Introduction

This paper suggests a change in presentation of the requirements tables in the standard library.

The existing tables are awkward and frequently do not use established best practice for presenting requirements.

The following pages present the container and regular expression requirements in a new format for comment. No semantic changes are intended.

# 22 Containers library

## 22.1 General

1. This Clause describes components that C++ programs may use to organize collections of information.

2. The following subclauses describe container requirements, and components for sequence containers and associative containers, as summarized in Table 72.

### Table 72: Containers library summary

## 22.2 Requirements

### 22.2.1 Preamble

1. Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.

2. All of the complexity requirements in this Clause are stated solely in terms of the number of operations on the contained objects.

   [Example 1: The copy constructor of type `vector<vector<int>>` has linear complexity, even though the complexity of copying each contained `vector<int>` is itself linear. — end example]

3. For the components affected by subclause 22.2 that declare an `allocator_type`, objects stored in these components shall be constructed using the function `allocator_traits<allocator_type>::rebind_traits<U>::construct` and destroyed using the function `allocator_traits<allocator_type>::rebind_traits<U>::destroy` (20.10.8.3), where `U` is either `allocator_type::value_type` or an internal type used by the container. These functions are called only for the container’s element type, not for internal types used by the container.

   [Note 1: This means, for example, that a node-based container would need to construct nodes containing aligned buffers and call `construct` to place the element into the buffer. — end note]

### 22.2.2 General containers

#### 22.2.2.1 General

1. In subclause 22.2.2,

   (1.1) — `X` denotes a container class containing objects of type `T`,
   (1.2) — `a` and `b` denote values of type `X`,
   (1.3) — `i` and `j` denote values of type (possibly const) `X::iterator`,
   (1.4) — `u` denotes an identifier,
   (1.5) — `r` denotes a non-const value of type `X`, and
   (1.6) — `rv` denotes a non-const rvalue of type `X`.

#### 22.2.2.2 Containers

1. A type `X` meets the `container` requirements if the following types and expressions are well-formed and have the specified semantics.

   (1.1) — The name `X::value_type` denotes the type `T`. `T` is `Cpp17Erasable` from `X` (see 22.2.2.1, below).
The name `X::reference` denotes the type `T&`.

The name `X::const_reference` denotes the type `const T&`.

The name `X::iterator` denotes a type that meets the forward iterator requirements (23.3.5.5) with value type `T`. The type `X::iterator` is convertible to `X::const_iterator`.

The name `X::const_iterator` denotes a type that meets the requirements of a constant iterator and those of a forward iterator with value type `T`.

The name `X::difference_type` denotes a signed integer type, identical to the difference type of `X::iterator` and `X::const_iterator`.

The name `X::size_type` denotes an unsigned integer type that can represent any non-negative value of `difference_type`.

`X u;` and `X u = X();` are statements, each with the following properties:

- **Postconditions**: `u.empty()`
- **Complexity**: Constant.

`X u(a);` and `X u = a;` are statements, each with the following properties:

- **Preconditions**: `T` is `Cpp17CopyInsertable` into `X` (see below).
- **Postconditions**: `u == a`
- **Complexity**: Linear.

`X u(rv);` and `X u = rv;` are statements, each with the following properties:

- **Postconditions**: `u` is equal to the value that `rv` had before this construction.
- **Complexity**: Linear for array and constant for all other standard containers.

`a = rv` is an expression with the following properties:

- **Result**: An lvalue of type `X`.
- **Effects**: All existing elements of `a` are either move assigned to or destroyed.
- **Postconditions**: If `a` and `rv` do not refer to the same object, `a` is equal to the value that `rv` had before this assignment.
- **Complexity**: Linear.

`a.X()` is an expression with the following properties:

- **Result**: `void`
- **Effects**: Destroys every element of `a`; any memory obtained is deallocated.
- **Complexity**: Linear.

`a.begin()` is an expression with the following properties:

- **Result**: A prvalue of type `iterator; const_iterator` for constant `a`.
- **Value**: An iterator referring to the first element in the container.
- **Complexity**: Constant.

`a.end()` is an expression with the following properties:

- **Result**: A prvalue of type `iterator; const_iterator` for constant `a`.
- **Value**: An iterator which is the past-the-end value for the container.
- **Complexity**: Constant.

`a.cbegin()` is an expression with the following properties:

- **Result**: A prvalue of type `const_iterator`.
- **Value**: `const_cast<X const&>(a).begin()`
- **Complexity**: Constant.
\begin{verbatim}
a.cend() is an expression with the following properties:
   Result: A prvalue of type const_iterator.
   Value: const_cast<X const&>(a).end()
   Complexity: Constant.

i <=> j is an expression with the following properties:
   Result: A prvalue of type strong_ordering.
   Constraints: X::iterator meets the random access iterator requirements.
   Complexity: Constant.

a == b is an expression with the following properties:
   Preconditions: T meets the Cpp17EqualityComparable requirements
   Result: Convertible to bool.
   Value: equal(a.begin(), a.end(), b.begin(), b.end())
   [Note 1: The algorithm equal is defined in 25.6.11. — end note]
   Complexity: Constant if a.size() != b.size(), linear otherwise.
   Remarks: == is an equivalence relation.

a != b is an expression with the following properties:
   Effects: Equivalent to !(a == b).

a.swap(b) is an expression with the following properties:
   Result: void
   Effects: Exchanges the contents of a and b.
   Complexity: Linear for array and constant for all other standard containers.

swap(a, b) is an expression with the following properties:
   Effects: Equivalent to a.swap(b).

r = a is an expression with the following properties:
   Result: An lvalue of type X.
   Postconditions: r == a.
   Complexity: Linear.

a.size() is an expression with the following properties:
   Result: A prvalue of type size_type.
   Value: distance(a.begin(), a.end()), i.e. the number of elements in the container.
   Complexity: Constant.
   Remarks: The number of elements is defined by the rules of constructors, inserts, and erases.

a.max_size() is an expression with the following properties:
   Result: A prvalue of type size_type.
   Returns: distance(begin(), end()) for the largest possible container.
   Complexity: Constant.

a.empty() is an expression with the following properties:
   Result: Convertible to bool.
   Value: a.begin() == a.end()
   Complexity: Constant.
   Remarks: If the container is empty, then a.empty() is true.
\end{verbatim}
In the expressions
\[
\begin{align*}
    i &= j \\
    i &
eq j \\
    i &< j \\
    i &> j \\
    i &\leq j \\
    i &\geq j \\
    i &> j \\
    i &\leq j
\end{align*}
\]
where \(i\) and \(j\) denote objects of a container’s iterator type, either or both may be replaced by an object of the container’s const_iterator type referring to the same element with no change in semantics.

Unless otherwise specified, all containers defined in this Clause obtain memory using an allocator (see 16.4.4.6).

[Note 2: In particular, containers and iterators do not store references to allocated elements other than through the allocator’s pointer type, i.e., as objects of type \(P\) or \(\text{pointer_traits<P>::template rebind<unspecified>}\), where \(P\) is \(\text{allocator_traits<allocator_type>::pointer}\). — end note]

Copy constructors for these container types obtain an allocator by calling \(\text{allocator_traits<allocator_type>::select_on_container_copy_construction}\) on the allocator belonging to the container being copied. Move constructors obtain an allocator by move construction from the allocator belonging to the container being moved. Such move construction of the allocator shall not exit via an exception. All other constructors for these container types take a const allocator_type& argument.

[Note 3: If an invocation of a constructor uses the default value of an optional allocator argument, then the allocator type must support value-initialization. — end note]

A copy of this allocator is used for any memory allocation and element construction performed, by these constructors and by all member functions, during the lifetime of each container object or until the allocator is replaced. The allocator may be replaced only via assignment or \(\text{swap()}\). Allocator replacement is performed by copy assignment, move assignment, or swapping of the allocator only if

\[
\begin{align*}
    &\text{(55.1)} \quad \text{allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value}, \\
    &\text{(55.2)} \quad \text{allocator_traits<allocator_type>::propagate_on_container_move_assignment::value}, \text{ or} \\
    &\text{(55.3)} \quad \text{allocator_traits<allocator_type>::propagate_on_container_swap::value}
\end{align*}
\]

is true within the implementation of the corresponding container operation. In all container types defined in this Clause, the member \(\text{get_allocator}()\) returns a copy of the allocator used to construct the container or, if that allocator has been replaced, a copy of the most recent replacement.

The expression \(a\.\text{swap}(b)\), for containers \(a\) and \(b\) of a standard container type other than \(\text{array}\), shall exchange the values of \(a\) and \(b\) without invoking any move, copy, or swap operations on the individual container elements. Lvalues of any \(\text{Compare}\), \(\text{Pred}\), or \(\text{Hash}\) types belonging to \(a\) and \(b\) shall be swappable and shall be exchanged by calling \(\text{swap}\) as described in 16.4.4.3. If \(\text{allocator_traits<allocator_type>::propagate_on_container_swap::value}\) is true, then lvalues of type \(\text{allocator_type}\) shall be swappable and the allocators of \(a\) and \(b\) shall also be exchanged by calling \(\text{swap}\) as described in 16.4.4.3. Otherwise, the allocators shall not be swapped, and the behavior is undefined unless \(a\.\text{get_allocator}() == b\.\text{get_allocator}()\). Every iterator referring to an element in one container before the swap shall refer to the same element in the other container after the swap. It is unspecified whether an iterator with value \(a\.\text{end}()\) before the swap will have value \(b\.\text{end}()\) after the swap.

### 22.2.2.3 Reversible container requirements

A type \(X\) meets the reversible container requirements if \(X\) meets the container requirements, the iterator type of \(X\) belongs to the bidirectional or random access iterator categories (23.3), and the following types and expressions are well-formed and have the specified semantics.

\[
\begin{align*}
    &\text{(1.1)} \quad \text{The name } X::\text{reverse_iterator} \text{ denotes the type } \text{reverse_iterator}<X::\text{iterator}>, \text{ an iterator type whose value type is T}. \\
    &\text{(1.2)} \quad \text{The name } X::\text{const_reverse_iterator} \text{ denotes the type } \text{reverse_iterator}<X::\text{const_iterator}>, \text{ a constant iterator type whose value type is T}.
\end{align*}
\]

\(a\.\text{rbegin}()\) is an expression with the following properties:

\[
\begin{align*}
\text{Result: reverse_iterator; const_reverse_iterator for constant a}
\end{align*}
\]
Value: reverse_iterator(end())

Complexity: Constant.

a.rend() is an expression with the following properties:

Result: reverse_iterator; const_reverse_iterator for constant a

Value: reverse_iterator(begin())

Complexity: Constant.

a.crbegin() is an expression with the following properties:

Result: const_reverse_iterator

Value: const_cast<X const&>(a).rbegin()

Complexity: Constant.

a.crend() is an expression with the following properties:

Result: const_reverse_iterator

Value: const_cast<X const&>(a).rend()

Complexity: Constant.

Unless otherwise specified (see 22.2.7.2, 22.2.8.2, 22.3.8.4, and 22.3.11.5) all container types defined in this Clause meet the following additional requirements:

(14.1) if an exception is thrown by an insert() or emplace() function while inserting a single element, that function has no effects.

