# std::forward_like

Deducing This [P0847R7] is expected to land in C++23.

Its examples use a hypothetical `std::forward_like<decltype(self)>(variable)` facility because `std::forward<decltype(v)>(v)` is insufficient. This paper proposes `std::forward_like` to cater to this scenario.
2 Status of this paper

This paper has been accepted by LEWG as proposed (with the merge model). This is `fmrg::forward_like` in
the appendix. LWG has approved this paper for a plenary vote with the changes in this revision on 2022-05-13.

3 Revision Log

— R0 -> R1: wording changed to current wording, no semantic changes.

4 Proposal

Add the `forward_like` function template to the utility header.

```cpp
template <typename T>
[[nodiscard]] constexpr auto forward_like(auto&& x) noexcept -> __forward_like_t<T, decltype(x)>
{
    return static_cast<__forward_like_t<T, decltype(x)>>((x));
}
```

where `__forward_like_t<T, U>` is a metafunction defined with the `merge` model table (below); or, more succinctly:

```cpp
template <typename T, typename U>
using __override_ref_t = std::conditional_t<std::is_rvalue_reference_v<T>,
    std::remove_reference_t<U> &&, U &>

template <typename T, typename U>
using __copy_const_t = std::conditional_t<std::is_const_v<std::remove_reference_t<T>>,
    U const, U>

template <typename T, typename U>
using __forward_like_t = __override_ref_t
    T &&,
    __copy_const_t<T, std::remove_reference_t<U>>;
```

5 Use cases

In order to decide between the three models, let’s look at use-cases.

5.1 A lambda that forwards its capture

This was the very first use-case for *deducing this*: a callback lambda that can be used in either “retry” (lvalue)
or “try or fail” (rvalue, use-once) algorithms with optimal efficiency.

With the `merge` model:

```cpp
auto callback = [m=get_message(), &scheduler](this auto &&self) -> bool {
    return scheduler.submit(std::forward_like<decltype(self)>(m));
};
callback(); // retry(callback)
std::move(callback)(); // try-or-fail(rvalue)
```

Or, with the `tuple` or `language` models:
auto callback = [m=getMessage(), &scheduler](this auto &self) -> bool {
    return scheduler.submit(std::forward_like<decltype(self), decltype(m)>)(m);
};
callback(); // retry(callback)
std::move(callback)(); // try-or-fail(rvalue)

Note that tuple and language models have significant problems when applied to reference captures - see the section on that below.

5.2 Returning “far” owned state

This is a family of cases where we are forwarding a member “owned” by the Owner, but perhaps not directly contained by it.

With the merge model:

```cpp
struct fwd {
    std::unique_ptr<std::string> ptr;
    std::optional<std::string> opt;
    std::deque<std::string> container;

    auto get_ptr(this auto&& self) -> std::string {
        if (ptr) { return std::forward_like<decltype(self)>(*ptr); }
        return "";
    }

    auto get_opt(this auto&& self) -> std::string {
        if (opt) { return std::forward_like<decltype(self)>(*m); }
        return "";
    }

    auto operator[](this auto&& self, size_t i) -> std::string {
        return std::forward_like<decltype(self)>(container[i]);
    }
};
```

and so on.

— The language and tuple models fail here - we need an alternative way to cast the far state into an rvalue (they both leave lvalue arguments as lvalues).
— In the optional case, we are lucky, and notice optional provides an rvalue accessor, which means we could spell the line as *std::forward<decltype(self)>(self).opt.
— However, deque does not provide an rvalue subscript operator (though it could);
— but unique_ptr’s operator*() will never provide the appropriate cast, as pointers have shallow semantics.

merge is the only model that satisfies this use case.

5.3 Why merge const-qualifiers?

Because one never wants to take const away from const members, that would be wrong.

```cpp
template<typename T>
struct by_ptr {
    std::shared_ptr<T> far;
    auto get(this auto&& self) {
        return std::forward_like<decltype(self)>(*self.far);
    }
};
```
5.4 Returning “far” owned-state from free-function interfaces

Not all uses require deducing this. The problem already occurs with free-function interfaces like `match(f, g).

```cpp
template <typename T, typename U>
struct either {
    int idx; // 0 for T, 1 for U
    std::array<std::byte, max(sizeof(T), sizeof(U))> buf;

    friend auto match(similar<either> auto&& self_, auto&& f, auto&& g) -> void {
        if (self_.idx == 0) {
            FWD(f)(std::forward_like<decltype(self_)>(*T) self_.buf.data());
        } else {
            FWD(g)(std::forward_like<decltype(self_)>(*U) self_.buf.data());
        }
    }
};
```

C-style casts used for brevity.

