Project: Programming Language C++  
Audience: LEWG

## Abstract

We propose to fix a hole intentionally left in std::optional —

An optional over a reference such that the post condition on assignment is independent of the engaged state, always producing a rebound reference, and assigning a U to a T is disallowed by static\_assert if a U can not be bound to a T&.

## Changes Since Last Version

- **Changes since R6**
  - strike refref specialization
  - add converting assignment operator
  - add converting in place constructor
- **Changes since R5**
  - refref specialization
  - fix monadic constraints on base template
- **Changes since R4**
  - feature test macro
  - value\_or updates from P3091
- **Changes since R3**
  - make\_optional discussion - always value

— value\_or discussion - always value

## 1 Comparison table

### 1.1 Using a raw pointer result for an element search function

This is the convention the C++ core guidelines suggest, to use a raw pointer for representing optional non-owning references. However, there is a user-required check against ‘`nullptr`’, no type safety meaning no safety against mis-interpreting such a raw pointer, for example by using pointer arithmetic on it.

```
Cat* cat = find_cat("Fido");
if (cat!=nullptr) { return doit(*cat); }           std::optional<Cat&> cat = find_cat("Fido");
                                                               return cat.and_then(doit);
```

### 1.2 returning result of an element search function via a (smart) pointer

The disadvantage here is that `std::experimental::observer_ptr<T>` is both non-standard and not well named, therefore this example uses `shared_ptr` that would have the advantage of avoiding dangling through potential lifetime extension. However, on the downside is still the explicit checks against the `nullptr` on the client side, failing so risks undefined behavior.

```
std::shared_ptr<Cat> cat = find_cat("Fido");      std::optional<Cat&> cat = find_cat("Fido");
if (cat != nullptr) /* ... */                  cat.and_then([](Cat& thecat){/* ... */})
```

### 1.3 returning result of an element search function via an iterator

This might be the obvious choice, for example, for associative containers, especially since their iterator stability guarantees. However, returning such an iterator will leak the underlying container type as well necessarily requires one to know the sentinel of the container to check for the not-found case.

```
std::map<std::string, Cat>::iterator cat        std::optional<Cat&> cat
= find_cat("Fido");                           = find_cat("Fido");
if (cat != theunderlyingmap.end())/* ... */   cat.and_then([](Cat& thecat){/* ... */})
```

### 1.4 Using an `optional<T*>` as a substitute for `optional<T&>`

This approach adds another level of indirection and requires two checks to take a definite action.

```
//Mutable optional
std::optional<Cat*> c = find_cat("Fido");      std::optional<Cat&> c = find_cat("Fido");
if (c) {                                         if (c) {
    if (*c) {                                     *c = Cat("Fynn", color::orange);
        *c.value() = Cat("Fynn", color::orange);    }
    }                                              //or
}                                                 o.transform([](Cat& c){
                                                 c = Cat("Fynn", color::orange);
});
```

## 2 Motivation

Other than the standard library’s implementation of `optional`, `optionals` holding references are common. The desire for such a feature is well understood, and many `optional` types in commonly used libraries provide it, with the semantics proposed here. One standard library implementation already provides an implementation of `std::optional<T&>` but disables its use, because the standard forbids it.

The research in JeanHeyd Meneide’s \_References for Standard Library Vocabulary Types - an optional case study.\_ [P1683R0] shows conclusively that rebind semantics are the only safe semantic as assign through on engaged is too bug-prone. Implementations that attempt assign-through are abandoned. The standard library should follow existing practice and supply an `optional<T&>` that rebinds on assignment.

Additional background reading on `optional<T&>` can be found in JeanHeyd Meneide’s article \_To Bind and Loose a Reference\_ [REFBIND].

In freestanding environments or for safety-critical libraries, an optional type over references is important to implement containers, that otherwise as the standard library either would cause undefined behavior when accessing an non-available element, throw an exception, or silently create the element. Returning a plain pointer for such an optional reference, as the core guidelines suggest, is a non-type-safe solution and doesn't protect in any way from accessing an non-existing element by a `nullptr` de-reference. In addition, the monadic APIs of `std::optional` makes is especially attractive by streamlining client code receiving such an optional reference, in contrast to a pointer that requires an explicit `nullptr` check and de-reference.

