A view of 0 or 1 elements: views::maybe

Steve Downey (sdowney@gmail.com)

Document #: P1255R8
Date: 2022-07-11
Project: Programming Language C++
Audience: SG9, LEWG

Abstract

This paper proposes views::maybe a range adaptor that produces a view with cardinality 0 or 1 which adapts copyable object types, values, and nullable types such as std::optional and pointer to object types.

1 Before / After Table

```cpp
1. auto&& opt = possible_value();
   if (opt) {
       // a few dozen lines ...
       use(*opt); // is *opt OK ?
   }

2. for (auto&& opt : views::maybe(possible_value())) {
       // a few dozen lines...
       use(opt); // opt is OK
   }
```

```cpp
std::optional o{7};
if (o) {
    *o = 9;
    std::cout << "o=" << *o << " prints 9\n";
}
// o prints 9

std::optional o{7};
for (auto i : views::maybe(std::ref(o))) {
    i = 9;
    std::cout << "i=" << i << " prints 9\n";
}
// o prints 9
```

```cpp
std::vector<int> v{2, 3, 4, 5, 6, 7, 8, 9, 1};
auto test = [](int i) -> std::optional<int> {
    switch (i) {
    case 1:
    case 3:
    case 7:
    case 9:
        return i;
    default:
        return {};
    }
};
auto&& r = v | ranges::views::transform(test) | ranges::views::filter([](auto x) { return bool(x); }) | ranges::views::transform([](auto x) { return *x; }) | ranges::views::transform([](int i) {
    std::cout << i;
    return i;
});
```

2 Motivation

In writing range transformation it is useful to be able to lift a value into a view that is either empty or contains the value. For types that are nullable, constructing an empty view for disengaged values and providing a view to the underlying value is useful as well. The adapter `views::single` fills a similar purpose for non-nullable values, lifting a single value into a view, and `views::empty` provides a range of no values of a given type. The type `views::maybe` can be used to unify `single` and `empty` into a single type for further processing. This is in particular useful when translating list comprehensions.

```cpp
std::vector<std::optional<int>> v{
    std::optional<int>{42},
    std::optional<int>{},
    std::optional<int>{6 * 9}};

auto r = views::join(
    views::transform(v, views::maybe));
for (auto i : r) {
    std::cout << i; // prints 42 and 54
}
```

In addition to range transformation pipelines, `views::maybe` can be used in range based for loops, allowing the nullable value to not be dereferenced within the body. This is of small value in small examples in contrast to testing the nullable in an if statement, but with longer bodies the dereference is often far away from the test. Often the first line in the body of the if is naming the dereferenced nullable, and lifting the dereference into the for loop eliminates some boilerplate code, the same way that range based for loops do.
auto&& opt = possible_value();
if (opt) {
    // a few dozen lines ...
    use(*opt); // is *opt OK ?
}
}

for (auto&& opt :
     views::maybe(possible_value())) {
    // a few dozen lines ...
    use(opt); // opt is OK
}

The view can be on a std::reference_wrapper, allowing the underlying nullable to be modified:

std::optional o{7};
for (auto&& i : views::maybe(std::ref(o))) {
    i = 9;
    std::cout << "i=" << i << " prints 9\n";
}

std::cout << "o=" << *o << " prints 9\n";

Of course, if the nullable is empty, there is nothing in the view to modify.

auto oe = std::optional<int>{};
for (int i : views::maybe(std::ref(oe)))
    std::cout << "i=" << i << " \n"; // does not print

Converting an optional type into a view can make APIs that return optional types, such as lookup operations, easier to work with in range pipelines.

std::unordered_set<int> set{1, 3, 7, 9};

auto flt = [=](int i) -> std::optional<int> {
    if (set.contains(i))
        return i;
    else
        return {};
};

for (auto i :
        ranges::iota_view{1, 10} |
            ranges::views::transform(flt)) {
    for (auto j : views::maybe(i)) {
        for (auto k :
                     ranges::iota_view(0, j))
            std::cout << '\a';
        std::cout << '\n';
    }
}

