[Example 2: tie functions allow one to create tuples that unpack tuples into variables. ignore can be used for
elements that are not needed:]
int i; std::string s;
tie(i, ignore, s) = make_tuple(42, 3.14, "C++");
// i == 42, s == "C++"
—end example]

template<tuple_like... Tuples>
constexpr tuple<CTypes...> tuple_cat(Tuples&&... tpls);

Let n be sizeof...(Tuples). For every integer 0 ≤ i < n:
(1) Let T_i be the i_th type in Tuples.
(2) Let U_i be remove_cvref_t<T_i>.
(3) Let tp_i be the i_th element in the function parameter pack tpls.
(4) Let S_i be tuple_size_v<U_i>.
(5) Let E_i^k be tuple_element_t<k, U_i>.
(6) Let e_i^k be get<k>(std::forward<T_i>(tp_i)).
(7) Let Elms_i be a pack of the types E_0^i, ..., E_{S_i−1}^i.
(8) Let elems_i be a pack of the expressions e_0^i, ..., e_{S_i−1}^i.

The types in CTypes are equal to the ordered sequence of the expanded packs of types Elms_0, ..., Elms_1, ..., Elms_{n−1}. Let elems be the ordered sequence of the expanded packs of expressions elems_0, ..., elems_{n−1}.
Mandates: \( \text{isconstructible} \_v<\text{CTypes}, \text{decltype(celems)}> \_&& \ldots \) is true.

Returns: \( \text{tuple}<\text{CTypes} \ldots>(\text{celems} \ldots) \).

### 22.4.6 Calling a function with a tuple of arguments

\[\text{tuple.apply}\]

```cpp
template<class F, tuple-like Tuple>
constexpr decltype(auto) apply(F&& f, Tuple&& t) noexcept(see below);
```

Effects: Given the exposition-only function:

```cpp
namespace std {
    template<class F, tuple-like Tuple, size_t... I>
    constexpr decltype(auto) apply_impl(F&& f, Tuple&& t, index_sequence<I...>) {
        return INVOKE(std::forward<F>(f), get<I>(std::forward<Tuple>(t))...); // see 22.10.4
    }
}
```

Equivalent to:

```cpp
return apply_impl(std::forward<F>(f), std::forward<Tuple>(t),
    make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{});
```

Remarks: Let \( I \) be the pack 0, 1, ..., \( (\text{tuple_size} \_v<\text{remove_reference} \_t<\text{Tuple}>> - 1) \). The exception specification is equivalent to:

```cpp
noexcept(invoke(std::forward<F>(f), get<I>(std::forward<Tuple>(t))...))
```

### 22.4.7 Tuple helper classes

\[\text{tuple.helper}\]

```cpp
template<class T> struct tuple_size;
```

All specializations of \text{tuple.size} meet the \text{Cpp17UnaryTypeTrait} requirements (21.3.2) with a base characteristic of \text{integral_constant} \_v<size\_t, N> for some \( N \).

```cpp
template<class... Types>
struct tuple_size\_v<tuple<Types\ldots>> : public integral_constant\_v<size\_t, sizeof...(Types)> { };
```

```cpp
template<size_t I, class... Types>
struct tuple\_element\_v<I, tuple<Types\ldots>> {
    using type = TI;
};
```

Mandates: \( I < \text{sizeof} \_v<(\text{Types})> \)

Type: \( \text{TI} \) is the type of the \( I \)th element of \text{Types}, where indexing is zero-based.
Let TS denote `tuple_size<T>` of the cv-unqualified type T. If the expression TS::value is well-formed when treated as an unevaluated operand (7.2.3), then each specialization of the template meets the Cpp17UnaryTypeTrait requirements (21.3.2) with a base characteristic of

\[\text{integral_constant<size_t, TS::value}\]

Otherwise, it has no member value.

Access checking is performed as if in a context unrelated to TS and T. Only the validity of the immediate context of the expression is considered.

[Note 1: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

In addition to being available via inclusion of the `<tuple>` header, the template is available when any of the headers `<array>` (24.3.2), `<ranges>` (26.2), or `<utility>` (22.2.1) are included.

Let TE denote `tuple_element_t<I, T>` of the cv-unqualified type T. Then each specialization of the template meets the Cpp17TransformationTrait requirements (21.3.2) with a member typedef that names the type `add_const_t<TE>`.

In addition to being available via inclusion of the `<tuple>` header, the template is available when any of the headers `<array>` (24.3.2), `<ranges>` (26.2), or `<utility>` (22.2.1) are included.

**22.4.8 Element access**

\[\text{tuple.element}\]

\[
\begin{align*}
\text{template}&<\text{size_t } I, \text{ class... } \text{Types}> \\
\text{constexpr }& \text{tuple_element_t}<I, \text{ tuple<Types...>>}& \\
\text{get}&(\text{tuple<Types...>>& t) \text{ noexcept}; \\
\text{template}&<\text{size_t } I, \text{ class... } \text{Types}> \\
\text{constexpr }& \text{tuple_element_t}<I, \text{ tuple<Types...>>&&} & \\
\text{get}&(\text{tuple<Types...>>&& t) \text{ noexcept}; \quad \text{// Note A} \\
\text{template}&<\text{size_t } I, \text{ class... } \text{Types}> \\
\text{constexpr }& \text{const tuple_element_t}<I, \text{ tuple<Types...>>}& \\
\text{get}&(\text{const tuple<Types...>>& t) \text{ noexcept}; \quad \text{// Note B} \\
\text{template}&<\text{size_t } I, \text{ class... } \text{Types}> \\
\text{constexpr }& \text{const tuple_element_t}<I, \text{ tuple<Types...>>&&} & \\
\text{get}&(\text{const tuple<Types...>>&& t) \text{ noexcept}; \\
\end{align*}
\]

Mandates: I < sizeof...(Types).

Returns: A reference to the Ith element of t, where indexing is zero-based.

[Note 1: [Note A] If a type T in Types is some reference type X&, the return type is X&, not X&&. However, if the element type is a non-reference type T, the return type is T&&. — end note]

[Note 2: [Note B] Constness is shallow. If a type T in Types is some reference type X&, the return type is X&, not const X&. However, if the element type is a non-reference type T, the return type is const T&. This is consistent with how constness is defined to work for non-static data members of reference type. — end note]

\[
\begin{align*}
\text{template}&<\text{class } T, \text{ class... } \text{Types}> \\
\text{constexpr }& T& \text{get}(\text{tuple<Types...>>& t) \text{ noexcept}; \\
\text{template}&<\text{class } T, \text{ class... } \text{Types}> \\
\text{constexpr }& T&& \text{get}(\text{tuple<Types...>>&& t) \text{ noexcept}; \\
\text{template}&<\text{class } T, \text{ class... } \text{Types}> \\
\text{constexpr }& \text{const } T& \text{get}(\text{const tuple<Types...>>& t) \text{ noexcept}; \\
\text{template}&<\text{class } T, \text{ class... } \text{Types}> \\
\text{constexpr }& \text{const } T&& \text{get}(\text{const tuple<Types...>>&& t) \text{ noexcept}; \\
\end{align*}
\]

Mandates: The type T occurs exactly once in Types.

Returns: A reference to the element of t corresponding to the type T in Types.

[Example 1]:

\[
\begin{align*}
\text{const tuple<int, const int, double, double> } & \text{t}(1, 2, 3.4, 5.6); \\
\text{const int& } i1 & = \text{get<int>(t)}; \quad \text{// OK, i1 has value 1} \\
\text{const int& } i2 & = \text{get<const int>(t)}; \quad \text{// OK, i2 has value 2}
\end{align*}
\]
```
const double& d = get<double>(t); // error: type double is not unique within t

[Note 3: The reason get is a non-member function is that if this functionality had been provided as a member function, code where the type depended on a template parameter would have required using the template keyword. — end note]

22.4.9 Relational operators

```}
```template<class... TTypes, class... UTypes>
constexpr bool operator==(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

1 For the first overload let UTuple be tuple<UTypes>.

2 Mandates: For all i, where 0 \leq i < sizeof...(TTypes), get<i>(t) == get<i>(u) is a valid expression. sizeof...(TTypes) equals tuple_size_v<UTuple>.

3 Preconditions: For all i, decltype(get<i>(t) == get<i>(u)) models boolean-testable.

4 Returns: true if get<i>(t) == get<i>(u) for all i, otherwise false.

[Note 1: If sizeof...(TTypes) equals zero, returns true. — end note]

5 Remarks:

6 — The elementary comparisons are performed in order from the zeroth index upwards. No comparisons or element accesses are performed after the first equality comparison that evaluates to false.

7 — The second overload is to be found via argument-dependent lookup (6.5.4) only.

```template<class... TTypes, class... UTypes>
constexpr common_comparison_category_t<
    synth-three-way-result<TTypes, UTuple>...
>
operator<=>(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

6 For the second overload, Elems denotes the pack of types tuple_element_t<0, UTuple>, tuple_element_t<1, UTuple>, ..., tuple_element_t<tuple_size_v<UTuple> - 1, UTuple>.

7 Effects: Performs a lexicographical comparison between t and u. If sizeof...(TTypes) equals zero, returns strong_ordering::equal. Otherwise, equivalent to:

```
if (auto c = synth-three-way(get<0>(t), get<0>(u)); c != 0) return c;
return t.tail <=> u.tail;
```

where r.tail for some r is a tuple containing all but the first element of r.

8 Remarks: The second overload is to be found via argument-dependent lookup (6.5.4) only.

[Note 2: The above definition does not require t.tail (or u.tail) to be constructed. It might not even be possible, as t and u are not required to be copy constructible. Also, all comparison operator functions are short circuited; they do not perform element accesses beyond what is required to determine the result of the comparison. — end note]

22.4.10 common_reference related specializations

In the descriptions that follow:

1.1 — Let TTypes be a pack formed by the sequence of tuple_element_t<i>, TTuple> for every integer 0 \leq i < tuple_size_v<TTuple>.

1.2 — Let UTypes be a pack formed by the sequence of tuple_element_t<i>, UTuple> for every integer 0 \leq i < tuple_size_v<UTuple>.

```template<
    tuple-like TTuple, tuple-like UTuple,
    template<class> class TQual, template<class> class UQual>
struct basic_common_reference<
    TTuple, UTuple, TQual, UQual> {
    using type = see below;
};
```
TTuple is a specialization of tuple or UTuple is a specialization of tuple.

is_same_v<TTuple, decay_t<TTuple>> is true.

is_same_v<UTuple, decay_t<UTuple>> is true.

tuple_size_v<TTuple> equals tuple_size_v<UTuple>.

tuple<common_reference_t<TQual<TTypes>, UQual<UTypes>>...> denotes a type.

The member typedef-name type denotes the type tuple<common_reference_t<TQual<TTypes>, UQual<UTypes>>...>.

template<tuple-like TTuple, tuple-like UTuple>
struct common_type<TTuple, UTuple> {
    using type = see below;
};

Constraints:

TTuple is a specialization of tuple or UTuple is a specialization of tuple.

is_same_v<TTuple, decay_t<TTuple>> is true.

is_same_v<UTuple, decay_t<UTuple>> is true.

tuple_size_v<TTuple> equals tuple_size_v<UTuple>.

tuple<common_type_t<TTypes, UTypes>>... denotes a type.

The member typedef-name type denotes the type tuple<common_type_t<TTypes, UTypes>>...>.

22.4.11 Tuple traits [tuple.traits]

template<class... Types, class Alloc>
struct uses_allocator<tuple<Types...>, Alloc> : true_type {
    Preconditions: Alloc meets the Cpp17Allocator requirements (16.4.4.6.1).

[Note 1: Specialization of this trait informs other library components that tuple can be constructed with an allocator, even though it does not have a nested allocator_type. — end note]

22.4.12 Tuple specialized algorithms [tuple.special]

template<class... Types>
constexpr void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below);

template<class... Types>
constexpr void swap(const tuple<Types...>& x, const tuple<Types...>& y) noexcept(see below);

Constraints:

For the first overload, (is_swappable_v<TTypes> && ...) is true.

For the second overload, (is_swappable_v<const Types> && ...) is true.

Effects: As if by x.swap(y).

Remarks: The exception specification is equivalent to:

noexcept(x.swap(y))

22.5 Optional objects [optional]

22.5.1 In general [optional.general]

Subclause 22.5 describes class template optional that represents optional objects. An optional object is an object that contains the storage for another object and manages the lifetime of this contained object, if any. The contained object may be initialized after the optional object has been initialized, and may be destroyed before the optional object has been destroyed. The initialization state of the contained object is tracked by the optional object.

22.5.2 Header <optional> synopsis [optional.syn]

#include <optional> // see 17.11.1
namespace std {

    // 22.5.3, class template optional
    template<class T>
    class optional;

    template<class T>
    concept is-derived-from-optional = requires(const T& t) {
        []<class U>(const optional<U>&){ }(t);
    };

    // 22.5.4, no-value state indicator
    struct nullopt_t;
    inline constexpr nullopt_t nullopt;

    // 22.5.5, class bad_optional_access
    class bad_optional_access;

    // 22.5.6, relational operators
    template<class T, class U>
    constexpr bool operator==(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator!=(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator<(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator>(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator<=(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator>=(const optional<T>&, const optional<U>&);
    template<class T, three_way_comparable_with<T> U>
    constexpr compare_three_way_result_t<T, U> operator<=>(const optional<T>&, const optional<U>&);

    // 22.5.7, comparison with nullopt
    template<class T> constexpr bool operator==(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr strong_ordering operator<=>(const optional<T>&, nullopt_t) noexcept;

    // 22.5.8, comparison with T
    template<class T, class U> constexpr bool operator==(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator==(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator!=(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator!=(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator<(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator<(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator>(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator>(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator<=(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator<=(const T&, const optional<U>&);
    template<class T, class U> constexpr bool operator>=(const optional<T>&, const U&);
    template<class T, class U> constexpr bool operator>=(const T&, const optional<U>&);
    template<class T, class U>
    requires (!is-derived-from-optional<U>) && three_way_comparable_with<T, U>
    constexpr compare_three_way_result_t<T, U> operator<=>(const optional<T>&, const U&);

    // 22.5.9, specialized algorithms
    template<class T>
    constexpr void swap(optional<T>&, optional<T>&) noexcept;

template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &;
template<class F> constexpr auto transform(F&& f) const &&;

template<class F> constexpr optional or_else(F&& f) &&;
template<class F> constexpr optional or_else(F&& f) const &;

// 22.5.3.8, modifiers
constexpr void reset() noexcept;

private:
    T *val;       // exposition only
};

template<class T>
    optional(T) -> optional<T>;

1 Any instance of optional<T> at any given time either contains a value or does not contain a value. When an instance of optional<T> contains a value, it means that an object of type T, referred to as the optional object’s contained value, is allocated within the storage of the optional object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate its contained value. When an object of type optional<T> is contextually converted to bool, the conversion returns true if the object contains a value; otherwise the conversion returns false.

2 When an optional<T> object contains a value, member val points to the contained value.

3 T shall be a type other than cv in_place_t or cv nullopt_t that meets the Cpp17Destructible requirements (Table 35).

22.5.3.2 Constructors [optional ctor]  
The exposition-only variable template converts-from-any-cvref is used by some constructors for optional.

1 The exposition-only variable template converts-from-any-cvref is used by some constructors for optional.

2 Postconditions: *this does not contain a value.

3 Remarks: No contained value is initialized. For every object type T these constructors are constexpr constructors (9.2.6).

constexpr optional(optional&& rhs);

4 Effects: If rhs contains a value, direct-non-list-initializes the contained value with *rhs.

5 Postconditions: rhs.has_value() == this->has_value().

6 Throws: Any exception thrown by the selected constructor of T.

7 Remarks: This constructor is defined as deleted unless is_copy_constructible_v<T> is true. If is_trivially_copy_constructible_v<T> is true, this constructor is trivial.
constexpr optional(optional&& rhs) noexcept(
  see below);

Constraints: is_move_constructible_v<T> is true.

Effects: If rhs contains a value, direct-non-list-initializes the contained value with std::move(*rhs).
  rhs.has_value() is unchanged.

Postconditions: rhs.has_value() == this->has_value().

Throws: Any exception thrown by the selected constructor of T.

Remarks: The exception specification is equivalent to is_nothrow_move_constructible_v<T>. If
  is_trivially_move_constructible_v<T> is true, this constructor is trivial.

template<class... Args> constexpr explicit optional(in_place_t, Args&&... args);

Constraints: is_constructible_v<T, Args...> is true.

Effects: Direct-non-list-initializes the contained value with std::forward<Args>(args)....

Postconditions: *this contains a value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If T’s constructor selected for the initialization is a constexpr constructor, this constructor is
  a constexpr constructor.

template<class U, class... Args>
  constexpr explicit optional(in_place_t, initializer_list<U> il, Args&&... args);

Constraints: is_constructible_v<T, initializer_list<U>&, Args...> is true.

Effects: Direct-non-list-initializes the contained value with il, std::forward<Args>(args)....

Postconditions: *this contains a value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If T’s constructor selected for the initialization is a constexpr constructor, this constructor is
  a constexpr constructor.

template<class U = T> constexpr explicit(optional(U&& v);

Constraints:
  — is_constructible_v<T, U> is true,
  — is_same_v<remove_cvref_t<U>, in_place_t> is false,
  — is_same_v<remove_cvref_t<U>, optional> is false, and
  — if T is cv bool, remove_cvref_t<U> is not a specialization of optional.

Effects: Direct-non-list-initializes the contained value with std::forward<U>(v).

Postconditions: *this contains a value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If T’s selected constructor is a constexpr constructor, this constructor is a constexpr
  constructor. The expression inside explicit is equivalent to:

!is_convertible_v<U, T>

template<class U> constexpr explicit(optional(const optional<U>& rhs);

Constraints:
  — is_constructible_v<T, const U&> is true, and
  — if T is not cv bool, converts-from-any-cvref<T, optional<U>> is false.

Effects: If rhs contains a value, direct-non-list-initializes the contained value with *rhs.

Postconditions: rhs.has_value() == this->has_value().

Throws: Any exception thrown by the selected constructor of T.

Remarks: The expression inside explicit is equivalent to:

!is_convertible_v<const U&, T>
template<class U> constexpr explicit(optional<optional<U>&& rhs);  

Constraints:
- is_constructible_v<T, U> is true, and
- if T is not cv bool, converts-from-any-cvref<T, optional<U>> is false.

Effects: If rhs contains a value, direct-non-list-initializes the contained value with std::move(*rhs). rhs.has_value() is unchanged.
Postconditions: rhs.has_value() == this->has_value().

Remarks: The expression inside explicit is equivalent to:

!is_convertible_v<U, T>  

22.5.3.3 Destructor

constexpr ~optional();  

Effects: If is_trivially_destructible_v<T> != true and *this contains a value, calls val->T::~T()  

Remarks: If is_trivially_destructible_v<T> is true, then this destructor is trivial.

22.5.3.4 Assignment

constexpr optional<T>& operator=(nullopt_t) noexcept;  

Effects: If *this contains a value, calls val->T::~T() to destroy the contained value; otherwise no effect.  

Postconditions: *this does not contain a value.  

Returns: *this.

constexpr optional<T>& operator=(const optional& rhs);  

Effects: See Table 58.

Table 58: optional::operator=(const optional&) effects

<table>

<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
<td>no effect</td>
</tr>
</tbody>
</table>

Postconditions: rhs.has_value() == this->has_value().  

Returns: *this.

Remarks: If any exception is thrown, the result of the expression this->has_value() remains unchanged. If an exception is thrown during the call to T's copy constructor, no effect. If an exception is thrown during the call to T's copy assignment, the state of its contained value is as defined by the exception safety guarantee of T's copy assignment. This operator is defined as deleted unless is_copy_constructible_v<T> is true and is_copyAssignable_v<T> is true. If is_trivially_copy_constructible_v<T> && is_trivially_copyAssignable_v<T> && is_trivially_destructible_v<T> is true, this assignment operator is trivial.

constexpr optional& operator=(optional&& rhs) noexcept(see below);  

Constraints: is_move_constructible_v<T> is true and is_moveAssignable_v<T> is true.

Effects: See Table 59. The result of the expression rhs.has_value() remains unchanged.
Postconditions: rhs.has_value() == this->has_value().  

Returns: *this.
Table 59: `optional::operator=(optional&&)` effects

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>assigns <code>std::move(*rhs)</code> to the contained value</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling <code>val-&gt;T::~T()</code></td>
</tr>
</tbody>
</table>

**Remarks:** The exception specification is equivalent to:

- `is_nothrow_move_assignable_v<T> && is_nothrow_move_constructible_v<T>`

If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`'s move constructor, the state of `*rhs.val` is determined by the exception safety guarantee of `T`'s move constructor. If an exception is thrown during the call to `T`'s move assignment, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of `T`'s move assignment. If `is_trivially_move_constructible_v<T> && is_trivially_move_assignable_v<T> && is_trivially_destructible_v<T>` is true, this assignment operator is trivial.

Template:

```cpp
template<class U = T> constexpr optional<T>& operator=(U&& v);
```

**Constraints:**

- `is_same_v<remove_cvref_t<U>, optional>` is false, conjunction_v<is_scalar<T>, is_same<T, decay_t<U>>> is false, is_constructible_v<T, U> is true, and is_assignable_v<T&, U> is true.

**Effects:** If `*this contains a value`, assigns `std::forward<U>(v)` to the contained value; otherwise direct-non-list-initializes the contained value with `std::forward<U>(v)`.

**Postconditions:** *this contains a value.

**Returns:** *this.

**Remarks:** If any exception is thrown, the result of the expression `this->has_value()` remains unchanged. If an exception is thrown during the call to `T`’s constructor, the state of `v` is determined by the exception safety guarantee of `T`’s constructor. If an exception is thrown during the call to `T`’s assignment, the state of `*val` and `v` is determined by the exception safety guarantee of `T`’s assignment.

Template:

```cpp
template<class U> constexpr optional<T>& operator=(const optional<U>& rhs);
```

**Constraints:**

- `is_constructible_v<T, const U&>` is true,
- `isAssignable_v<T, const U&>` is true,
- `converts-from-any-cvref<T, optional<U>>` is false,
- `is_assignable_v<T, optional<U>&>` is false,
- `is_assignable_v<T, optional<U>&&>` is false,
- `isAssignable_v<T, const optional<U>&>` is false,
- `isAssignable_v<T, const optional<U>&&>` is false.

**Effects:** See Table 60.

Table 60: `optional::operator=(const optional<U>&)` effects

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>assigns <code>*rhs</code> to the contained value</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling <code>val-&gt;T::~T()</code></td>
</tr>
</tbody>
</table>

§ 22.5.3.4
Postconditions: \( \text{rhs}.\text{has\_value}() == \text{this}->\text{has\_value}() \).

Returns: \(*\text{this}.*

Remarks: If any exception is thrown, the result of the expression \( \text{this}->\text{has\_value}() \) remains unchanged. If an exception is thrown during the call to \( \text{T} \)'s constructor, the state of \(*\text{rhs}.\text{val}\) is determined by the exception safety guarantee of \( \text{T} \)'s constructor. If an exception is thrown during the call to \( \text{T} \)'s assignment, the state of \(*\text{val}\) and \(*\text{rhs}.\text{val}\) is determined by the exception safety guarantee of \( \text{T} \)'s assignment.

\[
\text{template}<\text{class } \text{U}> \text{ constexpr optional}<\text{T}>& \text{ operator=} (\text{optional}<\text{U}>&& \text{ rhs});
\]

Constraints:

1. \((24.1)\) \text{is\_constructible\_v<} \text{T}, \text{U} \text{> is true.}
2. \((24.2)\) \text{is\_assignable\_v<} \text{T&}, \text{U} \text{> is true,}
3. \((24.3)\) \text{converts\_from\_any\_cvref<} \text{T}, \text{optional<} \text{U} \text{> is false,}
4. \((24.4)\) \text{is\_assignable\_v<} \text{T&}, \text{optional<} \text{U}&> \text{> is false,}
5. \((24.5)\) \text{is\_assignable\_v<} \text{T&}, \text{optional<} \text{U}&&> \text{> is false, and}
6. \((24.6)\) \text{is\_assignable\_v<} \text{T&}, \text{const\ optional<} \text{U}&> \text{> is false, and}
7. \((24.7)\) \text{is\_assignable\_v<} \text{T&}, \text{const\ optional<} \text{U}&&> \text{> is false.}

Effects: See Table 61. The result of the expression \( \text{rhs}.\text{has\_value}() \) remains unchanged.

Table 61: \text{optional::operator=} (\text{optional<} \text{U} \text{>&& rhs}) \text{ effects}

<table>
<thead>
<tr>
<th>\text{rhs contains a value}</th>
<th>\text{rhs does not contain a value}</th>
</tr>
</thead>
<tbody>
<tr>
<td>assigns \text{std::move}(*\text{rhs}) to the contained value</td>
<td>\text{direct-non-list-initializes the contained value with std::move(*\text{rhs})}</td>
</tr>
<tr>
<td>destroys the contained value by calling \text{val}-&gt;\text{T}::\text{~T}()</td>
<td>no effect</td>
</tr>
</tbody>
</table>

Postconditions: \( \text{rhs}.\text{has\_value}() == \text{this}->\text{has\_value}() \).

Returns: \(*\text{this}.*

Remarks: If any exception is thrown, the result of the expression \( \text{this}->\text{has\_value}() \) remains unchanged. If an exception is thrown during the call to \( \text{T} \)'s constructor, the state of \(*\text{rhs}.\text{val}\) is determined by the exception safety guarantee of \( \text{T} \)'s constructor. If an exception is thrown during the call to \( \text{T} \)'s assignment, the state of \(*\text{val}\) and \(*\text{rhs}.\text{val}\) is determined by the exception safety guarantee of \( \text{T} \)'s assignment.

\[
\text{template}<\text{... Args}> \text{ constexpr } \text{T}& \text{ emplace(Args}&&\text{... args);}\
\]

Mandates: \text{is\_constructible\_v<} \text{T}, \text{Args}...> \text{ is true.}

Effects: Calls \(*\text{this} = \text{nullopt}.\) Then direct\-non\-list\-initializes the contained value with \text{std::forward}<\text{Args}>(\text{args})\ldots.

Postconditions: \(*\text{this} \text{ contains a value.}

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of \( \text{T} \).

Remarks: If an exception is thrown during the call to \( \text{T} \)'s constructor, \(*\text{this} \) does not contain a value, and the previous \(*\text{val} \) (if any) has been destroyed.

\[
\text{template}<\text{class } \text{U}, \text{... Args}> \text{ constexpr } \text{T}& \text{ emplace(initializer\_list<} \text{U} \text{>} \text{ il, Args}&&\text{... args);}\
\]

Constraints: \text{is\_constructible\_v<} \text{T}, \text{initializer\_list<} \text{U}&, \text{Args}...> \text{ is true.}

Effects: Calls \(*\text{this} = \text{nullopt}.\) Then direct\-non\-list\-initializes the contained value with \text{il, std::forward<}\text{Args}>(\text{args})\ldots.
Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If an exception is thrown during the call to T’s constructor, *this does not contain a value, and the previous *val (if any) has been destroyed.

22.5.3.5 Swap

```cpp
constexpr void swap(optional& rhs) noexcept(see below);
```

Mandates: is_move_constructible_v<T> is true.

Preconditions: T meets the Cpp17Swappable requirements (16.4.4.3).

Effects: See Table 62.

Table 62: optional::swap(optional&) effects

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>direct-non-list-initializes the contained value of *this with std::move(*rhs), followed by rhs.val-&gt;T::~T(); postcondition is that *this contains a value and rhs does not contain a value</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>direct-non-list-initializes the contained value of rhs with std::move(**this)), followed by val-&gt;T::~T(); postcondition is that *this does not contain a value and rhs contains a value</td>
</tr>
</tbody>
</table>

Throws: Any exceptions thrown by the operations in the relevant part of Table 62.

Remarks: The exception specification is equivalent to:

```cpp
is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T>
```

If any exception is thrown, the results of the expressions this->has_value() and rhs.has_value() remain unchanged. If an exception is thrown during the call to function swap, the state of *val and *rhs.val is determined by the exception safety guarantee of swap for lvalues of T. If an exception is thrown during the call to T’s move constructor, the state of *val and *rhs.val is determined by the exception safety guarantee of T’s move constructor.

22.5.3.6 Observers

```cpp
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
```

Preconditions: *this contains a value.

Returns: val.

Remarks: These functions are constexpr functions.

```cpp
constexpr const Tk& operator*() const & noexcept;
constexpr Tk& operator*() & noexcept;
```

Preconditions: *this contains a value.

Returns: *val.

Remarks: These functions are constexpr functions.

§ 22.5.3.6
constexpr T&& operator*() && noexcept;
constexpr const T&& operator*() const && noexcept;

Preconditions: *this contains a value.
Effects: Equivalent to: return std::move(*val);

constexpr explicit operator bool() const noexcept;
Returns: true if and only if *this contains a value.
Remarks: This function is a constexpr function.

constexpr bool has_value() const noexcept;
Returns: true if and only if *this contains a value.
Remarks: This function is a constexpr function.

constexpr const T& value() const &;
constexpr T& value() &;
Effects: Equivalent to:
return has_value() ? *val : throw bad_optional_access();

constexpr T&& value() &&;
constexpr const T&& value() const &&;
Effects: Equivalent to:
return has_value() ? std::move(*val) : throw bad_optional_access();

template<class U> constexpr T value_or(U&& v) const &;
Mandates: is_copy_constructible_v<T> && is_convertible_v<U&&, T> is true.
Effects: Equivalent to:
return has_value() ? **this : static_cast<T>(std::forward<U>(v));

template<class U> constexpr T value_or(U&& v) &&;
Mandates: is_move_constructible_v<T> && is_convertible_v<U&&, T> is true.
Effects: Equivalent to:
return has_value() ? std::move(**this) : static_cast<T>(std::forward<U>(v));

22.5.3.7 Monadic operations

template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) const &;
Let U be invoke_result_t<F, decltype(value())>.
Mandates: remove_cvref_t<U> is a specialization of optional.
Effects: Equivalent to:
if (*this) {
    return invoke(std::forward<F>(f), value());
} else {
    return remove_cvref_t<U>();
}

template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
Let U be invoke_result_t<F, decltype(std::move(value()))>.
Mandates: remove_cvref_t<U> is a specialization of optional.
Effects: Equivalent to:
if (*this) {
    return invoke(std::forward<F>(f), std::move(value()));
} else {
Let \( U \) be \( \text{remove_cv_t<invoke_result_t<F, decltype(value())>>} \).

**Mandates:** \( U \) is a non-array object type other than \text{in_place_t} or \text{nullopt_t}. The declaration

\[
U u (\text{invoke}(\text{std::forward}<F>(f), \text{value}()));
\]

is well-formed for some invented variable \( u \).

[Note 1: There is no requirement that \( U \) is movable (9.4.1). — end note]

**Returns:** If \( *\text{this} \) contains a value, an \text{optional<U>} object whose contained value is direct-non-list-initialized with \( \text{invoke} (\text{std::forward}<F>(f), \text{value}()); \) otherwise, \text{optional<U>}().

Let \( U \) be \( \text{remove_cv_t<invoke_result_t<F, decltype(std::move(value()))>>} \).

**Mandates:** \( U \) is a non-array object type other than \text{in_place_t} or \text{nullopt_t}. The declaration

\[
U u (\text{invoke}(\text{std::forward}<F>(f), \text{std::move(value())}));
\]

is well-formed for some invented variable \( u \).

[Note 2: There is no requirement that \( U \) is movable (9.4.1). — end note]

**Returns:** If \( *\text{this} \) contains a value, an \text{optional<U>} object whose contained value is direct-non-list-initialized with \( \text{invoke} (\text{std::forward}<F>(f), \text{std::move(value())}); \) otherwise, \text{optional<U>}().

**Constraints:** \( F \) models \text{invocable<>} and \( T \) models \text{copy_constructible}.

**Effects:** Equivalent to:

\[
\text{if } (*\text{this}) \{ \\
\quad \text{return } *\text{this}; \\
\} \text{ else } \\
\quad \text{return } \text{std::forward}<F>(f());
\]

**Constraints:** \( F \) models \text{invocable<>} and \( T \) models \text{move_constructible}.

**Mandates:** \text{is_same_v<remove_cvref_t<invoke_result_t<F>>, optional>} is true.

**Effects:** Equivalent to:

\[
\text{if } (*\text{this}) \{ \\
\quad \text{return std::move(*this);} \\
\} \text{ else } \\
\quad \text{return std::forward}<F>(f());
\]

22.5.3.8 **Modifiers**

\text{constexpr void reset()} noexcept;

**Effects:** If \( *\text{this} \) contains a value, calls \text{val->T::~T()} to destroy the contained value; otherwise no effect.

**Postconditions:** \( *\text{this} \) does not contain a value.

22.5.4 **No-value state indicator**

\text{struct nullopt_t{see below};}
\text{inline constexpr nullopt_t nullopt(unspecified);}
The struct `nullopt_t` is an empty class type used as a unique type to indicate the state of not containing a value for `optional` objects. In particular, `optional<T>` has a constructor with `nullopt_t` as a single argument; this indicates that an optional object not containing a value shall be constructed.

Type `nullopt_t` shall not have a default constructor or an initializer-list constructor, and shall not be an aggregate.

### 22.5.5 Class `bad_optional_access`

```cpp
namespace std {
    class bad_optional_access : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}
```

The class `bad_optional_access` defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an optional object that does not contain a value.

```cpp
const char* what() const noexcept override;
```

**Returns:** An implementation-defined NTS.

### 22.5.6 Relational operators

```cpp
template<class T, class U> constexpr bool operator==(const optional<T>& x, const optional<U>& y);
```

**Mandates:** The expression `*x == *y` is well-formed and its result is convertible to `bool`.

**[Note 1: T need not be Cpp17EqualityComparable. — end note]**

**Returns:** If `x.has_value() != y.has_value()`, `false`; otherwise if `x.has_value() == false, true;` otherwise `*x == *y`.

**Remarks:** Specializations of this function template for which `*x == *y` is a core constant expression are constexpr functions.

```cpp
template<class T, class U> constexpr bool operator!=(const optional<T>& x, const optional<U>& y);
```

**Mandates:** The expression `*x != *y` is well-formed and its result is convertible to `bool`.

**Returns:** If `x.has_value() != y.has_value()`, `true`; otherwise, if `x.has_value() == false, false;` otherwise `*x != *y`.

**Remarks:** Specializations of this function template for which `*x != *y` is a core constant expression are constexpr functions.

```cpp
template<class T, class U> constexpr bool operator<(const optional<T>& x, const optional<U>& y);
```

**Mandates:** The expression `*x < *y` is well-formed and its result is convertible to `bool`.

**Returns:** If `!y`, `false`; otherwise, if `!x, true;` otherwise `*x < *y`.

**Remarks:** Specializations of this function template for which `*x < *y` is a core constant expression are constexpr functions.

```cpp
template<class T, class U> constexpr bool operator>(const optional<T>& x, const optional<U>& y);
```

**Mandates:** The expression `*x > *y` is well-formed and its result is convertible to `bool`.

**Returns:** If `!x, false;` otherwise, if `!y, true;` otherwise `*x > *y`.

**Remarks:** Specializations of this function template for which `*x > *y` is a core constant expression are constexpr functions.

```cpp
template<class T, class U> constexpr bool operator<=(const optional<T>& x, const optional<U>& y);
```

**Mandates:** The expression `*x <= *y` is well-formed and its result is convertible to `bool`.

**Returns:** If `!x`, `true;` otherwise, if `!y, false;` otherwise `*x <= *y`.

**Remarks:** Specializations of this function template for which `*x <= *y` is a core constant expression are constexpr functions.

§ 22.5.6
template<class T, class U> constexpr bool operator>=(const optional<T>& x, const optional<U>& y);

Mandates: The expression \(*x >= *y\) is well-formed and its result is convertible to bool.

Returns: If \(!y\), true; otherwise, if \(!x, false; otherwise \(*x >= *y\).

Remarks: Specializations of this function template for which \(*x >= *y\) is a core constant expression are constexpr functions.

template<class T, three_way_comparable_with<T> U>
constexpr compare_three_way_result_t<T, U> operator<=>(const optional<T>& x, const optional<U>& y);

Returns: If \(x && y\), \(*x <=> *y\); otherwise \(x.has_value() <=> y.has_value()\).

Remarks: Specializations of this function template for which \(*x <=> *y\) is a core constant expression are constexpr functions.

22.5.7 Comparison with nullopt

[optional.nullops]

template<class T> constexpr bool operator==(const optional<T>& x, nullopt_t) noexcept;

Returns: \(!x\).

template<class T> constexpr strong_ordering operator<=>(const optional<T>& x, nullopt_t) noexcept;

Returns: \(x.has_value() <=> false\).

22.5.8 Comparison with T

[optional.comp.with.t]

template<class T, class U> constexpr bool operator==(const optional<T>& x, const U& v);

Mandates: The expression \(*x == v\) is well-formed and its result is convertible to bool.

[Note 1: \(T\) need not be \(Cpp17EqualityComparable\). — end note]

Effects: Equivalent to: return \(x.has_value() ? *x == v : false\);

template<class T, class U> constexpr bool operator==(const T& v, const optional<U>& x);

Mandates: The expression \(v == *x\) is well-formed and its result is convertible to bool.

Effects: Equivalent to: return \(x.has_value() ? v == *x : false\);

template<class T, class U> constexpr bool operator!=(const optional<T>& x, const U& v);

Mandates: The expression \(*x != v\) is well-formed and its result is convertible to bool.

Effects: Equivalent to: return \(x.has_value() ? *x != v : true\);

template<class T, class U> constexpr bool operator!=(const T& v, const optional<U>& x);

Mandates: The expression \(v != *x\) is well-formed and its result is convertible to bool.

Effects: Equivalent to: return \(x.has_value() ? v != *x : true\);

template<class T, class U> constexpr bool operator<(const optional<T>& x, const U& v);

Mandates: The expression \(*x < v\) is well-formed and its result is convertible to bool.

Effects: Equivalent to: return \(x.has_value() ? *x < v : false\);

template<class T, class U> constexpr bool operator<(const T& v, const optional<U>& x);

Mandates: The expression \(v < *x\) is well-formed and its result is convertible to bool.

Effects: Equivalent to: return \(x.has_value() ? v < *x : false\);

template<class T, class U> constexpr bool operator>(const optional<T>& x, const U& v);

Mandates: The expression \(*x > v\) is well-formed and its result is convertible to bool.

Effects: Equivalent to: return \(x.has_value() ? *x > v : false\);

template<class T, class U> constexpr bool operator>(const T& v, const optional<U>& x);

Mandates: The expression \(v > *x\) is well-formed and its result is convertible to bool.

Effects: Equivalent to: return \(x.has_value() ? v > *x : true\);
```cpp
template<class T, class U> constexpr bool operator<=(const optional<T>& x, const U& v);
```

**Mandates**: The expression *x <= v* is well-formed and its result is convertible to bool.

**Effects**: Equivalent to: return x.has_value() ? *x <= v : true;

```cpp
template<class T, class U> constexpr bool operator<=(const T& v, const optional<U>& x);
```

**Mandates**: The expression v <= *x is well-formed and its result is convertible to bool.

**Effects**: Equivalent to: return x.has_value() ? v <= *x : false;

```cpp
template<class T, class U> constexpr bool operator>=(const optional<T>& x, const U& v);
```

**Mandates**: The expression *x >= v is well-formed and its result is convertible to bool.

**Effects**: Equivalent to: return x.has_value() ? *x >= v : false;

```cpp
template<class T, class U> constexpr bool operator>=(const T& v, const optional<U>& x);
```

**Mandates**: The expression v >= *x is well-formed and its result is convertible to bool.

**Effects**: Equivalent to: return x.has_value() ? v >= *x : true;

```cpp
template<class T, class U>
requires (!is-derived-from-optional<U>) && three_way_comparable_with<T, U>
constexpr compare_three_way_result_t<T, U>
operator<=>(const optional<T>& x, const U& v);
```

**Effects**: Equivalent to: return x.has_value() ? *x <=> v : strong_ordering::less;

### 22.5.9 Specialized algorithms

```cpp
template<class T>
constexpr void swap(optional<T>& x, optional<T>& y) noexcept(noexcept(x.swap(y)));
```

**Constraints**: is_move_constructible_v<T> is true and is_swappable_v<T> is true.

**Effects**: Calls x.swap(y).

```cpp
template<class T> constexpr optional<decay_t<T>> make_optional(T&& v);
```

**Returns**: optional<decay_t<T>>(std::forward<T>(v)).

```cpp
template<class T, class... Args>
constexpr optional<T> make_optional(Args&&... args);
```

**Effects**: Equivalent to: return optional<T>(in_place, std::forward<Args>(args)...);

```cpp
template<class T, class U, class... Args>
constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);
```

**Effects**: Equivalent to: return optional<T>(in_place, il, std::forward<Args>(args)...);

### 22.5.10 Hash support

```cpp
template<class T> struct hash<optional<T>>;
```

The specialization hash<optional<T>> is enabled (22.10.19) if and only if hash<remove_const_t<T>> is enabled. When enabled, for an object o of type optional<T>, if o.has_value() == true, then hash<optional<T>>()(o) evaluates to the same value as hash<remove_const_t<T>>()(o); otherwise it evaluates to an unspecified value. The member functions are not guaranteed to be noexcept.