There is a principled reason not to provide a partial specialization over `T&` as the semantics are in some ways subtly different than the primary template. Assignment may have side-effects not present in the primary, which has pure value semantics. However, I argue this is misleading, as reference semantics often has side-effects. The proposed semantic is similar to what an `optional<std::reference_wrapper<T>>` provides, with much greater usability.

There are well motivated suggestions that perhaps instead of an `optional<T&>` there should be an `optional_ref<T>` that is an independent primary template. This proposal rejects that, because we need a policy over all sum types as to how reference semantics should work, as `optional` is a variant over `T` and monostate. That the library sum type can not express the same range of types as the product type, tuple, is an increasing problem as we add more types logically equivalent to a variant. The template types `optional` and `expected` should behave as extensions of `variant<T, monostate>` and `variant<T, E>`, or we lose the ability to reason about generic types.

That we can't guarantee from `std::tuple<Args...>` (product type) that `std::variant<Args...>` (sum type) is valid, is a problem, and one that reflection can't solve. A language sum type could, but we need agreement on the semantics.

The semantics of a variant with a reference are as if it holds the address of the referent when referring to that referent. All other semantics are worse. Not being able to express a `variant<T&>` is inconsistent, hostile, and strictly worse than disallowing it.

Thus, we expect future papers to propose `std::expected<T&, E>` and `std::variant` with the ability to hold references. The latter can be used as an iteration type over `std::tuple` elements.

### 3 Design

The design is straightforward. The `optional<T&>` holds a pointer to the underlying object of type `T`, or `nullptr` if the optional is disengaged. The implementation is simple, especially with C++20 and up techniques, using concept constraints. As the held pointer is a primitive regular type with reference semantics, many operations can be defaulted and are `noexcept` by nature. See [Downey\_smd\_optional\_optional\_T] and [rawgithu58:online]. The `optional<T&>` implementation is less than 200 lines of code, much of it the monadic functions with identical textual implementations with different signatures and different overloads being called.

In place construction is not supported as it would just be a way of providing immediate life-time issues.

#### 3.1 Relational Operations

The definitions of the relational operators are the same as for the base template. Interoperable comparisons between `T` and `optional<T&>` work as expected. This is not true for the boost `optional<T&>`.

#### 3.2 make\_optional

Because of existing code, `make_optional<T&>` must return `optional<T>` rather than `optional<T&>`. Returning `optional<T&>` is consistent and defensible, and a few optional implementations in production make this choice. It is, however, quite easy to construct a `make_optional` expression that deduces a different category causing possibly dangerous changes to code.

There was some discussion about using library technology to allow selection of the reference overload via the literal spelling `make_optional<int&>`. There was anti-consensus to do so. There are existing instances of that spelling that today return an `optional<T>`, although it is very likely these are mistakes or possibly other optionals. The spelling `optional<T&>{}` is acceptable as there is no multi-argument emplacement version as there is no location to construct such an instance.

There was also discussion of using `std::reference_wrapper` to indicate reference use, in analogy with `std::tuple`. Unfortunately there are existing uses of optional over `reference_wrapper` as a workaround for lack of reference specialization, and it would be a breaking change for such code.

### 3.3 Trivial construction

Construction of `optional<T>` should be trivial, because it is straightforward to implement, and `optional<T>` is trivial. Boost is not.

### 3.4 Value Category Affects value()

For several implementations there are distinct overloads for functions depending on value category, with the same implementation. However, this makes it very easy to accidentally steal from the underlying referred to object. Value category should be shallow. Thanks to many people for pointing this out. If “Deducing this” had been used, the problem would have been much more subtle in code review.

### 3.5 Shallow vs Deep const

There is some implementation divergence in optionals about deep const for `optional<T>`. That is, can the referred to `int` be modified through a `const optional<int>`. Does `operator->()` return an `int*` or a `const int*`, and does `operator*()` return an `int&` or a `const int&`. I believe it is overall more defensible if the `const` is shallow as it would be for a struct `ref int * p`; where the constness of the struct ref does not affect if the `p` pointer can be written through. This is consistent with the rebinding behavior being proposed.