6 Issue: Forwarding reference captures

There is a significant gotcha with the language and tuple models.

In lambdas with reference captures, find an unsolvable problem: `&` and `=` captures do not produce a distinguishing `decltype`. (notice lines (a) and (c) are the same!)

```cpp
int x;
int z;
[&x, &y=x, z](this auto&& self) {
    forward_like<decltype(self), decltype(x)>x; /* a: int&& */
    forward_like<decltype(self), decltype(y)>y; /* b: int& (!) */
    forward_like<decltype(self), decltype(z)>z; /* c: int&& */
    forward_like<decltype(self), decltype(y)>x; /* d: int& (and typo!) */
}();
```

The inconsistency here is dangerous.

— With the language and tuple models, we get inconsistent behavior between (a) and (b), which is extremely surprising, especially if one considers `&]-style captures.

— We also get consistent behavior between lines (a) and (c), which is a surprise in this case.

— (d) also exposes the brittle nature of typos with this model; we must reference the parameter twice so we run into problems with typos. This is impossible with the merge model, which is orthogonalized.

— With the merge model, we get consistent behavior - rvalue if invoked as an rvalue, lvalue if invoked as lvalue. Simple, predictable, obvious.

7 Open Questions

Is LEWG is happy with the name `forward_like`?
Some alternative names: `forward_member`, (feel free to suggest more).

8 Design Discussion

As `forward`, `forward_like` is a type cast that only influences the value category of an expression.

`forward_like` is a facility for forwarding the value category of an object-expression `m` (usually a member) based on the value category of the owning object-expression `o`.

When `m` is an actual member and thus `o.m` a valid expression, this is usually spelled as `forward<decltype(o)>()(o).m` in C++20 code.

When `o.m` is not a valid expression, *i.e.* members of lambda closures, one needs `forward_like<*/see below*>()(m)`.

This leads to three possible models, called `merge`, `tuple`, and `language`.

— **merge**: we merge the `const` qualifiers, and adopt the value category of the Owner
— **tuple**: what `std::get<0>(tuple<Member> Owner)` does.
— **language**: what `std::forward<decltype(Owner)>(o).m` does.

The main scenario that `forward_like` caters to is adapting “far” objects. Neither the tuple nor the language scenarios do the right thing for that main use-case, so the `merge` model is proposed.

For completeness, the tables of all three approaches to reference-casting are presented.

8.1 The common parts

All the models agree on the following table of cv-ref qualifiers of the inputs and outputs of the facility:

<table>
<thead>
<tr>
<th>n</th>
<th>Owner</th>
<th>Member</th>
<th>forward_like&lt;o&gt;o(m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>&amp;</td>
<td></td>
<td>kk</td>
</tr>
<tr>
<td>2</td>
<td>&amp;&amp;</td>
<td></td>
<td>k</td>
</tr>
<tr>
<td>3</td>
<td>const</td>
<td></td>
<td>constkk</td>
</tr>
<tr>
<td>4</td>
<td>const&amp;</td>
<td></td>
<td>constk</td>
</tr>
<tr>
<td>5</td>
<td>const&amp;&amp;</td>
<td></td>
<td>constkk</td>
</tr>
<tr>
<td>6</td>
<td>const&amp; &amp;</td>
<td></td>
<td>constk</td>
</tr>
<tr>
<td>7</td>
<td>const &amp;&amp;</td>
<td></td>
<td>constkk</td>
</tr>
<tr>
<td>8</td>
<td>&amp;</td>
<td></td>
<td>const</td>
</tr>
<tr>
<td>9</td>
<td>&amp;&amp;</td>
<td></td>
<td>const&amp;</td>
</tr>
<tr>
<td>10</td>
<td>const</td>
<td></td>
<td>constk</td>
</tr>
<tr>
<td>11</td>
<td>const&amp;</td>
<td></td>
<td>constk</td>
</tr>
<tr>
<td>12</td>
<td>const&amp;&amp;</td>
<td></td>
<td>constkk</td>
</tr>
<tr>
<td>13</td>
<td>&amp;</td>
<td></td>
<td>k</td>
</tr>
<tr>
<td>14</td>
<td>&amp;&amp;</td>
<td></td>
<td>kk</td>
</tr>
<tr>
<td>15</td>
<td>&amp;</td>
<td></td>
<td>const &amp;</td>
</tr>
<tr>
<td>16</td>
<td>&amp;&amp;</td>
<td></td>
<td>const &amp;k</td>
</tr>
<tr>
<td>17</td>
<td>const&amp;</td>
<td></td>
<td>const &amp;</td>
</tr>
<tr>
<td>18</td>
<td>const&amp;&amp;</td>
<td></td>
<td>const &amp;k</td>
</tr>
</tbody>
</table>