(14.2) if an exception is thrown by a push_back(), push_front(), emplace_back(), or emplace_front() function, that function has no effects.

(14.3) no erase(), clear(), pop_back() or pop_front() function throws an exception.

(14.4) no copy constructor or assignment operator of a returned iterator throws an exception.

(14.5) no swap() function throws an exception.

(14.6) no swap() function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped.

[Note 1: The end() iterator does not refer to any element, so it can be invalidated. — end note]

Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

A contiguous container is a container whose member types iterator and const_iterator meet the Cpp17RandomAccessIterator requirements (23.3.5.7) and model contiguous_iterator (23.3.4.14).

22.2.2.4 Optional container requirements

The following operations are provided for some types of containers but not others. Those containers for which the listed operations are provided shall implement the semantics as described unless otherwise stated. If the iterators passed to lexicographical_compare_three_way meet the constexpr iterator requirements (23.3.1) then the operations described below are implemented by constexpr functions.

a <=> b is an expression with the following properties:

Result: A prvalue of type synth-three-way-result<X::value_type>.

Preconditions: Either <=> is defined for values of type (possibly const) T, or < is defined for values of type (possibly const) T and < is a total ordering relationship.

Value: lexicographical_compare_three_way(a.begin(), a.end(), b.begin(), b.end(), synth-three-way)

[Note 1: The algorithm lexicographical_compare_three_way is defined in Clause 25. — end note]

Complexity: Linear.
22.2.2.5 Allocator-aware containers

All of the containers defined in Clause 22 and in 21.3.3 except array meet the additional requirements of an allocator-aware container, as described below.

Given an allocator type \( A \) and given a container type \( X \) having a value_type identical to \( T \) and an allocator_type identical to \( \text{allocator_traits}<A>::\text{rebind_alloc}<T> \) and given an lvalue \( m \) of type \( A \), a pointer \( p \) of type \( T* \), an expression \( v \) of type (possibly const) \( T \), and an rvalue \( rv \) of type \( T \), the following terms are defined. If \( X \) is not allocator-aware, the terms below are defined as if \( A \) were \( \text{allocator}<T> \) — no allocator object needs to be created and user specializations of \( \text{allocator}<T> \) are not instantiated:

1. \( T \) is Cpp17DefaultInsertable into \( X \) means that the following expression is well-formed:
   \[
   \text{allocator_traits}<A>::\text{construct}(m, p)
   \]
   where \( p \) is the address of the uninitialized storage for the element allocated within \( X \).

2. \( T \) is Cpp17MoveInsertable into \( X \) means that the following expression is well-formed:
   \[
   \text{allocator_traits}<A>::\text{construct}(m, p, rv)
   \]
   and its evaluation causes the following postcondition to hold: The value of \( *p \) is equivalent to the value of \( rv \) before the evaluation.

[Note 1: \( rv \) remains a valid object. Its state is unspecified — end note]

3. \( T \) is Cpp17CopyInsertable into \( X \) means that, in addition to \( T \) being Cpp17MoveInsertable into \( X \), the following expression is well-formed:
   \[
   \text{allocator_traits}<A>::\text{construct}(m, p, v)
   \]
   and its evaluation causes the following postcondition to hold: The value of \( v \) is unchanged and is equivalent to \( *p \).

4. \( T \) is Cpp17EmplaceConstructible into \( X \) from args, for zero or more arguments args, means that the following expression is well-formed:
   \[
   \text{allocator_traits}<A>::\text{construct}(m, p, \text{args})
   \]

[Note 2: A container calls \( \text{allocator_traits}<A>::\text{construct}(m, p, \text{args}) \) to construct an element at \( p \) using \( \text{args} \), with \( m == \text{get_allocator()} \). The default \( \text{construct} \) in \( \text{allocator} \) will call \( \text{::new}((\text{void}*)p) T(\text{args}) \), but specialized allocators can choose a different definition. — end note]

In this subclause,

- \( X \) denotes an allocator-aware container class with a value_type of \( T \) using an allocator of type \( A \),
- \( u \) denotes a variable,
- \( a \) and \( b \) denote non-const lvalues of type \( X \),
- \( c \) denotes an lvalue of type const \( X \),
- \( t \) denotes an lvalue or a const rvalue of type \( X \), and
- \( rv \) denotes a non-const rvalue of type \( X \), and
- \( m \) is a value of type \( A \).

A type \( X \) meets the allocator-aware container requirements if \( X \) meets the container requirements and the following types and expressions are well-formed and have the specified semantics.

- \( X::\text{allocator_type} \) denotes the type \( A \). \( X::\text{allocator_type}::\text{value_type} \) is the same as \( X::\text{value_type} \).

\( \text{c.get_allocator()} \) is an expression with the following properties:

Result: \( A \)

Complexity: Constant.

\( X u; \) and \( X u = X() \) are statements, each with the following properties:

Preconditions: \( A \) meets the Cpp17DefaultConstructible requirements.
Postconditions: \( u.\text{empty()} \) returns \( \text{true} \), \( u.\text{get_allocator()} == \text{A}() \).

Complexity: Constant.

\( X \ u(m); \) is a statement with the following properties:

Postconditions: \( u.\text{empty()} \) returns \( \text{true} \), \( u.\text{get_allocator()} == m \).

Complexity: Constant.

\( X \ u(t, m); \) is a statement with the following properties:

Preconditions: \( T \) is \( \text{Cpp17CopyInsertable} \) into \( X \).

Postconditions: \( u == t, u.\text{get_allocator()} == m \)

Complexity: Linear.

\( X \ u(rv); \) is a statement with the following properties:

Postconditions: \( u \) has the same elements as \( rv \) had before this construction; the value of \( u.\text{get_allocator()} \) is the same as the value of \( rv.\text{get_allocator()} \) before this construction.

Complexity: Constant.

\( X \ u(rv, m); \) is a statement with the following properties:

Preconditions: \( T \) is \( \text{Cpp17MoveInsertable} \) into \( X \).

Postconditions: \( u \) has the same elements, or copies of the elements, that \( rv \) had before this construction, \( u.\text{get_allocator()} == m \).

Complexity: Constant if \( m == rv.\text{get_allocator()} \), otherwise linear.

\( a = t \) is an expression with the following properties:

Result: An lvalue of type \( X \).

Preconditions: \( T \) is \( \text{Cpp17CopyInsertable} \) into \( X \) and \( \text{Cpp17CopyAssignable} \).

Postconditions: \( a == t \) is \( \text{true} \).

Complexity: Linear.

\( a = rv \) is an expression with the following properties:

Result: An lvalue of type \( X \).

Preconditions: If \( \text{allocator_traits<allocator_type>::propagate_on_container_move_assignment::value} \) is \( \text{false} \), \( T \) is \( \text{Cpp17MoveInsertable} \) into \( X \) and \( \text{Cpp17MoveAssignable} \).

Effects: All existing elements of \( a \) are either move assigned to or destroyed.

Postconditions: If \( a \) and \( rv \) do not refer to the same object, \( a \) is equal to the value that \( rv \) had before this assignment.

Complexity: Linear.

\( a.\text{swap}(b) \) is an expression with the following properties:

Result: \( \text{void} \)

Effects: Exchanges the contents of \( a \) and \( b \).

Complexity: Constant.

The behavior of certain container member functions and deduction guides depends on whether types qualify as input iterators or allocators. The extent to which an implementation determines that a type cannot be an input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators. Likewise, the extent to which an implementation determines that a type cannot be an allocator is unspecified, except that as a minimum a type \( A \) shall not qualify as an allocator unless it meets both of the following conditions:

(31.1) The qualified-id \( A::\text{value_type} \) is valid and denotes a type (13.10.3).

(31.2) The expression \( \text{declval}<A&>().\text{allocate}(\text{size_t}) \) is well-formed when treated as an unevaluated operand.
22.2.3 Container data races

For purposes of avoiding data races (16.4.6.10), implementations shall consider the following functions to be `const`: `begin`, `end`, `rbegin`, `rend`, `front`, `back`, `data`, `find`, `lower_bound`, `upper_bound`, `equal_range`, and, except in associative or unordered associative containers, `operator[]`.

Notwithstanding 16.4.6.10, implementations are required to avoid data races when the contents of the contained object in different elements in the same container, excepting `vector<bool>`, are modified concurrently.

[Note 1: For a `vector<int>` `x` with a size greater than one, `x[1] = 5` and `*x.begin() = 10` can be executed concurrently without a data race, but `x[0] = 5` and `*x.begin() = 10` executed concurrently can result in a data race. As an exception to the general rule, for a `vector<bool>` `y`, `y[0] = true` can race with `y[1] = true`. — end note]

22.2.4 Sequence containers

A sequence container organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides four basic kinds of sequence containers: `vector`, `forward_list`, `list`, and `deque`. In addition, `array` is provided as a sequence container which provides limited sequence operations because it has a fixed number of elements. The library also provides container adaptors that make it easy to construct abstract data types, such as stacks or queues, out of the basic sequence container kinds (or out of other kinds of sequence containers that the user defines).

[Note 1: The sequence containers offer the programmer different complexity trade-offs. `vector` is appropriate in most circumstances. `array` has a fixed size known during translation. `list` or `forward_list` support frequent insertions and deletions from the middle of the sequence. `deque` supports efficient insertions and deletions taking place at the beginning or at the end of the sequence. When choosing a container, remember `vector` is best; leave a comment to explain if you choose from the rest! — end note]

In this subclause,

- `X` denotes a sequence container class,
- `a` denotes a value of type `X` containing elements of type `T`,
- `u` denotes the name of a variable being declared,
- `A` denotes `X::allocator_type` if the qualified-id `X::allocator_type` is valid and denotes a type (13.10.3) and `allocator<T>` if it doesn’t,
- `i` and `j` denote iterators that meet the `Cpp17InputIterator` requirements and refer to elements implicitly convertible to `value_type`.
- `[i, j)` denotes a valid range,
- `il` designates an object of type `initializer_list<value_type>`.
- `n` denotes a value of type `X::size_type`.
- `p` denotes a valid constant iterator to `a`.
- `q` denotes a valid dereferenceable constant iterator to `a`.
- `{q1, q2}` denotes a valid range of constant iterators in `a`.
- `t` denotes an lvalue or a const rvalue of `X::value_type`, and
- `rv` denotes a non-const rvalue of `X::value_type`.
- `Args` denotes a template parameter pack;
- `args` denotes a function parameter pack with the pattern `Args&&`.

The complexities of the expressions are sequence dependent.

A type `X` meets the sequence container requirements if `X` meets the container requirements and the following statements and expressions are well-formed and have the specified semantics.

[X `u(n, t);` is a statement with the following properties:

- Preconditions: `T` is `Cpp17CopyInsertable` into `X`.
- Effects: Constructs a sequence container with `n` copies of `t`.
- Postconditions: `distance(u.begin(), u.end()) == n` is true.]
X u(i, j); is a statement with the following properties:

- **Preconditions**: T is Cpp17EmplaceConstructible into X from *i. For vector, if the iterator does not meet the Cpp17ForwardIterator requirements (23.3.5.5), T is also Cpp17MoveInsertable into X.
- **Effects**: Constructs a sequence container equal to the range [i, j). Each iterator in the range [i, j) is dereferenced exactly once.
- **Postconditions**: distance(u.begin(), u.end()) == distance(i, j) is true.

