# 1 Getting Started

This paper is one of several interrelated papers for a proposed Graph Library for the Standard C++ Library. The Table 1 describes all the related papers.

Paper	Status	Description		
P1709	Inactive	Original proposal, now separated into the following papers.		
P3126	Active	Overview, describes the big picture of what we are proposing.		
P3127	Active	Background and Terminology provides the motivation, theoretical background, and		
		terminology used across the other documents.		
P3128	Active	Algorithms covers the initial algorithms as well as the ones we'd like to see in the future.		
P3129	Active	Views has helpful views for traversing a graph.		
P3130	Active	Graph Container Interface is the core interface used for uniformly accessing graph data		
		structures by views and algorithms. It is also designed to easily adapt to existing graph data		
		structures.		
P3131	Active	Graph Containers describes a proposed high-performance compressed_graph container. It		
		also discusses how to use containers in the standard library to define a graph, and how to		
		adapt existing graph data structures.		
P3337	Active	Comparison to other graph libraries on performance and usage syntax. Not published		
		yet.		

Table 1: Graph Library Papers

Reading them in order will give the best overall picture. If you're limited on time, you can use the following guide to focus on the papers that are most relevant to your needs.

#### Reading Guide

- If you're **new to the Graph Library**, we recommend starting with the *Overview* (P3126) paper to understand the focus and scope of our proposals. You'll also want to check out how it stacks up against other graph libraries in performance and usage syntax in the *Comparison* (P3337) paper.
- If you want to **understand the terminology and theoretical background** that underpins what we're doing, you should read the *Background and Terminology* (P3127) paper.
- If you want to use the algorithms, you should read the Algorithms (P3128) and Graph Containers (P3131) papers. You may also find the Views (P3129) and Graph Container Interface (P3130) papers helpful.
- If you want to **write new algorithms**, you should read the *Views* (P3129), *Graph Container Interface* (P3130), and *Graph Containers* (P3131) papers. You'll also want to review existing implementations in the reference library for examples of how to write the algorithms.
- If you want to **use your own graph data structures**, you should read the *Graph Container Interface* (P3130) and *Graph Containers* (P3131) papers.

# 2 Revision History

### P3337r0

 New paper comparing the Graph Library to the NWGraph and Boost Graph Libraries on performance and usage syntax.

§2.0

# 3 Naming Conventions

Table 2 shows the naming conventions used throughout the Graph Library documents.

Template		Variable	
Parameter	Type Alias	Names	Description
G			Graph
	<pre>graph_reference_t<g></g></pre>	g	Graph reference
GV		val	Graph Value, value or reference
EL		el	Edge list
V	vertex_t <g></g>		Vertex descriptor
	vertex_reference_t <g></g>	u,v	Vertex descriptor reference. u is the source (or only) vertex. v is the target vertex.
VId	vertex_id_t <g></g>	uid, vid, source	Vertex id. uid is the source (or only) vertex id. vid is the target vertex id.
VV	vertex_value_t <g></g>	val	Vertex Value, value or reference. This can be either the user-defined value on a vertex, or a value returned by a function object (e.g. VVF) that is related to the vertex.
VR	vertex_range_t <g></g>	ur, vr	Vertex Range
VI	vertex_iterator_t <g></g>	ui,vi	Vertex Iterator. ui is the source (or only) vertex iterator. vi is the target vertex iterator.
		first,last	first and last are the begin and end iterators of a vertex range.
VVF		vvf	Vertex Value Function: vvf(u) → vertex value, or vvf(uid) → vertex value, depending on requirements of the consuming algorithm or view.
VProj		vproj	Vertex info projection function: vproj(u) → vertex_info <vid,vv>.</vid,vv>
	 partition_id_t <g></g>	pid	Partition id.
	Par or	P	Number of partitions.
PVR	<pre>partition_vertex_range_t<g></g></pre>	pur,pvr	Partition vertex range.
E	edge_t <g></g>	r , r	Edge descriptor
_	edge_reference_t <g></g>	uv,vw	Edge descriptor reference. $uv$ is an edge from vertices $u$ to $v$ . $vw$ is an edge from vertices $v$
EV	edge_value_t <g></g>	val	to w. Edge Value, value or reference. This can be either the user-defined value on an edge, or a value returned by a function object (e.g. EVF) that is related to the edge.
ER	vertex_edge_range_t <g></g>		Edge Range for edges of a vertex
EI	vertex_edge_iterator_t <g></g>	uvi,vwi	Edge Iterator for an edge of a vertex. $\tt uvi$ is an iterator for an edge from vertices $\tt u$ to $\tt v$ . $\tt vwi$ is an iterator for an edge from vertices $\tt v$
D.C.		C	tow.
EVF		evf	Edge Value Function: $evf(uv) \rightarrow edge$ value.
EProj		eproj	Edge info projection function: eproj(uv) $\rightarrow$ edge_info <vid,sourced,ev>.</vid,sourced,ev>

