parameter. Each subobject is assigned in the manner appropriate to its type:

- if the subobject is of class type, as if by a call to operator= with the subobject as the object expression and the corresponding subobject of x as a single function argument (as if by explicit qualification; that is, ignoring any possible virtual overriding functions in more derived classes);
- if the subobject is an array, each element is assigned, in the manner appropriate to the element type;
- if the subobject is of scalar type, the built-in assignment operator is used.

It is unspecified whether subobjects representing virtual base classes are assigned more than once by the implicitly-defined copy/move assignment operator.

[Example 3:

```cpp
struct V { }
struct A : virtual V { }
struct B : virtual V { }
struct C : B, A { }
```

It is unspecified whether the virtual base class subobject V is assigned twice by the implicitly-defined copy/move assignment operator for C. — end example]

The implicitly-defined copy assignment operator for a union X copies the object representation (6.8) of X. If the source and destination of the assignment are not the same object, then for each object nested within (6.7.2) the object that is the source of the copy, a corresponding object o nested within the destination is created, and the lifetime of o begins before the copy is performed.

11.4.7 Destructors

A declaration whose declarator-id has an unqualified-id that begins with a ~ declares a prospective destructor; its declarator shall be a function declarator (9.3.4.6) of the form

```cpp
ptr-declarator ( parameter-declaration-clause ) noexcept-specifier attribute-specifier-seq_opt
```

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

- in a member-declaration that belongs to the member-specification of a class or class template but is not a friend declaration (11.8.4), the id-expression is ~class-name and the class-name is the injected-class-name (11.1) of the immediately-enclosing entity or
- otherwise, the id-expression is nested-name-specifier ~class-name and the class-name is the injected-class-name of the class nominated by the nested-name-specifier.

A prospective destructor shall take no arguments (9.3.4.6). Each decl-specifier of the decl-specifier-seq of a prospective destructor declaration (if any) shall be friend, inline, virtual, constexpr, or consteval.
If a class has no user-declared prospective destructor, a prospective destructor is implicitly declared as defaulted (9.5). An implicitly-declared prospective destructor is an inline public member of its class.

An implicitly-declared prospective destructor for a class \( X \) will have the form

\[
\sim X()
\]

At the end of the definition of a class, overload resolution is performed among the prospective destructors declared in that class with an empty argument list to select the destructor for the class, also known as the selected destructor. The program is ill-formed if overload resolution fails. Destructor selection does not constitute a reference to, or odr-use (6.3) of, the selected destructor, and in particular, the selected destructor may be deleted (9.5.3).

The address of a destructor shall not be taken. A destructor can be invoked for a \( \text{const} \), \( \text{volatile} \), or \( \text{const volatile} \) object. \( \text{const} \) and \( \text{volatile} \) semantics (9.2.9.2) are not applied on an object under destruction. They stop being in effect when the destructor for the most derived object (6.7.2) starts.

\[\text{Note 1: A declaration of a destructor that does not have a noexcept-specifier has the same exception specification as if it had been implicitly declared (14.5). — end note}\]

A defaulted destructor for a class \( X \) is defined as deleted if:

1. \( X \) is a union-like class that has a variant member with a non-trivial destructor,
2. any potentially constructed subobject has class type \( M \) (or array thereof) and \( M \) has a deleted destructor or a destructor that is inaccessible from the defaulted destructor,
3. or, for a virtual destructor, lookup of the non-array deallocation function results in an ambiguity or in a function that is deleted or inaccessible from the defaulted destructor.

A destructor is trivial if it is not user-provided and if:

1. the destructor is not virtual,
2. all of the direct base classes of its class have trivial destructors, and
3. for all of the non-static data members of its class that are of class type (or array thereof), each such class has a trivial destructor.

Otherwise, the destructor is non-trivial.

A defaulted destructor is a constexpr destructor if it satisfies the requirements for a constexpr destructor (9.2.6).

A destructor that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.3) or when it is explicitly defaulted after its first declaration.

Before a defaulted destructor for a class is implicitly defined, all the non-user-provided destructors for its base classes and its non-static data members are implicitly defined.

A prospective destructor can be declared virtual (11.7.3) and with a pure-specifier (11.7.4). If the destructor of a class is virtual and any objects of that class or any derived class are created in the program, the destructor shall be defined.

\[\text{Note 2: Some language constructs have special semantics when used during destruction; see 11.9.5. — end note}\]

After executing the body of the destructor and destroying any objects with automatic storage duration allocated within the body, a destructor for class \( X \) calls the destructors for \( X \)'s direct non-variant non-static data members, the destructors for \( X \)'s non-virtual direct base classes and, if \( X \) is the most derived class (11.9.3), its destructor calls the destructors for \( X \)'s virtual base classes. All destructors are called as if they were referenced with a qualified name, that is, ignoring any possible virtual overriding destructors in more derived classes. Bases and members are destroyed in the reverse order of the completion of their constructor (see 11.9.3).

\[\text{Note 3: A return statement (8.7.4) in a destructor might not directly return to the caller; before transferring control to the caller, the destructors for the members and bases are called. — end note}\]

Destructors for elements of an array are called in reverse order of their construction (see 11.9).

A destructor is invoked implicitly

1. for a constructed object with static storage duration (6.7.5.2) at program termination (6.9.3.4),
2. for a constructed object with thread storage duration (6.7.5.3) at thread exit,
3. for a constructed object with automatic storage duration (6.7.5.4) when the block in which an object is created exits (8.8),
for a constructed temporary object when its lifetime ends (7.3.5, 6.7.7).

In each case, the context of the invocation is the context of the construction of the object. A destructor may also be invoked implicitly through use of a delete-expression (7.6.2.9) for a constructed object allocated by a new-expression (7.6.2.8); the context of the invocation is the delete-expression.

[Note 4: An array of class type contains several subobjects for each of which the destructor is invoked. — end note]

A destructor can also be invoked explicitly. A destructor is potentially invoked if it is invoked or as specified in 7.6.2.8, 8.7.4, 9.4.2, 11.9.3, and 14.2. A program is ill-formed if a destructor that is potentially invoked is deleted or not accessible from the context of the invocation.

At the point of definition of a virtual destructor (including an implicit definition), the non-array deallocation function is determined as if for the expression delete this appearing in a non-virtual destructor of the destructor’s class (see 7.6.2.9). If the lookup fails or if the deallocation function has a deleted definition (9.5), the program is ill-formed.

[Note 5: This assures that a deallocation function corresponding to the dynamic type of an object is available for the delete-expression (11.11). — end note]

In an explicit destructor call, the destructor is specified by a ~ followed by a type-name or decltype-specifier that denotes the destructor’s class type. The invocation of a destructor is subject to the usual rules for member functions (11.4.2); that is, if the object is not of the destructor’s class type and not of a class derived from the destructor’s class type (including when the destructor is invoked via a null pointer value), the program has undefined behavior.

[Note 6: Invoking delete on a null pointer does not call the destructor; see 7.6.2.9. — end note]

[Example 1:

```cpp
struct B {
    virtual ~B() { }
};
struct D : B {
    ~D() { }
};
D D_object;
typedef B B_alias;
B* B_ptr = &D_object;

void f() {
    D_object.B::~B();          // calls B’s destructor
    B_ptr->~B();                // calls D’s destructor
    B_ptr->~B_alias();          // calls D’s destructor
    B_ptr->B_alias::~B();       // calls B’s destructor
    B_ptr->B_alias::~B_alias(); // calls B’s destructor
}

—end example]

[Note 7: An explicit destructor call must always be written using a member access operator (7.6.1.5) or a qualified-id (7.5.4.3); in particular, the unary-expression ~X() in a member function is not an explicit destructor call (7.6.2.2). — end note]

[Note 8: Explicit calls of destructors are rarely needed. One use of such calls is for objects placed at specific addresses using a placement new-expression. Such use of explicit placement and destruction of objects can be necessary to cope with dedicated hardware resources and for writing memory management facilities. For example,

```cpp
void* operator new(std::size_t, void* p) { return p; }
struct X {
    X(int);
    ~X();
};
void f(X* p);

void g() {    // rare, specialized use:
    char* buf = new char[sizeof(X)];
    X* p = new(buf) X(222);        // use buf[] and initialize
    f(p);
}
```
Once a destructor is invoked for an object, the object’s lifetime ends; the behavior is undefined if the destructor is invoked for an object whose lifetime has ended (6.7.3).

[Example 2: If the destructor for an object with automatic storage duration is explicitly invoked, and the block is subsequently left in a manner that would ordinarily invoke implicit destruction of the object, the behavior is undefined.
—end example]

[Note 9: The notation for explicit call of a destructor can be used for any scalar type name (7.5.4.4). Allowing this makes it possible to write code without having to know if a destructor exists for a given type. For example:

```c
typedef int I;
I* p;
p->I::~I();
—end note]
```

A destructor shall not be a coroutine.

11.4.8 Conversions

11.4.8.1 General

Type conversions of class objects can be specified by constructors and by conversion functions. These conversions are called user-defined conversions and are used for implicit type conversions (7.3), for initialization (9.4), and for explicit type conversions (7.6.1.4, 7.6.3, 7.6.1.9).

User-defined conversions are applied only where they are unambiguous (6.5.2, 11.4.8.3). Conversions obey the access control rules (11.8). Access control is applied after ambiguity resolution (6.5).

[Note 1: See 12.2 for a discussion of the use of conversions in function calls as well as examples below. —end note]

At most one user-defined conversion (constructor or conversion function) is implicitly applied to a single value.

[Example 1:
```c
struct X {
    operator int();
};

struct Y {
    operator X();
};

Y a;
int b = a; // error: no viable conversion (a.operator X().operator int() not considered)
int c = X(a); // OK: a.operator X().operator int()
—end example]
```

11.4.8.2 Conversion by constructor

A constructor that is not explicit (9.2.3) specifies a conversion from the types of its parameters (if any) to the type of its class. Such a constructor is called a converting constructor.

[Example 1:
```c
struct X {
    X(int);
    X(const char*, int = 0);
    X(int, int);
};

void f(X arg) {
    X a = 1; // a = X(1)
    X b = "Jessie"; // b = X("Jessie", 0)
    a = 2; // a = X(2)
    f(3); // f(X(3))
```
f({1, 2});              // f(X(1,2))
}

/* end example */

[Note 1: An explicit constructor constructs objects just like non-explicit constructors, but does so only where the
direct-initialization syntax (9.4) or where casts (7.6.1.9, 7.6.3) are explicitly used; see also 12.2.2.5. A default constructor can
be an explicit constructor; such a constructor will be used to perform default-initialization or value-initialization (9.4).

Example 2:

struct Z {
  explicit Z();
  explicit Z(int);
  explicit Z(int, int);
};

Z a;                   // OK: default-initialization performed
Z b();                 // OK: direct initialization syntax used
Z c = {};              // error: copy-list-initialization
Z a1 = 1;              // error: no implicit conversion
Z a3 = Z(1);           // OK: direct initialization syntax used
Z a2(1);               // OK: direct initialization syntax used
Z* p = new Z(1);       // OK: direct initialization syntax used
Z a4 = (Z)1;           // OK: explicit cast used
Z a5 = static_cast<Z>(1); // OK: explicit cast used
Z a6 = { 3, 4 };       // error: no implicit conversion
/* end example */

/* end note */

A non-explicit copy/move constructor (11.4.5.3) is a converting constructor.

[Note 2: An implicitly-declared copy/move constructor is not an explicit constructor; it can be called for implicit type
conversions. — end note]

11.4.8.3 Conversion functions

A member function of a class X with a name of the form

conversion-function-id:
  operator conversion-type-id

conversion-type-id:
  type-specifier-seq conversion-declarator_opt

conversion-declarator:
  ptr-operator conversion-declarator_opt

shall have no parameters and specifies a conversion from X to the type specified by the conversion-type-id,
interpreted as a type-id (9.3.2). Such functions are called conversion functions. A decl-specifier in the
decl-specifier-seq of a conversion function (if any) shall be neither a defining-type-specifier nor static. The
type of the conversion function (9.3.4.6) is “function taking no parameter returning
conversion-type-id”. A conversion function is never used to convert a (possibly cv-qualified) object to the (possibly cv-qualified)
same object type (or a reference to it), to a (possibly cv-qualified) base class of that type (or a reference to
it), or to cv void.102

[Example 1:

struct X {
  operator int();
  operator auto() -> short; // error: trailing return type
};

void f(X a) {
  int i = int(a);
  i = (int)a;
}

102] These conversions are considered as standard conversions for the purposes of overload resolution (12.2.4.2, 12.2.4.2.5) and
therefore initialization (9.4) and explicit casts (7.6.1.9). A conversion to cv void does not invoke any conversion function (7.6.1.9).
Even though never directly called to perform a conversion, such conversion functions can be declared and can potentially be
reached through a call to a virtual conversion function in a base class.

§ 11.4.8.3
i = a;
}

In all three cases the value assigned will be converted by X::operator int(). — end example]

A conversion function may be explicit (9.2.3), in which case it is only considered as a user-defined conversion for direct-initialization (9.4). Otherwise, user-defined conversions are not restricted to use in assignments and initializations.

[Example 2:

```cpp
class Y { }
struct Z {
    explicit operator Y() const;
};

void h(Z z) {
    Y y1(z); // OK: direct-initialization
    Y y2 = z; // error: no conversion function candidate for copy-initialization
    Y y3 = (Y)z; // OK: cast notation
}
```

void g(X a, X b) {
    int i = (a) ? 1+a : 0;
    int j = (a&&b) ? a+b : i;
    if (a) {
    }
}
— end example]

The conversion-type-id shall not represent a function type nor an array type. The conversion-type-id in a conversion-function-id is the longest sequence of tokens that could possibly form a conversion-type-id.

[Note 1: This prevents ambiguities between the declarator operator * and its expression counterparts.

[Example 3:

```cpp
&ac.operator int*i; // syntax error:
  // parsed as: & (ac.operator int) * i
  // not as: & (ac.operator int)* i
```

The * is the pointer declarator and not the multiplication operator. — end example]

This rule also prevents ambiguities for attributes.

[Example 4:

```cpp
operator int [[noreturn]] () ; // error: noreturn attribute applied to a type
— end example]
— end note]

[Note 2: A conversion function in a derived class hides only conversion functions in base classes that convert to the same type. A conversion function template with a dependent return type hides only templates in base classes that correspond to it (6.5.2); otherwise, it hides and is hidden as a non-template function. Function overload resolution (12.2.4) selects the best conversion function to perform the conversion.

[Example 5:

```cpp
struct X {
    operator int();
};

struct Y : X {
    operator char();
};

void f(Y & a) {
    if (a) {               // error: ambiguous between X::operator int() and Y::operator char()
    }
— end example]
```
Conversion functions can be virtual.

A conversion function template shall not have a deduced return type (9.2.9.6).

[Example 6:

```cpp
struct S {
    operator auto() const { return 10; }    // OK
    template<class T>
    operator auto() const { return 1.2; }   // error: conversion function template
};
```

—end example]

### 11.4.9 Static members

#### 11.4.9.1 General

A static member `s` of class `X` may be referred to using the `qualified-id` expression `X::s`; it is not necessary to use the class member access syntax (7.6.1.5) to refer to a static member. A static member may be referred to using the class member access syntax, in which case the object expression is evaluated.

[Example 1:

```cpp
struct process {
    static void reschedule();
};
process& g();

void f() {
    process::reschedule();    // OK: no object necessary
    g().reschedule();         // `g()` is called
}
```

—end example]

Static members obey the usual class member access rules (11.8). When used in the declaration of a class member, the `static` specifier shall only be used in the member declarations that appear within the `member-specification` of the class definition.

[Note 1: It cannot be specified in member declarations that appear in namespace scope. — end note]

#### 11.4.9.2 Static member functions

[Note 1: The rules described in 11.4.2 apply to static member functions. — end note]

[Note 2: A static member function does not have a `this` pointer (7.5.2). A static member function cannot be qualified with `const`, `volatile`, or `virtual` (9.3.4.6). — end note]

#### 11.4.9.3 Static data members

A static data member is not part of the subobjects of a class. If a static data member is declared `thread-local` there is one copy of the member per thread. If a static data member is not declared `thread-local` there is one copy of the data member that is shared by all the objects of the class.

A static data member shall not be `mutable` (9.2.2). A static data member shall not be a direct member (11.4) of an unnamed (11.1) or local (11.6) class or of a (possibly indirectly) nested class (11.4.11) thereof.

The declaration of a non-inline static data member in its class definition is not a definition and may be of an incomplete type other than `cv void`.

[Note 1: The `initializer` in the definition of a static data member is in the scope of its class (6.4.6). — end note]

[Example 1:

```cpp
class process {
    static process* run_chain;
    static process* running;
};

process* process::running = get_main();
process* process::run_chain = running;
```
The definition of the static data member run_chain of class process inhabits the global scope; the notation process::run_chain indicates that the member run_chain is a member of class process and in the scope of class process. In the static data member definition, the initializer expression refers to the static data member running of class process. — end example]

[Note 2: Once the static data member has been defined, it exists even if no objects of its class have been created.]

[Example 2: In the example above, run_chain and running exist even if no objects of class process are created by the program. — end example]

The initialization and destruction of static data members is described in 6.9.3.2, 6.9.3.3, and 6.9.3.4. — end note]

4 If a non-volatile non-inline const static data member is of integral or enumeration type, its declaration in the class definition can specify a brace-or-equal-initializer in which every initializer-clause that is an assignment-expression is a constant expression (7.7). The member shall still be defined in a namespace scope if it is odr-used (6.3) in the program and the namespace scope definition shall not contain an initializer. The declaration of an inline static data member (which is a definition) may specify a brace-or-equal-initializer. If the member is declared with the constexpr specifier, it may be redeclared in namespace scope with no initializer (this usage is deprecated; see D.7). Declarations of other static data members shall not specify a brace-or-equal-initializer.

5 [Note 3: There is exactly one definition of a static data member that is odr-used (6.3) in a valid program. — end note]

6 [Note 4: Static data members of a class in namespace scope have the linkage of the name of the class (6.6). — end note]

11.4.10 Bit-fields [class.bit]

A member-declarator of the form

identifier_opt attribute-specifier-seq_opt : constant-expression brace-or-equal-initializer_opt

specifies a bit-field. The optional attribute-specifier-seq appertains to the entity being declared. A bit-field shall not be a static member. A bit-field shall have integral or enumeration type; the bit-field semantic property is not part of the type of the class member. The constant-expression shall be an integral constant expression with a value greater than or equal to zero and is called the width of the bit-field. If the width of a bit-field is larger than the width of the bit-field’s type (or, in case of an enumeration type, of its underlying type), the extra bits are padding bits (6.8). Allocation of bit-fields within a class object is implementation-defined. Alignment of bit-fields is implementation-defined. Bit-fields are packed into some addressable allocation unit.

[Note 1: Bit-fields straddle allocation units on some machines and not on others. Bit-fields are assigned right-to-left on some machines, left-to-right on others. — end note]

2 A declaration for a bit-field that omits the identifier declares an unnamed bit-field. Unnamed bit-fields are not members and cannot be initialized. An unnamed bit-field shall not be declared with a cv-qualified type.

[Note 2: An unnamed bit-field is useful for padding to conform to externally-imposed layouts. — end note]

As a special case, an unnamed bit-field with a width of zero specifies alignment of the next bit-field at an allocation unit boundary. Only when declaring an unnamed bit-field may the width be zero.

3 The address-of operator & shall not be applied to a bit-field, so there are no pointers to bit-fields. A non-const reference shall not be bound to a bit-field (9.4.4).

[Note 3: If the initializer for a reference of type const T& is an lvalue that refers to a bit-field, the reference is bound to a temporary initialized to hold the value of the bit-field; the reference is not bound to the bit-field directly. See 9.4.4. — end note]

4 If a value of integral type (other than bool) is stored into a bit-field of width N and the value would be representable in a hypothetically signed or unsigned integer type with width N and the same signedness as the bit-field’s type, the original value and the value of the bit-field compare equal. If the value true or false is stored into a bit-field of type bool of any size (including a one bit bit-field), the original bool value and the value of the bit-field compare equal. If a value of an enumeration type is stored into a bit-field of the same type and the width is large enough to hold all the values of that enumeration type (9.7.1), the original value and the value of the bit-field compare equal.

[Example 1:]

    enum BOOL { FALSE=0, TRUE=1 };

§ 11.4.10 276
struct A {
    BOOL b:1;
};
A a;
void f() {
    a.b = TRUE;
    if (a.b == TRUE)  // yields true
        {/* ... */}
}
—end example

11.4.11 Nested class declarations  
A class can be declared within another class. A class declared within another is called a nested class.

[Note 1: See 7.5.4 for restrictions on the use of non-static data members and non-static member functions. — end note]

[Example 1:  
int x;
int y;

struct enclose {
    int x;
    static int s;

    struct inner {
        void f(int i) {
            int a = sizeof(x);  // OK: operand of sizeof is an unevaluated operand
            x = i;             // error: assign to enclose::x
            s = i;             // OK: assign to enclose::s
            ::x = i;           // OK: assign to global x
            y = i;             // OK: assign to global y
        }
    void g(enclose* p, int i) {
        p->x = i;         // OK: assign to enclose::x
    }
};
}

inner* p = 0;  // error: inner not found
—end example]

[Note 2: Nested classes can be defined either in the enclosing class or in an enclosing namespace; member functions and static data members of a nested class can be defined either in the nested class or in an enclosing namespace scope.

[Example 2:  
struct enclose {
    struct inner {
        static int x;
        void f(int i);
    }
};

int enclose::inner::x = 1;

void enclose::inner::f(int i) { /* ... */}

class E {
    class I1;  // forward declaration of nested class
    class I2;
    class I1 {  
    }
};
class E::I2 {  
};  // definition of nested class

§ 11.4.11  277
A friend function (11.8.4) defined within a nested class has no special access rights to members of an enclosing class.

### 11.5 Unions

#### 11.5.1 General

A union is a class defined with the class-key union.

1. In a union, a non-static data member is active if its name refers to an object whose lifetime has begun and has not ended (6.7.3). At most one of the non-static data members of an object of union type can be active at any time, that is, the value of at most one of the non-static data members can be stored in a union at any time.

   [Note 1: One special guarantee is made in order to simplify the use of unions: If a standard-layout union contains several standard-layout structs that share a common initial sequence (11.4), and if a non-static data member of an object of this standard-layout union type is active and is one of the standard-layout structs, it is permitted to inspect the common initial sequence of any of the standard-layout struct members; see 11.4. — end note]

2. The size of a union is sufficient to contain the largest of its non-static data members. Each non-static data member is allocated as if it were the sole member of a non-union class.

   [Note 2: A union object and its non-static data members are pointer-interconvertible (6.8.3, 7.6.1.9). As a consequence, all non-static data members of a union object have the same address. — end note]

3. A union can have member functions (including constructors and destructors), but it shall not have virtual (11.7.3) functions. A union shall not have base classes. A union shall not be used as a base class. If a union contains a non-static data member of reference type the program is ill-formed.

   [Note 3: Absent default member initializers (11.4), if any non-static data member of a union has a non-trivial default constructor (11.4.5.2), copy constructor, move constructor (11.4.5.3), copy assignment operator, move assignment operator (11.4.6), or destructor (11.4.7), the corresponding member function of the union must be user-provided or it will be implicitly deleted (9.5.3) for the union. — end note]

4. When the left operand of an assignment operator involves a member access expression (7.6.1.5) that nominates a union member, it may begin the lifetime of that union member, as described below. For an expression E, define the set S(E) of subexpressions of E as follows:

   - If E is of the form A.B, S(E) contains the elements of S(A), and also contains A.B if B names a union member of a non-class, non-array type, or of a class type with a trivial default constructor that is not deleted, or an array of such types.

   - If E is of the form A[B] and is interpreted as a built-in array subscripting operator, S(E) is S(A) if A is of array type, S(B) if B is of array type, and empty otherwise.

   - Otherwise, S(E) is empty.

In an assignment expression of the form E1 = E2 that uses either the built-in assignment operator (7.6.19) or a trivial assignment operator (11.4.6), for each element X of S(E1), if modification of X would have undefined behavior under 6.7.3, an object of the type of X is implicitly created in the nominated storage; no initialization is performed and the beginning of its lifetime is sequenced after the value computation of the left and right operands and before the assignment.

   [Note 4: This ends the lifetime of the previously-active member of the union, if any (6.7.3). — end note]

5. [Example 1: Consider the following union:

   ```cpp
   union U {
     int i;
     float f;
     std::string s;
   };
   ```

   Since std::string (21.3) declares non-trivial versions of all of the special member functions, U will have an implicitly deleted default constructor, copy/move constructor, copy/move assignment operator, and destructor. To use U, some or all of these member functions must be user-provided. — end example]

   [Example 2: union A { int x; int y[4]; };

§ 11.5.1 278
struct B { A a; };  
union C { B b; int k; };  

int f() {
  C c;  // does not start lifetime of any union member
  c.b.a.y[3] = 4;  // OK: S(c.b.a.y[3]) contains c.b and c.b.a.y;
  // creates objects to hold union members c.b and c.b.a.y
  return c.b.a.y[3];  // OK: c.b.a.y refers to newly created object (see 6.7.3)
}

struct X { const int a; int b; };  
union Y { X x; int k; };  

void g() {
  Y y = { { 1, 2 } };  // OK, y.x is active union member (11.4)
  int n = y.x.a;
  y.k = 4;  // OK: ends lifetime of y.x, y.k is active member of union
  y.x.b = n;  // undefined behavior: y.x.b modified outside its lifetime,
  // S(y.x.b) is empty because X’s default constructor is deleted,
  // so union member y.x’s lifetime does not implicitly start
}

—end example—

7 [Note 5: In cases where the above rule does not apply, the active member of a union can only be changed by the use of a placement new-expression. — end note]

[Example 3: Consider an object u of a union type U having non-static data members m of type M and n of type N. If M has a non-trivial destructor and N has a non-trivial constructor (for instance, if they declare or inherit virtual functions), the active member of u can be safely switched from m to n using the destructor and placement new-expression as follows:
  u.m.~M();
  new (&u.n) N;
—end example—]

11.5.2 Anonymous unions

A union of the form

  union { member-specification } ;

is called an anonymous union; it defines an unnamed type and an unnamed object of that type called an anonymous union member if it is a non-static data member or an anonymous union variable otherwise. Each member-declaration in the member-specification of an anonymous union shall either define one or more public non-static data members or be a static_assert-declaration. Nested types, anonymous unions, and functions shall not be declared within an anonymous union. The names of the members of an anonymous union are bound in the scope inhabited by the union declaration.

[Example 1:

  void f() {
    union { int a; const char* p; };
    a = 1;
    p = "Jennifer";
  }

Here a and p are used like ordinary (non-member) variables, but since they are union members they have the same address. — end example—]

2 Anonymous unions declared in the scope of a namespace with external linkage shall be declared static. Anonymous unions declared at block scope shall be declared with any storage class allowed for a block variable, or with no storage class. A storage class is not allowed in a declaration of an anonymous union in a class scope.

3 [Note 1: A union for which objects, pointers, or references are declared is not an anonymous union.

[Example 2:

  void f() {
    union { int aa; char* p; } obj, *ptr = &obj;
    aa = 1;  // error
  }

§ 11.5.2 279
ptr->aa = 1;     // OK
}

The assignment to plain aa is ill-formed since the member name is not visible outside the union, and even if it were visible, it is not associated with any particular object. — end example
— end note

[Note 2: Initialization of unions with no user-declared constructors is described in 9.4.2. — end note]

4 A union-like class is a union or a class that has an anonymous union as a direct member. A union-like class X has a set of variant members. If X is a union, a non-static data member of X that is not an anonymous union is a variant member of X. In addition, a non-static data member of an anonymous union that is a member of X is also a variant member of X. At most one variant member of a union may have a default member initializer.

[Example 3:]
union U {
    int x = 0;
    union {
        int k;
    }
    union {
        int z;
        int y = 1;     // error: initialization for second variant member of U
    }
};
— end example]

## 11.6 Local class declarations

A class can be declared within a function definition; such a class is called a local class.

[Note 1: A declaration in a local class cannot odr-use (6.3) a local entity from an enclosing scope. — end note]

[Example 1:]
int x;
void f() {
    static int s;
    int x;
    const int N = 5;
    extern int q();
    int arr[2];
    auto [y, z] = arr;

    struct local {
        int g() { return x; }        // error: odr-use of non-odr-usable variable x
        int h() { return s; }        // OK
        int k() { return ::x; }       // OK
        int l() { return q(); }       // OK
        int m() { return N; }         // OK; not an odr-use
        int* n() { return &N; }       // error: odr-use of non-odr-usable variable N
        int p() { return y; }         // error: odr-use of non-odr-usable structured binding y
    };
}

local* p = 0;     // error: local not found
— end example]

2 An enclosing function has no special access to members of the local class; it obeys the usual access rules (11.8). Member functions of a local class shall be defined within their class definition, if they are defined at all.

3 If class X is a local class a nested class Y may be declared in class X and later defined in the definition of class X or be later defined in the same scope as the definition of class X. A class nested within a local class is a local class.

4 [Note 2: A local class cannot have static data members (11.4.9.3). — end note]
11.7 Derived classes

11.7.1 General

A list of base classes can be specified in a class definition using the notation:

```
base-clause:
  : base-specifier-list

base-specifier-list:
  base-specifier ... opt
  , base-specifier-list , base-specifier ... opt

base-specifier:
  attribute-specifier-seq opt class-or-decltype
  attribute-specifier-seq opt virtual access-specifier opt class-or-decltype
  attribute-specifier-seq opt access-specifier virtual opt class-or-decltype

class-or-decltype:
  nested-name-specifier opt type-name
  nested-name-specifier template simple-template-id
decltype-specifier

access-specifier:
  private
  protected
  public
```

The optional attribute-specifier-seq appertains to the base-specifier.

The component names of a class-or-decltype are those of its nested-name-specifier, type-name, and/or simple-template-id. A class-or-decltype shall denote a (possibly cv-qualified) class type that is not an incompletely defined class (11.4); any cv-qualifiers are ignored. The class denoted by the class-or-decltype of a base-specifier is called a direct base class for the class being defined. The lookup for the component name of the type-name or simple-template-id is type-only (6.5). A class \( B \) is a base class of a class \( D \) if it is a direct base class of \( D \) or a direct base class of one of \( D \)'s base classes. A class is an indirect base class of another if it is a base class but not a direct base class. A class is said to be (directly or indirectly) derived from its (direct or indirect) base classes.

[Note 1: See 11.8 for the meaning of access-specifier. — end note]

Members of a base class are also members of the derived class.

[Note 2: Constructors of a base class can be explicitly inherited (9.9). Base class members can be referred to in expressions in the same manner as other members of the derived class, unless their names are hidden or ambiguous (6.5.2). The scope resolution operator :: (7.5.4.3) can be used to refer to a direct or indirect base member explicitly, even if it is hidden in the derived class. A derived class can itself serve as a base class subject to access control; see 11.8.3. A pointer to a derived class can be implicitly converted to a pointer to an accessible unambiguous base class (7.3.12). An lvalue of a derived class type can be bound to a reference to an accessible unambiguous base class (9.4.4). — end note]

3 The base-specifier-list specifies the type of the base class subobjects contained in an object of the derived class type.

[Example 1:]

```
struct Base {
  int a, b, c;
};

struct Derived : Base {
  int b;
};

struct Derived2 : Derived {
  int c;
};
```

Here, an object of class \( \text{Derived2} \) will have a subobject of class \( \text{Derived} \) which in turn will have a subobject of class \( \text{Base} \). — end example]

4 A base-specifier followed by an ellipsis is a pack expansion (13.7.4).

5 The order in which the base class subobjects are allocated in the most derived object (6.7.2) is unspecified.
Note 3: A derived class and its base class subobjects can be represented by a directed acyclic graph (DAG) where an arrow means “directly derived from” (see Figure 3). An arrow need not have a physical representation in memory. A DAG of subobjects is often referred to as a “subobject lattice”. — end note

![Figure 3: Directed acyclic graph](fig:cadg)

Note 4: Initialization of objects representing base classes can be specified in constructors; see 11.9.3. — end note

Note 5: A base class subobject can have a layout different from the layout of a most derived object of the same type. A base class subobject can have a polymorphic behavior (11.9.5) different from the polymorphic behavior of a most derived object of the same type. A base class subobject can be of zero size; however, two subobjects that have the same class type and that belong to the same most derived object cannot be allocated at the same address (6.7.2). — end note

11.7.2 Multiple base classes

A class can be derived from any number of base classes.

Note 1: The use of more than one direct base class is often called multiple inheritance. — end note

Example 1:
```cpp
class A { /* ... */ };
class B { /* ... */ };
class C { /* ... */ };
class D : public A, public B, public C { /* ... */ };
```

— end example

Note 2: The order of derivation is not significant except as specified by the semantics of initialization by constructor (11.9.3), cleanup (11.4.7), and storage layout (11.4, 11.8.2). — end note

A class shall not be specified as a direct base class of a derived class more than once.

Note 3: A class can be an indirect base class more than once and can be a direct and an indirect base class. There are limited things that can be done with such a class; lookup that finds its non-static data members and member functions in the scope of the derived class will be ambiguous. However, the static members, enumerations and types can be unambiguously referred to. — end note

Example 2:
```cpp
class X { /* ... */ };
class Y : public X, public X { /* ... */ }; // error
class L { public: int next; /* ... */ };
class A : public L { /* ... */ };
class B : public L { /* ... */ };
class C : public A, public B { void f(); /* ... */ }; // well-formed
class D : public A, public L { void f(); /* ... */ }; // well-formed
```

— end example

Note 4: A base class specifier that does not contain the keyword `virtual` specifies a non-virtual base class. A base class specifier that contains the keyword `virtual` specifies a virtual base class. For each distinct occurrence of a non-virtual base class in the class lattice of the most derived class, the most derived object (6.7.2) shall contain a corresponding distinct base class subobject of that type. For each distinct base class that is specified virtual, the most derived object shall contain a single base class subobject of that type.

Note 4: For an object of class type C, each distinct occurrence of a (non-virtual) base class L in the class lattice of C corresponds one-to-one with a distinct L subobject within the object of type C. Given the class C defined above, an object of class C will have two subobjects of class L as shown in Figure 4.
In such lattices, explicit qualification can be used to specify which subobject is meant. The body of function `C::f` can refer to the member `next` of each `L` subobject:

```cpp
void C::f() { A::next = B::next; }  // well-formed
```

Without the `A::` or `B::` qualifiers, the definition of `C::f` above would be ill-formed because of ambiguity (6.5.2).

—end note

6 [Note 5: In contrast, consider the case with a virtual base class:

```cpp
class V { /* ... */ };  
class A : virtual public V { /* ... */ };  
class B : virtual public V { /* ... */ };  
class C : public A, public B { /* ... */ };  
```

For an object `c` of class type `C`, a single subobject of type `V` is shared by every base class subobject of `c` that has a virtual base class of type `V`. Given the class `C` defined above, an object of class `C` will have one subobject of class `V`, as shown in Figure 5. —end note

7 [Note 6: A class can have both virtual and non-virtual base classes of a given type.

```cpp
class B { /* ... */ };  
class X : virtual public B { /* ... */ };  
class Y : virtual public B { /* ... */ };  
class Z : public B { /* ... */ };  
class AA : public X, public Y, public Z { /* ... */ };  
```

For an object of class `AA`, all virtual occurrences of base class `B` in the class lattice of `AA` correspond to a single `B` subobject within the object of type `AA`, and every other occurrence of a (non-virtual) base class `B` in the class lattice of `AA` corresponds one-to-one with a distinct `B` subobject within the object of type `AA`. Given the class `AA` defined above, class `AA` has two subobjects of class `B`: `Z`’s `B` and the virtual `B` shared by `X` and `Y`, as shown in Figure 6.

---

**Figure 5**: Virtual base  [fig:class.virt]

**Figure 6**: Virtual and non-virtual base  [fig:class.virtnonvirt]
11.7.3 Virtual functions

A non-static member function is a virtual function if it is first declared with the keyword virtual or if it overrides a virtual member function declared in a base class (see below).\footnote{103} [Note 1: Virtual functions support dynamic binding and object-oriented programming. — end note]

A class with a virtual member function is called a polymorphic class.\footnote{104}

If a virtual member function \( F \) is declared in a class \( B \), and, in a class \( D \) derived (directly or indirectly) from \( B \), a declaration of a member function \( G \) corresponds (6.4.1) to a declaration of \( F \), ignoring trailing requires-clauses, then \( G \) overrides \( F \). For convenience we say that any virtual function overrides itself.

A virtual member function \( V \) of a class object \( S \) is a final overrider unless the most derived class (6.7.2) of which \( S \) is a base class subobject (if any) has another member function that overrides \( V \). In a derived class, if a virtual member function of a base class subobject has more than one final overrider the program is ill-formed.

\textbf{Example 1:}

```c
struct A {
    virtual void f();
};
struct B : virtual A {
    virtual void f();
};
struct C : B, virtual A {
    using A::f;
};

void foo() {
    C c;
    c.f(); // calls B::f, the final overrider
    c.C::f(); // calls A::f because of the using-declaration
}
```

\textbf{Example 2:}

```c
struct A { virtual void f(); }; struct B : A { }; struct C : A { void f(); }; struct D : B, C { }; // OK: A::f and C::f are the final overriders // for the B and C subobjects, respectively
```

\textbf{Note 2:} A virtual member function does not have to be visible to be overridden, for example,

```c
struct B {
    virtual void f();
};
struct D : B {
    void f(int);
};
struct D2 : D {
    void f();
};
```

the function \( f(int) \) in class \( D \) hides the virtual function \( f() \) in its base class \( B \); \( D::f(int) \) is not a virtual function. However, \( f() \) declared in class \( D2 \) has the same name and the same parameter list as \( B::f(), \) and therefore is a virtual function that overrides the function \( B::f() \) even though \( B::f() \) is not visible in class \( D2 \). — end note]

\footnote{103} The use of the virtual specifier in the declaration of an overriding function is valid but redundant (has empty semantics).
\footnote{104} If all virtual functions are immediate functions, the class is still polymorphic even if its internal representation does not otherwise require any additions for that polymorphic behavior.
\footnote{105} A function with the same name but a different parameter list (Clause 12) as a virtual function is not necessarily virtual and does not override. Access control (11.8) is not considered in determining overriding.
If a virtual function \( f \) in some class \( \text{B} \) is marked with the `virt-specifier` `final` and in a class \( \text{D} \) derived from \( \text{B} \) a function \( \text{D}::f \) overrides \( \text{B}::f \), the program is ill-formed.

[Example 3:]

\[
\begin{aligned}
\text{struct B} & \{ \\
\text{virtual void f()} \text{ const final;}
\}; \\
\text{struct D} & : \text{B} \{ \\
\text{void f()} \text{ const;} & \quad \text{\textit{// error: D::f attempts to override final B::f}}
\}; \\
\end{aligned}
\]

— end example]

If a virtual function is marked with the `virt-specifier` `override` and does not override a member function of a base class, the program is ill-formed.

[Example 4:]

\[
\begin{aligned}
\text{struct B} & \{ \\
\text{virtual void f(int);} \\
\}; \\
\text{struct D} & : \text{B} \{ \\
\text{virtual void f(long) override;} & \quad \text{\textit{// error: wrong signature overriding B::f}}
\text{virtual void f(int) override;} & \quad \text{\textit{// OK}}
\}; \\
\end{aligned}
\]

— end example]

A virtual function shall not have a trailing `requires-clause` (9.3).

[Example 5:]

\[
\begin{aligned}
\text{template<typename T> struct A} & \{ \\
\text{virtual void f()} \text{ requires true;} & \quad \text{\textit{// error: virtual function cannot be constrained (13.5.3)}}
\}; \\
\end{aligned}
\]

— end example]

The return type of an overriding function shall be either identical to the return type of the overridden function or covariant with the classes of the functions. If a function \( \text{D}::f \) overrides a function \( \text{B}::f \), the return types of the functions are covariant if they satisfy the following criteria:

1. Both are pointers to classes, both are lvalue references to classes, or both are rvalue references to classes.
2. The class in the return type of \( \text{B}::f \) is the same class as the class in the return type of \( \text{D}::f \), or is an unambiguous and accessible direct or indirect base class of the class in the return type of \( \text{D}::f \).
3. Both pointers or references have the same cv-qualification and the class type in the return type of \( \text{D}::f \) has the same cv-qualification as or less cv-qualification than the class type in the return type of \( \text{B}::f \).

If the class type in the covariant return type of \( \text{D}::f \) differs from that of \( \text{B}::f \), the class type in the return type of \( \text{D}::f \) shall be complete at the locus (6.4.2) of the overriding declaration or shall be the class type \( \text{D} \). When the overriding function is called as the final overrider of the overridden function, its result is converted to the type returned by the (statically chosen) overridden function (7.6.1.3).

[Example 6:]

\[
\begin{aligned}
\text{class B} & \{ \}; \\
\text{class D} & : \text{private B} \{ \text{friend class Derived;} \}; \\
\text{struct Base} & \{ \\
\text{virtual void vf1();} \\
\text{virtual void vf2();} \\
\text{virtual void vf3();} \\
\text{virtual B* vf4();} \\
\text{virtual B* vf5();} \\
\text{void f();}
\};
\end{aligned}
\]

106) Multi-level pointers to classes or references to multi-level pointers to classes are not allowed.
struct No_good : public Base {
    D* vf4(); // error: B (base class of D) inaccessible
};

class A;
struct Derived : public Base {
    void vf1(); // virtual and overrides Base::vf1()
    void vf2(int); // not virtual, hides Base::vf2()
    char vf3(); // error: invalid difference in return type only
    D* vf4(); // OK: returns pointer to derived class
    A* vf5(); // error: returns pointer to incomplete class
    void f();
};

void g() {
    Derived d;
    Base* bp = &d; // standard conversion:
        Derived* to Base*
    bp->vf1(); // calls Derived::vf1()
    bp->vf2(); // calls Base::vf2()
    bp->f(); // calls Base::f() (not virtual)
    B* p = bp->vf4(); // calls Derived::vf4() and converts the
        result to B*
    Derived* dp = &d; // calls Derived::vf4() and does not
        convert the result to B*
    D* q = dp->vf4(); // error: argument mismatch
    dp->vf2();
}

—end example|

[Note 3: The interpretation of the call of a virtual function depends on the type of the object for which it is called (the dynamic type), whereas the interpretation of a call of a non-virtual member function depends only on the type of the pointer or reference denoting that object (the static type) (7.6.1.3). — end note]

[Note 4: The virtual specifier implies membership, so a virtual function cannot be a non-member (9.2.3) function. Nor can a virtual function be a static member, since a virtual function call relies on a specific object for determining which function to invoke. A virtual function declared in one class can be declared a friend (11.8.4) in another class. — end note]

A virtual function declared in a class shall be defined, or declared pure (11.7.4) in that class, or both; no diagnostic is required (6.3).

[Example 7: Here are some uses of virtual functions with multiple base classes:

struct A {
    virtual void f();
};

struct B1 : A {
    // note non-virtual derivation
    void f();
};

struct B2 : A {
    void f();
};

struct D : B1, B2 {
    // D has two separate A subobjects
};

void foo() {
    D d;
    // A* ap = &d; // would be ill-formed: ambiguous
    B1* b1p = &d;
    A* ap = b1p;
    D* dp = &d;
    ap->f(); // calls D::B1::f
In class D above there are two occurrences of class A and hence two occurrences of the virtual member function A::f. The final overrider of B1::A::f is B1::f and the final overrider of B2::A::f is B2::f. — end example

[Example 8: The following example shows a function that does not have a unique final overrider:

```cpp
struct A {
    virtual void f();
};

struct VB1 : virtual A {
    // note virtual derivation
    void f();
};

struct VB2 : virtual A {
    void f();
};

struct Error : VB1, VB2 {
    // error
};

struct Okay : VB1, VB2 {
    void f();
};
```

Both VB1::f and VB2::f override A::f but there is no overrider of both of them in class Error. This example is therefore ill-formed. Class Okay is well-formed, however, because Okay::f is a final overrider. — end example]

[Example 9: The following example uses the well-formed classes from above.

```cpp
struct VB1a : virtual A {
    // does not declare f
};

struct Da : VB1a, VB2 {
};

void foe() {
    VB1a* vblap = new Da;
    vblap->f(); // calls VB2::f
}
```

— end example]

Explicit qualification with the scope operator (7.5.4.3) suppresses the virtual call mechanism.

[Example 10:

```cpp
class B { public: virtual void f(); }; 
class D : public B { public: void f(); }; 

void D::f() { /* ... */ B::f(); } 
```

Here, the function call in D::f really does call B::f and not D::f. — end example]

A deleted function (9.5) shall not override a function that is not deleted. Likewise, a function that is not deleted shall not override a deleted function.

A constexpr virtual function shall not override a virtual function that is not constexpr. A constexpr virtual function shall not be overridden by a virtual function that is not constexpr.

11.7.4 Abstract classes [class.abstract]

[Note 1: The abstract class mechanism supports the notion of a general concept, such as a shape, of which only more concrete variants, such as circle and square, can actually be used. An abstract class can also be used to define an interface for which derived classes provide a variety of implementations. — end note]

A virtual function is specified as a pure virtual function by using a pure-specifier (11.4) in the function declaration in the class definition.

[Note 2: Such a function might be inherited: see below. — end note]

A class is an abstract class if it has at least one pure virtual function.
A pure virtual function need be defined only if called with, or as if with (11.4.7), the qualified-id syntax (7.5.4.3).

Example 1:
```cpp
class point { /* ... */ };  // abstract class
class shape {
    point center;
    public:
    point where() { return center; }
    void move(point p) { center=p; draw(); }
    virtual void rotate(int) = 0;  // pure virtual
    virtual void draw() = 0;      // pure virtual
};
```

Example 2:
```cpp
struct C {
    virtual void f() = 0 { };  // error
};
```

Example 3:
```cpp
class ab_circle : public shape {
    int radius;
    public:
    void rotate(int) { }
    // ab_circle::draw() is a pure virtual
};
```

Since shape::draw() is a pure virtual function ab_circle::draw() is a pure virtual by default. The alternative declaration,
```cpp
class circle : public shape {
    int radius;
    public:
    void rotate(int) { }
    void draw();  // a definition is required somewhere
};
```

would make class circle non-abstract and a definition of circle::draw() must be provided. — end example]

Note 6: An abstract class can be derived from a class that is not abstract, and a pure virtual function can override a virtual function which is not pure. — end note]

Member functions can be called from a constructor (or destructor) of an abstract class; the effect of making a virtual call (11.7.3) to a pure virtual function directly or indirectly for the object being created (or destroyed) from such a constructor (or destructor) is undefined.

11.8 Member access control [class.access]

11.8.1 General [class.access.general]

A member of a class can be

1. private, that is, it can be named only by members and friends of the class in which it is declared;
2. protected, that is, it can be named only by members and friends of the class in which it is declared, by classes derived from that class, and by their friends (see 11.8.5); or
3. public, that is, it can be named anywhere without access restriction.
A constructor or destructor can be named by an expression (6.3) even though it has no name. — end note

A member of a class can also access all the members to which the class has access. A local class of a member function may access the same members that the member function itself may access.\(^\text{107}\)

Members of a class defined with the keyword `class` are `private` by default. Members of a class defined with the keywords `struct` or `union` are public by default.

[Example 1:
```c
class X {
  int a;     // X::a is private by default
};

struct S {
  int a;     // S::a is public by default
};
```
] — end example]

Access control is applied uniformly to declarations and expressions.

[Note 2: Access control applies to members nominated by friend declarations (11.8.4) and using-declarations (9.9). — end note]

When a using-declarator is named, access control is applied to it, not to the declarations that replace it. For an overload set, access control is applied only to the function selected by overload resolution.

[Note 3: Because access control applies to the declarations named, if access control is applied to a typedef name, only the accessibility of the typedef name itself is considered. The accessibility of the entity referred to by the typedef is not considered. For example,
```c
class A {
  typedef int I;  // private member
  int f();
  friend I g(I);
  static I x;
  template<int> struct Q;
  template<int> friend struct R;
private:
  struct B { };   // B is public
};
```
] — end note]

Access control does not prevent members from being found by name lookup or implicit conversions to base classes from being considered. — end note]

The interpretation of a given construct is established without regard to access control. If the interpretation established makes use of inaccessible members or base classes, the construct is ill-formed.

All access controls in 11.8 affect the ability to name a class member from the declaration of a particular entity, including parts of the declaration preceding the name of the entity being declared and, if the entity is a class, the definitions of members of the class appearing outside the class’s member-specification.

[Note 5: This access also applies to implicit references to constructors, conversion functions, and destructors. — end note]

[Example 2:
```c
class A {
  typedef int I;  // private member
  int f();
  friend I g(I);
  static I x;
  template<int> struct Q;
  template<int> friend struct R;
protected:
  struct B { };   // B is public
};
```
] 107) Access permissions are thus transitive and cumulative to nested and local classes.
Here, all the uses of A::I are well-formed because A::f, A::x, and A::Q are members of class A and g and R are friends of class A. This implies, for example, that access checking on the first use of A::I must be deferred until it is determined that this use of A::I is the return type of a member of class A. Similarly, the use of A::B as a base-specifier is well-formed because D is derived from A, so checking of base-specifiers must be deferred until the entire base-specifier-list has been seen. —end example[

Access is checked for a default argument (9.3.4.7) at the point of declaration, rather than at any points of use of the default argument. Access checking for default arguments in function templates and in member functions of class templates is performed as described in 13.9.2.

Access for a default template-argument (13.2) is checked in the context in which it appears rather than at any points of use of it.

[Example 3:

```cpp
class B { }
template <class T> class C {
protected:
    typedef T TT;
};
template <class U, class V = typename U::TT> class D : public U { }
D<C<B>> d;  // access error, C::TT is protected
@end example]

11.8.2 Access specifiers [class.access.spec]

Member declarations can be labeled by an access-specifier (11.7):

access-specifier : member-specification opt

An access-specifier specifies the access rules for members following it until the end of the class or until another access-specifier is encountered.

[Example 1:

```cpp
class X {
    int a; // X::a is private by default: class used
    public:
        int b; // X::b is public
        int c; // X::c is public
};
@end example]

Any number of access specifiers is allowed and no particular order is required.

[Example 2:

```cpp
struct S {
    int a; // S::a is public by default: struct used
    protected:
        int b; // S::b is protected
    private:
        int c; // S::c is private
    public:
        int d; // S::d is public
};
@end example]
[Note 1: The effect of access control on the order of allocation of data members is specified in 7.6.9. — end note]

When a member is redeclared within its class definition, the access specified at its redeclaration shall be the same as at its initial declaration.

[Example 3:

```c
struct S {
    class A;
    enum E : int;
    private:
        class A { }; // error: cannot change access
        // error: cannot change access
    enum E: int { e0 }
};
```
—end example]

[Note 2: In a derived class, the lookup of a base class name will find the injected-class-name instead of the name of the base class in the scope in which it was declared. The injected-class-name might be less accessible than the name of the base class in the scope in which it was declared. — end note]

[Example 4:

```c
class A { }
class B : private A { }
class C : public B {
    A* p; // error: injected-class-name A is inaccessible
    ::A* q; // OK
};
```
—end example]

### 11.8.3 Accessibility of base classes and base class members [class.access.base]

1 If a class is declared to be a base class (11.7) for another class using the `public` access specifier, the public members of the base class are accessible as public members of the derived class and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the `protected` access specifier, the public and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the `private` access specifier, the public and protected members of the base class are accessible as private members of the derived class.108

2 In the absence of an `access-specifier` for a base class, `public` is assumed when the derived class is defined with the `class-key struct` and `private` is assumed when the class is defined with the `class-key class`.

[Example 1:

```c
class B { /* ... */ };
class D1 : private B { /* ... */ };
class D2 : public B { /* ... */ };
class D3 : B { /* ... */ }; // B private by default
struct D4 : public B { /* ... */ };
struct D5 : private B { /* ... */ };
struct D6 : B { /* ... */ }; // B public by default
class D7 : protected B { /* ... */ };
struct D8 : protected B { /* ... */ };
```
Here `B` is a public base of `D2`, `D4`, and `D6`, a private base of `D1`, `D3`, and `D5`, and a protected base of `D7` and `D8`. —end example]

3 [Note 1: A member of a private base class can be inaccessible as inherited, but accessible directly. Because of the rules on pointer conversions (7.3.12) and explicit casts (7.6.1.4, 7.6.1.9, 7.6.3), a conversion from a pointer to a derived class to a pointer to an inaccessible base class can be ill-formed if an implicit conversion is used, but well-formed if an explicit cast is used. For example,

```c
class B {
    public:
    int mi; // non-static member
```
static int si;  // static member
};
class D : private B {
};
class DD : public D {
    void f();
};

void DD::f() {
    mi = 3;  // error: mi is private in D
    si = 3;  // error: si is private in D
    ::B b;
    b.mi = 3;  // OK (b.mi is different from this->mi)
    b.si = 3;  // OK (b.si is different from this->si)
    ::B::si = 3;  // OK
    ::B* bp1 = this;  // error: B is a private base class
    ::B* bp2 = (::B*)this;  // OK with cast
    bp2->mi = 3;  // OK: access through a pointer to B.
}

—end note

4 A base class B of N is accessible at R, if

(4.1) — an invented public member of B would be a public member of N, or
(4.2) — R occurs in a direct member or friend of class N, and an invented public member of B would be a private or protected member of N, or
(4.3) — R occurs in a direct member or friend of a class P derived from N, and an invented public member of B would be a private or protected member of P, or
(4.4) — there exists a class S such that B is a base class of S accessible at R and S is a base class of N accessible at R.

[Example 2:

class B {
    public:
        int m;
};

class S: private B {
    friend class N;
};

class N: private S {
    void f() {
        B* p = this;  // OK because class S satisfies the fourth condition above: B is a base class of N
        // accessible in f() because B is an accessible base class of S and S is an accessible
        // base class of N.
    }
};

—end example]

5 If a base class is accessible, one can implicitly convert a pointer to a derived class to a pointer to that base class (7.3.12, 7.3.13).

[Note 2: It follows that members and friends of a class X can implicitly convert an X* to a pointer to a private or protected immediate base class of X. — end note]

The access to a member is affected by the class in which the member is named. This naming class is the class in whose scope name lookup performed a search that found the member.

[Note 3: This class can be explicit, e.g., when a qualified-id is used, or implicit, e.g., when a class member access operator (7.6.1.5) is used (including cases where an implicit “this->” is added). If both a class member access operator and a qualified-id are used to name the member (as in p->T::m), the class naming the member is the class denoted by the nested-name-specifier of the qualified-id (that is, T). — end note]

A member m is accessible at the point R when named in class N if

§ 11.8.3
(5.1) — \( m \) as a member of \( N \) is public, or

(5.2) — \( m \) as a member of \( N \) is private, and \( R \) occurs in a direct member or friend of class \( N \), or

(5.3) — \( m \) as a member of \( N \) is protected, and \( R \) occurs in a direct member or friend of class \( N \), or in a member of a class \( P \) derived from \( N \), where \( m \) as a member of \( P \) is public, private, or protected, or

(5.4) — there exists a base class \( B \) of \( N \) that is accessible at \( R \), and \( m \) is accessible at \( R \) when named in class \( B \).

[Example 3:

```cpp
class B;
class A {
private:
    int i;
    friend void f(B*);
};
class B : public A { };
void f(B* p) {
    p->i = 1;  // OK: B* can be implicitly converted to A*, and f has access to i in A
}
```

— end example]

6 If a class member access operator, including an implicit “\texttt{this->}”, is used to access a non-static data member or non-static member function, the reference is ill-formed if the left operand (considered as a pointer in the “.” operator case) cannot be implicitly converted to a pointer to the naming class of the right operand.

[Note 4: This requirement is in addition to the requirement that the member be accessible as named. — end note]

11.8.4 Friends [class.friend]

1 A friend of a class is a function or class that is given permission to name the private and protected members of the class. A class specifies its friends, if any, by way of friend declarations. Such declarations give special access rights to the friends, but they do not make the nominated friends members of the befriending class.

[Example 1: The following example illustrates the differences between members and friends:

```cpp
class X {
    int a;
    friend void friend_set(X*, int);
public:
    void member_set(int);
};

void friend_set(X* p, int i) { p->a = i; }
void X::member_set(int i) { a = i; }

void f() {
    X obj;
    friend_set(&obj,10);
    obj.member_set(10);
}
```

— end example]

2 Declaring a class to be a friend implies that private and protected members of the class granting friendship can be named in the base-specifiers and member declarations of the befriended class.

[Example 2:

```cpp
class A {
    class B { };
    friend class X;
};

struct X : A::B { // OK: A::B accessible to friend
    A::B mx;
    // OK: A::B accessible to member of friend
    class Y {
        A::B my;
        // OK: A::B accessible to nested member of friend
    };
};
```
A friend declaration that does not declare a function shall have one of the following forms:

friend elaborated-type-specifier;
friend simple-type-specifier;
friend typename-specifier;

[Note 1: A friend declaration can be the declaration in a template-declaration (13.1, 13.7.5). — end note]

If the type specifier in a friend declaration designates a (possibly cv-qualified) class type, that class is declared as a friend; otherwise, the friend declaration is ignored.

[Example 4:

class C;
typedef C Ct;

class X1 {
    friend C;
    // OK: class C is a friend
};

class X2 {
    friend Ct;
    // OK: class C is a friend
    friend D;
    // error: D not found
    friend class D;
    // OK: elaborated-type-specifier declares new class
};

template <typename T> class R {
    friend T;
};

R<C> rc;
// class C is a friend of R<C>
R<int> Ri;
// OK: "friend int;" is ignored

— end example]

4 A function first declared in a friend declaration has the linkage of the namespace of which it is a member (6.6). Otherwise, the function retains its previous linkage (9.2.2).

[Note 2: A friend declaration refers to an entity, not (all overloads of) a name. A member function of a class X can be a friend of a class Y.

[Example 5:

class Y {
    friend char* X::foo(int);
    friend X::X(char);
    // constructors can be friends
    friend X::~X();
    // destructors can be friends
};

— end example]

— end note]
A function may be defined in a friend declaration of a class if and only if the class is a non-local class (11.6) and the function name is unqualified.

[Example 6:]
```cpp
class M {
friend void f() { }
};
```

Such a function is implicitly an inline (9.2.8) function if it is attached to the global module.

[Note 3: If a friend function is defined outside a class, it is not in the scope of the class. — end note]

No storage-class-specifier shall appear in the decl-specifier-seq of a friend declaration.

A member nominated by a friend declaration shall be accessible in the class containing the friend declaration. The meaning of the friend declaration is the same whether the friend declaration appears in the private, protected, or public (11.4) portion of the class member-specification.

Friendship is neither inherited nor transitive.

[Example 7:]
```cpp
class A {
friend class B;
int a;
};

class B {
friend class C;
};

class C {
void f(A* p) {
p->a++;
}  // error: C is not a friend of A despite being a friend of a friend
};

class D : public B {
void f(A* p) {
p->a++;
}  // error: D is not a friend of A despite being derived from a friend
};
```

[Note 4: A friend declaration never binds any names (9.3.4, 9.2.9.4). — end note]

[Example 8:]
```cpp
// Assume f and g have not yet been declared.
void h(int);
template <class T> void f2(T);
namespace A {

class X {
friend void f(X);  // A::f(X) is a friend
friend void g();  // A::g is a friend
friend void h(int);  // A::h is a friend
friend void f2<> (int);  // ::f2<> (int) is a friend

void g() { f(x); }  // definition of A::g
void f(X) { /* ... */ }  // definition of A::f
void h(int) { /* ... */ }  // definition of A::h
```
using A::x;

void h() {
  A::f(x);
  A::X::f(x);     // error: f is not a member of A::X
  A::X::Y::g();   // error: g is not a member of A::X::Y
}

— end example]

[Example 9:

class X;
void a();
void f() {
  class Y;
  extern void b();
  class A {
    friend class X; // OK, but X is a local class, not ::X
    friend class Y; // OK
    friend class Z; // OK, introduces local class Z
    friend void a(); // error, ::a is not considered
    friend void b(); // OK
    friend void c(); // error
  };
  X* px;        // OK, but ::X is found
  Z* pz;        // error: no Z is found
}

— end example]

11.8.5 Protected member access [class.protected]

An additional access check beyond those described earlier in 11.8 is applied when a non-static data member
or non-static member function is a protected member of its naming class (11.8.3). As described earlier,
access to a protected member is granted because the reference occurs in a friend or direct member of some
class C. If the access is to form a pointer to member (7.6.2.2), the nested-name-specifier shall denote
C or a class derived from C. All other accesses involve a (possibly implicit) object expression (7.6.1.5). In this case,
the class of the object expression shall be C or a class derived from C.

[Example 1:

class B {
  protected:
    int i;
    static int j;
};

class D1 : public B {
};

class D2 : public B {
  friend void fr(B*,D1*,D2*);
  void mem(B*,D1*);
};

void fr(B* pb, D1* p1, D2* p2) {
  pb->i = 1;        // error
  p1->i = 2;        // error
  p2->i = 3;        // OK (access through a D2)
  p2->B::i = 4;     // OK (access through a D2, even though naming class is B)
  int B::* pmi_B = &B::i; // error
  int B::* pmi_B2 = &D2::i; // OK (type of &D2::i is int B::*)

109) This additional check does not apply to other members, e.g., static data members or enumerator member constants.
B::j = 5;  // error: not a friend of naming class B
D2::j = 6;  // OK (because refers to static member)
}

void D2::mem(B* pb, D1* p1) {
    pb->i = 1;   // error
    p1->i = 2;   // error
    i = 3;      // OK (access through this)
    B::i = 4;   // OK (access through this, qualification ignored)
    int B::* pmi_B = &B::i;
    int B::* pmi_B2 = &D2::i;
    j = 5;      // OK (because j refers to static member)
    B::j = 6;   // OK (because B::j refers to static member)
}

void g(B* pb, D1* p1, D2* p2) {
    pb->i = 1;   // error
    p1->i = 2;   // error
    p2->i = 3;   // error
}

—end example—

11.8.6 Access to virtual functions

The access rules (11.8) for a virtual function are determined by its declaration and are not affected by the rules for a function that later overrides it.

[Example 1:

```c
class B {
public:
    virtual int f();
};

class D : public B {
private:
    int f();
};

void f() {
    D d;
    B* pb = &d;
    D* pd = &d;
    pb->f();   // OK: B::f() is public, D::f() is invoked
    pd->f();   // error: D::f() is private
}
```
—end example—

2 Access is checked at the call point using the type of the expression used to denote the object for which the member function is called (B* in the example above). The access of the member function in the class in which it was defined (D in the example above) is in general not known.

11.8.7 Multiple access

If a declaration can be reached by several paths through a multiple inheritance graph, the access is that of the path that gives most access.

[Example 1:

```c
class W { public: void f(); };  
class A : private virtual W { };  
class B : public virtual W { };  
class C : public A, public B {
    void f() { W::*f(); }  // OK
};
```

Since W::*f() is available to C::*f() along the public path through B, access is allowed. —end example—

§ 11.8.7 297
11.8.8 Nested classes

A nested class is a member and as such has the same access rights as any other member. The members of an enclosing class have no special access to members of a nested class; the usual access rules (11.8) shall be obeyed.

[Example 1:

class E {
    int x;
    class B { };

class I {
    B b;       // OK: E::I can access E::B
    int y;
    void f(E* p, int i) {
        p->x = i;   // OK: E::I can access E::x
    }
};

    int g(I* p) {
        return p->y;   // error: I::y is private
    }
};
—end example]

11.9 Initialization

11.9.1 General

When no initializer is specified for an object of (possibly cv-qualified) class type (or array thereof), or the initializer has the form (), the object is initialized as specified in 9.4.

An object of class type (or array thereof) can be explicitly initialized; see 11.9.2 and 11.9.3.

When an array of class objects is initialized (either explicitly or implicitly) and the elements are initialized by constructor, the constructor shall be called for each element of the array, following the subscript order; see 9.3.4.5.

[Note 1: Destructors for the array elements are called in reverse order of their construction. — end note]

11.9.2 Explicit initialization

An object of class type can be initialized with a parenthesized expression-list, where the expression-list is construed as an argument list for a constructor that is called to initialize the object. Alternatively, a single assignment-expression can be specified as an initializer using the = form of initialization. Either direct-initialization semantics or copy-initialization semantics apply; see 9.4.

[Example 1:

struct complex {
    complex();
    complex(double);
    complex(double,double);
};

complex sqrt(complex,complex);

complex a(1);       // initialized by calling complex(double) with argument 1
complex b = a;       // initialized as a copy of a
complex c = complex(1,2); // initialized by calling complex(double,double) with arguments 1 and 2
complex d = sqrt(b,c); // initialized by calling sqrt(complex,complex) with d as its result object
complex e;           // initialized by calling complex()
complex f = 3;        // initialized by calling complex(double) with argument 3
complex g = { 1, 2 }; // initialized by calling complex(double, double) with arguments 1 and 2
—end example]

[Note 1: Overloading of the assignment operator (12.4.3.2) has no effect on initialization. — end note]
An object of class type can also be initialized by a \textit{braced-init-list}. List-initialization semantics apply; see 9.4 and 9.4.5.

\begin{example}
\begin{verbatim}
complex v[6] = { 1, complex(1,2), complex(), 2 };
\end{verbatim}
\end{example}

Here, \texttt{complex::complex(double)} is called for the initialization of \texttt{v[0]} and \texttt{v[3]}, \texttt{complex::complex(double, double)} is called for the initialization of \texttt{v[1]}, \texttt{complex::complex()} is called for the initialization \texttt{v[2]}, \texttt{v[4]}, and \texttt{v[5]}. For another example,

\begin{verbatim}
struct X {
    int i;
    float f;
    complex c;
} x = { 99, 88.8, 77.7 };
\end{verbatim}

Here, \texttt{x.i} is initialized with 99, \texttt{x.f} is initialized with 88.8, and \texttt{complex::complex(double)} is called for the initialization of \texttt{x.c}. —end example

\begin{note}
Braces can be elided in the \textit{initializer-list} for any aggregate, even if the aggregate has members of a class type with user-defined type conversions; see 9.4.2. —end note
\end{note}

\begin{note}
If \( T \) is a class type with no default constructor, any declaration of an object of type \( T \) (or array thereof) is ill-formed if no \textit{initializer} is explicitly specified (see 11.9 and 9.4). —end note
\end{note}

\begin{note}
The order in which objects with static or thread storage duration are initialized is described in 6.9.3.3 and 8.8. —end note
\end{note}

\subsection{Initializing bases and members \hfill [class.base.init]}

In the definition of a constructor for a class, initializers for direct and virtual base class subobjects and non-static data members can be specified by a \textit{ctor-initializer}, which has the form

\begin{verbatim}
ctor-initializer:
    : mem-initializer-list
mem-initializer-list:
    mem-initializer \opt
    mem-initializer-list , mem-initializer \opt
mem-initializer:
    mem-initializer-id ( expression-list \opt )
    mem-initializer-id braced-init-list
mem-initializer-id:
    class-or-decltype
    identifier
\end{verbatim}

Lookup for an unqualified name in a \textit{mem-initializer-id} ignores the constructor’s function parameter scope.

\begin{note}
If the constructor’s class contains a member with the same name as a direct or virtual base class of the class, a \textit{mem-initializer-id} naming the member or base class and composed of a single identifier refers to the class member. A \textit{mem-initializer-id} for the hidden base class can be specified using a qualified name. —end note
\end{note}

Unless the \textit{mem-initializer-id} names the constructor’s class, a non-static data member of the constructor’s class, or a direct or virtual base of that class, the \textit{mem-initializer} is ill-formed.

A \textit{mem-initializer-list} can initialize a base class using any \textit{class-or-decltype} that denotes that base class type.

\begin{example}
\begin{verbatim}
struct A { A(); };
typedef A global_A;
struct B { };
struct C: public A, public B { C(); };
C::C(): global_A() { }  // mem-initializer for base A
\end{verbatim}
\end{example}

\begin{note}
If a \textit{mem-initializer-id} is ambiguous because it designates both a direct non-virtual base class and an indirect virtual base class, the \textit{mem-initializer} is ill-formed.
\end{note}

\begin{example}
\begin{verbatim}
struct A { A(); };
struct B: public virtual A { };
\end{verbatim}
\end{example}
struct C: public A, public B { C(); };  
C::C(): A() { }  // error: which A?

— end example]

5 A ctor-initializer may initialize a variant member of the constructor’s class. If a ctor-initializer specifies more than one mem-initializer for the same member or for the same base class, the ctor-initializer is ill-formed.

6 A mem-initializer-list can delegate to another constructor of the constructor’s class using any class-or-decltype that denotes the constructor’s class itself. If a mem-initializer-id designates the constructor’s class, it shall be the only mem-initializer; the constructor is a delegating constructor, and the constructor selected by the mem-initializer is the target constructor. The target constructor is selected by overload resolution. Once the target constructor returns, the body of the delegating constructor is executed. If a constructor delegates to itself directly or indirectly, the program is ill-formed, no diagnostic required.

[Example 3]:

struct C {
    C( int ) { }  // #1: non-delegating constructor
    C( char c ) : C(42.0) { }  // #2: delegates to #1
    C( double d ) : C(‘a’) { }  // #3: ill-formed due to recursion with #4
};

— end example

7 The expression-list or braced-init-list in a mem-initializer is used to initialize the designated subobject (or, in the case of a delegating constructor, the complete class object) according to the initialization rules of 9.4 for direct-initialization.

[Example 4]:

struct B1 { B1(int); /* ... */
};
struct B2 { B2(int); /* ... */
};
struct D : B1, B2 {
    D(int);
    B1 b;
    const int c;
};

D::D(int a) : B2(a+1), B1(a+2), c(a+3), b(a+4) { /* ... */
D d(10);
— end example

[Note 2]: The initialization performed by each mem-initializer constitutes a full-expression (6.9.1). Any expression in a mem-initializer is evaluated as part of the full-expression that performs the initialization. — end note]

A mem-initializer where the mem-initializer-id denotes a virtual base class is ignored during execution of a constructor of any class that is not the most derived class.

8 A temporary expression bound to a reference member in a mem-initializer is ill-formed.

[Example 5]:

struct A {
    A() : v(42) { }  // error
    const int& v;
};

— end example

9 In a non-delegating constructor, if a given potentially constructed subobject is not designated by a mem-initializer-id (including the case where there is no mem-initializer-list because the constructor has no ctor-initializer), then

(9.1) — if the entity is a non-static data member that has a default member initializer (11.4) and either

(9.1.1) — the constructor’s class is a union (11.5), and no other variant member of that union is designated by a mem-initializer-id or

(9.1.2) — the constructor’s class is not a union, and, if the entity is a member of an anonymous union, no other member of that union is designated by a mem-initializer-id,
the entity is initialized from its default member initializer as specified in 9.4;

— otherwise, if the entity is an anonymous union or a variant member (11.5.2), no initialization is performed;

— otherwise, the entity is default-initialized (9.4).

[Note 3: An abstract class (11.7.4) is never a most derived class, thus its constructors never initialize virtual base classes, therefore the corresponding mem-initializers can be omitted. — end note]

An attempt to initialize more than one non-static data member of a union renders the program ill-formed.

[Note 4: After the call to a constructor for class X for an object with automatic or dynamic storage duration has completed, if the constructor was not invoked as part of value-initialization and a member of X is neither initialized nor given a value during execution of the compound-statement of the body of the constructor, the member has an indeterminate value. — end note]

[Example 6]:

```cpp
struct A {
    A();
};

struct B {
    B(int);
};

struct C {
    C() { } // initializes members as follows:
    A a; // OK: calls A::A()
    const B b; // error: B has no default constructor
    int i; // OK: i has indeterminate value
    int j = 5; // OK: j has the value 5
};
```

—end example]

10 If a given non-static data member has both a default member initializer and a mem-initializer, the initialization specified by the mem-initializer is performed, and the non-static data member’s default member initializer is ignored.

[Example 7: Given]

```cpp
struct A {
    int i = /* some integer expression with side effects */ ;
    A(int arg) : i(arg) { } // ...
};
```

the A(int) constructor will simply initialize i to the value of arg, and the side effects in i’s default member initializer will not take place. —end example]

11 A temporary expression bound to a reference member from a default member initializer is ill-formed.

[Example 8]:

```cpp
struct A {
    A() = default; // OK
    A(int v) : v(v) { } // OK
    const int& v = 42; // OK
};
```

```cpp
A a1; // error: ill-formed binding of temporary to reference
A a2(1); // OK, unfortunately
```

—end example]

12 In a non-delegating constructor, the destructor for each potentially constructed subobject of class type is potentially invoked (11.4.7).

[Note 5: This provision ensures that destructors can be called for fully-constructed subobjects in case an exception is thrown (14.3). — end note]

13 In a non-delegating constructor, initialization proceeds in the following order:
(13.1) First, and only for the constructor of the most derived class (6.7.2), virtual base classes are initialized in the order they appear on a depth-first left-to-right traversal of the directed acyclic graph of base classes, where “left-to-right” is the order of appearance of the base classes in the derived class base-specifier-list.

(13.2) Then, direct base classes are initialized in declaration order as they appear in the base-specifier-list (regardless of the order of the mem-initializers).

(13.3) Then, non-static data members are initialized in the order they were declared in the class definition (again regardless of the order of the mem-initializers).

(13.4) Finally, the compound-statement of the constructor body is executed.

[Note 6: The declaration order is mandated to ensure that base and member subobjects are destroyed in the reverse order of initialization. — end note]

[Example 9:

```c
struct V {
    V();
    V(int);
};

struct A : virtual V {
    A();
    A(int);
};

struct B : virtual V {
    B();
    B(int);
};

struct C : A, B, virtual V {
    C();
    C(int);
};

A::A(int i) : V(i) { /* ... */ }
B::B(int i) { /* ... */ }
C::C(int i) { /* ... */ }
V v(1);          // use V(int)
A a(2);          // use V(int)
B b(3);          // use V()
C c(4);          // use V()
```

—end example]

[Note 7: The expression-list or braced-init-list of a mem-initializer is in the function parameter scope of the constructor and can use this to refer to the object being initialized. — end note]

[Example 10:

```c
class X {
    int a;
    int b;
    int i;
    int j;
    public:
        const int& r;
    X(int i): r(a), b(i), i(i), j(this->i) { }
};
```

initializes X::r to refer to X::a, initializes X::b with the value of the constructor parameter i, initializes X::i with the value of the constructor parameter i, and initializes X::j with the value of X::i; this takes place each time an object of class X is created. — end example]

Member functions (including virtual member functions, 11.7.3) can be called for an object under construction. Similarly, an object under construction can be the operand of the typeid operator (7.6.1.8) or of a dynamic_cast (7.6.1.7). However, if these operations are performed in a ctor-initializer (or in a function called directly

§ 11.9.3
or indirectly from a ctor-initializer) before all the mem-initializers for base classes have completed, the program has undefined behavior.

[Example 11:

```c++
class A {
public:
  A(int);
};

class B : public A {
  int j;
public:
  int f();
  B() : A(f()), j(f()) { } // undefined behavior: calls member function but base A not yet initialized
};

class C {
public:
  C(int);
};

class D : public B, C {
  int i;
public:
  D() : C(f()), i(f()) { } // well-defined: bases are all initialized
};

—end example]

[Note 8: 11.9.5 describes the result of virtual function calls, typeid and dynamic_casts during construction for the well-defined cases; that is, describes the polymorphic behavior of an object under construction. — end note]

A mem-initializer followed by an ellipsis is a pack expansion (13.7.4) that initializes the base classes specified by a pack expansion in the base-specifier-list for the class.

[Example 12:

```c++
template<class... Mixins>
class X : public Mixins... {
public:
  X(const Mixins&... mixins) : Mixins(mixins)... { }
};

—end example]

11.9.4 Initialization by inherited constructor

[class.inhctor.init]

When a constructor for type B is invoked to initialize an object of a different type D (that is, when the constructor was inherited (9.9)), initialization proceeds as if a defaulted default constructor were used to initialize the D object and each base class subobject from which the constructor was inherited, except that the B subobject is initialized by the invocation of the inherited constructor. The complete initialization is considered to be a single function call; in particular, the initialization of the inherited constructor’s parameters is sequenced before the initialization of any part of the D object.

[Example 1:

```c++
struct B1 {
  B1(int, ...) { }
};

struct B2 {
  B2(double) { }
};

int get();
```
struct D1 : B1 {
    using B1::B1;    // inherits B1(int, ...)
    int x;
    int y = get();
};

void test() {
    D1 d(2, 3, 4);    // OK: B1 is initialized by calling B1(2, 3, 4),
    // then d.x is default-initialized (no initialization is performed),
    // then d.y is initialized by calling get()
    D1 e;    // error: D1 has a deleted default constructor
}

struct D2 : B2 {
    using B2::B2;
    B1 b;
};

D2 f(1.0);    // error: B1 has a deleted default constructor

struct W { W(int); };    // inherits all constructors from class T
struct X : virtual W { using W::W; X() = delete; };    // inherits all constructors from class T
struct Y : X { using X::X; }
struct Z : Y, virtual W { using Y::Y; };
Z z(0);    // OK: initialization of Y does not invoke default constructor of X

template<class T> struct Log : T {
    using T::T;
    ~Log() { std::clog << "Destroying wrapper" << std::endl; }
};

Class template Log wraps any class and forwards all of its constructors, while writing a message to the standard log whenever an object of class Log is destroyed. —end example]

2 If the constructor was inherited from multiple base class subobjects of type B, the program is ill-formed.

[Example 2:]

struct A { A(int); };    // inherits all constructors from class T
struct B : A { using A::A; };    // inherits all constructors from class T
struct C1 : B { using B::B; };    // inherits all constructors from class T
struct C2 : B { using B::B; };    // inherits all constructors from class T

struct D1 : C1, C2 {
    using C1::C1;
    using C2::C2;
};

struct V1 : virtual B { using B::B; };    // inherits all constructors from class T
struct V2 : virtual B { using B::B; };    // inherits all constructors from class T

struct D2 : V1, V2 {
    using V1::V1;
    using V2::V2;
};

D1 d1(0);    // error: ambiguous
D2 d2(0);    // OK: initializes virtual B base class, which initializes the A base class
    // then initializes the V1 and V2 base classes as if by a defaulted default constructor

struct M { M(); M(int); };    // inherits all constructors from class T
struct N : M { using M::M; };    // inherits all constructors from class T
struct O : M {};    // inherits all constructors from class T
struct P : N, O { using N::N; using O::O; }

P p(0);    // OK: use M(0) to initialize N’s base class,
When an object is initialized by an inherited constructor, initialization of the object is complete when the initialization of all subobjects is complete.

11.9.5 Construction and destruction [class.cdtor]

1 For an object with a non-trivial constructor, referring to any non-static member or base class of the object before the constructor begins execution results in undefined behavior. For an object with a non-trivial destructor, referring to any non-static member or base class of the object after the destructor finishes execution results in undefined behavior.

[Example 1:

```cpp
struct X { int i; };  // non-trivial
struct Y : X { Y(); };  // non-trivial

struct A { int a; };  // non-trivial
struct B : public A { int j; Y y; };  // non-trivial

extern B bobj;
B* pb = &bobj;  // OK
int* p1 = &bobj.a;  // undefined behavior: refers to base class member
int* p2 = &bobj.y.i;  // undefined behavior: refers to member’s member

A* pa = &bobj;  // undefined behavior: upcast to a base class type
B bobj;  // definition of bobj

extern X xobj;
int* p3 = &xobj.i;  // OK, X is a trivial class
X xobj;
```

For another example,

```cpp
struct W { int j; };
struct X : public virtual W { };  // non-trivial
struct Y {
  int* p;
  X x;
  Y() : p(&x.j) {  // undefined, x is not yet constructed
    }
};
```

—end example]}

2 During the construction of an object, if the value of the object or any of its subobjects is accessed through a gval that is not obtained, directly or indirectly, from the constructor’s this pointer, the value of the object or subobject thus obtained is unspecified.

[Example 2:

```cpp
struct C;
void no_opt(C*);

struct C {
  int c;
  C() : c(0) { no_opt(this); }
};

const C cobj;

void no_opt(C* cpotr) {
  int i = cobj.c * 100;  // value of cobj.c is unspecified
  cpotr->c = 1;
  cout << cobj.c * 100  // value of cobj.c is unspecified
    << ’\n’;
}
```

§ 11.9.5
extern struct D d;
struct D {
    D(int a) : a(a), b(d.a) {}
    int a, b;
};
D d = D(1);  // value of d.b is unspecified

--- end example ---

To explicitly or implicitly convert a pointer (a glvalue) referring to an object of class X to a pointer (reference) to a direct or indirect base class B of X, the construction of X and the construction of all of its direct or indirect bases that directly or indirectly derive from B shall have started and the destruction of these classes shall not have completed, otherwise the conversion results in undefined behavior. To form a pointer to (or access the value of) a direct non-static member of an object obj, the construction of obj shall have started and its destruction shall not have completed, otherwise the computation of the pointer value (or accessing the member value) results in undefined behavior.

[Example 3:

```c
struct A { }
struct B : virtual A { }
struct C : B { }
struct D : virtual A { D(A*); }
struct X { X(A*); }

struct E : C, D, X {
    E() : D(this),  // undefined behavior: upcast from E* to A* might use path E* → D* → A*
        // but D is not constructed
        // “D((C*this)” would be defined: E* → C* is defined because E() has started,
        // and C* → A* is defined because C is fully constructed
    X(this) {}    // defined: upon construction of X, C/B/D/A sublattice is fully constructed
};
--- end example ---
```

Member functions, including virtual functions (11.7.3), can be called during construction or destruction (11.9.3). When a virtual function is called directly or indirectly from a constructor or from a destructor, including during the construction or destruction of the class’s non-static data members, and the object to which the call applies is the object (call it x) under construction or destruction, the function called is the final overrider in the constructor’s or destructor’s class and not one overriding it in a more-derived class. If the virtual function call uses an explicit class member access (7.6.1.5) and the object expression refers to the complete object of x or one of that object’s base class subobjects but not x or one of its base class subobjects, the behavior is undefined.

[Example 4:

```c
struct V {
    virtual void f();
    virtual void g();
};

struct A : virtual V {
    virtual void f();
};

struct B : virtual V {
    virtual void g();
    B(V*, A*);
};

struct D : A, B {
    virtual void f();
    virtual void g();
    D() : B((A* this, this) { }
};
```

§ 11.9.5
The `typeid` operator (7.6.1.8) can be used during construction or destruction (11.9.3). When `typeid` is used in a constructor (including the mem-initializer or default member initializer (11.4) for a non-static data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of `typeid` refers to the object under construction or destruction, `typeid` yields the `std::type_info` object representing the constructor or destructor’s class. If the operand of `typeid` refers to the object under construction or destruction and the static type of the operand is neither the constructor or destructor’s class nor one of its bases, the behavior is undefined.

Dynamic casts (7.6.1.7) can be used during construction or destruction (11.9.3). When a `dynamic_cast` is used in a constructor (including the mem-initializer or default member initializer for a non-static data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of the `dynamic_cast` refers to the object under construction or destruction, this object is considered to be a most derived object that has the type of the constructor or destructor’s class. If the operand of the `dynamic_cast` refers to the object under construction or destruction and the static type of the operand is not a pointer to or object of the constructor or destructor’s own class or one of its bases, the `dynamic_cast` results in undefined behavior.

### Example 5:

```cpp
struct V {
    virtual void f();
};

struct A ;
struct B : virtual V {
    B(V*, A*);
};

struct D : A, B {
    D() : B((A*)this, this) { }
};

B::B(V* v, A* a) {
    typeid(*this);
    typeid(v);
    typeid(a);
    dynamic_cast<B*>(v);
    dynamic_cast<B*>(a);
}
```

--- end example

### 11.9.6 Copy/move elision

When certain criteria are met, an implementation is allowed to omit the copy/move construction of a class object, even if the constructor selected for the copy/move operation and/or the destructor for the object have side effects. In such cases, the implementation treats the source and target of the omitted copy/move operation as simply two different ways of referring to the same object. If the first parameter of the selected constructor is an rvalue reference to the object’s type, the destruction of that object occurs when the target would have been destroyed; otherwise, the destruction occurs at the later of the times when the two objects would have been destroyed without the optimization. This elision of copy/move operations, called *copy elision*, is permitted in the following circumstances (which may be combined to eliminate multiple copies):

---

110) Because only one object is destroyed instead of two, and one copy/move constructor is not executed, there is still one object destroyed for each one constructed.
— in a return statement in a function with a class return type, when the expression is the name of a non-volatile object with automatic storage duration (other than a function parameter or a variable introduced by the exception-declaration of a handler (14.4)) with the same type (ignoring cv-qualification) as the function return type, the copy/move operation can be omitted by constructing the object directly into the function call’s return object

— in a throw-expression (7.6.18), when the operand is the name of a non-volatile object with automatic storage duration (other than a function or catch-clause parameter) that belongs to a scope that does not contain the innermost enclosing compound-statement associated with a try-block (if there is one), the copy/move operation can be omitted by constructing the object directly into the exception object

— in a coroutine (9.5.4), a copy of a coroutine parameter can be omitted and references to that copy replaced with references to the corresponding parameter if the meaning of the program will be unchanged except for the execution of a constructor and destructor for the parameter copy object

— when the exception-declaration of an exception handler (14.1) declares an object of the same type (except for cv-qualification) as the exception object (14.2), the copy operation can be omitted by treating the exception-declaration as an alias for the exception object if the meaning of the program will be unchanged except for the execution of constructors and destructors for the object declared by the exception-declaration.

[Note 1: There cannot be a move from the exception object because it is always an lvalue. — end note]

Copy elision is not permitted where an expression is evaluated in a context requiring a constant expression (7.7) and in constant initialization (6.9.3.2).

[Note 2: It is possible that copy elision is performed if the same expression is evaluated in another context. — end note]

2 [Example 1:]

class Thing {
  public:
    Thing();
    ~Thing();
    Thing(const Thing&);
  
  Thing f() {
    Thing t;
    return t;
  }

  Thing t2 = f();

  struct A {
    void *p;
    constexpr A(): p(this) {} 
  };

  constexpr A g() {
    A loc;
    return loc;
  }

  constexpr A a;  // well-formed, a.p points to a
  constexpr A b = g();  // error: b.p would be dangling (7.7)

  void h() {
    A c = g();  // well-formed, c.p may point to c or to an ephemeral temporary
  }

Here the criteria for elision can eliminate the copying of the object t with automatic storage duration into the result object for the function call f(), which is the non-local object t2. Effectively, the construction of t can be viewed as directly initializing t2, and that object’s destruction will occur at program exit. Adding a move constructor to Thing has the same effect, but it is the move construction from the object with automatic storage duration to t2 that is elided. — end example]
An implicitly movable entity is a variable of automatic storage duration that is either a non-volatile object or an rvalue reference to a non-volatile object type. In the following copy-initialization contexts, a move operation is first considered before attempting a copy operation:

1. If the expression in a return (8.7.4) or co_return (8.7.5) statement is a (possibly parenthesized) id-expression that names an implicitly movable entity declared in the body or parameter-declaration-clause of the innermost enclosing function or lambda-expression, or
2. if the operand of a throw-expression (7.6.18) is a (possibly parenthesized) id-expression that names an implicitly movable entity that belongs to a scope that does not contain the compound-statement of the innermost try-block or function-try-block (if any) whose compound-statement or ctor-initializer contains the throw-expression.

Overload resolution to select the constructor for the copy or the return_value overload to call is first performed as if the expression or operand were an rvalue. If the first overload resolution fails or was not performed, overload resolution is performed again, considering the expression or operand as an lvalue.

[Note 3: This two-stage overload resolution is performed regardless of whether copy elision will occur. It determines the constructor or the return_value overload to be called if elision is not performed, and the selected constructor or return_value overload must be accessible even if the call is elided. —end note]

4. Example 2:
   ```cpp
class Thing {
   public:
   Thing();
   ~Thing();
   Thing(Thing&&);
   private:
   Thing(const Thing&);
   };

   Thing f(bool b) {
   Thing t;
   if (b)
   throw t; // OK: Thing(Thing&&) used (or elided) to throw t
   return t; // OK: Thing(Thing&&) used (or elided) to return t
   }

   Thing t2 = f(false); // OK: no extra copy/move performed, t2 constructed by call to f
   ```

5. Example 3:
   ```cpp
template<class T> void g(const T&);

template<class T> void f() {
  T x;
  try {
    T y;
    try { g(x); } 
    catch (...) {
      if (/.../*)
        throw x; // does not move
      throw y; // moves
    }
  } g(y);
  ```
11.10 Comparisons

11.10.1 Defaulted comparison operator functions

A defaulted comparison operator function (12.4.3) for some class C shall be a non-template function that is:

1.1 a non-static const non-volatile member of C having one parameter of type const C& and either no ref-qualifier or the ref-qualifier &, or

1.2 a friend of C having either two parameters of type const C& or two parameters of type C.

A comparison operator function for class C that is defaulted on its first declaration and is not defined as deleted is implicitly defined when it is odr-used or needed for constant evaluation. Name lookups in the defaulted definition of a comparison operator function are performed from a context equivalent to its function-body. A definition of a comparison operator as defaulted that appears in a class shall be the first declaration of that function.

A defaulted \( <\) or \( ==\) operator function for class C is defined as deleted if any non-static data member of C is of reference type or C has variant members (11.5.2).

A binary operator expression \( a @ b \) is usable if either:

3.1 \( a \) or \( b \) is of class or enumeration type and overload resolution (12.2) as applied to \( a @ b \) results in a usable candidate, or

3.2 neither \( a \) nor \( b \) is of class or enumeration type and \( a @ b \) is a valid expression.

A defaulted comparison function is constexpr-compatible if it satisfies the requirements for a constexpr function (9.2.6) and no overload resolution performed when determining whether to delete the function results in a usable candidate that is a non-constexpr function.

\[\text{Note 1: This includes the overload resolutions performed:}\]

4.1 for an \( <\) operator whose return type is not auto, when determining whether a synthesized three-way comparison is defined,

4.2 for an \( <\) operator whose return type is auto or for an \( ==\), for a comparison between an element of the expanded list of subobjects and itself, or

4.3 for a secondary comparison operator \( @ \), for the expression \( x @ y \).

\[\text{— end note}\]

If the member-specification does not explicitly declare any member or friend named \( ==\), an \( ==\) operator function is declared implicitly for each three-way comparison operator function defined as defaulted in the member-specification, with the same access and function-definition and in the same class scope as the respective three-way comparison operator function, except that the return type is replaced with bool and the declarator-id is replaced with \( ==\).

\[\text{Note 2: Such an implicitly-declared == operator for a class X is defined as defaulted in the definition of X and has the same parameter-declaration-clause and trailing requires-clause as the respective three-way comparison operator function. It is declared with friend, virtual, constexpr, or consteval if the three-way comparison operator function is so declared. If the three-way comparison operator function has no noexcept-specifier, the implicitly-declared == operator function has an implicit exception specification (14.5) that can differ from the implicit exception specification of the three-way comparison operator function. — end note}\]

[Example 1:

\[
\text{template<typename T> struct X \{}
\text{    friend constexpr std::partial_ordering operator<\>(X, X) requires (sizeof(T) \! = 1) = default;}
\text{    // implicitly declares: friend constexpr bool operator==(X, X) requires (sizeof(T) \! = 1) = default;}

\text{    [[nodiscard]] virtual std::strong_ordering operator<\>(const X&) const = default;}
\text{    // implicitly declares: [[nodiscard]] virtual bool operator==(const X&) const = default;}
\text{\}};}\]

§ 11.10.1
The direct base class subobjects of `C`, in the order of their declaration in the `base-specifier-list` of `C`, followed by the non-static data members of `C`, in the order of their declaration in the `member-specification` of `C`, form a list of subobjects. In that list, any subobject of array type is recursively expanded to the sequence of its elements, in the order of increasing subscript. Let `x_i` be an lvalue denoting the `i`th element in the expanded list of subobjects for an object `x` (of length `n`), where `x_i` is formed by a sequence of derived-to-base conversions (12.2.4.2), class member access expressions (7.6.1.5), and array subscript expressions (7.6.1.2) applied to `x`.

### 11.10.2 Equality operator [class.eq]

1. A defaulted equality operator function (12.4.3) shall have a declared return type `bool`.

2. A defaulted `==` operator function for a class `C` is defined as deleted unless, for each `x_i` in the expanded list of subobjects for an object `x` of type `C`, `x_i == x_i` is usable (11.10.1).

3. The return value `V` of a defaulted `==` operator function with parameters `x` and `y` is determined by comparing corresponding elements `x_i` and `y_i` in the expanded lists of subobjects for `x` and `y` (in increasing index order) until the first index `i` where `x_i == y_i` yields a result value which, when contextually converted to `bool`, yields `false`. If no such index exists, `V` is `true`. Otherwise, `V` is `false`.

   **[Example 1]:**
   ```
   struct D {
      int i;
      friend bool operator==(const D& x, const D& y) = default;
      // OK, returns x.i == y.i
   };
   ```

### 11.10.3 Three-way comparison [class.spaceship]

1. The synthesized three-way comparison of type `R` (17.11.2) of glvalues `a` and `b` of the same type is defined as follows:

   (1.1) — If `a <=> b` is usable (11.10.1), `static_cast<R>(a <=> b)`.

   (1.2) — Otherwise, if overload resolution for `a <=> b` is performed and finds at least one viable candidate, the synthesized three-way comparison is not defined.

   (1.3) — Otherwise, if `R` is not a comparison category type, or either the expression `a == b` or the expression `a < b` is not usable, the synthesized three-way comparison is not defined.

   (1.4) — Otherwise, if `R` is `strong_ordering`, then
   ```
   a == b ? strong_ordering::equal :
   a < b  ? strong_ordering::less :
   strong_ordering::greater
   ```

   (1.5) — Otherwise, if `R` is `weak_ordering`, then
   ```
   a == b ? weak_ordering::equivalent :
   a < b  ? weak_ordering::less :
   weak_ordering::greater
   ```

   (1.6) — Otherwise (when `R` is `partial_ordering`),
   ```
   a == b ? partial_ordering::equivalent :
   a < b  ? partial_ordering::less :
   b < a  ? partial_ordering::greater :
   partial_ordering::unordered
   ```

   **[Note 1]:** A synthesized three-way comparison is ill-formed if overload resolution finds usable candidates that do not otherwise meet the requirements implied by the defined expression. — end note

2. Let `R` be the declared return type of a defaulted three-way comparison operator function, and let `x_i` be the elements of the expanded list of subobjects for an object `x` of type `C`.

§ 11.10.3 311
If $R$ is `auto`, then let $cv_i$ be the type of the expression $x_i \leftrightarrow x_i$. The operator function is defined as deleted if that expression is not usable or if $R_i$ is not a comparison category type (17.11.2.1) for any $i$. The return type is deduced as the common comparison type (see below) of $R_0$, $R_1$, ..., $R_{n-1}$.

Otherwise, $R$ shall not contain a placeholder type. If the synthesized three-way comparison of type $R_i$ between any objects $x_i$ and $x_i$ is not defined, the operator function is defined as deleted.

The return value $V$ of type $R$ of the defaulted three-way comparison operator function with parameters $x$ and $y$ of the same type is determined by comparing corresponding elements $x_i$ and $y_i$ in the expanded lists of subobjects for $x$ and $y$ (in increasing index order) until the first index $i$ where the synthesized three-way comparison of type $R$ between $x_i$ and $y_i$ yields a result value $v_i$ where $v_i \neq 0$, contextually converted to `bool`, yields `true`; $V$ is a copy of $v_i$. If no such index exists, $V$ is `static_cast<R>(std::strong_ordering::equal)`.

The common comparison type $U$ of a possibly-empty list of $n$ comparison category types $T_0$, $T_1$, ..., $T_{n-1}$ is defined as follows:

1. If at least one $T_i$ is `std::partial_ordering`, $U$ is `std::partial_ordering` (17.11.2.2).
2. Otherwise, if at least one $T_i$ is `std::weak_ordering`, $U$ is `std::weak_ordering` (17.11.2.3).
3. Otherwise, $U$ is `std::strong_ordering` (17.11.2.4).

[Note 2: In particular, this is the result when $n$ is 0. — end note]

### 11.10.4 Secondary comparison operators

A secondary comparison operator is a relational operator (7.6.9) or the `!=` operator. A defaulted operator function (12.4.3) for a secondary comparison operator `@` shall have a declared return type `bool`.

The operator function with parameters $x$ and $y$ is defined as deleted if

1. overload resolution (12.2), as applied to $x \@ y$, does not result in a usable candidate, or
2. the candidate selected by overload resolution is not a rewritten candidate.

Otherwise, the operator function yields $x \@ y$. The defaulted operator function is not considered as a candidate in the overload resolution for the `@` operator.

[Example 1:

```cpp
struct HasNoLessThan {}

struct C {
  friend HasNoLessThan operator<=>(const C&, const C&);
  bool operator<(const C&) const = default;  // OK, function is deleted
};
```

—end example]

### 11.11 Free store

Any allocation function for a class T is a static member (even if not explicitly declared `static`).

[Example 1:

```cpp
class Arena;
struct B {
  void* operator new(std::size_t, Arena*);
};
struct D1 : B {
};

Arena* ap;
void foo(int i) {
  new (ap) D1;     // calls B::operator new(std::size_t, Arena*)
  new D1[i];      // calls ::operator new[](std::size_t)
  new D1;        // error: ::operator new(std::size_t) hidden
}
```

—end example]

Any deallocation function for a class X is a static member (even if not explicitly declared `static`).

[Example 2:
class X {
  void operator delete(void*);
  void operator delete[](void*, std::size_t);
};

class Y {
  void operator delete(void*, std::size_t);
  void operator delete[](void*);
};

—end example

4 Since member allocation and deallocation functions are static they cannot be virtual.

[Note 1: However, when the cast-expression of a delete-expression refers to an object of class type with a virtual destructor, because the deallocation function is chosen by the destructor of the dynamic type of the object, the effect is the same in that case. For example,

```c
struct B {
  virtual ~B();
  void operator delete(void*, std::size_t);
};

struct D : B {
  void operator delete(void*);
};

struct E : B {
  void log_deletion();
  void operator delete(E *p, std::destroying_delete_t) {
    p->log_deletion();
    p->~E();
    ::operator delete(p);
  }
};

void f() {
  B* bp = new D;
  delete bp; // 1: uses D::operator delete(void*)
  bp = new E;
  delete bp; // 2: uses E::operator delete(E*, std::destroying_delete_t)
}
```

Here, storage for the object of class D is deallocated by D::operator delete(), and the object of class E is destroyed and its storage is deallocated by E::operator delete(), due to the virtual destructor. —end note]

[Note 2: Virtual destructors have no effect on the deallocation function actually called when the cast-expression of a delete-expression refers to an array of objects of class type. For example,

```c
struct B {
  virtual ~B();
  void operator delete[](void*, std::size_t);
};

struct D : B {
  void operator delete[](void*, std::size_t);
};

void f(int i) {
  D* dp = new D[i];
  delete [] dp; // uses D::operator delete[](void*, std::size_t)
  B* bp = new D[1];
  delete[] bp; // undefined behavior
}
```

—end note]

5 Access to the deallocation function is checked statically, even if a different one is actually executed.
Example 3: For the call on line “// 1” above, if `B::operator delete()` had been private, the delete expression would have been ill-formed. — end example

Note 3: If a deallocation function has no explicit `noexcept-specifier`, it has a non-throwing exception specification (14.5). — end note
12 Overloading

12.1 Preamble

[Note 1: Each of two or more entities with the same name in the same scope, which must be functions or function templates, is commonly called an “overload”. — end note]

When a function is named in a call, which function declaration is being referenced and the validity of the call are determined by comparing the types of the arguments at the point of use with the types of the parameters in the declarations in the overload set. This function selection process is called overload resolution and is defined in 12.2.

[Example 1:

double abs(double);
int abs(int);

abs(1);        // calls abs(int);
abs(1.0);      // calls abs(double);
— end example]

12.2 Overload resolution

12.2.1 General

Overload resolution is a mechanism for selecting the best function to call given a list of expressions that are to be the arguments of the call and a set of candidate functions that can be called based on the context of the call. The selection criteria for the best function are the number of arguments, how well the arguments match the parameter-type-list of the candidate function, how well (for non-static member functions) the object matches the implicit object parameter, and certain other properties of the candidate function.

[Note 1: The function selected by overload resolution is not guaranteed to be appropriate for the context. Other restrictions, such as the accessibility of the function, can make its use in the calling context ill-formed. — end note]

Overload resolution selects the function to call in seven distinct contexts within the language:

(2.1) invocation of a function named in the function call syntax (12.2.2.2);
(2.2) invocation of a function call operator, a pointer-to-function conversion function, a reference-to-pointer-to-function conversion function, or a reference-to-function conversion function on a class object named in the function call syntax (12.2.2.3);
(2.3) invocation of the operator referenced in an expression (12.2.2.3);
(2.4) invocation of a constructor for default- or direct-initialization (9.4) of a class object (12.2.2.4);
(2.5) invocation of a user-defined conversion for copy-initialization (9.4) of a class object (12.2.2.5);
(2.6) invocation of a conversion function for initialization of an object of a non-class type from an expression of class type (12.2.2.6); and
(2.7) invocation of a conversion function for conversion in which a reference (9.4.4) will be directly bound (12.2.2.7).

Each of these contexts defines the set of candidate functions and the list of arguments in its own unique way. But, once the candidate functions and argument lists have been identified, the selection of the best function is the same in all cases:

(2.8) First, a subset of the candidate functions (those that have the proper number of arguments and meet certain other conditions) is selected to form a set of viable functions (12.2.3).
(2.9) Then the best viable function is selected based on the implicit conversion sequences (12.2.4.2) needed to match each argument to the corresponding parameter of each viable function.

If a best viable function exists and is unique, overload resolution succeeds and produces it as the result. Otherwise overload resolution fails and the invocation is ill-formed. When overload resolution succeeds, and the best viable function is not accessible (11.8) in the context in which it is used, the program is ill-formed.
Overload resolution results in a *usable candidate* if overload resolution succeeds and the selected candidate is either not a function (12.5), or is a function that is not deleted and is accessible from the context in which overload resolution was performed.

### 12.2.2 Candidate functions and argument lists

#### 12.2.2.1 General

The subclauses of 12.2.2 describe the set of candidate functions and the argument list submitted to overload resolution in each context in which overload resolution is used. The source transformations and constructions defined in these subclauses are only for the purpose of describing the overload resolution process. An implementation is not required to use such transformations and constructions.

The set of candidate functions can contain both member and non-member functions to be resolved against the same argument list. So that argument and parameter lists are comparable within this heterogeneous set, a member function is considered to have an extra first parameter, called the *implicit object parameter*, which represents the object for which the member function has been called. For the purposes of overload resolution, both static and non-static member functions have an implicit object parameter, but constructors do not.

Similarly, when appropriate, the context can construct an argument list that contains an *implied object argument* as the first argument in the list to denote the object to be operated on.

For non-static member functions, the type of the implicit object parameter is

1. “lvalue reference to `cv X`” for functions declared without a ref-qualifier or with the `&` ref-qualifier
2. “rvalue reference to `cv X`” for functions declared with the `&&` ref-qualifier

where `X` is the class of which the function is a member and `cv` is the cv-qualification on the member function declaration.

For conversion functions, the function is considered to be a member of the class of the implied object argument for the purpose of defining the type of the implicit object parameter. For non-conversion functions nominated by a using-declaration in a derived class, the function is considered to be a member of the derived class for the purpose of defining the type of the implicit object parameter. For static member functions, the implicit object parameter is considered to match any object (since if the function is selected, the object is discarded).

During overload resolution, the implied object argument is indistinguishable from other arguments. The implicit object parameter, however, retains its identity since no user-defined conversions can be applied to achieve a type match with it. For non-static member functions declared without a ref-qualifier, even if the implicit object parameter is not const-qualified, an rvalue can be bound to the parameter as long as in all other respects the argument can be converted to the type of the implicit object parameter.

Because other than in list-initialization only one user-defined conversion is allowed in an implicit conversion sequence, special rules apply when selecting the best user-defined conversion (12.2.4, 12.2.4.2).

In each case where conversion functions of a class `S` are considered for initializing an object or reference of type `T`, the candidate functions include the result of a search for the conversion-function-id operator `T` in `S`. 

§ 12.2.2.1
Each such case also defines sets of permissible types for explicit and non-explicit conversion functions; each (non-template) conversion function that

(7.1) — is a non-hidden member of \( S \),

(7.2) — yields a permissible type, and,

(7.3) — for the former set, is non-explicit

is also a candidate function. If initializing an object, for any permissible type \( cvU \), any \( cv2U \), \( cv2U\& \), or \( cv2U\&& \) is also a permissible type. If the set of permissible types for explicit conversion functions is empty, any candidates that are explicit are discarded.

8 In each case where a candidate is a function template, candidate function template specializations are generated using template argument deduction (13.10.4, 13.10.3). If a constructor template or conversion function template has an explicit-specifier whose constant-expression is value-dependent (13.8.3), template argument deduction is performed first and then, if the context admits only candidates that are not explicit and the generated specialization is explicit (9.2.3), it will be removed from the candidate set. Those candidates are then handled as candidate functions in the usual way. A given name can refer to, or a conversion can consider, one or more function templates as well as a set of non-template functions. In such a case, the candidate functions generated from each function template are combined with the set of non-template candidate functions.

9 A defaulted move special member function (11.4.5.3, 11.4.6) that is defined as deleted is excluded from the set of candidate functions in all contexts. A constructor inherited from class type \( C \) (11.9.4) that has a first parameter of type “reference to \( cv1P \)” (including such a constructor instantiated from a template) is excluded from the set of candidate functions when constructing an object of type \( cv2D \) if the argument list has exactly one argument and \( C \) is reference-related to \( P \) and \( P \) is reference-related to \( D \).

[Example 3:

```
struct A {
    A(); // #1
    A(A &&); // #2
    template<typename T> A(T &&); // #3
};
struct B : A {
    using A::A;
    B(const B &); // #4
    B(B &&) = default; // #5, implicitly deleted
    struct X { X(X &&) = delete; } x;
};
extern B b1;
B b2 = static_cast<B&&>(b1); // calls #4: #1 is not viable, #2, #3, and #5 are not candidates
struct C { operator B&&(); }; // calls #4
```

—end example]

12.2.2.2 Function call syntax

In a function call (7.6.1.3)

```
postfix-expression ( expression-list_opt )
```

if the postfix-expression names at least one function or function template, overload resolution is applied as specified in 12.2.2.2.2. If the postfix-expression denotes an object of class type, overload resolution is applied as specified in 12.2.2.2.3.

1 If the postfix-expression is the address of an overload set, overload resolution is applied using that set as described above. If the function selected by overload resolution is a non-static member function, the program is ill-formed.

111) The process of argument deduction fully determines the parameter types of the function template specializations, i.e., the parameters of function template specializations contain no template parameter types. Therefore, except where specified otherwise, function template specializations and non-template functions (9.3.4.6) are treated equivalently for the remainder of overload resolution.
[Note 1: The resolution of the address of an overload set in other contexts is described in 12.3. — end note]

12.2.2.2.2 Call to named function

1 Of interest in 12.2.2.2 are only those function calls in which the postfix-expression ultimately contains an id-expression that denotes one or more functions. Such a postfix-expression, perhaps nested arbitrarily deep in parentheses, has one of the following forms:

postfix-expression:
  id-expression
  postfix-expression . id-expression
  postfix-expression -> id-expression
  primary-expression

These represent two syntactic subcategories of function calls: qualified function calls and unqualified function calls.

2 In qualified function calls, the function is named by an id-expression preceded by an -> or . operator. Since the construct A->B is generally equivalent to (*A).B, the rest of Clause 12 assumes, without loss of generality, that all member function calls have been normalized to the form that uses an object and the . operator. Furthermore, Clause 12 assumes that the postfix-expression that is the left operand of the . operator has type “cv T” where T denotes a class.\(^{112}\) The function declarations found by name lookup (6.5.2) constitute the set of candidate functions. The argument list is the expression-list in the call augmented by the addition of the left operand of the . operator in the normalized member function call as the implied object argument (12.2.2).

3 In unqualified function calls, the function is named by a primary-expression. The function declarations found by name lookup (6.5) constitute the set of candidate functions. Because of the rules for name lookup, the set of candidate functions consists (1) entirely of non-member functions or (2) entirely of member functions of some class T. In case (1), the argument list is the same as the expression-list in the call. In case (2), the argument list is the expression-list in the call augmented by the addition of an implied object argument as in a qualified function call. If the current class is, or is derived from, T, and the keyword this (7.5.2) refers to it, then the implied object argument is (*this). Otherwise, a contrived object of type T becomes the implied object argument;\(^{113}\) if overload resolution selects a non-static member function, the call is ill-formed.

12.2.2.3 Call to object of class type

1 If the postfix-expression E in the function call syntax evaluates to a class object of type “cv T”, then the set of candidate functions includes at least the function call operators of T. The function call operators of T are the results of a search for the name operator() in the scope of T.

2 In addition, for each non-explicit conversion function declared in T of the form

\[
\text{operator conversion-type-id ( ) cv-qualifier-seq opt ref-qualifier opt noexcept-specifier opt attribute-specifier-seq opt ;}
\]

where the optional cv-qualifier-seq is the same cv-qualification as, or a greater cv-qualification than, cv, and where conversion-type-id denotes the type “pointer to function of (P_1, ..., P_n) returning R”, or the type “reference to pointer to function of (P_1, ..., P_n) returning R”, or the type “reference to function of (P_1, ..., P_n) returning R”, a surrogate call function with the unique name call-function and having the form

\[
\text{R call-function ( conversion-type-id F, P_1 a_1, ..., P_n a_n ) \{ return F (a_1, ..., a_n); \}}
\]

is also considered as a candidate function. Similarly, surrogate call functions are added to the set of candidate functions for each non-explicit conversion function declared in a base class of T provided the function is not hidden within T by another intervening declaration.\(^{114}\)

3 The argument list submitted to overload resolution consists of the argument expressions present in the function call syntax preceded by the implied object argument (E).

[Note 1: When comparing the call against the function call operators, the implied object argument is compared against the implicit object parameter of the function call operator. When comparing the call against a surrogate call function, the implied object argument is compared against the first parameter of the surrogate call function. The conversion function from which the surrogate call function was derived will be used in the conversion sequence for

\(^{112}\) Note that cv-qualifiers on the type of objects are significant in overload resolution for both glvalue and class prvalue objects.

\(^{113}\) An implied object argument is contrived to correspond to the implicit object parameter attributed to member functions during overload resolution. It is not used in the call to the selected function. Since the member functions all have the same implicit object parameter, the contrived object will not be the cause to select or reject a function.

\(^{114}\) Note that this construction can yield candidate call functions that cannot be differentiated one from the other by overload resolution because they have identical declarations or differ only in their return type. The call will be ambiguous if overload resolution cannot select a match to the call that is uniquely better than such undifferentiable functions.
that parameter since it converts the implied object argument to the appropriate function pointer or reference required by that first parameter. — end note]

Example 1:

```c
int f1(int);
int f2(float);
typedef int (*fp1)(int);
typedef int (*fp2)(float);
struct A {
  operator fp1() { return f1; }
  operator fp2() { return f2; }
} a;
int i = a(1); // calls f1 via pointer returned from conversion function
```

— end example

12.2.2.3 Operators in expressions [over.match.oper]

If no operand of an operator in an expression has a type that is a class or an enumeration, the operator is assumed to be a built-in operator and interpreted according to 7.6.

[Note 1: Because ., .*, and :: cannot be overloaded, these operators are always built-in operators interpreted according to 7.6. ?: cannot be overloaded, but the rules in this subclause are used to determine the conversions to be applied to the second and third operands when they have class or enumeration type (7.6.16). — end note]

Example 1:

```c
struct String {
  String (const String&);
  String (const char*);
  operator const char* () {
  }
};
String operator + (const String&, const String&);

void f() {
  const char* p= "one" + "two"; // error: cannot add two pointers; overloaded operator+ not considered
  // because neither operand has class or enumeration type
  int I = 1 + 1; // always evaluates to 2 even if class or enumeration types exist
  // that would perform the operation.
}
```

— end example

If either operand has a type that is a class or an enumeration, a user-defined operator function can be declared that implements this operator or a user-defined conversion can be necessary to convert the operand to a type that is appropriate for a built-in operator. In this case, overload resolution is used to determine which operator function or built-in operator is to be invoked to implement the operator. Therefore, the operator notation is first transformed to the equivalent function-call notation as summarized in Table 17 (where @ denotes one of the operators covered in the specified subclause). However, the operands are sequenced in the order prescribed for the built-in operator (7.6).

Table 17: Relationship between operator and function call notation [tab:over.match.oper]

For a unary operator @ with an operand of type cv1 T1, and for a binary operator @ with a left operand of type cv1 T1 and a right operand of type cv2 T2, four sets of candidate functions, designated member candidates, non-member candidates, built-in candidates, and rewritten candidates, are constructed as follows:

§ 12.2.2.3
If $T_1$ is a complete class type or a class currently being defined, the set of member candidates is the result of a search for \( \text{operator}@ \) in the scope of $T_1$; otherwise, the set of member candidates is empty.

For the operators \( \ast, [ ] \), or \( \rightarrow \), the set of non-member candidates is empty; otherwise, it includes the result of unqualified lookup for \( \text{operator}@ \) in the rewritten function call (6.5.3, 6.5.4), ignoring all member functions. However, if no operand has a class type, only those non-member functions in the lookup set that have a first parameter of type $T_1$ or “reference to $\text{cv} \ T_1$”, when $T_1$ is an enumeration type, or (if there is a right operand) a second parameter of type $T_2$ or “reference to $\text{cv} \ T_2$”, when $T_2$ is an enumeration type, are candidate functions.

For the operator \( , \), the unary operator \&, or the operator \( \rightarrow \), the built-in candidates set is empty. For all other operators, the built-in candidates include all of the candidate operator functions defined in 12.5 that, compared to the given operator,

1. have the same operator name, and
2. accept the same number of operands, and
3. accept operand types to which the given operand or operands can be converted according to 12.2.4.2, and
4. do not have the same parameter-type-list as any non-member candidate that is not a function template specialization.

The rewritten candidate set is determined as follows:

1. For the relational (7.6.9) operators, the rewritten candidates include all non-rewritten candidates for the expression $x \leftrightarrow y$.
2. For the relational (7.6.9) and three-way comparison (7.6.8) operators, the rewritten candidates also include a synthesized candidate, with the order of the two parameters reversed, for each non-rewritten candidate for the expression $y \leftrightarrow x$.
3. For the \( \neq \) operator (7.6.10), the rewritten candidates include all non-rewritten candidates for the expression $x == y$.
4. For the equality operators, the rewritten candidates also include a synthesized candidate, with the order of the two parameters reversed, for each non-rewritten candidate for the expression $y == x$.
5. For all other operators, the rewritten candidate set is empty.

[Note 2: A candidate synthesized from a member candidate has its implicit object parameter as the second parameter, thus implicit conversions are considered for the first, but not for the second, parameter. — end note]

For the built-in assignment operators, conversions of the left operand are restricted as follows:

1. no temporaries are introduced to hold the left operand, and
2. no user-defined conversions are applied to the left operand to achieve a type match with the left-most parameter of a built-in candidate.

For all other operators, no such restrictions apply.

The set of candidate functions for overload resolution for some operator \( \oplus \) is the union of the member candidates, the non-member candidates, the built-in candidates, and the rewritten candidates for that operator \( \oplus \).

The argument list contains all of the operands of the operator. The best function from the set of candidate functions is selected according to 12.2.3 and 12.2.4.115

[Example 2:] fix