### 22.6 Variants

#### 22.6.1 In general

A variant object holds and manages the lifetime of a value. If the variant holds a value, that value's type has to be one of the template argument types given to variant. These template arguments are called alternatives.

#### 22.6.2 Header <variant> synopsis

#include <compare> // see 17.11.1
namespace std {

   // 22.6.3, class template variant
   template<class... Types>
      class variant;

   // 22.6.4, variant helper classes
   template<class T> struct variant_size;        // not defined
   template<class T> struct variant_size<const T>;
   template<class T>
     constexpr size_t variant_size_v = variant_size<T>::value;

   template<class... Types>
      struct variant_size<variant<Types...>>;

   template<class T, class... Types>
      constexpr bool holds_alternative(const variant<Types...>&) noexcept;

   template<size_t I, class... Types>
      constexpr variant_alternative_t<I, variant<Types...>>& get(variant<Types...>&);
   template<size_t I, class... Types>
      constexpr variant_alternative_t<I, variant<Types...>>&& get(variant<Types...>&&);
   template<size_t I, class... Types>
      constexpr const variant_alternative_t<I, variant<Types...>>& get(const variant<Types...>&);
   template<size_t I, class... Types>
      constexpr const variant_alternative_t<I, variant<Types...>>&& get(const variant<Types...>&&);

            template<class... Types>
            constexpr bool operator>=(const variant<Types...>&, const variant<Types...>&);

            template<class... Types> requires (three_way_comparable<Types> && ...)
            constexpr common_comparison_category_t<compare_three_way_result_t<Types>...>
                operator<=>(const variant<Types...>&, const variant<Types...>&);

            // 22.6.7, visitation
            template<class Visitor, class... Variants>
                constexpr
                see below visit(Visitor&&, Variants&&...);

            template<class R, class Visitor, class... Variants>
                constexpr R visit(Visitor&&, Variants&&...);

            // 22.6.8, class monostate
            struct monostate;

            // 22.6.9, monostate relational operators
            constexpr bool operator==(monostate, monostate) noexcept;
            constexpr strong_ordering operator<=>(monostate, monostate) noexcept;

            // 22.6.10, specialized algorithms
            template<class... Types>
                constexpr void swap(variant<Types...>&, variant<Types...>&) noexcept(see below);

            // 22.6.11, class bad_variant_access
            class bad_variant_access;

            // 22.6.12, hash support
            template<class T> struct hash;
            template<class... Types> struct hash<variant<Types...>>;
            template<> struct hash<monostate>;
    }
}
Any instance of `variant` at any given time either holds a value of one of its alternative types or holds no value. When an instance of `variant` holds a value of alternative type `T`, it means that a value of type `T`, referred to as the `variant` object’s contained value, is allocated within the storage of the `variant` object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the contained value.

All types in `Types` shall meet the `Cpp17Destructible` requirements (Table 35).

A program that instantiates the definition of `variant` with no template arguments is ill-formed.

### 22.6.3.2 Constructors

In the descriptions that follow, let `i` be in the range `[0, sizeof...(Types))`, and `T_i` be the `i`th type in `Types`.

```cpp
constexpr variant() noexcept(see below);
```

**Constraints**: `is_default_constructible_v<T_0>` is true.

**Effects**: Constructs a `variant` holding a value-initialized value of type `T_0`.

**Postconditions**: `valueless_by_exception()` is false and `index()` is 0.

**Throws**: Any exception thrown by the value-initialization of `T_0`.

**Remarks**: This function is `constexpr` if and only if the value-initialization of the alternative type `T_0` would satisfy the requirements for a `constexpr` function. The exception specification is equivalent to `is_nothrow_default_constructible_v<T_0>`.

[Note 1: See also class `monostate`. — end note]

```cpp
constexpr variant(const variant& w);
```

**Effects**: If `w` holds a value, initializes the `variant` to hold the same alternative as `w` and direct-initializes the contained value with `get<j>(w)`, where `j` is `w.index()`. Otherwise, initializes the `variant` to not hold a value.

**Throws**: Any exception thrown by direct-initializing any `T_i` for all `i`.

**Remarks**: This constructor is defined as deleted unless `is_copy_constructible_v<T_i>` is true for all `i`. If `is_trivially_copy_constructible_v<T_i>` is true for all `i`, this constructor is trivial.
constexpr variant(variant&& w) noexcept(see below);

Constraints: is_move_constructible_v<Tj> is true for all i.

Effects: If w holds a value, initializes the variant to hold the same alternative as w and direct-initializes the contained value with get<j>(std::move(w)), where j is w.index(). Otherwise, initializes the variant to not hold a value.

Throws: Any exception thrown by move-constructing any Ti for all i.

Remarks: The exception specification is equivalent to the logical AND of is_nothrow_move_constructible_v<Ti> for all i. If is_trivially_move_constructible_v<Ti> is true for all i, this constructor is trivial.

template<class T> constexpr variant(T&& t) noexcept(see below);

Let Tj be a type that is determined as follows: build an imaginary function FUN(Ti) for each alternative type Ti for which Ti x[] = {std::forward<T>(t)}; is well-formed for some invented variable x. The overload FUN(Tj) selected by overload resolution for the expression FUN(std::forward<T>(t)) defines the alternative Tj which is the type of the contained value after construction.

Constraints:
(15.1) sizeof...(Types) is nonzero,
(15.2) is_same_v<remove_cvref_t<T>, variant> is false,
(15.3) remove_cvref_t<T> is neither a specialization of in_place_type_t nor a specialization of in_place_index_t,
(15.4) is_constructible_v<Tj, T> is true, and
(15.5) the expression FUN(std::forward<T>(t)) (with FUN being the above-mentioned set of imaginary functions) is well-formed.

[Note 2: variant<string, string> v("abc"); is ill-formed, as both alternative types have an equally viable constructor for the argument. —end note]

Effects: Initializes *this to hold the alternative type Tj and direct-non-list-initializes the contained value with std::forward<T>(t).

Postconditions: holds_alternative<Tj>(*this) is true.

Throws: Any exception thrown by the initialization of the selected alternative Tj.

Remarks: The exception specification is equivalent to is_nothrow_constructible_v<Tj, T>. If Tj’s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

template<class T, class... Args> constexpr explicit variant(in_place_type_t<T>, Args&&... args);

Constraints:
(20.1) There is exactly one occurrence of T in Types... and
(20.2) is_constructible_v<T, Args...> is true.

Effects: Direct-non-list-initializes the contained value of type T with std::forward<Args>(args)....

Postconditions: holds_alternative<T>(*this) is true.

Throws: Any exception thrown by calling the selected constructor of T.

Remarks: If T’s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

template<class T, class U, class... Args>
constexpr explicit variant(in_place_type_t<T>, initializer_list<U> il, Args&&... args);

Constraints:
(25.1) There is exactly one occurrence of T in Types... and
(25.2) is_constructible_v<T, initializer_list<U>&, Args...> is true.
Effects: Direct-non-list-initializes the contained value of type T with \( il, \text{std::forward<Args>(args)} \)....

Postconditions: \( \text{holds_alternative<T>(*this)} \) is true.

Throws: Any exception thrown by calling the selected constructor of T.

Remarks: If T's selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

```
template<size_t I, class... Args> constexpr explicit variant(in_place_index_t<I>, Args&&... args);
```

Constraints:

(30.1) I is less than sizeof...(Types) and
(30.2) \( \text{is_constructible_v<T}_I, \text{Args...}} \) is true.

Effects: Direct-non-list-initializes the contained value of type \( T_I \) with \( \text{std::forward<Args>(args)} \)....

Postconditions: index() is I.

Throws: Any exception thrown by calling the selected constructor of \( T_I \).

Remarks: If \( T_I \)'s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

```
template<size_t I, class U, class... Args> constexpr explicit variant(in_place_index_t<I>, initializer_list<U> il, Args&&... args);
```

Constraints:

(35.1) I is less than sizeof...(Types) and
(35.2) \( \text{is_constructible_v<T}_I, \text{initializer_list<U>&, Args...}} \) is true.

Effects: Direct-non-list-initializes the contained value of type \( T_I \) with \( il, \text{std::forward<Args>(args)} \)....

Postconditions: index() is I.

Remarks: If \( T_I \)'s selected constructor is a constexpr constructor, this constructor is a constexpr constructor.

22.6.3.3 Destructor [variant.dtor]

```
constexpr ~variant();
```

Effects: If \( \text{valueless_by_exception()} \) is false, destroys the currently contained value.

Remarks: If \( \text{is_trivially_destructible_v<T}_i \) is true for all \( T_i \), then this destructor is trivial.

22.6.3.4 Assignment [variant.assign]

```
constexpr variant& operator=(const variant& rhs);
```

Let \( j \) be \( \text{rhs.index()} \).

Effects:

(2.1) If neither \( *\text{this} \) nor \( \text{rhs} \) holds a value, there is no effect.
(2.2) Otherwise, if \( *\text{this} \) holds a value but \( \text{rhs} \) does not, destroys the value contained in \( *\text{this} \) and sets \( *\text{this} \) to not hold a value.
(2.3) Otherwise, if \( \text{index()} == j \), assigns the value contained in \( \text{rhs} \) to the value contained in \( *\text{this} \).
(2.4) Otherwise, if either \( \text{is_nothrow_copy_constructible_v<T}_j \) is true or \( \text{is_nothrow_move_constructible_v<T}_j \) is false, equivalent to \( \text{emplace<j>(get<j>(rhs))} \).
(2.5) Otherwise, equivalent to \( \text{operator=(variant(rhs))} \).

Postconditions: \( \text{index()} == \text{rhs.index()} \).

Returns: \( *\text{this} \).

Remarks: This operator is defined as deleted unless \( \text{is_copy_constructible_v<T}_i \) &\& \( \text{is_copy_assignable_v<T}_i \) is true for all \( i \). If \( \text{is_trivially_copy_constructible_v<T}_i \) &\& \( \text{is_trivially_...} \)
copy_assignable_v<T, i> && is_trivially_destructible_v<T, i> is true for all i, this assignment operator is trivial.

constexpr variant& operator=(variant&& rhs) noexcept(see below);

Let j be rhs.index().

Constraints: is_move_constructible_v<T, i> && is_move_assignable_v<T, i> is true for all i.

Effects:
(8.1) — If neither *this nor rhs holds a value, there is no effect.
(8.2) — Otherwise, if *this holds a value but rhs does not, destroys the value contained in *this and sets *this to not hold a value.
(8.3) — Otherwise, if index() == j, assigns get<j>(std::move(rhs)) to the value contained in *this.
(8.4) — Otherwise, equivalent to emplace<j>(get<j>(std::move(rhs))).

Returns: *this.

Remarks: If is_trivially_move_constructible_v<T, i> && is_trivially_move_assignable_v<T, i> && is_trivially_destructible_v<T, i> is true for all i, this assignment operator is trivial. The exception specification is equivalent to is_nothrow_move_constructible_v<T, i> && is_nothrow_move_assignable_v<T, i> for all i.

(10.1) — If an exception is thrown during the call to T_j’s move construction (with j being rhs.index()), the variant will hold no value.
(10.2) — If an exception is thrown during the call to T_j’s move assignment, the state of the contained value is as defined by the exception safety guarantee of T_j’s move assignment; index() will be j.

template<class T> constexpr variant& operator=(T&& t) noexcept(see below);

Let T_j be a type that is determined as follows: build an imaginary function FUN(T_i) for each alternative type T_i for which T_i x[] = {std::forward<T>(t)} is well-formed for some invented variable x. The overload FUN(T_j) selected by overload resolution for the expression FUN(std::forward<T>(t)) defines the alternative T_j which is the type of the contained value after assignment.

Constraints:
(12.1) — is_same_v<remove_cvref_t<T>, variant> is false,
(12.2) — assignable_v<T_j, T> && is_constructible_v<T_j, T> is true, and
(12.3) — the expression FUN(std::forward<T>(t)) (with FUN being the above-mentioned set of imaginary functions) is well-formed.

[Note 1:

variant<string, string> v;
  v = "abc";

is ill-formed, as both alternative types have an equally viable constructor for the argument. — end note]

Effects:
(13.1) — If *this holds a T_j, assigns std::forward<T>(t) to the value contained in *this.
(13.2) — Otherwise, if is_nothrow_constructible_v<T_j, T> || !is_nothrow_move_constructible_v<T_j, T> is true, equivalent to emplace<j>(std::forward<T>(t)).
(13.3) — Otherwise, equivalent to emplace<j>(T_j(std::forward<T>(t))).

Postconditions: holds_alternative_v<T_j>(*this) is true, with T_j selected by the imaginary function overload resolution described above.

Returns: *this.

Remarks: The exception specification is equivalent to:

is_nothrow_assignable_v<T, i> && is_nothrow_constructible_v<T, i> &&

(16.1) — If an exception is thrown during the assignment of std::forward<T>(t) to the value contained in *this, the state of the contained value and t are as defined by the exception safety guarantee of the assignment expression; valueless_by_exception() will be false.
If an exception is thrown during the initialization of the contained value, the variant object is permitted to not hold a value.

### 22.6.3.5 Modifiers

```cpp
template<class T, class... Args> constexpr T& emplace(Args&&... args);
```

1. **Constraints:** `is_constructible_v<T, Args...>` is true, and T occurs exactly once in `Types`.
2. **Effects:** Equivalent to:
   ```cpp
   return emplace<
   ```
   ```cpp
   where \( I \) is the zero-based index of T in `Types`.
   ```cpp

```cpp
template<class T, class U, class... Args>
constexpr T& emplace(initializer_list<U> il, Args&&... args);
```

3. **Constraints:** `is_constructible_v<T, initializer_list<U>&, Args...>` is true, and T occurs exactly once in `Types`.
4. **Effects:** Equivalent to:
   ```cpp
   return emplace<
   ```
   ```cpp
   where \( I \) is the zero-based index of T in `Types`.
   ```cpp

```cpp
template<size_t I, class... Args>
constexpr variant_alternative_t<I, variant<Types...>>& emplace(Args&&... args);
```

5. **Mandates:** \( I < \) `sizeof...(Types)`.
6. **Constraints:** `is_constructible_v<T_I, Args...>` is true.
7. **Effects:** Destroys the currently contained value if `valueless_by_exception()` is false. Then direct-non-list-initializes the contained value of type \( T_I \) with the arguments `std::forward<Args>(args)`.
8. **Postconditions:** `index()` is \( I \).
9. **Returns:** A reference to the new contained value.
10. **Throws:** Any exception thrown during the initialization of the contained value.
11. **Remarks:** If an exception is thrown during the initialization of the contained value, the variant is permitted to not hold a value.

```cpp
template<size_t I, class U, class... Args>
constexpr variant_alternative_t<I, variant<Types...>>&
emplace(initializer_list<U> il, Args&&... args);
```

12. **Mandates:** \( I < \) `sizeof...(Types)`.
13. **Constraints:** `is_constructible_v<T_I, initializer_list<U>&, Args...>` is true.
14. **Effects:** Destroys the currently contained value if `valueless_by_exception()` is false. Then direct-non-list-initializes the contained value of type \( T_I \) with \( il, std::forward<Args>(args)\).
15. **Postconditions:** `index()` is \( I \).
16. **Returns:** A reference to the new contained value.
17. **Throws:** Any exception thrown during the initialization of the contained value.
18. **Remarks:** If an exception is thrown during the initialization of the contained value, the variant is permitted to not hold a value.

### 22.6.3.6 Value status

```cpp
constexpr bool valueless_by_exception() const noexcept;
```

1. **Effects:** Returns false if and only if the variant holds a value.
2. **Note 1:** It is possible for a variant to hold no value if an exception is thrown during a type-changing assignment or emplacement. The latter means that even a `variant<float, int>` can become `valueless_by_exception()`, for instance by
   ```cpp
   struct S { operator int() { throw 42; };
   variant<float, int> v{12.f};
   ```
v.emplace<1>(S());
— end note]

constexpr size_t index() const noexcept;

3 Effects: If `valueless_by_exception()` is true, returns `variant_npos`. Otherwise, returns the zero-based index of the alternative of the contained value.

22.6.3.7 Swap

constexpr void swap(variant& rhs) noexcept;

1 Mandates: is_move_constructible_v<T_i> is true for all i.

2 Preconditions: Each T_i meets the Cpp17Swappable requirements (16.4.4.3).

3 Effects:
   (1.1) If `valueless_by_exception()` && rhs.`valueless_by_exception()` no effect.
   (1.2) Otherwise, if `index() == rhs.index()`, calls `swap(get<i>(*this), get<i>(rhs))` where i is `index()`.
   (1.3) Otherwise, exchanges values of rhs and *this.

4 Throws: If `index() == rhs.index()` any exception thrown by `swap(get<i>(*this), get<i>(rhs))` with i being `index()`. Otherwise, any exception thrown by the move constructor of T_i or T_j with i being `index()` and j being `rhs.index()`.

5 Remarks: If an exception is thrown during the call to function `swap(get<i>(*this), get<i>(rhs))`, the states of the contained values of *this and of rhs are determined by the exception safety guarantee of swap for lvalues of T_i with i being `index()`. If an exception is thrown during the exchange of the values of *this and rhs, the states of the values of *this and of rhs are determined by the exception safety guarantee of variant’s move constructor. The exception specification is equivalent to the logical AND of is_nothrow_move_constructible_v<T_i> && is_nothrow_swappable_v<T_i> for all i.

22.6.4 variant helper classes

template<class T> struct variant_size;

1 All specializations of variant_size meet the Cpp17UnaryTypeTrait requirements (21.3.2) with a base characteristic of integral_constant<size_t, N> for some N.

template<class T> struct variant_size<const T>;

2 Let VS denote variant_size<T> of the cv-unqualified type T. Then each specialization of the template meets the Cpp17UnaryTypeTrait requirements (21.3.2) with a base characteristic of integral_constant<size_t, VS::value>.

template<class... Types>
struct variant_size<Types...>() : integral_constant<size_t, sizeof...(Types)> { };

template<size_t I, class T> struct variant_alternative<I, const T>;

3 Let VA denote variant_alternative<I, T> of the cv-unqualified type T. Then each specialization of the template meets the Cpp17UnaryTypeTrait requirements (21.3.2) with a member typedef `type` that names the type add_const_t<VA::type>.

4 Mandates: I < sizeof...(Types).

5 Type: The type T_i.

22.6.5 Value access

template<class T, class... Types>
constexpr bool holds_alternative(const variant<Types...>& v) noexcept;

1 Mandates: The type T occurs exactly once in Types.

2 Returns: true if `index()` is equal to the zero-based index of T in Types.
template<
    size_t I,
    class... Types>
constexpr variant_alternative_t<I, variant<Types...>>
    get(variant<Types...>& v);

template<
    size_t I,
    class... Types>
constexpr variant_alternative_t<I, variant<Types...>>
    get(variant<Types...>&& v);

template<
    size_t I,
    class... Types>
constexpr const variant_alternative_t<I, variant<Types...>>&
    get(const variant<Types...>& v);

template<
    size_t I,
    class... Types>
constexpr const variant_alternative_t<I, variant<Types...>>
    get(const variant<Types...>&& v);

Mandates: I < sizeof...(Types).

Effects: If \texttt{v.index()} is \texttt{I}, returns a reference to the object stored in the \texttt{variant}. Otherwise, throws an exception of type \texttt{bad_variant_access}.

template<class T,
    class... Types>
constexpr T&
    get(variant<Types...>& v);

template<class T,
    class... Types>
constexpr T&&
    get(variant<Types...>&& v);

template<class T,
    class... Types>
constexpr const T&
    get(const variant<Types...>& v);

template<class T,
    class... Types>
constexpr const T&&
    get(const variant<Types...>&& v);

Mandates: The type \texttt{T} occurs exactly once in \texttt{Types}.

Effects: If \texttt{v} holds a value of type \texttt{T}, returns a reference to that value. Otherwise, throws an exception of type \texttt{bad_variant_access}.

template<size_t I,
    class... Types>
constexpr add_pointer_t<
    variant_alternative_t<I, variant<Types...>>>
    get_if(variant<Types...>* v) noexcept;

template<size_t I,
    class... Types>
constexpr add_pointer_t<const
    variant_alternative_t<I, variant<Types...>>>
    get_if(const variant<Types...>* v) noexcept;

Mandates: I < sizeof...(Types).

Returns: A pointer to the value stored in the \texttt{variant}, if \texttt{v} \texttt{!=} \texttt{nullptr} and \texttt{v->index()} \texttt{==} \texttt{I}. Otherwise, returns \texttt{nullptr}.

template<class T,
    class... Types>
constexpr add_pointer_t<T>
    get_if(variant<Types...>* v) noexcept;

template<class T,
    class... Types>
constexpr add_pointer_t<const T>
    get_if(const variant<Types...>* v) noexcept;

Mandates: The type \texttt{T} occurs exactly once in \texttt{Types}.

Effects: Equivalent to: \texttt{return get_if<\texttt{i}>(\texttt{v});} with \texttt{i} being the zero-based index of \texttt{T} in \texttt{Types}.

### 22.6.6 Relational operators

template<class... Types>
constexpr bool operator==(const variant<Types...>& v,
    const variant<Types...>& w);

Mandates: get<\texttt{i}>(\texttt{v}) \texttt{==} get<\texttt{i}>(\texttt{w}) is a valid expression that is convertible to \texttt{bool}, for all \texttt{i}.

Returns: If \texttt{v.index()} \texttt{!=} \texttt{w.index()}, \texttt{false}; otherwise if \texttt{v.valueless_by_exception()}, \texttt{true}; otherwise get<\texttt{i}>(\texttt{v}) \texttt{==} get<\texttt{i}>(\texttt{w}) with \texttt{i} being \texttt{v.index()}.

template<class... Types>
constexpr bool operator!=(const variant<Types...>& v,
    const variant<Types...>& w);

Mandates: get<\texttt{i}>(\texttt{v}) \texttt{!=} get<\texttt{i}>(\texttt{w}) is a valid expression that is convertible to \texttt{bool}, for all \texttt{i}.

Returns: If \texttt{v.index()} \texttt{!=} \texttt{w.index()}, \texttt{true}; otherwise if \texttt{v.valueless_by_exception()}, \texttt{false}; otherwise get<\texttt{i}>(\texttt{v}) \texttt{!=} get<\texttt{i}>(\texttt{w}) with \texttt{i} being \texttt{v.index()}.

template<class... Types>
constexpr bool operator<(const variant<Types...>& v,
    const variant<Types...>& w);

Mandates: get<\texttt{i}>(\texttt{v}) \texttt{<} get<\texttt{i}>(\texttt{w}) is a valid expression that is convertible to \texttt{bool}, for all \texttt{i}.
Returns: If \( w\text{.valueless\_by\_exception()}, \text{false} \); otherwise if \( v\text{.valueless\_by\_exception()}, \text{true} \); otherwise, if \( v\text{.index()} < w\text{.index()} \), \text{true} \); otherwise if \( v\text{.index()} > w\text{.index()} \), \text{false} \); otherwise \( \text{get}<i>(v) < \text{get}<i>(w) \) with \( i \) being \( v\text{.index()} \).

\[
\text{template<class... Types>}
\text{constexpr bool operator\&(const variant<Types...>& v, const variant<Types...>& w);}\]

\[
\text{Mandates: get}<i>(v) > get<i>(w) \text{ is a valid expression that is convertible to bool, for all } i.}
\]

\[
\text{Returns: If v.valueless\_by\_exception(), \text{false}; otherwise if w.valueless\_by\_exception(), \text{true}; otherwise, if v.index() > w.index(), \text{true}; otherwise if v.index() < w.index(), \text{false}; otherwise get}<i>(v) > get<i>(w) \text{ with } i \text{ being } v\text{.index()}.}
\]

\[
\text{template<class... Types>}
\text{constexpr bool operator<=\&(const variant<Types...>& v, const variant<Types...>& w);}\]

\[
\text{Mandates: get}<i>(v) \leq get<i>(w) \text{ is a valid expression that is convertible to bool, for all } i.}
\]

\[
\text{Returns: If v.valueless\_by\_exception(), \text{false}; otherwise if w.valueless\_by\_exception(), \text{true}; otherwise, if v.index() > w.index(), \text{true}; otherwise if v.index() < w.index(), \text{false}; otherwise get}<i>(v) \leq get<i>(w) \text{ with } i \text{ being } v\text{.index()}.}
\]

\[
\text{template<class... Types> requires (three\_way\_comparable<Types> && ...)}
\text{constexpr common\_comparison\_category\_t<compare\_three\_way\_result\_t<Types>...> operator<=>\&(const variant<Types...>& v, const variant<Types...>& w);}\]

\[
\text{Effects: Equivalent to:}
\]
\[
\text{if (v.valueless\_by\_exception() && w.valueless\_by\_exception())}
\text{return strong\_ordering::equal;}
\text{if (v.valueless\_by\_exception()) return strong\_ordering::less;}
\text{if (w.valueless\_by\_exception()) return strong\_ordering::greater;}
\text{if (auto c = v.index() <=> w.index(); c != 0) return c;}
\text{return get}<i>(v) <=> get<i>(w);}\]

\[
\text{with } i \text{ being } v\text{.index()}.}
\]
Let $m$ be a pack of $n$ values of type `size_t`. Such a pack is valid if $0 \leq m_i < \text{variant\_size\_v<remove\_reference\_t<T_i>>}$ for all $0 \leq i < n$. For each valid pack $m$, let $e(m)$ denote the expression:

```cpp
INVOKER(std::forward<Visitor>(vis), get<m>(std::forward<V>(vars))...) // see 22.10.4
```
for the first form and

```cpp
INVOKER<R>(std::forward<Visitor>(vis), get<m>(std::forward<V>(vars))...) // see 22.10.4
```
for the second form.

**Mandates:** For each valid pack $m$, $e(m)$ is a valid expression. All such expressions are of the same type and value category.

**Returns:** $e(m)$, where $m$ is the pack for which $m_i$ is `as-variant vars_i.index()` for all $0 \leq i < n$. The return type is `decltype(e(m))` for the first form.

**Throws:** `bad_variant_access` if `(as-variant vars).valueless_by_exception() || ...` is true.

**Complexity:** For $n \leq 1$, the invocation of the callable object is implemented in constant time, i.e., for $n = 1$, it does not depend on the number of alternative types of $V_0$. For $n > 1$, the invocation of the callable object has no complexity requirements.

### 22.6.8 Class `monostate` [variant.monostate]

```cpp
struct monostate{};
```

The class `monostate` can serve as a first alternative type for a `variant` to make the `variant` type default constructible.

### 22.6.9 `monostate` relational operators [variant.monostate.relops]

```cpp
constexpr bool operator==(monostate, monostate) noexcept { return true; }
customexpr strong_ordering operator<=>(monostate, monostate) noexcept {
  return strong_ordering::equal;
}
```

**Note 1:** `monostate` objects have only a single state; they thus always compare equal. — end note]

### 22.6.10 Specialized algorithms [variant.specalg]

```cpp
template<class... Types>
constexpr void swap(variant<Types...>& v, variant<Types...>& w) noexcept(see below);
```

**Constraints:** `is_move_constructible_v<T_i>` \& \& `is_swappable_v<T_i>` is true for all $i$.

**Effects:** Equivalent to `v.swap(w)`.

**Remarks:** The exception specification is equivalent to `noexcept(v.swap(w))`.

### 22.6.11 Class `bad_variant_access` [variant.bad.access]

```cpp
namespace std {
  class bad_variant_access : public exception {
    public:
      // see 17.9.3 for the specification of the special member functions
      const char* what() const noexcept override;
    }
}
```

Objects of type `bad_variant_access` are thrown to report invalid accesses to the value of a `variant` object.

```cpp
const char* what() const noexcept override;
```

**Returns:** An implementation-defined `ntbs`.

### 22.6.12 Hash support [variant.hash]

```cpp
template<class... Types> struct hash<variant<Types...>>;
```

The specialization `hash<Types...>` is enabled (22.10.19) if and only if every specialization in `hash<remove_const_t<Types>>...` is enabled. The member functions are not guaranteed to be `noexcept`. 
22.7 Storage for any type

22.7.1 General

Subclause 22.7 describes components that C++ programs may use to perform operations on objects of a discriminated type.

[Note 1: The discriminated type can contain values of different types but does not attempt conversion between them, i.e., 5 is held strictly as an int and is not implicitly convertible either to "5" or to 5.0. This indifference to interpretation but awareness of type effectively allows safe, generic containers of single values, with no scope for surprises from ambiguous conversions. — end note]

22.7.2 Header <any> synopsis

```cpp
namespace std {
    // 22.7.3, class bad_any_cast
    class bad_any_cast;
    
    // 22.7.4, class any
    class any;
    
    // 22.7.5, non-member functions
    void swap(any& x, any& y) noexcept;

    template<class T, class... Args>
    any make_any(Args&&... args);
    
    template<class T, class U, class... Args>
    any make_any(initializer_list<U> il, Args&&... args);

    template<class T>
    T any_cast(const any& operand);
    template<class T>
    T any_cast(any& operand);
    template<class T>
    T any_cast(any&& operand);
    
    template<class T>
    const T* any_cast(const any* operand) noexcept;
    template<class T>
    T* any_cast(any* operand) noexcept;
}
```

22.7.3 Class bad_any_cast

```cpp
namespace std {
    class bad_any_cast : public bad_cast {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    }
}
```

1 Objects of type bad_any_cast are thrown by a failed any_cast (22.7.5).

2 Returns: An implementation-defined Ntbs.

22.7.4 Class any

22.7.4.1 General

```cpp
namespace std {
    class any {
        public:
            // 22.7.4.2, construction and destruction
```
An object of class `any` stores an instance of any type that meets the constructor requirements or it has no value, and this is referred to as the state of the class `any` object. The stored instance is called the contained value. Two states are equivalent if either they both have no value, or they both have a value and the contained values are equivalent.

The non-member `any_cast` functions provide type-safe access to the contained value.

Implementations should avoid the use of dynamically allocated memory for a small contained value. However, any such small-object optimization shall only be applied to types `T` for which `is_nothrow_move_constructible_v<T>` is true.

**Example 1:** A contained value of type `int` could be stored in an internal buffer, not in separately-allocated memory.

---

### 22.7.4.2 Construction and destruction

```cpp
cconstexpr any() noexcept;
any(const any& other);
any(any&& other) noexcept;
template<class T>
    any(T&& value);
template<class T, class... Args>
    explicit any(in_place_type_t<T>, Args&&...);
template<class T, class U, class... Args>
    explicit any(in_place_type_t<T>, initializer_list<U>, Args&&...);
~any();

// 22.7.4.3, assignments
any& operator=(const any& rhs);
any& operator=(any&& rhs) noexcept;
template<class T>
    any& operator=(T&& rhs);

// 22.7.4.4, modifiers
template<class T, class... Args>
    decay_t<T>& emplace(Args&&...);
template<class T, class U, class... Args>
    decay_t<T>& emplace(initializer_list<U>, Args&&...);
void reset() noexcept;
void swap(any& rhs) noexcept;

// 22.7.4.5, observers
bool has_value() const noexcept;
const type_info& type() const noexcept;
```

---

1. Postconditions: `has_value()` is false.
2. Effects: If `other.has_value()` is false, constructs an object that has no value. Otherwise, equivalent to `any(in_place_type<T>, any_cast<const T&>(other))` where `T` is the type of the contained value.
3. Throws: Any exceptions arising from calling the selected constructor for the contained value.
4. Effects: If `other.has_value()` is false, constructs an object that has no value. Otherwise, constructs an object of type `any` that contains either the contained value of `other`, or contains an object of the same type constructed from the contained value of `other` considering that contained value as an rvalue.
template<class T>
  any(T&& value);

Let VT be decay_t<T>.

Constraints: VT is not the same type as any, VT is not a specialization of in_place_type_t, and is_copy_constructible_v<VT> is true.

Preconditions: VT meets the Cpp17CopyConstructible requirements.

Effects: Constructs an object of type any that contains an object of type VT direct-initialized with std::forward<T>(value).

Throws: Any exception thrown by the selected constructor of VT.

template<class T, class... Args>
explicit any(in_place_type_t<T>, Args&&... args);

Let VT be decay_t<T>.

Constraints: is_copy_constructible_v<VT> is true and is_constructible_v<VT, Args...> is true.

Preconditions: VT meets the Cpp17CopyConstructible requirements.

Effects: Direct-non-list-initializes the contained value of type VT with std::forward<Args>(args)....

Postconditions: *this contains a value of type VT.

Throws: Any exception thrown by the selected constructor of VT.

template<class T, class U, class... Args>
explicit any(in_place_type_t<T>, initializer_list<U> il, Args&&... args);

Let VT be decay_t<T>.

Constraints: is_copy_constructible_v<VT> is true and is_constructible_v<VT, initializer_list<U>&, Args...> is true.

Preconditions: VT meets the Cpp17CopyConstructible requirements.

Effects: Direct-non-list-initializes the contained value of type VT with il, std::forward<Args>(args)....

Postconditions: *this contains a value.

Throws: Any exception thrown by the selected constructor of VT.

~any();

Effects: As if by reset().

22.7.4.3 Assignment [any.assign]

any& operator=(const any& rhs);

Effects: As if by any(rhs).swap(*this). No effects if an exception is thrown.

Returns: *this.

Throws: Any exceptions arising from the copy constructor for the contained value.

any& operator=(any&& rhs) noexcept;

Effects: As if by any(std::move(rhs)).swap(*this).

Postconditions: The state of *this is equivalent to the original state of rhs.

Returns: *this.

template<class T>
any& operator=(T&& rhs);

Let VT be decay_t<T>.

Constraints: VT is not the same type as any and is_copy_constructible_v<VT> is true.

Preconditions: VT meets the Cpp17CopyConstructible requirements.
Constructs an object \texttt{tmp} of type \texttt{any} that contains an object of type \texttt{VT} direct-initialized with \texttt{std::forward<T>(rhs)}, and \texttt{tmp.swap(*this)}. No effects if an exception is thrown.

Returns: \texttt{*this}.

Throws: Any exception thrown by the selected constructor of \texttt{VT}.

22.7.4.4 Modifiers

\begin{verbatim}
template<class T, class... Args>
  decay_t<T>& emplace(Args&&... args);
\end{verbatim}

Let \texttt{VT} be \texttt{decay_t<T>}.

Constraints: \texttt{is_copy_constructible_v<VT>} is true and \texttt{is_constructible_v<VT, Args...>} is true.

Preconditions: VT meets the \texttt{Cpp17CopyConstructible} requirements.

Effects: Calls \texttt{reset()}. Then direct-non-list-initializes the contained value of type \texttt{VT} with \texttt{std::forward<Args>(args)...}.

Postconditions: \texttt{*this} contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of \texttt{VT}.

Remarks: If an exception is thrown during the call to \texttt{VT’s constructor}, \texttt{*this} does not contain a value, and any previously contained value has been destroyed.

\begin{verbatim}
template<class T, class U, class... Args>
  decay_t<T>& emplace(initializer_list<U> il, Args&&... args);
\end{verbatim}

Let \texttt{VT} be \texttt{decay_t<T>}.

Constraints: \texttt{is_copy_constructible_v<VT>} is true and \texttt{is_constructible_v<VT, initializer_list<U>&, Args...>} is true.

Preconditions: \texttt{VT} meets the \texttt{Cpp17CopyConstructible} requirements.

Effects: Calls \texttt{reset()}. Then direct-non-list-initializes the contained value of type \texttt{VT} with \texttt{il, std::forward<Args>(args)...}.

Postconditions: \texttt{*this} contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of \texttt{VT}.

Remarks: If an exception is thrown during the call to \texttt{VT’s constructor}, \texttt{*this} does not contain a value, and any previously contained value has been destroyed.

\begin{verbatim}
void reset() noexcept;
\end{verbatim}

Effects: If \texttt{has_value()} is \texttt{true}, destroys the contained value.

Postconditions: \texttt{has_value()} is \texttt{false}.

\begin{verbatim}
void swap(any& rhs) noexcept;
\end{verbatim}

Effects: Exchanges the states of \texttt{*this} and \texttt{rhs}.

22.7.4.5 Observers

\begin{verbatim}
bool has_value() const noexcept;
\end{verbatim}

Returns: \texttt{true} if \texttt{*this} contains an object, otherwise \texttt{false}.

\begin{verbatim}
const type_info& type() const noexcept;
\end{verbatim}

Returns: \texttt{typeid(T)} if \texttt{*this} has a contained value of type \texttt{T}, otherwise \texttt{typeid(void)}.

\[\text{Note 1: Useful for querying against types known either at compile time or only at runtime.} \text{— end note}\]
22.7.5 Non-member functions

```cpp
void swap(any& x, any& y) noexcept;
```

**Effects:** Equivalent to `x.swap(y)`.

```cpp
template<class T, class... Args>
any make_any(Args&&... args);
```

**Effects:** Equivalent to: `return any(in_place_type<T>, std::forward<Args>(args)...);`

```cpp
template<class T, class U, class... Args>
any make_any(initializer_list<U> il, Args&&... args);
```

**Effects:** Equivalent to: `return any(in_place_type<T>, il, std::forward<Args>(args)...);`

```cpp
template<class T>
T any_cast(const any& operand);
```

```cpp
template<class T>
T any_cast(any& operand);
```

```cpp
template<class T>
T any_cast(any&& operand);
```

Let `U` be the type `remove_cvref_t<T>`.

**Mandates:** For the first overload, `is_constructible_v<T, const U&>` is true. For the second overload, `is_constructible_v<T, U&>` is true. For the third overload, `is_constructible_v<T, U>` is true.

**Returns:** For the first and second overload, `static_cast<T>(*any_cast<U>(&operand))`. For the third overload, `static_cast<T>(std::move(*any_cast<U>(&operand)))`.

**Throws:** `bad_any_cast` if `operand.type() != typeid(remove_reference_t<T>)`.

**Example 1:**

```cpp
any x(5);
assert(any_cast<int>(x) == 5); // cast to value
assert_cast<int&>(x) = 10; // cast to reference
assert_cast<int>(x) == 10; // cast to value

x = \"Meow\"; // x holds const char*
assert(strcmp(any_cast<const char*>(x), \"Meow\") == 0);
any_cast<const char&>(x) = \"Harry\";
assert(strcmp(any_cast<const char*>(x), \"Harry\") == 0);

x = string("Meow"); // x holds string
string s, s2("Jane");
s = move(any_cast<string&>(x)); // move from any
assert(s == \"Meow\");
any_cast<string&>(x) = move(s2); // move to any
assert(any_cast<const string&>(x) == \"Jane\"); // error: cannot any_cast away const
```

**Example 2:**

```cpp
 any_cast<string&>(y);
```

```cpp
template<class T>
const T* any_cast(const any* operand) noexcept;
```

```cpp
template<class T>
T* any_cast(any* operand) noexcept;
```

**Returns:** If `operand != nullptr && operand->type() != typeid(T)`, a pointer to the object contained by `operand`; otherwise, `nullptr`.

```cpp
[Example 2:
```
bool is_string(const any& operand) {
    return any_cast<string>(&operand) != nullptr;
}

— end example]

22.8  Expected objects

22.8.1  In general

Subclause 22.8 describes the class template expected that represents expected objects. An expected<T, E> object holds an object of type T or an object of type unexpected<E> and manages the lifetime of the contained objects.

22.8.2  Header <expected> synopsis

namespace std {
    // 22.8.3, class template unexpected
    template<class E> class unexpected;

    // 22.8.4, class template bad_expected_access
    template<class E> class bad_expected_access;

    // 22.8.5, specialization for void
    template<> class bad_expected_access<void>;

    // in-place construction of unexpected values
    struct unexpect_t {
        explicit unexpect_t() = default;
    };

    inline constexpr unexpect_t unexpect{};

    // 22.8.6, class template expected
    template<class T, class E> class expected;

    // 22.8.7, partial specialization of expected for void types
    template<class T, class E> requires is_void_v<T> class expected<T, E>;
}
constexpr void swap(unexpected& other) noexcept;

template<
    class E2>
friend constexpr bool operator==(const unexpected&, const unexpected<E2>&);

friend constexpr void swap(unexpected& x, unexpected& y) noexcept(noexcept(x.swap(y)));

private:
    E unex; // exposition only
};

template<class E> unexpected(E) -> unexpected<E>;

2 A program that instantiates the definition of unexpected for a non-object type, an array type, a specialization of unexpected, or a cv-qualified type is ill-formed.

22.8.3.2 Constructors

template<
    class Err = E>
constexpr explicit unexpected(Err&& e);

Constraints:
(1.1) is_same_v<remove_cvref_t<Err>, unexpected> is false; and
(1.2) is_same_v<remove_cvref_t<Err>, in_place_t> is false; and
(1.3) is_constructible_v<E, Err> is true.

Effects: Direct-non-list-initializes unex with std::forward<Err>(e).

Throws: Any exception thrown by the initialization of unex.

template<
    class... Args>
constexpr explicit unexpected(in_place_t, Args&&... args);

Constraints: is_constructible_v<E, Args...> is true.

Effects: Direct-non-list-initializes unex with std::forward<Args>(args)....

Throws: Any exception thrown by the initialization of unex.

template<
    class U, class... Args>
constexpr explicit unexpected(in_place_t, initializer_list<U> il, Args&&... args);

Constraints: is_constructible_v<E, initializer_list<U>&, Args...> is true.

Effects: Direct-non-list-initializes unex with il, std::forward<Args>(args)....

Throws: Any exception thrown by the initialization of unex.

22.8.3.3 Observers

constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
constexpr E&& error() && noexcept;

Returns: unex.

22.8.3.4 Swap

constexpr void swap(unexpected& other) noexcept(is_nothrow_swappable_v<E>);

Mandates: is_swappable_v<E> is true.