Table 2: Naming Conventions for Types and Variables

§3.0

For the algorithms in this paper, the reference implementation of the proposed graph library is referred to as **graph-v2** [1]. A recent library that this implementation is based on is referred to as **NWGraph** [2, 3]. **BGL** is used to refer to algorithms using the Boost Graph Library [4].

# 4 Syntax Comparison

In this section, we provide a usage syntax comparison of several graph algorithms in Tier 1 of P3128 against the equivalent implementations in **BGL** and the more recent **NWGraph**. These algorithms are breadth-first search (BFS, Figure 1), connected components (CC, Figure 2), single source shortest paths (SSSP, Figure 3), and triangle counting (TC, Figure 4). We take these algorithms from the GAP Benchmark Suite [5]. We defer to later sections any discussion of underlying implementation details and resulting performance.

Unlike BGL, graph-v2 does not specify edge direction as a graph property. If a graph in graph-v2 implemented by container::compressed\_graph is undirected, then it will contain distinct edges in both directions. BGL has a boost::graph::undirectedS property which can be used in the boost::graph::adjacency\_matrix class to specify an undirected graph, but not in the boost::graph::compressed\_sparse\_row\_graph class. Thus in Figures 1-4, the BGL graph type always includes boost::graph::directedS . Similar to graph-v2, undirected graphs must contain the edges in both directions.

Intermediate data structures (e.g., edge lists) will be needed to construct the compressed graph structures. In order to focus on the differences in algorithm syntax, we omit code which populates the graph data structures. See the tests or examples in the **graph-v2** repository (https://github.com/stdgraph/graph-v2) to better understand graph construction. In the following subsections, we address the syntax differences for each of these algorithms.

```
using namespace std;
using namespace std;
using namespace boost;
                                                      using namespace graph;
using G = compressed_sparse_row_graph<</pre>
                                                      using G = container::compressed_graph<</pre>
            directedS, no_property, no_property>;
                                                                 void, void, void, uint32_t, uint32_t>;
using Vertex = graph_traits<G>::vertex_descriptor;
                                                      using VId = vertex_id_t<G>;
Gg;
                                                      Gg:
//populate g
                                                      // populate g
vector<Vertex> parents(num_vertices(g));
                                                      vector<VId> parents(size(vertices(g));
auto vis = make_bfs_visitor(
                                                      auto bfs =
 make_pair(
                                                        edges_breadth_first_search_view<G,void,true>(
   record_predecessors(parents.begin(),
                                                           g, 0);
                        on_tree_edge())));
                                                      for (auto&& [uid, vid, uv] : bfs) {
breadth_first_search(g,
                     vertex(0, g),
                                                        parents[vid] = uid;
                     visitor(vis));
                     (a) BGL
                                                                         (b) graph-v2
```

Figure 1: Breadth-First Search Syntax Comparison

#### 4.1 Breadth-First Search

Figure 1 compares the simplest **BGL** BFS visitor against the range-based-for loop implementation of **graph-v2**. BFS is often described as a graph algorithm, though a BFS traversal by itself does not actually perform any task. In reality, it is a data access pattern which specifies an order vertices and edges should be processed by some higher level algorithm. **BGL** provides a very customizable interface to this data access pattern through the use of visitors which allows users to customize function calls during BFS events. For example **discover\_vertex** is called when a vertex is encountered for the first time; **examine\_vertex** is called when a vertex is popped from the

§4.1 4

```
using namespace std;
                                                     using namespace std;
using namespace boost;
                                                     using namespace graph;
using G =
                                                     using G =
 compressed_sparse_row_graph<
                                                       container::compressed_graph
    directedS, no_property, no_property>;
                                                          void, void, void, uint32_t, uint32_t>;
G g;
                                                     Gg;
//populate g
                                                     //populate g
vector<size_t> c(num_vertices(g)); //components
                                                     vector<size_t> c(size(vertices(g))); //components
int num_cmps = connected_components(g, &c[0]);
                                                     int num_cmps = connected_components(g, c);
```

(a)  $\mathbf{BGL}$  (b)  $\mathbf{graph-v2}$ 

Figure 2: Connected Components Syntax Comparison

queue; examine\_edge is called on each edge of a vertex when it is discovered, etc. Figure 1(a) demonstrates the usage of a BFS visitor record\_predecessors which is called upon event on\_tree\_edge during BFS traversal to store the parent node of every discovered vertex.

