Abstract

We propose a view `enumerate` whose value type is a struct with 2 members index and value representing respectively the position and value of the elements in the adapted range.

Revisions

R4

This revision is intended to illustrate the effort necessary to support named fields for index and value. In previous revisions, the value and reference types were identical, a regrettable blunder that made the wording and implementation efforts smaller than they are. reference and value_type types however needs to be different, if only to make the `ranges::to` presented in this very paper.

If that direction is acceptable, better wording will be provided to account for these new reference and value_type types.

This revision also gets rid of the `const index` value as LEWG strongly agreed that it was a terrible idea to begin with, one that would make composition with other views cumbersome.

R3

• Typos and minor wording improvements

R2, following mailing list reviews

• Make value_type different from reference to match other views
• Remove inconsistencies between the wording and the description
• Add relevant includes and namespaces to the examples

R1

• Fix the index type

</tbody>
</table>

Motivation

The impossibility to extract an index from a range-based for loop leads to the use of non-range based for loop, or the introduction of a variable in the outer scope. This is both more verbose and error-prone: in the example above, the type of index is incorrect.

enumerate is a library solution solving this problem, enabling the use of range-based for loops in more cases.

It also composes nicely with other range facilities: The following creates a map from a vector using the position of each element as key.

my_vector | views::enumerate | ranges::to<map>;

This feature exists in some form in Python, Rust, Go (backed into the language), and in many C++ libraries: ranges-v3, folly, boost::ranges (indexed).

The existence of this feature or lack thereof is the subject of recurring stackoverflow questions.

Design

The result is a simple aggregate the simple type that would satisfy the common_--reference requirements

Following the trend of using meaningful names instead of returning pairs or tuples, this proposal uses structured with named public members.

struct result {
    count index;
    T value;
};
This design was previously discussed by LEWGI in Belfast in the context of P1894R0 [2].

Unfortunately, to satisfy the indirectly_readable requirements, the value_type and reference_type must have a common reference.

This adds some complexity to the design. Below would be the minimum implementation of the value & reference types:

```cpp
template <typename count_type, typename T>
struct result {
    count_type index;
    T value;

default
    result() requires std::is_default_constructible_v<T>; =

    template <typename U>
    requires std::constructible_from<T, U>
    result(count_type index, U& value)
    noexcept( std::is_nothrow_constructible_v<T, U> )
    : index(index), value(std::forward<U>(value)) {}

    result( const result & other) requires std::copyable<T> =

    template <typename U>
    requires std::constructible_from<T, U>
    result(result<count_type, U>& other)
    noexcept( std::is_nothrow_constructible_v<T, U> )
    : index(other.index), value(other.value) {};

    result & operator=( const result & other) requires std::assignable_from<T, T> =

    template <typename U>
    requires std::convertible_to<U, T>
    result & operator=( const result<count_type, U>& other)
    noexcept( std::is_nothrow_constructible_v<T, U> )
    { index = other.index;
      value = other.value;
      return *this;
    }

    constexpr bool operator==( const result<count_type, U>& other) const noexcept {
      return other.index == index && other.value == value;
    }

    template <typename U>
    requires std::three_way_comparable_with<T,U>
    constexpr auto operator<=>( const result<count_type, U>& other) const noexcept {
      std::tie(index, value) <=> std::tie(other.index, other.value);
    }

    template <typename U>
    friend void swap(result & a, result<count_type, U>& b);
};
```

I think it's very important here not to try to recreate a pair. This type should not be a general-
purpose type with different names than pair. As such it has fewer constructors (doesn't need to be constructed from literals), no deduction guides, etc. Missing at the moment is support for `tuple_size`, `tuple_element`, `get`. Ideally convertibility to `tuple` is desired. This could be dealt with something like P2165R0 [1](a paper which needs a redesign to support types like array...).

Despite that newly discovered complexity, I remained convince that it's worth the effort to get these names, and several people have expressed to me that they want names “if we can get them”.

**count_type**

`count_type` is defined as follow:

- `ranges::range_size_t<Base>` if `Base` models `ranges::sized_range`
- Otherwise, `make_unsigned_t<ranges::range_difference_t<Base>>`

This is consistent with ranges-v3 and allows the view to support both sized and non-sized ranges.

**Performance**

An optimizing compiler can generate the same machine code for `views::enumerate` as it would for an equivalent for loop. [Compiler Explorer](https://www.compiler-explorer.com)

**Implementation**

This proposal has been implemented (Github) There exist an implementation in ranges-v3 (where the enumerate view uses zip_with and a pair value type).

**Proposal**

We propose a view `enumerate` whose value type is a struct with 2 members `index` and `value` representing respectively the position and value of the elements in the adapted range.

**Wording**

- **Enumerate view**

  `enumerate_view` presents a view with a value type that represents both the position and value of the adapted view's value-type.

  The name `views::enumerate` denotes a range adaptor object. Given the subexpressions `E` the expression `views::enumerate(E)` is expression-equivalent to `enumerate_view[E]`.