Effects: Equivalent to: using std::swap; swap(unex, other.unex);
friend constexpr void swap(unexpected& x, unexpected& y) noexcept(noexcept(x.swap(y)));  

Constraints: is_swappable_v<E> is true.

Effects: Equivalent to x.swap(y).

22.8.3.5 Equality operator

```
template<class E2>
friend constexpr bool operator==(const unexpected& x, const unexpected<E2>& y);
```

Mandates: The expression x.error() == y.error() is well-formed and its result is convertible to bool.

Returns: x.error() == y.error().

22.8.4 Class template bad_expected_access

```
namespace std {
    template<class E>
    class bad_expected_access : public bad_expected_access<void> {
        public:
            explicit bad_expected_access(E);
            const char* what() const noexcept override;
            E& error() & noexcept;
            const E& error() const & noexcept;
            E&& error() && noexcept;
            const E&& error() const && noexcept;

        private:
            E unex;  // exposition only
    };
}
```

The class template bad_expected_access defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an expected<T, E> object for which has_value() is false.

```
explicit bad_expected_access(E e);
```

Effects: Initializes unex with std::move(e).

```
const E& error() const & noexcept;
E& error() & noexcept;
```

Returns: unex.

```
E&& error() && noexcept;
const E&& error() const && noexcept;
```

Returns: std::move(unex).

```
const char* what() const noexcept override;
```

Returns: An implementation-defined Ntbs.

22.8.5 Class template specialization bad_expected_access<void>

```
namespace std {
    template<class>
    class bad_expected_access<void> : public exception {
        protected:
            bad_expected_access() noexcept;
            bad_expected_access(const bad_expected_access&);
            bad_expected_access(bad_expected_access&);  
            bad_expected_access& operator=(const bad_expected_access&);
            bad_expected_access& operator=(bad_expected_access&);
            ~bad_expected_access();
```
public:
  const char* what() const noexcept override;
};

const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

22.8.6 Class template expected  
22.8.6.1 General

namespace std {
  template<class T, class E>
  class expected {
  public:
    using value_type = T;
    using error_type = E;
    using unexpected_type = unexpected<E>;

    template<class U>
    using rebind = expected<U, error_type>;

    // 22.8.6.2, constructors
    constexpr expected();
    constexpr expected(const expected&);
    constexpr expected(expected&&) noexcept;
    template<class U, class G>
    constexpr explicit(expected&) noexcept;
    template<class U, class G>
    constexpr explicit(expected&&) noexcept;
    template<class U = T>
    constexpr explicit(U&& v);
    template<class G>
    constexpr explicit(G&& v);
    template<class... Args>
    constexpr explicit(expected&);  

    template<class U = T> constexpr T& emplace(Args&&...);
    template<class U, class... Args>
    constexpr T& emplace(initializer_list<U>, Args&&...);
  }

  // 22.8.6.3, destructor
  constexpr ~expected();

  // 22.8.6.4, assignment

private:
  bool has_val;  // exposition only
union {
  T val;  // exposition only
  E unex;  // exposition only
};

1 Any object of type expected<T, E> either contains a value of type T or a value of type E within its own storage. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate
the object of type T or the object of type E. Member \texttt{has\_val} indicates whether the \texttt{expected<T, E>} object contains an object of type T.

2 A type T is a valid value type for \texttt{expected}, if \texttt{remove\_cv\_t<T>} is void or a complete non-array object type that is not \texttt{in\_place\_t}, \texttt{unexpected\_t}, or a specialization of \texttt{unexpected}. A program which instantiates class template \texttt{expected<T, E>} with an argument T that is not a valid value type for \texttt{expected} is ill-formed. A program that instantiates the definition of the template \texttt{expected<T, E>} with a type for the E parameter that is not a valid template argument for \texttt{unexpected} is ill-formed.

3 When T is not \texttt{cv void}, it shall meet the \texttt{Cpp17Destructible} requirements (Table 35). E shall meet the \texttt{Cpp17Destructible} requirements.

22.8.6.2 Constructors

The exposition-only variable template \texttt{converts\_from\_any\_cvref} defined in 22.5.3.2 is used by some constructors for \texttt{expected}.

\begin{verbatim}
constexpr expected();
Constraints: \texttt{is\_default\_constructible\_v<T>} is true.
Effects: Value-initializes \texttt{val}.
Postconditions: \texttt{has\_value()} is true.
Throws: Any exception thrown by the initialization of \texttt{val}.

constexpr expected(const expected& rhs);
Effects: If \texttt{rhs.has\_value()} is true, direct-non-list-initializes \texttt{val} with \texttt{*rhs}. Otherwise, direct-non-list-initializes \texttt{unex} with \texttt{rhs.error()}.
Postconditions: \texttt{rhs.has\_value()} == \texttt{this->has\_value()}.
Throws: Any exception thrown by the initialization of \texttt{val} or \texttt{unex}.
Remarks: This constructor is defined as deleted unless

\begin{enumerate}
\item \texttt{is\_copy\_constructible\_v<T>} is true and
\item \texttt{is\_copy\_constructible\_v<E>} is true.
\end{enumerate}
This constructor is trivial if

\begin{enumerate}
\item \texttt{is\_trivially\_copy\_constructible\_v<T>} is true and
\item \texttt{is\_trivially\_copy\_constructible\_v<E>} is true.
\end{enumerate}

constexpr expected(expected&& rhs) noexcept;
Constraints:

\begin{enumerate}
\item \texttt{is\_move\_constructible\_v<T>} is true and
\item \texttt{is\_move\_constructible\_v<E>} is true.
\end{enumerate}
Effects: If \texttt{rhs.has\_value()} is true, direct-non-list-initializes \texttt{val} with \texttt{std::move(*rhs)}. Otherwise, direct-non-list-initializes \texttt{unex} with \texttt{std::move(rhs.error())}.
Postconditions: \texttt{rhs.has\_value()} is unchanged; \texttt{rhs.has\_value()} == \texttt{this->has\_value()} is true.
Throws: Any exception thrown by the initialization of \texttt{val} or \texttt{unex}.
Remarks: The exception specification is equivalent to \texttt{is\_nothrow\_move\_constructible\_v<T>} && \texttt{is\_nothrow\_move\_constructible\_v<E>}.
This constructor is trivial if

\begin{enumerate}
\item \texttt{is\_trivially\_move\_constructible\_v<T>} is true and
\item \texttt{is\_trivially\_move\_constructible\_v<E>} is true.
\end{enumerate}

\begin{verbatim}
template<class U, class G>
constexpr explicit(see below) expected(const expected<U, G>& rhs);
template<class U, class G>
constexpr explicit(see below) expected(expected<U, G>&& rhs);
\end{verbatim}
\end{verbatim}
— UF be const U& for the first overload and U for the second overload.
— GF be const G& for the first overload and G for the second overload.

Constraints:

— is_constructible_v<T, UF> is true; and
— is_constructible_v<E, GF> is true; and
— if T is not cv bool, converts-from-any-cvref<T, expected<U, G>> is false; and
— is_constructible_v<unexpected<E>, expected<U, G>>& is false; and
— is_constructible_v<unexpected<E>, expected<U, G>> is false; and
— is_constructible_v<unexpected<E>, const expected<U, G>>& is false; and
— is_constructible_v<unexpected<E>, const expected<U, G>> is false.

Effects: If rhs.has_value(), direct-non-list-initializes val with std::forward<UF>(*rhs). Otherwise, direct-non-list-initializes unex with std::forward<GF>(rhs.error()).

Postconditions: rhs.has_value() is unchanged; rhs.has_value() == this->has_value() is true.

Throes: Any exception thrown by the initialization of val or unex.

Remarks: The expression inside explicit is equivalent to !is_convertible_v<UF, T> || !is_convertible_v<GF, E>.

```cpp
template<class U = T>
constexpr explicit(!is_convertible_v<U, T>) expected(U&& v);
```

Constraints:

— is_same_v<remove_cvref_t<U>, in_place_t> is false; and
— is_same_v<expected, remove_cvref_t<U>> is false; and
— remove_cvref_t<U> is not a specialization of unexpected; and
— is_constructible_v<T, U> is true; and
— if T is cv bool, remove_cvref_t<U> is not a specialization of expected.

Effects: Direct-non-list-initializes val with std::forward<UF>(v).

Postconditions: has_value() is true.

Throws: Any exception thrown by the initialization of val.

```cpp
template<class G>
constexpr explicit(!is_convertible_v<const G&, E>) expected(const unexpected<G>& e);
```

Let GF be const G& for the first overload and G for the second overload.

Constraints: is_constructible_v<E, GF> is true.

Effects: Direct-non-list-initializes unex with std::forward<GF>(e.error()).

Postconditions: has_value() is false.

Throws: Any exception thrown by the initialization of unex.

```cpp
template<class... Args>
constexpr explicit expected(in_place_t, Args&&... args);
```

Constraints: is_constructible_v<T, Args...> is true.

Effects: Direct-non-list-initializes val with std::forward<Args>(args)....

Postconditions: has_value() is true.

Throws: Any exception thrown by the initialization of val.

```cpp
template<class U, class... Args>
constexpr explicit expected(in_place_t, initializer_list<U> il, Args&&... args);
```

Constraints: is_constructible_v<T, initializer_list<U>&, Args...> is true.
Effects: Direct-non-list-initializes \texttt{val} with \texttt{il}, std::forward<\texttt{Args}>(\texttt{args})....

Postconditions: \texttt{has_value()} is true.

Throws: Any exception thrown by the initialization of \texttt{val}.

\begin{verbatim}
template<class... Args>
constexpr explicit expected(unexpect_t, Args&&... args);
\end{verbatim}

Effects: Direct-non-list-initializes \texttt{unex} with std::forward<\texttt{Args}>(\texttt{args})....

Postconditions: \texttt{has_value()} is false.

Throws: Any exception thrown by the initialization of \texttt{unex}.

\begin{verbatim}
template<class U, class... Args>
constexpr explicit expected(unexpect_t, initializer_list<U> il, Args&&... args);
\end{verbatim}

Effects: Direct-non-list-initializes \texttt{unex} with \texttt{il}, std::forward<\texttt{Args}>(\texttt{args})....

Postconditions: \texttt{has_value()} is false.

Throws: Any exception thrown by the initialization of \texttt{unex}.

22.8.6.3 Destructor [expected.object.dtor]

constexpr ~expected();

Effects: If \texttt{has_value()} is true, destroys \texttt{val}, otherwise destroys \texttt{unex}.

Remarks: If is_trivially_destructible_v<T> is true, and is_trivially_destructible_v<E> is true, then this destructor is a trivial destructor.

22.8.6.4 Assignment [expected.object.assign]

This subclause makes use of the following exposition-only function:

\begin{verbatim}
template<class T, class U, class... Args>
constexpr void reinit-expected(T& newval, U& oldval, Args&&... args) { // exposition only
  if constexpr (is_nothrow_constructible_v<T, Args...>) {
    destroy_at(addressof(oldval));
    construct_at(addressof(newval), std::forward<Args>(args)...);
  } else if constexpr (is_nothrow_move_constructible_v<T>) {
    T tmp(std::forward<Args>(args)...);
    destroy_at(addressof(oldval));
    construct_at(addressof(newval), std::move(tmp));
  } else {
    U tmp(std::move(oldval));
    destroy_at(addressof(oldval));
    try {
      construct_at(addressof(newval), std::forward<Args>(args)...);
    } catch (...) {
      construct_at(addressof(oldval), std::move(tmp));
      throw;
    }
  }
}
\end{verbatim}

constexpr expected& operator=(const expected& rhs);

Effects:

(2.1) — If this->\texttt{has_value()} \&\& rhs.\texttt{has_value()} is true, equivalent to \texttt{val} = \*rhs.

(2.2) — Otherwise, if this->\texttt{has_value()} is true, equivalent to:

\texttt{reinit-expected}(\texttt{unex}, \texttt{val}, rhs.error())

(2.3) — Otherwise, if rhs.\texttt{has_value()} is true, equivalent to:

\texttt{reinit-expected}(\texttt{val}, \texttt{unex}, \*rhs)
— Otherwise, equivalent to `unex = rhs.error()`.

Then, if no exception was thrown, equivalent to: `has_val = rhs.has_value(); return *this;`

*Returns:* `*this`.

*Remarks:* This operator is defined as deleted unless:

1. `is_copy_assignable_v<T>` is true and
2. `is_copy_constructible_v<T>` is true and
3. `is_copy_assignable_v<E>` is true and
4. `is_copy_constructible_v<E>` is true and
5. `is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is true.

```cpp
constexpr expected& operator=(expected&& rhs) noexcept;
```

*Constraints:*

1. `is_move_constructible_v<T>` is true and
2. `is_move_assignable_v<T>` is true and
3. `is_move_constructible_v<E>` is true and
4. `is_move_assignable_v<E>` is true and
5. `is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E>` is true.

*Effects:*

1. If `this->has_value()` && `rhs.has_value()` is true, equivalent to `val = std::move(*rhs)`.
2. Otherwise, if `this->has_value()` is true, equivalent to:
   ```cpp
   reinit-expected(unex, val, std::move(rhs.error()))
   ```
3. Otherwise, if `rhs.has_value()` is true, equivalent to:
   ```cpp
   reinit-expected(val, unex, std::move(*rhs))
   ```
4. Otherwise, equivalent to `unex = std::move(rhs.error())`.

Then, if no exception was thrown, equivalent to: `has_val = rhs.has_value(); return *this;`

*Returns:* `*this`.

*Remarks:* The exception specification is equivalent to:

```cpp
template<class U = T>
constexpr expected& operator=(U&& v);
```

*Constraints:*

1. `is_same_v<expected, remove_cvref_t<U>>` is false; and
2. `remove_cvref_t<U>` is not a specialization of `unexpected`; and
3. `is_constructible_v<T, U>` is true; and
4. `isAssignable_v<T&, U>` is true; and
5. `is_nothrow_move_constructible_v<T, U> || is_nothrow_move_constructible_v<T> && is_nothrow_move_constructible_v<E> && is_nothrow_move_constructible_v<E>` is true.

*Effects:*

1. If `has_value()` is true, equivalent to: `val = std::forward<U>(v)`;
2. Otherwise, equivalent to:
   ```cpp
   reinit-expected(val, unex, std::forward<U>(v));
   has_val = true;
   ```

*Returns:* `*this`. 

§ 22.8.6.4 743
template<class G>
constexpr expected& operator=(const unexpected<G>& e);
template<class G>
constexpr expected& operator=(unexpected<G>&& e);

Let GF be const G& for the first overload and G for the second overload.

Constraints:

(13.1) is_constructible_v<E, GF> is true; and
(13.2) is_assignable_v<E&, GF> is true; and
(13.3) is_nothrow_constructible_v<E, GF> || is_nothrow_move_constructible_v<T> ||
       is_nothrow_move_constructible_v<E> is true.

Effects:

(14.1) If has_value() is true, equivalent to:
       reinit-expected(unex, val, std::forward<GF>(e.error()));
       has_val = false;
(14.2) Otherwise, equivalent to: unex = std::forward<GF>(e.error());

Returns: *this.

template<class... Args>
constexpr T& emplace(Args&&... args) noexcept;

Constraints: is_nothrow_constructible_v<T, Args...> is true.

Effects: Equivalent to:

if (has_value()) {
    destroy_at(addressof(val));
} else {
    destroy_at(addressof(unex));
    has_val = true;
}
return *construct_at(addressof(val), std::forward<Args>(args)...);

template<class U, class... Args>
constexpr T& emplace(initializer_list<U> il, Args&&... args) noexcept;

Constraints: is_nothrow_constructible_v<T, initializer_list<U>&, Args...> is true.

Effects: Equivalent to:

if (has_value()) {
    destroy_at(addressof(val));
} else {
    destroy_at(addressof(unex));
    has_val = true;
}
return *construct_at(addressof(val), il, std::forward<Args>(args)...);

22.8.6.5 Swap [expected.object.swap]

constexpr void swap(expected& rhs) noexcept(see below);

Constraints:

(1.1) is_swappable_v<T> is true and
(1.2) is_swappable_v<E> is true and
(1.3) is_move_constructible_v<T> && is_move_constructible_v<E> is true, and
(1.4) is_nothrow_move_constructible_v<T> || is_nothrow_move_constructible_v<E> is true.

Effects: See Table 63.

For the case where rhs.value() is false and this->has_value() is true, equivalent to:

if constexpr (is_nothrow_move_constructible_v<E>) {
    E tmp(std::move(rhs.unex));
Table 63: swap(expected&) effects

<table>
<thead>
<tr>
<th>this-&gt;has_value()</th>
<th>!this-&gt;has_value()</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs.has_value()</td>
<td>equivalent to: using std::swap; swap(val, rhs.val); calls rhs.swap(*this)</td>
</tr>
<tr>
<td>!rhs.has_value()</td>
<td>see below</td>
</tr>
</tbody>
</table>

```
destroy_at(addressof(rhs.unex));
try {
    construct_at(addressof(rhs.val), std::move(val));
    destroy_at(addressof(val));
    construct_at(addressof(unex), std::move(tmp));
} catch(...) {
    construct_at(addressof(rhs.unex), std::move(tmp));
    throw;
}
} else {
    T tmp(std::move(val));
    destroy_at(addressof(val));
    try {
        construct_at(addressof(unex), std::move(rhs.unex));
        destroy_at(addressof(rhs.unex));
        construct_at(addressof(rhs.val), std::move(tmp));
    } catch(...) {
        construct_at(addressof(val), std::move(tmp));
        throw;
    }
}
has_val = false;
rhs.has_val = true;
```

3 **Throws:** Any exception thrown by the expressions in the Effects.

4 **Remarks:** The exception specification is equivalent to:

```
is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T> && is_nothrow_move_constructible_v<E> && is_nothrow_swappable_v<E>
```

5 **Effects:** Equivalent to x.swap(y).

22.8.6.6 Observers

```
constexpr const T* operator->() const noexcept;
constexpr T* operator->() noexcept;
```

1 **Preconditions:** has_value() is true.

2 **Returns:** addressof(val).

```
constexpr const Tk* operator*() const & noexcept;
constexpr Tk* operator*() & noexcept;
```

3 **Preconditions:** has_value() is true.

4 **Returns:** val.

```
constexpr Tk& operator*() & noexcept;
constexpr const Tk& operator*() const & noexcept;
```

5 **Preconditions:** has_value() is true.

6 **Returns:** std::move(val).

constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;

Returns: has_val.

constexpr const T& value() const &;
constexpr T& value() &;

Mandates: is_copy_constructible_v<E> is true.

Returns: val, if has_value() is true.

Throws: bad_expected_access(as_const(error())) if has_value() is false.

constexpr T&& value() &&;
constexpr const T&& value() const &&;

Mandates: is_copy_constructible_v<E> is true.

Returns: std::move(val), if has_value() is true.

Throws: bad_expected_access(std::move(error())) if has_value() is false.

constexpr E& error() & noexcept;
constexpr const E& error() const & noexcept;

Preconditions: has_value() is false.

Returns: unex.

constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;

Preconditions: has_value() is false.

Returns: std::move(unex).

template<class U> constexpr T value_or(U&& v) const &;

Mandates: is_copy_constructible_v<T> is true and is_convertible_v<U, T> is true.

Returns: has_value() ? **this : static_cast<T>(std::forward<U>(v)).

template<class U> constexpr T value_or(U&& v) &&;

Mandates: is_move_constructible_v<T> is true and is_convertible_v<U, T> is true.

Returns: has_value() ? std::move(**this) : static_cast<T>(std::forward<U>(v)).

template<class G = E> constexpr E error_or(G&& e) const &;

Mandates: is_copy_constructible_v<E> is true and is_convertible_v<G, E> is true.

Returns: std::forward<G>(e) if has_value() is true, error() otherwise.

template<class G = E> constexpr E error_or(G&& e) &&;

Mandates: is_move_constructible_v<E> is true and is_convertible_v<G, E> is true.

Returns: std::forward<G>(e) if has_value() is true, std::move(error()) otherwise.

### 22.8.6.7 Monadic operations

Let U be remove_cvref_t<invoke_result_t<F, decltype(value())>>.

Constraints: is_constructible_v<E, decltype(error())> is true.

Mandates: U is a specialization of expected and is_same_v<U::error_type, E> is true.

Effects: Equivalent to:

```cpp
if (has_value())
    return invoke(std::forward<F>(f), value());
else
    return U(unexpect, error());
```
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;

Let U be remove_cvref_t<invoke_result_t<F, decltype(std::move(value()))>>.
Constraints: is_constructible_v<E, decltype(std::move(error()))> is true.
Mandates: U is a specialization of expected and is_same_v<U::error_type, E> is true.
Effects: Equivalent to:
    if (has_value())
        return invoke(std::forward<F>(f), std::move(value()));
    else
        return U(unexpect, std::move(error()));

template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) const &;

Let G be remove_cvref_t<invoke_result_t<F, decltype(error())>>.
Constraints: is_constructible_v<T, decltype(value())> is true.
Mandates: G is a specialization of expected and is_same_v<G::value_type, T> is true.
Effects: Equivalent to:
    if (has_value())
        return G(in_place, value());
    else
        return invoke(std::forward<F>(f), error());

template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;

Let U be remove_cvref_t<invoke_result_t<F, decltype(std::move(value()))>>.
Constraints: is_constructible_v<E, decltype(std::move(error()))> is true.
Mandates: U is a specialization of expected and is_same_v<U::error_type, E> is true.
Effects:
    — If has_value() is false, returns expected<U, E>(unexpect, error()).
    — Otherwise, if is_void_v<U> is false, returns an expected<U, E> object whose has_val member is true and val member is direct-non-list-initialized with invoke(std::forward<F>(f), value()).
    — Otherwise, evaluates invoke(std::forward<F>(f), value()) and then returns expected<U, E>().

§ 22.8.6.7
Mandates: U is a valid value type for expected. If is_void_v<U> is false, the declaration
U u(invoke(std::forward<F>(f), std::move(value())));
is well-formed for some invented variable u.

Effects:
(24.1) If has_value() is false, returns expected<U, E>(unexpect, std::move(error())).
(24.2) Otherwise, if is_void_v<U> is false, returns an expected<U, E> object whose has_val member is true and val member is direct-non-list-initialized with invoke(std::forward<F>(f), std::move(value())).
(24.3) Otherwise, evaluates invoke(std::forward<F>(f), std::move(value())) and then returns expected<U, E>().

template<class F> constexpr auto transform_error(F&& f) &;
template<class F> constexpr auto transform_error(F&& f) const &;

Let G be remove_cv_t<invoke_result_t<F, decltype(error())>>.

Constraints: is_constructible_v<T, decltype(value())> is true.

Mandates: G is a valid template argument for unexpected (22.8.3.1) and the declaration
G g(invoke(std::forward<F>(f), value()));
is well-formed.

Returns: If has_value() is true, expected<T, G>(in_place, value()); otherwise, an expected<T, G> object whose has_val member is false and unex member is direct-non-list-initialized with invoke(std::forward<F>(f), error()).

template<class F> constexpr auto transform_error(F&& f) &&;
template<class F> constexpr auto transform_error(F&& f) const &&;

Let G be remove_cv_t<invoke_result_t<F, decltype(std::move(error()))>>.

Constraints: is_constructible_v<T, decltype(value())> is true.

Mandates: G is a valid template argument for unexpected (22.8.3.1) and the declaration
G g(invoke(std::forward<F>(f), std::move(error())));
is well-formed.

Returns: If has_value() is true, expected<T, G>(in_place, std::move(value())); otherwise, an expected<T, G> object whose has_val member is false and unex member is direct-non-list-initialized with invoke(std::forward<F>(f), std::move(error())).

22.8.6.8 Equality operators

template<class T2, class E2> requires (!is_void_v<T2>)
friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);

Mandates: The expressions *x == *y and x.error() == y.error() are well-formed and their results are convertible to bool.

Returns: If x.has_value() does not equal y.has_value(), false; otherwise if x.has_value() is true, *x == *y; otherwise x.error() == y.error().

template<class T2> friend constexpr bool operator==(const expected& x, const T2& v);

Mandates: The expression *x == v is well-formed and its result is convertible to bool.

[Note 1: T need not be Cpp17EqualityComparable. — end note]

Returns: x.has_value() && static_cast<bool>(*x == v).

template<class E2> friend constexpr bool operator==(const expected& x, const unexpected<E2>& e);

Mandates: The expression x.error() == e.error() is well-formed and its result is convertible to bool.

Returns: !x.has_value() && static_cast<bool>(x.error() == e.error()).
22.8.7 Partial specialization of expected for void types

22.8.7.1 General

```cpp
template<class T, class E> requires is_void_v<T>
class expected<T, E> {
    public:
        using value_type = T;
        using error_type = E;
        using unexpected_type = unexpected<E>;

        template<class U>
        using rebind = expected<U, error_type>;

    // 22.8.7.2, constructors
    constexpr expected() noexcept;
    constexpr expected(const expected&);
    constexpr expected(expected&&) noexcept(
        see below);
    template<class U, class G>
    constexpr explicit(see below) expected(const expected<U, G>&);
    template<class U, class G>
    constexpr explicit(see below) expected(expected<U, G>&&);

    template<class G>
    constexpr explicit(see below) expected(const unexpected<G>&);
    template<class G>
    constexpr explicit(see below) expected(unexpected<G>&&);

    constexpr explicit expected(in_place_t) noexcept;
    template<class... Args>
    constexpr explicit expected(unexpect_t, Args&&...);
    template<class U, class... Args>
    constexpr explicit expected(unexpect_t, initializer_list<U>, Args&&...);

    // 22.8.7.3, destructor
    constexpr ~expected();

    // 22.8.7.4, assignment
    constexpr expected& operator=(const expected&);
    constexpr expected& operator=(expected&&) noexcept(
        see below);
    template<class G>
    constexpr expected& operator=(const unexpected<G>&);
    template<class G>
    constexpr expected& operator=(unexpected<G>&&);
    constexpr void emplace() noexcept;

    // 22.8.7.5, swap
    constexpr void swap(expected&) noexcept(
        see below);
    friend constexpr void swap(expected& x, expected& y) noexcept(
        noexcept(x.swap(y)));

    // 22.8.7.6, observers
    constexpr explicit operator bool() const noexcept;
    constexpr bool has_value() const noexcept;
    constexpr void operator*() const noexcept;
    constexpr void value() const &;
    constexpr void value() &&;
    constexpr const E& error() const & noexcept;
    constexpr E& error() & noexcept;
    constexpr const E&& error() const && noexcept;
    constexpr E&& error() && noexcept;
    template<class G = E>
    constexpr E error_or(G&&) const &;
    template<class G = E>
    constexpr E error_or(G&&) &&;
```

§ 22.8.7.1
// 22.8.7.7, monadic operations

```cpp
template<class F> constexpr auto and_then(F&& f) &;
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &;
template<class F> constexpr auto and_then(F&& f) const &&;
template<class F> constexpr auto or_else(F&& f) &;
template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &;
template<class F> constexpr auto or_else(F&& f) const &&;
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &;
template<class F> constexpr auto transform(F&& f) const &&;
template<class F> constexpr auto transform_error(F&& f) &;
template<class F> constexpr auto transform_error(F&& f) &&;
template<class F> constexpr auto transform_error(F&& f) const &;
template<class F> constexpr auto transform_error(F&& f) const &&;
```

// 22.8.7.8, equality operators

```cpp
template<class T2, class E2> requires is_void_v<T2>
friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);
template<class E2>
friend constexpr bool operator==(const expected&, const unexpected<E2>&);
```

```cpp
private:
    bool has_val; // exposition only
    union {
        E unex; // exposition only
    }; // exposition only
```

1. Any object of type `expected<T, E>` either represents a value of type `T`, or contains a value of type `E` within its own storage. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the object of type `E`. Member `has_val` indicates whether the `expected<T, E>` object represents a value of type `T`.

2. A program that instantiates the definition of the template `expected<T, E>` with a type for the `E` parameter that is not a valid template argument for `unexpected` is ill-formed.

3. `E` shall meet the requirements of `Cpp17Destructible` (Table 35).

### 22.8.7.2 Constructors

```cpp
constexpr expected() noexcept;
```

**Postconditions:** `has_value()` is true.

```cpp
constexpr expected(const expected& rhs);
```

**Effects:** If `rhs.has_value()` is false, direct-non-list-initializes `unex` with `rhs.error()`.

**Postconditions:** `rhs.has_value()` == `this->has_value()`.

**Throws:** Any exception thrown by the initialization of `unex`.

**Remarks:** This constructor is defined as deleted unless `is_copy_constructible_v<E>` is true.

This constructor is trivial if `is_trivially_copy_constructible_v<E>` is true.

```cpp
constexpr expected(expected&& rhs) noexcept(is_nothrow_move_constructible_v<E>);
```

**Effects:** If `rhs.has_value()` is false, direct-non-list-initializes `unex` with `std::move(rhs.error())`.

**Postconditions:** `rhs.has_value()` is unchanged; `rhs.has_value()` == `this->has_value()` is true.

**Throws:** Any exception thrown by the initialization of `unex`.

**Remarks:** This constructor is trivial if `is_trivially_move_constructible_v<E>` is true.

§ 22.8.7.2 750
template<class U, class G>
constexpr explicit(!is_convertible_v<const G&, E>) expected(const expected<U, G>& rhs);
template<class U, class G>
constexpr explicit(!is_convertible_v<G, E>) expected(expected<U, G>&& rhs);

Let GF be const G& for the first overload and G for the second overload.

Constraints:
(13.1) is_void_v<U> is true; and
(13.2) is_constructible_v<E, GF> is true; and
(13.3) is_constructible_v<unexpected<E>, expected<U, G>&> is false; and
(13.4) is_constructible_v<unexpected<E>, expected<U, G>> is false; and
(13.5) is_constructible_v<expected<U, G>, const expected<U, G>&> is false; and
(13.6) is_constructible_v<unexpected<E>, const expected<U, G>> is false.

Effects: If rhs.has_value() is false, direct-non-list-initializes unex with std::forward<GF>(rhs.error()).

Postconditions: rhs.has_value() is unchanged; rhs.has_value() == this->has_value() is true.

Throws: Any exception thrown by the initialization of unex.

template<class G>
constexpr explicit(!is_convertible_v<const G&, E>) expected(const unexpected<G>& e);
template<class G>
constexpr explicit(!is_convertible_v<G, E>) expected(unexpected<G>&& e);

Let GF be const G& for the first overload and G for the second overload.

Constraints: is_constructible_v<E, GF> is true.

Effects: Direct-non-list-initializes unex with std::forward<GF>(e.error()).

Postconditions: has_value() is false.

Throws: Any exception thrown by the initialization of unex.

constexpr explicit expected(in_place_t) noexcept;

Postconditions: has_value() is true.

template<class... Args>
constexpr explicit expected(unexpect_t, Args&&... args);

Constraints: is_constructible_v<E, Args...> is true.

Effects: Direct-non-list-initializes unex with std::forward<Args>(args)....

Postconditions: has_value() is false.

Throws: Any exception thrown by the initialization of unex.

template<class U, class... Args>
constexpr explicit expected(unexpect_t, initializer_list<U> il, Args&&... args);

Constraints: is_constructible_v<E, initializer_list<U>&, Args...> is true.

Effects: Direct-non-list-initializes unex with il, std::forward<Args>(args)....

Postconditions: has_value() is false.

Throws: Any exception thrown by the initialization of unex.

22.8.7.3 Destructor [expected.void.dtor]

constexpr ~expected();

Effects: If has_value() is false, destroys unex.

Remarks: If is_trivially_destructible_v<E> is true, then this destructor is a trivial destructor.
22.8.7.4 Assignment

```cpp
constexpr expected& operator=(const expected& rhs);
```

**Effects:**

1. If `this->has_value() && rhs.has_value()` is true, no effects.
2. Otherwise, if `this->has_value()` is true, equivalent to: `construct_at(addressof(unex), rhs.unex); has_val = false;`
3. Otherwise, if `rhs.has_value()` is true, destroys `unex` and sets `has_val` to true.
4. Otherwise, equivalent to `unex = rhs.error()`.

**Returns:** `*this`.

**Remarks:** This operator is defined as deleted unless `is_copy_assignable_v<E>` is true and `is_copy_constructible_v<E>` is true.

```cpp
constexpr expected& operator=(expected&& rhs) noexcept;
```

**Effects:**

1. If `this->has_value() && rhs.has_value()` is true, no effects.
2. Otherwise, if `this->has_value()` is true, equivalent to: `construct_at(addressof(unex), std::move(rhs.unex)); has_val = false;`
3. Otherwise, if `rhs.has_value()` is true, destroys `unex` and sets `has_val` to true.
4. Otherwise, equivalent to `unex = std::move(rhs.error())`.

**Returns:** `*this`.

**Remarks:** The exception specification is equivalent to `is_nothrow_move_constructible_v<E> && is_nothrow_move_assignable_v<E>`.

This operator is defined as deleted unless `is_move_constructible_v<E>` is true and `is_move_assignable_v<E>` is true.

```cpp
template<class G>
constexpr expected& operator=(const unexpected<G>& e);
template<class G>
constexpr expected& operator=(unexpected<G>&& e);
```

Let `GF` be `const G&` for the first overload and `G` for the second overload.

**Constraints:** `is_constructible_v<E, GF>` is true and `is_assignable_v<E&, GF>` is true.

**Effects:**

1. If `has_value()` is true, equivalent to: `construct_at(addressof(unex), std::forward<GF>(e.error())); has_val = false;`
2. Otherwise, equivalent to: `unex = std::forward<GF>(e.error());`

**Returns:** `*this`.

```cpp
constexpr void emplace() noexcept;
```

**Effects:** If `has_value()` is false, destroys `unex` and sets `has_val` to true.

22.8.7.5 Swap

```cpp
constexpr void swap(expected& rhs) noexcept;
```

**Constraints:** `is_swappable_v<E>` is true and `is_move_constructible_v<E>` is true.

**Effects:** See Table 64.

For the case where `rhs.value()` is false and `this->has_value()` is true, equivalent to:

```cpp
construct_at(addressof(unex), std::move(rhs.unex));
has_val = false;
```
friend constexpr void swap(expected& x, expected& y) noexcept(noexcept(x.swap(y)));

22.8.7.6 Observers

constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;

Returns: has_val.

constexpr void operator*() const noexcept;
Preconditions: has_value() is true.

constexpr void value() const &;
Throws: bad_expected_access(error()) if has_value() is false.

constexpr void value() &&;
Throws: bad_expected_access(std::move(error())) if has_value() is false.

constexpr const E& error() const & noexcept;
constexpr E& error() & noexcept;
Preconditions: has_value() is false.

constexpr E&& error() && noexcept;
constexpr const E&& error() const && noexcept;
Preconditions: has_value() is false.

template<class G = E> constexpr E error_or(G&& e) const &;
Mandates: is_move_constructible_v<E> is true and is_convertible_v<G, E> is true.

template<class G = E> constexpr E error_or(G&& e) &&;
Mandates: is_move_constructible_v<E> is true and is_convertible_v<G, E> is true.

22.8.7.7 Monadic operations

template<class F> constexpr F auto and_then(F&& f) &;
template<class F> constexpr F auto and_then(F&& f) const &;

Let U be remove_cvref_t<invoke_result_t<F>>.
Constraints: is_constructible_v<E, decltype(error())> is true.
Mandates: U is a specialization of expected and is_same_v<U::error_type, E> is true.
Effects: Equivalent to:

```cpp
if (has_value())
    return invoke(std::forward<F>(f));
else
    return U(unexpect, error());
```

```cpp
template<class F> constexpr auto and_then(F&& f) &&;
template<class F> constexpr auto and_then(F&& f) const &&;
```

Let \( U \) be `remove_cvref_t<invoke_result_t<F>>`.

Constraints: is_constructible_v<E, decltype(std::move(error()))> is true.

Mandates: \( U \) is a specialization of `expected` and `is_same_v<U::error_type, E>` is true.

Effects: Equivalent to:

```cpp
if (has_value())
    return invoke(std::forward<F>(f));
else
    return U(unexpect, std::move(error()));
```

```cpp
template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &&;
```

Let \( G \) be `remove_cvref_t<invoke_result_t<F, decltype(error())>>`.

Mandates: \( G \) is a specialization of `expected` and `is_same_v<G::value_type, T>` is true.

Effects: Equivalent to:

```cpp
if (has_value())
    return G();
else
    return invoke(std::forward<F>(f), error());
```

```cpp
template<class F> constexpr auto or_else(F&& f) &&;
template<class F> constexpr auto or_else(F&& f) const &&;
```

Let \( G \) be `remove_cvref_t<invoke_result_t<F, decltype(std::move(error()))>>`.

Mandates: \( G \) is a specialization of `expected` and `is_same_v<G::value_type, T>` is true.

Effects: Equivalent to:

```cpp
if (has_value())
    return G();
else
    return invoke(std::forward<F>(f), std::move(error()));
```

```cpp
template<class F> constexpr auto transform(F&& f) &;
template<class F> constexpr auto transform(F&& f) const &;
```

Let \( U \) be `remove_cvref_t<invoke_result_t<F>>`.

Constraints: is_constructible_v<E, decltype(error())> is true.

Mandates: \( U \) is a valid value type for `expected`. If `is_void_v<U>` is false, the declaration

\[
U u(invoke(std::forward<F>(f)));
\]

is well-formed.

Effects:

(18.1) If `has_value()` is false, returns `expected<U, E>(unexpected, error())`.

(18.2) Otherwise, if `is_void_v<U>` is false, returns an `expected<U, E>` object whose `has_val` member is true and `val` member is direct-non-list-initialized with `invoke(std::forward<F>(f))`.

(18.3) Otherwise, evaluates `invoke(std::forward<F>(f))` and then returns `expected<U, E>()`.

```cpp
template<class F> constexpr auto transform(F&& f) &&;
template<class F> constexpr auto transform(F&& f) const &&;
```

Let \( U \) be `remove_cvref_t<invoke_result_t<F>>`.
20 Constraints: is_constructible_v<E, decltype(std::move(error()))> is true.

21 Mandates: U is a valid value type for expected. If is_void_v<U> is false, the declaration

U u(invoke(std::forward<F>(f)));

is well-formed.

22 Effects:

(22.1) — If has_value() is false, returns expected<U, E>(unexpect, std::move(error())).

(22.2) — Otherwise, if is_void_v<U> is false, returns an expected<U, E> object whose has_val member

is true and val member is direct-non-list-initialized with invoke(std::forward<F>(f)).

(22.3) — Otherwise, evaluates invoke(std::forward<F>(f)) and then returns expected<U, E>().

23 template<class F> constexpr auto transform_error(F&& f) &;
template<class F> constexpr auto transform_error(F&& f) const &;

24 Let G be remove_cv_t<invoke_result_t<F, decltype(error())>>.

25 Mandates: G is a valid template argument for unexpected (22.8.3.1) and the declaration

G g(invoke(std::forward<F>(f), error()));

is well-formed.

26 Returns: If has_value() is true, expected<T, G>(); otherwise, an expected<T, G> object whose

has_val member is false and unex member is direct-non-list-initialized with invoke(std::for-
ward<F>(f), error()).

27 template<class F> constexpr auto transform_error(F&& f) &&;
template<class F> constexpr auto transform_error(F&& f) const &&;

28 Let G be remove_cv_t<invoke_result_t<F, decltype(std::move(error()))>>.

29 Mandates: G is a valid template argument for unexpected (22.8.3.1) and the declaration

G g(invoke(std::forward<F>(f), std::move(error())));

is well-formed.

30 Returns: If has_value() is true, expected<T, G>(); otherwise, an expected<T, G> object whose

has_val member is false and unex member is direct-non-list-initialized with invoke(std::for-
ward<F>(f), std::move(error())).

22.8.7.8 Equality operators [expected.void.eq]

template<class T2, class E2> requires is_void_v<T2>

friend constexpr bool operator==(const expected& x, const expected<T2, E2>& y);

1 Mandates: The expression x.error() == y.error() is well-formed and its result is convertible to bool.

2 Returns: If x.has_value() does not equal y.has_value(), false; otherwise x.has_value() ||

static_cast<bool>(x.error() == y.error()).

template<class E2>

friend constexpr bool operator==(const expected& x, const unexpected<E2>& e);

3 Mandates: The expression x.error() == e.error() is well-formed and its result is convertible to bool.

4 Returns: !x.has_value() && static_cast<bool>(x.error() == e.error()).

22.9 Bitsets [bitset]

22.9.1 Header <bitset> synopsis [bitset.syn]

1 The header <bitset> defines a class template and several related functions for representing and manipulating

fixed-size sequences of bits.

