1 Introduction

The evolution of constexpr since C++11 allows us to make more and more parts constexpr. For example, [P0980R1] makes std::string constexpr. [P1004R2] does the same for std::vector. Microsoft’s implementation [MSVCVector] shows that all member functions in std::vector are constexpr now.
When I wrote the test implementation for [P2273R0] (Making `unique_ptr constexpr`) I more or less simply added `constexpr` to all member functions of `unique_ptr`.

[P1235R0] proposed to make all functions implicitly `constexpr`. Looking at the examples of `vector` and [P1235R0] there seems to be a desire to reduce declarators.

I propose to allow `constexpr` in the class-head, acting much like `final`, declaring that all member functions, including special member functions, in this class are implicitly `constexpr`:

Currently
```
class SomeType {
public:
  constexpr bool empty() const { /* */ }
  constexpr auto size() const { /* */ }
  constexpr void clear() { /* */ }
  // ...
};
```

With proposal
```
class SomeType constexpr {
public:
  bool empty() const { /* */ }
  auto size() const { /* */ }
  void clear() { /* */ }
  // ...
};
```

2 Implementation

This proposal was implemented in a fork of LLVM/Clang from the author [GHUPImpl]. The change was small and easy to apply.

3 The design

The goal is to use the existing model of `final` and apply it to `constexpr`. This reduces the noise resulting from entirely `constexpr`-classes as we have it now.

3.1 What about out-of-line definitions?

This proposal does not change how out-of-line definitions of `constexpr` member functions work. They continue to work the same way as if someone puts `constexpr` directly at the member function. The out-of-line definition will not compile.

3.2 What about a member function that already carries `constexpr`?

Well, doing things twice to be sure never hurts. The member function will be `constexpr` in a `constexpr` class regardless of whether it is declared `constexpr` again at member function level.

3.3 Do we need `constexpr(false)`?

I don't know. Feel free to bring use-cases.

My current answer is: no. If we see a `constexpr` class not only as a noise reduction in reading and writing but also as a promise "you can use this entire class in a `constexpr`-context", disabling the `constexpr`ness of certain member function makes this promise weak.
3.4 What about friend?

A friend declaration is different. Such a declaration is only in the namespace of a class but isn’t a member of that class. On the reflector Ville Voutilainen provided a good example that even in a constexpr class we might have a friend declaration for an ostream operator [ml16332], which cannot be constexpr.

Therefore, this paper proposes that friend declaration are unaffected of a constexpr class. They remain as they are and need to be marked constexpr even in a constexpr class.

3.5 What about static member functions?

By this proposal static member functions get implicitly marked constexpr in a constexpr class.

3.6 What about inheritance?

Consider the following examples:

```cpp
struct BaseExpr constexpr {  
    int foo() { return 42; } // this member function is constexpr
};

struct DerivedA : BaseExpr {  
    int bar() { return 21; } // this member function is _not_ constexpr
};

struct Base {  
    int foo() { return 42; } // this member function is _not_ constexpr
};

struct DerivedB constexpr : Base {  
    int bar() { return 21; } // this member function is constexpr
};
```

Listing 3.1: constexpr class and inheritance

In the case of DerivedA, where a class derives from a constexpr class, only the member functions of the constexpr base class are constexpr. There is no constexpr inheritance. It seems to constrain the design space of classes too much if only constexpr classes can derive from constexpr classes.

In the case of DerivedB, where the derived class is marked as constexpr, but the base class isn’t, this proposal makes all member functions of the derived class constexpr while those of the base class remain as they are. constexpr for member functions explicitly marked constexpr in the base class and non-constexpr for all the others.

3.7 What about a forward declaration?

Consider this:

```cpp
struct Forward constexpr;
```
Analogous to `final`, the above is only a forward declaration that cannot have a specifier. Hence, the code above is ill-formed by this proposal.

The same goes for class templates or specializations of class templates. Only the specialization marked as `constexpr` does have all member functions implicitly `constexpr`. All other don’t.

### 3.8 Is adding or removing `constexpr` from the class-head a breaking change?

Say we have a class before this proposal, and after this proposal, the class author adds `constexpr` in the class-head, is this a breaking change? The short answer is no. The longer is it depends. By adding `constexpr` in the class-head all member functions of a class become `constexpr`. If this class had non-`constexpr` member functions before this change, then users can observe a behavioral change. However, this change is equal to adding `constexpr` to all the member functions of a class manually, what we have done in [P1004R2] to `std::vector`. This was not considered a breaking change, nor an ABI change.

### 3.9 Can this be solved with metaclasses?

Another question that came up is, can this feature be implemented with metaclasses. One idea is to provide such a facility with the STL. [MCSrc] lists a possible implementation that was shown in a Twitter discussion [MCSrcTweet].

While a `constexpr` class is implementable with the current state of metaclasses, it doesn’t seem like the right tool for the job. A `constexpr` class is something simple and generic. There is no need to let the compiler generate something for us. The combination of such a metaclasses library part with other metaclasses elements, like promising shape example [P0707R4], is unclear.

### 3.10 Syntax choices

We have a couple of different syntax options:

```cpp
1 class D constexpr : B {}; // A
2 class constexpr D : B {}; // B
3 class D : B constexpr {}; // C
4 constexpr class D : B {}; // D
```

A seems natural. `final` would be right of `constexpr`:

B seems a bit confusing because its before the class name. The question is does it go before or after attributes.