Where deeper constness is desired, `optional<const T>` would prevent non const access to the underlying object.

### 3.6 Conditional Explicit

As in the base template, `explicit` is made conditional on the type used to construct the optional. `explicit(!std::is_convertible_v<U, T>)`. This is not present in boost::optional, leading to differences in construction between braced initialization and = that can be surprising.

### 3.7 value\_or

~~Have `value_or` return a `T&`. Check that the supplied value can be bound to a `T&`.~~

After extensive discussion, it seems there is no particularly wonderful solution for `value_or` that does not involve a time machine. Implementations of optionals that support reference semantics diverge over the return type, and the current one is arguably wrong, and should use something based on `common_reference_type`, which of course did not exist when optional was standardized.

The weak consensus is to return a `T` from `optional<T>::value_or` as this is least likely to cause issues. There was at least one strong objection to this choice, but all other choices had more objections. The author intends to propose free functions `reference_or`, `value_or`, `or_invoke`, and `yield_if` over all types modeling optional-like, concept `std::maybe`, in the next revision of [P1255R12]. This would cover optional, expected, and pointer types.

Having `value_or` return by value also allows the common case of using a literal as the alternative to be expressed concisely.

### 3.8 in\_place\_t construction

The reference specialization allows a limited form of `in_place` construction where the argument can be converted to the appropriate reference without creation of a temporary. As the reference specialization is non-owning, there is no “place” for a temporary to be constructed that will not dangle. For cases where the lifetime of the constructed object would match the lifetime of the optional, the temporary can be constructed explicitly, instead.

### 3.9 Converting assignment

A similarly limited converting assignment operator is provided for cases where an `optional<U>` has a value or refers to a value which can be converted to a `T&` without construction of a temporary. In particular, converting an `optional<T>` to an `optional<T const&>` is supported.

### **3.10 Compiler Explorer Playground**

See <https://compiler-explorer.com/z/zKqE3sn87> for an updated playground with relevant Google Test functions and various optional implementations made available for cross reference including a flattend in-place version of the reference implementation.

## **4 Proposal**

Add an lvalue reference specialization for the std::optional template.

## **5 Wording**

The wording here cross references and adopts the wording in [P3091R2].

## 8.1 Optional objects

[optional]

### 8.1.1 General

[optional.general]

- <sup>1</sup> Subclause 8.1 describes class template `optional` that represents optional objects. An *optional object* is an object that contains the storage for another object and manages the lifetime of this contained object, if any. The contained object may be initialized after the optional object has been initialized, and may be destroyed before the optional object has been destroyed. The initialization state of the contained object is tracked by the optional object.

### 8.1.2 Header <optional> synopsis

[optional.syn]

```
// mostly freestanding
#include <compare>           // see ???

namespace std {
    // 8.1.3, class template optional for object types
    template <class T>
    class optional; // partially freestanding

    // 8.1.4, class template optional for reference types
    template <class T>
    class optional<T&>; // partially freestanding

    template <class T>
    inline constexpr bool ranges::enable_view<optional<T>> = true;
    template <class T>
    inline constexpr auto format_kind<optional<T>> = range_format::disabled;

    template<class T>
    concept is-derived-from-optional = requires(const T& t) {           // exposition only
        []<class U>(const optional<U>&){ }(t);
    };
}

// 8.1.5, no-value state indicator
struct nullopt_t{see below};
inline constexpr nullopt_t nullopt(unspecified);

// 8.1.6, class bad_optional_access
class bad_optional_access;

// 8.1.7, relational operators
template<class T, class U>
constexpr bool operator==(const optional<T>&, const optional<U>&);
template<class T, class U>
constexpr bool operator!=(const optional<T>&, const optional<U>&);
template<class T, class U>
constexpr bool operator<(const optional<T>&, const optional<U>&);
template<class T, class U>
constexpr bool operator>(const optional<T>&, const optional<U>&);
template<class T, class U>
constexpr bool operator<=(const optional<T>&, const optional<U>&);
template<class T, class U>
constexpr bool operator>=(const optional<T>&, const optional<U>&);
template<class T, three_way_comparable_with<T> U>
constexpr compare_three_way_result_t<T, U>
operator<=>(const optional<T>&, const optional<U>&);

// ??, comparison with nullopt
template<class T> constexpr bool operator==(const optional<T>&, nullopt_t) noexcept;
template<class T>
constexpr strong_ordering operator<=>(const optional<T>&, nullopt_t) noexcept;
```

```

// ??, comparison with T
template<class T, class U> constexpr bool operator==(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator==(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator!=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator!=(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator<(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator<(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator>(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator>(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator<=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator<=(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator>=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator>=(const T&, const optional<U>&);

template<class T, class U>
    requires (!is-derived-from-optional<U>) && three_way_comparable_with<T, U>
constexpr compare_three_way_result_t<T, U>
operator<=>(const optional<T>&, const U&);

// 8.8, specialized algorithms
template<class T>
constexpr void swap(optional<T>&, optional<T>&) noexcept(see below);

template<class T>
constexpr optional<see below> make_optional(T&&);

template<class T, class... Args>
constexpr optional<T> make_optional(Args&&... args);

template<class T, class U, class... Args>
constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);

// 8.9, hash support
template<class T> struct hash;
template<class T> struct hash<optional<T>>;
}
```