#include <string> // see 23.4.2
#include <iosfwd> // for istream (31.7.1), ostream (31.7.2), see 31.3.1
namespace std {

  template<size_t N> class bitset;

  // 22.9.4, bitset operators
  template<size_t N>
  constexpr bitset<N> operator&(const bitset<N>&, const bitset<N>&) noexcept;
  template<size_t N>
  constexpr bitset<N> operator|(const bitset<N>&, const bitset<N>&) noexcept;
  template<size_t N>
  constexpr bitset<N> operator^(const bitset<N>&, const bitset<N>&) noexcept;

  template<class charT, class traits, size_t N>
  basic_istream<charT, traits>&
  operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
  template<class charT, class traits, size_t N>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
}

22.9.2 Class template bitset

22.9.2.1 General

namespace std {

  template<size_t N> class bitset {
  public:
    // bit reference
    class reference {
      friend class bitset;
      constexpr reference() noexcept;
      constexpr reference(const reference&) = default;

      constexpr reference(const reference& x) noexcept;
      // for b[i] = x;
      constexpr reference& operator=(bool x) noexcept;
      // for b[i] = b[j];
      constexpr reference& operator=(const reference&) noexcept;
      // for b[i] = b[j];
      constexpr bool operator~() const noexcept;
      // flips the bit
      constexpr reference& flip() noexcept;
      // for b[i].flip();
    };

    // 22.9.2.2, constructors
    constexpr bitset() noexcept;
    constexpr bitset(unsigned long long val) noexcept;
    template<class charT, class traits, class Allocator>
    constexpr explicit bitset(
      const basic_string<charT, traits, Allocator>& str,
      typename basic_string<charT, traits, Allocator>::size_type pos = 0,
      typename basic_string<charT, traits, Allocator>::size_type n = basic_string<charT, traits, Allocator>::npos,
      charT zero = charT('0'),
      charT one = charT('1'));
    template<class charT>
    constexpr explicit bitset(
      const charT* str,
      typename basic_string<charT>::size_type n = basic_string<charT>::npos,
      charT zero = charT('0'),
      charT one = charT('1'));

    // 22.9.2.3, bitset operations
    constexpr bitset& operator&=(const bitset& rhs) noexcept;
    constexpr bitset& operator|=(const bitset& rhs) noexcept;
    constexpr bitset& operator^=(const bitset& rhs) noexcept;
    constexpr bitset& operator<<=(size_t pos) noexcept;
    constexpr bitset& operator>>=(size_t pos) noexcept;
    constexpr bitset operator<<(size_t pos) const noexcept;
    constexpr bitset operator>>(size_t pos) const noexcept;

  public:
    constexpr reference(const reference&) = default;
    constexpr ~reference() noexcept;
    constexpr reference& operator=(bool x) noexcept;
    // for b[i] = x;
    constexpr reference& operator=(const reference& x) noexcept;
    // for b[i] = b[j];
    constexpr bool operator~() const noexcept;
    // flips the bit
    constexpr reference& flip() noexcept;
    // for b[i].flip();
  };
};
The class template `bitset<N>` describes an object that can store a sequence consisting of a fixed number of bits, `N`.

Each bit represents either the value zero (reset) or one (set). To toggle a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position `pos`. When converting between an object of class `bitset<N>` and a value of some integral type, bit position `pos` corresponds to the bit value `1 << pos`.

The integral value corresponding to two or more bits is the sum of their bit values.

The functions described in 22.9.2 can report three kinds of errors, each associated with a distinct exception:

1. An `invalid-argument` error is associated with exceptions of type `invalid_argument` (19.2.5);
2. An `out-of-range` error is associated with exceptions of type `out_of_range` (19.2.7);
3. An `overflow` error is associated with exceptions of type `overflow_error` (19.2.10).

### 22.9.2.2 Constructors

**Effect:** Initializes all bits in *this to zero.

```cpp
constexpr bitset() noexcept;
```

**Effect:** Initializes the first `M` bit positions to the corresponding bit values in `val`. `M` is the smaller of `N` and the number of bits in the value representation (6.8.1) of `unsigned long long`. If `M < N`, the remaining bit positions are initialized to zero.

```cpp
constexpr bitset(unsigned long long val) noexcept;
```

**Template Parameters**
- `charT` (char): Character type.
- `traits` (traits): Traits of character type.
- `Allocator` (Allocator): Allocator type.

**Effect:** Initializes all bits in `*this` to zero.

```cpp
template<class charT, class traits, class Allocator>
constexpr explicit bitset(
    const basic_string<charT, traits, Allocator>& str,
    typename basic_string<charT, traits, Allocator>::size_type pos = 0,
);  
```
typedef basic_string<charT, traits, Allocator>::size_type n
    = basic_string<charT, traits, Allocator>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));

Effects: Determines the effective length rlen of the initializing string as the smaller of n and str.size() - pos. Initializes the first M bit positions to values determined from the corresponding characters in the string str. M is the smaller of N and rlen.

An element of the constructed object has value zero if the corresponding character in str, beginning at position pos, is zero. Otherwise, the element has the value one. Character position pos + M - 1 corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions.

If M < N, remaining bit positions are initialized to zero.

The function uses traits::eq to compare the character values.

Throws: out_of_range if pos > str.size() or invalid_argument if any of the rlen characters in str beginning at position pos is other than zero or one.

template<class charT>
constexpr explicit bitset(
    const charT* str,
    typename basic_string<charT>::size_type n = basic_string<charT>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));

Effects: As if by:

bitset(n == basic_string<charT>::npos
    ? basic_string<charT>(str)
    : basic_string<charT>(str, n),
    0, n, zero, one)

22.9.2.3 Members [bitset.members]

constexpr bitset& operator&=(const bitset& rhs) noexcept;

Effects: Clears each bit in *this for which the corresponding bit in rhs is clear, and leaves all other bits unchanged.

Returns: *this.

constexpr bitset& operator|=(const bitset& rhs) noexcept;

Effects: Sets each bit in *this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.

Returns: *this.

constexpr bitset& operator^=(const bitset& rhs) noexcept;

Effects: Toggles each bit in *this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.

Returns: *this.

constexpr bitset& operator<<=(size_t pos) noexcept;

Effects: Replaces each bit at position I in *this with a value determined as follows:

(7.1) If I < pos, the new value is zero;
(7.2) If I >= pos, the new value is the previous value of the bit at position I - pos.

Returns: *this.

constexpr bitset& operator>>=(size_t pos) noexcept;

Effects: Replaces each bit at position I in *this with a value determined as follows:

(9.1) If pos >= N - I, the new value is zero;
(9.2) If pos < N - I, the new value is the previous value of the bit at position I + pos.
Returns: *this.

constexpr bitset operator<<(size_t pos) const noexcept;

Returns: bitset(*this) <<= pos.

constexpr bitset operator>>(size_t pos) const noexcept;

constexpr bitset& set() noexcept;

Effects: Sets all bits in *this.

Returns: *this.

constexpr bitset& set(size_t pos, bool val = true);

Effects: Stores a new value in the bit at position pos in *this. If val is true, the stored value is one, otherwise it is zero.

Returns: *this.

Throws: out_of_range if pos does not correspond to a valid bit position.

constexpr bitset& reset() noexcept;

Effects: Resets all bits in *this.

Returns: *this.

constexpr bitset& reset(size_t pos);

Effects: Resets the bit at position pos in *this.

Returns: *this.

Throws: out_of_range if pos does not correspond to a valid bit position.

constexpr bitset operator~() const noexcept;

Effects: Constructs an object x of class bitset and initializes it with *this.

Returns: x.flip().

constexpr bitset& flip() noexcept;

Effects: Toggles all bits in *this.

Returns: *this.

constexpr bitset& flip(size_t pos);

Effects: Toggles the bit at position pos in *this.

Returns: *this.

Throws: out_of_range if pos does not correspond to a valid bit position.

constexpr bool operator[](size_t pos) const;

Preconditions: pos is valid.

Returns: true if the bit at position pos in *this has the value one, otherwise false.

Throws: Nothing.

constexpr bitset::reference operator[](size_t pos);

Preconditions: pos is valid.

Returns: An object of type bitset::reference such that (*this)[pos] == this->test(pos), and such that (*this)[pos] = val is equivalent to this->set(pos, val).

Throws: Nothing.

Remarks: For the purpose of determining the presence of a data race (6.9.2), any access or update through the resulting reference potentially accesses or modifies, respectively, the entire underlying bitset.
constexpr unsigned long to_ulong() const;

Returns: x.

Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented as type unsigned long.

constexpr unsigned long long to_ullong() const;

Returns: x.

Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented as type unsigned long long.

template<class charT = char,  
    class traits = char_traits<charT>,  
    class Allocator = allocator<charT>>
constexpr basic_string<charT, traits, Allocator>  
to_string(charT zero = charT('0'), charT one = charT('1')) const;

Effects: Constructs a string object of the appropriate type and initializes it to a string of length N characters. Each character is determined by the value of its corresponding bit position in *this. Character position N - 1 corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions. Bit value zero becomes the character zero, bit value one becomes the character one.

Returns: The created object.

constexpr size_t count() const noexcept;

Returns: A count of the number of bits set in *this.

constexpr size_t size() const noexcept;

Returns: N.

constexpr bool operator==(const bitset& rhs) const noexcept;

Returns: true if the value of each bit in *this equals the value of the corresponding bit in rhs.

constexpr bool test(size_t pos) const;

Returns: true if the bit at position pos in *this has the value one.

Throws: out_of_range if pos does not correspond to a valid bit position.

constexpr bool all() const noexcept;

Returns: count() == size().

constexpr bool any() const noexcept;

Returns: count() != 0.

constexpr bool none() const noexcept;

Returns: count() == 0.

22.9.3 bitset hash support

template<size_t N> struct hash<bitset<N>>;

The specialization is enabled (22.10.19).

22.9.4 bitset operators

template<size_t N>
constexpr bitset<N> operator&(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;

Returns: bitset<N>(lhs) &= rhs.

template<size_t N>
constexpr bitset<N> operator|(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;

Returns: bitset<N>(lhs) |= rhs.
template<size_t N>
constexpr bitset<N> operator^(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;

Returns: \(\text{bitset}<N>(\text{lhs}) = \text{rhs}\).

template<class charT, class traits, size_t N>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, bitset<N>& x);

A formatted input function (31.7.5.3).

Effects: Extracts up to \(N\) characters from is. Stores these characters in a temporary object \(str\) of type basic_string<charT, traits>, then evaluates the expression \(x = \text{bitset}<N>(\text{str})\). Characters are extracted and stored until any of the following occurs:

- \(N\) characters have been extracted and stored;
- end-of-file occurs on the input sequence;
- the next input character is neither is.widen('0') nor is.widen('1') (in which case the input character is not extracted).

If \(N > 0\) and no characters are stored in \(str\), ios_base::failbit is set in the input function's local error state before setstate is called.

Returns: is.

22.10 Function objects

22.10.1 General

A function object type is an object type (6.8.1) that can be the type of the postfix-expression in a function call (7.6.1.3, 12.2.2.2).204 A function object is an object of a function object type. In the places where one would expect to pass a pointer to a function to an algorithmic template (Clause 27), the interface is specified to accept a function object. This not only makes algorithmic templates work with pointers to functions, but also enables them to work with arbitrary function objects.

22.10.2 Header <functional> synopsis

```cpp
namespace std {
    // 22.10.5, invoke
    template<class F, class... Args>
    constexpr invoke_result_t<F, Args...> invoke(F&& f, Args&&... args) noexcept(is_nothrow_invocable_v<F, Args...>); // freestanding

    template<class R, class F, class... Args>
    constexpr R invoke_r(F&& f, Args&&... args) noexcept(is_nothrow_invocable_r_v<R, F, Args...>); // freestanding

    // 22.10.6, reference_wrapper
    template<class T> class reference_wrapper;

    template<class T> constexpr reference_wrapper<T> ref(T&&) noexcept;  // freestanding
    template<class T> constexpr reference_wrapper<const T> cref(const T&&) noexcept;    // freestanding
    template<class T> void ref(const ref T&&) = delete;
    template<class T> void cref(const cref T&&) = delete;          // freestanding
}
```

204) Such a type is a function pointer or a class type which has a member operator() or a class type which has a conversion to a pointer to function.
template<class T>

    }
}

[Example 1: If a C++ program wants to have a by-element addition of two vectors a and b containing double and put the result into a, it can do:
    transform(a.begin(), a.end(), b.begin(), a.begin(), plus<double>());
— end example]

[Example 2: To negate every element of a:
    transform(a.begin(), a.end(), a.begin(), negate<double>());
— end example]

22.10.3 Definitions

The following definitions apply to this Clause:

1 A call signature is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.

2 A callable type is a function object type (22.10) or a pointer to member.

3 A callable object is an object of a callable type.

4 A call wrapper type is a type that holds a callable object and supports a call operation that forwards to that object.

5 A call wrapper is an object of a call wrapper type.

6 A target object is the callable object held by a call wrapper.

7 A call wrapper type may additionally hold a sequence of objects and references that may be passed as arguments to the target object. These entities are collectively referred to as bound argument entities.

8 The target object and bound argument entities of the call wrapper are collectively referred to as state entities.

22.10.4 Requirements

Define INVOKE(f, t_1, t_2, ..., t_N) as follows:

(1.1) — (t_1::*f)(t_2, ..., t_N) when f is a pointer to a member function of a class T and is_same_v<T, remove_cvref_t<decltype(t_1)>> || is_base_of_v<T, remove_cvref_t<decltype(t_1)>> is true;
(1.2) — (t_1.get()::*f)(t_2, ..., t_N) when f is a pointer to a member function of a class T and remove_cvref_t<decltype(t_1)> is a specialization of reference_wrapper;
(1.3) — ((t_1).*f)(t_2, ..., t_N) when f is a pointer to a member function of a class T and t_1 does not satisfy the previous two items;
Every call wrapper (22.10.3) meets the \texttt{Cpp17MoveConstructible} and \texttt{Cpp17Destructible} requirements. An argument forwarding call wrapper is a call wrapper that can be called with an arbitrary argument list and delivers the arguments to the target object as references. This forwarding step delivers rvalue arguments as rvalue references and lvalue arguments as lvalue references.

\textbf{[Note 1:} In a typical implementation, argument forwarding call wrappers have an overloaded function call operator of the form

\begin{verbatim}
 template<class... UnBoundArgs>
 constexpr R operator()(UnBoundArgs&&... unbound_args)
 { return *this; }
\end{verbatim}

\textbf{[end note]}\]

A \textit{perfect forwarding call wrapper} is an argument forwarding call wrapper that forwards its state entities to the underlying call expression. This forwarding step delivers a state entity of type $T$ as \textit{cv T} when the call is performed on an lvalue of the call wrapper type and as \textit{cv T} otherwise, where \textit{cv} represents the cv-qualifiers of the call wrapper and where \textit{cv} shall be neither \textit{volatile} nor \textit{const volatile}.

A \textit{call pattern} defines the semantics of invoking a perfect forwarding call wrapper. A postfix call performed on a perfect forwarding call wrapper is expression-equivalent (3.21) to an expression $e$ determined from its call pattern \texttt{cp} by replacing all occurrences of the arguments of the call wrapper and its state entities with references as described in the corresponding forwarding steps.

A \textit{simple call wrapper} is a perfect forwarding call wrapper that meets the \texttt{Cpp17CopyConstructible} and \texttt{Cpp17CopyAssignable} requirements and whose copy constructor, move constructor, and assignment operators are constexpr functions that do not throw exceptions.

The copy/move constructor of an argument forwarding call wrapper has the same apparent semantics as if memberwise copy/move of its state entities were performed (11.4.5.3).

\textbf{[Note 2:} This implies that each of the copy/move constructors has the same exception-specification as the corresponding implicit definition and is declared as constexpr if the corresponding implicit definition would be considered to be constexpr. \textbf{[end note]}\]

Argument forwarding call wrappers returned by a given standard library function template have the same type if the types of their corresponding state entities are the same.

\section*{22.10.5 \texttt{invoke} functions \hfill [\texttt{func.invoke}].}

\begin{verbatim}
 template<class F, class... Args>
 constexpr invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
 noexcept(is_nothrow_invocable_v<F, Args...>);
\end{verbatim}

\textbf{Constraints:} $\text{is\_invocable\_v}\ <F, \text{Args...}> \text{ is true.}$

\textbf{Returns:} $\text{INVOKE}(\text{std::forward}\ <F>(f), \text{std::forward}\ <\text{Args}> (args) \ldots)$ (22.10.4).

\begin{verbatim}
 template<class R, class F, class... Args>
 constexpr R invoke_r(F&& f, Args&&... args)
 noexcept(is_nothrow_invocable_r_v<R, F, Args...>);
\end{verbatim}

\textbf{Constraints:} $\text{is\_invocable\_r\_v}\ <R, F, \text{Args...}> \text{ is true.}$

\textbf{Returns:} $\text{INVOKE}\ <R>(\text{std::forward}\ <F>(f), \text{std::forward}\ <\text{Args}> (args) \ldots)$ (22.10.4).
22.10.6 Class template reference_wrapper

namespace std {
    template<class T> class reference_wrapper {
    public:
        // types
        using type = T;

        // 22.10.6.2, constructors
        template<class U>
        constexpr reference_wrapper(U&&) noexcept;
        constexpr reference_wrapper(const reference_wrapper& x) noexcept;

        // 22.10.6.3, assignment
        constexpr reference_wrapper& operator=(const reference_wrapper& x) noexcept;

        // 22.10.6.4, access
        constexpr operator T& () const noexcept;
        constexpr T& get() const noexcept;

        // 22.10.6.5, invocation
        template<class... ArgTypes>
        constexpr invoke_result_t<T&, ArgTypes...> operator()(ArgTypes&&...) const
            noexcept(is_nothrow_invocable_v<T&, ArgTypes...>);
    }
}

reference_wrapper<T> is a Cpp17CopyConstructible and Cpp17CopyAssignable wrapper around a reference to an object or function of type T.

The template parameter T of reference_wrapper may be an incomplete type.

22.10.6.2 Constructors

    template<class U>
    constexpr reference_wrapper(U&& u) noexcept;

Let FUN denote the exposition-only functions

    void FUN(T&) noexcept;
    void FUN(T&&) = delete;

Constraints: The expression FUN(declval<U>()) is well-formed and is_same_v<remove_cvref_t<U>, reference_wrapper> is false.

Effects: Creates a variable r as if by T& r = std::forward<U>(u), then constructs a reference_wrapper object that stores a reference to r.

Remarks: The exception specification is equivalent to noexcept(FUN(declval<U>())).

22.10.6.3 Assignment

    constexpr reference_wrapper& operator=(const reference_wrapper& x) noexcept;

Postconditions: *this stores a reference to x.get().

22.10.6.4 Access

    constexpr operator T& () const noexcept;

Returns: The stored reference.
constexpr T& get() const noexcept;

Returns: The stored reference.

### 22.10.6.5 Invocation

```cpp
template<class... ArgTypes>
constexpr invoke_result_t<T&, ArgTypes...>
operator()(ArgTypes&&... args) const noexcept(is_nothrow_invocable_v<T&, ArgTypes...>);
```

Mandates: T is a complete type.

Returns: `INVOKE(get(), std::forward<ArgTypes>(args)...)` (22.10.4)

### 22.10.6.6 Helper functions

The template parameter T of the following ref and cref function templates may be an incomplete type.

```cpp
template<class T> constexpr reference_wrapper<T> ref(T& t) noexcept;

Returns: `reference_wrapper<T>(t)`.

template<class T> constexpr reference_wrapper<T> ref(reference_wrapper<T> t) noexcept;

Returns: t.

template<class T> constexpr reference_wrapper<const T> cref(const T& t) noexcept;

Returns: `reference_wrapper<const T>(t)`.

template<class T> constexpr reference_wrapper<const T> cref(reference_wrapper<T> t) noexcept;

Returns: t.
```

### 22.10.6.7 common_reference related specializations

```cpp
namespace std {
    template<class T>
    constexpr bool is-ref-wrapper = false; // exposition only

    template<class T>
    constexpr bool is-ref-wrapper<reference_wrapper<T>> = true;

    template<class R, class T, class RQ, class TQ>
    concept ref-wrap-common-reference-exists-with =
        is-ref-wrapper<R> &&
        requires { typename common_reference_t<typename R::type&, TQ>; } &&
        convertible_to<RQ, common_reference_t<typename R::type&, TQ>>;

    template<class R, class T, template<class> class RQual, template<class> class TQual>
    requires (ref-wrap-common-reference-exists-with<R, T, RQual<R>, TQual<T>> &&
               !ref-wrap-common-reference-exists-with<T, R, TQual<T>, RQual<R>>)
    struct basic_common_reference<R, T, RQual, TQual> {
        using type = common_reference_t<typename R::type&, TQual<T>>;
    };

    template<class T, class R, template<class> class TQual, template<class> class RQual>
    requires (ref-wrap-common-reference-exists-with<R, T, RQual<R>, TQual<T>> &&
               !ref-wrap-common-reference-exists-with<T, R, TQual<T>, RQual<R>>)
    struct basic_common_reference<T, R, TQual, RQual> {
        using type = common_reference_t<typename R::type&, TQual<T>>;
    };
}
```

### 22.10.7 Arithmetic operations

#### 22.10.7.1 General

The library provides basic function object classes for all of the arithmetic operators in the language (7.6.5, 7.6.6).
22.10.7.2 Class template plus

```cpp
template<class T = void> struct plus {
    constexpr T operator()(const T& x, const T& y) const;
};
```

1 Returns: $x + y$.

```cpp
template<> struct plus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) + std::forward<U>(u));
    using is_transparent = unspecified;
};
```

2 Returns: $\text{std::forward}<\text{T}>(t) + \text{std::forward}<\text{U}>(u)$.

22.10.7.3 Class template minus

```cpp
template<class T = void> struct minus {
    constexpr T operator()(const T& x, const T& y) const;
};
```

1 Returns: $x - y$.

```cpp
template<> struct minus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) - std::forward<U>(u));
    using is_transparent = unspecified;
};
```

2 Returns: $\text{std::forward}<\text{T}>(t) - \text{std::forward}<\text{U}>(u)$.

22.10.7.4 Class template multiplies

```cpp
template<class T = void> struct multiplies {
    constexpr T operator()(const T& x, const T& y) const;
};
```

1 Returns: $x \cdot y$.

```cpp
template<> struct multiplies<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) * std::forward<U>(u));
    using is_transparent = unspecified;
};
```

2 Returns: $\text{std::forward}<\text{T}>(t) \ast \text{std::forward}<\text{U}>(u)$.

22.10.7.5 Class template divides

```cpp
template<class T = void> struct divides {
    constexpr T operator()(const T& x, const T& y) const;
};
```

2 Returns: $\text{std::forward}<\text{T}>(t) / \text{std::forward}<\text{U}>(u)$.

§ 22.10.7.5
template<> struct divides<void> {
    template<class T, class U>
    constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) / std::forward<U>(u));
};

Returns: std::forward<T>(t) / std::forward<U>(u).

22.10.7.6 Class template modulus

```
template<class T = void> struct modulus {
    constexpr T operator()(const T& x, const T& y) const;
};
```

Returns: x % y.

22.10.7.7 Class template negate

```
template<class T = void> struct negate {
    constexpr T operator()(const T& x) const;
};
```

Returns: -x.

22.10.8 Comparisons

22.10.8.1 General

The library provides basic function object classes for all of the comparison operators in the language (7.6.9, 7.6.10).

For templates less, greater, less_equal, and greater_equal, the specializations for any pointer type yield a result consistent with the implementation-defined strict total order over pointers (3.27).
[Note 1: If \( a < b \) is well-defined for pointers \( a \) and \( b \) of type \( P \), then \( (a < b) == \text{less}<P>()(a, b) \), \( (a > b) == \text{greater}<P>()(a, b) \), and so forth. — end note]

For template specializations `less<void>, greater<void>, less_equal<void>, and greater_equal<void>`, if the call operator calls a built-in operator comparing pointers, the call operator yields a result consistent with the implementation-defined strict total order over pointers.

### 22.10.8.2 Class template `equal_to`

```cpp
template<class T = void> struct equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};
constexpr bool operator()(const T& x, const T& y) const;

1 Returns: \( x == y \).

template<> struct equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) == std::forward<U>(u));
    using is_transparent = unspecified;
};
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) == std::forward<U>(u));
2 Returns: std::forward<T>(t) == std::forward<U>(u).
```

### 22.10.8.3 Class template `not_equal_to`

```cpp
template<class T = void> struct not_equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};
constexpr bool operator()(const T& x, const T& y) const;

1 Returns: \( x != y \).

template<> struct not_equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) != std::forward<U>(u));
    using is_transparent = unspecified;
};
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) != std::forward<U>(u));
2 Returns: std::forward<T>(t) != std::forward<U>(u).
```

### 22.10.8.4 Class template `greater`

```cpp
template<class T = void> struct greater {
    constexpr bool operator()(const T& x, const T& y) const;
};
constexpr bool operator()(const T& x, const T& y) const;

1 Returns: \( x > y \).

template<> struct greater<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) > std::forward<U>(u));
    using is_transparent = unspecified;
};
```
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) > std::forward<U>(u));

Returns: std::forward<T>(t) > std::forward<U>(u).

22.10.8.5 Class template less

template<class T = void> struct less {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x < y.

template<> struct less<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) < std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) < std::forward<U>(u));

Returns: std::forward<T>(t) < std::forward<U>(u).

22.10.8.6 Class template greater_equal

template<class T = void> struct greater_equal {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x >= y.

template<> struct greater_equal<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) >= std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) >= std::forward<U>(u));

Returns: std::forward<T>(t) >= std::forward<U>(u).

22.10.8.7 Class template less_equal

template<class T = void> struct less_equal {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x <= y.

template<> struct less_equal<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) <= std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) <= std::forward<U>(u));

Returns: std::forward<T>(t) <= std::forward<U>(u).
22.10.8.8 Class compare_three_way

```cpp
namespace std {
  struct compare_three_way {
    template<class T, class U>
    constexpr auto operator()(T&& t, U&& u) const;
  
    using is_transparent = unspecified;
  
  } // compare_three_way

  template<class T, class U>
  constexpr auto operator()(T&& t, U&& u) const;
}
```

Constraints: T and U satisfy `three_way_comparable_with`.

Preconditions: If the expression `std::forward<T>(t) <=> std::forward<U>(u)` results in a call to a built-in operator `<>`, comparing pointers of type P, the conversion sequences from both T and U to P are equality-preserving (18.2); otherwise, T and U model `three_way_comparable_with`.

Effects:

(3.1) — If the expression `std::forward<T>(t) <=> std::forward<U>(u)` results in a call to a built-in operator `<>`, comparing pointers of type P, returns `strong_ordering::less` if (the converted value of) t precedes u in the implementation-defined strict total order over pointers (3.27), `strong_ordering::greater` if u precedes t, and otherwise `strong_ordering::equal`.

(3.2) — Otherwise, equivalent to: return `std::forward<T>(t) <=> std::forward<U>(u);`

22.10.9 Concept-constrained comparisons

```cpp
struct ranges::equal_to {
  template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const;

  using is_transparent = unspecified;

};
```

Constraints: T and U satisfy `equality_comparable_with`.

Preconditions: If the expression `std::forward<T>(t) == std::forward<U>(u)` results in a call to a built-in operator `==`, comparing pointers, the conversion sequences from both T and U to P are equality-preserving (18.2); otherwise, T and U model `equality_comparable_with`.

Effects:

(3.1) — If the expression `std::forward<T>(t) == std::forward<U>(u)` results in a call to a built-in operator `==`, comparing pointers: returns `false` if either (the converted value of) t precedes u or u precedes t in the implementation-defined strict total order over pointers (3.27) and otherwise `true`.

(3.2) — Otherwise, equivalent to: return `std::forward<T>(t) == std::forward<U>(u);`

```cpp
struct ranges::not_equal_to {
  template<class T, class U>
  constexpr bool operator()(T&& t, U&& u) const;

  using is_transparent = unspecified;

};
```

Constraints: T and U satisfy `equality_comparable_with`.

Effects: Equivalent to:

```
return !ranges::equal_to{}(std::forward<T>(t), std::forward<U>(u));
```
struct ranges::greater {
    template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

Constraints: T and U satisfy totally_ordered_with.

Effects: Equivalent to:
    return ranges::less{}(std::forward<U>(u), std::forward<T>(t));

struct ranges::less {
    template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

Constraints: T and U satisfy totally_ordered_with.

Preconditions: If the expression std::forward<T>(t) < std::forward<U>(u) results in a call to a built-in operator < comparing pointers of type P, the conversion sequences from both T and U to P are equality-preserving (18.2); otherwise, T and U model totally_ordered_with. For any expressions ET and EU such that decltype((ET)) is T and decltype((EU)) is U, exactly one of ranges::less{}(ET, EU), ranges::less{}(EU, ET), or ranges::equal_to{}(ET, EU) is true.

Effects: (10.1)
    — If the expression std::forward<T>(t) < std::forward<U>(u) results in a call to a built-in operator < comparing pointers: returns true if (the converted value of) t precedes u in the implementation-defined strict total order over pointers (3.27) and otherwise false.
    — Otherwise, equivalent to: return std::forward<T>(t) < std::forward<U>(u);

struct ranges::greater_equal {
    template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

Constraints: T and U satisfy totally_ordered_with.

Effects: Equivalent to:
    return !ranges::less{}(std::forward<T>(t), std::forward<U>(u));

struct ranges::less_equal {
    template<class T, class U>
    constexpr bool operator()(T&& t, U&& u) const;

    using is_transparent = unspecified;
};

template<class T, class U>
constexpr bool operator()(T&& t, U&& u) const;

Constraints: T and U satisfy totally_ordered_with.

Effects: Equivalent to:
    return !ranges::less{}(std::forward<U>(u), std::forward<T>(t));

§ 22.10.9
22.10.10 Logical operations

22.10.10.1 General

The library provides basic function object classes for all of the logical operators in the language (7.6.14, 7.6.15, 7.6.2.2).

22.10.10.2 Class template logical_and

```cpp
template<class T = void> struct logical_and {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
```

Returns: \(x \&\& y\).

```cpp
template<> struct logical_and<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) && std::forward<U>(u));
    using is_transparent = unspecified;
};
```

Returns: \(\text{std::forward}(t) \&\& \text{std::forward}(u)\).

22.10.10.3 Class template logical_or

```cpp
template<class T = void> struct logical_or {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

Returns: \(x \lor y\).

```cpp
template<> struct logical_or<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) || std::forward<U>(u));
    using is_transparent = unspecified;
};
```

Returns: \(\text{std::forward}(t) \lor \text{std::forward}(u)\).

22.10.10.4 Class template logical_not

```cpp
template<class T = void> struct logical_not {
    constexpr bool operator()(const T& x) const;
};
```

Returns: \(!x\).

```cpp
template<> struct logical_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(!std::forward<T>(t));
    using is_transparent = unspecified;
};
```

Returns: \(!\text{std::forward}(t)\).
22.10.11 Bitwise operations

22.10.11 General

The library provides basic function object classes for all of the bitwise operators in the language (7.6.11, 7.6.13, 7.6.12, 7.6.2.2).

22.10.11.2 Class template bit_and

template<class T = void> struct bit_and {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x & y.

template<> struct bit_and<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) & std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) & std::forward<U>(u));

Returns: std::forward<T>(t) & std::forward<U>(u).

22.10.11.3 Class template bit_or

template<class T = void> struct bit_or {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x | y.

template<> struct bit_or<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) | std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) | std::forward<U>(u));

Returns: std::forward<T>(t) | std::forward<U>(u).

22.10.11.4 Class template bit_xor

template<class T = void> struct bit_xor {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x ^ y.

template<> struct bit_xor<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) ^ std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) ^ std::forward<U>(u));

Returns: std::forward<T>(t) ^ std::forward<U>(u).
22.10.11.5 Class template bit_not

```cpp
template<class T = void>
struct bit_not {
    constexpr T operator()(const T& x) const;
};
```

```cpp
constexpr T operator()(const T& x) const;
```

Returns: \(~x\).

```cpp
template<> struct bit_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(~std::forward<T>(t));
    using is_transparent = unspecified;
};
```

```cpp
template<class T> constexpr auto operator()(T&& t) const
    -> decltype(~std::forward<T>(t));
```

Returns: \(~std::forward<T>(t)\).

22.10.12 Class identity

```cpp
struct identity {
    template<class T>
        constexpr T&& operator()(T&& t) const noexcept;
    using is_transparent = unspecified;
};
```

```cpp
template<class T>
    constexpr T&& operator()(T&& t) const noexcept;
```

Effects: Equivalent to: `return std::forward<T>(t);`

22.10.13 Function template not_fn

```cpp
template<class F> constexpr unspecified not_fn(F&& f);
```

In the text that follows:

- \(g\) is a value of the result of a `not_fn` invocation,
- \(FD\) is the type `decay_t<F>`,
- \(fd\) is the target object of \(g\) (22.10.3) of type \(FD\), direct-non-list-initialized with `std::forward<F>(f)`,
- \(call_args\) is an argument pack used in a function call expression (7.6.1.3) of \(g\).

Mandates: `is_constructible_v<FD, F> && is_move_constructible_v<FD>` is true.

Preconditions: \(FD\) meets the `Cpp17MoveConstructible` requirements.

Returns: A perfect forwarding call wrapper (22.10.4) \(g\) with call pattern `!invoke(fd, call_args...)`.

Throws: Any exception thrown by the initialization of \(fd\).

22.10.14 Function templates bind_front and bind_back

```cpp
template<class F, class... Args>
    constexpr unspecified bind_front(F&& f, Args&&... args);
```

```cpp
template<class F, class... Args>
    constexpr unspecified bind_back(F&& f, Args&&... args);
```

Within this subclause:

- \(g\) is a value of the result of a `bind_front` or `bind_back` invocation,
- \(FD\) is the type `decay_t<F>`,
- \(fd\) is the target object of \(g\) (22.10.3) of type \(FD\), direct-non-list-initialized with `std::forward<F>(f)`,
BoundArgs is a pack that denotes decay_t<Args>..., bound_args is a pack of bound argument entities of g (22.10.3) of types BoundArgs..., direction-non-list-initialized with std::forward<Args>(args)..., respectively, and call_args is an argument pack used in a function call expression (7.6.1.3) of g.

Mandates:

\[
\begin{align*}
\text{is_constructible_v<FD, F> } & \& \\
\text{is_move_constructible_v<FD> } & \& \\
\text{(is_constructible_v<BoundArgs, Args> } & \& \ldots \& \text{) } & \& \\
\text{(is_move_constructible_v<BoundArgs> } & \& \ldots \& \text{)}
\end{align*}
\]

is true.

Preconditions: FD meets the Cpp17MoveConstructible requirements. For each Ti in BoundArgs, if Ti is an object type, Ti meets the Cpp17MoveConstructible requirements.

Returns: A perfect forwarding call wrapper (22.10.4) g with call pattern:

1. `invoke(fd, bound_args..., call_args...)` for a bind_front invocation, or
2. `invoke(fd, call_args..., bound_args...)` for a bind_back invocation.

Throws: Any exception thrown by the initialization of the state entities of g (22.10.3).

22.10.15 Function object binders

22.10.15.1 General

Subclause 22.10.15 describes a uniform mechanism for binding arguments of callable objects.

22.10.15.2 Class template is_bind_expression

```
namespace std {
    template<class T> struct is_bind_expression;  // see below
}
```

The class template is_bind_expression can be used to detect function objects generated by bind. The function template bind uses is_bind_expression to detect subexpressions.

Specializations of the is_bind_expression template shall meet the Cpp17UnaryTypeTrait requirements (21.3.2). The implementation provides a definition that has a base characteristic of true_type if T is a type returned from bind, otherwise it has a base characteristic of false_type. A program may specialize this template for a program-defined type T to have a base characteristic of true_type to indicate that T should be treated as a subexpression in a bind call.

22.10.15.3 Class template is_placeholder

```
namespace std {
    template<class T> struct is_placeholder;  // see below
}
```

The class template is_placeholder can be used to detect the standard placeholders _1, _2, and so on (22.10.15.5). The function template bind uses is_placeholder to detect placeholders.

Specializations of the is_placeholder template shall meet the Cpp17UnaryTypeTrait requirements (21.3.2). The implementation provides a definition that has the base characteristic of integral_constant<int, J> if T is the type of std::placeholders::_J, otherwise it has a base characteristic of integral_constant<int, 0>. A program may specialize this template for a program-defined type T to have a base characteristic of integral_constant<int, N> with N > 0 to indicate that T should be treated as a placeholder type.

22.10.15.4 Function template bind

```
template<class T> struct is_bind_expression;  // see below
```

In the text that follows:

1. g is a value of the result of a bind invocation,
2. FD is the type decay_t<F>,
3. fd is an lvalue that is a target object of g (22.10.3) of type FD direct-non-list-initialized with std::forward<F>(f),
4. Ti is the i^th type in the template parameter pack BoundArgs,
if the value of \((7.1)\) is not zero, the argument is \(\text{std::forward<}\ U\ j, u_j...&&;\)

(7.4) otherwise, the value is \(\text{td}_i\) and its type \(V_i\) is \(cv\ \text{TD}_i&&.\)

The value of the target argument \(v_{td}\) is \(fd\) and its corresponding type \(v_{td}\) is \(cv\ FD&&.\)

22.10.15.5 Placeholders

 namespace std::placeholders {
    // \(M\) is the number of placeholders
    see below _1;
    see below _2;
    ...
    see below _M;
}

1 The number \(M\) of placeholders is implementation-defined.
All placeholder types meet the \texttt{Cpp17DefaultConstructible} and \texttt{Cpp17CopyConstructible} requirements, and their default constructors and copy/move constructors are constexpr functions that do not throw exceptions. It is implementation-defined whether placeholder types meet the \texttt{Cpp17CopyAssignable} requirements, but if so, their copy assignment operators are constexpr functions that do not throw exceptions.

Placeholders should be defined as:

\begin{verbatim}
inline constexpr unspecified _1{};
\end{verbatim}

If they are not, they are declared as:

\begin{verbatim}
extern unspecified _1;
\end{verbatim}

Placeholders are freestanding items (16.3.3.6).

\textbf{22.10.16 Function template \texttt{mem\_fn}}

\begin{verbatim}
template<class R, class T> constexpr unspecified mem_fn(R T::* pm) noexcept;
\end{verbatim}

\textit{Returns:} A simple call wrapper (22.10.4) \texttt{fn} with call pattern \texttt{invoke(pm, call\_args...)}, where \texttt{pm} is the target object of \texttt{fn} of type \texttt{R T::*} direct-non-list-initialized with \texttt{pm}, and \texttt{call\_args} is an argument pack used in a function call expression (7.6.1.3) of \texttt{fn}.

\textbf{22.10.17 Polymorphic function wrappers}

\textbf{22.10.17.1 General}

Subclause 22.10.17 describes polymorphic wrapper classes that encapsulate arbitrary callable objects.

\textbf{22.10.17.2 Class \texttt{bad\_function\_call}}

An exception of type \texttt{bad\_function\_call} is thrown by \texttt{fn::operator()} (22.10.17.3.5) when the function wrapper object has no target.

\begin{verbatim}
namespace std {
    class bad_function_call : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    }
}
\end{verbatim}

\textit{Returns:} An implementation-defined ntbs.

\textbf{22.10.17.3 Class template \texttt{function}}

\textbf{22.10.17.3.1 General}

\begin{verbatim}
namespace std {
    template<class> class function; // not defined

    template<class R, class... ArgTypes>
    class function<R(ArgTypes...)> {
        public:
            using result_type = R;

            // 22.10.17.3.2, construct/copy/destroy
            function() noexcept;
            function(nullptr_t) noexcept;
            function(const function&);
            function(function&&) noexcept;
            template<class F> function(F&&);

            function& operator=(const function&);
            function& operator=(function&&);
            function& operator=(nullptr_t) noexcept;
            template<class F> function& operator=(F&&);
            template<class F> function& operator=(reference_wrapper<F>) noexcept;

            ~function();
    }
}
\end{verbatim}
The function class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (22.10.3), given a call signature (22.10.3).

A callable type (22.10.3) \( F \) is \texttt{Lvalue-Callable} for argument types \texttt{ArgTypes} and return type \( R \) if the expression \( \texttt{INVOKER<R>(declval<F&>(), declval<ArgTypes>()...)}, \) considered as an unevaluated operand (7.2.3), is well-formed (22.10.4).

The function class template is a call wrapper (22.10.3) whose call signature (22.10.3) is \( R(\texttt{ArgTypes}...) \).

[Note 1: The types deduced by the deduction guides for \texttt{function} might change in future revisions of C++. — end note]
Mandates:

— is_copy_constructible_v<FD> is true, and
— is_constructible_v<FD, F> is true.

Preconditions: FD meets the Cpp17CopyConstructible requirements.

Postconditions: !*this is true if any of the following hold:

— f is a null function pointer value.
— f is a null member pointer value.
— remove_cvref_t<F> is a specialization of the function class template, and !f is true.

Otherwise, *this has a target object of type FD direct-non-list-initialized with std::forward<F>(f).

Throws: Nothing if FD is a specialization of reference_wrapper or a function pointer type. Otherwise, may throw bad_alloc or any exception thrown by the initialization of the target object.

Recommended practice: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where f refers to an object holding only a pointer or reference to an object and a member function pointer.

template<class F> function(F) -> function<see below>;

Constraints: &F::operator() is well-formed when treated as an unevaluated operand and either

— F::operator() is a non-static member function and decltype(&F::operator()) is either of the form R(G::*)(A...) cv k_opt noexcept opt or of the form R(*)(G, A...) noexcept opt for a type G, or

— F::operator() is a static member function and decltype(&F::operator()) is of the form R(*)(A...) noexcept opt.

Remarks: The deduced type is function<R(A...)>.

[Example 1:

```cpp
void f() {
    int i{5};
    function g = [&](double) { return i; }; // deduces function<int(double)>
}
```]

Effects: As if by function(f).swap(*this);

Returns: *this.

function& operator=(const function& f);

Effects: Replaces the target of *this with the target of f.

Returns: *this.

function& operator=(function&& f);

Effects: As if by:

function(std::forward<F>(f)).swap(*this);

Returns: *this.

function& operator=(nullptr_t) noexcept;

Effects: If *this != nullptr, destroys the target of this.

Postconditions: !(*this).

Returns: *this.

function& operator=(std::forward<F>(f)) noexcept;

Effects: As if by:

function(std::forward<F>(f)).swap(*this);

Returns: *this.

template<class F> function& operator=(reference_wrapper<F> f) noexcept;

Effects: As if by:

function(f).swap(*this);
Returns: *this.
~function();

Effects: If *this != nullptr, destroys the target of this.

22.10.17.3.3 Modifiers
void swap(function& other) noexcept;

Effects: Interchanges the target objects of *this and other.

22.10.17.3.4 Capacity
explicit operator bool() const noexcept;

Returns: true if *this has a target, otherwise false.

22.10.17.3.5 Invocation
R operator()(ArgTypes... args) const;

Returns: INVOKE<f>(std::forward<ArgTypes>(args)...)
(22.10.4), where f is the target object (22.10.3) of *this.

Throws: bad_function_call if !*this; otherwise, any exception thrown by the target object.

22.10.17.3.6 Target access
const type_info& target_type() const noexcept;

Returns: If *this has a target of type T, typeid(T); otherwise, typeid(void).

template<class T> T* target() noexcept;
template<class T> const T* target() const noexcept;

Returns: If target_type() == typeid(T) a pointer to the stored function target; otherwise a null pointer.

22.10.17.3.7 Null pointer comparison operator functions

template<class R, class... ArgTypes>
bool operator==(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;

Returns: !f.

22.10.17.3.8 Specialized algorithms

template<class R, class... ArgTypes>
void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2) noexcept;

Effects: As if by: f1.swap(f2);

22.10.17.4 Move only wrapper

22.10.17.4.1 General

The header provides partial specializations of move_only_function for each combination of the possible replacements of the placeholders cv, ref, and noex where

(1.1) — cv is either const or empty,
(1.2) — ref is either &, &&, or empty, and
(1.3) — noex is either true or false.

For each of the possible combinations of the placeholders mentioned above, there is a placeholder inv-quals defined as follows:

(2.1) — If ref is empty, let inv-quals be cv&,
(2.2) — otherwise, let inv-quals be cv ref.

22.10.17.4.2 Class template move_only_function

namespace std {
    template<class... S> class move_only_function;
}  // not defined

§ 22.10.17.4.2 782
template<class R, class... ArgTypes>
class move_only_function<R(ArgTypes...) cv ref noexcept(noex)> {
public:
    using result_type = R;

    // 22.10.17.4.3, constructors, assignment, and destructor
    move_only_function() noexcept;
    move_only_function(nullptr_t) noexcept;
    move_only_function(move_only_function&&) noexcept;
    template<class F> move_only_function(F&&);
    template<class T, class... Args>
        explicit move_only_function(in_place_type_t<T>, Args&&...);
    template<class T, class U, class... Args>
        explicit move_only_function(in_place_type_t<T>, initializer_list<U>, Args&&...);

    move_only_function& operator=(move_only_function&&);
    move_only_function& operator=(nullptr_t) noexcept;
    template<class F> move_only_function& operator=(F&&);

    ~move_only_function();

    // 22.10.17.4.4, invocation
    explicit operator bool() const noexcept;

    R operator()(ArgTypes...) cv ref noexcept(noex);

    // 22.10.17.4.5, utility
    void swap(move_only_function&) noexcept;
    friend void swap(move_only_function&, move_only_function&) noexcept;
    friend bool operator==(const move_only_function&, nullptr_t) noexcept;

private:
    template<class VT>
        static constexpr bool is-callable-from = see below; // exposition only
};

1 The move_only_function class template provides polymorphic wrappers that generalize the notion of a callable object (22.10.3). These wrappers can store, move, and call arbitrary callable objects, given a call signature.

2 Recommended practice: Implementations should avoid the use of dynamically allocated memory for a small contained value.

   [Note 1: Such small-object optimization can only be applied to a type T for which is_nothrow_move_constructible_v<T> is true. —end note]

22.10.17.4.3 Constructors, assignment, and destructor [func.wrap.move.ctor]

template<class VT>
    static constexpr bool is-callable-from = see below;

1 If noex is true, is-callable-from<VT> is equal to:
   is_nothrow_invocable_r_v<R, VT cv ref, ArgTypes...> &&
   is_nothrow_invocable_r_v<R, VT inv-quals, ArgTypes...>

Otherwise, is-callable-from<VT> is equal to:
   is_invocable_r_v<R, VT cv ref, ArgTypes...> &&
   is_invocable_r_v<R, VT inv-quals, ArgTypes...>

move_only_function() noexcept;
move_only_function(nullptr_t) noexcept;

2 Postconditions: *this has no target object.
move_only_function(move_only_function&& f) noexcept;

Postconditions: The target object of *this is the target object f had before construction, and f is in a valid state with an unspecified value.

template<class F> move_only_function(F&& f);

Let VT be decay_t<F>.

Constraints:

(5.1) remove_cvref_t<F> is not the same type as move_only_function, and
(5.2) remove_cvref_t<F> is not a specialization of in_place_type_t, and
(5.3) is-callable-from<VT> is true.

Mandates: is_constructible_v<VT, F> is true.

Preconditions: VT meets the Cpp17Destructible requirements, and if is_move_constructible_v<VT> is true, VT meets the Cpp17MoveConstructible requirements.

Postconditions: *this has no target object if any of the following hold:

(8.1) f is a null function pointer value, or
(8.2) f is a null member pointer value, or
(8.3) remove_cvref_t<F> is a specialization of the move_only_function class template, and f has no target object.

Otherwise, *this has a target object of type VT direct-non-list-initialized with std::forward<F>(f).

Throws: Any exception thrown by the initialization of the target object. May throw bad_alloc unless VT is a function pointer or a specialization of reference_wrapper.

template<class T, class... Args>
explicit move_only_function(in_place_type_t<T>, Args&&... args);

Let VT be decay_t<T>.

Constraints:

(11.1) is_constructible_v<VT, Args...> is true, and
(11.2) is-callable-from<VT> is true.

Mandates: VT is the same type as T.

Preconditions: VT meets the Cpp17Destructible requirements, and if is_move_constructible_v<VT> is true, VT meets the Cpp17MoveConstructible requirements.

Postconditions: *this has a target object of type VT direct-non-list-initialized with std::forward<Args>(args)...

Throws: Any exception thrown by the initialization of the target object. May throw bad_alloc unless VT is a function pointer or a specialization of reference_wrapper.

template<class T, class U, class... Args>
explicit move_only_function(in_place_type_t<T>, initializer_list<U> ilist, Args&&... args);

Let VT be decay_t<T>.

Constraints:

(17.1) is_constructible_v<VT, initializer_list<U>&, Args...> is true, and
(17.2) is-callable-from<VT> is true.

Mandates: VT is the same type as T.

Preconditions: VT meets the Cpp17Destructible requirements, and if is_move_constructible_v<VT> is true, VT meets the Cpp17MoveConstructible requirements.

Postconditions: *this has a target object of type VT direct-non-list-initialized with ilist, std::forward<Args>(args)...

Throws: Any exception thrown by the initialization of the target object. May throw bad_alloc unless VT is a function pointer or a specialization of reference_wrapper.
move_only_function& operator=(move_only_function&& f);

Effects: Equivalent to: move_only_function(std::move(f)).swap(*this);

Returns: *this.

move_only_function& operator=(nullptr_t) noexcept;

Effects: Destroys the target object of *this, if any.

Returns: *this.

template<class F> move_only_function& operator=(F&& f);

Effects: Equivalent to: move_only_function(std::forward<F>(f)).swap(*this);

Returns: *this.

move_only_function& operator=(move_only_function&& f);

Effects: Equivalent to: move_only_function(std::move(f)).swap(*this);

Returns: *this.

move_only_function& operator=(nullptr_t) noexcept;

Effects: Destroys the target object of *this, if any.

Returns: *this.

22.10.17.4.4 Invocation

explicit operator bool() const noexcept;

Returns: true if *this has a target object, otherwise false.

R operator()(ArgTypes... args) cv ref noexcept(noex);

Preconditions: *this has a target object.

Effects: Equivalent to:

return INVOKE<R>(static_cast<F inv-quals>(f), std::forward<ArgTypes>(args)...);

where f is an lvalue designating the target object of *this and F is the type of f.

22.10.17.4.5 Utility

void swap(move_only_function& other) noexcept;

Effects: Exchanges the target objects of *this and other.

friend void swap(move_only_function& f1, move_only_function& f2) noexcept;

Effects: Equivalent to f1.swap(f2).

friend bool operator==(const move_only_function& f, nullptr_t) noexcept;

Returns: true if f has no target object, otherwise false.

22.10.18 Searchers

22.10.18.1 General

Subclause 22.10.18 provides function object types (22.10) for operations that search for a sequence [pat_first, pat_last) in another sequence [first, last) that is provided to the object’s function call operator. The first sequence (the pattern to be searched for) is provided to the object’s constructor, and the second (the sequence to be searched) is provided to the function call operator.

Each specialization of a class template specified in 22.10.18 shall meet the Cpp17CopyConstructible and Cpp17CopyAssignable requirements. Template parameters named

(2.1) — ForwardIterator,
(2.2) — ForwardIterator1,
(2.3) — ForwardIterator2,
(2.4) — RandomAccessIterator,
(2.5) — RandomAccessIterator1,
(2.6) — RandomAccessIterator2, and
(2.7) — BinaryPredicate

§ 22.10.18.1
of templates specified in 22.10.18 shall meet the same requirements and semantics as specified in 27.1. Template parameters named Hash shall meet the Cpp17Hash requirements (Table 37).

The Boyer-Moore searcher implements the Boyer-Moore search algorithm. The Boyer-Moore-Horspool searcher implements the Boyer-Moore-Horspool search algorithm. In general, the Boyer-Moore searcher will use more memory and give better runtime performance than Boyer-Moore-Horspool.

22.10.18.2 Class template default_searcher

```cpp
namespace std {
    template<class ForwardIterator1, class BinaryPredicate = equal_to<>>
    class default_searcher {
        public:
            constexpr default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                                      BinaryPredicate pred = BinaryPredicate());

            template<class ForwardIterator2>
            constexpr pair<ForwardIterator2, ForwardIterator2>
            operator()(ForwardIterator2 first, ForwardIterator2 last) const;
        private:
            ForwardIterator1 pat_first_;  // exposition only
            ForwardIterator1 pat_last_;   // exposition only
            BinaryPredicate pred_;        // exposition only
        }
    }
}
```

1 Effects: Constructs a default_searcher object, initializing pat_first_ with pat_first, pat_last_ with pat_last, and pred_ with pred.
2 Throws: Any exception thrown by the copy constructor of BinaryPredicate or ForwardIterator1.

```cpp
template<class ForwardIterator2>
constexpr pair<ForwardIterator2, ForwardIterator2>
operator()(ForwardIterator2 first, ForwardIterator2 last) const;
```

3 Effects: Returns a pair of iterators i and j such that
   - i == search(first, last, pat_first_, pat_last_, pred_), and
   - if i == last, then j == last, otherwise j == next(i, distance(pat_first_, pat_last_)).

22.10.18.3 Class template boyer_moore_searcher

```cpp
namespace std {
    template<class RandomAccessIterator1,  
               class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,  
               class BinaryPredicate = equal_to<>>
    class boyer_moore_searcher {
        public:
            boyer_moore_searcher(RandomAccessIterator1 pat_first,  
                                  RandomAccessIterator1 pat_last,  
                                  Hash hf = Hash(),  
                                  BinaryPredicate pred = BinaryPredicate());

            template<class RandomAccessIterator2>
            pair<RandomAccessIterator2, RandomAccessIterator2>
            operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
        private:
            RandomAccessIterator1 pat_first_;  // exposition only
            RandomAccessIterator1 pat_last_;   // exposition only
            Hash hash_;                        // exposition only
            BinaryPredicate pred_;            // exposition only
        }
    }
}
```

§ 22.10.18.3 786
boyer_moore_searcher(RandomAccessIterator1 pat_first,
    RandomAccessIterator1 pat_last,
    Hash hf = Hash(),
    BinaryPredicate pred = BinaryPredicate());

1. **Preconditions:** The value type of RandomAccessIterator1 meets the Cpp17DefaultConstructible, the Cpp17CopyConstructible, and the Cpp17CopyAssignable requirements.

2. Let V be iterator_traits<RandomAccessIterator1>::value_type. For any two values A and B of type V, if pred(A, B) == true, then hf(A) == hf(B) is true.

3. **Effects:** Initializes pat_first_ with pat_first, pat_last_ with pat_last, hash_ with hf, and pred_ with pred.

4. **Throses:** Any exception thrown by the copy constructor of RandomAccessIterator1, or by the default constructor, copy constructor, or the copy assignment operator of the value type of RandomAccessIterator1, or the copy constructor or operator() of BinaryPredicate or Hash. May throw bad_alloc if additional memory needed for internal data structures cannot be allocated.

5. template<class RandomAccessIterator2>
   pair<RandomAccessIterator2, RandomAccessIterator2>
   operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

6. **Mandates:** RandomAccessIterator1 and RandomAccessIterator2 have the same value type.

7. **Effects:** Finds a subsequence of equal values in a sequence.

8. **Returns:** A pair of iterators i and j such that
   - i is the first iterator in the range [first, last - (pat_last_ - pat_first_)) such that for every non-negative integer n less than pat_last_ - pat_first_ the following condition holds:
     pred(*(i + n), *(pat_first_ + n)) != false, and
   - j == next(i, distance(pat_first_, pat_last_)).

9. **Returns** make_pair(first, first) if [pat_first_, pat_last_) is empty, otherwise returns make_pair(last, last) if no such iterator is found.

10. **Complexity:** At most (last - first) * (pat_last_ - pat_first_) applications of the predicate.
**Preconditions:** The value type of `RandomAccessIterator1` meets the `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, and `Cpp17CopyAssignable` requirements.

Let `V` be `iterator_traits<RandomAccessIterator1>::value_type`. For any two values `A` and `B` of type `V`, if `pred(A, B) == true`, then `hf(A) == hf(B)` is true.

**Effects:** Initializes `pat_first_` with `pat_first_`, `pat_last_` with `pat_last_`, `hash_` with `hf`, and `pred_` with `pred`.

**Throws:** Any exception thrown by the copy constructor of `RandomAccessIterator1`, or by the default constructor, copy constructor, or the copy assignment operator of the value type of `RandomAccessIterator1`, or the copy constructor or `operator()` of `BinaryPredicate` or `Hash`. May throw `bad_alloc` if additional memory needed for internal data structures cannot be allocated.

```cpp
template<class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
```

**Mandates:** `RandomAccessIterator1` and `RandomAccessIterator2` have the same value type.

**Effects:** Finds a subsequence of equal values in a sequence.

**Returns:** A pair of iterators `i` and `j` such that

(7.1) — `i` is the first iterator in the range `[first, last - (pat_last_ - pat_first_ - 1)]` such that for every non-negative integer `n` less than `pat_last_ - pat_first_` the following condition holds:

\[
pred(*(i + n), *(pat_first_ + n)) != false, \text{ and}
\]

(7.2) — `j` is the first iterator in the range `[first, last - (pat_last_ - pat_first_)]` such that for every non-negative integer `n` less than `pat_last_ - pat_first_` the following condition holds:

\[
pred(*(j + n), *(pat_first_ + n)) != false, \text{ and}
\]

**Returns:** `make_pair(first, first)` if `pat_first_ == pat_last_` is empty, otherwise returns `make_pair(last, last)` if no such iterator is found.

**Complexity:** At most `(last - first) * (pat_last_ - pat_first_)` applications of the predicate.

### 22.10.19 Class template `hash` [unord.hash]

The unordered associative containers defined in 24.5 use specializations of the class template `hash` (22.10.2) as the default hash function.

Each specialization of `hash` is either enabled or disabled, as described below.

[Note 1: Enabled specializations meet the `Cpp17Hash` requirements, and disabled specializations do not. — end note]

Each header that declares the template `hash` provides enabled specializations of `hash` for `nullptr_t` and all cv-unqualified arithmetic, enumeration, and pointer types. For any type `Key` for which neither the library nor the user provides an explicit or partial specialization of the class template `hash`, `hash<Key>` is disabled.

If the library provides an explicit or partial specialization of `hash<Key>`, that specialization is enabled except as noted otherwise, and its member functions are `noexcept` except as noted otherwise.

If `H` is a disabled specialization of `hash`, these values are `false`: `is_default_constructible_v<H>`, `is_copy_constructible_v<H>`, `is_move_constructible_v<H>`, `is_copyAssignable_v<H>`, and `is_moveAssignable_v<H>`. Disabled specializations of `hash` are not function object types (22.10).

[Note 2: This means that the specialization of `hash` exists, but any attempts to use it as a `Cpp17Hash` will be ill-formed. — end note]

An enabled specialization `hash<Key>` will:

(5.1) — meet the `Cpp17Hash` requirements (Table 37), with `Key` as the function call argument type, the `Cpp17DefaultConstructible` requirements (Table 30), the `Cpp17CopyAssignible` requirements (Table 34), the `Cpp17Swappable` requirements (16.4.4.3),

(5.2) — meet the requirement that if `k1 == k2` is true, `h(k1) == h(k2)` is also true, where `h` is an object of type `hash<Key>` and `k1` and `k2` are objects of type `Key`;

(5.3) — meet the requirement that the expression `h(k)`, where `h` is an object of type `hash<Key>` and `k` is an object of type `Key`, shall not throw an exception unless `hash<Key>` is a program-defined specialization.
22.11 Class type_index

22.11.1 Header <typeindex> synopsis

```cpp
#include <compare> // see 17.11.1
```

namespace std {
    class type_index;
    template<class T> struct hash;
    template<> struct hash<type_index>;
}

22.11.2 type_index overview

namespace std {
    class type_index {
    public:
        type_index(const type_info& rhs) noexcept;
        bool operator==(const type_index& rhs) const noexcept;
        bool operator<(const type_index& rhs) const noexcept;
        bool operator>(const type_index& rhs) const noexcept;
        bool operator<=(const type_index& rhs) const noexcept;
        bool operator>=(const type_index& rhs) const noexcept;
        strong_ordering operator<=>(const type_index& rhs) const noexcept;
        size_t hash_code() const noexcept;
        const char* name() const noexcept;
    private:
        const type_info* target; // exposition only
        // Note that the use of a pointer here, rather than a reference,
        // means that the default copy/move constructor and assignment
        // operators will be provided and work as expected.
    }
}

1 The class type_index provides a simple wrapper for type_info which can be used as an index type in associative containers (24.4) and in unordered associative containers (24.5).

22.11.3 type_index members

```cpp
type_index(const type_info& rhs) noexcept;
    
    Effects: Constructs a type_index object, the equivalent of target = &rhs.
```

```cpp
bool operator==(const type_index& rhs) const noexcept;
    
    Returns: *target == *rhs.target.
```

```cpp
bool operator<(const type_index& rhs) const noexcept;
    
    Returns: target->before(*rhs.target).
```

```cpp
bool operator>(const type_index& rhs) const noexcept;
    
    Returns: rhs.target->before(*target).
```

```cpp
bool operator<=(const type_index& rhs) const noexcept;
    
    Returns: !rhs.target->before(*target).
```

```cpp
bool operator>=(const type_index& rhs) const noexcept;
    
    Returns: !target->before(*rhs.target).
```

```cpp
strong_ordering operator<=>(const type_index& rhs) const noexcept;
    
    Effects: Equivalent to:
        if (*target == *rhs.target) return strong_ordering::equal;
        if (target->before(*rhs.target)) return strong_ordering::less;
        return strong_ordering::greater;
```
size_t hash_code() const noexcept;

Returns: target->hash_code().

const char* name() const noexcept;

Returns: target->name().

22.11.4 Hash support

template<> struct hash<type_index>;

For an object index of type type_index, hash<type_index>()(index) shall evaluate to the same result as index.hash_code().

22.12 Execution policies

22.12.1 In general

Subclause 22.12 describes classes that are execution policy types. An object of an execution policy type indicates the kinds of parallelism allowed in the execution of an algorithm and expresses the consequent requirements on the element access functions.

[Example 1:

```cpp
using namespace std;
vector<int> v = /* ... */;

// standard sequential sort
sort(v.begin(), v.end());

// explicitly sequential sort
sort(execution::seq, v.begin(), v.end());

// permitting parallel execution
sort(execution::par, v.begin(), v.end());

// permitting vectorization as well
sort(execution::par_unseq, v.begin(), v.end());
```
—end example]

[Note 1: Implementations can provide additional execution policies to those described in this standard as extensions to address parallel architectures that require idiosyncratic parameters for efficient execution. —end note]

22.12.2 Header <execution> synopsis

```cpp
namespace std {

    // 22.12.3, execution policy type trait
template<class T> struct is_execution_policy;
template<class T> constexpr bool is_execution_policy_v = is_execution_policy<T>::value;
}

namespace std::execution {

    // 22.12.4, sequenced execution policy
class sequenced_policy;

    // 22.12.5, parallel execution policy
class parallel_policy;

    // 22.12.6, parallel and unsequenced execution policy
class parallel_unsequenced_policy;

    // 22.12.7, unsequenced execution policy
class unsequenced_policy;

    // 22.12.8, execution policy objects
inline constexpr sequenced_policy seq{ unspecified };
inline constexpr parallel_policy par{ unspecified };
inline constexpr parallel_unsequenced_policy par_unseq{ unspecified };
```
22.12.3 Execution policy type trait

template<class T> struct is_execution_policy { see below };  

1  

is_execution_policy can be used to detect execution policies for the purpose of excluding function signatures from otherwise ambiguous overload resolution participation.

2  

is_execution_policy<T> is a Cpp17UnaryTypeTrait with a base characteristic of true_type if T is
the type of a standard or implementation-defined execution policy, otherwise false_type.

[Note 1: This provision reserves the privilege of creating non-standard execution policies to the library
implementation. — end note]

3  

The behavior of a program that adds specializations for is_execution_policy is undefined.

22.12.4 Sequenced execution policy

class execution::sequenced_policy { unspecified };  

1  

The class execution::sequenced_policy is an execution policy type used as a unique type to disam-
biguate parallel algorithm overloading and require that a parallel algorithm’s execution may not be
parallelized.

2  

During the execution of a parallel algorithm with the execution::sequenced_policy policy, if the
invocation of an element access function exits via an exception, terminate is invoked (14.6.2).

22.12.5 Parallel execution policy

class execution::parallel_policy { unspecified };  

1  

The class execution::parallel_policy is an execution policy type used as a unique type to disam-
biguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be
parallelized.

2  

During the execution of a parallel algorithm with the execution::parallel_policy policy, if the
invocation of an element access function exits via an exception, terminate is invoked (14.6.2).

22.12.6 Parallel and unsequenced execution policy

class execution::parallel_unsequenced_policy { unspecified };  

1  

The class execution::parallel_unsequenced_policy is an execution policy type used as a unique type to disam-
biguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be
parallelized and vectorized.

2  

During the execution of a parallel algorithm with the execution::parallel_unsequenced_policy policy, if the
invocation of an element access function exits via an exception, terminate is invoked (14.6.2).

22.12.7 Unsequenced execution policy

class execution::unsequenced_policy { unspecified };  

1  

The class unsequenced_policy is an execution policy type used as a unique type to disambiguate parallel
algorithm overloading and indicate that a parallel algorithm’s execution may be vectorized, e.g., executed on
a single thread using instructions that operate on multiple data items.

2  

During the execution of a parallel algorithm with the execution::unsequenced_policy policy, if the
invocation of an element access function exits via an exception, terminate is invoked (14.6.2).

22.12.8 Execution policy objects

inline constexpr execution::sequenced_policy execution::seq{ unspecified };  
inline constexpr execution::parallel_policy execution::par{ unspecified };  
inline constexpr execution::parallel_unsequenced_policy execution::par_unseq{ unspecified };  
inline constexpr execution::unsequenced_policy execution::unseq{ unspecified };  

1  

The header <execution> declares global objects associated with each type of execution policy.
22.13 Primitive numeric conversions

22.13.1 Header <charconv> synopsis

When a function is specified with a type placeholder of \texttt{integer-type}, the implementation provides overloads for all cv-unqualified signed and unsigned integer types and \texttt{char} in lieu of \texttt{integer-type}. When a function is specified with a type placeholder of \texttt{floating-point-type}, the implementation provides overloads for all cv-unqualified floating-point types (6.8.2) in lieu of \texttt{floating-point-type}.

namespace std {
    // floating-point format for primitive numerical conversion
    enum class chars_format {
        scientific = unspecified,
        fixed = unspecified,
        hex = unspecified,
        general = fixed | scientific
    };

    // 22.13.2, primitive numerical output conversion
    struct to_chars_result {
        char* ptr;
        errc ec;
        friend bool operator==(const to_chars_result&, const to_chars_result&) = default;
    };

    constexpr to_chars_result to_chars(char* first, char* last, integer-type value, int base = 10);
    to_chars_result to_chars(char* first, char* last, bool value, int base = 10) = delete;
    to_chars_result to_chars(char* first, char* last, floating-point-type value);
    to_chars_result to_chars(char* first, char* last, floating-point-type value, chars_format fmt);
    to_chars_result to_chars(char* first, char* last, floating-point-type value, chars_format fmt, int precision);
}

// 22.13.3, primitive numerical input conversion
struct from_chars_result {
    const char* ptr;
    errc ec;
    friend bool operator==(const from_chars_result&, const from_chars_result&) = default;
};

constexpr from_chars_result from_chars(const char* first, const char* last, integer-type& value, int base = 10);
from_chars_result from_chars(const char* first, const char* last, floating-point-type& value, chars_format fmt = chars_format::general);

The type \texttt{chars_format} is a bitmask type (16.3.3.3.3) with elements \texttt{scientific}, \texttt{fixed}, and \texttt{hex}.

The types \texttt{to_chars_result} and \texttt{from_chars_result} have the data members and special members specified above. They have no base classes or members other than those specified.

22.13.2 Primitive numeric output conversion

All functions named \texttt{to_chars} convert \texttt{value} into a character string by successively filling the range [\texttt{first, last}], where [\texttt{first, last}] is required to be a valid range. If the member \texttt{ec} of the return value is such that the value is equal to the value of a value-initialized \texttt{errc}, the conversion was successful and the member \texttt{ptr} is the one-past-the-end pointer of the characters written. Otherwise, the member \texttt{ec} has the value \texttt{errc::value_too_large}, the member \texttt{ptr} has the value \texttt{last}, and the contents of the range [\texttt{first, last}] are unspecified.

The functions that take a floating-point \texttt{value} but not a \texttt{precision} parameter ensure that the string representation consists of the smallest number of characters such that there is at least one digit before the radix point (if present) and parsing the representation using the corresponding \texttt{from_chars} function recovers \texttt{value} exactly.
If there are several such representations, the representation with the smallest difference from the floating-point argument value is chosen, resolving any remaining ties using rounding according to round_to_nearest (17.3.4).

The functions taking a chars_format parameter determine the conversion specifier for printf as follows: The conversion specifier is f if fmt is chars_format::fixed, e if fmt is chars_format::scientific, a (without leading "0x" in the result) if fmt is chars_format::hex, and g if fmt is chars_format::general.

```cpp
constexpr to_chars_result to_chars(char* first, char* last, integer-type value, int base = 10);
```

- **Preconditions:** base has a value between 2 and 36 (inclusive).
- **Effects:** The value of value is converted to a string of digits in the given base (with no redundant leading zeroes). Digits in the range 10..35 (inclusive) are represented as lowercase characters a..z. If value is less than zero, the representation starts with '−'.
- **Throws:** Nothing.

```cpp
to_chars_result to_chars(char* first, char* last, floating-point-type value);
```

- **Effects:** value is converted to a string in the style of printf in the "C" locale. The conversion specifier is f or e, chosen according to the requirement for a shortest representation (see above); a tie is resolved in favor of f.
- **Throws:** Nothing.

```cpp
to_chars_result to_chars(char* first, char* last, floating-point-type value, chars_format fmt);
```

- **Preconditions:** fmt has the value of one of the enumerators of chars_format.
- **Effects:** value is converted to a string in the style of printf in the "C" locale.
- **Throws:** Nothing.

```cpp
to_chars_result to_chars(char* first, char* last, floating-point-type value, chars_format fmt, int precision);
```

- **Preconditions:** fmt has the value of one of the enumerators of chars_format.
- **Effects:** value is converted to a string in the style of printf in the "C" locale with the given precision.
- **Throws:** Nothing.

See also: ISO C 7.21.6.1

#### 22.13.3 Primitive numeric input conversion

All functions named from_chars analyze the string [first,last) for a pattern, where [first,last) is required to be a valid range. If no characters match the pattern, value is unmodified, the member ptr of the return value is first and the member ec is equal to errc::invalid_argument.

- **Note 1:** If the pattern allows for an optional sign, but the string has no digit characters following the sign, no characters match the pattern. — end note

Otherwise, the characters matching the pattern are interpreted as a representation of a value of the type of value. The member ptr of the return value points to the first character not matching the pattern, or has the value last if all characters match. If the parsed value is not in the range representable by the type of value, value is unmodified and the member ec of the return value is equal to errc::result_out_of_range. Otherwise, value is set to the parsed value, after rounding according to round_to_nearest (17.3.4), and the member ec is value-initialized.

```cpp
constexpr from_chars_result from_chars(const char* first, const char* last, integer-type& value, int base = 10);
```

- **Preconditions:** base has a value between 2 and 36 (inclusive).
- **Effects:** The pattern is the expected form of the subject sequence in the "C" locale for the given nonzero base, as described for strtol, except that no "0x" or "0X" prefix shall appear if the value of base is 16, and except that '−' is the only sign that may appear, and only if value has a signed type.
- **Throws:** Nothing.
from_chars_result from_chars(const char* first, const char* last, floating-point-type& value,
    chars_format fmt = chars_format::general);

5  Preconditions: fmt has the value of one of the enumerators of chars_format.
6  Effects: The pattern is the expected form of the subject sequence in the "C" locale, as described for
5  strtod, except that
6
(6.1)  — the sign ‘+’ may only appear in the exponent part;
(6.2)  — if fmt has chars_format::scientific set but not chars_format::fixed, the otherwise optional
6  exponent part shall appear;
(6.3)  — if fmt has chars_format::fixed set but not chars_format::scientific, the optional exponent
6  part shall not appear; and
(6.4)  — if fmt is chars_format::hex, the prefix "0x" or "0X" is assumed.

[Example 1: The string 0x123 is parsed to have the value 0 with remaining characters x123. — end
5  example]

In any case, the resulting value is one of at most two floating-point values closest to the value of the
5  string matching the pattern.

7  Throws: Nothing.

1 The class template format_to_n_result has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

22.14.2 Format string

22.14.2.1 In general

A format string for arguments args is a (possibly empty) sequence of replacement fields, escape sequences, and characters other than { and }. Let charT be the character type of the format string. Each character that is not part of a replacement field or an escape sequence is copied unchanged to the output. An escape
sequence is one of \{ \text{ or } \}. It is replaced with \{ \text{ or } \}, respectively, in the output. The syntax of replacement fields is as follows:

```plaintext
replacement-field:
  \{ arg-id_{opt} format-specifier_{opt} \}

arg-id:
  0
  positive-integer

positive-integer:
  nonzero-digit
  positive-integer digit

nonnegative-integer:
  digit
  nonnegative-integer digit

nonzero-digit: one of
  1 2 3 4 5 6 7 8 9

digit: one of
  0 1 2 3 4 5 6 7 8 9

format-specifier:
  : format-spec

format-spec:
  as specified by the formatter specialization for the argument type
```

2 The `arg-id` field specifies the index of the argument in `args` whose value is to be formatted and inserted into the output instead of the replacement field. If there is no argument with the index `arg-id` in `args`, the string is not a format string for `args`. The optional `format-specifier` field explicitly specifies a format for the replacement value.

3 [Example 1]:

```plaintext
string s = format("{0}\-{1}\); // value of s is "8-9"
```

4 If all `arg-ids` in a format string are omitted (including those in the `format-spec`, as interpreted by the corresponding `formatter` specialization), argument indices 0, 1, 2, ... will automatically be used in that order. If some `arg-ids` are omitted and some are present, the string is not a format string.

[Note 1: A format string cannot contain a mixture of automatic and manual indexing. — end note]

[Example 2]:

```plaintext
string s0 = format("{} to {}\); // OK, automatic indexing
string s1 = format("{1} to {}\); // OK, manual indexing
string s2 = format("{0} to {}\); // not a format string (mixing automatic and manual indexing), // ill-formed
string s3 = format("{} to {}\); // not a format string (mixing automatic and manual indexing), // ill-formed
```

5 The `format-spec` field contains format specifications that define how the value should be presented. Each type can define its own interpretation of the `format-spec` field. If `format-spec` does not conform to the format specifications for the argument type referred to by `arg-id`, the string is not a format string for `args`.

[Example 3]:

1. For arithmetic, pointer, and string types the `format-spec` is interpreted as a `std-format-spec` as described in (22.14.2.2).
2. For chrono types the `format-spec` is interpreted as a `chrono-format-spec` as described in (29.12).
3. For user-defined `formatter` specializations, the behavior of the `parse` member function determines how the `format-spec` is interpreted.

---

§ 22.14.2.1 797
22.14.2.2 Standard format specifiers

1 Each *formatter* specialization described in 22.14.6.3 for fundamental and string types interprets *format-spec* as a *std-format-spec*.

[Note 1: The format specification can be used to specify such details as minimum field width, alignment, padding, and decimal precision. Some of the formatting options are only supported for arithmetic types. — end note]

The syntax of format specifications is as follows:

```
std-format-spec:
    fill-and-align_opt sign_opt # opt 0 opt width opt precision opt L opt type_opt
fill-and-align:
    fill_opt align
fill:
    any character other than { or }
align: one of
    < > ^
sign: one of
    + - space
width:
    positive-integer
    \{ arg-id_opt \}
precision:
    . nonnegative-integer
    \{ arg-id_opt \}
type: one of
    a A b B c d e E f F g G o p s x X
```

2 Field widths are specified in defnadjfield widthunits; the number of column positions required to display a sequence of characters in a terminal. The *minimum field width* is the number of field width units a replacement field minimally requires of the formatted sequence of characters produced for a format argument. The *estimated field width* is the number of field width units that are required for the formatted sequence of characters produced for a format argument independent of the effects of the *width* option. The *padding width* is the greater of 0 and the difference of the minimum field width and the estimated field width.

[Note 2: The POSIX `wcswidth` function is an example of a function that, given a string, returns the number of column positions required by a terminal to display the string. — end note]

3 The *fill character* is the character denoted by the *fill* option or, if the *fill* option is absent, the space character. For a format specification in UTF-8, UTF-16, or UTF-32, the fill character corresponds to a single Unicode scalar value.

[Note 3: The presence of a *fill* option is signaled by the character following it, which must be one of the alignment options. If the second character of *std-format-spec* is not a valid alignment option, then it is assumed that the *fill* and *align* options are both absent. — end note]

4 The *align* option applies to all argument types. The meaning of the various alignment options is as specified in Table 65.

[Example 1:]

```
char c = 120;
string s0 = format("{:6}" , 42);  // value of s0 is " 42"
string s1 = format("{:6}" , 'x');  // value of s1 is "x "
string s2 = format("{:>6}" , 'x');  // value of s2 is "x*****
string s3 = format("{:>6}" , 'x');  // value of s3 is "*****x"
string s4 = format("{*:6}" , 'x');  // value of s4 is "**x***"
string s5 = format("{:*<6}" , 'c');  // value of s5 is " 120"
string s6 = format("{:6}" , true);  // value of s6 is "true"
string s7 = format("{:<6.3}" , "123456"); // value of s7 is "123***
string s8 = format("{:02}" , 1234);  // value of s8 is "1234"
string s9 = format("{:<8}" , 12);  // value of s9 is " 12"
string sA = format("{:>8}" , "12345678"); // value of sA is "12345678"
```
— end example]
Note 4: The fill, align, and 0 options have no effect when the minimum field width is not greater than the estimated field width because padding width is 0 in that case. Since fill characters are assumed to have a field width of 1, use of a character with a different field width can produce misaligned output. The U+1F921 clown face character has a field width of 2. The examples above that include that character illustrate the effect of the field width when that character is used as a fill character as opposed to when it is used as a formatting argument. —end note

Table 65: Meaning of align options  [tab:format.align]

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;</code></td>
<td>Forces the formatted argument to be aligned to the start of the field by inserting ( n ) fill characters after the formatted argument where ( n ) is the padding width. This is the default for non-arithmetic non-pointer types, <code>charT</code>, and <code>bool</code>, unless an integer presentation type is specified.</td>
</tr>
<tr>
<td><code>&gt;</code></td>
<td>Forces the formatted argument to be aligned to the end of the field by inserting ( n ) fill characters before the formatted argument where ( n ) is the padding width. This is the default for arithmetic types other than <code>charT</code> and <code>bool</code>, pointer types, or when an integer presentation type is specified.</td>
</tr>
<tr>
<td><code>^</code></td>
<td>Forces the formatted argument to be centered within the field by inserting ( \left\lfloor \frac{n}{2} \right\rfloor ) fill characters before and ( \left\lceil \frac{n}{2} \right\rceil ) fill characters after the formatted argument, where ( n ) is the padding width.</td>
</tr>
</tbody>
</table>

The `sign` option is only valid for arithmetic types other than `charT` and `bool` or when an integer presentation type is specified. The meaning of the various options is as specified in Table 66.

Table 66: Meaning of sign options  [tab:format.sign]

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>+</code></td>
<td>Indicates that a sign should be used for both non-negative and negative numbers. The + sign is inserted before the output of <code>to_chars</code> for non-negative numbers other than negative zero. [Note 5: For negative numbers and negative zero the output of <code>to_chars</code> will already contain the sign so no additional transformation is performed. —end note]</td>
</tr>
<tr>
<td><code>-</code></td>
<td>Indicates that a sign should be used for negative numbers and negative zero only (this is the default behavior).</td>
</tr>
<tr>
<td><code>space</code></td>
<td>Indicates that a leading space should be used for non-negative numbers other than negative zero, and a minus sign for negative numbers and negative zero.</td>
</tr>
</tbody>
</table>

The `#` option causes the alternate form to be used for the conversion. This option is valid for arithmetic types other than `charT` and `bool` or when an integer presentation type is specified, and not otherwise. For integral types, the alternate form inserts the base prefix (if any) specified in Table 68 into the output after the sign character (possibly space) if there is one, or before the output of `to_chars` otherwise. For floating-point types, the alternate form causes the result of the conversion of finite values to always contain a decimal-point character, even if no digits follow it. Normally, a decimal-point character appears in the result of these conversions only if a digit follows it. In addition, for `g` and `G` conversions, trailing zeros are not removed from the result.

The 0 option is valid for arithmetic types other than `charT` and `bool` or when an integer presentation type is specified. For formatting arguments that have a value other than an infinity or a NaN, this option pads the
formatted argument by inserting the 0 character \( n \) times following the sign or base prefix indicators (if any) where \( n = 0 \) if the align option is present and is the padding width otherwise.

[Example 3:

```c
char c = 120;
string s1 = format("{:+06d}", c); // value of s1 is "+00120"
string s2 = format("{:06x}", 0xa); // value of s2 is "0x000a"
string s3 = format("{:<06}", -42); // value of s3 is "-42 " (0 has no effect)
string s4 = format("{:06}", inf); // value of s4 is " inf" (0 has no effect)
```

—end example]

The width option specifies the minimum field width. If the width option is absent, the minimum field width is 0.

If \{ arg-id \opt \} is used in a width or precision option, the value of the corresponding formatting argument is used as the value of the option. If the corresponding formatting argument is not of standard signed or unsigned integer type, or its value is negative, an exception of type format_error is thrown.

If positive-integer is used in a width option, the value of the decimal integer is used as the value of the option.

For the purposes of width computation, a string is assumed to be in a locale-independent, implementation-defined encoding. Implementations should use either UTF-8, UTF-16, or UTF-32, on platforms capable of displaying Unicode text in a terminal.

[Note 6: This is the case for Windows [205]-based and many POSIX-based operating systems. — end note]

For a sequence of characters in UTF-8, UTF-16, or UTF-32, an implementation should use as its field width the sum of the field widths of the first code point of each extended grapheme cluster. Extended grapheme clusters are defined by UAX #29 of the Unicode Standard. The following code points have a field width of 2:

13.1 — any code point with the East_Asian_Width="W" or East_Asian_Width="F" Derived Extracted Property as described by UAX #44 of the Unicode Standard

13.2 — U+4D00 – U+4DFF (Yijing Hexagram Symbols)

13.3 — U+1F300 – U+1F5FF (Miscellaneous Symbols and Pictographs)

13.4 — U+1F900 – U+1F9FF (Supplemental Symbols and Pictographs)

The field width of all other code points is 1.

For a sequence of characters in neither UTF-8, UTF-16, nor UTF-32, the field width is unspecified.

The precision option is valid for floating-point and string types. For floating-point types, the value of this option specifies the precision to be used for the floating-point presentation type. For string types, this option specifies the longest prefix of the formatted argument to be included in the replacement field such that the field width of the prefix is no greater than the value of this option.

If nonnegative-integer is used in a precision option, the value of the decimal integer is used as the value of the option.

When the L option is used, the form used for the conversion is called the locale-specific form. The L option is only valid for arithmetic types, and its effect depends upon the type.

17.1 — For integral types, the locale-specific form causes the context’s locale to be used to insert the appropriate digit group separator characters.

17.2 — For floating-point types, the locale-specific form causes the context’s locale to be used to insert the appropriate digit group and radix separator characters.

17.3 — For the textual representation of bool, the locale-specific form causes the context’s locale to be used to insert the appropriate string as if obtained with numpunct::truename or numpunct::falsename.

The type determines how the data should be presented.

The available string presentation types are specified in Table 67.

The meaning of some non-string presentation types is defined in terms of a call to to_chars. In such cases, let [first, last) be a range large enough to hold the to_chars output and value be the formatting argument

205) Windows® is a registered trademark of Microsoft Corporation. This information is given for the convenience of users of this document and does not constitute an endorsement by ISO or IEC of this product.
value. Formatting is done as if by calling `to_chars` as specified and copying the output through the output iterator of the format context.

[Note 7: Additional padding and adjustments are performed prior to copying the output through the output iterator as specified by the format specifiers. — end note]

The available integer presentation types for integral types other than `bool` and `charT` are specified in Table 68.