This capability is very powerful but often cumbersome if the BFS traversal simply requires vertex and edge access upon visiting. For this reason **graph-v2** provides a simple, range-based-for loop BFS traversal called a view. Figure 1(b) demonstrates how the visited edge uv and incident vertices uid and vid are exposed to the library user to store the parent information explicitly. The authors of this proposal acknowledge that some power users still want the full customization provided by visitors, and we plan to add them to this proposal.

Also note **BGL** often requires the use of vertex descriptors to uniquely identify vertices, as shown by the **graph\_traits<G>::vertex\_descriptor** type in Figure 1(a). Algorithms written using **graph-v2** use a unique vertex id, as shown by the **vertex\_id\_t<G>** type in Figure 1(b). This same difference is seen in the algorithms that follow.

### 4.2 Connected Components

From Figure 2 we see little difference in how the connected components algorithm is used in **graph-v2** and **BGL**. However when looking at the function definition there is a slight difference in the requirements on the resulting component vector **c** . **graph-v2** requires the component data structure to meet the concept requirements of **std::ranges::random\_access\_range** which requires the data structure to be contiguous. **BGL** requires a map data structure which satisfies **BGL**'s own WritablePropertyMapConcept (C++20 concepts were not available at the time). This concept only requires the data structure by indexable by vertex id, so the data structure need not be contiguous.

### 4.3 Single Source Shortest Paths

SSSP algorithm computes for every vertex (1) a distance from the start vertex, and (2) a predecessor vertex along the shortest path. A commonly used SSSP algorithm is the Dijkstra algorithm, which is available in **BGL** and **graph-v2** and shown in Figure 3.

Of the four algorithms discussed here, only SSSP makes use of an edge property associated with the input graph, the distance used to compute shortest paths. In Figure 3 we see a difference in how each implementation accesses this distance property of an edge. **BGL** creates a property map for the edge weights so the algorithm can access an edge's weight via it's edge descriptor. This **BGL** example is more general than necessary since if the weight map is not provided, the Dijkstra implmentation creates a default one based on the edge weight property tag in the graph type declaration (property<edge\_weight\_t, int>). Property maps can be confusing and difficult to use which is why **graph-v2** provides the equivalent functionality using a lambda function shown in Figure 3(b). The user tells the algorithm how it will access the distance property given an edge reference.

§4.3 5

```
using namespace std;
using namespace std;
using namespace boost;
                                                      using namespace graph;
using G = compressed_sparse_row_graph<</pre>
                                                      using G = container::compressed_graph<</pre>
            directedS, no_property,
                                                                  int, void, void, uint32_t, uint32_t>;
           property<edge_weight_t, int>>;
using Vertex = graph_traits<G>::vertex_descriptor;
                                                     using VId = vertex id t<G>;
Gg;
                                                      Gg;
//populate g
                                                      //populate g
vector<Vertex> p(num_vertices(g)); //predecessors
                                                      vector<VId> p(size(vertices(g))); //predecessors
                                                      vector<int> d(size(vertices(g))); //distances
vector<int> d(num_vertices(g)); //distances
                                                      init_shortest_paths(distance, predecessors);
property_map< graph_t, edge_weight_t >::type
                                                      auto weight_fn =
 weightmap = get(edge_weight, g);
                                                        [&g] (graph::edge_reference_t<graph_type> uv)
                                                          -> int {
                                                             return edge_value(g, uv);
                                                          };
dijkstra_shortest_paths(
 g, vertex(0, g),
 predecessor_map(
    make_iterator_property_map(
       p.begin(), get(vertex_index, g))).
    distance map(
       make_iterator_property_map(
          d.begin(), get(vertex_index, g))));
                                                     dijkstra_shortest_paths(g, 0, d, p, weight_fn);
                     (a) BGL
                                                                         (b) graph-v2
```

Figure 3: Single Source Shortest Paths Syntax Comparison

**BGL** also requires property maps be used to store the resulting path and distance unlike **graph-v2**. This leads to a much more verbose function call to Dijkstra than the equivalent **graph-v2** usage.