X(il) is an expression with the following properties:

- **Effects**: Equivalent to X(il.begin(), il.end()).

a = il is an expression with the following properties:

- **Result**: An lvalue of type X.
- **Preconditions**: T is Cpp17CopyInsertable into X and Cpp17CopyAssignable.
- **Effects**: Assigns the range [il.begin(), il.end()) into a. All existing elements of a are either assigned to or destroyed.
- **Returns**: *this.

aemplace(p, args) is an expression with the following properties:

- **Result**: A prvalue of type iterator.
- **Preconditions**: T is Cpp17EmplaceConstructible into X from args. For vector and deque, T is also Cpp17MoveInsertable into X and Cpp17MoveAssignable.
- **Effects**: Inserts an object of type T constructed with std::forward<Args>(args)... before p.
- **Note 2**: args can directly or indirectly refer to a value in a. —end note
- **Returns**: An iterator that points to the new element constructed from args into a.

a.insert(p, t) is an expression with the following properties:

- **Result**: A prvalue of type iterator.
- **Preconditions**: T is Cpp17CopyInsertable into X. For vector and deque, T is also Cpp17CopyAssignable.
- **Effects**: Inserts a copy of t before p.
- **Returns**: An iterator that points to the copy of t inserted into a.

a.insert(p, rv) is an expression with the following properties:

- **Result**: A prvalue of type iterator.
- **Preconditions**: T is Cpp17MoveInsertable into X. For vector and deque, T is also Cpp17MoveAssignable.
- **Effects**: Inserts a copy of rv before p.
- **Returns**: An iterator that points to the copy of rv inserted into a.

a.insert(p, n, t) is an expression with the following properties:

- **Result**: A prvalue of type iterator.
- **Preconditions**: T is Cpp17CopyInsertable into X and Cpp17CopyAssignable.
- **Effects**: Inserts n copies of t before p.
- **Returns**: An iterator that points to the copy of the first element inserted into a, or p if n == 0.

a.insert(p, i, j) is an expression with the following properties:

- **Result**: A prvalue of type iterator.
- **Preconditions**: T is Cpp17EmplaceConstructible into X from *i. For vector and deque, T is also Cpp17MoveInsertable into X, Cpp17MoveConstructible, Cpp17MoveAssignable, and swappable (16.4.4.3). Neither i nor j are iterators into a.
- **Effects**: Inserts copies of elements in [i, j) before p. Each iterator in the range [i, j) shall be dereferenced exactly once.
Returns: An iterator that points to the copy of the first element inserted into \( a \), or \( p \) if \( i == j \).

\( \text{a.insert(p, il)} \) is an expression with the following properties:

Effects: Equivalent to \( \text{a.insert(p, il.begin(), il.end())} \).

\( \text{a.erase(q)} \) is an expression with the following properties:

Result: A prvalue of type \text{iterator}.

Preconditions: For \text{vector} and \text{deque}, \( T \) is \text{Cpp17MoveAssignable}.

Effects: Erases the element pointed to by \( q \).

Returns: An iterator that points to the element immediately following \( q \) prior to the element being erased. If no such element exists, \( a.end() \) is returned.

\( \text{a.erase(q1, q2)} \) is an expression with the following properties:

Result: A prvalue of type \text{iterator}.

Preconditions: For \text{vector} and \text{deque}, \( T \) is \text{Cpp17MoveAssignable}.

Effects: Erases the elements in the range \([q1, q2)\).

Returns: An iterator that points to the element pointed to by \( q2 \) prior to any elements being erased. If no such element exists, \( a.end() \) is returned.

\( \text{a.clear()} \) is an expression with the following properties:

Result: \text{void}

Effects: Destroys all elements in \( a \). Invalidates all references, pointers, and iterators referring to the elements of \( a \) and may invalidate the past-the-end iterator.

Postconditions: \( \text{a.empty()} \) is \text{true}.

Complexity: Linear.

\( \text{a.assign(i, j)} \) is an expression with the following properties:

Result: \text{void}

Preconditions: \( T \) is \text{Cpp17EmplaceConstructible} into \( X \) from \( *i \) and assignable from \( *i \). For \text{vector}, if the iterator does not meet the forward iterator requirements (23.3.5.5), \( T \) is also \text{Cpp17MoveInsertable} into \( X \). Neither \( i \) nor \( j \) are iterators into \( a \).

Effects: Replaces elements in \( a \) with a copy of \([i, j)\). Invalidates all references, pointers and iterators referring to the elements of \( a \). For \text{vector} and \text{deque}, also invalidates the past-the-end iterator. Each iterator in the range \([i, j)\) shall be dereferenced exactly once.

\( \text{a.assign(il)} \) is an expression with the following properties:

Effects: Equivalent to \( \text{a.assign(il.begin(), il.end())} \).

\( \text{a.assign(n, t)} \) is an expression with the following properties:

Result: \text{void}

Preconditions: \( T \) is \text{Cpp17CopyInsertable} into \( X \) and \text{Cpp17CopyAssignable}. \( t \) is not a reference into \( a \).

Effects: Replaces elements in \( a \) with \( n \) copies of \( t \). Invalidates all references, pointers and iterators referring to the elements of \( a \). For \text{vector} and \text{deque}, also invalidates the past-the-end iterator.

For every sequence container defined in this Clause and in Clause 21:

- If the constructor

  \[
  \text{template<class InputIterator>}
  
  X(InputIterator first, InputIterator last, 
  \text{const allocator_type& alloc = allocator_type()});
  \]

  is called with a type \text{InputIterator} that does not qualify as an input iterator, then the constructor shall not participate in overload resolution.

- If the member functions of the forms:
template<class InputIterator>
return-type F(const_iterator p, InputIterator first, InputIterator last); // such as insert

template<class InputIterator>
return-type F(InputIterator first, InputIterator last); // such as append, assign

template<class InputIterator>
return-type F(const_iterator i1, const_iterator i2, InputIterator first, InputIterator last); // such as replace

are called with a type InputIterator that does not qualify as an input iterator, then these functions shall not participate in overload resolution.

— A deduction guide for a sequence container shall not participate in overload resolution if it has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter, or if it has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.

The following operations are provided for some types of sequence containers but not others. An implementation shall implement them so as to take amortized constant time.

a.front() is an expression with the following properties:
Result: reference; const_reference for constant a.
Returns: *a.begin()
Remarks: Required for basic_string, array, deque, forward_list, list, and vector.

a.back() is an expression with the following properties:
Effects: Equivalent to:
auto tmp = a.end();
--tmp;
return *tmp;
Remarks: Required for basic_string, array, deque, list, and vector.

a.emplace_front(args) is an expression with the following properties:
Result: reference
Preconditions: T is Cpp17EmplaceConstructible into X from args.
Effects: Prepends an object of type T constructed with std::forward<Args>(args)....
Returns: a.front().
Remarks: Required for deque, forward_list, and list.

a.emplace_back(args) is an expression with the following properties:
Result: reference
Preconditions: T is Cpp17EmplaceConstructible into X from args. For vector, T is also Cpp17MoveInsertable into X.
Effects: Appends an object of type T constructed with std::forward<Args>(args)....
Returns: a.back().
Remarks: Required for deque, list, and vector.

a.push_front(t) is an expression with the following properties:
Result: void
Preconditions: T is Cpp17CopyInsertable into X.
Effects: Prepends a copy of t.
Remarks: Required for deque, forward_list, and list.
a.push_front(rv) is an expression with the following properties:

Result: void
Preconditions: T is Cpp17MoveInsertable into X.
Effects: Prepends a copy of rv.
Remarks: Required for deque, forward_list, and list.

a.push_back(t) is an expression with the following properties:

Result: void
Preconditions: T is Cpp17CopyInsertable into X.
Effects: Appends a copy of t.
Remarks: Required for basic_string, deque, list, and vector.

a.push_back(rv) is an expression with the following properties:

Result: void
Preconditions: T is Cpp17MoveInsertable into X.
Effects: Appends a copy of rv.
Remarks: Required for basic_string, deque, list, and vector.

a.pop_front() is an expression with the following properties:

Result: void
Preconditions: a.empty() is false.
Effects: Destroys the first element.
Remarks: Required for deque, forward_list, and list.

a.pop_back() is an expression with the following properties:

Result: void
Preconditions: a.empty() is false.
Effects: Destroys the last element.
Remarks: Required for basic_string, deque, list, and vector.

a[n] is an expression with the following properties:

Result: reference; const_reference for constant a
Returns: *(a.begin() + n)
Remarks: Required for basic_string, array, deque, and vector.

a.at(n) is an expression with the following properties:

Result: reference; const_reference for constant a
Returns: *(a.begin() + n)
Throws: out_of_range if n >= a.size().
Remarks: Required for basic_string, array, deque, and vector.

22.2.5 Node handles

22.2.5.1 Overview

A node handle is an object that accepts ownership of a single element from an associative container (22.2.7) or an unordered associative container (22.2.8). It may be used to transfer that ownership to another container with compatible nodes. Containers with compatible nodes have the same node handle type. Elements may be transferred in either direction between container types in the same row of Table 73.

If a node handle is not empty, then it contains an allocator that is equal to the allocator of the container when the element was extracted. If a node handle is empty, it contains no allocator.
explicit operator bool() const noexcept;

Returns: ptr_ != nullptr.

[[nodiscard]] bool empty() const noexcept;

Returns: ptr_ == nullptr.

22.2.5.5 Modifiers

`void swap(node-handle& nh)`

noexcept(ator_traits::propagate_on_container_swap::value ||
ator_traits::is_always_equal::value);

Preconditions: !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap::value is true, or alloc_ == nh.alloc_.

Effects: Calls swap(ptr_, nh.ptr_). If !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap::value is true calls swap(alloc_, nh.alloc_).

22.2.6 Insert return type

The associative containers with unique keys and the unordered containers with unique keys have a member function `insert` that returns a nested type `insert_return_type`. That return type is a specialization of the template specified in this subclause.

```cpp
template<class Iterator, class NodeType>
struct insert-return-type
{
    Iterator position;
    bool inserted;
    NodeType node;
};
```

The name `insert-return-type` is exposition only. `insert-return-type` has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

22.2.7 Associative containers

22.2.7.1 General

Associative containers provide fast retrieval of data based on keys. The library provides four basic kinds of associative containers: `set`, `multiset`, `map` and `multimap`.

Each associative container is parameterized on `Key` and an ordering relation `Compare` that induces a strict weak ordering (25.8) on elements of `Key`. In addition, `map` and `multimap` associate an arbitrary mapped type `T` with the `Key`. The object of type `Compare` is called the `comparison object` of a container.

The phrase “equivalence of keys” means the equivalence relation imposed by the comparison object. That is, two keys `k1` and `k2` are considered to be equivalent if for the comparison object `comp`, `comp(k1, k2) == false` & `comp(k2, k1) == false`.