```cpp
string s0 = format("{}", 42); // value of s0 is "42"
string s1 = format("{0:b} {0:d} {0:o} {0:x}", 42); // value of s1 is "101010 42 52 2a"
string s2 = format("{0:#x}", 42); // value of s2 is "0x2a 0X2A"
string s3 = format("{:L}", 1234); // value of s3 can be "1,234" // (depending on the locale)
```

—end example]

The available `charT` presentation types are specified in Table 69.

The available `bool` presentation types are specified in Table 70.
The available floating-point presentation types and their meanings for values other than infinity and NaN are specified in Table 71. For lower-case presentation types, infinity and NaN are formatted as inf and nan, respectively. For upper-case presentation types, infinity and NaN are formatted as INF and NAN, respectively.

[Note 9: In either case, a sign is included if indicated by the sign option. — end note]

Table 71: Meaning of type options for floating-point types [tab:format.type.float]

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>If precision is specified, equivalent to <code>to_chars(first, last, value, chars_format::hex, precision)</code> where precision is the specified formatting precision; equivalent to <code>to_chars(first, last, value, chars_format::hex)</code> otherwise.</td>
</tr>
<tr>
<td>A</td>
<td>The same as a, except that it uses uppercase letters for digits above 9 and P to indicate the exponent.</td>
</tr>
<tr>
<td>e</td>
<td>Equivalent to <code>to_chars(first, last, value, chars_format::scientific, precision)</code> where precision is the specified formatting precision, or 6 if precision is not specified.</td>
</tr>
<tr>
<td>E</td>
<td>The same as e, except that it uses E to indicate exponent.</td>
</tr>
<tr>
<td>f, F</td>
<td>Equivalent to <code>to_chars(first, last, value, chars_format::fixed, precision)</code> where precision is the specified formatting precision, or 6 if precision is not specified.</td>
</tr>

</table>

22.14.3 Error reporting [format.err.report]

Formatting functions throw format_error if an argument fmt is passed that is not a format string for args. They propagate exceptions thrown by operations of formatter specializations and iterators. Failure to allocate storage is reported by throwing an exception as described in 16.4.6.13.

22.14.4 Class template basic_format_string [format.fmt.string]

```cpp
namespace std {
    template<class charT, class... Args>
    struct basic_format_string {
        private:
            basic_string_view<charT> str; // exposition only

        public:
            template<class T> constexpr basic_format_string(const T& s);
```
constexpr basic_string_view<charT> get() const noexcept { return str; }
};

template<class T> consteval basic_format_string(const T& s);

Constraints:  const T& models convertible_to basic_string_view<charT>.

Effects: Direct-non-list-initializes str with s.

Remarks: A call to this function is not a core constant expression (7.7) unless there exist args of types Args such that str is a format string for args.

22.14.5 Formatting functions

In the description of the functions, operator + is used for some of the iterator categories for which it does not have to be defined. In these cases the semantics of a + n are the same as in 27.2.

template<class... Args>
string format(format_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
return vformat(fmt.str, make_format_args(args...));

template<class... Args>
wstring format(wformat_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
return vformat(fmt.str, make_wformat_args(args...));

template<class... Args>
string format(const locale& loc, format_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
return vformat(loc, fmt.str, make_format_args(args...));

template<class... Args>
wstring format(const locale& loc, wformat_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
return vformat(loc, fmt.str, make_wformat_args(args...));

Returns: A string object holding the character representation of formatting arguments provided by args formatted according to specifications given in fmt. If present, loc is used for locale-specific formatting.

Throws: As specified in 22.14.3.

template<class Out, class... Args>
Out format_to(Out out, format_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
return vformat_to(std::move(out), fmt.str, make_format_args(args...));

template<class Out, class... Args>
Out format_to(Out out, wformat_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
return vformat_to(std::move(out), fmt.str, make_wformat_args(args...));

template<class Out, class... Args>
Out format_to(Out out, const locale& loc, format_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
return vformat_to(std::move(out), loc, fmt.str, make_format_args(args...));

§ 22.14.5
template<class Out, class... Args>
    Out format_to(Out out, const locale& loc, wformat_string<Args...> fmt, Args&&... args);

Effects: Equivalent to:
    return vformat_to(std::move(out), loc, fmt.str, make_wformat_args(args...));

Constraints: Out satisfies output_iterator<const charT&>.

Preconditions: Out models output_iterator<const charT&>.

Effects: Places the character representation of formatting the arguments provided by args, formatted
according to the specifications given in fmt, into the range [out, out + N), where N is the number of
characters in that character representation. If present, loc is used for locale-specific formatting.

Returns: out + N.

Throws: As specified in 22.14.3.

Let charT be decltype(fmt::value_type).

Preconditions: Out satisfies output_iterator<const charT&>.

Effects: Places the first M characters of the character representation of formatting the arguments
provided by args, formatted according to the specifications given in fmt, into the range [out, out + M). If present, loc is used for locale-specific formatting.

Returns: {out + M, N}.

Throws: As specified in 22.14.3.

§ 22.14.5
template<class... Args>
size_t formatted_size(const locale& loc, wformat_string<Args...> fmt, Args&&... args);

Let charT be decltype(fmt.str)::value_type.

Preconditions: formatter<remove_cvref_t<T>, charT> meets the BasicFormatter requirements (22.14.6.1) for each T in Args.

Returns: The number of characters in the character representation of formatting arguments args formatted according to specifications given in fmt. If present, loc is used for locale-specific formatting.

Throws: As specified in 22.14.3.

22.14.6 Formatter

22.14.6.1 Formatter requirements

1 A type F meets the BasicFormatter requirements if it meets the
(1.1) — Cpp17DefaultConstructible (Table 30),
(1.2) — Cpp17CopyConstructible (Table 32),
(1.3) — Cpp17CopyAssignable (Table 34),
(1.4) — Cpp17Swappable (16.4.4.3), and
(1.5) — Cpp17Destructible (Table 35)

requirements, and the expressions shown in Table 73 are valid and have the indicated semantics.

2 A type F meets the Formatter requirements if it meets the BasicFormatter requirements and the expressions shown in Table 74 are valid and have the indicated semantics.

3 Given character type charT, output iterator type Out, and formatting argument type T, in Table 73 and Table 74:

(3.1) — f is a value of type (possibly const) F,
(3.2) — g is an lvalue of type F,
(3.3) — u is an lvalue of type T,
(3.4) — t is a value of a type convertible to (possibly const) T,
(3.5) — PC is basic_format_parse_context<charT>,
(3.6) — FC is basic_format_context<Out, charT>,
(3.7) — pc is an lvalue of type PC, and
(3.8) — fc is an lvalue of type FC.

pc.begin() points to the beginning of the format-spec (22.14.2) of the replacement field being formatted in the format string. If format-spec is empty then either pc.begin() == pc.end() or *pc.begin() == '}'.

22.14.6.2 Concept formattable

Let fmt-iter-for<charT> be an unspecified type that models output_iterator<const charT&> (25.3.4.10).

template<class T, class Context,
    class Formatter = typename Context::template formatter_type<remove_const_t<T>>> concept formattable-with = // exposition only
    semiregular<Formatter> &
    requires(Formatter& f, const Formatter& cf, T& t, Context fc,
        basic_format_parse_context<typename Context::char_type> pc)
    {
        { f.parse(pc) } -> same_as<typename decltype(pc)::iterator>;
        { cf.format(t, fc) } -> same_as<typename Context::iterator>;
    };

template<class T, class charT>
concept formattable =
    formattable-with<remove_reference_t<T>, basic_format_context<fmt-iter-for<charT>>>;

§ 22.14.6.2 805
Table 73: BasicFormatter requirements  [tab:formatter.basic]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Requirement</th>
</tr>
</thead>
</table>
| g.parse(pc)    | PC::iterator| Parses format-spec (22.14.2) for type T in the range [pc.begin(), pc.end()) until the first unmatched character. Throws format_error unless the whole range is parsed or the unmatched character is `.  
[Note 1: This allows formatters to emit meaningful error messages. — end note] Stores the parsed format specifiers in *this and returns an iterator past the end of the parsed range. |
| f.format(u, fc) | FC::iterator| Formats u according to the specifiers stored in *this, writes the output to fc.out(), and returns an iterator past the end of the output range. The output shall only depend on u, fc.locale(), fc.arg(n) for any value n of type size_t, and the range [pc.begin(), pc.end()) from the last call to f.parse(pc). |

Table 74: Formatter requirements  [tab:formatter]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>f.format(t, fc)</td>
<td>FC::iterator</td>
<td>Formats t according to the specifiers stored in *this, writes the output to fc.out(), and returns an iterator past the end of the output range. The output shall only depend on t, fc.locale(), fc.arg(n) for any value n of type size_t, and the range [pc.begin(), pc.end()) from the last call to f.parse(pc).</td>
</tr>
<tr>
<td>f.format(u, fc)</td>
<td>FC::iterator</td>
<td>As above, but does not modify u.</td>
</tr>
</tbody>
</table>

2 A type T and a character type charT model formattable if formatter<remove_cvref_t<T>, charT> meets the BasicFormatter requirements (22.14.6.1) and, if remove_reference_t<T> is const-qualified, the Formatter requirements.

22.14.6.3 Formatter specializations  [format.formatter.spec]

1 The functions defined in 22.14.5 use specializations of the class template formatter to format individual arguments.

2 Let charT be either char or wchar_t. Each specialization of formatter is either enabled or disabled, as described below. A debug-enabled specialization of formatter additionally provides a public, constexpr, non-static member function set_debug_format() which modifies the state of the formatter to be as if the type of the std-format-spec parsed by the last call to parse were ? Each header that declares the template formatter provides the following enabled specializations:

   (2.1) — The debug-enabled specializations
   template<> struct formatter<char, char>;
   template<> struct formatter<char, wchar_t>;
   template<> struct formatter<wchar_t, wchar_t>;

   (2.2) — For each charT, the debug-enabled string type specializations
   template<> struct formatter<charT*, charT>;
   template<> struct formatter<const charT*, charT>;
   template<size_t N> struct formatter<charT[N], charT>;
   template<class traits, class Allocator>
   struct formatter<basic_string<charT, traits, Allocator>, charT>;

§ 22.14.6.3
template<class traits>
struct formatter<basic_string_view<charT, traits>, charT>;

(2.3) — For each charT, for each cv-unqualified arithmetic type ArithmeticT other than char, wchar_t, char8_t, char16_t, or char32_t, a specialization

    template<> struct formatter<ArithmeticT, charT>;

(2.4) — For each charT, the pointer type specializations

    template<> struct formatter<nullptr_t, charT>;
    template<> struct formatter<void*, charT>;
    template<> struct formatter<const void*, charT>;

The parse member functions of these formatters interpret the format specification as a std-format-spec as described in 22.14.2.2.

[Note 1: Specializations such as formatter<wchar_t, char> and formatter<const char*, wchar_t> that would require implicit multibyte / wide string or character conversion are disabled. — end note]

3 For any types T and charT for which neither the library nor the user provides an explicit or partial specialization of the class template formatter, formatter<T, charT> is disabled.

4 If the library provides an explicit or partial specialization of formatter<T, charT>, that specialization is enabled and meets the Formatter requirements except as noted otherwise.

5 If F is a disabled specialization of formatter, these values are false:

    (5.1) — is_default_constructible_v<F>,
    (5.2) — is_copy_constructible_v<F>,
    (5.3) — is_move_constructible_v<F>,
    (5.4) — is_copy_assignable_v<F>, and
    (5.5) — is_move_assignable_v<F>.

6 An enabled specialization formatter<T, charT> meets the BasicFormatter requirements (22.14.6.1).

[Example 1:
    
    #include <format>
    
    enum color { red, green, blue };  
    const char* color_names[] = { "red", "green", "blue" };

    template<> struct std::formatter<color> : std::formatter<const char*> {
        auto format(color c, format_context& ctx) const {
            return formatter<const char*>::format(color_names[c], ctx);
        }
    };

    struct err {};

    std::string s0 = std::format("{}", 42); // OK, library-provided formatter
    std::string s1 = std::format("{}", L"foo"); // error: disabled formatter
    std::string s2 = std::format("{0}" , red); // OK, user-provided formatter
    std::string s3 = std::format("{0}" , err()); // error: disabled formatter

    — end example]

22.14.6.4 Formatting escaped characters and strings [format.string.escaped]

A character or string can be formatted as escaped to make it more suitable for debugging or for logging.

The escaped string E representation of a string S is constructed by encoding a sequence of characters as follows. The associated character encoding CE for charT (Table 12) is used to both interpret S and construct E.

(2.1) — U+0022 QUOTATION MARK (") is appended to E.
(2.2) — For each code unit sequence X in S that either encodes a single character, is a shift sequence, or is a sequence of ill-formed code units, processing is in order as follows:
(2.2.1) — If X encodes a single character C, then:
--- If \( C \) is one of the characters in Table 75, then the two characters shown as the corresponding escape sequence are appended to \( E \).

--- Otherwise, if \( C \) is not U+0020 SPACE and

--- \( CE \) is UTF-8, UTF-16, or UTF-32 and \( C \) corresponds to a Unicode scalar value whose Unicode property General_Category has a value in the groups Separator (Z) or Other (C), as described by UAX #44 of the Unicode Standard, or

--- \( CE \) is UTF-8, UTF-16, or UTF-32 and \( C \) corresponds to a Unicode scalar value with the Unicode property Grapheme_Extend=Yes as described by UAX #44 of the Unicode Standard and \( C \) is not immediately preceded in \( S \) by a character \( P \) appended to \( E \) without translation to an escape sequence, or

--- \( CE \) is neither UTF-8, UTF-16, nor UTF-32 and \( C \) is one of an implementation-defined set of separator or non-printable characters

then the sequence \( \backslash \{ \text{hex-digit-sequence} \} \) is appended to \( E \), where \text{hex-digit-sequence} is the shortest hexadecimal representation of \( C \) using lower-case hexadecimal digits.

--- Otherwise, \( C \) is appended to \( E \).

--- Otherwise, if \( X \) is a shift sequence, the effect on \( E \) and further decoding of \( S \) is unspecified.

\textit{Recommended practice}: A shift sequence should be represented in \( E \) such that the original code unit sequence of \( S \) can be reconstructed.

--- Otherwise (\( X \) is a sequence of ill-formed code units), each code unit \( U \) is appended to \( E \) in order as the sequence \( \backslash \{ \text{hex-digit-sequence} \} \), where \text{hex-digit-sequence} is the shortest hexadecimal representation of \( U \) using lower-case hexadecimal digits.

--- Finally, U+0022 QUOTATION MARK (" ) is appended to \( E \).

Table 75: Mapping of characters to escape sequences

<table>
<thead>
<tr>
<th>Character Escape sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>U+0009 CHARACTER TABULATION \t</td>
</tr>
<tr>
<td>U+000A LINE FEED \n</td>
</tr>
<tr>
<td>U+000D CARRIAGE RETURN \r</td>
</tr>
<tr>
<td>U+0022 QUOTATION MARK &quot;</td>
</tr>
<tr>
<td>U+005C REVERSE SOLIDUS \</td>
</tr>
</tbody>
</table>

--- The escaped string representation of a character \( C \) is equivalent to the escaped string representation of a string of \( C \), except that:

--- the result starts and ends with U+0027 APOSTROPE (’ ) instead of U+0022 QUOTATION MARK ("), and

--- if \( C \) is U+0027 APOSTROPE, the two characters \( \backslash \) are appended to \( E \), and

--- if \( C \) is U+0022 QUOTATION MARK, then \( C \) is appended unchanged.

\[ \text{Example 1:} \]

```cpp
string s0 = format("[{}]", "\t\illo");  // s0 has value: [h \illo]
string s1 = format("[{:?}]", "\t\illo");  // s1 has value: [\"h\t\illo\"]
string s3 = format("[{:?}, {:?}]", "\", ''); // s3 has value: [\"\", '\']
```

\[ \text{// The following examples assume use of the UTF-8 encoding} \]

```cpp
string s4 = format("[{:?}]", string("\0 \n \t \x02 \x1b", 9));  // s4 has value: [\"\0\n\t\u{02}\u{1b}\"]
string s5 = format("[{:?}]", "\xc3\xa28");  // invalid UTF-8, s5 has value: [\"\x{c3}\"]
string s7 = format("[{:?}]", "\u0301");  // s7 has value: [\u0301]
string s8 = format("[{:?}]", "\u0301");  // s8 has value: [\u0301]
```

\[ \text{-- end example} \]

\[ \text{22.14.6.5 Class template basic_format_parse_context} \]

```cpp
namespace std {
    template<
```
class basic_format_parse_context {
public:
  using char_type = charT;
  using const_iterator = typename basic_string_view<charT>::const_iterator;
  using iterator = const_iterator;
  iterator begin_; // exposition only
  iterator end_; // exposition only
  enum indexing { unknown, manual, automatic }; // exposition only
  indexing indexing_; // exposition only
  size_t next_arg_id_; // exposition only
  size_t num_args_; // exposition only

  constexpr explicit basic_format_parse_context(basic_string_view<charT> fmt,
      size_t num_args = 0) noexcept;
  basic_format_parse_context(const basic_format_parse_context&) = delete;
  basic_format_parse_context& operator=(const basic_format_parse_context&) = delete;
  constexpr const_iterator begin() const noexcept;
  constexpr const_iterator end() const noexcept;
  constexpr void advance_to(const_iterator it);
  constexpr size_t next_arg_id();
  constexpr void check_arg_id(size_t id);
};

An instance of basic_format_parse_context holds the format string parsing state consisting of the format string range being parsed and the argument counter for automatic indexing.

conestr explicit basic_format_parse_context(basic_string_view<charT> fmt,
    size_t num_args = 0) noexcept;
  basic_format_parse_context(const basic_format_parse_context&) = delete;
  basic_format_parse_context& operator=(const basic_format_parse_context&) = delete;
  constexpr const_iterator begin() const noexcept;
  constexpr const_iterator end() const noexcept;
  constexpr void advance_to(const_iterator it);
  constexpr size_t next_arg_id();
  constexpr void check_arg_id(size_t id);
};

1 An instance of basic_format_parse_context holds the format string parsing state consisting of the format string range being parsed and the argument counter for automatic indexing.

conestr explicit basic_format_parse_context(basic_string_view<charT> fmt,
    size_t num_args = 0) noexcept;
  basic_format_parse_context(const basic_format_parse_context&) = delete;
  basic_format_parse_context& operator=(const basic_format_parse_context&) = delete;
  constexpr const_iterator begin() const noexcept;
  constexpr const_iterator end() const noexcept;
  constexpr void advance_to(const_iterator it);
  constexpr size_t next_arg_id();
  constexpr void check_arg_id(size_t id);
};

1 An instance of basic_format_parse_context holds the format string parsing state consisting of the format string range being parsed and the argument counter for automatic indexing.

2 Effects: Initializes begin_ with fmt.begin(), end_ with fmt.end(), indexing_ with unknown, next_arg_id_ with 0, and num_args_ with num_args.

constexpr const_iterator begin() const noexcept;
Returns: begin_.

constexpr const_iterator end() const noexcept;
Returns: end_.

constexpr void advance_to(const_iterator it);
Preconditions: end() is reachable from it.
Effects: Equivalent to: begin_ = it;

constexpr size_t next_arg_id();
Effects: If indexing_ != manual is true, equivalent to:
  if (indexing_ == unknown)
    indexing_ = automatic;
  return next_arg_id_++;

8 Throws: format_error if indexing_ == manual is true which indicates mixing of automatic and manual argument indexing.

9 Remarks: Let cur-arg-id be the value of next_arg_id prior to this call. Call expressions where cur-arg-id >= num_args_ is true are not core constant expressions (7.7).

constexpr void check_arg_id(size_t id);
Effects: If indexing_ != automatic is true, equivalent to:

§ 22.14.6.5
if (indexing_ == unknown)
    indexing_ = manual;

Throws: format_error if indexing_ == automatic is true which indicates mixing of automatic and manual argument indexing.

Remarks: Call expressions where id >= num_args_ is true are not core constant expressions (7.7).

22.14.6.6 Class template basic_format_context

```cpp
namespace std {
    template<class Out, class charT>
    class basic_format_context {
    public:
        using iterator = Out;
        using char_type = charT;
        template<class T> using formatter_type = formatter<T, charT>;
        basic_format_arg<basic_format_context> arg(size_t id) const noexcept;
        std::locale locale();
        iterator out();
        void advance_to(iterator it);
    }
}
```

1 An instance of `basic_format_context` holds formatting state consisting of the formatting arguments and the output iterator.

2 `Out` shall model `output_iterator<const charT&>`.

3 `format_context` is an alias for a specialization of `basic_format_context` with an output iterator that appends to `string`, such as `back_insert_iterator<string>`. Similarly, `wformat_context` is an alias for a specialization of `basic_format_context` with an output iterator that appends to `wstring`.

4 Recommended practice: For a given type `charT`, implementations should provide a single instantiation of `basic_format_context` for appending to `basic_string<charT>`, `vector<charT>`, or any other container with contiguous storage by wrapping those in temporary objects with a uniform interface (such as a `span<charT>`) and polymorphic reallocation.

```cpp
basic_format_arg<basic_format_context> arg(size_t id) const noexcept;
```

5 Returns: `args_.get(id)`.

```cpp
std::locale locale();
```

6 Returns: The locale passed to the formatting function if the latter takes one, and `std::locale()` otherwise.

```cpp
iterator out();
```

7 Effects: Equivalent to: return `std::move(out_)`;

```cpp
void advance_to(iterator it);
```

8 Effects: Equivalent to: `out_ = std::move(it)`;

[Example 1]:
```cpp
struct S { int value; }

template<> struct std::formatter<S> {
    size_t width_arg_id = 0;
    // Parses a width argument id in the format { digit }.
    constexpr auto parse(format_parse_context& ctx) {
        auto iter = ctx.begin();
        auto get_char = [&]() { return iter != ctx.end() ? *iter : 0; };
        auto it = iter;
        while (get_char() == '{') {
            ++iter;
            ++get_char();
        }
        while (get_char() == '0') {
            ++iter;
            ++get_char();
        }
        return it;
    }
};
```
if (get_char() != '{')
    return iter;
++iter;
    char c = get_char();
if (!isdigit(c) || (++iter, get_char()) != '}
    throw format_error("invalid format");
width_arg_id = c - '0';
ctx.check_arg_id(width_arg_id);
return ++iter;
}

// Formats an S with width given by the argument width_arg_id.
auto format(S s, format_context& ctx) const {
    int width = visit_format_arg([](auto value) -> int {
        if constexpr (!is_integral_v<decltype(value)>)
            throw format_error("width is not integral");
        else if (value < 0 || value > numeric_limits<int>::max())
            throw format_error("invalid width");
        else
            return value;
    }, ctx.arg(width_arg_id));
    return format_to(ctx.out(), "{0:x<{1}}", s.value, width);
};

std::string s = std::format("{0:{1}}", S{42}, 10); // value of s is "xxxxxxxx42"

22.14.7 Formatting of ranges [format.range]
22.14.7.1 Variable template format_kind [format.range.fmtkind]

template<ranges::input_range R>
requires same_as<R, remove_cvref_t<R>>
constexpr range_format format_kind<R> = see below;

A program that instantiates the primary template of format_kind is ill-formed.

For a type R, format_kind<R> is defined as follows:
(2.1) — If same_as<remove_cvref_t<ranges::range_reference_t<R>>, R> is true, format_kind<R>
    is range_format::disabled.
    [Note 1: This prevents constraint recursion for ranges whose reference type is the same range type. For
    example, std::filesystem::path is a range of std::filesystem::path. — end note]
(2.2) — Otherwise, if the qualified-id R::key_type is valid and denotes a type:
(2.2.1) — If the qualified-id R::mapped_type is valid and denotes a type, let U be remove_cvref_t<
    ranges::range_reference_t<R>>. If either U is a specialization of pair or U is a specialization of
tuple and tuple_size_v<U> == 2, format_kind<R> is range_format::map.
(2.2.2) — Otherwise, format_kind<R> is range_format::set.
(2.3) — Otherwise, format_kind<R> is range_format::sequence.

Remarks: Pursuant to 16.4.5.2.1, users may specialize format_kind for cv-unqualified program-defined
types that model ranges::input_range. Such specializations shall be usable in constant expressions
(7.7) and have type const range_format.

22.14.7.2 Class template range_formatter [format.range.formatter]

namespace std {
    template<class T, class charT = char>
    requires same_as<remove_cvref_t<T>, T> && formattable<T, charT>
    class range_formatter {
        formatter<T, charT> underlying;
        basic_string_view<charT> separator_ = STATICALLY-WIDEN<charT>(" ");
        basic_string_view<charT> opening-bracket_ = STATICALLY-WIDEN<charT>("[");
        basic_string_view<charT> closing-bracket_ = STATICALLY-WIDEN<charT>
        ("\]");
        // exposition only
    }
}
The class template `range_formatter` is a utility for implementing `formatter` specializations for range types.

`range_formatter` interprets `format-spec` as a `range-format-spec`. The syntax of format specifications is as follows:

```
range-format-spec:
  range-fill-and-align_opt width_opt n_opt range-type_opt range-underlying-spec_opt
range-fill-and-align:
  range-fill_opt align
range-fill:
  any character other than { or } or :
range-type:
  m
  s
  ?s
range-underlying-spec:
  : format-spec
```

For `range_formatter<\text{T}, \text{charT}>`, the `format-spec` in a `range-underlying-spec`, if any, is interpreted by `formatter<\text{T}, \text{charT}>`.

The `range-fill-and-align` is interpreted the same way as a `fill-and-align` (22.14.2.2). The productions `align` and `width` are described in 22.14.2.

The `n` option causes the range to be formatted without the opening and closing brackets.

[Note 1: This is equivalent to invoking `set_brackets({}, {})`. — end note]

The `range-type` specifier changes the way a range is formatted, with certain options only valid with certain argument types. The meaning of the various type options is as specified in Table 76.

If the `range-type` is `s` or `?s`, then there shall be no `n` option and no `range-underlying-spec`.

```
constexpr void set_separator(basic_string_view<charT> sep) noexcept;
Effects: Equivalent to: separator_ = sep;
```

```
constexpr void set_brackets(basic_string_view<charT> opening,
  basic_string_view<charT> closing) noexcept;
Effects: Equivalent to:
  opening-bracket_ = opening;
  closing-bracket_ = closing;
```

```
template<class ParseContext>
 constexpr typename ParseContext::iterator
  parse(ParseContext& ctx);
```

```
template<ranges::input_range R, class FormatContext
  requires formattable<ranges::range_reference_t<R>, charT> &&
  same_as<remove_cvref_t<ranges::range_reference_t<R>>, T>
  typename FormatContext::iterator
  format(R&& r, FormatContext& ctx) const;
```

§ 22.14.7.2

812
Table 76: Meaning of range-type options [tab:formatter.range.type]

<table>
<thead>
<tr>
<th>Option</th>
<th>Requirements</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>m</td>
<td>T shall be either a specialization of pair or a specialization of tuple such that ( \text{tuple_size_v} &lt; T &gt; ) is 2.</td>
<td>Indicates that the opening bracket should be &quot;{&quot;, the closing bracket should be &quot;}&quot;, the separator should be &quot;,&quot;, and each range element should be formatted as if m were specified for its tuple-type. [Note 2: If the n option is provided in addition to the m option, both the opening and closing brackets are still empty. — end note]</td>
</tr>
<tr>
<td>s</td>
<td>T shall be charT.</td>
<td>Indicates that the range should be formatted as a string.</td>
</tr>
<tr>
<td>?s</td>
<td>T shall be charT.</td>
<td>Indicates that the range should be formatted as an escaped string (22.14.6.4).</td>
</tr>
</tbody>
</table>

The values of opening-bracket_, closing-bracket_, and separator_ are modified if and only if required by the range-type or the n option, if present. If:

(9.1) the range-type is neither s nor ?s,
(9.2) underlying_.set_debug_format() is a valid expression, and
(9.3) there is no range-underlying-spec,

then calls underlying_.set_debug_format().

Returns: An iterator past the end of the range-format-spec.

```
template<ranges::input_range R, class FormatContext>
requires formattable<ranges::range_reference_t<R>, charT> &&
same_as<remove_cvref_t<ranges::range_reference_t<R>>, T>
typename FormatContext::iterator
format(R&& r, FormatContext& ctx) const;
```

Effects: Writes the following into ctx.out(), adjusted according to the range-format-spec:

(11.1) If the range-type was s, then as if by formatting basic_string<charT>(from_range, r).
(11.2) Otherwise, if the range-type was ?s, then as if by formatting basic_string<charT>(from_range, r) as an escaped string (22.14.6.4).
(11.3) Otherwise,
  (11.3.1) opening-bracket_,
  (11.3.2) for each element e of the range r:
    (11.3.2.1) the result of writing e via underlying_ and
  (11.3.2.2) separator_, unless e is the last element of r, and
  (11.3.3) closing-bracket_.

Returns: An iterator past the end of the output range.

22.14.7.3 Class template range-default-formatter [format.range.fmtdef]

namespace std {

    template<ranges::input_range R, class charT>
    struct range-default-formatter<range_format::sequence, R, charT> {
        // exposition only
        private:
            using maybe-const-r = fmt-maybe-const<R, charT>;          // exposition only
            range_formatter<remove_cvref_t<ranges::range_reference_t<maybe-const-r>>, charT> underlying_;  // exposition only

        public:
            constexpr void set_separator(basic_string_view<charT> sep) noexcept;

    };

```

§ 22.14.7.3
constexpr void set_brackets(basic_string_view<charT> opening,
            basic_string_view<charT> closing) noexcept;

template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);

template<class FormatContext>
typename FormatContext::iterator
format(maybe_const_r elems, FormatContext& ctx) const;

constexpr void set_separator(basic_string_view<charT> sep) noexcept;

Effects: Equivalent to: underlying_.set_separator(sep);

constexpr void set_brackets(basic_string_view<charT> opening,
            basic_string_view<charT> closing) noexcept;

Effects: Equivalent to: underlying_.set_brackets(opening, closing);

template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);

Effects: Equivalent to: return underlying_.parse(ctx);

template<class FormatContext>
typename FormatContext::iterator
format(maybe_const_r elems, FormatContext& ctx) const;

Effects: Equivalent to: return underlying_.format(elems, ctx);

22.14.7.4 Specialization of range-default-formatter for maps
[format.range.fmtmap]
`underlying_.underlying().set_separator(STATICALLY-WIDEN<charT>(":"));`

```cpp
template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);
```

**Effects:** Equivalent to: return `underlying_.parse(ctx);`

```cpp
template<class FormatContext>
typename FormatContext::iterator
format(maybe-const-map r, FormatContext& ctx) const;
```

**Effects:** Equivalent to: return `underlying_.format(r, ctx);`

### 22.14.7.5 Specialization of `range-default-formatter` for sets

```cpp
namespace std {
    template<ranges::input_range R, class charT>
    struct range-default-formatter<range_format::set, R, charT> {
        private:
            using maybe-const-set = fmt-maybe-const<R, charT>;  // exposition only
            range_formatter<remove_cvref_t<ranges::range_reference_t<maybe-const-set>>, charT> underlying_;  // exposition only

        public:
            constexpr range-default-formatter();

            template<class ParseContext>
            constexpr typename ParseContext::iterator
            parse(ParseContext& ctx);

            template<class FormatContext>
            typename FormatContext::iterator
            format(maybe-const-set r, FormatContext& ctx) const;
    };
}
```

`constexpr range-default-formatter();`

**Effects:** Equivalent to:

`underlying_.set_brackets(STATICALLY-WIDEN<charT>("{"), STATICALLY-WIDEN<charT>(""));`

```cpp
template<class ParseContext>
constexpr typename ParseContext::iterator
parse(ParseContext& ctx);
```

**Effects:** Equivalent to: return `underlying_.parse(ctx);`

```cpp
template<class FormatContext>
typename FormatContext::iterator
format(maybe-const-set r, FormatContext& ctx) const;
```

**Effects:** Equivalent to: return `underlying_.format(r, ctx);`

### 22.14.7.6 Specialization of `range-default-formatter` for strings

```cpp
namespace std {
    template<range_format K, ranges::input_range R, class charT>
    requires (K == range_format::string || K == range_format::debug_string)
    struct range-default-formatter<K, R, charT> {
        private:
            formatter<basic_string<charT>, charT> underlying_;  // exposition only

        public:
            template<class ParseContext>
            constexpr typename ParseContext::iterator
            parse(ParseContext& ctx);
    };
}
```

`§ 22.14.7.6 815`
Mandates: same_as<remove_cvref_t<range_reference_t<R>>, charT> is true.

Effects: Equivalent to:

```cpp
auto i = underlying_.parse(ctx);
if constexpr (K == range_format::debug_string) {
    underlying_.set_debug_format();
}
return i;
```

The type of `r` is `const R&` if `ranges::input_range<const R>` is true and `R&` otherwise.

Effects: Let `s` be a basic_string<charT> such that ranges::equal(s, r) is true. Equivalent to:

```
return underlying_.format(s, ctx);
```

22.14.8 Arguments

22.14.8.1 Class template basic_format_arg

```cpp
namespace std {
    template<class Context>
    class basic_format_arg {
    public:
        class handle;

        using char_type = typename Context::char_type; // exposition only

        variant<monostate, bool, char_type,
            int, unsigned int, long long int, unsigned long long int,
            float, double, long double,
            const char_type*, basic_string_view<char_type>,
            const void*, handle> value; // exposition only

        template<class T> explicit basic_format_arg(T& v) noexcept;
        // exposition only

        public:
            basic_format_arg() noexcept;
            explicit operator bool() const noexcept;
        };
    }
}
```

An instance of `basic_format_arg` provides access to a formatting argument for user-defined formatters.

The behavior of a program that adds specializations of `basic_format_arg` is undefined.

```
basic_format_arg() noexcept;
```

Postconditions: !(*this).

```
template<class T> explicit basic_format_arg(T& v) noexcept;
```

Constraints: `T` satisfies `formattable-with<Context>`.

```
Preconditions: If decay_t<T> is char_type* or const char_type*, static_cast<const char_type*>(v) points to a NTCTS (3.36).
```
Effects: Let TD be remove_const_t<T>.

- If TD is bool or char_type, initializes value with \( v \);
- otherwise, if TD is char and char_type is wchar_t, initializes value with static_cast<wchar_t>(v);
- otherwise, if TD is a signed integer type and sizeof(TD) <= sizeof(int), initializes value with static_cast<int>(v);
- otherwise, if TD is an unsigned integer type and sizeof(TD) <= sizeof(unsigned int), initializes value with static_cast<unsigned int>(v);
- otherwise, if TD is a signed integer type and sizeof(TD) <= sizeof(long long int), initializes value with static_cast<long long int>(v);
- otherwise, if TD is an unsigned integer type and sizeof(TD) <= sizeof(unsigned long long int), initializes value with static_cast<unsigned long long int>(v);
- otherwise, if TD is a standard floating-point type, initializes value with \( v \);
- otherwise, if decay_t<TD> is char_type* or const char_type*, initializes value with static_cast<const char_type*>(v);
- otherwise, if is_void_v<remove_pointer_t<TD>> is true or is_null_pointer_v<TD> is true, initializes value with static_cast<const void*>(v);
- otherwise, initializes value with handle(v).

[Note 1: Constructing basic_format_arg from a pointer to a member is ill-formed unless the user provides an enabled specialization of formatter for that pointer to member type. — end note]
format_ctx.advance_to(f.format(*const_cast<TQ*>(static_cast<const TD*>(ptr)), format_ctx));

void format(basic_format_parse_context<char_type>& parse_ctx, Context& format_ctx) const;

Effects: Equivalent to: format_(parse_ctx, format_ctx, ptr_);

template<class Visitor, class Context>
decltype(auto) visit_format_arg(Visitor&& vis, basic_format_arg<Context> arg);

Effects: Equivalent to: return visit(std::forward<Visitor>(vis), arg.value);

22.14.8.2 Class template format-arg-store

namespace std {
    template<class Context, class... Args>
    class format-arg-store {
        array<basic_format_arg<Context>, sizeof...(Args)> args; // exposition only
    };
}

1 An instance of format-arg-store stores formatting arguments.

template<class Context = format_context, class... Args>
format-arg-store<Context, Args...> make_format_args(Args&&... fmt_args);

2 Preconditions: The type typename Context::template formatter_type<remove_cvref_t<T>> meets the BasicFormatter requirements (22.14.6.1) for each T in Args.

3 Returns: An object of type format-arg-store<Context, Args...> whose args data member is initialized with {basic_format_arg<Context>(fmt_args)...}.

template<class... Args>
format-arg-store<wformat_context, Args...> make_wformat_args(Args&&... args);

Effects: Equivalent to: return make_format_args<wformat_context>(args...);

22.14.8.3 Class template basic_format_args

namespace std {
    template<class Context>
    class basic_format_args {
        size_t size_; // exposition only
        const basic_format_arg<Context>* data_; // exposition only

        public:
            basic_format_args() noexcept;

        template<class... Args>
            basic_format_args(const format-arg-store<Context, Args...>& store) noexcept;

            basic_format_arg<Context> get(size_t i) const noexcept;
    };
}

1 An instance of basic_format_args provides access to formatting arguments. Implementations should optimize the representation of basic_format_args for a small number of formatting arguments.

[Note 1: For example, by storing indices of type alternatives separately from values and packing the former. — end note]

basic_format_args() noexcept;

2 Effects: Initializes size_ with 0.
template<class... Args>
    basic_format_args(const format_arg_store<Context, Args...>& store) noexcept;

Effects: Initializes size_ with sizeof...(Args) and data_ with store.args.data().

basic_format_arg<Context> get(size_t i) const noexcept;

Returns: i < size_ ? data_[i] : basic_format_arg<Context>().

22.14.9 Tuple formatter

For each of pair and tuple, the library provides the following formatter specialization where pair-or-tuple
is the name of the template:

namespace std {
    template<class charT, formattable<charT>... Ts>
    struct formatter<pair-or-tuple<Ts...>, charT> {
        private:
            tuple<formatter<remove_cvref_t<Ts>, charT>...> underlying_;  // exposition only
            basic_string_view<charT> separator_ = STATICALLY-WIDEN<charT>(" ");  // exposition only
            basic_string_view<charT> opening_bracket_ = STATICALLY-WIDEN<charT>("(");  // exposition only
            basic_string_view<charT> closing_bracket_ = STATICALLY-WIDEN<charT>(")");  // exposition only
        public:
            constexpr void set_separator(basic_string_view<charT> sep) noexcept;
            constexpr void set_brackets(basic_string_view<charT> opening,
                                         basic_string_view<charT> closing) noexcept;
    
        template<class ParseContext>
        constexpr typename ParseContext::iterator parse(ParseContext& ctx);  
    
        template<class FormatContext>
        typename FormatContext::iterator format(see belouk elems, FormatContext& ctx) const;
    
    
        constexpr typenamex ParseContext::iterator
        parse(ParseContext& ctx);
    
        template<class FormatContext>
        typename FormatContext::iterator
        format(see belouk elems, FormatContext& ctx) const;
    
    
    

2 The parse member functions of these formatters interpret the format specification as a tuple-format-spec
according to the following syntax:

tuple-format-spec:
    tuple-fill-and-align_opt width_opt tuple-type_opt

tuple-fill-and-align:
    tuple-fill opt align

tuple-fill:
    any character other than { or } or :

tuple-type:
    m
    n

3 The tuple-fill-and-align is interpreted the same way as a fill-and-align (22.14.2.2). The productions align and
width are described in 22.14.2.

