Hazard Pointers: Proposed Interface and Wording for Concurrency TS 2

1 Introduction

This paper contains proposed interface and wording for hazard pointers [1], a technique for safe deferred reclamation. This wording is based on N4700 draft [2]. An implementation is in the Folly open source library [3].

This paper needs review by LWG for inclusion in Concurrency TS 2.

The proposal was voted to be forwarded by SG1 to LEWG in Rapperswil in June 2018, and was voted to be forwarded by LEWG to LWG in San Diego in November 2018.
2 History/Changes from Previous Release

Until the June 2018 Rapperswil meeting the interface and wording for hazard pointers were presented together with those for RCU (Read-Copy-Update) [4] in P0566 [5] with associated Bugzilla Bug #382. For the history of P0566 see the last revision P0566R5 (pre-Rapperswil). Earlier interface proposals are in P0233 [6]. This paper is a revision of the hazard pointer related parts of P0566. The RCU related parts are now in P1122, and the chapter headings from P0566 are now in P0940.

2021-01 Changes in [P1121R2] from [P1121R1] (pre-Kona)

- Changes are highlighted in this version for convenience.
- Updates are based on feedback from LWG for D1122R3 (RCU).
- Add namespace std::experimental::inline concurrency_v2.
- Change class to struct.
- Make hazard_pointer_clean_up noexcept.
- Make retire noexcept.
- Several additions to the wording for retire.

2019-01 Changes in [P1121R1] (pre-Kona) from [P1121R0] (pre-San Diego)

- Removed Section 3 of P1121R1, which provided detailed background for LEWG review in San Diego.
- Changed instances of "Requires" to "Mandates" and "Expects" according to N4762 [structure.specifications].

2018-11 LEWG Review in San Diego

- LEWG voted to approve the API changes proposed in P1121R1 and to forward the proposal to LWG for wording review towards inclusion in Concurrency TS 2.

2018-10 Changes in [P1121R0] (pre-San Diego) from [P0566R5] (pre-Rapperswil)

- Edited the wording of hazard_pointer_obj_base retire(): Added a clarifying note.
- Removed instances of the word "then". Added the word "reclaim" to clarify the meaning of "expression".
- Changed "hazptr" to "hazard_pointer" in class and function names.
- Changed the class name "hazptr_holder" to "hazard_pointer".
• Changed the member function name "reset_protected" to "reset_protection".
• Changed the free function name "hazptr_cleanup" to "hazard_pointer_clean_up".

2018-06 LEWG Review in Rapperswil
• See details in Section 3 of P1121R0.

2018-06 SG1 Review in Rapperswil
• SG1 voted to forward the proposal to LEWG, provided that the following changes to the wording of hazptr_obj_base retire are made: Add a clarifying note. Remove instances of the word "then". Add the word "reclaim" to clarify the meaning of "expression".

3 Proposed wording

? Hazard Pointers [hazard_pointer]
1. The lifetime of each hazard pointer is split into a series of nonoverlapping epochs, with each epoch associated with a particular pointer to a hazard_pointer_obj_base instance (or NULL). Consecutive epochs associated with the same instance are treated as distinct epochs. The initial epoch of each hazard pointer is associated with NULL.
2. Certain ways of starting a hazard pointer epoch associated with a pointer to an object will defer reclamation of that object until the end of the epoch.
3. The hazard pointer library allows for multiple hazard pointer domains, where the reclamation of objects in one domain is not affected by the hazard pointers in different domains. It is possible for the same thread to participate in multiple domains concurrently.
4. Operations on hazard pointers are exposed through the hazard_pointer class. Each instance of hazard_pointer owns and operates on at most one hazard pointer. Each hazard_pointer call to protect, try_protect, or reset_protection begins a new epoch and ends the previous one for the owned hazard pointer. Non-empty construction begins an epoch associated with NULL, and destruction of a non-empty hazard_pointer ends its epoch.
5. A hazard pointer domain contains a set of hazard pointers. A domain is responsible for reclaiming objects retired to it (by calling hazard_pointer_obj_base retire), when such objects are not protected by hazard pointers that belong to this domain (including when this domain is destroyed).
6. A hazard_pointer_obj_base O is definitely reclaimable in domain D at program point P if:
   a. there is a call to O.retire(reclaim, D), and it happens before P, and
   b. For each epoch E in D associated with O, the end of E happens before P.
7. A `hazard_pointer_obj_base` object \( O \) is *possibly reclaimable* in domain \( D \) at program point \( P \) if:
   a. There is a call to \( O\text{.retire}(\text{reclaim}, D) \) and \( P \) does not happen before the call, and
   b. For each epoch \( E \) in \( D \) associated with \( O \), \( P \) does not happen before the end of \( E \).