Commentary:

— For value-type members, we follow the forwarding category of the parent.
— If the parent is an lvalue, the result is an lvalue even for references.
— `const` is merged for these cases
8.2 The differing parts

The models differ in the following cases (for the three models of `forward_like`).

<table>
<thead>
<tr>
<th>n</th>
<th>Owner</th>
<th>Member</th>
<th>‘merge’</th>
<th>‘tuple’</th>
<th>‘language’</th>
</tr>
</thead>
<tbody>
<tr>
<td>19</td>
<td>&amp; &amp;</td>
<td>k</td>
<td>k</td>
<td>k</td>
<td>k</td>
</tr>
<tr>
<td>20</td>
<td>&amp; &amp;</td>
<td>&amp; &amp;</td>
<td>k</td>
<td>k</td>
<td>k</td>
</tr>
<tr>
<td>21</td>
<td>const</td>
<td>k</td>
<td>const &amp;k</td>
<td>k</td>
<td>k</td>
</tr>
<tr>
<td>22</td>
<td>const &amp;k</td>
<td>&amp;</td>
<td>const &amp;k</td>
<td>k</td>
<td>k</td>
</tr>
<tr>
<td>23</td>
<td>const &amp;k</td>
<td>&amp;</td>
<td>const &amp;k</td>
<td>k</td>
<td>k</td>
</tr>
<tr>
<td>24</td>
<td>const &amp;k</td>
<td>&amp;</td>
<td>const &amp;k</td>
<td>k</td>
<td>k</td>
</tr>
<tr>
<td>25</td>
<td>&amp; &amp;</td>
<td>&amp; &amp;</td>
<td>&amp; &amp;</td>
<td>&amp;</td>
<td>&amp;</td>
</tr>
<tr>
<td>26</td>
<td>const</td>
<td>&amp; &amp;</td>
<td>const &amp;k</td>
<td>k</td>
<td>k</td>
</tr>
<tr>
<td>27</td>
<td>const &amp;k</td>
<td>&amp; &amp;</td>
<td>const &amp;k</td>
<td>k</td>
<td>k</td>
</tr>
<tr>
<td>28</td>
<td>const &amp;k</td>
<td>&amp; &amp;</td>
<td>const &amp;k</td>
<td>k</td>
<td>k</td>
</tr>
<tr>
<td>29</td>
<td>const &amp;k</td>
<td>&amp; &amp;</td>
<td>const &amp;k</td>
<td>k</td>
<td>const &amp;k</td>
</tr>
<tr>
<td>30</td>
<td>&amp; &amp;</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
</tr>
<tr>
<td>31</td>
<td>const</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
</tr>
<tr>
<td>32</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
</tr>
<tr>
<td>33</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
</tr>
<tr>
<td>34</td>
<td>&amp; &amp;</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
</tr>
<tr>
<td>35</td>
<td>const</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
</tr>
<tr>
<td>36</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
<td>const &amp;k</td>
</tr>
</tbody>
</table>

Commentary:

— **language** is obviously wrong in all cases (25, 28, 34, 36) where both are rvalues - those should be rvalues. In addition, it requires both Owner and Member types to be explicit template parameters.
— **tuple**: collapses the value category of Owner and Member, inherits `const` from member. Plausible, but has problems with use-cases, and needs both Owner and Member types to be explicit template parameters.
— **merge**: merges the `const` from Owner and Member, uses the value category of Owner. Needs only Owner to be an explicit template parameter.

