1 Problem Description

C++ groups integers into sets as follows:

There are five standard signed integer types: "signed char", "short int", "int", "long int", and "long long int".

For each of the *standard signed integer types*, there exists a corresponding (but different) *standard unsigned integer type* : "unsigned char", "unsigned short int", "unsigned int", "unsigned long int", and "unsigned long long int".

Type bool is a distinct type that has the same object representation, value representation, and alignment requirements as an implementation-defined unsigned integer type.

C on the other hand groups integers into sets in "Subclause 6.2.5 Types" as:

There are five *standard signed integer types*, designated as signed char, short int, int, long int, and long long int.

There may also be implementation-defined extended signed integer types.31) The standard signed integer types, bit-precise signed integer types, and extended signed integer types are collectively called *signed integer types*.32)

For each of the *signed integer types*, there is a corresponding (but different) *unsigned integer type* The type bool and the *unsigned integer types* that correspond to the *standard signed integer types* are the *standard unsigned integer types*.

This means that in C bool is a standard unsigned integer type while in C++ it is not. This is very confusing for anyone including implementers, programmers, or educators when dealing with integer behavior where people assume similar if not identical behaviors. Furthermore, calling bool an unsigned type is misleading because it doesn't wrap around and has special conversion rules. For example, as an unsigned type you would expect (bool) 4 to be 0 not 1.

Another problem with the existing text is that the term "unsigned integer type(s)" is used before it is defined, and when it is defined it has a different meaning.

Because this proposal addresses many defects where the term unsigned integer type was incorrectly used to apply to the bool type, this proposal does change the semantics from C23.

1.1 C Integer Types

N3550 working draft subclause 6.2.5 Types paragraph 4 through 8 define the following terms and relationships:

Paragraph 22 adds the following terms and relationships:

1.2 Bit-precise Integers

The user community has provided feedback that they would like <code>signed_BitInt(1)</code> to behave the same way as <code>struct S { signed int i : 1; };</code> works -- so it can hold the values 0 and -1. This is a more feasible approach now that C23 only supports two's complement. In two's complement, the most-significant bit (MSB) is a value bit with a negative weight, so an _BitInt(1) can have two values: -1 and 0.

One example of an application is splitting a wide product as a sum of multiple subproducts.

If we take the example of a product between two 33 bits signed integers a and b, on an FPGA that has DSP able to compute 32x32 products, the product can be computed as follows:

- Each input is split between its MSB (a_h and b_h), and the remaining 32 low bits (a_1 and b_1).
- The result is ((a_h x b_h) << 64) + ((a_h x b_l + b_h x a_l) << 32) + a_l x b_l.
- This computation uses only one DSP for a_1 x b_1, the three other products are done inexpensively on fpga logic.

Both a_h and b_h are conceptually _BitInt(1) (one bit integers that can be either 0 or -1). There is no difference with the unsigned case for the 1x1 product, but in the case of non-square products such as $a_h \times b_1$, it is important that the product gives $-b_1$ when the a_h bit is set, otherwise the result is false.

This example is in the case of a full square product and can look a bit artificial, but when computed truncated product (which makes sense on FPGA, as it is less expensive than computing the full product) the case of subproducts involving a 1-bit signed integer can also appear.

1.3 Preserve Existing Language with New Meaning

Generally speaking, the use of the term *unsigned integer type* used throughout the standard predates the introduction of the bool type and is not meant to apply to the bool type.

In subclause "5.3.5.3.2 Characteristics of integer types <limits.h> and <stdint.h>" paragraph 2, the bool type is included:

For all unsigned integer types for which <limits.h> or <stdint.h> define a macro with suffix _WIDTH holding its width N, there is a macro with suffix _MAX holding the maximal value 2^N - 1 that is representable by the type and that has the same type as would an expression that is an object of the corresponding type converted according to the integer promotions.

Subclause 6.2.6.2 paragraph 2 states that "The type bool has one value bit and (sizeof(bool)*CHAR_BIT) - 1 padding bits. The width of an unsigned type is the number of value bits. For the bool type, this is always one. Consequently, the specification of a _WIDTH for the bool type has dubious value, but is not wrong. Conceptually, a Boolean does not have a maximal value as it only stores the values false and true. The specification of a _MAX macro for the bool type is conceptually incorrect.