[Note 1: This is not necessarily the same as the result of `k1 == k2`. — end note]

For any two keys `k1` and `k2` in the same container, calling `comp(k1, k2)` shall always return the same value.

An associative container supports `unique keys` if it may contain at most one element for each key. Otherwise, it supports `equivalent keys`. The `set` and `map` classes support unique keys; the `multiset` and `multimap` classes support equivalent keys. For `multiset` and `multimap`, `insert`, `emplace`, and `erase` preserve the relative ordering of equivalent elements.

For `set` and `multiset` the value type is the same as the key type. For `map` and `multimap` it is equal to `pair<const Key, T>`.

`iterator` of an associative container is of the bidirectional iterator category. For associative containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type.

[Note 2: `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists. — end note]
In this subclause,

---

(7.1) \( X \) denotes an associative container class,

(7.2) \( a \) denotes a value of type \( X \),

(7.3) \( a_2 \) denotes a value of a type with nodes compatible with type \( X \) (Table 73),

(7.4) \( b \) denotes a possibly const value of type \( X \),

(7.5) \( u \) denotes the name of a variable being declared,

(7.6) \( a_{\text{uniq}} \) denotes a value of type \( X \) when \( X \) supports unique keys,

(7.7) \( a_{\text{eq}} \) denotes a value of type \( X \) when \( X \) supports multiple keys,

(7.8) \( a_{\text{tran}} \) denotes a possibly const value of type \( X \) when the qualified-id \( X::\text{key_compare}::\text{is_transparent} \) is valid and denotes a type (13.10.3),

(7.9) \( i \) and \( j \) meet the Cpp17InputIterator requirements and refer to elements implicitly convertible to value_type,

(7.10) \([i, j)\) denotes a valid range,

(7.11) \( p \) denotes a valid constant iterator to \( a \),

(7.12) \( q \) denotes a valid dereferenceable constant iterator to \( a \),

(7.13) \( r \) denotes a valid dereferenceable iterator to \( a \),

(7.14) \([q_1, q_2)\) denotes a valid range of constant iterators in \( a \),

(7.15) \( \text{il} \) designates an object of type \( \text{initializer_list<value_type>} \),

(7.16) \( t \) denotes a value of type \( X::\text{value_type} \),

(7.17) \( k \) denotes a value of type \( X::\text{key_type} \), and

(7.18) \( c \) denotes a possibly const value of type \( X::\text{key_compare} \),

(7.19) \( k_1 \) is a value such that \( a \) is partitioned (25.8) with respect to \( c(r, k_1) \), with \( r \) the key value of \( e \) and \( e \) in \( a \);

(7.20) \( k_u \) is a value such that \( a \) is partitioned with respect to \( c(k_u, r) \);

(7.21) \( k_e \) is a value such that \( a \) is partitioned with respect to \( c(r, k_e) \) and \( !c(k_e, r) \), with \( c(r, k_e) \) implying \( !c(k_e, r) \).

(7.22) \( A \) denotes the storage allocator used by \( X \), if any, or allocator<\( X::\text{value_type} \)> otherwise,

(7.23) \( \text{m} \) denotes an allocator of a type convertible to \( A \), and \( \text{nh} \) denotes a non-const rvalue of type \( \text{X::node_type} \).

---

A type \( X \) meets the associative container requirements if \( X \) meets all the requirements of an allocator-aware container (22.2.2.1) and the following statements and expressions are well-formed and have the specified semantics, except that for map and multimap, the requirements placed on value_type in 22.2.2.5 apply instead to key_type and mapped_type.

[Note 3: For example, in some cases key_type and mapped_type are required to be Cpp17CopyAssignable even though the associated value_type, pair<const key_type, mapped_type>, is not Cpp17CopyAssignable. — end note]

---

(8.1) The name \( X::\text{key_type} \) denotes the type Key.

(8.2) For map and multimap only, the name \( X::\text{mapped_type} \) denotes T.

(8.3) For set and multiset only, the name \( X::\text{value_type} \) denotes Key.

(8.4) For map and multimap only, the name \( X::\text{value_type} \) denotes pair<const Key, T>.

(8.5) Preconditions: \( X::\text{value_type} \) is Cpp17Erasable from \( X \).

(8.6) The name \( X::\text{key_compare} \) denotes Compare. Preconditions: key_compare is Cpp17CopyConstructible.

(8.7) The name \( X::\text{value_compare} \) denotes a binary predicate type. It is the same as key_compare for set and multiset; is an ordering relation on pairs induced by the first component (i.e., Key) for map and multimap.

(8.8) The name \( X::\text{node_type} \) denotes a specialization of the node-handle class template (22.2.5), such that the public nested types are the same types as the corresponding types in \( X \).
X(c) is an expression with the following properties:

**Effects**: Constructs an empty container. Uses a copy of \( c \) as a comparison object.

**Complexity**: Constant.

\[ X(u) = X(); \] and \( X(u) \) are statements, each with the following properties:

**Preconditions**: \( \textit{key\_compare} \) meets the \textit{Cpp17DefaultConstructible} requirements.

**Effects**: Constructs an empty container. Uses \( \textit{Compare()} \) as a comparison object.

**Complexity**: Constant.

\[ X(i, j, c); \] is an expression with the following properties:

**Preconditions**: \( \textit{value\_type} \) is \textit{Cpp17EmplaceConstructible} into \( X \) from \*\( \text{i} \).

**Effects**: Constructs an empty container and inserts elements from the range \([i, j)\) into it; uses \( c \) as a comparison object.

**Complexity**: \( N \log N \) in general, where \( N \) has the value \( \textit{distance}(i, j) \); linear if \([i, j)\) is sorted with \( \textit{value\_comp()} \).

\[ X(i, j) \] is an expression with the following properties:

**Preconditions**: \( \textit{key\_compare} \) meets the \textit{Cpp17DefaultConstructible} requirements. \( \textit{value\_type} \) is \textit{Cpp17EmplaceConstructible} into \( X \) from \*\( \text{i} \).

**Effects**: Constructs an empty container and inserts elements from the range \([i, j)\) into it; uses \( \textit{Compare()} \) as a comparison object.

**Complexity**: \( N \log N \) in general, where \( N \) has the value \( \textit{distance}(i, j) \); linear if \([i, j)\) is sorted with \( \textit{value\_comp()} \).

\[ X(il, c) \] is an expression with the following properties:

**Effects**: Equivalent to \( X(il.\text{begin}(), il.\text{end}(), c) \).

\[ X(il) \] is an expression with the following properties:

**Effects**: Equivalent to \( X(il.\text{begin}(), il.\text{end}()) \).

\[ a = il \] is an expression with the following properties:

**Result**: \( X& \)

**Preconditions**: \( \textit{value\_type} \) is \textit{Cpp17CopyInsertable} into \( X \) and \textit{Cpp17CopyAssignable}.

**Effects**: Assigns the range \([il.\text{begin}(), il.\text{end}())\) into \( a \). All existing elements of \( a \) are either assigned to or destroyed.

**Complexity**: \( N \log N \) in general, where \( N \) has the value \( il.\text{size}() + a.\text{size}(); \) linear if \([il.\text{begin}(), il.\text{end}())\) is sorted with \( \textit{value\_comp()} \).

\[ b.\textit{key\_comp()} \] is an expression with the following properties:

**Result**: \( X::\textit{key\_compare} \)

**Returns**: The comparison object out of which \( b \) was constructed.

**Complexity**: Constant.

\[ b.\textit{value\_comp()} \] is an expression with the following properties:

**Result**: \( X::\textit{value\_compare} \)

**Returns**: An object of \( \textit{value\_compare} \) constructed out of the comparison object.

**Complexity**: Constant.

\[ a.\textit{uniq}\_emplace(args) \] is an expression with the following properties:

**Result**: \( \text{pair<iterator, bool>} \)

**Preconditions**: \( \textit{value\_type} \) is \textit{Cpp17EmplaceConstructible} into \( X \) from \( args \).
Effects: Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...` if and only if there is no element in the container with key equivalent to the key of `t`.

Returns: The `bool` component of the returned pair is `true` if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of `t`.

**Complexity:** Logarithmic.

### `a_eq.emplace(args)`

is an expression with the following properties:

**Result:** Iterator

**Preconditions:** `value_type` is `Cpp17EmplaceConstructible` into `X` from `args`.

**Effects:** Inserts a `value_type` object `t` constructed with `std::forward<Args>(args)...`. If a range containing elements equivalent to `t` exists in `a_eq`, `t` is inserted at the end of that range.

**Returns:** An iterator pointing to the newly inserted element.

**Complexity:** Logarithmic.

### `a.emplace_hint(p, args)`

is an expression with the following properties:

**Result:** Iterator

**Effects:** Equivalent to `a.emplace(std::forward<Args>(args)...), except that the element is inserted as close as possible to the position just prior to `p`.

**Returns:** An iterator pointing to the element with the key equivalent to the newly inserted element.

**Complexity:** Logarithmic in general, but amortized constant if the element is inserted right before `p`.

### `a_uniq.insert(t)`

is an expression with the following properties:

**Result:** Pair<iterator, bool>

**Preconditions:** If `t` is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.

**Effects:** Inserts `t` if and only if there is no element in the container with key equivalent to the key of `t`.

**Returns:** The `bool` component of the returned pair is `true` if and only if the insertion takes place, and the `iterator` component of the pair points to the element with key equivalent to the key of `t`.

**Complexity:** Logarithmic.

### `a_eq.insert(t)`

is an expression with the following properties:

**Result:** Iterator

**Preconditions:** If `t` is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.

**Effects:** Inserts `t` and returns the iterator pointing to the newly inserted element. If a range containing elements equivalent to `t` exists in `a_eq`, `t` is inserted at the end of that range.

**Complexity:** Logarithmic.

### `a.insert(p, t)`

is an expression with the following properties:

**Result:** Iterator

**Preconditions:** If `t` is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.

**Effects:** Inserts `t` if and only if there is no element with key equivalent to the key of `t` in containers with unique keys; always inserts `t` in containers with equivalent keys. `t` is inserted as close as possible to the position just prior to `p`.

**Returns:** An iterator pointing to the element with key equivalent to the key of `t`.

**Complexity:** Logarithmic in general, but amortized constant if `t` is inserted right before `p`.

### `a.insert(i, j)`

is an expression with the following properties:

**Result:** void
Preconditions: value_type is Cpp17EmplaceConstructible into X from *i. Neither i nor j are iterators into a.

Effects: Inserts each element from the range [i, j) if and only if there is no element with key equivalent to the key of that element in containers with unique keys; always inserts that element in containers with equivalent keys.

Complexity: \( N \log(a.size() + N) \), where \( N \) has the value \( \text{distance}(i, j) \).

a.insert(il) is an expression with the following properties:

Effects: Equivalent to a.insert(il.begin(), il.end()).

a_uniq.insert(nh) is an expression with the following properties:

Result: insert_return_type

Preconditions: nh is empty or a_uniq.get_allocator() == nh.get_allocator() is true.

Effects: If nh is empty, has no effect. Otherwise, inserts the element owned by nh if and only if there is no element in the container with a key equivalent to nh.key().