### 3 Lazy monadic pythagorean triples

Eric Niebler’s pythagorean triple example, using current C++ and proposed views::maybe.
"and_then" creates a new view by applying a transformation to each element in an input range, and flattening the resulting range of ranges. A.K.A. bind (This uses one syntax for constrained lambdas in C++20.)

```cpp
inline constexpr auto and_then = [](auto&& r, auto fun) {
  return decltype(r)(r) |
    std::ranges::views::transform(std::move(fun)) |
    std::ranges::views::join;
};
```

"yield_if" takes a bool and a value and returns a view of zero or one elements.

```cpp
inline constexpr auto yield_if = [](bool b, auto x) {
  return b ? maybe_view{std::move(x)} : maybe_view<decltype(x){};
};
```

```cpp
void print_triples() {
  using std::ranges::views::iota;
  auto triples = and_then(iota(1), [](int z) {
    return and_then(iota(1, z + 1), [=](int x) {
      return and_then(iota(x, z + 1), [=](int y) {
        return yield_if(x * x + y * y == z * z,
          std::make_tuple(x, y, z));
      });
    });
  });

  // Display the first 10 triples
  for (auto triple : triples | std::ranges::views::take(10)) {
    std::cout << '(' << std::get<0>(triple) << ','
      << std::get<1>(triple) << ','
      << std::get<2>(triple) << ')' << '
  ;
}
```

The implementation of `yield_if` is essentially the type unification of `single` and `empty` into `maybe`, returning an empty on false, and a range containing one value on true.

### 4 Proposal

Add a range adaptor object `views::maybe`, returning a view over an object, capturing by value. For `nullable` objects, provide a zero size range for objects which are disengaged. A `nullable` object is one that is both contextually convertible to bool and for which the type produced by dereferencing is an equality preserving object. Non void pointers, `std::optional`, and the proposed `std::expected` [P0323R9] types all models `nullable`. Function pointers do not, as functions are not objects. Iterators do not generally model `nullable`, as they are not required to be contextually convertible to bool.

### 5 Borrowed Range

A borrowed range is one whose iterators cannot be invalidated by ending the lifetime of the range. For `views::maybe`, the iterators are `T*`, where `T` is essentially the type of the dereferenced nullable. For raw
pointers and reference_wrapper over nullable types, the iterator for maybe_view points directly to the underlying object, and thus matches the semantics of borrowed_range. This means that maybe_view is conditionally borrowed. A maybe_view<shared_ptr>, however, is not a borrowed range, as it participates in ownership of the shared_ptr and might invalidate the iterators if upon the end of its lifetime it is the last owner.

An example of code that is enabled by borrowed ranges, if unlikely code:

```cpp
num = 42;
int k = *std::ranges::find(views::maybe(&num), num);
```

Providing the facility is not a significant cost, and conveys the semantics correctly, even if the simple examples are not hugely motivating. Particularly as there is no real implementation impact, other than providing template variable specializations for enable_borrowed_range.

6 Design

The basis of the design is to hybridize views::single and views::empty. If the view is over a value that is not nullable it is like a single view if constructed with a value, or is of size zero otherwise. For nullable types, if the underlying object claims to hold a value, as determined by checking if the object when converted to bool is true, begin and end of the view are equivalent to the address of the held value within the underlying object and one past the underlying object. If the underlying object does not have a value, begin and end return nullptr. views::maybe also has support for std::reference_wrapper, allowing writes through the iterator to pass through to the object held in the wrapper.

7 Implementation

A publically available implementation at https://github.com/steve-downey/view_maybe based on the Ranges implementation in libstdc++. There are no particular implementation difficulties or tricks. The declarations are essentially what is quoted in the Wording section and the implementations are described as effects.

8 Wording

26.2 Synopsis

Modify 26.2 Header <ranges> synopsis

```cpp
// 26.2 maybe view
template<copy_constructible T>
requires see below;
class maybe_view;

template <typename T>
constexpr inline bool enable_borrowed_range<maybe_view<T*>> = true;

template <typename T>
constexpr inline bool enable_borrowed_range<maybe_view<reference_wrapper<T>>> = true;

namespace views { inline constexpr unspecified maybe = unspecified; }
```

26.2.1 Maybe View

26.2.1.1 Overview

maybe_view is a range adaptor that produces a view with cardinality 0 or 1. It adapts copyable object types and nullable types. If the type is nullable, the view is empty if the nullable is empty.