[1]: https://www.range-v3.org
[Example:

```cpp
vector<int> vec{ 1, 2, 3 };  
for (auto [index, value] : enumerate(vec) )  
    cout << index << " :: " << value ' '; // prints: 0:1 1:2 2:3

— end example]
```

Class template `enumerate_view`

```cpp
namespace std::ranges {

    template <typename count_type, typename T>
    struct enumerate_result_t {

        count_type index;
        T value;

        result() requires std::is_default_constructible_v<T> = default;

        template <typename U>
        requires std::constructible_from<T, U>
        result(count_type index, U&& value) noexcept(std::is_nothrow_constructible_v<T, U>);

        result(const result & other)
        requires std::copyable<T> = default;

        template <typename U>
        requires std::constructible_from<T, U>
        result(result<count_type, U> && other)
        noexcept(std::is_nothrow_constructible_v<T, U>);

        template <typename U>
        requires std::constructible_from<T, U>
        result(const result<count_type, U> & other)
        noexcept(std::is_nothrow_constructible_v<T, U>);

        result & operator=(const result & other)
        requires std::assignable_from<T, T> = default;

        template <typename U>
        requires std::convertible_to<U, T>
        result & operator=(const result<count_type, U> & other)
        noexcept(noexcept(value = std::forward<result<count_type, U>>(other).value));

        template <typename U>
        requires std::equality_comparable_with<T,U>
        constexpr bool operator==(const result<count_type, U> &other) const noexcept;

    template <typename U>
    requires std::equality_comparable_with<T,U>
    constexpr bool operator==(const result<count_type, U> &other) const noexcept;

    template <typename U>
    requires std::equality_comparable_with<T,U>
    constexpr bool operator==(const result<count_type, U> &other) const noexcept;

    template <typename U>
    requires std::equality_comparable_with<T,U>
    constexpr bool operator==(const result<count_type, U> &other) const noexcept;
```
```
requires std::three_way_comparable_with<T,U>
constexpr auto operator<=>(const result<count_type, U> &other) const noexcept;

template <typename U>
friend void swap(result & a, result<count_type, U> & b);
};

template<input_range V>
requires view<V>
class enumerate_view : public view_interface<enumerate_view<V>> {

private:
  V base_ = {};

  template <bool Const>
  class iterator; // exposition only
  template <bool Const>
  struct sentinel; // exposition only

public:

  constexpr enumerate_view() = default;
  constexpr enumerate_view(V base);

  constexpr auto begin() requires (!simple_view<V>)
  { return iterator<false>(ranges::begin(base_), 0); } 

  constexpr auto begin() const requires simple_view<V>
  { return iterator<true>(ranges::begin(base_), 0); } 

  constexpr auto end()
  { return sentinel<false>{end(base_)}; } 

  constexpr auto end()
  requires common_range<V> && sized_range<V>
  { return iterator<false>{ranges::end(base_),
                            static_cast<range_difference_t<V>>(size())}; } 

  constexpr auto end() const
  requires range<const V>
  { return sentinel<true>{ranges::end(base_)}; } 

  constexpr auto end() const
  requires common_range<const V> && sized_range<V>
  { return iterator<true>{ranges::end(base_),
                            static_cast<range_difference_t<V>>(size())}; } 

  constexpr auto size()
  requires sized_range<V>
  { return ranges::size(base_); }

iterator::count_type is defined as follow:

• ranges::range_size_t<Base> if Base models ranges::sized_range
• Otherwise, make_unsigned_t<ranges::range_difference_t<Base>>

constexpr explicit iterator(iterator_t<Base> current, range_difference_t<Base> pos = 0);

Effects: Initializes current with move(current) and pos with static_cast<count_type>(pos).
constexpr iterator(iterator<!Const> i)
requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

**Effects:** Initializes `current_` with `move(i.current_)` and `pos` with `i.pos_`.

constexpr iterator_t<Base> base() const&
requires copyable<iterator_t<Base>>;

**Effects:** Equivalent to: `return current_;`

constexpr iterator_t<Base> base() &&;

**Effects:** Equivalent to: `return move(current_);`

constexpr iterator& operator++();

**Effects:** Equivalent to:
```cpp
    ++pos;
    ++current_;
    return *this;
```

constexpr void operator++(int) requires (!forward_range<Base>);

**Effects:** Equivalent to:
```cpp
    ++pos;
    ++current_;  
```

constexpr iterator operator++(int) requires forward_range<Base>;

**Effects:** Equivalent to:
```cpp
    auto temp = *this;
    ++pos;
    ++current_;  
    return temp;
```

constexpr iterator& operator--() requires bidirectional_range<Base>;

**Effects:** Equivalent to:
```cpp
    --pos_;  
    --current_;  
    return *this;
```

constexpr iterator operator--(int) requires bidirectional_range<Base>;

**Effects:** Equivalent to:
auto temp = *this;
--current_.
--pos_.
return temp;

constexpr iterator& operator+=(difference_type n);
requires random_access_range<Base>;

Effects: Equivalent to:
    current_ += n;
    pos_ += n;
    return *this;