Removing bool from the set of *unsigned integer types* eliminates the requirement to provide both these macros without changing this subclause. To retain this requirement, bool will need to be explicitly added. I think the right thing to do here is to keep the requirement for **_WIDTH** but eliminate the requirement for **_MAX**.

Subclause 6.7.3.3 Enumeration specifiers allows the underlying type for an enumeration to be a bool in paragraph 2:

If it is not explicitly specified, the underlying type is the enumeration's compatible type, which is either char or a standard or extended signed or unsigned integer type.

And again in paragraph 4:

For all the integer constant expressions which make up the values of the enumeration constants, there shall be a type capable of representing all the values that is a standard or extended signed or unsigned integer type, or char.

And again in paragraph 12:

— a suitably sized unsigned integer type, excluding the bit-precise unsigned integer types, capable of representing the value of the previous enumeration constant plus one.

A signed integer type is chosen if the previous enumeration constant being added is of signed integer type. An unsigned integer type is chosen if the previous enumeration constant is of unsigned integer type.

In subclause "7.18.3 Count Leading Zeros" paragraph 2, the bool type is included:

The **generic_return_type** type shall be a suitably large unsigned integer type capable of representing the computed result.

However, because the input type has at least width 8, the return type can never be bool. Consequently, removing bool from the set of unsigned integer types does not alter the semantics and the text can remain unchanged.

In subclause "7.33.1 Introduction" paragraph 4, the bool type is included in the two highlighted locations:

The macros defined are **NULL** (described in 7.22); **WCHAR_MIN**, **WCHAR_MAX**, and **WCHAR_WIDTH** (described in 7.23);

which expand to an expression of signed or unsigned integer type (that is potentially not an integer constant expression) whose value is nonzero if:

— the wide execution encoding (6.2.9) is capable of representing every character in the required Unicode set:

- the width of wchar t is at least 8, 16, or 32 for UTF-8, UTF-16, or UTF-32, respectively;

- and, the values of a sequence of wchar t objects consumed and produced by related character

functions have a values consistent with a sequence of code units of the UTF-8, UTF-16, or

2 Proposal

This paper proposes removing the type bool from the set of *unsigned integer types* and from the set of *standard unsigned integer types* and adding the type bool to the set of *basic types* and the set of *integer types*.

The type unsigned _BitInt(1) is eliminated as a separate type and is now simply treated as one of the *bit-precise unsigned integer types*.

The relationship between signed and unsigned integer types is therefore greatly simplified:

The type bool is added to the set of basic types.

The type bool is added to the set of integer types.

We could also say that integer types consist of enumerated types and basic types.

3 Proposed Text

Text in green is added to the C2Y working draft n3467. Text in red that has been struck through is removed from the C2Y working draft n3467.

Modify subclause "6.2.5 Types", paragraph 5:

A bit-precise signed integer type is designated as **_BitInt(N)** where N is an integer constant expression that specifies the number of bits that are used to represent the type, including the sign bit with the same object representation as a signed integer type of width N. Each value of N designates a distinct type.

Modify subclause "6.2.5 Types", paragraph 8:

For each of the signed integer types, there is a corresponding (but different) unsigned integer type (designated with the keyword unsigned) that uses the same amount of storage (including sign information) and has the same alignment requirements. The type bool and the unsigned integer types that correspond to the standard signed integer types are the standard unsigned integer types. The unsigned integer types that correspond to the extended signed integer types are the extended unsigned integer types. In addition to the unsigned integer types that correspond to the bit-precise signed integer types there is the type unsigned _BitInt(1), which uses one bit to represent the type. Collectively, unsigned _BitInt(1) and t The unsigned integer types that correspond to the bit-precise signed integer types are the bit-precise unsigned integer types. The standard unsigned integer types, bit-precise unsigned integer types, and extended unsigned integer types are collectively called unsigned integer types.³⁴

The type bool and the unsigned integer types that correspond to the standard signed integer types are the standard unsigned integer types.

Modify subclause "6.2.5 Types", paragraph 11:

The range of nonnegative values of a signed integer type is a subrange of the corresponding unsigned integer type, and the representation of the same value in each type is the same.³⁵⁾ The range of representable values for the unsigned integer types is 0 to $2^{N} - 1$ (inclusive). A computation involving unsigned operands can never produce an overflow, because arithmetic for the unsigned integer types is performed modulo 2^{N} .