The name views::maybe denotes a customization point object ([customization.point.object]). For some subexpression E, the expression views::maybe<E> is expression-equivalent to:
maybe_view(E), the view specified below, if the expression is well formed, where decay-copy(E) is moved into the maybe_view

otherwise views::maybe(E) is ill-formed.

[Note 1: Whenever views::maybe(E) is a valid expression, it is a prvalue whose type models view. — end note]

Example 1:

```cpp
optional o{4};
maybe_view m{o};
for (int i : m)
    cout << i;     // prints 4
```

26.2.1.2 Concept nullable

Types that:

1. are contextually convertible to bool
2. are dereferenceable
3. have const references which are dereferenceable
4. the iter_reference_t of the type and the iter_reference_t of the const type, will:
   1. satisfy is_lvalue_reference
   2. satisfy is_object when the reference is removed
   3. for const pointers to the referred to types, satisfy convertible_to
5. or are a reference_wrapper around a type that satisfies nullable

model the exposition only nullable concept

Given a value i of type I, I models nullable only if the expression *i is equality-preserving.

[Note 1: The expression *i is required to be valid via the exposition-only nullable concept. — end note]

For convenience, the exposition-only concepts is-reference-wrapper-v. nullable, nullable_ref, and copyable_object are used below.

```cpp
// exposition only
template <class T>
concept nullable =
    std::is_object_v<T> && requires(T& t, const T& ct) {
        bool(ct);
        *(t);
        *(ct);
    };

template <class T>
concept nullable_val =
    nullable<T> &&
    readable_references<std::iter_reference_t<T>,
    std::iter_reference_t<const T>>;

template <typename, template <typename...> class>
inline constexpr bool is_v = false;

template <typename... Ts, template <typename...> class C>
inline constexpr bool is_v<Ts...>, C> = true;

template <class T>
concept nullable_ref = is_v<T, std::reference_wrapper> &&
    nullable_val<typename T::type>;

template <class T>
inline constexpr bool is_reference_wrapper_v =
    is_v<T, std::reference_wrapper>;
```
template <class T>
concept copyable_object = (std::copy_constructible<T> &&
  std::is_object_v<T>);

26.2.1.3 Class template maybe_view

```cpp
template <typename Value>
requires(copyable_object<Value>) class maybe_view
 : public ranges::view_interface<maybe_view<Value>> {
 private:
  std::optional<Value> value_; // exposition only

 public:
  constexpr maybe_view() = default;
  constexpr explicit maybe_view(Value const& value);
  constexpr explicit maybe_view(Value&& value);
  template <class... Args>
  requires std::constructible_from<Value, Args...>
  constexpr maybe_view(std::in_place_t, Args&&... args);

  constexpr Value* begin() noexcept;
  constexpr const Value* begin() const;
  constexpr Value* end() noexcept;
  constexpr const Value* end() const noexcept;
  constexpr size_t size() const noexcept;
  constexpr Value* data() noexcept;
  constexpr const Value* data() const noexcept;
};
```

1. **Effects:** Initializes `value_` with `maybe`.
2. **Effects:** Initializes `value_` with `std::move(maybe)`.
3. **Effects:** Initializes `value_` as if by `value_in_place, forward<Args>(args)...`.
4. **Returns:** `data()`.
5. **Returns:** `data() + size()`.
6. **Effects:** Equivalent to:
   ```cpp
   return bool(value_);
   ```
7. **Returns:** `std::addressof(*value_)`;
constexpr const T* data() const noexcept;