```cpp
struct A {
    operator int();
};
A operator+(const A&, const A&);
void m() {
    A a, b;
    a + b;  // operator+(a, b) chosen over int(a) + int(b)
}
```

115) If the set of candidate functions is empty, overload resolution is unsuccessful.
If a rewritten operator\(\leftrightarrow\) candidate is selected by overload resolution for an operator \(\&\), \(x \& y\) is interpreted as \(0 \& (y \leftrightarrow x)\) if the selected candidate is a synthesized candidate with reversed order of parameters, or \((x \leftrightarrow y) \& 0\) otherwise, using the selected rewritten operator\(\leftrightarrow\) candidate. Rewritten candidates for the operator \(\&\) are not considered in the context of the resulting expression.

If a rewritten operator\(==\) candidate is selected by overload resolution for an operator \(\&\), its return type shall be \(cv\) \(bool\), and \(x \& y\) is interpreted as:

1. if \(\&\) is \(!=\) and the selected candidate is a synthesized candidate with reversed order of parameters, \(! (y == x)\),
2. otherwise, if \(\&\) is \(!=\), \(! (x == y)\),
3. otherwise (when \(\&\) is \(==\)), \(y == x\),

in each case using the selected rewritten operator\(==\) candidate.

If a built-in candidate is selected by overload resolution, the operands of class type are converted to the types of the corresponding parameters of the selected operation function, except that the second standard conversion sequence of a user-defined conversion sequence (12.2.4.2.3) is not applied. Then the operator is treated as the corresponding built-in operator and interpreted according to 7.6.

Example 3:
```cpp
struct X {
    operator double();
};

struct Y {
    operator int*();
};

int *a = Y() + 100.0; // error: pointer arithmetic requires integral operand
int *b = Y() + X(); // error: pointer arithmetic requires integral operand
```

The second operand of operator \(->\) is ignored in selecting an operator\(->\) function, and is not an argument when the operator\(->\) function is called. When operator\(->\) returns, the operator \(->\) is applied to the value returned, with the original second operand.\(^{116}\)

If the operator is the operator \(\&\), the unary operator \&, or the operator \(->\), and there are no viable functions, then the operator is assumed to be the built-in operator and interpreted according to 7.6.

Note 3: The lookup rules for operators in expressions are different than the lookup rules for operator function names in a function call, as shown in the following example:
```cpp
struct A { }
void operator + (A, A); // error: global operator hidden by member

struct B {
    void operator + (B);
    void f ()
};

A a;

void B::f() {
    operator+ (a,a); // error: global operator hidden by member
    a + a; // OK: calls global operator+
}
```

12.2.2.4 Initialization by constructor

When objects of class type are direct-initialized (9.4), copy-initialized from an expression of the same or a derived class type (9.4), or default-initialized (9.4), overload resolution selects the constructor. For

\(^{116}\) If the value returned by the operator\(->\) function has class type, this can result in selecting and calling another operator\(->\) function. The process repeats until an operator\(->\) function returns a value of non-class type.
direct-initialization or default-initialization that is not in the context of copy-initialization, the candidate functions are all the constructors of the class of the object being initialized. For copy-initialization (including default initialization in the context of copy-initialization), the candidate functions are all the converting constructors (11.4.8.2) of that class. The argument list is the expression-list or assignment-expression of the initializer.

12.2.2.5 Copy-initialization of class by user-defined conversion

Under the conditions specified in 9.4, as part of a copy-initialization of an object of class type, a user-defined conversion can be invoked to convert an initializer expression to the type of the object being initialized. Overload resolution is used to select the user-defined conversion to be invoked.

[Note 1: The conversion performed for indirect binding to a reference to a possibly cv-qualified class type is determined in terms of a corresponding non-reference copy-initialization. — end note]

Assuming that “cv1 T” is the type of the object being initialized, with T a class type, the candidate functions are selected as follows:

1. The converting constructors (11.4.8.2) of T are candidate functions.
2. When the type of the initializer expression is a class type “cv S”, conversion functions are considered. The permissible types for non-explicit conversion functions are T and any class derived from T. When initializing a temporary object (11.4) to be bound to the first parameter of a constructor where the parameter is of type “reference to cv2 T” and the constructor is called with a single argument in the context of direct-initialization of an object of type “cv3 T”, the permissible types for explicit conversion functions are the same; otherwise there are none.

In both cases, the argument list has one argument, which is the initializer expression.

[Note 2: This argument will be compared against the first parameter of the constructors and against the implicit object parameter of the conversion functions. — end note]

12.2.2.6 Initialization by conversion function

Under the conditions specified in 9.4, as part of an initialization of an object of non-class type, a conversion function can be invoked to convert an initializer expression of class type to the type of the object being initialized. Overload resolution is used to select the conversion function to be invoked. Assuming that “cv T” is the type of the object being initialized, the candidate functions are selected as follows:

1. The permissible types for non-explicit conversion functions are those that can be converted to type T via a standard conversion sequence (12.2.4.2.2). For direct-initialization, the permissible types for explicit conversion functions are those that can be converted to type T with a (possibly trivial) qualification conversion (7.3.6); otherwise there are none.

The argument list has one argument, which is the initializer expression.

[Note 1: This argument will be compared against the implicit object parameter of the conversion functions. — end note]

12.2.2.7 Initialization by conversion function for direct reference binding

Under the conditions specified in 9.4.4, a reference can be bound directly to the result of applying a conversion function to an initializer expression. Overload resolution is used to select the conversion function to be invoked. Assuming that “reference to cv1 T” is the type of the reference being initialized, the candidate functions are selected as follows:

1. Let R be a set of types including

   — “lvalue reference to cv2 T2” (when initializing an lvalue reference or an rvalue reference to function) and
   — “cv1 T2” and “rvalue reference to cv1 T2” (when initializing an rvalue reference or an lvalue reference to function)

for any T2. The permissible types for non-explicit conversion functions are the members of R where “cv1 T” is reference-compatible (9.4.4) with “cv2 T2”. For direct-initialization, the permissible types for explicit conversion functions are the members of R where T2 can be converted to type T with a (possibly trivial) qualification conversion (7.3.6); otherwise there are none.

The argument list has one argument, which is the initializer expression.
12.2.2.8 Initialization by list-initialization

When objects of non-aggregate class type \( T \) are list-initialized such that 9.4.5 specifies that overload resolution is performed according to the rules in this subclause or when forming a list-initialization sequence according to 12.2.2.6, overload resolution selects the constructor in two phases:

1. If the initializer list is not empty or \( T \) has no default constructor, overload resolution is first performed where the candidate functions are the initializer-list constructors (9.4.5) of the class \( T \) and the argument list consists of the initializer list as a single argument.

2. Otherwise, or if no viable initializer-list constructor is found, overload resolution is performed again, where the candidate functions are all the constructors of the class \( T \) and the argument list consists of the elements of the initializer list.

In copy-list-initialization, if an explicit constructor is chosen, the initialization is ill-formed.

12.2.2.9 Class template argument deduction

When resolving a placeholder for a deduced class type (9.2.9.7) where the template-name names a primary class template \( C \), a set of functions and function templates, called the guides of \( C \), is formed comprising:

1. If \( C \) is defined, for each constructor of \( C \), a function template with the following properties:

   - The template parameters are the template parameters of \( C \) followed by the template parameters (including default template arguments) of the constructor, if any.
   - The types of the function parameters are those of the constructor.
   - The return type is the class template specialization designated by \( C \) and template arguments corresponding to the template parameters of \( C \).

2. If \( C \) is not defined or does not declare any constructors, an additional function template derived as above from a hypothetical constructor \( C() \).

3. An additional function template derived as above from a hypothetical constructor \( C(C) \), called the copy deduction candidate.

4. For each deduction-guide, a function or function template with the following properties:

   - The template parameters, if any, and function parameters are those of the deduction-guide.
   - The return type is the simple-template-id of the deduction-guide.

In addition, if \( C \) is defined and its definition satisfies the conditions for an aggregate class (9.4.2) with the assumption that any dependent base class has no virtual functions and no virtual base classes, and the initializer is a non-empty braced-init-list or parenthesized expression-list, and there are no deduction-guides for \( C \), the set contains an additional function template, called the aggregate deduction candidate, defined as follows. Let \( x_1, \ldots, x_n \) be the elements of the initializer-list or designated-initializer-list of the braced-init-list, or of the expression-list. For each \( x_i \), let \( e_i \) be the corresponding aggregate element of \( C \) or of one of its (possibly recursive) subaggregates that would be initialized by \( x_i \) (9.4.2) if

1. brace elision is not considered for any aggregate element that has a dependent non-array type or an array type with a value-dependent bound, and
2. each non-trailing aggregate element that is a pack expansion is assumed to correspond to no elements of the initializer list, and
3. a trailing aggregate element that is a pack expansion is assumed to correspond to all remaining elements of the initializer list (if any).

If there is no such aggregate element \( e_i \) for any \( x_i \), the aggregate deduction candidate is not added to the set. The aggregate deduction candidate is derived as above from a hypothetical constructor \( C(T_1, \ldots, T_n) \), where

1. if \( e_i \) is of array type and \( x_i \) is a braced-init-list or string-literal, \( T_i \) is an rvalue reference to the declared type of \( e_i \), and
2. otherwise, \( T_i \) is the declared type of \( e_i \).

Note: This argument will be compared against the implicit object parameter of the conversion functions. — end note
except that additional parameter packs of the form $P_j \ldots$ are inserted into the parameter list in their original aggregate element position corresponding to each non-trailing aggregate element of type $P_j$ that was skipped because it was a parameter pack, and the trailing sequence of parameters corresponding to a trailing aggregate element that is a pack expansion (if any) is replaced by a single parameter of the form $T_n \ldots$.

When resolving a placeholder for a deduced class type (9.2.9.3) where the template-name names an alias template $A$, the defining-type-id of $A$ must be of the form

\[
\text{typename}_{\text{opt}} \text{ nested-name-specifier}_{\text{opt}} \text{ template}_{\text{opt}} \text{ simple-template-id}
\]

as specified in 9.2.9.3. The guides of $A$ are the set of functions or function templates formed as follows. For each function or function template $f$ in the guides of the template named by the simple-template-id of the defining-type-id, the template arguments of the return type of $f$ are deduced from the defining-type-id of $A$ according to the process in 13.10.3.6 with the exception that deduction does not fail if not all template argument arguments are deduced. Let $g$ denote the result of substituting these deductions into $f$. If substitution succeeds, form a function or function template $f'$ with the following properties and add it to the set of guides of $A$:

1. The function type of $f'$ is the function type of $g$.
2. If $f$ is a function template, $f'$ is a function template whose template parameter list consists of all the template parameters of $A$ (including their default template arguments) that appear in the above deductions or (recursively) in their default template arguments, followed by the template parameters of $f$ that were not deduced (including their default template arguments), otherwise $f'$ is not a function template.
3. The associated constraints (13.5.3) are the conjunction of the associated constraints of $g$ and a constraint that is satisfied if and only if the arguments of $A$ are deducible (see below) from the return type.
4. If $f$ is a copy deduction candidate, then $f'$ is considered to be so as well.
5. If $f$ was generated from a deduction-guide (13.7.2.3), then $f'$ is considered to be so as well.
6. The explicit-specifier of $f'$ is the explicit-specifier of $g$ (if any).

The arguments of a template $A$ are said to be deducible from a type $T$ if, given a class template

\[
\text{template } <\text{typename}> \text{ class AA;}
\]

with a single partial specialization whose template parameter list is that of $A$ and whose template argument list is a specialization of $A$ with the template argument list of $A$ (13.8.3.2), $\text{AA}<T>$ matches the partial specialization.

Initialization and overload resolution are performed as described in 9.4 and 12.2.2.4, 12.2.2.5, or 12.2.2.8 (as appropriate for the type of initialization performed) for an object of a hypothetical class type, where the guides of the template named by the placeholder are considered to be the constructors of that class type for the purpose of forming an overload set, and the initializer is provided by the context in which class template argument deduction was performed. The following exceptions apply:

1. The first phase in 12.2.2.8 (considering initializer-list constructors) is omitted if the initializer list consists of a single expression of type $cv \ U$, where $U$ is, or is derived from, a specialization of the class template directly or indirectly named by the placeholder.
2. During template argument deduction for the aggregate deduction candidate, the number of elements in a trailing parameter pack is only deduced from the number of remaining function arguments if it is not otherwise deduced.

If the function or function template was generated from a constructor or deduction-guide that had an explicit-specifier, each such notional constructor is considered to have that same explicit-specifier. All such notional constructors are considered to be public members of the hypothetical class type.

[Example 1:]

\[
\text{template } <\text{class } T> \text{ struct A } \{
\begin{align*}
\text{explicit A(} & \text{const } T &, \ldots \text{) noexcept; } \quad \text{\#1} \\
A( & T &, \ldots); \quad \text{\#2}
\end{align*}
\};
\]

\[
i; \quad \text{\#1} \quad \text{\#2}
\]

\[
\text{A a1 = \{ i, i \}; } \quad \text{\#1} \quad \text{\#2}
\]

// error: explicit constructor \#1 selected in copy-list-initialization during deduction, cannot deduce from non-forwarding rvalue reference in \#2

§ 12.2.2.9
A a2(i, i);        // OK, #1 deduces to A<int> and also initializes
A a3(0, i);        // OK, #2 deduces to A<int> and also initializes
A a4 = {0, i};     // OK, #2 deduces to A<int> and also initializes

template <class T> A(const T&, const T&) -> A<T&>; // #3
template <class T> explicit A(T&&, T&&) -> A<T>;  // #4

A a5 = {0, 1};     // error: explicit deduction guide #4 selected in copy-list-initialization during deduction
A a6(0,1);        // OK, #4 deduces to A<int> and #2 initializes
A a7 = {0, i};     // error: #3 deduces to A<int&>, #1 and #2 declare same constructor
A a8(0,i);        // error: #3 deduces to A<int&>, #1 and #2 declare same constructor

template <class T> struct B {
    template <class U> using TA = T;
    template <class U> B(U, TA<U>);
};
B b{(int*)0, (char*)0};  // OK, deduces B<char*>}

template <typename T>
struct S {
    T x;
    T y;
};

template <typename T>
struct C {
    S<T> s;
    T t;
};

template <typename T>
struct D {
    S<int> s;
    T t;
};

C c1 = {1, 2};       // error: deduction failed
C c2 = {1, 2, 3};    // error: deduction failed
C c3 = {{1u, 2u}, 3}; // OK, deduces C<int>

D d1 = {1, 2};       // error: deduction failed
D d2 = {1, 2, 3};    // OK, braces elided, deduces D<int>

template <typename T>
struct E {
    T t;
    decltype(t) t2;
};
E e1 = {1, 2};       // OK, deduces E<int>

template <typename... T>
struct Types {};

template <typename... T>
struct F : Types<T...>, T... {};

struct X {};
struct Y {};
struct Z {};
struct W { operator Y(); };

§ 12.2.2.9
6 [Example 2:]

```cpp
Example 2:
```template <class T, class U> struct C {
    C(T, U);  // #1
};
template<class T, class U>
C(T, U) -> C<T, std::type_identity_t<U>>;  // #2

template<class V> using A = C<V *, V *>
template<std::integral W> using B = A<W>

int i;
double d;
A a1(&i, &i);  // deduces A<int>
A a2(i, i);  // error: cannot deduce V * from i
A a3(&i, &d);  // error: #1: cannot deduce (V*, V*) from (int *, double *)
    // #2: cannot deduce A<int> from C<int *, double *>
B b1(&i, &i);  // deduces B<int>
B b2(&d, &d);  // error: cannot deduce B<int> from C<double *, double *>
```

Possible exposition-only implementation of the above procedure:

```cpp
// The following concept ensures a specialization of A is deduced.
template <class> class AA;
template <class V> class AA<A<V>> { };  
template <class T> concept deduces_A = requires { sizeof(AA<T>); };

// f1 is formed from the constructor #1 of C, generating the following function template
template<T, U>
auto f1(T, U) -> C<T, U>;

// Deducing arguments for C<T, U> from C<V *, V*> deduces T as V * and U as V *:
// f1' is obtained by transforming f1 as described by the above procedure.
template<class V> requires deduces_A<C<V *, V *>>
auto f1_prime(V *, V*) -> C<V *, V *>

// f2 is formed from the deduction-guide #2 of C
// Deducing arguments for C<T, std::type_identity_t<U>> from C<V *, V*> deduces T as V *:
// f2' is obtained by transforming f2 as described by the above procedure.
template<class V, class U>
requires deduces_A<C<V *, std::type_identity_t<U>>>  
    auto f2_prime(V *, U) -> C<V *, std::type_identity_t<U>>;

// The following concept ensures a specialization of B is deduced.
template <class> class BB;
template <class V> class BB<B<V>> { };  
template <class T> concept deduces_B = requires { sizeof(BB<T>); };

// The guides for B derived from the above f1' and f2' for A are as follows:
template<std::integral W>
requires deduces_A<C<W *, W *> && deduces_B<C<W *, W *>>
    auto f1_prime_for_B(W *, W *) -> C<W *, W *>

template<std::integral W, class U>
requires deduces_A<C<W *, std::type_identity_t<U>>> &&
    deduces_B<C<W *, std::type_identity_t<U>>>  
    auto f2_prime_for_B(W *, U) -> C<W *, std::type_identity_t<U>>;

—end example]
**12.2.3 Viable functions**

From the set of candidate functions constructed for a given context (12.2.2), a set of viable functions is chosen, from which the best function will be selected by comparing argument conversion sequences and associated constraints (13.5.3) for the best fit (12.2.4). The selection of viable functions considers associated constraints, if any, and relationships between arguments and function parameters other than the ranking of conversion sequences.

1 First, to be a viable function, a candidate function shall have enough parameters to agree in number with the arguments in the list.

2 Second, for a function to be viable, if it has associated constraints (13.5.3), those constraints shall be satisfied (13.5.2).

3 Third, for F to be a viable function, there shall exist for each argument an implicit conversion sequence (12.2.4.2) that converts that argument to the corresponding parameter of F. If the parameter has reference type, the implicit conversion sequence includes the operation of binding the reference, and the fact that an lvalue reference to non-Const cannot be bound to an rvalue and that an rvalue reference cannot be bound to an lvalue can affect the viability of the function (see 12.2.4.2.5).

**12.2.4 Best viable function**

**12.2.4.1 General**

1 Define \( ICS^i(F) \) as follows:

- If \( F \) is a static member function, \( ICS^1(F) \) is defined such that \( ICS^1(F) \) is neither better nor worse than \( ICS^1(G) \) for any function \( G \), and, symmetrically, \( ICS^1(G) \) is neither better nor worse than \( ICS^1(F) \); otherwise, let \( ICS^i(F) \) denote the implicit conversion sequence that converts the \( i \)th argument in the list to the type of the \( i \)th parameter of viable function \( F \). 12.2.4.2 defines the implicit conversion sequences and 12.2.4.3 defines what it means for one implicit conversion sequence to be a better conversion sequence or worse conversion sequence than another.

2 Given these definitions, a viable function \( F_1 \) is defined to be a better function than another viable function \( F_2 \) if for all arguments \( i \), \( ICS^i(F_1) \) is not a worse conversion sequence than \( ICS^i(F_2) \), and then

- for some argument \( j \), \( ICS^j(F_1) \) is a better conversion sequence than \( ICS^j(F_2) \), or, if not that,

- the context is an initialization by user-defined conversion (see 9.4, 12.2.2.6, and 12.2.2.7) and the standard conversion sequence from the return type of \( F_1 \) to the destination type (i.e., the type of the entity being initialized) is a better conversion sequence than the standard conversion sequence from the return type of \( F_2 \) to the destination type.

**Example 1:**

```c
struct A {
    A();
    operator int();
    operator double();
} a;
int i = a; // a.operator int() followed by no conversion is better than
// a.operator double() followed by a conversion to int
float x = a; // ambiguous: both possibilities require conversions,
// and neither is better than the other
```

117) If a function is a static member function, this definition means that the first argument, the implied object argument, has no effect in the determination of whether the function is better or worse than any other function.
or, if not that,

(2.3) the context is an initialization by conversion function for direct reference binding (12.2.2.7) of a reference to function type, the return type of \( F_1 \) is the same kind of reference (lvalue or rvalue) as the reference being initialized, and the return type of \( F_2 \) is not

[Example 2:
```
template <class T> struct A {
    operator T&();  // #1
    operator T&&(); // #2
};
typedef int Fn();
A<Fn> a;
Fn& lf = a;       // calls #1
Fn&& rf = a;     // calls #2
```
— end example]

or, if not that,

(2.4) \( F_1 \) is not a function template specialization and \( F_2 \) is a function template specialization, or, if not that,

(2.5) \( F_1 \) and \( F_2 \) are function template specializations, and the function template for \( F_1 \) is more specialized than the template for \( F_2 \) according to the partial ordering rules described in 13.7.7.3, or, if not that,

(2.6) \( F_1 \) and \( F_2 \) are non-template functions with the same parameter-type-lists, and \( F_1 \) is more constrained than \( F_2 \) according to the partial ordering of constraints described in 13.5.5, or if not that,

(2.7) \( F_1 \) is a constructor for a class \( D \), \( F_2 \) is a constructor for a base class \( B \) of \( D \), and for all arguments the corresponding parameters of \( F_1 \) and \( F_2 \) have the same type

[Example 3:
```
struct A {
    A(int = 0);
};
struct B: A {
    using A::A;
    B();
};

int main() {
    B b;       // OK, B::B()
}
```
— end example]

or, if not that,

(2.8) \( F_2 \) is a rewritten candidate (12.2.2.3) and \( F_1 \) is not

[Example 4:
```
struct S {
    friend auto operator<=>(const S&, const S&) = default; // #1
    friend bool operator<(const S&, const S&);         // #2
};
bool b = S() < S(); // calls #2
```
— end example]

or, if not that,

(2.9) \( F_1 \) and \( F_2 \) are rewritten candidates, and \( F_2 \) is a synthesized candidate with reversed order of parameters and \( F_1 \) is not

[Example 5:
```
struct S {
    friend std::weak_ordering operator<=>(const S&, int); // #1
    friend std::weak_ordering operator<=>(int, const S&); // #2
};
```
bool b = 1 < S(); // calls #2
—end example]

or, if not that

— (2.10) F1 is generated from a deduction-guide (12.2.2.9) and F2 is not, or, if not that,

— (2.11) F1 is the copy deduction candidate (12.2.2.9) and F2 is not, or, if not that,

— (2.12) F1 is generated from a non-template constructor and F2 is generated from a constructor template.

[Example 6:

template <class T> struct A {
    using value_type = T;
    A(value_type); // #1
    A(const A&); // #2
    A(T, T, int); // #3
    template<class U>
    A(int, T, U); // #4
    // #5 is the copy deduction candidate, A(A)
};

A x(1, 2, 3); // uses #3, generated from a non-template constructor

template <class T>
A(T) -> A<T>;; // #6, less specialized than #5

A a(42); // uses #6 to deduce A<int> and #1 to initialize
A b = a; // uses #5 to deduce A<int> and #2 to initialize

template <class T>
A(A<T>) -> A<A<T>>; // #7, as specialized as #5

A b2 = a; // uses #7 to deduce A<A<int>> and #1 to initialize

—end example]

3 If there is exactly one viable function that is a better function than all other viable functions, then it is the one selected by overload resolution; otherwise the call is ill-formed.118

[Example 7:

void Fcn(const int*, short);
void Fcn(int*, int);

int i;
short s = 0;

void f() {
    Fcn(&i, s); // is ambiguous because &i -> int* is better than &i -> const int*
    // but s -> short is also better than s -> int

    Fcn(&i, 1L); // calls Fcn(int*, int), because &i -> int* is better than &i -> const int*
    // and 1L -> short and 1L -> int are indistinguishable

    Fcn(&i, 'c'); // calls Fcn(int*, int), because &i -> int* is better than &i -> const int*
    // and c -> int is better than c -> short
}
—end example]

4 If the best viable function resolves to a function for which multiple declarations were found, and if any two of these declarations inhabit different scopes and specify a default argument that made the function viable, the program is ill-formed.118

§ 12.2.4.1

118) The algorithm for selecting the best viable function is linear in the number of viable functions. Run a simple tournament to find a function \( W \) that is not worse than any opponent it faced. Although it is possible that another function \( F \) that \( W \) did not face is at least as good as \( W \), \( F \) cannot be the best function because at some point in the tournament \( F \) encountered another function \( G \) such that \( F \) was not better than \( G \). Hence, either \( W \) is the best function or there is no best function. So, make a second pass over the viable functions to verify that \( W \) is better than all other functions.
Example 8:

```c
namespace A {
    extern "C" void f(int = 5);
}
namespace B {
    extern "C" void f(int = 5);
}

using A::f;
using B::f;

void use() {
    f(3); // OK, default argument was not used for viability
    f();  // error: found default argument twice
}
```

12.2.4.2 Implicit conversion sequences

12.2.4.2.1 General

An implicit conversion sequence is a sequence of conversions used to convert an argument in a function call to the type of the corresponding parameter of the function being called. The sequence of conversions is an implicit conversion as defined in 7.3, which means it is governed by the rules for initialization of an object or reference by a single expression (9.4, 9.4.4).

Implicit conversion sequences are concerned only with the type, cv-qualification, and value category of the argument and how these are converted to match the corresponding properties of the parameter.

[Note 1: Other properties, such as the lifetime, storage class, alignment, accessibility of the argument, whether the argument is a bit-field, and whether a function is deleted (9.5.3), are ignored. So, although an implicit conversion sequence can be defined for a given argument-parameter pair, the conversion from the argument to the parameter might still be ill-formed in the final analysis. — end note]

A well-formed implicit conversion sequence is one of the following forms:

1. a standard conversion sequence (12.2.4.2.2),
2. a user-defined conversion sequence (12.2.4.2.3), or
3. an ellipsis conversion sequence (12.2.4.2.4).

However, if the target is

1. the first parameter of a constructor or
2. the implicit object parameter of a user-defined conversion function and the constructor or user-defined conversion function is a candidate by
   1. 12.2.2.4, when the argument is the temporary in the second step of a class copy-initialization,
   2. 12.2.2.5, 12.2.2.6, or 12.2.2.7 (in all cases), or
   3. the second phase of 12.2.2.8 when the initializer list has exactly one element that is itself an initializer list, and the target is the first parameter of a constructor of class X, and the conversion is to X or reference to cv X,

user-defined conversion sequences are not considered.

[Note 2: These rules prevent more than one user-defined conversion from being applied during overload resolution, thereby avoiding infinite recursion. — end note]

Example 1:

```c
struct Y { Y(int); }
struct A { operator int(); }
Y y1 = A(); // error: A::operator int() is not a candidate

struct X { X(); }
struct B { operator X(); }
B b;
X x{(b)}; // error: B::operator X() is not a candidate
```
For the case where the parameter type is a reference, see 12.2.4.2.5.

When the parameter type is not a reference, the implicit conversion sequence models a copy-initialization of the parameter from the argument expression. The implicit conversion sequence is the one required to convert the argument expression to a prvalue of the type of the parameter.

[Note 3: When the parameter has a class type, this is a conceptual conversion defined for the purposes of Clause 12; the actual initialization is defined in terms of constructors and is not a conversion. — end note]

Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion.

[Example 2: A parameter of type \texttt{A} can be initialized from an argument of type \texttt{const A}. The implicit conversion sequence for that case is the identity sequence; it contains no “conversion” from \texttt{const A} to \texttt{A}. — end example]

When the parameter has a class type and the argument expression has the same type, the implicit conversion sequence is an identity conversion. When the parameter has a class type and the argument expression has a derived class type, the implicit conversion sequence is a derived-to-base conversion from the derived class to the base class.

[Note 4: There is no such standard conversion; this derived-to-base conversion exists only in the description of implicit conversion sequences. — end note]

A derived-to-base conversion has Conversion rank (12.2.4.2.2).

In all contexts, when converting to the implicit object parameter or when converting to the left operand of an assignment operation only standard conversion sequences are allowed.

If no conversions are required to match an argument to a parameter type, the implicit conversion sequence is the standard conversion sequence consisting of the identity conversion (12.2.4.2.2).

If no sequence of conversions can be found to convert an argument to a parameter type, the implicit conversion sequence cannot be formed.

If there are multiple well-formed implicit conversion sequences converting the argument to the parameter type, the implicit conversion sequence associated with the parameter is defined to be the unique conversion sequence designated the \textit{ambiguous conversion sequence}. For the purpose of ranking implicit conversion sequences as described in 12.2.4.3, the ambiguous conversion sequence is treated as a user-defined conversion sequence that is indistinguishable from any other user-defined conversion sequence.

[Note 5: This rule prevents a function from becoming non-viable because of an ambiguous conversion sequence for one of its parameters.]

[Example 3:]

```cpp
class B;
class A { A (B&);};
class B { operator A () {}; }
class C { C (B&); }
void f(A) {} 
void f(C) {}
B b;
f(b); // error: ambiguous because there is a conversion \texttt{b} \rightarrow \texttt{C} (via constructor)
// and an (ambiguous) conversion \texttt{b} \rightarrow \texttt{A} (via constructor or conversion function)

void f(B) {}
f(b); // OK, unambiguous

— end example]
— end note]
```

If a function that uses the ambiguous conversion sequence is selected as the best viable function, the call will be ill-formed because the conversion of one of the arguments in the call is ambiguous.

The three forms of implicit conversion sequences mentioned above are defined in the following subclauses.

12.2.4.2.2 Standard conversion sequences

Table 18 summarizes the conversions defined in 7.3 and partitions them into four disjoint categories: Lvalue Transformation, Qualification Adjustment, Promotion, and Conversion.
[Note 1: These categories are orthogonal with respect to value category, cv-qualification, and data representation: the Lvalue Transformations do not change the cv-qualification or data representation of the type; the Qualification Adjustments do not change the value category or data representation of the type; and the Promotions and Conversions do not change the value category or cv-qualification of the type. — end note]

2 [Note 2: As described in 7.3, a standard conversion sequence either is the Identity conversion by itself (that is, no conversion) or consists of one to three conversions from the other four categories. If there are two or more conversions in the sequence, the conversions are applied in the canonical order: Lvalue Transformation, Promotion or Conversion, Qualification Adjustment. — end note]

3 Each conversion in Table 18 also has an associated rank (Exact Match, Promotion, or Conversion). These are used to rank standard conversion sequences (12.2.4.3). The rank of a conversion sequence is determined by considering the rank of each conversion in the sequence and the rank of any reference binding (12.2.4.2.5). If any of those has Conversion rank, the sequence has Conversion rank; otherwise, if any of those has Promotion rank, the sequence has Promotion rank; otherwise, the sequence has Exact Match rank.

12.2.4.2.3 User-defined conversion sequences [over.ics.user]

1 A user-defined conversion sequence consists of an initial standard conversion sequence followed by a user-defined conversion (11.4.8) followed by a second standard conversion sequence. If the user-defined conversion is specified by a constructor (11.4.8.2), the initial standard conversion sequence converts the source type to the type of the first parameter of that constructor. If the user-defined conversion is specified by a conversion function (11.4.8.3), the initial standard conversion sequence converts the source type to the type of the implicit object parameter of that conversion function.

2 The second standard conversion sequence converts the result of the user-defined conversion to the target type for the sequence; any reference binding is included in the second standard conversion sequence. Since an implicit conversion sequence is an initialization, the special rules for initialization by user-defined conversion apply when selecting the best user-defined conversion for a user-defined conversion sequence (see 12.2.4 and 12.2.4.2).

3 If the user-defined conversion is specified by a specialization of a conversion function template, the second standard conversion sequence shall have exact match rank.

4 A conversion of an expression of class type to the same class type is given Exact Match rank, and a conversion of an expression of class type to a base class of that type is given Conversion rank, in spite of the fact that a constructor (i.e., a user-defined conversion function) is called for those cases.

12.2.4.2.4 Ellipsis conversion sequences [over.ics.ellipsis]

1 An ellipsis conversion sequence occurs when an argument in a function call is matched with the ellipsis parameter specification of the function called (see 7.6.1.3).
12.2.4.2.5 Reference binding

When a parameter of reference type binds directly (9.4.4) to an argument expression, the implicit conversion sequence is the identity conversion, unless the argument expression has a type that is a derived class of the parameter type, in which case the implicit conversion sequence is a derived-to-base conversion (12.2.4.2).

Example 1:

```c
struct A {};
struct B : public A {} b;
int f(A&);
int f(B&);
int i = f(b);  // calls f(B&), an exact match, rather than f(A&), a conversion
```

If the parameter binds directly to the result of applying a conversion function to the argument expression, the implicit conversion sequence is a user-defined conversion sequence (12.2.4.2.3), with the second standard conversion sequence either an identity conversion or, if the conversion function returns an entity of a type that is a derived class of the parameter type, a derived-to-base conversion.

When a parameter of reference type is not bound directly to an argument expression, the conversion sequence is the one required to convert the argument expression to the referenced type according to 12.2.4.2. Conceptually, this conversion sequence corresponds to copy-initializing a temporary of the referenced type with the argument expression. Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion.

Except for an implicit object parameter, for which see 12.2.2, an implicit conversion sequence cannot be formed if it requires binding an lvalue reference other than a reference to a non-volatile const type to an rvalue or binding an rvalue reference to an lvalue other than a function lvalue.

Note 1: This means, for example, that a candidate function cannot be a viable function if it has a non-const lvalue reference parameter (other than the implicit object parameter) and the corresponding argument would require a temporary to be created to initialize the lvalue reference (see 9.4.4). — end note

Other restrictions on binding a reference to a particular argument that are not based on the types of the reference and the argument do not affect the formation of an implicit conversion sequence, however.

Example 2: A function with an “lvalue reference to int” parameter can be a viable candidate even if the corresponding argument is an int bit-field. The formation of implicit conversion sequences treats the int bit-field as an int lvalue and finds an exact match with the parameter. If the function is selected by overload resolution, the call will nonetheless be ill-formed because of the prohibition on binding a non-const lvalue reference to a bit-field (9.4.4). — end example

12.2.4.2.6 List-initialization sequence

When an argument is an initializer list (9.4.5), it is not an expression and special rules apply for converting it to a parameter type.

If the initializer list is a designated-initializer-list, a conversion is only possible if the parameter has an aggregate type that can be initialized from the initializer list according to the rules for aggregate initialization (9.4.2), in which case the implicit conversion sequence is a user-defined conversion sequence whose second standard conversion sequence is an identity conversion.

Note 1: Aggregate initialization does not require that the members are declared in designation order. If, after overload resolution, the order does not match for the selected overload, the initialization of the parameter will be ill-formed (9.4.5).

Example 1:

```c
struct A { int x, y; };
struct B { int y, x; };
void f(A a, int);
void f(B b, ...);
void g(A a);
void g(B b);
void h() {
  f({.x = 1, .y = 2}, 0);  // OK; calls #1
  f({.y = 2, .x = 1}, 0);  // error: selects #1, initialization of a fails
  g({.x = 1, .y = 2});     // due to non-matching member order (9.4.5)
  g({.x = 1, .y = 2});     // error: ambiguous between #3 and #4
}
Otherwise, if the parameter type is an aggregate class `X` and the initializer list has a single element of type `cv U`, where `U` is `X` or a class derived from `X`, the implicit conversion sequence is the one required to convert the element to the parameter type.

4 Otherwise, if the parameter type is a character array and the initializer list has a single element that is an appropriately-typed string-literal (9.4.3), the implicit conversion sequence is the identity conversion.

5 Otherwise, if the parameter type is `std::initializer_list<X>` and all the elements of the initializer list can be implicitly converted to `X`, the implicit conversion sequence is the worst conversion necessary to convert an element of the list to `X`, or if the initializer list has no elements, the identity conversion. This conversion can be a user-defined conversion even in the context of a call to an initializer-list constructor.

[Example 2:]

```cpp
void f(std::initializer_list<int>);  // Example 2
f( {} );                   // OK: f(initializer_list<int>) identity conversion
f( {1,2,3} );               // OK: f(initializer_list<int>) identity conversion
f( {'a','b'} );             // OK: f(initializer_list<int>) integral promotion
f( {1.0} );                 // error: narrowing
```

6 Otherwise, if the parameter type is "array of N X" or "array of unknown bound of X", if there exists an implicit conversion sequence from each element of the initializer list (and from `{}` in the former case if N exceeds the number of elements in the initializer list) to `X`, the implicit conversion sequence is the worst such implicit conversion sequence.

7 Otherwise, if the parameter is a non-aggregate class `X` and overload resolution per 12.2.2.8 chooses a single best constructor `C` of `X` to perform the initialization of an object of type `X` from the argument initializer list:

- If `C` is not an initializer-list constructor and the initializer list has a single element of type `cv U`, where `U` is `X` or a class derived from `X`, the implicit conversion sequence has Exact Match rank if `U` is `X`, or Conversion rank if `U` is derived from `X`.

- Otherwise, the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion.

If multiple constructors are viable but none is better than the others, the implicit conversion sequence is the ambiguous conversion sequence. User-defined conversions are allowed for conversion of the initializer list elements to the constructor parameter types except as noted in 12.2.4.2.

[Example 3:]

```cpp
struct A {
    A(std::initializer_list<int>);  // #1
    A(std::initializer_list<complex<double>>); // #2
    A(std::initializer_list<std::string>);   // #3
};
A a( 1.0,2.0 );                           // OK, uses #1

void g(A);  // OK, uses #3
    g( {"foo", "bar" } );

typedef int IA[3];
void h(const IA&);  // OK: identity conversion
    h( { 1, 2, 3 } );
```

119) Since there are no parameters of array type, this will only occur as the referenced type of a reference parameter.
struct B {
    B(int, double);
};
void g(B);
g( {'a', 'b'} ); // OK: g(B(int, double)) user-defined conversion
g( {1.0, 1.0} ); // error: narrowing

void f(B);
f( {'a', 'b'} ); // error: ambiguous f(A) or f(B)

struct C {
    C(std::string);
};
void h(C);
h( "foo" ); // OK: h(C(std::string("foo")))

struct D {
    D(A, C);
};
void i(D);
i( {1,2}, {"bar"} ); // OK: i(D(A(std::initializer_list<int>{1,2}), C(std::string("bar"))))

—end example—

8 Otherwise, if the parameter has an aggregate type which can be initialized from the initializer list according to the rules for aggregate initialization (9.4.2), the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion.

[Example 4:]
struct A {
    int m1;
    double m2;
};
void f(A);
f( {'a', 'b'} ); // OK: f(A(int,double)) user-defined conversion
f( {1.0} ); // error: narrowing
—end example—

9 Otherwise, if the parameter is a reference, see 12.2.4.2.5.

[Note 2: The rules in this subclause will apply for initializing the underlying temporary for the reference. — end note]

[Example 5:]
struct A {
    int m1;
    double m2;
};
void f(const A&);
f( {'a', 'b'} ); // OK: f(A(int,double)) user-defined conversion
f( {1.0} ); // error: narrowing

void g(const double &);
g({1}); // same conversion as int to double
—end example—

10 Otherwise, if the parameter type is not a class:

(10.1) — if the initializer list has one element that is not itself an initializer list, the implicit conversion sequence is the one required to convert the element to the parameter type;

[Example 6:]
void f(int);
f( {'a'} ); // OK: same conversion as char to int
f( {1.0} ); // error: narrowing

§ 12.2.4.2.6 335
if the initializer list has no elements, the implicit conversion sequence is the identity conversion.

Example 7:

```c
void f(int);
f( { } );  // OK: identity conversion
```

In all cases other than those enumerated above, no conversion is possible.

### 12.2.4.3 Ranking implicit conversion sequences

This subclause defines a partial ordering of implicit conversion sequences based on the relationships better conversion sequence and better conversion. If an implicit conversion sequence $S_1$ is defined by these rules to be a better conversion sequence than $S_2$, then it is also the case that $S_2$ is a worse conversion sequence than $S_1$. If conversion sequence $S_1$ is neither better than nor worse than conversion sequence $S_2$, $S_1$ and $S_2$ are said to be indistinguishable conversion sequences.

When comparing the basic forms of implicit conversion sequences (as defined in 12.2.4.2):

1. a standard conversion sequence (12.2.4.2.2) is a better conversion sequence than a user-defined conversion sequence or an ellipsis conversion sequence, and
2. a user-defined conversion sequence (12.2.4.2.3) is a better conversion sequence than an ellipsis conversion sequence (12.2.4.2.4).

Two implicit conversion sequences of the same form are indistinguishable conversion sequences unless one of the following rules applies:

1. List-initialization sequence $L_1$ is a better conversion sequence than list-initialization sequence $L_2$ if
   1. $L_1$ converts to `std::initializer_list<X>` for some $X$ and $L_2$ does not, or, if not that,
   2. $L_1$ and $L_2$ convert to arrays of the same element type, and either the number of elements $n_1$ initialized by $L_1$ is less than the number of elements $n_2$ initialized by $L_2$, or $n_1 = n_2$ and $L_2$ converts to an array of unknown bound and $L_1$ does not, even if one of the other rules in this paragraph would otherwise apply.

Example 1:

```c
void f1(int);  // #1
void f1(std::initializer_list<long>);  // #2
void g1() { f1({42}); }  // chooses #2

void f2(std::pair<const char*, const char*>);  // #3
void f2(std::initializer_list<std::string>);  // #4
void g2() { f2({"foo","bar"}); }  // chooses #4
```

Example 2:

```c
void f(int (&&)[2]);  // #1
void f(double (&&)[2]);  // #2
void f(int (&&)[2]);  // #3

f( {1} );  // Calls #1: Better than #2 due to conversion, better than #3 due to bounds
f( {1.0} );  // Calls #2: Identity conversion is better than floating-integral conversion
f( {1.0, 2.0} );  // Calls #2: Identity conversion is better than floating-integral conversion
f( {1, 2} );  // Calls #2: Converting to array of known bound is better than to unknown bound,
              // and an identity conversion is better than floating-integral conversion
```

Standard conversion sequence $S_1$ is a better conversion sequence than standard conversion sequence $S_2$ if

1. $S_1$ is a proper subsequence of $S_2$ (comparing the conversion sequences in the canonical form defined by 12.2.4.2.2, excluding any Lvalue Transformation; the identity conversion sequence is considered to be a subsequence of any non-identity conversion sequence) or, if not that,
— the rank of $S_1$ is better than the rank of $S_2$, or $S_1$ and $S_2$ have the same rank and are distinguishable by the rules in the paragraph below, or, if not that,

— $S_1$ and $S_2$ include reference bindings (9.4.4) and neither refers to an implicit object parameter of a non-static member function declared without a ref-qualifier, and $S_1$ binds an rvalue reference to an rvalue and $S_2$ binds an lvalue reference

**[Example 3]**

```
int i;
int f1();
int&& f2();
int g(const int&);
int g(const int&&);
int j = g(i);  // calls g(const int&)
in k = g(f1());  // calls g(const int&&)
in l = g(f2());  // calls g(const int&&)
```

```c
struct A {
    A& operator<<(int);
    void p() &;
    void p() &&;
};
```

```
A& operator<<(A&&, char);
A() << 1;  // calls A::operator<<(int)
A() << "c";  // calls operator<<(A&&, char)
A a;
a << 1;  // calls A::operator<<(int)
a << "c";  // calls A::operator<<(int)
A().p();  // calls A::p()&
a.p();  // calls A::p()&&
```

— end example]

or, if not that,

— $S_1$ and $S_2$ include reference bindings (9.4.4) and $S_1$ binds an lvalue reference to a function lvalue and $S_2$ binds an rvalue reference to a function lvalue

**[Example 4]**

```
int f(void (&)());  // #1
int f(void (&&)());  // #2
void g();
int i1 = f(g);  // calls #1
```

— end example]

or, if not that,

— $S_1$ and $S_2$ differ only in their qualification conversion (7.3.6) and yield similar types $T_1$ and $T_2$, respectively, where $T_1$ can be converted to $T_2$ by a qualification conversion.

**[Example 5]**

```
int f(const volatile int *);
int f(const int *);
in i;
in j = f(&i);  // calls f(const int*)
```

— end example]

or, if not that,

— $S_1$ and $S_2$ include reference bindings (9.4.4), and the types to which the references refer are the same type except for top-level cv-qualifiers, and the type to which the reference initialized by $S_2$ refers is more cv-qualified than the type to which the reference initialized by $S_1$ refers.

**[Example 6]**

```
int f(const int &);
int f(int &);
int g(const int &);
```
int g(int);

int i;
int j = f(i);    // calls f(int k)
int k = g(i);    // ambiguous

struct X {
  void f() const;
  void f();
};
void g(const X& a, X b) {
  a.f();     // calls X::f() const
  b.f();    // calls X::f()
}

—end example]

(3.3) — User-defined conversion sequence U1 is a better conversion sequence than another user-defined conversion sequence U2 if they contain the same user-defined conversion function or constructor or they initialize the same class in an aggregate initialization and in either case the second standard conversion sequence of U1 is better than the second standard conversion sequence of U2.

[Example 7:
struct A {
  operator short();
} a;
int f(int);
int f(float);
int i = f(a);    // calls f(int), because short → int is
                 // better than short → float.

—end example]

4 Standard conversion sequences are ordered by their ranks: an Exact Match is a better conversion than a Promotion, which is a better conversion than a Conversion. Two conversion sequences with the same rank are indistinguishable unless one of the following rules applies:

(4.1) — A conversion that does not convert a pointer or a pointer to member to bool is better than one that does.

(4.2) — A conversion that promotes an enumeration whose underlying type is fixed to its underlying type is better than one that promotes to the promoted underlying type, if the two are different.

(4.3) — If class B is derived directly or indirectly from class A, conversion of B* to A* is better than conversion of B* to void*, and conversion of A* to void* is better than conversion of B* to void*.

(4.4) — If class B is derived directly or indirectly from class A and class C is derived directly or indirectly from B,

(4.4.1) — conversion of C* to B* is better than conversion of C* to A*,

[Example 8:
struct A {};
struct B : public A {};
struct C : public B {};
C* pc;
int f(A*);
int f(B*);
int i = f(pc);    // calls f(B*)

—end example]

(4.4.2) — binding of an expression of type C to a reference to type B is better than binding an expression of type C to a reference to type A,

(4.4.3) — conversion of A::* to B::* is better than conversion of A::* to C::*,

(4.4.4) — conversion of C to B is better than conversion of C to A,

(4.4.5) — conversion of B* to A* is better than conversion of C* to A*,
(4.4.6) binding of an expression of type B to a reference to type A is better than binding an expression of type C to a reference to type A,

(4.4.7) conversion of B::* to C::* is better than conversion of A::* to C::* , and

(4.4.8) conversion of B to A is better than conversion of C to A.

[Note 1: Compared conversion sequences will have different source types only in the context of comparing the second standard conversion sequence of an initialization by user-defined conversion (see 12.2.4); in all other contexts, the source types will be the same and the target types will be different. — end note]

12.3 Address of an overload set

An id-expression whose terminal name refers to an overload set S and that appears without arguments is resolved to a function, a pointer to function, or a pointer to member function for a specific function that is chosen from a set of functions selected from S determined based on the target type required in the context (if any), as described below. The target can be

(1.1) an object or reference being initialized (9.4, 9.4.4, 9.4.5),

(1.2) the left side of an assignment (7.6.19),

(1.3) a parameter of a function (7.6.1.3),

(1.4) a parameter of a user-defined operator (12.4),

(1.5) the return value of a function, operator function, or conversion (8.7.4),

(1.6) an explicit type conversion (7.6.1.4, 7.6.1.9, 7.6.3), or

(1.7) a non-type template-parameter (13.4.3).

The id-expression can be preceded by the & operator.

[Note 1: Any redundant set of parentheses surrounding the function name is ignored (7.5.3). — end note]

2 If there is no target, all non-template functions named are selected. Otherwise, a non-template function with type F is selected for the function type FT of the target type if F (after possibly applying the function pointer conversion (7.3.14)) is identical to FT.

[Note 2: That is, the class of which the function is a member is ignored when matching a pointer-to-member-function type. — end note]

3 The specialization, if any, generated by template argument deduction (13.10.4, 13.10.3.3, 13.10.2) for each function template named is added to the set of selected functions considered.

4 Non-member functions and static member functions match targets of function pointer type or reference to function type. Non-static member functions match targets of pointer-to-member-function type.

[Note 3: If a non-static member function is chosen, the result can be used only to form a pointer to member (7.6.2.2). — end note]

5 All functions with associated constraints that are not satisfied (13.5.3) are eliminated from the set of selected functions. If more than one function in the set remains, all function template specializations in the set are eliminated if the set also contains a function that is not a function template specialization. Any given non-template function F0 is eliminated if the set contains a second non-template function that is more constrained than F0 according to the partial ordering rules of 13.5.5. Any given function template specialization F1 is eliminated if the set contains a second function template specialization whose function template is more specialized than the function template of F1 according to the partial ordering rules of 13.7.7.3. After such eliminations, if any, there shall remain exactly one selected function.

[Example 1:

```c
int f(double);
int f(int);
int (*pfd)(double) = &f; // selects f(double)
int (*pfi)(int) = &f;    // selects f(int)
int (*pfe)(...) = &f;    // error: type mismatch
int (&rfi)(int) = f;     // selects f(int)
int (&rfd)(double) = f;  // selects f(double)
void g() {
  (int (*)(int))&f;     // cast expression as selector
}
```
The initialization of `pfe` is ill-formed because no `f()` with type `int(...)` has been declared, and not because of any ambiguity. For another example,

```c
struct X {
    int f(int);
    static int f(long);
};
```

```c
int (X::*p1)(int) = &X::f; // OK
int (*)(p2)(int) = &X::f; // error: mismatch
int (*)(p3)(long) = &X::f; // OK
int (X::*p4)(long) = &X::f; // error: mismatch
int (X::*p5)(int) = &X::f; // error: wrong syntax for
                          // pointer to member
int (*)(p6)(long) = &X::f; // OK
```

—end example

[Note 4: If `f` and `g` are both overload sets, the Cartesian product of possibilities is considered to resolve `f(&g)`, or the equivalent expression `f(g)`. — end note]

[Note 5: Even if `B` is a public base of `D`, we have

```c
D* f();
B* (*)(p1)() = &f; // error
```

void g(D*);
void (*)(p2)(B*) = &g; // error

—end note]

## 12.4 Overloaded operators

### 12.4.1 General

A declaration whose declarator-id is an operator-function-id shall declare a function or function template or an explicit instantiation or specialization of a function template. A function so declared is an operator function. A function template so declared is an operator function template. A specialization of an operator function template is also an operator function. An operator function is said to implement the operator named in its operator-function-id.

`operator-function-id: operator operator`

`operator: one of
  new  delete  new[]  delete[]  co_await  ()  [ ]  ->  -*`

`~  !  +  -  *  %  ^  &  |  =  +=  -=  *=  /=  %=  ^=  &=  |=  ^=  <<=  >>=`

`[]  <<  >>  <<=  >>=  ++  --`

[Note 1: The operators `new[]`, `delete[]`, `()`, and `[ ]` are formed from more than one token. The latter two operators are function call (7.6.1.3) and subscritping (7.6.1.2). — end note]

Both the unary and binary forms of

```c
+  -  *  &
```

can be overloaded.

[Note 2: The following operators cannot be overloaded:

```c
.  *  ::  ?;
```

nor can the preprocessing symbols `#` (15.6.3) and `##` (15.6.4). — end note]

Operator functions are usually not called directly; instead they are invoked to evaluate the operators they implement (12.4.2 – 12.4.7). They can be explicitly called, however, using the `operator-function-id` as the name of the function in the function call syntax (7.6.1.3).

[Example 1:

```c
complex z = a.operator+(b); // complex z = a+b;
void* p = operator new(sizeof(int)*n);
```
The allocation and deallocation functions, `operator new`, `operator new[]`, `operator delete`, and `operator delete[]`, are described completely in 6.7.5.5. The attributes and restrictions found in the rest of 12.4 do not apply to them unless explicitly stated in 6.7.5.5.

The `co_await` operator is described completely in 7.6.2.4. The attributes and restrictions found in the rest of 12.4 do not apply to it unless explicitly stated in 7.6.2.4.

An operator function shall either be a non-static member function or be a non-member function that has at least one parameter whose type is a class, a reference to a class, an enumeration, or a reference to an enumeration. It is not possible to change the precedence, grouping, or number of operands of operators. The meaning of the operators `=`, (unary) `&`, and `, (comma), predefined for each type, can be changed for specific class types by defining operator functions that implement these operators. Likewise, the meaning of the operators (unary) `&` and `, (comma) can be changed for specific enumeration types. Operator functions are inherited in the same manner as other base class functions.

An operator function shall be a prefix unary, binary, function call, subscripting, class member access, increment, or decrement operator function.

[Note 3: The identities among certain predefined operators applied to basic types (for example, `++a ≡ a+=1`) need not hold for operator functions. Some predefined operators, such as `+=`, require an operand to be an lvalue when applied to basic types; this is not required by operator functions. — end note]

An operator function cannot have default arguments (9.3.4.7), except where explicitly stated below. Operator functions cannot have more or fewer parameters than the number required for the corresponding operator, as described in the rest of 12.4.

Operators not mentioned explicitly in subclauses 12.4.3.2 through 12.4.7 act as ordinary unary and binary operators obeying the rules of 12.4.2 or 12.4.3.

### 12.4.2 Unary operators

A **prefix unary operator function** is a function named `operator@` for a prefix unary-operator `@` (7.6.2.2) that is either a non-static member function (11.4.2) with no parameters or a non-member function with one parameter. For a **unary-expression** of the form `cast-expression` `operator @ ()`, the operator function is selected by overload resolution (12.2.2.3). If a member function is selected, the expression is interpreted as `cast-expression . operator @ ()`

Otherwise, if a non-member function is selected, the expression is interpreted as `operator @ ()`

[Note 1: The operators `++` and `--` (7.6.2.3) are described in 12.4.7. — end note]

[Note 2: The unary and binary forms of the same operator have the same name. Consequently, a unary operator can hide a binary operator from an enclosing scope, and vice versa. — end note]

### 12.4.3 Binary operators

A **binary operator function** is a function named `operator@` for a binary operator `@` that is either a non-static member function (11.4.2) with one parameter or a non-member function with two parameters. For an expression `x @ y` with subexpressions `x` and `y`, the operator function is selected by overload resolution (12.2.2.3). If a member function is selected, the expression is interpreted as `x . operator @ ( y )`

Otherwise, if a non-member function is selected, the expression is interpreted as `operator @ ( x , y )`

An **equality operator function** is an operator function for an equality operator (7.6.10). A **relational operator function** is an operator function for a relational operator (7.6.9). A **three-way comparison operator function** is an operator function for the three-way comparison operator (7.6.8). A **comparison operator function** is an equality operator function, a relational operator function, or a three-way comparison operator function.

### 12.4.3.2 Simple assignment

A **simple assignment operator function** is a binary operator function named `operator=`. A simple assignment operator function shall be a non-static member function.
[Note 1: Because only standard conversion sequences are considered when converting to the left operand of an assignment operation (12.2.4.2), an expression \( x = y \) with a subexpression \( x \) of class type is always interpreted as \( x.\text{operator}=(y) \). — end note]

[Note 2: Since a copy assignment operator is implicitly declared for a class if not declared by the user (11.4.6), a base class assignment operator function is always hidden by the copy assignment operator function of the derived class. — end note]

[Note 3: Any assignment operator function, even the copy and move assignment operators, can be virtual. For a derived class \( D \) with a base class \( B \) for which a virtual copy/move assignment has been declared, the copy/move assignment operator in \( D \) does not override \( B \)'s virtual copy/move assignment operator.

Example 1:

```cpp
struct B {
  virtual int operator=(int);
  virtual B& operator=(const B&);
};
struct D : B {
  virtual int operator=(int);
  virtual D& operator=(const B&);
};

D dobj1;
D dobj2;
B* bptr = &dobj1;

void f() {
  bptr->operator=(99); // calls D::operator=(int)
  *bptr = 99; // ditto
  bptr->operator=(dobj2); // calls D::operator=(const B&)
  *bptr = dobj2; // ditto
  dobj1 = dobj2; // calls implicitly-declared D::operator=(const D&)
}
```

— end example

— end note

12.4.4 Function call [over.call]

A function call operator function is a function named \( \text{operator}() \) that is a non-static member function with an arbitrary number of parameters. It may have default arguments. For an expression of the form

\[
\text{postfix-expression} (\text{expression-list}_{\text{opt}})
\]

where the \text{postfix-expression} is of class type, the operator function is selected by overload resolution (12.2.2.2.3). If a surrogate call function for a conversion function named \( \text{operator conversion-type-id} \) is selected, the expression is interpreted as

\[
\text{postfix-expression} . \text{operator conversion-type-id} () (\text{expression-list}_{\text{opt}})
\]

Otherwise, the expression is interpreted as

\[
\text{postfix-expression} . \text{operator} () (\text{expression-list}_{\text{opt}})
\]

12.4.5 Subscripting [over.sub]

A subscripting operator function is a function named \( \text{operator}[] \) that is a non-static member function with exactly one parameter. For an expression of the form

\[
\text{postfix-expression} [\text{expr-or-braced-init-list}]
\]

the operator function is selected by overload resolution (12.2.2.3). If a member function is selected, the expression is interpreted as

\[
\text{postfix-expression} . \text{operator} [] (\text{expr-or-braced-init-list})
\]

Example 1:

```cpp
struct X {
  Z operator[](std::initializer_list<int>);
};
X x;
x[{1,2,3}] = 7; // OK: meaning x.operator[](\{1,2,3\})
int a[10];
```
a[1,2,3] = 7; // error: built-in subscript operator

—end example

12.4.6 Class member access

A class member access operator function is a function named `operator->` that is a non-static member function taking no parameters. For an expression of the form

```
postfix-expression -> template_opt id-expression
```

the operator function is selected by overload resolution (12.2.2.3), and the expression is interpreted as

```
(postfix-expression . operator -> () ) -> template_opt id-expression
```

12.4.7 Increment and decrement

An increment operator function is a function named `operator++`. If this function is a non-static member function with no parameters, or a non-member function with one parameter, it defines the prefix increment operator `++` for objects of that type. If the function is a non-static member function with one parameter (which shall be of type `int`) or a non-member function with two parameters (the second of which shall be of type `int`), it defines the postfix increment operator `++` for objects of that type. When the postfix increment is called as a result of using the `++` operator, the `int` argument will have value zero.¹²⁰

[Example 1:
```
struct X {
    X& operator++(); // prefix ++a
    X operator++(int); // postfix a++
};

struct Y { }
    Y& operator++(Y&); // prefix ++b
    Y operator++(Y&, int); // postfix b++

void f(X a, Y b) {
    ++a; // a.operator++();
    a++; // a.operator++(0);
    ++b; // operator++(b);
    b++; // operator++(b, 0);

    a.operator++(); // explicit call: like ++a;
    a.operator++(0); // explicit call: like a++;
    operator++(b); // explicit call: like ++b;
    operator++(b, 0); // explicit call: like b++;
}
```
—end example

²

A decrement operator function is a function named `operator--` and is handled analogously to an increment operator function.

12.5 Built-in operators

The candidate operator functions that represent the built-in operators defined in 7.6 are specified in this subclause. These candidate functions participate in the operator overload resolution process as described in 12.2.2.3 and are used for no other purpose.

[Note 1: Because built-in operators take only operands with non-class type, and operator overload resolution occurs only when an operand expression originally has class or enumeration type, operator overload resolution can resolve to a built-in operator only when an operand has a class type that has a user-defined conversion to a non-class type appropriate for the operand, or when an operand has an enumeration type that can be converted to a type appropriate for the operator. Also note that some of the candidate operator functions given in this subclause are more permissive than the built-in operators themselves. As described in 12.2.2.3, after a built-in operator is selected by overload resolution the expression is subject to the requirements for the built-in operator given in 7.6, and therefore to any additional semantic constraints given there. In some cases, user-written candidates with the same name and parameter types as a built-in candidate operator function cause the built-in operator function to not be included in the set of candidate functions. —end note]

¹²⁰ Calling `operator++` explicitly, as in expressions like `a.operator++(2)`, has no special properties: The argument to `operator++` is 2.
In this subclause, the term promoted integral type is used to refer to those integral types which are preserved by integral promotion (7.3.7) (including e.g. int and long but excluding e.g. char).

[Note 2: In all cases where a promoted integral type is required, an operand of unscoped enumeration type will be acceptable by way of the integral promotions. —end note]

In the remainder of this subclause, \( vq \) represents either volatile or no cv-qualifier.

For every pair \((T, vq)\), where \(T\) is an arithmetic type other than bool, there exist candidate operator functions of the form

\[ vq \ T \& \ operator\++\( (vq \ T\&) \); \]
\[ T \ operator\++\( (vq \ T\&, \ int) \); \]

For every pair \((T, vq)\), where \(T\) is an arithmetic type other than bool, there exist candidate operator functions of the form

\[ vq \ T \& \ operator\--\( (vq \ T\&) \); \]
\[ T \ operator\--\( (vq \ T\&, \ int) \); \]

For every pair \((T, vq)\), where \(T\) is a cv-qualified or cv-unqualified object type, there exist candidate operator functions of the form

\[ T\* vq \& \ operator\++\( (T\* vq\&) \); \]
\[ T\* vq \& \ operator\--\( (T\* vq\&) \); \]
\[ T\* \ operator\++\( (T\* vq\&, \ int) \); \]
\[ T\* \ operator\--\( (T\* vq\&, \ int) \); \]

For every cv-qualified or cv-unqualified object type \(T\), there exist candidate operator functions of the form

\[ T\& \ operator*\( (T\*); \]

For every function type \(T\) that does not have cv-qualifiers or a ref-qualifier, there exist candidate operator functions of the form

\[ T\& \ operator*\( (T\*); \]

For every type \(T\) there exist candidate operator functions of the form

\[ T \ operator\+(T); \]
\[ T \ operator\-(T); \]

For every promoted integral type \(T\), there exist candidate operator functions of the form

\[ T \ operator\-(T); \]

For every quintuple \((C1, C2, T, cv1, cv2)\), where \(C2\) is a class type, \(C1\) is the same type as \(C2\) or is a derived class of \(C2\), and \(T\) is an object type or a function type, there exist candidate operator functions of the form

\[ cv12 \ T \& \ operator\->\*\( (cv1 \ C1\*, \ cv2 \ T \ C2\::\*); \]

where \(cv12\) is the union of \(cv1\) and \(cv2\). The return type is shown for exposition only; see 7.6.4 for the determination of the operator’s result type.

For every pair of types \(L\) and \(R\), where each of \(L\) and \(R\) is a floating-point or promoted integral type, there exist candidate operator functions of the form

\[ LR \ operator\*(L, R); \]
\[ LR \ operator/(L, R); \]
\[ LR \ operator+(L, R); \]
\[ LR \ operator-(L, R); \]
\[ bool \ operator==(L, R); \]
\[ bool \ operator!=(L, R); \]
\[ bool \ operator<(L, R); \]
\[ bool \ operator>(L, R); \]
\[ bool \ operator<=(L, R); \]
\[ bool \ operator>=(L, R); \]

where \(LR\) is the result of the usual arithmetic conversions (7.4) between types \(L\) and \(R\).

For every integral type \(T\) there exists a candidate operator function of the form

\[ std::strong_ordering \ operator<=>(T, T); \]
For every pair of floating-point types $L$ and $R$, there exists a candidate operator function of the form

```cpp
std::partial_ordering operator<(L, R);
```

For every cv-qualified or cv-unqualified object type $T$ there exist candidate operator functions of the form

```cpp
T* operator+(T*, std::ptrdiff_t);
T& operator[](T*, std::ptrdiff_t);
T* operator-(T*, std::ptrdiff_t);
T* operator+(std::ptrdiff_t, T*);
T& operator[](std::ptrdiff_t, T*);
```

For every $T$, where $T$ is a pointer to object type, there exist candidate operator functions of the form

```cpp
std::ptrdiff_t operator-(T, T);
```

where $R$ is the result type specified in 7.6.8.

For every $T$, where $T$ is a pointer-to-member type or `std::nullptr_t`, there exist candidate operator functions of the form

```cpp
bool operator==(T, T);
bool operator!=(T, T);
```

For every pair of promoted integral types $L$ and $R$, there exist candidate operator functions of the form

```cpp
LR operator%(L, R);
LR operator&(L, R);
LR operator^(L, R);
LR operator|(L, R);
L operator<<(L, R);
L operator>>(L, R);
```

where $LR$ is the result of the usual arithmetic conversions (7.4) between types $L$ and $R$.

For every triple $(L, vq, R)$, where $L$ is an arithmetic type, and $R$ is a floating-point or promoted integral type, there exist candidate operator functions of the form

```cpp
vq Lk operator=(vq Lk, R);
vq Lk operator==(vq Lk, R);
vq Lk operator!=(vq Lk, R);
vq Lk operator<=(vq Lk, R);
vq Lk operator>==(vq Lk, R);
```

For every pair $(T, vq)$, where $T$ is any type, there exist candidate operator functions of the form

```cpp
T*vqk operator=(T*vqk, T*);
```

For every pair $(T, vq)$, where $T$ is an enumeration or pointer-to-member type, there exist candidate operator functions of the form

```cpp
vq Tk operator=(vq Tk, T);
```

For every pair $(T, vq)$, where $T$ is a cv-qualified or cv-unqualified object type, there exist candidate operator functions of the form

```cpp
T*vqk operator+(T*vqk, std::ptrdiff_t);
T*vqk operator-=(T*vqk, std::ptrdiff_t);
```

For every triple $(L, vq, R)$, where $L$ is an integral type, and $R$ is a promoted integral type, there exist candidate operator functions of the form

```cpp
vq Lk operator%(vq Lk, R);
vq Lk operator<=(vq Lk, R);
vq Lk operator>=(vq Lk, R);
```
There also exist candidate operator functions of the form

```cpp
bool operator!(bool);
bool operator&&(bool, bool);
bool operator||(bool, bool);
```

For every pair of types \( L \) and \( R \), where each of \( L \) and \( R \) is a floating-point or promoted integral type, there exist candidate operator functions of the form

```cpp
LR operator?: (bool, L, R);
```

where \( LR \) is the result of the usual arithmetic conversions (7.4) between types \( L \) and \( R \).

[Note 3: As with all these descriptions of candidate functions, this declaration serves only to describe the built-in operator for purposes of overload resolution. The operator "?:" cannot be overloaded. —end note]

For every type \( T \), where \( T \) is a pointer, pointer-to-member, or scoped enumeration type, there exist candidate operator functions of the form

```cpp
T operator?: (bool, T, T);
```

12.6 User-defined literals

```
literal-operator-id:
operator string-literal identifier
operator user-defined-string-literal
```

1 The string-literal or user-defined-string-literal in a literal-operator-id shall have no encoding-prefix and shall contain no characters other than the implicit terminating '\0'. The ud-suffix of the user-defined-string-literal or the identifier in a literal-operator-id is called a literal suffix identifier. Some literal suffix identifiers are reserved for future standardization; see 16.4.5.3.6. A declaration whose literal-operator-id uses such a literal suffix identifier is ill-formed, no diagnostic required.

2 A declaration whose declarator-id is a literal-operator-id shall declare a function or function template that belongs to a namespace (it could be a friend function (11.8.4)) or an explicit instantiation or specialization of a function template. A function declared with a literal-operator-id is a literal operator. A function template declared with a literal-operator-id is a literal operator template.

3 The declaration of a literal operator shall have a parameter-declaration-clause equivalent to one of the following:

```cpp
const char*
unsigned long long int
long double
char
wchar_t
char8_t
char16_t
char32_t
```

If a parameter has a default argument (9.3.4.7), the program is ill-formed.

4 A raw literal operator is a literal operator with a single parameter whose type is `const char*`.

5 A numeric literal operator template is a literal operator template whose template-parameter-list has a single template-parameter that is a non-type template parameter pack (13.7.4) with element type `char`. A string literal operator template is a literal operator template whose template-parameter-list comprises a single non-type template-parameter of class type. The declaration of a literal operator template shall have an empty parameter-declaration-clause and shall declare either a numeric literal operator template or a string literal operator template.

6 Literal operators and literal operator templates shall not have C language linkage.

[Note 1: Literal operators and literal operator templates are usually invoked implicitly through user-defined literals (5.13.8). However, except for the constraints described above, they are ordinary namespace-scope functions and

§ 12.6
function templates. In particular, they are looked up like ordinary functions and function templates and they follow the same overload resolution rules. Also, they can be declared\texttt{inline} or\texttt{constexpr}, they can have internal, module, or external linkage, they can be called explicitly, their addresses can be taken, etc. — end note

8 [Example 1:

```cpp
void operator "" _km(long double); // OK
string operator '"' _i18n(const char*, std::size_t); // OK
template <char...> double operator '"' _\u03C0(); // OK: UCN for lowercase pi
float operator '"' _e(const char*); // OK
float operator '"'E(const char*); // ill-formed, no diagnostic required:
   // reserved literal suffix (16.4.5.3.6, 5.13.8)
double operator""_Bq(long double); // OK: does not use the reserved identifier _Bq (5.10)
double operator""_Bq(long double); // ill-formed, no diagnostic required:
   // uses the reserved identifier _Bq (5.10)
float operator " " _B(const char*); // error: non-empty string-literal
string operator "" 5X(const char*, std::size_t); // error: invalid literal suffix identifier
double operator "" _miles(double); // error: invalid parameter-declaration-clause
template <char...> int operator "" _j(const char*); // error: invalid parameter-declaration-clause
extern "C" void operator "" _m(long double); // error: C language linkage
— end example]

§ 12.6 347
13 Templates [temp]

13.1 Preamble [temp.pre]

A template defines a family of classes, functions, or variables, an alias for a family of types, or a concept.

1 A template defines a family of classes, functions, or variables, an alias for a family of types, or a concept.

template-declaration:
  template-head declaration
  template-head concept-definition

template-head:
  template < template-parameter-list > requires-clause opt

template-parameter-list:
  template-parameter
  template-parameter-list , template-parameter

requires-clause:
  requires constraint-logical-or-expression

constraint-logical-or-expression:
  constraint-logical-and-expression
  constraint-logical-or-expression | constraint-logical-and-expression

constraint-logical-and-expression:
  primary-expression
  constraint-logical-and-expression && primary-expression

[Note 1: The > token following the template-parameter-list of a template-declaration can be the product of replacing a >> token by two consecutive > tokens (13.3). — end note]

2 The declaration in a template-declaration (if any) shall

(2.1) — declare or define a function, a class, or a variable, or
(2.2) — define a member function, a member class, a member enumeration, or a static data member of a class
  template or of a class nested within a class template, or
(2.3) — define a member template of a class or class template, or
(2.4) — be a deduction-guide, or
(2.5) — be an alias-declaration.

3 A template-declaration is a declaration. A declaration introduced by a template declaration of a variable is a
variable template. A variable template at class scope is a static data member template.

[Example 1:

```cpp
template<class T>
constexpr T pi = T(3.1415926535897932385L);

template<class T>
T circular_area(T r) {
  return pi<T> * r * r;
}

struct matrix_constants {
  template<class T>
    using pauli = hermitian_matrix<T, 2>;
  template<class T>
    constexpr static pauli<T> sigma1 = {{ 0, 1 }, { 1, 0 }};
  template<class T>
    constexpr static pauli<T> sigma2 = {{ 0, -1i }, { 1i, 0 }};
  template<class T>
    constexpr static pauli<T> sigma3 = {{ 1, 0 }, { 0, -1 }};
};
```

— end example]

4 [Note 2: A template-declaration can appear only as a namespace scope or class scope declaration. — end note]
Its declaration shall not be an export-declaration. In a function template declaration, the unqualified-id of the declarator-id shall be a name.

[Note 3: A class or variable template declaration of a simple-template-id declares a partial specialization (13.7.6). —end note]

5 In a template-declaration, explicit specialization, or explicit instantiation the init-declarator-list in the declaration shall contain at most one declarator. When such a declaration is used to declare a class template, no declarator is permitted.

6 A specialization (explicit or implicit) of one template is distinct from all specializations of any other template. A template, an explicit specialization (13.9.4), and a partial specialization shall not have C language linkage.

[Note 4: Default arguments for function templates and for member functions of class templates are considered definitions for the purpose of template instantiation (13.7) and must obey the one-definition rule (6.3). —end note]

7 [Note 5: A template cannot have the same name as any other name bound in the same scope (6.4.1), except that a function template can share a name with non-template functions (9.3.4.6) and/or function templates (13.10.4). Specializations, including partial specializations (13.7.6), do not reintroduce or bind names. Their target scope is the target scope of the primary template, so all specializations of a template belong to the same scope as it does. —end note]

8 An entity is templated if it is

(a.1) — a template,

(a.2) — an entity defined (6.2) or created (6.7.7) in a templated entity,

(a.3) — a member of a templated entity,

(a.4) — an enumerator for an enumeration that is a templated entity, or

(a.5) — the closure type of a lambda-expression (7.5.5.2) appearing in the declaration of a templated entity.

[Note 6: A local class, a local or block variable, or a friend function defined in a templated entity is a templated entity. —end note]

9 A template-declaration is written in terms of its template parameters. The optional requires-clause following a template-parameter-list allows the specification of constraints (13.5.3) on template arguments (13.4). The requires-clause introduces the constraint-expression that results from interpreting the constraint-logical-or-expression as a constraint-expression. The constraint-logical-or-expression of a requires-clause is an unevaluated operand (7.2.3).

[Note 7: The expression in a requires-clause uses a restricted grammar to avoid ambiguities. Parentheses can be used to specify arbitrary expressions in a requires-clause.

[Example 2:

```cpp
template<int N> requires N == sizeof new unsigned short
int f();  // error: parentheses required around == expression
```

—end example]

—end note]

10 A definition of a function template, member function of a class template, variable template, or static data member of a class template shall be reachable from the end of every definition domain (6.3) in which it is implicitly instantiated (13.9.2) unless the corresponding specialization is explicitly instantiated (13.9.3) in some translation unit; no diagnostic is required.

### 13.2 Template parameters

The syntax for template-parameters is:

```
template-parameter:
  type-parameter
  parameter-declaration

type-parameter:
  type-parameter-key . . . opt identifier opt
  type-parameter-key identifier opt = type-id
  type-constraint . . . opt identifier opt
  type-constraint identifier opt = type-id
  template-head type-parameter-key . . . opt identifier opt
  template-head type-parameter-key identifier opt = id-expression
```

§ 13.2 349
type-parameter-key:  
  class 
  typename

type-constraint:  
  nested-name-specifier_opt concept-name 
  nested-name-specifier_opt concept-name < template-argument-list_opt>

The component names of a type-constraint are its concept-name and those of its nested-name-specifier (if any).

[Note 1: The > token following the template-parameter-list of a type-parameter can be the product of replacing a >> token by two consecutive > tokens (13.3). —end note]

There is no semantic difference between class and typename in a type-parameter-key. typename followed by an unqualified-id names a template type parameter. typename followed by a qualified-id denotes the type in a non-type parameter-declaration. A template-parameter of the form class identifier is a type-parameter.

[Example 1:]
```cpp
class T { /* ... */ }; 
int i; 

template<class T, T i> void f(T t) {
  T t1 = i;  // template-parameters T and i 
  ::T t2 = ::i;  // global namespace members T and i 
}
```

Here, the template f has a type-parameter called T, rather than an unnamed non-type template-parameter of class T. —end example]

A storage class shall not be specified in a template-parameter declaration. Types shall not be defined in a template-parameter declaration.

[Note 2: A template argument can be a class template or alias template. For example,]
```cpp
template<class K, class V, template<class T> class C = myarray>
class Map {
  C<K> key;
  C<V> value;
};
```

—end note]

A type-constraint Q that designates a concept C can be used to constrain a contextually-determined type or template type parameter pack T with a constraint-expression E defined as follows. If Q is of the form C<A_1, ···, A_n>, then let E' be C<T, A_1, ···, A_n>. Otherwise, let E' be C<T>. If T is not a pack, then E is E', otherwise E is (E' && ...). This constraint-expression E is called the immediately-declared constraint of Q for T. The concept designated by a type-constraint shall be a type concept (13.7.9).

A type-parameter that starts with a type-constraint introduces the immediately-declared constraint of the type-constraint for the parameter.

[Example 2:]
```cpp
template<typename T> concept C1 = true; 
template<typename... Ts> concept C2 = true; 
template<typename T, typename U> concept C3 = true; 

template<C1 T> struct s1;  // associates C1<T>
template<C1... Ts> concept C2 = true;  // associates (C1<T> && ...)
template<C2... Ts> concept C3 = true;  // associates (C2<T> && ...)
template<C3<int> T> struct s4;  // associates C3<T, int>
template<C3<int>... T> struct s5;  // associates (C3<T, int> && ...)
```

121) Since template template-parameters and template template-arguments are treated as types for descriptive purposes, the terms non-type parameter and non-type argument are used to refer to non-type, non-template parameters and arguments.
A non-type template-parameter shall have one of the following (possibly cv-qualified) types:

(6.1) — a structural type (see below),
(6.2) — a type that contains a placeholder type (9.2.9.6), or
(6.3) — a placeholder for a deduced class type (9.2.9.7).

The top-level cv-qualifiers on the template-parameter are ignored when determining its type.

A structural type is one of the following:

(7.1) — a scalar type, or
(7.2) — an lvalue reference type, or
(7.3) — a literal class type with the following properties:

(7.3.1) — all base classes and non-static data members are public and non-mutable and
(7.3.2) — the types of all bases classes and non-static data members are structural types or (possibly multi-dimensional) array thereof.

An id-expression naming a non-type template-parameter of class type T denotes a static storage duration object of type const T, known as a template parameter object, whose value is that of the corresponding template argument after it has been converted to the type of the template-parameter. All such template parameters in the program of the same type with the same value denote the same template parameter object. A template parameter object shall have constant destruction (7.7).

[Note 3: If an id-expression names a non-type non-reference template-parameter, then it is a prvalue if it has non-class type. Otherwise, if it is of class type T, it is an lvalue and has type const T (7.5.4.2). — end note]

[Example 3:]
using X = int;
struct A {};
template<const X& x, int i, A a> void f() {
  i++;
  // error: change of template-parameter value
  &x; // OK
  &i; // error: address of non-reference template-parameter
  &a; // OK
  int& ri = i; // error: non-const reference bound to temporary
  const int& cri = i; // OK: const reference bound to temporary
  const A& ra = a; // OK: const reference bound to a template parameter object
}

[Note 4: A non-type template-parameter cannot be declared to have type cv void.]

[Example 4:]
template<void v> class X; // error
template<void* pv> class Y; // OK

[end example]

[end note]

A non-type template-parameter of type “array of T” or of function type T is adjusted to be of type “pointer to T”.

[Example 5:]
template<int* a> struct R { /* ... */ };  
template<int b[5]> struct S { /* ... */ };  
int p;
R<&p> v;   // OK
S<&p> x;   // OK due to parameter adjustment
int v[5];
R<&v> y;   // OK due to implicit argument conversion
S<&v> z;   // OK due to both adjustment and conversion

[end example]

§ 13.2 351
A non-type template parameter declared with a type that contains a placeholder type with a type-constraint introduces the immediately-declared constraint of the type-constraint for the invented type corresponding to the placeholder (9.3.4.6).

A default template-argument is a template-argument (13.4) specified after = in a template-parameter. A default template-argument may be specified for any kind of template-parameter (type, non-type, template) that is not a template parameter pack (13.7.4). A default template-argument may be specified in a template declaration. A default template-argument shall not be specified in the template-parameter-lists of the definition of a member of a class template that appears outside of the member’s class. A default template-argument shall not be specified in a friend class template declaration. If a friend function template declaration D specifies a default template-argument, that declaration shall be a definition and there shall be no other declaration of the function template which is reachable from D or from which D is reachable.

The set of default template-arguments available for use is obtained by merging the default arguments from all prior declarations of the template in the same way default function arguments are (9.3.4.7).

[Example 6:

```cpp
template<class T1, class T2 = int> class A;
template<class T1 = int, class T2> class A;
```

is equivalent to

```cpp
template<class T1 = int, class T2 = int> class A;
```

—end example]

If a template-parameter of a class template, variable template, or alias template has a default template-argument, each subsequent template-parameter shall either have a default template-argument supplied or be a template parameter pack. If a template-parameter of a primary class template, primary variable template, or alias template is a template parameter pack, it shall be the last template-parameter. A template parameter pack of a function template shall not be followed by another template parameter unless that template parameter can be deduced from the parameter-type-list (9.3.4.6) of the function template or has a default argument (13.10.3). A template parameter of a deduction guide template (13.7.2.3) that does not have a default argument shall be deducible from the parameter-type-list of the deduction guide template.

[Example 7:

```cpp
template<class T1 = int, class T2> class B;    // error
//U can be neither deduced from the parameter-type-list nor specified
template<class... T, class... U> void f() { }  // error
template<class... T, class U> void g() { }    // error
```

—end example]

A template-parameter shall not be given default arguments by two different declarations if one is reachable from the other.

[Example 8:

```cpp
template<class T = int> class X;
template<class T = int> class X { /* ... */ };  // error
```

—end example]

When parsing a default template-argument for a non-type template-parameter, the first non-nested > is taken as the end of the template-parameter-list rather than a greater-than operator.

[Example 9:

```cpp
template<int i = 3 > 4 >
class X { /* ... */ };  // syntax error
```

```cpp
template<int i = (3 > 4) >
class Y { /* ... */ };  // OK
```

—end example]

A template-parameter of a template template-parameter is permitted to have a default template-argument. When such default arguments are specified, they apply to the template template-parameter in the scope of the template template-parameter.

[Example 10:
template <template <class TT = float> class T> struct A {
    inline void f();
    inline void g();
};
template <template <class TT> class T> void A<T>::f() {
    T<> t;  // error: TT has no default template argument
}
template <template <class TT = char> class T> void A<T>::g() {
    T<> t;  // OK, T<char>
}
— end example]

18 If a template-parameter is a type-parameter with an ellipsis prior to its optional identifier or is a parameter-declaration that declares a pack (9.3.4.6), then the template-parameter is a template parameter pack (13.7.4). A template parameter pack that is a parameter-declaration whose type contains one or more unexpanded packs is a pack expansion. Similarly, a template parameter pack that is a type-parameter with a template-parameter-list containing one or more unexpanded packs is a pack expansion. A type parameter pack with a type-constraint that contains an unexpanded parameter pack is a pack expansion. A template parameter pack that is a pack expansion shall not expand a template parameter pack declared in the same template-parameter-list.

[Example 11:

    template <class... Types>
    class Tuple;  // Types is a template type parameter pack
    // but not a pack expansion

template <class T, int... Dims>
    struct multi_array;
    // Dims is a non-type template parameter pack
    // but not a pack expansion

template <class... T>
    struct value_holder {
        template <T... Values> struct apply { };
    };
    // Values is a non-type template parameter pack
    // and a pack expansion

template <class... T, T... Values>
    struct static_array;
    // error: Values expands template type parameter
    // pack T within the same template parameter list
— end example]

13.3 Names of template specializations [temp.names]

A template specialization (13.9) can be referred to by a template-id:

\[
\begin{align*}
\text{simple-template-id:} & \quad \text{template-name} < \text{template-argument-list}_{opt} > \\
\text{template-id:} & \quad \text{simple-template-id} \\
& \quad \text{operator-function-id} < \text{template-argument-list}_{opt} > \\
& \quad \text{literal-operator-id} < \text{template-argument-list}_{opt} > \\
\text{template-name:} & \quad \text{identifier} \\
\text{template-argument-list:} & \quad \text{template-argument} \ldots_{opt} \\
& \quad \text{template-argument-list}, \text{template-argument} \ldots_{opt} \\
\text{template-argument:} & \quad \text{constant-expression} \\
& \quad \text{type-id} \\
& \quad \text{id-expression}
\end{align*}
\]

The component name of a simple-template-id, template-id, or template-name is the first name in it.

A < is interpreted as the delimiter of a template-argument-list if it follows a name that is not a conversion-function-id and

that follows the keyword template or a - after a nested-name-specifier or in a class member access expression, or
— for which name lookup finds the injected-class-name of a class template or finds any declaration of a template, or
— that is an unqualified name for which name lookup either finds one or more functions or finds nothing, or
— that is a terminal name in a using-declarator (9.9), in a declarator-id (9.3.4), or in a type-only context other than a nested-name-specifier (13.8).

[Note 1: If the name is an identifier, it is then interpreted as a template-name. The keyword `template` is used to indicate that a dependent qualified name (13.8.3.2) denotes a template where an expression might appear. — end note]

[Example 1:

```cpp
struct X {
    template<std::size_t> X* alloc();
    template<std::size_t> static X* adjust();
};

template<class T> void f(T* p) {
    T* p1 = p->alloc<200>();      // error: < means less than
    T* p2 = p->template alloc<200>(); // OK: < starts template argument list
    T::adjust<100>();            // error: < means less than
    T::template adjust<100>();   // OK: < starts template argument list
}
```
—end example]

4 When parsing a template-argument-list, the first non-nested `>` is taken as the ending delimiter rather than a greater-than operator. Similarly, the first non-nested `>>` is treated as two consecutive but distinct `>` tokens, the first of which is taken as the end of the template-argument-list and completes the template-id.

[Note 2: The second `>` token produced by this replacement rule can terminate an enclosing template-id construct or it can be part of a different construct (e.g., a cast). — end note]

[Example 2:

```cpp
template<int i> class X { /* ... */ };
X<1<2> x1;                    // syntax error
X<(1>2)> x2;                 // OK

template<class T> class Y { /* ... */ };
Y<X<1>> x3;                   // OK, same as Y<1> > x3;
Y<X<6>1>> x4;                 // syntax error
Y<X<6>1>>) x5;                // OK
```
—end example]

5 The keyword `template` shall not appear immediately after a declarative nested-name-specifier (7.5.4.3).

6 A name prefixed by the keyword `template` shall be followed by a template argument list or refer to a class template or an alias template. The latter case is deprecated (D.10). The keyword `template` shall not appear immediately before a `~` token (as to name a destructor).

[Note 3: The keyword `template` cannot be applied to non-template members of class templates. — end note]

[Note 4: As is the case with the typename prefix, the template prefix is allowed even when lookup for the name would already find a template. — end note]

[Example 3:

```cpp
template<class T> struct A {
    void f(int);
    template <class U> void f(U);
};

template<class T> void f(T t) {
    A<T> a;
    a.template f<t>();          // OK: calls template
```
a.template f(t);  \[// \text{error: not a template-id}\]
}

template <class T> struct B {
    template <class T2> struct C { 
    
    }; // deprecated: T::C is assumed to name a class template:
    template <class T, template <class X> class TT = T::template C> struct D { 
    D<B<int>> > db;
    
    — end example]

7 A template-id is valid if

(7.1) — there are at most as many arguments as there are parameters or a parameter is a template parameter

(7.2) — there is an argument for each non-deducible non-pack parameter that does not have a default template-

(7.3) — each template-argument matches the corresponding template-parameter (13.4),

(7.4) — substitution of each template argument into the following template parameters (if any) succeeds, and

(7.5) — if the template-id is non-dependent, the associated constraints are satisfied as specified in the next

A simple-template-id shall be valid unless it names a function template specialization (13.10.3).

[Example 4]:

template<class T, T::type n = 0> class X;
struct S {
    using type = int;
};

using T1 = X<S, int, int>;  \[// \text{error: too many arguments}\]
using T2 = X<int>;  \[// \text{error: no default argument for first template parameter}\]
using T3 = X<int>;  \[// \text{error: value 1 does not match type-parameter}\]
using T4 = X<int>;  \[// \text{error: substitution failure for second template parameter}\]
using T5 = X<S>;  \[// \text{OK}\]

— end example]

8 When the template-name of a simple-template-id names a constrained non-function template or a constrained
template template-parameter, and all template-arguments in the simple-template-id are non-dependent (13.8.3.5),
the associated constraints (13.5.3) of the constrained template shall be satisfied (13.5.2).

[Example 5]:

template<typename T> concept C1 = sizeof(T) != sizeof(int);

template<C1 T> struct S1 { 
};
template<C1 T> using Ptr = T*;

S1<int>* p;  \[// \text{error: constraints not satisfied}\]
Ptr<int> p;  \[// \text{error: constraints not satisfied}\]

template<typename T>
struct S2 { Ptr<int> x; 
};  \[// \text{ill-formed, no diagnostic required}\]

template<typename T>
struct S3 { Ptr<T> x; 
};  \[// \text{OK, satisfaction is not required}\]

S3<int> x;  \[// \text{error: constraints not satisfied}\]

template<typename T>
struct S4 { 
X<int> x;  \[// \text{ill-formed, no diagnostic required}\]
};
template<
typename T> concept C2 = sizeof(T) == 1;

template<C2 T> struct S { };   // error: constraints not satisfied

template struct S<char[2]>;      // error: constraints not satisfied

— end example |

9 A concept-id is a simple-template-id where the template-name is a concept-name. A concept-id is a prvalue of type bool, and does not name a template specialization. A concept-id evaluates to true if the concept’s normalized constraint-expression (13.5.3) is satisfied (13.5.2) by the specified template arguments and false otherwise.

[Note 5: Since a constraint-expression is an unevaluated operand, a concept-id appearing in a constraint-expression is not evaluated except as necessary to determine whether the normalized constraints are satisfied. — end note]

[Example 6:

template<typename T> concept C = true;
static_assert(C<int>);       // OK

— end example]

13.4 Template arguments

13.4.1 General

There are three forms of template-argument, corresponding to the three forms of template-parameter: type, non-type and template. The type and form of each template-argument specified in a template-id shall match the type and form specified for the corresponding parameter declared by the template in its template-parameter-list. When the parameter declared by the template is a template parameter pack (13.7.4), it will correspond to zero or more template-arguments.

[Example 1:

template<class T> class Array {
  T* v;
  int sz;
public:
  explicit Array(int);
  T& operator[](int);
  T& elem(int i) { return v[i]; }
};

Array<int> v1(20);
typedef std::complex<double> dcomplex;       // std::complex is a standard library template
Array<dcomplex> v2(30);
Array<dcomplex> v3(40);

void bar() {
  v1[3] = 7;
  v2[3] = v3.elem(4) = dcomplex(7,8);
}

— end example]

2 The template argument list of a template-head is a template argument list in which the n\textsuperscript{th} template argument has the value of the n\textsuperscript{th} template parameter of the template-head. If the n\textsuperscript{th} template parameter is a template parameter pack (13.7.4), the n\textsuperscript{th} template argument is a pack expansion whose pattern is the name of the template parameter pack.

3 In a template-argument, an ambiguity between a type-id and an expression is resolved to a type-id, regardless of the form of the corresponding template-parameter.\[123\]

[Example 2:

template<class T> void f();
template<int I> void f();

123] There is no such ambiguity in a default template-argument because the form of the template-parameter determines the allowable forms of the template-argument.
void g() {
    f<int>()();  // int() is a type-id: call the first f()
}

—end example

[Note 1: Names used in a template-argument are subject to access control where they appear. Because a template-parameter is not a class member, no access control applies. —end note]

[Example 3:

```cpp
template<class T> class X {
    static T t;
};

class Y {
    private:
        struct S { /* ... */ };  // OK: S is accessible
        X<S> x;  // X<Y::S> has a static member of type Y::S
        // OK: even though Y::S is private
    }

    X<Y::S> y;  // error: S not accessible
—end example]

For a template-argument that is a class type or a class template, the template definition has no special access rights to the members of the template-argument.

[Example 4:

```cpp
template <template <class TT> class T> class A {
    typename T<int>::S s;
};

template <class U> class B {
    private:
        struct S { /* ... */ };  // OK: has no access to B::S
    }

    A<B> b;  // error: A has no access to B::S
—end example]

When template argument packs or default template-arguments are used, a template-argument list can be empty. In that case the empty <> brackets shall still be used as the template-argument-list.

[Example 5:

```cpp
template<class T = char> class String;
String<>* p;  // OK: String<char>
String* q;  // syntax error

template<class ... Elements> class Tuple;
Tuple<>* t;  // OK: Elements is empty
Tuple* u;  // syntax error
—end example]

An explicit destructor call (11.4.7) for an object that has a type that is a class template specialization may explicitly specify the template-arguments.

[Example 6:

```cpp
template<class T> struct A {
    ~A();
};

void f(A<int>* p, A<int>* q) {
    p->A<int>::~A();  // OK: destructor call
    q->A<int>::~A<int>();  // OK: destructor call
}
—end example]

§ 13.4.1
If the use of a template-argument gives rise to an ill-formed construct in the instantiation of a template specialization, the program is ill-formed.

When name lookup for the component name of a template-id finds an overload set, both non-template functions in the overload set and function templates in the overload set for which the template-arguments do not match the template-parameters are ignored.

[Note 2: If none of the function templates have matching template-parameters, the program is ill-formed. — end note]

When a simple-template-id does not name a function, a default template-argument is implicitly instantiated (13.9.2) when the value of that default argument is needed.

[Example 7:

```cpp
template<typename T, typename U = int> struct S { };    
S<bool>* p;     // the type of p is S<bool, int>*
```
The default argument for U is instantiated to form the type S<bool, int>*. — end example]

A template-argument followed by an ellipsis is a pack expansion (13.7.4).

### 13.4.2 Template type arguments

A template-argument for a template-parameter which is a type shall be a type-id.

[Example 1:

```cpp
template <class T> class X { };    
template <class T> void f(T t) { }     
struct {} unnamed_obj;
```]

void f() {
    struct A { };    
    enum { e1 };    
    typedef struct {} B;    
    B b;    
    X<A> x1;     // OK    
    X<A*> x2;    // OK    
    X<B> x3;     // OK    
    f(e1);       // OK    
    f(unnamed_obj); // OK    
    f(b);        // OK
}

— end example]

[Note 1: A template type argument can be an incomplete type (6.8). — end note]

### 13.4.3 Template non-type arguments

If the type T of a template-parameter (13.2) contains a placeholder type (9.2.9.6) or a placeholder for a deduced class type (9.2.9.7), the type of the parameter is the type deduced for the variable x in the invented declaration

\[ T x = \text{template-argument} ; \]

If a deduced parameter type is not permitted for a template-parameter declaration (13.2), the program is ill-formed.

A template-argument for a non-type template-parameter shall be a converted constant expression (7.7) of the type of the template-parameter.

[Note 1: If the template-argument is an overload set (or the address of such, including forming a pointer-to-member), the matching function is selected from the set (12.3). — end note]

For a non-type template-parameter of reference or pointer type, or for each non-static data member of reference or pointer type in a non-type template-parameter of class type or subobject thereof, the reference or pointer value shall not refer to or be the address of (respectively):

1. a temporary object (6.7.7),
2. a string literal object (5.13.5),
3. the result of a typeid expression (7.6.1.8),
— a predefined __func__ variable (9.5.1), or
— a subobject (6.7.2) of one of the above.

[Example 1:

template<const int* pci> struct X { /* ... */
};
int ai[10];
X<ai> xi; // array to pointer and qualification conversions

struct Y { /* ... */
};
template<const Y& b> struct Z { /* ... */
};
Y y;
Z<y> z; // no conversion, but note extra cv-qualification

template<int (&pa)[5]> struct W { /* ... */
};
int b[5];
W<b> w; // no conversion

void f(char);
void f(int);

template<void (*pf)(int)> struct A { /* ... */
};
A<&f> a; // selects f(int)

template<auto n> struct B { /* ... */
};
B<5> b1; // OK, template parameter type is int
B<"a"> b2; // OK, template parameter type is char
B<2.5> b3; // OK, template parameter type is double
B<void(0)> b4; // error: template parameter type cannot be void
— end example]

[Note 2: A string-literal (5.13.5) is not an acceptable template-argument for a template-parameter of non-class type.

[Example 2:

template<class T, T p> class X {
    /* ... */
};
X<const char*, "Studebaker"> x; // error: string literal object as template-argument
X<const char*, "Knop" + 1> x2; // error: subobject of string literal object as template-argument

cosn char p[] = "Vivisectionist";
X<const char*, p> y; // OK

struct A {
    constexpr A(const char*) {}
};
X<A, "Pyrophoricity"> z; // OK, string-literal is a constructor argument to A
— end example]
— end note]

[Note 3: A temporary object is not an acceptable template-argument when the corresponding template-parameter has reference type.

[Example 3:

template<const int& CRI> struct B { /* ... */
};
B<1> b1; // error: temporary would be required for template argument

int c = 1;
B<c> b2; // OK

struct X { int n; };

§ 13.4.3 359
struct Y { const int &r; }

template<Y y> struct C { /* ... */ }

C<Y{X{1}.n}> c; // error: subobject of temporary object used to initialize
                 // reference member of template parameter

—end example

—end note

13.4.4 Template template arguments
Coworker

A template-argument for a template template-parameter shall be the name of a class template or an alias

template, expressed as id-expression. Only primary templates are considered when matching the template
template argument with the corresponding parameter; partial specializations are not considered even if their
parameter lists match that of the template template parameter.

Any partial specializations (13.7.6) associated with the primary template are considered when a specialization
based on the template template-parameter is instantiated. If a specialization is not reachable from the point of
instantiation, and it would have been selected had it been reachable, the program is ill-formed, no diagnostic
required.

[Example 1:

template<class T> class A { // primary template
    int x;
};
template<class T> class A<T*> { // partial specialization
    long x;
};
template<template<class U> class V> class C { 
    V<int> y;
    V<int*> z;
};
C<A> c; // V<int> within C<A> uses the primary template, so c.y.x has type int
         // V<int*> within C<A> uses the partial specialization, so c.z.x has type long
—end example]

A template-argument matches a template template-parameter \( P \) when \( P \) is at least as specialized as the
template-argument \( A \). In this comparison, if \( P \) is unconstrained, the constraints on \( A \) are not considered. If \( P \)
contains a template parameter pack, then \( A \) also matches \( P \) if each of \( A \)’s template parameters matches the
corresponding template parameter in the template-head of \( P \). Two template parameters match if they are of the
same kind (type, non-type, template), for non-type template-parameters, their types are equivalent (13.7.7.2),
and for template template-parameters, each of their corresponding template-template parameters matches, recursively.
When \( P \)’s template-head contains a template parameter pack (13.7.4), the template parameter pack will
match zero or more template parameters or template parameter packs in the template-head of \( A \) with the
same type and form as the template parameter pack in \( P \) (ignoring whether those template parameters are
template parameter packs).

[Example 2:

template<class T> class A { /* ... */ }

template<class T, class U = T> class B { /* ... */ }

template<class ... Types> class C { /* ... */ }

template<auto n> class D { /* ... */ }

template<template<class> class P> class X { /* ... */ }

template<template<class ...> class Q> class Y { /* ... */ }

template<template<int> class R> class Z { /* ... */ }

X<A> xa; // OK
X<B> xb; // OK
X<C> xc; // OK
Y<A> ya; // OK
Y<B> yb; // OK
Y<C> yc; // OK
Z<D> zd; // OK
—end example]

[Example 3:
template <class T> struct eval;

    template <template <class, class...> class TT, class T1, class... Rest>
    struct eval<TT<T1, Rest...>> { };

template <class T1> struct A;
    template <class T1, class T2> struct B;
    template <int N> struct C;
    template <class T1, int N> struct D;
    template <class T1, class T2, int N = 17> struct E;

eval<A<int>> eA;  // OK: matches partial specialization of eval
    eval<B<int, float>> eB;  // OK: matches partial specialization of eval
    eval<C<17>> eC;  // error: C does not match TT in partial specialization
    eval<D<int, 17>> eD;  // error: D does not match TT in partial specialization
    eval<E<int, float>> eE;  // error: E does not match TT in partial specialization

—end example—

Example 4:

    template<typename T> concept C = requires (T t) { t.f(); };
    template<typename T> concept D = C<T> && requires (T t) { t.g(); };

    template<template<C> class P> struct S { };
    template<C> struct X { };
    template<D> struct Y { };
    template<typename T> struct Z { };

    S<X> s1;  // OK, X and P have equivalent constraints
    S<Y> s2;  // error: P is not at least as specialized as Y
    S<Z> s3;  // OK, P is at least as specialized as Z

—end example—

4 A template template-parameter P is at least as specialized as a template template-argument A if, given
the following rewrite to two function templates, the function template corresponding to P is at least as
specialized as the function template corresponding to A according to the partial ordering rules for function
templates (13.7.7.3). Given an invented class template X with the template-head of A (including default
arguments and requires-clause, if any):

(4.1) — Each of the two function templates has the same template parameters and requires-clause (if any),
respectively, as P or A.

(4.2) — Each function template has a single function parameter whose type is a specialization of X with template
arguments corresponding to the template parameters from the respective function template where, for
each template parameter PP in the template-head of the function template, a corresponding template
argument AA is formed. If PP declares a template parameter pack, then AA is the pack expansion
PP... (13.7.4); otherwise, AA is the id-expression PP.

If the rewrite produces an invalid type, then P is not at least as specialized as A.
In order for a constrained template to be instantiated (13.9), its associated constraints (13.5.3) shall be satisfied as described in the following subclauses.

[Note 1: Forming the name of a specialization of a class template, a variable template, or an alias template (13.3) requires the satisfaction of its constraints. Overload resolution (12.2.3) requires the satisfaction of constraints on functions and function templates. — end note]

### 13.5.2.2 Logical operations

There are two binary logical operations on constraints: conjunction and disjunction.

[Note 1: These logical operations have no corresponding C++ syntax. For the purpose of exposition, conjunction is spelled using the symbol $\land$ and disjunction is spelled using the symbol $\lor$. The operands of these operations are called the left and right operands. In the constraint $A \land B$, $A$ is the left operand, and $B$ is the right operand. — end note]

A **conjunction** is a constraint taking two operands. To determine if a conjunction is satisfied, the satisfaction of the first operand is checked. If that is not satisfied, the conjunction is not satisfied. Otherwise, the conjunction is satisfied if and only if the second operand is satisfied.

A **disjunction** is a constraint taking two operands. To determine if a disjunction is satisfied, the satisfaction of the first operand is checked. If that is not satisfied, the disjunction is not satisfied. Otherwise, the disjunction is satisfied if and only if the second operand is satisfied.

**Example 1:**

```cpp
template<typename T>
constexpr bool get_value() { return T::value; }

template<typename T>
requires (sizeof(T) > 1) && (get_value<T>())
void f(T);

void f('a'); // OK: calls f(int)
```

In the satisfaction of the associated constraints (13.5.3) of $f$, the constraint $\text{sizeof(char)} > 1$ is not satisfied; the second operand is not checked for satisfaction. — end example]

**Example 2:**

```cpp
template <class T> concept sad = false;

template <class T> int f1(T) requires (!sad<T>);

template <class T> int f1(T) requires (!sad<T>) && true;

int i1 = f1(42); // ambiguous, !sad<T> atomic constraint expressions (13.5.2.3)
// are not formed from the same expression

int i2 = f2(42); // OK, !sad<T> atomic constraint expressions both come from not_sad

int i3 = f3(42); // error: associated constraints not satisfied due to substitution failure

int i4 = f4(42); // OK, substitution failure contained within sad_nested_type
```

Here, requires (!sad<type>) requires that there is a nested type that is not sad, whereas requires (!sad_nested_type<T>) requires that there is no sad nested type. — end example]

— end note]
13.5.2.3 Atomic constraints [temp.constr.atomic]

An atomic constraint is formed from an expression $E$ and a mapping from the template parameters that appear within $E$ to template arguments that are formed via substitution during constraint normalization in the declaration of a constrained entity (and, therefore, can involve the unsubstituted template parameters of the constrained entity), called the parameter mapping (13.5.3).

[Note 1: Atomic constraints are formed by constraint normalization (13.5.4). $E$ is never a logical AND expression (7.6.14) nor a logical OR expression (7.6.15). —end note]

Two atomic constraints, $e_1$ and $e_2$, are identical if they are formed from the same appearance of the same expression and if, given a hypothetical template $A$ whose template-parameter-list consists of template-parameters corresponding and equivalent (13.7.7.2) to those mapped by the parameter mappings of the expression, a template-id naming $A$ whose template-arguments are the targets of the parameter mapping of $e_1$ is the same (13.6) as a template-id naming $A$ whose template-arguments are the targets of the parameter mapping of $e_2$.

[Note 2: The comparison of parameter mappings of atomic constraints operates in a manner similar to that of declaration matching with alias template substitution (13.7.8).]

[Example 1:

```cpp
template <unsigned N> constexpr bool Atomic = true;
template <unsigned N> concept C = Atomic<N>;
template <unsigned N> concept Add1 = C<N + 1>;
template <unsigned N> concept AddOne = C<N + 1>;
template <unsigned M> void f()
    requires Add1<2 * M>;
template <unsigned M> int f()
    requires AddOne<2 * M> && true;

int x = f<0>();    // OK, the atomic constraints from concept C in both fs are Atomic<N>
                  // with mapping similar to $N \mapsto 2 \cdot M + 1$

template <unsigned N> struct WrapN;
template <unsigned N> using Add1Ty = WrapN<N + 1>;
template <unsigned N> using AddOneTy = WrapN<N + 1>;
template <unsigned M> void g(Add1Ty<2 * M> *);
template <unsigned M> void g(AddOneTy<2 * M> *);

void h() {
    g<0>(nullptr);    // OK, there is only one g
}
```
—end example]

This similarity includes the situation where a program is ill-formed, no diagnostic required, when the meaning of the program depends on whether two constructs are equivalent, and they are functionally equivalent but not equivalent.

[Example 2:

```cpp
template <unsigned N> void f2()
    requires Add1<2 * N>;
template <unsigned N> int f2()
    requires Add1<2 * N> && true;
void h2() {
    f2<0>();    // ill-formed, no diagnostic required:
                // requires determination of subsumption between atomic constraints that are
                // functionally equivalent but not equivalent
}
```
—end example]

—end note]

3 To determine if an atomic constraint is satisfied, the parameter mapping and template arguments are first substituted into its expression. If substitution results in an invalid type or expression, the constraint is not satisfied. Otherwise, the lvalue-to-rvalue conversion (7.3.2) is performed if necessary, and $E$ shall be a constant expression of type `bool`. The constraint is satisfied if and only if evaluation of $E$ results in `true`. 

§ 13.5.2.3 363
If, at different points in the program, the satisfaction result is different for identical atomic constraints and template arguments, the program is ill-formed, no diagnostic required.

**Example 3:**

```cpp
template<typename T> concept C =
    sizeof(T) == 4 && !true;  // requires atomic constraints sizeof(T) == 4 and !true

template<typename T> struct S {
    constexpr operator bool() const { return true; }
};

template<typename T> requires (S<T>{})
void f(T);  // #1
void f(int);  // #2

void g() {
    f(0);  // error: expression S<int>{} does not have type bool
    // while checking satisfaction of deduced arguments of #1;
    // call is ill-formed even though #2 is a better match
}
```

**— end example**

### 13.5.3 Constrained declarations

A template declaration (13.1) or templated function declaration (9.3.4.6) can be constrained by the use of a `requires-clause`. This allows the specification of constraints for that declaration as an expression:

```
constraint-expression:
    logical-or-expression
```

Constraints can also be associated with a declaration through the use of `type-constraints` in a template-parameter-list or parameter-type-list. Each of these forms introduces additional `constraint-expressions` that are used to constrain the declaration.

A declaration’s **associated constraints** are defined as follows:

1. If there are no introduced `constraint-expressions`, the declaration has no associated constraints.
2. Otherwise, if there is a single introduced `constraint-expression`, the associated constraints are the normal form (13.5.4) of that expression.
3. Otherwise, the associated constraints are the normal form of a logical AND expression (7.6.14) whose operands are in the following order:
   1. the `constraint-expression` introduced by each `type-constraint` (13.2) in the declaration’s `template-parameter-list`, in order of appearance, and
   2. the `constraint-expression` introduced by a `requires-clause` following a `template-parameter-list` (13.1), and
   3. the `constraint-expression` introduced by each `type-constraint` in the parameter-type-list of a function declaration, and
   4. the `constraint-expression` introduced by a trailing `requires-clause` (9.3) of a function declaration (9.3.4.6).

The formation of the associated constraints establishes the order in which constraints are instantiated when checking for satisfaction (13.5.2).

**Example 1:**

```cpp
template<typename T> concept C = true;

template<C T> void f1(T);
template<typename T> requires C<T> void f2(T);
template<typename T> void f3(T) requires C<T>;
```

The functions `f1`, `f2`, and `f3` have the associated constraint `C<T>.

```cpp
template<typename T> concept C1 = true;
template<typename T> concept C2 = sizeof(T) > 0;
```
template<C1 T> void f4(T) requires C2<T>;
template<typename T> requires C1<T> && C2<T> void f5(T);

The associated constraints of f4 and f5 are C1<T> ∧ C2<T>.

template<C1 T> requires C2<T> void f6();
template<C2 T> requires C1<T> void f7();

The associated constraints of f6 are C1<T> ∧ C2<T>, and those of f7 are C2<T> ∧ C1<T>. — end example

4 When determining whether a given introduced constraint-expression \( C_1 \) of a declaration in an instantiated specialization of a templated class is equivalent (13.7.7.2) to the corresponding constraint-expression \( C_2 \) of a declaration outside the class body, \( C_1 \) is instantiated. If the instantiation results in an invalid expression, the constraint-expressions are not equivalent.

[Note 1: This can happen when determining which member template is specialized by an explicit specialization declaration. — end note]

[Example 2:

template <class T> concept C = true;
template <class T> struct A {
    template <class U> U f(U) requires C<typename T::type>; // #1
    template <class U> U f(U) requires C<T>; // #2
};

template <> template <class U>
U A<int>::f(U u) requires C<int> { return u; } // OK, specializes #2

Substituting int for T in C<typename T::type> produces an invalid expression, so the specialization does not match #1. Substituting int for T in C<T> produces C<int>, which is equivalent to the constraint-expression for the specialization, so it does match #2. — end example

13.5.4 Constraint normalization [temp.constr.normal]

The normal form of an expression \( E \) is a constraint (13.5.2) that is defined as follows:

1. The normal form of an expression \( E \) is the normal form of \( E \).
2. The normal form of an expression \( E_1 \ || \ E_2 \) is the disjunction (13.5.2.2) of the normal forms of \( E_1 \) and \( E_2 \).
3. The normal form of an expression \( E_1 \ && \ E_2 \) is the conjunction of the normal forms of \( E_1 \) and \( E_2 \).
4. The normal form of a concept-id \( C<A_1, A_2, \ldots, A_n> \) is the normal form of the constraint-expression of \( C \), after substituting \( A_1, A_2, \ldots, A_n \) for \( C \)'s respective template parameters in the parameter mappings in each atomic constraint. If any such substitution results in an invalid type or expression, the program is ill-formed; no diagnostic is required.

[Example 1:

template<typename T> concept A = T::value || true;
template<typename U> concept B = A<U*>;
template<typename V> concept C = B<V&&>;

Normalization of B's constraint-expression is valid and results in T::value (with the mapping T↦U*) ∨ true (with an empty mapping), despite the expression T::value being ill-formed for a pointer type T. Normalization of C's constraint-expression results in the program being ill-formed, because it would form the invalid type V&& in the parameter mapping. — end example]

5. The normal form of any other expression \( E \) is the atomic constraint whose expression is \( E \) and whose parameter mapping is the identity mapping.

2 The process of obtaining the normal form of a constraint-expression is called normalization.

[Note 1: Normalization of constraint-expressions is performed when determining the associated constraints (13.5.2) of a declaration and when evaluating the value of an id-expression that names a concept specialization (7.5.4). — end note]

3 [Example 2:

template<typename T> concept C1 = sizeof(T) == 1;
template<typename T> concept C2 = C1<T> && 1 == 2;
template<typename T> concept C3 = requires { typename T::type; };
template<typename T> concept C4 = requires (T x) { ++x; }

§ 13.5.4 365
template<C2 U> void f1(U); // #1
template<C3 U> void f2(U); // #2
template<C4 U> void f3(U); // #3

The associated constraints of #1 are sizeof(T) == 1 (with mapping T → U) ∧ 1 == 2.
The associated constraints of #2 are requires { typename T::type; } (with mapping T → U).
The associated constraints of #3 are requires { T x { ++x; } } (with mapping T → U). — end example

### 13.5.5 Partial ordering by constraints

A constraint \(P\) subsumes a constraint \(Q\) if and only if, for every disjunctive clause \(P_i\) in the disjunctive normal form\(^{124}\) of \(P\), \(P_i\) subsumes every conjunctive clause \(Q_j\) in the conjunctive normal form\(^{125}\) of \(Q\), where

1. \(a\) disjunctive clause \(P_i\) subsumes a conjunctive clause \(Q_j\) if and only if there exists an atomic constraint \(P_{ia}\) in \(P_i\) for which there exists an atomic constraint \(Q_{jb}\) in \(Q_j\) such that \(P_{ia}\) subsumes \(Q_{jb}\), and

2. an atomic constraint \(A\) subsumes another atomic constraint \(B\) if and only if \(A\) and \(B\) are identical using the rules described in 13.5.2.3.

**Example 1:** Let \(A\) and \(B\) be atomic constraints (13.5.2.3). The constraint \(A \land B\) subsumes \(A\), but \(A\) does not subsume \(A \lor B\). The constraint \(A\) subsumes \(A \lor B\), but \(A \lor B\) does not subsume \(A\). Also note that every constraint subsumes itself. — end example

**Note 1:** The subsumption relation defines a partial ordering on constraints. This partial ordering is used to determine

1. the best viable candidate of non-template functions (12.2.4),
2. the address of a non-template function (12.3),
3. the matching of template template arguments (13.4.4),
4. the partial ordering of class template specializations (13.7.6.3), and
5. the partial ordering of function templates (13.7.7.3).

— end note

A declaration \(D_1\) is at least as constrained as a declaration \(D_2\) if

1. \(D_1\) and \(D_2\) are both constrained declarations and \(D_1\)’s associated constraints subsume those of \(D_2\); or
2. \(D_2\) has no associated constraints.

A declaration \(D_1\) is more constrained than another declaration \(D_2\) when \(D_1\) is at least as constrained as \(D_2\), and \(D_2\) is not at least as constrained as \(D_1\).

**Example 2:**

```cpp
template<typename T> concept C1 = requires(T t) { --t; };
template<typename T> concept C2 = C1<T> && requires(T t) { ++t; };

template<typename T> concept C3 = sizeof(T) == 1;

template<concept C1 T> void f1(T); // #1
template<concept C2 T> void f2(T); // #2
template<concept C3 T> void f3(T); // #3

template<concept C2 T> void f(T); // #4

define(1);   // selects #1
f((int*)0);  // selects #2
f(true);     // selects #3 because C1<bool> is not satisfied
f(0);        // selects #4
— end example
```

### 13.6 Type equivalence

Two template-ids are the same if

1. their template-names, operator-function-ids, or literal-operator-ids refer to the same template, and
2. their corresponding type template-arguments are the same type, and

---

124) A constraint is in disjunctive normal form when it is a disjunction of clauses where each clause is a conjunction of atomic constraints. For atomic constraints \(A\), \(B\), and \(C\), the disjunctive normal form of the constraint \(A \lor (B \land C)\) is \((A \lor B) \land (A \lor C)\). Its disjunctive clauses are \((A \lor B)\) and \((A \lor C)\).

125) A constraint is in conjunctive normal form when it is a conjunction of clauses where each clause is a disjunction of atomic constraints. For atomic constraints \(A\), \(B\), and \(C\), the constraint \(A \land (B \lor C)\) is in conjunctive normal form. Its conjunctive clauses are \(A\) and \((B \lor C)\).
(1.3) — their corresponding non-type template-arguments are template-argument-equivalent (see below) after conversion to the type of the template-parameter, and

(1.4) — their corresponding template template-arguments refer to the same template.

Two template-ids that are the same refer to the same class, function, or variable.

2 Two values are template-argument-equivalent if they are of the same type and

(2.1) — they are of integral type and their values are the same, or

(2.2) — they are of floating-point type and their values are identical, or

(2.3) — they are of type std::nullptr_t, or

(2.4) — they are of enumeration type and their values are the same,126 or

(2.5) — they are of pointer type and they have the same pointer value, or

(2.6) — they are of pointer-to-member type and they refer to the same class member or are both the null member pointer value, or

(2.7) — they are of reference type and they refer to the same object or function, or

(2.8) — they are of array type and their corresponding elements are template-argument-equivalent,127 or

(2.9) — they are of union type and either they both have no active member or they have the same active member and their active members are template-argument-equivalent, or

(2.10) — they are of class type and their corresponding direct subobjects and reference members are template-argument-equivalent.

3 [Example 1:]

```cpp
template<class E, int size> class buffer { /* ... */ };  
buffer<char, 2*512> x;  
buffer<char, 1024> y;  
```
declares x and y to be of the same type, and

```cpp
template<class T, void(*err_fct)()> class list { /* ... */ };  
list<int, &error_handler1> x1;  
list<int, &error_handler2> x2;  
list<int, &error_handler2> x3;  
list<char, &error_handler2> x4;  
```
declares x2 and x3 to be of the same type. Their type differs from the types of x1 and x4.