## 8.3 Class template `optional` for object types

[[optional.optional](#)]

### 8.3.1 General

[[optional.optional.general](#)]

```

namespace std {
    template<class T>
    class optional {
        public:
            using value_type      = T;
            using iterator         = implementation-defined;           // see 8.3.6
            using const_iterator   = implementation-defined;           // see 8.3.6

// 8.3.2, constructors
    constexpr optional() noexcept;
    constexpr optional(nullopt_t) noexcept;
    constexpr optional(const optional&);
    constexpr optional(optional&&) noexcept(see below);

    template<class... Args>
        constexpr explicit optional(in_place_t, Args&&...);
    template<class U, class... Args>
        constexpr explicit optional(in_place_t, initializer_list<U>, Args&&...);
    template<class U = T>
        constexpr explicit(see below) optional(U&&);
    template<class U>
        constexpr explicit(see below) optional(const optional<U>&);
    template<class U>
        constexpr explicit(see below) optional(optional<U>&&);

    
```

```

// 3.3, destructor
constexpr ~optional();

// 3.4, assignment
constexpr optional& operator=(nullopt_t) noexcept;
constexpr optional& operator=(const optional&);
constexpr optional& operator=(optional&&) noexcept(see below);
template<class U = T> constexpr optional& operator=(U&&);
template<class U> constexpr optional& operator=(const optional<U>&);
template<class U> constexpr optional& operator=(optional<U>&&);
template<class... Args> constexpr T& emplace(Args&&...);
template<class U, class... Args> constexpr T& emplace(initializer_list<U>, Args&&...);

// 3.5, swap
constexpr void swap(optional&) noexcept(see below);

// 3.6, iterator support
constexpr iterator begin() noexcept;
constexpr const_iterator begin() const noexcept;
constexpr iterator end() noexcept;
constexpr const_iterator end() const noexcept;

// 3.7, observers
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
constexpr const T& operator*() const & noexcept;
constexpr T& operator*() & noexcept;
constexpr T&& operator*() && noexcept;
constexpr const T&& operator*() const && noexcept;
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
constexpr const T& value() const &;                                //freestanding-deleted
constexpr T& value() &;                                         //freestanding-deleted
constexpr T&& value() &&;                                       //freestanding-deleted
constexpr const T&& value() const &&;                         //freestanding-deleted
template<class U> constexpr T value_or(U&&) const &;
template<class U> constexpr T value_or(U&&) &&;

// 3.8, monadic operations

template<class F> constexpr auto transform(F&& f) const &&;
template<class F> constexpr optional or_else(F&& f) &&;
template<class F> constexpr optional or_else(F&& f) const &;

// 3.9, modifiers
constexpr void reset() noexcept;

private:
    T *val;           // exposition only
};

template<class T>
optional(T) -> optional<T>;
}

```

<sup>1</sup> Any instance of `optional<T>` at any given time either contains a value or does not contain a value. When an instance of `optional<T>` *contains a value*, it means that an object of type `T`, referred to as the optional object's

*contained value*, is allocated within the storage of the optional object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate its contained value. When an object of type `optional<T>` is contextually converted to `bool`, the conversion returns `true` if the object contains a value; otherwise the conversion returns `false`.