## 4.4 Triangle Counting

**BGL** does not provide a triangle counting algorithm similar to the one proposed in **graph-v2**. The code example in Figure 4(a) is representative of what is currently available in **BGL**; it iterates through the vertices, counting the number of triangles incident on every vertex, and adjusts for overcounting at the end.

**graph-v2** provides a much more efficient implementation with a high level interface shown in Figure 4(b). The underlying **graph-v2** implementation performs a set intersection of the neighbor list of vertices u and v, only if v is a neighbor of u. This approach requires the edges of a vertex to be stored in lexicographic order (by target vertex id), and to only contain successor edges (target vertex id greater than source vertex id). The latter requirement is equivalent to the graph only containing the upper triangular portion of the adjacency matrix. Then the set intersection is limited to neighbors with vertex ids greater than u and v, avoiding duplicate counting.

In fairness to **BGL**, especially for the purposes of the performance comparison in Section 5, we implement TC in **BGL** using the same set intersection approach used inside **graph-v2**. Figure 5 compares the underlying implementation syntax for each library. Note again for **BGL** the need to go through vertex descriptors to access the out edges of a vertex while **graph-v2** uses a vertex id. The **incidence\_iterator** in **graph-v2** is not random access and requires != comparison. When using the same != comparison in the **BGL** example, we find the while loop to continue past the end of a neighbor list, so the comparison operator is used instead. This is not expected and perhaps a bug in the **BGL** version we use.

§4.4 6

```
using namespace boost;
                                                    using namespace graph;
using G =
                                                    using G =
 compressed_sparse_row_graph
                                                      container::compressed_graph
    directedS, no_property, no_property>;
                                                        void, void, uint32_t, uint32_t>;
using Vertex = graph_traits<G>::vertex_descriptor;
                                                    Gg;
Gg;
//populate g
                                                    //populate g
size_t count{0};
for(size_t i = 0; i < N; i++) {</pre>
 Vertex cur = vertex(i, g);
 count += num_triangles_on_vertex(g, cur);
count /= 6;
                                                    size_t count = triangle_count(g);
                     (a) BGL
                                                                   (b) graph-v2
```