```cpp
template<class T> struct X { };  
template<class> struct Y { };  
X<Y<int>> y;  
X<Z<int>> z;  
```
declares y and z to be of the same type. — end example]

4 If an expression e is type-dependent (13.8.3.3), decltype(e) denotes a unique dependent type. Two such decltype-specifiers refer to the same type only if their expressions are equivalent (13.7.7.2).

[Note 1: However, such a type might be aliased, e.g., by a typedef-name. — end note]

13.7 Template declarations

13.7.1 General

The template parameters of a template are specified in the angle bracket enclosed list that immediately follows the keyword template.

A primary template declaration is one in which the name of the template is not followed by a template-argument-list. The template argument list of a primary template is the template argument list of its template-head (13.4). A template declaration in which the name of the template is followed by a template-argument-list is a partial specialization (13.7.6) of the template named in the declaration, which shall be a class or variable template.

For purposes of name lookup and instantiation, default arguments, type-constraints, requires-clauses (13.1), and noexcept-specifiers of function templates and of member functions of class templates are considered

126 The identity of enumerators is not preserved.

127 An array as a template-parameter decays to a pointer.
definitions; each default argument, \textit{type-constraint}, \textit{requires-clause}, or \textit{noexcept-specifier} is a separate definition which is unrelated to the templated function definition or to any other default arguments \textit{type-constraints}, \textit{requires-clauses}, or \textit{noexcept-specifiers}. For the purpose of instantiation, the substatements of a constexpr if statement (§8.5.2) are considered definitions.

Because an \textit{alias-declaration} cannot declare a \textit{template-id}, it is not possible to partially or explicitly specialize an alias template.

\section*{13.7.2 Class templates \protect[\textit{temp.class}]

\subsection*{13.7.2.1 General \protect[\textit{temp.class.general}]

1. A \textit{class template} defines the layout and operations for an unbounded set of related types.

2. \textbf{[Example 1:} It is possible for a single class template List to provide an unbounded set of class definitions: one class List<T> for every type T, each describing a linked list of elements of type T. Similarly, a class template Array describing a contiguous, dynamic array can be defined like this:

   \begin{verbatim}
   template<class T> class Array {
   T* v;
   int sz;
   public:
   explicit Array(int);
   T& operator[](int);
   T& elem(int i) { return v[i]; }
   };
   \end{verbatim}

   The prefix \texttt{template<class T>} specifies that a template is being declared and that a \textit{type-name} T can be used in the declaration. In other words, \texttt{Array} is a parameterized type with T as its parameter. \textit{—end example}]

3. \textbf{[Note 1:} When a member of a class template is defined outside of the class template definition, the member definition is defined as a template definition with the \textit{template-head} equivalent to that of the class template. The names of the template parameters used in the definition of the member can differ from the template parameter names used in the class template definition. The class template name in the member definition is followed by the template argument list of the \textit{template-head} (§13.4).

\textbf{[Example 2:}

   \begin{verbatim}
   template<class T1, class T2> struct A {
   void f1();
   void f2();
   };
   template<class T2, class T1> void A<T2,T1>::f1() { } // OK
   template<class T2, class T1> void A<T1,T2>::f2() { } // error
   \end{verbatim}

   \begin{verbatim}
   template<class ... Types> struct B {
   void f3();
   void f4();
   };
   template<class ... Types> void B<Types ...>::f3() { } // OK
   template<class ... Types> void B<Types>::f4() { } // error
   \end{verbatim}

   \begin{verbatim}
   template<typename T> concept C = true;
   template<typename T> concept D = true;
   template<C T> struct S {
   void f();
   void g();
   void h();
   template<D U> struct Inner;
   };
   template<C A> void S<A>::f() { } // OK: template-heads match
   template<typename T> void S<T>::g() { } // error: no matching declaration for S<T>
   \end{verbatim}

   \begin{verbatim}
   template<typename T> requires C<T> void S<T>::h() { } // ill-formed, no diagnostic required: template-heads are
   \end{verbatim}

   \begin{verbatim}
   // functionally equivalent but not equivalent
   \end{verbatim}
In a partial specialization, explicit specialization or explicit instantiation of a class template, the class-key shall agree in kind with the original class template declaration (9.2.9.4).

13.7.2.2 Member functions of class templates [temp.mem.func]

A member function of a class template may be defined outside of the class template definition in which it is declared.

[Example 1:

```cpp
template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int i) { return v[i]; }
};
```

declares three member functions of a class template. The subscript function can be defined like this:

```cpp
template<class T> T& Array<T>::operator[](int i) {
    if (i<0 || sz<=i) error("Array: range error");
    return v[i];
}
```

A constrained member function can be defined out of line:

```cpp
template<typename T> concept C = requires {
    typename T::type;
};
template<typename T> struct S {
    void f() requires C<T>;
    void g() requires C<T>;
};
template<typename T>
void S<T>::f() requires C<T> { } // OK
template<typename T>
void S<T>::g() { } // error: no matching function in S<T>
```

The template-arguments for a member function of a class template are determined by the template-arguments of the type of the object for which the member function is called.

[Example 2: The template-argument for Array<T>::operator[] will be determined by the Array to which the subscripting operation is applied.

```cpp
Array<int> v1(20);
Array<dcomplex> v2(30);
v1[3] = 7; // Array<int>::operator[]
v2[3] = dcomplex(7,8); // Array<dcomplex>::operator[]
```

—end example]

13.7.2.3 Deduction guides [temp.deduct.guide]

Deduction guides are used when a template-name appears as a type specifier for a deduced class type (9.2.9.7). Deduction guides are not found by name lookup. Instead, when performing class template argument deduction (12.2.2.9), all reachable deduction guides declared for the class template are considered.

deduction-guide:
    explicit-specifieropt template-name ( parameter-declaration-clause ) -> simple-template-id ;
2 [Example 1:

```cpp
template<class T, class D = int>
struct S {
    T data;
};
template<class U>
S(U) -> S<typename U::type>;

struct A {
    using type = short;
    operator type();
};
S x(A()); // x is of type S<short, int>

— end example]

3 The same restrictions apply to the parameter-declaration-clause of a deduction guide as in a function declaration (9.3.4.6). The simple-template-id shall name a class template specialization. The template-name shall be the same identifier as the template-name of the simple-template-id. A deduction-guide shall inhabit the scope to which the corresponding class template belongs and, for a member class template, have the same access. Two deduction guide declarations for the same class template shall not have equivalent parameter-declaration-clauses if either is reachable from the other.

13.7.2.4 Member classes of class templates

A member class of a class template may be defined outside the class template definition in which it is declared. [Note 1: The member class must be defined before its first use that requires an instantiation (13.9.2). For example,

```cpp
template<class T> struct A {
    class B;
};
A<int>::B* b1; // OK: requires A to be defined but not A::B

template<class T> class A<T>::B { }
A<int>::B b2; // OK: requires A::B to be defined

— end note]

13.7.2.5 Static data members of class templates

A definition for a static data member or static data member template may be provided in a namespace scope enclosing the definition of the static member’s class template.

[Example 1:

```cpp
template<class T> class X {
    static T s;
};
template<class T> T X<T>::s = 0;

struct limits {
    template<class T>
        static const T min; // declaration
};

template<class T>
const T limits::min = { }; // definition

— end example]

2 An explicit specialization of a static data member declared as an array of unknown bound can have a different bound from its definition, if any.

[Example 2:

```cpp
template <class T> struct A {
    static int i[];         // 4 elements
};
template <class T> int A<T>::i[]; // 4 elements

template <> int A<int>::i[] = { 1 }; // OK: 1 element

§ 13.7.2.5 370
13.7.2.6 Enumeration members of class templates

An enumeration member of a class template may be defined outside the class template definition.

[Example 1:

```cpp
template<class T> struct A {
    enum E : T;
};
A<int> a;
```

```cpp
template<class T> enum A<T>::E : T { e1, e2 };
A<int>::E e = A<int>::e1;
```

—end example]

13.7.3 Member templates

A template can be declared within a class or class template; such a template is called a member template. A member template can be defined within or outside its class definition or class template definition. A member template of a class template that is defined outside of its class template definition shall be specified with a template-head equivalent to that of the class template followed by a template-head equivalent to that of the member template (13.7.7.2).

[Example 1:

```cpp
template<class T> struct string {
    template<class T2> int compare(const T2&);
    template<class T2> string(const string<T2>& s) { /* ... */ }
};
```

```cpp
template<class T> template<class T2> int string<T>::compare(const T2& s) {
}
```

—end example]

[Example 2:

```cpp
template<typename T> concept C1 = true;
template<typename T> concept C2 = sizeof(T) <= 4;
```

```cpp
template<C1 T> struct S {
    template<C2 U> void f(U);
    template<C2 U> void g(U);
};
```

```cpp
template<C1 T> template<C2 U>
void S<T>::f(U) { } // OK
```

```cpp
template<C1 T> template<typename U>
void S<T>::g(U) { } // error: no matching function in S<T>
```

—end example]

2 A local class of non-closure type shall not have member templates. Access control rules (11.8) apply to member template names. A destructor shall not be a member template. A non-template member function (9.3.4.6) with a given name and type and a member function template of the same name, which could be used to generate a specialization of the same type, can both be declared in a class. When both exist, a use of that name and type refers to the non-template member unless an explicit template argument list is supplied.

[Example 3:

```cpp
template <class T> struct A {
    void f(int);
    template <class T2> void f(T2);
};
```

```cpp
template <> void A<int>::f(int) { } // non-template member function
```

```cpp
template <> template <> void A<int>::f<>(int) { } // member function template specialization
```
```cpp
int main() {
    A<char> ac;
    ac.f(1); // non-template
    ac.f('c'); // template
    ac.f<>(); // template
}
—end example]

A member function template shall not be declared virtual.

[Example 4:
```cpp
template <class T> struct AA {
    template <class C> virtual void g(C); // error
    virtual void f(); // OK
};
—end example]

A specialization of a member function template does not override a virtual function from a base class.

[Example 5:
```cpp
class B {
    virtual void f(int); }

class D : public B {
    template <class T> void f(T); // does not override B::f(int)
    void f(int i) { f<>(i); } // overriding function that calls the function template specialization
};
—end example]

[Note 1: A specialization of a conversion function template is referenced in the same way as a non-template conversion function that converts to the same type (11.4.8.3).]

[Example 6:
```cpp
struct A {
    template <class T> operator T*();
};
template <class T> A::operator T*() { return 0; }
template <> A::operator char*() { return 0; } // specialization
template A::operator void*(); // explicit instantiation

int main() {
    A a;
    int* ip;
    ip = a.operator int*(); // explicit call to template operator A::operator int*()
}
—end example]

There is no syntax to form a template-id (13.3) by providing an explicit template argument list (13.10.2) for a conversion function template. —end note]

13.7.4 Variadic templates

A template parameter pack is a template parameter that accepts zero or more template arguments.

[Example 1:
```cpp
template<class ... Types> struct Tuple { };
Tuple<> t0; // Types contains no arguments
Tuple<int> t1; // Types contains one argument: int
Tuple<int, float> t2; // Types contains two arguments: int and float
Tuple<> error; // error: 0 is not a type
—end example]

A function parameter pack is a function parameter that accepts zero or more function arguments.

[Example 2:
template<class ... Types> void f(Types ... args);

f(); // args contains no arguments
f(1); // args contains one argument: int
f(2, 1.0); // args contains two arguments: int and double
— end example

3 An init-capture pack is a lambda capture that introduces an init-capture for each of the elements in the pack expansion of its initializer.

[Example 3:

```cpp
template <typename... Args>
void foo(Args... args) {
    [...xs=args]{
        bar(xs...); // xs is an init-capture pack
    }
}

foo(); // xs contains zero init-captures
foo(1); // xs contains one init-capture
— end example
```

] 4 A pack is a template parameter pack, a function parameter pack, or an init-capture pack. The number of elements of a template parameter pack or a function parameter pack is the number of arguments provided for the parameter pack. The number of elements of an init-capture pack is the number of elements in the pack expansion of its initializer.

5 A pack expansion consists of a pattern and an ellipsis, the instantiation of which produces zero or more instantiations of the pattern in a list (described below). The form of the pattern depends on the context in which the expansion occurs. Pack expansions can occur in the following contexts:

(5.1) — In a function parameter pack (9.3.4.6); the pattern is the parameter-declaration without the ellipsis.
(5.2) — In a using-declaration (9.9); the pattern is a using-declarator.
(5.3) — In a template parameter pack that is a pack expansion (13.2):
   (5.3.1) — if the template parameter pack is a parameter-declaration; the pattern is the parameter-declaration without the ellipsis;
   (5.3.2) — if the template parameter pack is a type-parameter; the pattern is the corresponding type-parameter without the ellipsis.
(5.4) — In an initializer-list (9.4); the pattern is an initializer-clause.
(5.5) — In a base-specifier-list (11.7); the pattern is a base-specifier.
(5.6) — In a mem-initializer-list (11.9.3) for a mem-initializer whose mem-initializer-id denotes a base class; the pattern is the mem-initializer.
(5.7) — In a template-argument-list (13.4); the pattern is a template-argument.
(5.8) — In an attribute-list (9.12.1); the pattern is an attribute.
(5.9) — In an alignment-specifier (9.12.2); the pattern is the alignment-specifier without the ellipsis.
(5.10) — In a capture-list (7.5.5.3); the pattern is the capture without the ellipsis.
(5.11) — In a sizeof... expression (7.6.2.5); the pattern is an identifier.
(5.12) — In a fold-expression (7.5.6); the pattern is the cast-expression that contains an unexpanded pack.

[Example 4:

```cpp
template<class ... Types> void f(Types ... rest);
template<class ... Types> void g(Types ... rest) {
    f(&rest ...); // "&rest ..." is a pack expansion; "&rest" is its pattern
}
— end example
```

6 For the purpose of determining whether a pack satisfies a rule regarding entities other than packs, the pack is considered to be the entity that would result from an instantiation of the pattern in which it appears.
A pack whose name appears within the pattern of a pack expansion is expanded by that pack expansion. An appearance of the name of a pack is only expanded by the innermost enclosing pack expansion. The pattern of a pack expansion shall name one or more packs that are not expanded by a nested pack expansion; such packs are called unexpanded packs in the pattern. All of the packs expanded by a pack expansion shall have the same number of arguments specified. An appearance of a name of a pack that is not expanded is ill-formed.

[Example 5:]
```cpp
template<typename...> struct Tuple {};  
template<typename T1, typename T2> struct Pair {};  

template<class ... Args1> struct zip {  
    template<class ... Args2> struct with {  
        typedef Tuple<Pair<Args1, Args2> ... > type;  
    };  
};  

typedef zip<short, int>::with<unsigned short, unsigned>::type T1;  
    // T1 is Tuple<Pair<short, unsigned short>, Pair<int, unsigned>>  
typedef zip<short>::with<unsigned short, unsigned>::type T2;  
    // error: different number of arguments specified for Args1 and Args2  

template<class ... Args>  
    void g(Args ... args) {  
        f(const_cast<const Args*>(&args)...);  
            // OK: “Args” and “args” are expanded  
        f(args);  
            // error: pattern does not contain any packs  
        f(h(args ...) + args ...);  
            // OK: first “args” expanded within h,  
                    // second “args” expanded within f  
    }  
```  
—end example]  

The instantiation of a pack expansion that is neither a `sizeof...` expression nor a `fold-expression` produces a list of elements E₁, E₂, ⋯, Eₙ, where N is the number of elements in the pack expansion parameters. Each Eᵢ is generated by instantiating the pattern and replacing each pack expansion parameter with its iᵗʰ element. All of the Eᵢ become items in the enclosing list.

[Note 1: The variety of list varies with the context: `expression-list`, `base-specifier-list`, `template-argument-list`, etc. —end note]

When N is zero, the instantiation of the expansion produces an empty list. Such an instantiation does not alter the syntactic interpretation of the enclosing construct, even in cases where omitting the list entirely would otherwise be ill-formed or would result in an ambiguity in the grammar.

[Example 6:]
```cpp
template<class... T> struct X : T... { };  
template<class... T> void f(T... values) {  
    X<T...> x(values...);  
}  

template void f<>();  
    // OK: X<> has no base classes  
    // x is a variable of type X<> that is value-initialized  
```  
—end example]
The instantiation of a \texttt{sizeof...} expression (7.6.2.5) produces an integral constant containing the number of elements in the pack it expands.

The instantiation of a \texttt{fold-expression} produces:

\begin{align}
(10.1) & \quad ((E_1 \ op \ E_2) \ op \cdots) \ op \ E_N \ \text{for a unary left fold}, \\
(10.2) & \quad E_1 \ op \ (\cdots \ op \ (E_{N-1} \ op \ E_N)) \ \text{for a unary right fold}, \\
(10.3) & \quad (((E \ op \ E_1) \ op \ E_2) \ op \cdots) \ op \ E_N \ \text{for a binary left fold}, \text{ and} \\
(10.4) & \quad E_1 \ op \ (\cdots \ op \ (E_{N-1} \ op \ (E_N \ op \ E))) \ \text{for a binary right fold}. \\
\end{align}

In each case, \texttt{\textit{op}} is the \textit{fold-operator}, \texttt{\textit{N}} is the number of elements in the pack expansion parameters, and each \texttt{\textit{E}_{\textit{i}}} is generated by instantiating the pattern and replacing each pack expansion parameter with its \textit{i}th element. For a binary fold-expression, \texttt{\textit{E}} is generated by instantiating the \textit{cast-expression} that did not contain an unexpanded pack.

[Example 7:]
\begin{verbatim}
    template<typename ...Args>
    bool all(Args ...args) { return (... && args); }

    bool b = all(true, true, true, false);
\end{verbatim}

Within the instantiation of \texttt{all}, the returned expression expands to \(((true \ && \ true) \ && \ true) \ && \ false\), which evaluates to \texttt{false}. —end example]

If \texttt{\textit{N}} is zero for a unary fold-expression, the value of the expression is shown in Table 19; if the operator is not listed in Table 19, the instantiation is ill-formed.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Value when pack is empty</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;&amp;</td>
<td>true</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>void()</td>
</tr>
</tbody>
</table>

13.7.5  Friends  

A friend of a class or class template can be a function template or class template, a specialization of a function template or class template, or a non-template function or class.

[Example 1:]
\begin{verbatim}
    template<class T> class task;
    template<class T> task<T>* preempt(task<T>*);

    template<class T> class task {
        friend void next_time();
        friend void process(task<T>*){
        friend task<T>* preempt<T>(task<T>*){
        template<class C> friend int func(C);

        friend class task<int>;
        template<class P> friend class frd;
    }

    Here, each specialization of the \texttt{task} class template has the function \texttt{next\_time} as a friend; because \texttt{process} does not have explicit \texttt{template-arguments}, each specialization of the \texttt{task} class template has an appropriately typed function \texttt{process} as a friend, and this friend is not a function template specialization; because the friend \texttt{preempt} has an explicit \texttt{template-argument} \texttt{T}, each specialization of the \texttt{task} class template has the appropriate specialization of the function template \texttt{preempt} as a friend; and each specialization of the \texttt{task} class template has all specializations of the function template \texttt{func} as friends. Similarly, each specialization of the \texttt{task} class template has the class template specialization \texttt{task<int>} as a friend, and has all specializations of the class template \texttt{frd} as friends. —end example]

2 Friend classes, class templates, functions, or function templates can be declared within a class template. When a template is instantiated, its friend declarations are found by name lookup as if the specialization had been explicitly declared at its point of instantiation.
A friend template may be declared within a class or class template. A friend function template may be defined within a class or class template, but a friend class template may not be defined in a class or class template. In these cases, all specializations of the friend class or friend function template are friends of the class or class template granting friendship.

Example 2:
```cpp
class A {
    template<class T> friend class B; // OK
    template<class T> friend void f(T) { /* ... */ } // OK
};
```

Example 3:
```cpp
class X {
    template<class T> friend struct A;
    class Y { }; // OK
};

template<class T> struct A { X::Y ab; }; // OK
template<class T> struct A<T*> { X::Y ab; }; // OK
```

Example 4:
```cpp
template<class T> struct A {
    struct B { }; // grants friendship to A<int>::B even though
    void f(); // it is not a specialization of A<T>::B
    struct D {
        void g();
    ];
    T h();
    template<T U> T i();
};

template<struct A<int> {
    struct B { }; // OK
    int f();
    struct D {
        void g();
    ];
    template<int U> int i();
};

template<struct A<float*> {
    int *h();
};

class C {
    template<class T> friend struct A<T>::B; // grants friendship to A<int>::B even though
    template<class T> friend void A<T>::f(); // does not grant friendship to A<int>::f()
```
A friend template shall not be declared in a local class.

Friend declarations shall not declare partial specializations.

Example 5:
```cpp
template<class T> class A { }
class X {
template<class T> friend class A<T*>;
};
```

When a friend declaration refers to a specialization of a function template, the function parameter declarations shall not include default arguments, nor shall the `inline`, `constexpr`, or `consteval` specifiers be used in such a declaration.

A non-template friend declaration with a `requires-clause` shall be a definition. A friend function template with a constraint that depends on a template parameter from an enclosing template shall be a definition. Such a constrained friend function or function template declaration does not declare the same function or function template as a declaration in any other scope.

### 13.7.6 Partial specialization

#### 13.7.6.1 General

A partial specialization of a template provides an alternative definition of the template that is used instead of the primary definition when the arguments in a specialization match those given in the partial specialization (13.7.6.2). A declaration of the primary template shall precede any partial specialization of that template. A partial specialization shall be reachable from any use of a template specialization that would make use of the partial specialization as the result of an implicit or explicit instantiation; no diagnostic is required.

Two partial specialization declarations declare the same entity if they are partial specializations of the same template and have equivalent `template-heads` and template argument lists (13.7.7.2). Each partial specialization is a distinct template.

Example 1:
```cpp
template<class T1, class T2, int I> class A { }
template<class T, int I> class A<T, T*, I> { }
template<class T1, class T2, int I> class A<T1*, T2, I> { }
template<class T> class A<int, T*, 5> { }
template<class T1, class T2, int I> class A<T1, T2*, I> { }
```
The first declaration declares the primary (unspecialized) class template. The second and subsequent declarations declare partial specializations of the primary template. —end example

A partial specialization may be constrained (13.5).

Example 2:
```cpp
template<concept T> concept C = true;
template<typename T> struct X {  }
template<typename T> struct X<T> {  }  // #1
template<C T> struct X<T> {  }  // #2
```
Both partial specializations are more specialized than the primary template. #1 is more specialized because the deduction of its template arguments from the template argument list of the class template specialization succeeds, while the reverse does not. #2 is more specialized because the template arguments are equivalent, but the partial specialization is more constrained (13.5.5). —end example

The template argument list of a partial specialization is the `template-argument-list` following the name of the template.
A partial specialization may be declared in any scope in which the corresponding primary template may be defined (9.3.4, 11.4, 13.7.3).

Example 3:

```cpp
template<class T> struct A {
    struct C {
        template<class T2> struct B {};
        template<class T2> struct B<T2**> {};
    };
};

// partial specialization of A<T>::C::B<T2>
template<class T> template<class T2>
struct A<T>::C::B<T2*> {};

A<short>::C::B<int*> absip; // uses partial specialization #2
```

Partial specialization declarations do not introduce a name. Instead, when the primary template name is used, any reachable partial specializations of the primary template are also considered.

Note 1: One consequence is that a using-declaration which refers to a class template does not restrict the set of partial specializations that are found through the using-declaration. —end note

Example 4:

```cpp
namespace N {
    template<class T1, class T2> class A {};
} // primary template

using N::A; // refers to the primary template

namespace N {
    template<class T> class A<T, T*> {};
} // partial specialization

A<int,int*> a; // uses the partial specialization, which is found through the using-declaration
               // which refers to the primary template
```

A non-type argument is non-specialized if it is the name of a non-type parameter. All other non-type arguments are specialized.

Within the argument list of a partial specialization, the following restrictions apply:

9.1 — The type of a template parameter corresponding to a specialized non-type argument shall not be dependent on a parameter of the partial specialization.

Example 5:

```cpp
template <class T, T t> struct C {};
template <class T> struct C<T, 1>; // error

template< int X, int (*array_ptr)[X] > class A {};
int array[5];
template< int X > class A<X,*array> {}; // error
```

9.2 — The partial specialization shall be more specialized than the primary template (13.7.6.3).

9.3 — The template parameter list of a partial specialization shall not contain default template argument values.

9.4 — An argument shall not contain an unexpanded pack. If an argument is a pack expansion (13.7.4), it shall be the last argument in the template argument list.

The usual access checking rules do not apply to non-dependent names used to specify template arguments of the simple-template-id of the partial specialization.

128) There is no context in which they would be used.
[Note 2: The template arguments can be private types or objects that would normally not be accessible. Dependent names cannot be checked when declaring the partial specialization, but will be checked when substituting into the partial specialization. — end note]

13.7.6.2 Matching of partial specializations

When a template is used in a context that requires an instantiation of the template, it is necessary to determine whether the instantiation is to be generated using the primary template or one of the partial specializations. This is done by matching the template arguments of the template specialization with the template argument lists of the partial specializations.

1. If exactly one matching partial specialization is found, the instantiation is generated from that partial specialization.

2. If more than one matching partial specialization is found, the partial order rules (13.7.6.3) are used to determine whether one of the partial specializations is more specialized than the others. If such a partial specialization exists, the instantiation is generated from that partial specialization; otherwise, the use of the template is ambiguous and the program is ill-formed.

3. If no matches are found, the instantiation is generated from the primary template.

A partial specialization matches a given actual template argument list if the template arguments of the partial specialization can be deduced from the actual template argument list (13.10.3), and the deduced template arguments satisfy the associated constraints of the partial specialization, if any (13.5.3).

Example 1:

```cpp
template<class T1, class T2, int I> class A { }; // #1
template<class T, int I> class A<T, T*, I> { }; // #2
template<class T1, class T2, int I> class A<T1*, T2, I> { }; // #3
template<class T> class A<int, T*, 5> { }; // #4
template<class T1, class T2, int I> class A<T1, T2*, I> { }; // #5
```

A<int, int, 1> a1; // uses #1
A<int, int*, 1> a2; // uses #2, T is int, I is 1
A<int, char*, 5> a3; // uses #4, T is char
A<int, char*, 1> a4; // uses #5, T1 is int, T2 is char, I is 1
A<int*, int*, 2> a5; // ambiguous: matches #3 and #5

Example 2:

```cpp
template<typename T> concept C = requires (T t) { t.f(); };  
template<typename T> struct S { };  // #1
template<C T> struct S<T> { };  // #2
```

struct Arg { void f(); };  // uses #1; the constraints of #2 are not satisfied
S<Arg> s2;  // uses #2; both constraints are satisfied but #2 is more specialized

Example 3:

```cpp
template <int I, int J> struct A {};  
template <int I> struct A<I+5, I*2> {};  // error
```

```cpp
template <int I> struct A<I, I> {};  // OK
```

```cpp
template <int I, int J, int K> struct B {};  
template <int I> struct B<I, I*2, 2> {};  // OK
```

— end example]

If the template arguments of a partial specialization cannot be deduced because of the structure of its template-parameter-list and the template-id, the program is ill-formed.

Example 3:

```cpp
template <int I, int J> struct A {};  
template <int I> struct A<I+5, I*2> {};  // error
```

```cpp
template <int I> struct A<I, I> {};  // OK
```

```cpp
template <int I, int J, int K> struct B {};  
template <int I> struct B<I, I*2, 2> {};  // OK
```

— end example]
In a name that refers to a specialization of a class or variable template (e.g., `A<int, int, 1>`), the argument list shall match the template parameter list of the primary template. The template arguments of a partial specialization are deduced from the arguments of the primary template.

13.7.6.3 Partial ordering of partial specializations

For two partial specializations, the first is more specialized than the second if, given the following rewrite to two function templates, the first function template is more specialized than the second according to the ordering rules for function templates (13.7.7.3):

1. Each of the two function templates has the same template parameters and associated constraints (13.5.3) as the corresponding partial specialization.
2. Each function template has a single function parameter whose type is a class template specialization where the template arguments are the corresponding template parameters from the function template for each template argument in the template-argument-list of the simple-template-id of the partial specialization.

Example 1:

```cpp
template<int I, int J, class T> class X { };
template<int I, int J> class X<I, J, int> { }; // #1
template<int I> class X<I, I, int> { }; // #2

template<int I0, int J0> void f(X<I0, J0, int>); // A
template<int I0> void f(X<I0, I0, int>); // B

template <auto v> class Y { };
template <auto* p> class Y<p> { }; // #3
template <auto** pp> class Y<pp> { }; // #4

template <auto* p0> void g(Y<p0>); // C
template <auto** pp0> void g(Y<pp0>); // D
```

According to the ordering rules for function templates, the function template `B` is more specialized than the function template `A` and the function template `D` is more specialized than the function template `C`. Therefore, the partial specialization #2 is more specialized than the partial specialization #1 and the partial specialization #4 is more specialized than the partial specialization #3. —end example

Example 2:

```cpp
template<typename T> concept C = requires (T t) { t.f(); };
template<typename T> concept D = C<T> && requires (T t) { t.f(); };

template<typename T> class S { };
template<C T> class S<T> { }; // #1
template<D T> class S<T> { }; // #2

template<C T> void f(S<T>); // A
template<D T> void f(S<T>); // B
```

The partial specialization #2 is more specialized than #1 because `B` is more specialized than `A`. —end example

13.7.6.4 Members of class template partial specializations

The members of the class template partial specialization are unrelated to the members of the primary template. Class template partial specialization members that are used in a way that requires a definition shall be defined; the definitions of members of the primary template are never used as definitions for members of a class template partial specialization. An explicit specialization of a member of a class template partial specialization is declared in the same way as an explicit specialization of a member of the primary template.

Example 1:

```cpp
// primary class template
template<class T, int I> struct A {
    void f();
};

// member of primary class template
template<class T, int I> void A<T,I>::f() { }
```
// class template partial specialization
template<class T> struct A<T,2> {
    void f();
    void g();
    void h();
};

// member of class template partial specialization
template<class T> void A<T,2>::g() { }

// explicit specialization
template<> void A<char,2>::h() { }

int main() {
    A<char,0> a0;
    A<char,2> a2;
    a0.f(); // OK, uses definition of primary template's member
    a2.g(); // OK, uses definition of partial specialization's member
    a2.h(); // OK, uses definition of explicit specialization's member
    a2.f(); // error: no definition of f for A<T,2>; the primary template is not used here
}

—end example

2 If a member template of a class template is partially specialized, the member template partial specializations are member templates of the enclosing class template; if the enclosing class template is instantiated (13.9.2, 13.9.3), a declaration for every member template partial specialization is also instantiated as part of creating the members of the class template specialization. If the primary member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the partial specializations of the member template are ignored for this specialization of the enclosing class template. If a partial specialization of the member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the primary member template and its other partial specializations are still considered for this specialization of the enclosing class template.

[Example 2:

```cpp
template<class T> struct A {
    template<class T2> struct B {}; // #1
    template<class T2> struct B<T2*> {}; // #2
};

template<> template<class T2> struct A<short>::B {}; // #3
A<char>::B<int*> abcip; // uses #2
A<short>::B<int*> absip; // uses #3
A<char>::B<int> abci; // uses #1
—end example
```

13.7.7 Function templates
13.7.7.1 General

1 A function template defines an unbounded set of related functions.

[Example 1: A family of sort functions can be declared like this:

```cpp
template<class T> class Array { }
template<class T> void sort(Array<T>&);
—end example
```

2 [Note 1: A function template can have the same name as other function templates and non-template functions (9.3.4.6) in the same scope. —end note]

A non-template function is not related to a function template (i.e., it is never considered to be a specialization), even if it has the same name and type as a potentially generated function template specialization.129

129 That is, declarations of non-template functions do not merely guide overload resolution of function template specializations with the same name. If such a non-template function is odr-used (6.3) in a program, it must be defined; it will not be implicitly instantiated using the function template definition.

§ 13.7.7.1 381
13.7.7.2 Function template overloading

It is possible to overload function templates so that two different function template specializations have the same type.

[Example 1:

```cpp
// translation unit 1:
template<class T>
void f(T*);

void g(int* p) {
  f(p); // calls f<int*>(int*)
}

// translation unit 2:
template<class T>
void f(T);

void h(int* p) {
  f(p); // calls f<int*>(int*)
}
```

--end example]

Such specializations are distinct functions and do not violate the one-definition rule (6.3).

The signature of a function template is defined in Clause 3. The names of the template parameters are significant only for establishing the relationship between the template parameters and the rest of the signature.

[Note 1: Two distinct function templates can have identical function return types and function parameter lists, even if overload resolution alone cannot distinguish them.

```cpp
template<class T> void f();
template<int I> void f();
// OK: overloads the first template
distinguishable with an explicit template argument list
```

--end note]

When an expression that references a template parameter is used in the function parameter list or the return type in the declaration of a function template, the expression that references the template parameter is part of the signature of the function template. This is necessary to permit a declaration of a function template in one translation unit to be linked with another declaration of the function template in another translation unit and, conversely, to ensure that function templates that are intended to be distinct are not linked with one another.

[Example 2:

```cpp
template <int I, int J> A<I+J> f(A<I>, A<J>); // #1

template <int K, int L> A<K+L> f(A<K>, A<L>); // same as #1

template <int I, int J> A<I-J> f(A<I>, A<J>); // different from #1
```

--end example]

[Note 2: Most expressions that use template parameters use non-type template parameters, but it is possible for an expression to reference a type parameter. For example, a template type parameter can be used in the `sizeof` operator. --end note]

Two expressions involving template parameters are considered equivalent if two function definitions containing the expressions would satisfy the one-definition rule (6.3), except that the tokens used to name the template parameters may differ as long as a token used to name a template parameter in one expression is replaced by another token that names the same template parameter in the other expression. Two unevaluated operands that do not involve template parameters are considered equivalent if two function definitions containing the expressions would satisfy the one-definition rule, except that the tokens used to name types and declarations may differ as long as they name the same entities, and the tokens used to form concept-ids may differ as long as the two template-ids are the same (13.6).

[Note 3: For instance, `A<42>` and `A<40+2>` name the same type. --end note]

Two lambda-expressions are never considered equivalent.

[Note 4: The intent is to avoid lambda-expressions appearing in the signature of a function template with external linkage. --end note]

For determining whether two dependent names (13.8.3) are equivalent, only the name itself is considered, not the result of name lookup.

[Note 5: If such a dependent name is unqualified, it is looked up from the first declaration of the function template (13.8.4.2). --end note]

[Example 3:

```cpp
template <int I, int J> void f(A<I+J>); // #1

template <int K, int L> void f(A<K+L>); // same as #1
```

§ 13.7.7.2 382
Two potentially-evaluated expressions involving template parameters that are not equivalent are functionally equivalent if, for any given set of template arguments, the evaluation of the expression results in the same value. Two unevaluated operands that are not equivalent are functionally equivalent if, for any given set of template arguments, the expressions perform the same operations in the same order with the same entities.

Example 4:

```cpp
template<int I> concept C = true;
template<typename T> struct A {
    void f() requires C<2>; // #1
    void f() requires true; // OK, different functions
};
```

6 Two template-heads are equivalent if their template-parameter-lists have the same length, corresponding template-parameters are equivalent and are both declared with type-constraints that are equivalent if either template-parameter is declared with a type-constraint, and if either template-head has a requires-clause, they both have requires-clauses and the corresponding constraint-expressions are equivalent. Two template-parameters are equivalent under the following conditions:

- they declare template parameters of the same kind,
- if either declares a template parameter pack, they both do,
- if they declare non-type template parameters, they have equivalent types ignoring the use of type-constraints for placeholder types, and
- if they declare template template parameters, their template parameters are equivalent.

When determining whether types or type-constraints are equivalent, the rules above are used to compare expressions involving template parameters. Two template-heads are functionally equivalent if they accept and are satisfied by (13.5.2) the same set of template argument lists.

7 If the validity or meaning of the program depends on whether two constructs are equivalent, and they are functionally equivalent but not equivalent, the program is ill-formed, no diagnostic required.

8 [Note 7: This rule guarantees that equivalent declarations will be linked with one another, while not requiring implementations to use heroic efforts to guarantee that functionally equivalent declarations will be treated as distinct. For example, the last two declarations are functionally equivalent and would cause a program to be ill-formed:]

```cpp
// guaranteed to be the same
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+10>);

// guaranteed to be different
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+11>);

// ill-formed, no diagnostic required
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+1+2+3+4>);
```
13.7.7.3 Partial ordering of function templates

If multiple function templates share a name, the use of that name can be ambiguous because template argument deduction (13.10.3) may identify a specialization for more than one function template. Partial ordering of overloaded function template declarations is used in the following contexts to select the function template to which a function template specialization refers:

1. during overload resolution for a call to a function template specialization (12.2.4);
2. when the address of a function template specialization is taken;
3. when a placement operator delete that is a function template specialization is selected to match a placement operator new (6.7.5.3, 7.6.2.8);
4. when a friend function declaration (13.7.5), an explicit instantiation (13.9.3) or an explicit specialization (13.9.4) refers to a function template specialization.

Partial ordering selects which of two function templates is more specialized than the other by transforming each template in turn (see next paragraph) and performing template argument deduction using the function type. The deduction process determines whether one of the templates is more specialized than the other. If so, the more specialized template is the one chosen by the partial ordering process. If both deductions succeed, the partial ordering selects the more constrained template (if one exists) as determined below.

To produce the transformed template, for each type, non-type, or template template parameter (including template parameter packs (13.7.4) thereof) synthesize a unique type, value, or class template respectively and substitute it for each occurrence of that parameter in the function type of the template.

Each function template $M$ that is a member function is considered to have a new first parameter of type $X(M)$, described below, inserted in its function parameter list. If exactly one of the function templates was considered by overload resolution via a rewritten candidate (12.2.2.3) with a reversed order of parameters, then the order of the function parameters in its transformed template is reversed. For a function template $M$ with cv-qualifiers $cv$ that is a member of a class $A$:

- The type $X(M)$ is “rvalue reference to $cv$ $A$” if the optional ref-qualifier of $M$ is && or if $M$ has no ref-qualifier and the positionally-corresponding parameter of the other transformed template has rvalue reference type; if this determination depends recursively upon whether $X(M)$ is an rvalue reference type, it is not considered to have rvalue reference type.
- Otherwise, $X(M)$ is “lvalue reference to $cv$ $A$”.

Using the transformed function template’s function type, perform type deduction against the other template as described in 13.10.3.5.

---

Example 1:

```cpp
struct A {};
template<class T> struct B {
    template<class R> int operator*(R&);
};

template<class T, class R> int operator*(T&, R&);

// The declaration of B::operator* is transformed into the equivalent of
// template<class R> int operator*(B<A>&, R&);

int main() {
    A a;
    B<A> b;
    b * a;  // calls #1
}
```

---

Example 2:

Using the transformed function template’s function type, perform type deduction against the other template as described in 13.10.3.5.
template<class T> struct A { A(); }

template<class T> void f(T);
template<class T> void f(T*);
template<class T> void f(const T*);

template<class T> void g(T);
template<class T> void g(T&);

template<class T> void h(const T&);
template<class T> void h(A<T>&);

void m() {
    const int* p;
    f(p);                  // f(const T*) is more specialized than f(T) or f(T*)
    float x;
    g(x);                  // ambiguous: g(T) or g(T&)
    A<int> z;
    h(z);                  // overload resolution selects h(A<T&>)
    const A<int> z2;       // h(const T&) is called because h(A<T&>) is not callable
    h(z2);
}

—end example—

5 [Note 3: Since, in a call context, such type deduction considers only parameters for which there are explicit call arguments, some parameters are ignored (namely, function parameter packs, parameters with default arguments, and ellipsis parameters)].

[Example 3:]

template<class T> void f(T); // #1
template<class T> void f(T*, int=1); // #2
template<class T> void g(T); // #3
template<class T> void g(T*, ...); // #4

int main() {
    int* ip;
    f(ip);                  // calls #2
    g(ip);                  // calls #4
}

—end example—

[Example 4:]

template<class T, class U> struct A { };  

template<class T, class U> void f(U, A<U, T>* p = 0); // #1
template<class T, class U> void f(U, A<U, U>* p = 0); // #2
template<class T> void g(T, T = T()); // #3
template<class T, class... U> void g(T, U...); // #4

void h() {
    f<int>(42, (A<int, int>*0);
    f<int>(42);                  // calls #2
    g(42);                      // error: ambiguous
    g(42);                      // error: ambiguous
}

—end example—

[Example 5:]

template<class T, class... U> void f(T, U...); // #1
template<class T> void f(T); // #2
template<class T, class... U> void g(T*, U...); // #3
template<class T> void g(T); // #4

void h(int i) {
    f(&i);                  // OK: calls #2
If deduction against the other template succeeds for both transformed templates, constraints can be considered as follows:

(6.1) — If their template-parameter-lists (possibly including template-parameters invented for an abbreviated function template (9.3.4.6)) or function parameter lists differ in length, neither template is more specialized than the other.

(6.2) — Otherwise:

(6.2.1) — If exactly one of the templates was considered by overload resolution via a rewritten candidate with reversed order of parameters:

(6.2.1.1) — If, for either template, some of the template parameters are not deducible from their function parameters, neither template is more specialized than the other.

(6.2.1.2) — If there is either no reordering or more than one reordering of the associated template-parameter-list such that

(6.2.1.2) — the corresponding template-parameters of the template-parameter-lists are equivalent and

(6.2.1.2) — the function parameters that positionally correspond between the two templates are of the same type,

neither template is more specialized than the other.

(6.2.2) — Otherwise, if the corresponding template-parameters of the template-parameter-lists are not equivalent (13.7.7.2) or if the function parameters that positionally correspond between the two templates are not of the same type, neither template is more specialized than the other.

(6.3) — Otherwise, if the context in which the partial ordering is done is that of a call to a conversion function and the return types of the templates are not the same, then neither template is more specialized than the other.

(6.4) — Otherwise, if one template is more constrained than the other (13.5.5), the more constrained template is more specialized than the other.

(6.5) — Otherwise, neither template is more specialized than the other.

[Example 6]:

```cpp
g(&i); \hfill // OK: calls #3
```

1 If deduction against the other template succeeds for both transformed templates, constraints can be considered as follows:

(6.1) — If their template-parameter-lists (possibly including template-parameters invented for an abbreviated function template (9.3.4.6)) or function parameter lists differ in length, neither template is more specialized than the other.

(6.2) — Otherwise:

(6.2.1) — If exactly one of the templates was considered by overload resolution via a rewritten candidate with reversed order of parameters:

(6.2.1.1) — If, for either template, some of the template parameters are not deducible from their function parameters, neither template is more specialized than the other.

(6.2.1.2) — If there is either no reordering or more than one reordering of the associated template-parameter-list such that

(6.2.1.2) — the corresponding template-parameters of the template-parameter-lists are equivalent and

(6.2.1.2) — the function parameters that positionally correspond between the two templates are of the same type,

neither template is more specialized than the other.

(6.2.2) — Otherwise, if the corresponding template-parameters of the template-parameter-lists are not equivalent (13.7.7.2) or if the function parameters that positionally correspond between the two templates are not of the same type, neither template is more specialized than the other.

(6.3) — Otherwise, if the context in which the partial ordering is done is that of a call to a conversion function and the return types of the templates are not the same, then neither template is more specialized than the other.

(6.4) — Otherwise, if one template is more constrained than the other (13.5.5), the more constrained template is more specialized than the other.

(6.5) — Otherwise, neither template is more specialized than the other.

[Example 6]:

```cpp
template <typename> constexpr bool True = true;
template <typename T> concept C = True<T>;
void f(C auto &, auto &) = delete;
template <C Q> void f(Q &, C auto &);

void g(struct A *ap, struct B *bp) {
    f(*ap, *bp); \hfill // OK: Can use different methods to produce template parameters
}

template <typename T, typename U> struct X {};

template <typename T, C U, typename V> bool operator==(X<T, U>, V) = delete;
template <C T, C U, C V> bool operator==(T, X<U, V>);

void h() {
    X<void *, int>{} == 0; \hfill // OK: Correspondence of [T, U, V] and [U, V, T]
}
```

13.7.8 Alias templates

A template-declaration in which the declaration is an alias-declaration (9.1) declares the identifier to be an alias template. An alias template is a name for a family of types. The name of the alias template is a template-name.
When a \textit{template-id} refers to the specialization of an alias template, it is equivalent to the associated type obtained by substitution of its \textit{template-arguments} for the \textit{template-parameters} in the \textit{defining-type-id} of the alias template.

\textbf{[Note 1: An alias template name is never deduced. — end note]}

\textbf{[Example 1]}

\begin{verbatim}
template<class T> struct Alloc { /* ... */ };
template<class T> using Vec = vector<T, Alloc<T>>;
Vec<int> v; // same as vector<int, Alloc<int>> v;

template<class T>
void process(Vec<T>& v)
{ /* ... */ }

template<class T>
void process(vector<T, Alloc<T>>& w)
{ /* ... */ } // error: redefinition

template<template<class> class TT>
void f(TT<int>);
f(v); // error: Vec not deduced

template<template<class,class> class TT>
void g(TT<int, Alloc<int>>);
g(v); // OK: TT = vector
\end{verbatim}

\textbf{—end example}\n
However, if the \textit{template-id} is dependent, subsequent template argument substitution still applies to the \textit{template-id}.

\textbf{[Example 2]}

\begin{verbatim}
template<typename...> using void_t = void;
template<typename T> void_t<typename T::foo> f();
f<int>(); // error: int does not have a nested type foo
\end{verbatim}

\textbf{—end example}\n
The \textit{defining-type-id} in an alias template declaration shall not refer to the alias template being declared. The type produced by an alias template specialization shall not directly or indirectly make use of that specialization.

\textbf{[Example 3]}

\begin{verbatim}
template <class T> struct A;
template <class T> using B = typename A<T>::U;
template <class T> struct A {
typedef B<T> U;
};
B<short> b; // error: instantiation of B<short> uses own type via A<short>::U
\end{verbatim}

\textbf{—end example}\n
The type of a \textit{lambda-expression} appearing in an alias template declaration is different between instantiations of that template, even when the \textit{lambda-expression} is not dependent.

\textbf{[Example 4]}

\begin{verbatim}
template <class T>
using A = decltype([] { }); // A<int> and A<char> refer to different closure types
\end{verbatim}

\textbf{—end example}\n
\section{Concept definitions \[temp.concept\]}

A \textit{concept} is a template that defines constraints on its template arguments.

\begin{verbatim}
class-definition:
concept concept-name = constraint-expression ;
\end{verbatim}
A concept-definition declares a concept. Its identifier becomes a concept-name referring to that concept within its scope.

[Example 1:

```cpp
template<typename T>
concept C = requires(T x) {
    { x == x } -> std::convertible_to<bool>;
};

template<typename T>
    requires C<T> // C constrains f1(T) in constraint-expression
T f1(T x) { return x; }

template<C T> // C, as a type-constraint, constrains f2(T)
T f2(T x) { return x; }
```
—end example]

A concept-definition shall inhabit a namespace scope (6.4.5).

A concept shall not have associated constraints (13.5.3).

A concept is not instantiated (13.9).

[Note 1: A concept-id (13.3) is evaluated as an expression. A concept cannot be explicitly instantiated (13.9.3), explicitly specialized (13.9.4), or partially specialized (13.7.6). — end note]

The constraint-expression of a concept-definition is an unevaluated operand (7.2.3).

The first declared template parameter of a concept definition is its prototype parameter. A type concept is a concept whose prototype parameter is a type template-parameter.

13.8 Name resolution

13.8.1 General

A name that appears in a declaration $D$ of a template $T$ is looked up from where it appears in an unspecified declaration of $T$ that is or is reachable from $D$ and from which no other declaration of $T$ that contains the usage of the name is reachable. If the name is dependent (as specified in 13.8.3), it is looked up for each specialization (after substitution) because the lookup depends on a template parameter.

[Note 1: Some dependent names are also looked up during parsing to determine that they are dependent or to interpret following < tokens. Uses of other names might be type-dependent or value-dependent (13.8.3.3, 13.8.3.4). A using-declarator is never dependent in a specialization and is therefore replaced during lookup for that specialization (6.5). — end note]

[Example 1:

```cpp
struct A { operator int(); };  
template<class B, class T>
struct D : B {
    T get() { return operator T(); } // conversion-function-id is dependent
};
int f(D<A, int> d) { return d.get(); } // OK: lookup finds A::operator int
```
—end example]

[Example 2:

```cpp
void f(char);

template<class T> void g(T t) {
    f(t); // f(char)
    f(T(t)); // dependent
    f(t); // dependent
    dd++; // not dependent; error: declaration for dd not found
}

enum E { e ];
void f(E);
```
double dd;
void h() {
  g(e);    // will cause one call of f(char) followed by two calls of f(E)
  g('a');  // will cause three calls of f(char)
}
—end example

Example 3:

struct A {
  struct B { /* ... */};
  int a;
  int Y;
};

int a;

template<class T> struct Y : T {
  struct B { /* ... */};
  B b;     // The B defined in Y
  void f(int i) { a = i; }    // ::a
  Y* p;   // Y<T>
};

Y<A> ya;

The members A::B, A::a, and A::Y of the template argument A do not affect the binding of names in Y<A>. —end example

2 If the validity or meaning of the program would be changed by considering a default argument or default template argument introduced in a declaration that is reachable from the point of instantiation of a specialization (13.8.4.1) but is not found by lookup for the specialization, the program is ill-formed, no diagnostic required.

typename-specifier:
  typename nested-name-specifier identifier
  typename nested-name-specifier template_opt simple-template-id

3 The component names of a typename-specifier are its identifier (if any) and those of its nested-name-specifier and simple-template-id (if any). A typename-specifier denotes the type or class template denoted by the simple-type-specifier (9.2.9.3) formed by omitting the keyword typename.

[Note 2: The usual qualified name lookup (6.5.5) applies even in the presence of typename. — end note]

Example 4:

struct A {
  struct X { };  
  int X;
};
struct B {
  struct X { }
};
template<class T> void f(T t) {
  typename T::X x;
}
void foo() {
  A a;
  B b;
  f(b);    // OK: T::X refers to B::X
  f(a);    // error: T::X refers to the data member A::X not the struct A::X
}
—end example

4 A qualified or unqualified name is said to be in a type-only context if it is the terminal name of

4.1 — a typename-specifier, nested-name-specifier, elaborated-type-specifier, class-or-decltype, or
4.2 — a type-specifier of a
— new-type-id,
— defining-type-id,
— conversion-type-id,
— trailing-return-type,
— default argument of a type-parameter, or
— type-id of a static_cast, const_cast, reinterpret_cast, or dynamic_cast, or
— a decl-specifier of the decl-specifier-seq of a
decl-specifier of the decl-specifier-seq of a
decl-specifier of the decl-specifier-seq of a
decl-specifier of the decl-specifier-seq of a
decl-specifier of the decl-specifier-seq of a
— simple-declaration or a function-definition in namespace scope,
— member-declaration,
— parameter-declaration in a member-declaration, unless that parameter-declaration appears in a
default argument,
— parameter-declaration in a declarator of a function or function template declaration whose declarator-
id is qualified, unless that parameter-declaration appears in a default argument,
— parameter-declaration in a lambda-declarator or requirement-parameter-list, unless that parameter-declaration appears in a default argument, or
— parameter-declaration of a (non-type) template-parameter.

Example 5:

```cpp
template<class T> T::R f(); // OK, return type of a function declaration at global scope
template<class T> void f(T::R); // ill-formed, no diagnostic required: attempt to declare a void variable template

template<class T> struct S {
    using Ptr = PtrTraits<T>::Ptr;
    T::R f(T::P p); // OK, in a defining-type-id
    return static_cast<T::R>(p); // OK, type-id of a static_cast
}
auto g() -> S<T*>::Ptr; // OK, trailing-return-type
};
template<typename T> void f() {
    void (*pf)(T::X); // variable pf of type void* initialized with T::X
    void g(T::X); // error: T::X at block scope does not denote a type
        (attempt to declare a void variable)
}

— end example]
```

5 A qualified-id whose terminal name is dependent and that is in a type-only context is considered to denote a type. A name that refers to a using-declarator whose terminal name is dependent is interpreted as a typedef-name if the using-declarator uses the keyword `typename`.

Example 6:

```cpp
template <class T> void f(int i) {
    T::x * i; // expression, not the declaration of a variable i
}

struct Foo {
    typedef int x;
};

struct Bar {
    static int const x = 5;
};

int main() {
    f<Bar>(1); // OK
    f<Foo>(1); // error: Foo::x is a type
}
```

130) This includes friend function declarations.
The validity of a template may be checked prior to any instantiation.

[Note 3: Knowing which names are type names allows the syntax of every template to be checked in this way. — end note]

The program is ill-formed, no diagnostic required, if:

1. no valid specialization can be generated for a template or a substatement of a constexpr if statement (8.5.2) within a template and the template is not instantiated, or
2. any constraint-expression in the program, introduced or otherwise, has (in its normal form) an atomic constraint A where no satisfaction check of A could be well-formed and no satisfaction check of A is performed, or
3. every valid specialization of a variadic template requires an empty template parameter pack, or
4. a hypothetical instantiation of a template immediately following its definition would be ill-formed due to a construct that does not depend on a template parameter, or
5. the interpretation of such a construct in the hypothetical instantiation is different from the interpretation of the corresponding construct in any actual instantiation of the template.

[Note 4: This can happen in situations including the following:

1. a type used in a non-dependent name is incomplete at the point at which a template is defined but is complete at the point at which an instantiation is performed, or
2. lookup for a name in the template definition found a using-declaration, but the lookup in the corresponding scope in the instantiation does not find any declarations because the using-declaration was a pack expansion and the corresponding pack is empty, or
3. an instantiation uses a default argument or default template argument that had not been defined at the point at which the template was defined, or
4. constant expression evaluation (7.7) within the template instantiation uses
   a. the value of a const object of integral or unscoped enumeration type or
   b. the value of a constexpr object or
   c. the value of a reference or
   d. the definition of a constexpr function, and that entity was not defined when the template was defined, or
5. a class template specialization or variable template specialization that is specified by a non-dependent simple-template-id is used by the template, and either it is instantiated from a partial specialization that was not defined when the template was defined or it names an explicit specialization that was not declared when the template was defined.

— end note]

Otherwise, no diagnostic shall be issued for a template for which a valid specialization can be generated.

[Note 5: If a template is instantiated, errors will be diagnosed according to the other rules in this document. Exactly when these errors are diagnosed is a quality of implementation issue. — end note]

Example 7:

```cpp
int j;
template<class T> class X {
    void f(T t, int i, char* p) {
        t = i; // diagnosed if X::f is instantiated, and the assignment to t is an error
        p = i; // may be diagnosed even if X::f is not instantiated
        p = j; // may be diagnosed even if X::f is not instantiated
        X<T>::g(t); // OK
        X<T>::h(); // may be diagnosed even if X::f is not instantiated
    }
    void g(T t) {
        *; // may be diagnosed even if X::g is not instantiated
    }
};
```
template<class... T> struct A {
    void operator++(int, T... t); // error: too many parameters
};
template<class... T> union X : T... { }; // error: union with base class
template<class... T> struct A : T..., T... { }; // error: duplicate base class
—end example]

[Note 6: For purposes of name lookup, default arguments and noexcept-specifiers of function templates and default arguments and noexcept-specifiers of member functions of class templates are considered definitions (13.7). — end note]

13.8.2 Locally declared names
[temp.local]

Like normal (non-template) classes, class templates have an injected-class-name (11.1). The injected-class-name can be used as a template-name or a type-name. When it is used with a template-argument-list, as a template-argument for a template template-parameter, or as the final identifier in the elaborated-type-specifier of a friend class template declaration, it is a template-name that refers to the class template itself. Otherwise, it is a type-name equivalent to the template-name followed by the template-parameters of the class template enclosed in <>.

When the inject-class-name of a class template specialization or partial specialization is used as a type-name, it is equivalent to the template-name followed by the template-arguments of the class template specialization or partial specialization enclosed in <>.

[Example 1:

template<template<class> class T> class A { }
template<class T> class Y;
template<> class Y<int> {
    Y* p;
    // meaning Y<int>
    Y<char>* q;
    // meaning Y<char>
    A<int>* a;
    // meaning A<int>
    class B {
        template<class> friend class Y;
        // meaning ::Y
    };
};
—end example]

The injected-class-name of a class template or class template specialization can be used as either a template-name or a type-name wherever it is named.

[Example 2:

template <class T> struct Base { 
    Base* p;
};

template <class T> struct Derived: public Base<T> {
    typename Derived::Base* p;
    // meaning Derived::Base<T>
};

template<class T, template<class> class U = T::Base> struct Third { 
    Third<Derived<int> > t;
    // OK: default argument uses injected-class-name as a template
—end example]

A lookup that finds an injected-class-name (6.5.2) can result in an ambiguity in certain cases (for example, if it is found in more than one base class). If all of the injected-class-names that are found refer to specializations of the same class template, and if the name is used as a template-name, the reference refers to the class template itself and not a specialization thereof, and is not ambiguous.

[Example 3:

template <class T> struct Base { 
};
template <class T> struct Derived: Base<int>, Base<char> {
    typename Derived::Base b;
    // error: ambiguous
    typename Derived::Base<double> d;
    // OK
};

§ 13.8.2 392
When the normal name of the template (i.e., the name from the enclosing scope, not the injected-class-name) is used, it always refers to the class template itself and not a specialization of the template.

Example 4:
```cpp
template<class T> class X {
    X* p; // meaning X<T>
    X<T>* p2;
    X<int>* p3; // error: missing template argument list
    ::X* p4; // ::X does not refer to the injected-class-name
};
```

The name of a template-parameter shall not be bound to any following declaration contained by the scope to which the template-parameter belongs.

Example 5:
```cpp
template<class T, int i> class Y {
    int T; // error: template-parameter hidden
    void f() { 
        char T; // error: template-parameter hidden
    } 
    friend void T(); // OK: no name bound
};
```

Unqualified name lookup considers the template parameter scope of a template-declaration immediately after the outermost scope associated with the template declared (even if its parent scope does not contain the template-parameter-list).

Note 1: The scope of a class template, including its non-dependent base classes (13.8.3.2, 6.5.2), is searched before its template parameter scope. —end note

Example 6:
```cpp
struct B { }; 
namespace N {
    typedef void V;
    template<class T> struct A : B {
        typedef void C;
        void f();
    template<class U> void g(U);
};
}
```

Example 6:
```cpp
template<class V> void N::A<B>::g(C) {
    B b; // B is the base class, not the template parameter
    C c; // C is the template parameter, not A's C
}
```

13.8.3 Dependent names

13.8.3.1 General

Inside a template, some constructs have semantics which may differ from one instantiation to another. Such a construct depends on the template parameters. In particular, types and expressions may depend on the type and/or value of template parameters (as determined by the template arguments) and this determines the context for name lookup for certain names. An expression may be type-dependent (that is, its type
may depend on a template parameter) or *value-dependent* (that is, its value when evaluated as a constant expression (7.7) may depend on a template parameter) as described below.

A dependent call is an expression, possibly formed as a non-member candidate for an operator (12.2.2.3), of the form:

\[
\text{postfix-expression ( expression-list_{opt} )}
\]

where the postfix-expression is an unqualified-id and

1. any of the expressions in the expression-list is a pack expansion (13.7.4),
2. any of the expressions or braced-init-lists in the expression-list is type-dependent (13.8.3.3), or
3. the unqualified-id is a template-id in which any of the template arguments depends on a template parameter.

The component name of an unqualified-id (7.5.4.2) is dependent if

1. it is a conversion-function-id whose conversion-type-id is dependent, or
2. it is operator= and the current class is a templated entity, or
3. the unqualified-id is the postfix-expression in a dependent call.

[Note 1: Such names are looked up only at the point of the template instantiation (13.8.4.1) in both the context of the template definition and the context of the point of instantiation (13.8.4.2). — end note]

**Example 1:**

```cpp
template<class T> struct X : B<T> {
    typename T::A* pa;
    void f(B<T>* pb) {
        static int i = B<T>::i;
        pb->j++;
    }
};
```

The base class name B<T>, the type name T::A, the names B<T>::i and pb->j explicitly depend on the template-parameter. —end example

### 13.8.3.2 Dependent types

1. A name or template-id refers to the current instantiation if it is
   1. in the definition of a class template, a nested class of a class template, a member of a class template, or a member of a nested class of a class template, the injected-class-name (11.1) of the class template or nested class,
   2. in the definition of a primary class template or a member of a primary class template, the name of the class template followed by the template argument list of its template-head (13.4) enclosed in <> (or an equivalent template alias specialization),
   3. in the definition of a nested class of a class template, the name of the nested class referenced as a member of the current instantiation, or
   4. in the definition of a class template partial specialization or a member of a class template partial specialization, the name of the class template followed by a template argument list equivalent to that of the partial specialization (13.7.6) enclosed in <> (or an equivalent template alias specialization).

2. A template argument that is equivalent to a template parameter can be used in place of that template parameter in a reference to the current instantiation. For a template type-parameter, a template argument is equivalent to a template parameter if it denotes the same type. For a non-type template parameter, a template argument is equivalent to a template parameter if it is an identifier that names a variable that is equivalent to the template parameter. A variable is equivalent to a template parameter if

   1. it has the same type as the template parameter (ignoring cv-qualification) and
   2. its initializer consists of a single identifier that names the template parameter or, recursively, such a variable.

[Note 1: Using a parenthesized variable name breaks the equivalence. — end note]

**Example 1:**

```cpp
template <class T> class A {
    A* pl; // A is the current instantiation
};
```
A dependent base class is a base class that is a dependent type and is not the current instantiation.

Note 2: A base class can be the current instantiation in the case of a nested class naming an enclosing class as a base.

Example 2:

```cpp
template<class T> struct A {
    typedef int M;
    struct B {
        typedef void M;
        struct C;
    };
};
```

```cpp
template<class T> struct A<T>::B::C : A<T> {
    M m; // OK, A<T>::M
};
```

Example 3:

```cpp
template <class T> class A {
    static const int i = 5;
    int n1[i]; // i refers to a member of the current instantiation
    int n2[A::i]; // A::i refers to a member of the current instantiation
    int n3[A<T>::i]; // A<T>::i refers to a member of the current instantiation
    int f();
};
```
template <class T> int A<T>::f() {
    return i;  // i refers to a member of the current instantiation
}

—end example—

A qualified or unqualified name names a dependent member of the current instantiation if it is a member of the current instantiation that, when looked up, refers to at least one member declaration (including a using-declarator whose terminal name is dependent) of a class that is the current instantiation.

5 A qualified name (6.5.5) is dependent if

(5.1) — it is a conversion-function-id whose conversion-type-id is dependent, or
(5.2) — its lookup context is dependent and is not the current instantiation, or
(5.3) — its lookup context is the current instantiation and it is operator=, or
(5.4) — its lookup context is the current instantiation and has at least one dependent base class, and qualified name lookup for the name finds nothing (6.5.5).

[Example 4:

```c
struct A {
    using B = int;
    A f();
};
struct C : A {};  
template<class T>
void g(T t) {
    decltype(t.A::f()):B i;  // error: typename needed to interpret B as a type
}
template void g(C);  // ...even though A is ::A here
```

—end example—

6 If, for a given set of template arguments, a specialization of a template is instantiated that refers to a member of the current instantiation with a qualified name, the name is looked up in the template instantiation context. If the result of this lookup differs from the result of name lookup in the template definition context, name lookup is ambiguous.

[Example 5:

```c
struct A {
    int m;
};
struct B {
    int m;
};

template<typename T>
struct C : A, T {
    int f() { return this->m; }  // finds A::m in the template definition context
    int g() { return m; }  // finds A::m in the template definition context
};

template int C<B>::f();  // error: finds both A::m and B::m
template int C<B>::g();  // OK: transformation to class member access syntax
// does not occur in the template definition context; see 11.4.3
```

—end example—

7 A type is dependent if it is

(7.1) — a template parameter,
(7.2) — denoted by a dependent (qualified) name,
(7.3) — a nested class or enumeration that is a direct member of a class that is the current instantiation,
(7.4) — a cv-qualified type where the cv-unqualified type is dependent,

(131) Every instantiation of a class template declares a different set of assignment operators.
— a compound type constructed from any dependent type,
— an array type whose element type is dependent or whose bound (if any) is value-dependent,
— a function type whose parameters include one or more function parameter packs,
— a function type whose exception specification is value-dependent,
— denoted by a `simple-template-id` in which either the template name is a template parameter or any of the template arguments is a dependent type or an expression that is type-dependent or value-dependent or is a pack expansion,\(^{132}\) or
— denoted by `decltype(expression)`, where `expression` is type-dependent (13.8.3.3).

[Note 3: Because typedefs do not introduce new types, but instead simply refer to other types, a name that refers to a typedef that is member of the current instantiation is dependent only if the type referred to is dependent. — end note]

### 13.8.3.3 Type-dependent expressions

1 Except as described below, an expression is type-dependent if any subexpression is type-dependent.
2 `this` is type-dependent if the current class (7.5.2) is dependent (13.8.3.2).
3 An `id-expression` is type-dependent if it is a `template-id` that is not a concept-id and is dependent; or if its terminal name is
   — associated by name lookup with one or more declarations declared with a dependent type,
   — associated by name lookup with a non-type `template-parameter` declared with a type that contains a placeholder type (9.2.9.6),
   — associated by name lookup with a variable declared with a type that contains a placeholder type (9.2.9.6) where the initializer is type-dependent,
   — associated by name lookup with one or more declarations of member functions of a class that is the current instantiation declared with a return type that contains a placeholder type,
   — associated by name lookup with a structured binding declaration (9.6) whose `brace-or-equal-initializer` is type-dependent,
   — the `identifier __func__` (9.5.1), where any enclosing function is a template, a member of a class template, or a generic lambda,
   — a `conversion-function-id` that specifies a dependent type, or
   — dependent

or if it names a dependent member of the current instantiation that is a static data member of type “array of unknown bound of T” for some T (13.7.2.5). Expressions of the following forms are type-dependent only if the type specified by the `type-id`, `simple-type-specifier` or `new-type-id` is dependent, even if any subexpression is type-dependent:

```
simple-type-specifier ( expression-list_opt )
::opt new new-placement_opt new-type-id new-initializer_opt
dynamic_cast < type-id > ( expression )
static_cast < type-id > ( expression )
const_cast < type-id > ( expression )
reinterpret_cast < type-id > ( expression )
```

4 Expressions of the following forms are never type-dependent (because the type of the expression cannot be dependent):

\(^{132}\) This includes an injected-class-name (11.1) of a class template used without a `template-argument-list`. 

literal
sizeof unary-expression
sizeof ( type-id )
sizeof ... ( identifier )
alignof ( type-id )
typeid ( expression )
typeid ( type-id )
::opt delete cast-expression
::opt delete [ ] cast-expression
throw assignment-expressionopt
noexcept ( expression )

[Note 1: For the standard library macro offsetof, see 17.2. — end note]

5 A class member access expression (7.6.1.5) is type-dependent if the terminal name of its id-expression, if any, is dependent or the expression refers to a member of the current instantiation and the type of the referenced member is dependent.

[Note 2: In an expression of the form x.y or xp->y the type of the expression is usually the type of the member y of the class of x (or the class pointed to by xp). However, if x or xp refers to a dependent type that is not the current instantiation, the type of y is always dependent. — end note]

6 A braced-init-list is type-dependent if any element is type-dependent or is a pack expansion.

7 A fold-expression is type-dependent.

13.8.3.4 Value-dependent expressions [temp.dep.constexpr]

1 Except as described below, an expression used in a context where a constant expression is required is value-dependent if any subexpression is value-dependent.

2 An id-expression is value-dependent if:

   (2.1) it is a concept-id and any of its arguments are dependent,
   (2.2) it is type-dependent,
   (2.3) it is the name of a non-type template parameter,
   (2.4) it names a static data member that is a dependent member of the current instantiation and is not initialized in a member-declarator,
   (2.5) it names a static member function that is a dependent member of the current instantiation, or
   (2.6) it names a potentially-constant variable (7.7) that is initialized with an expression that is value-dependent.

Expressions of the following form are value-dependent if the unary-expression or expression is type-dependent or the type-id is dependent:

   sizeof unary-expression
   sizeof ( type-id )
typeid ( expression )
typeid ( type-id )
alignof ( type-id )
noexcept ( expression )

[Note 1: For the standard library macro offsetof, see 17.2. — end note]

3 Expressions of the following form are value-dependent if either the type-id or simple-type-specifier is dependent or the expression or cast-expression is value-dependent:

   simple-type-specifier ( expression-listopt )
   static_cast < type-id > ( expression )
   const_cast < type-id > ( expression )
   reinterpret_cast < type-id > ( expression )
   ( type-id ) cast-expression

4 Expressions of the following form are value-dependent:

   sizeof ... ( identifier )
   fold-expression

5 An expression of the form &qualified-id where the qualified-id names a dependent member of the current instantiation is value-dependent. An expression of the form &cast-expression is also value-dependent if
evaluating cast-expression as a core constant expression (7.7) succeeds and the result of the evaluation refers to a templated entity that is an object with static or thread storage duration or a member function.

13.8.3.5 Dependent template arguments

A type template-argument is dependent if the type it specifies is dependent.

A non-type template-argument is dependent if its type is dependent or the constant expression it specifies is value-dependent.

Furthermore, a non-type template-argument is dependent if the corresponding non-type template-parameter is of reference or pointer type and the template-argument designates or points to a member of the current instantiation or a member of a dependent type.

A template template-parameter is dependent if it names a template-parameter or its terminal name is dependent.

13.8.4 Dependent name resolution

13.8.4.1 Point of instantiation

For a function template specialization, a member function template specialization, or a specialization for a member function or static data member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization and the context from which it is referenced depends on a template parameter, the point of instantiation of the specialization is the point of instantiation of the enclosing specialization. Otherwise, the point of instantiation for such a specialization follows the namespace scope declaration or definition that refers to the specialization.

If a function template or member function of a class template is called in a way which uses the definition of a default argument of that function template or member function, the point of instantiation of the default argument is the point of instantiation of the function template or member function specialization.

For a noexcept-specifier of a function template specialization or specialization of a member function of a class template, if the noexcept-specifier is implicitly instantiated because it is needed by another template specialization and the context that requires it depends on a template parameter, the point of instantiation of the specialization that requires it. Otherwise, the point of instantiation follows the namespace scope declaration or definition that requires the noexcept-specifier.

For a class template specialization, a class member template specialization, or a specialization for a class member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization, and the context from which the specialization is referenced depends on a template parameter, the point of instantiation of the specialization is immediately before the point of instantiation of the enclosing template. Otherwise, the point of instantiation follows the namespace scope declaration or definition that refers to the specialization.

If a virtual function is implicitly instantiated, its point of instantiation is immediately following the point of instantiation of its enclosing class template specialization.

An explicit instantiation definition is an instantiation point for the specialization or specializations specified by the explicit instantiation.

A specialization for a function template, a member function template, or of a member function or static data member of a class template may have multiple points of instantiations within a translation unit, and in addition to the points of instantiation described above,

- for any such specialization that has a point of instantiation within the declaration-seq of the translation-unit, prior to the private-module-fragment (if any), the point after the declaration-seq of the translation-unit is also considered a point of instantiation, and
- for any such specialization that has a point of instantiation within the private-module-fragment, the end of the translation unit is also considered a point of instantiation.

A specialization for a class template has at most one point of instantiation within a translation unit. A specialization for any template may have points of instantiation in multiple translation units. If two different points of instantiation give a template specialization different meanings according to the one-definition rule (6.3), the program is ill-formed, no diagnostic required.
13.8.4.2 Candidate functions

If a dependent call (13.8.3) would be ill-formed or would find a better match had the lookup for its dependent name considered all the function declarations with external linkage introduced in the associated namespaces in all translation units, not just considering those declarations found in the template definition and template instantiation contexts (6.5.4), then the program is ill-formed, no diagnostic required.

Example 1:

Source file "X.h":

```cpp
namespace Q {
    struct X { }
}
```

Source file "G.h":

```cpp
namespace Q {
    void g_impl(X, X);
}
```

Module interface unit of M1:

```cpp
module;
#include "X.h"
#include "G.h"
export module M1;
export template<typename T>
    void g(T t) {
        g_impl(t, Q::X{ }); // ADL in definition context finds Q::g_impl, g_impl not discarded
    }
```

Module interface unit of M2:

```cpp
module;
#include "X.h"
export module M2;
import M1;
void h(Q::X x) {
    g(x); // OK
}
```

—end example

Example 2:

Module interface unit of Std:

```cpp
export module Std;
export template<typename Iter>
    void indirect_swap(Iter lhs, Iter rhs) {
        swap(*lhs, *rhs); // swap not found by unqualified lookup, can be found only via ADL
    }
```

Module interface unit of M:

```cpp
export module M;
import Std;

struct S { /* ... */ }; // #1
void swap(S& s, S& t); // #1
void f(S* p, S* q) {
    indirect_swap(p, q); // finds #1 via ADL in instantiation context
}
```

—end example

Example 3:

Source file "X.h":

```cpp
struct X { /* ... */ }
```
X operator+(X, X);

Module interface unit of F:

```cpp
eexport module F;
export template<typename T>
void f(T t) {
   t + t;
}
```

Module interface unit of M:

```cpp
module;
#include "X.h"
export module M;
import F;
void g(X x) {
   f(x);
   // OK: instantiates f from F,
   // operator+ is visible in instantiation context
}
```

— end example] 5

[Example 4:

Module interface unit of A:

```cpp
export module A;
export template<typename T>
void f(T t) {
   cat(t, t);  // #1
   dog(t, t);  // #2
}
```

Module interface unit of B:

```cpp
export module B;
import A;
export template<typename T, typename U>
void g(T t, U u) {
   f(t);
}
```

Source file "foo.h", not an importable header:

```cpp
struct foo {
   friend int cat(foo, foo);
};
int dog(foo, foo);
```

Module interface unit of C1:

```cpp
module;
#include "foo.h"  // dog not referenced, discarded
export module C1;
import B;
export template<typename T>
void h(T t) {
   g(foo{ }, t);
}
```

Translation unit:

```cpp
import C1;
void i() {
   h(0);  // error: dog not found at #2
}
```

Importable header "bar.h":

```cpp
struct bar {
   friend int cat(bar, bar);
};
int dog(bar, bar);
```
Module interface unit of C2:

```c
module;
#include "bar.h"    // imports header unit "bar.h"
export module C2;
import B;
export template<typename T>
    void j(T t) {
        g(bar{ }, t);
    }
```

Translation unit:
```c
import C2;
void k() {
    j(0);  // OK, dog found in instantiation context:
    // visible at end of module interface unit of C2
}
```

--- end example]

13.9 Template instantiation and specialization [temp.spec]

13.9.1 General [temp.spec.general]

1 The act of instantiating a function, a variable, a class, a member of a class template, or a member template is referred to as template instantiation.

2 A function instantiated from a function template is called an instantiated function. A class instantiated from a class template is called an instantiated class. A member function, a member class, a member enumeration, or a static data member of a class template instantiated from the member definition of the class template is called, respectively, an instantiated member function, member class, member enumeration, or static data member. A member function instantiated from a member function template is called an instantiated member function. A member class instantiated from a member class template is called an instantiated member class. A variable instantiated from a variable template is called an instantiated variable. A static data member instantiated from a static data member template is called an instantiated static data member.

3 An explicit specialization may be declared for a function template, a variable template, a class template, a member of a class template, or a member template. An explicit specialization declaration is introduced by `template<>`. In an explicit specialization declaration for a variable template, a class template, a member of a class template, or a class member template, the variable or class that is explicitly specialized shall be specified with a `simple-template-id`. In the explicit specialization declaration for a function template or a member function template, the function or member function explicitly specialized may be specified using a `template-id`.

[Example 1]:
```c
template<class T = int> struct A {
    static int x;
};
template<class U> void g(U) { }

template<> struct A<double> { }; // specialize for T == double
template<> struct A<> { };       // specialize for T == int
template<> void g(char) {}      // specialize for U == char
    // U is deduced from the parameter type
template<> void g<int>(int) {}  // specialize for U == int
template<> int A<char>::x = 0;  // specialize for T == char

template<class T = int> struct B {
    static int x;
};
template<> int B<>::x = 1;     // specialize for T == int
```

--- end example]

4 An instantiated template specialization can be either implicitly instantiated (13.9.2) for a given argument list or be explicitly instantiated (13.9.3). A specialization is a class, variable, function, or class member that is
either instantiated (13.9.2) from a templated entity or is an explicit specialization (13.9.4) of a templated entity.

5 For a given template and a given set of template-arguments,

(5.1) — an explicit instantiation definition shall appear at most once in a program,

(5.2) — an explicit specialization shall be defined at most once in a program, as specified in 6.3, and

(5.3) — both an explicit instantiation and a declaration of an explicit specialization shall not appear in a program unless the explicit specialization is reachable from the explicit instantiation.

An implementation is not required to diagnose a violation of this rule if neither declaration is reachable from the other.

6 The usual access checking rules do not apply to names in a declaration of an explicit instantiation or explicit specialization, with the exception of names appearing in a function body, default argument, base-clause, member-specification, enumerator-list, or static data member or variable template initializer.

[Note 1: In particular, the template arguments and names used in the function declarator (including parameter types, return types and exception specifications) can be private types or objects that would normally not be accessible. —end note]

7 Each class template specialization instantiated from a template has its own copy of any static members.

[Example 2:

    template<class T> class X {
        static T s;
    };
    template<class T> T X<T>::s = 0;
    X<int> aa;
    X<char*> bb;
    X<int> has a static member s of type int and X<char*> has a static member s of type char*. — end example]

8 If a function declaration acquired its function type through a dependent type (13.8.3.2) without using the syntactic form of a function declarator, the program is ill-formed.

[Example 3:

    template<class T> struct A {
        static T t;
    };
    typedef int function();
    A<function> a;  // error: would declare A<function>::t as a static member function
    — end example]

13.9.2 Implicit instantiation [temp.inst]

1 A template specialization $E$ is a declared specialization if there is a reachable explicit instantiation definition (13.9.3) or explicit specialization declaration (13.9.4) for $E$, or if there is a reachable explicit instantiation declaration for $E$ and $E$ is not

(1.1) — an inline function,

(1.2) — declared with a type deduced from its initializer or return value (9.2.9.6),

(1.3) — a potentially-constant variable (7.7), or

(1.4) — a specialization of a templated class.

[Note 1: An implicit instantiation in an importing translation unit cannot use names with internal linkage from an imported translation unit (6.6). —end note]

2 Unless a class template specialization is a declared specialization, the class template specialization is implicitly instantiated when the specialization is referenced in a context that requires a completely-defined object type or when the completeness of the class type affects the semantics of the program.

[Note 2: In particular, if the semantics of an expression depend on the member or base class lists of a class template specialization, the class template specialization is implicitly generated. For instance, deleting a pointer to class type depends on whether or not the class declares a destructor, and a conversion between pointers to class type depends on the inheritance relationship between the two classes involved. —end note]

[Example 1:
template<
class T> class B { /* ... */ };  
_template<
class T> class D : public B<T> { /* ... */ }; 

void f(void*);  
void f(B<int>*); 

void g(D<int>* p, D<char>* pp, D<double>* ppp) {
    f(p);  // instantiation of D<int> required: call f(B<int>*)
    B<char>* q = pp;  // instantiation of D<char> required: convert D<char>* to B<char>*
    delete ppp;  // instantiation of D<double> required
}

— end example 

If the template selected for the specialization (13.7.6.2) has been declared, but not defined, at the point of instantiation (13.8.4.1), the instantiation yields an incomplete class type (6.8).

Example 2:

```
template<class T> class X;
X<char> ch;  // error: incomplete type X<char>
```

— end example 

[Note 3: Within a template declaration, a local class (11.6) or enumeration and the members of a local class are never considered to be entities that can be separately instantiated (this includes their default arguments, noexcept-specifiers, and non-static data member initializers, if any, but not their type-constraints or requires-clauses). As a result, the dependent names are looked up, the semantic constraints are checked, and any templates used are instantiated as part of the instantiation of the entity within which the local class or enumeration is declared. — end note]

3 The implicit instantiation of a class template specialization causes

(3.1) — the implicit instantiation of the declarations, but not of the definitions, of the non-deleted class member functions, member classes, scoped member enumerations, static data members, member templates, and friends; and

(3.2) — the implicit instantiation of the definitions of deleted member functions, unscoped member enumerations, and member anonymous unions.

The implicit instantiation of a class template specialization does not cause the implicit instantiation of default arguments or noexcept-specifiers of the class member functions.

Example 3:

```
template<class T>
struct C {
    void f() { T x; }
    void g() = delete;
};
C<void> c;  // OK, definition of C<void>::f is not instantiated at this point

template<> void C<int>::g() { }  // error: redefinition of C<int>::g
```

— end example 

However, for the purpose of determining whether an instantiated redeclaration is valid according to 6.3 and 11.4, a declaration that corresponds to a definition in the template is considered to be a declaration.

Example 4:

```
template<class T, class U>
struct Outer {
    template<class X, class Y> struct Inner;  
    template<class Y> struct Inner<T, Y>;  // #1a
    template<class Y> struct Inner<T, Y> { };  // #1b; OK: valid redeclaration of #1a
    template<class Y> struct Inner<U, Y> { };  // #2
};

Outer<int, int> outer;  // error at #2
```

Outer<int, int>::Inner<int, Y> is redeclared at #1b. (It is not defined but noted as being associated with a definition in Outer<T, U>.) #2 is also a redeclaration of #1a. It is noted as associated with a definition, so it is an invalid redeclaration of the same partial specialization.

§ 13.9.2 404
template<typename T> struct Friendly {
  template<typename U> friend int f(U) { return sizeof(T); }
};

Friendly<char> fc;
Friendly<float> ff;  // error: produces second definition of f(U)

Unless a member of a templated class is a declared specialization, the specialization of the member is implicitly instantiated when the specialization is referenced in a context that requires the member definition to exist or if the existence of the definition of the member affects the semantics of the program; in particular, the initialization (and any associated side effects) of a static data member does not occur unless the static data member is itself used in a way that requires the definition of the static data member to exist.

5 Unless a function template specialization is a declared specialization, the function template specialization is implicitly instantiated when the specialization is referenced in a context that requires a function definition to exist or if the existence of the definition affects the semantics of the program. A function whose declaration was instantiated from a friend function definition is implicitly instantiated when it is referenced in a context that requires a function definition to exist or if the existence of the definition affects the semantics of the program. Unless a call is to a function template explicit specialization or to a member function of an explicitly specialized class template, a default argument for a function template or a member function of a class template is implicitly instantiated when the function is called in a context that requires the value of the default argument.

[Note 4: An inline function that is the subject of an explicit instantiation declaration is not a declared specialization; the intent is that it still be implicitly instantiated when odr-used (6.3) so that the body can be considered for inlining, but that no out-of-line copy of it be generated in the translation unit. — end note]

6 [Example 5:]

    template<class T> struct Z {
    public:
    void f();
    void g();
    private:
    void h() {
        Z<int> a;  // instantiation of class Z<int> required
        Z<char> p;  // instantiation of class Z<char> not required
        Z<double> q;  // instantiation of class Z<double> not required

        a.f();  // instantiation of Z<int>::f() required
        p->g();  // instantiation of class Z<char> required, and
                 // instantiation of Z<char>::g() required
    }
    }

Nothing in this example requires class Z<double>, Z<int>::g(), or Z<char>::f() to be implicitly instantiated. — end example]

7 Unless a variable template specialization is a declared specialization, the variable template specialization is implicitly instantiated when it is referenced in a context that requires a variable definition to exist or if the existence of the definition affects the semantics of the program. A default template argument for a variable template is implicitly instantiated when the variable template is referenced in a context that requires the value of the default argument.

8 The existence of a definition of a variable or function is considered to affect the semantics of the program if the value of the variable or function is needed for constant evaluation by an expression (7.7), even if constant evaluation of the expression is not required or if constant expression evaluation does not use the definition.

[Example 6:]

    template<typename T> constexpr int f() { return T::value; }
    template<bool B, typename T> void g(decltype(B ? f<T>() : 0));
    template<bool B, typename T> void h(decltype(int{B ? f<T>() : 0}));
    void x() {
        g<false, int>(0);  // OK, B ? f<T>() : 0 is not potentially constant evaluated
        h<false, int>(0);  // error, instantiates f<int> even though B evaluates to false and
9 If the function selected by overload resolution (12.2) can be determined without instantiating a class template definition, it is unspecified whether that instantiation actually takes place.

Example 7:

```c++
template <class T> struct S {
    operator int();
};
void f(int);
void f(S<int>&);
void f(S<float>);

void g(S<int>& sr) {
    f(sr);  // instantiation of S<int> allowed but not required
    // instantiation of S<float> allowed but not required
}
```

—end example

10 If a function template or a member function template specialization is used in a way that involves overload resolution, a declaration of the specialization is implicitly instantiated (13.10.4).

11 An implementation shall not implicitly instantiate a function template, a variable template, a member template, a non-virtual member function, a member class or static data member of a templated class, or a substatement of a constexpr if statement (8.5.2), unless such instantiation is required.

Note 5: The instantiation of a generic lambda does not require instantiation of substatements of a constexpr if statement within its compound-statement unless the call operator template is instantiated. —end note

It is unspecified whether or not an implementation implicitly instantiates a virtual member function of a class template if the virtual member function would not otherwise be instantiated. The use of a template specialization in a default argument shall not cause the template to be implicitly instantiated except that a class template may be instantiated where its complete type is needed to determine the correctness of the default argument. The use of a default argument in a function call causes specializations in the default argument to be implicitly instantiated.

12 If a function template \( f \) is called in a way that requires a default argument to be used, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the default argument is done as if the default argument had been an initializer used in a function template specialization with the same scope, the same template parameters and the same access as that of the function template \( f \) used at that point, except that the scope in which a closure type is declared (7.5.5.2) – and therefore its associated namespaces – remain as determined from the context of the definition for the default argument. This analysis is called default argument instantiation. The instantiated default argument is then used as the argument of \( f \).

13 Each default argument is instantiated independently.

Example 8:

```c++
template<class T> void f(T x, T y = ydef(T()), T z = zdef(T()));

class A { }
A zdef(A);

void g(A a, A b, A c) {
    f(a, b, c);  // no default argument instantiation
    f(a, b);    // default argument \( z = zdef(T()) \) instantiated
    f(a);      // error: \( ydef \) is not declared
}
```

—end example

14 The noexcept-specifier of a function template specialization is not instantiated along with the function declaration; it is instantiated when needed (14.5). If such an noexcept-specifier is needed but has not yet been
instantiated, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the noexcept-specifier is done as if it were being done as part of instantiating the declaration of the specialization at that point.

[Note 6: 13.8.4.1 defines the point of instantiation of a template specialization. — end note]

There is an implementation-defined quantity that specifies the limit on the total depth of recursive instantiations (Annex B), which could involve more than one template. The result of an infinite recursion in instantiation is undefined.

[Example 9:]
```c++
template<class T> class X {
    X<T>* p; // OK
    X<T*> a; // implicit generation of X<T> requires
              // the implicit instantiation of X<T*> which requires
              // the implicit instantiation of X<T**> which ...
};
```
—end example

15 The type-constraints and requires-clause of a template specialization or member function are not instantiated along with the specialization or function itself, even for a member function of a local class; substitution into the atomic constraints formed from them is instead performed as specified in 13.5.3 and 13.5.2.3 when determining whether the constraints are satisfied or as specified in 13.5.3 when comparing declarations.

[Note 7: The satisfaction of constraints is determined during template argument deduction (13.10.3) and overload resolution (12.2). — end note]

[Example 10:]
```c++
template<typename T> concept C = sizeof(T) > 2;
template<typename T> concept D = C<T> && sizeof(T) > 4;
template<typename T> struct S {
    S() requires C<T> { } // #1
    S() requires D<T> { } // #2
};
S<char> s1; // error: no matching constructor
S<char[8]> s2; // OK, calls #2
```

16 When S<char> is instantiated, both constructors are part of the specialization. Their constraints are not satisfied, and they suppress the implicit declaration of a default constructor for S<char> (11.4.5.2), so there is no viable constructor for s1. —end example

[Example 11:]
```c++
template<typename T> struct S1 {
    template<typename U>
    requires false
    struct Inner1; // ill-formed, no diagnostic required
};
template<typename T> struct S2 {
    template<typename U>
    requires (sizeof(T[-(int)sizeof(T)]) > 1)
    struct Inner2; // ill-formed, no diagnostic required
};
```

17 The class S1<T>::Inner1 is ill-formed, no diagnostic required, because it has no valid specializations. S2 is ill-formed, no diagnostic required, since no substitution into the constraints of its Inner2 template would result in a valid expression. —end example

13.9.3 Explicit instantiation

A class, function, variable, or member template specialization can be explicitly instantiated from its template. A member function, member class or static data member of a class template can be explicitly instantiated from the member definition associated with its class template.

The syntax for explicit instantiation is:
explicit-instantiation:
  externempl, template declaration

There are two forms of explicit instantiation: an explicit instantiation definition and an explicit instantiation declaration. An explicit instantiation declaration begins with the `extern` keyword.

3 An explicit instantiation shall not use a storage-class-specifier (9.2.2) other than `thread_local`. An explicit instantiation of a function template, member function of a class template, or variable template shall not use the `inline, constexpr, or consteval` specifiers. No attribute-specifier-seq (9.12.1) shall appertain to an explicit instantiation.

4 If the explicit instantiation is for a class or member class, the elaborated-type-specifier in the declaration shall include a simple-template-id; otherwise, the declaration shall be a simple-declaration whose init-declarator-list comprises a single init-declarator that does not have an initializer. If the explicit instantiation is for a variable template specialization, the unqualified-id in the declarator shall be a simple-template-id.

[Example 1:
  template<class T> class Array { void mf(); };  
  template class Array<char>;  
  template void Array<int>::mf();

  template<class T> void sort(Array<T>& v) { /* ... */ }  
  template void sort(Array<char>&);  // argument is deduced here

  namespace N {
    template<class T> void f(T&);  
  }  
  template void N::f<int>(int&);
—end example]

5 An explicit instantiation does not introduce a name (6.4.1). A declaration of a function template, a variable template, a member function or static data member of a class template, or a member function template of a class or class template shall be reachable from any explicit instantiation of that entity. A definition of a class template, a member class of a class template, or a member class template of a class or class template shall be reachable from any explicit instantiation of that entity unless an explicit specialization of the entity with the same template arguments is reachable therefrom. If the declaration of the explicit instantiation names an implicitly-declared special member function (11.4.4), the program is ill-formed.

6 The declaration in an explicit-instantiation and the declaration produced by the corresponding substitution into the templated function, variable, or class are two declarations of the same entity.

[Note 1: These declarations are required to have matching types as specified in 6.6, except as specified in 14.5.

[Example 2:
  template<typename T> T var = {};  
  template float var<float>;  // OK, instantiated variable has type float  
  template int var<int[16]>>[];  // OK, absence of major array bound is permitted  
  template int *var<int>;  // error: instantiated variable has type int

  template<typename T> auto av = T();  
  template int av<int>;  // OK, variable with type int can be redeclared with type auto

  template<typename T> auto f() {}  
  template void f<int>();  // error: function with deduced return type  
  // redeclared with non-deduced return type (9.2.9.6)
—end example
—end note]

Despite its syntactic form, the declaration in an explicit-instantiation for a variable is not itself a definition and does not conflict with the definition instantiated by an explicit instantiation definition for that variable.

7 For a given set of template arguments, if an explicit instantiation of a template appears after a declaration of an explicit specialization for that template, the explicit instantiation has no effect. Otherwise, for an explicit instantiation definition, the definition of a function template, a variable template, a member function template, or a member function or static data member of a class template shall be present in every translation unit in which it is explicitly instantiated.
A trailing template-argument can be left unspecified in an explicit instantiation of a function template specialization or of a member function template specialization provided it can be deduced (13.10.3.7). If all template arguments can be deduced, the empty template argument list <> may be omitted.

Example 3:
```cpp
template<class T> class Array { /* ... */ };  
template<class T> void sort(Array<T>& v) { /* ... */ }

// instantiate sort<Array<int>&) — template-argument deduced  
template void sort<Array<int>&);
```

— end example]

Note 2: An explicit instantiation of a constrained template is required to satisfy that template’s associated constraints (13.5.3). The satisfaction of constraints is determined when forming the template name of an explicit instantiation in which all template arguments are specified (13.3), or, for explicit instantiations of function templates, during template argument deduction (13.10.3.7) when one or more trailing template arguments are left unspecified.
— end note

An explicit instantiation that names a class template specialization is also an explicit instantiation of the same kind (declaration or definition) of each of its direct non-template members that has not been previously explicitly specialized in the translation unit containing the explicit instantiation, provided that the associated constraints, if any, of that member are satisfied by the template arguments of the explicit instantiation (13.5.3, 13.5.2), except as described below.

Note 3: In addition, it will typically be an explicit instantiation of certain implementation-dependent data about the class. — end note

An explicit instantiation definition that names a class template specialization explicitly instantiates the class template specialization and is an explicit instantiation definition of only those members that have been defined at the point of instantiation.

An explicit instantiation of a prospective destructor (11.4.7) shall correspond to the selected destructor of the class.

If an entity is the subject of both an explicit instantiation declaration and an explicit instantiation definition in the same translation unit, the definition shall follow the declaration. An entity that is the subject of an explicit instantiation declaration and that is also used in a way that would otherwise cause an implicit instantiation (13.9.2) in the translation unit shall be the subject of an explicit instantiation definition somewhere in the program; otherwise the program is ill-formed, no diagnostic required.

Note 4: This rule does apply to inline functions even though an explicit instantiation declaration of such an entity has no other normative effect. This is needed to ensure that if the address of an inline function is taken in a translation unit in which the implementation chose to suppress the out-of-line body, another translation unit will supply the body. — end note

An explicit instantiation declaration shall not name a specialization of a template with internal linkage.

An explicit instantiation does not constitute a use of a default argument, so default argument instantiation is not done.

Example 4:
```cpp
char* p = 0;

template<class T> T g(T x = &p) { return x; }
template int g<int>(int);

// OK even though &p isn’t an int.
```

13.9.4 Explicit specialization [temp.expl.spec]

An explicit specialization of any of the following:

(1.1) function template
(1.2) class template
(1.3) variable template
(1.4) member function of a class template
(1.5) static data member of a class template
(1.6) member class of a class template

§ 13.9.4
--- member enumeration of a class template
--- member class template of a class or class template
--- member function template of a class or class template
can be declared by a declaration introduced by template<>; that is:

```c++
template<>
```

**Example 1:**

```c++
template<class T> class stream;
template<> class stream<char> { /* ... */ };  
template<class T> class Array { /* ... */};
template<class T> void sort(Array<T>& v) { /* ... */ }
template<> void sort<char*>(Array<char*>&);
```

Given these declarations, `stream<char>` will be used as the definition of streams of `char`; other streams will be handled by class template specializations instantiated from the class template. Similarly, `sort<char*>` will be used as the sort function for arguments of type `Array<char*>`; other `Array` types will be sorted by functions generated from the template.  

--- end example

2 An explicit specialization shall not use a storage-class-specifier (9.2.2) other than `thread_local`.

3 An explicit specialization may be declared in any scope in which the corresponding primary template may be defined (9.3.4, 11.4, 13.7.3).

4 An explicit specialization does not introduce a name (6.4.1). A declaration of a function template, class template, or variable template being explicitly specialized shall be reachable from the declaration of the explicit specialization.

**Note 1:** A declaration, but not a definition of the template is required.  
--- end note

The definition of a class or class template shall be reachable from the declaration of an explicit specialization for a member template of the class or class template.

**Example 2:**

```c++
template<> class X<int> { /* ... */ };  // error: X not a template  
template<class T> class X;
template<> class X<char*> { /* ... */ };  // OK: X is a template  
--- end example
```

5 A member function, a member function template, a member class, a member enumeration, a member class template, a static data member, or a static data member template of a class template may be explicitly specialized for a class specialization that is implicitly instantiated; in this case, the definition of the class template shall be reachable from the explicit specialization for the member of the class template. If such an explicit specialization for the member of a class template names an implicitly-declared special member function (11.4.4), the program is ill-formed.

6 A member of an explicitly specialized class is not implicitly instantiated from the member declaration of the class template; instead, the member of the class template specialization shall itself be explicitly defined if its definition is required. The definition of the class template explicit specialization shall be reachable from the definition of any member of it. The definition of an explicitly specialized class is unrelated to the definition of a generated specialization. That is, its members need not have the same names, types, etc. as the members of a generated specialization. Members of an explicitly specialized class template are defined in the same manner as members of normal classes, and not using the template<> syntax. The same is true when defining a member of an explicitly specialized member class. However, template<> is used in defining a member of an explicitly specialized member class template that is specialized as a class template.

**Example 3:**

```c++
template<class T> struct A {
    struct B {  };  
```
template<class U> struct C { };

template<> struct A<int> {
    void f(int);
};

void h() {
    A<int> a;
    a.f(16);     // A<int>::f must be defined somewhere
}

// template<> not used for a member of an explicitly specialized class template
void A<int>::f(int) { /* ... */ }

template<> struct A<char>::B {
};
// template<> also not used when defining a member of an explicitly specialized member class
void A<char>::B::f() { /* ... */ }

template<> template<class U> struct A<char>::C {
};
// template<> is used when defining a member of an explicitly specialized member class
// specialized as a class template
template<> template<class U> void A<char>::C<U>::f() { /* ... */ }

// template<> not permitted
template<> void sort<String>(Array<String>& v); // error: specialization after use of primary template

template<> void sort<>(Array<char*>& v); // OK: sort<char*> not yet used

template<class T> struct A {
    enum E : T;
    enum class S : T;
};

template<> struct A<int>::E : int { eint }; // OK
template<> enum class A<int>::S : int { sint };  // OK
template<class T> enum A<T>::E : T { eT };
template<class T> enum class A<T>::S : T { sT };  
template<> enum class A<char>::S : char { schar };  // OK

// error: A<char>::E was instantiated when A<char> was instantiated

—end example

The placement of explicit specialization declarations for function templates, class templates, variable templates, member functions of class templates, static data members of class templates, member classes of class templates, member enumerations of class templates, member class templates of class templates, member function templates of class templates, static data member templates of class templates, member functions of member templates of non-template classes, static data member templates of non-template classes, member function templates of member classes of class templates, etc., and the placement of partial specialization declarations of class templates, variable templates, member class templates of non-template classes, static data member templates of non-template classes, member class templates of class templates, etc., can affect whether a program is well-formed according to the relative positioning of the explicit specialization declarations and their points of instantiation in the translation unit as specified above and below. When writing a specialization, be careful about its location; or to make it compile will be such a trial as to kindle its self-immolation.

A simple-template-id that names a class template explicit specialization that has been declared but not defined can be used exactly like the names of other incompletely-defined classes (6.8).

[Example 5:

```cpp
template<class T> class X;  // X is a class template
template<> class X<int>;
X<int>* p;  // OK: pointer to declared class X<int>
X<int> x;  // error: object of incomplete class X<int>
—end example]
```

A trailing template-argument can be left unspecified in the template-id naming an explicit function template specialization provided it can be deduced (13.10.3.7).

[Example 6:

```cpp
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v);
// explicit specialization for sort(Array<int>&)
// with deduced template-argument of type int
template<> void sort(Array<int>&);
—end example]
```

[Note 2: An explicit specialization of a constrained template is required to satisfy that template’s associated constraints (13.5.3). The satisfaction of constraints is determined when forming the template name of an explicit specialization in which all template arguments are specified (13.3), or, for explicit specializations of function templates, during template argument deduction (13.10.3.7) when one or more trailing template arguments are left unspecified. —end note]

A function with the same name as a template and a type that exactly matches that of a template specialization is not an explicit specialization (13.7.7).

Whether an explicit specialization of a function or variable template is inline, constexpr, or an immediate function is determined by the explicit specialization and is independent of those properties of the template.

[Example 7:

```cpp
template<class T> void f(T) { /* ... */ }
template<class T> inline T g(T) { /* ... */ }

template<> inline void f<>(int) { /* ... */ }  // OK: inline
template<> int g<>(int) { /* ... */ }  // OK: not inline
—end example]

§ 13.9.4 412
An explicit specialization of a static data member of a template or an explicit specialization of a static data member template is a definition if the declaration includes an initializer; otherwise, it is a declaration.

[Note 3: The definition of a static data member of a template for which default-initialization is desired can use functional cast notation (7.6.1.4):]

```cpp
template<> X Q<int>::x; // declaration
template<> X Q<int>::x(); // error: declares a function
template<> X Q<int>::x = X(); // definition
—end note]
```

A member or a member template of a class template may be explicitly specialized for a given implicit instantiation of the class template, even if the member or member template is defined in the class template definition. An explicit specialization of a member or member template is specified using the syntax for explicit specialization.

[Example 8:]

```cpp
template<class T> struct A {
    void f(T);
    template<class X1> void g1(T, X1);
    template<class X2> void g2(T, X2);
    void h(T) { }
};
// specialization
template<> void A<int>::f(int);
// out of class member template definition
template<class T> template<class X1> void A<T>::g1(T, X1) { }
// member template specialization
template<> template<class X1> void A<int>::g1(int, X1);
// member template specialization
template<> template<> class A<int>::B<double>;
template<> template<> void A<char>::B<char>::mf();
—end example]
```

A member or a member template may be nested within many enclosing class templates. In an explicit specialization for such a member, the member declaration shall be preceded by a `template<>` for each enclosing class template that is explicitly specialized.

[Example 9:]

```cpp
template<class T1> class A {
    template<class T2> class B {
        void mf();
    };
    template<> template<> class A<int>::B<double>;
    template<> template<> void A<char>::B<char>::mf();
—end example]
```

In an explicit specialization declaration for a member of a class template or a member template that appears in namespace scope, the member template and some of its enclosing class templates may remain unspecialized, except that the declaration shall not explicitly specialize a class member template if its enclosing class templates are not explicitly specialized as well. In such an explicit specialization declaration, the keyword `template` followed by a `template-parameter-list` shall be provided instead of the `template<>` preceding the explicit specialization declaration of the member. The types of the `template-parameters` in the `template-parameter-list` shall be the same as those specified in the primary template definition.
Example 10:

```cpp
template <class T1> class A {
    template<class T2> class B {
        template<class T3> void mf1(T3);
        void mf2();
    };
    template <> template <class X>
    class A<int>::B {
        template <class T> void mf1(T);
    };
    template <> template <> template<class T>
    void A<int>::B<double>::mf1(T t) { }
    template <class Y> template <>
    void A<Y>::B<double>::mf2() { } // error: B<double> is specialized but
    // its enclosing class template A is not
};
```

—end example

18 A specialization of a member function template, member class template, or static data member template of a
non-specialized class template is itself a template.

19 An explicit specialization declaration shall not be a friend declaration.

20 Default function arguments shall not be specified in a declaration or a definition for one of the following
explicit specializations:

(20.1) — the explicit specialization of a function template;

(20.2) — the explicit specialization of a member function template;

(20.3) — the explicit specialization of a member function of a class template where the class template specialization
to which the member function specialization belongs is implicitly instantiated.

[Note 4: Default function arguments can be specified in the declaration or definition of a member function of a
class template specialization that is explicitly specialized. — end note]

### 13.10 Function template specializations

#### 13.10.1 General

A function instantiated from a function template is called a function template specialization; so is an explicit
specialization of a function template. Template arguments can be explicitly specified when naming the
function template specialization, deduced from the context (e.g., deduced from the function arguments in a
call to the function template specialization, see 13.10.3), or obtained from default template arguments.

2 Each function template specialization instantiated from a template has its own copy of any static variable.

Example 1:

```cpp
template<class T> void f(T* p) {
    static T s;
};

void g(int a, char* b) {
    f(&a); // calls f<int>(int*)
    f(&b); // calls f<char*>(char**)
}
```

Here `f<int>(int*)` has a static variable `s` of type `int` and `f<char*>(char**)` has a static variable `s` of type `char*`.

—end example

#### 13.10.2 Explicit template argument specification

Template arguments can be specified when referring to a function template specialization that is not a
specialization of a constructor template by qualifying the function template name with the list of `template-arguments`
in the same way as `template-arguments` are specified in uses of a class template specialization.

Example 1:

```cpp
template<class T> void sort(Array<T>& v);
```
void f(Array<dcomplex>& cv, Array<int>& ci) {
    sort<dcomplex>(cv);  // sort(Array<dcomplex>&)
    sort<int>(ci);        // sort(Array<int>&)
}

and

template<class U, class V> U convert(V v);

void g(double d) {
    int i = convert<int,double>(d);  // int convert(double)
    char c = convert<char,double>(d); // char convert(double)
}

— end example |

2 Template arguments shall not be specified when referring to a specialization of a constructor template (11.4.5, 6.5.5.2).

3 A template argument list may be specified when referring to a specialization of a function template

- when a function is called,
- when the address of a function is taken, when a function initializes a reference to function, or when a pointer to member function is formed,
- in an explicit specialization,
- in an explicit instantiation, or
- in a friend declaration.

4 Trailing template arguments that can be deduced (13.10.3) or obtained from default template-arguments may be omitted from the list of explicit template-arguments.

[Note 1: A trailing template parameter pack (13.7.4) not otherwise deduced will be deduced as an empty sequence of template arguments. — end note]

If all of the template arguments can be deduced, they may all be omitted; in this case, the empty template argument list <> itself may also be omitted.

[Example 2:

template<class X, class Y> X f(Y);

template<class X, class Y, class ... Z> X g(Y);

void h() {
    int i = f<int>(5.6);   // Y deduced as double
    int j = f(5.6);        // error: X cannot be deduced
    f<void>(f<int, bool>); // Y for outer f deduced as int (*)(bool)
    f<void>(f<int>);       // error: f<int> does not denote a single function template specialization
    int k = g<int>(5.6);   // Y deduced as double; Z deduced as an empty sequence
    f<void>(g<int, bool>); // Y for outer f deduced as int (*)(bool),
                          // Z deduced as an empty sequence
}
— end example |

5 [Note 2: An empty template argument list can be used to indicate that a given use refers to a specialization of a function template even when a non-template function (9.3.4.6) is visible that would otherwise be used. For example:

template <class T> int f(T);     // #1
int f(int);                       // #2
int k = f(1);                     // uses #2
int l = f<>(1);                   // uses #1
— end note]

6 Template arguments that are present shall be specified in the declaration order of their corresponding template-parameters. The template argument list shall not specify more template-arguments than there are corresponding template-parameters unless one of the template-parameters is a template parameter pack.

[Example 3:

template<class X, class Y, class Z> X f(Y,Z);

template<class ... Args> void f2();
void g() {
    f<int, const char*, double>("aa", 3.0);
    f<int, const char*>("aa", 3.0); // Z deduced as double
    f<"aa", 3.0>; // Y deduced as const char*: Z deduced as double
    f("aa", 3.0); // error: X cannot be deduced
    f2<char, short, int, long>(); // OK
}  
—end example

Implicit conversions (7.3) will be performed on a function argument to convert it to the type of the corresponding function parameter if the parameter type contains no template-parameters that participate in template argument deduction.

[Note 3: Template parameters do not participate in template argument deduction if they are explicitly specified. For example,

```cpp
template<class T> void f(T);
```

class Complex {
    Complex(double);
};

void g() {
    f<Complex>(1);  // OK, means f<Complex>(Complex(1))
}
—end note]

Template argument deduction can extend the sequence of template arguments corresponding to a template parameter pack, even when the sequence contains explicitly specified template arguments.

[Example 4:

```cpp
template<class ... Types> void f(Types ... values);
```

```cpp
void g() {
    f<int*, float*>(0, 0, 0); // Types deduced as the sequence int*, float*, int
}
—end example]

13.10.3 Template argument deduction

13.10.3.1 General

When a function template specialization is referenced, all of the template arguments shall have values. The values can be explicitly specified or, in some cases, be deduced from the use or obtained from default template-arguments.

[Example 1:

```cpp
void f(Array<dcomplex>& cv, Array<int>& ci) {
    sort(cv); // calls sort(Array<dcomplex>&)
    sort(ci); // calls sort(Array<int>&)
}
```

and

```cpp
void g(double d) {
    int i = convert<int>(d); // calls convert<int, double>(double)
    int c = convert<char>(d); // calls convert<char, double>(double)
}
—end example]

2 When an explicit template argument list is specified, if the given template-id is not valid (13.3), type deduction fails. Otherwise, the specified template argument values are substituted for the corresponding template parameters as specified below.
After this substitution is performed, the function parameter type adjustments described in 9.3.4.6 are performed.

[Example 2: A parameter type of “void (const int, int[5])” becomes “void(*)(int, int*)”. — end example]

[Note 1: A top-level qualifier in a function parameter declaration does not affect the function type but still affects the type of the function parameter variable within the function. — end note]

[Example 3:

```cpp
template <class T> void f(T t);
template <class X> void g(const X x);
template <class Z> void h(Z, Z*);

int main() {
    // #1: function type is f(int), t is non const
    f<int>(1);

    // #2: function type is f(int), t is const
    f<const int>(1);

    // #3: function type is g(int), x is const
    g<int>(1);

    // #4: function type is g(int), x is const
    g<const int>(1);

    // #5: function type is h(int, const int*)
    h<const int>(1,0);
}
```
— end example]

[Note 2: f<int>(1) and f<const int>(1) call distinct functions even though both of the functions called have the same function type. — end note]

The resulting substituted and adjusted function type is used as the type of the function template for template argument deduction. If a template argument has not been deduced and its corresponding template parameter has a default argument, the template argument is determined by substituting the template arguments determined for preceding template parameters into the default argument. If the substitution results in an invalid type, as described above, type deduction fails.

[Example 4:

```cpp
template <class T, class U = double>
void f(T t = 0, U u = 0);

void g() {
    f(1, 'c'); // f<int,char>(1,'c')
    f(1);     // f<int,double>(1,0)
    f();      // error: T cannot be deduced
    f<int>(); // f<int,double>(0,0)
    f<int,char>(); // f<int,char>(0,0)
}
```
— end example]

When all template arguments have been deduced or obtained from default template arguments, all uses of template parameters in the template parameter list of the template are replaced with the corresponding deduced or default argument values. If the substitution results in an invalid type, as described above, type deduction fails. If the function template has associated constraints (13.5.3), those constraints are checked for satisfaction (13.5.2). If the constraints are not satisfied, type deduction fails. In the context of a function call, if type deduction has not yet failed, then for those function parameters for which the function call has arguments, each function parameter with a type that was non-dependent before substitution of any explicitly-specified template arguments is checked against its corresponding argument; if the corresponding argument cannot be implicitly converted to the parameter type, type deduction fails.

[Note 3: Overload resolution will check the other parameters, including parameters with dependent types in which no template parameters participate in template argument deduction and parameters that became non-dependent due to substitution of explicitly-specified template arguments. — end note]
If type deduction has not yet failed, then all uses of template parameters in the function type are replaced with the corresponding deduced or default argument values. If the substitution results in an invalid type, as described above, type deduction fails.

[Example 5:

template <class T> struct Z {
    typedef typename T::x xx;
};
template <class T> concept C = requires { typename T::A; };
template <C T> typename Z<T>::xx f(void *, T); // #1
template <class T> void f(int, T); // #2
struct A {} a;
struct ZZ {
    template <class T, class = typename Z<T>::xx> operator T *();
    operator int();
};

int main() {
    ZZ zz;
f(1, a); // OK, deduction fails for #1 because there is no conversion from int to void *
f(zz, 42); // OK, deduction fails for #1 because C<int> is not satisfied
}
—end example]

At certain points in the template argument deduction process it is necessary to take a function type that makes use of template parameters and replace those template parameters with the corresponding template arguments. This is done at the beginning of template argument deduction when any explicitly specified template arguments are substituted into the function type, and again at the end of template argument deduction when any template arguments that were deduced or obtained from default arguments are substituted.

The substitution occurs in all types and expressions that are used in the function type and in template parameter declarations. The expressions include not only constant expressions such as those that appear in array bounds or as nontype template arguments but also general expressions (i.e., non-constant expressions) inside sizeof, decltype, and other contexts that allow non-constant expressions. The substitution proceeds in lexical order and stops when a condition that causes deduction to fail is encountered. If substitution into different declarations of the same function template would cause template instantiations to occur in a different order or not at all, the program is ill-formed; no diagnostic required.

[Note 4: The equivalent substitution in exception specifications is done only when the noexcept-specifier is instantiated, at which point a program is ill-formed if the substitution results in an invalid type or expression. — end note]

[Example 6:

template <class T> struct A { using X = typename T::X; };  
template <class T> typename T::X f(typename A<T>::X);
template <class T> void f(...){ }  
template <class T> auto g(typename A<T>::X) -> typename T::X;  
template <class T> void g(...){ }  
template <class T> typename T::X h(typename A<T>::X);  
template <class T> auto h(typename A<T>::X) -> typename T::X; // redeclaration  
template <class T> void h(...){ }  

void x() {
    f<int>(0); // OK, substituting return type causes deduction to fail
    g<int>(0); // error, substituting parameter type instantiates A<int>
    h<int>(0); // ill-formed, no diagnostic required
}
—end example]

If a substitution results in an invalid type or expression, type deduction fails. An invalid type or expression is one that would be ill-formed, with a diagnostic required, if written using the substituted arguments.

[Note 5: If no diagnostic is required, the program is still ill-formed. Access checking is done as part of the substitution process. — end note]
Only invalid types and expressions in the immediate context of the function type, its template parameter types, and its \texttt{explicit-specifier} can result in a deduction failure.

\textit{[Note 6: The substitution into types and expressions can result in effects such as the instantiation of class template specializations and/or function template specializations, the generation of implicitly-defined functions, etc. Such effects are not in the “immediate context” and can result in the program being ill-formed. — end note]}

A \texttt{lambda-expression} appearing in a function type or a template parameter is not considered part of the immediate context for the purposes of template argument deduction.

\textit{[Note 7: The intent is to avoid requiring implementations to deal with substitution failure involving arbitrary statements.}

\textit{[Example 7]}

\begin{verbatim}
template <class T>
    auto f(T) -> decltype([]() { T::invalid; }());
void f(...);
f(0);    // error: invalid expression not part of the immediate context

template <class T, std::size_t = sizeof([]() { T::invalid; })>
    void g(T);
void g(...);
g(0);    // error: invalid expression not part of the immediate context

template <class T>
    auto h(T) -> decltype([]() -> typename T::invalid { });
void h(...);
h(0);    // error: invalid expression not part of the immediate context

template <class T>
    auto i(T) -> decltype([]() { });
void i(...);
i(0);    // error: invalid expression not part of the immediate context

template <class T>
    auto j(T t) -> decltype([](auto x) -> decltype(x.invalid) { } (t));
void j(...);
j(0);    // deduction fails on #1, calls #2
— end example]

— end note]

\textit{[Example 8]}

\begin{verbatim}
struct X { }; struct Y { Y(X) {} };

template <class T> auto f(T t1, T t2) -> decltype(t1 + t2);
// #1
X f(Y, Y);
// #2
X x1, x2;
X x3 = f(x1, x2); // deduction fails on #1 (cannot add X+X), calls #2
— end example]

— end note]

\textit{[Note 8: Type deduction can fail for the following reasons:}

(11.1) — Attempting to instantiate a pack expansion containing multiple packs of differing lengths.

(11.2) — Attempting to create an array with an element type that is \texttt{void}, a function type, or a reference type, or attempting to create an array with a size that is zero or negative.

\textit{[Example 9]}

\begin{verbatim}
template <class T> int f(T[5]);
int I = f<int>(0);
int j = f<void>(0); // invalid array
— end example]
\end{verbatim}
— Attempting to use a type that is not a class or enumeration type in a qualified name.

[Example 10]:
```cpp
template <class T> int f(typename T::B*);
int i = f<int>(0);
— end example
```

— Attempting to use a type in a nested-name-specifier of a qualified-id when that type does not contain the specified member, or

(11.4.1) — the specified member is not a type where a type is required, or
(11.4.2) — the specified member is not a template where a template is required, or
(11.4.3) — the specified member is not a non-type where a non-type is required.

[Example 11]:
```cpp
template <int I> struct X { };
template <template <class T> class> struct Z { };
template <class T> void f(typename T::Y*) {}
template <class T> void g(X<T::N>*) {}
struct A {};
struct B { int Y; }
struct C {
  typedef int N;
};
struct D {
  typedef int TT;
};

int main() {
  // Deduction fails in each of these cases:
  f<A>(0);  // A does not contain a member Y
  f<B>(0);  // The Y member of B is not a type
  g<C>(0);  // The N member of C is not a non-type
  h<D>(0);  // The TT member of D is not a template
}
— end example
```

— Attempting to create a pointer to reference type.

— Attempting to create a reference to void.

— Attempting to create “pointer to member of T” when T is not a class type.

[Example 12]:
```cpp
template <class T> int f(int T::*);
int i = f<int>(0);
— end example
```

— Attempting to give an invalid type to a non-type template parameter.

[Example 13]:
```cpp
template <class T, T*> struct S {};
template <class T> int f(S<T, T()>*);
struct X {};
int i0 = f<X>(0);
— end example
```

— Attempting to perform an invalid conversion in either a template argument expression, or an expression used in the function declaration.

[Example 14]:
```cpp
template <class T, T*> int f(int);
int i2 = f<int, 1>(0);  // can’t conv 1 to int*
— end example
```
— Attempting to create a function type in which a parameter has a type of `void`, or in which the return type is a function type or array type.

— end note]

[Example 15: In the following example, assuming a `signed char` cannot represent the value 1000, a narrowing conversion (9.4.5) would be required to convert the template-argument of type `int` to `signed char`, therefore substitution fails for the second template (13.4.3).