Effects: Equivalent to:
return std::addressof(*value_);

template <typename Maybe>
requires(copyable_object<Maybe> &&
  (nullable_val<Maybe> || nullable_ref<Maybe>))
class maybe_view<Maybe> : public ranges::view_interface<maybe_view<Maybe>> {
  private:
    using T = see below;
    copyable-box<Maybe> value_; // exposition only

  public:
    constexpr maybe_view() = default;
    constexpr explicit maybe_view(Maybe const& maybe);
    constexpr explicit maybe_view(Maybe&& maybe);
    template <class... Args>
      requires std::constructible_from<Maybe, Args...>
        constexpr maybe_view(std::in_place_t, Args&&... args);

    constexpr T* begin() noexcept;
    constexpr const T* begin() const noexcept;
    constexpr T* end() noexcept;
    constexpr const T* end() const noexcept;
    constexpr size_t size() const noexcept;
    constexpr T* data() noexcept;
    constexpr const T* data() const noexcept;
};

// For Exposition
using T = std::remove_reference_t<
  iter_reference_t<typename unwrap_reference_t<Maybe>>>;

constexpr explicit maybe_view(Maybe const& maybe);
Effects: Initializes value_ with maybe.
constexpr explicit maybe_view(Maybe&& maybe);
Effects: Initializes value_ with std::move(maybe).

template<class... Args>
constexpr maybe_view(in_place_t, Args&&... args);
Effects: Initializes value_ as if by value_in_place, forward<Args>(args)....

constexpr T* begin() noexcept;
constexpr const T* begin() const noexcept;

Returns: data();
constexpr T* end() noexcept;
constexpr const T* end() const noexcept;

Returns: data() + size();

static constexpr size_t size() noexcept;
Effects: Equivalent to:
if constexpr (*is-reference-wrapper-v*<Maybe>) {
    return bool(value_.get().get());
} else {
    return bool(value_.get());
}

constexpr T* data() noexcept;

**Effects:** Equivalent to:

```cpp
Maybe& m = *value_;  
if constexpr (*is-reference-wrapper-v*<Maybe>) {  
    return m.get() ? addressof(*(m.get())) : nullptr;
} else {
    return m ? addressof(*m) : nullptr;
}
```

9 **Impact on the standard**

A pure library extension, affecting no other parts of the library or language.

The proposed changes are relative to the current working draft [N4910].

**Document history**

— **Changes since D7**, presented to SG9 on 2022.07.11
  — Layout issues
  — References include paper source
  — Citation abbreviation form to ‘abstract’
  — ‘nuulable’ typo fix
  — Markdown backticks to tcode
  — ToC depth and chapter numbers for Ranges
  — No technical changes to paper — all presentation

— **Changes since R7**
  — Update all Wording.
  — Convert to standards latex macros for wording.
  — Removed discussion of list comprehension desugaring - will move to yield_if paper.

— **Changes since R6**
  — Extend to all object types in order to support list comprehension
  — Track working draft changes for Ranges
  — Add discussion of _borrowed_range_
  — Add an example where pipelines use references.
  — Add support for proxy references (explore std::pointer_traits, etc).
— Make std::views::maybe model std::ranges::borrowed_range if it’s not holding the object by value.
— Add a const propagation section discussing options, existing precedent and proposing the option that the author suggests.

— Changes since R5
— Fix reversed before/after table entry
— Update to match C++20 style [N4849] and changes in Ranges since [P0896R3]
— size is now size_t, like other ranges are also
— add synopsis for adding to ‘<ranges>’ header
— Wording clean up, formatting, typesetting
— Add implementation notes and references

— Changes since R4
— Use std::unwrap_reference
— Remove conditional ‘noexcept’ness
— Adopted the great concept renaming

— Changes since R3
— Always Capture
— Support reference_wrapper

— Changes since R2
— Reflects current code as reviewed
— Nullable concept specification
— Remove Readable as part of the specification, use the useful requirements from Readable
— Wording for views::maybe as proposed
— Appendix A: wording for a view_maybe that always captures

— Changes since R1
— Refer to views::all
— Use wording ‘range adaptor object’

— Changes since R0
— Remove customization point objects
— Concept ‘Nullable’, for exposition
— Capture rvalues by decay copy
— Remove maybe_view as a specified type