- 2 When an `optional<T>` object contains a value, member `val` points to the contained value.
- 3 `T` shall be a [non-array object](#) type other than `cv in_place_t` or `cv nullopt_t` that meets the *Cpp17Destructible* requirements ()�.

```
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) const &;
```

1 Let `U` be `invoke_result_t<F, decltype(*val)>`.

2 *Mandates:* `remove_cvref_t<U>` is a specialization of `optional`.

3 *Effects:* Equivalent to:

```
if (*this) {
    return invoke(std::forward<F>(f), *val);
} else {
    return remove_cvref_t<U>();
```

```
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
```

4 Let `U` be `invoke_result_t<F, decltype(std::move(*val))>`.

5 *Mandates:* `remove_cvref_t<U>` is a specialization of `optional`.

6 *Effects:* Equivalent to:

```
if (*this) {
    return invoke(std::forward<F>(f), std::move(*val));
} else {
    return remove_cvref_t<U>();
```

```
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;
```

7 Let `U` be `remove_cv_t<invoke_result_t<F, decltype(*val)>>`.

8 *Mandates:* `U` is a [reference or](#) non-array object type other than `in_place_t` or `nullopt_t`. The declaration

```
U u(involve(std::forward<F>(f), *val));
```

is well-formed for some invented variable `u`.

[*Note 1:* There is no requirement that `U` is movable. — *end note*]

9 *Returns:* If `*this` contains a value, an `optional<U>` object whose contained value is direct-non-list-initialized with `involve(std::forward<F>(f), *val)`; otherwise, `optional<U>()`.

```
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &&;
```

10 Let `U` be `remove_cv_t<invoke_result_t<F, decltype(std::move(*val))>>`.

11 *Mandates:* U is a [reference or](#) non-array object type other than `in_place_t` or `nullopt_t`. The declaration

```
U u(invoker(std::forward<F>(f), std::move(*val)));
```

is well-formed for some invented variable u.

[*Note 2:* There is no requirement that U is movable. — *end note*]

12 *Returns:* If `*this` contains a value, an `optional<U>` object whose contained value is direct-non-list-initialized with `invoker(std::forward<F>(f), std::move(*val))`; otherwise, `optional<U>()`.

```
template<class F> constexpr optional or_else(F&& f) const &;
```

13 *Constraints:* F models `invocable` and T models `copy_constructible`.

14 *Mandates:* `is_same_v<remove_cvref_t<invoke_result_t<F>>, optional>` is true.

15 *Effects:* Equivalent to:

```
if (*this) {
    return *this;
} else {
    return std::forward<F>(f)();
}
```

```
template<class F> constexpr optional or_else(F&& f) &&;
```

16 *Constraints:* F models `invocable` and T models `move_constructible`.

17 *Mandates:* `is_same_v<remove_cvref_t<invoke_result_t<F>>, optional>` is true.

18 *Effects:* Equivalent to:

```
if (*this) {
    return std::move(*this);
} else {
    return std::forward<F>(f)();
}
```

            template <class U> constexpr explicit(see below) optional(const optional<U>& rhs) noexcept;

            constexpr ~optional() = default;

            //◆◆◆.4.3, assignment
            constexpr optional& operator=(nullopt_t) noexcept;
            constexpr optional& operator=(const optional& rhs) noexcept = default;
```

```

constexpr optional& operator=(optional&& rhs) noexcept      = default;
template <class U = T>
constexpr optional& operator=(U&& u);

template <class U> constexpr optional& operator=(const optional<U>& rhs) noexcept;
template <class U> constexpr optional& operator=(optional<U>&& rhs);
template <class U> constexpr optional& emplace(U&& u) noexcept;

// 4.4.4, swap
constexpr void swap(optional& rhs) noexcept;