```cpp
template <int> int f(int);
template <signed char> int f(int);
int i1 = f<1000>(0); // OK
int i2 = f<1>(0); // ambiguous; not narrowing
```

— end example]

13.10.3.2 Deducing template arguments from a function call [temp.deduct.call] 1

Template argument deduction is done by comparing each function template parameter type (call it $P$) that contains template-parameters that participate in template argument deduction with the type of the corresponding argument of the call (call it $A$) as described below. If removing references and cv-qualifiers from $P$ gives $\text{std::initializer_list}<P'>$ or $P'[N]$ for some $P'$ and $N$ and the argument is a non-empty initializer list (9.4.5), then deduction is performed instead for each element of the initializer list independently, taking $P'$ as separate function template parameter types $P'_i$ and the $i$th initializer element as the corresponding argument. In the $P'[N]$ case, if $N$ is a non-type template parameter, $N$ is deduced from the length of the initializer list. Otherwise, an initializer list argument causes the parameter to be considered a non-deduced context (13.10.3.6).

[Example 1:

```cpp
template<class T> void f(std::initializer_list<T>);
f({1,2,3}); // $T$ deduced as `int`
f({1,"asdf"}); // error: $T$ deduced as both `int` and `const char*`

template<class T> void g(T);
g({1,2,3}); // error: no argument deduced for $T$

template<class T, int N> void h(T const(&)[N]);
h({1,2,3}); // $T$ deduced as `int`; $N$ deduced as 3

template<class T> void j(T const(&)[3]);
j({42}); // $T$ deduced as `int`; array bound not considered

struct Aggr { int i; int j; };  
template<int N> void k(Aggr const(&)[N]);
k({1,2,3}); // error: deduction fails, no conversion from `int` to `Aggr`
k({{1},{2},{3}}); // OK, $N$ deduced as 3

template<int M, int N> void m(int const(&)[M][N]);
m({{1,2},{3,4}}); // $M$ and $N$ both deduced as 2

template<class T, int N> void n(T const(&)[N], T);
n({{1,2},{3,4}},Aggr()); // $OK$, $T$ is `Aggr`, $N$ is 3

template<typename T, int N> void o(T (* const (&)[N])(T)) { }  
int f1(int);
int f4(int);
char f4(char);
o(&f1, &f4); // OK, $T$ deduced as `int` from first element, nothing
// deduced from second element, $N$ deduced as 2
o(&f1, static_cast<char*>(char>)(&f4)); // error: conflicting deductions for $T$
```

— end example]

For a function parameter pack that occurs at the end of the parameter-declaration-list, deduction is performed for each remaining argument of the call, taking the type $P$ of the declarator-id of the function parameter pack as the corresponding function template parameter type. Each deduction deduces template arguments for
subsequent positions in the template parameter packs expanded by the function parameter pack. When a function parameter pack appears in a non-deduced context (13.10.3.6), the type of that pack is never deduced.

[Example 2:
```cpp
template<class ... Types> void f(Types& ...);
template<class T1, class ... Types> void g(T1, Types ...);
template<class T1, class ... Types> void g1(Types ..., T1);
void h(int x, float& y) {
    const int z = x;
    f(x, y, z);               // Types deduced as int, float, const int
    g(x, y, z);               // T1 deduced as int; Types deduced as float, int
    g1(x, y, z);              // error: Types is not deduced
    g1<int, int, int>(x, y, z);        // OK, no deduction occurs
}
```
—end example
]

2 If P is not a reference type:

(2.1) — If A is an array type, the pointer type produced by the array-to-pointer standard conversion (7.3.3) is used in place of A for type deduction; otherwise,

(2.2) — If A is a function type, the pointer type produced by the function-to-pointer standard conversion (7.3.4) is used in place of A for type deduction; otherwise,

(2.3) — If A is a cv-qualified type, the top-level cv-qualifiers of A’s type are ignored for type deduction.

3 If P is a cv-qualified type, the top-level cv-qualifiers of P’s type are ignored for type deduction. If P is a reference type, the type referred to by P is used for type deduction.

[Example 3:
```cpp
template<class T> int f(const T&);
int n1 = f(5);                   // calls f<int>(const int&)
const int i = 0;
int n2 = f(i);                   // calls f<int>(const int&)
template <class T> int g(volatile T&);
int n3 = g(i);                   // calls g<const int>(const volatile int&)
```
—end example
]

A forwarding reference is an rvalue reference to a cv-unqualified template parameter that does not represent a template parameter of a class template (during class template argument deduction (12.2.2.9)). If P is a forwarding reference and the argument is an lvalue, the type “lvalue reference to A” is used in place of A for type deduction.

[Example 4:
```cpp
template <class T> int f(T&& heisenreference);
template <class T> int g(const T&&);
int i;
int n1 = f(i);                   // calls f<int&>(int&)                        // #1: T&& is not a forwarding reference.
int n2 = f(0);                   // calls f<int&>(int&)                        // #2: U&& is a forwarding reference.
int n3 = g(i);                   // error: would call g<int&(const int&&), which
// would bind an rvalue reference to an lvalue

template <class T> struct A {
    template <class U>
    A(T&&, U&&, int*);  // #1: T&& is not a forwarding reference.
        // U&& is a forwarding reference.
    A(T&&, int*);       // #2
};
template <class T> A(T&&, int*) -> A<T>;            // #3: T&& is a forwarding reference.

int *ip;
A a{i, 0, ip};        // error: cannot deduce from #1
A a0{i, 0, ip};       // uses #1 to deduce A<int> and #1 to initialize
A a2{i, ip};          // uses #3 to deduce A<int&> and #2 to initialize
```
In general, the deduction process attempts to find template argument values that will make the deduced \( A \) identical to \( A \) (after the type \( A \) is transformed as described above). However, there are three cases that allow a difference:

1. If the original \( P \) is a reference type, the deduced \( A \) (i.e., the type referred to by the reference) can be more cv-qualified than the transformed \( A \).

2. The transformed \( A \) can be another pointer or pointer-to-member type that can be converted to the deduced \( A \) via a function pointer conversion (7.3.14) and/or qualification conversion (7.3.6).

3. If \( P \) is a class and \( P \) has the form \texttt{simple-template-id}, then the transformed \( A \) can be a derived class \( D \) of the deduced \( A \). Likewise, if \( P \) is a pointer to a class of the form \texttt{simple-template-id}, the transformed \( A \) can be a pointer to a derived class \( D \) pointed to by the deduced \( A \). However, if there is a class \( C \) that is a (direct or indirect) base class of \( D \) and derived (directly or indirectly) from a class \( B \) and that would be a valid deduced \( A \), the deduced \( A \) cannot be \( B \) or pointer to \( B \), respectively.

Example 5:

```cpp
template <typename... T> struct X;
template <> struct X<> {}; 
template <typename T, typename... Ts> struct X<T, Ts...> : X<Ts...> {}; 
struct D : X<int> {}; 
struct E : X<>{}, X<int> {}; 

template <typename... T>
int f(const X<T...>&); 
int x = f(D()); // calls f<int>, not f<> // B is X<>{}, C is X<int>
int z = f(E()); // calls f<int>, not f<> 
```

Note 1: If a template-parameter is not used in any of the function parameters of a function template, or is used only in a non-deduced context, its corresponding template-argument cannot be deduced from a function call and the template-argument must be explicitly specified.

Example 6:

```cpp
// Only one function of an overload set matches the call so the function parameter is a deduced context. 
template <class T> int f(T (*p)(T));
int g(int);
int g(char);
int i = f(g); // calls f(int (*)(int)) 
```

Example 7:

```cpp
// Ambiguous deduction causes the second function parameter to be a non-deduced context.
template <class T> int f(T, T (*p)(T));
int g(int);
char g(char);
int i = f(1, g); // calls f(int, int (*)(int)) 
```

Example 8:
template <class T> int f(T, T (*p)(T));
char g(char);
template <class T> T g(T);
int i = f(1, g);  // calls f(int, int (*)(int))

13.10.3.3 Deducing template arguments taking the address of a function template
[temp.deduct.funcaddr]

Template arguments can be deduced from the type specified when taking the address of an overload set (12.3).
If there is a target, the function template’s function type and the target type are used as the types of P and A,
and the deduction is done as described in 13.10.3.6. Otherwise, deduction is performed with empty sets of
types P and A.

1 A placeholder type (9.2.9.6) in the return type of a function template is a non-deduced context. If template
argument deduction succeeds for such a function, the return type is determined from instantiation of the
function body.

13.10.3.4 Deducing conversion function template arguments 
[temp.deduct.conv]

Template argument deduction is done by comparing the return type of the conversion function template (call
it P) with the type specified by the conversion-type-id of the conversion-function-id being looked up (call it A)
as described in 13.10.3.6. If the conversion-function-id is constructed during overload resolution (12.2.2),
the following transformations apply.

2 If P is a reference type, the type referred to by P is used in place of P for type deduction and for any further
references to or transformations of P in the remainder of this subclause.

3 If A is not a reference type:

   (3.1) — If P is an array type, the pointer type produced by the array-to-pointer standard conversion (7.3.3) is
   used in place of P for type deduction; otherwise,

   (3.2) — If P is a function type, the pointer type produced by the function-to-pointer standard conversion (7.3.4)
   is used in place of P for type deduction; otherwise,

   (3.3) — If P is a cv-qualified type, the top-level cv-qualifiers of P’s type are ignored for type deduction.

4 If A is a cv-qualified type, the top-level cv-qualifiers of A’s type are ignored for type deduction. If A is a
reference type, the type referred to by A is used for type deduction.

5 In general, the deduction process attempts to find template argument values that will make the deduced A
identical to A. However, certain attributes of A may be ignored:

   (5.1) — If the original A is a reference type, any cv-qualifiers of A (i.e., the type referred to by the reference).

   (5.2) — If the original A is a function pointer or pointer-to-member-function type, its noexcept.

   (5.3) — Any cv-qualifiers in A that can be restored by a qualification conversion.

6 These attributes are ignored only if type deduction would otherwise fail. If ignoring them allows more than
one possible deduced A, the type deduction fails.

13.10.3.5 Deducing template arguments during partial ordering 
[temp.deduct.partial]

Template argument deduction is done by comparing certain types associated with the two function templates
being compared.

2 Two sets of types are used to determine the partial ordering. For each of the templates involved there is the
original function type and the transformed function type.

[Note 1: The creation of the transformed type is described in 13.7.7.3. — end note]
The deduction process uses the transformed type as the argument template and the original type of the
other template as the parameter template. This process is done twice for each type involved in the partial
ordering comparison: once using the transformed template-1 as the argument template and template-2 as the
parameter template and again using the transformed template-2 as the argument template and template-1 as
the parameter template.

3 The types used to determine the ordering depend on the context in which the partial ordering is done:
In the context of a function call, the types used are those function parameter types for which the function call has arguments.\textsuperscript{133}

In the context of a call to a conversion function, the return types of the conversion function templates are used.

In other contexts (13.7.7.3) the function template’s function type is used.

Each type nominated above from the parameter template and the corresponding type from the argument template are used as the types of $P$ and $A$.

Before the partial ordering is done, certain transformations are performed on the types used for partial ordering:

- If $P$ is a reference type, $P$ is replaced by the type referred to.
- If $A$ is a reference type, $A$ is replaced by the type referred to.

If both $P$ and $A$ were reference types (before being replaced with the type referred to above), determine which of the two types (if any) is more cv-qualified than the other; otherwise the types are considered to be equally cv-qualified for partial ordering purposes. The result of this determination will be used below.

Remove any top-level cv-qualifiers:

- If $P$ is a cv-qualified type, $P$ is replaced by the cv-unqualified version of $P$.
- If $A$ is a cv-qualified type, $A$ is replaced by the cv-unqualified version of $A$.

Using the resulting types $P$ and $A$, the deduction is then done as described in 13.10.3.6. If $P$ is a function parameter pack, the type $A$ of each remaining parameter type of the argument template is compared with the type $P$ of the $\text{declator-id}$ of the function parameter pack. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. Similarly, if $A$ was transformed from a function parameter pack, it is compared with each remaining parameter type of the parameter template. If deduction succeeds for a given type, the type from the argument template is considered to be at least as specialized as the type from the parameter template.

\textit{Example 1:}

\begin{verbatim}
template<class... Args> void f(Args... args);       // #1
template<class T1, class... Args> void f(T1 a1, Args... args); // #2
template<class T1, class T2> void f(T1 a1, T2 a2);        // #3

f();       // calls #1
f(1, 2, 3); // calls #2
f(1, 2);   // calls #3; non-variadic template #3 is more specialized
           // than the variadic templates #1 and #2

@end example
\end{verbatim}

If, for a given type, the types are identical after the transformations above and both $P$ and $A$ were reference types (before being replaced with the type referred to above):

- if the type from the argument template was an lvalue reference and the type from the parameter template was not, the parameter type is not considered to be at least as specialized as the argument type; otherwise,

- if the type from the argument template is more cv-qualified than the type from the parameter template (as described above), the parameter type is not considered to be at least as specialized as the argument type.

Function template $F$ is \textit{at least as specialized as} function template $G$ if, for each pair of types used to determine the ordering, the type from $F$ is at least as specialized as the type from $G$. $F$ is \textit{more specialized than} $G$ if $F$ is at least as specialized as $G$ and $G$ is not at least as specialized as $F$.

If, after considering the above, function template $F$ is at least as specialized as function template $G$ and vice-versa, and if $G$ has a trailing function parameter pack for which $F$ does not have a corresponding parameter, and if $F$ does not have a trailing function parameter pack, then $F$ is more specialized than $G$.

\textsuperscript{133} Default arguments are not considered to be arguments in this context; they only become arguments after a function has been selected.

\section*{§ 13.10.3.5}
In most cases, deduction fails if not all template parameters have values, but for partial ordering purposes a template parameter may remain without a value provided it is not used in the types being used for partial ordering.

[Note 2: A template parameter used in a non-deduced context is considered used. — end note]

[Example 2:

```cpp
template <class T> T f(int); // #1
template <class T, class U> T f(U); // #2
void g() {
    f<int>(1); // calls #1
}
```
—end example]

[Note 3: Partial ordering of function templates containing template parameter packs is independent of the number of deduced arguments for those template parameter packs. — end note]

[Example 3:

```cpp
template<class ...> struct Tuple { };
template<class ... Types> void g(Tuple<Types ...>); // #1
template<class T1, class ... Types> void g(Tuple<T1, Types ...>); // #2
template<class T1, class ... Types> void g(Tuple<T1, Types& ...>); // #3
g(Tuple<>()); // calls #1
g(Tuple<int, float>()); // calls #2
g(Tuple<int, float&>()); // calls #3
```
—end example]

13.10.3.6 Deducing template arguments from a type [temp.deduct.type]

Template arguments can be deduced in several different contexts, but in each case a type that is specified in terms of template parameters (call it \( P \)) is compared with an actual type (call it \( A \)), and an attempt is made to find template argument values (a type for a type parameter, a value for a non-type parameter, or a template for a template parameter) that will make \( P \), after substitution of the deduced values (call it the deduced \( A \)), compatible with \( A \).

In some cases, the deduction is done using a single set of types \( P \) and \( A \), in other cases, there will be a set of corresponding types \( P \) and \( A \). Type deduction is done independently for each \( P/A \) pair, and the deduced template argument values are then combined. If type deduction cannot be done for any \( P/A \) pair, or if for any pair the deduction leads to more than one possible set of deduced values, or if different pairs yield different deduced values, or if any template argument remains neither deduced nor explicitly specified, template argument deduction fails. The type of a type parameter is only deduced from an array bound if it is not otherwise deduced.

A given type \( P \) can be composed from a number of other types, templates, and non-type values:

1. A function type includes the types of each of the function parameters and the return type.
2. A pointer-to-member type includes the type of the class object pointed to and the type of the member pointed to.
3. A type that is a specialization of a class template (e.g., \( A<\text{int}> \)) includes the types, templates, and non-type values referenced by the template argument list of the specialization.
4. An array type includes the array element type and the value of the array bound.

In most cases, the types, templates, and non-type values that are used to compose \( P \) participate in template argument deduction. That is, they may be used to determine the value of a template argument, and template argument deduction fails if the value so determined is not consistent with the values determined elsewhere. In certain contexts, however, the value does not participate in type deduction, but instead uses the values of template arguments that were either deduced elsewhere or explicitly specified. If a template parameter is used only in non-deduced contexts and is not explicitly specified, template argument deduction fails.

[Note 1: Under 13.10.3.2, if \( P \) contains no template-parameters that appear in deduced contexts, no deduction is done, so \( P \) and \( A \) need not have the same form. — end note]

The non-deduced contexts are:
© ISO/IEC

— The nested-name-specifier of a type that was specified using a qualified-id.

— The expression of a decltype-specifier.

— A non-type template argument or an array bound in which a subexpression references a template parameter.

— A template parameter used in the parameter type of a function parameter that has a default argument that is being used in the call for which argument deduction is being done.

— A function parameter for which the associated argument is an overload set (12.3), and one or more of the following apply:

  — more than one function matches the function parameter type (resulting in an ambiguous deduction), or

  — no function matches the function parameter type, or

  — the overload set supplied as an argument contains one or more function templates.

— A function parameter for which the associated argument is an initializer list (9.4.5) but the parameter does not have a type for which deduction from an initializer list is specified (13.10.3.2).

  [Example 1:]
  
  template<class T> void g(T);
  g({1,2,3});  // error: no argument deduced for T

  — end example]

— A function parameter pack that does not occur at the end of the parameter-declaration-list.

6 When a type name is specified in a way that includes a non-deduced context, all of the types that comprise that type name are also non-deduced. However, a compound type can include both deduced and non-deduced types.

[Example 2: If a type is specified as A<T>::B<T2>, both T and T2 are non-deduced. Likewise, if a type is specified as A<1+J>::X<T>, I, J, and T are non-deduced. If a type is specified as void f(typename A<T>::B, A<T>), the T in A<T>::B is non-deduced but the T in A<T> is deduced. — end example]

7 [Example 3: Here is an example in which different parameter/argument pairs produce inconsistent template argument deductions:

  template<class T> void f(T x, T y) { /* ... */ }
  struct A { /* ... */ };
  struct B : A { /* ... */ };
  void g(A a, B b) {
    f(a,b);  // error: T deduced as both A and B
    f(b,a);  // error: T deduced as both A and B
    f(a,a);  // OK: T is A
    f(b,b);  // OK: T is B
  }

Here is an example where two template arguments are deduced from a single function parameter/argument pair. This can lead to conflicts that cause type deduction to fail:

  template <class T, class U> void f( T (*)( T, U, U ) );

  int g1( int, float, float);
  char g2( int, float, float);
  int g3( int, char, float);

  void r() {
    f(g1);  // OK: T is int and U is float
    f(g2);  // error: T deduced as both char and int
    f(g3);  // error: U deduced as both char and float
  }

Here is an example where a qualification conversion applies between the argument type on the function call and the deduced template argument type:

  template<class T> void f(const T*) { }
  int* p;

§ 13.10.3.6 427
Here is an example where the template argument is used to instantiate a derived class type of the corresponding function parameter type:

```c++
void s() {
    f(p); // f(const int*)
}
```

A template type argument \(T\), a template template argument \(TT\) or a template non-type argument \(i\) can be deduced if \(P\) and \(A\) have one of the following forms:

- \(T\)
- \(cv\ T\)
- \(T*\)
- \(T&\)
- \(T&&\)
- \(T[i]\) (where \(T\) represents a parameter-type-list (9.3.4.6) where at least one parameter type contains a \(T\), and \(i\) represents template argument lists where at least one argument contains an \(i\) and \(<\) represents template argument lists where no argument contains a \(T\) or an \(i\).

If \(P\) has a form that contains \(<T>\) or \(<i>\), then each argument \(P_i\) of the respective template argument list of \(P\) is compared with the corresponding argument \(A_i\) of the corresponding template argument list of \(A\). If the template argument list of \(P\) contains a pack expansion that is not the last template argument, the entire template argument list is a non-deduced context. If \(P_i\) is a pack expansion, then the pattern of \(P_i\) is compared with each remaining argument in the template argument list of \(A\). Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by \(P_i\). During partial ordering (13.10.3.5), if \(A_i\) was originally a pack expansion:

1. if \(P\) does not contain a template argument corresponding to \(A_i\), then \(A_i\) is ignored;
2. otherwise, if \(P_i\) is not a pack expansion, template argument deduction fails.

[Example 4:]

---

© ISO/IEC N4885

§ 13.10.3.6
template<class T1, class... Z> class S;  // #1
template<class T1, class... Z> class S<T1, const Z&...> { };  // #2
template<class T1, class T2> class S<T1, const T2&> { };  // #3
S<int, const int&> s;  // both #2 and #3 match; #3 is more specialized

template<class T, class... U> struct A { };  // #1
template<class T1, class T2, class... U> struct A<T1, T2*, U...> { };  // #2
template<class T1, class T2> struct A<T1, T2> { };  // #3
template struct A<int, int*>;  // selects #2

—end example

10 Similarly, if P has a form that contains (T), then each parameter type Pᵢ of the respective parameter-type-list (9.3.4.6) of P is compared with the corresponding parameter type Aᵢ of the corresponding parameter-type-list of A. If P and A are function types that originated from deduction when taking the address of a function template (13.10.3.3) or when deducing template arguments from a function declaration (13.10.3.7) and Pᵢ and Aᵢ are parameters of the top-level parameter-type-list of P and A, respectively, Pᵢ is adjusted if it is a forwarding reference (13.10.3.2) and Aᵢ is an lvalue reference, in which case the type of Pᵢ is changed to be the template parameter type (i.e., T&& is changed to simply T).

[Note 2: As a result, when Pᵢ is T&& and Aᵢ is X&, the adjusted Pᵢ will be T, causing T to be deduced as X&&. — end note]

Example 5:

template <class T> void f(T&&);

template <> void f(int&) { }  // #1
template <> void f(int&&) { }  // #2

void g(int i) {
  f(i);  // calls f<int&>(int&), i.e., #1
  f(0);  // calls f<int&>(int&&), i.e., #2
}

—end example

If the parameter-declaration corresponding to Pᵢ is a function parameter pack, then the type of its declarator-id is compared with each remaining parameter type in the parameter-type-list of A. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. During partial ordering (13.10.3.5), if Aᵢ was originally a function parameter pack:

10.1 — if P does not contain a function parameter type corresponding to Aᵢ then Aᵢ is ignored;

10.2 — otherwise, if Pᵢ is not a function parameter pack, template argument deduction fails.

Example 6:

template<class T, class... U> void f(T*, U...) { }  // #1

template<class T> void f(T) { }  // #2

template void f(int*);  // selects #1

—end example

11 These forms can be used in the same way as T is for further composition of types.

Example 7:

X<int> (*)(char[6]) is of the form
template-name<T> (*)(type[i]) which is a variant of
type (*)(T)
where type is X<int> and T is char[6]. — end example

12 Template arguments cannot be deduced from function arguments involving constructs other than the ones specified above.

13 When the value of the argument corresponding to a non-type template parameter P that is declared with a dependent type is deduced from an expression, the template parameters in the type of P are deduced from the type of the value.

Example 8:
The type of N in the type T[N] is std::size_t.

[Example 9:]

```cpp
template<typename T> struct S;
template<typename T, T n> struct S<int[n]> {
    using Q = T;
};
```

using V = decltype(sizeof 0);
using V = S<int[42]>::Q;  // OK; T was deduced as std::size_t from the type int[42]

—end example—

[Example 10:]

```cpp
template<class T, T i> void f(int (&a)[i]);
int v[10];
void g() {
    f(v);                       // OK: T is std::size_t
}
```

—end example—

[Note 3: Except for reference and pointer types, a major array bound is not part of a function parameter type and cannot be deduced from an argument:]

```cpp
template<int i> void f1(int a[10][i]);
template<int i> void f2(int a[i][20]);
template<int i> void f3(int (&a)[i][20]);
```

void g() {
    int v[10][20];
    f1(v);           // OK: i deduced as 20
    f1<20>(v);       // OK
    f2(v);           // error: cannot deduce template-argument i
    f2<10>(v);       // OK
    f3(v);           // OK: i deduced as 10
}

—end note—

[Note 4: If, in the declaration of a function template with a non-type template parameter, the non-type template parameter is used in a subexpression in the function parameter list, the expression is a non-deduced context as specified above.]

[Example 11:]

```cpp
template <int i> class A { /* ... */ };
template <int i> void g(A<i+1>);
template <int i> void f(A<i>, A<i+1>);
void k() {
    A<1> a1;
    A<2> a2;
    g(a1);                 // error: deduction fails for expression i+1
    g<0>(a1);              // OK
    f(a1, a2);             // OK
}
```

—end example—
[Note 5: Template parameters do not participate in template argument deduction if they are used only in non-deduced contexts. For example,

```cpp
template<int i, typename T>
T deduce(typename A<T>::X x, // T is not deduced here
         T t,         // but T is deduced here
type B<i>::Y y);  // i is not deduced here

A<int> a;
B<77>  b;

int x = deduce<77>({a.xm, 62, b.ym});    // T deduced as int; a.xm must be convertible to A<int>::X
// i is explicitly specified to be 77; b.ym must be convertible to B<77>::Y
```

--- end note ---

If `P` has a form that contains `<i>`, and if the type of `i` differs from the type of the corresponding template parameter of the template named by the enclosing `simple-template-id`, deduction fails. If `P` has a form that contains `[i]`, and if the type of `i` is not an integral type, deduction fails.\[134\]

**Example 12:**

```cpp
template<int i> class A { /* ... */ };
template<short s> void f(A<s>);
void k1() {
    A<1> a;
    f(a);  // error: deduction fails for conversion from int to short
    f<1>(a); // OK
}

template<const short cs> class B { };
template<short s> void g(B<s>);
void k2() {
    B<1> b;
    g(b); // OK: cv-qualifiers are ignored on template parameter types
}
```

--- end example ---

A template argument can be deduced from a function, pointer to function, or pointer-to-member-function type.

**Example 13:**

```cpp
template<class T> void f(void(*)(T,int));
template<class T> void foo(T,int);
void g(int,int);
void g(char,int);
void h(int,int,int);
void h(char,int);

int m() {
    f(&g);  // error: ambiguous
    f(&h); // OK: void h(char,int) is a unique match
    f(&foo);  // error: type deduction fails because foo is a template
}
```

--- end example ---

A template type-parameter cannot be deduced from the type of a function default argument.

**Example 14:**

```cpp
template <class T> void f(T = 5, T = 7);
void g() {
    f(1);  // OK: call f<int>(1,7)
    f(); // error: cannot deduce T
}
```

\[134\] Although the template-argument corresponding to a template-parameter of type `bool` can be deduced from an array bound, the resulting value will always be `true` because the array bound will be nonzero.
The template-argument corresponding to a template template-parameter is deduced from the type of the template-argument of a class template specialization used in the argument list of a function call.

Example 15:

```cpp
template <template <class T> class X> struct A { };  
template <template <class T> class X> void f(A<X>) { }  
template<class T> struct B { };  
A<int> ab;  
f(ab);  // calls f(A<int>)
```

Example 16:

```cpp
template<class> struct X { };  
template<class R, class ... ArgTypes> struct X<R(int, ArgTypes ...)>:: { };  
template<class ... Types> struct Y { };  
template<class T, class ... Types> struct Y<T, Types& ...> { };  

template<class ... Types> int f(void (*)(Types ...));  
void g(int, float);
X<int> x1;  // uses primary template  
X<int(int, float, double)> x2;  // uses partial specialization; ArgTypes contains float, double  
X<int(float, int)> x3;  // uses primary template  
Y<int>;  // use primary template; Types is empty  
Y<int&, float&, double&> y2;  // uses partial specialization; T is int&, Types contains float, double  
Y<int, float, double> y3;  // uses primary template; Types contains int, float, double  

int fv = f(g);  // OK; Types contains int, float
```

13.10.3.7 Deducing template arguments from a function declaration

In a declaration whose declarator-id refers to a specialization of a function template, template argument deduction is performed to identify the specialization to which the declaration refers. Specifically, this is done for explicit instantiations (13.9.3), explicit specializations (13.9.4), and certain friend declarations (13.7.5). This is also done to determine whether a deallocation function template specialization matches a placement operator new (6.7.5.5.3, 7.6.2.8). In all these cases, P is the type of the function template being considered as a potential match and A is either the function type from the declaration or the type of the deallocation function that would match the placement operator new as described in 7.6.2.8. The deduction is done as described in 13.10.3.6.

If, for the set of function templates so considered, there is either no match or more than one match after partial ordering has been considered (13.7.7.3), deduction fails and, in the declaration cases, the program is ill-formed.

13.10.4 Overload resolution

When a call of a function or function template is written (explicitly, or implicitly using the operator notation), template argument deduction (13.10.3) and checking of any explicit template arguments (13.4) are performed for each function template to find the template argument values (if any) that can be used with that function template to instantiate a function template specialization that can be invoked with the call arguments or, for conversion function templates, that can convert to the required type. For each function template, if the argument deduction and checking succeeds, the template-arguments (deduced and/or explicit) are used to synthesize the declaration of a single function template specialization which is added to the candidate functions set to be used in overload resolution. If, for a given function template, argument deduction fails or the synthesized function template specialization would be ill-formed, no such function is added to the set of candidate functions for that template. The complete set of candidate functions includes all the synthesized
declarations and all of the non-template functions found by name lookup. The synthesized declarations are
treated like any other functions in the remainder of overload resolution, except as explicitly noted in 12.2.4.\footnote{135}

2 \[Example 1\]:

\[
\begin{aligned}
\text{template<}\text{class T} & \text{> T max(T a, T b) \{ return a>b?a:b; \}} \\
\text{void f(int a, int b, char c, char d) \{} \\
\text{int m1 = max(a,b);} & \quad \text{// max(int, int)} \\
\text{char m2 = max(c,d);} & \quad \text{// max(char, char)} \\
\text{int m3 = max(a,c);} & \quad \text{// error: cannot generate max(int, char)} \\
\text{}}
\end{aligned}
\]

Adding the non-template function

\[
\text{int max(int, int);}
\]
to the example above would resolve the third call, by providing a function that can be called for max(a,c) after using
the standard conversion of char to int for c. \textit{— end example}\]

3 \[Example 2\]: Here is an example involving conversions on a function argument involved in \textit{template-argument} deduction:

\[
\begin{aligned}
\text{template<}\text{class T} & \text{> struct B \{ /* ... */ \}}; \\
\text{template<}\text{class T} & \text{> struct D : public B<T> \{ /* ... */ \}}; \\
\text{template<}\text{class T} & \text{> void f(B<T>&);} \\
\text{void g(B<int>& bi, D<int>& di) \{} \\
\text{f(bi);} & \quad \text{// f(bi)} \\
\text{f(di);} & \quad \text{// f(B<int>&)di)} \\
\text{}}
\end{aligned}
\]

\textit{— end example}\]

4 \[Example 3\]: Here is an example involving conversions on a function argument not involved in \textit{template-parameter} deduction:

\[
\begin{aligned}
\text{template<}\text{class T} & \text{> void f(T*, int);} & \quad \text{// #1} \\
\text{template<}\text{class T} & \text{> void f(T, char);} & \quad \text{// #2} \\
\text{void h(int* pi, int i, char c) \{} \\
\text{f(pi,i);} & \quad \text{// #1: f<int>(pi,i)} \\
\text{f(pi,c);} & \quad \text{// #2: f<int*>(pi,c)} \\
\text{f(i,c);} & \quad \text{// #2: f<int>(i,c)} \\
\text{f(i,i);} & \quad \text{// #2: f<int>(i, char(i))} \\
\text{}}
\end{aligned}
\]

\textit{— end example}\]

5 Only the signature of a function template specialization is needed to enter the specialization in a set of
candidate functions. Therefore only the function template declaration is needed to resolve a call for which a
template specialization is a candidate.

\[Example 4\]:

\[
\begin{aligned}
\text{template<}\text{class T} & \text{> void f(T);} & \quad \text{// declaration} \\
\text{void g()} \{} \\
\text{f("Annemarie");} & \quad \text{// call of f<const char*}} \\
\text{}}
\end{aligned}
\]
The call of f is well-formed even if the template f is only declared and not defined at the point of the call. The
program will be ill-formed unless a specialization for f<const char*> is explicitly instantiated in some translation
unit (13.1). \textit{— end example}\]

\footnote{135}{The parameters of function template specializations contain no template parameter types. The set of conversions allowed on
deduced arguments is limited, because the argument deduction process produces function templates with parameters that either
match the call arguments exactly or differ only in ways that can be bridged by the allowed limited conversions. Non-deduced
arguments allow the full range of conversions. Note also that 12.2.4 specifies that a non-template function will be given preference
over a template specialization if the two functions are otherwise equally good candidates for an overload match.}
14 Exception handling

14.1 Preamble

Exception handling provides a way of transferring control and information from a point in the execution of a thread to an exception handler associated with a point previously passed by the execution. A handler will be invoked only by throwing an exception in code executed in the handler’s try block or in functions called from the handler’s try block.

```
try-block:
  try compound-statement handler-seq
function-try-block:
  try ctor-initializer<opt> compound-statement handler-seq
handler-seq:
  handler handler-seq<opt>
handler:
  catch ( exception-declaration ) compound-statement
exception-declaration:
  attribute-specifier-seq<opt> type-specifier-seq declarator
  attribute-specifier-seq<opt> type-specifier-seq abstract-declarator<opt>
  ...
```

The optional attribute-specifier-seq in an exception-declaration appertains to the parameter of the catch clause (14.4).

1 A try-block is a statement (8.1).

[Note 1: Within this Clause “try block” is taken to mean both try-block and function-try-block. — end note]

2 A goto or switch statement shall not be used to transfer control into a try block or into a handler.

[Example 1:

```c
void f() {
  goto l1; // error
  goto l2; // error
  try {
    goto l1; // OK
    goto l2; // error
    l1: ;
  } catch (...) {
    l2: ;
    goto l1; // error
    goto l2; // OK
  }
}
```
—end example]

A goto, break, return, or continue statement can be used to transfer control out of a try block or handler. When this happens, each variable declared in the try block will be destroyed in the context that directly contains its declaration.

[Example 2:

```c
lab: try {
  T1 t1;
  try {
    T2 t2;
    if (condition)
      goto lab;
  } catch(...) { /* handler 2 */ }
} catch(...) { /* handler 1 */ }
```
Here, executing `goto lab;` will destroy first `t2`, then `t1`, assuming the `condition` does not declare a variable. Any exception thrown while destroying `t2` will result in executing `handler 2`; any exception thrown while destroying `t1` will result in executing `handler 1`. —end example]

4 A `function-try-block` associates a `handler-seq` with the `ctor-initializer, if present, and the compound-statement. An exception thrown during the execution of the `compound-statement` or, for constructors and destructors, during the initialization or destruction, respectively, of the class’s subobjects, transfers control to a handler in a `function-try-block` in the same way as an exception thrown during the execution of a `try-block` transfers control to other handlers.

[Example 3:

```cpp
int f(int);
class C {
    int i;
    double d;
public:
    C(int, double);
};
C::C(int ii, double id)
try : i(f(ii)), d(id) {
    // constructor statements
} catch (...) {
    // handles exceptions thrown from the ctor-initializer and from the constructor statements
}
—end example]

5 In this Clause, “before” and “after” refer to the “sequenced before” relation (6.9.1).

14.2 Throwing an exception [except.throw]

1 Throwing an exception transfers control to a handler.

[Note 1: An exception can be thrown from one of the following contexts: `throw-expressions` (7.6.18), allocation functions (6.7.5.5.2), `dynamic_cast` (7.6.1.7), `typeid` (7.6.1.8), `new-expression`s (7.6.2.8), and standard library functions (16.3.2.4). —end note]

An object is passed and the type of that object determines which handlers can catch it.

[Example 1:

```cpp
throw "Help!";
```
can be caught by a `handler` of `const char*` type:

```cpp
try {
    // ...
} catch(const char* p) {
    // handle character string exceptions here
}
```

and

```cpp
class Overflow {
    public:
        Overflow(char, double, double);
    };

void f(double x) {
    throw Overflow('+', x, 3.45e107);
}
```
can be caught by a handler for exceptions of type `Overflow`:

```cpp
try {
    f(1.2);
} catch(Overflow & oo) {
    // handle exceptions of type Overflow here
}
—end example]

§ 14.2
When an exception is thrown, control is transferred to the nearest handler with a matching type (14.4); “nearest” means the handler for which the compound-statement or ctor-initializer following the try keyword was most recently entered by the thread of control and not yet exited.

Throwing an exception copy-initializes (9.4, 11.4.5.3) a temporary object, called the exception object. An lvalue denoting the temporary is used to initialize the variable declared in the matching handler (14.4). If the type of the exception object would be an incomplete type, an abstract class type (11.7.4), or a pointer to an incomplete type other than cv void the program is ill-formed.

The memory for the exception object is allocated in an unspecified way, except as noted in 6.7.5.5.2. If a handler exits by rethrowing, control is passed to another handler for the same exception object. The points of potential destruction for the exception object are:

- (4.1) when an active handler for the exception exits by any means other than rethrowing, immediately after the destruction of the object (if any) declared in the exception-declaration in the handler;
- (4.2) when an object of type std::exception_ptr (17.9.7) that refers to the exception object is destroyed, before the destructor of std::exception_ptr returns.

Among all points of potential destruction for the exception object, there is an unspecified last one where the exception object is destroyed. All other points happen before that last one (6.9.2.2).

The implementation may then deallocate the memory for the exception object; any such deallocation is done in an unspecified way.

When the thrown object is a class object, the constructor selected for the copy-initialization as well as the constructor selected for a copy-initialization considering the thrown object as an lvalue shall be non-deleted and accessible, even if the copy/move operation is elided (11.9.6). The destructor is potentially invoked (11.4.7).

An exception is considered caught when a handler for that exception becomes active (14.4).

If the exception handling mechanism handling an uncaught exception (14.6.3) directly invokes a function that exits via an exception, the function std::terminate is invoked (14.6.2).

[Example 2:]
```cpp
struct C {
    C() { }  // Nothing is destroyed.
    C(const C&) {
        if (std::uncaught_exceptions()) {
            throw 0; // throw during copy to handler's exception-declaration object (14.4)
        }
    }
};

int main() {
    try {
        throw C(); // calls std::terminate if construction of the handler's exception-declaration object is not elided (11.9.6)
    } catch(C) { }
    // Nothing is destroyed.
    // std::terminate is invoked.
}
```

[Note 4: An exception can have active handlers and still be considered uncaught if it is rethrown. — end note]

14.3 Constructors and destructors [except.ctor]

As control passes from the point where an exception is thrown to a handler, objects with automatic storage duration are destroyed by a process, specified in this subclause, called stack unwinding.

Each object with automatic storage duration is destroyed if it has been constructed, but not yet destroyed, since the try block was entered. If an exception is thrown during the destruction of temporaries or local
variables for a `return` statement (8.7.4), the destructor for the returned object (if any) is also invoked. The objects are destroyed in the reverse order of the completion of their construction.

[Example 1:]

```cpp
struct A {};

struct Y { ~Y() noexcept(false) { throw 0; } };

A f() {
  try {
    A a;
    Y y;
    A b;
    return {}; // #1
  } catch (...) {
  }
  return {}; // #2
}
```

At #1, the returned object of type `A` is constructed. Then, the local variable `b` is destroyed (8.7). Next, the local variable `y` is destroyed, causing stack unwinding, resulting in the destruction of the returned object, followed by the destruction of the local variable `a`. Finally, the returned object is constructed again at #2. — end example]

If the initialization or destruction of an object other than by delegating constructor is terminated by an exception, the destructor is invoked for each of the object’s direct subobjects and, for a complete object, virtual base class subobjects, whose initialization has completed (9.4) and whose destructor has not yet begun execution, except that in the case of destruction, the variant members of a union-like class are not destroyed.

[Note 1: If such an object has a reference member that extends the lifetime of a temporary object, this ends the lifetime of the reference member, so the lifetime of the temporary object is effectively not extended. — end note]

The subobjects are destroyed in the reverse order of the completion of their construction. Such destruction is sequenced before entering a handler of the `function-try-block` of the constructor or destructor, if any.

If the `compound-statement` of the `function-body` of a delegating constructor for an object exits via an exception, the object’s destructor is invoked. Such destruction is sequenced before entering a handler of the `function-try-block` of a delegating constructor for that object, if any.

[Note 2: If the object was allocated by a `new-expression` (7.6.2.8), the matching deallocation function (6.7.5.5.3), if any, is called to free the storage occupied by the object. — end note]

### 14.4 Handling an exception [except.handle]

The `exception-declaration` in a `handler` describes the type(s) of exceptions that can cause that `handler` to be entered. The `exception-declaration` shall not denote an incomplete type, an abstract class type, or an rvalue reference type. The `exception-declaration` shall not denote a pointer or reference to an incomplete type, other than “pointer to cv void”.

A `handler` is a match for an exception object of type `E` if

- The `handler` is of type `cv T` or `cv T&` and `E` and `T` are the same type (ignoring the top-level `cv-qualifiers`), or
- the `handler` is of type `cv T` or `cv T&` and `T` is an unambiguous public base class of `E`, or
- the `handler` is of type `cv T` or `const T&` where `T` is a pointer or pointer-to-member type and `E` is a pointer or pointer-to-member type that can be converted to `T` by one or more of
  - a standard pointer conversion (7.3.12) not involving conversions to pointers to private or protected or ambiguous classes
  - a function pointer conversion (7.3.14)
  - a qualification conversion (7.3.6), or
- the `handler` is of type `cv T` or `const T&` where `T` is a pointer or pointer-to-member type and `E` is `std::nullptr_t`.

§ 14.4
[Note 1: A throw-expression whose operand is an integer literal with value zero does not match a handler of pointer or pointer-to-member type. A handler of reference to array or function type is never a match for any exception object (7.6.18). — end note]

[Example 1:

class Matherr { /* ... */ virtual void vf(); };  
class Overflow: public Matherr { /* ... */ };  
class Underflow: public Matherr { /* ... */ };  
class Zerodivide: public Matherr { /* ... */ };  

void f() {
  try {
    g();
  } catch (Overflow oo) {
    // ...
  } catch (Matherr mm) {
    // ...
  }
}

Here, the Overflow handler will catch exceptions of type Overflow and the Matherr handler will catch exceptions of type Matherr and of all types publicly derived from Matherr including exceptions of type Underflow and Zerodivide. — end example]

4 The handlers for a try block are tried in order of appearance.

[Note 2: This makes it possible to write handlers that can never be executed, for example by placing a handler for a final derived class after a handler for a corresponding unambiguous public base class. — end note]

5 A ... in a handler’s exception-declaration functions similarly to ... in a function parameter declaration; it specifies a match for any exception. If present, a ... handler shall be the last handler for its try block.

6 If no match is found among the handlers for a try block, the search for a matching handler continues in a dynamically surrounding try block of the same thread.

7 A handler is considered active when initialization is complete for the parameter (if any) of the catch clause.

[Note 3: The stack will have been unwound at that point. — end note]

Also, an implicit handler is considered active when the function std::terminate is entered due to a throw. A handler is no longer considered active when the catch clause exits.

8 The exception with the most recently activated handler that is still active is called the currently handled exception.

9 If no matching handler is found, the function std::terminate is invoked; whether or not the stack is unwound before this invocation of std::terminate is implementation-defined (14.6.2).

10 Referring to any non-static member or base class of an object in the handler for a function-try-block of a constructor or destructor for that object results in undefined behavior.

11 Exceptions thrown in destructors of objects with static storage duration or in constructors of objects associated with non-block variables with static storage duration are not caught by a function-try-block on the main function (6.9.3.1). Exceptions thrown in destructors of objects with thread storage duration or in constructors of objects associated with non-block variables with thread storage duration are not caught by a function-try-block on the initial function of the thread.

12 If a return statement (8.7.4) appears in a handler of the function-try-block of a constructor, the program is ill-formed.

13 The currently handled exception is rethrown if control reaches the end of a handler of the function-try-block of a constructor or destructor. Otherwise, flowing off the end of the compound-statement of a handler of a function-try-block is equivalent to flowing off the end of the compound-statement of that function (see 8.7.4).

14 The variable declared by the exception-declaration, of type cv T or cv T&, is initialized from the exception object, of type E, as follows:

(14.1) — if T is a base class of E, the variable is copy-initialized (9.4) from the corresponding base class subobject of the exception object;

(14.2) — otherwise, the variable is copy-initialized (9.4) from the exception object.
The lifetime of the variable ends when the handler exits, after the destruction of any objects with automatic storage duration initialized within the handler.

15 When the handler declares an object, any changes to that object will not affect the exception object. When the handler declares a reference to an object, any changes to the referenced object are changes to the exception object and will have effect should that object be rethrown.

### 14.5 Exception specifications

The predicate indicating whether a function cannot exit via an exception is called the exception specification of the function. If the predicate is false, the function has a potentially-throwing exception specification, otherwise it has a non-throwing exception specification. The exception specification is either defined implicitly, or defined explicitly by using a noexcept-specifier as a suffix of a function declarator (9.3.4.6).

```
noexcept-specifier:
  noexcept ( constant-expression )
  noexcept
```

1 In a noexcept-specifier, the constant-expression, if supplied, shall be a contextually converted constant expression of type bool (7.7); that constant expression is the exception specification of the function type in which the noexcept-specifier appears. A ( token that follows noexcept is part of the noexcept-specifier and does not commence an initializer (9.4). The noexcept-specifier noexcept without a constant-expression is equivalent to the noexcept-specifier noexcept(true).

2 If a declaration of a function does not have a noexcept-specifier, the declaration has a potentially throwing exception specification unless it is a destructor or a deallocation function or is defaulted on its first declaration, in which cases the exception specification is as specified below and no other declaration for that function shall have a noexcept-specifier. In an explicit instantiation (13.9.3) a noexcept-specifier may be specified, but is not required. If a noexcept-specifier is specified in an explicit instantiation, the exception specification shall be the same as the exception specification of all other declarations of that function. A diagnostic is required only if the exception specifications are not the same within a single translation unit.

3 If a virtual function has a non-throwing exception specification, all declarations, including the definition, of any function that overrides that virtual function in any derived class shall have a non-throwing exception specification, unless the overriding function is defined as deleted.

[Example 1]:
```
struct B {
  virtual void f() noexcept;
  virtual void g();
  virtual void h() noexcept = delete;
};

struct D: B {
  void f(); // error
  void g() noexcept; // OK
  void h() = delete; // OK
};
```

The declaration of D::f is ill-formed because it has a potentially-throwing exception specification, whereas B::f has a non-throwing exception specification. — end example]

4 Whenever an exception is thrown and the search for a handler (14.4) encounters the outermost block of a function with a non-throwing exception specification, the function std::terminate is invoked (14.6.2).

[Note 1: An implementation is not permitted to reject an expression merely because, when executed, it throws or might throw an exception from a function with a non-throwing exception specification. — end note]

[Example 2]:
```
extern void f(); // potentially-throwing

void g() noexcept {
  f(); // valid, even if f throws
  throw 42; // valid, effectively a call to std::terminate
}
```

The call to f is well-formed even though, when called, f might throw an exception. — end example]
An expression \( E \) is potentially-throwing if

(6.1) \( E \) is a function call (7.6.1.3) whose postfix-expression has a function type, or a pointer-to-function type, with a potentially-throwing exception specification, or

(6.2) \( E \) implicitly invokes a function (such as an overloaded operator, an allocation function in a new-expression, a constructor for a function argument, or a destructor if \( E \) is a full-expression (6.9.1)) that is potentially-throwing, or

(6.3) \( E \) is a throw-expression (7.6.18), or

(6.4) \( E \) is a dynamic_cast expression that casts to a reference type and requires a runtime check (7.6.1.7), or

(6.5) \( E \) is a typeid expression applied to a (possibly parenthesized) built-in unary * operator applied to a pointer to a polymorphic class type (7.6.1.8), or

(6.6) any of the immediate subexpressions (6.9.1) of \( E \) is potentially-throwing.

An implicitly-declared constructor for a class \( X \), or a constructor without a noexcept-specifier that is defaulted on its first declaration, has a potentially-throwing exception specification if and only if any of the following constructs is potentially-throwing:

(7.1) a constructor selected by overload resolution in the implicit definition of the constructor for class \( X \) to initialize a potentially constructed subobject, or

(7.2) a subexpression of such an initialization, such as a default argument expression, or,

(7.3) for a default constructor, a default member initializer.

[Note 2: Even though destructors for fully-constructed subobjects are invoked when an exception is thrown during the execution of a constructor (14.3), their exception specifications do not contribute to the exception specification of the constructor, because an exception thrown from such a destructor would call the function `std::terminate` rather than escape the constructor (14.2, 14.6.2). — end note]

The exception specification for an implicitly-declared destructor, or a destructor without a noexcept-specifier, is potentially-throwing if and only if any of the destructors for any of its potentially constructed subobjects is potentially-throwing or the destructor is virtual and the destructor of any virtual base class is potentially-throwing.

The exception specification for an implicitly-declared assignment operator, or an assignment-operator without a noexcept-specifier that is defaulted on its first declaration, is potentially-throwing if and only if the invocation of any assignment operator in the implicit definition is potentially-throwing.

A deallocation function (6.7.5.5.3) with no explicit noexcept-specifier has a non-throwing exception specification.

The exception specification for a comparison operator function (12.4.3) without a noexcept-specifier that is defaulted on its first declaration is potentially-throwing if and only if any expression in the implicit definition is potentially-throwing.

[Example 3:

```cpp
struct A {
    A(int = (A(5), 0)) noexcept;
    A(const A&) noexcept;
    A(A&&) noexcept;
    ~A();
};
struct B {
    B() noexcept;
    B(const B&) = default; // implicit exception specification is noexcept(true)
    B(B&&, int = (throw 42, 0)) noexcept;
    ~B() noexcept(false);
};
int n = 7;
struct D : public A, public B {
    int * p = new int[n];
    // D::D() potentially-throwing, as the operator may throw bad_alloc or bad_array_new_length
    // D::D(const D&) non-throwing
    // D::D(D&&) potentially-throwing, as the default argument for B's constructor may throw
    // D::D() potentially-throwing
```]
Furthermore, if \( A::\sim A() \) were virtual, the program would be ill-formed since a function that overrides a virtual function from a base class shall not have a potentially-throwing exception specification if the base class function has a non-throwing exception specification. — end example]

13 An exception specification is considered to be needed when:

13.1 — in an expression, the function is selected by overload resolution (12.2, 12.3);
13.2 — the function is odr-used (6.3) or, if it appears in an unevaluated operand, would be odr-used if the expression were potentially-evaluated;
13.3 — the exception specification is compared to that of another declaration (e.g., an explicit specialization or an overriding virtual function);
13.4 — the function is defined; or
13.5 — the exception specification is needed for a defaulted function that calls the function.

[Note 3: A defaulted declaration does not require the exception specification of a base member function to be evaluated until the implicit exception specification of the derived function is needed, but an explicit noexcept-specifier needs the implicit exception specification to compare against. — end note]

The exception specification of a defaulted function is evaluated as described above only when needed; similarly, the noexcept-specifier of a specialization of a function template or member function of a class template is instantiated only when needed.

14.6 Special functions

14.6.1 General

The function std::terminate (14.6.2) is used by the exception handling mechanism for coping with errors related to the exception handling mechanism itself. The function std::current_exception() (17.9.7) and the class std::nested_exception (17.9.8) can be used by a program to capture the currently handled exception.

14.6.2 The std::terminate function

[Note 1: These situations are:

14.6.2.1 — when the exception handling mechanism, after completing the initialization of the exception object but before activation of a handler for the exception (14.2), calls a function that exits via an exception, or
14.6.2.2 — when the exception handling mechanism cannot find a handler for a thrown exception (14.4), or
14.6.2.3 — when the search for a handler (14.4) encounters the outermost block of a function with a non-throwing exception specification (14.5), or
14.6.2.4 — when the destruction of an object during stack unwinding (14.3) terminates by throwing an exception, or
14.6.2.5 — when initialization of a non-block variable with static or thread storage duration (6.9.3.3) exits via an exception, or
14.6.2.6 — when destruction of an object with static or thread storage duration exits via an exception (6.9.3.4), or
14.6.2.7 — when execution of a function registered with std::atexit or std::at_quick_exit exits via an exception (17.5), or
14.6.2.8 — when a throw-expression (7.6.18) with no operand attempts to rethrow an exception and no exception is being handled (14.2), or
14.6.2.9 — when the function std::nested_exception::rethrow_nested is called for an object that has captured no exception (17.9.8), or
14.6.2.10 — when execution of the initial function of a thread exits via an exception (32.4.3.3), or
14.6.2.11 — for a parallel algorithm whose ExecutionPolicy specifies such behavior (20.18.4, 20.18.5, 20.18.6), when execution of an element access function (25.3.1) of the parallel algorithm exits via an exception (25.3.4), or
14.6.2.12 — when the destructor or the move assignment operator is invoked on an object of type std::thread that refers to a joinable thread (32.4.3.4, 32.4.3.5), or
14.6.2.13 — when a call to a wait(), wait_until(), or wait_for() function on a condition variable (32.6.4, 32.6.5) fails to meet a postcondition.}
In such cases, the function \texttt{std::terminate} is invoked (17.9.5). In the situation where no matching handler is found, it is implementation-defined whether or not the stack is unwound before \texttt{std::terminate} is invoked. In the situation where the search for a handler (14.4) encounters the outermost block of a function with a non-throwing exception specification (14.5), it is implementation-defined whether the stack is unwound, unwound partially, or not unwound at all before the function \texttt{std::terminate} is invoked. In all other situations, the stack shall not be unwound before the function \texttt{std::terminate} is invoked. An implementation is not permitted to finish stack unwinding prematurely based on a determination that the unwind process will eventually cause an invocation of the function \texttt{std::terminate}.

14.6.3 The \texttt{std::uncaught_exceptions} function

An exception is considered uncaught after completing the initialization of the exception object (14.2) until completing the activation of a handler for the exception (14.4).

[Note 1: As a consequence, an exception is considered uncaught during any stack unwinding resulting from it being thrown. — end note]

If an exception is rethrown (7.6.18, 17.9.7), it is considered uncaught from the point of rethrow until the rethrown exception is caught. The function \texttt{std::uncaught_exceptions} (17.9.6) returns the number of uncaught exceptions in the current thread.

lparen:
   a ( character not immediately preceded by whitespace

§ 15.1
A preprocessing directive consists of a sequence of preprocessing tokens that satisfies the following constraints:

- At the start of translation phase 4, the first token in the sequence, referred to as a directive-introducing token, begins with the first character in the source file (optionally after whitespace containing no new-line characters) or follows whitespace containing at least one new-line character, and is
  
  (1.1) — a # preprocessing token, or
  
  (1.2) — an import preprocessing token immediately followed on the same logical line by a header-name, <, identifier, string-literal, or : preprocessing token, or
  
  (1.3) — a module preprocessing token immediately followed on the same logical line by an identifier, :, or ; preprocessing token, or
  
  (1.4) — an export preprocessing token immediately followed on the same logical line by one of the two preceding forms.

The last token in the sequence is the first token within the sequence that is immediately followed by whitespace containing a new-line character.\(^{136}\)

\[\textbf{Note 1}:\] A new-line character ends the preprocessing directive even if it occurs within what would otherwise be an invocation of a function-like macro. \(-\text{end note}\]

\[\textbf{Example 1}:\]

\begin{verbatim}
#     // preprocessing directive
module ;     // preprocessing directive
export module leftrightpad; // preprocessing directive
import <string>; // preprocessing directive
export import "squee"; // preprocessing directive
import rightpad; // preprocessing directive
import :part; // preprocessing directive
module     // not a preprocessing directive
;          // not a preprocessing directive
export     // not a preprocessing directive
import     // not a preprocessing directive
foo;       // not a preprocessing directive
export     // not a preprocessing directive
import foo; // preprocessing directive (ill-formed at phase 7)
import :: // not a preprocessing directive
import -> // not a preprocessing directive
\end{verbatim}

A sequence of preprocessing tokens is only a text-line if it does not begin with a directive-introducing token. A sequence of preprocessing tokens is only a conditionally-supported-directive if it does not begin with any of the directive names appearing after a # in the syntax. A conditionally-supported-directive is conditionally-supported with implementation-defined semantics.

At the start of phase 4 of translation, the group of a pp-global-module-fragment shall contain neither a text-line nor a pp-import.

\(^{136}\) Thus, preprocessing directives are commonly called “lines”. These “lines” have no other syntactic significance, as all whitespace is equivalent except in certain situations during preprocessing (see the # character string literal creation operator in 15.6.3, for example).
When in a group that is skipped (15.2), the directive syntax is relaxed to allow any sequence of preprocessing tokens to occur between the directive name and the following new-line character.

The only whitespace characters that shall appear between preprocessing tokens within a preprocessing directive (from just after the directive-introducing token through just before the terminating new-line character) are space and horizontal-tab (including spaces that have replaced comments or possibly other whitespace characters in translation phase 3).

The implementation can process and skip sections of source files conditionally, include other source files, import macros from header units, and replace macros. These capabilities are called preprocessing, because conceptually they occur before translation of the resulting translation unit.

The preprocessing tokens within a preprocessing directive are not subject to macro expansion unless otherwise stated.

[Example 2: In:

```c
#define EMPTY
EMPTY # include <file.h>
```

the sequence of preprocessing tokens on the second line is not a preprocessing directive, because it does not begin with a # at the start of translation phase 4, even though it will do so after the macro EMPTY has been replaced. — end example]

## 15.2 Conditional inclusion

[cpp.cond]

```c
defined-macro-expression:
  defined identifier
  defined ( identifier )

h-preprocessing-token:
  any preprocessing-token other than >

h-pp-tokens:
  h-preprocessing-token
  h-pp-tokens h-preprocessing-token

header-name-tokens:
  string-literal
  < h-pp-tokens >

has-include-expression:
  __has_include ( header-name )
  __has_include ( header-name-tokens )

has-attribute-expression:
  __has_cpp_attribute ( pp-tokens )
```

1 The expression that controls conditional inclusion shall be an integral constant expression except that identifiers (including those lexically identical to keywords) are interpreted as described below\(^{137}\) and it may contain zero or more defined-macro-expressions and/or has-include-expressions and/or has-attribute-expressions as unary operator expressions.

2 A defined-macro-expression evaluates to 1 if the identifier is currently defined as a macro name (that is, if it is predefined or if it has one or more active macro definitions (15.5), for example because it has been the subject of a `#define` preprocessing directive without an intervening `#undef` directive with the same subject identifier), 0 if it is not.

3 The second form of has-include-expression is considered only if the first form does not match, in which case the preprocessing tokens are processed just as in normal text.

4 The header or source file identified by the parenthesized preprocessing token sequence in each contained has-include-expression is searched for as if that preprocessing token sequence were the `#include` directive, except that no further macro expansion is performed. If such a directive would not satisfy the syntactic requirements of a `#include` directive, the program is ill-formed. The has-include-expression evaluates to 1 if the search for the source file succeeds, and to 0 if the search fails.

5 Each has-attribute-expression is replaced by a non-zero pp-number matching the form of an integer-literal if the implementation supports an attribute with the name specified by interpreting the pp-tokens, after macro

---

\(^{137}\) Because the controlling constant expression is evaluated during translation phase 4, all identifiers either are or are not macro names — there simply are no keywords, enumeration constants, etc.
expansion, as an attribute-token, and by 0 otherwise. The program is ill-formed if the pp-tokens do not match the form of an attribute-token.

6 For an attribute specified in this document, the value of the has-attribute-expression is given by Table 20. For other attributes recognized by the implementation, the value is implementation-defined.

[Note 1: It is expected that the availability of an attribute can be detected by any non-zero result. — end note]

Table 20: __has_cpp_attribute values  [tab:cpp.cond.ha]

<table>

</table>

7 The #ifdef and #ifndef directives, and the defined conditional inclusion operator, shall treat __has_-include and __has_cpp_attribute as if they were the names of defined macros. The identifiers __has_-include and __has_cpp_attribute shall not appear in any context not mentioned in this subclause.

8 Each preprocessing token that remains (in the list of preprocessing tokens that will become the controlling expression) after all macro replacements have occurred shall be in the lexical form of a token (5.6).

9 Preprocessing directives of the forms

```c
#define constant-expression new-line group
#define constant-expression new-line group
```

check whether the controlling constant expression evaluates to nonzero.

10 Prior to evaluation, macro invocations in the list of preprocessing tokens that will become the controlling constant expression are replaced (except for those macro names modified by the defined unary operator), just as in normal text. If the token defined is generated as a result of this replacement process or use of the defined unary operator does not match one of the two specified forms prior to macro replacement, the behavior is undefined.

11 After all replacements due to macro expansion and evaluations of defined-macro-expressions, has-include-expressions, and has-attribute-expressions have been performed, all remaining identifiers and keywords, except for true and false, are replaced with the pp-number 0, and then each preprocessing token is converted into a token.

[Note 2: An alternative token (5.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not subject to this replacement. — end note]

12 The resulting tokens comprise the controlling constant expression which is evaluated according to the rules of 7.7 using arithmetic that has at least the ranges specified in 17.3. For the purposes of this token conversion and evaluation all signed and unsigned integer types act as if they have the same representation as, respectively, intmax_t or uintmax_t (17.4).

[Note 3: Thus on an implementation where std::numeric_limits<int>::max() is 0x7FFF and std::numeric_limits<unsigned int>::max() is 0xFFFF, the integer literal 0x8000 is signed and positive within a #if expression even though it is unsigned in translation phase 7 (5.2). — end note]

This includes interpreting character-literals, which may involve converting escape sequences into execution character set members. Whether the numeric value for these character-literals matches the value obtained when an identical character-literal occurs in an expression (other than within a #if or #elif directive) is implementation-defined.

[Note 4: Thus, the constant expression in the following #if directive and if statement (8.5.2) is not guaranteed to evaluate to the same value in these two contexts:

```c
#if 'z' - 'a' == 25
if ('z' - 'a' == 25)
```

§ 15.2
Also, whether a single-character character-literal may have a negative value is implementation-defined. Each subexpression with type bool is subjected to integral promotion before processing continues.

Preprocessing directives of the forms

\[
\texttt{# ifdef} \ \texttt{identifier} \ \texttt{new-line} \ \texttt{group}\_	exttt{opt} \\
\texttt{# ifndef} \ \texttt{identifier} \ \texttt{new-line} \ \texttt{group}\_	exttt{opt}
\]

check whether the identifier is or is not currently defined as a macro name. Their conditions are equivalent to \#if defined \texttt{identifier} and \#if !defined \texttt{identifier} respectively.

Each directive’s condition is checked in order. If it evaluates to false (zero), the group that it controls is skipped: directives are processed only through the name that determines the directive in order to keep track of the level of nested conditionals; the rest of the directives’ preprocessing tokens are ignored, as are the other preprocessing tokens in the group. Only the first group whose control condition evaluates to true (nonzero) is processed; any following groups are skipped and their controlling directives are processed as if they were in a group that is skipped. If none of the conditions evaluates to true, and there is a \#else directive, the group controlled by the \#else is processed; lacking a \#else directive, all the groups until the \#endif are skipped.

[Example 1: This demonstrates a way to include a library optional facility only if it is available:

```c
#include <optional>

if (__cpp_lib_optional >= 201603)
define have_optional 1
endif

if (__cpp_lib_experimental_optional >= 201411)
define experimentalOptional 1
endif

ifndef have_optional
define have_optional 0
endif
```
—end example]

[Example 2: This demonstrates a way to use the attribute [[acme::deprecated]] only if it is available.

```c
if (__has_cpp_attribute(acme::deprecated))
define ATTR_DEPRECATED(msg) [[acme::deprecated(msg)]]
else
define ATTR_DEPRECATED(msg) [[deprecated(msg)]]
endif
ATTR_DEPRECATED("This function is deprecated") void anvil();
```
—end example]

15.3 Source file inclusion [cpp.include]

A \#include directive shall identify a header or source file that can be processed by the implementation.

A preprocessing directive of the form

\[
\texttt{# include} \ < \texttt{h-char-sequence}> \ \texttt{new-line}
\]

searches a sequence of implementation-defined places for a header identified uniquely by the specified sequence between the < and > delimiters, and causes the replacement of that directive by the entire contents of the header. How the places are specified or the header identified is implementation-defined.

A preprocessing directive of the form

\[
\texttt{# include} \ " \texttt{q-char-sequence}\ " \ \texttt{new-line}
\]

138) As indicated by the syntax, a preprocessing token cannot follow a \#else or \#endif directive before the terminating new-line character. However, comments can appear anywhere in a source file, including within a preprocessing directive.
causes the replacement of that directive by the entire contents of the source file identified by the specified sequence between the " delimiters. The named source file is searched for in an implementation-defined manner. If this search is not supported, or if the search fails, the directive is reprocessed as if it read

```
#include <h-char-sequence> new-line
```

with the identical contained sequence (including > characters, if any) from the original directive.

4 A preprocessing directive of the form

```
#include pp-tokens new-line
```

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after `include` in the directive are processed just as in normal text (i.e., each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined. The method by which a sequence of preprocessing tokens between a < and a > preprocessing token pair or a pair of " characters is combined into a single header name preprocessing token is implementation-defined.

5 The implementation shall provide unique mappings for sequences consisting of one or more nondigits or digits (5.10) followed by a period (.) and a single nondigit. The first character shall not be a digit. The implementation may ignore distinctions of alphabetical case.

6 A `#include` preprocessing directive may appear in a source file that has been read because of a `#include` directive in another file, up to an implementation-defined nesting limit.

7 If the header identified by the `header-name` denotes an importable header (10.3), it is implementation-defined whether the `#include` preprocessing directive is instead replaced by an `import` directive (15.5) of the form

```
import header-name ; new-line
```

8 [Note 1: An implementation can provide a mechanism for making arbitrary source files available to the `< >` search. However, using the `< >` form for headers provided with the implementation and the " " form for sources outside the control of the implementation achieves wider portability. For instance:

```
#include <stdio.h>
#include <unistd.h>
#include "usefullib.h"
#include "myprog.h"
```

—end note]

9 [Example 1: This illustrates macro-replaced `#include` directives:

```
#if VERSION == 1
#define INCFILE "vers1.h"
#else VERSION == 2
#define INCFILE "vers2.h" // and so on
#else
#define INCFILE "versN.h"
#endif
#include INCFILE
```

—end example]

15.4 Module directive

```
pp-module:
export_opt module pp-tokens_opt ; new-line
```

1 A `pp-module` shall not appear in a context where `module` or (if it is the first token of the `pp-module`) `export` is an identifier defined as an object-like macro.

2 Any preprocessing tokens after the `module` preprocessing token in the `module` directive are processed just as in normal text.

[Note 1: Each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens. — end note]

3 The `module` and `export` (if it exists) preprocessing tokens are replaced by the `module-keyword` and `export-keyword` preprocessing tokens respectively.

139) Note that adjacent string-literals are not concatenated into a single string-literal (see the translation phases in 5.2); thus, an expansion that results in two string-literals is an invalid directive.
15.5 Header unit importation

PP-IMPORT:

export_opt import header-name pp-tokens_opt ; new-line
export_opt import header-name-tokens pp-tokens_opt ; new-line
export_opt import pp-tokens ; new-line

A PP-IMPORT shall not appear in a context where IMPORT or (if it is the first token of the PP-IMPORT) EXPORT is an identifier defined as an object-like macro.

The preprocessing tokens after the IMPORT preprocessing token in the IMPORT control-line are processed just as in normal text (i.e., each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens).

The point of macro import for the first two forms of PP-IMPORT is immediately after the new-line terminating the PP-IMPORT. The last form of PP-IMPORT is only considered if the first two forms did not match, and does not have a point of macro import.

If a PP-IMPORT is produced by source file inclusion (including by the rewrite produced when a #include directive names an importable header) while processing the group of a module-file, the program is ill-formed.

In all three forms of PP-IMPORT, the IMPORT and EXPORT (if it exists) preprocessing tokens are replaced by the IMPORT-KEYWORD and EXPORT-KEYWORD preprocessing tokens respectively.

Additionally, in the second form of PP-IMPORT, a header-name token is formed as if the header-name-tokens were the pp-tokens of a #include directive. The header-name-tokens are replaced by the header-name token.

Each #define directive encountered when preprocessing each translation unit in a program results in a distinct macro definition.

[Note 4: A predefined macro name (15.11) is not introduced by a #define directive. Implementations providing mechanisms to redefine additional macros are encouraged to not treat them as being introduced by a #define directive. — end note]

Each macro definition has at most one point of definition in each translation unit and at most one point of undefinition, as follows:

(5.1) — The point of definition of a macro definition within a translation unit \( T \) is
(5.1.1) — if the #define directive of the macro definition occurs within \( T \), the point at which that directive occurs, or otherwise,
(5.1.2) — if the macro name is not lexically identical to a keyword (5.11) or to the identifiers module or import, the first point of macro import in \( T \) of a header unit containing a point of definition for the macro definition, if any.

In the latter case, the macro is said to be imported from the header unit.

(5.2) — The point of undefinition of a macro definition within a translation unit is the first point at which a #undef directive naming the macro occurs after its point of definition, or the first point of macro import of a header unit containing a point of undefinition for the macro definition, whichever (if any) occurs first.

A macro directive is active at a source location if it has a point of definition in that translation unit preceding the location, and does not have a point of undefinition in that translation unit preceding the location.

If a macro would be replaced or redefined, and multiple macro definitions are active for that macro name, the active macro definitions shall all be valid redefinitions of the same macro (15.6).

[Note 5: The relative order of PP-IMPORTs has no bearing on whether a particular macro definition is active. — end note]
15.6 Macro replacement

15.6.1 General

Two replacement lists are identical if and only if the preprocessing tokens in both have the same number, ordering, spelling, and whitespace separation, where all whitespace separations are considered identical.

An identifier currently defined as an object-like macro (see below) may be redefined by another `#define` preprocessing directive provided that the second definition is an object-like macro definition and the two replacement lists are identical, otherwise the program is ill-formed. Likewise, an identifier currently defined as a function-like macro (see below) may be redefined by another `#define` preprocessing directive provided that the second definition is a function-like macro definition that has the same number and spelling of parameters, and the two replacement lists are identical, otherwise the program is ill-formed.

--- end example

There shall be whitespace between the identifier and the replacement list in the definition of an object-like macro.

If the `identifier-list` in the macro definition does not end with an ellipsis, the number of arguments (including those arguments consisting of no preprocessing tokens) in an invocation of a function-like macro shall equal the number of parameters in the macro definition. Otherwise, there shall be at least as many arguments in the invocation as there are parameters in the macro definition (excluding the `...`). There shall exist a `)` preprocessing token that terminates the invocation.

The identifiers `__VA_ARGS__` and `__VA_OPT__` shall occur only in the `replacement-list` of a function-like macro that uses the ellipsis notation in the parameters.
A parameter identifier in a function-like macro shall be uniquely declared within its scope.

The identifier immediately following the `define` is called the `macro name`. There is one name space for macro names. Any whitespace characters preceding or following the replacement list of preprocessing tokens are not considered part of the replacement list for either form of macro.

If a `#` preprocessing token, followed by an identifier, occurs lexically at the point at which a preprocessing directive can begin, the identifier is not subject to macro replacement.

A preprocessing directive of the form

```
# define identifier replacement-list new-line
```

defines an `object-like macro` that causes each subsequent instance of the macro name to be replaced by the replacement list of preprocessing tokens that constitute the remainder of the directive. The replacement list is then rescanned for more macro names as specified below.

[Example 2]: The simplest use of this facility is to define a “manifest constant”, as in
```
#define TABSIZE 100
int table[TABSIZE];
```

A preprocessing directive of the form

```
# define identifier lparen identifier-list opt ) replacement-list new-line
# define identifier lparen ... ) replacement-list new-line
# define identifier lparen identifier-list , ... ) replacement-list new-line
```

defines a `function-like macro` with parameters, whose use is similar syntactically to a function call. The parameters are specified by the optional list of identifiers. Each subsequent instance of the function-like macro name followed by a `)` as the next preprocessing token introduces the sequence of preprocessing tokens that is replaced by the replacement list in the definition (an invocation of the macro). The replaced sequence of preprocessing tokens is terminated by the matching `)` preprocessing token, skipping intervening matched pairs of left and right parenthesis preprocessing tokens. Within the sequence of preprocessing tokens making up an invocation of a function-like macro, new-line is considered a normal whitespace character.

The sequence of preprocessing tokens bounded by the outside-most matching parentheses forms the list of arguments for the function-like macro. The individual arguments within the list are separated by comma preprocessing tokens, but comma preprocessing tokens between matching inner parentheses do not separate arguments. If there are sequences of preprocessing tokens within the list of arguments that would otherwise act as preprocessing directives, the behavior is undefined.

[Example 3]: The following defines a function-like macro whose value is the maximum of its arguments. It has the disadvantages of evaluating one or the other of its arguments a second time (including side effects) and generating more code than a function if invoked several times. It also cannot have its address taken, as it has none.
```
#define max(a, b) ((a) > (b) ? (a) : (b))
```

The parentheses ensure that the arguments and the resulting expression are bound properly. —end example]

If there is a `)` immediately preceding the `)` in the function-like macro definition, then the trailing arguments (if any), including any separating comma preprocessing tokens, are merged to form a single item: the `variable arguments`. The number of arguments so combined is such that, following merger, the number of arguments is either equal to or one more than the number of parameters in the macro definition (excluding the `...`).

## 15.6.2 Argument substitution

```
va-opt-replacement: __VA_OPT__ ( pp-tokens_opt )
```

After the arguments for the invocation of a function-like macro have been identified, argument substitution takes place. For each parameter in the replacement list that is neither preceded by a `#` or `##` preprocessing token nor followed by a `#` preprocessing token, the preprocessing tokens naming the parameter are replaced by a token sequence determined as follows:

---

140) Since, by macro-replacement time, all `character-literals` and `string-literals` are preprocessing tokens, not sequences possibly containing identifier-like subsequences (see 5.2, translation phases), they are never scanned for macro names or parameters.

141) An alternative token (5.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not possible to define a macro whose name is the same as that of an alternative token.

142) A `conditionally-supported-directive` is a preprocessing directive regardless of whether the implementation supports it.
— If the parameter is of the form \texttt{va-opt-replacement}, the replacement preprocessing tokens are the preprocessing token sequence for the corresponding argument, as specified below.

— Otherwise, the replacement preprocessing tokens are the preprocessing tokens of corresponding argument after all macros contained therein have been expanded. The argument’s preprocessing tokens are completely macro replaced before being substituted as if they formed the rest of the preprocessing file with no other preprocessing tokens being available.

\begin{example}
\begin{verbatim}
#define LPAREN() (                      
#define G(Q) 42                        
#define F(R, X, ...) __VA_OPT__(G R X) )

int x = F(LPAREN(), 0, <:-);    // replaced by int x = 42;
\end{verbatim}
\end{example}

An identifier \texttt{__VA_ARGS__} that occurs in the replacement list shall be treated as if it were a parameter, and the variable arguments shall form the preprocessing tokens used to replace it.

\begin{example}
\begin{verbatim}
#define debug(...) fprintf(stderr, __VA_ARGS__)
#define showlist(...) puts(#__VA_ARGS__)
#define report(test, ...) ((test) ? puts(#test) : printf(__VA_ARGS__))

debug("Flag");
showlist(The first, second, and third items.);
report(x>y, "x is %d but y is %d", x, y);
\end{verbatim}
\end{example}

The identifier \texttt{__VA_OPT__} shall always occur as part of the preprocessing token sequence \texttt{va-opt-replacement}; its closing \texttt{)} is determined by skipping intervening pairs of matching left and right parentheses in its pp-tokens. The pp-tokens of a \texttt{va-opt-replacement} shall not contain \texttt{__VA_OPT__}. If the pp-tokens would be ill-formed as the replacement list of the current function-like macro, the program is ill-formed. A \texttt{va-opt-replacement} is treated as if it were a parameter, and the preprocessing token sequence for the corresponding argument is defined as follows. If the substitution of \texttt{__VA_ARGS__} as neither an operand of \texttt{#} nor \texttt{##} consists of no preprocessing tokens, the argument consists of a single placemarker preprocessing token (15.6.4, 15.6.5). Otherwise, the argument consists of the results of the expansion of the contained pp-tokens as the replacement list of the current function-like macro before removal of placemarker tokens, rescanning, and further replacement.

[Note 1: The placemarker tokens are removed before stringization (15.6.3), and can be removed by rescanning and further replacement (15.6.5). — end note]

\begin{example}
\begin{verbatim}
#define F(...) f(0 __VA_OPT__(,) __VA_ARGS__)
#define G(X, ...) f(0, X __VA_OPT__(,) __VA_ARGS__)
#define SDEF(sname, ...) S sname __VA_OPT__(= { __VA_ARGS__ })
#define EMP
F(a, b, c) // replaced by f(0, a, b, c)
F() // replaced by f(0)
F(EMP) // replaced by f(0)
G(a, b, c) // replaced by f(0, a, b, c)
G(a) // replaced by f(0, a)
G(a) // replaced by f(0, a)
SDEF(foo); // replaced by S foo;
SDEF(bar, 1, 2); // replaced by S bar = { 1, 2 };
\end{verbatim}
\end{example}
```c
#define H1(X, ...) X __VA_OPT__(##) __VA_ARGS__  // error: ## may not appear at
// the beginning of a replacement list (15.6.4)
#define H2(X, Y, ...) __VA_OPT__(X ## Y,) __VA_ARGS__
H2(a, b, c, d)    // replaced by ab, c, d
#define H3(X, ...) #__VA_OPT__(X##X X##X)
H3(, 0)           // replaced by ""
#define H4(X, ...) __VA_OPT__(a X ## X) ## b
H4(, 1)           // replaced by a b
#define H5A(...) __VA_OPT__()/**/__VA_OPT__()  
#define H5B(X) a ## X ## b
#define H5C(X) H5B(X)
H5C(H5A())        // replaced by ab
@end example
```

15.6.3 The `#` operator

1. Each `#` preprocessing token in the replacement list for a function-like macro shall be followed by a parameter as the next preprocessing token in the replacement list.

2. A character string literal is a string-literal with no prefix. If, in the replacement list, a parameter is immediately preceded by a `#` preprocessing token, both are replaced by a single character string literal preprocessing token that contains the spelling of the preprocessing token sequence for the corresponding argument (excluding placemarker tokens). Let the stringizing argument be the preprocessing token sequence for the corresponding argument with placemarkers removed. Each occurrence of whitespace between the stringizing argument’s preprocessing tokens becomes a single space character in the character string literal. White space before the first preprocessing token and after the last preprocessing token comprising the stringizing argument is deleted. Otherwise, the original spelling of each preprocessing token in the stringizing argument is retained in the character string literal, except for special handling for producing the spelling of string-literals and character-literals: a `\` character is inserted before each " and \ character of a character-literal or string-literal (including the delimiting " characters). If the replacement that results is not a valid character string literal, the behavior is undefined. The character string literal corresponding to an empty stringizing argument is "". The order of evaluation of `#` and `##` operators is unspecified.

15.6.4 The `##` operator

1. A `##` preprocessing token shall not occur at the beginning or at the end of a replacement list for either form of macro definition.

2. If, in the replacement list of a function-like macro, a parameter is immediately preceded or followed by a `##` preprocessing token, the parameter is replaced by the corresponding argument’s preprocessing token sequence; however, if an argument consists of no preprocessing tokens, the parameter is replaced by a placemarker preprocessing token instead.\[143\]

3. For both object-like and function-like macro invocations, before the replacement list is reexamined for more macro names to replace, each instance of a `##` preprocessing token in the replacement list (not from an argument) is deleted and the preceding preprocessing token is concatenated with the following preprocessing token. Placemarker preprocessing tokens are handled specially: concatenation of two placemarkers results in a single placemarker preprocessing token, and concatenation of a placemarker with a non-placemarker preprocessing token results in the non-placemarker preprocessing token. If the result is not a valid preprocessing token, the behavior is undefined. The resulting token is available for further macro replacement. The order of evaluation of `##` operators is unspecified.

4. Example 1: The sequence

```c
#define str(s)  # s
#define xstr(s) str(s)
#define debug(s, t) printf("x" # s "x" # t "= %s", \x#s, x ## t)
```

143) Placemarker preprocessing tokens do not appear in the syntax because they are temporary entities that exist only within translation phase 4.
#define INCFILE(n) vers ## n
#define glue(a, b) a ## b
#define xglue(a, b) glue(a, b)
#define HIGHLOW "hello"
#define LOW LOW "", world"
def bug(1, 2);
fputs(str(strncmp("abc\0d", "abc", '\4') // this goes away
== 0) str(: @
), s);
#include xstr(INCFILE(2).h)
glue(HIGH, LOW);
xglue(HIGH, LOW)
results in
printf("x1= %d, x2= %s", x1, x2);
fputs("strncmp("abc\0d", "abc", '\4') == 0": @
", s);
#include "vers2.h"
(after macro replacement, before file access)
"hello";
"hello" ", world"
or, after concatenation of the character string literals,
printf("x1= %d, x2= %s", x1, x2);
#include "vers2.h"
(after macro replacement, before file access)
"hello";
"hello, world"
Space around the # and ## tokens in the macro definition is optional. —end example]

Example 2: In the following fragment:
#define hash_hash # ## #
#define mkstr(a) # a
#define in_between(a) mkstr(a)
#define join(c, d) in_between(c hash_hash d)
char p[] = join(x, y);
// equivalent to char p[] = "x ## y";
The expansion produces, at various stages:

join(x, y)
in_between(x hash_hash y)
in_between(x ## y)
mkstr(x ## y)
"x ## y"
In other words, expanding hash_hash produces a new token, consisting of two adjacent sharp signs, but this new
token is not the ## operator. —end example]

Example 3: To illustrate the rules for placemaker preprocessing tokens, the sequence
#define t(x,y,z) x ## y ## z
int j[] = { t(1,2,3), t(,4,5), t(6,,7), t(8,,),
t(10,,), t(,,11), t(,,12), t(,,) };
results in
int j[] = { 123, 45, 67, 89,
10, 11, 12, };
—end example]

15.6.5 Rescanning and further replacement [cpp.rescan]

After all parameters in the replacement list have been substituted and # and ## processing has taken place, all
placemarker preprocessing tokens are removed. Then the resulting preprocessing token sequence is rescanned,
along with all subsequent preprocessing tokens of the source file, for more macro names to replace.

Example 1: The sequence
#define x 3
#define f(a) f(x * (a))
#undef x
#define x 2

§ 15.6.5 454
#define g f
#define z z[0]
#define h g(~
#define m(a) a(w)
#define w 0,1
#define t(a) a
#define p() int
#define q(x) x
#define r(x,y) x ## y
#define str(x) # x

f(y+1) + f(f(z)) % t(t(g)(0) + t)(1);
g(x+(3,4)-w) | h 5) & m
(f)^m(m);
p() i[q()] = { q(1), r(2,3), r(4,), r(,5), r(,) };
char c[2][6] = { str(hello), str() };
results in
f(2 * (y+1)) + f(2 * (f(2 * (z[0]))) % f(2 * (0)) + t(1));
f(2 * (2+(3,4)-0,1)) | f(2 * (~ 5)) & f(2 * (0,1))^m(0,1);
int i[] = { 1, 23, 4, 5, };
char c[2][6] = { "hello", "" };
—end example]
3 If the name of the macro being replaced is found during this scan of the replacement list (not including the rest of the source file’s preprocessing tokens), it is not replaced. Furthermore, if any nested replacements encounter the name of the macro being replaced, it is not replaced. These nonreplaced macro name preprocessing tokens are no longer available for further replacement even if they are later (re)examined in contexts in which that macro name preprocessing token would otherwise have been replaced.

4 The resulting completely macro-replaced preprocessing token sequence is not processed as a preprocessing directive even if it resembles one, but all pragma unary operator expressions within it are then processed as specified in 15.12 below.

15.6.6 Scope of macro definitions [cpp.scope]
1 A macro definition lasts (independent of block structure) until a corresponding #undef directive is encountered or (if none is encountered) until the end of the translation unit. Macro definitions have no significance after translation phase 4.

2 A preprocessing directive of the form

   # undef identifier new-line

causes the specified identifier no longer to be defined as a macro name. It is ignored if the specified identifier is not currently defined as a macro name.

15.7 Line control [cpp.line]
1 The string-literal of a #line directive, if present, shall be a character string literal.

2 The line number of the current source line is one greater than the number of new-line characters read or introduced in translation phase 1 (5.2) while processing the source file to the current token.

3 A preprocessing directive of the form

   # line digit-sequence new-line

causes the implementation to behave as if the following sequence of source lines begins with a source line that has a line number as specified by the digit sequence (interpreted as a decimal integer). If the digit sequence specifies zero or a number greater than 2147483647, the behavior is undefined.

4 A preprocessing directive of the form

   # line digit-sequence " s-char-sequenceopt " new-line

sets the presumed line number similarly and changes the presumed name of the source file to be the contents of the character string literal.

5 A preprocessing directive of the form

   # line pp-tokens new-line

§ 15.7
(that does not match one of the two previous forms) is permitted. The preprocessing tokens after `line` on the directive are processed just as in normal text (each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined; otherwise, the result is processed as appropriate.

### 15.8 Error directive

A preprocessing directive of the form

```
# error pp-tokens_opt new-line
```

causes the implementation to produce a diagnostic message that includes the specified sequence of preprocessing tokens, and renders the program ill-formed.

### 15.9 Pragma directive

A preprocessing directive of the form

```
# pragma pp-tokens_opt new-line
```

causes the implementation to behave in an implementation-defined manner. The behavior may cause translation to fail or cause the translator or the resulting program to behave in a non-conforming manner. Any pragma that is not recognized by the implementation is ignored.

### 15.10 Null directive

A preprocessing directive of the form

```
# new-line
```

has no effect.

### 15.11 Predefined macro names

The following macro names shall be defined by the implementation:

- `__cplusplus`
  - The integer literal `202002L`.
  - [Note 1: Future revisions of C++ will replace the value of this macro with a greater value. — end note]

The names listed in Table 21 shall be defined to the corresponding integer literal.

- [Note 2: Future revisions of C++ might replace the values of these macros with greater values. — end note]

- `__DATE__`
  - The date of translation of the source file: a character string literal of the form "Mmm dd yyyy", where the names of the months are the same as those generated by the `asctime` function, and the first character of `dd` is a space character if the value is less than 10. If the date of translation is not available, an implementation-defined valid date shall be supplied.

- `__FILE__`
  - The presumed name of the current source file (a character string literal).

- `__LINE__`
  - The presumed line number (within the current source file) of the current source line (an integer literal).

- `__STDC_HOSTED__`
  - The integer literal 1 if the implementation is a hosted implementation or the integer literal 0 if it is a freestanding implementation (4.1).

- `__STDCPP_DEFAULT_NEW_ALIGNMENT__`
  - An integer literal of type `std::size_t` whose value is the alignment guaranteed by a call to `operator new(std::size_t)` or `operator new[](std::size_t)`.
  - [Note 3: Larger alignments will be passed to `operator new(std::size_t, std::align_val_t)`, etc. (7.6.2.8). — end note]

144) The presumed source file name can be changed by the `#line` directive.
145) The presumed line number can be changed by the `#line` directive.
The time of translation of the source file: a character string literal of the form "hh:mm:ss" as in the time generated by the \texttt{asctime} function. If the time of translation is not available, an implementation-defined valid time shall be supplied.

2 The following macro names are conditionally defined by the implementation:

```c
__STDC__
```
Whether __STDC__ is predefined and if so, what its value is, are implementation-defined.

```c
__STDC_MB_MIGHT_NEQ_WC__
```
The integer literal 1, intended to indicate that, in the encoding for `wchar_t`, a member of the basic character set need not have a code value equal to its value when used as the lone character in an ordinary character literal.

```c
__STDC_VERSION__
```
Whether __STDC_VERSION__ is predefined and if so, what its value is, are implementation-defined.

```c
__STDC_ISO_10646__
```
An integer literal of the form `yyyymmL` (for example, 199712L). If this symbol is defined, then every character in the Unicode required set, when stored in an object of type `wchar_t`, has the same value as the code point of that character. The Unicode required set consists of all the characters that are defined by ISO/IEC 10646, along with all amendments and technical corrigenda as of the specified year and month.

```c
__STDCPP STRICT POINTER SAFETY__
```
Defined, and has the value integer literal 1, if and only if the implementation has strict pointer safety (6.7.5.5.4).

```c
__STDCPP THREADS__
```
Defined, and has the value integer literal 1, if and only if a program can have more than one thread of execution (6.9.2).

3 The values of the predefined macros (except for __FILE__ and __LINE__) remain constant throughout the translation unit.

4 If any of the pre-defined macro names in this subclause, or the identifier `defined`, is the subject of a `#define` or a `#undef` preprocessing directive, the behavior is undefined. Any other predefined macro names shall begin with a leading underscore followed by an uppercase letter or a second underscore.

### 15.12 Pragma operator

A unary operator expression of the form:

```c
_Pragma ( string-literal )
```

is processed as follows: The `string-literal` is destringized by deleting the L prefix, if present, deleting the leading and trailing double-quotes, replacing each escape sequence \" by a double-quote, and replacing each escape sequence \\ by a single backslash. The resulting sequence of characters is processed through translation phase 3 to produce preprocessing tokens that are executed as if they were the `pp-tokens` in a pragma directive. The original four preprocessing tokens in the unary operator expression are removed.

2 [Example 1:

```c
#pragma listing on ".\listing.dir"
```
can also be expressed as:

```c
#define LISTING(x) PRAGMA(listing on #x)
#define PRAGMA(x) _Pragma(#x)
```

LISTING( ..\listing.dir )

— end example]
16 Library introduction

16.1 General

This Clause describes the contents of the C++ standard library, how a well-formed C++ program makes use of the library, and how a conforming implementation may provide the entities in the library.

The following subclauses describe the method of description (16.3) and organization (16.4.2) of the library. 16.4, Clause 17 through Clause 32, and Annex D specify the contents of the library, as well as library requirements and constraints on both well-formed C++ programs and conforming implementations.

Detailed specifications for each of the components in the library are in Clause 17–Clause 32, as shown in Table 22.

</tbody>
</table>

The language support library (Clause 17) provides components that are required by certain parts of the C++ language, such as memory allocation (7.6.2.8, 7.6.2.9) and exception processing (Clause 14).

The concepts library (Clause 18) describes library components that C++ programs may use to perform compile-time validation of template arguments and perform function dispatch based on properties of types.

The diagnostics library (Clause 19) provides a consistent framework for reporting errors in a C++ program, including predefined exception classes.

The general utilities library (Clause 20) includes components used by other library elements, such as a predefined storage allocator for dynamic storage management (6.7.5.5), and components used as infrastructure in C++ programs, such as tuples and function wrappers.

The strings library (Clause 21) provides support for manipulating text represented as sequences of type char, sequences of type char8_t, sequences of type char16_t, sequences of type char32_t, sequences of type wchar_t, and sequences of any other character-like type.

The containers (Clause 22), iterators (Clause 23), ranges (Clause 24), and algorithms (Clause 25) libraries provide a C++ program with access to a subset of the most widely used algorithms and data structures.

The numerics library (Clause 26) provides numeric algorithms and complex number components that extend support for numeric processing. The valarray component provides support for n-at-a-time processing, potentially implemented as parallel operations on platforms that support such processing. The random number component provides facilities for generating pseudo-random numbers.

The time library (Clause 27) provides generally useful time utilities.

The localization library (Clause 28) provides extended internationalization support for text processing.

§ 16.1
The input/output library (Clause 29) provides the *iostream* components that are the primary mechanism for C++ program input and output. They can be used with other elements of the library, particularly strings, locales, and iterators.

The regular expressions library (Clause 30) provides regular expression matching and searching.

The atomic operations library (Clause 31) allows more fine-grained concurrent access to shared data than is possible with locks.

The thread support library (Clause 32) provides components to create and manage threads, including mutual exclusion and interthread communication.

### 16.2 The C standard library

The C++ standard library also makes available the facilities of the C standard library, suitably adjusted to ensure static type safety.

The descriptions of many library functions rely on the C standard library for the semantics of those functions. In some cases, the signatures specified in this document may be different from the signatures in the C standard library, and additional overloads may be declared in this document, but the behavior and the preconditions (including any preconditions implied by the use of an ISO C *restrict* qualifier) are the same unless otherwise stated.

### 16.3 Method of description

#### 16.3.1 General

Subclause 16.3 describes the conventions used to specify the C++ standard library. 16.3.2 describes the structure of Clause 17 through Clause 32 and Annex D. 16.3.3 describes other editorial conventions.

#### 16.3.2 Structure of each clause

Each library clause contains the following elements, as applicable:

1. Summary
2. Requirements
3. Detailed specifications
4. References to the C standard library

#### 16.3.2.1 Elements

- Summary
- Requirements
- Detailed specifications
- References to the C standard library

#### 16.3.2.2 Summary

The Summary provides a synopsis of the category, and introduces the first-level subclauses. Each subclause also provides a summary, listing the headers specified in the subclause and the library entities provided in each header.

The contents of the summary and the detailed specifications include:

- macros
- values
- types and alias templates
- classes and class templates
- functions and function templates
- objects and variable templates
- concepts

#### 16.3.2.3 Requirements

Requirements describe constraints that shall be met by a C++ program that extends the standard library. Such extensions are generally one of the following:

- Template arguments
- Derived classes

146) To save space, items that do not apply to a Clause are omitted. For example, if a Clause does not specify any requirements, there will be no “Requirements” subclause.
Containers, iterators, and algorithms that meet an interface convention or model a concept

The string and iostream components use an explicit representation of operations required of template arguments. They use a class template `char_traits` to define these constraints.

Interface convention requirements are stated as generally as possible. Instead of stating “class `X` has to define a member function `operator++()`”, the interface requires “for any object `x` of class `X`, `++x` is defined”. That is, whether the operator is a member is unspecified.

Requirements are stated in terms of well-defined expressions that define valid terms of the types that meet the requirements. For every set of well-defined expression requirements there is either a named concept or a table that specifies an initial set of the valid expressions and their semantics. Any generic algorithm (Clause 25) that uses the well-defined expression requirements is described in terms of the valid expressions for its template type parameters.

The library specification uses a typographical convention for naming requirements. Names in *italic* type that begin with the prefix `Cpp17` refer to sets of well-defined expression requirements typically presented in tabular form, possibly with additional prose semantic requirements. For example, `Cpp17Destructible` (Table 34) is such a named requirement. Names in *constant width* type refer to library concepts which are presented as a concept definition (Clause 13), possibly with additional prose semantic requirements. For example, `destructible` (18.4.10) is such a named requirement.

Template argument requirements are sometimes referenced by name. See 16.3.3.3.

In some cases the semantic requirements are presented as C++ code. Such code is intended as a specification of equivalence of a construct to another construct, not necessarily as the way the construct must be implemented.\(^{147}\)

Required operations of any concept defined in this document need not be total functions; that is, some arguments to a required operation may result in the required semantics failing to be met.

> [Example 1: The required `<` operator of the `totally_ordered` concept (18.5.4) does not meet the semantic requirements of that concept when operating on NaNs. — end example]

This does not affect whether a type models the concept.

A declaration may explicitly impose requirements through its associated constraints (13.5.3). When the associated constraints refer to a concept (13.7.9), the semantic constraints specified for that concept are additionally imposed on the use of the declaration.

### Detailed specifications

The detailed specifications each contain the following elements:

1. **name and brief description**
2. **synopsis (class definition or function declaration, as appropriate)**
3. **restrictions on template arguments, if any**
4. **description of class invariants**
5. **description of function semantics**

Descriptions of class member functions follow the order (as appropriate):\(^{148}\)

1. **constructor(s) and destructor**
2. **copying, moving & assignment functions**
3. **comparison operator functions**
4. **modifier functions**
5. **observer functions**
6. **operators and other non-member functions**

Descriptions of function semantics contain the following elements (as appropriate):\(^{149}\)

---

147) Although in some cases the code given is unambiguously the optimum implementation.

148) To save space, items that do not apply to a class are omitted. For example, if a class does not specify any comparison operator functions, there will be no “Comparison operator functions” subclause.

149) To save space, elements that do not apply to a function are omitted. For example, if a function specifies no preconditions, there will be no *Preconditions:* element.
© ISO/IEC N4885

— **Constraints**: the conditions for the function’s participation in overload resolution (12.2).

  [Note 1: Failure to meet such a condition results in the function’s silent non-viability. — end note]

  [Example 1: An implementation can express such a condition via a constraint-expression (13.5.3). — end example]

— **Mandates**: the conditions that, if not met, render the program ill-formed.

  [Example 2: An implementation can express such a condition via the constant-expression in a static_assert-declaration (9.1). If the diagnostic is to be emitted only after the function has been selected by overload resolution, an implementation can express such a condition via a constraint-expression (13.5.3) and also define the function as deleted. — end example]

— **Preconditions**: the conditions that the function assumes to hold whenever it is called; violation of any preconditions results in undefined behavior.

— **Effects**: the actions performed by the function.

— **Synchronization**: the synchronization operations (6.9.2) applicable to the function.

— **Postconditions**: the conditions (sometimes termed observable results) established by the function.

— **Returns**: a description of the value(s) returned by the function.

— **Throws**: any exceptions thrown by the function, and the conditions that would cause the exception.

— **Complexity**: the time and/or space complexity of the function.

— **Remarks**: additional semantic constraints on the function.

— **Error conditions**: the error conditions for error codes reported by the function.

4 Whenever the Effects element specifies that the semantics of some function F are Equivalent to some code sequence, then the various elements are interpreted as follows. If F’s semantics specifies any Constraints or Mandates elements, then those requirements are logically imposed prior to the equivalent-to semantics. Next, the semantics of the code sequence are determined by the Constraints, Mandates, Preconditions, Effects, Synchronization, Postconditions, Returns, Throws, Complexity, Remarks, and Error conditions specified for the function invocations contained in the code sequence. The value returned from F is specified by F’s Returns element, or if F has no Returns element, a non-void return from F is specified by the return statements (8.7.4) in the code sequence. If F’s semantics contains a Throws, Postconditions, or Complexity element, then that supersedes any occurrences of that element in the code sequence.

5 For non-reserved replacement and handler functions, Clause 17 specifies two behaviors for the functions in question: their required and default behavior. The default behavior describes a function definition provided by the implementation. The required behavior describes the semantics of a function definition provided by either the implementation or a C++ program. Where no distinction is explicitly made in the description, the behavior described is the required behavior.

6 If the formulation of a complexity requirement calls for a negative number of operations, the actual requirement is zero operations.\(^{(1)}\)

7 Complexity requirements specified in the library clauses are upper bounds, and implementations that provide better complexity guarantees meet the requirements.

8 Error conditions specify conditions where a function may fail. The conditions are listed, together with a suitable explanation, as the enum class errc constants (19.5).

16.3.2.5 C library

1 Paragraphs labeled “See also” contain cross-references to the relevant portions of other standards (Clause 2).

16.3.3 Other conventions

16.3.3.1 General

Subclause 16.3.3 describes several editorial conventions used to describe the contents of the C++ standard library. These conventions are for describing implementation-defined types (16.3.3.3), and member functions (16.3.3.4).

\(^{(1)}\) This simplifies the presentation of complexity requirements in some cases.
16.3.3.2 Exposition-only functions

Several function templates defined in Clause 17 through Clause 32 and Annex D are only defined for the purpose of exposition. The declaration of such a function is followed by a comment ending in exposition only.

The following are defined for exposition only to aid in the specification of the library:

```cpp
template<class T> constexpr decay_t<T> decay-copy(T&& v) noexcept(is_nothrow_convertible_v<T,decay_t<T>>) // exposition only
{
    return std::forward<T>(v);
}
```

```cpp
constexpr auto synth-three-way = []<class T, class U>(const T& t, const U& u) requires requires {
    { t < u } -> boolean-testable;
    { u < t } -> boolean-testable;
}
{
    if constexpr (three_way_comparable_with<T, U>) {
        return t <=> u;
    } else {
        if (t < u) return weak_ordering::less;
        if (u < t) return weak_ordering::greater;
        return weak_ordering::equivalent;
    }
};
```

```cpp
template<class T, class U=T>
using synth-three-way-result = decltype(synth-three-way(declval<T&>(), declval<U&>()));
```

16.3.3.3 Type descriptions

16.3.3.3.1 General

The Requirements subclauses may describe names that are used to specify constraints on template arguments. These names are used in library Clauses to describe the types that may be supplied as arguments by a C++ program when instantiating template components from the library.

Certain types defined in Clause 29 are used to describe implementation-defined types. They are based on other types, but with added constraints.

16.3.3.3.2 Exposition-only types

Several types defined in Clause 17 through Clause 32 and Annex D are defined for the purpose of exposition. The declaration of such a type is followed by a comment ending in exposition only.

```cpp
namespace std {
    extern "C" using some-handler = int(int, void*, double); // exposition only
}
```

The type placeholder some-handler can now be used to specify a function that takes a callback parameter with C language linkage.

16.3.3.3.3 Enumerated types

Several types defined in Clause 29 are enumerated types. Each enumerated type may be implemented as an enumeration or as a synonym for an enumeration.

The enumerated type enumerated can be written:

```cpp
enum enumerated { V0, V1, V2, V3, ... };
```

151) Examples from 16.4.4 include: Cpp17EqualityComparable, Cpp17LessThanComparable, Cpp17CopyConstructible. Examples from 23.3 include: Cpp17InputIterator, Cpp17ForwardIterator.

152) Such as an integer type, with constant integer values (6.8.2).
Here, the names $C_0$, $C_1$, etc. represent enumerated elements for this particular enumerated type. All such elements have distinct values.

16.3.3.3.4 Bitmask types

Several types defined in Clause 17 through Clause 32 and Annex D are bitmask types. Each bitmask type can be implemented as an enumerated type that overloads certain operators, as an integer type, or as a set (20.9.2).

2 The bitmask type bitmask can be written:

```c
// For exposition only.
// int_type is an integral type capable of representing all values of the bitmask type.
enum bitmask : int_type {
    V0 = 1 << 0, V1 = 1 << 1, V2 = 1 << 2, V3 = 1 << 3, ...
};
```

```c
inline constexpr bitmask C0(V0);
inline constexpr bitmask C1(V1);
inline constexpr bitmask C2(V2);
inline constexpr bitmask C3(V3);
```

```c
constexpr bitmask operator&(bitmask X, bitmask Y) {
    return static_cast<bitmask>(static_cast<int_type>(X) & static_cast<int_type>(Y));
}
```

```c
constexpr bitmask operator|(bitmask X, bitmask Y) {
    return static_cast<bitmask>(static_cast<int_type>(X) | static_cast<int_type>(Y));
}
```

```c
constexpr bitmask operator^(bitmask X, bitmask Y) {
    return static_cast<bitmask>(static_cast<int_type>(X) ^ static_cast<int_type>(Y));
}
```

```c
constexpr bitmask operator~(bitmask X) {
    return static_cast<bitmask>(~static_cast<int_type>(X));
}
```

```c
bitmask& operator&=(bitmask& X, bitmask Y) {
    X = X & Y; return X;
}
```

```c
bitmask& operator|=(bitmask& X, bitmask Y) {
    X = X | Y; return X;
}
```

```c
bitmask& operator^=(bitmask& X, bitmask Y) {
    X = X ^ Y; return X;
}
```

Here, the names $C_0$, $C_1$, etc. represent bitmask elements for this particular bitmask type. All such elements have distinct, nonzero values such that, for any pair $C_i$ and $C_j$ where $i \neq j$, $C_i$ & $C_j$ is nonzero and $C_i$ & $C_j$ is zero. Additionally, the value 0 is used to represent an empty bitmask, in which no bitmask elements are set.

4 The following terms apply to objects and values of bitmask types:

- (4.1) To set a value $Y$ in an object $X$ is to evaluate the expression $X |\text{= } Y$.
- (4.2) To clear a value $Y$ in an object $X$ is to evaluate the expression $X &\text{= } Y$.
- (4.3) The value $Y$ is set in the object $X$ if the expression $X & Y$ is nonzero.

16.3.3.3.5 Character sequences

16.3.3.3.5.1 General

The C standard library makes widespread use of characters and character sequences that follow a few uniform conventions:
A letter is any of the 26 lowercase or 26 uppercase letters in the basic execution character set.

The decimal-point character is the (single-byte) character used by functions that convert between a (single-byte) character sequence and a value of one of the floating-point types. It is used in the character sequence to denote the beginning of a fractional part. It is represented in Clause 17 through Clause 32 and Annex D by a period, '.', which is also its value in the "C" locale, but may change during program execution by a call to std::setlocale(int, const char*),\(^{153}\) or by a change to a locale object, as described in 28.3 and Clause 29.

A character sequence is an array object (9.3.4.5) \(A\) that can be declared as \(T A[N]\), where \(T\) is any of the types char, unsigned char, or signed char (6.8.2), optionally qualified by any combination of const or volatile. The initial elements of the array have defined contents up to and including an element determined by some predicate. A character sequence can be designated by a pointer value \(S\) that points to its first element.

16.3.3.5.2 Byte strings \([\text{byte.strings}]\)

A null-terminated byte string, or NTBS, is a character sequence whose highest-addressed element with defined content has the value zero (the terminating null character); no other element in the sequence has the value zero.\(^{154}\)

The length of an NTBS is the number of elements that precede the terminating null character. An empty NTBS has a length of zero.

The value of an NTBS is the sequence of values of the elements up to and including the terminating null character.

A static NTBS is an NTBS with static storage duration.\(^{155}\)

16.3.3.5.3 Multibyte strings \([\text{multibyte.strings}]\)

A null-terminated multibyte string, or NTMBS, is an NTBS that constitutes a sequence of valid multibyte characters, beginning and ending in the initial shift state.\(^{156}\)

A static NTMBS is an NTMBS with static storage duration.

16.3.3.6 Customization Point Object types \([\text{customization.point.object}]\)

A customization point object is a function object (20.14) with a literal class type that interacts with program-defined types while enforcing semantic requirements on that interaction.

The type of a customization point object, ignoring cv-qualifiers, shall model semiregular (18.6).

All instances of a specific customization point object type shall be equal (18.2).

The type \(T\) of a customization point object shall model invocable<const T&, Args...> (18.7.2) when the types in Args... meet the requirements specified in that customization point object’s definition. When the types of Args... do not meet the customization point object’s requirements, \(T\) shall not have a function call operator that participates in overload resolution.

Each customization point object type constrains its return type to model a particular concept.

[Note 1: Many of the customization point objects in the library evaluate function call expressions with an unqualified name which results in a call to a program-defined function found by argument dependent name lookup (6.5.4). To preclude such an expression resulting in a call to unconstrained functions with the same name in namespace std, customization point objects specify that lookup for these expressions is performed in a context that includes deleted overloads matching the signatures of overloads defined in namespace std. When the deleted overloads are viable, program-defined overloads need be more specialized (13.7.7.3) or more constrained (13.5.5) to be used by a customization point object. — end note]  

16.3.3.4 Functions within classes \([\text{functions.within.classes}]\)

For the sake of exposition, Clause 17 through Clause 32 and Annex D do not describe copy/move constructors, assignment operators, or (non-virtual) destructors with the same apparent semantics as those that can be

---

153) declared in <locale> (28.5.1).
154) Many of the objects manipulated by function signatures declared in <cstring> (21.5.3) are character sequences or NTBSs. The size of some of these character sequences is limited by a length value, maintained separately from the character sequence.
155) A string-literal, such as "abc", is a static NTBS.
156) An NTBS that contains characters only from the basic execution character set is also an NTMBS. Each multibyte character then consists of a single byte.
generated by default (11.4.5.3, 11.4.6, 11.4.7). It is unspecified whether the implementation provides explicit definitions for such member function signatures, or for virtual destructors that can be generated by default.

16.3.3.5 Private members

Clause 17 through Clause 32 and Annex D do not specify the representation of classes, and intentionally omit specification of class members (11.4). An implementation may define static or non-static class members, or both, as needed to implement the semantics of the member functions specified in Clause 17 through Clause 32 and Annex D.

For the sake of exposition, some subclauses provide representative declarations, and semantic requirements, for private members of classes that meet the external specifications of the classes. The declarations for such members are followed by a comment that ends with exposition only, as in:

```
streambuf* sb;     // exposition only
```

An implementation may use any technique that provides equivalent observable behavior.

16.4 Library-wide requirements

16.4.1 General

Subclause 16.4 specifies requirements that apply to the entire C++ standard library. Clause 17 through Clause 32 and Annex D specify the requirements of individual entities within the library.

Requirements specified in terms of interactions between threads do not apply to programs having only a single thread of execution.

16.4.2 describes the library’s contents and organization, 16.4.3 describes how well-formed C++ programs gain access to library entities, 16.4.4 describes constraints on types and functions used with the C++ standard library, 16.4.5 describes constraints on well-formed C++ programs, and 16.4.6 describes constraints on conforming implementations.

16.4.2 Library contents and organization

16.4.2.1 General

16.4.2.2 describes the entities and macros defined in the C++ standard library. 16.4.2.3 lists the standard library headers and some constraints on those headers. 16.4.2.4 lists requirements for a freestanding implementation of the C++ standard library.

16.4.2.2 Library contents

The C++ standard library provides definitions for the entities and macros described in the synopses of the C++ standard library headers (16.4.2.3), unless otherwise specified.

All library entities except operator new and operator delete are defined within the namespace std or namespaces nested within namespace std.157 It is unspecified whether names declared in a specific namespace are declared directly in that namespace or in an inline namespace inside that namespace.158

Whenever a name x defined in the standard library is mentioned, the name x is assumed to be fully qualified as ::std::x, unless explicitly described otherwise. For example, if the Effects: element for library function F is described as calling library function G, the function ::std::G is meant.

16.4.2.3 Headers

Each element of the C++ standard library is declared or defined (as appropriate) in a header.159

The C++ standard library provides the C++ library headers, shown in Table 23.

The facilities of the C standard library are provided in the additional headers shown in Table 24.160

The headers listed in Table 23, or, for a freestanding implementation, the subset of such headers that are provided by the implementation, are collectively known as the importable C++ library headers.

[Note 1: Importable C++ library headers can be imported as module units (10.3). —end note]
Table 23: C++ library headers  [tab:headers.cpp]

| <algorithm>  | <forward_list>  | <numbers>  | <streambuf>  |
| <any>        | <fstream>       | <numeric>  | <string>     |
| <array>      | <functional>    | <optional> | <string_view>|
| <atomic>     | <future>        | <ostream>  | <streambuf>  |
| <barrier>    | <initializer_list> | <queue>    | <sstream>    |
| <bit>        | <iomani>        | <random>   | <system_error>|
| <bitset>     | <ios>           | <ranges>   | <thread>     |
| <chrono>     | <iosfwd>        | <ratio>    | <tuple>      |
| <compare>    | <iostream>      | <regex>    | <typeindex>  |
| <complex>    | <iostream>      | <scopulatedallocator> | <typeinfo>  |
| <concepts>   | <list>          | <semaphore> | <type_traits>|
| <coroutine>  | <latch>         | <set>      | <unordered_map>|
| <deque>      | <limits>        | <shared_mutex> | <unordered_set>|
| <exception>  | <locale>        | <source_location> | <utility>  |
| <execution>  | <locale>        | <span>     | <valarray>   |
| <filesystem> | <map>           | <sstream>  | <variant>    |
| <format>     | <memory>        | <stack>    | <vector>     |
| <functional> | <memory_resource> | <stacktrace> | <version>   |
| <future>     | <mutex>         | <stdexcept>          |
| <initializer_list> | <new> | <stop_token>|

Table 24: C++ headers for C library facilities  [tab:headers.cpp.c]

| <cassert>    | <cfenv>         | <climits>   | <csetjmp>   | <cstddef>   | <cstdint> |
| <cctype>     | <cfloat>        | <clocale>   | <csignal>   | <cstdlib>   | <cstring> |
| <cerrno>     | <cstdarg>       | <cstdio>    | <cstddef>   | <cstdlib>   | <ctime>   |
| <cuchar>     | <cwchar>        | <cwctype>   |             |             |          |

[Example 1:]

```cpp
import <vector>;  // imports the <vector> header unit
std::vector<int> vi;  // OK
```

—end example]

5 Except as noted in Clause 16 through Clause 32 and Annex D, the contents of each header <name> is the same as that of the corresponding header name.h as specified in the C standard library (Clause 2). In the C++ standard library, however, the declarations (except for names which are defined as macros in C) are within namespace scope (6.4.5) of the namespace std. It is unspecified whether these names (including any overloads added in Clause 17 through Clause 32 and Annex D) are first declared within the global namespace scope and are then injected into namespace std by explicit using-declarations (9.9).

6 Names which are defined as macros in C shall be defined as macros in the C++ standard library, even if C grants license for implementation as functions.

[Note 2: The names defined as macros in C include the following: assert, offsetof, setjmp, va_arg, va_end, and va_start. —end note]

7 Names that are defined as functions in C shall be defined as functions in the C++ standard library.161

8 Identifiers that are keywords or operators in C++ shall not be defined as macros in C++ standard library headers.162

9 D.11, C standard library headers, describes the effects of using the name.h (C header) form in a C++ program.163

161) This disallows the practice, allowed in C, of providing a masking macro in addition to the function prototype. The only way to achieve equivalent inline behavior in C++ is to provide a definition as an extern inline function.

162) In particular, including the standard header <iso646.h> has no effect.

163) The "<".h" headers dump all their names into the global namespace, whereas the newer forms keep their names in namespace std. Therefore, the newer forms are the preferred forms for all uses except for C++ programs which are intended to be strictly compatible with C.
Annex K of the C standard describes a large number of functions, with associated types and macros, which “promote safer, more secure programming” than many of the traditional C library functions. The names of the functions have a suffix of _s, most of them provide the same service as the C library function with the unsuffixed name, but generally take an additional argument whose value is the size of the result array. If any C++ header is included, it is implementation-defined whether any of these names is declared in the global namespace. (None of them is declared in namespace std.)

Table 25 lists the Annex K names that may be declared in some header. These names are also subject to the restrictions of 16.4.5.3.3.

16.4.2.4 Freestanding implementations

Two kinds of implementations are defined: hosted and freestanding (4.1); the kind of the implementation is implementation-defined. For a hosted implementation, this document describes the set of available headers.

A freestanding implementation has an implementation-defined set of headers. This set shall include at least the headers shown in Table 26.

The supplied version of the header <cstdlib> (17.2.2) shall declare at least the functions abort, atexit, at_quick_exit, exit, and quick_exit (17.5). The supplied version of the header <atomic> (31.2) shall meet the same requirements as for a hosted implementation except that support for always lock-free integral atomic types (31.5) is implementation-defined, and whether or not the type aliases atomic_signed_lock_free and atomic_unsigned_lock_free are defined (31.3) is implementation-defined. The other headers listed in this table shall meet the same requirements as for a hosted implementation.

16.4.3 Using the library

16.4.3.1 Overview

Subclause 16.4.3 describes how a C++ program gains access to the facilities of the C++ standard library. 16.4.3.2 describes effects during translation phase 4, while 16.4.3.3 describes effects during phase 8 (5.2).

16.4.3.2 Headers

The entities in the C++ standard library are defined in headers, whose contents are made available to a translation unit when it contains the appropriate #include preprocessing directive (15.3) or the appropriate import declaration (10.3).

A translation unit may include library headers in any order (5.1). Each may be included more than once, with no effect different from being included exactly once, except that the effect of including either <cassert> (19.3.2) or <assert.h> (D.11) depends each time on the lexically current definition of NDEBUG.
Table 26: C++ headers for freestanding implementations [tab:headers.cpp.fs]

3 A translation unit shall include a header only outside of any declaration or definition and, in the case of a module unit, only in its global-module-fragment, and shall include the header or import the corresponding header unit lexically before the first reference in that translation unit to any of the entities declared in that header. No diagnostic is required.

16.4.3.3 Linkage [using.linkage]

1 Entities in the C++ standard library have external linkage (6.6). Unless otherwise specified, objects and functions have the default extern "C++" linkage (9.11).

2 Whether a name from the C standard library declared with external linkage has extern "C" or extern "C++" linkage is implementation-defined. It is recommended that an implementation use extern "C++" linkage for this purpose.165

3 Objects and functions defined in the library and required by a C++ program are included in the program prior to program startup.

4 See also replacement functions (16.4.5.6), runtime changes (16.4.5.7).

16.4.4 Requirements on types and expressions [utility.requirements]

16.4.4.1 General [utility.requirements.general]
1 16.4.4.2 describes requirements on types and expressions used to instantiate templates defined in the C++ standard library. 16.4.4.3 describes the requirements on swappable types and swappable expressions. 16.4.4.4 describes the requirements on pointer-like types that support null values. 16.4.4.5 describes the requirements on hash function objects. 16.4.4.6 describes the requirements on storage allocators.

16.4.4.2 Template argument requirements [utility.arg.requirements]
1 The template definitions in the C++ standard library refer to various named requirements whose details are set out in Tables 27–34. In these tables, T is an object or reference type to be supplied by a C++ program instantiating a template; a, b, and c are values of type (possibly const) T; s and t are modifiable lvalues of type T; u denotes an identifier; rv is an rvalue of type T; and v is an lvalue of type (possibly const) T or an rvalue of type const T.

2 In general, a default constructor is not required. Certain container class member function signatures specify T() as a default argument. T() shall be a well-defined expression (9.4) if one of those signatures is called using the default argument (9.3.4.7).

165) The only reliable way to declare an object or function signature from the C standard library is by including the header that declares it, notwithstanding the latitude granted in 7.1.4 of the C Standard.

</tr>
</tbody>
</table>

16.4.4.3 Swappable requirements [swappable.requirements]

1. This subclause provides definitions for swappable types and expressions. In these definitions, let \( t \) denote an expression of type \( T \), and let \( u \) denote an expression of type \( U \).

2. An object \( t \) is swappable with an object \( u \) if and only if:

   a. the expressions \( \text{swap}(t, u) \) and \( \text{swap}(u, t) \) are valid when evaluated in the context described below, and
Table 32: Cpp17MoveAssignable requirements

</tr>
</tbody>
</table>

Table 34: Cpp17Destructible requirements  

<table>
<thead>
<tr>
<th>Expression</th>
<th>Post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>u.~T()</td>
<td>All resources owned by u are reclaimed, no exception is propagated.</td>
</tr>
</tbody>
</table>

[Note 3: Array types and non-object types are not Cpp17Destructible. — end note]

(2.2) — these expressions have the following effects:

(2.2.1) — the object referred to by t has the value originally held by u and

(2.2.2) — the object referred to by u has the value originally held by t.

3 The context in which swap(t, u) and swap(u, t) are evaluated shall ensure that a binary non-member function named “swap” is selected via overload resolution (12.2) on a candidate set that includes:

(3.1) — the two swap function templates defined in <utility> (20.2.1) and

(3.2) — the lookup set produced by argument-dependent lookup (6.5.4).

[Note 1: If T and U are both fundamental types or arrays of fundamental types and the declarations from the header <utility> are in scope, the overall lookup set described above is equivalent to that of the qualified name lookup applied to the expression std::swap(t, u) or std::swap(u, t) as appropriate. — end note]

[Note 2: It is unspecified whether a library component that has a swappable requirement includes the header <utility> to ensure an appropriate evaluation context. — end note]

4 An rvalue or lvalue t is swappable if and only if t is swappable with any rvalue or lvalue, respectively, of type T.

5 A type X meeting any of the iterator requirements (23.3) meets the Cpp17ValueSwappable requirements if, for any dereferenceable object x of type X, *x is swappable.

6 [Example 1: User code can ensure that the evaluation of swap calls is performed in an appropriate context under the various conditions as follows:

```cpp
#include <utility>

// Requires: std::forward<T>(t) shall be swappable with std::forward<U>(u).
template<class T, class U>
void value_swap(T&& t, U&& u) {
    using std::swap;
    swap(std::forward<T>(t), std::forward<U>(u)); // OK: uses “swappable with” conditions
    // for rvalues and lvalues
}
```

§ 16.4.4.3 472
// Requires: lvalues of T shall be swappable.