Returns: If nh is empty, inserted is false, position is end(), and node is empty. Otherwise if the insertion took place, inserted is true, position points to the inserted element, and node is empty; if the insertion failed, inserted is false, node has the previous value of nh, and position points to an element with a key equivalent to nh.key().

Complexity: Logarithmic.

a_eq.insert(nh) is an expression with the following properties:

Result: iterator

Preconditions: nh is empty or a_eq.get_allocator() == nh.get_allocator() is true.

Effects: If nh is empty, has no effect and returns a_eq.end(). Otherwise, inserts the element owned by nh and returns an iterator pointing to the newly inserted element. If a range containing elements with keys equivalent to nh.key() exists in a_eq, the element is inserted at the end of that range.

Postconditions: nh is empty.

Complexity: Logarithmic.

a.insert(p, nh) is an expression with the following properties:

Result: iterator

Preconditions: nh is empty or a.get_allocator() == nh.get_allocator() is true.

Effects: If nh is empty, has no effect and returns a.end(). Otherwise, inserts the element owned by nh if and only if there is no element with key equivalent to nh.key() in containers with unique keys; always inserts the element owned by nh in containers with equivalent keys. The element is inserted as close as possible to the position just prior to p.

Postconditions: nh is empty if insertion succeeds, unchanged if insertion fails.

Returns: An iterator pointing to the element with key equivalent to nh.key().

Complexity: Logarithmic in general, but amortized constant if the element is inserted right before p.

a.extract(k) is an expression with the following properties:

Result: node_type

Effects: Removes the first element in the container with key equivalent to k.

Returns: A node_type owning the element if found, otherwise an empty node_type.

Complexity: log(a.size())

a.extract(q) is an expression with the following properties:

Result: node_type

Effects: Removes the element pointed to by q.

Returns: A node_type owning that element.
a.merge(a2)  is an expression with the following properties:

**Result:** void

**Preconditions:** a.get_allocator() == a2.get_allocator().

**Effects:** Attempts to extract each element in a2 and insert it into a using the comparison object of a. In containers with unique keys, if there is an element in a with key equivalent to the key of an element from a2, then that element is not extracted from a2.

**Postconditions:** Pointers and references to the transferred elements of a2 refer to those same elements but as members of a. Iterators referring to the transferred elements will continue to refer to their elements, but they now behave as iterators into a, not into a2.

**Throws:** Nothing unless the comparison object throws.

**Complexity:** N \log(a.size()+N), where N has the value a2.size().

a.erase(k)  is an expression with the following properties:

**Result:** size_type

**Effects:** Erases all elements in the container with key equivalent to k.

**Returns:** The number of erased elements.

**Complexity:** \log(a.size()) + a.count(k)

a.erase(q)  is an expression with the following properties:

**Result:** iterator

**Effects:** Erases the element pointed to by q.

**Returns:** An iterator pointing to the element immediately following q prior to the element being erased. If no such element exists, returns a.end().

**Complexity:** Amortized constant.

a.erase(r)  is an expression with the following properties:

**Result:** iterator

**Effects:** Erases the element pointed to by r.

**Returns:** An iterator pointing to the element immediately following r prior to the element being erased. If no such element exists, returns a.end().

**Complexity:** Amortized constant.

a.erase(q1, q2)  is an expression with the following properties:

**Result:** iterator

**Effects:** Erases all the elements in the range \([q1, q2)\).

**Returns:** An iterator pointing to the element pointed to by q2 prior to any elements being erased. If no such element exists, a.end() is returned.

**Complexity:** \log(a.size()) + N, where N has the value distance(q1, q2).

a.clear()  is an expression with the following properties:

**Effects:** Equivalent to a.erase(a.begin(), a.end()).

**Postconditions:** a.empty() is true.

**Complexity:** Linear in a.size().

b.find(k)  is an expression with the following properties:

**Result:** iterator; const_iterator for constant b.

**Returns:** An iterator pointing to an element with the key equivalent to k, or b.end() if such an element is not found.
Complexity: Logarithmic.

\texttt{a\_tran.find(ke)} is an expression with the following properties:

\textbf{Result:} iterator; const\_iterator for constant \texttt{a\_tran}.

\textbf{Returns:} An iterator pointing to an element with key \texttt{r} such that \!c(\texttt{r, ke}) \&\& \!c(\texttt{ke, r}) is true, or \texttt{a\_tran.end()} if such an element is not found.

Complexity: Logarithmic.

\texttt{b.count(k)} is an expression with the following properties:

\textbf{Result:} \texttt{size\_type}

\textbf{Returns:} The number of elements with key equivalent to \texttt{k}.

\textbf{Complexity:} log(\texttt{b.size()}) + \texttt{b.count(k)}

\texttt{a\_tran.count(ke)} is an expression with the following properties:

\textbf{Result:} \texttt{size\_type}

\textbf{Returns:} The number of elements with key \texttt{r} such that \!c(\texttt{r, ke}) \&\& \!c(\texttt{ke, r}).

\textbf{Complexity:} log(\texttt{a\_tran.size()}) + \texttt{a\_tran.count(ke)}

\texttt{b.contains(k)} is an expression with the following properties:

\textbf{Result:} bool

\textbf{Effects:} Equivalent to: \texttt{return b.find(k) != b.end();}

\texttt{a\_tran.contains(ke)} is an expression with the following properties:

\textbf{Result:} bool

\textbf{Effects:} Equivalent to: \texttt{return a\_tran.find(ke) != a\_tran.end();}

\texttt{b.lower_bound(k)} is an expression with the following properties:

\textbf{Result:} iterator; const\_iterator for constant \texttt{b}.

\textbf{Returns:} An iterator pointing to the first element with key not less than \texttt{k}, or \texttt{b.end()} if such an element is not found.

\textbf{Complexity:} Logarithmic.

\texttt{a\_tran.lower_bound(kl)} is an expression with the following properties:

\textbf{Result:} iterator; const\_iterator for constant \texttt{a\_tran}.

\textbf{Returns:} An iterator pointing to the first element with key \texttt{r} such that \!c(\texttt{r, kl}), or \texttt{a\_tran.end()} if such an element is not found.

\textbf{Complexity:} Logarithmic.

\texttt{b.upper_bound(k)} is an expression with the following properties:

\textbf{Result:} iterator; const\_iterator for constant \texttt{b}.

\textbf{Returns:} An iterator pointing to the first element with key greater than \texttt{k}, or \texttt{b.end()} if such an element is not found.

\textbf{Complexity:} Logarithmic.

\texttt{a\_tran.upper_bound(ku)} is an expression with the following properties:

\textbf{Result:} iterator; const\_iterator for constant \texttt{a\_tran}.

\textbf{Returns:} An iterator pointing to the first element with key \texttt{r} such that \texttt{c(ku, r)}, or \texttt{a\_tran.end()} if such an element is not found.

\textbf{Complexity:} Logarithmic.

\texttt{b.equal_range(k)} is an expression with the following properties:

\textbf{Result:} pair<iterator, iterator>; pair<const\_iterator, const\_iterator> for constant \texttt{b}.
Effects: Equivalent to: return make_pair(b.lower_bound(k), b.upper_bound(k));

Complexity: Logarithmic.

\texttt{a\_tran.equal\_range(ke)} is an expression with the following properties:

Result: \texttt{pair<iterator, iterator>; pair<const\ iterator, const\ iterator>} for constant \texttt{a\_tran}.

Effects: Equivalent to: return make_pair(a\_tran.lower\_bound(ke), a\_tran.upper\_bound(ke));

Complexity: Logarithmic.

The \texttt{insert} and \texttt{emplace} members shall not affect the validity of iterators and references to the container, and the \texttt{erase} members shall invalidate only iterators and references to the erased elements.

The \texttt{extract} members invalidate only iterators to the removed element; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a \texttt{node\_type} is undefined behavior. References and pointers to an element obtained while it is owned by a \texttt{node\_type} are invalidated if the element is successfully inserted.

The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators \texttt{i} and \texttt{j} such that distance from \texttt{i} to \texttt{j} is positive, the following condition holds:

\begin{equation}
\text{value\_comp(*j, *i)} = \text{false}
\end{equation}

For associative containers with unique keys the stronger condition holds:

\begin{equation}
\text{value\_comp(*i, *j)} \neq \text{false}
\end{equation}

When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, through either a copy constructor or an assignment operator, the target container shall then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.

The member function templates \texttt{find}, \texttt{count}, \texttt{contains}, \texttt{lower\_bound}, \texttt{upper\_bound}, and \texttt{equal\_range} shall not participate in overload resolution unless the \texttt{qualified\_id Compare::is\_transparent} is valid and denotes a type (13.10.3).

A deduction guide for an associative container shall not participate in overload resolution if any of the following are true:

- It has an \texttt{Input\ iterator} template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
- It has an \texttt{Allocator} template parameter and a type that does not qualify as an allocator is deduced for that parameter.
- It has a \texttt{Compare} template parameter and a type that qualifies as an allocator is deduced for that parameter.

22.2.7.2 Exception safety guarantees

1 For associative containers, no \texttt{clear()} function throws an exception. \texttt{erase(k)} does not throw an exception unless that exception is thrown by the container’s \texttt{Compare} object (if any).

2 For associative containers, if an exception is thrown by any operation from within an \texttt{insert} or \texttt{emplace} function inserting a single element, the insertion has no effect.

3 For associative containers, no \texttt{swap} function throws an exception unless that exception is thrown by the swap of the container’s \texttt{Compare} object (if any).

22.2.8 Unordered associative containers

22.2.8.1 General

Unordered associative containers provide an ability for fast retrieval of data based on keys. The worst-case complexity for most operations is linear, but the average case is much faster. The library provides four unordered associative containers: \texttt{unordered\_set}, \texttt{unordered\_map}, \texttt{unordered\_multiset}, and \texttt{unordered\_multimap}. 

§ 22.2.8.1 823
Unordered associative containers conform to the requirements for Containers (22.2), except that the expressions 
\( a == b \) and \( a != b \) have different semantics than for the other container types.

Each unordered associative container is parameterized by \( \text{Key} \), by a function object type \( \text{Hash} \) that meets the Cpp17Hash requirements (16.4.5) and acts as a hash function for argument values of type \( \text{Key} \), and by a binary predicate \( \text{Pred} \) that induces an equivalence relation on values of type \( \text{Key} \). Additionally, \text{unordered_map} and \text{unordered_multimap} associate an arbitrary \text{mapped type} \( T \) with the Key.

The container’s object of type \( \text{Hash} \) — denoted by \( \text{hash} \) — is called the \text{hash function} of the container. The container’s object of type \( \text{Pred} \) — denoted by \( \text{pred} \) — is called the \text{key equality predicate} of the container.

Two values \( k_1 \) and \( k_2 \) are considered equivalent if the container’s key equality predicate \( \text{pred}(k_1, k_2) \) is valid and returns \text{true} when passed those values. If \( k_1 \) and \( k_2 \) are equivalent, the container’s hash function shall return the same value for both.

