Abstract

Character literals in preprocessor conditional should behave like they do in C++ expression. This proposal first appeared as part of P2178R1 [3].

Motivation

Consider the following code:

```c
#if 'A' == '\x41'
  //...
#endif
if ('A' == 0x41){}
```

Both conditions are not guaranteed to yield a similar result, as the value of character literals in preprocessor conditional is not required to be identical to that of character literals in expressions.

However, a survey of the 1300+ open sources projects available on vcpkg shows that the primary use case for these macros is exactly to detect the narrow literal encoding at compile time and all compilers available on compiler explorer treat these literals as if they were in the narrow literal encoding.

Notably, a few libraries use that pattern to detect EBCDIC or ASCII narrow literal encoding. Of the 50 usages of the pattern, all but one were in C libraries.

For example, this code is in sqlite.c

```c
/*
** Check to see if this machine uses EBCDIC. (Yes, believe it or not, there are still machines out there that use EBCDIC.) */
#if 'A' == '\x301'
  # define SQLITE_EBCDIC 1
```
While we think there should be a better way to detect encodings in C++ [1], there is no reason to deprecate that feature.

Instead, we recommend adopting the standard practice and user expectation of converting these literals to the narrow literal encoding before evaluating them.

SG16 poll

August 26th, 2020
Poll: Proposal 11 (of P2178R0 [2]): We agree that the same character encoding should be used for character literal in translation phase 4 and 7.

Attendees: 10
No objection to unanimous consent.

Wording

Preprocessing directives [cpp]

Conditional inclusion [cpp.cond]

The resulting tokens comprise the controlling constant expression which is evaluated according to the rules of [expr.const] using arithmetic that has at least the ranges specified in [support.limits]. For the purposes of this token conversion and evaluation all signed and unsigned integer types act as if they have the same representation as, respectively, intmax_t or uintmax_t. [Note: Thus on an implementation where std::numeric_limits<int>::max() is \texttt{0x7FFF} and std::numeric_limits<unsigned int>::max() is \texttt{0xFFFF}, the integer literal \texttt{0x8000} is signed and positive within a \#if expression even though it is unsigned in translation phase 7. — end note] This includes interpreting character-literal s which may involve converting escape sequences into execution character set members. Whether the numeric value for these character-literal s matches the value obtained when an identical character-literal occurs in an expression (other than within a \#if or \#elif directive) is implementation-defined. [Note: Thus, the constant expression in the following \#if directive and if statement is not guaranteed to evaluate to the same value in these two contexts:

\[
\#if \ 'z' - 'a' == 25 \\
\text{if} \ ('z' - 'a' == 25)
\]

— end note] Also, whether a single-character character-literal may have a negative value is implementation-defined. This include interpreting character-literal according to the rules in
[lex.ccon]. [Note: The associated character encodings of literals are the same in #if and #elif directives and in any expression. — end note]

Each subexpression with type bool is subjected to integral promotion before processing continues.