```cpp
template<class T>
void lv_swap(T& t1, T& t2) {
    using std::swap;
    swap(t1, t2);  // OK: uses swappable conditions for lvalues of type T
}
```

```cpp
namespace N {
    struct A { int m; }
    struct Proxy { A* a; }
    Proxy proxy(A& a) { return Proxy{ &a }; }

    void swap(A& x, Proxy p) {  // OK: uses context equivalent to swappable
        std::swap(x.m, p.a->m);
        // conditions for fundamental types
    }
    void swap(Proxy p, A& x) { swap(x, p); }  // satisfy symmetry constraint
}
```

```cpp
int main() {
    int i = 1, j = 2;
    lv_swap(i, j);
    assert(i == 2 && j == 1);
    N::A a1 = { 5 }, a2 = { -5 };
    value_swap(a1, proxy(a2));  // satisfy symmetry constraint
    assert(a1.m == -5 && a2.m == 5);
}
```

—end example—

16.4.4.4 Cpp17NullablePointer requirements [nullpointer.requirements]

A Cpp17NullablePointer type is a pointer-like type that supports null values. A type P meets the Cpp17NullablePointer requirements if:

1.1 — P meets the Cpp17EqualityComparable, Cpp17DefaultConstructible, Cpp17CopyConstructible, Cpp17CopyAssignable, and Cpp17Destructible requirements,

1.2 — lvalues of type P are swappable (16.4.4.3),

1.3 — the expressions shown in Table 35 are valid and have the indicated semantics, and

1.4 — P meets all the other requirements of this subclause.

A value-initialized object of type P produces the null value of the type. The null value shall be equivalent only to itself. A default-initialized object of type P may have an indeterminate value.

[Note 1: Operations involving indeterminate values can cause undefined behavior. — end note]

An object p of type P can be contextually converted to bool (7.3). The effect shall be as if p != nullptr had been evaluated in place of p.

No operation which is part of the Cpp17NullablePointer requirements shall exit via an exception.

In Table 35, u denotes an identifier, t denotes a non-const lvalue of type P, a and b denote values of type (possibly const) P, and np denotes a value of type (possibly const) std::nullptr_t.

16.4.4.5 Cpp17Hash requirements [hash.requirements]

A type H meets the Cpp17Hash requirements if:

1.1 — it is a function object type (20.14),

1.2 — it meets the Cpp17CopyConstructible (Table 31) and Cpp17Destructible (Table 34) requirements, and

1.3 — the expressions shown in Table 36 are valid and have the indicated semantics.

Given Key is an argument type for function objects of type H, in Table 36 h is a value of type (possibly const) H, u is an lvalue of type Key, and k is a value of a type convertible to (possibly const) Key.

16.4.4.6 Cpp17Allocator requirements [allocator.requirements]

16.4.4.6.1 General [allocator.requirements.general]

1 The library describes a standard set of requirements for allocators, which are class-type objects that encapsulate the information about an allocation model. This information includes the knowledge of pointer types, the type of their difference, the type of the size of objects in this allocation model, as well as the memory allocation and deallocation primitives for it. All of the string types (Clause 21), containers (Clause 22) (except array), string buffers and string streams (Clause 29), and match_results (Clause 30) are parameterized in terms of allocators.

2 The class template allocator_traits (20.10.9) supplies a uniform interface to all allocator types. Table 37 describes the types manipulated through allocators. Table 38 describes the requirements on allocator types and thus on types used to instantiate allocator_traits. A requirement is optional if the last column of Table 38 specifies a default for a given expression. Within the standard library allocator_traits template, an optional requirement that is not supplied by an allocator is replaced by the specified default expression. A user specialization of allocator_traits may provide different defaults and may provide defaults for different requirements than the primary template. Within Tables 37 and 38, the use of move and forward always refers to std::move and std::forward, respectively.

<td>is_empty&lt;X&gt;::type</td>
</tr>
</tbody>
</table>

---

3 Note A: The member class template rebind in the table above is effectively a typedef template.

4 Note B: If X::propagate_on_container_copy_assignment::value is true, X shall meet the Cpp17CopyAssignable requirements (Table 33) and the copy operation shall not throw exceptions. If X::propagate_on_container_move_assignment::value is true, X shall meet the Cpp17MoveAssignable requirements (Table 32) and the move operation shall not throw exceptions. If X::propagate_on_container_swap::value is true, X shall be swappable (16.4.4.3) and the swap operation shall not throw exceptions. An allocator type X shall meet the Cpp17CopyConstructible requirements (Table 31). The X::pointer, X::const_pointer, X::void_pointer, and X::const_void_pointer types shall meet the Cpp17NullablePointer requirements (Table 35). No constructor, comparison operator function, copy operation, move operation, or swap operation on these pointer types shall exit via an exception. X::pointer and X::const_pointer shall also meet the requirements for a Cpp17RandomAccessIterator (23.3.5.7) and the additional requirement that, when a and (a + n) are dereferenceable pointer values for some integral value n, addressof(*(a + n)) == addressof(*a) + n is true.

5 Let x1 and x2 denote objects of (possibly different) types X::void_pointer, X::const_void_pointer, X::pointer, or X::const_ptr. Then, x1 and x2 are equivalently-valued pointer values, if and only if both x1 and x2 can be explicitly converted to the two corresponding objects px1 and px2 of type X::const_

pointer, using a sequence of static_casts using only these four types, and the expression px1 == px2 evaluates to true.

7 Let w1 and w2 denote objects of type X::void_pointer. Then for the expressions
   w1 == w2
   w1 != w2
either or both objects may be replaced by an equivalently-valued object of type X::const_void_pointer with no change in semantics.

8 Let p1 and p2 denote objects of type X::pointer. Then for the expressions
   p1 == p2
   p1 != p2
   p1 < p2
   p1 <= p2
   p1 > p2
   p1 >= p2
   p1 - p2
either or both objects may be replaced by an equivalently-valued object of type X::const_pointer with no change in semantics.

9 An allocator may constrain the types on which it can be instantiated and the arguments for which its construct or destroy members may be called. If a type cannot be used with a particular allocator, the allocator class or the call to construct or destroy may fail to instantiate.

10 If the alignment associated with a specific over-aligned type is not supported by an allocator, instantiation of the allocator for that type may fail. The allocator also may silently ignore the requested alignment.

[Note 3: Additionally, the member function allocate for that type can fail by throwing an object of type bad_alloc. — end note]

[Example 2: The following is an allocator class template supporting the minimal interface that meets the requirements of Table 38:]

§ 16.4.4.6.1 478
template<class Tp>
struct SimpleAllocator {
    typedef Tp value_type;
    SimpleAllocator(ctor args);

    template<class T> SimpleAllocator(const SimpleAllocator<T>& other);

    [[nodiscard]] Tp* allocate(std::size_t n);
    void deallocate(Tp* p, std::size_t n);
};

template<class T, class U>
bool operator==(const SimpleAllocator<T>&, const SimpleAllocator<U>&);

16.4.4.6.2 Allocator completeness requirements

If X is an allocator class for type T, X additionally meets the allocator completeness requirements if, whether or not T is a complete type:

(1.1) — X is a complete type, and
(1.2) — all the member types of allocator_traits<X> other than value_type are complete types.

16.4.5 Constraints on programs

16.4.5.1 Overview

Subclause 16.4.5 describes restrictions on C++ programs that use the facilities of the C++ standard library. The following subclauses specify constraints on the program’s use of namespaces (16.4.5.2.1), its use of various reserved names (16.4.5.3), its use of headers (16.4.5.4), its use of standard library classes as base classes (16.4.5.5), its definitions of replacement functions (16.4.5.6), and its installation of handler functions during execution (16.4.5.7).

16.4.5.2 Namespace use

16.4.5.2.1 Namespace std

Unless otherwise specified, the behavior of a C++ program is undefined if it adds declarations or definitions to namespace std or to a namespace within namespace std.

2 Unless explicitly prohibited, a program may add a template specialization for any standard library class template to namespace std provided that (a) the added declaration depends on at least one program-defined type and (b) the specialization meets the standard library requirements for the original template.\(^\text{167}\)

3 The behavior of a C++ program is undefined if it declares an explicit or partial specialization of any standard library variable template, except where explicitly permitted by the specification of that variable template.

4 The behavior of a C++ program is undefined if it declares

(4.1) — an explicit specialization of any member function of a standard library class template, or
(4.2) — an explicit specialization of any member function template of a standard library class or class template, or
(4.3) — an explicit or partial specialization of any member class template of a standard library class or class template, or
(4.4) — a deduction guide for any standard library class template.

A program may explicitly instantiate a class template defined in the standard library only if the declaration (a) depends on the name of at least one program-defined type and (b) the instantiation meets the standard library requirements for the original template.

6 Let F denote a standard library function (16.4.6.4), a standard library static member function, or an instantiation of a standard library function template. Unless F is designated an addressable function, the

\(^{167}\) Any library code that instantiates other library templates must be prepared to work adequately with any user-supplied specialization that meets the minimum requirements of this document.
behavior of a C++ program is unspecified (possibly ill-formed) if it explicitly or implicitly attempts to form a pointer to \( F \).

[Note 1: Possible means of forming such pointers include application of the unary `&` operator (7.6.2.2), `addressof` (20.10.11), or a function-to-pointer standard conversion (7.3.4). — end note]

Moreover, the behavior of a C++ program is unspecified (possibly ill-formed) if it attempts to form a reference to \( F \) or if it attempts to form a pointer-to-member designating either a standard library non-static member function (16.4.6.5) or an instantiation of a standard library member function template.

7 Other than in namespace `std` or in a namespace within namespace `std`, a program may provide an overload for any library function template designated as a customization point, provided that (a) the overload’s declaration depends on at least one user-defined type and (b) the overload meets the standard library requirements for the customization point.\(^{168}\)

[Note 2: This permits a (qualified or unqualified) call to the customization point to invoke the most appropriate overload for the given arguments. — end note]

8 A translation unit shall not declare namespace `std` to be an inline namespace (9.8.2).

16.4.5.2.2 Namespace `posix` \(^{[namespace.posix]}\)

The behavior of a C++ program is undefined if it adds declarations or definitions to namespace `posix` or to a namespace within namespace `posix` unless otherwise specified. The namespace `posix` is reserved for use by ISO/IEC/IEEE 9945 and other POSIX standards.

16.4.5.2.3 Namespaces for future standardization \(^{[namespace.future]}\)

Top-level namespaces whose `namespace-name` consists of `std` followed by one or more digits (5.10) are reserved for future standardization. The behavior of a C++ program is undefined if it adds declarations or definitions to such a namespace.

[Example 1: The top-level namespace `std2` is reserved for use by future revisions of this International Standard. — end example]

16.4.5.3 Reserved names \(^{[reserved.names]}\)

16.4.5.3.1 General \(^{[reserved.names.general]}\)

The C++ standard library reserves the following kinds of names:

(1.1) — macros
(1.2) — global names
(1.3) — names with external linkage

2 If a program declares or defines a name in a context where it is reserved, other than as explicitly allowed by Clause 16, its behavior is undefined.

16.4.5.3.2 Zombie names \(^{[zombie.names]}\)

In namespace `std`, the following names are reserved for previous standardization:

(1.1) — `auto_ptr`,
(1.2) — `auto_ptr_ref`,
(1.3) — `binary_function`,
(1.4) — `binary_negate`,
(1.5) — `bind1st`,
(1.6) — `bind2nd`,
(1.7) — `binder1st`,
(1.8) — `binder2nd`,
(1.9) — `const_mem_fun1_ref_t`,

\(^{168}\) Any library customization point must be prepared to work adequately with any user-defined overload that meets the minimum requirements of this document. Therefore an implementation can elect, under the as-if rule (6.9.1), to provide any customization point in the form of an instantiated function object (20.14) even though the customization point’s specification is in the form of a function template. The template parameters of each such function object and the function parameters and return type of the object’s `operator()` must match those of the corresponding customization point’s specification.
The following names are reserved as member types for previous standardization, and may not be used as a name for object-like macros in portable code:

2 The following names are reserved as member types for previous standardization, and may not be used as a name for object-like macros in portable code:

- argument_type,
- first_argument_type,
- io_state,
- open_mode,
- second_argument_type,
- seek_dir.

3 The name stossc is reserved as a member function for previous standardization, and may not be used as a name for function-like macros in portable code.

4 The header names <ccomplex>, <ciso646>, <cstlalign>, <cstlbool>, and <ctcmath> are reserved for previous standardization.
16.4.5.3.3 Macro names

1 A translation unit that includes a standard library header shall not \#define or \#undef names declared in any standard library header.

2 A translation unit shall not \#define or \#undef names lexically identical to keywords, to the identifiers listed in Table 4, or to the attribute-tokens described in 9.12, except that the names likely and unlikely may be defined as function-like macros (15.6).

16.4.5.3.4 External linkage

1 Each name declared as an object with external linkage in a header is reserved to the implementation to designate that library object with external linkage, both in namespace std and in the global namespace.

2 Each global function signature declared with external linkage in a header is reserved to the implementation to designate that function signature with external linkage.

3 Each name from the C standard library declared with external linkage is reserved to the implementation for use as a name with extern "C" linkage, both in namespace std and in the global namespace.

4 Each function signature from the C standard library declared with external linkage is reserved to the implementation for use as a function signature with both extern "C" and extern "C++" linkage, or as a name of namespace scope in the global namespace.

16.4.5.3.5 Types

1 For each type \( T \) from the C standard library, the types \( ::T \) and \( \text{std}::T \) are reserved to the implementation and, when defined, \( ::T \) shall be identical to \( \text{std}::T \).

16.4.5.3.6 User-defined literal suffixes

1 Literal suffix identifiers (12.6) that do not start with an underscore are reserved for future standardization.

16.4.5.4 Headers

1 If a file with a name equivalent to the derived file name for one of the C++ standard library headers is not provided as part of the implementation, and a file with that name is placed in any of the standard places for a source file to be included (15.3), the behavior is undefined.

16.4.5.5 Derived classes

1 Virtual member function signatures defined for a base class in the C++ standard library may be overridden in a derived class defined in the program (11.7.3).

16.4.5.6 Replacement functions

1 Clause 17 through Clause 32 and Annex D describe the behavior of numerous functions defined by the C++ standard library. Under some circumstances, however, certain of these function descriptions also apply to replacement functions defined in the program.

2 A C++ program may provide the definition for any of the following dynamic memory allocation function signatures declared in header <new> (6.7.5.5, 17.6.2):

- \( \text{operator new(\text{std}::size\_t)} \)
- \( \text{operator new(\text{std}::size\_t, \text{std}::\text{align}\_val\_t)} \)
- \( \text{operator new(\text{std}::size\_t, \text{const std}::\text{nothrow\_t}}) \)
- \( \text{operator new(\text{std}::size\_t, \text{std}::\text{align}\_val\_t, \text{const std}::\text{nothrow\_t}}) \)
- \( \text{operator delete(\text{void}*)} \)
- \( \text{operator delete(\text{void}*, \text{std}::\text{size}\_t)} \)
- \( \text{operator delete(\text{void}*, \text{std}::\text{align}\_val\_t)} \)
- \( \text{operator delete(\text{void}*, \text{std}::\text{size}\_t, \text{std}::\text{align}\_val\_t)} \)
- \( \text{operator delete(\text{void}*, \text{const std}::\text{nothrow\_t}}) \)
- \( \text{operator delete(\text{void}*, \text{std}::\text{align}\_val\_t, \text{const std}::\text{nothrow\_t}}) \)

---

169) The list of such reserved names includes errno, declared or defined in <cerrno> (19.4.2).
170) The list of such reserved function signatures with external linkage includes setjmp(jmp_buf), declared or defined in <csetjmp> (17.13.3), and va_end(va_list), declared or defined in <cstdlib> (17.13.2).
171) The function signatures declared in <uchar> (21.5.5), <wchar> (21.5.4), and <cwctype> (21.5.2) are always reserved, notwithstanding the restrictions imposed in subclause 4.5.1 of Amendment 1 to the C Standard for these headers.
operator new[](std::size_t)
operator new[](std::size_t, std::align_val_t)
operator new[](std::size_t, const std::nothrow_t&)
operator new[](std::size_t, std::align_val_t, const std::nothrow_t&)
operator delete[](void*)
operator delete[](void*, std::size_t)
operator delete[](void*, std::align_val_t)
operator delete[](void*, std::size_t, std::align_val_t)
operator delete[](void*, const std::nothrow_t&)
operator delete[](void*, std::align_val_t, const std::nothrow_t&)

3 The program’s definitions are used instead of the default versions supplied by the implementation (17.6.3). Such replacement occurs prior to program startup (6.3, 6.9.3). The program’s declarations shall not be specified as inline. No diagnostic is required.

16.4.5.7 Handler functions

The C++ standard library provides a default version of the following handler function (Clause 17):

1 — terminate_handler

2 A C++ program may install different handler functions during execution, by supplying a pointer to a function defined in the program or the library as an argument to (respectively):

(2.1) — set_new_handler
(2.2) — set_terminate

See also subclauses 17.6.4, Storage allocation errors, and 17.9, Exception handling.

3 A C++ program can get a pointer to the current handler function by calling the following functions:

(3.1) — get_new_handler
(3.2) — get_terminate

Calling the set_* and get_* functions shall not incur a data race. A call to any of the set_* functions shall synchronize with subsequent calls to the same set_* function and to the corresponding get_* function.

16.4.5.8 Other functions

In certain cases (replacement functions, handler functions, operations on types used to instantiate standard library template components), the C++ standard library depends on components supplied by a C++ program. If these components do not meet their requirements, this document places no requirements on the implementation.

2 In particular, the effects are undefined in the following cases:

(2.1) — For replacement functions (17.6.3), if the installed replacement function does not implement the semantics of the applicable Required behavior: paragraph.
(2.2) — For handler functions (17.6.4.3, 17.9.5.1), if the installed handler function does not implement the semantics of the applicable Required behavior: paragraph.
(2.3) — For types used as template arguments when instantiating a template component, if the operations on the type do not implement the semantics of the applicable Requirements subclause (16.4.4.6, 22.2, 23.3, 25.2, 26.2). Operations on such types can report a failure by throwing an exception unless otherwise specified.
(2.4) — If any replacement function or handler function or destructor operation exits via an exception, unless specifically allowed in the applicable Required behavior: paragraph.
(2.5) — If an incomplete type (6.8) is used as a template argument when instantiating a template component or evaluating a concept, unless specifically allowed for that component.

16.4.5.9 Function arguments

Each of the following applies to all arguments to functions defined in the C++ standard library, unless explicitly stated otherwise.

(1.1) — If an argument to a function has an invalid value (such as a value outside the domain of the function or a pointer invalid for its intended use), the behavior is undefined.
If a function argument is described as being an array, the pointer actually passed to the function shall have a value such that all address computations and accesses to objects (that would be valid if the pointer did point to the first element of such an array) are in fact valid.

If a function argument binds to an rvalue reference parameter, the implementation may assume that this parameter is a unique reference to this argument, except that the argument passed to a move-assignment operator may be a reference to *this (16.4.6.16).

[Note 1: If the type of a parameter is a forwarding reference (13.10.3.2) that is deduced to an lvalue reference type, then the argument is not bound to an rvalue reference. — end note]

[Note 2: If a program casts an lvalue to an xvalue while passing that lvalue to a library function (e.g., by calling the function with the argument std::move(x)), the program is effectively asking that function to treat that lvalue as a temporary object. The implementation is free to optimize away aliasing checks which would possibly be needed if the argument was an lvalue. — end note]

16.4.5.10 Library object access

The behavior of a program is undefined if calls to standard library functions from different threads may introduce a data race. The conditions under which this may occur are specified in 16.4.6.10.

[Note 1: Modifying an object of a standard library type that is shared between threads risks undefined behavior unless objects of that type are explicitly specified as being shareable without data races or the user supplies a locking mechanism. — end note]

2 If an object of a standard library type is accessed, and the beginning of the object’s lifetime (6.7.3) does not happen before the access, or the access does not happen before the end of the object’s lifetime, the behavior is undefined unless otherwise specified.

[Note 2: This applies even to objects such as mutexes intended for thread synchronization. — end note]

16.4.5.11 Semantic requirements

A sequence Args of template arguments is said to model a concept C if Args satisfies C (13.5.3) and meets all semantic requirements (if any) given in the specification of C.

2 If the validity or meaning of a program depends on whether a sequence of template arguments models a concept, and the concept is satisfied but not modeled, the program is ill-formed, no diagnostic required.

3 If the semantic requirements of a declaration’s constraints (16.3.2.3) are not modeled at the point of use, the program is ill-formed, no diagnostic required.

16.4.6 Conforming implementations

16.4.6.1 Overview

Subclause 16.4.6 describes the constraints upon, and latitude of, implementations of the C++ standard library.

2 An implementation’s use of headers is discussed in 16.4.6.2, its use of macros in 16.4.6.3, non-member functions in 16.4.6.4, member functions in 16.4.6.5, data race avoidance in 16.4.6.10, access specifiers in 16.4.6.11, class derivation in 16.4.6.12, and exceptions in 16.4.6.13.

16.4.6.2 Headers

A C++ header may include other C++ headers. A C++ header shall provide the declarations and definitions that appear in its synopsis. A C++ header shown in its synopsis as including other C++ headers shall provide the declarations and definitions that appear in the synopses of those other headers.

2 Certain types and macros are defined in more than one header. Every such entity shall be defined such that any header that defines it may be included after any other header that also defines it (6.3).

3 The C standard library headers (D.11) shall include only their corresponding C++ standard library header, as described in 16.4.2.3.

16.4.6.3 Restrictions on macro definitions

The names and global function signatures described in 16.4.2.2 are reserved to the implementation.

2 All object-like macros defined by the C standard library and described in this Clause as expanding to integral constant expressions are also suitable for use in #if preprocessor directives, unless explicitly stated otherwise.
16.4.6.4 Non-member functions

1 It is unspecified whether any non-member functions in the C++ standard library are defined as inline (9.2.8).

2 A call to a non-member function signature described in Clause 17 through Clause 32 and Annex D shall behave as if the implementation declared no additional non-member function signatures.\(^ {172}\)

3 An implementation shall not declare a non-member function signature with additional default arguments.

4 Unless otherwise specified, calls made by functions in the standard library to non-operator, non-member functions do not use functions from another namespace which are found through argument-dependent name lookup (6.5.4).

[Note 1: The phrase “unless otherwise specified” applies to cases such as the swappable with requirements (16.4.4.3). The exception for overloaded operators allows argument-dependent lookup in cases like that of \texttt{ostream\_iterator::operator=} (23.6.3.3):

\begin{itemize}
  \item Effects:
    \begin{itemize}
      \item *\texttt{out\_stream} << \texttt{value};
      \item if (\texttt{delim} != 0)
        \begin{itemize}
          \item *\texttt{out\_stream} << \texttt{delim};
        \end{itemize}
      \item return *this;
    \end{itemize}
\end{itemize}

—end note]

16.4.6.5 Member functions

1 It is unspecified whether any member functions in the C++ standard library are defined as inline (9.2.8).

2 For a non-virtual member function described in the C++ standard library, an implementation may declare a different set of member function signatures, provided that any call to the member function that would select an overload from the set of declarations described in this document behaves as if that overload were selected.

[Note 1: For instance, an implementation can add parameters with default values, or replace a member function with default arguments with two or more member functions with equivalent behavior, or add additional signatures for a member function name. —end note]

16.4.6.6 Friend functions

1 Whenever this document specifies a friend declaration of a function or function template within a class or class template definition, that declaration shall be the only declaration of that function or function template provided by an implementation.

[Note 1: In particular, an implementation is not allowed to provide an additional declaration of that function or function template at namespace scope. —end note]

[Note 2: Such a friend function or function template declaration is known as a hidden friend, as it is visible neither to ordinary unqualified lookup (6.5.3) nor to qualified lookup (6.5.5). —end note]

16.4.6.7 constexpr functions and constructors

1 This document explicitly requires that certain standard library functions are constexpr (9.2.6). An implementation shall not declare any standard library function signature as constexpr except for those where it is explicitly required. Within any header that provides any non-defining declarations of constexpr functions or constructors an implementation shall provide corresponding definitions.

16.4.6.8 Requirements for stable algorithms

1 When the requirements for an algorithm state that it is “stable” without further elaboration, it means:

\begin{enumerate}
  \item For the sort algorithms the relative order of equivalent elements is preserved.
  \item For the remove and copy algorithms the relative order of the elements that are not removed is preserved.
  \item For the merge algorithms, for equivalent elements in the original two ranges, the elements from the first range (preserving their original order) precede the elements from the second range (preserving their original order).
\end{enumerate}

16.4.6.9 Reentrancy

1 Except where explicitly specified in this document, it is implementation-defined which functions in the C++ standard library may be recursively reentered.

\footnote{\( ^{172}\) A valid C++ program always calls the expected library non-member function. An implementation can also define additional non-member functions that would otherwise not be called by a valid C++ program.}
16.4.6.10 Data race avoidance

1 This subclause specifies requirements that implementations shall meet to prevent data races (6.9.2). Every standard library function shall meet each requirement unless otherwise specified. Implementations may prevent data races in cases other than those specified below.

2 A C++ standard library function shall not directly or indirectly access objects (6.9.2) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s arguments, including this.

3 A C++ standard library function shall not directly or indirectly modify objects (6.9.2) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s non-const arguments, including this.

4 [Note 1: This means, for example, that implementations can’t use an object with static storage duration for internal purposes without synchronization because doing so can cause a data race even in programs that do not explicitly share objects between threads. — end note]

5 A C++ standard library function shall not access objects indirectly accessible via its arguments or via elements of its container arguments except by invoking functions required by its specification on those container elements.

6 Operations on iterators obtained by calling a standard library container or string member function may access the underlying container, but shall not modify it.

7 Implementations may share their own internal objects between threads if the objects are not visible to users and are protected against data races.

8 Unless otherwise specified, C++ standard library functions shall perform all operations solely within the current thread if those operations have effects that are visible (6.9.2) to users.

9 [Note 3: This allows implementations to parallelize operations if there are no visible side effects. — end note]

16.4.6.11 Protection within classes

1 It is unspecified whether any function signature or class described in Clause 17 through Clause 32 and Annex D is a friend of another class in the C++ standard library.

16.4.6.12 Derived classes

1 An implementation may derive any class in the C++ standard library from a class with a name reserved to the implementation.

2 Certain classes defined in the C++ standard library are required to be derived from other classes in the C++ standard library. An implementation may derive such a class directly from the required base or indirectly through a hierarchy of base classes with names reserved to the implementation.

3 In any case:

(3.1) Every base class described as virtual shall be virtual;

(3.2) Every base class not specified as virtual shall not be virtual;

(3.3) Unless explicitly stated otherwise, types with distinct names shall be distinct types. 173

4 All types specified in the C++ standard library shall be non-final types unless otherwise specified.

16.4.6.13 Restrictions on exception handling

1 Any of the functions defined in the C++ standard library can report a failure by throwing an exception of a type described in its Throws: paragraph, or of a type derived from a type named in the Throws: paragraph that would be caught by an exception handler for the base type.

2 Functions from the C standard library shall not throw exceptions except when such a function calls a program-supplied function that throws an exception. 175

---

173) There is an implicit exception to this rule for types that are described as synonyms for basic integral types, such as size_t (17.2) and streamoff (29.5.2).

174) That is, the C library functions can all be treated as if they are marked noexcept. This allows implementations to make performance optimizations based on the absence of exceptions at runtime.

175) The functions qsort() and bsearch() (25.12) meet this condition.
Destructor operations defined in the C++ standard library shall not throw exceptions. Every destructor in the C++ standard library shall behave as if it had a non-throwing exception specification.

Functions defined in the C++ standard library that do not have a *Throws:* paragraph but do have a potentially-throwing exception specification may throw implementation-defined exceptions. Implementations should report errors by throwing exceptions of or derived from the standard exception classes (17.6.4.1, 17.9, 19.2).

An implementation may strengthen the exception specification for a non-virtual function by adding a non-throwing exception specification.

16.4.6.14 Restrictions on storage of pointers

Objects constructed by the standard library that may hold a user-supplied pointer value or an integer of type `std::intptr_t` shall store such values in a traceable pointer location (6.7.5.5.4).

16.4.6.15 Value of error codes

Certain functions in the C++ standard library report errors via a `std::error_code` (19.5.4.1) object. That object's `category()` member shall return `std::system_category()` for errors originating from the operating system, or a reference to an implementation-defined `error_category` object for errors originating elsewhere. The implementation shall define the possible values of `value()` for each of these error categories.

[Example 1: For operating systems that are based on POSIX, implementations should define the `std::system_category` values as identical to the POSIX `errno` values, with additional values as defined by the operating system’s documentation. Implementations for operating systems that are not based on POSIX should define values identical to the operating system’s values. For errors that do not originate from the operating system, the implementation may provide enums for the associated values. — end example]

16.4.6.16 Moved-from state of library types

Objects of types defined in the C++ standard library may be moved from (11.4.5.3). Move operations may be explicitly specified or implicitly generated. Unless otherwise specified, such moved-from objects shall be placed in a valid but unspecified state.

An object of a type defined in the C++ standard library may be move-assigned (11.4.6) to itself. Unless otherwise specified, such an assignment places the object in a valid but unspecified state.
17 Language support library

17.1 General

This Clause describes the function signatures that are called implicitly, and the types of objects generated implicitly, during the execution of some C++ programs. It also describes the headers that declare these function signatures and define any related types.

The following subclauses describe common type definitions used throughout the library, characteristics of the predefined types, functions supporting start and termination of a C++ program, support for dynamic memory management, support for dynamic type identification, support for exception processing, support for initializer lists, and other runtime support, as summarized in Table 39.

lldiv_t lldiv(long long int numer, long long int denom);

1 The contents and meaning of the header <cstdlib> are the same as the C standard library header <stdlib.h>, except that it does not declare the type wchar_t, and except as noted in 17.2.3, 17.2.4, 17.5, 20.10.12, 21.5.6, 25.12, 26.6.10, and 26.8.2.

[Note 1: Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (16.2). — end note]

See also: ISO C 7.22

17.2.3 Null pointers

The type nullptr_t is a synonym for the type of a nullptr expression, and it has the characteristics described in 6.8.2 and 7.3.12.

[Note 1: Although nullptr_t’s address cannot be taken, the address of another nullptr_t object that is an lvalue can be taken. — end note]

The macro NULL is an implementation-defined null pointer constant.\(^{177}\)

See also: ISO C 7.19

17.2.4 Sizes, alignments, and offsets

The macro offsetof(type, member-designator) has the same semantics as the corresponding macro in the C standard library header <stddef.h>, but accepts a restricted set of type arguments in this document. Use of the offsetof macro with a type other than a standard-layout class (11.2) is conditionally-supported.\(^{178}\)

\(^{177}\) Possible definitions include 0 and 0L, but not (void*)0.

\(^{178}\) Note that offsetof is required to work as specified even if unary operator& is overloaded for any of the types involved.
The expression `offsetof(type, member-designator)` is never type-dependent (13.8.3.3) and it is value-dependent (13.8.3.4) if and only if `type` is dependent. The result of applying the `offsetof` macro to a static data member or a function member is undefined. No operation invoked by the `offsetof` macro shall throw an exception and `nothrow(offsetof(type, member-designator))` shall be `true`.

The type `ptrdiff_t` is an implementation-defined signed integer type that can hold the difference of two subscripts in an array object, as described in 7.6.6.

The type `size_t` is an implementation-defined unsigned integer type that is large enough to contain the size in bytes of any object (7.6.2.5).

[Note 1: It is recommended that implementations choose types for `ptrdiff_t` and `size_t` whose integer conversion ranks (6.8.5) are no greater than that of `signed long int` unless a larger size is necessary to contain all the possible values. — end note]

The type `max_align_t` is a trivial standard-layout type whose alignment requirement is at least as great as that of every scalar type, and whose alignment requirement is supported in every context (6.7.6).

See also: ISO C 7.19

17.2.5 byte type operations [support.types.byteops]

```cpp
template<class IntType>
constexpr byte& operator<<=(byte& b, IntType shift) noexcept;

Constraints: is_integral_v<IntType> is true.
Effects: Equivalent to: return b = b << shift;

template<class IntType>
constexpr byte operator<<=(byte b, IntType shift) noexcept;

Constraints: is_integral_v<IntType> is true.
Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(b) << shift);

template<class IntType>
constexpr byte& operator>>(byte& b, IntType shift) noexcept;

Constraints: is_integral_v<IntType> is true.
Effects: Equivalent to: return b = b >> shift;

template<class IntType>
constexpr byte operator>>(byte b, IntType shift) noexcept;

Constraints: is_integral_v<IntType> is true.
Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(b) >> shift);

constexpr byte& operator|=(byte& l, byte r) noexcept;

Effects: Equivalent to: return l = l | r;

constexpr byte operator|(byte l, byte r) noexcept;

Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(l) | static_cast<unsigned int>(r));

constexpr byte& operator&=(byte& l, byte r) noexcept;

Effects: Equivalent to: return l = l & r;

constexpr byte operator&(byte l, byte r) noexcept;

Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(l) & static_cast<unsigned int>(r));

constexpr byte& operator^=(byte& l, byte r) noexcept;

Effects: Equivalent to: return l = l ^ r;

```
constexpr byte operator^(byte l, byte r) noexcept;

Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(l) ^ static_cast<unsigned int>(r));

constexpr byte operator~(byte b) noexcept;

Effects: Equivalent to:
return static_cast<byte>(~static_cast<unsigned int>(b));

template<class IntType>
constexpr IntType to_integer(byte b) noexcept;

Constraints: is_integral_v<IntType> is true.

Effects: Equivalent to:
return static_cast<IntType>(b);

17.3 Implementation properties

17.3.1 General

The headers <limits> (17.3.3), <climits> (17.3.6), and <cfloat> (17.3.7) supply characteristics of implementation-dependent arithmetic types (6.8.2).

17.3.2 Header <version> synopsis

The header <version> supplies implementation-dependent information about the C++ standard library (e.g., version number and release date).

Each of the macros defined in <version> is also defined after inclusion of any member of the set of library headers indicated in the corresponding comment in this synopsis.

[Note 1: Future revisions of C++ might replace the values of these macros with greater values. — end note]

    template<> class numeric_limits<long double>;

17.3.4 Floating-point type properties

17.3.4.1 Type \texttt{float\_round\_style}

namespace std {
    enum float_round_style {
        round_indeterminate = -1,
        round_toward_zero = 0,
        round_to_nearest = 1,
        round_toward_infinity = 2,
        round_toward_neg_infinity = 3
    };
}

The rounding mode for floating-point arithmetic is characterized by the values:

(1.1) \texttt{round\_indeterminate} if the rounding style is indeterminable
(1.2) \texttt{round\_toward\_zero} if the rounding style is toward zero
(1.3) \texttt{round\_to\_nearest} if the rounding style is to the nearest representable value
(1.4) \texttt{round\_toward\_infinity} if the rounding style is toward infinity
(1.5) \texttt{round\_toward\_neg\_infinity} if the rounding style is toward negative infinity

17.3.4.2 Type \texttt{float\_denorm\_style}

namespace std {
    enum float_denorm_style {
        denorm_indeterminate = -1,
        denorm_absent = 0,
        denorm_present = 1
    };
}

The presence or absence of subnormal numbers (variable number of exponent bits) is characterized by the values:

(1.1) \texttt{denorm\_indeterminate} if it cannot be determined whether or not the type allows subnormal values
(1.2) \texttt{denorm\_absent} if the type does not allow subnormal values
(1.3) \texttt{denorm\_present} if the type does allow subnormal values

17.3.5 Class template \texttt{numeric\_limits}

17.3.5.1 General

The \texttt{numeric\_limits} class template provides a C++ program with information about various properties of the implementation’s representation of the arithmetic types.
namespace std {
    template<class T> class numeric_limits {
    public:
        static constexpr bool is_specialized = false;
        static constexpr T min() noexcept { return T(); }
        static constexpr T max() noexcept { return T(); }
        static constexpr T lowest() noexcept { return T(); }
        static constexpr int digits = 0;
        static constexpr int digits10 = 0;
        static constexpr int max_digits10 = 0;
        static constexpr bool is_signed = false;
        static constexpr bool is_integer = false;
        static constexpr bool is_exact = false;
        static constexpr int radix = 0;
        static constexpr T epsilon() noexcept { return T(); }
        static constexpr T round_error() noexcept { return T(); }
        static constexpr int min_exponent = 0;
        static constexpr int min_exponent10 = 0;
        static constexpr int max_exponent = 0;
        static constexpr int max_exponent10 = 0;
        static constexpr bool has_infinity = false;
        static constexpr bool has_quiet_NaN = false;
        static constexpr bool has_signaling_NaN = false;
        static constexpr float_denorm_style has_denorm = denorm_absent;
        static constexpr bool has_denorm_loss = false;
        static constexpr T infinity() noexcept { return T(); }
        static constexpr T quiet_NaN() noexcept { return T(); }
        static constexpr T signaling_NaN() noexcept { return T(); }
        static constexpr T denorm_min() noexcept { return T(); }
        static constexpr bool is_iec559 = false;
        static constexpr bool is_bounded = false;
        static constexpr bool is_modulo = false;
        static constexpr bool traps = false;
        static constexpr float_round_style round_style = round_toward_zero;
    };
}

2 For all members declared static constexpr in the numeric_limits template, specializations shall define these values in such a way that they are usable as constant expressions.

3 For the numeric_limits primary template, all data members are value-initialized and all member functions return a value-initialized object.

[Note 1: This means all members have zero or false values unless numeric_limits is specialized for a type. — end note]

4 Specializations shall be provided for each arithmetic type, both floating-point and integer, including bool. The member is_specialized shall be true for all such specializations of numeric_limits.

5 The value of each member of a specialization of numeric_limits on a cv-qualified type cv T shall be equal to the value of the corresponding member of the specialization on the unqualified type T.

6 Non-arithmetic standard types, such as complex<T> (26.4.3), shall not have specializations.

17.3.5.2 numeric_limits members [numeric.limits.members]

1 Each member function defined in this subclause is signal-safe (17.13.5).

    static constexpr T min() noexcept;

2 Minimum finite value.179

179) Equivalent to CHAR_MIN, SHRT_MIN, FLT_MIN, DBL_MIN, etc.
For floating-point types with subnormal numbers, returns the minimum positive normalized value.

Meaningful for all specializations in which `is_bounded != false`, or `is_bounded == false && is_signed == false`.

```
static constexpr T max() noexcept;
```
Maximum finite value.\(^{180}\)

Meaningful for all specializations in which `is_bounded != false`.

```
static constexpr T lowest() noexcept;
```
A finite value \(x\) such that there is no other finite value \(y\) where \(y < x\).\(^{181}\)

Meaningful for all specializations in which `is_bounded != false`.

```
static constexpr int digits;
```
Number of \(\text{radix}\) digits that can be represented without change.

For integer types, the number of non-sign bits in the representation.

For floating-point types, the number of \(\text{radix}\) digits in the mantissa.\(^{182}\)

```
static constexpr int digits10;
```
Number of base 10 digits that can be represented without change.\(^{183}\)

Meaningful for all specializations in which `is_bounded != false`.

```
static constexpr int max_digits10;
```
Number of base 10 digits required to ensure that values which differ are always differentiated.

Meaningful for all floating-point types.

```
static constexpr bool is_signed;
```
\(\text{true}\) if the type is signed.

Meaningful for all specializations.

```
static constexpr bool is_integer;
```
\(\text{true}\) if the type is integer.

Meaningful for all specializations.

```
static constexpr bool is_exact;
```
\(\text{true}\) if the type uses an exact representation. All integer types are exact, but not all exact types are integer. For example, rational and fixed-exponent representations are exact but not integer.

Meaningful for all specializations.

```
static constexpr int radix;
```
For floating-point types, specifies the base or \(\text{radix}\) of the exponent representation (often 2).\(^{184}\)

For integer types, specifies the base of the representation.\(^{185}\)

Meaningful for all specializations.

```
static constexpr T epsilon() noexcept;
```
Machine epsilon: the difference between 1 and the least value greater than 1 that is representable.\(^{186}\)

Meaningful for all floating-point types.

\(^{180}\) Equivalent to `CHAR_MAX`, `SHRT_MAX`, `FLT_MAX`, `DBL_MAX`, etc.

\(^{181}\) `lowest()` is necessary because not all floating-point representations have a smallest (most negative) value that is the negative of the largest (most positive) finite value.

\(^{182}\) Equivalent to `FLT_MANT_DIG`, `DBL_MANT_DIG`, `LDBL_MANT_DIG`.

\(^{183}\) Equivalent to `FLT_DIG`, `DBL_DIG`, `LDBL_DIG`.

\(^{184}\) Equivalent to `FLT_RADIX`.

\(^{185}\) Distinguishes types with bases other than 2 (e.g. BCD).

\(^{186}\) Equivalent to `FLT_EPSILON`, `DBL_EPSILON`, `LDBL_EPSILON`. 

§ 17.3.5.2
static constexpr T round_error() noexcept;
  Measure of the maximum rounding error.\(^{187}\)

static constexpr int min_exponent;
  Minimum negative integer such that \(\text{radix}\) raised to the power of one less than that integer is a
  normalized floating-point number.\(^{188}\)

static constexpr int min_exponent10;
  Minimum negative integer such that \(10\) raised to that power is in the range of normalized floating-point
  numbers.\(^{189}\)

static constexpr int max_exponent;
  Maximum positive integer such that \(\text{radix}\) raised to the power one less than that integer is a representable
  finite floating-point number.\(^{190}\)

static constexpr int max_exponent10;
  Maximum positive integer such that \(10\) raised to that power is in the range of representable finite
  floating-point numbers.\(^{191}\)

static constexpr bool has_infinity;
  \textbf{true} if the type has a representation for positive infinity.

static constexpr bool has_quiet_NaN;
  \textbf{true} if the type has a representation for a quiet (non-signaling) “Not a Number”.\(^{192}\)

static constexpr bool has_signaling_NaN;
  \textbf{true} if the type has a representation for a signaling “Not a Number”.\(^{193}\)

static constexpr float_denorm_style has_denorm;
  \textbf{denorm_present} if the type allows subnormal values (variable number of exponent bits), \(^{194}\)
  \textbf{denorm_absent} if the type does not allow subnormal values, and \textbf{denorm_indeterminate} if it is indeterminate
  at compile time whether the type allows subnormal values.

static constexpr bool has_denorm_loss;
  \textbf{true} if loss of accuracy is detected as a denormalization loss, rather than as an inexact result.\(^{195}\)

\(^{187}\) Rounding error is described in LIA-1 Section 5.2.4 and Annex C Rationale Section C.5.2.4 — Rounding and rounding
  constants.

\(^{188}\) Equivalent to \texttt{FLT\_MIN\_EXP}, \texttt{DBL\_MIN\_EXP}, \texttt{LDBL\_MIN\_EXP}.

\(^{189}\) Equivalent to \texttt{FLT\_MIN\_10\_EXP}, \texttt{DBL\_MIN\_10\_EXP}, \texttt{LDBL\_MIN\_10\_EXP}.

\(^{190}\) Equivalent to \texttt{FLT\_MAX\_EXP}, \texttt{DBL\_MAX\_EXP}, \texttt{LDBL\_MAX\_EXP}.

\(^{191}\) Equivalent to \texttt{FLT\_MAX\_10\_EXP}, \texttt{DBL\_MAX\_10\_EXP}, \texttt{LDBL\_MAX\_10\_EXP}.

\(^{192}\) Required by LIA-1.

\(^{193}\) Required by LIA-1.

\(^{194}\) Required by LIA-1.

\(^{195}\) See ISO/IEC/IEEE 60559.
static constexpr T infinity() noexcept;

Representation of positive infinity, if available.\footnote{Required by LIA-1.}

Meaningful for all specializations for which \texttt{has\_infinity} \(!= \texttt{false}\). Required in specializations for which \texttt{is\_iec559} \(!= \texttt{false}\).

\begin{verbatim}
49
48 Representation of positive infinity, if available.\footnote{Required by LIA-1.}
49 Meaningful for all specializations for which \texttt{has\_infinity} \(!= \texttt{false}\). Required in specializations for which \texttt{is\_iec559} \(!= \texttt{false}\).
50
\end{verbatim}

static constexpr T quiet_NaN() noexcept;

Representation of a quiet “Not a Number”, if available.\footnote{Required by LIA-1.}

Meaningful for all specializations for which \texttt{has\_quiet\_NaN} \(!= \texttt{false}\). Required in specializations for which \texttt{is\_iec559} \(!= \texttt{false}\).

\begin{verbatim}
50
51 Representation of a quiet “Not a Number”, if available.\footnote{Required by LIA-1.}
51 Meaningful for all specializations for which \texttt{has\_quiet\_NaN} \(!= \texttt{false}\). Required in specializations for which \texttt{is\_iec559} \(!= \texttt{false}\).
52
\end{verbatim}

static constexpr T signaling_NaN() noexcept;

Representation of a signaling “Not a Number”, if available.\footnote{Required by LIA-1.}

Meaningful for all specializations for which \texttt{has\_signaling\_NaN} \(!= \texttt{false}\). Required in specializations for which \texttt{is\_iec559} \(!= \texttt{false}\).

\begin{verbatim}
52
53 Representation of a signaling “Not a Number”, if available.\footnote{Required by LIA-1.}
53 Meaningful for all specializations for which \texttt{has\_signaling\_NaN} \(!= \texttt{false}\). Required in specializations for which \texttt{is\_iec559} \(!= \texttt{false}\).
54
\end{verbatim}

static constexpr T denorm_min() noexcept;

Minimum positive subnormal value.\footnote{Required by LIA-1.}

Meaningful for all floating-point types.

In specializations for which \texttt{has\_denorm} \(!= \texttt{false}\), returns the minimum positive normalized value.

\begin{verbatim}
54
55 Minimum positive subnormal value.\footnote{Required by LIA-1.}
56 Meaningful for all floating-point types.
56 In specializations for which \texttt{has\_denorm} \(!= \texttt{false}\), returns the minimum positive normalized value.
57
\end{verbatim}

static constexpr bool is_iec559;

\texttt{true} if and only if the type adheres to ISO/IEC/IEEE 60559.\footnote{ISO/IEC/IEEE 60559:2011 is the same as IEEE 754-2008.}

Meaningful for all floating-point types.

\begin{verbatim}
57
58 Minimum positive subnormal value.\footnote{Required by LIA-1.}
58 Meaningful for all floating-point types.
58 In specializations for which \texttt{has\_denorm} \(!= \texttt{false}\), returns the minimum positive normalized value.
59
\end{verbatim}

static constexpr bool is_bounded;

\texttt{true} if the set of values representable by the type is finite.\footnote{Required by LIA-1.}

\begin{verbatim}
59
60 Minimum positive subnormal value.\footnote{Required by LIA-1.}
60 Meaningful for all specializations.
60 In specializations for which \texttt{has\_denorm} \(!= \texttt{false}\), returns the minimum positive normalized value.
61
\end{verbatim}

\begin{verbatim}
[Note 1: All fundamental types (6.8.2) are bounded. This member would be \texttt{false} for arbitrary precision types. —end note]
\end{verbatim}

Meaningful for all specializations.

\begin{verbatim}
61
62 Minimum positive subnormal value.\footnote{Required by LIA-1.}
62 Meaningful for all specializations.
62 In specializations for which \texttt{has\_denorm} \(!= \texttt{false}\), returns the minimum positive normalized value.
63
\end{verbatim}

\begin{verbatim}
true if the type is modulo.\footnote{Required by LIA-1.}
\begin{verbatim}
A type is modulo if, for any operation involving \texttt{+}, \texttt{-}, or \texttt{*} on values of that type whose result would fall outside the range \texttt{[min(), max()]}, the value returned differs from the true value by an integer multiple of \texttt{max() - min() + 1}.
[Example 1: \texttt{is\_modulo} is \texttt{false} for signed integer types (6.8.2) unless an implementation, as an extension to this document, defines signed integer overflow to wrap. —end example]
\end{verbatim}
\end{verbatim}

Meaningful for all specializations.

\begin{verbatim}
62
63 Minimum positive subnormal value.\footnote{Required by LIA-1.}
63 Meaningful for all specializations.
63 In specializations for which \texttt{has\_denorm} \(!= \texttt{false}\), returns the minimum positive normalized value.
64
\end{verbatim}

\begin{verbatim}
true if, at the start of the program, there exists a value of the type that would cause an arithmetic operation using that value to trap.\footnote{Required by LIA-1.}
\end{verbatim}

Meaningful for all specializations.

\begin{verbatim}
64
65 Minimum positive subnormal value.\footnote{Required by LIA-1.}
65 Meaningful for all specializations.
65 In specializations for which \texttt{has\_denorm} \(!= \texttt{false}\), returns the minimum positive normalized value.
66
\end{verbatim}

\begin{verbatim}
true if tinyness is detected before rounding.\footnote{Required by LIA-1.}
\end{verbatim}

Meaningful for all floating-point types.

\begin{verbatim}
66
67 Minimum positive subnormal value.\footnote{Required by LIA-1.}
67 Meaningful for all specializations.
67 In specializations for which \texttt{has\_denorm} \(!= \texttt{false}\), returns the minimum positive normalized value.

static constexpr float_round_style round_style;

The rounding style for the type.\textsuperscript{205}

Meaningful for all floating-point types. Specializations for integer types shall return \textit{round_toward_-zero}.

\subsection{17.3.5.3 \texttt{numericLimits} Specializations \hfill \texttt{[numeric.special]}}

All members shall be provided for all specializations. However, many values are only required to be meaningful under certain conditions (for example, \texttt{epsilon()} is only meaningful if \texttt{is_integer} is \texttt{false}). Any value that is not “meaningful” shall be set to 0 or \texttt{false}.

\begin{example}

namespace std {

    template<> class numeric_limits<float> {

    public:
        static constexpr bool is_specialized = true;
        static constexpr float min() noexcept { return 1.17549435E-38F; }
        static constexpr float max() noexcept { return 3.40282347E+38F; }
        static constexpr float lowest() noexcept { return -3.40282347E+38F; }
        static constexpr int digits = 24;
        static constexpr int digits10 = 6;
        static constexpr int max_digits10 = 9;
        static constexpr bool is_signed = true;
        static constexpr bool is_integer = false;
        static constexpr bool is_exact = false;
        static constexpr int radix = 2;
        static constexpr float epsilon() noexcept { return 1.19209290E-07F; }
        static constexpr float round_error() noexcept { return 0.5F; }
        static constexpr int min_exponent = -125;
        static constexpr int min_exponent10 = -37;
        static constexpr int max_exponent = +128;
        static constexpr int max_exponent10 = +38;
        static constexpr bool has_infinity = true;
        static constexpr bool has_quiet_NaN = true;
        static constexpr bool has_signaling_NaN = true;
        static constexpr float_denorm_style has_denorm = denorm_absent;
        static constexpr bool has_denorm_loss = false;
        static constexpr float infinity() noexcept { return value; }
        static constexpr float quiet_NaN() noexcept { return value; }
        static constexpr float signaling_NaN() noexcept { return value; }
        static constexpr float denorm_min() noexcept { return min(); }
        static constexpr bool is_iec559 = true;
        static constexpr bool is_bounded = true;
        static constexpr bool is_modulo = false;
        static constexpr bool traps = true;
        static constexpr bool tinyness_before = true;
    }

    static constexpr float_round_style round_style = round_to_nearest;
}

\end{example}

\textsuperscript{3} The specialization for \texttt{bool} shall be provided as follows:

\textsuperscript{205} Equivalent to \texttt{FLT_ROUNDS}. Required by LIA-1.
namespace std {
    template<> class numeric_limits<bool> {
        public:
            static constexpr bool is_specialized = true;
            static constexpr bool min() noexcept { return false; }
            static constexpr bool max() noexcept { return true; }
            static constexpr bool lowest() noexcept { return false; }
            static constexpr int digits = 1;
            static constexpr int digits10 = 0;
            static constexpr int max_digits10 = 0;
            static constexpr bool is_signed = false;
            static constexpr bool is_integer = true;
            static constexpr bool is_exact = true;
            static constexpr int radix = 2;
            static constexpr bool epsilon() noexcept { return 0; }
            static constexpr bool round_error() noexcept { return 0; }
            static constexpr int min_exponent = 0;
            static constexpr int min_exponent10 = 0;
            static constexpr int max_exponent = 0;
            static constexpr int max_exponent10 = 0;
            static constexpr bool has_infinity = false;
            static constexpr bool has_quiet_NaN = false;
            static constexpr bool has_signaling_NaN = false;
            static constexpr float_denorm_style has_denorm = denorm_absent;
            static constexpr bool has_denorm_loss = false;
            static constexpr bool infinity() noexcept { return 0; }
            static constexpr bool quiet_NaN() noexcept { return 0; }
            static constexpr bool signaling_NaN() noexcept { return 0; }
            static constexpr bool denorm_min() noexcept { return 0; }
            static constexpr bool is_iec559 = false;
            static constexpr bool is_bounded = true;
            static constexpr bool is_modulo = false;
            static constexpr bool traps = false;
            static constexpr float_round_style round_style = round_toward_zero;
    }
}

17.4 Integer types

17.4.1 General

The header `<cstdint>` (17.4.2) supplies integer types having specified widths, and macros that specify limits of integer types.

17.4.2 Header `<cstdint>` synopsis

```c
namespace std {
    using int8_t = signed integer type; // optional
    using int16_t = signed integer type; // optional
    using int32_t = signed integer type; // optional
    using int64_t = signed integer type; // optional
    using intN_t = see below; // optional
}```
using int_fast8_t = signed integer type;
using int_fast16_t = signed integer type;
using int_fast32_t = signed integer type;
using int_fast64_t = signed integer type;
using int_fastN_t = see below;   // optional

using int_least8_t = signed integer type;
using int_least16_t = signed integer type;
using int_least32_t = signed integer type;
using int_least64_t = signed integer type;
using int_leastN_t = see below;   // optional

using intmax_t = signed integer type;
using intptr_t = signed integer type;   // optional

using uint8_t = unsigned integer type;   // optional
using uint16_t = unsigned integer type;   // optional

#define UINTPTR_MAX see below   // optional

#define PTRDIFF_MIN see below
#define PTRDIFF_MAX see below
#define SIZE_MAX see below

#define SIG_ATOMIC_MIN see below
#define SIG_ATOMIC_MAX see below
The header defines all types and macros the same as the C standard library header `<stdint.h>`.

See also: ISO C 7.20

All types that use the placeholder \( N \) are optional when \( N \) is not 8, 16, 32, or 64. The exact-width types int\( N \)_t and uint\( N \)_t for \( N \) = 8, 16, 32, and 64 are also optional; however, if an implementation defines integer types with the corresponding width and no padding bits, it defines the corresponding typedef names. Each of the macros listed in this subclause is defined if and only if the implementation defines the corresponding typedef name.

[Note 1: The macros INT\( N \)_C and UINT\( N \)_C correspond to the typedef names int_least\( N \)_t and uint_least\( N \)_t, respectively. — end note]

17.5 Startup and termination

[[noreturn]] void _Exit(int status) noexcept;

1 Effects: This function has the semantics specified in the C standard library.
2 Remarks: The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to `atexit()` (6.9.3.4). The function `_Exit` is signal-safe (17.13.5).

[[noreturn]] void abort() noexcept;

2 Effects: This function has the semantics specified in the C standard library.
3 Remarks: The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to `atexit()` (6.9.3.4). The function `abort` is signal-safe (17.13.5).

```c
int atexit(c_atexit_handler* f) noexcept;
int atexit(atexit_handler* f) noexcept;
```

4 Effects: The `atexit()` functions register the function pointed to by \( f \) to be called without arguments at normal program termination. It is unspecified whether a call to `atexit()` that does not happen before (6.9.2) a call to `exit()` will succeed.
5 Implementation limits: The implementation shall support the registration of at least 32 functions.
6 Returns: The `atexit()` function returns zero if the registration succeeds, nonzero if it fails.

```
[[noreturn]] void exit(int status);
```

9 Effects:
10 — First, objects with thread storage duration and associated with the current thread are destroyed. Next, objects with static storage duration are destroyed and functions registered by calling `atexit` are called.\(^{206}\) See 6.9.3.4 for the order of destructors and calls. (Objects with automatic storage duration are not destroyed as a result of calling `exit()`.)\(^{207}\) If a registered function invoked by `exit` exits via an exception, the function `std::terminate` is invoked (14.6.2).

\(^{206}\) A function is called for every time it is registered.
\(^{207}\) Objects with automatic storage duration are all destroyed in a program whose `main` function (6.9.3.1) contains no objects with automatic storage duration and executes the call to `exit()`. Control can be transferred directly to such a `main` function by throwing an exception that is caught in `main`. 

§ 17.5
Next, all open C streams (as mediated by the function signatures declared in `<cstdio>` (29.12.1)) with unwritten buffered data are flushed, all open C streams are closed, and all files created by calling `tmpfile()` are removed.

Finally, control is returned to the host environment. If `status` is zero or `EXIT_SUCCESS`, an implementation-defined form of the status `successful termination` is returned. If `status` is `EXIT_FAILURE`, an implementation-defined form of the status `unsuccessful termination` is returned. Otherwise the status returned is implementation-defined.

```
int at_quick_exit(atexit-handler* f) noexcept;
int at_quick_exit(c-atexit-handler* f) noexcept;
```

**Effects:** The `at_quick_exit()` functions register the function pointed to by `f` to be called without arguments when `quick_exit` is called. It is unspecified whether a call to `at_quick_exit()` that does not happen before (6.9.2) all calls to `quick_exit` will succeed.

[Note 3: The `at_quick_exit()` functions do not introduce a data race (16.4.6.10). — end note]

[Note 4: The order of registration could be indeterminate if `at_quick_exit` was called from more than one thread. — end note]

[Note 5: The `at_quick_exit` registrations are distinct from the `atexit` registrations, and applications might need to call both registration functions with the same argument. — end note]

**Implementation limits:** The implementation shall support the registration of at least 32 functions.

**Returns:** Zero if the registration succeeds, nonzero if it fails.

```
[[noreturn]] void quick_exit(int status) noexcept;
```

**Effects:** Functions registered by calls to `at_quick_exit` are called in the reverse order of their registration, except that a function shall be called after any previously registered functions that had already been called at the time it was registered. Objects shall not be destroyed as a result of calling `quick_exit`. If a registered function invoked by `quick_exit` exits via an exception, the function `std::terminate` is invoked (14.6.2).

[Note 6: A function registered via `at_quick_exit` is invoked by the thread that calls `quick_exit`, which can be a different thread than the one that registered it, so registered functions cannot rely on the identity of objects with thread storage duration. — end note]

After calling registered functions, `quick_exit` shall call `_Exit(status)`.

**Remarks:** The function `quick_exit` is signal-safe (17.13.5) when the functions registered with `at_quick_exit` are.

See also: ISO C 7.22.4

17.6 Dynamic memory management [support.dynamic]

17.6.1 General [support.dynamic.general]

The header `<new>` defines several functions that manage the allocation of dynamic storage in a program. It also defines components for reporting storage management errors.

17.6.2 Header `<new>` synopsis [new.syn]

```
namespace std {
    // 17.6.4, storage allocation errors
    class bad_alloc;
    class bad_array_new_length;

    struct destroying_delete_t {
        explicit destroying_delete_t() = default;
    };
    inline constexpr destroying_delete_t destroying_delete{};

    // global operator new control
    enum class align_val_t : size_t {
```

208) The macros `EXIT_FAILURE` and `EXIT_SUCCESS` are defined in `<cstdlib>` (17.2.2).
struct nothrow_t { explicit nothrow_t() = default; }; extern const nothrow_t nothrow;

using new_handler = void (*)();
new_handler get_new_handler() noexcept;
new_handler set_new_handler(new_handler new_p) noexcept;

// 17.6.5, pointer optimization barrier
template<class T> [[nodiscard]] constexpr T* launder(T* p) noexcept;

// 17.6.6, hardware interference size
inline constexpr size_t hardware_destructive_interference_size = implementation-defined;
inline constexpr size_t hardware_constructive_interference_size = implementation-defined;

17.6.3 Storage allocation and deallocation

1 Except where otherwise specified, the provisions of 6.7.5.5 apply to the library versions of operator new and operator delete. If the value of an alignment argument passed to any of these functions is not a valid alignment value, the behavior is undefined.

17.6.3.2 Single-object forms

[[nodiscard]] void* operator new(std::size_t size);
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment);
[[nodiscard]] void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;
void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, const std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

§ 17.6.3.2 506
3 Required behavior: Return a non-null pointer to suitably aligned storage (6.7.5.5), or else throw a bad_alloc exception. This requirement is binding on any replacement versions of these functions.

4 Default behavior:

(4.1) Executes a loop: Within the loop, the function first attempts to allocate the requested storage. Whether the attempt involves a call to the C standard library functions malloc or aligned_alloc is unspecified.

(4.2) Returns a pointer to the allocated storage if the attempt is successful. Otherwise, if the current new_handler (17.6.4.5) is a null pointer value, throws bad_alloc.

(4.3) Otherwise, the function calls the current new_handler function (17.6.4.3). If the called function returns, the loop repeats.

(4.4) The loop terminates when an attempt to allocate the requested storage is successful or when a called new_handler function does not return.

```
[[nodiscard]] void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

5 Effects: Same as above, except that these are called by a placement version of a new-expression when a C++ program prefers a null pointer result as an error indication, instead of a bad_alloc exception.

6 Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

7 Required behavior: Return a non-null pointer to suitably aligned storage (6.7.5.5), or else return a null pointer. Each of these nothrow versions of operator new returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

8 Default behavior: Calls operator new(size), or operator new(size, alignment), respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

9 [Example 1]:
```
T* p1 = new T;  // throws bad_alloc if it fails
T* p2 = new(nothrow) T;  // returns nullptr if it fails
```

-- end example

```
void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
```

10 Preconditions: ptr is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) operator new(std::size_t) or operator new(std::size_t, std::align_val_t) which has not been invalidated by an intervening call to operator delete.

11 If an implementation has strict pointer safety (6.7.5.5.4) then ptr is a safely-derived pointer.

12 If the alignment parameter is not present, ptr was returned by an allocation function without an alignment parameter. If present, the alignment argument is equal to the alignment argument passed to the allocation function that returned ptr. If present, the size argument is equal to the size argument passed to the allocation function that returned ptr.

13 Effects: The deallocation functions (6.7.5.5.3) called by a delete-expression (7.6.2.9) to render the value of ptr invalid.

14 Replaceable: A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a size parameter is defined, the program should also define the corresponding function with a size parameter. If a function with a size parameter is defined, the program shall also define the corresponding version without the size parameter.

[Note 1: The default behavior below might change in the future, which will require replacing both deallocation functions when replacing the allocation function. — end note]
Required behavior: A call to an operator delete with a size parameter may be changed to a call to the corresponding operator delete without a size parameter, without affecting memory allocation.

[Note 2: A conforming implementation is for operator delete(void* ptr, std::size_t size) to simply call operator delete(ptr). — end note]

Default behavior: The functions that have a size parameter forward their other parameters to the corresponding function without a size parameter.

[Note 3: See the note in the above Replaceable: paragraph. — end note]

Default behavior: If ptr is null, does nothing. Otherwise, reclaims the storage allocated by the earlier call to operator new.

Remarks: It is unspecified under what conditions part or all of such reclaimed storage will be allocated by subsequent calls to operator new or any of aligned_alloc, calloc, malloc, or realloc, declared in <cstdlib> (17.2.2).

```cpp
void operator delete(void* ptr, std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

Preconditions: ptr is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) operator new(std::size_t) or operator new(std::size_t, std::align_val_t) which has not been invalidated by an intervening call to operator delete.

If an implementation has strict pointer safety (6.7.5.5.4) then ptr is a safely-derived pointer.

If the alignment parameter is not present, ptr was returned by an allocation function without an alignment parameter. If present, the alignment argument is equal to the alignment argument passed to the allocation function that returned ptr.

Effects: The deallocation functions (6.7.5.5.3) called by the implementation to render the value of ptr invalid when the constructor invoked from a nothrow placement version of the new-expression throws an exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Default behavior: Calls operator delete(ptr), or operator delete(ptr, alignment), respectively.

### 17.6.3.3 Array forms

[[nodiscard]] void* operator new[](std::size_t size);
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment);

Effects: The allocation functions (6.7.5.5.2) called by the array form of a new-expression (7.6.2.8) to allocate size bytes of storage. The second form is called for a type with new-extended alignment, and the first form is called otherwise.209 Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library. Required behavior: Same as for the corresponding single-object forms. This requirement is binding on any replacement versions of these functions.

Default behavior: Returns operator new(size), or operator new(size, alignment), respectively.

[[nodiscard]] void* operator new[](std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment,
const std::nothrow_t&) noexcept;

Effects: Same as above, except that these are called by a placement version of a new-expression when a C++ program prefers a null pointer result as an error indication, instead of a bad_alloc exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Required behavior: Return a non-null pointer to suitably aligned storage (6.7.5.5), or else return a null pointer. Each of these nothrow versions of operator new[] returns a pointer obtained as if acquired

---

209 It is not the direct responsibility of operator new[] or operator delete[] to note the repetition count or element size of the array. Those operations are performed elsewhere in the array new and delete expressions. The array new expression, can, however, increase the size argument to operator new[] to obtain space to store supplemental information.
from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

**Default behavior:** Calls `operator new[](size)`, or `operator new[](size, alignment)`, respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

```cpp
void operator delete[](void* ptr) noexcept;
void operator delete[](void* ptr, std::size_t size) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment) noexcept;
void operator delete[](void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
```

**Preconditions:** `ptr` is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new[](std::size_t)` or `operator new[](std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete[]`.

If an implementation has strict pointer safety (6.7.5.5.4) then `ptr` is a safely-derived pointer.

If the `alignment` parameter is not present, `ptr` was returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument is equal to the `alignment` argument passed to the allocation function that returned `ptr`. If present, the `size` argument is equal to the `size` argument passed to the allocation function that returned `ptr`.

**Effects:** The deallocation functions (6.7.5.5.3) called by the array form of a `delete-expression` to render the value of `ptr` invalid.

**Replaceable:** A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a `size` parameter is defined, the program should also define the corresponding function with a `size` parameter. If a function with a `size` parameter is defined, the program shall also define the corresponding version without the `size` parameter.

>[Note 1: The default behavior below might change in the future, which will require replacing both deallocation functions when replacing the allocation function. — end note]

**Required behavior:** A call to an `operator delete[]` with a `size` parameter may be changed to a call to the corresponding `operator delete[]` without a `size` parameter, without affecting memory allocation.

>[Note 2: A conforming implementation is for `operator delete[](void* ptr, std::size_t size)` to simply call `operator delete[](ptr)`. — end note]

**Default behavior:** The functions that have a `size` parameter forward their other parameters to the corresponding function without a `size` parameter. The functions that do not have a `size` parameter forward their parameters to the corresponding `operator delete` (single-object) function.

```cpp
void operator delete[](void* ptr, const std::nothrow_t&) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

**Preconditions:** `ptr` is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new[](std::size_t)` or `operator new[](std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete[]`.

If an implementation has strict pointer safety (6.7.5.5.4) then `ptr` is a safely-derived pointer.

If the `alignment` parameter is not present, `ptr` was returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument is equal to the `alignment` argument passed to the allocation function that returned `ptr`.

**Effects:** The deallocation functions (6.7.5.5.3) called by the implementation to render the value of `ptr` invalid when the constructor invoked from a nothrow placement version of the array `new-expression` throws an exception.

**Replaceable:** A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

**Default behavior:** Calls `operator delete[](ptr)`, or `operator delete[](ptr, alignment)`, respectively.
17.6.3.4 Non-allocating forms

These functions are reserved; a C++ program may not define functions that displace the versions in the C++ standard library (16.4.5). The provisions of 6.7.5.5 do not apply to these reserved placement forms of operator new and operator delete.

[[nodiscard]] void* operator new(std::size_t size, void* ptr) noexcept;

Returns: ptr.

Remarks: Intentionally performs no other action.

[Example 1: This can be useful for constructing an object at a known address:

void* place = operator new(sizeof(Something));
Something* p = new (place) Something();
—end example]

[[nodiscard]] void* operator new[](std::size_t size, void* ptr) noexcept;

Returns: ptr.

Remarks: Intentionally performs no other action.

void operator delete(void* ptr, void*) noexcept;

Preconditions: If an implementation has strict pointer safety (6.7.5.5.4) then ptr is a safely-derived pointer.

Effects: Intentionally performs no action.

Remarks: Default function called when any part of the initialization in a placement new-expression that invokes the library’s non-array placement operator new terminates by throwing an exception (7.6.2.8).

void operator delete[](void* ptr, void*) noexcept;

Preconditions: If an implementation has strict pointer safety (6.7.5.5.4) then ptr is a safely-derived pointer.

Effects: Intentionally performs no action.

Remarks: Default function called when any part of the initialization in a placement new-expression that invokes the library’s array placement operator new terminates by throwing an exception (7.6.2.8).

17.6.3.5 Data races

For purposes of determining the existence of data races, the library versions of operator new, user replacement versions of global operator new, the C standard library functions aligned_alloc, calloc, and malloc, the library versions of operator delete, user replacement versions of operator delete, the C standard library function free, and the C standard library function realloc shall not introduce a data race (16.4.6.10). Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before (6.9.2) the next allocation (if any) in this order.

17.6.4 Storage allocation errors

17.6.4.1 Class bad_alloc

namespace std {
    class bad_alloc : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}

The class bad_alloc defines the type of objects thrown as exceptions by the implementation to report a failure to allocate storage.

const char* what() const noexcept override;

Returns: An implementation-defined NTBS.
17.6.4.2 Class bad_array_new_length

namespace std {
    class bad_array_new_length : public bad_alloc {
    public:
        // see 17.9.3 for the specification of the special member functions
        const char* what() const noexcept override;
    }
}

1 The class bad_array_new_length defines the type of objects thrown as exceptions by the implementation to report an attempt to allocate an array of size less than zero or greater than an implementation-defined limit (7.6.2.8).

    const char* what() const noexcept override;

2 Returns: An implementation-defined NTBS.

17.6.4.3 Type new_handler

using new_handler = void (*)();

1 The type of a handler function to be called by operator new() or operator new[] () (17.6.3) when they cannot satisfy a request for additional storage.

2 Required behavior: A new_handler shall perform one of the following:

    (2.1) make more storage available for allocation and then return;

    (2.2) throw an exception of type bad_alloc or a class derived from bad_alloc;

    (2.3) terminate execution of the program without returning to the caller.

17.6.4.4 set_new_handler

new_handler set_new_handler(new_handler new_p) noexcept;

1 Effects: Establishes the function designated by new_p as the current new_handler.

2 Returns: The previous new_handler.

3 Remarks: The initial new_handler is a null pointer.

17.6.4.5 get_new_handler

new_handler get_new_handler() noexcept;

1 Returns: The current new_handler.

[Note 1: This can be a null pointer value. — end note]

17.6.5 Pointer optimization barrier

template<class T> [[nodiscard]] constexpr T* launder(T* p) noexcept;

1 Mandates: !is_function_v<T> && !is_void_v<T> is true.

2 Preconditions: p represents the address A of a byte in memory. An object X that is within its lifetime (6.7.3) and whose type is similar (7.3.6) to T is located at the address A. All bytes of storage that would be reachable through the result are reachable through p (see below).

3 Returns: A value of type T* that points to X.

4 Remarks: An invocation of this function may be used in a core constant expression if and only if the (converted) value of its argument may be used in place of the function invocation. A byte of storage b is reachable through a pointer value that points to an object Y if there is an object Z, pointer-interconvertible with Y, such that b is within the storage occupied by Z, or the immediately-enclosing array object if Z is an array element.

5 [Note 1: If a new object is created in storage occupied by an existing object of the same type, a pointer to the original object can be used to refer to the new object unless its complete object is a const object or it is a base class subobject; in the latter cases, this function can be used to obtain a usable pointer to the new object. See 6.7.3. — end note]

6 [Example 1: § 17.6.5 511]
struct X { int n; };
const X *p = new const X{3};
const int a = p->n;
new (const_cast<X*>(p)) const X{5};  // p does not point to new object (6.7.3) because its type is const
const int b = p->n;    // undefined behavior
const int c = std::launder(p)->n;  // OK

--- end example ---

17.6.6 Hardware interference size

[hardware.interference]

inline constexpr size_t hardware_destructive_interference_size = implementation-defined;

This number is the minimum recommended offset between two concurrently-accessed objects to avoid additional performance degradation due to contention introduced by the implementation. It shall be at least alignof(max_align_t).

[Example 1:]
struct keep_apart {
    alignas(hardware_destructive_interference_size) atomic<int> cat;
    alignas(hardware_destructive_interference_size) atomic<int> dog;
};
--- end example ---

inline constexpr size_t hardware_constructive_interference_size = implementation-defined;

This number is the maximum recommended size of contiguous memory occupied by two objects accessed with temporal locality by concurrent threads. It shall be at least alignof(max_align_t).

[Example 2:]
struct together {
    atomic<int> dog;
    int puppy;
};
struct kennel {
    // Other data members...
    alignas(sizeof(together)) together pack;
    // Other data members...
};
static_assert(sizeof(together) <= hardware_constructive_interference_size);
--- end example ---

17.7 Type identification

[support.rtti]

17.7.1 General

[support.rtti.general]
The header `<typeinfo>` defines a type associated with type information generated by the implementation. It also defines two types for reporting dynamic type identification errors.

17.7.2 Header `<typeinfo>` synopsis

[typeinfo.syn]

namespace std {
    class type_info;
    class bad_cast;
    class bad_typeid;
}

17.7.3 Class `type_info`

typeinfo.syn]

namespace std {
    class type_info {
    public:
        virtual ~type_info();
        bool operator==(const type_info& rhs) const noexcept;
        bool before(const type_info& rhs) const noexcept;
        size_t hash_code() const noexcept;
        const char* name() const noexcept;
    };
The class `type_info` describes type information generated by the implementation (7.6.1.8). Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoding rule, and collating sequence for types are all unspecified and may differ between programs.

```cpp
bool operator==(const type_info& rhs) const noexcept;
```

**Effects**: Compares the current object with `rhs`.

**Returns**: `true` if the two values describe the same type.

```cpp
bool before(const type_info& rhs) const noexcept;
```

**Effects**: Compares the current object with `rhs`.

**Returns**: `true` if `*this` precedes `rhs` in the implementation’s collation order.

```cpp
size_t hash_code() const noexcept;
```

**Returns**: An unspecified value, except that within a single execution of the program, it shall return the same value for any two `type_info` objects which compare equal.

**Remarks**: An implementation should return different values for two `type_info` objects which do not compare equal.

```cpp
const char* name() const noexcept;
```

**Returns**: An implementation-defined `ntbs`.

**Remarks**: The message may be a null-terminated multibyte string (16.3.3.5.3), suitable for conversion and display as a `wstring` (21.3, 28.4.2.5).

### 17.7.4 Class bad_cast

```cpp
namespace std {
    class bad_cast : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    }
}
```

The class `bad_cast` defines the type of objects thrown as exceptions by the implementation to report the execution of an invalid `dynamic_cast` expression (7.6.1.7).

```cpp
const char* what() const noexcept override;
```

**Returns**: An implementation-defined `ntbs`.

### 17.7.5 Class bad_typeid

```cpp
namespace std {
    class bad_typeid : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    }
}
```

The class `bad_typeid` defines the type of objects thrown as exceptions by the implementation to report a null pointer in a `typeid` expression (7.6.1.8).

```cpp
const char* what() const noexcept override;
```

**Returns**: An implementation-defined `ntbs`. 
17.8 Source location

17.8.1 Header <source_location> synopsis

The header <source_location> defines the class source_location that provides a means to obtain source location information.

```cpp
namespace std {
    struct source_location {
        // source location construction
        static consteval source_location current() noexcept;
        constexpr source_location() noexcept;
        // source location field access
        constexpr uint_least32_t line() const noexcept;
        constexpr uint_least32_t column() const noexcept;
        constexpr const char* file_name() const noexcept;
        constexpr const char* function_name() const noexcept;
    };

private:
    uint_least32_t line_; // exposition only
    uint_least32_t column_; // exposition only
    const char* file_name_; // exposition only
    const char* function_name_; // exposition only
};
```

1 The type source_location meets the Cpp17DefaultConstructible, Cpp17CopyConstructible, Cpp17Copy-Assignable, and Cpp17Destructible requirements (16.4.4.2). Lvalues of type source_location are swappable (16.4.4.3). All of the following conditions are true:

1.1 is_nothrow_move_constructible_v<source_location>
1.2 is_nothrow_move_assignable_v<source_location>
1.3 is_nothrow_swappable_v<source_location>

[Note 1: The intent of source_location is to have a small size and efficient copying. It is unspecified whether the copy/move constructors and the copy/move assignment operators are trivial and/or constexpr. — end note]

2 The data members file_name_ and function_name_ always each refer to an ntbs.

3 The copy/move constructors and the copy/move assignment operators of source_location meet the following postconditions: Given two objects lhs and rhs of type source_location, where lhs is a copy/move result of rhs, and where rhs_p is a value denoting the state of rhs before the corresponding copy/move operation, then each of the following conditions is true:

3.1 strcmp(lhs.file_name(), rhs_p.file_name()) == 0
3.2 strcmp(lhs.function_name(), rhs_p.function_name()) == 0
3.3 lhs.line() == rhs_p.line()
3.4 lhs.column() == rhs_p.column()

17.8.2 Class source_location

17.8.2.1 General

```cpp
static consteval source_location current() noexcept;
```

Returns:

1.1 When invoked by a function call whose postfix-expression is a (possibly parenthesized) id-expression naming current, returns a source_location with an implementation-defined value. The value should be affected by #line (15.7) in the same manner as for __LINE__ and __FILE__. The
values of the exposition-only data members of the returned `source_location` object are indicated in Table 40.

Table 40: Value of object returned by `current`  

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>line_</td>
<td>A presumed line number (15.11). Line numbers are presumed to be 1-indexed; however, an implementation is encouraged to use 0 when the line number is unknown.</td>
</tr>
<tr>
<td>column_</td>
<td>An implementation-defined value denoting some offset from the start of the line denoted by line_. Column numbers are presumed to be 1-indexed; however, an implementation is encouraged to use 0 when the column number is unknown.</td>
</tr>
<tr>
<td>file_name_</td>
<td>A presumed name of the current source file (15.11) as an <code>ntbs</code>.</td>
</tr>
<tr>
<td>function_name_</td>
<td>A name of the current function such as in <code>__func__</code> (9.5.1) if any, an empty string otherwise.</td>
</tr>
</tbody>
</table>

1. Otherwise, when invoked in some other way, returns a `source_location` whose data members are initialized with valid but unspecified values.

2. Remarks: Any call to `current` that appears as a default member initializer (11.4), or as a subexpression thereof, should correspond to the location of the constructor definition or aggregate initialization that uses the default member initializer. Any call to `current` that appears as a default argument (9.3.4.7), or as a subexpression thereof, should correspond to the location of the invocation of the function that uses the default argument (7.6.1.3).

3. [Example 1:]

```cpp
struct s {
    source_location member = source_location::current();
    int other_member;
    s(source_location loc = source_location::current())
        : member(loc)        // values of member refer to the location of the calling function (9.3.4.7)
        {}                  
    s(int blather) :
        other_member(blather)
        {}                  
    s(double)       // values of member refer to this location
        {}                  
};
void f(source_location a = source_location::current()) {
    source_location b = source_location::current();       // values in b refer to this line
}

void g() {
    f();                  // f’s first argument corresponds to this line of code
    source_location c = source_location::current();
    f(c);                 // f’s first argument gets the same values as c, above
}
```  

— end example ]

4. `constexpr source_location() noexcept;`  

Remarks: Any call to `current` that appears as a default member initializer (11.4), or as a subexpression thereof, should correspond to the location of the constructor definition or aggregate initialization that uses the default member initializer. Any call to `current` that appears as a default argument (9.3.4.7), or as a subexpression thereof, should correspond to the location of the invocation of the function that uses the default argument (7.6.1.3).

3. Remarks: Any call to `current` that appears as a default member initializer (11.4), or as a subexpression thereof, should correspond to the location of the constructor definition or aggregate initialization that uses the default member initializer. Any call to `current` that appears as a default argument (9.3.4.7), or as a subexpression thereof, should correspond to the location of the invocation of the function that uses the default argument (7.6.1.3).

4. `constexpr source_location() noexcept;`  

Remarks: Any call to `current` that appears as a default member initializer (11.4), or as a subexpression thereof, should correspond to the location of the constructor definition or aggregate initialization that uses the default member initializer. Any call to `current` that appears as a default argument (9.3.4.7), or as a subexpression thereof, should correspond to the location of the invocation of the function that uses the default argument (7.6.1.3).

4. `constexpr source_location() noexcept;`  

Remarks: Any call to `current` that appears as a default member initializer (11.4), or as a subexpression thereof, should correspond to the location of the constructor definition or aggregate initialization that uses the default member initializer. Any call to `current` that appears as a default argument (9.3.4.7), or as a subexpression thereof, should correspond to the location of the invocation of the function that uses the default argument (7.6.1.3).
17.8.2.3 Observers

constexpr uint_least32_t line() const noexcept;

Returns: line_.

constexpr uint_least32_t column() const noexcept;

Returns: column_.

constexpr const char* file_name() const noexcept;

Returns: file_name_.

constexpr const char* function_name() const noexcept;

Returns: function_name_.

17.9 Exception handling

17.9.1 General

The header <exception> defines several types and functions related to the handling of exceptions in a C++ program.

17.9.2 Header <exception> synopsis

namespace std {
    class exception;
    class bad_exception;
    class nested_exception;

    using terminate_handler = void (*)(void);
    terminate_handler get_terminate() noexcept;
    terminate_handler set_terminate(terminate_handler f) noexcept;
    [[noreturn]] void terminate() noexcept;

    int uncaught_exceptions() noexcept;
    using exception_ptr = unspecified;
    exception_ptr current_exception() noexcept;
    [[noreturn]] void rethrow_exception(exception_ptr p);
    template<class E> exception_ptr make_exception_ptr(E e) noexcept;
    template<class T> [[noreturn]] void throw_with_nested(T&& t);
    template<class E> void rethrow_if_nested(const E& e);
}

17.9.3 Class exception

namespace std {
    class exception {
    public:
        exception() noexcept;
        exception(const exception&) noexcept;
        exception& operator=(const exception&) noexcept;
        virtual ~exception();
        virtual const char* what() const noexcept;
    }
}

The class exception defines the base class for the types of objects thrown as exceptions by C++ standard library components, and certain expressions, to report errors detected during program execution.

Each standard library class $T$ that derives from class exception has the following publicly accessible member functions, each of them having a non-throwing exception specification (14.5):

1. default constructor (unless the class synopsis shows other constructors)
2. copy constructor
The copy constructor and the copy assignment operator meet the following postcondition: If two objects \textit{lhs} and \textit{rhs} both have dynamic type \textit{T} and \textit{lhs} is a copy of \textit{rhs}, then \texttt{strcmp(lhs.what(), rhs.what())} is equal to 0. The \texttt{what()} member function of each such \textit{T} satisfies the constraints specified for \texttt{exception::what()} (see below).

\begin{verbatim}
exception(const exception& rhs) noexcept;
exception& operator=(const exception& rhs) noexcept;

Postconditions: If \*this and \textit{rhs} both have dynamic type \texttt{exception} then the value of the expression 
\texttt{strcmp(what(), rhs.what())} shall equal 0.

virtual ~exception();

Effects: Destroys an object of class \texttt{exception}.

virtual const char* what() const noexcept override;

Returns: An implementation-defined nTBS.

Remarks: The message may be a null-terminated multibyte string (16.3.3.5.3), suitable for conversion and display as a \texttt{wstring} (21.3, 28.4.2.5). The return value remains valid until the exception object from which it is obtained is destroyed or a non-\texttt{const} member function of the exception object is called.
\end{verbatim}

17.9.4 Class \texttt{bad\_exception} 

\begin{verbatim}
namespace std {
  class bad_exception : public exception {
    public:
      // see 17.9.3 for the specification of the special member functions
      const char* what() const noexcept override;
  }
}
\end{verbatim}

1 The class \texttt{bad\_exception} defines the type of the object referenced by the \texttt{exception\_ptr} returned from a call to \texttt{current\_exception} (17.9.7) when the currently active exception object fails to copy.

\begin{verbatim}
const char* what() const noexcept override;

Returns: An implementation-defined nTBS.
\end{verbatim}

17.9.5 Abnormal termination 

17.9.5.1 Type \texttt{terminate\_handler} 

\begin{verbatim}
using terminate_handler = void (*)();
\end{verbatim}

1 The type of a \texttt{handler function} to be invoked by \texttt{terminate} when terminating exception processing.

\begin{verbatim}
Required behavior: A \texttt{terminate\_handler} shall terminate execution of the program without returning to the caller.
\end{verbatim}

\begin{verbatim}
Default behavior: The implementation's default \texttt{terminate\_handler} calls \texttt{abort()}.
\end{verbatim}

17.9.5.2 \texttt{set\_terminate} 

\begin{verbatim}
terminate_handler set_terminate(terminate_handler f) noexcept;
\end{verbatim}

1 \texttt{Effects}: Establishes the function designated by \textit{f} as the current handler function for terminating exception processing.

\begin{verbatim}
Returns: The previous \texttt{terminate\_handler}.
\end{verbatim}

\begin{verbatim}
Remarks: It is unspecified whether a null pointer value designates the default \texttt{terminate\_handler}.
\end{verbatim}

17.9.5.3 \texttt{get\_terminate} 

\begin{verbatim}
terminate_handler get_terminate() noexcept;
\end{verbatim}

\begin{verbatim}
Returns: The current \texttt{terminate\_handler}.
\end{verbatim}

\begin{verbatim}
[Note 1: This can be a null pointer value. — end note]
\end{verbatim}
17.9.5.4 `terminate`

```cpp
[noreturn] void terminate() noexcept;
```

**Effects:** Calls a `terminate_handler` function. It is unspecified which `terminate_handler` function will be called if an exception is active during a call to `set_terminate`. Otherwise calls the current `terminate_handler` function.

[Note 1: A default `terminate_handler` is always considered a callable handler in this context. — end note]

**Remarks:** Called by the implementation when exception handling must be abandoned for any of several reasons (14.6.2). May also be called directly by the program.

17.9.6 `uncaught_exceptions`

```cpp
int uncaught_exceptions() noexcept;
```

**Returns:** The number of uncaught exceptions (14.6.3).

**Remarks:** When `uncaught_exceptions() > 0`, throwing an exception can result in a call of the function `std::terminate` (14.6.2).

17.9.7 Exception propagation

```cpp
using exception_ptr = unspecified;
```

The type `exception_ptr` can be used to refer to an exception object.

```cpp
exception_ptr meets the requirements of Cpp17NullablePointer (Table 35).
```

Two non-null values of type `exception_ptr` are equivalent and compare equal if and only if they refer to the same exception.

The default constructor of `exception_ptr` produces the null value of the type.

`exception_ptr` shall not be implicitly convertible to any arithmetic, enumeration, or pointer type.

[Note 1: An implementation can use a reference-counted smart pointer as `exception_ptr`. — end note]

For purposes of determining the presence of a data race, operations on `exception_ptr` objects shall access and modify only the `exception_ptr` objects themselves and not the exceptions they refer to. Use of `rethrow_exception` on `exception_ptr` objects that refer to the same exception object shall not introduce a data race.

[Note 2: If `rethrow_exception` rethrows the same exception object (rather than a copy), concurrent access to that rethrown exception object can introduce a data race. Changes in the number of `exception_ptr` objects that refer to a particular exception do not introduce a data race. — end note]

```cpp
exception_ptr current_exception() noexcept;
```

**Returns:** An `exception_ptr` object that refers to the currently handled exception (14.4) or a copy of the currently handled exception, or a null `exception_ptr` object if no exception is being handled. The referenced object shall remain valid at least as long as there is an `exception_ptr` object that refers to it. If the function needs to allocate memory and the attempt fails, it returns an `exception_ptr` object that refers to an instance of `bad_alloc`. It is unspecified whether the return values of two successive calls to `current_exception` refer to the same exception object.

[Note 3: That is, it is unspecified whether `current_exception` creates a new copy each time it is called. — end note]

If the attempt to copy the current exception object throws an exception, the function returns an `exception_ptr` object that refers to the thrown exception or, if this is not possible, to an instance of `bad_exception`.

[Note 4: The copy constructor of the thrown exception can also fail, so the implementation is allowed to substitute a `bad_exception` object to avoid infinite recursion. — end note]

```cpp
[noreturn] void rethrow_exception(exception_ptr p);
```

**Preconditions:** p is not a null pointer.

**Throws:** The exception object to which p refers.
template<class E> exception_ptr make_exception_ptr(E e) noexcept;

Effects: Creates an exception_ptr object that refers to a copy of e, as if:
try {
    throw e;
} catch(...) {
    return current_exception();
}

[Note 5: This function is provided for convenience and efficiency reasons. — end note]

17.9.8 nested_exception

namespace std {
    class nested_exception {
    public:
        nested_exception() noexcept;
        nested_exception(const nested_exception&) noexcept = default;
        nested_exception& operator=(const nested_exception&) noexcept = default;
        virtual ~nested_exception() = default;

        // access functions
        [[noreturn]] void rethrow_nested() const;
        exception_ptr nested_ptr() const noexcept;
    }

    template<class T> [[noreturn]] void throw_with_nested(T& t);
    template<class E> void rethrow_if_nested(const E& e);
};

The class nested_exception is designed for use as a mixin through multiple inheritance. It captures the currently handled exception and stores it for later use.

[Note 1: nested_exception has a virtual destructor to make it a polymorphic class. Its presence can be tested for with dynamic_cast. — end note]

nested_exception() noexcept;

Effects: The constructor calls current_exception() and stores the returned value.

[[noreturn]] void rethrow_nested() const;

Effects: If nested_ptr() returns a null pointer, the function calls the function std::terminate. Otherwise, it throws the stored exception captured by *this.

exception_ptr nested_ptr() const noexcept;

Returns: The stored exception captured by this nested_exception object.

template<class T> [[noreturn]] void throw_with_nested(T& t);

Let U be decay_t<T>.

Preconditions: U meets the Cpp17CopyConstructible requirements.

Throws: If is_class_v<U> &is_final_v<U> &is_base_of_v<nested_exception, U> is true, an exception of unspecified type that is publicly derived from both U and nested_exception and constructed from std::forward<T>(t), otherwise std::forward<T>(t).

template<class E> void rethrow_if_nested(const E& e);

Effects: If E is not a polymorphic class type, or if nested_exception is an inaccessible or ambiguous base class of E, there is no effect. Otherwise, performs:
if (auto p = dynamic_cast<const nested_exception*>(addressof(e)))
    p->rethrow_nested();
17.10 Initializer lists

17.10.1 General

The header `<initializer_list>` defines a class template and several support functions related to list-initialization (see 9.4.5). All functions specified in 17.10 are signal-safe (17.13.5).

17.10.2 Header `<initializer_list>` synopsis

```cpp
namespace std {
    template<class E> class initializer_list {
        public:
            using value_type = E;
            using reference = const E&;
            using const_reference = const E&;
            using size_type = size_t;
            using iterator = const E*;
            using const_iterator = const E*;

            constexpr initializer_list() noexcept;
            constexpr size_t size() const noexcept; // number of elements
            constexpr const E* begin() const noexcept; // first element
            constexpr const E* end() const noexcept; // one past the last element
    };

    // 17.10.5, initializer list range access
    template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;
    template<class E> constexpr const E* end(initializer_list<E> il) noexcept;
}
```

An object of type `initializer_list<E>` provides access to an array of objects of type `const E`.

[Note 1: A pair of pointers or a pointer plus a length would be obvious representations for `initializer_list`. `initializer_list` is used to implement initializer lists as specified in 9.4.5. Copying an initializer list does not copy the underlying elements. — end note]

2 If an explicit specialization or partial specialization of `initializer_list` is declared, the program is ill-formed.

17.10.3 Initializer list constructors

```cpp
constexpr initializer_list() noexcept;
```

Postconditions: `size() == 0`.

17.10.4 Initializer list access

```cpp
constexpr const E* begin() const noexcept;
```

Returns: A pointer to the beginning of the array. If `size() == 0` the values of `begin()` and `end()` are unspecified but they shall be identical.

```cpp
constexpr const E* end() const noexcept;
```

Returns: `begin() + size()`.

17.10.5 Initializer list range access

```cpp
template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;
```

Returns: `il.begin()`.

§ 17.10.5 520
template<class E> constexpr const E* end(initializer_list<E> il) noexcept;

Returns: il.end().

17.11 Comparisons

17.11.1 Header <compare> synopsis

The header <compare> specifies types, objects, and functions for use primarily in connection with the three-way comparison operator (7.6.8).

namespace std {
  // 17.11.2, comparison category types
  class partial_ordering;
  class weak_ordering;
  class strong_ordering;

  // named comparison functions
  constexpr bool is_eq (partial_ordering cmp) noexcept { return cmp == 0; }
  constexpr bool is_neq (partial_ordering cmp) noexcept { return cmp != 0; }
  constexpr bool is_lt (partial_ordering cmp) noexcept { return cmp < 0; }
  constexpr bool is_lteq(partial_ordering cmp) noexcept { return cmp <= 0; }
  constexpr bool is_gt (partial_ordering cmp) noexcept { return cmp > 0; }
  constexpr bool is_gteq(partial_ordering cmp) noexcept { return cmp >= 0; }

  // 17.11.3, common comparison category type
  template<class... Ts>
    struct common_comparison_category { using type = see below; };
  template<class... Ts>
    using common_comparison_category_t = typename common_comparison_category<Ts...>::type;

  // 17.11.4, concept three_way_comparable
  template<class T, class Cat = partial_ordering>
    concept three_way_comparable = see below;
  template<class T, class U, class Cat = partial_ordering>
    concept three_way_comparable_with = see below;

  // 17.11.5, result of three-way comparison
  template<class T, class U = T> struct compare_three_way_result;
  template<class T, class U = T>
    using compare_three_way_result_t = typename compare_three_way_result<T, U>::type;

  // 20.14.8.8, class compare_three_way
  struct compare_three_way;

  // 17.11.6, comparison algorithms
  inline namespace unspecified {
    inline constexpr unspecified strong_order = unspecified;
    inline constexpr unspecified weak_order = unspecified;
    inline constexpr unspecified partial_order = unspecified;
    inline constexpr unspecified compare_strong_order_fallback = unspecified;
    inline constexpr unspecified compare_weak_order_fallback = unspecified;
    inline constexpr unspecified compare_partial_order_fallback = unspecified;
  }
}

17.11.2 Comparison category types

17.11.2.1 Preamble

The types partial_ordering, weak_ordering, and strong_ordering are collectively termed the comparison category types. Each is specified in terms of an exposition-only data member named value whose value typically corresponds to that of an enumerator from one of the following exposition-only enumerations:

enum class ord { equal = 0, equivalent = equal, less = -1, greater = 1 }; // exposition only
enum class ncmp { unordered = -127 };  // exposition only

[Note 1: The type strong_ordering corresponds to the term total ordering in mathematics. — end note]

The relational and equality operators for the comparison category types are specified with an anonymous parameter of unspecified type. This type shall be selected by the implementation such that these parameters can accept literal 0 as a corresponding argument.

[Example 1: nullptr_t meets this requirement. — end example]

In this context, the behavior of a program that supplies an argument other than a literal 0 is undefined.

For the purposes of subclause 17.11.2, substitutability is the property that \( f(a) == f(b) \) is true whenever \( a == b \) is true, where \( f \) denotes a function that reads only comparison-salient state that is accessible via the argument's public const members.

### 17.11.2.2 Class partial_ordering

The partial_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits all of the six two-way comparison operators (7.6.9, 7.6.10), (b) does not imply substitutability, and (c) permits two values to be incomparable.

```cpp
namespace std {

class partial_ordering {
   int value;  // exposition only
   bool is_ordered;  // exposition only

   // exposition-only constructors
   constexpr explicit partial_ordering(ord v) noexcept : value(int(v)), is_ordered(true) {}  // exposition only
   constexpr explicit partial_ordering(ncmp v) noexcept : value(int(v)), is_ordered(false) {}  // exposition only

   public:
      // valid values
      static const partial_ordering less;
      static const partial_ordering equivalent;
      static const partial_ordering greater;
      static const partial_ordering unordered;

      // comparisons
      friend constexpr bool operator==(partial_ordering v, unspecified) noexcept;
      friend constexpr bool operator==(partial_ordering v, partial_ordering w) noexcept = default;
      friend constexpr bool operator<(partial_ordering v, unspecified) noexcept;
      friend constexpr bool operator>(partial_ordering v, unspecified) noexcept;
      friend constexpr bool operator<=(partial_ordering v, unspecified) noexcept;
      friend constexpr bool operator>=(partial_ordering v, unspecified) noexcept;
      friend constexpr bool operator<(unspecified, partial_ordering v) noexcept;
      friend constexpr bool operator>(unspecified, partial_ordering v) noexcept;
      friend constexpr bool operator<=(unspecified, partial_ordering v) noexcept;
      friend constexpr bool operator>=(unspecified, partial_ordering v) noexcept;

      friend constexpr partial_ordering operator<=>(partial_ordering v, unspecified) noexcept;
      friend constexpr partial_ordering operator<=>(unspecified, partial_ordering v) noexcept;

   };

   // valid values' definitions
   inline constexpr partial_ordering partial_ordering::less(ord::less);
   inline constexpr partial_ordering partial_ordering::equivalent(ord::equivalent);
   inline constexpr partial_ordering partial_ordering::greater(ord::greater);
   inline constexpr partial_ordering partial_ordering::unordered(ncmp::unordered);

   constexpr bool operator==(partial_ordering v, unspecified) noexcept;
   constexpr bool operator==(partial_ordering v, unspecified) noexcept;
   constexpr bool operator<(partial_ordering v, unspecified) noexcept;
   constexpr bool operator<(unspecified, partial_ordering v) noexcept;
   constexpr bool operator<=(partial_ordering v, unspecified) noexcept;
   constexpr bool operator<=(unspecified, partial_ordering v) noexcept;
   constexpr bool operator>(unspecified, partial_ordering v) noexcept;
   constexpr bool operator>(partial_ordering v, unspecified) noexcept;
   constexpr bool operator>=(partial_ordering v, unspecified) noexcept;
   constexpr bool operator>=(unspecified, partial_ordering v) noexcept;
   constexpr bool operator<=>(partial_ordering v, unspecified) noexcept;
   constexpr bool operator<=>(unspecified, partial_ordering v) noexcept;

210 That is, \( a < b \), \( a == b \), and \( a > b \) might all be false.
17.11.2.3 Class weak_ordering

The weak_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits all of the six two-way comparison operators (7.6.9, 7.6.10), and (b) does not imply substitutability.

```cpp
namespace std {
    class weak_ordering {
        int value; // exposition only
        // exposition-only constructors
        constexpr explicit weak_ordering(ord v) noexcept : value(int(v)) {} // exposition only
        public:
        // valid values
        static const weak_ordering less;
        static const weak_ordering equivalent;
        static const weak_ordering greater;
        // conversions
        constexpr operator partial_ordering() const noexcept;
        // comparisons
        friend constexpr bool operator==(weak_ordering v, unspecified) noexcept;
        friend constexpr bool operator==(weak_ordering v, weak_ordering w) noexcept = default;
        friend constexpr bool operator<( weak_ordering v, unspecified) noexcept;
        friend constexpr bool operator>( weak_ordering v, unspecified) noexcept;
        friend constexpr bool operator<=(weak_ordering v, unspecified) noexcept;
        friend constexpr bool operator>=(weak_ordering v, unspecified) noexcept;
        friend constexpr weak_ordering operator<=>(weak_ordering v, unspecified) noexcept;
        friend constexpr weak_ordering operator<=>(unspecified, weak_ordering v) noexcept;
    }
    // valid values' definitions
    inline constexpr weak_ordering weak_ordering::less(ord::less);
    inline constexpr weak_ordering weak_ordering::equivalent(ord::equivalent);
    inline constexpr weak_ordering weak_ordering::greater(ord::greater);
}

constexpr operator partial_ordering() const noexcept;

Returns: ’v < 0 ? partial_ordering::greater : v > 0 ? partial_ordering::less : v.’
 constexpr bool operator==(weak_ordering v, unspecified) noexcept;
constexpr bool operator< (weak_ordering v, unspecified) noexcept;
constexpr bool operator> (weak_ordering v, unspecified) noexcept;
constexpr bool operator<=(weak_ordering v, unspecified) noexcept;
constexpr bool operator>=(weak_ordering v, unspecified) noexcept;

  Returns: v.value @ 0 for operator@.

constexpr bool operator< (unspecified, weak_ordering v) noexcept;
constexpr bool operator> (unspecified, weak_ordering v) noexcept;
constexpr bool operator<= (unspecified, weak_ordering v) noexcept;
constexpr bool operator>= (unspecified, weak_ordering v) noexcept;

  Returns: 0 @ v.value for operator@.

constexpr weak_ordering operator<=(weak_ordering v, unspecified) noexcept;

Returns: v < 0 ? weak_ordering::greater : v > 0 ? weak_ordering::less : v.

17.11.2.4 Class strong_ordering [cmp.strongord]

The strong_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits all of the six two-way comparison operators (7.6.9, 7.6.10), and (b) does imply substitutability.

namespace std {
  class strong_ordering {
    int value; // exposition only

    // exposition-only constructors
    constexpr explicit strong_ordering(ord v) noexcept : value(int(v)) {} // exposition only

    public:
      // valid values
      static const strong_ordering less;
      static const strong_ordering equal;
      static const strong_ordering equivalent;
      static const strong_ordering greater;

      // conversions
      constexpr operator partial_ordering() const noexcept;
      constexpr operator weak_ordering() const noexcept;

      // comparisons
    friend constexpr bool operator==(strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator==(strong_ordering v, strong_ordering w) noexcept = default;
    friend constexpr bool operator< (strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator> (strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator<=(strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator>=(strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator< (unspecified, strong_ordering v) noexcept;
    friend constexpr bool operator> (unspecified, strong_ordering v) noexcept;
    friend constexpr bool operator<= (unspecified, strong_ordering v) noexcept;
    friend constexpr bool operator>= (unspecified, strong_ordering v) noexcept;
    friend constexpr strong_ordering operator<=(strong_ordering v, unspecified) noexcept;
    friend constexpr strong_ordering operator>=(strong_ordering v, unspecified) noexcept;
    }

    // valid values' definitions
    inline constexpr strong_ordering strong_ordering::less(ord::less);
    inline constexpr strong_ordering strong_ordering::equal(ord::equal);
    inline constexpr strong_ordering strong_ordering::equivalent(ord::equivalent);
    inline constexpr strong_ordering strong_ordering::greater(ord::greater);
  }

§ 17.11.2.4
constexpr operator partial_ordering() const noexcept;

Returns:

value == 0 ? partial_ordering::equivalent :
value < 0 ? partial_ordering::less :
partial_ordering::greater

constexpr operator weak_ordering() const noexcept;

Returns:

value == 0 ? weak_ordering::equivalent :
value < 0 ? weak_ordering::less :
weak_ordering::greater

constexpr bool operator==(strong_ordering v, unspecified) noexcept;
constexpr bool operator< (strong_ordering v, unspecified) noexcept;
constexpr bool operator> (strong_ordering v, unspecified) noexcept;
constexpr bool operator<=(strong_ordering v, unspecified) noexcept;
constexpr bool operator>=(strong_ordering v, unspecified) noexcept;

Returns: v.value @ 0 for operator@.

constexpr bool operator< (unspecified, strong_ordering v) noexcept;
constexpr bool operator> (unspecified, strong_ordering v) noexcept;
constexpr bool operator<= (unspecified, strong_ordering v) noexcept;
constexpr bool operator>= (unspecified, strong_ordering v) noexcept;

Returns: v < 0 ? strong_ordering::greater : v > 0 ? strong_ordering::less : v.

17.11.3 Class template common_comparison_category [cmp.common]

The type common_comparison_category provides an alias for the strongest comparison category to which all of the template arguments can be converted.

[Note 1: A comparison category type is stronger than another if they are distinct types and an instance of the former can be converted to an instance of the latter. —end note]

template<class... Ts>
struct common_comparison_category {
    using type = see below;
};

Remarks: The member typedef-name type denotes the common comparison type (11.10.3) of Ts..., the expanded parameter pack, or void if any element of Ts is not a comparison category type.

[Note 2: This is std::strong_ordering if the expansion is empty. —end note]

17.11.4 Concept three_way_comparable [cmp.concept]

template<class T, class Cat>
concept compares-as = // exposition only
same_as<common_comparison_category_t<T, Cat>, Cat>;

template<class T, class U>
concept partially-ordered-with = // exposition only
requires(const remove_reference_t<T>& t, const remove_reference_t<U>& u) {
    { t < u } -> boolean-testable;
    { t > u } -> boolean-testable;
    { t <= u } -> boolean-testable;
    { t >= u } -> boolean-testable;
    { u < t } -> boolean-testable;
    { u > t } -> boolean-testable;
}
Let \( t \) and \( u \) be lvalues of types `const remove_reference_t<T>` and `const remove_reference_t<U>`, respectively. \( T \) and \( U \) model `partially-ordered-with<T, U>` only if:

1. \( t < u, t <= u, t > u, t >= u, u < t, u <= t, u > t, \) and \( u >= t \) have the same domain.
2. `bool(t < u) == bool(u > t)` is true.
3. `bool(u < t) == bool(t > u)` is true.
4. `bool(t <= u) == bool(u >= t)` is true.
5. `bool(u <= t) == bool(t >= u)` is true.

```cpp
template<class T, class Cat = partial_ordering>
concept three_way_comparable =
    weakly-equality-comparable-with<T, T> && partially-ordered-with<T, T> &&
    requires(const remove_reference_t<T>& a, const remove_reference_t<T>& b) {
        { a <=> b } -> compares-as<Cat>;
    };
```

Let \( a \) and \( b \) be lvalues of type `const remove_reference_t<T>`. \( T \) and \( Cat \) model `three_way_comparable<T, Cat>` only if:

1. `bool(a == b)` is true,
2. `bool(a != b)` is true,
3. `((a <=> b) <=> 0)` and `(0 <=> (b <=> a))` are equal,
4. `bool(a < b)` is true,
5. `bool(a > b)` is true,
6. `bool(a <= b)` is true,
7. `bool(a >= b)` is true.
8. `Cat(t <=> u) == Cat(C(t) <=> C(u))` is true.
9. `bool(t < u)` is true,
10. `bool(t > u)` is true.