Figure 4: Triangle Counting Syntax Comparison

§4.4 7

```
using namespace boost;
                                                      using namespace graph;
using G =
                                                      using G =
 compressed_sparse_row_graph
                                                        container::compressed_graph
    directedS, no_property>;
                                                          void, void, void, uint32_t, uint32_t>;
using edge_iterator = graph_traits<G>::
    out_edge_iterator;
                                                      size_t N(size(vertices(g)));
size_t N(num_vertices(g));
size_t triangles(0);
                                                      size_t triangles(0);
for (size_t uid = 0; uid < N; ++uid) {</pre>
                                                     for (vertex_id_t<G> uid = 0; uid < N; ++uid) {</pre>
 Vertex u = vertex(uid, g);
 std::pair<edge_iterator, edge_iterator>
   u_neighbors = out_edges(u, g);
 auto i = u_neighbors.first;
                                                        incidence_iterator<G> i(g, uid);
                                                        auto ie = end(edges(g, uid));
 auto ie = u_neighbors.second;
                                                        while (i != ie) {
 while (i < ie) {
   size_t vid = target(*i, g);
                                                         auto&& [vid, uv] = *i;

# 5 Performance Comparison

### 5.1 Experimental Setup

To evaluate the performance of this proposed library, we compare its reference implementation (graph-v2) against BGL and NWGraph on a subset of the GAP Benchmark Suite [5]. This comparison includes four of the five GAP algorithms that are in the tier 1 algorithm list of this proposal: breadth-first search (BFS), connected components (CC), single-source shortest paths (SSSP), and triangle counting (TC). The performance of NWGraph on the algorithms and a comparison to other graph frameworks was carried out in [6]. Table 3 summarizes the graphs specified by the GAP benchmark. These graphs were chosen with a variety of degree distributions and diameters, and to be large (with edge counts into the billions) but still fit on shared memory machines.

We compare to **BGL** because it the commonly used sequential C++ graph library as described above. **NWGraph** is the direct predecessor of **graph-v2**, with many of the **NWGraph** authors contributing to this library proposal and the **graph-v2** reference implementation. It was implemented with many of the ideas of this proposal in mind, e.g. graphs as a range of ranges and generic algorithms that support any data structure that meet the concept requirements. Since the two implementations are based on similar ideas, we expect similar experimental performance, and include **NWGraph** to verify **graph-v2** does not introduce any performance overhead.

Name	Description	#Vertices	# Edges	Degree	(Un)directed	References
		(M)	(M)	Distribution		
road	USA road network	23.9	57.7	bounded	undirected	[7]
Twitter	Twitter follower links	61.6	1,468.4	power	directed	[8]
web	Web crawl of .sk domain	50.6	1,930.3	power	directed	[9]
kron	Synthetic graph	134.2	2,111.6	power	undirected	[10]
urand	Uniform random graph	134.2	2,147.5	normal	undirected	[11]

Table 3: Summary of GAP Benchmark Graphs

The **NWGraph** authors published a similar comparison to BGL in which they demonstrated performance improvement of **NWGraph** over BGL [2]. To simplify experimental setup, we rerun these new experiments using the same machine used in that paper, (compute nodes consisting of two Intel® Xeon® Gold 6230 processors, each with 20 physical cores running at 2.1 GHz, and 188GB of memory per processor). All three implementations were compiled into a single experimental driver to ensure uniform compiler setup (gcc 13.2 using -Ofast -march=native compilation flags.) Additionally any graph preprocessing such as symmetricization (for undirected algorithms) or vertex relabeling are guaranteed to be the same for all three implementations.

#### 5.2 Experimental Analysis

Table 4 summarizes our GAP benchmark results for **graph-v2** compared to **BGL** and **NWGraph**. In addition to runtime, the table contains the number of connected components and the number of triangles for each graph as this is helpful for understanding performance. The below subsections consider each GAP algorithm, describe the specific algorithm implementation(s) tested for each library, and examine the performance results.

#### 5.2.1 Breadth-First Search

All implementations of BFS use a sequential push variant that one could find in a textbook (no direction optimization or parallel processing of frontier). As mentioned in Section 4, **BGL** contains support for visitors which is not available in **NWGraph** or the version of **graph-v2** being tested here.

BFS results are competitive between the libraries, with the **graph-v2** implementation achieving the fastest time on all but the road graph. **NWGraph** has noticably worse performance on kron and urand. **BGL** underperforms on web by 2x but this run only takes around 4s.

§5.2

Algorithm	Library	Variant	road	twitter	kron	web	urand
	BGL		0.99s	7.82s	17.40s	4.13s	59.05s
BFS	NWGraph		0.88s	9.08s	25.04s	2.09s	68.18s
	$\operatorname{graph-v2}$		0.92s	7.00s	15.93s	2.61s	55.13s
			1 CC	19.9M CC	71.2M CC	123 CC	1 CC
CC	$\operatorname{BGL}$	DFS-based	1.30s	32.03s	71.38s	11.93s	94.80s
	$\operatorname{graph-v2}$	DFS-based	0.76s	27.87s	41.21s	6.64s	64.87s
	NWGraph	Afforest	1.15s	6.09s	28.42s	3.29s	28.73s
	$\operatorname{graph-v2}$	Afforest	0.97s	5.85s	23.37s	3.16s	33.84s