4 The tuple-type specifier changes the way a pair or tuple is formatted, with certain options only valid with
certain argument types. The meaning of the various type options is as specified in Table 77.

costexpr void set_separator(basic_string_view<charT> sep) noexcept;

Effects: Equivalent to: separator_ = sep;

costexpr void set_brackets(basic_string_view<charT> opening,
                                      basic_string_view<charT> closing) noexcept;

Effects: Equivalent to:
opening_bracket_ = opening;
closing_bracket_ = closing;
Table 77: Meaning of tuple-type options [tab:formatter.tuple.type]

<table>
<thead>
<tr>
<th>Option</th>
<th>Requirements</th>

</table>

22.14.10 Class format_error [format.error]

namespace std {
  class format_error : public runtime_error {
    public:
      explicit format_error(const string& what_arg);
      explicit format_error(const char* what_arg);
  }
}

1 The class format_error defines the type of objects thrown as exceptions to report errors from the formatting library.

format_error(const string& what_arg);

2 Postconditions: strcmp(what(), what_arg.c_str()) == 0.

format_error(const char* what_arg);

3 Postconditions: strcmp(what(), what_arg) == 0.
22.15  Bit manipulation

22.15.1  General

1  The header `<bit>` provides components to access, manipulate and process both individual bits and bit sequences.

22.15.2  Header `<bit>` synopsis

```cpp
// all freestanding
namespace std {
  // 22.15.3, bit_cast
  template<class To, class From>
  constexpr To bit_cast(const From& from) noexcept;

  // 22.15.4, byteswap
  template<class T>
  constexpr T byteswap(T value) noexcept;

  // 22.15.5, integral powers of 2
  template<class T>
  constexpr bool has_single_bit(T x) noexcept;
  template<class T>
  constexpr T bit_ceil(T x);
  template<class T>
  constexpr T bit_floor(T x) noexcept;
  template<class T>
  constexpr int bit_width(T x) noexcept;

  // 22.15.6, rotating
  template<class T>
  [[nodiscard]] constexpr T rotl(T x, int s) noexcept;
  template<class T>
  [[nodiscard]] constexpr T rotr(T x, int s) noexcept;

  // 22.15.7, counting
  template<class T>
  constexpr int countl_zero(T x) noexcept;
  template<class T>
  constexpr int countl_one(T x) noexcept;
  template<class T>
  constexpr int countr_zero(T x) noexcept;
  template<class T>
  constexpr int countr_one(T x) noexcept;
  template<class T>
  constexpr int popcount(T x) noexcept;

  // 22.15.8, endian
  enum class endian {
    little = see below,                // (1.1)
    big = see below,                   // (1.2)
    native = see below
  };
}
```

22.15.3  Function template `bit_cast`

```cpp
template<class To, class From>
constexpr To bit_cast(const From& from) noexcept;
```

1  Constraints:

1. `(1.1)`  `sizeof(To) == sizeof(From)` is true;
2. `(1.2)`  `is_trivially_copyable_v<To>` is true; and
3. `(1.3)`  `is_trivially_copyable_v<From>` is true.
Returns: An object of type To. Implicitly creates objects nested within the result (6.7.2). Each bit of the value representation of the result is equal to the corresponding bit in the object representation of from. Padding bits of the result are unspecified. For the result and each object created within it, if there is no value of the object’s type corresponding to the value representation produced, the behavior is undefined. If there are multiple such values, which value is produced is unspecified. A bit in the value representation of the result is indeterminate if it does not correspond to a bit in the value representation of from or corresponds to a bit of an object that is not within its lifetime or has an indeterminate value (6.7.4). For each bit in the value representation of the result that is indeterminate, the smallest object containing that bit has an indeterminate value; the behavior is undefined unless that object is of unsigned ordinary character type or std::byte type. The result does not otherwise contain any indeterminate values.

Remarks: This function is constexpr if and only if To, From, and the types of all subobjects of To and From are types T such that:

(3.1) — is_union_v<T> is false;
(3.2) — is_pointer_v<T> is false;
(3.3) — is_member_pointer_v<T> is false;
(3.4) — is_volatile_v<T> is false; and
(3.5) — T has no non-static data members of reference type.

22.15.4 byteswap

template<class T>
constexpr T byteswap(T value) noexcept;

Constraints: T models integral.
Mandates: T does not have padding bits (6.8.1).
Let the sequence \( R \) comprise the bytes of the object representation of value in reverse order.
Returns: An object \( \nu \) of type T such that each byte in the object representation of \( \nu \) is equal to the byte in the corresponding position in \( R \).

22.15.5 Integral powers of 2

template<class T>
constexpr bool has_single_bit(T x) noexcept;

Constraints: T is an unsigned integer type (6.8.2).
Returns: true if \( x \) is an integral power of two; false otherwise.

template<class T>
constexpr T bit_ceil(T x);
Let \( N \) be the smallest power of 2 greater than or equal to \( x \).
Constraints: T is an unsigned integer type (6.8.2).
Preconditions: \( N \) is representable as a value of type T.
Returns: \( N \).
Throws: Nothing.
Remarks: A function call expression that violates the precondition in the Preconditions: element is not a core constant expression (7.7).

template<class T>
constexpr T bit_floor(T x) noexcept;
Constraints: T is an unsigned integer type (6.8.2).
Returns: If \( x == 0 \), 0; otherwise the maximal value \( y \) such that has_single_bit(\( y \)) is true and \( y <= x \) .
template<class T>
constexpr int bit_width(T x) noexcept;

Constraints: T is an unsigned integer type (6.8.2).

Returns: If x == 0, 0; otherwise one plus the base-2 logarithm of x, with any fractional part discarded.

22.15.6 Rotating

In the following descriptions, let N denote numeric_limits<T>::digits.

template<class T>
[[nodiscard]] constexpr T rotl(T x, int s) noexcept;

Constraints: T is an unsigned integer type (6.8.2).

Let r be s % N.

Returns: If r is 0, x; if r is positive, (x << r) | (x >> (N - r)); if r is negative, rotr(x, -r).

template<class T>
[[nodiscard]] constexpr T rotr(T x, int s) noexcept;

Constraints: T is an unsigned integer type (6.8.2).

Let r be s % N.

Returns: If r is 0, x; if r is positive, (x >> r) | (x << (N - r)); if r is negative, rotl(x, -r).

22.15.7 Counting

In the following descriptions, let N denote numeric_limits<T>::digits.

template<class T>
constexpr int countl_zero(T x) noexcept;

Constraints: T is an unsigned integer type (6.8.2).

Returns: The number of consecutive 0 bits in the value of x, starting from the most significant bit.

[Note 1: Returns N if x == 0. — end note]

template<class T>
constexpr int countl_one(T x) noexcept;

Constraints: T is an unsigned integer type (6.8.2).

Returns: The number of consecutive 1 bits in the value of x, starting from the most significant bit.

[Note 2: Returns N if x == numeric_limits<T>::max(). — end note]

template<class T>
constexpr int countr_zero(T x) noexcept;

Constraints: T is an unsigned integer type (6.8.2).

Returns: The number of consecutive 0 bits in the value of x, starting from the least significant bit.

[Note 3: Returns N if x == 0. — end note]

template<class T>
constexpr int countr_one(T x) noexcept;

Constraints: T is an unsigned integer type (6.8.2).

Returns: The number of consecutive 1 bits in the value of x, starting from the least significant bit.

[Note 4: Returns N if x == numeric_limits<T>::max(). — end note]

template<class T>
constexpr int popcount(T x) noexcept;

Constraints: T is an unsigned integer type (6.8.2).

Returns: The number of 1 bits in the value of x.
Two common methods of byte ordering in multibyte scalar types are big-endian and little-endian in the execution environment. Big-endian is a format for storage of binary data in which the most significant byte is placed first, with the rest in descending order. Little-endian is a format for storage of binary data in which the least significant byte is placed first, with the rest in ascending order. This subclause describes the endianness of the scalar types of the execution environment.

```cpp
enum class endian {
    little = see below,
    big = see below,
    native = see below
};
```

If all scalar types have size 1 byte, then all of `endian::little`, `endian::big`, and `endian::native` have the same value. Otherwise, `endian::little` is not equal to `endian::big`. If all scalar types are big-endian, `endian::native` is equal to `endian::big`. If all scalar types are little-endian, `endian::native` is equal to `endian::little`. Otherwise, `endian::native` is not equal to either `endian::big` or `endian::little`. 
23  Strings library

23.1  General

1 This Clause describes components for manipulating sequences of any non-array trivial standard-layout (6.8.1) type. Such types are called *char-like types*, and objects of char-like types are called *char-like objects* or simply *characters*.

2 The following subclauses describe a character traits class, string classes, and null-terminated sequence utilities, as summarized in Table 78.

<table>

</table>

23.2  Character traits

23.2.1 General

1 Subclause 23.2 defines requirements on classes representing *character traits*, and defines a class template `char_traits<charT>`, along with five specializations, `char_traits<char>`, `char_traits<char8_t>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`, that meet those requirements.

2 Most classes specified in 23.4, 23.3, and Clause 31 need a set of related types and functions to complete the definition of their semantics. These types and functions are provided as a set of member *typedef-names* and functions in the template parameter *traits* used by each such template. Subclause 23.2 defines the semantics of these members.

3 To specialize those templates to generate a string, string view, or iostream class to handle a particular character container type (3.10) `C`, that and its related character traits class `X` are passed as a pair of parameters to the string, string view, or iostream template as parameters `charT` and `traits`. If `X::char_type` is not the same type as `C`, the program is ill-formed.

23.2.2 Character traits requirements

1 In Table 79, `X` denotes a traits class defining types and functions for the character container type `C`; `c` and `d` denote values of type `C`; `p` and `q` denote values of type `const C*`; `s` denotes a value of type `C*`; `n`, `i`, and `j` denote values of type `size_t`; `e` and `f` denote values of type `X::int_type`; `pos` denotes a value of type `X::pos_type`; and `r` denotes an lvalue of type `C`. No expression which is part of the character traits requirements specified in this subclause 23.2.2 shall exit via an exception.

2 The class template

```
template<class charT> struct char_traits;
```

is provided in the header `<string>` as a basis for explicit specializations.

### 23.2.3 Traits typedefs

```
using int_type = see below;
```

1 Preconditions: int_type shall be able to represent all of the valid characters converted from the corresponding char_type values, as well as an end-of-file value, eof().

```
using state_type = see below;
```

2 Preconditions: state_type meets the Cpp17Destructible (Table 35), Cpp17CopyAssignable (Table 34), Cpp17CopyConstructible (Table 32), and Cpp17DefaultConstructible (Table 30) requirements.

### 23.2.4 char_traits specializations

#### 23.2.4.1 General

```
namespace std {
    template<> struct char_traits<char> {
        using char_type = char;
        using int_type = int;
        using off_type = streamoff;
        using pos_type = streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
    }
}
```

1 The header `<string>` defines five specializations of the class template char_traits: char_traits<char>, char_traits<char8_t>, char_traits<char16_t>, char_traits<char32_t>, and char_traits<wchar_t>.

#### 23.2.4.2 struct char_traits<char>

```
namespace std {
    template<> struct char_traits<char> {
        using char_type = char;
        using int_type = int;
        using off_type = streamoff;
        using pos_type = streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
    }
}
```

---

206) If eof() can be held in char_type then some iostreams operations can give surprising results.
The type `mbstate_t` is defined in `<cwchar>` and can represent any of the conversion states that can occur in an implementation-defined set of supported multibyte character encoding rules.

The two-argument member `assign` is defined identically to the built-in operator `=`. The two-argument members `eq` and `lt` are defined identically to the built-in operators `==` and `<` for type `unsigned char`.

The member `eof()` returns EOF.

23.2.4.3 `struct char_traits<char8_t>`

```cpp
namespace std {
    template<> struct char_traits<char8_t> {
        using char_type = char8_t;
        using int_type = unsigned int;
        using off_type = streamoff;
        using pos_type = u8streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n,
                                               const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}
```

1 The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<` respectively.

2 The member `eof()` returns an implementation-defined constant that cannot appear as a valid UTF-8 code unit.

23.2.4.4 `struct char_traits<char16_t>`

```cpp
namespace std {
    template<> struct char_traits<char16_t> {
        using char_type = char16_t;
        using int_type = uint_least16_t;
        using off_type = streamoff;
        using pos_type = u16streampos;
    }
}
```
using state_type = mbstate_t;
using comparison_category = strong_ordering;

static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
static constexpr bool eq(char_type c1, char_type c2) noexcept;
static constexpr bool lt(char_type c1, char_type c2) noexcept;
static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
static constexpr size_t length(const char_type* s);
static constexpr const char_type* find(const char_type* s, size_t n,
    const char_type& a);
static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
static constexpr char_type* assign(char_type* s, size_t n, char_type a);
static constexpr int_type not_eof(int_type c) noexcept;
static constexpr char_type to_char_type(int_type c) noexcept;
static constexpr int_type to_int_type(char_type c) noexcept;
static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
static constexpr int_type eof() noexcept;

namespace std {
    template<> struct char_traits<char32_t> { 
        using char_type = char32_t;
        using int_type = uint_least32_t;
        using off_type = streamoff;
        using pos_type = u32streampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n,
            const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
};

1 The two-argument members assign, eq, and lt are defined identically to the built-in operators =, ==, and <, respectively.

2 The member eof() returns an implementation-defined constant that cannot appear as a valid UTF-16 code unit.
23.2.4.6 struct char_traits<wchar_t>  

namespace std {
    template<> struct char_traits<wchar_t> {  
        using char_type = wchar_t;
        using int_type = wint_t;
        using off_type = streamoff;
        using pos_type = wstreampos;
        using state_type = mbstate_t;
        using comparison_category = strong_ordering;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static constexpr char_type* move(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static constexpr char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
};

1 The two-argument members assign, eq, and lt are defined identically to the built-in operators =, ==, and <, respectively.

2 The member eof() returns WEOF.

23.3 String view classes

23.3.1 General

1 The class template basic_string_view describes an object that can refer to a constant contiguous sequence of char-like (23.1) objects with the first element of the sequence at position zero. In the rest of 23.3, the type of the char-like objects held in a basic_string_view object is designated by charT.

2 [Note 1: The library provides implicit conversions from const charT* and std::basic_string<charT, ...> to std::basic_string_view<charT, ...> so that user code can accept just std::basic_string_view<charT> as a non-templated parameter wherever a sequence of characters is expected. User-defined types can define their own implicit conversions to std::basic_string_view<charT> in order to interoperate with these functions. — end note]

23.3.2 Header <string_view> synopsis

template<> struct hash<wstring_view>;

inline namespace literals {
  inline namespace string_view_literals {
    constexpr string_view operator"sv(const char* str, size_t len) noexcept;
    constexpr u8string_view operator"sv(const char8_t* str, size_t len) noexcept;
    constexpr u16string_view operator"sv(const char16_t* str, size_t len) noexcept;
    constexpr u32string_view operator"sv(const char32_t* str, size_t len) noexcept;
    constexpr wstring_view operator"sv(const wchar_t* str, size_t len) noexcept;
  }
}

1 The function templates defined in 22.2.2 and 25.7 are available when <string_view> is included.

23.3.3 Class template basic_string_view

23.3.3.1 General

namespace std {
  template<class charT, class traits = char_traits<charT>>
  class basic_string_view {
  public:
    // types
    using traits_type = traits;
    using value_type = charT;
    using pointer = value_type*;
    using const_pointer = const value_type*;
    using reference = value_type&;
    using const_reference = const value_type&;
    using const_iterator = implementation-defined; // see 23.3.3.4
    using iterator = const_iterator;
    using const_reverse_iterator = reverse_iterator<const_iterator>;
    using reverse_iterator = const_reverse_iterator;
    using size_type = size_t;
    using difference_type = ptrdiff_t;
    static constexpr size_type npos = size_type(-1);

207) Because basic_string_view refers to a constant sequence, iterator and const_iterator are the same type.
// 23.3.3.2, construction and assignment
constexpr basic_string_view() noexcept;
constexpr basic_string_view(const basic_string_view&) noexcept = default;
constexpr basic_string_view& operator=(const basic_string_view&) noexcept = default;
constexpr basic_string_view(const charT* str);
basic_string_view(nullptr_t) = delete;
constexpr basic_string_view(const charT* str, size_type len);
template<class It, class End>
    constexpr basic_string_view(It begin, End end);
template<class R>
    constexpr explicit basic_string_view(R&& r);

// 23.3.3.4, iterator support
constexpr const_iterator begin() const noexcept;
constexpr const_iterator end() const noexcept;
constexpr const_iterator cbegin() const noexcept;
constexpr const_iterator cend() const noexcept;
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

// 23.3.3.5, capacity
constexpr size_type size() const noexcept;
constexpr size_type length() const noexcept;
constexpr size_type max_size() const noexcept;

constexpr size_type find_last_not_of(basic_string_view s, size_type pos = npos) const noexcept;
constexpr size_type find_last_not_of(charT c, size_type pos = npos) const noexcept;
constexpr size_type find_last_not_of(const charT* s, size_type pos, size_type n) const;
constexpr size_type find_last_not_of(const charT* s, size_type pos = npos) const;

private:
    const_pointer data_;        // exposition only
    size_type size_;            // exposition only

// 23.3.3.3, deduction guides

template<class It, class End>
    basic_string_view(It, End) -> basic_string_view<iter_value_t<It>>;

template<class R>
    basic_string_view(R&&) -> basic_string_view<ranges::range_value_t<R>>;

1 In every specialization basic_string_view<charT, traits>, the type traits shall meet the character
   traits requirements (23.2).
   [Note 1: The program is ill-formed if traits::char_type is not the same type as charT. — end note]
2 For a basic_string_view str, any operation that invalidates a pointer in the range
   [str.data(), str.data() + str.size()]
   invalidates pointers, iterators, and references returned from str's member functions.
3 The complexity of basic_string_view member functions is $O(1)$ unless otherwise specified.
4 basic_string_view<charT, traits> is a trivially copyable type (6.8.1).

23.3.3.2 Construction and assignment [string.view.cons]

constexpr basic_string_view() noexcept;
1 Postconditions: size_ == 0 and data_ == nullptr.
constexpr basic_string_view(const charT* str);
2 Preconditions: [str, str + traits::length(str)) is a valid range.
   Effects: Constructs a basic_string_view, initializing data_ with str and initializing size_ with
   traits::length(str).
Complexity: $\Theta(\text{traits::length(str)})$. 

```cpp
constexpr basic_string_view(const charT* str, size_type len);
```

**Preconditions:** $[\text{str, str + len}]$ is a valid range.

**Effects:** Constructs a `basic_string_view`, initializing `data_` with `str` and initializing `size_` with `len`.

```cpp
template<class It, class End>
constexpr basic_string_view(It begin, End end);
```

**Constraints:**
- It satisfies `contiguous_iterator`.
- End satisfies `sized_sentinel_for<It>`.
- `is_same_v<iter_value_t<It>, charT>` is true.
- `is_convertible_v<End, size_type>` is false.

**Preconditions:**
- $[\text{begin, end})$ is a valid range.
- It models `contiguous_iterator`.
- End models `sized_sentinel_for<It>`.

**Effects:** Initializes `data_` with `to_address(begin)` and initializes `size_` with `end - begin`.

**Throws:** When and what `end - begin` throws.

```cpp
template<class R>
constexpr explicit basic_string_view(R&& r);
```

Let $d$ be an lvalue of type `remove_cvref_t<R>`.

**Constraints:**
- `remove_cvref_t<R>` is not the same type as `basic_string_view`.
- R models `ranges::contiguous_range` and `ranges::sized_range`.
- `is_same_v<ranges::range_value_t<R>, charT>` is true.
- `is_convertible_v<R, const charT*>` is false, and
- $d$.operator ::std::basic_string_view<\text{charT, traits}>().$ is not a valid expression.

**Effects:** Initializes `data_` with `ranges::data(r)` and `size_` with `ranges::size(r)`.

**Throws:** Any exception thrown by `ranges::data(r)` and `ranges::size(r)`.

### 23.3.3.3 Deduction guides [string.view.deduct]

```cpp
template<class It, class End>
basic_string_view(It, End) -> basic_string_view<iter_value_t<It>>;
```

**Constraints:**
- It satisfies `contiguous_iterator`.
- End satisfies `sized_sentinel_for<It>`.

```cpp
template<class R>
basic_string_view(R&&) -> basic_string_view<ranges::range_value_t<R>>;
```

**Constraints:** R satisfies `ranges::contiguous_range`.

### 23.3.3.4 Iterator support [string.view.iterators]

```cpp
using const_iterator = implementation-defined;
```

A type that meets the requirements of a constant `Cpp17RandomAccessIterator (25.3.5.7)`, models `contiguous_iterator (25.3.4.14)`, and meets the `constexpr iterator requirements (25.3.1)`, whose `value_type` is the template parameter `charT`.

All requirements on container iterators (24.2) apply to `basic_string_view::const_iterator` as well.
constexpr const_iterator begin() const noexcept;
constexpr const_iterator cbegin() const noexcept;

Returns: An iterator such that
— if !empty(), addressof(*begin()) == data_,
— otherwise, an unspecified value such that [begin(), end()) is a valid range.

constexpr const_iterator end() const noexcept;
constexpr const_iterator cend() const noexcept;

Returns: begin() + size().

constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;

Returns: const_reverse_iterator(end()).

constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

Returns: const_reverse_iterator(begin()).

23.3.3.5 Capacity

constexpr size_type size() const noexcept;
constexpr size_type length() const noexcept;

Returns: size_.

constexpr size_type max_size() const noexcept;

Returns: The largest possible number of char-like objects that can be referred to by a basic_string_view.

[[nodiscard]] constexpr bool empty() const noexcept;

Returns: size_ == 0.

23.3.3.6 Element access

constexpr const_reference operator[](size_type pos) const;

Preconditions: pos < size().

Returns: data_[pos].

Throws: Nothing.

[Note 1: Unlike basic_string::operator[], basic_string_view::operator[](size()) has undefined behavior instead of returning charT(). — end note]

constexpr const_reference at(size_type pos) const;

Returns: data_[pos].

Throws: out_of_range if pos >= size().

constexpr const_reference front() const;

Preconditions: !empty().

Returns: data_[0].

Throws: Nothing.

constexpr const_reference back() const;

Preconditions: !empty().

Returns: data_[size() - 1].

Throws: Nothing.
constexpr const_pointer data() const noexcept;

Returns: data_.

[Note 2: Unlike basic_string::data() and string-literals, data() can return a pointer to a buffer that is not
null-terminated. Therefore it is typically a mistake to pass data() to a function that takes just a const charT* and
expects a null-terminated string. —end note]

### 23.3.3.7 Modifiers

```cpp
constexpr void remove_prefix(size_type n);

Preconditions: n <= size().
Effects: Equivalent to: data_ += n; size_ -= n;
```

### 23.3.3.8 String operations

```cpp
constexpr basic_string_view substr(size_type pos = 0, size_type n = npos) const;

Let rlen be the smaller of n and size() - pos.
Preconditions: [s, s + rlen) is a valid range.
Effects: Determines rlen, the effective length of the string to reference.
Returns: basic_string_view(data() + pos, rlen).
Throws: out_of_range if pos > size().
Complexity: \(O(rlen)\).
```

```cpp
constexpr basic_string_view substring(size_type pos = 0, size_type n = npos) const;

Let rlen be the smaller of n and size() - pos.
Effects: Determines rlen, the effective length of the string to reference.
Returns: basic_string_view(data() + pos, rlen).
Throws: out_of_range if pos > size().
```

```cpp
constexpr int compare(basic_string_view str) const noexcept;

Let rlen be the smaller of size() and str.size().
Effects: Determines rlen, the effective length of the strings to compare. The function then compares
the two strings by calling traits::compare(data(), str.data(), rlen).
Returns: The nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as
indicated in Table 80.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>size() &lt; str.size()</td>
<td>&lt; 0</td>
</tr>
<tr>
<td>size() == str.size()</td>
<td>0</td>
</tr>
<tr>
<td>size() &gt; str.size()</td>
<td>&gt; 0</td>
</tr>
</tbody>
</table>

Complexity: \(O(rlen)\).

```cpp
constexpr int compare(size_type pos1, size_type n1, basic_string_view str) const;

Effects: Equivalent to: return substr(pos1, n1).compare(str);
```
constexpr int compare(size_type pos1, size_type n1, basic_string_view str, size_type pos2, size_type n2) const;

**Effects:** Equivalent to: return substr(pos1, n1).compare(str.substr(pos2, n2));

constexpr int compare(const charT* s) const;

**Effects:** Equivalent to: return compare(basic_string_view(s));

constexpr int compare(size_type pos1, size_type n1, const charT* s) const;

**Effects:** Equivalent to: return substr(pos1, n1).compare(basic_string_view(s));

constexpr int compare(size_type pos1, size_type n1, const charT* s, size_type n2) const;

**Effects:** Equivalent to: return substr(pos1, n1).compare(basic_string_view(s, n2));

constexpr bool starts_with(basic_string_view x) const noexcept;

**Effects:** Equivalent to: return substr(0, x.size()) == x;

constexpr bool starts_with(charT x) const noexcept;

**Effects:** Equivalent to: return !empty() && traits::eq(front(), x);

constexpr bool starts_with(const charT* x) const;

**Effects:** Equivalent to: return starts_with(basic_string_view(x));

constexpr bool ends_with(basic_string_view x) const noexcept;

**Effects:** Equivalent to:
return size() >= x.size() && compare(size() - x.size(), npos, x) == 0;

constexpr bool ends_with(charT x) const noexcept;

**Effects:** Equivalent to: return !empty() && traits::eq(back(), x);

constexpr bool ends_with(const charT* x) const;

**Effects:** Equivalent to: return ends_with(basic_string_view(x));

constexpr bool contains(basic_string_view x) const noexcept;
constexpr bool contains(charT x) const noexcept;
constexpr bool contains(const charT* x) const;

**Effects:** Equivalent to: return find(x) != npos;

23.3.3.9 Searching

Member functions in this subclause have complexity $O(\text{size() } \star \text{str.size()})$ at worst, although implementations should do better.

Let $F$ be one of find, rfind, find_first_of, find_last_of, find_first_not_of, and find_last_not_of.

(2.1) Each member function of the form

```cpp
constexpr return-type F(const charT* s, size_type pos) const;
```

has effects equivalent to:

```cpp
return F(basic_string_view(s), pos);
```

(2.2) Each member function of the form

```cpp
constexpr return-type F(const charT* s, size_type pos, size_type n) const;
```

has effects equivalent to:

```cpp
return F(basic_string_view(s, n), pos);
```

(2.3) Each member function of the form

```cpp
constexpr return-type F(charT c, size_type pos) const noexcept;
```

has effects equivalent to:

```cpp
return F(basic_string_view(addressof(c), 1), pos);
```

```cpp
constexpr size_type find(basic_string_view str, size_type pos = 0) const noexcept;
```

Let $\text{xpos}$ be the lowest position, if possible, such that the following conditions hold:

(3.1) $\text{pos} \leq \text{xpos}$

§ 23.3.3.9
<table>
<thead>
<tr>
<th>Line</th>
<th>Text</th>
</tr>
</thead>
</table>
| 4    | Effects: Determines `xpos`.
| 5    | Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.
| 6    | Let `xpos` be the highest position, if possible, such that the following conditions hold: |
| 6.1  |   - `xpos <= pos` |
| 6.2  |   - `xpos + str.size() <= size()` |
| 6.3  |   - `traits::eq(at(xpos + I), str.at(I))` for all elements `I` of the string referenced by `str`.
| 7    | Effects: Determines `xpos`.
| 8    | Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.
| 9    | Let `xpos` be the lowest position, if possible, such that the following conditions hold: |
| 9.1  |   - `pos <= xpos` |
| 9.2  |   - `xpos < size()` |
| 9.3  |   - `traits::eq(at(xpos), str.at(I))` for some element `I` of the string referenced by `str`.
| 10   | Effects: Determines `xpos`.
| 11   | Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.
| 12   | Let `xpos` be the highest position, if possible, such that the following conditions hold: |
| 12.1 |   - `xpos <= pos` |
| 12.2 |   - `xpos < size()` |
| 12.3 |   - `traits::eq(at(xpos), str.at(I))` for some element `I` of the string referenced by `str`.
| 13   | Effects: Determines `xpos`.
| 14   | Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.
| 15   | Let `xpos` be the lowest position, if possible, such that the following conditions hold: |
| 15.1 |   - `pos <= xpos` |
| 15.2 |   - `xpos < size()` |
| 15.3 |   - `traits::eq(at(xpos), str.at(I))` for no element `I` of the string referenced by `str`.
| 16   | Effects: Determines `xpos`.
| 17   | Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.
| 18   | Let `xpos` be the highest position, if possible, such that the following conditions hold: |
| 18.1 |   - `xpos <= pos` |
| 18.2 |   - `xpos < size()` |
| 18.3 |   - `traits::eq(at(xpos), str.at(I))` for no element `I` of the string referenced by `str`.
| 19   | Effects: Determines `xpos`.
| 20   | Returns: `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

### 23.3.4 Non-member comparison functions

Let `S` be `basic_string_view<charT, traits>`, and `sv` be an instance of `S`. Implementations shall provide sufficient additional overloads marked `constexpr` and `noexcept` so that an object `t` with an implicit conversion
to \( S \) can be compared according to Table 81.

Table 81: Additional basic_string_view comparison overloads

<table>
<thead>
<tr>
<th>Expression</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>( t == sv )</td>
<td>( S(t) == sv )</td>
</tr>
<tr>
<td>( sv == t )</td>
<td>( sv == S(t) )</td>
</tr>
<tr>
<td>( t != sv )</td>
<td>( S(t) != sv )</td>
</tr>
<tr>
<td>( sv != t )</td>
<td>( sv != S(t) )</td>
</tr>
<tr>
<td>( t &lt; sv )</td>
<td>( S(t) &lt; sv )</td>
</tr>
<tr>
<td>( sv &lt; t )</td>
<td>( sv &lt; S(t) )</td>
</tr>
<tr>
<td>( t &gt; sv )</td>
<td>( S(t) &gt; sv )</td>
</tr>
<tr>
<td>( sv &gt; t )</td>
<td>( sv &gt; S(t) )</td>
</tr>
<tr>
<td>( t &lt;= sv )</td>
<td>( S(t) &lt;= sv )</td>
</tr>
<tr>
<td>( sv &lt;= t )</td>
<td>( sv &lt;= S(t) )</td>
</tr>
<tr>
<td>( t &gt;= sv )</td>
<td>( S(t) &gt;= sv )</td>
</tr>
<tr>
<td>( sv &gt;= t )</td>
<td>( sv &gt;= S(t) )</td>
</tr>
<tr>
<td>( t &lt;=&gt; sv )</td>
<td>( S(t) &lt;=&gt; sv )</td>
</tr>
<tr>
<td>( sv &lt;=&gt; t )</td>
<td>( sv &lt;=&gt; S(t) )</td>
</tr>
</tbody>
</table>

*Example 1:* A sample conforming implementation for `operator==` would be:

```cpp
template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs, basic_string_view<charT, traits> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}
```

Returns: \( lhs.compare(rhs) == 0 \).

*Example 2:* `operator<=>` would be:

```cpp
template<class charT, class traits>
constexpr operator<=>(basic_string_view<charT, traits> lhs, basic_string_view<charT, traits> rhs) noexcept {
    return static_cast<comparison_category>(lhs.compare(rhs) <=> 0);
}
```

Let \( R \) denote the type `traits::comparison_category` if that qualified-id is valid and denotes a type (13.10.3), otherwise \( R \) is weak_ordering.

*Mandates:* \( R \) denotes a comparison category type (17.11.2).

Returns: \( static_cast<R>(lhs.compare(rhs) <=> 0) \).

### 23.3.5 Inserters and extractors

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, basic_string_view<charT, traits> str);
```

*Effects:* Behaves as a formatted output function (31.7.6.3.1) of \( os \). Forms a character sequence \( seq \), initially consisting of the elements defined by the range `[str.begin(), str.end())`. Determines padding for \( seq \) as described in 31.7.6.3.1. Then inserts \( seq \) as if by calling `os.rdbuf()->sputc(seq, n)`, where \( n \) is the larger of `os.width()` and `str.size()`; then calls `os.width(0)`.

Returns: \( os \)
23.3.6 Hash support

```cpp
template<> struct hash<string_view>;
template<> struct hash<u8string_view>;
template<> struct hash<u16string_view>;
template<> struct hash<u32string_view>;
template<> struct hash<wstring_view>;
```

1 The specialization is enabled (22.10.19).

[Note 1: The hash value of a string view object is equal to the hash value of the corresponding string object (23.4.6). — end note]

23.3.7 Suffix for basic_string_view literals

```cpp
constexpr string_view operator"sv(const char* str, size_t len) noexcept;
```

1 Returns: string_view{str, len}.

```cpp
constexpr u8string_view operator"sv(const char8_t* str, size_t len) noexcept;
```

2 Returns: u8string_view{str, len}.

```cpp
constexpr u16string_view operator"sv(const char16_t* str, size_t len) noexcept;
```

3 Returns: u16string_view{str, len}.

```cpp
constexpr u32string_view operator"sv(const char32_t* str, size_t len) noexcept;
```

4 Returns: u32string_view{str, len}.

```cpp
constexpr wstring_view operator"sv(const wchar_t* str, size_t len) noexcept;
```

5 Returns: wstring_view{str, len}.

23.4 String classes

23.4.1 General

1 The header `<string>` defines the basic_string class template for manipulating varying-length sequences of char-like objects and five typedef-names, string, u8string, u16string, u32string, and wstring, that name the specializations basic_string<char>, basic_string<char8_t>, basic_string<char16_t>, basic_string<char32_t>, and basic_string<wchar_t>, respectively.

23.4.2 Header `<string>` synopsis

```cpp
#include <compare>  // see 17.11.1
#include <initializer_list>  // see 17.10.2
namespace std {
    // 23.4.3, basic_string
    template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>
    class basic_string;
    template<class charT, class traits, class Allocator>
    constexpr basic_string<charT, traits, Allocator>
    operator+(const basic_string<charT, traits, Allocator>& lhs,
               const basic_string<charT, traits, Allocator>& rhs);
    template<class charT, class traits, class Allocator>
    constexpr basic_string<charT, traits, Allocator>
    operator+(basic_string<charT, traits, Allocator>&& lhs,
               const basic_string<charT, traits, Allocator>& rhs);
    template<class charT, class traits, class Allocator>

The class template `basic_string` describes objects that can store a sequence consisting of a varying number of arbitrary char-like objects with the first element of the sequence at position zero. Such a sequence is also called a “string” if the type of the char-like objects that it holds is clear from context. In the rest of 23.4.3, the type of the char-like objects held in a `basic_string` object is designated by `charT`.

A specialization of `basic_string` is a contiguous container (24.2.2.2).

In all cases, `[data() + size()]` is a valid range, `data() + size()` points at an object with value `charT()` (a “null terminator”), and `size() <= capacity()` is true.

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_string {
        public:

class Allocator = allocator<ranges::range_value_t<R>>>>
basic_string(from_range_t, R&&, Allocator = Allocator())
-> basic_string<ranges::range_value_t<R>, char_traits<ranges::range_value_t<R>>,
  Allocator>;

template<class charT,
class traits,
class Allocator = allocator<charT>>
explicit basic_string(basic_string_view<charT, traits>, const Allocator& = Allocator())
-> basic_string<charT, traits, Allocator>;

template<class charT,
class traits,
class Allocator = allocator<charT>>
basic_string(basic_string_view<charT, traits>,
  typename see below::size_type, typename see below::size_type,
  const Allocator& = Allocator())
-> basic_string<charT, traits, Allocator>;

A size_type parameter type in a basic_string deduction guide refers to the size_type member type of the type deduced by the deduction guide.

The types iterator and const_iterator meet the constexpr iterator requirements (25.3.1).

23.4.3.2 General requirements

1 If any operation would cause size() to exceed max_size(), that operation throws an exception object of type length_error.

2 If any member function or operator of basic_string throws an exception, that function or operator has no other effect on the basic_string object.
In every specialization `basic_string<charT, traits, Allocator>`, the type `allocator_traits<Allocator>::value_type` shall name the same type as `charT`. Every object of type `basic_string<charT, traits, Allocator>` uses an object of type `Allocator` to allocate and free storage for the contained `charT` objects as needed. The `Allocator` object used is obtained as described in 24.2.2.1. In every specialization `basic_string<charT, traits, Allocator>`, the type `traits` shall meet the character traits requirements (23.2).

[Note 1: Every specialization `basic_string<charT, traits, Allocator>` is an allocator-aware container, but does not use the allocator’s `construct` and `destroy` member functions (24.2.2.1). — end note]

[Note 2: The program is ill-formed if `traits::char_type` is not the same type as `charT`. — end note]

References, pointers, and iterators referring to the elements of a `basic_string` sequence may be invalidated by the following uses of that `basic_string` object:

1. Passing as an argument to any standard library function taking a reference to non-const `basic_string` as an argument.
2. Calling non-const member functions, except `operator[]`, `at`, `data`, `front`, `back`, `begin`, `rbegin`, `end`, and `rend`.

23.4.3.3 Constructors and assignment operators

```cpp
constexpr explicit basic_string(const Allocator& a) noexcept;
```

**Postconditions:** `size()` is equal to 0.

```cpp
constexpr basic_string(const basic_string& str);
constexpr basic_string(basic_string&& str) noexcept;
```

**Effects:** Constructs an object whose value is that of `str` prior to this call.

**Remarks:** In the second form, `str` is left in a valid but unspecified state.

```cpp
constexpr basic_string(const basic_string& str, size_type pos,
                       const Allocator& a = Allocator());
constexpr basic_string(const basic_string& str, size_type pos, size_type n,
                       const Allocator& a = Allocator());
constexpr basic_string(basic_string&& str, size_type pos,
                       const Allocator& a = Allocator());
constexpr basic_string(basic_string&& str, size_type pos, size_type n,
                       const Allocator& a = Allocator());
```

**Let**

1. `s` be the value of `str` prior to this call and
2. `rlen` be `pos + min(n, s.size() - pos)` for the overloads with parameter `n`, and `s.size()` otherwise.

**Effects:** Constructs an object whose initial value is the range `[s.data() + pos, s.data() + rlen]`.

**Throws:** `out_of_range` if `pos > s.size()`.

**Remarks:** For the overloads with a `basic_string&&` parameter, `str` is left in a valid but unspecified state.

**Recommended practice:** For the overloads with a `basic_string&&` parameter, implementations should avoid allocation if `s.get_allocator() == a` is true.