```cpp
template<class T, class U, class Cat = partial_ordering>
concept three_way_comparable_with =
    three_way_comparable<T, Cat> &&
    three_way_comparable<U, Cat> &&
    common_reference_with<const remove_reference_t<T>&, const remove_reference_t<U>&> &&
    three_way_comparable<
        common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>, Cat> &&
        weakly-equality-comparable-with<T, U> && partially-ordered-with<T, U> &&
        requires(const remove_reference_t<T>& t, const remove_reference_t<U>& u) {
            { t <=> u } -> compares-as<Cat>;
            { u <=> t } -> compares-as<Cat>;
        };
```

Let \( t \) and \( u \) be lvalues of types `const remove_reference_t<T>` and `const remove_reference_t<U>`, respectively. Let \( C \) be `common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>`. \( T, U, \) and \( Cat \) model `three_way_comparable_with<T, U, Cat>` only if:

1. `t <= u` and `u <= t` have the same domain,
2. `(t <= u) <= 0)` and `(0 <= (u <= t))` are equal,
3. `bool(t == u)` is true,
4. `bool(t != u)` is true,
5. `Cat(t <= u) == Cat(C(t) <= C(u))` is true,
6. `bool(t < u)` is true,
7. `bool(t > u)` is true.
8. `bool(t <= u)` is true,
(3.9) \( (t \leftrightarrow u \geq 0) = \text{bool}(t \geq u) \) is true, and
(3.10) if `Cat` is convertible to `strong_ordering`, `T` and `U` model `totally_ordered_with<T, U>` (18.5.4).

17.11.5 Result of three-way comparison [cmp.result]

The behavior of a program that adds specializations for the `compare_three_way_result` template defined in this subclause is undefined.

For the `compare_three_way_result` type trait applied to the types `T` and `U`, let `t` and `u` denote lvalues of types `const remove_reference_t<T>` and `const remove_reference_t<U>`, respectively. If the expression `t \leftrightarrow u` is well-formed when treated as an unevaluated operand (7.2.3), the member `typedef-name` type denotes the type `decltype(t \leftrightarrow u)`. Otherwise, there is no member type.

17.11.6 Comparison algorithms [cmp.alg]

The name `strong_order` denotes a customization point object (16.3.3.6). Given subexpressions `E` and `F`, the expression `strong_order(E, F)` is expression-equivalent (3.21) to the following:

(1.1) If the decayed types of `E` and `F` differ, `strong_order(E, F)` is ill-formed.
(1.2) Otherwise, `strong_ordering(strong_order(E, F))` if it is a well-formed expression with overload resolution performed in a context that does not include a declaration of `std::strong_order`.
(1.3) Otherwise, if the decayed type `T` of `E` is a floating-point type, yields a value of type `strong_ordering` that is consistent with the ordering observed by `T`'s comparison operators, and if `numeric_limits<T>::is_iec559` is `true`, is additionally consistent with the `totalOrder` operation as specified in ISO/IEC/IEEE 60559.
(1.4) Otherwise, `strong_ordering(compare_three_way()(E, F))` if it is a well-formed expression.
(1.5) Otherwise, `strong_order(E, F)` is ill-formed.

[Note 1: Ill-formed cases above result in substitution failure when `strong_order(E, F)` appears in the immediate context of a template instantiation. — end note]

The name `weak_order` denotes a customization point object (16.3.3.6). Given subexpressions `E` and `F`, the expression `weak_order(E, F)` is expression-equivalent (3.21) to the following:

(2.1) If the decayed types of `E` and `F` differ, `weak_order(E, F)` is ill-formed.
(2.2) Otherwise, `weak_ordering(weak_order(E, F))` if it is a well-formed expression with overload resolution performed in a context that does not include a declaration of `std::weak_order`.
(2.3) Otherwise, if the decayed type `T` of `E` is a floating-point type, yields a value of type `weak_ordering` that is consistent with the ordering observed by `T`'s comparison operators and `strong_order`, and if `numeric_limits<T>::is_iec559` is `true`, is additionally consistent with the following equivalence classes, ordered from lesser to greater:

(2.3.1) together, all negative NaN values;
(2.3.2) negative infinity;
(2.3.3) each normal negative value;
(2.3.4) each subnormal negative value;
(2.3.5) together, both zero values;
(2.3.6) each subnormal positive value;
(2.3.7) each normal positive value;
(2.3.8) positive infinity;
(2.3.9) together, all positive NaN values.
(2.4) Otherwise, `weak_ordering(compare_three_way()(E, F))` if it is a well-formed expression.
(2.5) Otherwise, `weak_ordering(strong_order(E, F))` if it is a well-formed expression.
(2.6) Otherwise, `weak_order(E, F)` is ill-formed.

[Note 2: Ill-formed cases above result in substitution failure when `weak_order(E, F)` appears in the immediate context of a template instantiation. — end note]
The name `partial_order` denotes a customization point object (16.3.3.3.6). Given subexpressions `E` and `F`, the expression `partial_order(E, F)` is expression-equivalent (3.21) to the following:

1. If the decayed types of `E` and `F` differ, `partial_order(E, F)` is ill-formed.
2. Otherwise, `partial_ordering(partial_order(E, F))` if it is a well-formed expression with overload resolution performed in a context that does not include a declaration of `std::partial_order`.
3. Otherwise, `partial_ordering(compare_three_way()(E, F))` if it is a well-formed expression.
4. Otherwise, `partial_ordering(weak_order(E, F))` if it is a well-formed expression.
5. Otherwise, `partial_order(E, F)` is ill-formed.

[Note 3: Ill-formed cases above result in substitution failure when `partial_order(E, F)` appears in the immediate context of a template instantiation. — end note]

The name `compare_strong_order_fallback` denotes a customization point object (16.3.3.3.6). Given subexpressions `E` and `F`, the expression `compare_strong_order_fallback(E, F)` is expression-equivalent (3.21) to:

1. If the decayed types of `E` and `F` differ, `compare_strong_order_fallback(E, F)` is ill-formed.
2. Otherwise, `strong_order(E, F)` if it is a well-formed expression.
3. Otherwise, if the expressions `E == F` and `E < F` are both well-formed and convertible to `bool`,
   ```
   E == F ? strong_ordering::equal :
   E < F ? strong_ordering::less :
   strong_ordering::greater
   ```
   except that `E` and `F` are evaluated only once.
4. Otherwise, `compare_strong_order_fallback(E, F)` is ill-formed.

[Note 4: Ill-formed cases above result in substitution failure when `compare_strong_order_fallback(E, F)` appears in the immediate context of a template instantiation. — end note]

The name `compare_weak_order_fallback` denotes a customization point object (16.3.3.3.6). Given subexpressions `E` and `F`, the expression `compare_weak_order_fallback(E, F)` is expression-equivalent (3.21) to:

1. If the decayed types of `E` and `F` differ, `compare_weak_order_fallback(E, F)` is ill-formed.
2. Otherwise, `weak_order(E, F)` if it is a well-formed expression.
3. Otherwise, if the expressions `E == F` and `E < F` are both well-formed and convertible to `bool`,
   ```
   E == F ? weak_ordering::equivalent :
   E < F ? weak_ordering::less :
   weak_ordering::greater
   ```
   except that `E` and `F` are evaluated only once.
4. Otherwise, `compare_weak_order_fallback(E, F)` is ill-formed.

[Note 5: Ill-formed cases above result in substitution failure when `compare_weak_order_fallback(E, F)` appears in the immediate context of a template instantiation. — end note]

The name `compare_partial_order_fallback` denotes a customization point object (16.3.3.3.6). Given subexpressions `E` and `F`, the expression `compare_partial_order_fallback(E, F)` is expression-equivalent (3.21) to:

1. If the decayed types of `E` and `F` differ, `compare_partial_order_fallback(E, F)` is ill-formed.
2. Otherwise, `partial_order(E, F)` if it is a well-formed expression.
3. Otherwise, if the expressions `E == F`, `E < F`, and `F < E` are all well-formed and convertible to `bool`,
   ```
   E == F ? partial_ordering::equivalent :
   E < F ? partial_ordering::less :
   F < E ? partial_ordering::greater :
   partial_ordering::unordered
   ```
   except that `E` and `F` are evaluated only once.
4. Otherwise, `compare_partial_order_fallback(E, F)` is ill-formed.
17.12 Coroutines

17.12.1 General

The header `<coroutine>` defines several types providing compile and run-time support for coroutines in a C++ program.

17.12.2 Header `<coroutine>` synopsis

```
#include <compare>     // see 17.11.1

namespace std {
    // 17.12.3, coroutine traits
    template<class R, class... ArgTypes>
        struct coroutine_traits;

    // 17.12.4, coroutine handle
    template<class Promise = void>
        struct coroutine_handle;

    // 17.12.4.8, comparison operators
    constexpr bool operator==(coroutine_handle<> x, coroutine_handle<> y) noexcept;
    constexpr strong_ordering operator<=>(coroutine_handle<> x, coroutine_handle<> y) noexcept;

    // 17.12.4.9, hash support
    template<class T> struct hash;
    template<class P> struct hash<coroutine_handle<P>>;

    // 17.12.5, no-op coroutines
    struct noop_coroutine_promise;
    template<> struct coroutine_handle<noop_coroutine_promise>;
    using noop_coroutine_handle = coroutine_handle<noop_coroutine_promise>;
    noop_coroutine_handle noop_coroutine() noexcept;

    // 17.12.6, trivial awaitables
    struct suspend_never;
    struct suspend_always;
}
```

17.12.3 Coroutine traits

17.12.3.1 General

Subclause 17.12.3 defines requirements on classes representing coroutine traits, and defines the class template `coroutine_traits` that meets those requirements.

17.12.3.2 Class template coroutine_traits

The header `<coroutine>` defines the primary template `coroutine_traits` such that if `ArgTypes` is a parameter pack of types and if the qualified-id `R::promise_type` is valid and denotes a type (13.10.3), then `coroutine_traits<R,ArgTypes...>` has the following publicly accessible member:

```
    using promise_type = typename R::promise_type;
```

Otherwise, `coroutine_traits<R,ArgTypes...>` has no members.

Program-defined specializations of this template shall define a publicly accessible nested type named `promise_type`. 

[Note 6: Ill-formed cases above result in substitution failure when `compare_partial_order_fallback(E, F)` appears in the immediate context of a template instantiation. — end note]
17.12.4 Class template coroutine_handle

17.12.4.1 General

namespace std {
    template<>
    struct coroutine_handle<void>
    {
        // 17.12.4.2, construct/reset
        constexpr coroutine_handle() noexcept;
        constexpr coroutine_handle(nullptr_t) noexcept;
        coroutine_handle& operator=(nullptr_t) noexcept;

        // 17.12.4.4, export/import
        constexpr void* address() const noexcept;
        static constexpr coroutine_handle from_address(void* addr);

        // 17.12.4.5, observers
        constexpr explicit operator bool() const noexcept;
        bool done() const;

        // 17.12.4.6, resumption
        void operator()() const;
        void resume() const;
        void destroy() const;

        private:
            void* ptr; // exposition only
    };

    template<class Promise>
    struct coroutine_handle
    {
        // 17.12.4.2, construct/reset
        constexpr coroutine_handle() noexcept;
        constexpr coroutine_handle(nullptr_t) noexcept;
        static coroutine_handle from_promise(Promise&);
        coroutine_handle& operator=(nullptr_t) noexcept;

        // 17.12.4.4, export/import
        constexpr void* address() const noexcept;
        static constexpr coroutine_handle from_address(void* addr);

        // 17.12.4.3, conversion
        constexpr operator coroutine_handle<>() const noexcept;

        // 17.12.4.5, observers
        constexpr explicit operator bool() const noexcept;
        bool done() const;

        // 17.12.4.6, resumption
        void operator()() const;
        void resume() const;
        void destroy() const;

        // 17.12.4.7, promise access
        Promise& promise() const;

        private:
            void* ptr; // exposition only
    };
}

1 An object of type coroutine_handle<T> is called a coroutine handle and can be used to refer to a suspended or executing coroutine. A coroutine_handle object whose member address() returns a null pointer value
does not refer to any coroutine. Two coroutine_handle objects refer to the same coroutine if and only if their member address() returns the same non-null value.

If a program declares an explicit or partial specialization of coroutine_handle, the behavior is undefined.

### 17.12.4.2 Construct/reset

```cpp
constexpr coroutine_handle() noexcept;
coroutine_handle(nullptr_t) noexcept;
```

**Postconditions:** address() == nullptr.

```cpp
static coroutine_handle from_promise(Promise& p);
```

**Preconditions:** p is a reference to a promise object of a coroutine.

**Postconditions:** addressof(h.promise()) == addressof(p).

**Returns:** A coroutine handle h referring to the coroutine.

```cpp
coroutine_handle& operator=(nullptr_t) noexcept;
```

**Postconditions:** address() == nullptr.

**Returns:** *this.

### 17.12.4.3 Conversion

```cpp
constexpr operator coroutine_handle<>() const noexcept;
```

**Effects:** Equivalent to: return coroutine_handle<>::from_address(address());

### 17.12.4.4 Export/import

```cpp
constexpr void* address() const noexcept;
```

**Returns:** ptr.

```cpp
static constexpr coroutine_handle<> coroutine_handle<>::from_address(void* addr);
```

**Preconditions:** addr was obtained via a prior call to address on an object whose type is a specialization of coroutine_handle.

**Postconditions:** from_address(address()) == *this.

```cpp
static coroutine_handle<Promise> coroutine_handle<Promise>::from_address(void* addr);
```

**Preconditions:** addr was obtained via a prior call to address on an object of type cv coroutine_handle<Promise>.

**Postconditions:** from_address(address()) == *this.

### 17.12.4.5 Observers

```cpp
constexpr explicit operator bool() const noexcept;
```

**Returns:** address() != nullptr.

```cpp
bool done() const;
```

**Preconditions:** *this refers to a suspended coroutine.

**Returns:** true if the coroutine is suspended at its final suspend point, otherwise false.

### 17.12.4.6 Resumption

```cpp
void operator()() const;
```

Resuming a coroutine via resume, operator(), or destroy on an execution agent other than the one on which it was suspended has implementation-defined behavior unless each execution agent either is an instance of std::thread or std::jthread, or is the thread that executes main.

[Note 1: A coroutine that is resumed on a different execution agent should avoid relying on consistent thread identity throughout, such as holding a mutex object across a suspend point. — end note]

[Note 2: A concurrent resumption of the coroutine can result in a data race. — end note]
void resume() const;

**Preconditions**: *this refers to a suspended coroutine. The coroutine is not suspended at its final suspend point.

**Effects**: Resumes the execution of the coroutine.

void destroy() const;

**Preconditions**: *this refers to a suspended coroutine.

**Effects**: Destroys the coroutine (9.5.4).

### 17.12.4.7 Promise access

Promise& promise() const;

**Preconditions**: *this refers to a coroutine.

**Returns**: A reference to the promise of the coroutine.

### 17.12.4.8 Comparison operators

conestr bool operator==(coroutine_handle<> x, coroutine_handle<> y) noexcept;

**Returns**: x.address() == y.address().

conestr strong_ordering operator<=>(coroutine_handle<> x, coroutine_handle<> y) noexcept;

**Returns**: compare_three_way()(x.address(), y.address()).

### 17.12.4.9 Hash support

template<class P> struct hash<coroutine_handle<P>>;

The specialization is enabled (20.14.19).

### 17.12.5 No-op coroutines

#### 17.12.5.1 Class noop_coroutine_promise

struct noop_coroutine_promise {};

The class *noop_coroutine_promise* defines the promise type for the coroutine referred to by *noop_coroutine_handle* (17.12.2).

#### 17.12.5.2 Class coroutine_handle<noop_coroutine_promise>

namespace std {
    template<class>
    struct coroutine_handle<noop_coroutine_promise> {
        // 17.12.5.2.1, conversion
        constexpr operator coroutine_handle<>() const noexcept;

        // 17.12.5.2.2, observers
        constexpr explicit operator bool() const noexcept;
        constexpr bool done() const noexcept;

        // 17.12.5.2.3, resumption
        constexpr void operator()() const noexcept;
        constexpr void resume() const noexcept;
        constexpr void destroy() const noexcept;

        // 17.12.5.2.4, promise access
        noop_coroutine_promise& promise() const noexcept;

        // 17.12.5.2.5, address
        constexpr void* address() const noexcept;
    private:
        coroutine_handle<unspecified>
        void* ptr; // exposition only
    }
}
17.12.5.2.1 Conversion

constexpr operator coroutine_handle<>() const noexcept;

Effects: Equivalent to: return coroutine_handle<>::from_address(address());

17.12.5.2.2 Observers

constexpr explicit operator bool() const noexcept;

Returns: true.

constexpr bool done() const noexcept;

Returns: false.

17.12.5.2.3 Resumption

constexpr void operator()() const noexcept;
constexpr void resume() const noexcept;
constexpr void destroy() const noexcept;

Effects: None.

Remarks: If noop_coroutine_handle is converted to coroutine_handle<>, calls to operator(), resume and destroy on that handle will also have no observable effects.

17.12.5.2.4 Promise access

noop_coroutine_promise& promise() const noexcept;

Returns: A reference to the promise object associated with this coroutine handle.

17.12.5.2.5 Address

constexpr void* address() const noexcept;

Returns: ptr.

Remarks: A noop_coroutine_handle’s ptr is always a non-null pointer value.

17.12.5.3 Function noop_coroutine

noop_coroutine_handle noop_coroutine() noexcept;

Returns: A handle to a coroutine that has no observable effects when resumed or destroyed.

Remarks: A handle returned from noop_coroutine may or may not compare equal to a handle returned from another invocation of noop_coroutine.

17.12.6 Trivial awaitables

namespace std {
    struct suspend_never {
        constexpr bool await_ready() const noexcept { return true; }
        constexpr void await_suspend(coroutine_handle<>) const noexcept {}
        constexpr void await_resume() const noexcept {};
    };
    struct suspend_always {
        constexpr bool await_ready() const noexcept { return false; }
        constexpr void await_suspend(coroutine_handle<>) const noexcept {}
        constexpr void await_resume() const noexcept {};
    };
};

[Note 1: The types suspend_never and suspend_always can be used to indicate that an await-expression either never suspends or always suspends, and in either case does not produce a value. — end note]
17.13 Other runtime support

17.13.1 General

Headers `<csetjmp>` (nonlocal jumps), `<csignal>` (signal handling), `<cstdlib>` (variable arguments), and `<cstdarg>` (runtime environment `getenv`, `system`), provide further compatibility with C code.

Calls to the function `getenv` (17.2.2) shall not introduce a data race (16.4.6.10) provided that nothing modifies the environment.

[Note 1: Calls to the POSIX functions `setenv` and `putenv` modify the environment. — end note]

A call to the `setlocale` function (28.5) may introduce a data race with other calls to the `setlocale` function or with calls to functions that are affected by the current C locale. The implementation shall behave as if no library function other than `locale::global` calls the `setlocale` function.

17.13.2 Header `<cstdarg>` synopsis

```cpp
namespace std {
    using va_list = see below;
}

#define va_arg(V, P) see below
#define va_copy(VDST, VSRC) see below
#define va_end(V) see below
#define va_start(V, P) see below
```

1 The contents of the header `<cstdarg>` are the same as the C standard library header `<stdarg.h>`, with the following changes: The restrictions that ISO C places on the second parameter to the `va_start` macro in header `<stdarg.h>` are different in this document. The parameter `parmN` is the rightmost parameter in the variable parameter list of the function definition (the one just before the `...`). If the parameter `parmN` is a pack expansion (13.7.4) or an entity resulting from a lambda capture (7.5.5), the program is ill-formed, no diagnostic required. If the parameter `parmN` is of a reference type, or of a type that is not compatible with the type that results when passing an argument for which there is no parameter, the behavior is undefined. See also: ISO C 7.16.1.1

17.13.3 Header `<csetjmp>` synopsis

```cpp
namespace std {
    using jmp_buf = see below;
    [[noreturn]] void longjmp(jmp_buf env, int val);
}

#define setjmp(env) see below
```

1 The contents of the header `<csetjmp>` are the same as the C standard library header `<setjmp.h>`. The function signature `longjmp(jmp_buf jbuf, int val)` has more restricted behavior in this document. A `setjmp/longjmp` call pair has undefined behavior if replacing the `setjmp` and `longjmp` by `catch` and `throw` would invoke any non-trivial destructors for any objects with automatic storage duration. A call to `setjmp` or `longjmp` has undefined behavior if invoked in a suspension context of a coroutine (7.6.2.4). See also: ISO C 7.13

17.13.4 Header `<csignal>` synopsis

```cpp
namespace std {
    using sig_atomic_t = see below;

    // 17.13.5, signal handlers
    extern "C" using signal-handler = void(int); // exposition only
    signal-handler* signal(int sig, signal-handler* func);

    int raise(int sig);
}
```

211) Note that `va_start` is required to work as specified even if unary `operator&` is overloaded for the type of `parmN`. 

§ 17.13.4 534
#define SIG_DFL see below
#define SIG_ERR see below
#define SIG_IGN see below
#define SIGABRT see below
#define SIGFPE see below
#define SIGILL see below
#define SIGINT see below
#define SIGSEGV see below
#define SIGTERM see below

1 The contents of the header `<csignal>` are the same as the C standard library header `<signal.h>`.

17.13.5 Signal handlers

1 A call to the function `signal` synchronizes with any resulting invocation of the signal handler so installed.

2 A plain lock-free atomic operation is an invocation of a function `f` from Clause 31, such that:

(2.1) — `f` is the function `atomic_is_lock_free()`, or

(2.2) — `f` is the member function `is_lock_free()`, or

(2.3) — `f` is a non-static member function invoked on an object `A`, such that `A.is_lock_free()` yields `true`, or

(2.4) — `f` is a non-member function, and for every pointer-to-atomic argument `A` passed to `f`, `atomic_is_lock_free(A)` yields `true`.

3 An evaluation is signal-safe unless it includes one of the following:

(3.1) — a call to any standard library function, except for plain lock-free atomic operations and functions explicitly identified as signal-safe;

[Note 1: This implicitly excludes the use of `new` and `delete` expressions that rely on a library-provided memory allocator. — end note]

(3.2) — an access to an object with thread storage duration;

(3.3) — a `dynamic_cast` expression;

(3.4) — throwing of an exception;

(3.5) — control entering a `try-block` or `function-try-block`;

(3.6) — initialization of a variable with static storage duration requiring dynamic initialization (6.9.3.3, 8.8); or

(3.7) — waiting for the completion of the initialization of a variable with static storage duration (8.8).

A signal handler invocation has undefined behavior if it includes an evaluation that is not signal-safe.

4 The function `signal` is signal-safe if it is invoked with the first argument equal to the signal number corresponding to the signal that caused the invocation of the handler.

See also: ISO C 7.14

---

212) Such initialization can occur because it is the first odr-use (6.3) of that variable.
18 Concepts library

18.1 General

This Clause describes library components that C++ programs may use to perform compile-time validation
of template arguments and perform function dispatch based on properties of types. The purpose of these
concepts is to establish a foundation for equational reasoning in programs.

The following subclauses describe language-related concepts, comparison concepts, object concepts, and
callable concepts as summarized in Table 41.

Table 41: Fundamental concepts library summary

<table>
<thead>
<tr>
<th>Subclause</th>

</tbody>
</table>

18.2 Equality preservation

An expression is equality-preserving if, given equal inputs, the expression results in equal outputs. The inputs
to an expression are the set of the expression’s operands. The output of an expression is the expression’s
result and all operands modified by the expression. For the purposes of this subclause, the operands of an
expression are the largest subexpressions that include only:

(1.1) — an id-expression (7.5.4), and

(1.2) — invocations of the library function templates std::move, std::forward, and std::declval (20.2.4,
        20.2.6).

[Example 1: The operands of the expression a = std::move(b) are a and std::move(b). — end example]

2 Not all input values need be valid for a given expression.

[Example 2: For integers a and b, the expression a / b is not well-defined when b is 0. This does not preclude the
expression a / b being equality-preserving. — end example]

The domain of an expression is the set of input values for which the expression is required to be well-defined.

3 Expressions required to be equality-preserving are further required to be stable: two evaluations of such an
expression with the same input objects are required to have equal outputs absent any explicit intervening
modification of those input objects.

[Note 1: This requirement allows generic code to reason about the current values of objects based on knowledge
of the prior values as observed via equality-preserving expressions. It effectively forbids spontaneous changes to an
object, changes to an object from another thread of execution, changes to an object as side effects of non-modifying
expressions, and changes to an object as side effects of modifying a distinct object if those changes could be observable
to a library function via an equality-preserving expression that is required to be valid for that object. — end note]

4 Expressions declared in a requires-expression in the library clauses are required to be equality-preserving,
except for those annotated with the comment “not required to be equality-preserving.” An expression so
annotated may be equality-preserving, but is not required to be so.

5 An expression that may alter the value of one or more of its inputs in a manner observable to equality-
preserving expressions is said to modify those inputs. The library clauses use a notational convention to
specify which expressions declared in a requires-expression modify which inputs: except where otherwise
specified, an expression operand that is a non-constant lvalue or rvalue may be modified. Operands that
are constant lvalues or rvalues are required to not be modified. For the purposes of this subclause, the
cv-qualification and value category of each operand are determined by assuming that each template type
parameter denotes a cv-unqualified complete non-array object type.
Where a requires-expression declares an expression that is non-modifying for some constant lvalue operand, additional variations of that expression that accept a non-constant lvalue or (possibly constant) rvalue for the given operand are also required except where such an expression variation is explicitly required with differing semantics. These implicit expression variations are required to meet the semantic requirements of the declared expression. The extent to which an implementation validates the syntax of the variations is unspecified.

[Example 3:

```cpp
template<class T> concept C = requires(T a, T b, const T c, const T d) {
    c == d; // #1
    a = std::move(b); // #2
    a = c; // #3
};
```

For the above example:

(7.1) — Expression #1 does not modify either of its operands, #2 modifies both of its operands, and #3 modifies only its first operand a.

(7.2) — Expression #1 implicitly requires additional expression variations that meet the requirements for `c == d` (including non-modification), as if the expressions

```cpp
    c == b;
    std::move(c) == d;
    std::move(c) == std::move(b);
    std::move(c) == std::move(d);
    std::move(c) == std::move(b);
    a == d;
    a == std::move(b);
    std::move(a) == d;
    std::move(a) == std::move(b);
    std::move(a) == std::move(d);
    std::move(a) == std::move(b);
```

had been declared as well.

(7.3) — Expression #3 implicitly requires additional expression variations that meet the requirements for `a == c` (including non-modification of the second operand), as if the expressions `a == b` and `a = std::move(c)` had been declared. Expression #3 does not implicitly require an expression variation with a non-constant rvalue second operand, since expression #2 already specifies exactly such an expression explicitly.

— end example]

[Example 4: The following type T meets the explicitly stated syntactic requirements of concept C above but does not meet the additional implicit requirements:

```cpp
struct T {
    bool operator==(const T&) const { return true; }
    bool operator==(T&) = delete;
};
```

T fails to meet the implicit requirements of C, so T satisfies but does not model C. Since implementations are not required to validate the syntax of implicit requirements, it is unspecified whether an implementation diagnoses as ill-formed a program that requires `C<T>`. — end example]

18.3 Header <concepts> synopsis

```cpp
namespace std {
    // 18.4, language-related concepts
    // 18.4.2, concept same_as
    template<class T, class U>
    concept same_as = see below;

    // 18.4.3, concept derived_from
    template<class Derived, class Base>
    concept derived_from = see below;

    // 18.4.4, concept convertible_to
    template<class From, class To>
    concept convertible_to = see below;
}
```

§ 18.3 537
// 18.4.5, concept common_reference_with
template<class T, class U>
    concept common_reference_with = see below;

// 18.4.6, concept common_with
template<class T, class U>
    concept common_with = see below;

// 18.4.7, arithmetic concepts
template<class T>
    concept integral = see below;
template<class T>
    concept signed_integral = see below;
template<class T>
    concept unsigned_integral = see below;
template<class T>

}  

18.4 Language-related concepts
18.4.1 General

Subclause 18.4 contains the definition of concepts corresponding to language features. These concepts express relationships between types, type classifications, and fundamental type properties.

18.4.2 Concept same_as

template<class T, class U>
  concept same_as_impl = is_same_v<T, U>;  // exposition only

template<class T, class U>
  concept same_as = same_as_impl<T, U> && same_as_impl<U, T>;
  // [Note 1: same_as<T, U> subsumes same_as<U, T> and vice versa. —end note]

18.4.3 Concept derived_from

template<class Derived, class Base>
  concept derived_from =
      is_base_of_v<Base, Derived> &&
      is_convertible_v<const volatile Derived*, const volatile Base*>;
      // [Note 1: derived_from<Derived, Base> is satisfied if and only if Derived is publicly and unambiguously derived from Base, or Derived and Base are the same class type ignoring cv-qualifiers. —end note]
18.4.4 Concept convertible_to

1 Given types `From` and `To` and an expression `E` whose type and value category are the same as those of `declval<From>()`, `convertible_to<From, To>` requires `E` to be both implicitly and explicitly convertible to type `To`. The implicit and explicit conversions are required to produce equal results.

```
template<class From, class To>
concept convertible_to =
    is_convertible_v<From, To> &&
    requires(add_rvalue_reference_t<From> (&f)()) {
        static_cast<To>(f());
    };
```

2 Let `FromR` be `add_rvalue_reference_t<From>` and `test` be the invented function:

```
To test(FromR (&f)()) {
    return f();
}
```

and let `f` be a function with no arguments and return type `FromR` such that `f()` is equality-preserving. Types `From` and `To` model `convertible_to<From, To>` only if:

1. `To` is not an object or reference-to-object type, or `static_cast<To>(f())` is equal to `test(f)`.
2. `FromR` is not a reference-to-object type, or
   1. If `FromR` is an rvalue reference to a non const-qualified type, the resulting state of the object referenced by `f()` after either above expression is valid but unspecified (16.4.6.16).
   2. Otherwise, the object referred to by `f()` is not modified by either above expression.

18.4.5 Concept common_reference_with

1 For two types `T` and `U`, if `common_reference_t<T, U>` is well-formed and denotes a type `C` such that both `convertible_to<T, C>` and `convertible_to<U, C>` are modeled, then `T` and `U` share a common reference type, `C`.

```
template<class T, class U>
concept common_reference_with =
    same_as<common_reference_t<T, U>, common_reference_t<U, T>>,
    convertible_to<T, common_reference_t<T, U>>,
    convertible_to<U, common_reference_t<T, U>>;
```

2 Let `C` be `common_reference_t<T, U>`. Let `t1` and `t2` be equality-preserving expressions (18.2) such that `decltype((t1))` and `decltype((t2))` are each `T`, and let `u1` and `u2` be equality-preserving expressions such that `decltype((u1))` and `decltype((u2))` are each `U`. `T` and `U` model `common_reference_with<T, U>` only if:

1. `C(t1)` equals `C(t2)` if and only if `t1` equals `t2`, and
2. `C(u1)` equals `C(u2)` if and only if `u1` equals `u2`.

3 [Note 2: Users can customize the behavior of `common_reference_with` by specializing the `basic_common_reference` class template (20.15.8.7). — end note]

18.4.6 Concept common_with

1 If `T` and `U` can both be explicitly converted to some third type, `C`, then `T` and `U` share a common type, `C`.

```
template<class T, class U>
concept common_with =
    same_as<common_type_t<T, U>, common_type_t<U, T>>,
    requires {
        static_cast<common_type_t<T, U>>(declval<T>());
        static_cast<common_type_t<T, U>>(declval<U>());
    };
```

[Note 1: `C` can be the same as `T` or `U`, or can be a different type. `C` is not necessarily unique. — end note]
Let $C$ be `common_type_t<T, U>`. Let $t_1$ and $t_2$ be equality-preserving expressions (18.2) such that `decltype((t1))` and `decltype((t2))` are each $T$, and let $u_1$ and $u_2$ be equality-preserving expressions such that `decltype((u1))` and `decltype((u2))` are each $U$. $T$ and $U$ model `common_with<T, U>` only if:

1. $C(t_1)$ equals $C(t_2)$ if and only if $t_1$ equals $t_2$, and
2. $C(u_1)$ equals $C(u_2)$ if and only if $u_1$ equals $u_2$.

[Note 2: Users can customize the behavior of `common_with` by specializing the `common_type` class template (20.15.8.7). —end note]

### 18.4.7 Arithmetic concepts

[concepts.arithmetic]

```cpp
template<class T>
concept integral = is_integral_v<T>;

template<class T>
concept signed_integral = integral<T> && is_signed_v<T>;

template<class T>
concept unsigned_integral = integral<T> && !signed_integral<T>;

template<class T>
concept floating_point = is_floating_point_v<T>;
```

[Note 1: `signed_integral` can be modeled even by types that are not signed integer types (6.8.2); for example, `char`. —end note]

[Note 2: `unsigned_integral` can be modeled even by types that are not unsigned integer types (6.8.2); for example, `bool`. —end note]

### 18.4.8 Concept assignable_from

[concept.assignable]

```cpp
template<class LHS, class RHS>
concept assignable_from =
    is_lvalue_reference_v<LHS> &&
    common_reference_with<const remove_reference_t<LHS>&, const remove_reference_t<RHS>&> &&
    requires(LHS lhs, RHS&& rhs) {
        ( lhs = std::forward<RHS>(rhs) ) -> same_as<LHS>;
    };
```

Let:

1. $\text{lhs}$ be an lvalue that refers to an object $\text{lcopy}$ such that `decltype((\text{lhs}))` is $\text{LHS}$,
2. $\text{rhs}$ be an expression such that `decltype((\text{rhs}))` is $\text{RHS}$, and
3. $\text{rcopy}$ be a distinct object that is equal to $\text{rhs}$.

$L\text{HS}$ and $\text{RHS}$ model `assignable_from<LHS, RHS>` only if:

1. $\text{addressof(lhs = rhs)} == \text{addressof(lcopy)}$.
2. After evaluating $\text{lhs = rhs}$:
   1. $\text{lhs}$ is equal to $\text{rcopy}$, unless $\text{rhs}$ is a non-const xvalue that refers to $\text{lcopy}$.
   2. If $\text{rhs}$ is a non-const xvalue, the resulting state of the object to which it refers is valid but unspecified (16.4.6.16).
   3. Otherwise, if $\text{rhs}$ is a glvalue, the object to which it refers is not modified.

[Note 1: Assignment need not be a total function (16.3.2.3); in particular, if assignment to an object $\text{x}$ can result in a modification of some other object $\text{y}$, then $\text{x} = \text{y}$ is likely not in the domain of $\text{=}$. —end note]
18.4.9 Concept swappable

Let \( t_1 \) and \( t_2 \) be equality-preserving expressions that denote distinct equal objects of type \( T \), and let \( u_1 \) and \( u_2 \) similarly denote distinct equal objects of type \( U \).

[Note 1: \( t_1 \) and \( u_1 \) can denote distinct objects, or the same object. — end note]

An operation exchanges the values denoted by \( t_1 \) and \( u_1 \) if and only if the operation modifies neither \( t_2 \) nor \( u_2 \) and:

1. If \( T \) and \( U \) are the same type, the result of the operation is that \( t_1 \) equals \( u_2 \) and \( u_1 \) equals \( t_2 \).
2. If \( T \) and \( U \) are different types and common_reference_with<decltype((t1)), decltype((u1))> is modeled, the result of the operation is that \( C(t_1) \) equals \( C(u_2) \) and \( C(u_1) \) equals \( C(t_2) \) where \( C \) is common_reference_t<decltype((t1)), decltype((u1))>.

The name \texttt{ranges::swap} denotes a customization point object (16.3.3.3.6). The expression \texttt{ranges::swap(E1, E2)} for subexpressions \( E_1 \) and \( E_2 \) is expression-equivalent to an expression \( S \) determined as follows:

1. \( S \) is (void)\texttt{swap(E1, E2)}\(^{213} \) if \( E_1 \) or \( E_2 \) has class or enumeration type (6.8.3) and that expression is valid, with overload resolution performed in a context that includes the declaration

```
template<class T>
void \texttt{swap}(T&, T&) = delete;
```

and does not include a declaration of \texttt{ranges::swap}. If the function selected by overload resolution does not exchange the values denoted by \( E_1 \) and \( E_2 \), the program is ill-formed, no diagnostic required.

2. Otherwise, if \( E_1 \) and \( E_2 \) are lvalues of array types (6.8.3) with equal extent and \texttt{ranges::swap(*E1, *E2)} is a valid expression, \( S \) is (void)\texttt{ranges::swap_ranges(E1, E2)}, except that noexcept(\( S \)) is equal to noexcept(ranges::swap(*E1, *E2)).

3. Otherwise, if \( E_1 \) and \( E_2 \) are lvalues of the same type \( T \) that models move_constructible<T> and assignable_from<T, T>, \( S \) is an expression that exchanges the denoted values. \( S \) is a constant expression if

   1. \( T \) is a literal type (6.8),
   2. both \( E_1 = \texttt{std::move}(E2) \) and \( E_2 = \texttt{std::move}(E1) \) are constant subexpressions (3.14), and
   3. the full-expressions of the initializers in the declarations
```
T ti(\texttt{std::move}(E1));
T t2(\texttt{std::move}(E2));
```

are constant subexpressions.

noexcept(\( S \)) is equal to is_nothrow_move_constructible_v<T> \&\& is_nothrow_move_assignable_v<T>.

4. Otherwise, \texttt{ranges::swap(E1, E2)} is ill-formed.

[Note 2: This case can result in substitution failure when \texttt{ranges::swap(E1, E2)} appears in the immediate context of a template instantiation. — end note]

3 [Note 3: Whenever \texttt{ranges::swap(E1, E2)} is a valid expression, it exchanges the values denoted by \( E_1 \) and \( E_2 \) and has type void. — end note]

```
template<class T>
concept swappable = requires(T& a, T& b) { \texttt{ranges::swap}(a, b); };

template<class T, class U>
concept swappable_with =
    common_reference_with<\texttt{T}, U> \&\&
    requires(\texttt{T}& t, \texttt{U}& u) {
        \texttt{ranges::swap}(\texttt{std::forward<T>>(t), \texttt{std::forward<T>>(t))};
        \texttt{ranges::swap}(\texttt{std::forward<U>>(u), \texttt{std::forward<U>>(u))};
        \texttt{ranges::swap}(\texttt{std::forward<T>>(t), \texttt{std::forward<U>>(u))};
        \texttt{ranges::swap}(\texttt{std::forward<U>>(u), \texttt{std::forward<T>>(t))};
    };
```

4 [Note 4: The semantics of the \texttt{swappable} and \texttt{swappable_with} concepts are fully defined by the \texttt{ranges::swap} customization point object. — end note]

\(^{213}\) The name \texttt{swap} is used here unqualified.
Example 1: User code can ensure that the evaluation of `swap` calls is performed in an appropriate context under the various conditions as follows:

```cpp
#include <cassert>
#include <concepts>
#include <utility>

namespace ranges = std::ranges;

template<class T, std::swappable_with<T> U>
void value_swap(T&& t, U&& u) {
    ranges::swap(std::forward<T>(t), std::forward<U>(u));
}

template<std::swappable T>
void lv_swap(T& t1, T& t2) {
    ranges::swap(t1, t2);
}

namespace N {
    struct A { int m; };
    struct Proxy {
        A* a;
        Proxy(A& a) : a{&a} {}
        friend void swap(Proxy x, Proxy y) {
            ranges::swap(*x.a, *y.a);
        }
    };
    Proxy proxy(A& a) { return Proxy{ a }; }
}

int main() {
    int i = 1, j = 2;
    lv_swap(i, j);
    assert(i == 2 && j == 1);

    N::A a1 = { 5 }, a2 = { -5 };
    value_swap(a1, proxy(a2));
    assert(a1.m == -5 && a2.m == 5);
}
```

18.4.10 Concept `destructible` [concept.destructible]

The `destructible` concept specifies properties of all types, instances of which can be destroyed at the end of their lifetime, or reference types.

```cpp
template<class T>
concept destructible = is_nothrow_destructible_v<T>;
```

[Note 1: Unlike the Cpp17Destructible requirements (Table 34), this concept forbids destructors that are potentially throwing, even if a particular invocation of the destructor does not actually throw. —end note]

18.4.11 Concept `constructible_from` [concept.constructible]

The `constructible_from` concept constrains the initialization of a variable of a given type with a particular set of argument types.

```cpp
template<class T, class... Args>
concept constructible_from = destructible<T> && is_constructible_v<T, Args...>;
```

18.4.12 Concept `default_initializable` [concept.default.init]

```cpp
template<class T>
inline constexpr bool is-default-initializable = see below; // exposition only
```
template<class T>
    concept default_initializable = constructible_from<T> &&
    requires { T(); } &&
    is-default-initializable<T>;

For a type T, is-default-initializable<T> is true if and only if the variable definition
T t;
is well-formed for some invented variable t; otherwise it is false. Access checking is performed as if in
a context unrelated to T. Only the validity of the immediate context of the variable initialization is
considered.

18.4.13 Concept move_constructible [concept.moveconstructible]

template<class T>
    concept move_constructible = constructible_from<T, T> && convertible_to<T, T>;

If T is an object type, then let rv be an rvalue of type T and u2 a distinct object of type T equal to rv.
T models move_constructible only if

(1.1) — After the definition T u = rv;, u is equal to u2.
(1.2) — T(rv) is equal to u2.
(1.3) — If T is not const, rv’s resulting state is valid but unspecified (16.4.6.16); otherwise, it is unchanged.

18.4.14 Concept copy_constructible [concept.copyconstructible]

template<class T>
    concept copy_constructible =
    move_constructible<T> &&
    constructible_from<T, T> && convertible_to<T, T> &&
    constructible_from<T, const T> && convertible_to<const T, T>;

If T is an object type, then let v be an lvalue of type (possibly const) T or an rvalue of type const T.
T models copy_constructible only if

(1.1) — After the definition T u = v;, u is equal to v (18.2) and v is not modified.
(1.2) — T(v) is equal to v and does not modify v.

18.5 Comparison concepts [concepts.compare]

18.5.1 General [concepts.compare.general]

Subclause 18.5 describes concepts that establish relationships and orderings on values of possibly differing
object types.

18.5.2 Boolean testability [concept.booleantestable]

The exposition-only boolean-testable concept specifies the requirements on expressions that are convertible
to bool and for which the logical operators (7.6.14, 7.6.15, 7.6.2.2) have the conventional semantics.

template<class T>
    concept boolean-testable-impl = convertible_to<T, bool>; // exposition only

Let e be an expression such that decltype((e)) is T. T models boolean-testable-impl only if:

(2.1) — either remove_cvref_t<T> is not a class type, or a search for the names operator&&
in the scope of remove_cvref_t<T> finds nothing; and
(2.2) — argument-dependent lookup (6.5.4) for the names operator&& with T as the only
argument type finds no disqualifying declaration (defined below).

A disqualifying parameter is a function parameter whose declared type P

(3.1) — is not dependent on a template parameter, and there exists an implicit conversion sequence (12.2.4.2)
from e to P; or
(3.2) — is dependent on one or more template parameters, and either

(3.2.1) — P contains no template parameter that participates in template argument deduction (13.10.3.6), or

§ 18.5.2 544
4 A *key parameter* of a function template \( D \) is a function parameter of type \( cv \ X \) or reference thereto, where \( X \) names a specialization of a class template that has the same innermost enclosing non-inline namespace as \( D \), and \( X \) contains at least one template parameter that participates in template argument deduction.

**Example 1:** In

```cpp
namespace Z {
    template<class> struct C {};  
    template<class T>
    void operator&&<>(C<T> x, T y);  
    template<class T>
    void operator||(C<type_identity_t<T>> x, T y);  
}
```

the declaration of \( Z::\text{operator}\\&\& \) contains one key parameter, \( C<T> \ x \), and the declaration of \( Z::\text{operator}\\|\| \) contains no key parameters. —end example

5 A *disqualifying declaration* is

5.1 — a (non-template) function declaration that contains at least one disqualifying parameter; or

5.2 — a function template declaration that contains at least one disqualifying parameter, where

5.2.1 — at least one disqualifying parameter is a key parameter; or

5.2.2 — the declaration contains no key parameters; or

5.2.3 — the declaration declares a function template to which no name is bound (9.3.4).

6 [Note 1: The intention is to ensure that given two types \( T_1 \) and \( T_2 \) that each model *boolean-testable-impl*, the &\& and || operators within the expressions `declval<T1>() &\& declval<T2>()` and `declval<T1>() || declval<T2>()` resolve to the corresponding built-in operators. —end note]

```cpp
template<class T>
concept boolean-testable =  // exposition only
    boolean-testable-impl<T> &\& requires (T&& t) {
        { std::forward<T>(t) } -> boolean-testable-impl;
    };
```

7 Let \( e \) be an expression such that `decltype((e))` is \( T \). \( T \) models *boolean-testable* only if `bool(e) == !bool(!e)`.  

8 [Example 2: The types `bool`, `true_type` (20.15.3), `int*`, and `bitset<N>::reference` (20.9.2) model *boolean-testable*. —end example]

### 18.5.3 Concept equality_comparable

```cpp
template<class T, class U>
concept weakly-equality-comparable-with =  // exposition only
    requires(const remove_reference_t<T>& t, const remove_reference_t<U>& u) {
        { t == u } -> boolean-testable;
        { t != u } -> boolean-testable;
        { u == t } -> boolean-testable;
        { u != t } -> boolean-testable;
    };
```

1 Given types \( T \) and \( U \), let \( t \) and \( u \) be lvalues of types `const remove_reference_t<T>` and `const remove_reference_t<U>` respectively. \( T \) and \( U \) model *weakly-equality-comparable-with* \( T, U \) only if

1.1 — \( t == u, u == t, t != u, \) and \( u != t \) have the same domain.

1.2 — `bool(u == t) == bool(t == u)`.  

1.3 — `bool(t != u) == !bool(t == u)`.  

1.4 — `bool(u != t) == bool(t != u)`.
template<class T>
concept equality_comparable = weakly-equality-comparable-with<T, T>;

2 Let a and b be objects of type T. T models equality_comparable only if bool(a == b) is true when a is equal to b (18.2), and false otherwise.

[Note 1: The requirement that the expression a == b is equality-preserving implies that == is transitive and symmetric. — end note]

template<class T, class U>
concept equality_comparable_with =
equality_comparable<T> & equality_comparable<U> &
common_reference_with<const remove_reference_t<T>&, const remove_reference_t<U>&> &
equality_comparable<
common_reference_t<
const remove_reference_t<T>&,
const remove_reference_t<U>&> &
weakly-equality-comparable-with<T, U>;

4 Given types T and U, let t be an lvalue of type const remove_reference_t<T>, u be an lvalue of type const remove_reference_t<U>, and C be:

common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>
T and U model equality_comparable_with<T, U> only if bool(t == u) == bool(C(t) == C(u)).

18.5.4 Concept totally_ordered
[concept.totallyordered]

template<class T>
concept totally_ordered =
equality_comparable<T> & partially-ordered-with<T, T>;

1 Given a type T, let a, b, and c be lvalues of type const remove_reference_t<T>. T models totally_ordered only if

(1.1) — Exactly one of bool(a < b), bool(a > b), or bool(a == b) is true.
(1.2) — If bool(a < b) and bool(b < c), then bool(a < c).
(1.3) — bool(a <= b) == !bool(b < a).
(1.4) — bool(a >= b) == !bool(a < b).

template<class T, class U>
concept totally_ordered_with =
totally_ordered<T> & totally_ordered<U> &
equality_comparable_with<T, U> &
totally_ordered<
common_reference_t<
const remove_reference_t<T>&,
const remove_reference_t<U>&> &
partially-ordered-with<T, U>;

2 Given types T and U, let t be an lvalue of type const remove_reference_t<T>, u be an lvalue of type const remove_reference_t<U>, and C be:

common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>
T and U model totally_ordered_with<T, U> only if

(2.1) — bool(t < u) == bool(C(t) < C(u)).
(2.2) — bool(t > u) == bool(C(t) > C(u)).
(2.3) — bool(t <= u) == bool(C(t) <= C(u)).
(2.4) — bool(t >= u) == bool(C(t) >= C(u)).
(2.5) — bool(u < t) == bool(C(u) < C(t)).
(2.6) — bool(u > t) == bool(C(u) > C(t)).
(2.7) — bool(u <= t) == bool(C(u) <= C(t)).
(2.8) — bool(u >= t) == bool(C(u) >= C(t)).
18.6 Object concepts

This subclause describes concepts that specify the basis of the value-oriented programming style on which the library is based.

```cpp
template<class T>
concept movable = is_object_v<T> && move_constructible<T> && assignable_from<T&, T> && swappable<T>;

template<class T>
concept copyable = copy_constructible<T> && movable<T> && assignable_from<T&, const T&> && assignable_from<T&, const T>;

template<class T>
concept semiregular = copyable<T> && default_initializable<T>;

template<class T>
concept regular = semiregular<T> && equality_comparable<T>;
```

[Note 1: The `semiregular` concept is modeled by types that behave similarly to built-in types like `int`, except that they need not be comparable with `==`. — end note]

[Note 2: The `regular` concept is modeled by types that behave similarly to built-in types like `int` and that are comparable with `==`. — end note]

18.7 Callable concepts

18.7.1 General

The concepts in subclause 18.7 describe the requirements on function objects (20.14) and their arguments.

18.7.2 Concept `invocable`

```cpp
template<class F, class... Args>
concept invocable = requires(F&& f, Args&&... args) {
    invoke(std::forward<F>(f), std::forward<Args>(args)...); // not required to be equality-preserving
};
```

[Example 1: A function that generates random numbers can model `invocable`, since the `invoke` function call expression is not required to be equality-preserving (18.2). — end example]

18.7.3 Concept `regular_invocable`

```cpp
template<class F, class... Args>
concept regular_invocable = invocable<F, Args...>;
```

[Note 1: The `invoke` function call expression shall be equality-preserving (18.2) and shall not modify the function object or the arguments.

[Note 1: This requirement supersedes the annotation in the definition of `invocable`. — end note]

[Example 1: A random number generator does not model `regular_invocable`. — end example]

[Note 2: The distinction between `invocable` and `regular_invocable` is purely semantic. — end note]

18.7.4 Concept `predicate`

```cpp
template<class F, class... Args>
concept predicate =
    regular_invocable<F, Args...> && boolean-testable<invoke_result_t<F, Args...>>;
```

18.7.5 Concept `relation`

```cpp
template<class R, class T, class U>
concept relation =
    predicate<R, T, T> && predicate<R, U, U> &&
    predicate<R, T, U> && predicate<R, U, T>;
```
18.7.6 Concept equivalence_relation

\[
\text{template<class R, class T, class U>}
\text{concept equivalence_relation = relation<R, T, U>;}\]

A relation models equivalence_relation only if it imposes an equivalence relation on its arguments.

18.7.7 Concept strict_weak_order

\[
\text{template<class R, class T, class U>}
\text{concept strict_weak_order = relation<R, T, U>;}\]

A relation models strict_weak_order only if it imposes a strict weak ordering on its arguments.

The term strict refers to the requirement of an irreflexive relation (\(!\text{comp}(x, x)\) for all \(x\)), and the term weak to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define \(\text{equiv}(a, b)\) as \(!\text{comp}(a, b) \&\& !\text{comp}(b, a)\), then the requirements are that \(\text{comp}\) and \(\text{equiv}\) both be transitive relations:

1. \(\text{comp}(a, b) \&\& \text{comp}(b, c)\) implies \(\text{comp}(a, c)\)
2. \(\text{equiv}(a, b) \&\& \text{equiv}(b, c)\) implies \(\text{equiv}(a, c)\)

[Note 1: Under these conditions, it can be shown that]

1. \(\text{equiv}\) is an equivalence relation,
2. \(\text{comp}\) induces a well-defined relation on the equivalence classes determined by \(\text{equiv}\), and
3. the induced relation is a strict total ordering.

— end note]
19 Diagnostics library

19.1 General

This Clause describes components that C++ programs may use to detect and report error conditions.

The following subclauses describe components for reporting several kinds of exceptional conditions, documenting program assertions, and a global variable for error number codes, as summarized in Table 42.

19.2 Exception classes

19.2.1 General

The C++ standard library provides classes to be used to report certain errors (16.4.6.13) in C++ programs. In the error model reflected in these classes, errors are divided into two broad categories: logic errors and runtime errors.

The distinguishing characteristic of logic errors is that they are due to errors in the internal logic of the program. In theory, they are preventable.

By contrast, runtime errors are due to events beyond the scope of the program. They cannot be easily predicted in advance. The header <stdexcept> defines several types of predefined exceptions for reporting errors in a C++ program. These exceptions are related by inheritance.

19.2.2 Header <stdexcept> synopsis

namespace std {
    class logic_error;
    class domain_error;
    class invalid_argument;
    class length_error;
    class out_of_range;
    class runtime_error;
    class range_error;
    class overflow_error;
    class underflow_error;
}

19.2.3 Class logic_error

namespace std {
    class logic_error : public exception {
        public:
        explicit logic_error(const string& what_arg);
        explicit logic_error(const char* what_arg);
    };
}

The class logic_error defines the type of objects thrown as exceptions to report errors presumably detectable before the program executes, such as violations of logical preconditions or class invariants.

logic_error(const string& what_arg);

Postconditions: strcmp(what(), what_arg.c_str()) == 0.
logic_error(const char* what_arg);

Postconditions: strcmp(what(), what_arg) == 0.

19.2.4 Class domain_error

namespace std {
    class domain_error : public logic_error {
    public:
        explicit domain_error(const string& what_arg);
        explicit domain_error(const char* what_arg);
    };
}

1 The class domain_error defines the type of objects thrown as exceptions by the implementation to report domain errors.

domain_error(const string& what_arg);

Postconditions: strcmp(what(), what_arg.c_str()) == 0.

domain_error(const char* what_arg);

Postconditions: strcmp(what(), what_arg) == 0.

19.2.5 Class invalid_argument

namespace std {
    class invalid_argument : public logic_error {
    public:
        explicit invalid_argument(const string& what_arg);
        explicit invalid_argument(const char* what_arg);
    };
}

1 The class invalid_argument defines the type of objects thrown as exceptions to report an invalid argument.

invalid_argument(const string& what_arg);

Postconditions: strcmp(what(), what_arg.c_str()) == 0.

invalid_argument(const char* what_arg);

Postconditions: strcmp(what(), what_arg) == 0.

19.2.6 Class length_error

namespace std {
    class length_error : public logic_error {
    public:
        explicit length_error(const string& what_arg);
        explicit length_error(const char* what_arg);
    };
}

1 The class length_error defines the type of objects thrown as exceptions to report an attempt to produce an object whose length exceeds its maximum allowable size.

length_error(const string& what_arg);

Postconditions: strcmp(what(), what_arg.c_str()) == 0.

length_error(const char* what_arg);

Postconditions: strcmp(what(), what_arg) == 0.

19.2.7 Class out_of_range

namespace std {
    class out_of_range : public logic_error {
    public:
        explicit out_of_range(const string& what_arg);
        explicit out_of_range(const char* what_arg);
    };
}
The class `out_of_range` defines the type of objects thrown as exceptions to report an argument value not in its expected range.

```cpp
out_of_range(const string& what_arg);
Postconditions: strcmp(what(), what_arg.c_str()) == 0.

out_of_range(const char* what_arg);
Postconditions: strcmp(what(), what_arg) == 0.
```

### 19.2.8 Class `runtime_error` [runtime.error]

```cpp
namespace std {
    class runtime_error : public exception {
    public:
        explicit runtime_error(const string& what_arg);
        explicit runtime_error(const char* what_arg);
    };
}
```

The class `runtime_error` defines the type of objects thrown as exceptions to report errors presumably detectable only when the program executes.

```cpp
runtime_error(const string& what_arg);
Postconditions: strcmp(what(), what_arg.c_str()) == 0.

runtime_error(const char* what_arg);
Postconditions: strcmp(what(), what_arg) == 0.
```

### 19.2.9 Class `range_error` [range.error]

```cpp
namespace std {
    class range_error : public runtime_error {
    public:
        explicit range_error(const string& what_arg);
        explicit range_error(const char* what_arg);
    };
}
```

The class `range_error` defines the type of objects thrown as exceptions to report range errors in internal computations.

```cpp
range_error(const string& what_arg);
Postconditions: strcmp(what(), what_arg.c_str()) == 0.

range_error(const char* what_arg);
Postconditions: strcmp(what(), what_arg) == 0.
```

### 19.2.10 Class `overflow_error` [overflow.error]

```cpp
namespace std {
    class overflow_error : public runtime_error {
    public:
        explicit overflow_error(const string& what_arg);
        explicit overflow_error(const char* what_arg);
    };
}
```

The class `overflow_error` defines the type of objects thrown as exceptions to report an arithmetic overflow error.

```cpp
overflow_error(const string& what_arg);
Postconditions: strcmp(what(), what_arg.c_str()) == 0.
```
overflow_error(const char* what_arg);

Postconditions: strcmp(what(), what_arg) == 0.

19.2.11 Class underflow_error [underflow.error]

namespace std {
    class underflow_error : public runtime_error {
        public:
            explicit underflow_error(const string& what_arg);
            explicit underflow_error(const char* what_arg);
    };
}

1 The class underflow_error defines the type of objects thrown as exceptions to report an arithmetic underflow error.

underflow_error(const string& what_arg);

Postconditions: strcmp(what(), what_arg.c_str()) == 0.

underflow_error(const char* what_arg);

Postconditions: strcmp(what(), what_arg) == 0.

19.3 Assertions [assertions]

19.3.1 General [assertions.general]

1 The header <cassert> provides a macro for documenting C++ program assertions and a mechanism for disabling the assertion checks.

19.3.2 Header <cassert> synopsis [cassert.syn]

#define assert(E) see below

1 The contents are the same as the C standard library header <assert.h>, except that a macro named static_assert is not defined.

See also: ISO C 7.2

19.3.3 The assert macro [assertions.assert]

1 An expression assert(E) is a constant subexpression (3.14), if

— NDEBUG is defined at the point where assert is last defined or redefined, or

— E contextually converted to bool (7.3) is a constant subexpression that evaluates to the value true.

19.4 Error numbers [errno]

19.4.1 General [errno.general]

1 The contents of the header <cerrno> are the same as the POSIX header <errno.h>, except that errno shall be defined as a macro.

[Note 1: The intent is to remain in close alignment with the POSIX standard. — end note]

A separate errno value shall be provided for each thread.

19.4.2 Header <cerrno> synopsis [cerrno.syn]

19.5 System error support

19.5.1 General

Subclause 19.5 describes components that the standard library and C++ programs may use to report error conditions originating from the operating system or other low-level application program interfaces.

Components described in 19.5 shall not change the value of errno (19.4). Implementations should leave the error states provided by other libraries unchanged.

19.5.2 Header <system_error> synopsis

```cpp
#include <compare> // see 17.11.1

namespace std {
  class error_category;
  const error_category& generic_category() noexcept;
  const error_category& system_category() noexcept;

  class error_code;
  class error_condition;
  class system_error;

  template<class T>
  struct is_error_code_enum : public false_type {};

  template<class T>
  struct is_error_condition_enum : public false_type {};

  enum class errc {
    address_family_not_supported, // EAFNSUPPORT
    address_in_use, // EADDRINUSE
    address_not_available, // EADDRNOTAVAIL
    already_connected, // EISCONN
    argument_list_too_long, // E2BIG
    argument_out_of_domain, // EDOM
    bad_address, //EFAULT
    bad_file_descriptor, // EBADF
    bad_message, // EBADMSG
    broken_pipe, // EPIPE
    connection_aborted, // ECONNABORTED
    connection_already_in_progress, // EALREADY
    connection_refused, // ECONNREFUSED
    connection_reset, // ECONNRESET
    cross_device_link, // EXDEV
    destination_address_required, // EDESTADDRREQ
    device_or_resource_busy, // EBUSY
    directory_not_empty, // ENOTEMPTY
    executable_format_error, // ENOEXEC
    file_exists, // EXIST
    file_too_large, // EFBIG
    filename_too_long, // ENAMETOOLONG
    function_not_supported, // ENOSYS
    host_unreachable, // EHOSTUNREACH
    identifier_removed, // EIDRM
    illegal_byte_sequence, // EILSEQ
    inappropriate_io_control_operation, // ENOTTY
    interrupted, // EINTR
  }
```

template<class T>
inline constexpr bool is_error_condition_enum_v = is_error_condition_enum<T>::value;

1 The value of each enum errc constant shall be the same as the value of the <cerrno> macro shown in the above synopsis. Whether or not the <system_error> implementation exposes the <cerrno> macros is unspecified.

2 The is_error_code_enum and is_error_condition_enum templates may be specialized for program-defined types to indicate that such types are eligible for class error_code and class error_condition automatic conversions, respectively.

19.5.3 Class error_category

19.5.3.1 Overview

The class error_category serves as a base class for types used to identify the source and encoding of a particular category of error code. Classes may be derived from error_category to support categories of errors in addition to those defined in this document. Such classes shall behave as specified in subclause 19.5.3.

[Note 1: error_category objects are passed by reference, and two such objects are equal if they have the same address. If there is more than a single object of a custom error_category type, such equality comparisons can evaluate to false even for objects holding the same value. — end note]

namespace std {
class error_category {
public:
    constexpr error_category() noexcept;
    virtual ~error_category();
    error_category(const error_category&) = delete;
    error_category& operator=(const error_category&) = delete;
    virtual const char* name() const noexcept = 0;
    virtual error_condition default_error_condition(int ev) const noexcept;
    virtual bool equivalent(int code, const error_condition& condition) const noexcept;
    virtual bool equivalent(const error_code& code, int condition) const noexcept;
    virtual string message(int ev) const = 0;

    bool operator==(const error_category& rhs) const noexcept;
    strong_ordering operator<=>(const error_category& rhs) const noexcept;
};

class error_category& generic_category() noexcept;
class error_category& system_category() noexcept;
}

19.5.3.2 Virtual members

virtual const char* name() const noexcept = 0;

1 Returns: A string naming the error category.

virtual error_condition default_error_condition(int ev) const noexcept;

2 Returns: error_condition(ev, *this).
virtual bool equivalent(int code, const error_condition& condition) const noexcept;

3   \textit{Returns:} default_error_condition(code) == condition.

virtual bool equivalent(const error_code& code, int condition) const noexcept;

4   \textit{Returns:} *this == code.category() && code.value() == condition.

virtual string message(int ev) const = 0;

5   \textit{Returns:} A string that describes the error condition denoted by \textit{ev}.

\section*{19.5.3.3 Non-virtual members} \hfill [syserr.errcat.nonvirtuals]

\begin{enumerate}
\item \textbf{bool} \texttt{operator==}((const error_category& rhs) const noexcept;

1   \textit{Returns:} this == &rhs.

\item strong_ordering \texttt{operator\textless\textgreater}((const error_category& rhs) const noexcept;

2   \textit{Returns:} compare_three_way()((this, &rhs).

\begin{small}
\textit{[Note 1: compare_three_way (20.14.8.8) provides a total ordering for pointers. — end note]}
\end{small}
\end{enumerate}

\section*{19.5.3.4 Program-defined classes derived from error_category} \hfill [syserr.errcat.derived]

\begin{enumerate}
\item virtual const char* \texttt{name}() const noexcept = 0;

1   \textit{Returns:} A string naming the error category.

\item \texttt{virtual error_condition default_error_condition(int ev) const noexcept;}

2   \textit{Returns:} An object of type \texttt{error_condition} that corresponds to \textit{ev}.

\item virtual bool equivalent(int code, const error_condition& condition) const noexcept;

3   \textit{Returns:} true if, for the category of error represented by \texttt{*this}, \texttt{code} is considered equivalent to \texttt{condition}; otherwise, false.

\item virtual bool equivalent(const error_code& code, int condition) const noexcept;

4   \textit{Returns:} true if, for the category of error represented by \texttt{*this}, \texttt{code} is considered equivalent to \texttt{condition}; otherwise, false.
\end{enumerate}

\section*{19.5.3.5 Error category objects} \hfill [syserr.errcat.objects]

\begin{enumerate}
\item const error_category& \texttt{generic_category}() noexcept;

1   \textit{Returns:} A reference to an object of a type derived from class \texttt{error_category}. All calls to this function shall return references to the same object.

\item \textit{Remarks:} The object’s \texttt{default_error_condition} and \texttt{equivalent} virtual functions shall behave as specified for the class \texttt{error_category}. The object’s \texttt{name} virtual function shall return a pointer to the string "generic".

\item const error_category& \texttt{system_category}() noexcept;

3   \textit{Returns:} A reference to an object of a type derived from class \texttt{error_category}. All calls to this function shall return references to the same object.

\item \textit{Remarks:} The object’s \texttt{equivalent} virtual functions shall behave as specified for class \texttt{error_category}. The object’s \texttt{name} virtual function shall return a pointer to the string "system". The object’s \texttt{default_error_condition} virtual function shall behave as follows:

If the argument \textit{ev} corresponds to a POSIX \texttt{errno} value posv, the function shall return \texttt{error_condition(posv, generic_category())}. Otherwise, the function shall return \texttt{error_condition(ev, system_category())}. What constitutes correspondence for any given operating system is unspecified.

\begin{small}
\textit{[Note 1: The number of potential system error codes is large and unbounded, and some might not correspond to any POSIX \texttt{errno} value. Thus implementations are given latitude in determining correspondence. — end note]}
\end{small}
19.5.4 Class error_code

19.5.4.1 Overview

The class error_code describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces.

[Note 1: Class error_code is an adjunct to error reporting by exception. — end note]

namespace std {
    class error_code {
        public:
            // 19.5.4.2, constructors
            error_code() noexcept;
            error_code(int val, const error_category& cat) noexcept;
            template<class ErrorCodeEnum> error_code(ErrorCodeEnum e) noexcept;

            // 19.5.4.3, modifiers
            void assign(int val, const error_category& cat) noexcept;
            template<class ErrorCodeEnum> error_code& operator=(ErrorCodeEnum e) noexcept;
            void clear() noexcept;

            // 19.5.4.4, observers
            int value() const noexcept;
            const error_category& category() const noexcept;
            error_condition default_error_condition() const noexcept;
            string message() const;
            explicit operator bool() const noexcept;
        private:
            int val_;  // exposition only
            const error_category* cat_; // exposition only
    };

    // 19.5.4.5, non-member functions
    error_code make_error_code(errc e) noexcept;

    template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const error_code& ec);
};

19.5.4.2 Constructors

error_code() noexcept;

Postconditions: val_ == 0 and cat_ == &system_category().

error_code(int val, const error_category& cat) noexcept;

Postconditions: val_ == val and cat_ == &cat.

template<class ErrorCodeEnum>
error_code(ErrorCodeEnum e) noexcept;

Constraints: is_error_code_enum_v<ErrorCodeEnum> is true.

Postconditions: *this == make_error_code(e).

19.5.4.3 Modifiers

void assign(int val, const error_category& cat) noexcept;

Postconditions: val_ == val and cat_ == &cat.

template<class ErrorCodeEnum>
error_code& operator=(ErrorCodeEnum e) noexcept;

Constraints: is_error_code_enum_v<ErrorCodeEnum> is true.
```cpp
void clear() noexcept;

Postconditions: value() == 0 and category() == system_category().

19.5.4.4 Observers

int value() const noexcept;

Returns: val_.

const error_category& category() const noexcept;

Returns: *cat_.

error_condition default_error_condition() const noexcept;

Returns: category().default_error_condition(value()).

string message() const;

Returns: category().message(value()).

explicit operator bool() const noexcept;

Returns: value() != 0.

19.5.4.5 Non-member functions

error_code make_error_code(errc e) noexcept;

Returns: error_code(static_cast<int>(e), generic_category()).

template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const error_code& ec);

Effects: Equivalent to: return os << ec.category().name() << ':' << ec.value();

19.5.5 Class error_condition

19.5.5.1 Overview

The class error_condition describes an object used to hold values identifying error conditions.

[Note 1: error_condition values are portable abstractions, while error_code values (19.5.4) are implementation specific. —end note]

namespace std {
    class error_condition {
        public:
            // 19.5.5.2, constructors
            error_condition() noexcept;
            error_condition(int val, const error_category& cat) noexcept;
            template<class ErrorConditionEnum>
                error_condition(ErrorConditionEnum e) noexcept;

            // 19.5.5.3, modifiers
            void assign(int val, const error_category& cat) noexcept;
            template<class ErrorConditionEnum>
                error_condition& operator=(ErrorConditionEnum e) noexcept;
            void clear() noexcept;

            // 19.5.5.4, observers
            int value() const noexcept;
            const error_category& category() const noexcept;
            string message() const;
            explicit operator bool() const noexcept;
    }
}
```
private:
int val_;  // exposition only
const error_category* cat_;  // exposition only
};

19.5.5.2 Constructors
[syserr.errcondition.constructors]

error_condition() noexcept;
1

Postconditions: val_ == 0 and cat_ == &generic_category().

error_condition(int val, const error_category& cat) noexcept;
2

Postconditions: val_ == val and cat_ == &cat.

template<class ErrorConditionEnum>
error_condition(ErrorConditionEnum e) noexcept;
3

Constraints: is_error_condition_enum_v<ErrorConditionEnum> is true.

Postconditions: *this == make_error_condition(e).

19.5.5.3 Modifiers
[syserr.errcondition.modifiers]

void assign(int val, const error_category& cat) noexcept;
1

Postconditions: val_ == val and cat_ == &cat.

template<class ErrorConditionEnum>
error_condition& operator=(ErrorConditionEnum e) noexcept;
2

Constraints: is_error_condition_enum_v<ErrorConditionEnum> is true.

Postconditions: *this == make_error_condition(e).

Returns: *this.

void clear() noexcept;
4

Postconditions: value() == 0 and category() == generic_category().

19.5.5.4 Observers
[syserr.errcondition.observers]

int value() const noexcept;
1

Returns: val_.

const error_category& category() const noexcept;
2

Returns: *cat_.

string message() const;
3

Returns: category().message(value()).

explicit operator bool() const noexcept;
4

Returns: value() != 0.

19.5.5.5 Non-member functions
[syserr.errcondition.nonmembers]

error_condition make_error_condition(errc e) noexcept;
1

Returns: error_condition(static_cast<int>(e), generic_category()).

19.5.6 Comparison operator functions
[syserr.compare]

bool operator==(const error_code& lhs, const error_code& rhs) noexcept;
1

Returns:

lhs.category() == rhs.category() && lhs.value() == rhs.value()
bool operator==(const error_code& lhs, const error_condition& rhs) noexcept;

Returns:
    lhs.category().equivalent(lhs.value(), rhs) || rhs.category().equivalent(lhs, rhs.value())

bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;

Returns:
    lhs.category() == rhs.category() && lhs.value() == rhs.value()

strong_ordering operator<=>(const error_code& lhs, const error_code& rhs) noexcept;

Effects: Equivalent to:
    if (auto c = lhs.category() <=> rhs.category(); c != 0) return c;
    return lhs.value() <=> rhs.value();

strong_ordering operator<=>(const error_condition& lhs, const error_condition& rhs) noexcept;

Returns:
    if (auto c = lhs.category() <=> rhs.category(); c != 0) return c;
    return lhs.value() <=> rhs.value();

19.5.7 System error hash support

```cpp
template<> struct hash<error_code>;
template<> struct hash<error_condition>;
```

The specializations are enabled (20.14.19).

19.5.8 Class system_error

19.5.8.1 Overview

The class `system_error` describes an exception object used to report error conditions that have an associated error code. Such error conditions typically originate from the operating system or other low-level application program interfaces.

[Note 1: If an error represents an out-of-memory condition, implementations are encouraged to throw an exception object of type `bad_alloc` (17.6.4.1) rather than `system_error`. — end note]

```cpp
namespace std {
    class system_error : public runtime_error {
        public:
        system_error(error_code ec, const string& what_arg);
        system_error(error_code ec, const char* what_arg);
        system_error(error_code ec);
        system_error(int ev, const error_category& ecat, const string& what_arg);
        system_error(int ev, const error_category& ecat, const char* what_arg);
        system_error(int ev, const error_category& ecat);
        const error_code& code() const noexcept;
        const char* what() const noexcept override;
    }
};
```

19.5.8.2 Members

```cpp
system_error(error_code ec, const string& what_arg);
Postconditions: code() == ec and string_view(what()).find(what_arg.c_str()) != string_view::npos.

system_error(error_code ec, const char* what_arg);
Postconditions: code() == ec and string_view(what()).find(what_arg) != string_view::npos.

system_error(error_code ec);
Postconditions: code() == ec.
```
system_error(int ev, const error_category& ecat, const string& what_arg);

    Postconditions: code() == error_code(ev, ecat) and
                    string_view(what()).find(what_arg.c_str()) != string_view::npos.

system_error(int ev, const error_category& ecat, const char* what_arg);

    Postconditions: code() == error_code(ev, ecat) and
                    string_view(what()).find(what_arg) != string_view::npos.

system_error(int ev, const error_category& ecat);

    Postconditions: code() == error_code(ev, ecat).

    Returns: ec or error_code(ev, ecat), from the constructor, as appropriate.

    const error_code& code() const noexcept;

    Returns: ec or error_code(ev, ecat), from the constructor, as appropriate.

    const char* what() const noexcept override;

    Returns: An NTBS incorporating the arguments supplied in the constructor.

    [Note 1: The returned NTBS might be the contents of what_arg + ": " + code.message(). — end note]
20 General utilities library

20.1 General

This Clause describes utilities that are generally useful in C++ programs; some of these utilities are used by other elements of the C++ standard library. These utilities are summarized in Table 43.

Table 43: General utilities library summary

20.2 Utility components

20.2.1 Header <utility> synopsis

The header <utility> contains some basic function and class templates that are used throughout the rest of the library.

```cpp
#include <compare>     // see 17.11.1
#include <initializer_list> // see 17.10.2

namespace std {
    // 20.2.2, swap
    template<class T>
    constexpr void swap(T& a, T& b) noexcept(see below);
    template<class T, size_t N>
    constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);

    // 20.2.3, exchange
    template<class T, class U = T>
    constexpr T exchange(T& obj, U&& new_val);

    // 20.2.4, forward/move
    template<class T>
    constexpr T& forward(remove_reference_t<T>& t) noexcept;
    template<class T>
    constexpr T& forward(remove_reference_t<T>&& t) noexcept;
    template<class T>
    constexpr remove_reference_t<T>&& move(T&&) noexcept;
```
template<class T>
constexpr conditional_t<
    !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>
move_if_noexcept(T& x) noexcept;

// 20.2.5, as_const
template<class T>
constexpr add_const_t<T>& as_const(T& t) noexcept;
template<class T>
void as_const(const T& t) = delete;

// 20.2.6, declval
template<class T>
add_rvalue_reference_t<T> declval() noexcept;  // as unevaluated operand

// 20.2.7, integer comparison functions
template<class T, class U>
constexpr bool cmp_equal(T t, U u) noexcept;
template<class T, class U>
constexpr bool cmp_not_equal(T t, U u) noexcept;

template<class T, class U>
constexpr bool cmp_less(T t, U u) noexcept;
template<class T, class U>
constexpr bool cmp_greater(T t, U u) noexcept;
template<class T, class U>
constexpr bool cmp_less_equal(T t, U u) noexcept;
template<class T, class U>
constexpr bool cmp_greater_equal(T t, U u) noexcept;

template<class R, class T>
constexpr underlying_type_t<T> to_underlying(T value) noexcept;

// 20.2.8, to_underlying
template<class T>
constexpr underlying_type_t<T> to_underlying(T value) noexcept;

// 20.3, compile-time integer sequences
template<class T, T...>
struct integer_sequence;
template<size_t... I>
using index_sequence = integer_sequence<size_t, I...>;

template<class T, T N>
using make_integer_sequence = integer_sequence<T, see below>;
template<size_t N>
using make_index_sequence = make_integer_sequence<size_t, N>;

template<class... T>
using index_sequence_for = make_index_sequence<sizeof...(T)>;

// 20.4, class template pair
template<class T1, class T2>
struct pair;

// 20.4.3, pair specialized algorithms
template<class T1, class T2>
constexpr bool operator==(const pair<T1, T2>&, const pair<T1, T2>&);
template<class T1, class T2>
constexpr common_comparison_category_t<synth-three-way-result<T1>, synth-three-way-result<T2>> operator<=>(const pair<T1, T2>&, const pair<T1, T2>&);
template<class T1, class T2>
constexpr void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));

// 20.4.4, tuple-like access to pair

// 20.4.5, pair piecewise construction

 § 20.2.1 565
20.2.2 swap

```
template<class T>
constexpr void swap(T& a, T& b) noexcept(see below);
```

1. **Constraints:** `is_move_constructible_v<T>` is true and `is_move_assignable_v<T>` is true.
2. **Preconditions:** Type T meets the `Cpp17MoveConstructible` (Table 30) and `Cpp17MoveAssignable` (Table 32) requirements.
3. **Effects:** Exchanges values stored in two locations.
4. **Remarks:** This function is a designated customization point (16.4.5.2.1). The exception specification is equivalent to:
   ```
is_nothrow_move_constructible_v<T> && is_nothrow_move_assignable_v<T>
```

```
template<class T, size_t N>
constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);
```

5. **Constraints:** `is_swappable_v<T>` is true.
6. **Preconditions:** `a[i]` is swappable with `b[i]` for all `i` in the range `[0, N)`.
7. **Effects:** As if by `swap_ranges(a, a + N, b)`.

20.2.3 exchange

```
template<class T, class U = T>
constexpr T exchange(T& obj, U&& new_val);
```

1. **Effects:** Equivalent to:
   ```
   T old_val = std::move(obj);
   obj = std::forward<U>(new_val);
   return old_val;
   ```

20.2.4 Forward/move helpers

```
§ 20.2.4 566
```
template<class T> constexpr remove_reference_t<T>&& move(T&& t) noexcept;

Returns: static_cast<remove_reference_t<T>&&>(t).

Example 2:

```
template<class T, class A1>
shared_ptr<T> factory(A1&& a1) {
    return shared_ptr<T>(new T(std::forward<A1>(a1)));
}
```

```
struct A {
    A();
    A(const A&);  // copies from lvalues
    A(A&&);      // moves from rvalues
};
```

```
void g() {
    A a;
    shared_ptr<A> sp1 = factory<A>(a); // "a" binds to A(const A&)
    shared_ptr<A> sp1 = factory<A>(std::move(a)); // "a" binds to A(A&&)
}
```

In the first call to `factory`, `A1` is deduced as `A&`, so `a` is forwarded as a non-const lvalue. This binds to the constructor `A(const A&)`, which copies the value from `a`. In the second call to `factory`, because of the call `std::move(a)`, `A1` is deduced as `A`, so `a` is forwarded as an rvalue. This binds to the constructor `A(A&&)`, which moves the value from `a`. — end example]

```
template<class T> constexpr conditional_t<
    !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>,
    const T&, T&&>
movemove_if_noexcept(T& x) noexcept;
```

Returns: `std::move(x)`.

20.2.5 Function template as_const

```
template<class T> constexpr add_const_t<T>& as_const(T& t) noexcept;
```

Returns: `t`.

20.2.6 Function template declval

```
template<class T> add_rvalue_reference_t<T> declval() noexcept;
```

// as unevaluated operand

Mandates: This function is not odr-used (6.3).

Remarks: The template parameter `T` of `declval` may be an incomplete type.

[Example 1:

```
template<class To, class From> decltype(static_cast<To>(declval<From>())) convert(From&&);
```

declares a function template `convert` which only participates in overload resolution if the type `From` can be explicitly converted to type `To`. For another example see class template `common_type` (20.15.8.7). — end example]

20.2.7 Integer comparison functions

```
template<class T, class U>
constexpr bool cmp_equal(T t, U u) noexcept;
```

Mandates: Both `T` and `U` are standard integer types or extended integer types (6.8.2).

Effects: Equivalent to:

```
using UT = make_unsigned_t<T>;
using UU = make_unsigned_t<U>;
if constexpr (is_signed_v<T> == is_signed_v<U>)
    return t == u;
```
else if constexpr (is_signed_v<T>)
  return t < 0 ? false : UT(t) == u;
else
  return u < 0 ? false : t == UU(u);

template<class T, class U>
constexpr bool cmp_not_equal(T t, U u) noexcept;

Effects: Equivalent to: return !cmp_equal(t, u);

template<class T, class U>
constexpr bool cmp_less(T t, U u) noexcept;

Mandates: Both T and U are standard integer types or extended integer types (6.8.2).
Effects: Equivalent to:
  using UT = make_unsigned_t<T>;
  using UU = make_unsigned_t<U>;
  if constexpr (is_signed_v<T> == is_signed_v<U>)
    return t < u;
  else if constexpr (is_signed_v<T>)
    return t < 0 ? true : UT(t) < u;
  else
    return u < 0 ? false : t < UU(u);

template<class T, class U>
constexpr bool cmp_greater(T t, U u) noexcept;

Effects: Equivalent to: return cmp_less(u, t);

template<class T, class U>
constexpr bool cmp_less_equal(T t, U u) noexcept;

Effects: Equivalent to: return !cmp_greater(t, u);

template<class T, class U>
constexpr bool cmp_greater_equal(T t, U u) noexcept;

Effects: Equivalent to: return !cmp_less(t, u);

template<class R, class T>
constexpr bool in_range(T t) noexcept;

Mandates: Both T and R are standard integer types or extended integer types (6.8.2).
Effects: Equivalent to:
  return cmp_greater_equal(t, numeric_limits<R>::min()) &&
  cmp_less_equal(t, numeric_limits<R>::max());

[Note 1: These function templates cannot be used to compare byte, char, char8_t, char16_t, char32_t, wchar_t,
and bool. — end note]

20.2.8 Function template to_underlying

[utility.underlying]
template<class T>
constexpr underlying_type_t<T> to_underlying(T value) noexcept;

Returns: static_cast<underlying_type_t<T>>(value).

20.3 Compile-time integer sequences

[utility.underlying]

20.3.1 In general

The library provides a class template that can represent an integer sequence. When used as an argument to a function template the template parameter pack defining the sequence can be deduced and used in a pack expansion.

[Note 1: The index_sequence alias template is provided for the common case of an integer sequence of type size_t;
see also 20.5.5. — end note]
20.3.2 Class template integer_sequence

namespace std {
    template<class T, T... I> struct integer_sequence {
        using value_type = T;
        static constexpr size_t size() noexcept { return sizeof...(I); }
    };
}

Mandates: T is an integer type.

20.3.3 Alias template make_integer_sequence

template<class T, T N>
using make_integer_sequence = integer_sequence<T, see below>;

Mandates: N ≥ 0.

The alias template make_integer_sequence denotes a specialization of integer_sequence with N non-type template arguments. The type make_integer_sequence<T, N> is an alias for the type integer_sequence<T, 0, 1, ..., N-1>.

[Note 1: make_integer_sequence<int, 0> is an alias for the type integer_sequence<int>. —end note]

20.4 Pairs

20.4.1 In general

The library provides a template for heterogeneous pairs of values. The library also provides a matching function template to simplify their construction and several templates that provide access to pair objects as if they were tuple objects (see 20.5.6 and 20.5.7).

20.4.2 Class template pair

namespace std {
    template<class T1, class T2>
    struct pair {
        using first_type = T1;
        using second_type = T2;
        T1 first;
        T2 second;

        pair(const pair&) = default;
        pair(pair&&) = default;
        constexpr explicit(see below) pair();
        constexpr explicit(see below) pair(const T1& x, const T2& y);
        template<class U1, class U2>
            constexpr explicit(see below) pair(U1&& x, U2&& y);
        template<class U1, class U2>
            constexpr explicit(see below) pair(const pair<U1, U2>& p);
        template<class U1, class U2>
            constexpr explicit(see below) pair(pair<U1, U2>&& p);
        template<class... Args1, class... Args2>
            constexpr pair(piecewise_construct_t,
                tuple<Args1...> first_args, tuple<Args2...> second_args);

        constexpr pair& operator=(const pair& p);
        template<class U1, class U2>
            constexpr pair& operator=(const pair<U1, U2>& p);
        constexpr pair& operator=(pair&& p) noexcept(see below);
        template<class U1, class U2>
            constexpr pair& operator=(pair<U1, U2>&& p);
        constexpr void swap(pair& p) noexcept(see below);
    };
}
template<class T1, class T2>
  pair(T1, T2) -> pair<T1, T2>;
}

1 Constructors and member functions of pair do not throw exceptions unless one of the element-wise operations specified to be called for that operation throws an exception.

2 The defaulted move and copy constructor, respectively, of pair is a constexpr function if and only if all required element-wise initializations for move and copy, respectively, would satisfy the requirements for a constexpr function.

3 If (is_trivially_destructible_v<T1> && is_trivially_destructible_v<T2>) is true, then the destructor of pair is trivial.

4 pair<T, U> is a structural type (13.2) if T and U are both structural types. Two values p1 and p2 of type pair<T, U> are template-argument-equivalent (13.6) if and only if p1.first and p2.first are template-argument-equivalent and p1.second and p2.second are template-argument-equivalent.

constexpr explicit(see below) pair();

5 Constraints:
(5.1) is_default_constructible_v<first_type> is true and
(5.2) is_default_constructible_v<second_type> is true.

Effects: Value-initializes first and second.

Remarks: The expression inside explicit evaluates to true if and only if either first_type or second_type is not implicitly default-constructible.

[Note 1: This behavior can be implemented with a trait that checks whether a const first_type& or a const second_type& can be initialized with {}. — end note]

constexpr explicit(see below) pair(const T1& x, const T2& y);

6 Constraints:
(8.1) is_copy_constructible_v<first_type> is true and
(8.2) is_copy_constructible_v<second_type> is true.

Effects: Initializes first with x and second with y.

Remarks: The expression inside explicit is equivalent to:

!is_convertible_v<const first_type&, first_type> ||
!is_convertible_v<const second_type&, second_type>

template<class U1, class U2> constexpr explicit(see below) pair(U1&& x, U2&& y);

7 Constraints:
(11.1) is_constructible_v<first_type, U1> is true and
(11.2) is_constructible_v<second_type, U2> is true.

Effects: Initializes first with std::forward<U1>(x) and second with std::forward<U2>(y).

Remarks: The expression inside explicit is equivalent to:

!is_convertible_v<U1, first_type> || !is_convertible_v<U2, second_type>

template<class U1, class U2> constexpr explicit(see below) pair(const pair<U1, U2>& p);

8 Constraints:
(14.1) is_constructible_v<first_type, const U1&> is true and
(14.2) is_constructible_v<second_type, const U2&> is true.

Effects: Initializes members from the corresponding members of the argument.

Remarks: The expression inside explicit is equivalent to:

!is_convertible_v<const U1&, first_type> || !is_convertible_v<const U2&, second_type>

template<class U1, class U2> constexpr explicit(see below) pair(pair<U1, U2>&& p);

§ 20.4.2
is_constructible_v<first_type, U1> is true and
is_constructible_v<second_type, U2> is true.

**Effects**: Initializes first with std::forward<U1>(p.first) and second with std::forward<U2>(p.second).

**Remarks**: The expression inside explicit is equivalent to:

!is_convertible_v<U1, first_type> || !is_convertible_v<U2, second_type>

**Template**: template<class... Args1, class... Args2>
constexpr pair(piecewise_construct_t,
tuple<Args1...> first_args, tuple<Args2...> second_args);

**Mandates**: 
(20.1) is_constructible_v<first_type, Args1...> is true and
(20.2) is_constructible_v<second_type, Args2...> is true.

**Effects**: Initializes first with arguments of types Args1... obtained by forwarding the elements of first_args and initializes second with arguments of types Args2... obtained by forwarding the elements of second_args. (Here, forwarding an element x of type U within a tuple object means calling std::forward<U>(x).) This form of construction, whereby constructor arguments for first and second are each provided in a separate tuple object, is called *piecewise construction*.

**Operator**: constexpr pair& operator=(const pair& p);

**Effects**: Assigns p.first to first and p.second to second.

**Returns**: *this.

**Remarks**: This operator is defined as deleted unless is_copy_assignable_v<first_type> is true and is_copy_assignable_v<second_type> is true.

**Template**: template<class U1, class U2> constexpr pair& operator=(const pair<U1, U2>& p);

**Constraints**: 
(28.1) is_assignable_v<first_type&, const U1&> is true and
(28.2) is_assignable_v<second_type&, const U2&> is true.

**Effects**: Assigns p.first to first and p.second to second.

**Returns**: *this.

**Operator**: constexpr pair& operator=(pair&& p) noexcept(see below);

**Constraints**: 
(32.1) is_assignable_v<first_type&, U1> is true and
(32.2) is_assignable_v<second_type&, U2> is true.

**Effects**: Assigns to first with std::forward<U1>(p.first) and to second with std::forward<U2>(p.second).

**Returns**: *this.
constexpr void swap(pair& p) noexcept(see below);

35  **Preconditions:** first is swappable with (16.4.4.3) p.first and second is swappable with p.second.
36  **Effects:** Swaps first with p.first and second with p.second.
37  **Remarks:** The exception specification is equivalent to:
   is_nothrow_swappable_v<first_type> && is_nothrow_swappable_v<second_type>

### 20.4.3 Specialized algorithms

template<class T1, class T2>
constexpr bool operator==(const pair<T1, T2>& x, const pair<T1, T2>& y);

1  **Returns:** x.first == y.first && x.second == y.second.

template<class T1, class T2>
constexpr common_comparison_category_t<
   synth-three-way-result<T1>, synth-three-way-result<T2>>
operator<=>(const pair<T1, T2>& x, const pair<T1, T2>& y);

2  **Effects:** Equivalent to:
   if (auto c = synth-three-way(x.first, y.first); c != 0) return c;
   return synth-three-way(x.second, y.second);

template<class T1, class T2>
constexpr void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));

3  **Constraints:** is_swappable_v<T1> is true and is_swappable_v<T2> is true.
4  **Effects:** Equivalent to x.swap(y).

template<class T1, class T2>
constexpr pair<unwrap_ref_decay_t<T1>, unwrap_ref_decay_t<T2>> make_pair(T1&& x, T2&& y);

5  **Returns:**
   pair<unwrap_ref_decay_t<T1>, unwrap_ref_decay_t<T2>>(std::forward<T1>(x), std::forward<T2>(y))

6  **[Example 1]:** In place of:
   return pair<int, double>(5, 3.1415926); // explicit types
   a C++ program may contain:
   return make_pair(5, 3.1415926); // types are deduced
   —end example]

### 20.4.4 Tuple-like access to pair

template<class T1, class T2>
struct tuple_size<pair<T1, T2>> : integral_constant<size_t, 2> { };

template<size_t I, class T1, class T2>
struct tuple_element<I, pair<T1, T2>> {
   using type = see below ;
};

1  **Mandates:** I < 2.
2  **Type:** The type T1 if I is 0, otherwise the type T2.

template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>&& p) noexcept;

template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>&& p) noexcept;

template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>&& get(pair<T1, T2>&& p) noexcept;

template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>&& get(const pair<T1, T2>&& p) noexcept;

3  **Mandates:** I < 2.
Returns:

— If \( I \) is 0, returns a reference to \( \text{p.first} \).

— If \( I \) is 1, returns a reference to \( \text{p.second} \).

\[
\begin{align*}
\text{template<class T1, class T2> constexpr T1& &get(pair<T1, T2>& p) noexcept; } \\
\text{template<class T1, class T2> constexpr const T1& &get(const pair<T1, T2>& p) noexcept; } \\
\text{template<class T1, class T2> constexpr T1&& get(pair<T1, T2>&& p) noexcept; } \\
\text{template<class T1, class T2> constexpr const T1&& get(const pair<T1, T2>&& p) noexcept; }
\end{align*}
\]

Mandates: \( T1 \) and \( T2 \) are distinct types.

Returns: A reference to \( \text{p.first} \).

\[
\begin{align*}
\text{template<class T2, class T1> constexpr T2& &get(pair<T1, T2>& p) noexcept; } \\
\text{template<class T2, class T1> constexpr const T2& &get(const pair<T1, T2>& p) noexcept; } \\
\text{template<class T2, class T1> constexpr T2&& get(pair<T1, T2>&& p) noexcept; } \\
\text{template<class T2, class T1> constexpr const T2&& get(const pair<T1, T2>&& p) noexcept; }
\end{align*}
\]

Mandates: \( T1 \) and \( T2 \) are distinct types.

Returns: A reference to \( \text{p.second} \).

20.4.5 Piecewise construction [pair.piecewise]

```cpp
struct piecewise_construct_t {
  explicit piecewise_construct_t() = default;
};
inline constexpr piecewise_construct_t piecewise_construct();
```

The \textbf{struct piecewise_construct_t} is an empty class type used as a unique type to disambiguate constructor and function overloading. Specifically, \texttt{pair} has a constructor with \texttt{piecewise_construct} as the first argument, immediately followed by two \texttt{tuple} (20.5) arguments used for piecewise construction of the elements of the \texttt{pair} object.

20.5 Tuples [tuple]

20.5.1 In general [tuple.general]

Subclause 20.5 describes the tuple library that provides a tuple type as the class template \texttt{tuple} that can be instantiated with any number of arguments. Each template argument specifies the type of an element in the \texttt{tuple}. Consequently, tuples are heterogeneous, fixed-size collections of values. An instantiation of \texttt{tuple} with two arguments is similar to an instantiation of \texttt{pair} with the same two arguments. See 20.4.

20.5.2 Header \texttt{<tuple>} synopsis [tuple.syn]

```cpp
#include <compare> // see 17.11.1

namespace std {
  // 20.5.3, class template tuple
  template<class... Types>
    class tuple;

  // 20.5.4, tuple creation functions
  inline constexpr unspecified ignore;

  template<class... TTypes>
    constexpr tuple<unwrap_ref_decay_t<TTypes>...> make_tuple(TTypes&&...);

  template<class... TTypes>
    constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&... noexcept;
```
template<class... TTypes>
    constexpr tuple<TTypes&...> tie(TTypes&...)
        noexcept;

template<class... Tuples>
    constexpr tuple<CTypes...> tuple_cat(Tuples&&...);

// 20.5.5, calling a function with a tuple of arguments
template<class F, class Tuple>
    constexpr decltype(auto) apply(F&& f, Tuple&& t);

template<class T, class Tuple>
    constexpr T make_from_tuple(Tuple&& t);

// 20.5.6, tuple helper classes
template<class T> struct tuple_size;
// not defined
template<class T> struct tuple_size<const T>;

template<class... Types> struct tuple_size<tuple<Types...>>;

template<size_t I, class T> struct tuple_element;
// not defined
template<size_t I, class T> struct tuple_element<I, const T>;

template<size_t I, class... Types>
    struct tuple_element<I, tuple<Types...>>;

template<size_t I, class T>
    using tuple_element_t = typename tuple_element<I, T>::type;

// 20.5.7, element access
template<size_t I, class... Types>
    constexpr tuple_element_t<I, tuple<Types...>>&
        get(tuple<Types...>&) noexcept;

template<class T, class... Types>
    constexpr const T& get(const tuple<Types...>& t) noexcept;

template<class T, class... Types>
    constexpr const T&& get(const tuple<Types...>&& t) noexcept;

// 20.5.8, relational operators
template<class... TTypes, class... UTypes>
    constexpr bool operator==(const tuple<TTypes...>&, const
tuple<UTypes...>&);

template<class... TTypes, class... UTypes>
    constexpr common_comparison_category_t<
synth-three-way-result<
        TTypes, UTypes...>>
        operator<=>(const tuple<TTypes...>&, const
tuple<UTypes...>&);

// 20.5.9, allocator-related traits
template<class... Types, class Alloc>
    struct uses_allocator<
tuple<Types...>, Alloc>;

// 20.5.10, specialized algorithms
template<class... Types>
    constexpr void swap(tuple<Types...>& x, tuple<Types...>& y)
        noexcept(see below);
// 20.5.6, tuple helper classes
template<class T>
inline constexpr size_t tuple_size_v = tuple_size<T>::value;
}

20.5.3 Class template tuple

namespace std {
    template<class... Types>
    class tuple {
    public:
        // 20.5.3.1, tuple construction
        constexpr explicit(see below) tuple();
        constexpr explicit(see below) tuple(const Types&...); // only if sizeof...(Types) == 1
        template<class... UTypes>
        constexpr explicit(see below) tuple(UTypes&&...); // only if sizeof...(Types) == 1
        tuple(const tuple&) = default;
        tuple(tuple&&) = default;
        template<class... UTypes>
        constexpr explicit(see below) tuple(const tuple<UTypes...>&);
        template<class... UTypes>
        constexpr explicit(see below) tuple(tuple<UTypes...>&&);
        template<class U1, class U2>
        constexpr explicit(see below) tuple(const pair<U1, U2>&);
        template<class U1, class U2>
        constexpr explicit(see below) tuple(pair<U1, U2>&&); // only if sizeof...(Types) == 2

        // allocator-extended constructors
        template<class Alloc>
        constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a);
        template<class Alloc>
        constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, const Types&...);
        template<class Alloc, class... UTypes>
        constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, UTypes&&...);
        template<class Alloc>
        constexpr tuple(allocator_arg_t, const Alloc& a, const tuple&);
        template<class Alloc>
        constexpr tuple(allocator_arg_t, const Alloc& a, tuple&&);
        template<class Alloc, class... UTypes>
        constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&);
        template<class Alloc, class... UTypes>
        constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&&);
        template<class Alloc, class U1, class U2>
        constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&);
        template<class Alloc, class U1, class U2>
        constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&&); // only if sizeof...(Types) == 2

        // 20.5.3.2, tuple assignment
        constexpr tuple& operator=(const tuple&);
        constexpr tuple& operator=(tuple&&) noexcept(see below);
        template<class... UTypes>
        constexpr tuple& operator=(const tuple<UTypes...>&);
        template<class... UTypes>
        constexpr tuple& operator=(tuple<UTypes...>&&);
    } // class tuple
} // namespace std
template<class U1, class U2>
constexpr tuple& operator=(const pair<U1, U2>&);  // only if sizeof...(Types) == 2

// 20.5.3.3, tuple swap
constexpr void swap(tuple&) noexcept(see below);
};

template<class... UTypes>
tuple(UTypes...) -> tuple<UTypes...>;

template<class T1, class T2>
tuple(pair<T1, T2>) -> tuple<T1, T2>;

template<class Alloc, class... UTypes>
tuple(allocator_arg_t, Alloc, UTypes...) -> tuple<UTypes...>;

template<class Alloc, class T1, class T2>
tuple(allocator_arg_t, Alloc, pair<T1, T2>) -> tuple<T1, T2>;

template<class Alloc, class... UTypes>
tuple(allocator_arg_t, Alloc, tuple<UTypes...>) -> tuple<UTypes...>;

20.5.3.1 Construction [tuple.cnstr]

1 In the descriptions that follow, let \( i \) be in the range \([0, \text{sizeof...}(\text{Types}))\) in order, \( T_i \) be the \( i \)th type in \( \text{Types} \), and \( U_i \) be the \( i \)th type in a template parameter pack named \( \text{UTypes} \), where indexing is zero-based.

2 For each \( \text{tuple} \) constructor, an exception is thrown only if the construction of one of the types in \( \text{Types} \) throws an exception.

3 The defaulted move and copy constructor, respectively, of \( \text{tuple} \) is a constexpr function if and only if all required element-wise initializations for move and copy, respectively, would satisfy the requirements for a constexpr function. The defaulted move and copy constructor of \( \text{tuple<>()} \) are constexpr functions.

4 If \( \text{is_trivially_destructible_v<T_i>} \) is true for all \( T_i \), then the destructor of \( \text{tuple} \) is trivial.

5 The default constructor of \( \text{tuple<>()} \) is trivial.

constexpr explicit(see below) tuple();

6 Constraints: \( \text{is_default_constructible_v<T_i>} \) is true for all \( i \).

7 Effects: Value-initializes each element.

8 Remarks: The expression inside explicit evaluates to true if and only if \( T_i \) is not copy-list-initializable from an empty list for at least one \( i \).

[Note 1: This behavior can be implemented with a trait that checks whether a \( \text{const T}_i & \) can be initialized with \( {} \). — end note]

constexpr explicit(see below) tuple(const Types&...);

9 Constraints: sizeof...(\( \text{Types} \)) \( \geq 1 \) and \( \text{is_copy_constructible_v<T_i>} \) is true for all \( i \).

10 Effects: Initializes each element with the value of the corresponding parameter.

11 Remarks: The expression inside explicit is equivalent to:

\[ \neg \text{conjunction_v<is_convertible<const Types&, Types>...> } \]

template<class... UTypes> constexpr explicit(see below) tuple(UTypes&&... u);

12 Constraints: sizeof...((\( \text{Types} \)) equals sizeof...((\( \text{UTypes} \)) and sizeof...((\( \text{Types} \)) \( \geq 1 \) and \( \text{is_-constructible_v<T_i>, U_i> is true for all i.} \)

13 Effects: Initializes the elements in the tuple with the corresponding value in std::forward<\( \text{UTypes} \))(\( u \)).

14 Remarks: The expression inside explicit is equivalent to:

\[ \neg \text{conjunction_v<is_convertible<UTypes, Types>...> } \]

tuple(const tuple& u) = default;

15 Mandates: \( \text{is_copy_constructible_v<T_i>} \) is true for all \( i \).
Effects: Initializes each element of \*this with the corresponding element of u.

tuple(tuple&& u) = default;

Constraints: is_move_constructible_v<T_i> is true for all i.

Effects: For all i, initializes the i\textsuperscript{th} element of \*this with std::forward<T_i>(get<i>(u)).

template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>& u);

Constraints:

(19.1) sizeof...(Types) equals sizeof...(UTypes) and
(19.2) is_constructible_v<T_i, const U_i&> is true for all i, and
(19.3) either sizeof...(Types) is not 1, or (when Types... expands to T and UTypes... expands to U) is_convertible_v<const tuple<U>&, T>, is_constructible_v<T, const tuple<U>&>, and is_same_v<T, U> are all false.

Effects: Initializes each element of \*this with the corresponding element of u.

Remarks: The expression inside explicit is equivalent to:

!conjunction_v<is_convertible<Const UTypes&, Types>...>

template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>& u);

Constraints:

(21.1) sizeof...(Types) equals sizeof...(UTypes) and
(21.2) is_constructible_v<T_i, const U_i&> is true for all i, and
(21.3) either sizeof...(Types) is not 1, or (when Types... expands to T and UTypes... expands to U) is_convertible_v<const tuple<U>&, T>, is_constructible_v<T, const tuple<U>&>, and is_same_v<T, U> are all false.

Effects: For all i, initializes the i\textsuperscript{th} element of \*this with std::forward<T_i>(get<i>(u)).

Remarks: The expression inside explicit is equivalent to:

!conjunction_v<is_convertible<UTypes, Types>...>

template<class U1, class U2> constexpr explicit(see below) tuple(const pair<U1, U2>& u);

Constraints:

(25.1) sizeof...(Types) is 2,
(25.2) is_convertible_v<T_0, const U1&> is true, and
(25.3) is_convertible_v<T_1, const U2&> is true.

Effects: Initializes the first element with u.first and the second element with u.second.

Remarks: The expression inside explicit is equivalent to:

!is_convertible_v<const U1&, T_0> || !is_convertible_v<const U2&, T_1>

template<class U1, class U2> constexpr explicit(see below) tuple(pair<U1, U2>&& u);

Constraints:

(28.1) sizeof...(Types) is 2,
(28.2) is_convertible_v<T_0, U1> is true, and
(28.3) is_convertible_v<T_1, U2> is true.

Effects: Initializes the first element with std::forward<U1>(u.first) and the second element with std::forward<U2>(u.second).

Remarks: The expression inside explicit is equivalent to:

!is_convertible_v<U1, T_0> || !is_convertible_v<U2, T_1>

template<class Alloc>
constexpr explicit(see below)

tuple(allocator_arg_t, const Alloc& a);
template<class Alloc>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, const Types&...);

template<class Alloc, class... UTypes>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, UTypes&&...);

template<class Alloc>
constexpr tuple(allocator_arg_t, const Alloc& a, const tuple&);

template<class Alloc>
constexpr tuple(allocator_arg_t, const Alloc& a, tuple&&);

template<class Alloc, class... UTypes>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&);

template<class Alloc, class... UTypes>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&&);

template<class Alloc, class U1, class U2>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&);

template<class Alloc, class U1, class U2>
constexpr explicit(see below)
tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&&);

Preconditions: Alloc meets the Cpp17Allocator requirements (Table 38).

Effects: Equivalent to the preceding constructors except that each element is constructed with use
allocator construction (20.10.8.2).

20.5.3.2 Assignment

For each tuple assignment operator, an exception is thrown only if the assignment of one of the types in Types
throws an exception. In the function descriptions that follow, let \( i \) be in the range \([0, \text{sizeof...}(\text{Types})]\)
in order, \( T_i \) be the \( i \)th type in Types, and \( U_i \) be the \( i \)th type in a template parameter pack named UTypes,
where indexing is zero-based.

constexpr tuple& operator=(const tuple& u);

Effects: Assigns each element of \( u \) to the corresponding element of \(*\this\).
Returns: \*this.
Remarks: This operator is defined as deleted unless is_copyAssignable_v<T_i> is true for all \( i \).

constexpr tuple& operator=(tuple&& u) noexcept(see below);

Constraints: isMoveAssignable_v<T_i> is true for all \( i \).
Effects: For all \( i \), assigns std::forward<T_i>((get<i>(u))) to get<i>(*this).
Returns: *this.
Remarks: The exception specification is equivalent to the logical AND of the following expressions:

\[
is noexceptMoveAssignable_v<T_i>,
\]
where \( T_i \) is the \( i \)th type in Types.

template<class... UTypes> constexpr tuple& operator=(const tuple<UTypes...>& u);

Constraints:
(9.1) sizeof...(Types) equals sizeof...(UTypes) and
(9.2) isAssignable_v<T_i&, const U_i&> is true for all \( i \).
Effects: Assigns each element of \( u \) to the corresponding element of \(*\this\).
Returns: \*this.

template<class... UTypes> constexpr tuple& operator=(tuple<UTypes...>&& u);

Constraints:
(12.1) sizeof...(Types) equals sizeof...(UTypes) and
— is_assignable_v<Tₜₙ, Uₙ> is true for all \( i \).

**Effects:** For all \( i \), assigns `std::forward(Uᵢ)(getᵢ(u))` to `getᵢ(*this)`.

**Returns:** `*this`.

```cpp
template<class U₁, class U₂> constexpr tuple& operator=(const pair<U₁, U₂>& u);
```

**Constraints:**

- sizeof...(Types) is 2 and
- is_assignable_v<T₀&, const U₁&> is true, and
- is_assignable_v<T₁&, const U₂&> is true.

**Effects:** Assigns \( u.\text{first} \) to the first element of `*this` and \( u.\text{second} \) to the second element of `*this`.

**Returns:** `*this`.

### 20.5.3.3 swap

```cpp
constexpr void swap(tuple& rhs) noexcept;
```

**Preconditions:** Each element in `*this` is swappable with (16.4.4.3) the corresponding element in `rhs`.

**Effects:** Calls `swap` for each element in `*this` and its corresponding element in `rhs`.

**Throws:** Nothing unless one of the element-wise `swap` calls throws an exception.

**Remarks:** The exception specification is equivalent to the logical AND of the following expressions:

\[
\text{is_nothrow_swappable_v<Tᵢ>}
\]

where \( Tᵢ \) is the \( i \)-th type in `Types`.

### 20.5.4 Tuple creation functions

In the function descriptions that follow, the members of a template parameter pack \( X \text{Types} \) are denoted by \( Xᵢ \) for \( i \in [0, \text{sizeof}(X\text{Types})) \) in order, where indexing is zero-based.

```cpp
template<class... TTypes>
constexpr tuple<unwrap_ref_decay_t<TTypes>...> make_tuple(TTypes&&... t);
```

**Returns:** `tuple<unwrap_ref_decay_t<TTypes>...>(std::forward<TTypes>(t)...)`.

**Example 1:**

```cpp
int i; float j;
make_tuple(1, ref(i), cref(j))
```

creates a tuple of type `tuple<int, int&, const float&>`. — end example]

```cpp
template<class... TTypes>
constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&... t) noexcept;
```

**Effects:** Constructs a tuple of references to the arguments in \( t \) suitable for forwarding as arguments to a function. Because the result may contain references to temporary objects, a program shall ensure that the return value of this function does not outlive any of its arguments (e.g., the program should typically not store the result in a named variable).

**Returns:** `tuple<TTypes&&...>(std::forward<TTypes>(t)...)`. 

§ 20.5.4
template<class... TTypes>
constexpr tuple<TTypes&...> tie(TTypes&... t) noexcept;

Returns: tuple<TTypes&...>(t...). When an argument in t is ignore, assigning any value to the
corresponding tuple element has no effect.

[Example 2: tie functions allow one to create tuples that unpack tuples into variables. ignore can be used for
elements that are not needed:

```cpp
int i; std::string s;
tie(i, ignore, s) = make_tuple(42, 3.14, "C++");
// i == 42, s == "C++"
```
— end example]

template<class... Tuples>
constexpr tuple<CTypes...> tuple_cat(Tuples&&... tpls);

In the following paragraphs, let Ti be the i\textsuperscript{th} type in Tuples, Ui be remove_reference_t<Ti>, and tp\textsubscript{i} be the i\textsuperscript{th} parameter in the function parameter pack tpls, where all indexing is zero-based.

Preconditions: For all i, Ui is the type cv\textsubscript{i} tuple<Args\textsubscript{i},...>, where cv\textsubscript{i} is the (possibly empty) i\textsuperscript{th} cv-qualifier-seq and Args\textsubscript{i} is the template parameter pack representing the element types in Ui. Let A\textsubscript{ik} be the k\textsuperscript{th} type in Args\textsubscript{i}. For all A\textsubscript{ik} the following requirements are met:

(9.1) — If Ti is deduced as an lvalue reference type, then is_constructible_v<A\textsubscript{ik}, cv\textsubscript{i} A\textsubscript{ik} &> == true, otherwise

(9.2) — is_constructible_v<A\textsubscript{ik}, cv\textsubscript{i} A\textsubscript{ik}&&> == true.

Remarks: The types in CTypes are equal to the ordered sequence of the extended types Args\textsubscript{0},..., Args\textsubscript{n−1},... where n is equal to sizeof...(Tuples). Let e\textsubscript{i},... be the i\textsuperscript{th} ordered sequence of tuple elements of the resulting tuple object corresponding to the type sequence Args\textsubscript{i}.

Returns: A tuple object constructed by initializing the k\textsubscript{ik} type element e\textsubscript{ik} in e\textsubscript{i},... with

get<k\textsubscript{ik}>(std::forward<T<ti>>(tp\textsubscript{i}))

for each valid k\textsubscript{ik} and each group e\textsubscript{i} in order.

[Note 1: An implementation can support additional types in the template parameter pack Tuples that support the tuple-like protocol, such as pair and array. — end note]

20.5.5 Calling a function with a tuple of arguments

[template<

```cpp
template<class F, class Tuple>
constexpr decltype(auto) apply(F&& f, Tuple&& t);
```

1 Effects: Given the exposition-only function:

```cpp
template<class F, class Tuple, size_t... I>
constexpr decltype(auto) apply-impl(F&& f, Tuple&& t, index_sequence<I...>) {
  // exposition only
  return INVOKE(std::forward<F>(f), std::get<I>(std::forward<Tuple>(t))...);
  // see 20.14.4
}
```

Equivalent to:

```cpp
return apply-impl(std::forward<F>(f), std::forward<Tuple>(t),
  make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>{});
```

```cpp
template<class T, class Tuple>
constexpr T make_from_tuple(Tuple&& t);
```

2 Effects: Given the exposition-only function:

```cpp
template<class T, class Tuple, size_t... I>
constexpr T make-from-tuple-impl(Tuple&& t, index_sequence<I...>) {
  // exposition only
  return T(get<I>(std::forward<Tuple>(t))...);
}
```

Equivalent to:

```cpp
return make-from-tuple-impl<T>
  (forward<Tuple>(t),
   make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>{});
```

§ 20.5.5
20.5.6 Tuple helper classes

```
template<class T> struct tuple_size;  
All specializations of tuple_size meet the Cpp17UnaryTypeTrait requirements (20.15.2) with a base characteristic of integral_constant<size_t, N> for some N.
```

```
template<class... Types>
struct tuple_size<tuple<Types...>> : public integral_constant<size_t, sizeof...(Types)> { };  
```

```
template<size_t I, class... Types>
struct tuple_element<I, tuple<Types...>> {  
using type = TI;  
};  
```

Mandates: I < sizeof...(Types).

Type: TI is the type of the Ith element of Types, where indexing is zero-based.

```
template<class T> struct tuple_size<const T>;  
```

Let TS denote tuple_size<T> of the cv-unqualified type T. If the expression TS::value is well-formed when treated as an unevaluated operand, then each specialization of the template meets the Cpp17UnaryTypeTrait requirements (20.15.2) with a base characteristic of integral_constant<size_t, TS::value>

Otherwise, it has no member value.

Access checking is performed as if in a context unrelated to TS and T. Only the validity of the immediate context of the expression is considered.

```
[Note 1: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. —end note]
```

In addition to being available via inclusion of the <tuple> header, the template is available when any of the headers <array> (22.3.2), <ranges> (24.2), or <utility> (20.2.1) are included.

```
template<size_t I, class T> struct tuple_element<I, const T>;  
```

Let TE denote tuple_element_t<I, T> of the cv-unqualified type T. Then each specialization of the template meets the Cpp17TransformationTrait requirements (20.15.2) with a member typedef that names the type add_const_t<TE>.

In addition to being available via inclusion of the <tuple> header, the template is available when any of the headers <array> (22.3.2), <ranges> (24.2), or <utility> (20.2.1) are included.

20.5.7 Element access

```
template<size_t I, class... Types>
constexpr tuple_element_t<I, tuple<Types...>>&
get(tuple<Types...>& t) noexcept;
```

```
template<size_t I, class... Types>
constexpr tuple_element_t<I, tuple<Types...>>&&
get(tuple<Types...>&& t) noexcept;  
// Note A
```

```
template<size_t I, class... Types>
constexpr const tuple_element_t<I, tuple<Types...>>&
get(const tuple<Types...>& t) noexcept;  
// Note B
```

```
template<size_t I, class... Types>
constexpr const tuple_element_t<I, tuple<Types...>>&& get(const tuple<Types...>&& t) noexcept;  
```

Mandates: I < sizeof...(Types).

Returns: A reference to the Ith element of t, where indexing is zero-based.