9 Interface

In the **merge** model, the interface is:

```cpp
template <typename T>
[[nodiscard]] constexpr auto forward_like(auto&& x) noexcept -> __forward_like_t<T, decltype(x)> {
    return static_cast<__forward_like_t<T, decltype(x)>>((x));
}
```

In the **tuple** and **language** models, we would need both to be explicit:

```cpp
template <typename T, typename M>
[[nodiscard]] constexpr auto forward_like(__similar<M> auto&& x) noexcept -> __forward_like_t<T, M, decltype(x)> {
    return static_cast<__forward_like_t<T, M, decltype(x)>>((x));
}
```

(``__similar<T, U>`` is a concept that is satisfied by the two types if they are equal up to cv-ref qualifiers.)

However, because we need two explicit template parameters, the definition is compatible with calling it just `forward`, so we could use
std::forward<decltype(o), decltype(m)>(m)

instead of the longer forward_like<decltype(o), decltype(m)>(m) in these cases. This orthogonalizes the interface, which eases teaching. If forwarding members, just supply both!

The language and tuple models have bigger problems with the use cases, however, so this is just silver lining on a very dark cloud.

10 Proposed Wording

Notes on wording: should we endeavor to define the U parameter as not-explicitly-specifiable by the user, as above, or do it old-style as now?

Relative to [N4892].

Insert the following section in Header <utility> synopsis [utility.syn], under the last overload of forward:

```cpp
template<
    class T, 
    class U>
[[nodiscard]] constexpr auto forward_like(U&& x) noexcept -> see below;
```

Insert a new paragraph under [forward]/4 (which is example 1):

```cpp
template<class T, class U>
[[nodiscard]] constexpr auto forward_like(U&& x) noexcept -> see below;
```

Let COPY_CONST(A, B) be const B if A is a const type, otherwise B.

Let OVERRIDE_REF(A, B) be remove_reference_t<B>&& if A is an rvalue reference type, otherwise B&.

Let V be OVERRIDE_REF(T&, COPY_CONST(remove_reference_t<T>, remove_reference_t<U>)).

6 Returns: static_cast<V>(x).

7 Remarks: The return type is V.

[Example 2:

```cpp
struct accessor {
    vector<string>* container;

    decltype(auto) operator[](this auto&& self, size_t i) {
        return std::forward_like<decltype(self)][(*container)[i]];
    }
};

void g() {
    vector v{"a"s, "b"s};
    accessor a(&v);
    string& x = a[0]; // OK, binds to lvalue reference
    string&& y = std::move(a[0]); // OK, is rvalue reference
    string const&& z = std::move(as_const(a))[1]; // OK, is const&&
    string& w = as_const(a)[1]; // error: will not bind to non-const
}
```

– end example]

and renumber section.
10.1 Feature-test macro

Insert the following in Header synopsis [version.syn], in section 2:

```cpp
#define __cpp_lib_forward_like 20XXXXL // also in <utility>
```

11 Acknowledgements

— Barry Revzin, who wrote the wording for the semantics on the LWG session.
— Sarah from the #include discord for pointing out std::tuple's `get` has a better view on how to treat reference members than the language does, thus saving the facility from being a mess that duplicates the language.
— Yunlan Tang, who did some of the research for an early version of this paper.
— Barry Revzin, Sy Brand and Ben Deane, my dear co-authors of [P0847R7], without whom this paper would be irrelevant.
— Vittorio Romeo, who tried writing this paper first a few years ago.
— Jens Maurer, who wrote the initial wording, and Corentin Jabot also writing the wording. The current is a merge between both. And Jens Maurer again, for fixing the wording yet again.
— Tomasz Kamiński, for pointing out typos.
— JohelEGP from the cpplang slack for pointing out typos.

12 Appendix: code listing for implementation and tables

```cpp
#include <type_traits>