// 4.4.3.6, iterator support
constexpr iterator      begin() noexcept;
constexpr const_iterator begin() const noexcept;
constexpr iterator      end() noexcept;
constexpr const_iterator end() const noexcept;

// 4.4.6, observers
constexpr T*            operator->() const noexcept;
constexpr T&             operator*() const noexcept;
constexpr explicit operator bool() const noexcept;
constexpr bool           has_value() const noexcept;
constexpr T&             value() const;                                //freestanding-deleted
template <class U> constexpr T value_or(U&& u) const;

// 4.4.7, monadic operations
template <class F> constexpr auto and_then(F&& f) const;
template <class F> constexpr auto transform(F&& f) const -> optional<invoke_result_t<F, T>>;
template <class F> constexpr optional or_else(F&& f) const;

// 4.4.8, modifiers
constexpr void reset() noexcept;

private:
    T* val; //exposition only
};

}

4.4.2 Constructors [optionalref.ctor]

```

```
constexpr optional() noexcept;
constexpr optional(nullopt_t) noexcept;
```

1      *Postconditions:* \*this does not refer to a value.

2      *Remarks:* For all T& these constructors are constexpr constructors.

```
template <class Arg>
constexpr explicit optional(in_place_t, Arg&& arg);
```

3      *Constraints:*

(3.1)     — `is_constructible_v<add_lvalue_reference_t<T>, Arg>` is true

4      *Mandates:*

(4.1)     — `reference Converts_from_temporary_v<R, Arg>` is false

5      *Postconditions:* \*this refers to the T created by conversion from arg

```
template <class U = T>
constexpr explicit(see below) optional(U&& u) noexcept;
```

6      *Constraints:*

(6.1)     — `!is-derived-from-optional<decay_t<U>>` is true

```

7   Mandates:
(7.1)    — is_constructible_v<add_lvalue_reference_t<T>, U> is true
(7.2)    — is_lvalue_reference<U>::value is true
8   Effects: Direct-non-list-initializes val with addressof(u).
9   Postconditions: *this refers to a value.
10 Remarks: The expression inside explicit is equivalent to:
    !is_convertible_v<U, T>

    template <class U>
    constexpr explicit(see below) optional(const optional<U>& rhs) noexcept;

11  Mandates:
(11.1)   — is_constructible_v<add_lvalue_reference_t<T>, U> is true
12  Postconditions: If rhs.has_value() is true, *this refers to the same value, otherwise, *this does not refer to a value. Remarks: The expression inside explicit is equivalent to:
    is_convertible_v<U, T>

```

**◆◆◆.4.3 Assignment** [optionalref.assign]

```

constexpr optional& operator=(nullopt_t) noexcept;

1  Postconditions: *this does not refer to a value.
2  Returns: *this.

    template <class U = T>
    constexpr optional& operator=(U&& u);

```

3 *Constraints:*

(3.1) — `!is-derived-from-optional<decay_t<U>>` is true

4 *Mandates:*

(4.1) — `is_constructible_v<add_lvalue_reference_t<T>, U>` is true

(4.2) — `is_lvalue_reference<U>::value` is true

5 *Effects:* Assigns the `val` the value of `addressof(v)`.

6 *Postconditions:* `*this` refers to a value.

```

    template <class U>
    constexpr optional& operator=(const optional<U>& rhs) noexcept;

7  Mandates:
(7.1)   — is_constructible_v<add_lvalue_reference_t<T>, U> is true
(7.2)   — is_lvalue_reference<U>::value is true
8  Postconditions: rhs.has_value() == this->has_value().
9  Returns: *this.

    template <class U>
    constexpr optional& operator=(optional<U>&& rhs) noexcept;

```

10 *Mandates:*

(10.1) — `is_constructible_v<add_lvalue_reference_t<T>, U>` is true

(10.2) — `reference Converts_from_temporary_v<R, Arg>` is false

11 *Postconditions:* If `rhs.has_value()` is true, `*this` refers to the value obtained by converting the `rhs` referred to value to a `T&`, otherwise, `*this` does not refer to a value

12 *Returns:* `*this`.