```
[Note 1: [Note A] If a type T in Types is some reference type X&, the return type is X&, not X&&. However, if the element type is a non-reference type T, the return type is T&&. —end note]
```

§ 20.5.7 581
4 [Note 2: [Note B] Constness is shallow. If a type \( T \) in \( \text{Types} \) is some reference type \( \&X \), the return type is \( \&X \), not \( \text{const} \&X \). However, if the element type is a non-reference type \( T \), the return type is \( \text{const} \&T \). This is consistent with how constness is defined to work for member variables of reference type. — end note]

\[
\begin{align*}
\text{template}\langle\text{class } T, \text{class... Types}\rangle & \quad \text{constexpr } T& \text{ get}(\text{tuple<Types...}\& t) \text{ noexcept; } \\
\text{template}\langle\text{class } T, \text{class... Types}\rangle & \quad \text{constexpr } T&& \text{ get}(\text{tuple<Types...}\&\& t) \text{ noexcept; } \\
\text{template}\langle\text{class } T, \text{class... Types}\rangle & \quad \text{constexpr } \text{const } T& \text{ get}(\text{const tuple<Types...}\& t) \text{ noexcept; } \\
\text{template}\langle\text{class } T, \text{class... Types}\rangle & \quad \text{constexpr } \text{const } T&& \text{ get}(\text{const tuple<Types...}\&\& t) \text{ noexcept; }
\end{align*}
\]

5 \textbf{Mandates:} The type \( T \) occurs exactly once in \( \text{Types} \).

6 \textbf{Returns:} A reference to the element of \( t \) corresponding to the type \( T \) in \( \text{Types} \).

7 \textbf{[Example 1: ]}
\[
\begin{align*}
\text{const tuple<int, const int, double, double> } t(1, 2, 3.4, 5.6); \\
\text{const int& } i1 = \text{get<int>(t)}; \quad \text{// OK, } i1 \text{ has value } 1 \\
\text{const int& } i2 = \text{get<const int>(t)}; \quad \text{// OK, } i2 \text{ has value } 2 \\
\text{const double& } d = \text{get<double>(t)}; \quad \text{// error: type double is not unique within } t
\end{align*}
\]

—end example

8 [Note 3: The reason get is a non-member function is that if this functionality had been provided as a member function, code where the type depended on a template parameter would have required using the template keyword. — end note]

20.5.8 Relational operators [tuple.rel]

\[
\begin{align*}
\text{template}\langle\text{class... TTTypes, class... UTypes}\rangle & \quad \text{constexpr bool operator==(const tuple<TTTypes...}\& t, \text{const tuple<UTypes...}\& u); } \\
\text{template}\langle\text{class... TTTypes, class... UTypes}\rangle & \quad \text{constexpr \text{common_comparison_category_t<\text{synth-three-way-result<TTTypes, UTypes>...} \rangle operator<=>(const tuple<TTTypes...}\& t, \text{const tuple<UTypes...}\& u);}
\end{align*}
\]

4 \textbf{Effects:} Performs a lexicographical comparison between \( t \) and \( u \). For any two zero-length tuples \( t \) and \( u \), \( t <=> u \) returns \text{strong_ordering::equal}. Otherwise, equivalent to:
\[
\begin{align*}
\text{if (auto c = } \text{ synth-three-way}(\text{get<0>(t)}, \text{get<0>(u)}); \text{ c != 0) return c; } \\
\text{return } t\text{tail } <=> u\text{tail; }
\end{align*}
\]

where \( r\text{tail} \) for some tuple \( r \) is a tuple containing all but the first element of \( r \).

5 [Note 1: The above definition does not require \( t\text{tail} \) (or \( u\text{tail} \)) to be constructed. It might not even be possible, as \( t \) and \( u \) are not required to be copy constructible. Also, all comparison operator functions are short circuited; they do not perform element accesses beyond what is required to determine the result of the comparison. — end note]

20.5.9 Tuple traits [tuple.traits]

\[
\begin{align*}
\text{template}\langle\text{class... Types, class Alloc}\rangle & \quad \text{struct uses_allocator<tuple<Types...>, Alloc> : true_type { }}; \\
\end{align*}
\]

1 \textbf{Preconditions:} \( \text{Alloc} \) meets the \text{Cpp17Allocator} requirements (Table 38).

2 [Note 1: Specialization of this trait informs other library components that tuple can be constructed with an allocator, even though it does not have a nested allocator_type. — end note]
20.5.10 Tuple specialized algorithms

```
template<class... Types>
constexpr void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(
    see below);
```

1 Constraints: `is_swappable_v<T>` is true for every type `T` in `Types`.
2 Effects: As if by `x.swap(y)`.
3 Remarks: The exception specification is equivalent to:
   
   ```
   noexcept(x.swap(y))
   ```

20.6 Optional objects

20.6.1 In general

Subclause 20.6 describes class template `optional` that represents optional objects. An optional object is an object that contains the storage for another object and manages the lifetime of this contained object, if any. The contained object may be initialized after the optional object has been initialized, and may be destroyed before the optional object has been destroyed. The initialization state of the contained object is tracked by the optional object.

20.6.2 Header `<optional>` synopsis

```
#include <compare>

namespace std {

    // 20.6.3, class template optional
    template<class T>
    class optional;

    // 20.6.4, no-value state indicator
    struct nullopt_t;
    inline constexpr nullopt_t nullopt(unspecified);

    // 20.6.5, class bad_optional_access
    class bad_optional_access;

    // 20.6.6, relational operators
    template<class T, class U>
    constexpr bool operator==(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator!=(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator<(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator>(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator<=(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator>=(const optional<T>&, const optional<U>&);
    template<class T, three_way_comparable_with<T> U>
    constexpr compare_three_way_result_t<T,U> operator<=>(const optional<T>&, const optional<U>&);

    // 20.6.7, comparison with nullopt
    template<class T> constexpr bool operator==(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr strong_ordering operator<=>(const optional<T>&, nullopt_t) noexcept;

    // 20.6.8, comparison with U
    template<class T, class U> constexpr bool operator==(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator==(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator<(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator<(const T&, const optional<U>&);
```

§ 20.6.2
template<class T, class U> constexpr bool operator>(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator>(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator<=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator<=(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator>=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator>=(const T&, const optional<U>&);
template<class T, class U> constexpr compare_three_way_result_t<T,U> operator<=>(const optional<T>&, const U&);

// 20.6.9, specialized algorithms

// 20.6.10, hash support

20.6.3 Class template optional

20.6.3.1 General

namespace std {
  template<class T>
  class optional {
    public:
    using value_type = T;
    // 20.6.3.2, constructors
    constexpr optional() noexcept;
    constexpr optional(nullopt_t) noexcept;
    constexpr optional(const optional&);
    constexpr optional(optional&&) noexcept(see below);
    template<class... Args>
    constexpr explicit optional(in_place_t, Args&&...);
    template<class U, class... Args>
    constexpr explicit optional(in_place_t, initializer_list<U>, Args&&...);
    template<class U = T>
    constexpr explicit(see below) optional(U&&);
    template<class U>
    explicit(see below) optional(optional<U>&&);
    template<class U>
    explicit(see below) optional(optional<U>&&&);
    // 20.6.3.3, destructor
    ~optional();
    // 20.6.3.4, assignment
    optional& operator=(nullopt_t) noexcept;
    constexpr optional& operator=(const optional&);
    constexpr optional& operator=(optional&&) noexcept(see below);
    template<class U = T> optional& operator=(U&&);
    template<class U> optional& operator=(const optional<U>&);
    template<class U> optional& operator=(optional<U>&&);
    template<class... Args> T& emplace(Args&&...);
    template<class U, class... Args> T& emplace(initializer_list<U>, Args&&...);
  }
}
Any instance of `optional<T>` at any given time either contains a value or does not contain a value. When an instance of `optional<T>` contains a value, it means that an object of type `T`, referred to as the optional object’s `contained value`, is allocated within the storage of the optional object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate its contained value. The contained value shall be allocated in a region of the `optional<T>` storage suitably aligned for the type `T`. When an object of type `optional<T>` is contextually converted to `bool`, the conversion returns `true` if the object contains a value; otherwise the conversion returns `false`.

Member `val` is provided for exposition only. When an `optional<T>` object contains a value, `val` points to the contained value.

`T` shall be a type other than `cv in_place_t` or `cv nullopt_t` that meets the `Cpp17Destructible` requirements (Table 34).

### 20.6.3.2 Constructors

```cpp
constexpr optional() noexcept;
constexpr optional(nullopt_t) noexcept;
```

**Postconditions:** `*this` does not contain a value.

**Remarks:** No contained value is initialized. For every object type `T` these constructors are constexpr constructors (9.2.6).

```cpp
constexpr optional(const optional& rhs);
```

**Effects:** If `rhs` contains a value, initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `*rhs`.

**Postconditions:** `bool(rhs) == bool(*this)`.

**Throws:** Any exception thrown by the selected constructor of `T`.

**Remarks:** This constructor is defined as deleted unless `is_copy_constructible_v<T>` is `true`. If `is_trivially_copy_constructible_v<T>` is `true`, this constructor is trivial.

```cpp
constexpr optional(optional&& rhs) noexcept(see below);
```

**Constraints:** `is_move_constructible_v<T>` is `true`. 

---

© ISO/IEC N4885

§ 20.6.3.2 585
Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object of type T with the expression std::move(*rhs). bool(rhs) is unchanged.

Postconditions: bool(rhs) == bool(*this).

Throws: Any exception thrown by the selected constructor of T.

Remarks: The exception specification is equivalent to is_nothrow_move_constructible_v<T>. If is_trivially_move_constructible_v<T> is true, this constructor is trivial.

template<class... Args> constexpr explicit optional(in_place_t, Args&&... args);

Constraints: is_constructible_v<T, Args...> is true.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the arguments std::forward<Args>(args)....

Postconditions: *this contains a value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If T’s constructor selected for the initialization is a constexpr constructor, this constructor is a constexpr constructor.

template<class U, class... Args>
constexpr explicit optional(in_place_t, initializer_list<U> il, Args&&... args);

Constraints: is_constructible_v<T, initializer_list<U>&, Args...> is true.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the arguments il, std::forward<Args>(args)....

Postconditions: *this contains a value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If T’s constructor selected for the initialization is a constexpr constructor, this constructor is a constexpr constructor.

template<class U = T> constexpr explicit(optional(U&& v);

Constraints:

(27.1) is_constructible_v<T, const U&> is true,
(27.2) is_constructible_v<T, optional<U>&> is false,
(27.3) is_constructible_v<T, optional<U>&&> is false,
(27.4) is_constructible_v<T, const optional<U>&> is false,
(27.5) is_constructible_v<T, const optional<U>&&> is false,
(27.6) is_convertible_v<optional<U>&, T> is false,
(27.7) is_convertible_v<optional<U>&&, T> is false,
(27.8) is_convertible_v<optional<U>&, T> is false, and
(27.9) is_convertible_v<optional<U>&& T> is false.

§ 20.6.3.2
Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object of type T with the expression *rhs.

Postconditions: bool(rhs) == bool(*this).

Throws: Any exception thrown by the selected constructor of T.

Remarks: The expression inside explicit is equivalent to:

\[ !\text{isConvertible}_v\text{<const }U&\text{, }T\] 

\[
\text{template<class }U\text{> explicit(see below) optional(optional< }U&\text{& }\text{rhs);}
\]

Constraints:

1. isConstructible_v<T, U> is true,
2. isConstructible_v<T, optional< U>>& is false,
3. isConstructible_v<T, optional< U>&& is false,
4. isConstructible_v<T, const optional< U>>& is false,
5. isConstructible_v<T, const optional< U>&& is false,
6. isConvertible_v<optional< U>&, T> is false,
7. isConvertible_v<optional< U>&& , T> is false,
8. isConvertible_v<const optional< U>&, T> is false, and
9. isConvertible_v<const optional< U>&& , T> is false.

Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object of type T with the expression std::move(*rhs); bool(rhs) is unchanged.

Postconditions: bool(rhs) == bool(*this).

Throws: Any exception thrown by the selected constructor of T.

Remarks: The expression inside explicit is equivalent to:

\[ !\text{isConvertible}_v\text{<const }U&\text{, }T\] 

### 20.6.3.3 Destructor

~optional();

Effects: If isTriviallyDestructible_v<T> != true and *this contains a value, calls val->T::~T();

Remarks: If isTriviallyDestructible_v<T> is true, then this destructor is trivial.

### 20.6.3.4 Assignment

optional<T>& operator=(nullopt_t) noexcept;

Effects: If *this contains a value, calls val->T::~T() to destroy the contained value; otherwise no effect.

Postconditions: *this does not contain a value.

Returns: *this.

constexpr optional<T>& operator=(const optional& rhs);

Effects: See Table 44.

Postconditions: bool(rhs) == bool(*this).

Returns: *this.

Remarks: If any exception is thrown, the result of the expression bool(*this) remains unchanged. If an exception is thrown during the call to T's copy constructor, no effect. If an exception is thrown during the call to T's copy assignment, the state of its contained value is as defined by the exception safety guarantee of T's copy assignment. This operator is defined as deleted unless isCopyConstructible_v<T> is true and isCopyAssignable_v<T> is true. If isTriviallyCopyConstructible_v<T> && isTriviallyCopyAssignable_v<T> && isTriviallyDestructible_v<T> is true, this assignment operator is trivial.
constexpr optional& operator=(optional&& rhs) noexcept(see below);

**Constraints:** is_move_constructible_v<T> is true and is_move_assignable_v<T> is true.

**Effects:** See Table 45. The result of the expression bool(rhs) remains unchanged.

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>assigns std::move(*rhs) to the contained value</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
</tr>
</tbody>
</table>

**Postconditions:** bool(rhs) == bool(*this).

**Returns:** *this.

**Remarks:** The exception specification is equivalent to:

```cpp
is_nothrow_move_assignable_v<T> && is_nothrow_move_constructible_v<T>
```

If any exception is thrown, the result of the expression bool(*this) remains unchanged. If an exception is thrown during the call to T’s move constructor, the state of *rhs.val is determined by the exception safety guarantee of T’s move constructor. If an exception is thrown during the call to T’s move assignment, the state of *val and *rhs.val is determined by the exception safety guarantee of T’s move assignment. If is_trivially_move_constructible_v<T> && is_trivially_move_assignable_v<T> && is_trivially_destructible_v<T> is true, this assignment operator is trivial.

```cpp
template<class U = T> optional<T>& operator=(U&& v);
```

**Constraints:**

1. is_same_v<remove_cvref_t<U>, optional> is false, conjunction_v<is_scalar<T>, is_same<T, decay_t<U>>> is false, is_constructible_v<T, U> is true, and is_assignable_v<T& , U> is true.

**Effects:** If *this contains a value, assigns std::forward<U>(v) to the contained value; otherwise initializes the contained value as if direct-non-list-initializing object of type T with std::forward<U>(v).

**Postconditions:** *this contains a value.

**Returns:** *this.

**Remarks:** If any exception is thrown, the result of the expression bool(*this) remains unchanged. If an exception is thrown during the call to T’s constructor, the state of v is determined by the exception safety guarantee of T’s constructor. If an exception is thrown during the call to T’s assignment, the state of *val and v is determined by the exception safety guarantee of T’s assignment.

```cpp
template<class U> optional<T>& operator=(const optional<U>& rhs);
```

**Constraints:**

1. is_constructible_v<T, const U&> is true,
— \texttt{is\_assignable\_v<T\&, \_U\&> is true},
— \texttt{is\_constructible\_v<T, \_optional<\_U\&&> is false},
— \texttt{is\_constructible\_v<T, \_optional<\_U\&> is false},
— \texttt{is\_constructible\_v<T, \_const \_optional<\_U\&> is false},
— \texttt{is\_constructible\_v<T, \_const \_optional<\_U\&&> is false},
— \texttt{is\_convertible\_v<\_optional<\_U\&, T> is false},
— \texttt{is\_convertible\_v<\_optional<\_U\&&>, T> is false},
— \texttt{is\_convertible\_v<\_const \_optional<\_U\&>, T> is false},
— \texttt{is\_convertible\_v<\_const \_optional<\_U\&&>, T> is false},
— \texttt{is\_assignable\_v<T\&, \_optional<\_U\&> is false},
— \texttt{is\_assignable\_v<T\&, \_optional<\_U\&&> is false},
— \texttt{is\_assignable\_v<T\&, \_const \_optional<\_U\&> is false}, and
— \texttt{is\_assignable\_v<T\&, \_const \_optional<\_U\&&> is false}.

\textbf{Effects:} See Table 46.

Table 46: \texttt{optional::operator=(const \_optional<\_U\&&> \_rhs)} effects

<table>
<thead>
<tr>
<th>_this contains a value</th>
<th>_this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>_rhs contains a value</td>
<td>assigns _rhs to the contained value initializes the contained value as if direct-non-list-initializing an object of type _T with _rhs</td>
</tr>
<tr>
<td>_rhs does not contain a value</td>
<td>destroys the contained value by calling _val-&gt;T::_T() no effect</td>
</tr>
</tbody>
</table>

\textbf{Postconditions:} bool(\_rhs) == bool(\_this).

\textbf{Returns:} \_this.

\textbf{Remarks:} If any exception is thrown, the result of the expression bool(\_this) remains unchanged. If an exception is thrown during the call to \_T's constructor, the state of \_rhs.val is determined by the exception safety guarantee of \_T's constructor. If an exception is thrown during the call to \_T's assignment, the state of \_val and \_rhs.val is determined by the exception safety guarantee of \_T's assignment.

\texttt{template<class \_U> \_optional<\_T\&> operator=(\_optional<\_U\&& \_rhs)};

\textbf{Constraints:}

(24.1) — \texttt{is\_constructible\_v<\_T, \_U> is true},
(24.2) — \texttt{is\_assignable\_v<\_T\&, \_U\&> is true},
(24.3) — \texttt{is\_constructible\_v<\_T, \_optional<\_U\&> is false},
(24.4) — \texttt{is\_constructible\_v<\_T, \_optional<\_U\&&> is false},
(24.5) — \texttt{is\_constructible\_v<\_T, \_const \_optional<\_U\&> is false},
(24.6) — \texttt{is\_constructible\_v<\_T, \_const \_optional<\_U\&&> is false},
(24.7) — \texttt{is\_convertible\_v<\_optional<\_U\&>, \_T> is false},
(24.8) — \texttt{is\_convertible\_v<\_optional<\_U\&&>, \_T> is false},
(24.9) — \texttt{is\_convertible\_v<\_const \_optional<\_U\&>, \_T> is false},
(24.10) — \texttt{is\_convertible\_v<\_const \_optional<\_U\&&>, \_T> is false},
(24.11) — \texttt{is\_assignable\_v<\_T\&, \_optional<\_U\&> is false},
(24.12) — \texttt{is\_assignable\_v<\_T\&, \_optional<\_U\&&> is false},
(24.13) — \texttt{is\_assignable\_v<\_T\&, \_const \_optional<\_U\&> is false}, and
¡ is_assignable_v<T&, const optional<U>&&> is false.

Effects: See Table 47. The result of the expression bool(rhs) remains unchanged.

Table 47: optional::operator=(optional<U>&&) effects

<table>
<thead>
<tr>
<th></th>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>assigns std::move(*rhs) to the contained value</td>
<td>initializes the contained value as if direct-non-list-initializing an object of type T with std::move(*rhs)</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
<td>no effect</td>
</tr>
</tbody>
</table>

Postconditions: bool(rhs) == bool(*this).

Returns: *this.

Remarks: If any exception is thrown, the result of the expression bool(*this) remains unchanged. If an exception is thrown during the call to T's constructor, the state of *rhs.val is determined by the exception safety guarantee of T's constructor. If an exception is thrown during the call to T's assignment, the state of *val and *rhs.val is determined by the exception safety guarantee of T's assignment.

template<class... Args> T& emplace(Args&&... args);

Mandates: is_constructible_v<T, Args...> is true.

Effects: Calls *this = nullopt. Then initializes the contained value as if direct-non-list-initializing an object of type T with the arguments std::forward<Args>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Remarks: If an exception is thrown during the selected constructor of T.

template<class U, class... Args> T& emplace(initializer_list<U> il, Args&&... args);

Constraints: is_constructible_v<T, initializer_list<U>&, Args...> is true.

Effects: Calls *this = nullopt. Then initializes the contained value as if direct-non-list-initializing an object of type T with the arguments il, std::forward<Arge>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Remarks: Any exception thrown by the selected constructor of T.

 Remarks: If an exception is thrown during the selected constructor of T.

20.6.3.5 Swap

void swap(optional& rhs) noexcept(see below);

Mandates: is_move_constructible_v<T> is true.

Preconditions: Lvalues of type T are swappable.

Effects: See Table 48.

Throws: Any exceptions thrown by the operations in the relevant part of Table 48.

Remarks: The exception specification is equivalent to:

\[ is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T> \]
If any exception is thrown, the results of the expressions `bool(*this)` and `bool(rhs)` remain unchanged. If an exception is thrown during the call to function `swap`, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of `swap` for lvalues of `T`. If an exception is thrown during the call to `T`'s move constructor, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of `T`'s move constructor.

### 20.6.3.6 Observers

```cpp
constexpr const T* operator->() const;
constexpr T* operator->();
```

**Preconditions:** `*this` contains a value.

**Returns:** `val`.

**Throws:** Nothing.

**Remarks:** These functions are constexpr functions.

```cpp
constexpr const T& operator*() const&;
constexpr T& operator*() &;
```

**Preconditions:** `*this` contains a value.

**Returns:** `*val`.

**Throws:** Nothing.

**Remarks:** These functions are constexpr functions.

```cpp
constexpr T&& operator*() &&;
constexpr const T&& operator*() const&&;
```

**Preconditions:** `*this` contains a value.

**Effects:** Equivalent to: return `std::move(*val)`;

**Remarks:** These functions are constexpr functions.

```cpp
constexpr explicit operator bool() const noexcept;
```

**Returns:** `true` if and only if `*this` contains a value.

**Remarks:** This function is a constexpr function.
constexpr bool has_value() const noexcept;

Returns: true if and only if *this contains a value.

Remarks: This function is a constexpr function.

constexpr const T& value() const&;
constexpr T& value() &;

Effects: Equivalent to:
    return bool(*this) ? *val : throw bad_optional_access();

constexpr T&& value() &&;
constexpr const T&& value() const&&;

Effects: Equivalent to:
    return bool(*this) ? std::move(*val) : throw bad_optional_access();

template<class U> constexpr T value_or(U&& v) const&;

Mandates: is_copy_constructible_v<T> && is_convertible_v<U&&, T> is true.

Effects: Equivalent to:
    return bool(*this) ? **this : static_cast<T>(std::forward<U>(v));

template<class U> constexpr T value_or(U&& v) &&;

Mandates: is_move_constructible_v<T> && is_convertible_v<U&&, T> is true.

Effects: Equivalent to:
    return bool(*this) ? std::move(**this) : static_cast<T>(std::forward<U>(v));

20.6.3.7 Modifiers

void reset() noexcept;

Effects: If *this contains a value, calls val->T::~T() to destroy the contained value; otherwise no effect.

Postconditions: *this does not contain a value.

20.6.4 No-value state indicator

struct nullopt_t{see below};
inline constexpr nullopt_t nullopt(unspecified);

The struct nullopt_t is an empty class type used as a unique type to indicate the state of not containing a value for optional objects. In particular, optional<T> has a constructor with nullopt_t as a single argument; this indicates that an optional object not containing a value shall be constructed.

Type nullopt_t shall not have a default constructor or an initializer-list constructor, and shall not be an aggregate.

20.6.5 Class bad_optional_access

class bad_optional_access : public exception {
    public:
        // see 17.9.3 for the specification of the special member functions
        const char* what() const noexcept override;
    };

The class bad_optional_access defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an optional object that does not contain a value.

const char* what() const noexcept override;

Returns: An implementation-defined NTBS.

20.6.6 Relational operators

template<class T, class U> constexpr bool operator==(const optional<T>& x, const optional<U>& y);

Mandates: The expression *x == *y is well-formed and its result is convertible to bool.
[Note 1: T need not be Cpp17EqualityComparable. — end note]

Returns: If bool(x) != bool(y), false; otherwise if bool(x) == false, true; otherwise *x == *y.

Remarks: Specializations of this function template for which *x == *y is a core constant expression are constexpr functions.

template<class T, class U> constexpr bool operator!=(const optional<T>& x, const optional<U>& y);

Mandates: The expression *x != *y is well-formed and its result is convertible to bool.

Returns: If bool(x) != bool(y), true; otherwise, if bool(x) == false, false; otherwise *x != *y.

Remarks: Specializations of this function template for which *x != *y is a core constant expression are constexpr functions.

template<class T, class U> constexpr bool operator<(const optional<T>& x, const optional<U>& y);

Mandates: *x < *y is well-formed and its result is convertible to bool.

Returns: If !y, false; otherwise, if !x, true; otherwise *x < *y.

Remarks: Specializations of this function template for which *x < *y is a core constant expression are constexpr functions.

template<class T, class U> constexpr bool operator>(const optional<T>& x, const optional<U>& y);

Mandates: The expression *x > *y is well-formed and its result is convertible to bool.

Returns: If !x, false; otherwise, if !y, true; otherwise *x > *y.

Remarks: Specializations of this function template for which *x > *y is a core constant expression are constexpr functions.

template<class T, class U> constexpr bool operator<=(const optional<T>& x, const optional<U>& y);

Mandates: The expression *x <= *y is well-formed and its result is convertible to bool.

Returns: If !x, true; otherwise, if !y, false; otherwise *x <= *y.

Remarks: Specializations of this function template for which *x <= *y is a core constant expression are constexpr functions.

template<class T, class U> constexpr bool operator>=(const optional<T>& x, const optional<U>& y);

Mandates: The expression *x >= *y is well-formed and its result is convertible to bool.

Returns: If !y, true; otherwise, if !x, false; otherwise *x >= *y.

Remarks: Specializations of this function template for which *x >= *y is a core constant expression are constexpr functions.

template<class T, three_way_comparable_with<T> U>
constexpr compare_three_way_result_t<T,U> operator<=>(const optional<T>& x, const optional<U>& y);

Mandates: The expression *x <=> *y is well-formed and its result is convertible to bool.

Returns: If x && y, *x <=> *y; otherwise bool(x) <=> bool(y).

Remarks: Specializations of this function template for which *x <=> *y is a core constant expression are constexpr functions.

20.6.7 Comparison with nullopt [optional.nullops]

template<class T> constexpr bool operator==(const optional<T>& x, nullopt_t) noexcept;

Returns: !x.

template<class T> constexpr strong_ordering operator<=>(const optional<T>& x, nullopt_t) noexcept;

Returns: bool(x) <=> false.

20.6.8 Comparison with T [optional.comp.with.t]

template<class T, class U> constexpr bool operator==(const optional<T>& x, const U& v);

Mandates: The expression *x == v is well-formed and its result is convertible to bool.
Effects: Equivalent to: return bool(x) ? *x == v : false;

template<class T, class U> constexpr bool operator==(const T& v, const optional<U>& x);
Mandates: The expression v == *x is well-formed and its result is convertible to bool.
Effects: Equivalent to: return bool(x) ? v == *x : false;

template<class T, class U> constexpr bool operator!=(const optional<T>& x, const U& v);
Mandates: The expression v != *x is well-formed and its result is convertible to bool.
Effects: Equivalent to: return bool(x) ? v != *x : true;

template<class T, class U> constexpr bool operator>(const optional<T>& x, const U& v);
Mandates: The expression v < *x is well-formed and its result is convertible to bool.
Effects: Equivalent to: return bool(x) ? v < *x : true;

template<class T, class U> constexpr bool operator<=>(const optional<T>& x, const U& v);
Mandates: The expression v <= *x is well-formed and its result is convertible to bool.
Effects: Equivalent to: return bool(x) ? v <= *x : false;
20.6.9 Specialized algorithms

```cpp
template<class T> void swap(optional<T>& x, optional<T>& y) noexcept(noexcept(x.swap(y)));
```

Constraints:
- `is_move_constructible_v<T>` is true
- `is_swappable_v<T>` is true.

```cpp
template<class T> constexpr optional<decay_t<T>> make_optional(T&& v);
```

Returns:
- `optional<decay_t<T>>(std::forward<T>(v))`.

```cpp
template<class T, class... Args>
constexpr optional<T> make_optional(Args&&... args);
```

Effects:
Equivalent to:
- `return optional<T>(in_place, std::forward<Args>(args)...);`

```cpp
template<class T, class U, class... Args>
constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);
```

Effects:
Equivalent to:
- `return optional<T>(in_place, il, std::forward<Args>(args)...);`

20.6.10 Hash support

```cpp
template<class T> struct hash<optional<T>>;
```

The specialization `hash<optional<T>>` is enabled if and only if `hash<remove_const_t<T>>` is enabled. When enabled, for an object `o` of type `optional<T>`, if `bool(o) == true`, then `hash<optional<T>>(o)` evaluates to the same value as `hash<remove_const_t<T>>(*(o));` otherwise it evaluates to an unspecified value. The member functions are not guaranteed to be noexcept.

20.7 Variants

20.7.1 In general

A variant object holds and manages the lifetime of a value. If the `variant` holds a value, that value's type has to be one of the template argument types given to `variant`. These template arguments are called alternatives.

20.7.2 Header `<variant>` synopsis

```cpp
#include <compare> // see 17.11.1
```

```cpp
namespace std {
  // 20.7.3, class template variant
  template<class... Types>
  class variant;
```

```cpp
  // 20.7.4, variant helper classes
  template<class T> struct variant_size;
  // not defined
  template<class T> struct variant_size<const T>;
  template<class T>
  inline constexpr size_t variant_size_v = variant_size<T>::value;
```

```cpp
  template<class... Types>
  struct variant_size<typename variant<Types...>::type>;
```

```cpp
  template<size_t I, class T> struct variant_alternative;
  // not defined
  template<size_t I, class T> struct variant_alternative<const T>;
  template<size_t I, class T>
  using variant_alternative_t = typename variant_alternative<I, T>::type;
```

```cpp
  template<size_t I, class... Types>
  struct variant_alternative<I, variant<Types...>>;
```

```cpp
  inline constexpr size_t variant_npos = -1;
```

```cpp
  // 20.7.5, value access
  constexpr bool holds_alternative(const variant<Types...>&) noexcept;
```
template<
    size_t I,
    class... Types>
    constexpr variant_alternative_t<I, variant<Types...>>&
        get(variant<Types...>&);

template<
    size_t I,
    class... Types>
    constexpr variant_alternative_t<I, variant<Types...>>&&
        get(variant<Types...>&&);

template<
    size_t I,
    class... Types>
    constexpr const variant_alternative_t<I, variant<Types...>>&
        get(const variant<Types...>&);

constexpr bool operator==(monostate, monostate) noexcept;
constexpr strong_ordering operator<=>(monostate, monostate) noexcept;
20.7.3 Class template variant

20.7.3.1 General

namespace std {
    template<class... Types>
    class variant {
        public:
            // 20.7.3.2, constructors
            constexpr variant() noexcept;
            constexpr variant(const variant&);
            constexpr variant(variant&&) noexcept;
            template<class T>
            constexpr variant(T&&) noexcept;
            template<class T, class... Args>
            constexpr explicit variant(in_place_type_t<T>, Args&&...);
            template<class T, class U, class... Args>
            constexpr explicit variant(in_place_type_t<T>, initializer_list<U>, Args&&...);
            template<size_t I, class... Args>
            constexpr explicit variant(in_place_index_t<I>, Args&&...);
            template<size_t I, class U, class... Args>
            constexpr explicit variant(in_place_index_t<I>, initializer_list<U>, Args&&...);
            // 20.7.3.3, destructor
            ~variant();
            // 20.7.3.4, assignment
            constexpr variant& operator=(const variant&);
            constexpr variant& operator=(variant&&) noexcept;
            template<class T>
            variant& operator=(T&&) noexcept;
            // 20.7.3.5, modifiers
            template<class T, class... Args>
            T& emplace(Args&&...);
            template<class T, class U, class... Args>
            T& emplace(initializer_list<U>, Args&&...);
            template<
                size_t I, class... Args>
            variant_alternative_t<I, variant<Types...>>& emplace(Args&&...);
            template<
                size_t I, class U, class... Args>
            variant_alternative_t<I, variant<Types...>>& emplace(initializer_list<U>, Args&&...);
            // 20.7.3.6, value status
            constexpr bool valueless_by_exception() const noexcept;
            constexpr size_t index() const noexcept;
            // 20.7.3.7, swap
            void swap(variant&) noexcept;
        }
    }
}

§ 20.7.3.1 597
Any instance of `variant` at any given time either holds a value of one of its alternative types or holds no value. When an instance of `variant` holds a value of alternative type $T$, it means that a value of type $T$, referred to as the `variant` object’s contained value, is allocated within the storage of the `variant` object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the contained value. The contained value shall be allocated in a region of the `variant` storage suitably aligned for all types in `Types`.

All types in `Types` shall meet the `Cpp17Destructible` requirements (Table 34).

A program that instantiates the definition of `variant` with no template arguments is ill-formed.

### 20.7.3.2 Constructors

In the descriptions that follow, let $i$ be in the range $[0, \text{sizeof}(\text{Types}))$, and $T_i$ be the $i^{\text{th}}$ type in `Types`.

```cpp
constexpr variant() noexcept(see below);  
Constraints: $\text{is_default_constructible_v}<T_0>$ is true.
Effects: Constructs a `variant` holding a value-initialized value of type $T_0$.
Postconditions: $\text{valueless_by_exception()}$ is false and $\text{index()}$ is 0.
Throws: Any exception thrown by the value-initialization of $T_0$.
Remarks: This function is constexpr if and only if the value-initialization of the alternative type $T_0$ would satisfy the requirements for a constexpr function. The exception specification is equivalent to $\text{is_nothrow_default_constructible_v}<T_0>$.
[Note 1: See also class `monostate`. — end note]
```

```cpp
constexpr variant(const variant& w);  
Effects: If $w$ holds a value, initializes the `variant` to hold the same alternative as $w$ and direct-initializes the contained value with $\text{get}<j>(w)$, where $j$ is $w$.index(). Otherwise, initializes the `variant` to not hold a value.
Throws: Any exception thrown by direct-initializing any $T_i$ for all $i$.
Remarks: This constructor is defined as deleted unless $\text{is_copy_constructible_v}<T_i>$ is true for all $i$. If $\text{is_trivially_copy_constructible_v}<T_i>$ is true for all $i$, this constructor is trivial.
```

```cpp
constexpr variant(variant&& w) noexcept(see below);  
Constraints: $\text{is_move_constructible_v}<T_i>$ is true for all $i$.
Effects: If $w$ holds a value, initializes the `variant` to hold the same alternative as $w$ and direct-initializes the contained value with $\text{get}<j>(\text{std::move}(w))$, where $j$ is $w$.index(). Otherwise, initializes the `variant` to not hold a value.
Throws: Any exception thrown by move-constructing any $T_i$ for all $i$.
Remarks: The exception specification is equivalent to the logical AND of $\text{is_nothrow_move_constructible_v}<T_i>$ for all $i$. If $\text{is_trivially_move_constructible_v}<T_i>$ is true for all $i$, this constructor is trivial.
```

```cpp
template<class T> constexpr variant(T&& t) noexcept(see below);  
Let $T_j$ be a type that is determined as follows: build an imaginary function $\text{FUN}(T_i)$ for each alternative type $T_i$ for which $T_i \times [ ] = \{\text{std::forward}<T>(t)\}$ is well-formed for some invented variable $x$. The overload $\text{FUN}(T_j)$ selected by overload resolution for the expression $\text{FUN}(\text{std::forward}<T>(t))$ defines the alternative $T_j$ which is the type of the contained value after construction.
Constraints:
(15.1) $\text{sizeof}(\ldots(\text{Types}))$ is nonzero,
(15.2) $\text{is_same_v}<\text{remove_cvref_t}<T>, \text{variant}>$ is false,
(15.3) $\text{remove_cvref_t}<T>$ is neither a specialization of `in_place_type_t` nor a specialization of `in_place_index_t`.
```
is_constructible_v<Tj, T> \text{ is true, and}

the expression \text{FUN(std::forward<T>(t))} (with \text{FUN} being the above-mentioned set of imaginary functions) is well-formed.

[Note 2: \text{variant<string, string> v("abc");}

is ill-formed, as both alternative types have an equally viable constructor for the argument. — end note]

Effects: Initializes \text{*this} to hold the alternative type Tj and direct-initializes the contained value as if direct-non-list-initializing it with \text{std::forward<T>(t)}.

Postconditions: \text{holds_alternative<Tj>(*this) is true}.

Throws: Any exception thrown by the initialization of the selected alternative Tj.

Remarks: The exception specification is equivalent to \text{is_nothrow_constructible_v<Tj, T>}. If Tj’s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

template<class T, class... Args> constexpr explicit variant(in_place_type_t<T>, Args&&... args);

Constraints:

— There is exactly one occurrence of T in \text{Types}... and

— \text{is_constructible_v<T, Args...> is true}.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the arguments \text{std::forward<Args>(args)}....

Postconditions: \text{holds_alternative<T>(*this) is true}.

Throws: Any exception thrown by calling the selected constructor of T.

Remarks: If T’s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

template<class T, class U, class... Args> constexpr explicit variant(in_place_type_t<T>, initializer_list<U> il, Args&&... args);

Constraints:

— There is exactly one occurrence of T in \text{Types}... and

— \text{is_constructible_v<T, initializer_list<U>&, Args...> is true}.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the arguments il, std::forward<Args>(args)....

Postconditions: \text{holds_alternative<T>(*this) is true}.

Throws: Any exception thrown by calling the selected constructor of T.

Remarks: If T’s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

template<size_t I, class... Args> constexpr explicit variant(in_place_index_t<I>, Args&&... args);

Constraints:

— I is less than \text{sizeof...(Types)} and

— \text{is_constructible_v<TI, Args...> is true}.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type TI with the arguments std::forward<Args>(args)....

Postconditions: \text{index() is I}.

Throws: Any exception thrown by calling the selected constructor of TI.

Remarks: If TI’s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

template<size_t I, class U, class... Args> constexpr explicit variant(in_place_index_t<I>, initializer_list<U> il, Args&&... args);
I is less than sizeof...(Types) and

is_constructible_v<T, initializer_list<U>&, Args...> is true.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the arguments il, std::forward<Args>(args)....

Postconditions: index() is I.

Remarks: If T's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

20.7.3.3 Destructor

-variant();

Effects: If valueless_by_exception() is false, destroys the currently contained value.

Remarks: If is_trivially_destructible_v<T> is true for all T, then this destructor is trivial.

20.7.3.4 Assignment

constexpr variant& operator=(const variant& rhs);

Let j be rhs.index().

Effects:

(2.1) If neither *this nor rhs holds a value, there is no effect.
(2.2) Otherwise, if *this holds a value but rhs does not, destroys the value contained in *this and sets *this to not hold a value.
(2.3) Otherwise, if index() == j, assigns the value contained in rhs to the value contained in *this.
(2.4) Otherwise, if either is_nothrow_copy_constructible_v<T> is true or is_nothrow_move_constructible_v<T> is false, equivalent to emplace<j>(get<j>(get<j>(rhs))).
(2.5) Otherwise, equivalent to operator=(variant(rhs)).

Postconditions: index() == rhs.index().

Returns: *this.

Remarks: This operator is defined as deleted unless is_copy_constructible_v<T> && is_copyAssignable_v<T> is true for all T, if is_trivially_copy_constructible_v<T> && is_trivially_copyAssignable_v<T> is true for all T, then this assignment operator is trivial.

constexpr variant& operator=(variant&& rhs) noexcept;

Let j be rhs.index().

Constraints: is_move_constructible_v<T> && is_moveAssignable_v<T> is true for all T.

Effects:

(8.1) If neither *this nor rhs holds a value, there is no effect.
(8.2) Otherwise, if *this holds a value but rhs does not, destroys the value contained in *this and sets *this to not hold a value.
(8.3) Otherwise, if index() == j, assigns get<j>(std::move(rhs)) to the value contained in *this.
(8.4) Otherwise, equivalent to emplace<j>(get<j>(std::move(rhs))).

Returns: *this.

Remarks: If is_trivially_move_constructible_v<T> && is_trivially_moveAssignable_v<T> && is_trivially_destructible_v<T> is true for all T, if is_trivially_move_constructible_v<T> && is_trivially_moveAssignable_v<T> is true for all T, then this assignment operator is trivial. The exception specification is equivalent to is_nothrow_move_constructible_v<T> && is_nothrow_moveAssignable_v<T> for all T.

(10.1) If an exception is thrown during the call to T's move construction (with j being rhs.index()), the variant will hold no value.
(10.2) If an exception is thrown during the call to T's move assignment, the state of the contained value is as defined by the exception safety guarantee of T's move assignment; index() will be j.
Let \( T_j \) be a type that is determined as follows: build an imaginary function \( \text{FUN}(T_i) \) for each alternative type \( T_i \) for which \( T_i \times\{\text{std::forward}<T>(t)\} \) is well-formed for some invented variable \( x \). The overload \( \text{FUN}(T_i) \) selected by overload resolution for the expression \( \text{FUN}(<\text{std::forward}<T>(t)) \) defines the alternative \( T_j \) which is the type of the contained value after assignment.

### Constraints:

1. \( \text{is_same_v<remove_cvref_t<T>, variant> is false} \),
2. \( \text{is_assignable_v<T_j, & T> & is_constructible_v<T_j, T> is true} \),
3. the expression \( \text{FUN(<std::forward<T>(t))} \) (with \( \text{FUN} \) being the above-mentioned set of imaginary functions) is well-formed.

[Note 1:

\[
\text{variant<\text{string, string}> v};
\]

\( v = "abc"; \)

is ill-formed, as both alternative types have an equally viable constructor for the argument. — end note]

### Effects:

1. If \(*\text{this} \) holds a \( T_j \), assigns \( \text{std::forward}<T>(t) \) to the value contained in \(*\text{this} \).
2. Otherwise, if \( \text{is_nothrow_constructible_v<T_j, T> || !is_nothrow_move_constructible_v<T_j, T> is true} \), equivalent to \( \text{emplace<}j(\text{std::forward<}T>(t)) \).
3. Otherwise, equivalent to \( \text{operator=}(<\text{variant<}\text{std::forward<}T>(t)) \).

### Postconditions:

\( \text{holds_alternative<T_j>(*this)} \) is true, with \( T_j \) selected by the imaginary function overload resolution described above.

### Returns:

\(*\text{this} \).

### Remarks:

The exception specification is equivalent to:

\( \text{is_nothrow_assignable_v<T_j, & T> & is_nothrow_constructible_v<T_j, T> is true} \),

1. If an exception is thrown during the assignment of \( \text{std::forward}<T>(t) \) to the value contained in \(*\text{this} \), the state of the contained value and \( t \) are as defined by the exception safety guarantee of the assignment expression; \( \text{valueless_by_exception()} \) will be \text{false}.
2. If an exception is thrown during the initialization of the contained value, the \text{variant} object is permitted to not hold a value.

### 20.7.3.5 Modifiers

#### template<class T, class... Args> T& emplace(Args&&... args);

1. **Constraints:** \( \text{is_constructible_v<T, Args...> is true} \), and \( T \) occurs exactly once in \( \text{Types} \).
2. **Effects:** Equivalent to:

   \[
   \text{return emplace<}I(\text{std::forward<}Args>(args)...);\]

   where \( I \) is the zero-based index of \( T \) in \( \text{Types} \).

#### template<class T, class U, class... Args> T& emplace(initializer_list<U> il, Args&&... args);

3. **Constraints:** \( \text{is_constructible_v<T, initializer_list<U>&, Args...> is true} \), and \( T \) occurs exactly once in \( \text{Types} \).
4. **Effects:** Equivalent to:

   \[
   \text{return emplace<}(\text{il, std::forward<}Args>(args)...);\]

   where \( I \) is the zero-based index of \( T \) in \( \text{Types} \).

#### template<size_t I, class... Args> variant_alternative_t<I, variant<Types...>>& emplace(Args&&... args);

5. **Mandates:** \( I < \text{sizeof...(Types)} \).
6. **Constraints:** \( \text{is_constructible_v<T, Args...> is true} \).
Effects: Destroys the currently contained value if `valueless_by_exception()` is false. Then initializes the contained value as if direct-non-list-initializing a value of type `T_i` with the arguments `std::forward<Args>(args)`.

Postconditions: `index()` is `I`.

Returns: A reference to the new contained value.

Throws: Any exception thrown during the initialization of the contained value.

Remarks: If an exception is thrown during the initialization of the contained value, the `variant` is permitted to not hold a value.

```
template<size_t I, class U, class... Args>
variant_alternative_t<I, variant<Types...>>& emplace(initializer_list<U> il, Args&&... args);
```

Mandates: `I < sizeof...(Types)`.

Constraints: `is_constructible_v<T_i, initializer_list<U>&, Args...>` is true.

Effects: Destroys the currently contained value if `valueless_by_exception()` is false. Then initializes the contained value as if direct-non-list-initializing a value of type `T_i` with the arguments `il, std::forward<Args>(args)`.

Postconditions: `index()` is `I`.

Returns: A reference to the new contained value.

Throws: Any exception thrown during the initialization of the contained value.

Remarks: If an exception is thrown during the initialization of the contained value, the `variant` is permitted to not hold a value.

20.7.3.6 Value status

```cpp
constexpr bool valueless_by_exception() const noexcept;
```

Effects: Returns `false` if and only if the `variant` holds a value.

[Note 1: It is possible for a `variant` to hold no value if an exception is thrown during a type-changing assignment or emplacement. The latter means that even a `variant<float, int>` can become `valueless_by_exception()`, for instance by
```cpp
struct S { operator int() { throw 42; }};
variant<float, int> v{12.f};
v.emplace<1>(S());
```
—end note]

```cpp
constexpr size_t index() const noexcept;
```

Effects: If `valueless_by_exception()` is `true`, returns `variant::npos`. Otherwise, returns the zero-based index of the alternative of the contained value.

20.7.3.7 Swap

```cpp
void swap(variant& rhs) noexcept(see below);
```

Mandates: `is_move_constructible_v<T_i>` is true for all `i`.

Preconditions: Lvalues of type `T_i` are swappable (16.4.4.3).

Effects:

(3.1) — If `valueless_by_exception() && rhs.valueless_by_exception()` no effect.

(3.2) — Otherwise, if `index() == rhs.index()`, calls `swap(get<index>(*this), get<index>(rhs))` where `i` is `index()`.

(3.3) — Otherwise, exchanges values of `rhs` and `*this`.

Throws: If `index() == rhs.index()`, any exception thrown by `swap(get<index>(*this), get<index>(rhs))` with `i` being `index()`. Otherwise, any exception thrown by the move constructor of `T_i` or `T_j` with `i` being `index()` and `j` being `rhs.index()`.

Remarks: If an exception is thrown during the call to function `swap(get<index>(*this), get<index>(rhs))`, the states of the contained values of `*this` and of `rhs` are determined by the exception safety guarantee
of swap for lvalues of T, with i being index(). If an exception is thrown during the exchange of the values of *this and rhs, the states of the values of *this and of rhs are determined by the exception safety guarantee of variant’s move constructor. The exception specification is equivalent to the logical AND of is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T> for all i.

20.7.4 variant helper classes

```cpp
template<class T> struct variant_size;
```  
1 All specializations of variant_size meet the Cpp17UnaryTypeTrait requirements (20.15.2) with a base characteristic of integral_constant<size_t, N> for some N.

```cpp
template<class T> struct variant_size<const T>;
```  
2 Let VS denote variant_size<T> of the cv-unqualified type T. Then each specialization of the template meets the Cpp17UnaryTypeTrait requirements (20.15.2) with a base characteristic of integral_constant<size_t, VS::value>.

```cpp
template<
    class... Types>
struct variant_size<variant<Types...>> :
    integral_constant<
        size_t, sizeof...(Types)> { };
```  
3 Let VA denote variant_alternative<I, T> of the cv-unqualified type T. Then each specialization of the template meets the Cpp17TransformationTrait requirements (20.15.2) with a member typedef type that names the type add_const_t<VA::type>.

```cpp
variant_alternative<I, variant<Types...>>::type
```  
4 Mandates: I < sizeof...(Types).

```cpp
Type: The type T_I.
```  
20.7.5 Value access

```cpp
template<class T, class... Types>
constexpr bool holds_alternative(const variant<Types...>& v) noexcept;
```  
1 Mandates: The type T occurs exactly once in Types.

```cpp
template<
    size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>>& get(variant<Types...>& v);
```  
2 Returns: true if index() is equal to the zero-based index of T in Types.

```cpp
template<
    size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>>&& get(variant<Types...>&& v);
```  
3 Mandates: I < sizeof...(Types).

```cpp
template<
    size_t I, class... Types>
constexpr const variant_alternative_t<I, variant<Types...>>& get(const variant<Types...>& v);
```  
4 Effects: If v.index() is I, returns a reference to the object stored in the variant. Otherwise, throws an exception of type bad_variant_access.

```cpp
template<
    size_t I, class... Types>
constexpr const variant_alternative_t<I, variant<Types...>>&& get(const variant<Types...>&& v);
```  
5 Mandates: The type T occurs exactly once in Types.

```cpp
template<class T, class... Types> constexpr T& get(variant<Types...>& v);
```  
6 Effects: If v holds a value of type T, returns a reference to that value. Otherwise, throws an exception of type bad_variant_access.

```cpp
template<class T, class... Types> constexpr T&& get(variant<Types...>&& v);
```  
7 Effects: If v holds a value of type T, returns a reference to that value. Otherwise, throws an exception of type bad_variant_access.

```cpp
template<
    size_t I, class... Types>
constexpr add_pointer_t<
    variant_alternative_t<I, variant<Types...>>>
    get_if(variant<Types...>* v) noexcept;
```
template<
size_t I, class... Types>
constexpr add_pointer_t<
const variant_alternative_t<I, variant<Types...>>>
get_if(const variant<Types...>& v) noexcept;

Mandates: I < sizeof...(Types).

Returns: A pointer to the value stored in the variant, if v != nullptr and v->index() == I.
Otherwise, returns nullptr.

template<class T, class... Types>
constexpr bool operator==(const variant<Types...>& v, const variant<Types...>& w);

Mandates: The type T occurs exactly once in Types.

Effects: Equivalent to: return get_if<i>(v); with i being the zero-based index of T in Types.

20.7.6 Relational operators

template<class... Types>
constexpr bool operator==(const variant<Types...>& v, const variant<Types...>& w);

Mandates: get<i>(v) == get<i>(w) is a valid expression that is convertible to bool, for all i.

Returns: If v.index() != w.index(), false; otherwise if v.valueless_by_exception(), true; otherwise get<i>(v) == get<i>(w) with i being v.index().

template<class... Types>
constexpr bool operator!=(const variant<Types...>& v, const variant<Types...>& w);

Mandates: get<i>(v) != get<i>(w) is a valid expression that is convertible to bool, for all i.

Returns: If v.index() != w.index(), true; otherwise if v.valueless_by_exception(), false; otherwise get<i>(v) != get<i>(w) with i being v.index().

template<class... Types>
constexpr bool operator<(const variant<Types...>& v, const variant<Types...>& w);

Mandates: get<i>(v) < get<i>(w) is a valid expression that is convertible to bool, for all i.

Returns: If v.valueless_by_exception(), false; otherwise if w.valueless_by_exception(), true; otherwise if v.index() < w.index(), true; otherwise if v.index() > w.index(), false; otherwise get<i>(v) < get<i>(w) with i being v.index().

template<class... Types>
constexpr bool operator>(const variant<Types...>& v, const variant<Types...>& w);

Mandates: get<i>(v) > get<i>(w) is a valid expression that is convertible to bool, for all i.

Returns: If v.valueless_by_exception(), false; otherwise if w.valueless_by_exception(), true; otherwise if v.index() > w.index(), true; otherwise if v.index() < w.index(), false; otherwise get<i>(v) > get<i>(w) with i being v.index().

template<class... Types>
constexpr bool operator<=(const variant<Types...>& v, const variant<Types...>& w);

Mandates: get<i>(v) <= get<i>(w) is a valid expression that is convertible to bool, for all i.

Returns: If v.valueless_by_exception(), true; otherwise if w.valueless_by_exception(), false; otherwise if v.index() < w.index(), true; otherwise if v.index() > w.index(), false; otherwise get<i>(v) <= get<i>(w) with i being v.index().

template<class... Types>
constexpr bool operator>=(const variant<Types...>& v, const variant<Types...>& w);

Mandates: get<i>(v) >= get<i>(w) is a valid expression that is convertible to bool, for all i.

Returns: If w.valueless_by_exception(), true; otherwise if v.valueless_by_exception(), false; otherwise if v.index() > w.index(), true; otherwise if v.index() < w.index(), false; otherwise get<i>(v) >= get<i>(w) with i being v.index().

§ 20.7.6 604
template<class... Types> requires (three_way_comparable<Types> && ...)
constexpr common_comparison_category_t<compare_three_way_result_t<Types>...>
operator<=>(const variant<Types...>& v, const variant<Types...>& w);

Effects: Equivalent to:

if (v.valueless_by_exception() && w.valueless_by_exception())
  return strong_ordering::equal;
if (v.valueless_by_exception()) return strong_ordering::less;
if (w.valueless_by_exception()) return strong_ordering::greater;
if (auto c = v.index() <=> w.index(); c != 0) return c;
return get<i>(v) <=> get<i>(w);

with i being v.index().

20.7.7 Visitation

template<class Visitor, class... Variants>
constexpr see below visit(Visitor&& vis, Variants&&... vars);
template<class R, class Visitor, class... Variants>
constexpr R visit(Visitor&& vis, Variants&&... vars);

Let as-variant denote the following exposition-only function templates:

```cpp
template<class... Ts>
auto& as-variant(variant<Ts...>& var) { return var; }
template<class... Ts>
auto& as-variant(const variant<Ts...>& var) { return var; }
template<class... Ts>
auto& as-variant(variant<Ts...>&& var) { return std::move(var); }
template<class... Ts>
auto& as-variant(const variant<Ts...>&& var) { return std::move(var); }```

Let n be sizeof...(Variants). For each 0 ≤ i < n, let V_i denote the type
declaytype(as-variant(std::forward<Variants>(vars[i]))).

Constraints: V_i is a valid type for all 0 ≤ i < n.

Let V denote the pack of types V_i.

Let m be a pack of n values of type size_t. Such a pack is valid if
0 ≤ m_i < variant_size_v<remove_reference_t<V_i>> for all 0 ≤ i < n. For each valid pack m, let
e(m) denote the expression:

```
INVOLVE(std::forward<Visitor>(vis), get<m>(std::forward<V>(vars))...) // see 20.14.4
```

for the first form and

```
INVOLVE<R>(std::forward<Visitor>(vis), get<m>(std::forward<V>(vars))...) // see 20.14.4
```

for the second form.

Mandates: For each valid pack m, e(m) is a valid expression. All such expressions are of the same type
and value category.

Returns: e(m), where m is the pack for which m_i is as-variant(vars_i).index() for all 0 ≤ i < n.
The return type is decltype(e(m)) for the first form.

Throws: bad_variant_access if (as-variant(vars).valueless_by_exception() || ...) is true.

Complexity: For n ≤ 1, the invocation of the callable object is implemented in constant time, i.e., for
n = 1, it does not depend on the number of alternative types of V_0. For n > 1, the invocation of the
callable object has no complexity requirements.

20.7.8 Class monostate

struct monostate{};

The class monostate can serve as a first alternative type for a variant to make the variant
type default constructible.

20.7.9 monostate relational operators

```cpp
constexpr bool operator==(const monostate, const monostate) noexcept { return true; }
```
constexpr strong_ordering operator<=>(monostate, monostate) noexcept
{ return strong_ordering::equal; }

[Note 1: monostate objects have only a single state; they thus always compare equal. — end note]

20.7.10 Specialized algorithms

template<class... Types>
void swap(variant<Types...>& v, variant<Types...>& w) noexcept;

Constraints: is_move_constructible_v<Ti> && is_swappable_v<Ti> is true for all i.

Effects: Equivalent to v.swap(w).

Remarks: The exception specification is equivalent to noexcept(v.swap(w)).

20.7.11 Class bad_variant_access

class bad_variant_access : public exception {
public:
   // see 17.9.3 for the specification of the special member functions
   const char* what() const noexcept override;
};

Objects of type bad_variant_access are thrown to report invalid accesses to the value of a variant object.

const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

20.7.12 Hash support

template<class... Types> struct hash<variant<Types...>>;

The specialization hash<variant<Types...>> is enabled (20.14.19) if and only if every specialization in hash<remove_const_t<Types>>... is enabled. The member functions are not guaranteed to be noexcept.

template<> struct hash<monostate>;

The specialization is enabled (20.14.19).

20.8 Storage for any type

20.8.1 General

Subclause 20.8 describes components that C++ programs may use to perform operations on objects of a discriminated type.

[Note 1: The discriminated type can contain values of different types but does not attempt conversion between them, i.e., 5 is held strictly as an int and is not implicitly convertible either to "5" or to 5.0. This indifference to interpretation but awareness of type effectively allows safe, generic containers of single values, with no scope for surprises from ambiguous conversions. — end note]

20.8.2 Header <any> synopsis

namespace std {
   // 20.8.3, class bad_any_cast
   class bad_any_cast;

   // 20.8.4, class any
   class any;

   // 20.8.5, non-member functions
   void swap(any& x, any& y) noexcept;

   template<class T, class... Args>
   any make_any(Args&&... args);

   template<class T, class U, class... Args>
   any make_any(initializer_list<U> il, Args&&... args);

§ 20.8.2 606
template<class T>
T any_cast(const any& operand);

template<class T>
T any_cast(any& operand);

template<class T>
T any_cast(any&& operand);

template<class T>
const T* any_cast(const any* operand) noexcept;

template<class T>
T* any_cast(any* operand) noexcept;

20.8.3 Class bad_any_cast

class bad_any_cast : public bad_cast {
public:
    // see 17.9.3 for the specification of the special member functions
    const char* what() const noexcept override;
};

1 Objects of type bad_any_cast are thrown by a failed any_cast (20.8.5).

const char* what() const noexcept override;

2 Returns: An implementation-defined ntbs.

20.8.4 Class any

20.8.4.1 General

namespace std {
class any {
public:
    // 20.8.4.2, construction and destruction
    constexpr any() noexcept;
    any(const any& other);
    any(any&& other) noexcept;
    template<class T>
    any(T&& value);
    template<class T, class... Args>
    explicit any(in_place_type_t<T>, Args&&...);
    template<class T, class U, class... Args>
    explicit any(in_place_type_t<T>, initializer_list<U>, Args&&...);
    ~any();

    // 20.8.4.3, assignments
    any& operator=(const any& rhs);
    any& operator=(any&& rhs) noexcept;
    template<class T>
    any& operator=(T&& rhs);

    // 20.8.4.4, modifiers
    template<class T, class... Args>
    decay_t<T>& emplace(Args&&...);
    template<class T, class U, class... Args>
    decay_t<T>& emplace(initializer_list<U>, Args&&...);
    void reset() noexcept;
    void swap(any& rhs) noexcept;

§ 20.8.4.1
An object of class `any` stores an instance of any type that meets the constructor requirements or it has no value, and this is referred to as the state of the class `any` object. The stored instance is called the contained value. Two states are equivalent if either they both have no value, or they both have a value and the contained values are equivalent.

The non-member `any_cast` functions provide type-safe access to the contained value.

Implementations should avoid the use of dynamically allocated memory for a small contained value. However, any such small-object optimization shall only be applied to types `T` for which `is_nothrow_move_constructible_v<T>` is true.

Example 1: A contained value of type `int` could be stored in an internal buffer, not in separately-allocated memory. —end example

20.8.4.2 Construction and destruction

```cpp
// 20.8.4.5, observers
bool has_value() const noexcept;
const type_info& type() const noexcept;
};
```

```cpp
An object of class `any` stores an instance of any type that meets the constructor requirements or it has no value, and this is referred to as the state of the class `any` object. The stored instance is called the contained value. Two states are equivalent if either they both have no value, or they both have a value and the contained values are equivalent.

The non-member `any_cast` functions provide type-safe access to the contained value.

Implementations should avoid the use of dynamically allocated memory for a small contained value. However, any such small-object optimization shall only be applied to types `T` for which `is_nothrow_move_constructible_v<T>` is true.

[Example 1: A contained value of type `int` could be stored in an internal buffer, not in separately-allocated memory. —end example]`
17 Constraints: is_copy_constructible_v<VT> is true and is_constructible_v<VT, initializer_list<U>&, Args...> is true.
18 Preconditions: VT meets the Cpp17CopyConstructible requirements.
19 Effects: Initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments il, std::forward<Args>(args)....
20 Postconditions: *this contains a value.
21 Throws: Any exception thrown by the selected constructor of VT.

~any();

20.8.4.3 Assignment

any& operator=(const any& rhs);
1 Effects: As if by any(rhs).swap(*this). No effects if an exception is thrown.
2 Returns: *this.
3 Throws: Any exceptions arising from the copy constructor for the contained value.

any& operator=(any&& rhs) noexcept;
4 Effects: As if by any(std::move(rhs)).swap(*this).
5 Postconditions: The state of *this is equivalent to the original state of rhs.
6 Returns: *this.

template<class T>
any& operator=(T& rhs);
7 Let VT be decay_t<T>.
8 Constraints: VT is not the same type as any and is_copy_constructible_v<VT> is true.
9 Preconditions: VT meets the Cpp17CopyConstructible requirements.
10 Effects: Constructs an object tmp of type any that contains an object of type VT direct-initialized with std::forward<T>(rhs), and tmp.swap(*this). No effects if an exception is thrown.
11 Returns: *this.
12 Throws: Any exception thrown by the selected constructor of VT.

20.8.4.4 Modifiers

template<class T, class... Args>
decay_t<T>& emplace(Args&&... args);
1 Let VT be decay_t<T>.
2 Constraints: is_copy_constructible_v<VT> is true and is_constructible_v<VT, Args...> is true.
3 Preconditions: VT meets the Cpp17CopyConstructible requirements.
4 Effects: Calls reset(). Then initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments std::forward<Arge>(args)....
5 Postconditions: *this contains a value.
6 Returns: A reference to the new contained value.
7 Throws: Any exception thrown by the selected constructor of VT.
8 Remarks: If an exception is thrown during the call to VT's constructor, *this does not contain a value, and any previously contained value has been destroyed.

template<class T, class U, class... Args>
decay_t<T>& emplace(initializer_list<U> il, Args&&... args);
9 Let VT be decay_t<T>.
Constraints: `is_copy_constructible_v<VT>` is true and `is_constructible_v<VT, initializer_list<U>&, Args...>` is true.

Preconditions: VT meets the `Cpp17CopyConstructible` requirements.

Effects: Calls `reset()`. Then initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments `il, std::forward<Args>(args)....`

Postconditions: `*this` contains a value.

Returns: A reference to the new contained value.

Remarks: Any exception thrown by the selected constructor of VT.

void reset() noexcept;

Effects: If `has_value()` is true, destroys the contained value.

Postconditions: `has_value()` is false.

void swap(any& rhs) noexcept;

Effects: Exchanges the states of `*this` and rhs.

20.8.4.5 Observers

bool has_value() const noexcept;

Returns: true if `*this` contains an object, otherwise false.

const type_info& type() const noexcept;

Returns: `typeid(T)` if `*this` has a contained value of type T, otherwise `typeid(void)`.

[Note 1: Useful for querying against types known either at compile time or only at runtime. — end note]

20.8.5 Non-member functions

void swap(any& x, any& y) noexcept;

Effects: Equivalent to `x.swap(y).

template<class T, class... Args>
any make_any(Args&&... args);

Effects: Equivalent to: return any(in_place_type<T>, std::forward<Args>(args)...);

template<class T, class U, class... Args>
any make_any(initializer_list<U> il, Args&&... args);

Effects: Equivalent to: return any(in_place_type<T>, il, std::forward<Args>(args)...);

template<class T>
T any_cast(const any& operand);

template<class T>
T any_cast(any& operand);

template<class T>
T any_cast(any&& operand);

Let U be the type `remove_cvref_t<T>`.

Mandates: For the first overload, `is_constructible_v<T, const U&>` is true. For the second overload, `is_constructible_v<T, U&>` is true. For the third overload, `is_constructible_v<T, U>` is true.

Returns: For the first and second overload, `static_cast<T>(*any_cast<U>(koperand))`. For the third overload, `static_cast<T>(std::move(*any_cast<U>(koperand)))`.

Throws: bad_any_cast if `operand.type()` != `typeid(remove_reference_t<T>)`.

[Example 1]:

any x(5);
assert(any_cast<int>(x) == 5); // x holds int
any_cast<int&>(x) = 10; // cast to value

assert(any_cast<int>(x) == 10);

x = "Meow";  // x holds const char*
assert(strcmp(any_cast<const char*>(x), "Meow") == 0);
any_cast<const char*>(x) = "Harry";
assert(strcmp(any_cast<const char*>(x), "Harry") == 0);

x = string("Meow");  // x holds string
string s, s2("Jane");
s = move(any_cast<string&>(x));  // move from any
assert(s == "Meow");
any_cast<string&>(x) = move(s2);  // move to any
assert(any_cast<const string&>(x) == "Jane");

string cat("Meow");
const any y(cat);  // const y holds string
assert(any_cast<const string&>(y) == cat);

any_cast<string&>(y);  // error: cannot any_cast away const
— end example[

template<class T>
const T* any_cast(const any* operand) noexcept;
template<class T>
T* any_cast(any* operand) noexcept;

Returns: If operand != nullptr && operand->type() == typeid(T), a pointer to the object contained by operand; otherwise, nullptr.

[Example 2:
bool is_string(const any& operand) {
    return any_cast<string&>(operand) != nullptr;
}
— end example]

20.9 Bitsets
[bitset]

20.9.1 Header <bitset> synopsis
[bitset.syn]
The header <bitset> defines a class template and several related functions for representing and manipulating fixed-size sequences of bits.

#include <string>
#include <iosfwd>  // for istream (29.7.1), ostream (29.7.2), see 29.3.1

namespace std {
    template<size_t N> class bitset;

    // 20.9.4, bitset operators
    template<size_t N>
    bitset<N> operator&(const bitset<N>&, const bitset<N>&) noexcept;
template<size_t N>
    bitset<N> operator|(const bitset<N>&, const bitset<N>&) noexcept;
template<size_t N>
    bitset<N> operator^(const bitset<N>&, const bitset<N>&) noexcept;
template<class charT, class traits, size_t N>
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
template<class charT, class traits, size_t N>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
}
20.9.2 Class template `bitset`

20.9.2.1 General

```cpp
namespace std {
    template<size_t N> class bitset {
        public:
            // bit reference
            class reference {
                friend class bitset;
                reference() noexcept;
                reference(const reference&) = default;
                ~reference();
                reference& operator=(bool x) noexcept;
                reference& operator=(const reference&) noexcept;
                bool operator~() const noexcept;
                operator bool() const noexcept;
                reference& flip() noexcept;
            };
            // 20.9.2.2, constructors
            constexpr bitset() noexcept;
            constexpr bitset(unsigned long long val) noexcept;
            template<class charT, class traits, class Allocator>
            explicit bitset(
                const basic_string<charT, traits, Allocator>& str,
                typename basic_string<charT, traits, Allocator>::size_type pos = 0,
                typename basic_string<charT, traits, Allocator>::size_type n = basic_string<charT, traits, Allocator>::npos,
                charT zero = charT('0'),
                charT one = charT('1'));
            template<class charT>
            explicit bitset(
                const charT* str,
                typename basic_string<charT>::size_type n = basic_string<charT>::npos,
                charT zero = charT('0'),
                charT one = charT('1'));
            // 20.9.2.3, bitset operations
            bitset<N>& operator&=(const bitset<N>& rhs) noexcept;
            bitset<N>& operator|=(const bitset<N>& rhs) noexcept;
            bitset<N>& operator^=(const bitset<N>& rhs) noexcept;
            bitset<N>& operator<<=(size_t pos) noexcept;
            bitset<N>& operator>>=(size_t pos) noexcept;
            bitset<N>& set() noexcept;
            bitset<N>& set(size_t pos, bool val = true);
            bitset<N>& reset() noexcept;
            bitset<N> operator~() const noexcept;
            bitset<N>& flip() noexcept;
            // element access
            constexpr bool operator[](size_t pos) const; // for b[i];
            reference operator[](size_t pos) const; // for b[i];
            unsigned long to_ulong() const;
            unsigned long long to_ullong() const;
            template<class charT = char,
                     class traits = char_traits<charT>,
                     class Allocator = allocator<charT>>
            basic_string<charT, traits, Allocator>
            to_string(charT zero = charT('0'), charT one = charT('1')) const;
    };
```
size_t count() const noexcept;
constexpr size_t size() const noexcept;
bool operator==(const bitset<N>& rhs) const noexcept;
bool test(size_t pos) const;
bool all() const noexcept;
bool none() const noexcept;
bitset<N> operator<<(size_t pos) const noexcept;
bitset<N> operator>>(size_t pos) const noexcept;
};

// 20.9.3, hash support
template<class T> struct hash;
template<size_t N> struct hash<bitset<N>>;

The class template bitset<N> describes an object that can store a sequence consisting of a fixed number of bits, N.

Each bit represents either the value zero (reset) or one (set). To toggle a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position pos. When converting between an object of class bitset<N> and a value of some integral type, bit position pos corresponds to the bit value 1 << pos. The integral value corresponding to two or more bits is the sum of their bit values.

The functions described in 20.9.2 can report three kinds of errors, each associated with a distinct exception:

— an invalid_argument error is associated with exceptions of type invalid_argument (19.2.5);
— an out-of-range error is associated with exceptions of type out_of_range (19.2.7);
— an overflow error is associated with exceptions of type overflow_error (19.2.10).

20.9.2.2 Constructors

```cpp
constexpr bitset() noexcept;
Effects: Initializes all bits in *this to zero.
```n
```cpp
constexpr bitset(unsigned long long val) noexcept;
Effects: Initializes the first M bit positions to the corresponding bit values in val. M is the smaller of N and the number of bits in the value representation (6.8) of unsigned long long. If M < N, the remaining bit positions are initialized to zero.
```n
```cpp
template<class charT, class traits, class Allocator>
explicit bitset(
    const basic_string<charT, traits, Allocator>& str,
    typename basic_string<charT, traits, Allocator>::size_type pos = 0,
    typename basic_string<charT, traits, Allocator>::size_type n = basic_string<charT, traits, Allocator>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
Effects: Determines the effective length rlen of the initializing string as the smaller of n and str.size() - pos. Initializes the first M bit positions to values determined from the corresponding characters in the string str. M is the smaller of N and rlen.
An element of the constructed object has value zero if the corresponding character in str, beginning at position pos, is zero. Otherwise, the element has the value one. Character position pos + M - 1 corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions.
If M < N, remaining bit positions are initialized to zero.
The function uses traits::eq to compare the character values.
```n
Throws: out_of_range if pos > str.size() or invalid_argument if any of the rlen characters in str beginning at position pos is other than zero or one.
template<class charT>
explicit bitset(
    const charT* str,
    typename basic_string<charT>::size_type n = basic_string<charT>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));

Effects: As if by:

bitset(n == basic_string<charT>::npos
    ? basic_string<charT>(str)
    : basic_string<charT>(str, n),
0, n, zero, one)

20.9.2.3 Members

bitset<N>& operator&(const bitset<N>& rhs) noexcept;

Effects: Clears each bit in *this for which the corresponding bit in rhs is clear, and leaves all other bits unchanged.
Returns: *this.

bitset<N>& operator|(const bitset<N>& rhs) noexcept;

Effects: Sets each bit in *this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.
Returns: *this.

bitset<N>& operator^(const bitset<N>& rhs) noexcept;

Effects: Toggles each bit in *this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.
Returns: *this.

bitset<N>& operator<<=(size_t pos) noexcept;

Effects: Replaces each bit at position I in *this with a value determined as follows:

— If I < pos, the new value is zero;
— If I >= pos, the new value is the previous value of the bit at position I - pos.
Returns: *this.

bitset<N>& operator>>=(size_t pos) noexcept;

Effects: Replaces each bit at position I in *this with a value determined as follows:

— If pos >= N - I, the new value is zero;
— If pos < N - I, the new value is the previous value of the bit at position I + pos.
Returns: *this.

bitset<N>& set() noexcept;

Effects: Sets all bits in *this.
Returns: *this.

bitset<N>& set(size_t pos, bool val = true);

Effects: Stores a new value in the bit at position pos in *this. If val is true, the stored value is one, otherwise it is zero.
Returns: *this.
Throws: out_of_range if pos does not correspond to a valid bit position.

bitset<N>& reset() noexcept;

Effects: Resets all bits in *this.
Returns: *this.
bitset<N>& reset(size_t pos);

    Effects: Resets the bit at position pos in *this.
    Returns: *this.
    Throws: out_of_range if pos does not correspond to a valid bit position.

bitset<N> operator~() const noexcept;

    Effects: Constructs an object x of class bitset<N> and initializes it with *this.
    Returns: x.flip().

bitset<N>& flip() noexcept;

    Effects: Toggles all bits in *this.
    Returns: *this.

bitset<N>& flip(size_t pos);

    Effects: Toggles the bit at position pos in *this.
    Returns: *this.
    Throws: out_of_range if pos does not correspond to a valid bit position.

unsigned long to_ulong() const;

    Returns: x.
    Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented as type unsigned long.

unsigned long long to_ullong() const;

    Returns: x.
    Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented as type unsigned long long.

template<class charT = char,
    class traits = char_traits<charT>,
    class Allocator = allocator<charT>>
basic_string<charT, traits, Allocator> to_string(charT zero = charT('0'), charT one = charT('1')) const;

    Effects: Constructs a string object of the appropriate type and initializes it to a string of length N characters. Each character is determined by the value of its corresponding bit position in *this. Character position N - 1 corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions. Bit value zero becomes the character zero, bit value one becomes the character one.
    Returns: The created object.

size_t count() const noexcept;

    Returns: A count of the number of bits set in *this.

constexpr size_t size() const noexcept;

    Returns: N.

bool operator==(const bitset<N>& rhs) const noexcept;

    Returns: true if the value of each bit in *this equals the value of the corresponding bit in rhs.

bool test(size_t pos) const;

    Returns: true if the bit at position pos in *this has the value one.
    Throws: out_of_range if pos does not correspond to a valid bit position.

bool all() const noexcept;

    Returns: count() == size().
bool any() const noexcept;
   Returns: count() != 0.

bool none() const noexcept;
   Returns: count() == 0.

bitset<N> operator<<(size_t pos) const noexcept;
   Returns: bitset<N>(*this) <<= pos.

bitset<N> operator>>(size_t pos) const noexcept;
   Returns: bitset<N>(*this) >>= pos.

constexpr bool operator[](size_t pos) const;
   Preconditions: pos is valid.
   Returns: true if the bit at position pos in *this has the value one, otherwise false.
   Throws: Nothing.

bitset<N>::reference operator[](size_t pos);
   Preconditions: pos is valid.
   Returns: An object of type bitset<N>::reference such that (*this)[pos] == this->test(pos),
   and such that (*this)[pos] = val is equivalent to this->set(pos, val).
   Throws: Nothing.

Remarks: For the purpose of determining the presence of a data race (6.9.2), any access or update
through the resulting reference potentially accesses or modifies, respectively, the entire underlying
bitset.

20.9.3 bitset hash support

[bitset.hash]

template<size_t N> struct hash<bitset<N>>;
   The specialization is enabled (20.14.19).

20.9.4 bitset operators

[bitset.operators]

bitset<N> operator&(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
   Returns: bitset<N>(lhs) &= rhs.

bitset<N> operator|(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
   Returns: bitset<N>(lhs) |= rhs.

bitset<N> operator^(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
   Returns: bitset<N>(lhs) ^= rhs.

template<class charT, class traits, size_t N>
   basic_istream<charT, traits>&
   operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
   A formatted input function (29.7.4.3).

Effects: Extracts up to N characters from is. Stores these characters in a temporary object str of type
basic_string<charT, traits>, then evaluates the expression x = bitset<N>(str). Characters are
extracted and stored until any of the following occurs:
   (5.1) — N characters have been extracted and stored;
   (5.2) — end-of-file occurs on the input sequence;
   (5.3) — the next input character is neither is.widen(‘0’) nor is.widen(‘1’) (in which case the input
character is not extracted).
If N > 0 and no characters are stored in str, calls is.setstate(ios_base::failbit) (which may throw ios_base::failure (29.5.5.4)).

Returns: is.

template<class charT, class traits, size_t N>
 basic_ostream<charT, traits>&
 operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);

Returns:
 os << x.template to_string<charT, traits, allocator<charT>>(
       use_facet<ctype<charT>>(os.getloc()).widen('0'),
       use_facet<ctype<charT>>(os.getloc()).widen('1'))
(see 29.7.5.3).

20.10 Memory

20.10.1 In general

Subclause 20.10 describes the contents of the header <memory> (20.10.2) and some of the contents of the header <cstdlib> (17.2.2).

20.10.2 Header <memory> synopsis

The header <memory> defines several types and function templates that describe properties of pointers and pointer-like types, manage memory for containers and other template types, destroy objects, and construct objects in uninitialized memory buffers (20.10.3–20.10.11 and 25.11). The header also defines the templates unique_ptr, shared_ptr, weak_ptr, and various function templates that operate on objects of these types (20.11).

#include <compare>           // see 17.11.1

namespace std {
   // 20.10.3, pointer traits
   template<class Ptr> struct pointer_traits;
   template<class T> struct pointer_traits<T*>;

   // 20.10.4, pointer conversion
   template<class T>
      constexpr T* to_address(T* p) noexcept;
   template<class Ptr>
      constexpr auto to_address(const Ptr& p) noexcept;

   // 20.10.5, pointer safety
   enum class pointer_safety { relaxed, preferred, strict };  
   void declare_reachable(void* p);
   template<class T>
      T* undeclare_reachable(T* p);
   void declare_no_pointers(char* p, size_t n);
   void undeclare_no_pointers(char* p, size_t n);
   pointer_safety get_pointer_safety() noexcept;

   // 20.10.6, pointer alignment
   void* align(size_t alignment, size_t size, void*& ptr, size_t& space);
   template<size_t N, class T>
      [[nodiscard]] constexpr T* assume_aligned(T* ptr);

   // 20.10.7, allocator argument tag
   struct allocator_arg_t { explicit allocator_arg_t() = default; };  
   inline constexpr allocator_arg_t allocator_arg{};

   // 20.10.8, uses_allocator
   template<class T, class Alloc> struct uses_allocator;
// 20.10.8.1, uses_allocator

}
template<class U> using rebind = U*;

static constexpr pointer pointer_to(see below r) noexcept;
}

20.10.3.2 Member types

using element_type = see below;
1
Type: Ptr::element_type if the qualified-id Ptr::element_type is valid and denotes a type (13.10.3); otherwise, T if Ptr is a class template instantiation of the form SomePointer<T, Args>, where Args is zero or more type arguments; otherwise, the specialization is ill-formed.

using difference_type = see below;
2
Type: Ptr::difference_type if the qualified-id Ptr::difference_type is valid and denotes a type (13.10.3); otherwise, ptrdiff_t.

template<class U> using rebind = see below;
3
Alias template: Ptr::rebind<U> if the qualified-id Ptr::rebind<U> is valid and denotes a type (13.10.3); otherwise, SomePointer<U, Args> if Ptr is a class template instantiation of the form SomePointer<T, Args>, where Args is zero or more type arguments; otherwise, the instantiation of rebind is ill-formed.

20.10.3.3 Member functions

static pointer pointer_traits::pointer_to(see below r);
static constexpr pointer pointer_traits<T*>::pointer_to(see below r) noexcept;
1
Mandates: For the first member function, Ptr::pointer_to(r) is well-formed.
2
Preconditions: For the first member function, Ptr::pointer_to(r) returns a pointer to r through which indirection is valid.
3
Returns: The first member function returns Ptr::pointer_to(r). The second member function returns addressof(r).
4
Remarks: If element_type is cv void, the type of r is unspecified; otherwise, it is element_type&.

20.10.3.4 Optional members

Specializations of pointer_traits may define the member declared in this subclause to customize the behavior of the standard library.

static element_type* to_address(pointer p) noexcept;
1
Returns: A pointer of type element_type* that references the same location as the argument p.
2
[Note 1: This function is intended to be the inverse of pointer_to. If defined, it customizes the behavior of the non-member function to_address (20.10.4). — end note]

20.10.4 Pointer conversion

template<class T> constexpr T* to_address(T* p) noexcept;
1
Mandates: T is not a function type.
2
Returns: p.

template<class Ptr> constexpr auto to_address(const Ptr& p) noexcept;
3
Returns: pointer_traits<Ptr>::to_address(p) if that expression is well-formed (see 20.10.3.4), otherwise to_address(p.operator->()).

20.10.5 Pointer safety

A complete object is declared reachable while the number of calls to declare_reachable with an argument referencing the object exceeds the number of calls to undeclare_reachable with an argument referencing the object.
void declare_reachable(void* p);

Preconditions: p is a safely-derived pointer (6.7.5.5.4) or a null pointer value.

Effects: If p is not null, the complete object referenced by p is subsequently declared reachable (6.7.5.5.4).

Throws: May throw bad_alloc if the system cannot allocate additional memory that may be required to track objects declared reachable.

template<class T> T* undeclare_reachable(T* p);

Preconditions: If p is not null, the complete object referenced by p has been previously declared reachable, and is live (6.7.3) from the time of the call until the last undeclare_reachable(p) call on the object.

Returns: A safely derived copy of p which compares equal to p.

Throws: Nothing.

[Note 1: It is expected that calls to declare_reachable(p) consume a small amount of memory in addition to that occupied by the referenced object until the matching call to undeclare_reachable(p) is encountered. Thus, long-running programs where calls are not matched can exhibit a memory leak. —end note]

void declare_no_pointers(char* p, size_t n);

Preconditions: No bytes in the specified range are currently registered with declare_no_pointers(). If the specified range is in an allocated object, then it is entirely within a single allocated object. The object is live until the corresponding undeclare_no_pointers() call.

[Note 2: In a garbage-collecting implementation, the fact that a region in an object is registered with declare_no_pointers() does not prevent the object from being collected. —end note]

Effects: The n bytes starting at p no longer contain traceable pointer locations, independent of their type. Hence indirection through a pointer located there is undefined if the object it points to was created by global operator new and not previously declared reachable.

[Note 3: This can be used to inform a garbage collector or leak detector that this region of memory need not be traced. —end note]

Throws: Nothing.

[Note 4: The request can be ignored if a memory allocation needed by the implementation fails. —end note]

void undeclare_no_pointers(char* p, size_t n);

Preconditions: The same range has previously been passed to declare_no_pointers().

Effects: Unregisters a range registered with declare_no_pointers() for destruction. It shall be called before the lifetime of the object ends.

Throws: Nothing.

pointer_safety get_pointer_safety() noexcept;

Returns: pointer_safety::strict if the implementation has strict pointer safety (6.7.5.5.4). It is implementation-defined whether get_pointer_safety returns pointer_safety::relaxed or pointer_safety::preferred if the implementation has relaxed pointer safety.\[214\]

[ptr.align]

20.10.6 Pointer alignment

void* align(size_t alignment, size_t size, void*& ptr, size_t& space);

Preconditions:

(1.1) alignment is a power of two

(1.2) ptr represents the address of contiguous storage of at least space bytes

Effects: If it is possible to fit size bytes of storage aligned by alignment into the buffer pointed to by ptr with length space, the function updates ptr to represent the first possible address of such storage and decreases space by the number of bytes used for alignment. Otherwise, the function does nothing.

\[214\] pointer_safety::preferred can be returned to indicate that a leak detector is running so that the program can avoid spurious leak reports.
3 Returns: A null pointer if the requested aligned buffer would not fit into the available space, otherwise the adjusted value of ptr.

4 [Note 1: The function updates its ptr and space arguments so that it can be called repeatedly with possibly different alignment and size arguments for the same buffer. — end note]

```
template<size_t N, class T> [[nodiscard]] constexpr T* assume_aligned(T* ptr);
```

5 Mandates: N is a power of two.

6 Preconditions: ptr points to an object X of a type similar (7.3.6) to T, where X has alignment N (6.7.6).

7 Returns: ptr.

8 Throws: Nothing.

9 [Note 2: The alignment assumption on an object X expressed by a call to assume_aligned might result in generation of more efficient code. It is up to the program to ensure that the assumption actually holds. The call does not cause the compiler to verify or enforce this. An implementation might only make the assumption for those operations on X that access X through the pointer returned by assume_aligned. — end note]

20.10.7 Allocator argument tag

```
namespace std {
  struct allocator_arg_t {
    explicit allocator_arg_t() = default;
  }
  inline constexpr allocator_arg_t allocator_arg{};
}
```

1 The allocator_arg_t struct is an empty class type used as a unique type to disambiguate constructor and function overloading. Specifically, several types (see tuple 20.5) have constructors with allocator_arg_t as the first argument, immediately followed by an argument of a type that meets the Cpp17Allocator requirements (Table 38).

20.10.8 uses_allocator

20.10.8.1 uses_allocator trait

```
template<class T, class Alloc> struct uses_allocator;
```

1 Remarks: Automatically detects whether T has a nested allocator_type that is convertible from Alloc. Meets the Cpp17BinaryTypeTrait requirements (20.15.2). The implementation shall provide a definition that is derived from true_type if the qualified-id T::allocator_type is valid and denotes a type (13.10.3) and is_convertible_v<Alloc, T::allocator_type> != false, otherwise it shall be derived from false_type. A program may specialize this template to derive from true_type for a program-defined type T that does not have a nested allocator_type but nonetheless can be constructed with an allocator where either:

1. (1.1) — the first argument of a constructor has type allocator_arg_t and the second argument has type Alloc or
2. (1.2) — the last argument of a constructor has type Alloc.

20.10.8.2 Uses-allocator construction

```
uses_allocator_construction_args
```

1 Uses-allocator construction with allocator alloc and constructor arguments args... refers to the construction of an object of type T such that alloc is passed to the constructor of T if T uses an allocator type compatible with alloc. When applied to the construction of an object of type T, it is equivalent to initializing it with the value of the expression make_obj_using_allocator<T>(alloc, args...), described below.

2 The following utility functions support three conventions for passing alloc to a constructor:

1. (2.1) — If T does not use an allocator compatible with alloc, then alloc is ignored.
2. (2.2) — Otherwise, if T has a constructor invocable as T(allocator_arg, alloc, args...) (leading-allocator convention), then uses-allocator construction chooses this constructor form.
3. (2.3) — Otherwise, if T has a constructor invocable as T(args..., alloc) (trailing-allocator convention), then uses-allocator construction chooses this constructor form.

3 The uses_allocator_construction_args function template takes an allocator and argument list and produces (as a tuple) a new argument list matching one of the above conventions. Additionally, overloads are
provided that treat specializations of \texttt{pair} such that uses_allocator construction is applied individually to the first and second data members. The \texttt{make\_obj\_using\_allocator} and \texttt{uninitialized\_construct\_using\_allocator} function templates apply the modified constructor arguments to construct an object of type \texttt{T} as a return value or in-place, respectively.

\textbf{Note 1}: For \texttt{uses\_allocator\_construction\_args} and \texttt{make\_obj\_using\_allocator}, type \texttt{T} is not deduced and must therefore be specified explicitly by the caller. —end note

\begin{verbatim}
template<class T, class Alloc, class... Args>
constexpr auto uses_allocator_construction_args(const Alloc& alloc, Args&&... args) noexcept -> see below;

Constraints: \texttt{T} is not a specialization of \texttt{pair}.

Returns: A tuple value determined as follows:

(5.1) If \texttt{uses\_allocator\_v<T, Alloc>} is false and \texttt{is\_constructible\_v<T, Args...>} is true, return \texttt{forward\_as\_tuple(std::forward<Args>(args)...)}.

(5.2) Otherwise, if \texttt{uses\_allocator\_v<T, Alloc>} is true and \texttt{is\_constructible\_v<T, allocator\_arg\_t, const Alloc&, Args...>} is true, return \texttt{tuple<allocator\_arg\_t, const Alloc&, Args&&...>(allocator\_arg, alloc, std::forward<Args>(args)...)}.

(5.3) Otherwise, if \texttt{uses\_allocator\_v<T, Alloc>} is true and \texttt{is\_constructible\_v<T, Args..., const Alloc&>} is true, return \texttt{forward\_as\_tuple(std::forward<Args>(args)..., alloc)}.

(5.4) Otherwise, the program is ill-formed.
\end{verbatim}

\textbf{Note 2}: This definition prevents a silent failure to pass the allocator to a constructor of a type for which \texttt{uses\_allocator\_v<T, Alloc>} is true. —end note

\begin{verbatim}
template<class T, class Alloc, class Tuple1, class Tuple2>
constexpr auto uses_allocator_construction_args(const Alloc& alloc, piecewise_construct_t, Tuple1&& x, Tuple2&& y) noexcept -> see below;

Constraints: \texttt{T} is a specialization of \texttt{pair}.

Effects: For \texttt{T} specified as \texttt{pair<T1, T2>}, equivalent to:

\begin{verbatim}
return make_tuple(
    piecewise_construct,
    apply({&alloc}(..., args1) {
        return uses_allocator_construction_args<T1>(
            alloc, std::forward<decltype(args1)>(args1)...);
    }, std::forward<Tuple1>(x)),
    apply({&alloc}(..., args2) {
        return uses_allocator_construction_args<T2>(
            alloc, std::forward<decltype(args2)>(args2)...);
    }, std::forward<Tuple2>(y)));
\end{verbatim}
\end{verbatim}

\begin{verbatim}
template<class T, class Alloc>
constexpr auto uses_allocator_construction_args(const Alloc& alloc) noexcept -> see below;

Constraints: \texttt{T} is a specialization of \texttt{pair}.

Effects: Equivalent to:

\begin{verbatim}
return uses_allocator_construction_args<T>(alloc, piecewise_construct,
tuple<>{}, tuple<>());
\end{verbatim}
\end{verbatim}

\begin{verbatim}
template<class T, class Alloc, class U, class V>
constexpr auto uses_allocator_construction_args(const Alloc& alloc, U&& u, V&& v) noexcept -> see below;

Constraints: \texttt{T} is a specialization of \texttt{pair}.

Effects: Equivalent to:

\begin{verbatim}
return uses_allocator_construction_args<T>(alloc, piecewise_construct,
forward_as_tuple(std::forward<U>(u)),
forward_as_tuple(std::forward<V>(v)));
\end{verbatim}
\end{verbatim}
template<class T, class Alloc, class U, class V>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
    const pair<U,V>&& pr) noexcept -> see below;
Constraints: T is a specialization of pair.
Effects: Equivalent to:
    return uses_allocator_construction_args<T>(alloc, piecewise_construct,
        forward_as_tuple(pr.first),
        forward_as_tuple(pr.second));

template<class T, class Alloc, class U, class V>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
    pair<U,V>&& pr) noexcept -> see below;
Constraints: T is a specialization of pair.
Effects: Equivalent to:
    return uses_allocator_construction_args<T>(alloc, piecewise_construct,
        forward_as_tuple(std::move(pr).first),
        forward_as_tuple(std::move(pr).second));

template<class T, class Alloc, class... Args>
constexpr T make_obj_using_allocator(const Alloc& alloc, Args&&... args);
Effects: Equivalent to:
    return make_from_tuple<T>(uses_allocator_construction_args<T>(
        alloc, std::forward<Args>(args)...));

template<class T, class Alloc, class... Args>
constexpr T* uninitialized_construct_using_allocator(T* p, const Alloc& alloc, Args&&... args);
Effects: Equivalent to:
    return apply([&](<class... U>(U&&... xs) {
        return construct_at(p, std::forward<U>(xs)...);
    }, uses_allocator_construction_args<T>(alloc, std::forward<Args>(args)...));

20.10.9 Allocators
[allocator.traits]
20.10.9.1 General
[allocator.traits.general]
The class template allocator_traits supplies a uniform interface to all allocator types. An allocator cannot
be a non-class type, however, even if allocator_traits supplies the entire required interface.

[Note 1: Thus, it is always possible to create a derived class from an allocator. — end note]

namespace std {
    template<class Alloc> struct allocator_traits {
        using allocator_type = Alloc;
        using value_type = typename Alloc::value_type;
        using pointer = see below;
        using const_pointer = see below;
        using void_pointer = see below;
        using const_void_pointer = see below;
        using difference_type = see below;
        using size_type = see below;
        using propagate_on_container_copy_assignment = see below;
        using propagate_on_container_move_assignment = see below;
        using propagate_on_container_swap = see below;
        using is_always_equal = see below;

        template<class T> using rebind_alloc = see below;
        template<class T> using rebind_traits = allocator_traits<rebind_alloc<T>>;
    };
}
static constexpr void deallocate(Alloc& a, pointer p, size_type n);

template<class T, class... Args>
static constexpr void construct(Alloc& a, T* p, Args&&... args);

template<class T>
static constexpr void destroy(Alloc& a, T* p);

static constexpr size_type max_size(const Alloc& a) noexcept;

static constexpr Alloc select_on_container_copy_construction(const Alloc& rhs);
};

20.10.9.2 Member types

using pointer = see below;

1 Type: Alloc::pointer if the qualified-id Alloc::pointer is valid and denotes a type (13.10.3); otherwise, value_type*.

using const_pointer = see below;

2 Type: Alloc::const_pointer if the qualified-id Alloc::const_pointer is valid and denotes a type (13.10.3); otherwise, pointer_traits<pointer>::rebind<const value_type>.

using void_pointer = see below;

3 Type: Alloc::void_pointer if the qualified-id Alloc::void_pointer is valid and denotes a type (13.10.3); otherwise, pointer_traits<pointer>::rebind<void>.

using const_void_pointer = see below;

4 Type: Alloc::const_void_pointer if the qualified-id Alloc::const_void_pointer is valid and denotes a type (13.10.3); otherwise, pointer_traits<pointer>::rebind<const void>.

using difference_type = see below;

5 Type: Alloc::difference_type if the qualified-id Alloc::difference_type is valid and denotes a type (13.10.3); otherwise, pointer_traits<pointer>::difference_type.

using size_type = see below;

6 Type: Alloc::size_type if the qualified-id Alloc::size_type is valid and denotes a type (13.10.3); otherwise, make_unsigned_t<difference_type>.

using propagate_on_container_copy_assignment = see below;

7 Type: Alloc::propagate_on_container_copy_assignment if the qualified-id Alloc::propagate_on_container_copy_assignment is valid and denotes a type (13.10.3); otherwise false_type.

using propagate_on_container_move_assignment = see below;

8 Type: Alloc::propagate_on_container_move_assignment if the qualified-id Alloc::propagate_on_container_move_assignment is valid and denotes a type (13.10.3); otherwise false_type.

using propagate_on_container_swap = see below;

9 Type: Alloc::propagate_on_container_swap if the qualified-id Alloc::propagate_on_container_swap is valid and denotes a type (13.10.3); otherwise false_type.

using is_always_equal = see below;

10 Type: Alloc::is_always_equal if the qualified-id Alloc::is_always_equal is valid and denotes a type (13.10.3); otherwise is_empty<Alloc>::type.
template<class T> using rebind_alloc = see below;

Alias template: Alloc::rebind<T>::other if the qualified-id Alloc::rebind<T>::other is valid and denotes a type (13.10.3); otherwise, Alloc<T, Args> if Alloc is a class template instantiation of the form Alloc<U, Args>, where Args is zero or more type arguments; otherwise, the instantiation of rebind_alloc is ill-formed.

20.10.9.3 Static member functions

[[nodiscard]] static constexpr pointer allocate(Alloc& a, size_type n);
Returns: a.allocate(n).

[[nodiscard]] static constexpr pointer allocate(Alloc& a, size_type n, const_void_pointer hint);
Returns: a.allocate(n, hint) if that expression is well-formed; otherwise, a.allocate(n).

static constexpr void deallocate(Alloc& a, pointer p, size_type n);
Effects: Calls a.deallocate(p, n).
Throws: Nothing.

template<class T, class... Args>
static constexpr void construct(Alloc& a, T* p, Args&&... args);
Effects: Calls a.construct(p, std::forward<Args>(args)... ) if that call is well-formed; otherwise, invokes construct_at(p, std::forward<Args>(args)... ).

template<class T>
static constexpr void destroy(Alloc& a, T* p);
Effects: Calls a.destroy(p) if that call is well-formed; otherwise, invokes destroy_at(p).

static constexpr size_type max_size(const Alloc& a) noexcept;
Returns: a.max_size() if that expression is well-formed; otherwise, numeric_limits<

§ 20.10.10 The default allocator

20.10.10.1 General
All specializations of the default allocator meet the allocator completeness requirements (16.4.4.6.2).

namespace std {

template<class T> class allocator {
public:
    using value_type = T;
    using size_type = size_t;
    using difference_type = ptrdiff_t;
    using propagate_on_container_move_assignment = true_type;

    constexpr allocator() noexcept;
    constexpr allocator(const allocator&) noexcept;
    template<class U> constexpr allocator(const allocator<U>&) noexcept;
    constexpr ~allocator();
    constexpr allocator& operator=(const allocator&) = default;

    [[nodiscard]] constexpr T* allocate(size_t n);
    constexpr void deallocate(T* p, size_t n);
};

allocator_traits<allocator<T>>::is_always_equal::value is true for any T.
20.10.10.2 Members

1 Except for the destructor, member functions of the default allocator shall not introduce data races (6.9.2) as a result of concurrent calls to those member functions from different threads. Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before the next allocation (if any) in this order.

```cpp
[[nodiscard]] constexpr T* allocate(size_t n);
```

2 Mandates: T is not an incomplete type (6.8).

3 Returns: A pointer to the initial element of an array of n T.

4 Throws: bad_array_new_length if numeric_limits<size_t>::max() / sizeof(T) < n, or bad_alloc if the storage cannot be obtained.

5 Remarks: The storage for the array is obtained by calling ::operator new (17.6.3), but it is unspecified when or how often this function is called. This function starts the lifetime of the array object, but not that of any of the array elements.

```cpp
constexpr void deallocate(T* p, size_t n);
```

6 Preconditions: p is a pointer value obtained from allocate(). n equals the value passed as the first argument to the invocation of allocate which returned p.

7 Effects: Deallocates the storage referenced by p.

8 Remarks: Uses ::operator delete (17.6.3), but it is unspecified when this function is called.

20.10.10.3 Operators

```cpp
template<class T, class U>
constexpr bool operator==(const allocator<T>&, const allocator<U>&) noexcept;
```

1 Returns: true.

20.10.11 addressof

```cpp
template<class T> constexpr T* addressof(T& r) noexcept;
```

1 Returns: The actual address of the object or function referenced by r, even in the presence of an overloaded operator&.

2 Remarks: An expression addressof(E) is a constant subexpression (3.14) if E is an lvalue constant subexpression.

20.10.12 C library memory allocation

1 \[Note 1: The header <cstdlib> (17.2.2) declares the functions described in this subclause. — end note\]

```cpp
void* aligned_alloc(size_t alignment, size_t size);
void* calloc(size_t nmemb, size_t size);
void* malloc(size_t size);
void* realloc(void* ptr, size_t size);
```

2 Effects: These functions have the semantics specified in the C standard library.

3 Remarks: These functions do not attempt to allocate storage by calling ::operator new() (17.6.3).

4 Storage allocated directly with these functions is implicitly declared reachable (see 6.7.5.5.4) on allocation, ceases to be declared reachable on deallocation, and need not cease to be declared reachable as the result of an undeclare_reachable() call.

1 \[Note 2: This allows existing C libraries to remain unaffected by restrictions on pointers that are not safely derived, at the expense of providing far fewer garbage collection and leak detection options for malloc()-allocated objects. It also allows malloc() to be implemented with a separate allocation arena, bypassing the normal declare_reachable() implementation. — end note\]

5 These functions implicitly create objects (6.7.2) in the returned region of storage and return a pointer to a suitable created object. In the case of calloc and realloc, the objects are created before the storage is zeroed or copied, respectively.
void free(void* ptr);

Effects: This function has the semantics specified in the C standard library.

Remarks: This function does not attempt to deallocate storage by calling \texttt{operator delete()}. See also: ISO C 7.22.3

20.11 Smart pointers

20.11.1 Class template unique\_ptr

20.11.1.1 General

A \textit{unique pointer} is an object that owns another object and manages that other object through a pointer. More precisely, a unique pointer is an object \( u \) that stores a pointer to a second object \( p \) and will dispose of \( p \) when \( u \) is itself destroyed (e.g., when leaving block scope (8.8)). In this context, \( u \) is said to \textit{own} \( p \).

The mechanism by which \( u \) disposes of \( p \) is known as \( p \)'s associated \textit{deleter}, a function object whose correct invocation results in \( p \)'s appropriate disposition (typically its deletion).

Let the notation \( u.p \) denote the pointer stored by \( u \), and let \( u.d \) denote the associated deleter. Upon request, \( u \) can \textit{reset} (replace) \( u.p \) and \( u.d \) with another pointer and deleter, but properly disposes of its owned object via the associated deleter before such replacement is considered completed.

Each object of a type \( U \) instantiated from the \texttt{unique\_ptr} template specified in 20.11.1 has the strict ownership semantics, specified above, of a unique pointer. In partial satisfaction of these semantics, each such \( U \) is \texttt{Cpp17MoveConstructible} and \texttt{Cpp17MoveAssignable}, but is not \texttt{Cpp17CopyConstructible} nor \texttt{Cpp17CopyAssignable}. The template parameter \( T \) of \texttt{unique\_ptr} may be an incomplete type.

[Note 1: The uses of \texttt{unique\_ptr} include providing exception safety for dynamically allocated memory, passing ownership of dynamically allocated memory to a function, and returning dynamically allocated memory from a function. — end note]

20.11.1.2 Default deleters

20.11.1.2.1 In general

The class template \texttt{default\_delete} serves as the default deleter (destruction policy) for the class template \texttt{unique\_ptr}.

The template parameter \( T \) of \texttt{default\_delete} may be an incomplete type.

20.11.1.2.2 \texttt{default\_delete

namespace std {
    template<class T> struct default_delete {
        constexpr default_delete() noexcept = default;
        template<class U> default_delete(const default_delete\<U\>&) noexcept;
        void operator()\((T*)\) const;
    };
}

template<class U> default_delete(const default_delete\<U\>& other) noexcept;

Constraints: \( U* \) is implicitly convertible to \( T* \).

Effects: Constructs a \texttt{default\_delete} object from another \texttt{default\_delete\<U\>} object.

void operator()\((T*\text{ ptr})\) const;

Mandates: \( T \) is a complete type.

Effects: Calls \texttt{delete} on \texttt{ptr}.

20.11.1.2.3 \texttt{default\_delete\<T[]>}

namespace std {
    template<class T> struct default_delete\<T[]> {
        constexpr default_delete\() noexcept = default;
        template<class U> default_delete\(const default_delete\<U[]\>&\) noexcept;
        template<class U> void operator\((U*\text{ ptr})\) const;
    };
}

§ 20.11.2.3
template<class U> default_delete(const default_delete<U>& other) noexcept;

1 Constraints: U(*)[] is convertible to T(*)[].

2 Effects: Constructs a default_delete object from another default_delete<U[]> object.

template<class U> void operator()(U* ptr) const;

3 Constraints: U(*)[] is convertible to T(*)[].

4 Mandates: U is a complete type.

5 Effects: Calls delete[] on ptr.

20.11.1.3 unique_ptr for single objects [unique.ptr.single]

20.11.1.3.1 General [unique.ptr.single.general]

namespace std {
    template<class T, class D = default_delete<T>> class unique_ptr {
        public:
            using pointer = see below;
            using element_type = T;
            using deleter_type = D;

            // 20.11.1.3.2, constructors
            constexpr unique_ptr() noexcept;
            explicit unique_ptr(pointer p) noexcept;
            unique_ptr(pointer p, see below d1) noexcept;
            unique_ptr(pointer p, see below d2) noexcept;
            unique_ptr(unique_ptr&& u) noexcept;
            constexpr unique_ptr(nullptr_t) noexcept;
            template<class U, class E>
                unique_ptr(unique_ptr<U, E>&& u) noexcept;
            // 20.11.1.3.3, destructor
            ~unique_ptr();
            // 20.11.1.3.4, assignment
            unique_ptr& operator=(unique_ptr&& u) noexcept;
            template<class U, class E>
                unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
            unique_ptr& operator=(nullptr_t) noexcept;
            // 20.11.1.3.5, observers
            add_lvalue_reference_t<T> operator*() const;
            pointer operator->() const noexcept;
            pointer get() const noexcept;
            deleter_type& get_deleter() noexcept;
            const deleter_type& get_deleter() const noexcept;
            explicit operator bool() const noexcept;
            // 20.11.1.3.6, modifiers
            pointer release() noexcept;
            void reset(pointer p = pointer()) noexcept;
            void swap(unique_ptr& u) noexcept;

            // disable copy from lvalue
            unique_ptr(const unique_ptr&) = delete;
            unique_ptr& operator=(const unique_ptr&) = delete;
    };
}

1 The default type for the template parameter D is default_delete. A client-supplied template argument D shall be a function object type (20.14), lvalue reference to function, or lvalue reference to function object type for which, given a value d of type D and a value ptr of type unique_ptr<T, D>::pointer, the expression d(ptr) is valid and has the effect of disposing of the pointer as appropriate for that deleter.

2 If the deleter’s type D is not a reference type, D shall meet the Cpp17Destructible requirements (Table 34).
If the qualified-id remove_reference_t<D>::pointer is valid and denotes a type (13.10.3), then unique_ptr<T, D>::pointer shall be a synonym for remove_reference_t<D>::pointer. Otherwise unique_ptr<T, D>::pointer shall be a synonym for element_type*. The type unique_ptr<T, D>::pointer shall meet the Cpp17NullablePointer requirements (Table 35).

[Example 1: Given an allocator type X (Table 38) and letting A be a synonym for allocator_traits<X>, the types A::pointer, A::const_pointer, A::void_pointer, and A::const_void_pointer may be used as unique_ptr<T, D>::pointer. —end example]

### 20.11.1.3.2 Constructors [unique.ptr.single.ctor]

```cpp
constexpr unique_ptr() noexcept;
constexpr unique_ptr(nullptr_t) noexcept;
```

**Constraints:**

- `is_pointer_v<deleter_type>` is false and `is_default_constructible_v<deleter_type>` is true.

**Preconditions:**

- D meets the Cpp17DefaultConstructible requirements (Table 29), and that construction does not throw an exception.

**Effects:** Constructs a unique_ptr object that owns nothing, value-initializing the stored pointer and the stored deleter.

**Postconditions:**

- `get() == nullptr`
- `get_deleter()` returns a reference to the stored deleter.

```cpp
explicit unique_ptr(pointer p) noexcept;
unique_ptr(pointer p, const D& d) noexcept;
unique_ptr(pointer p, remove_reference_t<D>&& d) noexcept;
```

**Constraints:**

- `is_constructible_v<D, decltype(d)>` is true.

**Mandates:** These constructors are not selected by class template argument deduction (12.2.2.9).

**Preconditions:**

- For the first constructor, if D is not a reference type, D meets the Cpp17CopyConstructible requirements and such construction does not exit via an exception. For the second constructor, if D is not a reference type, D meets the Cpp17MoveConstructible requirements and such construction does not exit via an exception.

**Effects:** Constructs a unique_ptr object which owns p, initializing the stored pointer with p and value-initializing the stored deleter.

**Postconditions:**

- `get() == p`
- `get_deleter()` returns a reference to the stored deleter.

**Remarks:** If D is a reference type, the second constructor is defined as deleted.

```cpp
unique_ptr(unique_ptr&& u) noexcept;
```

**Constraints:**

- `is_move_constructible_v<D>` is true.

§ 20.11.1.3.2 635
Preconditions: If \( D \) is not a reference type, \( D \) meets the `Cpp17MoveConstructible` requirements (Table 30). Construction of the deleter from an rvalue of type \( D \) does not throw an exception.

Effects: Constructs a `unique_ptr` from \( u \). If \( D \) is a reference type, this deleter is copy constructed from \( u \)'s deleter; otherwise, this deleter is move constructed from \( u \)'s deleter.

[Note 1: The construction of the deleter can be implemented with `std::forward<D>`. — end note]

Postconditions: `get()` yields the value \( u.get() \) yielded before the construction. \( u.get() == \text{nullptr} \). `get_deleter()` returns a reference to the stored deleter that was constructed from \( u.get_deleter() \). If \( D \) is a reference type then `get_deleter()` and `u.get_deleter()` both reference the same lvalue deleter.

```cpp
template<class U, class E> unique_ptr(unique_ptr<U, E>&& u) noexcept;
```

Constraints:

(21.1) `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer`,

(21.2) \( U \) is not an array type, and

(21.3) \( D \) is a reference type and \( E \) is the same type as \( D \), or \( D \) is not a reference type and \( E \) is implicitly convertible to \( D \).

Preconditions: If \( E \) is not a reference type, construction of the deleter from an rvalue of type \( E \) is well-formed and does not throw an exception. Otherwise, \( E \) is a reference type and construction of the deleter from an lvalue of type \( E \) is well-formed and does not throw an exception.

Effects: Constructs a `unique_ptr` from \( u \). If \( E \) is a reference type, this deleter is copy constructed from \( u \)'s deleter; otherwise, this deleter is move constructed from \( u \)'s deleter.

[Note 2: The deleter constructor can be implemented with `std::forward<E>`. — end note]

Postconditions: `get()` yields the value \( u.get() \) yielded before the construction. \( u.get() == \text{nullptr} \). `get_deleter()` returns a reference to the stored deleter that was constructed from \( u.get_deleter() \).

20.11.1.3.3 Destructor

```cpp
~unique_ptr();
```

Preconditions: The expression `get_deleter()(get())` is well-formed, has well-defined behavior, and does not throw exceptions.

[Note 1: The use of `default_delete` requires \( T \) to be a complete type. — end note]

Effects: If `get() == \text{nullptr}` there are no effects. Otherwise `get_deleter()(get())`.

20.11.1.3.4 Assignment

```cpp
unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
```

Constraints:

(6.1) `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer`, and

(6.2) \( U \) is not an array type, and

(6.3) `is_assignable_v<D&, E&&>` is true.

Preconditions: If \( D \) is not a reference type, \( D \) meets the `Cpp17MoveAssignable` requirements (Table 32) and assignment of the deleter from an rvalue of type \( D \) does not throw an exception. Otherwise, \( D \) is a reference type; `remove_reference_t<D>` meets the `Cpp17CopyAssignable` requirements and assignment of the deleter from an lvalue of type \( D \) does not throw an exception.

Effects: Calls `reset(u.release())` followed by `get_deleter() = std::forward<D>(u.get_deleter())`.

Postconditions: If \( \text{this} != \text{addressof}(u) \), \( u.get() == \text{nullptr} \), otherwise \( u.get() \) is unchanged.

Returns: \( *\text{this} \).

```cpp
template<class U, class E> unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
```

Constraints:

(6.1) `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer`, and

(6.2) \( U \) is not an array type, and

(6.3) `is_assignable_v<D&, E&&>` is true.
Preconditions: If \( E \) is not a reference type, assignment of the deleter from an rvalue of type \( E \) is well-formed and does not throw an exception. Otherwise, \( E \) is a reference type and assignment of the deleter from an lvalue of type \( E \) is well-formed and does not throw an exception.

Effects: Calls `reset(u.release())` followed by `get_deleter() = std::forward<E>(u.get_deleter())`.

Postconditions: \( u.get() == \text{nullptr} \).

Returns: \(*\text{this}\).

unique_ptr& operator=(nullptr_t) noexcept;

Effects: As if by `reset()`.

Postconditions: \( \text{get()} == \text{nullptr} \).

Returns: \(*\text{this}\).

### 20.11.1.3.5 Observers

`add_lvalue_reference_t<T>` `operator*() const`;

Preconditions: \( \text{get()} \neq \text{nullptr} \).

Returns: \(*\text{get()}\).

`pointer operator->() const noexcept`;

Preconditions: \( \text{get()} \neq \text{nullptr} \).

Returns: `\text{get()}`.

[Note 1: The use of this function typically requires that \( T \) be a complete type. — end note]

`pointer get() const noexcept`;

Returns: The stored pointer.

`deleter_type& get_deleter() noexcept;`

`const deleter_type& get_deleter() const noexcept;`

Returns: A reference to the stored deleter.

`explicit operator bool() const noexcept`;

Returns: \( \text{get()} \neq \text{nullptr} \).

### 20.11.1.3.6 Modifiers

`pointer release() noexcept`;

Postconditions: \( \text{get()} == \text{nullptr} \).

Returns: The value \( \text{get()} \) had at the start of the call to `release`.

`void reset(pointer p = pointer()) noexcept;`

Preconditions: The expression `\text{get_deleter()}(\text{get()})` is well-formed, has well-defined behavior, and does not throw exceptions.

Effects: Assigns \( p \) to the stored pointer, and then if and only if the old value of the stored pointer, `old_p`, was not equal to `nullptr`, calls `\text{get_deleter()}(\text{old_p})`.

[Note 1: The order of these operations is significant because the call to `\text{get_deleter()}` might destroy \(*\text{this}\). — end note]

Postconditions: \( \text{get()} == p \).

[Note 2: The postcondition does not hold if the call to `\text{get_deleter()}` destroys \(*\text{this}\) since `\text{this}\rightarrow\text{get()}` is no longer a valid expression. — end note]

`void swap(unique_ptr& u) noexcept;`

Preconditions: \( \text{get_deleter()} \) is swappable (16.4.4.3) and does not throw an exception under `swap`.

Effects: Invokes `swap` on the stored pointers and on the stored deleters of \(*\text{this}\) and \( u \).
20.11.1.4  unique_ptr for array objects with a runtime length

20.11.1.4.1  General

namespace std {
    template<class T, class D> class unique_ptr<T[], D> {
        public:
            using pointer = see below;
            using element_type = T;
            using deleter_type = D;

        // 20.11.1.4.2, constructors
            constexpr unique_ptr() noexcept;
            template<class U> explicit unique_ptr(U p) noexcept;
            template<class U> unique_ptr(U p, see below d) noexcept;
            template<class U> unique_ptr(unique_ptr&& u) noexcept;
            template<class U, class E>
                unique_ptr(unique_ptr<U, E>&& u) noexcept;
            constexpr unique_ptr(nullptr_t) noexcept;

        // destructor
            ~unique_ptr();

        // assignment
            unique_ptr& operator=(unique_ptr&& u) noexcept;
            template<class U, class E>
                unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
            unique_ptr& operator=(nullptr_t) noexcept;

        // 20.11.1.4.4, observers
            T& operator[](size_t i) const;
            pointer get() const noexcept;
            deleter_type& get_deleter() noexcept;
            const deleter_type& get_deleter() const noexcept;
            explicit operator bool() const noexcept;

        // 20.11.1.4.5, modifiers
            pointer release() noexcept;
            template<class U> void reset(U p) noexcept;
            void reset(nullptr_t = nullptr) noexcept;
            void swap(unique_ptr& u) noexcept;

        // disable copy from lvalue
            unique_ptr(const unique_ptr&) = delete;
            unique_ptr& operator=(const unique_ptr&) = delete;
    };
}

1 A specialization for array types is provided with a slightly altered interface.

(1.1)  Conversions between different types of unique_ptr<T[], D> that would be disallowed for the corresponding pointer-to-array types, and conversions to or from the non-array forms of unique_ptr, produce an ill-formed program.

(1.2)  Pointers to types derived from T are rejected by the constructors, and by reset.

(1.3)  The observers operator* and operator-> are not provided.

(1.4)  The indexing observer operator[] is provided.

(1.5)  The default deleter will call delete[].

2 Descriptions are provided below only for members that differ from the primary template.

3 The template argument T shall be a complete type.
20.11.1.4.2 Constructors

\[\text{template<class U> explicit unique_ptr(U p) noexcept;}\]

This constructor behaves the same as the constructor in the primary template that takes a single parameter of type `pointer`.

\(\text{Constraints:}\)

\(\begin{align*}
(2.1) & \quad \text{U is the same type as } \text{pointer}, \text{ or} \\
(2.2) & \quad \text{pointer is the same type as } \text{element_type*}, \text{U is a pointer type } V*, \text{ and } V(*)[] \text{ is convertible to } \text{element_type(*)[]}.
\end{align*}\)

\[\text{template<class U> unique_ptr(U p, see below d) noexcept;}\]

\[\text{template<class U> unique_ptr(U p, see below d) noexcept;}\]

These constructors behave the same as the constructors in the primary template that take a parameter of type `pointer` and a second parameter.

\(\text{Constraints:}\)

\(\begin{align*}
(4.1) & \quad \text{U is the same type as } \text{pointer}, \\
(4.2) & \quad \text{U is } \text{nullptr_t}, \text{ or} \\
(4.3) & \quad \text{pointer is the same type as } \text{element_type*}, \text{U is a pointer type } V*, \text{ and } V(*)[] \text{ is convertible to } \text{element_type(*)[]}.
\end{align*}\)

\[\text{template<class U, class E> unique_ptr(unique_ptr<U, E>&& u) noexcept;}\]

This constructor behaves the same as in the primary template.

\(\text{Constraints: Where UP is unique_ptr<U, E>:}\)

\(\begin{align*}
(6.1) & \quad \text{U is an array type, and} \\
(6.2) & \quad \text{pointer is the same type as } \text{element_type*}, \text{ and} \\
(6.3) & \quad \text{UP::pointer is the same type as UP::element_type*}, \text{ and} \\
(6.4) & \quad \text{UP::element_type(*)[]} \text{ is convertible to } \text{element_type(*)[]}, \text{ and} \\
(6.5) & \quad \text{either D is a reference type and E is the same type as D, or D is not a reference type and E is implicitly convertible to D.}
\end{align*}\)

\[\text{[Note 1: This replaces the } \text{Constraints: specification of the primary template. — end note]}\]

20.11.1.4.3 Assignment

\[\text{template<class U, class E> unique_ptr operator=(unique_ptr<U, E>&& u) noexcept;}\]

This operator behaves the same as in the primary template.

\(\text{Constraints: Where UP is unique_ptr<U, E>:}\)

\(\begin{align*}
(2.1) & \quad \text{U is an array type, and} \\
(2.2) & \quad \text{pointer is the same type as } \text{element_type*}, \text{ and} \\
(2.3) & \quad \text{UP::pointer is the same type as UP::element_type*}, \text{ and} \\
(2.4) & \quad \text{UP::element_type(*)[]} \text{ is convertible to } \text{element_type(*)[]}, \text{ and} \\
(2.5) & \quad \text{is_assignable_v<D&, E&&> is true.}
\end{align*}\)

\[\text{[Note 1: This replaces the } \text{Constraints: specification of the primary template. — end note]}\]

20.11.1.4.4 Observers

\(\text{T& operator[](size_t i) const;}\)

\(\text{Preconditions: i < the number of elements in the array to which the stored pointer points.}\)

\(\text{Returns: get()[i].}\)
20.11.1.4.5 Modifiers

```cpp
void reset(nullptr_t p = nullptr) noexcept;
```

*Effects:* Equivalent to `reset(pointer())`.