[Note—The following example shows how hazard pointers allow updates to be carried out in the presence of concurrent readers. Each `hazard_pointer` instance in `print_name` is used through the call to `protect` to start an epoch associated with \( \text{ptr} \) to protect the object \( *\text{ptr} \) from being reclaimed by `\text{ptr}\text{.retire}` until the end of the epoch.

```cpp
struct Name : public hazard_pointer_obj_base<Name> { /* details */};
atomic<Name*> name;

// called often and in parallel!
void print_name() {
   hazard_pointer h = make_hazard_pointer();
   Name* ptr = h.protect(name);
   /* ... safe to access *ptr ... */
}

// called rarely
void update_name(Name* new_name) {
   Name* ptr = name.exchange(new_name);
   ptr->retire();
}
```

—end note]

**Header `<hazard_pointer>` synopsis**

```cpp
namespace std::experimental::inline concurrency_v2 {

   // ?.?, Struct hazard_pointer_domain:
   struct hazard_pointer_domain;

   // ?.?, Default hazard_pointer_domain:
   hazard_pointer_domain& hazard_pointer_default_domain() noexcept;

   // ?.?, Clean up
   void hazard_pointer_clean_up(
```
hazard_pointer_domain& domain = hazard_pointer_default_domain();
    noexcept;

// ?.?, Struct template hazard_pointer_obj_base:
template <typename T, typename D = default_delete<T>>
    struct hazard_pointer_obj_base;

// ?.?, Class hazard_pointer
struct hazard_pointer;

// ?.?, Construct non-empty hazard_pointer
hazard_pointer make_hazard_pointer(
    hazard_pointer_domain& domain = hazard_pointer_default_domain());

// ?.?, Hazard pointer swap
void swap(hazard_pointer&, hazard_pointer&) noexcept;
}

?? Class hazard_pointer_domain [hazard_pointer.domain]

1. The number of unreclaimed possibly reclaimable objects retired to a domain is bounded. The bound is implementation-defined. The bound is independent of other domains and may be a function of the number of hazard pointers in the domain, the number of threads that retire objects to the domain, and the number of threads that use hazard pointers that belong to the domain.

struct hazard_pointer_domain {
    // ?.?.? constructor:
    explicit hazard_pointer_domain(
        std::pmr::polymorphic_allocator<byte> poly_alloc = {});

    // disable copy and move constructors and assignment operators
    hazard_pointer_domain(const hazard_pointer_domain&) = delete;
    hazard_pointer_domain(hazard_pointer_domain&&) = delete;
    hazard_pointer_domain& operator=(const hazard_pointer_domain&) = delete;
    hazard_pointer_domain& operator=(hazard_pointer_domain&&) = delete;

    // ?.?.? destructor:
    ~hazard_pointer_domain();
private:
std::pmr::polymorphic_allocator<byte> alloc_; // exposition only

hazard_pointer_domain constructors [hazard_pointer.domain.constructor]
explicit hazard_pointer_domain(
    pmr::polymorphic_allocator<byte> poly_alloc = {});

   1. Effects: Sets alloc_ to poly_alloc.
   2. Throws: Nothing.
   3. Remarks: All allocation and deallocation of hazard pointers in this domain will use alloc_.

hazard_pointer_domain destructor [hazard_pointer.domain.destructor]
~hazard_pointer_domain();

   1. Expects: The destruction of all hazard pointers in this domain (including hazard pointers whose epochs are associated with NULL) and all retire() calls that take this domain as argument must happen before the destruction of the domain.
   2. Effects: Deallocates all hazard pointer storage used by this domain. Reclaims any remaining objects that were retired to this domain.
   3. Complexity: Linear in the number of objects retired to this domain that have not been reclaimed yet plus the number of hazard pointers contained in this domain.

Default hazard_pointer_domain [hazard_pointer.default_domain]

hazard_pointer_domain& hazard_pointer_default_domain() noexcept;

   1. Returns: A reference to the default hazard_pointer_domain.

Cleanup [hazard_pointer.cleanup]

void hazard_pointer_clean_up(
    hazard_pointer_domain& domain = hazard_pointer_default_domain()) noexcept;

   1. Effects: For a set of hazard_pointer_obj_base objects O in domain for which O.retire(reclaim, domain) has been called, ensures that O has been reclaimed. The set contains all definitely reclaimable objects at the point of cleanup, and may contain some possibly reclaimable objects.
   2. Synchronization: The end of evaluation of each reclaim expression of objects in the set synchronizes with the return from this call.