C seems very confusing. It creates the impression that `constexpr` applies to the base class.

D is ambiguous. We already have `constexpr class D{}` d.
This paper proposes syntax A.

4 Other parts of the language

The ability to list other specifiers like noexcept is something that comes up with this proposal.

4.1 What about consteval

For consistency reasons, consteval should be allowed like constexpr.

If consteval is allowed as well, there are more questions to answer. It seems to make sense to allow only one of both in the class-head. Now assume a class is marked constexpr:

```cpp
1 class SomeType constexpr {
2 public:
3   bool empty() const { /* */ }
4   // ...
5 };
```

Do we like to allow that a member function can be marked consteval and those overriding constexpr:

```cpp
1 class SomeType constexpr {
2 public:
3   bool empty() const { /* */ }
4   // ...
5   consteval bool whatsoeverFun() { /* */ }
6 };
```

The same goes the other way around. Assume we have a consteval class, should it be allowed that a member function can be down-grade to constexpr?

4.2 What about noexcept

noexcept acts differently than constexpr or final. Should I, as a developer, do something that is not allowed in, for example, a constexpr context the compiler gives me an error. Should I invoke a throwing function in a noexcept member function, I end up with a run-time error. It seems less desirable to me to create implicit noexcept member functions.

Another angle here are out-of-line definitions. If a full noexcept-class adds the implicit noexcept to all in-class definitions, what about out-of-line definitions? Should the also be implicitly noexcept? Should such out-of-line definitions need to be attributed with noexcept?

On the reflector, Giuseppe D’Angelo mentioned QT’s Point and std::complex as examples for noexcept data structures. A quick check revealed that both data structures seem not to throw exceptions, but even std::complex is not marked noexcept in the standard. The assumed reason for them not have been marked noexcept in C++11 is that adding or removing noexcept is an observable change. If we have two functions where one is marked noexcept, and the other isn’t, the typeid of them is different:

```cpp
1 #include <cassert>
2 #include <typeinfo>
```
4.3 What about `const`

Another thing that could be imaginable is to have `const` in the class-head, declaring all member functions in a class implicitly `const`. This proposal does not propose this. If there is a desire for it, a dedicated proposal seems best.

In general `const` is different because we can have out-of-line definitions which are explicitly marked `const` to distinguish them from the non-const overload. A `const`-only class would have only `const` member functions, making this issue simpler, but regarding teachability and readability, dropping the `const` from these functions does create a new kind that seems not desirable.

This paper does not propose to add `const` as a specifier in the class-head.

4.4 What about `override`

An `override` class where all member functions override those in a base class would at least solve the situation with an unwanted non-`virtual` destructor in the base class.

This paper does not propose to add `override` as a specifier in the class-head.

4.5 What about free functions?

Free functions are an interesting question. While with this proposal, the noise from `constexpr`ifying entire classes is reduced, we also have a lot of cases where many free functions are `constexpr`. One example is [P1645R1], which made more algorithms `constexpr`.

One approach here can be a `constexpr` namespace like below.

```cpp
namespace constexpr {
    bool Fun() { /* */ } // this function is constexpr
    bool Run() { /* */ } // this function is constexpr
}
```

This paper does not propose a `constexpr` namespace. If something like this is desirable, the author is open to bring another paper dedicated to such a feature.

5 Proposed wording

This wording is base on the working draft [N4885].
The wording does not include changes to STL containers. If this is desired, the author believes that it requires a new paper targeting LEWG.

Change in [dclconstexpr] 9.2.5:
The constexpr specifier shall be applied only to the definition of a variable or variable template or the declaration of a function or function template or a class definition. The consteval specifier shall be applied only to the declaration of a function or function template. ...

A constexpr or consteval specifier used in the declaration of a function declares that function to be a constexpr function. A constexpr specifier used in a class definition declares that all member functions in that class as constexpr functions. A function or constructor declared with the consteval specifier is called an immediate function. A destructor, an allocation function, or a deallocation function shall not be declared with the consteval specifier.

Change in [class.pre] 11.1:

```
class-head:
   class-key attribute-specifier-seq_opt class-head-name constexpr-class-constexpr-specifier_opt class-virt-specifier_opt base-clause_opt
   class-key attribute-specifier-seq_opt base-clause_opt

class-head-name:
   nested-name-specifier_opt class-name

constexpr-class-constexpr-specifier:
   constexpr

class-virt-specifier:
   final
```

Add after p7 in [class.pre] 11.1:

7 [Note: Class objects can be assigned (12.6.2.1, 11.4.5), passed as arguments to functions (9.4, 11.4.4.2), and returned by functions (except objects of classes for which copying or moving has been restricted; see 9.5.3 and 11.9). Other plausible operators, such as equality comparison, can be defined by the user; see 12.6. – end note]

8 If a class is marked with the `constexpr-class-constexpr-specifier constexpr` and it appears as a class-or-decltype in a base-clause[class.derived], the program is ill-formed. Whenever a class-key is followed by a class-head-name, the keyword constexpr, and a colon or left brace, constexpr is interpreted as a class-constexpr-specifier. [Example:

```
struct A;
struct A constexpr {}; // OK: definition of struct A

struct B constexpr; // ERROR: forward declaration of struct B with constexpr
```
– end example]
Modify [tab:cpp.predefined.ft]