```

template <class U>
constexpr optional& emplace(U&& u) noexcept;

13   Constraints:
(13.1)   — !is-derived-from-optional<decay_t<U>> is true
14   Effects: Assigns *this forward<U>(u)
15   Postconditions: *this refers to a value.

```

#### ◆◆.4.4 Swap

[optionalref.swap]

```

constexpr void swap(optional& rhs) noexcept;

1   Effects: *this and *rhs will refer to each others initial referred to objects.

```

#### ◆◆.4.5 Iterator support

[optionalref.iterators]

```

using iterator = implementation-defined;
using const_iterator = implementation-defined;

1   These types model contiguous_iterator, meet the Cpp17RandomAccessIterator requirements, and
    meet the requirements for constexpr iterators, with value type remove_cv_t<T>. The reference type is
    T& for iterator and const T& for const_iterator.

2   All requirements on container iterators apply to optional::iterator and optional::
    const_iterator as well.

constexpr iterator begin() noexcept;
constexpr const_iterator begin() const noexcept;

3   Returns: If has_value() is true, an iterator referring to the referred to value. Otherwise, a past-the-end
    iterator value.

constexpr iterator end() noexcept;
constexpr const_iterator end() const noexcept;

4   Returns: begin() + has_value().

```

#### ◆◆.4.6 Observers

[optionalref.observe]

```

constexpr T* operator->() const noexcept;

1   Returns: val.

constexpr T& operator*() const noexcept;

2   Preconditions: *this refers to a value.

3   Returns: *val.

constexpr explicit operator bool() const noexcept;

4   Returns: true if and only if *this refers to a value.

constexpr bool has_value() const noexcept;

5   Returns: true if and only if *this refers to a value.

constexpr T& value() const;

6   Effects: Equivalent to:
        if (has_value())
            return *value_;
        throw bad_optional_access();

```

```

template <class U>
constexpr T value_or(U&& u) const;

7   Mandates: is_constructible_v<add_lvalue_reference_t<T>, decltype(v)> is true.

8   Effects: Equivalent to: return has_value() ? U(**this) : U(std::forward<Args>(u));

```

#### ❖.❖.4.7 Monadic operations

[optionalref.monadic]

```
template <class F>
constexpr auto and_then(F&& f) const;

1 Let U be invoke_result_t<F, T&>.
2 Mandates: remove_cvref_t<U> is a specialization of optional.
3 Effects: Equivalent to:
    return has_value() ? invoke(forward<F>(f), value()) : result(nullopt);

template <class F>
constexpr auto transform(F&& f) const -> optional<invoke_result_t<F, T&>>;
4 Let U be remove_cv_t<invoke_result_t<F, T&>>.
5 Returns: If *this refers to a value, an optional<U> object whose referred to value is the result of
    invoke(forward<F>(f), *val); otherwise, optional<U>().
6
7 template <class F>
    constexpr optional or_else(F&& f) const;
Mandates: is_same_v<remove_cvref_t<invoke_result_t<F>>, optional> is true.
Effects: Equivalent to:
    if (has_value())
        return value()
    else
        return forward<F>(f)();
```

#### ❖.❖.4.8 Modifiers

[optionalref.mod]

```
constexpr void reset() noexcept;
1 Postconditions: *this does not refer to a value.
```

#### ❖.❖.5 No-value state indicator

[optional.nullopt]

#### ❖.❖.6 Class bad\_optional\_access

[optional.bad.access]

#### ❖.❖.7 Relational operators

[optional.relops]

#### ❖.❖.8 Specialized algorithms

[optional.specalg]

#### ❖.❖.9 Hash support

[optional.hash]

#### ❖.❖.10 Feature-test macro

[version.syn]

Add the following macro definition to [version.syn], header <version> synopsis, with the value selected by the editor to reflect the date of adoption of this paper:

```
#define __cpp_lib_optional_ref 20XXXXL // also in <ranges>, <tuple>, <utility>
```

## 6 Impact on the standard

A pure library extension, affecting no other parts of the library or language.  
The proposed changes are relative to the current working draft [N4910].

## Document history

- **Changes since R1**
  - Design points called out
- **Changes since R0**
  - Wording Updates
