## II. Introduction

`vector::release` returns a direct pointer to the memory array used internally by the vector to store its owned elements, and then releases ownership of the elements by setting the internal status to null status. Difference between `vector::release` and `vector::data` is just like difference between `unique_ptr::release` and `unique_ptr::get`.

## III. Motivation

The containers section of the standard library has become a familiar and valued tool over the years since standardisation, replacing low level manipulation of data structures and pointers with a consistent higher level interface.

However, standard library can't be used without conversion and data copy in interoperation between modern C++ and C or other language or even some of C++ libraries. For example, from `vector<char>` to `char[]`, there's no way to steal resource but copy. High level design usually causes overhead, but our (C++'s) goal is to achieve zero overhead. So why can't we think about to omit the data copy inside the conversion?

Remembering the old days without rvalue-reference, even within standard library, we do a lot of unnecessary copies to transfer data, while postbuilt in D language with GC can omit all of them. Now we've realized that we need "move", but only move construct and assignment between two object of same type can be done. Why can't we step a little further and make stealing resource possible in more situation than just from one vector to another vector? `unique_ptr` already has one solution: `unique_ptr::release`, because `unique_ptr` designer knows that not every `unique_ptr` users won't need a raw pointer. So do vector users, and `vector::data` can't meet our need for stealing resources.

This proposal extends the vector class with one member function `vector::release` without any changes to anything else, providing a way for stl users to steal the ownership of the memory originally owned by the vector.

## IV. Impact On the Standard

This proposal is an extension to vector class. It only adds a member function to vector class, which modified standard library headers. It does not require any changes in the core language. It has been implemented in standard C++.

## V. Design Decisions

### Example and Typical case

```
// vector::release
#include <iostream>
#include <vector>

struct input_t
{
    int* statistics_data;
    int  statistics_size;
    //other fields ignored
};
extern void input(input_t in);
extern void set_callback(void (*fn)(int)); //will call back after input
has been processed
void make_input ()
{
    std::vector<int> myvector;
    myvector.reserve(10000000);
    for(int i=0;i<50000000;++i)
        myvector.push_back(i*i);
    int n = myvector.size();
    int* p = myvector.release();
    input_t in;
    in.statistics_data = p;
    in.statistics_size = n;

    input(in);
}
int main ()
{
    set_callback([](int result) {std::cout<<result<<endl;});
    make_input();
    wait_for_result(); //some function to wait for result
    return 0;
}
```

In this example, myvector in make\_input() firstly finished it's job to collect data(data amount this job need in real world is dynamic depending on other conditions,so vector is chosen).Then the result should be input by calling function input(input\_t) which will pass the data to another thread to use.The

data don't have to be copied there, just passing pointer is ok, if we don't need touch these data anymore(giving up ownership) .

But unfortunately we used vector, and until now vector can only give up ownership of its elements to another vector. This proposal provides `vector::release` to solve this problem. After calling `myvector.release()`, `myvector` explicitly lost ownership of its elements and they are transfer to be used elsewhere and finally get deallocated via freeing `struct input_t`.

## **Destruction and deallocation issues**

Just as when using `unique_ptr::release` you must use `unique_ptr::get_deleter` very often, when you've called `vector::release`, you're on your own too. If you are handling `vector<MyClass>`, you must call `MyClass::~~MyClass` on the first `size()` elements, afterwards deallocate the chunk of memory. If you are handling `vector<MyClass, MyAllocator>`, you must also use `get_allocator()` to deallocate memory.

With destructor-less data types and default allocator, there are no such worries, while it's just the typical case for `vector::release`.

## **VI. Technical Specifications**

`vector::release` is designed to be a public member function of `vector` in this form:

```
value_type* release() noexcept;
```

### **Description**

Returns a direct pointer to the memory array used internally by the vector to store its owned elements, and then releases ownership of the elements by setting the internal status to null status.

Because elements in the vector are guaranteed to be stored in contiguous storage locations in the same order as represented by the vector, the pointer retrieved can be offset to access any element in the array.

### **Parameters**

None

## **Return value**

A pointer to the first element in the array used internally by the vector. Member type `value_type` is the type of the elements in the container, defined in `vector` as an alias of the first class template parameter (T).

## **Complexity**

Constant.

## **Iterator validity**

No changes.

## **Data races**

The container is modified , concurrently accessing or modifying is unsafe.

## **Exception safety**

No-throw guarantee: this member function never throws exceptions.