[Note 1: Thus, when an unordered associative container is instantiated with a non-default \( \text{Pred} \) parameter it usually needs a non-default \( \text{Hash} \) parameter as well. — end note]

For any two keys \( k_1 \) and \( k_2 \) in the same container, calling \( \text{pred}(k_1, k_2) \) shall always return the same value. For any key \( k \) in a container, calling \( \text{hash}(k) \) shall always return the same value.

An unordered associative container supports \text{unique keys} if it may contain at most one element for each key. Otherwise, it supports \text{equivalent keys}. \text{unordered_set} and \text{unordered_map} support unique keys. \text{unordered_multiset} and \text{unordered_multimap} support equivalent keys. In containers that support equivalent keys, elements with equivalent keys are adjacent to each other in the iteration order of the container. Thus, although the absolute order of elements in an unordered container is not specified, its elements are grouped into \text{equivalent-key groups} such that all elements of each group have equivalent keys. Mutating operations on unordered containers shall preserve the relative order of elements within each equivalent-key group unless otherwise specified.

For \text{unordered_set} and \text{unordered_multiset} the value type is the same as the key type. For \text{unordered_map} and \text{unordered_multimap} it is \text{pair<const Key, T>}.

For unordered containers where the value type is the same as the key type, both \( \text{iterator} \) and \( \text{const_iterator} \) are constant iterators. It is unspecified whether or not \( \text{iterator} \) and \( \text{const_iterator} \) are the same type.

[Note 2: \( \text{iterator} \) and \( \text{const_iterator} \) have identical semantics in this case, and \( \text{iterator} \) is convertible to \( \text{const_iterator} \). Users can avoid violating the one-definition rule by always using \( \text{const_iterator} \) in their function parameter lists. — end note]

The elements of an unordered associative container are organized into \text{buckets}. Keys with the same hash code appear in the same bucket. The number of buckets is automatically increased as elements are added to an unordered associative container, so that the average number of elements per bucket is kept below a bound. Reloading invalidates iterators, changes ordering between elements, and changes which buckets elements appear in, but does not invalidate pointers or references to elements. For \text{unordered_multiset} and \text{unordered_multimap}, reloading preserves the relative ordering of equivalent elements.

In this subclause,

- \( X \) denotes an unordered associative container class,
- \( a \) denotes a value of type \( X \),
- \( a2 \) denotes a value of a type with nodes compatible with type \( X \) (Table 73),
- \( b \) denotes a possibly const value of type \( X \),
- \( \text{auniq} \) denotes a value of type \( X \) when \( X \) supports unique keys,
- \( \text{aeq} \) denotes a value of type \( X \) when \( X \) supports equivalent keys,
- \( \text{a_tran} \) denotes a possibly const value of type \( X \) when the qualified-ids \( X::\text{key_equal::is_transparent} \)
  and \( X::\text{hasher::is_transparent} \) are both valid and denote types (13.10.3),
- \( i \) and \( j \) denote input iterators that refer to \text{value_type},
- \( [i, j) \) denotes a valid range,
- \( p \) and \( q2 \) denote valid constant iterators to \( a \),
- \( q \) and \( q1 \) denote valid dereferenceable constant iterators to \( a \),
- \( r \) denotes a valid dereferenceable iterator to \( a \)
A type \( X \) meets the unordered associative container requirements if \( X \) meets all the requirements of an alloc器-aware container (22.2.2.1) and the following statements and expressions are well-formed and have the specified semantics, except that for unordered_map and unordered_multimap, the requirements placed on value_type in 22.2.2.5 apply instead to key_type and mapped_type.

[Note 3: For example, key_type and mapped_type are sometimes required to be Cpp17CopyAssignable even though the associated value_type, pair<const key_type, mapped_type>, is not Cpp17CopyAssignable. — end note]

11 A type \( X \) meets the unordered associative container requirements if \( X \) meets all the requirements of an alloc器-aware container (22.2.2.1) and the following statements and expressions are well-formed and have the specified semantics, except that for unordered_map and unordered_multimap, the requirements placed on value_type in 22.2.2.5 apply instead to key_type and mapped_type.

12 Effects: Constructs an empty container with at least \( n \) buckets, using \( hf \) as the hash function and \( eq \) as the key equality predicate.

13 Complexity: \( \Theta(n) \)

14 Preconditions: key_equal meets the Cpp17DefaultConstructible requirements.
Effects: Constructs an empty container with at least \( n \) buckets, using \( hf \) as the hash function and \( key_equal() \) as the key equality predicate.

Complexity: \( \Theta(n) \)

\( X(n) \) is an expression with the following properties:

Preconditions: \( hasher \) and \( key_equal \) meet the \( \text{Cpp17DefaultConstructible} \) requirements.

Effects: Constructs an empty container with at least \( n \) buckets, using \( hasher() \) as the hash function and \( key_equal() \) as the key equality predicate.

Complexity: \( \Theta(n) \)

The statements \( X(a) = X() \) and \( X(a) \); each satisfy the following properties:

Preconditions: \( hasher \) and \( key_equal \) meet the \( \text{Cpp17DefaultConstructible} \) requirements.

Effects: Constructs an empty container with an unspecified number of buckets, using \( hasher() \) as the hash function and \( key_equal() \) as the key equality predicate.

Complexity: Constant.

\( X(i, j, n, hf, eq) \) is an expression with the following properties:

Preconditions: \( value_type \) is \( \text{Cpp17EmplaceConstructible} \) into \( X \) from \( *i \).

Effects: Constructs an empty container with at least \( n \) buckets, using \( hf \) as the hash function and \( eq \) as the key equality predicate, and inserts elements from \( [i, j) \) into it.

Complexity: Average case \( \Theta(N) \) (\( N \) is \( \text{distance}(i, j) \)), worst case \( \Theta(N^2) \).

\( X(i, j, n, hf) \) is an expression with the following properties:

Preconditions: \( key_equal \) meets the \( \text{Cpp17DefaultConstructible} \) requirements. \( value_type \) is \( \text{Cpp17EmplaceConstructible} \) into \( X \) from \( *i \).

Effects: Constructs an empty container with at least \( n \) buckets, using \( hf \) as the hash function and \( key_equal() \) as the key equality predicate, and inserts elements from \( [i, j) \) into it.

Complexity: Average case \( \Theta(N) \) (\( N \) is \( \text{distance}(i, j) \)), worst case \( \Theta(N^2) \).

\( X(i, j, n) \) is an expression with the following properties:

Preconditions: \( hasher \) and \( key_equal \) meet the \( \text{Cpp17DefaultConstructible} \) requirements. \( value_type \) is \( \text{Cpp17EmplaceConstructible} \) into \( X \) from \( *i \).

Effects: Constructs an empty container with at least \( n \) buckets, using \( hasher() \) as the hash function and \( key_equal() \) as the key equality predicate, and inserts elements from \( [i, j) \) into it.

Complexity: Average case \( \Theta(N) \) (\( N \) is \( \text{distance}(i, j) \)), worst case \( \Theta(N^2) \).

\( X(i, j) \) is an expression with the following properties:

Preconditions: \( hasher \) and \( key_equal \) meet the \( \text{Cpp17DefaultConstructible} \) requirements. \( value_type \) is \( \text{Cpp17EmplaceConstructible} \) into \( X \) from \( *i \).

Effects: Constructs an empty container with an unspecified number of buckets, using \( hasher() \) as the hash function and \( key_equal() \) as the key equality predicate, and inserts elements from \( [i, j) \) into it.

Complexity: Average case \( \Theta(N) \) (\( N \) is \( \text{distance}(i, j) \)), worst case \( \Theta(N^2) \).

\( X(il) \) is an expression with the following properties:

Effects: Equivalent to \( X(il.begin(), il.end()) \).

\( X(il, n) \) is an expression with the following properties:

Effects: Equivalent to \( X(il.begin(), il.end(), n) \).

\( X(il, n, hf) \) is an expression with the following properties:

Effects: Equivalent to \( X(il.begin(), il.end(), n, hf) \).
\begin{verbatim}
X(il, n, hf, eq) is an expression with the following properties:
   Effects: Equivalent to X(il.begin(), il.end(), n, hf, eq).

X(b) is an expression with the following properties:
   Effects: In addition to the container requirements (22.2.1), copies the hash function, predicate, and
   maximum load factor.
   Complexity: Average case linear in b.size(), worst case quadratic.

a = b is an expression with the following properties:
   Result: X&
   Effects: In addition to the container requirements, copies the hash function, predicate, and maximum
   load factor.
   Complexity: Average case linear in b.size(), worst case quadratic.

a = il is an expression with the following properties:
   Result: X&
   Preconditions: value_type is Cpp17CopyInsertable into X and Cpp17CopyAssignable.
   Effects: Assigns the range [il.begin(), il.end()) into a. All existing elements of a are either
   assigned to or destroyed.
   Complexity: Average case linear in il.size(), worst case quadratic.

b.hash_function() is an expression with the following properties:
   Result: hasher
   Returns: b's hash function.
   Complexity: Constant.

b.key_eq() is an expression with the following properties:
   Result: key_equal
   Returns: b's key equality predicate.
   Complexity: Constant.

a_uniq.emplace(args) is an expression with the following properties:
   Result: pair<iterator, bool>
   Preconditions: value_type is Cpp17EmplaceConstructible into X from args.
   Effects: Inserts a value_type object t constructed with std::forward<Args>(args)... if and only
   if there is no element in the container with key equivalent to the key of t.
   Returns: The bool component of the returned pair is true if and only if the insertion takes place, and
   the iterator component of the pair points to the element with key equivalent to the key of t.
   Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a_uniq.size()) \).

a_eq.emplace(args) is an expression with the following properties:
   Result: iterator
   Preconditions: value_type is Cpp17EmplaceConstructible into X from args.
   Effects: Inserts a value_type object t constructed with std::forward<Args>(args)... and
   Returns: An iterator pointing to the newly inserted element.
   Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a_eq.size()) \).

a.emplace_hint(p, args) is an expression with the following properties:
   Result: iterator
   Preconditions: value_type is Cpp17EmplaceConstructible into X from args.
\end{verbatim}
**Effects**: Equivalent to `a.emplace(std::forward<Args>(args)...)`.

**Returns**: An iterator pointing to the element with the key equivalent to the newly inserted element. The `const_iterator p` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

**Complexity**: Average case $O(1)$, worst case $O(a.size())$.

`a_uniq.insert(t)` is an expression with the following properties:

**Result**: `pair<iterator, bool>`

**Preconditions**: If `t` is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.

**Effects**: Inserts `t` if and only if there is no element in the container with key equivalent to the key of `t`.

**Returns**: The `bool` component of the returned pair indicates whether the insertion takes place, and the `iterator` component points to the element with key equivalent to the key of `t`.

**Complexity**: Average case $O(1)$, worst case $O(a_uniq.size())$.

`a_eq.insert(t)` is an expression with the following properties:

**Result**: `iterator`

**Preconditions**: If `t` is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.

**Effects**: Inserts `t`.

**Returns**: An iterator pointing to the newly inserted element.

**Complexity**: Average case $O(1)$, worst case $O(a_eq.size())$.

`a.insert(p, t)` is an expression with the following properties:

**Result**: `iterator`

**Preconditions**: If `t` is a non-const rvalue, `value_type` is `Cpp17MoveInsertable` into `X`; otherwise, `value_type` is `Cpp17CopyInsertable` into `X`.