[ Note: To avoid deadlock, this function must not be called while holding resources that may be required by such expressions. — end note ]
Class template `hazard_pointer_obj_base [hazard_pointer.base]`
The base class template of objects to be protected by hazard pointers.

```cpp
template <typename T, typename D = default_delete<T>>
struct hazard_pointer_obj_base {
  // retire
  void retire(
    D reclaim = {},
    hazard_pointer_domain& domain = hazard_pointer_default_domain())
    noexcept;

  void retire(hazard_pointer_domain& domain) noexcept;

protected:
  hazard_pointer_obj_base() = default;
};
```

1. If this template is instantiated with a `T` argument that is not publicly derived from `hazard_pointer_obj_base<T,D>` for some `D`, the program is ill-formed.
2. A client-supplied template argument `D` shall be a function object type for which, given a value `d` of type `D` and a value `ptr` of type `T*`, the expression `d(ptr)` is valid and has the effect of disposing of the pointer as appropriate for that deleter.
3. A client-supplied template argument `D` shall be a function object type ([function.object]) for which, given a value `d` of type `D` and a value `ptr` of type `T*`, the expression `d(ptr)` is valid and has the effect of disposing of the pointer as appropriate for that deleter.
4. A program may not add specializations of this template.

```cpp
void retire(
  D reclaim = {},
  hazard_pointer_domain& domain = hazard_pointer_default_domain()) noexcept;
```

1. Mandates: `is_move_constructible_v<D>` and `is_default_constructible_v<D>` are true.
2. Preconditions: `D` shall be `Cpp17MoveConstructible`. The `reclaim` expression `reclaim(static_cast<T*>(this))` shall be well-formed.
3. A template parameter `D` shall be a function object type ([function.object]), lvalue reference to function, or lvalue reference to function object type for which, given a value `d` of type `D` and a value `ptr` of type `T*`, the expression `d(ptr)` is valid, and has the effect of disposing of `ptr` as appropriate for that deleter.
4. When the template argument passed to `D` is trivially copyable, the resulting instance of `rcu_obj_base` will also be trivially copyable.
5. `T` may be an incomplete type.
6. Expects: The move constructor of `D` shall not throw an exception. The `reclaim` expression `reclaim(static_cast<T*>(this))` shall have well-defined behavior and shall not throw an exception.
7. Effects: Registers the expression `reclaim(static_cast<T*>(this))` to be evaluated asynchronously. For every hazard pointer in the domain, for epoch E associated with the value `static_cast<T*>(this)`:
   a. If the beginning of E happens before this call, the end of E strongly happens before the evaluation of the reclaim expression.
   b. If E began as part of an evaluation of `try_protect(ptr, src)` returning true (for some src and ptr == static_cast<T*>(this)), let its associated atomic load operation be labelled A. If there exists an atomic modification B on src such that A observes a modification that is modification-ordered before B, and B happens before this call, the end of E strongly happens before the evaluation of the reclaim expression. [Note: in typical use, a store to src sequenced before this call will be such atomic operation B.]
   [Note: Both of these preconditions convey the informal notion that the hazard pointer epoch begins before the retire() call occurs, as implied either by the happens-before relation or the coherence order of some source.]

The reclaim expression will be evaluated only once, and it will be evaluated by the evaluation of a `retire()` or `hazard_pointer_clean_up()` operation on domain.

This function may also evaluate any number of reclaim expressions for `hazard_pointer_obj_base` objects possibly reclaimable in domain.

[Note: To avoid deadlock, this function must not be called while holding resources required by such reclaim expressions. — end note]

```cpp
void retire(hazard_pointer_domain& domain) noexcept;
```

1. Effects: Equivalent to
   ```cpp
   retire({}, domain);
   ```

```cpp
72x260){? Class hazard_pointer [hazard_pointer_holder]
A hazard_pointer object acts as a local handle on a hidden hazard pointer, which can be used to protect at most a single `hazard_pointer_obj_base` object at a time. Every object of type hazard_pointer is either empty or owns exactly one hazard pointer, and has no protection against data races other than what is specified for the library generally ([res.on.data.races]). Every hazard pointer is owned by exactly one hazard_pointer object.