```cpp
template<class U> void reset(U p) noexcept;
```

This function behaves the same as the `reset` member of the primary template.

*Constraints:*

1. `U` is the same type as `pointer`, or
2. `pointer` is the same type as `element_type*`, `U` is a pointer type `V*`, and `V(*)[]` is convertible to `element_type(*)[]`.

20.11.1.5 Creation

```cpp
template<class T, class... Args> unique_ptr<T> make_unique(Args&&... args);
```

*Constraints:*

1. `T` is not an array type.

*Returns:* `unique_ptr<T>(new T(std::forward<Args>(args)...))`.

```cpp
template<class T> unique_ptr<T> make_unique(size_t n);
```

*Constraints:*

1. `T` is an array of unknown bound.

*Returns:* `unique_ptr<T>(new remove_extent_t<T>[n])`.

```cpp
template<class T, class... Args> unspecified make_unique(Args&&...); = delete;
```

*Constraints:*

1. `T` is an array of known bound.

```cpp
template<class T> unique_ptr<T> make_unique_for_overwrite();
```

*Constraints:*

1. `T` is not an array type.

*Returns:* `unique_ptr<T>(new T)`.

```cpp
template<class T> unique_ptr<T> make_unique_for_overwrite(size_t n);
```

*Constraints:*

1. `T` is an array of unknown bound.

*Returns:* `unique_ptr<T>(new remove_extent_t<T>[n])`.

```cpp
template<class T, class... Args> unspecified make_unique_for_overwrite(Args&&...); = delete;
```

*Constraints:*

1. `T` is an array of known bound.

20.11.1.6 Specialized algorithms

```cpp
template<class T, class D> void swap(unique_ptr<T, D>& x, unique_ptr<T, D>& y) noexcept;
```

*Effects:* Calls `x.swap(y)`.

```cpp
template<class T1, class D1, class T2, class D2>
bool operator==(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

*Returns:* `x.get() == y.get()`.

```cpp
template<class T1, class D1, class T2, class D2>
bool operator<(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

*Let CT denote*

```cpp
common_type_t<typename unique_ptr<T1, D1>::pointer, typename unique_ptr<T2, D2>::pointer>
```

*Mandates:*

1. `unique_ptr<T1, D1>::pointer` is implicitly convertible to CT and
2. `unique_ptr<T2, D2>::pointer` is implicitly convertible to CT.
Preconditions: The specialization `less<CT>` is a function object type (20.14) that induces a strict weak ordering (25.8) on the pointer values.

Returns: `less<CT>()(x.get(), y.get())`.

template<class T1, class D1, class T2, class D2>
bool operator>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: `y < x`.

template<class T1, class D1, class T2, class D2>
bool operator==(const unique_ptr<T1, D1>& x, nullptr_t) noexcept;

Returns: `!x`.

template<class T1, class D1, class T2, class D2>
bool operator<(const unique_ptr<T1, D1>& x, nullptr_t);

template<class T1, class D1, class T2, class D2>
bool operator<(nullptr_t, const unique_ptr<T1, D1>& x);

Preconditions: The specialization `less<unique_ptr<T, D>::pointer>` is a function object type (20.14) that induces a strict weak ordering (25.8) on the pointer values.

Returns: The first function template returns `less<unique_ptr<T, D>::pointer>()(x.get(), nullptr)`.

The second function template returns `less<unique_ptr<T, D>::pointer>()(nullptr, x.get())`.

template<class T, class D>
bool operator>(const unique_ptr<T, D>& x, nullptr_t);

template<class T, class D>
bool operator>(nullptr_t, const unique_ptr<T, D>& x);

Returns: The first function template returns `nullptr < x`. The second function template returns `x < nullptr`.

template<class T, class D>
bool operator<(const unique_ptr<T, D>& x, nullptr_t);

template<class T, class D>
bool operator<(nullptr_t, const unique_ptr<T, D>& x);

Returns: The first function template returns `!(nullptr < x)`. The second function template returns `!(x < nullptr)`.
template<class T, class D>
requires three_way_comparable<typename unique_ptr<T, D>::pointer>
compare_three_way_result_t<typename unique_ptr<T, D>::pointer>
operator<=>(const unique_ptr<T, D>& x, nullptr_t);

Returns:
compare_three_way(x.get(), static_cast<typename unique_ptr<T, D>::pointer>(nullptr)).

20.11.1.7 I/O

template<class E, class T, class Y, class D>
basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const unique_ptr<Y, D>& p);

Constraints: os << p.get() is a valid expression.

Effects: Equivalent to: os << p.get();

Returns: os.

20.11.2 Class bad_weak_ptr

namespace std {
    class bad_weak_ptr : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    }
}

An exception of type bad_weak_ptr is thrown by the shared_ptr constructor taking a weak_ptr.

const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

20.11.3 Class template shared_ptr

20.11.3.1 General

The shared_ptr class template stores a pointer, usually obtained via new. shared_ptr implements semantics of shared ownership; the last remaining owner of the pointer is responsible for destroying the object, or otherwise releasing the resources associated with the stored pointer. A shared_ptr is said to be empty if it does not own a pointer.

namespace std {
    template<class T> class shared_ptr {
        public:
            using element_type = remove_extent_t<T>;
            using weak_type = weak_ptr<T>;

            // 20.11.3.2, constructors
            constexpr shared_ptr() noexcept;
            constexpr shared_ptr(nullptr_t) noexcept : shared_ptr() {}  
            template<class Y>
                explicit shared_ptr(Y* p);
            template<class Y, class D>
                shared_ptr(Y* p, D d);
            template<class Y, class D, class A>
                shared_ptr(Y* p, D d, A a);
            template<class D>
                shared_ptr(nullptr_t p, D d);
            template<class D, class A>
                shared_ptr(nullptr_t p, D d, A a);
            template<class Y>
                shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
            template<class Y>
                shared_ptr(shared_ptr<Y>&& r, element_type* p) noexcept;
            shared_ptr(const shared_ptr& r) noexcept;
        }
    }
}
template<class Y>
    shared_ptr(const shared_ptr<Y>& r) noexcept;
shared_ptr(shared_ptr&& r) noexcept;
template<class Y>
    shared_ptr(shared_ptr<Y>&& r) noexcept;
template<class Y>
    explicit shared_ptr(const weak_ptr<Y>& r);
template<class Y, class D>
    shared_ptr(shared_ptr<Y, D>&& r);

// 20.11.3.3, destructor
~shared_ptr();

// 20.11.3.4, assignment
shared_ptr& operator=(const shared_ptr& r) noexcept;
template<class Y>
    shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;
shared_ptr& operator=(shared_ptr&& r) noexcept;
template<class Y>
    shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;
template<class Y, class D>
    shared_ptr& operator=(unique_ptr<Y, D>&& r);

// 20.11.3.5, modifiers
void swap(shared_ptr& r) noexcept;
void reset() noexcept;
template<class Y>
    void reset(Y* p);
template<class Y, class D>
    void reset(Y* p, D d);
template<class Y, class D, class A>
    void reset(Y* p, D d, A a);

// 20.11.3.6, observers
element_type* get() const noexcept;
T& operator*() const noexcept;
T* operator->() const noexcept;
element_type& operator[](ptrdiff_t i) const;
long use_count() const noexcept;
explicit operator bool() const noexcept;
template<class U>
    bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U>
    bool owner_before(const weak_ptr<U>& b) const noexcept;

};

template<class T>
    shared_ptr(weak_ptr<T>) -> shared_ptr<T>;
template<class T, class D>
    shared_ptr(unique_ptr<T, D>) -> shared_ptr<T>;

2 Specializations of shared_ptr shall be Cpp17CopyConstructible, Cpp17CopyAssignable, and Cpp17LessThanComparable, allowing their use in standard containers. Specializations of shared_ptr shall be contextually convertible to bool, allowing their use in boolean expressions and declarations in conditions.

3 The template parameter T of shared_ptr may be an incomplete type.
   [Note 1: T can be a function type. — end note]

4 [Example 1]:
   if (shared_ptr<X> px = dynamic_pointer_cast<X>(py)) {
      // do something with px
   }
   — end example]
For purposes of determining the presence of a data race, member functions shall access and modify only the `shared_ptr` and `weak_ptr` objects themselves and not objects they refer to. Changes in `use_count()` do not reflect modifications that can introduce data races.

For the purposes of subclause 20.11, a pointer type `Y*` is said to be **compatible with** a pointer type `T*` when either `Y*` is convertible to `T*` or `Y` is `U[N]` and `T` is `cv U[]`.

### 20.11.3.2 Constructors

In the constructor definitions below, enables `shared_from_this` with `p`, for a pointer `p` of type `Y*`, means that if `Y` has an unambiguous and accessible base class that is a specialization of `enable_shared_from_this (20.11.6)`, then `remove_cv_t<Y>*` shall be implicitly convertible to `T*` and the constructor evaluates the statement:

```cpp
if (p != nullptr && p->weak_this.expired())
    p->weak_this = shared_ptr<remove_cv_t<Y>>(*this, const_cast<remove_cv_t<Y>*>(p));
```

The assignment to the `weak_this` member is not atomic and conflicts with any potentially concurrent access to the same object (6.9.2).

```cpp
constexpr shared_ptr() noexcept;
```

**Postconditions**: `use_count() == 0 && get() == nullptr`.

```cpp
template<class Y> explicit shared_ptr(Y* p);
```

**Mandates**: `Y` is a complete type.

**Constraints**: When `T` is an array type, the expression `delete[] p` is well-formed and either `T` is `U[N]` and `Y(*)[N]` is convertible to `T*`, or `T` is `U[]` and `Y(*)[]` is convertible to `T*`. When `T` is not an array type, the expression `delete p` is well-formed and `Y*` is convertible to `T*`.

**Preconditions**: The expression `delete[] p`, when `T` is an array type, or `delete p`, when `T` is not an array type, has well-defined behavior, and does not throw exceptions.

**Effects**: When `T` is not an array type, constructs a `shared_ptr` object that owns the pointer `p`. Otherwise, constructs a `shared_ptr` that owns `p` and a deleter of an unspecified type that calls `delete[] p`. When `T` is not an array type, enables `shared_from_this` with `p`. If an exception is thrown, `delete p` is called when `T` is not an array type, `delete[] p` otherwise.

**Postconditions**: `use_count() == 1 && get() == p`.

**Throws**: `bad_alloc`, or an implementation-defined exception when a resource other than memory cannot be obtained.

```cpp
template<class Y, class D> shared_ptr(Y* p, D d);
template<class Y, class D, class A> shared_ptr(Y* p, D d, A a);
template<class D> shared_ptr(nullptr_t p, D d);
template<class D, class A> shared_ptr(nullptr_t p, D d, A a);
```

**Constraints**: `is_move_constructible_v<D>` is true, and `d(p)` is a well-formed expression. For the first two overloads:

- If `T` is an array type, then either `T` is `U[N]` and `Y(*)[N]` is convertible to `T*`, or `T` is `U[]` and `Y(*)[]` is convertible to `T*`.
- If `T` is not an array type, then `Y*` is convertible to `T*`.

**Preconditions**: Construction of `d` and a deleter of type `D` initialized with `std::move(d)` do not throw exceptions. The expression `d(p)` has well-defined behavior and does not throw exceptions. `A` meets the `Cpp17Allocator` requirements (Table 38).

**Effects**: Constructs a `shared_ptr` object that owns the object `p` and the deleter `d`. When `T` is not an array type, the first and second constructors enable `shared_from_this` with `p`. The second and fourth constructors shall use a copy of `a` to allocate memory for internal use. If an exception is thrown, `d(p)` is called.

**Postconditions**: `use_count() == 1 && get() == p`.

**Throws**: `bad_alloc`, or an implementation-defined exception when a resource other than memory cannot be obtained.
template<class Y> shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
template<class Y> shared_ptr(shared_ptr<Y>&& r, element_type* p) noexcept;

Effects: Constructs a shared_ptr instance that stores p and shares ownership with the initial value of r.

Postconditions: get() == p. For the second overload, r is empty and r.get() == nullptr.

[Note 1: Use of this constructor leads to a dangling pointer unless p remains valid at least until the ownership group of r is destroyed. — end note]

[Note 2: This constructor allows creation of an empty shared_ptr instance with a non-null stored pointer. — end note]

shared_ptr(const shared_ptr& r) noexcept;
template<class Y> shared_ptr(const shared_ptr<Y>& r) noexcept;

Constraints: For the second constructor, Y* is compatible with T*.

Effects: If r is empty, constructs an empty shared_ptr object; otherwise, constructs a shared_ptr object that shares ownership with r.

Postconditions: get() == r.get() && use_count() == r.use_count().

shared_ptr(shared_ptr& r) noexcept;
template<class Y> shared_ptr(shared_ptr<Y>&& r) noexcept;

Constraints: For the second constructor, Y* is compatible with T*.

Effects: Move constructs a shared_ptr instance from r.

Postconditions: *this shall contain the old value of r. r shall be empty. r.get() == nullptr.

template<class Y> explicit shared_ptr(const weak_ptr<Y>& r);

Constraints: Y* is compatible with T*.

Effects: Constructs a shared_ptr object that shares ownership with r and stores a copy of the pointer stored in r. If an exception is thrown, the constructor has no effect.

Postconditions: use_count() == r.use_count().

Throws: bad_weak_ptr when r.expired().

template<class Y, class D> shared_ptr(unique_ptr<Y, D>&& r);

Constraints: Y* is compatible with T* and unique_ptr<Y, D>::pointer is convertible to element_type*.

Effects: If r.get() == nullptr, equivalent to shared_ptr(). Otherwise, if D is not a reference type, equivalent to shared_ptr(r.release(), r.get_deleter()). Otherwise, equivalent to shared_ptr(r.release(), ref(r.get_deleter())). If an exception is thrown, the constructor has no effect.

20.11.3.3 Destructor [util.smartptr.shared.dest]

~shared_ptr();

Effects:

(1.1) — If *this is empty or shares ownership with another shared_ptr instance (use_count() > 1), there are no side effects.

(1.2) — Otherwise, if *this owns an object p and a deleter d, d(p) is called.

(1.3) — Otherwise, *this owns a pointer p, and delete p is called.

[Note 1: Since the destruction of *this decreases the number of instances that share ownership with *this by one, after *this has been destroyed all shared_ptr instances that shared ownership with *this will report a use_count() that is one less than its previous value. — end note]

20.11.3.4 Assignment [util.smartptr.shared.assign]

shared_ptr& operator=(const shared_ptr& r) noexcept;
template<class Y> shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;

Effects: Equivalent to shared_ptr(r).swap(*this).
Returns: *this.

[Note 1: The use count updates caused by the temporary object construction and destruction are not observable side effects, so the implementation can meet the effects (and the implied guarantees) via different means, without creating a temporary. In particular, in the example:

```cpp
class X {
public:
    virtual ~X() = default;
};

int x;

int main() {  // Runs freely
    X x;
    x = x;
    return 0;
}
```

Note: The use count updates caused by the temporary object construction and destruction are not observable side effects, so the implementation can meet the effects (and the implied guarantees) via different means, without creating a temporary. In particular, in the example:

```cpp
shared_ptr<int> p(new int);
shared_ptr<void> q(p);
p = p;
q = p;
```

both assignments can be no-ops. — end note]

shared_ptr& operator=(shared_ptr&& r) noexcept;

Effects: Equivalent to `shared_ptr(std::move(r)).swap(*this)`.

Returns: *this.

template<class Y> shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;

Effects: Equivalent to `shared_ptr(std::move(r)).swap(*this)`.

Returns: *this.

20.11.3.5 Modifiers

```cpp
void swap(shared_ptr& r) noexcept;

Effects: Exchanges the contents of *this and r.

void reset() noexcept;

Effects: Equivalent to `shared_ptr().swap(*this)`.

template<class Y> void reset(Y* p);

Effects: Equivalent to `shared_ptr(p).swap(*this)`.

template<class Y, class D> void reset(Y* p, D d);

Effects: Equivalent to `shared_ptr(p, d).swap(*this)`.

template<class Y, class D, class A> void reset(Y* p, D d, A a);

Effects: Equivalent to `shared_ptr(p, d, a).swap(*this)`.
```

20.11.3.6 Observers

```cpp
element_type* get() const noexcept;

Returns: The stored pointer.

T& operator*() const noexcept;

Preconditions: get() != 0.

Returns: *get().

Remarks: When T is an array type or cv void, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

T* operator->() const noexcept;

Preconditions: get() != 0.

Returns: get().

Remarks: When T is an array type, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

§ 20.11.3.6

646
element_type& operator[](ptrdiff_t i) const;

**Preconditions**: `get() != 0 && i >= 0`. If `T` is `U[N]`, `i < N`.

**Returns**: `get()[i]`.

**Throws**: Nothing.

**Remarks**: When `T` is not an array type, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

```
long use_count() const noexcept;
```

**Returns**: The number of `shared_ptr` objects, `*this` included, that share ownership with `*this`, or 0 when `*this` is empty.

**Synchronization**: None.

**[Note 1]**: `get() == nullptr` does not imply a specific return value of `use_count()`. — end note

**[Note 2]**: `weak_ptr<T>::lock()` can affect the return value of `use_count()`. — end note

**[Note 3]**: When multiple threads might affect the return value of `use_count()`, the result is approximate. In particular, `use_count() == 1` does not imply that accesses through a previously destroyed `shared_ptr` have in any sense completed. — end note

```
explicit operator bool() const noexcept;
```

**Returns**: `get() != 0`.

```
template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;
```

**Returns**: An unspecified value such that

- `x.owner_before(y)` defines a strict weak ordering as defined in 25.8;
- under the equivalence relation defined by `owner_before`, `!a.owner_before(b) && !b.owner_before(a)`, two `shared_ptr` or `weak_ptr` instances are equivalent if and only if they share ownership or are both empty.

## 20.11.3.7 Creation

The common requirements that apply to all `make_shared`, `allocate_shared`, `make_shared_for_overwrite`, and `allocate_shared_for_overwrite` overloads, unless specified otherwise, are described below.

```
template<class T, ...>
shared_ptr<T> make_shared(args);
template<class T, class A, ...>
shared_ptr<T> allocate_shared(const A& a, args);
template<class T, ...>
shared_ptr<T> make_shared_for_overwrite(args);
template<class T, class A, ...>
shared_ptr<T> allocate_shared_for_overwrite(const A& a, args);
```

**Preconditions**: A meets the Cpp17Allocator requirements (Table 38).

**Effects**: Allocates memory for an object of type `T` (or `U[N]` when `T` is `U[]`, where `N` is determined from `args` as specified by the concrete overload). The object is initialized from `args` as specified by the concrete overload. The `allocate_shared` and `allocate_shared_for_overwrite` templates use a copy of `a` (rebound for an unspecified `value_type`) to allocate memory. If an exception is thrown, the functions have no effect.

**Postconditions**: `r.get() != 0 && r.use_count() == 1`, where `r` is the return value.

**Returns**: A `shared_ptr` instance that stores and owns the address of the newly constructed object.

**Throws**: `bad_ptr` instance that stores and owns the address of the newly constructed object.

**Remarks**:

- Implementations should perform no more than one memory allocation.
  
  **[Note 1]**: This provides efficiency equivalent to an intrusive smart pointer. — end note
— When an object of an array type $U$ is specified to have an initial value of $u$ (of the same type), this shall be interpreted to mean that each array element of the object has as its initial value the corresponding element from $u$.

— When an object of an array type is specified to have a default initial value, this shall be interpreted to mean that each array element of the object has a default initial value.

— When a (sub)object of a non-array type $U$ is specified to have an initial value of $v$, or $U(1\ldots)$, where $1\ldots$ is a list of constructor arguments, make_shared shall initialize this (sub)object via the expression $::\text{new}(pv)$ $U(v)$ or $::\text{new}(pv)$ $U(1\ldots)$ respectively, where $pv$ has type void* and points to storage suitable to hold an object of type $U$.

— When a (sub)object of a non-array type is specified to have an initial value of $v$, or $U(1\ldots)$, where $1\ldots$ is a list of constructor arguments, allocate_shared shall initialize this (sub)object via the expression

- $\text{allocator_traits<A2>:\text{construct}}(a2, pv, v)$ or
- $\text{allocator_traits<A2>:\text{construct}}(a2, pv, 1\ldots)$

respectively, where $pv$ points to storage suitable to hold an object of type $U$ and $a2$ of type $A2$ is a rebound copy of the allocator $a$ passed to allocate_shared such that its value_type is remove_cv_t<U>.

— When a (sub)object of non-array type $U$ is specified to have a default initial value, make_shared shall initialize this (sub)object via the expression $::\text{new}(pv)$ $U()$, where $pv$ has type void* and points to storage suitable to hold an object of type $U$.

— When a (sub)object of non-array type $U$ is specified to have a default initial value, allocate_shared shall initialize this (sub)object via the expression $\text{allocator_traits<A2>:\text{construct}}(a2, pv)$, where $pv$ points to storage suitable to hold an object of type $U$ and $a2$ of type $A2$ is a rebound copy of the allocator $a$ passed to allocate_shared such that its value_type is remove_cv_t<u>.

— When a (sub)object of non-array type $U$ is initialized by make_shared_for_overwrite or allocate_shared_for_overwrite, it is initialized via the expression $::\text{new}(pv)$ $U$, where $pv$ has type void* and points to storage suitable to hold an object of type $U$.

— Array elements are initialized in ascending order of their addresses.

— When the lifetime of the object managed by the return value ends, or when the initialization of an array element throws an exception, the initialized elements are destroyed in the reverse order of their original construction.

— When a (sub)object of non-array type $U$ that was initialized by make_shared is to be destroyed, it is destroyed via the expression $pv\text{->U()}$ where $pv$ points to that object of type $U$.

— When a (sub)object of non-array type $U$ that was initialized by allocate_shared is to be destroyed, it is destroyed via the expression $\text{allocator_traits<A2>:\text{destroy}}(a2, pv)$ where $pv$ points to that object of type remove_cv_t<U> and $a2$ of type $A2$ is a rebound copy of the allocator $a$ passed to allocate_shared such that its value_type is remove_cv_t<u>.

[Note 2: These functions will typically allocate more memory than sizeof(T) to allow for internal bookkeeping structures such as reference counts. — end note]
template<class T> shared_ptr<T>
make_shared(size_t N);            // T is U[]
template<class T, class A>
shared_ptr<T> allocate_shared(const A& a, size_t N);  // T is U[]

Constraints: T is of the form U[].

Returns: A shared_ptr to an object of type U[N] with a default initial value, where U is remove_extent_t<T>.

[Example 2:
shared_ptr<double[]> p = make_shared<double[]>(1024);
// shared_ptr to a value-initialized double[1024]
shared_ptr<double[]> q = make_shared<double[]>(6);
// shared_ptr to a value-initialized double[6]
— end example]

template<class T>
shared_ptr<T> make_shared();        // T is U[N]
template<class T, class A>
shared_ptr<T> allocate_shared(const A& a);  // T is U[N]

Constraints: T is of the form U[].

Returns: A shared_ptr to an object of type T with a default initial value.

[Example 3:
shared_ptr<double[]> p = make_shared<double[]>(1024);
// shared_ptr to a value-initialized double[1024]
shared_ptr<double[]> q = make_shared<double[]>(6);
// shared_ptr to a value-initialized double[6]
— end example]

template<class T>
shared_ptr<T> make_shared(size_t N,
const remove_extent_t<T>& u);       // T is U[]
template<class T, class A>
shared_ptr<T> allocate_shared(const A& a, size_t N,
const remove_extent_t<T>& u);       // T is U[]

Constraints: T is of the form U[].

Returns: A shared_ptr to an object of type U[N], where U is remove_extent_t<T> and each array element has an initial value of u.

[Example 4:
shared_ptr<double[]> p = make_shared<double[](1024, 1.0);
// shared_ptr to a double[], where each element is 1.0
shared_ptr<double[]> q = make_shared<double[](6, {1.0, 0.0});
// shared_ptr to a double[6] element is {1.0, 0.0}
shared_ptr<vector<int[]>() r = make_shared<vector<int[]>()(4, {1, 2});
// shared_ptr to a vector<int[]>[4], where each vector has contents {1, 2}
— end example]

template<class T>
shared_ptr<T> make_shared(const remove_extent_t<T>& u); // T is U[N]
template<class T, class A>
shared_ptr<T> allocate_shared(const A& a,
const remove_extent_t<T>& u); // T is U[N]

Constraints: T is of the form U[].

Returns: A shared_ptr to an object of type T, where each array element of type remove_extent_t<T> has an initial value of u.

[Example 5:
shared_ptr<double[1024]> p = make_shared<double[](1024, 1.0);}
// shared_ptr to a double[1024], where each element is 1.0
shared_ptr<double[6][2]> q = make_shared<double[6][2]>({1.0, 0.0});
// shared_ptr to a double[6][2], where each double[2] element is {1.0, 0.0}
// shared_ptr to a vector<int>[4], where each vector has contents {1, 2}
—end example

template<class T>
shared_ptr<T> make_shared_for_overwrite();

template<class T, class A>
shared_ptr<T> allocate_shared_for_overwrite(const A& a);

Constraints: T is not an array of unknown bound.
Returns: A shared_ptr to an object of type T.

[Example 6:
struct X { double data[1024]; };
shared_ptr<X> p = make_shared_for_overwrite<X>();
// shared_ptr to a default-initialized X, where each element in X::data has an indeterminate value
shared_ptr<double[1024]> q = make_shared_for_overwrite<double[1024]>();
// shared_ptr to a default-initialized double[1024], where each element has an indeterminate value
—end example]

template<class T>
shared_ptr<T> make_shared_for_overwrite(size_t N);

template<class T, class A>
shared_ptr<T> allocate_shared_for_overwrite(const A& a, size_t N);

Constraints: T is an array of unknown bound.
Returns: A shared_ptr to an object of type U[N], where U is remove_extent_t<T>.

[Example 7:
shared_ptr<double[]> p = make_shared_for_overwrite<double[]>(1024);
// shared_ptr to a default-initialized double[1024], where each element has an indeterminate value
—end example]

20.11.3.8 Comparison [util.smartptr.shared.cmp]

template<class T, class U>
bool operator==(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
Returns: a.get() == b.get.

template<class T>
bool operator==(const shared_ptr<T>& a, nullptr_t) noexcept;
Returns: !a.

template<class T, class U>
strong_ordering operator<=>(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
Returns: compare_three_way()(a.get(), b.get()).
[Note 1: Defining a comparison operator function allows shared_ptr objects to be used as keys in associative containers. — end note]

template<class T>
strong_ordering operator<=>(const shared_ptr<T>& a, nullptr_t) noexcept;
Returns: compare_three_way()(a.get(), static_cast<typename shared_ptr<T>::element_type*>(nullptr)).

20.11.3.9 Specialized algorithms [util.smartptr.shared.spec]

§ 20.11.3.9 650
void swap(shared_ptr<T>& a, shared_ptr<T>& b) noexcept;

**Effects:** Equivalent to a.swap(b).

### 20.11.3.10 Casts

#### template<class T, class U>
shared_ptr<T> static_pointer_cast(const shared_ptr<U>& r) noexcept;

**Mandates:** The expression `static_cast<T*>(U*)nullptr` is well-formed.

**Returns:**

- Shared_ptr<T>(R, static_cast<typename shared_ptr<T>::element_type*>(r.get()))

  where R is r for the first overload, and std::move(r) for the second.

  [Note 1: The seemingly equivalent expression `shared_ptr<T>(static_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

#### template<class T, class U>
shared_ptr<T> dynamic_pointer_cast(const shared_ptr<U>& r) noexcept;

**Mandates:** The expression `dynamic_cast<T*>(U*)nullptr` is well-formed. The expression `dynamic_cast<typename shared_ptr<T>::element_type*>(r.get())` is well-formed.

**Preconditions:** The expression `dynamic_cast<typename shared_ptr<T>::element_type*>(r.get())` has well-defined behavior.

**Returns:**

- When `dynamic_cast<typename shared_ptr<T>::element_type*>(r.get())` returns a non-null value p, shared_ptr<T>(R, p), where R is r for the first overload, and std::move(r) for the second.

- Otherwise, shared_ptr<T>().

  [Note 2: The seemingly equivalent expression `shared_ptr<T>(dynamic_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

#### template<class T, class U>
shared_ptr<T> const_pointer_cast(const shared_ptr<U>& r) noexcept;

**Mandates:** The expression `const_cast<T*>(U*)nullptr` is well-formed.

**Returns:**

- Shared_ptr<T>(R, const_cast<typename shared_ptr<T>::element_type*>(r.get()))

  where R is r for the first overload, and std::move(r) for the second.

  [Note 3: The seemingly equivalent expression `shared_ptr<T>(const_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

#### template<class T, class U>
shared_ptr<T> reinterpret_pointer_cast(const shared_ptr<U>& r) noexcept;

**Mandates:** The expression `reinterpret_cast<T*>(U*)nullptr` is well-formed.

**Returns:**

- Shared_ptr<T>(R, reinterpret_cast<typename shared_ptr<T>::element_type*>(r.get()))

  where R is r for the first overload, and std::move(r) for the second.

  [Note 4: The seemingly equivalent expression `shared_ptr<T>(reinterpret_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. — end note]
20.11.3.11  get_deleter

```cpp
template<class D, class T>
D* get_deleter(const shared_ptr<T>& p) noexcept;
```

Returns: If p owns a deleter d of type cv-unqualified D, returns `addressof(d)`; otherwise returns `nullptr`. The returned pointer remains valid as long as there exists a `shared_ptr` instance that owns d.

[Note 1: It is unspecified whether the pointer remains valid longer than that. This can happen if the implementation doesn’t destroy the deleter until all `weak_ptr` instances that share ownership with p have been destroyed. — end note]

20.11.3.12  I/O

```cpp
template<class E, class T, class Y>
basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const shared_ptr<Y>& p);
```

Effects: As if by: `os << p.get();`

Returns: `os`.

20.11.4  Class template weak_ptr

20.11.4.1  General

The `weak_ptr` class template stores a weak reference to an object that is already managed by a `shared_ptr`. To access the object, a `weak_ptr` can be converted to a `shared_ptr` using the member function `lock`.

```cpp
namespace std {
    template<class T> class weak_ptr {
        public:
            using element_type = remove_extent_t<T>;

            // 20.11.4.2, constructors
            constexpr weak_ptr() noexcept;
            template<class Y>
                weak_ptr(const shared_ptr<Y>& r) noexcept;
            weak_ptr(const weak_ptr& r) noexcept;
            template<class Y>
                weak_ptr(const weak_ptr<Y>& r) noexcept;
            weak_ptr(weak_ptr&& r) noexcept;
            template<class Y>
                weak_ptr(weak_ptr<Y>&& r) noexcept;

            // 20.11.4.3, destructor
            ~weak_ptr();

            // 20.11.4.4, assignment
            weak_ptr& operator=(const weak_ptr& r) noexcept;
            template<class Y>
                weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
            template<class Y>
                weak_ptr& operator=(const shared_ptr<Y>& r) noexcept;
            weak_ptr& operator=(weak_ptr&& r) noexcept;
            template<class Y>
                weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;

            // 20.11.4.5, modifiers
            void swap(weak_ptr& r) noexcept;
            void reset() noexcept;

            // 20.11.4.6, observers
            long use_count() const noexcept;
            bool expired() const noexcept;
            template<class U>
                bool owner_before(const shared_ptr<U>& b) const noexcept;
            shared_ptr<T> lock() const noexcept;
        }
    }
}
```
Specializations of `weak_ptr` shall be `Cpp17CopyConstructible` and `Cpp17CopyAssignable`, allowing their use in standard containers. The template parameter `T` of `weak_ptr` may be an incomplete type.

### 20.11.4.2 Constructors

```cpp
template<class U>
bool owner_before(const weak_ptr<U>& b) const noexcept;
```

```cpp
weak_ptr(shared_ptr<T>) -> weak_ptr<T>;
```

2 Specializations of `weak_ptr` shall be `Cpp17CopyConstructible` and `Cpp17CopyAssignable`, allowing their use in standard containers. The template parameter `T` of `weak_ptr` may be an incomplete type.

#### Constructor

```cpp
constexpr weak_ptr() noexcept;
```

1 Effects: Constructs an empty `weak_ptr` object that stores a null pointer value.

2 Postconditions: `use_count() == 0`.

```cpp
weak_ptr(const weak_ptr& r) noexcept;
```

3 Constraints: For the first constructor, `Y*` is compatible with `T*`. If `r` is empty, constructs an empty `weak_ptr` object that stores a null pointer value; otherwise, constructs a `weak_ptr` object that shares ownership with `r` and stores a copy of the pointer stored in `r`.

4 Postconditions: `use_count() == r.use_count()`.

```cpp
weak_ptr(weak_ptr&& r) noexcept;
```

6 Constraints: For the second constructor, `Y*` is compatible with `T*`. If `r` is empty, stores a null pointer value, and `r.use_count() == 0`.

7 Effects: Move constructs a `weak_ptr` instance from `r`.

8 Postconditions: `*this` contains the old value of `r`. `r` is empty, stores a null pointer value, and `r.use_count() == 0`.

### 20.11.4.3 Destructor

```cpp
~weak_ptr();
```

1 Effects: Destroys this `weak_ptr` object but has no effect on the object its stored pointer points to.

### 20.11.4.4 Assignment

```cpp
weak_ptr& operator=(const weak_ptr& r) noexcept;
```

1 Effects: Equivalent to `weak_ptr(r).swap(*this)`.

2 Returns: `*this`.

3 Remarks: The implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary object.

```cpp
weak_ptr& operator=(weak_ptr&& r) noexcept;
```

4 Effects: Equivalent to `weak_ptr(std::move(r)).swap(*this)`.

5 Returns: `*this`.

### 20.11.4.5 Modifiers

```cpp
void swap(weak_ptr& r) noexcept;
```

1 Effects: Exchanges the contents of `*this` and `r`.

```cpp
void reset() noexcept;
```

2 Effects: Equivalent to `weak_ptr().swap(*this)`.

§ 20.11.4.5
20.11.4.6 Observers

long use_count() const noexcept;

Returns: 0 if *this is empty; otherwise, the number of shared_ptr instances that share ownership with *this.

bool expired() const noexcept;

Returns: use_count() == 0.

shared_ptr<T> lock() const noexcept;

Returns: expired() ? shared_ptr<T>() : shared_ptr<T>(*this), executed atomically.

template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;

Returns: An unspecified value such that

— x.owner_before(y) defines a strict weak ordering as defined in 25.8;
— under the equivalence relation defined by owner_before, !a.owner_before(b) && !b.owner_before(a), two shared_ptr or weak_ptr instances are equivalent if and only if they share ownership or are both empty.

20.11.4.7 Specialized algorithms

template<class T>
void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;

Effects: Equivalent to a.swap(b).

20.11.5 Class template owner_less

The class template owner_less allows ownership-based mixed comparisons of shared and weak pointers.

namespace std {
    template<class T = void> struct owner_less;

    template<class T> struct owner_less<shared_ptr<T>> {
        bool operator()(const shared_ptr<T>&, const shared_ptr<T>&) const noexcept;
        bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
        bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
    };

    template<class T> struct owner_less<weak_ptr<T>> {
        bool operator()(const weak_ptr<T>&, const weak_ptr<T>&) const noexcept;
        bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
        bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
    };

    template<> struct owner_less<void> {
        template<class T, class U>
        bool operator()(const shared_ptr<T>&, const shared_ptr<U>&) const noexcept;
        template<class T, class U>
        bool operator()(const shared_ptr<T>&, const weak_ptr<U>&) const noexcept;
        template<class T, class U>
        bool operator()(const weak_ptr<T>&, const shared_ptr<U>&) const noexcept;
        template<class T, class U>
        bool operator()(const weak_ptr<T>&, const weak_ptr<U>&) const noexcept;
        using is_transparent = unspecified;
    };
}

operator()(x, y) returns x.owner_before(y).

[Note 1: Note that

— operator() defines a strict weak ordering as defined in 25.8;]
two `shared_ptr` or `weak_ptr` instances are equivalent under the equivalence relation defined by `operator()`, `!operator()(a, b) \&\& !operator()(b, a)`, if and only if they share ownership or are both empty.

—end note

20.11.6 Class template `enable_shared_from_this`  
A class `T` can inherit from `enable_shared_from_this<T>` to inherit the `shared_from_this` member functions that obtain a `shared_ptr` instance pointing to `*this`.

Example 1:
```cpp
struct X: public enable_shared_from_this<X> { }

int main() {
    shared_ptr<X> p(new X);
    shared_ptr<X> q = p->shared_from_this();
    assert(p == q);
    assert(!p.owner_before(q) && !q.owner_before(p)); // p and q share ownership
}
```
—end example

namespace std {
    template<class T> class enable_shared_from_this {
    protected:
        constexpr enable_shared_from_this() noexcept;
        enable_shared_from_this(const enable_shared_from_this&) noexcept;
        enable_shared_from_this& operator=(const enable_shared_from_this&) noexcept;
        ~enable_shared_from_this();

    public:
        shared_ptr<T> shared_from_this();
        shared_ptr<T const> shared_from_this() const;
        weak_ptr<T> weak_from_this() noexcept;
        weak_ptr<T const> weak_from_this() const noexcept;

    private:
        mutable weak_ptr<T> weak_this; // exposition only
    };
}

The template parameter `T` of `enable_shared_from_this` may be an incomplete type.

```cpp
constexpr enable_shared_from_this() noexcept;
enable_shared_from_this(const enable_shared_from_this<T>&) noexcept;

Effects: Value-initializes `weak_this`.

enable_shared_from_this<T>& operator=(const enable_shared_from_this<T>&) noexcept;

Returns: `*this`.

[Note 1: `weak_this` is not changed. — end note]

shared_ptr<T> shared_from_this();
shared_ptr<T const> shared_from_this() const;

Returns: `shared_ptr<T>(weak_this)`.

weak_ptr<T> weak_from_this() noexcept;
weak_ptr<T const> weak_from_this() const noexcept;

Returns: `weak_this`.
```

20.11.7 Smart pointer hash support

Letting `UP` be `unique_ptr<T,D>`, the specialization `hash<UP>` is enabled (20.14.19) if and only if `hash<typename UP::pointer>` is enabled. When enabled, for an object `p` of type `UP`, `hash<UP>()(p)`
evaluates to the same value as `hash<typename UP::pointer>()(p.get())`. The member functions are not guaranteed to be `noexcept`.

```cpp
template<class T> struct hash<shared_ptr<T>>;
```

For an object `p` of type `shared_ptr<T>`, `hash<shared_ptr<T>>()(p)` evaluates to the same value as `hash<typename shared_ptr<T>::element_type*>(p.get())`.

### 20.12 Memory resources

#### 20.12.1 Header `<memory_resource>` synopsis

```cpp
namespace std::pmr {
    // 20.12.2, class memory_resource
    class memory_resource;

    bool operator==(const memory_resource& a, const memory_resource& b) noexcept;

    // 20.12.3, class template polymorphic_allocator
    template<class Tp = byte> class polymorphic_allocator;

    template<class T1, class T2>
    bool operator==(const polymorphic_allocator<T1>& a, const polymorphic_allocator<T2>& b) noexcept;

    // 20.12.4, global memory resources
    memory_resource* new_delete_resource() noexcept;
    memory_resource* null_memory_resource() noexcept;
    memory_resource* set_default_resource(memory_resource* r) noexcept;
    memory_resource* get_default_resource() noexcept;

    // 20.12.5, pool resource classes
    struct pool_options;
    class synchronized_pool_resource;
    class unsynchronized_pool_resource;
    class monotonic_buffer_resource;
}
```

### 20.12.2 Class memory_resource

#### 20.12.2.1 General

The `memory_resource` class is an abstract interface to an unbounded set of classes encapsulating memory resources.

```cpp
namespace std::pmr {
    class memory_resource {
        static constexpr size_t max_align = alignof(max_align_t);  // exposition only

    public:
        memory_resource() = default;
        memory_resource(const memory_resource&) = default;
        virtual ~memory_resource();

        memory_resource& operator=(const memory_resource&) = default;

        [[nodiscard]] void* allocate(size_t bytes, size_t alignment = max_align);
        void deallocate(void* p, size_t bytes, size_t alignment = max_align);

        bool is_equal(const memory_resource& other) const noexcept;

    private:
        virtual void* do_allocate(size_t bytes, size_t alignment) = 0;
        virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;
    }
}
```
virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;
};

20.12.2.2 Public member functions [mem.res.public]

~memory_resource();

Effects: Destroys this memory_resource.

[[nodiscard]] void* allocate(size_t bytes, size_t alignment = max_align);

Effects: Equivalent to: return do_allocate(bytes, alignment);

void deallocate(void* p, size_t bytes, size_t alignment = max_align);

Effects: Equivalent to do_deallocate(p, bytes, alignment).

bool is_equal(const memory_resource& other) const noexcept;

Effects: Equivalent to: return do_is_equal(other);

20.12.2.3 Private virtual member functions [mem.res.private]

virtual void* do_allocate(size_t bytes, size_t alignment) = 0;

Preconditions: alignment is a power of two.

Returns: A derived class shall implement this function to return a pointer to allocated storage (6.7.5.5.2) with a size of at least bytes, aligned to the specified alignment.

Throws: A derived class implementation shall throw an appropriate exception if it is unable to allocate memory with the requested size and alignment.

virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;

Preconditions: p was returned from a prior call to allocate(bytes, alignment) on a memory resource equal to *this, and the storage at p has not yet been deallocated.

Effects: A derived class shall implement this function to dispose of allocated storage.

Throws: Nothing.

virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;

Returns: A derived class shall implement this function to return true if memory allocated from this can be deallocated from other and vice-versa, otherwise false.

[Note 1: It is possible that the most-derived type of other does not match the type of this. For a derived class D, an implementation of this function can immediately return false if dynamic_cast<const D*>(&other) == nullptr. — end note]

20.12.2.4 Equality [mem.res.eq]

bool operator==(const memory_resource& a, const memory_resource& b) noexcept;

Returns: ka == &b || a.is_equal(b).

20.12.3 Class template polymorphic_allocator [mem.poly.allocation.class]

20.12.3.1 General [mem.poly.allocation.class.general]

A specialization of class template pmr::polymorphic_allocator meets the Cpp17Allocator requirements (Table 38). Constructed with different memory resources, different instances of the same specialization of pmr::polymorphic_allocator can exhibit entirely different allocation behavior. This runtime polymorphism allows objects that use polymorphic_allocator to behave as if they used different allocator types at run time even though they use the same static allocator type.

All specializations of class template pmr::polymorphic_allocator meet the allocator completeness requirements (16.4.4.6.2).

namespace std::pmr {
  template<class Tp = byte> class polymorphic_allocator {
    memory_resource* memory_rsrc; // exposition only
  
`§ 20.12.3.1`
public:
    using value_type = Tp;

    // 20.12.3.2, constructors
    polymorphic_allocator() noexcept;
    polymorphic_allocator(memory_resource* r);

    polymorphic_allocator(const polymorphic_allocator& other) = default;

    template<class U>
    polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;

    polymorphic_allocator& operator=(const polymorphic_allocator&) = delete;

    // 20.12.3.3, member functions
    [[nodiscard]] Tp* allocate(size_t n);
    void deallocate(Tp* p, size_t n);

    [[nodiscard]] void* allocate_bytes(size_t nbytes, size_t alignment = alignof(max_align_t));
    void deallocate_bytes(void* p, size_t nbytes, size_t alignment = alignof(max_align_t));

    template<class T> [[nodiscard]] T* allocate_object(size_t n = 1);
    template<class T> void deallocate_object(T* p, size_t n = 1);

    template<class T, class... CtorArgs> [[nodiscard]] T* new_object(CtorArgs&&... ctor_args);
    template<class T> void delete_object(T* p);

    template<class T, class... Args>
    void construct(T* p, Args&&... args);

    polymorphic_allocator select_on_container_copy_construction() const;

    memory_resource* resource() const;
};
void* allocate_bytes(size_t nbytes, size_t alignment = alignof(max_align_t));

Effects: Equivalent to: return memory_rsrc->allocate(nbytes, alignment);

[Note 1: The return type is void* (rather than, e.g., byte*) to support conversion to an arbitrary pointer type U* by static_cast<U*>(), thus facilitating construction of a U object in the allocated memory. — end note]

void deallocate_bytes(void* p, size_t nbytes, size_t alignment = alignof(max_align_t));

Effects: Equivalent to memory_rsrc->deallocate(p, nbytes, alignment).

template<class T>
[[nodiscard]] T* allocate_object(size_t n = 1);

Effects: Allocates memory suitable for holding an array of n objects of type T, as follows:

— if numeric_limits<size_t>::max() / sizeof(T) < n, throws bad_array_new_length,
— otherwise equivalent to:

    return static_cast<T*>(allocate_bytes(n*sizeof(T), alignof(T)));

[Note 2: T is not deduced and must therefore be provided as a template argument. — end note]

template<class T>
void deallocate_object(T* p, size_t n = 1);

Effects: Equivalent to deallocate_bytes(p, n*sizeof(T), alignof(T)).

template<class T, class... CtorArgs>
[[nodiscard]] T* new_object(CtorArgs&&... ctor_args);

Effects: Allocates and constructs an object of type T, as follows.
Equivalent to:

    T* p = allocate_object<T>();
    try {
        construct(p, std::forward<CtorArgs>(ctor_args)...);
        catch (...) {
            deallocate_object(p);
            throw;
        }
    }
    return p;

[Note 3: T is not deduced and must therefore be provided as a template argument. — end note]

template<class T>
void delete_object(T* p);

Effects: Equivalent to:

    allocator_traits<polymorphic_allocator>::destroy(*this, p);
    deallocate_object(p);

template<class T, class... Args>
void construct(T* p, Args&&... args);

Mandates: Uses-allocator construction of T with allocator *this (see 20.10.8.2) and constructor arguments std::forward<Args>(args)... is well-formed.

Effects: Construct a T object in the storage whose address is represented by p by uses-allocator construction with allocator *this and constructor arguments std::forward<Args>(args)....

Throws: Nothing unless the constructor for T throws.

polymorphic_allocator select_on_container_copy_construction() const;

Returns: polymorphic_allocator().

[Note 4: The memory resource is not propagated. — end note]

memory_resource* resource() const;

Returns: memory_rsrc.
20.12.3.4 Equality

```cpp
template<class T1, class T2>
bool operator==(const polymorphic_allocator<T1>& a,
               const polymorphic_allocator<T2>& b) noexcept;
```

Returns: \(*a.resource() == *b.resource()\).

20.12.4 Access to program-wide memory_resource objects

```cpp
memory_resource* new_delete_resource() noexcept;
```

Returns: A pointer to a static-duration object of a type derived from memory_resource that can serve as a resource for allocating memory using ::operator new and ::operator delete. The same value is returned every time this function is called. For a return value \(p\) and a memory resource \(r\), \(p->is_equal(r)\) returns \&r == p.

```cpp
memory_resource* null_memory_resource() noexcept;
```

Returns: A pointer to a static-duration object of a type derived from memory_resource for which allocate() always throws bad_alloc and for which deallocate() has no effect. The same value is returned every time this function is called. For a return value \(p\) and a memory resource \(r\), \(p->is_equal(r)\) returns \&r == p.

The default memory resource pointer is a pointer to a memory resource that is used by certain facilities when an explicit memory resource is not supplied through the interface. Its initial value is the return value of new_delete_resource().

```cpp
memory_resource* set_default_resource(memory_resource* r) noexcept;
```

Effects: If \(r\) is non-null, sets the value of the default memory resource pointer to \(r\), otherwise sets the default memory resource pointer to new_delete_resource().

Returns: The previous value of the default memory resource pointer.

Remarks: Calling the set_default_resource and get_default_resource functions shall not incur a data race. A call to the set_default_resource function shall synchronize with subsequent calls to the set_default_resource and get_default_resource functions.

```cpp
memory_resource* get_default_resource() noexcept;
```

Returns: The current value of the default memory resource pointer.

20.12.5 Pool resource classes

20.12.5.1 Classes synchronized_pool_resource and unsynchronized_pool_resource

The synchronized_pool_resource and unsynchronized_pool_resource classes (collectively called pool resource classes) are general-purpose memory resources having the following qualities:

1. Each resource frees its allocated memory on destruction, even if deallocate has not been called for some of the allocated blocks.
2. A pool resource consists of a collection of pools, serving requests for different block sizes. Each individual pool manages a collection of chunks that are in turn divided into blocks of uniform size, returned via calls to do_allocate. Each call to do_allocate(size, alignment) is dispatched to the pool serving the smallest blocks accommodating at least size bytes.
3. When a particular pool is exhausted, allocating a block from that pool results in the allocation of an additional chunk of memory from the upstream allocator (supplied at construction), thus replenishing the pool. With each successive replenishment, the chunk size obtained increases geometrically. [Note 1: By allocating memory in chunks, the pooling strategy increases the chance that consecutive allocations will be close together in memory. — end note]
4. Allocation requests that exceed the largest block size of any pool are fulfilled directly from the upstream allocator.
5. A pool_options struct may be passed to the pool resource constructors to tune the largest block size and the maximum chunk size.
A synchronized_pool_resource may be accessed from multiple threads without external synchronization and may have thread-specific pools to reduce synchronization costs. An unsynchronized_pool_resource class may not be accessed from multiple threads simultaneously and thus avoids the cost of synchronization entirely in single-threaded applications.

```cpp
namespace std::pmr {
    struct pool_options {
        size_t max_blocks_per_chunk = 0;
        size_t largest_required_pool_block = 0;
    };

class synchronized_pool_resource : public memory_resource {
    public:
        synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

        synchronized_pool_resource() : synchronized_pool_resource(pool_options(), get_default_resource()) {}  
        explicit synchronized_pool_resource(memory_resource* upstream) : synchronized_pool_resource(pool_options(), upstream) {}  
        explicit synchronized_pool_resource(const pool_options& opts) : synchronized_pool_resource(opts, get_default_resource()) {}  

        synchronized_pool_resource(const synchronized_pool_resource&) = delete;  
        virtual ~synchronized_pool_resource();

        synchronized_pool_resource& operator=(const synchronized_pool_resource&) = delete;

        void release();
        memory_resource* upstream_resource() const;
        pool_options options() const;

    protected:
        void* do_allocate(size_t bytes, size_t alignment) override;
        void do_deallocate(void* p, size_t bytes, size_t alignment) override;

        bool do_is_equal(const memory_resource& other) const noexcept override;
    };

class unsynchronized_pool_resource : public memory_resource {
    public:
        unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

        unsynchronized_pool_resource() : unsynchronized_pool_resource(pool_options(), get_default_resource()) {}  
        explicit unsynchronized_pool_resource(memory_resource* upstream) : unsynchronized_pool_resource(pool_options(), upstream) {}  
        explicit unsynchronized_pool_resource(const pool_options& opts) : unsynchronized_pool_resource(opts, get_default_resource()) {}  

        unsynchronized_pool_resource(const unsynchronized_pool_resource&) = delete;  
        virtual ~unsynchronized_pool_resource();

        unsynchronized_pool_resource& operator=(const unsynchronized_pool_resource&) = delete;

        void release();
        memory_resource* upstream_resource() const;
        pool_options options() const;

    protected:
        void* do_allocate(size_t bytes, size_t alignment) override;
        void do_deallocate(void* p, size_t bytes, size_t alignment) override;

        bool do_is_equal(const memory_resource& other) const noexcept override;
    };
}
```
The members of pool_options comprise a set of constructor options for pool resources. The effect of each option on the pool resource behavior is described below:

- **size_t max_blocks_per_chunk;**
  - The maximum number of blocks that will be allocated at once from the upstream memory resource (20.12.6) to replenish a pool. If the value of `max_blocks_per_chunk` is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose to use a smaller value than is specified in this field and may use different values for different pools.

- **size_t largest_required_pool_block;**
  - The largest allocation size that is required to be fulfilled using the pooling mechanism. Attempts to allocate a single block larger than this threshold will be allocated directly from the upstream memory resource. If `largest_required_pool_block` is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose a pass-through threshold larger than specified in this field.

### Constructors and destructors

- **synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);**
  - **Preconditions:** upstream is the address of a valid memory resource.
  - **Effects:** Constructs a pool resource object that will obtain memory from upstream whenever the pool resource is unable to satisfy a memory request from its own internal data structures. The resulting object will hold a copy of `upstream`, but will not own the resource to which `upstream` points.
    - [Note 1: The intention is that calls to `upstream->allocate()` will be substantially fewer than calls to `this->allocate()` in most cases. —end note]
    - The behavior of the pooling mechanism is tuned according to the value of the `opts` argument.
  - **Throws:** Nothing unless `upstream->allocate()` throws. It is unspecified if, or under what conditions, this constructor calls `upstream->allocate()`.

- **unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);**

- **virtual ~synchronized_pool_resource();**
- **virtual ~unsynchronized_pool_resource();**
  - **Effects:** Calls `release()`.

### Members

- **void release();**
  - **Effects:** Calls `upstream_resource()->deallocate()` as necessary to release all allocated memory.
    - [Note 1: The memory is released back to `upstream_resource()` even if `deallocate` has not been called for some of the allocated blocks. —end note]

- **memory_resource* upstream_resource() const;**
  - **Returns:** The value of the `upstream` argument provided to the constructor of this object.

- **pool_options options() const;**
  - **Returns:** The options that control the pooling behavior of this resource. The values in the returned struct may differ from those supplied to the pool resource constructor in that values of zero will be replaced with implementation-defined defaults, and sizes may be rounded to unspecified granularity.

- **void* do_allocate(size_t bytes, size_t alignment) override;**
  - **Effects:** If the pool selected for a block of size `bytes` is unable to satisfy the memory request from its own internal data structures, it will call `upstream_resource()->allocate()` to obtain more memory. If `bytes` is larger than that which the largest pool can handle, then memory will be allocated using `upstream_resource()->allocate()`.

---

\[\text{§ 20.12.5.4} \] 662
Returns: A pointer to allocated storage (6.7.5.2) with a size of at least bytes. The size and alignment of the allocated memory shall meet the requirements for a class derived from memory_resource (20.12.2).

Throws: Nothing unless upstream_resource()->allocate() throws.

```cpp
void do_deallocate(void* p, size_t bytes, size_t alignment) override;
```

Effects: Returns the memory at p to the pool. It is unspecified if, or under what circumstances, this operation will result in a call to upstream_resource()->deallocate().

Throws: Nothing.

```cpp
bool do_is_equal(const memory_resource& other) const noexcept override;
```

Returns: this == &other.

20.12.6 Class monotonic_buffer_resource

20.12.6.1 General

A monotonic_buffer_resource is a special-purpose memory resource intended for very fast memory allocations in situations where memory is used to build up a few objects and then is released all at once when the memory resource object is destroyed.

```cpp
namespace std::pmr {
class monotonic_buffer_resource : public memory_resource {
  memory_resource* upstream_rsrc; // exposition only
  void* current_buffer; // exposition only
  size_t next_buffer_size; // exposition only

  public:
    explicit monotonic_buffer_resource(memory_resource* upstream);
    monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);
    monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);
    monotonic_buffer_resource() : monotonic_buffer_resource(get_default_resource()) {}
    explicit monotonic_buffer_resource(size_t initial_size) : monotonic_buffer_resource(initial_size, get_default_resource()) {}
    monotonic_buffer_resource(void* buffer, size_t buffer_size) : monotonic_buffer_resource(buffer, buffer_size, get_default_resource()) {}

    monotonic_buffer_resource(const monotonic_buffer_resource&) = delete;
    virtual ~monotonic_buffer_resource();

    monotonic_buffer_resource& operator=(const monotonic_buffer_resource&) = delete;

    void release();
    memory_resource* upstream_resource() const;

    protected:
      void* do_allocate(size_t bytes, size_t alignment) override;
      void do_deallocate(void* p, size_t bytes, size_t alignment) override;

      bool do_is_equal(const memory_resource& other) const noexcept override;
};
```

20.12.6.2 Constructors and destructor

```cpp
explicit monotonic_buffer_resource(memory_resource* upstream);
monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);
```

Preconditions: upstream is the address of a valid memory resource. initial_size, if specified, is greater than zero.
monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);

Preconditions: upstream is the address of a valid memory resource. buffer_size is no larger than the number of bytes in buffer.

Effects: Sets upstream_rsrc to upstream, current_buffer to buffer, and next_buffer_size to buffer_size (but not less than 1), then increases next_buffer_size by an implementation-defined growth factor (which need not be integral).

~monotonic_buffer_resource();

Effects: Calls release().

20.12.6.3 Members

void release();

Effects: Calls upstream_rsrc->deallocate() as necessary to release all allocated memory. Resets current_buffer and next_buffer_size to their initial values at construction.

[Note 1: The memory is released back to upstream_rsrc even if some blocks that were allocated from this have not been deallocated from this. — end note]

memory_resource* upstream_resource() const;

Returns: The value of upstream_rsrc.

void* do_allocate(size_t bytes, size_t alignment) override;

Effects: If the unused space in current_buffer can fit a block with the specified bytes and alignment, then allocate the return block from current_buffer; otherwise set current_buffer to upstream_rsrc->allocate(n, m), where n is not less than max(bytes, next_buffer_size) and m is not less than alignment, and increase next_buffer_size by an implementation-defined growth factor (which need not be integral), then allocate the return block from the newly-allocated current_buffer.

Returns: A pointer to allocated storage (6.7.5.5.2) with a size of at least bytes. The size and alignment of the allocated memory shall meet the requirements for a class derived from memory_resource (20.12.2).

Throws: Nothing unless upstream_rsrc->allocate() throws.

void do_deallocate(void* p, size_t bytes, size_t alignment) override;

Effects: None.

Throws: Nothing.

Remarks: Memory used by this resource increases monotonically until its destruction.

bool do_is_equal(const memory_resource& other) const noexcept override;

Returns: this == &other.

20.13 Class template scoped_allocator_adaptor

20.13.1 Header <scoped_allocator> synopsis

namespace std {

// class template scoped allocator adaptor
template<class OuterAlloc, class... InnerAllocs>
class scoped_allocator_adaptor;

// 20.13.5, scoped allocator operators
template<class OuterA1, class OuterA2, class... InnerAllocs>
bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
               const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
}

The class template scoped_allocator_adaptor is an allocator template that specifies an allocator resource (the outer allocator) to be used by a container (as any other allocator does) and also specifies an inner allocator.
resource to be passed to the constructor of every element within the container. This adaptor is instantiated with one outer and zero or more inner allocator types. If instantiated with only one allocator type, the inner allocator becomes the scoped_allocator_adaptor itself, thus using the same allocator resource for the container and every element within the container and, if the elements themselves are containers, each of their elements recursively. If instantiated with more than one allocator, the first allocator is the outer allocator for use by the container, the second allocator is passed to the constructors of the container’s elements, and, if the elements themselves are containers, the third allocator is passed to the elements’ elements, and so on. If containers are nested to a depth greater than the number of allocators, the last allocator is used repeatedly, as in the single-allocator case, for any remaining recursions.

[Note 1: The scoped_allocator_adaptor is derived from the outer allocator type so it can be substituted for the outer allocator type in most expressions. —end note]

namespace std {
    template<class OuterAlloc, class... InnerAllocs>
    class scoped_allocator_adaptor : public OuterAlloc {
    private:
        using OuterTraits = allocator_traits<OuterAlloc>;  // exposition only
        scoped_allocator_adaptor<InnerAllocs...> inner;     // exposition only

    public:
        using outer_allocator_type = OuterAlloc;
        using inner_allocator_type = see below;
        using value_type = typename OuterTraits::value_type;
        using size_type = typename OuterTraits::size_type;
        using difference_type = typename OuterTraits::difference_type;
        using pointer = typename OuterTraits::pointer;
        using const_pointer = typename OuterTraits::const_pointer;
        using void_pointer = typename OuterTraits::void_pointer;
        using const_void_pointer = typename OuterTraits::const_void_pointer;

        using propagate_on_container_copy_assignment = see below;
        using propagate_on_container_move_assignment = see below;
        using propagate_on_container_swap = see below;

template<class T, class... Args>
  void construct(T* p, Args&&... args);

template<class T>
  void destroy(T* p);

scoped_allocator_adaptor select_on_container_copy_construction() const;

};

template<class OuterAlloc, class... InnerAllocs>
scoped_allocator_adaptor(OuterAlloc, InnerAllocs...)
  -> scoped_allocator_adaptor<OuterAlloc, InnerAllocs...>;

20.13.2 Member types

using inner_allocator_type = see below;

1 Type: scoped_allocator_adaptor<OuterAlloc> if sizeof...(InnerAllocs) is zero; otherwise, scoped_allocator_adaptor<InnerAllocs...>.

using propagate_on_container_copy_assignment = see below;

2 Type: true_type if allocator_traits<A>::propagate_on_container_copy_assignment::value is true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using propagate_on_container_move_assignment = see below;

3 Type: true_type if allocator_traits<A>::propagate_on_container_move_assignment::value is true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using propagate_on_container_swap = see below;

4 Type: true_type if allocator_traits<A>::propagate_on_container_swap::value is true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using is_always_equal = see below;

5 Type: true_type if allocator_traits<A>::is_always_equal::value is true for every A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

20.13.3 Constructors

scoped_allocator_adaptor();

1 Effects: Value-initializes the OuterAlloc base class and the inner allocator object.

template<class OuterA2>
  scoped_allocator_adaptor(OuterA2& outerAlloc, const InnerAllocs&... innerAllocs) noexcept;

2 Constraints: is_constructible_v<OuterAlloc, OuterA2> is true.

3 Effects: Initializes the OuterAlloc base class with std::forward<OuterA2>(outerAlloc) and inner with innerAllocs... (hence recursively initializing each allocator within the adaptor with the corresponding allocator from the argument list).

scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;

4 Effects: Initializes each allocator within the adaptor with the corresponding allocator from other.
scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;
5    \textit{Effects:} Move constructs each allocator within the adaptor with the corresponding allocator from \textit{other}.

\begin{verbatim}
template<class OuterA2>
    scoped_allocator_adaptor(
        const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& other) noexcept;

    \textit{Constraints:} is_constructible_v<OuterAlloc, const OuterA2&> is true.

    \textit{Effects:} Initializes each allocator within the adaptor with the corresponding allocator from \textit{other}.
\end{verbatim}

\begin{verbatim}
template<class OuterA2>
    scoped_allocator_adaptor(scoped_allocator_adaptor<OuterA2, InnerAllocs...>&& other) noexcept;

    \textit{Constraints:} is_constructible_v<OuterAlloc, OuterA2> is true.

    \textit{Effects:} Initializes each allocator within the adaptor with the corresponding allocator rvalue from \textit{other}.
\end{verbatim}

\section{20.13.4 Members [allocator.adaptor.members]}

In the \textit{construct} member functions, \textit{OUTERMOST}(x) is \textit{OUTERMOST}(x.outer_allocator()) if the expression x.outer_allocator() is valid \((13.10.3)\) and \textit{x} otherwise; \textit{OUTERMOST_ALLOC_TRAITS}(x) is allocator_traits<remove_reference_t<\textit{OUTERMOST}(x)>>.

\textbf{Note 1:} \textit{OUTERMOST}(x) and \textit{OUTERMOST_ALLOC_TRAITS}(x) are recursive operations. It is incumbent upon the definition of \textit{outer_allocator()} to ensure that the recursion terminates. It will terminate for all instantiations of \textit{scoped_allocator_adaptor}. \textit{— end note}\n
\begin{verbatim}
inner_allocator_type& inner_allocator() noexcept;
const inner_allocator_type& inner_allocator() const noexcept;

outer_allocator_type& outer_allocator() noexcept;
const outer_allocator_type& outer_allocator() const noexcept;

[[nodiscard]] pointer allocate(size_type n);

[[nodiscard]] pointer allocate(size_type n, const_void_pointer hint);

void deallocate(pointer p, size_type n) noexcept;

size_type max_size() const;
\end{verbatim}

\section{§ 20.13.4 Members [allocator.adaptor.members]}

\begin{verbatim}
void construct(T* p, Args&&... args);
\end{verbatim}

\textbf{Effects:} Equivalent to:

\begin{verbatim}
apply([p, \textit{this}](auto&&... newargs) {
    \textit{OUTERMOST_ALLOC_TRAITS}(*\textit{this})::construct(
        \textit{OUTERMOST}(*\textit{this}), p,
        std::forward<decltype(newargs)>(newargs)...);
    uses_allocator_construction_args<T>(\textit{inner_allocator()},
        std::forward<Args>(args)...));
\end{verbatim}
template<class T>
void destroy(T* p);

Effects: Calls OUTERMOST_ALLOC_TRAITS(*this)::destroy(OUTERMOST(*this), p).

scoped_allocator_adaptor select_on_container_copy_construction() const;

Returns: A new scoped_allocator_adaptor object where each allocator A in the adaptor is initialized
from the result of calling allocator_traits<A>::select_on_container_copy_construction() on
the corresponding allocator in *this.

20.13.5 Operators

template<class OuterA1, class OuterA2, class... InnerAllocs>
bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;

Returns: If sizeof...(InnerAllocs) is zero,
   a.outer_allocator() == b.outer_allocator()
otherwise
   a.outer_allocator() == b.outer_allocator() && a.inner_allocator() == b.inner_allocator()

20.14 Function objects

20.14.1 General

A function object type is an object type (6.8) that can be the type of the postfix-expression in a function call
(7.6.1.3, 12.2.2.2). A function object is an object of a function object type. In the places where one would
expect to pass a pointer to a function to an algorithmic template (Clause 25), the interface is specified to
accept a function object. This not only makes algorithmic templates work with pointers to functions, but
also enables them to work with arbitrary function objects.

20.14.2 Header <functional> synopsis

namespace std {
   // 20.14.5, invoke
   template<class F, class... Args>
   constexpr invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
      noexcept(is_nothrow_invocable_v<F, Args...>);

   // 20.14.6, reference_wrapper
   template<class T> class reference_wrapper;
   template<class T> constexpr reference_wrapper<T> ref(T&) noexcept;
   template<class T> constexpr reference_wrapper<const T> cref(const T&) noexcept;
   template<class T> void ref(const T&) = delete;
   template<class T> void cref(const T&) = delete;
   template<class T> constexpr reference_wrapper<T> ref(reference_wrapper<T>) noexcept;
   template<class T> constexpr reference_wrapper<const T> cref(reference_wrapper<T>) noexcept;

// 20.14.18, searchers
template<class ForwardIterator, class BinaryPredicate = equal_to<>>
class default_searcher;

template<class RandomAccessIterator,
    class Hash = hash<typename iterator_traits<RandomAccessIterator>::value_type>,
    class BinaryPredicate = equal_to<>>
class boyer_moore_searcher;

template<class RandomAccessIterator,
    class Hash = hash<typename iterator_traits<RandomAccessIterator>::value_type>,
    class BinaryPredicate = equal_to<>>
class boyer_moore_horspool_searcher;

// 20.14.19, class template hash
template<class T>
struct hash;

namespace ranges {
  // 20.14.9, concept-constrained comparisons
  struct equal_to;
  struct not_equal_to;
  struct greater;
  struct less;
  struct greater_equal;
  struct less_equal;
}

Example 1: If a C++ program wants to have a by-element addition of two vectors a and b containing double and put the result into a, it can do:
transform(a.begin(), a.end(), b.begin(), a.begin(), plus<double>())
—end example

Example 2: To negate every element of a:
transform(a.begin(), a.end(), a.begin(), negate<double>())
—end example

20.14.3 Definitions

The following definitions apply to this Clause:

A call signature is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.
A **callable type** is a function object type (20.14) or a pointer to member.

A **callable object** is an object of a callable type.

A **call wrapper type** is a type that holds a callable object and supports a call operation that forwards to that object.

A **call wrapper** is an object of a call wrapper type.

A **target object** is the callable object held by a call wrapper.

A call wrapper type may additionally hold a sequence of objects and references that may be passed as arguments to the target object. These entities are collectively referred to as **bound argument entities**.

The **target object** and bound argument entities of the call wrapper are collectively referred to as **state entities**.

### 20.14.4 Requirements

1. Define ```INVOKE(f, t₁, t₂, ..., tₙ)``` as follows:

   1.1. `(t₁.*f)(t₂, ..., tₙ)` when `f` is a pointer to a member function of a class `T` and `is_base_of_v<T, remove_reference_t<decltype(t₁)>>` is true;

   1.2. `(t₁.get().*f)(t₂, ..., tₙ)` when `f` is a pointer to a member function of a class `T` and `remove_cvref_t<decltype(t₁)>::is_a<T>` is a specialization of `reference_wrapper`;

   1.3. `(*t₁).*f(t₂, ..., tₙ)` when `f` is a pointer to a member function of a class `T` and `t₁` does not satisfy the previous two items;

   1.4. `t₁.*f` when `N == 1` and `f` is a pointer to data member of a class `T` and `is_base_of_v<T, remove_reference_t<decltype(t₁)>>` is true;

   1.5. `t₁.get().*f` when `N == 1` and `f` is a pointer to data member of a class `T` and `remove_cvref_t<decltype(t₁)>::is_a<T>` is a specialization of `reference_wrapper`;

   1.6. `(*t₁).*f` when `N == 1` and `f` is a pointer to data member of a class `T` and `t₁` does not satisfy the previous two items;

   1.7. `f(t₁, t₂, ..., tₙ)` in all other cases.

2. Define ```INVOKE<R>(f, t₁, t₂, ..., tₙ)``` as `static_cast<void>(INVOKE(f, t₁, t₂, ..., tₙ))` if `R` is `cv void` otherwise ```INVOKE(f, t₁, t₂, ..., tₙ)``` implicitly converted to `R`.

3. Every call wrapper (20.14.3) meets the **Cpp17MoveConstructible** and **Cpp17Destructible** requirements. An **argument forwarding call wrapper** is a call wrapper that can be called with an arbitrary argument list and delivers the arguments to the wrapped callable object as references. This forwarding step delivers rvalue arguments as rvalue references and lvalue arguments as lvalue references.

   *Note 1:* In a typical implementation, argument forwarding call wrappers have an overloaded function call operator of the form

   ```
   template<class... UnBoundArgs>
   constexpr R operator()(UnBoundArgs&&... unbound_args) cv-gsl;
   ```

   *end note*

4. A **perfect forwarding call wrapper** is an argument forwarding call wrapper that forwards its state entities to the underlying call expression. This forwarding step delivers a state entity of type `T` as `cv T&` when the call is performed on an lvalue of the call wrapper type and as `cv T&&` otherwise, where `cv` represents the cv-qualifiers of the call wrapper and where `cv` shall be neither `volatile` nor `const volatile`.

5. A **call pattern** defines the semantics of invoking a perfect forwarding call wrapper. A postfix call performed on a perfect forwarding call wrapper is expression-equivalent (3.21) to an expression `e` determined from its call pattern `cp` by replacing all occurrences of the arguments of the call wrapper and its state entities with references as described in the corresponding forwarding steps.

6. A **simple call wrapper** is a perfect forwarding call wrapper that meets the **Cpp17CopyConstructible** and **Cpp17CopyAssignable** requirements and whose copy constructor, move constructor, and assignment operators are constexpr functions that do not throw exceptions.

7. The copy/move constructor of an argument forwarding call wrapper has the same apparent semantics as if memberwise copy/move of its state entities were performed (11.4.5.3).
[Note 2: This implies that each of the copy/move constructors has the same exception-specification as the corresponding implicit definition and is declared as constexpr if the corresponding implicit definition would be considered to be constexpr. — end note]

8 Argument forwarding call wrappers returned by a given standard library function template have the same type if the types of their corresponding state entities are the same.

20.14.5 Function template invoke

```
.tmplatetemplate<class F, class... Args>
constexpr invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
    noexcept(is_nothrow_invocable_v<F, Args...>);
```

1 Returns: INVOLVE(std::forward<F>(f), std::forward<Args>(args)...) (20.14.4).

20.14.6 Class template reference_wrapper

20.14.6.1 General

```
namespace std {
    template<class T> class reference_wrapper {
    public:
        // types
        using type = T;

        // construct/copy/destroy
        template<class U>
            constexpr reference_wrapper(U&&) noexcept(see below);
        constexpr reference_wrapper(const reference_wrapper& x) noexcept;

        // assignment
        constexpr reference_wrapper& operator=(const reference_wrapper& x) noexcept;

        // access
        constexpr operator T& () const noexcept;
        constexpr T& get() const noexcept;

        // invocation
        template<class... ArgTypes>
            constexpr invoke_result_t<T&, ArgTypes...> operator()(ArgTypes&&...) const;
    }
}
```

1 reference_wrapper<T> is a Cpp17CopyConstructible and Cpp17CopyAssignable wrapper around a reference to an object or function of type T.

2 reference_wrapper<T> is a trivially copyable type (6.8).

3 The template parameter T of reference_wrapper may be an incomplete type.

20.14.6.2 Constructors and destructor

```
template<class U>
constexpr reference_wrapper(U&& u) noexcept(see below);
```

1 Let FUN denote the exposition-only functions

   void FUN(T&) noexcept;
   void FUN(T&&) = delete;

2 Constraints: The expression FUN(declval<U>()) is well-formed and is_same_v<remove_cvref_t<U>,
    reference_wrapper> is false.

3 Effects: Creates a variable r as if by T& r = std::forward<U>(u), then constructs a reference_-
    wrapper object that stores a reference to r.

4 Remarks: The exception specification is equivalent to noexcept(FUN(declval<U>()));
constexpr reference_wrapper(const reference_wrapper& x) noexcept;
5
Effects: Constructs a reference_wrapper object that stores a reference to x.get().

20.14.6.3 Assignment [refwrap.assign]
constexpr reference_wrapper& operator=(const reference_wrapper& x) noexcept;
1
Postconditions: *this stores a reference to x.get().

20.14.6.4 Access [refwrap.access]
constexpr operator T& () const noexcept;
1
Returns: The stored reference.
constexpr T& get() const noexcept;
2
Returns: The stored reference.

20.14.6.5 Invocation [refwrap.invoke]
template<class... ArgTypes>
constexpr invoke_result_t<T&, ArgTypes...> operator()(ArgTypes&&... args) const;
1
Mandates: T is a complete type.
2
Returns: INVOKE(get(), std::forward<ArgTypes>(args)...). (20.14.4)

20.14.6.6 Helper functions [refwrap.helpers]
1
The template parameter T of the following ref and cref function templates may be an incomplete type.
template<class T> constexpr reference_wrapper<T> ref(T& t) noexcept;
2
Returns: reference_wrapper<T>(t).
template<class T> constexpr reference_wrapper<T> ref(reference_wrapper<T> t) noexcept;
3
Returns: ref(t.get()).
template<class T> constexpr reference_wrapper<const T> cref(const T& t) noexcept;
4
Returns: cref(t.get()).

20.14.7 Arithmetic operations [arithmetic.operations]
20.14.7.1 General [arithmetic.operations.general]
1
The library provides basic function object classes for all of the arithmetic operators in the language (7.6.5, 7.6.6).

20.14.7.2 Class template plus [arithmetic.operations.plus]
template<class T = void> struct plus {
    constexpr T operator()(const T& x, const T& y) const;
};
constexpr T operator()(const T& x, const T& y) const;
1
Returns: x + y.
template<> struct plus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) + std::forward<U>(u));
        using is_transparent = unspecified;
};
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) + std::forward<U>(u));

2 Returns: std::forward<T>(t) + std::forward<U>(u).

20.14.7.3 Class template minus [arithmetic.operations.minus]

template<class T = void> struct minus {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1 Returns: x - y.

template<> struct minus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) - std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) - std::forward<U>(u));

2 Returns: std::forward<T>(t) - std::forward<U>(u).

20.14.7.4 Class template multiplies [arithmetic.operations.multiplies]

template<class T = void> struct multiplies {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1 Returns: x * y.

template<> struct multiplies<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) * std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) * std::forward<U>(u));

2 Returns: std::forward<T>(t) * std::forward<U>(u).

20.14.7.5 Class template divides [arithmetic.operations.divides]

template<class T = void> struct divides {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1 Returns: x / y.

template<> struct divides<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) / std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) / std::forward<U>(u));

2 Returns: std::forward<T>(t) / std::forward<U>(u).
20.14.7.6  Class template modulus

```cpp
template<class T = void> struct modulus {
    constexpr T operator()(const T& x, const T& y) const;
};
```

Returns: \( x \% y \).

```cpp
template<> struct modulus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) % std::forward<U>(u));
};
```

Returns: \( \text{std::forward}(t) \% \text{std::forward}(u) \).

20.14.7.7  Class template negate

```cpp
template<class T = void> struct negate {
    constexpr T operator()(const T& x) const;
};
```

Returns: \(-x\).

```cpp
template<> struct negate<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(-std::forward<T>(t));
};
```

Returns: \(-\text{std::forward}(t)\).

20.14.8  Comparisons

20.14.8.1  General

The library provides basic function object classes for all of the comparison operators in the language (7.6.9, 7.6.10).

For templates \texttt{less}, \texttt{greater}, \texttt{less_equal}, and \texttt{greater_equal}, the specializations for any pointer type yield a result consistent with the implementation-defined strict total order over pointers (3.27).

\[ \text{Note 1: If } a < b \text{ is well-defined for pointers } a \text{ and } b \text{ of type } P, \text{ then } (a < b) = \text{less}<P>()(a, b), (a > b) = \text{greater}<P>()(a, b), \text{ and so forth.} \quad \text{—end note} \]

For template specializations \texttt{less<void>}, \texttt{greater<void>}, \texttt{less_equal<void>}, and \texttt{greater_equal<void>}, if the call operator calls a built-in operator comparing pointers, the call operator yields a result consistent with the implementation-defined strict total order over pointers.

20.14.8.2  Class template equal_to

```cpp
template<class T = void> struct equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

Returns: \( x == y \).
template<> struct equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) == std::forward<U>(u));
    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) == std::forward<U>(u));
2

20.14.8.3 Class template not_equal_to
[comparisons.not.equal.to]
template<class T = void> struct not_equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};
constexpr bool operator()(const T& x, const T& y) const;
1
Returns: x != y.

template<> struct not_equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) != std::forward<U>(u));
    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) != std::forward<U>(u));
2
Returns: std::forward<T>(t) != std::forward<U>(u).

20.14.8.4 Class template greater
[comparisons.greater]
template<class T = void> struct greater {
    constexpr bool operator()(const T& x, const T& y) const;
};
constexpr bool operator()(const T& x, const T& y) const;
1
Returns: x > y.

template<> struct greater<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) > std::forward<U>(u));
    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) > std::forward<U>(u));
2
Returns: std::forward<T>(t) > std::forward<U>(u).

20.14.8.5 Class template less
[comparisons.less]
template<class T = void> struct less {
    constexpr bool operator()(const T& x, const T& y) const;
};
constexpr bool operator()(const T& x, const T& y) const;
1
Returns: x < y.

template<> struct less<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) < std::forward<U>(u));
};
using is_transparent = unspecified;
};
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) < std::forward<U>(u));

2

Returns: std::forward<T>(t) < std::forward<U>(u).

20.14.8.6 Class template greater_equal

[comparisons.greater.equal]
template<class T = void> struct greater_equal {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

1

Returns: x >= y.

template<> struct greater_equal<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) >= std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) >= std::forward<U>(u));

2

Returns: std::forward<T>(t) >= std::forward<U>(u).

20.14.8.7 Class template less_equal

[comparisons.less.equal]
template<class T = void> struct less_equal {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

1

Returns: x <= y.

template<> struct less_equal<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) <= std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) <= std::forward<U>(u));

2

Returns: std::forward<T>(t) <= std::forward<U>(u).

20.14.8.8 Class compare_three_way

[comparisons.three.way]

In this subclause, BUILTIN-PTR-THREE-WAY(T, U) for types T and U is a boolean constant expression. BUILTIN-PTR-THREE-WAY(T, U) is true if and only if <=> in the expression

declval<T>() <=> declval<U>()

resolves to a built-in operator comparing pointers.

struct compare_three_way {
    template<class T, class U>
        requires three_way_comparable_with<T, U> || BUILTIN-PTR-THREE-WAY(T, U)
        constexpr auto operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};
template<class T, class U>
requires three_way_comparable_with<T, U> || BUILTIN-PTR-THREE-WAY(T, U)
constexpr auto operator()(T&& t, U&& u) const;

Preconditions: If the expression std::forward<T>(t) <=> std::forward<U>(u) results in a call to a built-in operator <=> comparing pointers of type P, the conversion sequences from both T and U to P are equality-preserving (18.2).

Effects:
(3.1) — If the expression std::forward<T>(t) <=> std::forward<U>(u) results in a call to a built-in operator <=> comparing pointers of type P, returns strong_ordering::less if (the converted value of) t precedes u in the implementation-defined strict total order over pointers (3.27), strong_ordering::greater if u precedes t, and otherwise strong_ordering::equal.
(3.2) — Otherwise, equivalent to: return std::forward<T>(t) <=> std::forward<U>(u);

20.14.9 Concept-constrained comparisons

In this subclause, BUILTIN-PTR-CMP(T, op, U) for types T and U and where op is an equality (7.6.10) or relational operator (7.6.9) is a boolean constant expression. BUILTIN-PTR-CMP(T, op, U) is true if and only if op in the expression declval<T>() op declval<U>() resolves to a built-in operator comparing pointers.

struct ranges::equal_to {
  template<class T, class U>
  requires equality_comparable_with<T, U> || BUILTIN-PTR-CMP(T, ==, U)
  constexpr bool operator()(T&& t, U&& u) const;
  using is_transparent = unspecified;
};

Preconditions: If the expression std::forward<T>(t) == std::forward<U>(u) results in a call to a built-in operator == comparing pointers of type P, the conversion sequences from both T and U to P are equality-preserving (18.2).

Effects:
(3.1) — If the expression std::forward<T>(t) == std::forward<U>(u) results in a call to a built-in operator == comparing pointers: returns false if either (the converted value of) t precedes u or u precedes t in the implementation-defined strict total order over pointers (3.27) and otherwise true.
(3.2) — Otherwise, equivalent to: return std::forward<T>(t) == std::forward<U>(u);

struct ranges::not_equal_to {
  template<class T, class U>
  requires equality_comparable_with<T, U> || BUILTIN-PTR-CMP(T, ==, U)
  constexpr bool operator()(T&& t, U&& u) const;
  using is_transparent = unspecified;
};

operator() has effects equivalent to:
return !ranges::equal_to{}(std::forward<T>(t), std::forward<U>(u));

struct ranges::greater {
  template<class T, class U>
  requires totally_ordered_with<T, U> || BUILTIN-PTR-CMP(U, <, T)
  constexpr bool operator()(T&& t, U&& u) const;
  using is_transparent = unspecified;
};

operator() has effects equivalent to:
return ranges::less{}(std::forward<U>(u), std::forward<T>(t));
struct ranges::less {
    template<class T, class U>
        requires totally_ordered_with<T, U> || BUILTIN-PTR-CMP(T, <, U)
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

6  Preconditions: If the expression std::forward<T>(t) < std::forward<U>(u) results in a call to a built-in operator < comparing pointers of type P, the conversion sequences from both T and U to P are equality-preserving (18.2). For any expressions ET and EU such that decltype((ET)) is T and decltype((EU)) is U, exactly one of ranges::less{}(ET, EU), ranges::less{}(EU, ET), or ranges::equal_to{}(ET, EU) is true.

7  Effects:
(7.1) — If the expression std::forward<T>(t) < std::forward<U>(u) results in a call to a built-in operator < comparing pointers: returns true if (the converted value of) t precedes u in the implementation-defined strict total order over pointers (3.27) and otherwise false.
(7.2) — Otherwise, equivalent to: return std::forward<T>(t) < std::forward<U>(u);

struct ranges::greater_equal {
    template<class T, class U>
        requires totally_ordered_with<T, U> || BUILTIN-PTR-CMP(U, <, T)
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

8  operator() has effects equivalent to:
    return !ranges::less{}(std::forward<T>(t), std::forward<U>(u));

struct ranges::less_equal {
    template<class T, class U>
        requires totally_ordered_with<T, U> || BUILTIN-PTR-CMP(U, <, T)
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

9  operator() has effects equivalent to:
    return !ranges::less{}(std::forward<U>(u), std::forward<T>(t));

20.14.10 Logical operations
20.14.10.1 General

The library provides basic function object classes for all of the logical operators in the language (7.6.14, 7.6.15, 7.6.2.2).

20.14.10.2 Class template logical_and

template<class T = void> struct logical_and {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

1  Returns: x && y.

template<> struct logical_and<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) && std::forward<U>(u));

    using is_transparent = unspecified;
};
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) && std::forward<U>(u));

Returns: std::forward<T>(t) && std::forward<U>(u).

20.14.10.3 Class template logical_or

template<class T = void> struct logical_or {
constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x || y.

template<> struct logical_or<void> {
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) || std::forward<U>(u));

using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) || std::forward<U>(u));

Returns: std::forward<T>(t) || std::forward<U>(u).

20.14.10.4 Class template logical_not

template<class T = void> struct logical_not {
constexpr bool operator()(const T& x) const;
};

constexpr bool operator()(const T& x) const;

Returns: !x.

template<> struct logical_not<void> {
template<class T> constexpr auto operator()(T&& t) const
-> decltype(!std::forward<T>(t));

using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
-> decltype(!std::forward<T>(t));

Returns: !std::forward<T>(t).

20.14.11 Bitwise operations

20.14.11.1 General

The library provides basic function object classes for all of the bitwise operators in the language (7.6.11, 7.6.13, 7.6.12, 7.6.2.2).

20.14.11.2 Class template bit_and

template<class T = void> struct bit_and {
constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x & y.

template<> struct bit_and<void> {
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) & std::forward<U>(u));
using is_transparent = unspecified;
);

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) & std::forward<U>(u));

  Returns: std::forward<T>(t) & std::forward<U>(u).

20.14.11.3 Class template bit_or

template<class T = void> struct bit_or {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1 Returns: x | y.

template<> struct bit_or<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) | std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) | std::forward<U>(u));

2 Returns: std::forward<T>(t) | std::forward<U>(u).

20.14.11.4 Class template bit_xor

template<class T = void> struct bit_xor {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1 Returns: x ^ y.

template<> struct bit_xor<void> {
  template<class T> constexpr auto operator()(T&& t) const
    -> decltype(~std::forward<T>(t));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) ^ std::forward<U>(u));

2 Returns: std::forward<T>(t) ^ std::forward<U>(u).

20.14.11.5 Class template bit_not

template<class T = void> struct bit_not {
  constexpr T operator()(const T& x) const;
};

constexpr T operator()(const T& x) const;

1 Returns: ~x.

template<> struct bit_not<void> {
  template<class T> constexpr auto operator()(T&& t) const
    -> decltype(~std::forward<T>(t));

  using is_transparent = unspecified;
};
template<class T> constexpr auto operator()(T&&) const
  -> decltype(~std::forward<T>(t));

Returns: ~std::forward<T>(t).

20.14.12 Class identity

struct identity {
  template<class T>
    constexpr T&& operator()(T&& t) const noexcept;

  using is_transparent = unspecified;
};

template<class T>
  constexpr T&& operator()(T&& t) const noexcept;

1 Effects: Equivalent to: return std::forward<T>(t);

20.14.13 Function template not_fn

template<class F> constexpr unspecified not_fn(F&& f);

In the text that follows:
(1.1) g is a value of the result of a not_fn invocation,
(1.2) FD is the type decay_t<F>,
(1.3) fd is the target object of g (20.14.3) of type FD, direct-non-list-initialized with std::forward<F>
>\(\langle f\rangle\),
(1.4) call_args is an argument pack used in a function call expression (7.6.1.3) of g.

Mandates: is_constructible_v<FD, F> && is_move_constructible_v<FD> is true.

Preconditions: FD meets the Cpp17MoveConstructible requirements.

Returns: A perfect forwarding call wrapper g with call pattern invoke(fd, call_args...).

Throws: Any exception thrown by the initialization of fd.

20.14.14 Function template bind_front

template<class F, class... Args>
  constexpr unspecified bind_front(F&& f, Args&&... args);

Within this subclause:
(1.1) g is a value of the result of a bind_front invocation,
(1.2) FD is the type decay_t<F>,
(1.3) fd is the target object of g (20.14.3) of type FD, direct-non-list-initialized with std::forward<F>
>\(\langle f\rangle\),
(1.4) BoundArgs is a pack that denotes decay_t<Args>..., 
(1.5) bound_args is a pack of bound argument entities of g (20.14.3) of types BoundArgs..., direct-
non-list-initialized with std::forward<Args>(args)..., respectively, and
(1.6) call_args is an argument pack used in a function call expression (7.6.1.3) of g.

Mandates:

\[
\begin{align*}
\text{is_constructible_v<FD, F>} & \land \\
\text{is_move_constructible_v<FD>} & \land \\
\text{is_constructible_v<BoundArgs, Args>} & \land \\
\text{is_move_constructible_v<BoundArgs>} & \land \\
\text{is_constructible_v<BoundArgs, Args>} & \land \\
\text{is_move_constructible_v<BoundArgs>} & \land 
\end{align*}
\]

is true.

Preconditions: FD meets the Cpp17MoveConstructible requirements. For each T\(_i\) in BoundArgs, if T\(_i\) is an object type, T\(_i\) meets the Cpp17MoveConstructible requirements.
4 Returns: A perfect forwarding call wrapper \( g \) with call pattern \( \text{invoke}(\text{fd}, \text{bound_args}..., \text{call_args}...) \).

5 Throws: Any exception thrown by the initialization of the state entities of \( g \) (20.14.3).

20.14.15 Function object binders

20.14.15.1 General

Subclause 20.14.15 describes a uniform mechanism for binding arguments of callable objects.

20.14.15.2 Class template is_bind_expression

The class template \( \text{is_bind_expression} \) can be used to detect function objects generated by \( \text{bind} \). The function template \( \text{bind} \) uses \( \text{is_bind_expression} \) to detect subexpressions.

Specializations of the \( \text{is_bind_expression} \) template shall meet the \text{Cpp17UnaryTypeTrait} requirements (20.15.2). The implementation provides a definition that has a base characteristic of \text{true_type} if \( T \) is a type returned from \( \text{bind} \), otherwise it has a base characteristic of \text{false_type}. A program may specialize this template for a program-defined type \( T \) to have a base characteristic of \text{true_type} to indicate that \( T \) should be treated as a subexpression in a \( \text{bind} \) call.

20.14.15.3 Class template is_placeholder

The class template \( \text{is_placeholder} \) can be used to detect the standard placeholders \_1, \_2, and so on. The function template \( \text{bind} \) uses \( \text{is_placeholder} \) to detect placeholders.

Specializations of the \( \text{is_placeholder} \) template shall meet the \text{Cpp17UnaryTypeTrait} requirements (20.15.2). The implementation provides a definition that has the base characteristic of \text{integral_constant\<int, J>\>} if \( T \) is the type of \( \text{std::placeholders::_J} \), otherwise it has a base characteristic of \text{integral_constant\<int, 0>\>}.

A program may specialize this template for a program-defined type \( T \) to have a base characteristic of \text{integral_constant\<int, N>\>} with \( N > 0 \) to indicate that \( T \) should be treated as a placeholder type.

20.14.15.4 Function template bind

In the text that follows:

- \( g \) is a value of the result of a \( \text{bind} \) invocation,
- \( \text{FD} \) is the type \text{decay_t<\text{F}>},
- \( \text{fd} \) is an lvalue that is a target object of \( g \) (20.14.3) of type \text{FD} direct-non-list-initialized with \text{std::forward<\text{F}>}(\text{f}),
- \( \text{T}_i \) is the \( i \)th type in the template parameter pack \( \text{BoundArgs} \),
- \( \text{TD}_i \) is the type \text{decay_t<\text{T}_i>},
- \( \text{t}_i \) is the \( i \)th argument in the function parameter pack \( \text{bound_args} \),
- \( \text{td}_i \) is a bound argument entity of \( g \) (20.14.3) of type \text{TD}_i direct-non-list-initialized with \text{std::forward<\text{T}_i>(\text{t}_i)},
- \( \text{U}_j \) is the \( j \)th deduced type of the \( \text{UnBoundArgs&&...} \) parameter of the argument forwarding call wrapper, and
- \( \text{u}_j \) is the \( j \)th argument associated with \( \text{U}_j \).

\[
\begin{align*}
\text{template<class F, class... BoundArgs>} \quad & \text{constexpr unspecified bind(F&& f, BoundArgs&&... bound_args);} \\
\text{template<class R, class F, class... BoundArgs>} \quad & \text{constexpr unspecified bind(F&& f, BoundArgs&&... bound_args);} \\
\end{align*}
\]

Mandates: \( \text{is_constructible\_v<\text{FD}, F>} \) is true. For each \( \text{T}_i \) in \( \text{BoundArgs} \), \( \text{is_constructible\_v<\text{TD}_i, \text{T}_i>} \) is true.
Preconditions: $F_D$ and each $T_D_i$ meet the `CopyConstructible` and `Destructible` requirements.

$\text{INVOKED}_D(v_1, v_2, \ldots, v_N)$ (20.14.4) is a valid expression for some values $v_1, v_2, \ldots, v_N$, where $N$ has the value $\text{sizeof}(...)$. (20.14.4)

Returns: An argument forwarding call wrapper $g$ (20.14.4). A program that attempts to invoke a volatile-qualified $g$ is ill-formed. When $g$ is not volatile-qualified, invocation of $g(u_1, u_2, \ldots, u_M)$ is expression-equivalent (3.21) to

$\text{INVOKED}_D_{\text{static}}(v_1, v_N)$,

$\text{static} \ast v_i(v_1), \text{static} \ast v_N(v_N)$

for the first overload, and

$\text{INVOKED}_D\text{R}_D(v_2, v_N)$,

$\text{static} \ast v_i(v_1), \text{static} \ast v_N(v_N)$

for the second overload, where the values and types of the target argument $v_{fd}$ and of the bound arguments $v_1, v_2, \ldots, v_N$ are determined as specified below.

Throws: Any exception thrown by the initialization of the state entities of $g$.

[Note 1: If all of $F_D$ and $T_D_i$ meet the requirements of `CopyConstructible`. then the return type meets the requirements of `CopyConstructible`. — end note]

The values of the `bound arguments` $v_1, v_2, \ldots, v_N$ and their corresponding types $V_1, V_2, \ldots, V_N$ depend on the types $T_D_i$ derived from the call to `bind` and the cv-qualifiers $cv$ of the call wrapper $g$ as follows:

1. if $T_D_i$ is `reference_wrapper<T>`, the argument is $\text{td}_i \text{.get}()$ and its type $V_i$ is $T$;
2. if the value of `is_bind_expression_v<TD_i>` is true, the argument is $\text{static} \ast \text{cv} \ast T_D_i \text{.get}()\text{.forward}(U_j)(u_j)\ldots$ and its type $V_i$ is $\text{invocation_result_t<cv} \ast T_D_i, U_j\ldots$;
3. if the value $j$ of `is_placeholder_v<TD_i>` is not zero, the argument is $\text{std}::\text{forward}<U_j>(u_j)$ and its type $V_i$ is $U_j$;
4. otherwise, the value is $\text{td}_i$ and its type $V_i$ is $\text{cv} \ast T_D_i$.

The value of the target argument $v_{fd}$ is $fd$ and its corresponding type $V_{fd}$ is $\text{cv} \ast F_D \&$.

20.14.15.5 Placeholders

```cpp
namespace std::placeholders {
    // $M$ is the implementation-defined number of placeholders
    see below _1;
    see below _2;
    ...
    ...
    see below _M;
}
```

All placeholder types meet the `CopyConstructible` and `CopyConstructible` requirements, and their default constructors and copy/move constructors are constexpr functions that do not throw exceptions. It is implementation-defined whether placeholder types meet the `CopyConstructible` requirements, but if so, their copy assignment operators are constexpr functions that do not throw exceptions.

Placeholders should be defined as:

```cpp
inline constexpr unspecified _1{};
```

If they are not, they are declared as:

```cpp
extern unspecified _1;
```

20.14.16 Function template mem_fn

```cpp
template<class R, class T> constexpr mem_fn<R T::* pm) noexcept;
```

Returns: A simple call wrapper (20.14.3) $f_n$ with call pattern $\text{invoke}(pmd, \text{call_args})\ldots$, where $pmd$ is the target object of $f_n$ of type $R T::*$ direct-non-list-initialized with $pm$, and $\text{call_args}$ is an argument pack used in a function call expression (7.6.1.3) of $pm$.
20.14.17 Polymorphic function wrappers

20.14.17.1 General

Subclause 20.14.17 describes a polymorphic wrapper class that encapsulates arbitrary callable objects.

20.14.17.2 Class bad_function_call

An exception of type `bad_function_call` is thrown by `function::operator()` (20.14.17.3.5) when the function wrapper object has no target.

```cpp
namespace std {
    class bad_function_call : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    }
    const char* what() const noexcept override;

    Returns: An implementation-defined NTBS.
}
```

20.14.17.3 Class template function

20.14.17.3.1 General

```cpp
namespace std {
    template<class> class function; // not defined

template<class R, class... ArgTypes>
    class function<R(ArgTypes...)> {
        public:
            using result_type = R;

            // 20.14.17.3.2, construct/copy/destroy
            function() noexcept;
            function(nullptr_t) noexcept;
            function(const function&);
            function(function&&) noexcept;
            function(F);    
            template<class F> function(F);
            function& operator=(const function&);
            function& operator=(function&&);
            function& operator=(nullptr_t) noexcept;
            template<class F> function& operator=(reference_wrapper<F>) noexcept;
            function(F);    
            ~function();

            // 20.14.17.3.3, function modifiers
            void swap(function&) noexcept;

            // 20.14.17.3.4, function capacity
            explicit operator bool() const noexcept;

            // 20.14.17.3.5, function invocation
            R operator()(ArgTypes...) const;

            // 20.14.17.3.6, function target access
            const type_info& target_type() const noexcept;
            template<class T>
                T* target() noexcept;
            template<class T> const T* target() const noexcept;
        }
    }

template<class R, class... ArgTypes>
    function(R(*)(ArgTypes...)) -> function<R(ArgTypes...)>
```

§ 20.14.17.3.1

685
template<class F> function(F) -> function<see below>;
}

1. The `function` class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (20.14.3), given a call signature (20.14.3), allowing functions to be first-class objects.

2. A callable type (20.14.3) `F` is `Lvalue-Callable` for argument types `ArgTypes` and return type `R` if the expression `INVOKE<R>(declval<F&>(), declval<ArgTypes>()...)`, considered as an unevaluated operand (7.2), is well-formed (20.14.4).

3. The `function` class template is a call wrapper (20.14.3) whose call signature (20.14.3) is `R(ArgTypes...)`.

4. [Note 1: The types deduced by the deduction guides for `function` might change in future revisions of C++. — end note]

20.14.17.3.2 Constructors and destructor

function() noexcept;

1. Postconditions: `!*this`.

function(nullptr_t) noexcept;

2. Postconditions: `!*this`.

function(const function& f);

3. Postconditions: `!*this` if `!f`; otherwise, `*this` targets a copy of `f.target()`.

4. Throws: Nothing if `f`’s target is a specialization of `reference_wrapper` or a function pointer. Otherwise, may throw `bad_alloc` or any exception thrown by the copy constructor of the stored callable object.

5. Recommended practice: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f`’s target is an object holding only a pointer or reference to an object and a member function pointer.

function(function&& f) noexcept;

6. Postconditions: If `!f`, `*this` has no target; otherwise, the target of `*this` is equivalent to the target of `f` before the construction, and `f` is in a valid state with an unspecified value.

7. Recommended practice: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f`’s target is an object holding only a pointer or reference to an object and a member function pointer.

template<class F> function(F f);

8. Constraints: `F` is Lvalue-Callable (20.14.17.3) for argument types `ArgTypes...` and return type `R`.

9. Preconditions: `F` meets the `Cpp17CopyConstructible` requirements.

10. Postconditions: `!*this` if any of the following hold:

10.1. `f` is a null function pointer value.

10.2. `f` is a null member pointer value.

10.3. `F` is a specialization of the `function` class template, and `!f`.

11. Otherwise, `*this` targets a copy of `f` initialized with `std::move(f)`.

12. Throws: Nothing if `f` is a specialization of `reference_wrapper` or a function pointer. Otherwise, may throw `bad_alloc` or any exception thrown by `F`’s copy or move constructor.

13. Recommended practice: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f` is an object holding only a pointer or reference to an object and a member function pointer.

template<class F> function(F) -> function<see below>;

14. Constraints: `&F::operator()` is well-formed when treated as an unevaluated operand and `decltype(&F::operator())` is of the form `R(G::*)(A...) cv &opt noexcept opt` for a class type `G`.

15. Remarks: The deduced type is `function<R(A...)>`.
Example 1:

```cpp
void f() {
    int i{5};
    function g = [&](double) { return i; };  // deduces function<int(double)>
}
```

--- end example

function& operator=(const function& f);

*Effects:* As if by `function(f).swap(*this);`

*Returns:* *this.

function& operator=(function&& f);

*Effects:* Replaces the target of *this with the target of f.

*Returns:* *this.

function& operator=(nullptr_t) noexcept;

*Effects:* If *this != nullptr, destroys the target of this.

*Postconditions:* !(this).

*Returns:* *this.

```
template<class F> function& operator=(F&& f);
```

*Constraints:* `decay_t<F>` is Lvalue-Callable (20.14.17.3) for argument types `ArgTypes...` and return type R.

*Effects:* As if by: `function(std::forward<F>(f)).swap(*this);`

*Returns:* *this.

```
template<class F> function& operator=(reference_wrapper<F> f) noexcept;
```

*Effects:* As if by: `function(f).swap(*this);`

*Returns:* *this.

~function();

*Effects:* If *this != nullptr, destroys the target of this.

20.14.17.3.3 Modifiers

`void swap(function& other) noexcept;`

*Effects:* Interchanges the targets of *this and other.

20.14.17.3.4 Capacity

`explicit operator bool() const noexcept;`

*Returns:* true if *this has a target, otherwise false.

20.14.17.3.5 Invocation

R operator()(ArgTypes... args) const;

*Returns:* `INVOKE<f, std::forward<ArgTypes>(args)...>` (20.14.4), where f is the target object (20.14.3) of *this.

*Throws:* `bad_function_call` if *this; otherwise, any exception thrown by the wrapped callable object.

20.14.17.3.6 Target access

`const type_info& target_type() const noexcept;`

*Returns:* If *this has a target of type T, `typeid(T)`; otherwise, `typeid(void)`.
template<class T> T* target() noexcept;
template<class T> const T* target() const noexcept;

Returns: If target_type() == typeid(T) a pointer to the stored function target; otherwise a null pointer.

20.14.17.3.7 Null pointer comparison operator functions

template<class R, class... ArgTypes>
bool operator==(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;

Returns: !f.

20.14.17.3.8 Specialized algorithms

template<class R, class... ArgTypes>
void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2) noexcept;

Effects: As if by: f1.swap(f2);

20.14.18 Searchers

20.14.18.1 General

Subclause 20.14.18 provides function object types (20.14) for operations that search for a sequence [pat_first, pat_last) in another sequence [first, last) that is provided to the object’s function call operator. The first sequence (the pattern to be searched for) is provided to the object’s constructor, and the second (the sequence to be searched) is provided to the function call operator.

Each specialization of a class template specified in 20.14.18 shall meet the Cpp17CopyConstructible and Cpp17CopyAssignable requirements. Template parameters named

(2.1) — ForwardIterator,
(2.2) — ForwardIterator1,
(2.3) — ForwardIterator2,
(2.4) — RandomAccessIterator,
(2.5) — RandomAccessIterator1,
(2.6) — RandomAccessIterator2, and
(2.7) — BinaryPredicate

of templates specified in 20.14.18 shall meet the same requirements and semantics as specified in 25.1. Template parameters named Hash shall meet the Cpp17Hash requirements (Table 36).

3 The Boyer-Moore searcher implements the Boyer-Moore search algorithm. The Boyer-Moore-Horspool searcher implements the Boyer-Moore-Horspool search algorithm. In general, the Boyer-Moore searcher will use more memory and give better runtime performance than Boyer-Moore-Horspool.

20.14.18.2 Class template default_searcher

template<class ForwardIterator1, class BinaryPredicate = equal_to<>>
class default_searcher {
public:
constexpr default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last, 
BinaryPredicate pred = BinaryPredicate());

template<class ForwardIterator2>
constexpr pair<ForwardIterator2, ForwardIterator2>
operator()(ForwardIterator2 first, ForwardIterator2 last) const;

private:
ForwardIterator1 pat_first_; // exposition only
ForwardIterator1 pat_last_; // exposition only
BinaryPredicate pred_; // exposition only
};
constexpr default_searcher(ForwardIterator pat_first, ForwardIterator pat_last, 
   BinaryPredicate pred = BinaryPredicate());

Effects: Constructs a default_searcher object, initializing pat_first_ with pat_first, pat_last_ with pat_last, and pred_ with pred.

Throws: Any exception thrown by the copy constructor of BinaryPredicate or ForwardIterator1.

template<class ForwardIterator2>
constexpr pair<ForwardIterator2, ForwardIterator2> 
   operator()(ForwardIterator2 first, ForwardIterator2 last) const;

Effects: Returns a pair of iterators i and j such that

- (3.1) i == search(first, last, pat_first_, pat_last_, pred_), and
- (3.2) if i == last, then j == last, otherwise j == next(i, distance(pat_first_, pat_last_)).

20.14.18.3 Class template boyer_moore_searcher

template<class RandomAccessIterator1,
    class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
    class BinaryPredicate = equal_to<>>
    class boyer_moore_searcher {
    public:
        boyer_moore_searcher(RandomAccessIterator1 pat_first,
            RandomAccessIterator1 pat_last,
            Hash hf = Hash(),
            BinaryPredicate pred = BinaryPredicate());

          template<class RandomAccessIterator2>
            pair<RandomAccessIterator2, RandomAccessIterator2>
               operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

    private:
        RandomAccessIterator1 pat_first_; // exposition only
        RandomAccessIterator1 pat_last_; // exposition only
        Hash hash_; // exposition only
        BinaryPredicate pred_; // exposition only
    };

boyer_moore_searcher(RandomAccessIterator1 pat_first,
            RandomAccessIterator1 pat_last,
            Hash hf = Hash(),
            BinaryPredicate pred = BinaryPredicate());

Preconditions: The value type of RandomAccessIterator1 meets the Cpp17DefaultConstructible requirements, the Cpp17CopyConstructible requirements, and the Cpp17CopyAssignable requirements.

Let V be iterator_traits<RandomAccessIterator1>::value_type. For any two values A and B of type V, if pred(A, B) == true, then hf(A) == hf(B) is true.

Effects: Initializes pat_first_ with pat_first, pat_last_ with pat_last, hash_ with hf, and pred_ with pred.

Throws: Any exception thrown by the copy constructor of RandomAccessIterator1, or by the default constructor, copy constructor, or the copy assignment operator of the value type of RandomAccessIterator1, or the copy constructor or operator() of BinaryPredicate or Hash. May throw bad_alloc if additional memory needed for internal data structures cannot be allocated.

template<class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
   operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

Mandates: RandomAccessIterator1 and RandomAccessIterator2 have the same value type.

Effects: Finds a subsequence of equal values in a sequence.

Returns: A pair of iterators i and j such that
— i is the first iterator in the range \([\text{first}, \text{last} - (\text{pat_last_} - \text{pat_first_}))\) such that for every non-negative integer \(n\) less than \(\text{pat_last_} - \text{pat_first_}\) the following condition holds:

\[
\text{pred}(*(\text{i} + n), *(\text{pat_first_} + n)) \neq \text{false}, \text{ and}
\]

— \(j == \text{next}(\text{i}, \text{distance}(\text{pat_first_}, \text{pat_last_}))\).

Returns \(\text{make_pair}(\text{first}, \text{first})\) if \([\text{pat_first_}, \text{pat_last_})\) is empty, otherwise returns \(\text{make_pair}(\text{last}, \text{last})\) if no such iterator is found.

**Complexity:** At most \((\text{last} - \text{first}) \cdot (\text{pat_last_} - \text{pat_first_})\) applications of the predicate.

### 20.14.18.4 Class template boyer_moore_horspool_searcher

**template<class RandomAccessIterator1,**

...
Returns \texttt{make\_pair(first, first)} if \texttt{[pat\_first\_, pat\_last\_)} is empty, otherwise returns \texttt{make\_pair(last, last)} if no such iterator is found.

\textit{Complexity:} At most \((last - first) \times (pat\_last\_ - pat\_first\_)} applications of the predicate.

\section*{20.14.19 Class template \texttt{hash} \[unord.hash\]}

\begin{enumerate}
\item The unordered associative containers defined in 22.5 use specializations of the class template \texttt{hash} (20.14.2) as the default hash function.
\item Each specialization of \texttt{hash} is either enabled or disabled, as described below.
\begin{itemize}
\item [Note 1:] Enabled specializations meet the \texttt{Cpp17Hash} requirements, and disabled specializations do not. \hspace{-0.5em}— end note \end{itemize}
\item Each header that declares the template \texttt{hash} provides enabled specializations of \texttt{hash} for \texttt{nullptr\_t} and all cv-unqualified arithmetic, enumeration, and pointer types. For any type \texttt{Key} for which neither the library nor the user provides an explicit or partial specialization of the class template \texttt{hash}, \texttt{hash<Key>\}} is disabled.
\item If the library provides an explicit or partial specialization of \texttt{hash<Key>\}, that specialization is enabled except as noted otherwise, and its member functions are \texttt{noexcept} except as noted otherwise.
\item If \texttt{H} is a disabled specialization of \texttt{hash}, these values are \texttt{false}: \texttt{is\_default\_constructible\_v\<H\>\}, \texttt{is\_copy\_constructible\_v\<H\>\}, \texttt{is\_move\_constructible\_v\<H\>\}, \texttt{is\_copy\_assignable\_v\<H\>\}, and \texttt{is\_move\_assignable\_v\<H\>\}. Disabled specializations of \texttt{hash} are not function object types (20.14).
\begin{itemize}
\item [Note 2:] This means that the specialization of \texttt{hash} exists, but any attempts to use it as a \texttt{Cpp17Hash} will be ill-formed. \hspace{-0.5em}— end note \end{itemize}
\item An enabled specialization \texttt{hash<Key>\}} will:
\begin{enumerate}
\item — meet the \texttt{Cpp17Hash} requirements (Table 36), with \texttt{Key} as the function call argument type, the \texttt{Cpp17DefaultConstructible} requirements (Table 29), the \texttt{Cpp17CopyAssignable} requirements (Table 33),
\item — be swappable (16.4.4.3) for lvalues,
\item — meet the requirement that if \texttt{k1 == k2} is \texttt{true}, \texttt{h(k1) == h(k2)} is also \texttt{true}, where \texttt{h} is an object of type \texttt{hash<Key>\}} and \texttt{k1} and \texttt{k2} are objects of type \texttt{Key};
\item — meet the requirement that the expression \texttt{h(k)}, where \texttt{h} is an object of type \texttt{hash<Key>\}} and \texttt{k} is an object of type \texttt{Key}, shall not throw an exception unless \texttt{hash<Key>\}} is a program-defined specialization.
\end{enumerate}
\end{enumerate}

\section*{20.15 Metaprogramming and type traits \[meta\]}

\subsection*{20.15.1 General \[meta.general\]}

\begin{enumerate}
\item Subclause 20.15 describes components used by C++ programs, particularly in templates, to support the widest possible range of types, optimise template code usage, detect type related user errors, and perform type inference and transformation at compile time. It includes type classification traits, type property inspection traits, and type transformations. The type classification traits describe a complete taxonomy of all possible C++ types, and state where in that taxonomy a given type belongs. The type property inspection traits allow important characteristics of types or of combinations of types to be inspected. The type transformations allow certain properties of types to be manipulated.
\item All functions specified in 20.15 are signal-safe (17.13.5).
\end{enumerate}

\subsection*{20.15.2 Requirements \[meta rqmmts\]}

\begin{enumerate}
\item A \texttt{Cpp17UnaryTypeTrait} describes a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the property being described. It shall be \texttt{Cpp17DefaultConstructible}, \texttt{Cpp17CopyConstructible}, and publicly and unambiguously derived, directly or indirectly, from its \texttt{base characteristic}, which is a specialization of the template \texttt{integral\_constant\ (20.15.4)}, with the arguments to the template \texttt{integral\_constant\ \} determined by the requirements for the particular property being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the \texttt{Cpp17UnaryTypeTrait}.
\item A \texttt{Cpp17BinaryTypeTrait} describes a relationship between two types. It shall be a class template that takes two template type arguments and, optionally, additional arguments that help define the relationship being described. It shall be \texttt{Cpp17DefaultConstructible}, \texttt{Cpp17CopyConstructible}, and publicly and unambiguously derived, directly or indirectly, from its \texttt{base characteristic}, which is a specialization of the template \texttt{integral\_\};
\item constant\ (20.15.4), with the arguments to the template \texttt{integral\_constant\ \} determined by the requirements
for the particular relationship being described. The member names of the base characteristic shall not be
hidden and shall be unambiguously available in the `Cpp17BinaryTypeTrait`.

3 A `Cpp17TransformationTrait` modifies a property of a type. It shall be a class template that takes one
template type argument and, optionally, additional arguments that help define the modification. It shall
define a publicly accessible nested type named `type`, which shall be a synonym for the modified type.

4 Unless otherwise specified, the behavior of a program that adds specializations for any of the templates
specified in 20.15 is undefined.

5 Unless otherwise specified, an incomplete type may be used to instantiate a template specified in 20.15. The
behavior of a program is undefined if:

5.1 — an instantiation of a template specified in 20.15 directly or indirectly depends on an incompletely-defined
object type `T`, and

5.2 — that instantiation could yield a different result were `T` hypothetically completed.

20.15.3 Header `<type_traits>` synopsis

```cpp
namespace std {
    // 20.15.4, helper class
    template<class T, T v> struct integral_constant;

    template<bool B>
        using bool_constant = integral_constant<bool, B>;
    using true_type = bool_constant<true>;
    using false_type = bool_constant<false>;