**Effects**: Equivalent to `a.insert(t)`. The iterator `p` is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

**Returns**: An iterator pointing to the element with the key equivalent to that of `t`.

**Complexity**: Average case $O(1)$, worst case $O(a.size())$.

`a.insert(i, j)` is an expression with the following properties:

**Result**: `void`

**Preconditions**: `value_type` is `Cpp17EmplaceConstructible` into `X` from `*i`. Neither `i` nor `j` are iterators into `a`.

**Effects**: Equivalent to `a.insert(t)` for each element in `[i,j)`.

**Complexity**: Average case $O(N)$, where $N$ is `distance(i, j)`, worst case $O(N(a.size() + 1))$.

`a.insert(il)` is an expression with the following properties:

**Effects**: Equivalent to `a.insert(il.begin(), il.end())`.

`a_uniq.insert(nh)` is an expression with the following properties:

**Result**: `insert_return_type`

**Preconditions**: `nh` is empty or `a_uniq.get_allocator() == nh.get_allocator()` is true.

**Effects**: If `nh` is empty, has no effect. Otherwise, inserts the element owned by `nh` if and only if there is no element in the container with a key equivalent to `nh.key()`.

**Postconditions**: If `nh` is empty, `inserted` is `false`, `position` is `end()`, and `node` is empty. Otherwise if the insertion took place, `inserted` is `true`, `position` points to the inserted element, and `node` is empty; if the insertion failed, `inserted` is `false`, `node` has the previous value of `nh`, and `position` points to an element with a key equivalent to `nh.key()`.
Complexity: Average case $\Theta(1)$, worst case $\Theta(a\text{\_uniq} \cdot \text{size}())$.

\texttt{a\_eq.insert(nh)} is an expression with the following properties:

\begin{itemize}
  \item \textbf{Result}: iterator
  \item \textbf{Preconditions}: nh is empty or \texttt{a\_eq.get\_allocator()} == nh.get\_allocator() is true.
  \item \textbf{Effects}: If nh is empty, has no effect and returns \texttt{a\_eq.end()}. Otherwise, inserts the element owned by nh and returns an iterator pointing to the newly inserted element.
  \item \textbf{Postconditions}: nh is empty.
  \item \textbf{Complexity}: Average case $\Theta(1)$, worst case $\Theta(a\text{\_eq} \cdot \text{size}())$.
\end{itemize}

\texttt{a.insert(q, nh)} is an expression with the following properties:

\begin{itemize}
  \item \textbf{Result}: iterator
  \item \textbf{Preconditions}: nh is empty or \texttt{a.get\_allocator()} == nh.get\_allocator() is true.
  \item \textbf{Effects}: If nh is empty, has no effect and returns \texttt{a.end()}. Otherwise, inserts the element owned by nh if and only if there is no element with key equivalent to \texttt{nh.key()} in containers with unique keys; always inserts the element owned by nh in containers with equivalent keys. The iterator \texttt{q} is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.
  \item \textbf{Postconditions}: nh is empty if insertion succeeds, unchanged if insertion fails.
  \item \textbf{Returns}: An iterator pointing to the element with key equivalent to \texttt{nh.key()}.
  \item \textbf{Complexity}: Average case $\Theta(1)$, worst case $\Theta(a\cdot\text{size}())$.
\end{itemize}

\texttt{a.extract(k)} is an expression with the following properties:

\begin{itemize}
  \item \textbf{Result}: node\_type
  \item \textbf{Effects}: Removes an element in the container with key equivalent to \texttt{k}.
  \item \textbf{Returns}: A node\_type owning the element if found, otherwise an empty node\_type.
  \item \textbf{Complexity}: Average case $\Theta(1)$, worst case $\Theta(a\cdot\text{size}())$.
\end{itemize}

\texttt{a.extract(q)} is an expression with the following properties:

\begin{itemize}
  \item \textbf{Result}: node\_type
  \item \textbf{Effects}: Removes the element pointed to by \texttt{q}.
  \item \textbf{Returns}: A node\_type owning that element.
  \item \textbf{Complexity}: Average case $\Theta(1)$, worst case $\Theta(a\cdot\text{size}())$.
\end{itemize}

\texttt{a.merge(a2)} is an expression with the following properties:

\begin{itemize}
  \item \textbf{Result}: void
  \item \textbf{Preconditions}: \texttt{a.get\_allocator()} == \texttt{a2.get\_allocator()}.
  \item \textbf{Effects}: Attempts to extract each element in \texttt{a2} and insert it into \texttt{a} using the hash function and key equality predicate of \texttt{a}. In containers with unique keys, if there is an element in \texttt{a} with key equivalent to the key of an element from \texttt{a2}, then that element is not extracted from \texttt{a2}.
  \item \textbf{Postconditions}: Pointers and references to the transferred elements of \texttt{a2} refer to those same elements but as members of \texttt{a}. Iterators referring to the transferred elements and all iterators referring to \texttt{a} will be invalidated, but iterators to elements remaining in \texttt{a2} will remain valid.
  \item \textbf{Complexity}: Average case $\Theta(N)$, where \texttt{N} is \texttt{a2\cdotsize()} , worst case $\Theta(N\cdot a\cdot\text{size}() + N)$.
\end{itemize}

\texttt{a.erase(k)} is an expression with the following properties:

\begin{itemize}
  \item \textbf{Result}: size\_type
  \item \textbf{Effects}: Erases all elements with key equivalent to \texttt{k}.
  \item \textbf{Returns}: The number of elements erased.
  \item \textbf{Complexity}: Average case $\Theta(a\cdot\text{count}())$, worst case $\Theta(a\cdot\text{size}())$.
\end{itemize}
\texttt{a.erase(q)} is an expression with the following properties:

\begin{verbatim}
Result: iterator
Effects: Erases the element pointed to by q.
Returns: The iterator immediately following q prior to the erasure.
Complexity: Average case $\Theta(1)$, worst case $\Theta(a.size())$.
\end{verbatim}

\texttt{a.erase(r)} is an expression with the following properties:

\begin{verbatim}
Result: iterator
Effects: Erases the element pointed to by r.
Returns: The iterator immediately following r prior to the erasure.
Complexity: Average case $\Theta(1)$, worst case $\Theta(a.size())$.
\end{verbatim}

\texttt{a.erase(q1, q2)} is an expression with the following properties:

\begin{verbatim}
Result: iterator
Effects: Erases all elements in the range \([q1, q2)\).
Returns: The iterator immediately following the erased elements prior to the erasure.
Complexity: Average case linear in $\text{distance}(q1, q2)$, worst case $\Theta(a.size())$.
\end{verbatim}

\texttt{a.clear()} is an expression with the following properties:

\begin{verbatim}
Result: void
Effects: Erases all elements in the container.
Postconditions: \texttt{a.empty()} is true.
Complexity: Linear in \texttt{a.size()}.
\end{verbatim}

\texttt{b.find(k)} is an expression with the following properties:

\begin{verbatim}
Result: iterator; const_iterator for const b.
Returns: An iterator pointing to an element with key equivalent to k, or \texttt{b.end()} if no such element exists.
Complexity: Average case $\Theta(1)$, worst case $\Theta(b.size())$.
\end{verbatim}

\texttt{a_tran.find(ke)} is an expression with the following properties:

\begin{verbatim}
Result: iterator; const_iterator for const a_tran.
Returns: An iterator pointing to an element with key equivalent to ke, or \texttt{a_tran.end()} if no such element exists.
Complexity: Average case $\Theta(1)$, worst case $\Theta(a_tran.size())$.
\end{verbatim}

\texttt{b.count(k)} is an expression with the following properties:

\begin{verbatim}
Result: size_type
Returns: The number of elements with key equivalent to k.
Complexity: Average case $\Theta(b.count(k))$, worst case $\Theta(b.size())$.
\end{verbatim}

\texttt{a_tran.count(ke)} is an expression with the following properties:

\begin{verbatim}
Result: size_type
Returns: The number of elements with key equivalent to ke.
Complexity: Average case $\Theta(a_tran.count(ke))$, worst case $\Theta(a_tran.size())$.
\end{verbatim}

\texttt{b.contains(k)} is an expression with the following properties:

\begin{verbatim}
Effects: Equivalent to \texttt{b.find(k) != b.end()}
\end{verbatim}
a_tran.contains(ke) is an expression with the following properties:

Effects: Equivalent to a_tran.find(ke) != a_tran.end().

b.equal_range(k) is an expression with the following properties:

Result: pair<iterator, iterator>; pair<const_iterator, const_iterator> for const b.

Returns: A range containing all elements with keys equivalent to k. Returns make_pair(b.end(), b.end()) if no such elements exist.

Complexity: Average case $\Theta(b.count(k))$, worst case $\Theta(b.size())$.

a_tran.equal_range(ke) is an expression with the following properties:

Result: pair<iterator, iterator>; pair<const_iterator, const_iterator> for const a_tran.

Returns: A range containing all elements with keys equivalent to ke. Returns make_pair(a_tran.end(), a_tran.end()) if no such elements exist.

Complexity: Average case $\Theta(a\_tran.count(ke))$, worst case $\Theta(a\_tran.size())$.

b.bucket_count() is an expression with the following properties:

Result: size_type

Returns: The number of buckets that b contains.

Complexity: Constant.

b.max_bucket_count() is an expression with the following properties:

Result: size_type

Returns: An upper bound on the number of buckets that b can ever contain.

Complexity: Constant.

b.bucket(k) is an expression with the following properties:

Result: size_type

Preconditions: b.bucket_count() > 0.

Returns: The index of the bucket in which elements with keys equivalent to k would be found, if any such element existed. The return value is in the range $[0, b.bucket\_count())$.

Complexity: Constant.

b.bucket_size(n) is an expression with the following properties:

Result: size_type

Preconditions: n shall be in the range $[0, b.bucket\_count())$.

Returns: The number of elements in the nth bucket.

Complexity: $\Theta(b.bucket\_size(n))$

b.begin(n) is an expression with the following properties:

Result: local_iterator; const_local_iterator for const b.

Preconditions: n is in the range $[0, b.bucket\_count())$.

Returns: An iterator referring to the first element in the bucket. If the bucket is empty, then b.begin(n) == b.end(n).

Complexity: Constant.

b.end(n) is an expression with the following properties:

Result: local_iterator; const_local_iterator for const b.

Preconditions: n is in the range $[0, b.bucket\_count())$.

Returns: An iterator which is the past-the-end value for the bucket.