Modify subclause "6.2.5 Types", paragraph 18:

The type bool, the type char, the signed and unsigned integer types, and the floating types are collectively called the basic types. The basic types are complete object types. Even if the implementation defines two or more basic types to have the same representation, they are nevertheless distinct types.

Add the following paragraph and footnote after subclause "6.2.5 Types", paragraph 20:

Type **bool** is a distinct type that has the same object representation, value representation, and alignment requirements as an implementation-defined unsigned integer type.ⁿⁿ⁾ The values of type **bool** are **true** and **false**.

nn) There are no **signed**, **unsigned**, **short**, or **long bool** types or values.

Modify subclause "6.2.5 Types", paragraph 22:

The type **bool**, the type **char**, the signed and unsigned integer types, and the enumerated types are collectively called integer types. The integer and real floating types are collectively called real types.

Modify subclause "6.3.2.1 Boolean, characters, and integers", paragraph 1:

 The rank of any unsigned integer type shall equal the rank of the corresponding signed integer type, if any.

— The rank of type bool shall be less than the rank of all other standard integer types.

Modify subclause "6.7.3.3 Enumeration specifiers", paragraph 13:

For all enumerations without a fixed underlying type, each enumerated type shall be compatible with char or a signed or an unsigned integer type that is not bool or a bit-precise integer type. The choice of type is implementation-defined,¹⁴²⁾ but shall be capable of representing the values of all the members of the enumeration.¹⁴³⁾

Modify subclause "7.18.3 Count Leading Zeros", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the appropriate value based on the type of the input value, so long as provided that it is-a:

- a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.5 Count Trailing Zeros", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the appropriate value based on the type of the input value, so long as provided that it is-a:

- a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.6 Count Trailing Ones", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the appropriate value based on the type of the input value, so long as provided that it is a:

— a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.7 First Leading Zero", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the appropriate value based on the type of the input value, so long as provided that it is a:

- a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.8 First Leading One", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the appropriate value based on the type of the input value, so long as provided that it is-a:

- a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.9 First Trailing Zero", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the appropriate value based on the type of the input value, so long as provided that it is-a:

— a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.10 First Trailing One", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the appropriate value based on the type of the input value, so long as provided that it is a:

- a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.11 Count Zeros", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the previously described result for a given input value so long as provided that the *generic_value_type* is -a:

— a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.12 Count Ones", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the previously described result for a given input value so long as provided that the *generic_value_type* is -a:

- a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.13 Single-bit Check", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the previously described result for a given input value so long as provided that the *generic_value_type* is -a:

— a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.14 Bit Width", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the previously described result for a given input value so long as provided that the *generic_value_type* is -a:

- a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.15 Bit Floor", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the previously described result for a given input value so long as provided that the *generic_value_type* is -a:

- a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.16 Bit Ceiling", paragraph 2:

The type-generic function (marked by its *generic_value_type* argument) returns the previously described result for a given input value so long as provided that the *generic_value_type* is -a:

- a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, bit-precise unsigned integer type whose width matches a standard or extended integer type, excluding bool.

Modify subclause "7.18.17 Rotate Left", paragraph 4:

The type-generic function (marked by its *generic_value_type* argument) returns the previously above described result for a given input value so long as provided that the *generic_value_type* is:

— a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, a bit-precise unsigned integer type whose width matches any standard or extended integer type, excluding bool.

The *generic_count_type* count argument shall be a non-negative value of signed or unsigned integer type, or **char**.

Modify subclause "7.18.18 Rotate Right", paragraph 4:

The type-generic function (marked by its *generic_value_type* argument) returns the previously above described result for a given input value so long as provided that the *generic_value_type* is:

- a standard unsigned integer type, excluding bool;

- an extended unsigned integer type;

— or, a bit-precise unsigned integer type whose width matches any standard or extended integer type, excluding bool.

The *generic_count_type* count argument shall be a non-negative value of signed or unsigned integer type, or **char**.

Modify subclause "7.25.2.8 The strtol, strtoll, strtoul, and strtoull functions", paragraph 5:

If the subject sequence begins with a minus sign, the resulting value is the negative of the converted value; for the strtoul and strtoull functions whose return type is an unsigned integer type this action is performed in the return type.

Modify subclause "7.33.4.2.4 The wcstol, wcstoll, wcstoul, and wcstoull functions", paragraph 5:

If the subject sequence begins with a minus sign, the resulting value is the negative of the converted value; for the westoul and westoull functions whose return type is an unsigned integer type this action is performed in the return type.