	$\operatorname{graph-v2}$	Dijkstra	4.06s	104.38s	348.72s	33.77s	387.75s
	NWGraph	DeltaStepping	1.49s	24.48s	74.43s	12.53s	103.97s
			439K T	34.8B T	107B T	84.9B T	5.38K T
TC	$\operatorname{BGL}$	$\frac{1}{6}tr(A^3)$	1.34s	> 24 H	> 24 H	> 24 H	$4425.54\mathrm{s}$
	$\operatorname{BGL}$	Upper triangular	0.61s	$1672.71\mathrm{s}$	$8346.70\mathrm{s}$	$251.78 \mathrm{s}$	$405.37\mathrm{s}$
	NWGraph	Upper triangular	0.20s	567.97s	2962.32s	$107.85 \mathrm{s}$	$152.52\mathrm{s}$
	graph-v2	Upper triangular	0.17s	524.68s	2683.41s	71.10s	128.32s

Table 4: GAP Benchmark Performance: Time for GAP benchmark algorithms is shown for **BGL**, **NWGraph**, **graph-v2** 

#### 5.2.2 Connected Components

The **NWGraph** implementation of CC is based on the Afforest [12] algorithm. **BGL** does not provide an Afforest variant. Instead, **BGL** implements a simple depth-first search based CC algorithm. **graph-v2** contains implementations of both. However, the **graph-v2** implementation of Afforest does not contain support for parallel execution policies which **NWGraph** does, and does not contain the overhead of atomics.

It is likely that other researchers implementing the GAP benchmark use CC to refer to weakly connected components of a directed graph. As the DFS based CC implementation of **BGL** and **graph-v2** assumes an undirected graph, we make all graphs undirected before running these experiments.

Comparing the two DFS based implementations, **graph-v2** has consistently better performance, up to 2x, over the **BGL** implementation. The Afforest implementations outperform the DFS based implementations. Of the two Afforest implementations, **graph-v2** is slightly faster but this is reasonable considering it does not have the parallel overhead of the **NWGraph** implementation.

#### 5.2.3 Single Source Shortest Paths

Each graph library contains an implementation of Dijkstra's SSSP algorithm which we include in these experiments. Actually **NWGraph** contains multiple Dijkstra implementations, but we use the simplest one which is taken directly from the **NWGraph** benchmark directory. The GAP specification for SSSP only requires that the algorithm compute the shortest distance to every vertex, not the shortest path. We use a variant of SSSP that only computes shortest distances for all of these results.

Although we include performance numbers of the **NWGraph** implementation of Dijkstra, the SSSP results in [2] were based on delta-stepping. **NWGraph**'s delta-stepping implementation was highly tuned for performance compared to its Dijkstra implementation. Therefore we include **NWGraph** delta-stepping timing to consider its best "out of the box" performance. This implementation is not sequential as it contains **std::for\_each**, and is therefore not useful for helping us understand potential difference between libraries or their Dijkstra implementations.

SSSP results are mixed, with superior performance for **BGL** on twitter and web, while **BGL** fails by running out of memory on kron and urand. The edge distances required for SSSP make this a more memory intensive algorithm than the other GAP algorithms. The 2x performance of **BGL** over **NWGraph** and **graph-v2** on

§5.2

twitter is notable and calls for further investigation.

### 5.2.4 Triangle Counting

**NWGraph** and **graph-v2** contain similar implementations of TC that perform a set intersection of the neighbor list of vertices. This is discussed in Section 4 and the **graph-v2** code is shown in Figure 5(b). As noted in Section 4, the naïve **BGL** TC implementation shown in Figure 4(a) is very inefficient. For these performance experiments we include both the inefficient **BGL** approach, and our own **BGL** set intersection implementation shown in Figure 5(b).

TC performance from our naïve **BGL** implementation is far slower than the adjacency matrix set intersection used by **NWGraph** and **graph-v2**. Since the same triangle is counted six times in **BGL**, one can expect at least that much of a slowdown; however, the slowdown is often much worse likely due to poor memory access patterns. The **BGL** implementation of the set intersection approach is much faster than the naïve approach, but is still significantly slower than the **NWGraph** or **graph-v2** implementations, up to a factor of 3x on road and kron. It is unclear if this is a fundamental limitation of **BGL** or our implementation could be further optimized. **graph-v2** consistently outperforms **NWGraph**, up to 1.5x on web. This is surprising given the similarity of the implementations, and could indicate more efficient data access for the **graph-v2** graph data structure.

# 6 Memory Allocation

Unlike existing STL algorithms, the graph algorithms in the **graph-v2** reference implementation often need to allocate their own temporary data structures. Table 5 records the internal memory allocations required for **graph-v2**'s implementation of the GAP Benchmark algorithms where relevant. It is important to note that the memory usage is not prescribed by the algorithm interface in P3128, and is ultimately determined by the library implementer. Some memory use, such as the queues in BFS and SSSP, will probably be common to most implementations. However, the color map in BFS and the reindex map in CC (used to ensure the resulting component indices are contiguous) could potentially be avoided.

Algorithm	Required Internal Data	Max Size
BFS	queue	O( V )
	color map	V
CC	reindex map	O( components )
SSSP	priority queue	O( E )
TC	None	NA

Table 5: Internal Memory Allocations of GAP Benchmark Algorithm Implementations in graph-v2