Complexity: Constant.
b.cbegin(n) is an expression with the following properties:

177  
178  \textit{Result:} \texttt{const\_local\_iterator}
179  
180  \textit{Preconditions:} \textit{n} shall be in the range \([0, \ \texttt{b.bucket\_count()})\).
181  
182  \textit{Returns:} An iterator referring to the first element in the bucket. If the bucket is empty, then
183  
184  \texttt{b.cbegin(n) == b.cend(n)}.
185  
186  \textit{Complexity:} Constant.
187  

b.cend(n) is an expression with the following properties:

188  
189  \textit{Result:} \texttt{const\_local\_iterator}
190  
191  \textit{Preconditions:} \textit{n} is in the range \([0, \ \texttt{b.bucket\_count()})\).
192  
193  \textit{Returns:} An iterator which is the past-the-end value for the bucket.
194  
195  \textit{Complexity:} Constant.
196  

b.load_factor() is an expression with the following properties:

197  
198  \textit{Result:} float
199  
200  \textit{Returns:} The average number of elements per bucket.
201  
202  \textit{Complexity:} Constant.
203  

b.max_load_factor() is an expression with the following properties:

204  
205  \textit{Result:} float
206  
207  \textit{Returns:} A positive number that the container attempts to keep the load factor less than or equal to.
208  
209  The container automatically increases the number of buckets as necessary to keep the load factor below
210  
211  this number.
212  
213  \textit{Complexity:} Constant.
214  

a.max_load_factor(z) is an expression with the following properties:

215  
216  \textit{Result:} void
217  
218  \textit{Preconditions:} \textit{z} is positive. May change the container's maximum load factor, using \textit{z} as a hint.
219  
220  \textit{Complexity:} Constant.
221  

a.rehash(n) is an expression with the following properties:

222  
223  \textit{Result:} void
224  
225  \textit{Postconditions:} \texttt{a.bucket\_count()} \geq \texttt{a.size()} / \texttt{a.max\_load\_factor()} and \texttt{a.bucket\_count()} \geq \textit{n}.
226  
227  \textit{Complexity:} Average case linear in \texttt{a.size()}, worst case quadratic.
228  

a.reserve(n) is an expression with the following properties:

229  
230  \textit{Effects:} Equivalent to \texttt{a.rehash(\texttt{ceil(n / a.max\_load\_factor())})}.
231  

Two unordered containers \texttt{a} and \texttt{b} compare equal if \texttt{a.size()} == \texttt{b.size()} and, for every equivalent-key group \([\texttt{Ea1, Ea2})\) obtained from \texttt{a.equal\_range(Ea1)}, there exists an equivalent-key group \([\texttt{Eb1, Eb2})\) obtained from \texttt{b.equal\_range(Ea1)}, such that \texttt{is\_permutation(Ea1, Ea2, Eb1, Eb2)} returns true. For \texttt{unordered\_set} and \texttt{unordered\_map}, the complexity of \texttt{operator==} (i.e., the number of calls to the \texttt{==} operator of the \texttt{value\_type}, to the predicate returned by \texttt{key\_eq()}, and to the hasher returned by \texttt{hash\_function()}) is proportional to \(N\) in the average case and to \(N^2\) in the worst case, where \(N\) is \texttt{a.size()}. For \texttt{unordered\_multiset} and \texttt{unordered\_multimap}, the complexity of \texttt{operator==} is proportional to \(\sum E_i^2\) in the average case and to \(N^2\) in the worst case, where \(N\) is \texttt{a.size()}, and \(E_i\) is the size of the \textit{i}th equivalent-key group in \texttt{a}. However, if the respective elements of each corresponding pair of equivalent-key groups \texttt{Ea_i} and \texttt{Eb_i} are arranged in the same order (as is commonly the case, e.g., if \texttt{a} and \texttt{b} are unmodified copies of the same container), then the average-case complexity for \texttt{unordered\_multiset} and \texttt{unordered\_multimap} becomes proportional to \(N\) (but worst-case complexity remains \(O(N^2)\), e.g., for a pathologically bad hash function).

The behavior of a program that uses \texttt{operator==} or \texttt{operator!=} on unordered containers is undefined unless
the `Pred` function object has the same behavior for both containers and the equality comparison function for Key is a refinement\(^{218}\) of the partition into equivalent-key groups produced by `Pred`.

199 The iterator types `iterator` and `const_iterator` of an unordered associative container are of at least the forward iterator category. For unordered associative containers where the key type and value type are the same, both `iterator` and `const_iterator` are constant iterators.

200 The `insert` and `emplace` members shall not affect the validity of references to container elements, but may invalidate all iterators to the container. The `erase` members shall invalidate only iterators and references to the erased elements, and preserve the relative order of the elements that are not erased.

201 The `insert` and `emplace` members shall not affect the validity of iterators if 
\[(N+n) <= z * B\], where \(N\) is the number of elements in the container prior to the insert operation, \(n\) is the number of elements inserted, \(B\) is the container’s bucket count, and \(z\) is the container’s maximum load factor.

202 The `extract` members invalidate only iterators to the removed element, and preserve the relative order of the elements that are not erased; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a `node_type` is undefined behavior. References and pointers to an element obtained while it is owned by a `node_type` are invalidated if the element is successfully inserted.

203 The member function templates `find`, `count`, `equal_range`, and `contains` shall not participate in overload resolution unless the qualified-ids `Pred::is_transparent` and `Hash::is_transparent` are both valid and denote types (13.10.3).

204 A deduction guide for an unordered associative container shall not participate in overload resolution if any of the following are true:

(204.1) — It has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

(204.2) — It has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.

(204.3) — It has a `Hash` template parameter and an integral type or a type that qualifies as an allocator is deduced for that parameter.

(204.4) — It has a `Pred` template parameter and a type that qualifies as an allocator is deduced for that parameter.

22.2.8.2 Exception safety guarantees [unord.req.except]

1 For unordered associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container’s `Hash` or `Pred` object (if any).

2 For unordered associative containers, if an exception is thrown by any operation other than the container’s hash function from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

3 For unordered associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container’s `Hash` or `Pred` object (if any).

4 For unordered associative containers, if an exception is thrown from within a `rehash()` function other than by the container’s hash function or comparison function, the `rehash()` function has no effect.

22.3 Sequence containers [sequences]

22.3.1 In general [sequences.general]

1 The headers `<array>` (22.3.2), `<deque>` (22.3.3), `<forward_list>` (22.3.4), `<list>` (22.3.5), and `<vector>` (22.3.6) define class templates that meet the requirements for sequence containers.

2 The following exposition-only alias template may appear in deduction guides for sequence containers:

```
template<class InputIterator>
using iter-value-type = typename iterator_traits<InputIterator>::value_type; // exposition only
```

22.3.2 Header `<array>` synopsis [array.syn]

```
#include <compare>      // see 17.11.1
#include <initializer_list>   // see 17.10.2
```

\(^{218}\) Equality comparison is a refinement of partitioning if no two objects that compare equal fall into different partitions.
30  Regular expressions library [re]

30.1 General [re.general]
1  This Clause describes components that C++ programs may use to perform operations involving regular expression matching and searching.
2  The following subclauses describe a basic regular expression class template and its traits that can handle char-like (21.1) template arguments, two specializations of this class template that handle sequences of char and wchar_t, a class template that holds the result of a regular expression match, a series of algorithms that allow a character sequence to be operated upon by a regular expression, and two iterator types for enumerating regular expression matches, as summarized in Table 126.

30.2 Requirements [re.req]
1  This subclause defines requirements on classes representing regular expression traits.
   [Note 1: The class template regex_traits, defined in 30.6, meets these requirements. — end note]
2  The class template basic_regex, defined in 30.7, needs a set of related types and functions to complete the definition of its semantics. These types and functions are provided as a set of member typedef-names and functions in the template parameter traits used by the basic_regex class template. This subclause defines the semantics of these members.
3  To specialize class template basic_regex for a character container CharT and its related regular expression traits class Traits, use basic_regex<CharT, Traits>.
4  In the following requirements,
   (4.1) — X denotes a traits class defining types and functions for the character container type charT;
   (4.2) — u is an object of type X;
   (4.3) — v is an object of type const X;
   (4.4) — p is a value of type const charT*;
   (4.5) — I1 and I2 are input iterators (23.3.5.3); 
   (4.6) — F1 and F2 are forward iterators (23.3.5.5); 
   (4.7) — c is a value of type const charT; 
   (4.8) — s is an object of type X::string_type; 
   (4.9) — cs is an object of type const X::string_type; 
   (4.10) — b is a value of type bool; 
   (4.11) — I is a value of type int; 
   (4.12) — cl is an object of type X::char_class_type; and
loc is an object of type X::locale_type.

A traits class X meets the regular expression traits requirements if the following types and expressions are well-formed and have the specified semantics.

- The type X::char_type denotes charT, the character container type used in the implementation of class template basic_regex.
- The type X::string_type denotes the type basic_string<charT>.
- The type X::locale_type denotes a copy constructible type that represents the locale used by the traits class.
- The type X::char_class_type denotes a bitmask type (16.3.3.3.4) representing a particular character classification.

X::length(p)

Return type: size_t

Returns: The smallest i such that p[i] == 0.

Complexity: Linear in i.

v.translate(c)

Return type: X::char_type

Returns: A character such that for any character d that is to be considered equivalent to c then v.translate(c) == v.translate(d).

v.translate_nocase(c)

Return type: X::char_type

Returns: For all characters C that are to be considered equivalent to c when comparisons are to be performed without regard to case, then v.translate_nocase(c) == v.translate_nocase(C).

v.transform(F1, F2)

Return type: X::string_type

Returns: A sort key for the character sequence designated by the iterator range [F1, F2) such that if the character sequence [G1, G2) sorts before the character sequence [H1, H2) then v.transform(G1, G2) < v.transform(H1, H2).

v.transform_primary(F1, F2)

Return type: X::string_type

Returns: A sort key for the character sequence designated by the iterator range [F1, F2) such that if the character sequence [G1, G2) sorts before the character sequence [H1, H2) when character case is not considered then v.transform_primary(G1, G2) < v.transform_primary(H1, H2).

v.lookup_collatename(F1, F2)

Return type: X::string_type

Returns: A sequence of characters that represents the collating element consisting of the character sequence designated by the iterator range [F1, F2). Returns an empty string if the character sequence is not a valid collating element.

v.lookup_classname(F1, F2, b)

Return type: X::char_class_type

Returns: Converts the character sequence designated by the iterator range [F1, F2) into a value of a bitmask type that can subsequently be passed to isctype. Values returned from lookup_classname can be bitwise OR’ed together; the resulting value represents membership in either of the corresponding character classes. If b is true, the returned bitmask is suitable for matching characters without regard to their case. Returns 0 if the character sequence is not the name of a character class recognized by X. The value returned shall be independent of the case of the characters in the sequence.
v.isctype(c, cl)

Return type: bool
Returns: Returns true if character c is a member of one of the character classes designated by cl, false otherwise.

v.value(c, I)

Return type: int
Returns: Returns the value represented by the digit c in base I if the character c is a valid digit in base I; otherwise returns -1.

[Note 2: The value of I will only be 8, 10, or 16. — end note]

u.imbue(loc)

Return type: X::locale_type
Effects: Imbues u with the locale loc and returns the previous locale used by u if any.

v.getloc()

Return type: X::locale_type
Returns: Returns the current locale used by v, if any.

[Note 3: Class template regex_traits meets the requirements for a regular expression traits class when it is specialized for char or wchar_t. This class template is described in the header <regex>, and is described in 30.6. — end note]

30.3 Header <regex> synopsis