```cpp
struct hazard_pointer {
    hazard_pointer() noexcept;

    hazard_pointer(hazard_pointer&&) noexcept;
    hazard_pointer& operator=(hazard_pointer&&) noexcept;
```
hazard_pointer(const hazard_pointer&) = delete;
hazard_pointer& operator=(const hazard_pointer&) = delete;

~hazard_pointer();

bool empty() const noexcept;

template <typename T>
  T* protect(const atomic<T*>& src) noexcept;

template <typename T>
  bool try_protect(T*& ptr, const atomic<T*>& src) noexcept;

template <typename T>
  void reset_protection(const T* ptr) noexcept;
  void reset_protection(nullptr_t = nullptr) noexcept;
  void swap(hazard_pointer&) noexcept;
};

?? hazard_pointer constructors [hazard_pointer.holder.constructors]
hazard_pointer() noexcept;
  1. Effects: Constructs an empty hazard_pointer.

hazard_pointer(hazard_pointer&& other) noexcept;
  1. Effects: If other is empty, constructs an empty hazard_pointer. Otherwise, constructs a hazard_pointer that owns the hazard pointer originally owned by other. other becomes empty.

?? hazard_pointer destructor [hazard_pointer.holder.destructor]
~hazard_pointer();
  1. Effects: If *this is not empty, destroys the owned hazard pointer which ends its current epoch.

?? hazard_pointer assignment [hazard_pointer.holder.assignment]
hazard_pointer& operator=(hazard_pointer&& other) noexcept;
  1. Effects: If this == &other, no effect. Otherwise, if other is not empty, *this takes ownership of the hazard pointer originally owned by other, and other becomes empty. If *this was not empty before the call, destroys the owned hazard pointer which ends its current epoch
2. Returns: *this.

`.hazard_pointer empty [hazard_pointer.holder.empty]`

bool empty() const noexcept;

1. Returns: true if and only if *this is empty. [Note: An empty hazard_pointer is different from a nonempty hazard_pointer that owns a hazard pointer with epoch associated with NULL. An empty hazard_pointer does not own any hazard pointers. — end note]

`.hazard_pointer protect [hazard_pointer.holder.protect]`

template <typename T>
T* protect(const atomic<T*>& src) noexcept;

1. Expects: *this is not empty.
2. Effects: Equivalent to

   T* ptr = src.load(memory_order_relaxed);
   while (!try_protect(ptr, src)) {}
   return ptr;

`.hazard_pointer try_protect [hazard_pointer.holder.try_protect]`

template <typename T>
bool try_protect(T*& ptr, const atomic<T*>& src) noexcept;

1. Expects: *this is not empty.
2. Effects:
   a. Ends the owned hazard pointer's current epoch, and starts a new one.
   b. Performs an atomic acquire load on src. If src == ptr, the hazard pointer's new epoch is associated with the value ptr, and try_protect() returns true. Otherwise, the new epoch is associated with NULL, and try_protect() returns false.
   c. Sets ptr to the value read from src.
3. Returns: The result of the comparison. [Note: It is possible for try_protect to return true when ptr is a null pointer. — end note]

`.hazard_pointer reset_protection [hazard_pointer.holder.reset]`

template <typename T>
void reset_protection(const T* ptr) noexcept;

1. Expects: *this is not empty.
2. Effects: Ends the owned hazard pointer's current epoch, and begins a new one associated with ptr.

```cpp
void reset_protection(nullptr_t = nullptr) noexcept;
```

1. Expects: *this is not empty.
2. Effects: Ends the owned hazard pointer's current epoch, and begins a new one associated with NULL..

```cpp
??.? hazard_pointer swap[hazard_pointer.holder.swap]
```

```cpp
void swap(hazard_pointer& other) noexcept;
```

1. Effects: Swaps the hazard pointer ownership and the associated domain of this object with those of other. [Note: The owned hazard pointers, if any, remain unchanged during the swap and continue to protect the respective objects that they were protecting before the swap, if any. — end note]
2. Complexity: Constant.

```cpp
??. make_hazard_pointer [hazard_pointer.make]
```

```cpp
hazard_pointer make_hazard_pointer(
  hazard_pointer_domain& domain = hazard_pointer_default_domain());
```

1. Effects: Constructs a hazard pointer from domain, and returns a hazard_pointer that owns it.
2. Throws: Any exception thrown by domain.alloc_.allocate().

```cpp
??. hazard_pointer specialized algorithms [hazard_pointer.holder.special]
```

```cpp
void swap(hazard_pointer& a, hazard_pointer& b) noexcept;
```

1. Effects: Equivalent to a.swap(b).