```cpp
template<class T>
constexpr basic_string(const T& t, size_type pos, size_type n, const Allocator& a = Allocator());
```

**Constraints:** `is_convertible_v<const T, basic_string_view<charT, traits>>` is true.

**Effects:** Creates a variable, `sv`, as if by `basic_string_view<charT, traits> sv = t`; and then behaves the same as:

```cpp
basic_string(sv.substr(pos, n), a);
```

---

(208) For example, as an argument to non-member functions `swap()` (23.4.4.3), `operator>>()` (23.4.4.4), and `getline()` (23.4.4.4), or as an argument to `basic_string::swap()`.
template<class T>
constexpr explicit basic_string(const T& t, const Allocator& a = Allocator());

Constraints:
— is_convertible_v<const T&, basic_string_view<charT>, traits> is true and
— is_convertible_v<const T&, const charT*> is false.

Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t; and then behaves the same as basic_string(sv.data(), sv.size(), a).

constexpr basic_string(const charT* s, size_type n, const Allocator& a = Allocator());

Preconditions: [s, s + n) is a valid range.
Effects: Constructs an object whose initial value is the range [s, s + n).
Postconditions: size() is equal to n, and traits::compare(data(), s, n) is equal to 0.

constexpr basic_string(const charT* s, const Allocator& a = Allocator());

[Note 1: This affects class template argument deduction. — end note]
Effects: Equivalent to: basic_string(s, traits::length(s), a).

constexpr basic_string(size_type n, charT c, const Allocator& a = Allocator());

Constraints: Allocator is a type that qualifies as an allocator (24.2.2.1).
Effects: Constructs an object whose value consists of n copies of c.

template<class InputIterator>
constexpr basic_string(InputIterator begin, InputIterator end, const Allocator& a = Allocator());

Constraints: InputIterator is a type that qualifies as an input iterator (24.2.2.1).
Effects: Constructs a string from the values in the range [begin, end), as specified in 24.2.4.

template<container-compatible-range<charT> R>
constexpr basic_string(from_range_t, R&& rg, const Allocator& = Allocator());

Effects: Constructs a string from the values in the range rg, as specified in 24.2.4.

constexpr basic_string(initializer_list<charT> il, const Allocator& a = Allocator());

Effects: Equivalent to basic_string(il.begin(), il.end(), a).

customexpr basic_string(const basic_string& str, const Allocator& alloc);
customexpr basic_string(basic_string&& str, const Allocator& alloc);

Effects: Constructs an object whose value is that of str prior to this call. The stored allocator is constructed from alloc. In the second form, str is left in a valid but unspecified state.

Throws: The second form throws nothing if alloc == str.get_allocator().

template<class InputIterator, class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
basic_string(InputIterator, InputIterator, Allocator = Allocator())
-> basic_string<typename iterator_traits<InputIterator>::value_type, char_traits<typename iterator_traits<InputIterator>::value_type>, Allocator>;

Constraints: InputIterator is a type that qualifies as an input iterator, and Allocator is a type that qualifies as an allocator (24.2.2.1).

template<class charT, class traits, class Allocator = allocator<charT>>
explicit basic_string(basic_string_view<charT, traits>, const Allocator& = Allocator())
-> basic_string<charT, traits, Allocator>;

§ 23.4.3.3
template<class charT, 
  class traits, 
  class Allocator = allocator<charT>> 
basic_string(basic_string_view<charT, traits>, 
  typename see below::size_type, typename see below::size_type, 
  const Allocator& = Allocator()) 
-> basic_string<charT, traits, Allocator>;

Constraints: Allocator is a type that qualifies as an allocator (24.2.2.1).

constexpr basic_string& operator=(const basic_string& str);

Effects: If *this and str are the same object, has no effect. Otherwise, replaces the value of *this 
with a copy of str.

Returns: *this.

constexpr basic_string& operator=(basic_string&& str) 
noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value || 
  allocator_traits<Allocator>::is_always_equal::value);

Effects: Move assigns as a sequence container (24.2), except that iterators, pointers and references may 
be invalidated.

Returns: *this.

template<class T> 
constexpr basic_string& operator=(const T& t);

Constraints:
(32.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(32.2) is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
basic_string_view<charT, traits> sv = t; 
return assign(sv);

constexpr basic_string& operator=(const charT* s);

Effects: Equivalent to: return *this = basic_string_view<charT, traits>(s);

constexpr basic_string& operator=(charT c);

Effects: Equivalent to:
return *this = basic_string_view<charT, traits>(addressof(c), 1);

constexpr basic_string& operator=(initializer_list<charT> il);

Effects: Equivalent to:
return *this = basic_string_view<charT, traits>(il.begin(), il.size());

23.4.3.4 Iterator support

constexpr iterator begin() noexcept;
constexpr const_iterator begin() const noexcept;
constexpr const_iterator cbegin() const noexcept;

Returns: An iterator referring to the first character in the string.

constexpr iterator end() noexcept;
constexpr const_iterator end() const noexcept;
constexpr const_iterator cend() const noexcept;

Returns: An iterator which is the past-the-end value.

constexpr reverse_iterator rbegin() noexcept;
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;

Returns: An iterator which is semantically equivalent to reverse_iterator(end()).
# ISO/IEC N4944

4

`constexpr reverse_iterator rend() noexcept;
constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;`

*Returns:* An iterator which is semantically equivalent to `reverse_iterator(begin())`.

## 23.4.3.5 Capacity

4

`constexpr size_type size() const noexcept;
constexpr size_type length() const noexcept;

*Returns:* A count of the number of char-like objects currently in the string.

*Complexity:* Constant time.

`constexpr size_type max_size() const noexcept;

*Returns:* The largest possible number of char-like objects that can be stored in a `basic_string`.

*Complexity:* Constant time.

`constexpr void resize(size_type n, charT c);

*Effects:* Alters the value of `*this` as follows:

1. If `n <= size()`, erases the last `size() - n` elements.
2. If `n > size()`, appends `n - size()` copies of `c`.

`constexpr void resize(size_type n);

*Effects:* Equivalent to `resize(n, charT())`.

`template<class Operation> constexpr void resize_and_overwrite(size_type n, Operation op);

*Let*

1. `o = size()` before the call to `resize_and_overwrite`.
2. `k be min(o, n)`.
3. `p be a value of type charT* or charT* const, such that the range [p, p + n] is valid and this->compare(0, k, p, k) == 0 is true` before the call. The values in the range [p + k, p + n] may be indeterminate (6.7.4).
4. `m be a value of type size_type or const size_type equal to n`.
5. `OP be the expression std::move(op)(p, m)`.
6. `r = OP`.

*Mandates:* `OP` has an integer-like type (25.3.4.4).

*Preconditions:*

1. `OP` does not throw an exception or modify `p` or `m`.
2. `r > 0`.
3. `r ≤ m`.
4. `After evaluating OP there are no indeterminate values in the range [p, p + r]`.

*Effects:* Evaluates `OP`, replaces the contents of `*this` with `[p, p + r]`, and invalidates all pointers and references to the range `[p, p + n]`.

*Recommended practice:* Implementations should avoid unnecessary copies and allocations by, for example, making `p` a pointer into internal storage and by restoring `*(p + r)` to `charT()` after evaluating `OP`.

`constexpr size_type capacity() const noexcept;

*Returns:* The size of the allocated storage in the string.

*Complexity:* Constant time.

`constexpr void reserve(size_type res_arg);

*Effects:* A directive that informs a `basic_string` of a planned change in size, so that the storage allocation can be managed accordingly. After `reserve()`, `capacity()` is greater or equal to the..."
argument of reserve if reallocation happens; and equal to the previous value of capacity() otherwise.
Reallocation happens at this point if and only if the current capacity is less than the argument of reserve().

Throws: length_error if res_arg > max_size() or any exceptions thrown by allocator_traits<Allocator>::allocate.

constexpr void shrink_to_fit();

Effects: shrink_to_fit is a non-binding request to reduce capacity() to size().

[Note 1: The request is non-binding to allow latitude for implementation-specific optimizations. — end note]
It does not increase capacity(), but may reduce capacity() by causing reallocation.

Complexity: If the size is not equal to the old capacity, linear in the size of the sequence; otherwise constant.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

[Note 2: If no reallocation happens, they remain valid. — end note]

constexpr void clear() noexcept;

Effects: Equivalent to: erase(begin(), end());

[[nodiscard]] constexpr bool empty() const noexcept;

Effects: Equivalent to: return size() == 0;

23.4.3.6 Element access

constexpr const_reference operator[](size_type pos) const;
constexpr reference operator[](size_type pos);

Preconditions: pos <= size().

Returns: *(begin() + pos) if pos < size(). Otherwise, returns a reference to an object of type charT with value charT(), where modifying the object to any value other than charT() leads to undefined behavior.

Throws: Nothing.

Complexity: Constant time.

constexpr const_reference at(size_type pos) const;
constexpr reference at(size_type pos);

Returns: operator[](pos).

Throws: out_of_range if pos >= size().

constexpr charT& front() const;
constexpr charT& front();

Preconditions: !empty().

Effects: Equivalent to: return operator[](0);

constexpr const charT& back() const;
constexpr charT& back();

Preconditions: !empty().

Effects: Equivalent to: return operator[](size() - 1);

23.4.3.7Modifiers

23.4.3.7.1 basic_string::operator+=

constexpr basic_string& operator+=(const basic_string& str);

Effects: Equivalent to: return append(str);
template<class T>
constexpr basic_string& operator+=(const T& t);

Constraints:

(2.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(2.2) is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return append(sv);

constexpr basic_string& operator+=(const charT* s);

Effects: Equivalent to: return append(s);

constexpr basic_string& operator+=(charT c);

Effects: Equivalent to: return append(size_type{1}, c);

constexpr basic_string& operator+=(initializer_list<charT> il);

Effects: Equivalent to: return append(il);

23.4.3.7.2 basic_string::append [string.append]

constexpr basic_string& append(const basic_string& str);

Effects: Equivalent to: return append(str.data(), str.size());

constexpr basic_string& append(const basic_string& str, size_type pos, size_type n = npos);

Effects: Equivalent to:

return append(basic_string_view<charT, traits>(str).substr(pos, n));

template<class T>
constexpr basic_string& append(const T& t);

Constraints:

(3.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(3.2) is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return append(sv.data(), sv.size());

template<class T>
constexpr basic_string& append(const T& t, size_type pos, size_type n = npos);

Constraints:

(5.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(5.2) is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return append(sv.substr(pos, n));

constexpr basic_string& append(const charT* s, size_type n);

Preconditions: [s, s + n) is a valid range.

Effects: Appends a copy of the range [s, s + n) to the string.

Returns: *this.

constexpr basic_string& append(const charT* s);

Effects: Equivalent to: return append(s, traits::length(s));
constexpr basic_string& append(size_type n, charT c);

Effects: Appends n copies of c to the string.
Returns: *this.

template<class InputIterator>
constexpr basic_string& append(InputIterator first, InputIterator last);

Constraints: InputIterator is a type that qualifies as an input iterator (24.2.2.1).
Effects: Equivalent to: return append(basic_string(first, last, get_allocator()));

template<container-compatible-range<charT> R>
constexpr basic_string& append_range(R&& rg);

Effects: Equivalent to: return append(basic_string(from_range, std::forward<R>(rg), get_allocator()));

constexpr basic_string& append(initializer_list<charT> il);

Effects: Equivalent to: return append(il.begin(), il.size());

custom void push_back(charT c);

Effects: Equivalent to append(size_type{1}, c).

23.4.3.7.3 basic_string::assign [string.assign]

custom basic_string& assign(const basic_string& str);

Effects: Equivalent to: return *this = str;

custom basic_string& assign(basic_string&& str)
  noexcept(allocation_traits<Allocator>::propagate_on_container_move_assignment::value ||
  allocation_traits<Allocator>::is_always_equal::value);

Effects: Equivalent to: return *this = std::move(str);

custom basic_string& assign(const basic_string& str, size_type pos, size_type n = npos);

Effects: Equivalent to:
return assign(basic_string_view<charT, traits>(str).substr(pos, n));

template<class T>
constexpr basic_string& assign(const T& t);

Constraints:
(4.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(4.2) is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
basic_string_view<charT, traits> sv = t;
return assign(sv.data(), sv.size());

template<class T>
constexpr basic_string& assign(const T& t, size_type pos, size_type n = npos);

Constraints:
(6.1) is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(6.2) is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
basic_string_view<charT, traits> sv = t;
return assign(sv.substr(pos, n));

custom basic_string& assign(const charT* s, size_type n);

Preconditions: [s, s + n) is a valid range.

Effects: Replaces the string controlled by *this with a copy of the range [s, s + n).
Returns: *this.

```cpp
constexpr basic_string& assign(const charT* s);
```

Effects: Equivalent to: return assign(s, traits::length(s));

```cpp
constexpr basic_string& assign(initializer_list<charT> il);
```

Effects: Equivalent to: return assign(il.begin(), il.size());

```cpp
constexpr basic_string& assign(size_type n, charT c);
```

Effects: Equivalent to:
```
clear();
resize(n, c);
return *this;
```

```cpp
template<class InputIterator>
constexpr basic_string& assign(InputIterator first, InputIterator last);
```

Constraints: InputIterator is a type that qualifies as an input iterator (24.2.2.1).

Effects: Equivalent to: return assign(basic_string(first, last, get_allocator()));

```cpp
template<container-compatible-range<charT> R>
constexpr basic_string& assign_range(R&& rg);
```

Effects: Equivalent to: return assign(basic_string(from_range, std::forward<R>(rg), get_allocator()));

### 23.4.3.7.4 basic_string::insert

```cpp
constexpr basic_string& insert(size_type pos, const basic_string& str);
```

Effects: Equivalent to: return insert(pos, str.data(), str.size());

```cpp
constexpr basic_string& insert(size_type pos1, const basic_string& str, size_type pos2, size_type n = npos);
```

Effects: Equivalent to:
```
return insert(pos1, basic_string_view<charT, traits>(str), pos2, n);
```

```cpp
template<class T>
custom string& insert(size_type pos, const T& t);
```

Constraints:

1. is_convertible_v<const T&, basic_string_view<charT, traits>> is true
2. is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
```
basic_string_view<charT, traits> sv = t;
return insert(pos, sv.data(), sv.size());
```

```cpp
template<class T>
custom string& insert(size_type pos1, const T& t, size_type pos2, size_type n = npos);
```

Constraints:

1. is_convertible_v<const T&, basic_string_view<charT, traits>> is true
2. is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
```
basic_string_view<charT, traits> sv = t;
return insert(pos1, sv.substr(pos2, n));
```

```cpp
constexpr basic_string& insert(size_type pos, const charT* s, size_type n);
```

Preconditions: [s, s + n) is a valid range.
Effects: Inserts a copy of the range \([s, s + n]\) immediately before the character at position \(pos\) if \(pos < \text{size()}\), or otherwise at the end of the string.

Returns: \(*this\).

Throws:

- out_of_range if \(pos > \text{size()}\),
- length_error if \(n > \text{max_size()} - \text{size()}\), or
- any exceptions thrown by allocator_traits<Allocator>::allocate.

```
constexpr basic_string& insert(size_type pos, const charT* s);
```

Effects: Equivalent to: return insert(pos, s, traits::length(s));

```
constexpr basic_string& insert(size_type pos, size_type n, charT c);
```

Effects: Inserts \(n\) copies of \(c\) before the character at position \(pos\) if \(pos < \text{size()}\), or otherwise at the end of the string.

Returns: \(*this\)

Throws:

- out_of_range if \(pos > \text{size()}\),
- length_error if \(n > \text{max_size()} - \text{size()}\), or
- any exceptions thrown by allocator_traits<Allocator>::allocate.

```
constexpr iterator insert(const_iterator p, charT c);
```

Preconditions: \(p\) is a valid iterator on \(*this\).

Effects: Inserts a copy of \(c\) at the position \(p\).

Returns: An iterator which refers to the inserted character.

```
constexpr iterator insert(const_iterator p, size_type n, charT c);
```

Preconditions: \(p\) is a valid iterator on \(*this\).

Effects: Inserts \(n\) copies of \(c\) at the position \(p\).

Returns: An iterator which refers to the first inserted character, or \(p\) if \(n == 0\).

```
template<class InputIterator>
constexpr iterator insert(const_iterator p, InputIterator first, InputIterator last);
```

Constraints: InputIterator is a type that qualifies as an input iterator (24.2.2.1).

Preconditions: \(p\) is a valid iterator on \(*this\).

Effects: Equivalent to insert(p - begin(), basic_string(first, last, get_allocator())).

Returns: An iterator which refers to the first inserted character, or \(p\) if \(first == last\).

```
template<container-compatible-range<charT> R>
constexpr iterator insert_range(const_iterator p, R&& rg);
```

Preconditions: \(p\) is a valid iterator on \(*this\).

Effects: Equivalent to insert(p - begin(), basic_string(from_range, std::forward<R>(rg), get_allocator())).

Returns: An iterator which refers to the first inserted character, or \(p\) if \(rg\) is empty.

```
constexpr iterator insert(const_iterator p, initializer_list<charT> il);
```

Effects: Equivalent to: return insert(p, il.begin(), il.end());

```
23.4.3.7.5 basic_string::erase
```

```
constexpr basic_string& erase(size_type pos = 0, size_type n = npos);
```

Effects: Determines the effective length \(xlen\) of the string to be removed as the smaller of \(n\) and \(\text{size()} - \text{pos}\). Removes the characters in the range \([\text{begin()} + \text{pos}, \text{begin()} + \text{pos} + xlen]\).
Returns: *this.

Throws: out_of_range if pos > size().

constexpr iterator erase(const_iterator p);

Preconditions: p is a valid dereferenceable iterator on *this.

Effects: Removes the character referred to by p.

Returns: An iterator which points to the element immediately following p prior to the element being erased. If no such element exists, end() is returned.

Throws: Nothing.

constexpr iterator erase(const_iterator first, const_iterator last);

Preconditions: first and last are valid iterators on *this. [first, last) is a valid range.

Effects: Removes the characters in the range [first, last).

Returns: An iterator which points to the element pointed to by last prior to the other elements being erased. If no such element exists, end() is returned.

Throws: Nothing.

constexpr void pop_back();

Preconditions: !empty().

Effects: Equivalent to erase(end() - 1).

Throws: Nothing.

23.4.3.7.6 basic_string::replace

constexpr basic_string& replace(size_type pos1, size_type n1, const basic_string& str);

Effects: Equivalent to: return replace(pos1, n1, str.data(), str.size());

constexpr basic_string& replace(size_type pos1, size_type n1, const basic_string& str,
                                 size_type pos2, size_type n2 = npos);

Effects: Equivalent to:
          return replace(pos1, n1, basic_string_view<charT, traits>(str).substr(pos2, n2));

template<class T>
constexpr basic_string& replace(size_type pos1, size_type n1, const T& t);

Constraints:
(3.1) — is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(3.2) — is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
          basic_string_view<charT, traits> sv = t;
          return replace(pos1, n1, sv.data(), sv.size());

template<class T>
constexpr basic_string& replace(size_type pos1, size_type n1, const T& t,
                                 size_type pos2, size_type n2 = npos);

Constraints:
(5.1) — is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
(5.2) — is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
          basic_string_view<charT, traits> sv = t;
          return replace(pos1, n1, sv.substr(pos2, n2));

constexpr basic_string& replace(size_type pos1, size_type n1, const charT* s, size_type n2);

Preconditions: [s, s + n2) is a valid range.
Effects: Determines the effective length $xlen$ of the string to be removed as the smaller of $n1$ and $\text{size()} - \text{pos1}$. If $\text{size()} - xlen \geq \text{max_size()} - n2$ throws length_error. Otherwise, the function replaces the characters in the range $[\text{begin()} + \text{pos1}, \text{begin()} + \text{pos1} + xlen)$ with a copy of the range $[s, s + n2)$.  

Returns: *this.

Throws:

1. out_of_range if pos1 > size(),
2. length_error if the length of the resulting string would exceed max_size(), or
3. any exceptions thrown by allocator_traits<Allocator>::allocate.

```cpp
constexpr basic_string& replace(size_type pos, size_type n, const charT* s);
```

Effects: Equivalent to:

```cpp
return replace(pos, n, s, traits::length(s));
```

```cpp
constexpr basic_string& replace(size_type pos1, size_type n1, size_type n2, charT c);
```

Effects: Determines the effective length $xlen$ of the string to be removed as the smaller of $n1$ and $\text{size()} - \text{pos1}$. If $\text{size()} - xlen \geq \text{max_size()} - n2$ throws length_error. Otherwise, the function replaces the characters in the range $[\text{begin()} + \text{pos1}, \text{begin()} + \text{pos1} + xlen)$ with $n2$ copies of $c$.

Returns: *this.

Throws:

1. out_of_range if pos1 > size(),
2. length_error if the length of the resulting string would exceed max_size(), or
3. any exceptions thrown by allocator_traits<Allocator>::allocate.

```cpp
constexpr basic_string& replace(const_iterator i1, const_iterator i2, const basic_string& str);
```

Effects: Equivalent to:

```cpp
return replace(i1, i2, basic_string_view<charT, traits>(str));
```

```cpp
template<class T>
constexpr basic_string& replace(const_iterator i1, const_iterator i2, const T& t);
```

Constraints:

1. is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
2. is_convertible_v<const T&, const charT*> is false.

Preconditions: $[\text{begin()}, i1)$ and $[i1, i2)$ are valid ranges.

Effects: Equivalent to:

```cpp
basic_string_view<charT, traits> sv = t;
return replace(i1 - begin(), i2 - i1, sv.data(), sv.size());
```

```cpp
constexpr basic_string& replace(const_iterator i1, const_iterator i2, const_iterator i3, const_iterator i4);
```

Effects: Equivalent to:

```cpp
return replace(i1, i2, basic_string_view<charT, traits>(i3, i4));
```

```cpp
constexpr basic_string& replace(const_iterator i1, const_iterator i2, size_type n, charT c);
```

Preconditions: $[\text{begin()}, i1)$ and $[i1, i2)$ are valid ranges.

Effects: Equivalent to:

```cpp
return replace(i1 - begin(), i2 - i1, n, c);
```

```cpp
template<class InputIterator>
constexpr basic_string& replace(const_iterator i1, const_iterator i2, InputIterator j1, InputIterator j2);
```

Constraints: InputIterator is a type that qualifies as an input iterator (24.2.2.1).

Effects: Equivalent to:

```cpp
return replace(i1, i2, basic_string(j1, j2, get_allocator()));
```
template<typename charT, template<typename R> class container CompatibleRange>
constexpr basic_string& replace_with_range(const_iterator i1, const_iterator i2, R&& rg);

25. Effects: Equivalent to:

   return replace(i1, i2, basic_string(from_range, std::forward<R>(rg), get_allocator()));

constexpr basic_string& replace(const_iterator i1, const_iterator i2, initializer_list<charT> il);

26. Effects: Equivalent to: return replace(i1, i2, il.begin(), il.size());

23.4.3.7.7 basic_string::copy [string.copy]

constexpr size_type copy(charT* s, size_type n, size_type pos = 0) const;

1. Effects: Equivalent to: return basic_string_view<charT, traits>(*this).copy(s, n, pos);

[Note 1: This does not terminate s with a null object. — end note]

23.4.3.7.8 basic_string::swap [string.swap]

constexpr void swap(basic_string& s) noexcept((allocator_traits<Allocator>::propagate_on_container_swap::value ||
   allocator_traits<Allocator>::is_always_equal::value));

1. Preconditions: allocator_traits<Allocator>::propagate_on_container_swap::value is true or
   get_allocator() == s.get_allocator().

2. Postconditions: *this contains the same sequence of characters that was in s, s contains the same
   sequence of characters that was in *this.

23.4.3.8 String operations [string.ops]

23.4.3.8.1 Accessors [string.accessors]

constexpr const charT* c_str() const noexcept;
constexpr const charT* data() const noexcept;

1. Returns: A pointer p such that p + i == addressof(operator[](i)) for each i in [0, size()].

2. Complexity: Constant time.

3. Remarks: The program shall not modify any of the values stored in the character array; otherwise, the
   behavior is undefined.

constexpr charT* data() noexcept;

4. Returns: A pointer p such that p + i == addressof(operator[](i)) for each i in [0, size()].

5. Complexity: Constant time.

6. Remarks: The program shall not modify the value stored at p + size() to any value other than
   charT(); otherwise, the behavior is undefined.

constexpr operator basic_string_view<charT, traits>() const noexcept;

7. Effects: Equivalent to: return basic_string_view<charT, traits>(data(), size());

constexpr allocator_type get_allocator() const noexcept;

8. Returns: A copy of the Allocator object used to construct the string or, if that allocator has been
   replaced, a copy of the most recent replacement.

23.4.3.8.2 Searching [string.find]

Let F be one of find, rfind, find_first_of, find_last_of, find_first_not_of, and find_last_not_of.

(1.1) Each member function of the form

constexpr size_type F(const basic_string& str, size_type pos) const noexcept;

has effects equivalent to: return F(basic_string_view<charT, traits>(str), pos);
Each member function of the form
\[
\text{constexpr size_type } F(\text{const charT* } s, \text{size_type pos}) \text{ const;}
\]
has effects equivalent to:
\[
\text{return } F(\text{basic_string_view<charT, traits}>(s), \text{pos});
\]

Each member function of the form
\[
\text{constexpr size_type } F(\text{const charT* } s, \text{size_type pos, size_type n}) \text{ const;}
\]
has effects equivalent to:
\[
\text{return } F(\text{basic_string_view<charT, traits}>(s, n), \text{pos});
\]

Each member function of the form
\[
\text{constexpr size_type } F(\text{charT } c, \text{size_type pos}) \text{ const noexcept;}
\]
has effects equivalent to:
\[
\text{return } F(\text{basic_string_view<charT, traits}>(\text{addressof}(c), 1), \text{pos});
\]
is_convertible_v<const T&, basic_string_view<charT, traits>> is true and

is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:
return basic_string_view<charT, traits>(*this).substr(pos1, n1).compare(t);

template<class T>
constexpr int compare(size_type pos1, size_type n1, const T& t,
                     size_type pos2, size_type n2 = npos) const;

Constraints:

— is_convertible_v<const T&, basic_string_view<charT, traits>> is true and
— is_convertible_v<const T&, const charT*> is false.

Effects: Equivalent to:

basic_string_view<charT, traits> s = *this, sv = t;
return s.substr(pos1, n1).compare(sv.substr(pos2, n2));

castexpr int compare(const basic_string& str) const noexcept;

effects: Equivalent to:
return compare(basic_string_view<charT, traits>(str));

castexpr int compare(size_type pos1, size_type n1, const basic_string& str) const;

effects: Equivalent to: return compare(pos1, n1, basic_string_view<charT, traits>(str));

castexpr int compare(size_type pos1, size_type n1, const basic_string& str,
                     size_type pos2, size_type n2 = npos) const;

effects: Equivalent to:
return compare(pos1, n1, basic_string_view<charT, traits>(str), pos2, n2);

castexpr int compare(const charT* s) const;

effects: Equivalent to:
return compare(basic_string_view<charT, traits>(s));

castexpr int compare(size_type pos, size_type n1, const charT* s) const;

effects: Equivalent to:
return compare(pos, n1, basic_string_view<charT, traits>(s), pos2, n2);

castexpr int compare(size_type pos, size_type n1, const charT* s, size_type n2) const;

effects: Equivalent to:
return compare(pos, n1, basic_string_view<charT, traits>(s, n2));

23.4.3.8.5 basic_string::starts_with

constexpr bool starts_with(basic_string_view<charT, traits> x) const noexcept;
constexpr bool starts_with(charT x) const noexcept;
constexpr bool starts_with(const charT* x) const;

effects: Equivalent to:
return basic_string_view<charT, traits>(data(), size()).starts_with(x);

23.4.3.8.6 basic_string::ends_with

constexpr bool ends_with(basic_string_view<charT, traits> x) const noexcept;
constexpr bool ends_with(charT x) const noexcept;
constexpr bool ends_with(const charT* x) const;

effects: Equivalent to:
return basic_string_view<charT, traits>(data(), size()).ends_with(x);

23.4.3.8.7 basic_string::contains

constexpr bool contains(basic_string_view<charT, traits> x) const noexcept;
constexpr bool contains(charT x) const noexcept;
constexpr bool contains(const charT* x) const;

effects: Equivalent to:
return basic_string_view<charT, traits>(data(), size()).contains(x);

23.4.4 Non-member functions

23.4.4.1 operator+

```cpp
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs,
          const basic_string<charT, traits, Allocator>& rhs);
```

`Effects:` Equivalent to:

```cpp
  basic_string<charT, traits, Allocator> r = lhs;
  r.append(rhs);
  return r;
```

```cpp
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);
```

`Effects:` Equivalent to:

```cpp
  basic_string<charT, traits, Allocator> r = lhs;
  r.append(rhs);
  return r;
```

```cpp
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs,
          const basic_string<charT, traits, Allocator>& rhs);
```

`Effects:` Equivalent to:

```cpp
  lhs.append(rhs);
  return std::move(lhs);
```

```cpp
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs,
          basic_string<charT, traits, Allocator>&& rhs);
```

`Effects:` Equivalent to:

```cpp
  lhs.append(rhs);
  return std::move(lhs);
```

```cpp
except that both lhs and rhs are left in valid but unspecified states.
[Note 1: If lhs and rhs have equal allocators, the implementation can move from either. — end note]
```

```cpp
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const charT* lhs, basic_string<charT, traits, Allocator>&& rhs);
```

`Effects:` Equivalent to:

```cpp
  rhs.insert(0, lhs);
  return std::move(rhs);
```

```cpp
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const charT* lhs, const charT* rhs);
```

`Effects:` Equivalent to:

```cpp
  basic_string<charT, traits, Allocator> r = rhs;
  r.insert(0, lhs);
  return r;
```
template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(charT lhs, const basic_string<charT, traits, Allocator>& rhs);

Effects: Equivalent to:
   basic_string<charT, traits, Allocator> r = rhs;
   r.insert(r.begin(), lhs);
   return r;

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(charT lhs, basic_string<charT, traits, Allocator>&& rhs);

Effects: Equivalent to:
   rhs.insert(rhs.begin(), lhs);
   return std::move(rhs);

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs, charT rhs);

Effects: Equivalent to:
   basic_string<charT, traits, Allocator> r = lhs;
   r.push_back(rhs);
   return r;

template<class charT, class traits, class Allocator>
constexpr basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs, charT rhs);

Effects: Equivalent to:
   lhs.push_back(rhs);
   return std::move(lhs);

23.4.4.2 Non-member comparison operator functions

template<class charT, class traits, class Allocator>
constexpr bool
operator==(const basic_string<charT, traits, Allocator>& lhs, const basic_string<charT, traits, Allocator>& rhs) noexcept;

Effects: Let \( op \) be the operator. Equivalent to:
   return basic_string_view<charT, traits>(lhs) \( op \) basic_string_view<charT, traits>(rhs);

23.4.4.3 swap

template<class charT, class traits, class Allocator>
constexpr void
swap(basic_string<charT, traits, Allocator>& lhs, basic_string<charT, traits, Allocator>& rhs) noexcept(noexcept(lhs.swap(rhs)));

Effects: Equivalent to \( \text{lhs.swap} \text{rhs} \).
23.4.4.4 Inserters and extractors [string.io]

```cpp
template<class charT, class traits, class Allocator>
  basic_istream<charT, traits>&
  operator>>(basic_istream<charT, traits>& is, basic_string<charT, traits, Allocator>& str);
```

**Effects:** Behaves as a formatted input function (31.7.5.3.1). After constructing a `sentry` object, if the `sentry` object returns `true` when converted to a value of type `bool`, calls `str.erase()` and then extracts characters from `is` and appends them to `str` as if by calling `str.append(1, c)`. If `is.width()` is greater than zero, the maximum number `n` of characters appended is `is.width()`; otherwise `n` is `str.max_size()`. Characters are extracted and appended until any of the following occurs:

1. `n` characters are stored;
2. end-of-file occurs on the input sequence;
3. `isspace(c, is.getloc())` is `true` for the next available input character `c`.

After the last character (if any) is extracted, `is.width(0)` is called and the `sentry` object is destroyed.

If the function extracts no characters, `ios_base::failbit` is set in the input function’s local error state before `setstate` is called.

**Returns:** `is`.

```cpp
template<class charT, class traits, class Allocator>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& os, const basic_string<charT, traits, Allocator>& str);
```

**Effects:** Equivalent to: `return os << basic_string_view<charT, traits>(str);`

```cpp
template<class charT, class traits, class Allocator>
  basic_istream<charT, traits>&
  getline(basic_istream<charT, traits>& is, basic_string<charT, traits, Allocator>& str, charT delim);
```

**Effects:** Behaves as an unformatted input function (31.7.5.4), except that it does not affect the value returned by subsequent calls to `basic_istream<>::gcount()`. After constructing a `sentry` object, if the `sentry` object returns `true` when converted to a value of type `bool`, calls `str.erase()` and then extracts characters from `is` and appends them to `str` as if by calling `str.append(1, c)` until any of the following occurs:

1. end-of-file occurs on the input sequence;
2. `traits::eq(c, delim)` for the next available input character `c` (in which case, `c` is extracted but not appended);
3. `str.max_size()` characters are stored (in which case, `ios_base::failbit` is set in the input function’s local error state).

The conditions are tested in the order shown. In any case, after the last character is extracted, the `sentry` object is destroyed.

If the function extracts no characters, `ios_base::failbit` is set in the input function’s local error state before `setstate` is called.

**Returns:** `is`.

```cpp
template<class charT, class traits, class Allocator>
  basic_istream<charT, traits>&
  getline(basic_istream<charT, traits>& is, basic_string<charT, traits, Allocator>& str);
```

§ 23.4.4.4
template<class charT, class traits, class Allocator>
  basic_istream<charT, traits>& getline(basic_istream<charT, traits>&& is,
                                         basic_string<charT, traits, Allocator>& str);

Returns: getline(is, str, is.widen(‘\n’)).

23.4.4.5 Erasure [string.erasure]

```cpp
template<class charT, class traits, class Allocator, class U>
constexpr typename basic_string<charT, traits, Allocator>::size_type erase(basic_string<charT, traits, Allocator>& c, const U& value);
```

Effects: Equivalent to:

```cpp
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

```cpp
template<class charT, class traits, class Allocator, class Predicate>
constexpr typename basic_string<charT, traits, Allocator>::size_type erase_if(basic_string<charT, traits, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:

```cpp
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;
```

23.4.5 Numeric conversions [string.conversions]

```cpp
int stoi(const string& str, size_t* idx = nullptr, int base = 10);
long stol(const string& str, size_t* idx = nullptr, int base = 10);
unsigned long stoul(const string& str, size_t* idx = nullptr, int base = 10);
long long stoll(const string& str, size_t* idx = nullptr, int base = 10);
unsigned long long stoull(const string& str, size_t* idx = nullptr, int base = 10);
```

Effects: The first two functions call `strtol(str.c_str(), ptr, base)`, and the last three functions call
`strtoul(str.c_str(), ptr, base)`, `strtoll(str.c_str(), ptr, base)`, and `strtoull(str.c_str(), ptr, base)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != nullptr`, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

Throws: `invalid_argument` if `strtol`, `strtoul`, or `strtoull` reports that no conversion can be performed. Throws `out_of_range` if `stof`, `stod`, or `strtol` sets `errno` to `ERANGE`, or if the converted value is outside the range of representable values for the return type.

```cpp
float stof(const string& str, size_t* idx = nullptr);
double stod(const string& str, size_t* idx = nullptr);
long double stold(const string& str, size_t* idx = nullptr);
```

Effects: These functions call `strtof(str.c_str(), ptr)`, `strtod(str.c_str(), ptr)`, and `strtol(str.c_str(), ptr)` respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != nullptr`, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

Throws: `invalid_argument` if `strtof`, `strtod`, or `strtol` reports that no conversion can be performed. Throws `out_of_range` if `stof`, `stod`, or `strtol` sets `errno` to `ERANGE` or if the converted value is outside the range of representable values for the return type.
string to_string(int val);
string to_string(unsigned val);
string to_string(long val);
string to_string(unsigned long val);
string to_string(long long val);
string to_string(unsigned long long val);
string to_string(float val);
string to_string(double val);
string to_string(long double val);

7 Returns: Each function returns a string object holding the character representation of the value of its argument that would be generated by calling sprintf(buf, fmt, val) with a format specifier of "%d", "%u", "%ld", "%lu", "%lld", "%llu", "%f", "%f", or "%Lf", respectively, where buf designates an internal character buffer of sufficient size.

int stoi(const wstring& str, size_t* idx = nullptr, int base = 10);
long stol(const wstring& str, size_t* idx = nullptr, int base = 10);
unsigned long stoul(const wstring& str, size_t* idx = nullptr, int base = 10);
long long stoll(const wstring& str, size_t* idx = nullptr, int base = 10);
unsigned long long stoull(const wstring& str, size_t* idx = nullptr, int base = 10);

8 Effects: The first two functions call wcstol(str.c_str(), ptr, base), and the last three functions call wcstoul(str.c_str(), ptr, base), wcstoll(str.c_str(), ptr, base), and wcstoull(str.c_str(), ptr, base), respectively. Each function returns the converted result, if any. The argument ptr designates a pointer to an object internal to the function that is used to determine what to store at *idx. If the function does not throw an exception and idx != nullptr, the function stores in *idx the index of the first unconverted element of str.

Returns: The converted result.

9 Throws: invalid_argument if wcstol, wcstoul, wcstoll, or wcstoull reports that no conversion can be performed. Throws out_of_range if the converted value is outside the range of representable values for the return type.

float stof(const wstring& str, size_t* idx = nullptr);

double stod(const wstring& str, size_t* idx = nullptr);

long double stold(const wstring& str, size_t* idx = nullptr);

11 Effects: These functions call wcstof(str.c_str(), ptr), wcstod(str.c_str(), ptr), and wcstold(str.c_str(), ptr), respectively. Each function returns the converted result, if any. The argument ptr designates a pointer to an object internal to the function that is used to determine what to store at *idx. If the function does not throw an exception and idx != nullptr, the function stores in *idx the index of the first unconverted element of str.

Returns: The converted result.

12 Throws: invalid_argument if wcstof, wcstod, or wcstold reports that no conversion can be performed. Throws out_of_range if wcstof, wcstod, or wcstold sets errno to ERANGE.

wstring to_wstring(int val);
wstring to_wstring(unsigned val);
wstring to_wstring(long val);
wstring to_wstring(unsigned long val);
wstring to_wstring(long long val);
wstring to_wstring(unsigned long long val);
wstring to_wstring(float val);
wstring to_wstring(double val);

14 Returns: Each function returns a wstring object holding the character representation of the value of its argument that would be generated by calling swprintf(buf, buffsz, fmt, val) with a format specifier of L"%d", L"%u", L"%ld", L"%lu", L"%lld", L"%llu", L"%f", L"%F", or L"%Lf", respectively, where buf designates an internal character buffer of sufficient size buffsz.

23.4.6 Hash support

23.4.6.1 Template

template<class A> struct hash<basic_string<char, char_traits<char>, A>>;

§ 23.4.6
If \( S \) is one of these string types, \( SV \) is the corresponding string view type, and \( s \) is an object of type \( S \), then \( \text{hash}<S>()(s) == \text{hash}<SV>()(SV(s)) \).

### 23.4.7 Suffix for basic_string literals

```cpp
template<class A> struct hash<basic_string<char8_t, char_traits<char8_t>, A>>;
template<class A> struct hash<basic_string<char16_t, char_traits<char16_t>, A>>;
template<class A> struct hash<basic_string<char32_t, char_traits<char32_t>, A>>;
template<class A> struct hash<basic_string<wchar_t, char_traits<wchar_t>, A>>;
```

**Note 1:** The same suffix \( s \) is used for \( \text{chrono}::\text{duration} \) literals denoting seconds but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. — end note

### 23.5 Null-terminated sequence utilities

23.5.1 Header `<cctype>` synopsis

```cpp
namespace std {
    int isalnum(int c);
    int isalpha(int c);
    int isblank(int c);
    int iscntrl(int c);
    int isdigit(int c);
    int isgraph(int c);
    int islower(int c);
    int isprint(int c);
    int ispunct(int c);
    int isspace(int c);
    int isupper(int c);
    int isxdigit(int c);
    int tolower(int c);
    int toupper(int c);
}
```

The contents and meaning of the header `<cctype>` are the same as the C standard library header `<ctype.h>`.

**See also:** ISO C 7.4

23.5.2 Header `<cwctype>` synopsis

```cpp
namespace std {
    using wint_t = see below;
    using wctrans_t = see below;
    using wctype_t = see below;

    int iswalnum(wint_t wc);
    int iswalpha(wint_t wc);
    int iswblank(wint_t wc);
    int iswcntrl(wint_t wc);
    int iswdigit(wint_t wc);
    int iswgraph(wint_t wc);
    int iswlower(wint_t wc);
    int iswprint(wint_t wc);
    int iswpunct(wint_t wc);
    int iswspace(wint_t wc);
    int iswupper(wint_t wc);
    int iswxdigit(wint_t wc);
    int towlower(wint_t wc);
    int toupper(wint_t wc);
}
```

23.5.5 Header <cuchar> synopsis

namespace std {
  using mbstate_t = see below;
  using size_t = see 17.2.4;

  size_t mbtowc(wchar_t* pwc, const char* s, size_t n);
  int wctomb(char* s, wchar_t wchar);

  Effects: These functions have the semantics specified in the C standard library.

  Remarks: Calls to these functions may introduce a data race (16.4.6.10) with other calls to the same function.

  See also: ISO C 7.28

23.5.6 Multibyte / wide string and character conversion functions

1 [Note 1: The headers <cstdlib> (17.2.2), <cuchar> (23.5.5), and <cwchar> (23.5.4) declare the functions described in this subclause. — end note]

  int mbsinit(const mbstate_t* ps);
  int mblen(const char* s, size_t n);
  size_t mbstowcs(wchar_t* pwc, const char* s, size_t n);
  size_t wcstombs(char* s, const wchar_t* pwcs, size_t n);

  Effects: These functions have the semantics specified in the C standard library.

  See also: ISO C 7.22.7.1, 7.22.8, 7.29.6.2.1

  int mbtowc(wchar_t* pwc, const char* s, size_t n);
  int wctomb(char* s, wchar_t wchar);

  Effects: These functions have the semantics specified in the C standard library.

  Remarks: Calls to these functions may introduce a data race (16.4.6.10) with other calls to the same function.

§ 23.5.6
See also: ISO C 7.22.7

size_t mbrlen(const char* s, size_t n, mbstate_t* ps);
size_t mbrtowc(wchar_t* pwc, const char* s, size_t n, mbstate_t* ps);
size_t wcrtomb(char* s, wchar_t wc, mbstate_t* ps);
size_t mbsrtowcs(wchar_t* dst, const char** src, size_t len, mbstate_t* ps);
size_t wcsrtombs(char* dst, const wchar_t** src, size_t len, mbstate_t* ps);

Effects: These functions have the semantics specified in the C standard library.
Remarks: Calling these functions with an mbstate_t* argument that is a null pointer value may introduce a data race (16.4.6.10) with other calls to the same function with an mbstate_t* argument that is a null pointer value.

See also: ISO C 7.29.6.3

size_t mbtowc8(char8_t* pc8, const char* s, size_t n, mbstate_t* ps);

Effects: If s is a null pointer, equivalent to mbtowc8(nullptr, "", 1, ps). Otherwise, the function inspects at most n bytes beginning with the byte pointed to by s to determine the number of bytes needed to complete the next multibyte character (including any shift sequences). If the function determines that the next multibyte character is complete and valid, it determines the values of the corresponding UTF-8 code units and then, if pc8 is not a null pointer, stores the value of the first (or only) such code unit in the object pointed to by pc8. Subsequent calls will store successive UTF-8 code units without consuming any additional input until all the code units have been stored. If the corresponding Unicode character is U+0000 NULL, the resulting state described is the initial conversion state.

Returns: The first of the following that applies (given the current conversion state):

(8.1) 0, if the next n or fewer bytes complete the multibyte character that corresponds to the U+0000 NULL Unicode character (which is the value stored).
(8.2) between 1 and n (inclusive), if the next n or fewer bytes complete a valid multibyte character (whose first (or only) code unit is stored); the value returned is the number of bytes that complete the multibyte character.
(8.3) (size_t)(-3), if the next code unit resulting from a previous call has been stored (no bytes from the input have been consumed by this call).
(8.4) (size_t)(-2), if the next n bytes contribute to an incomplete (but potentially valid) multibyte character, and all n bytes have been processed (no value is stored).
(8.5) (size_t)(-1), if an encoding error occurs, in which case the next n or fewer bytes do not contribute to a complete and valid multibyte character (no value is stored); the value of the macro EILSEQ is stored in errno, and the conversion state is unspecified.

size_t c8rtomb(char* s, char8_t c8, mbstate_t* ps);

Effects: If s is a null pointer, equivalent to c8rtomb(buf, u8'\0', ps) where buf is an internal buffer. Otherwise, if c8 completes a sequence of valid UTF-8 code units, determines the number of bytes needed to represent the multibyte character (including any shift sequences), and stores the multibyte character representation in the array whose first element is pointed to by s. At most MB_CUR_MAX bytes are stored. If the multibyte character is a null character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state; the resulting state described is the initial conversion state.

Returns: The number of bytes stored in the array object (including any shift sequences). If c8 does not contribute to a sequence of char8_t corresponding to a valid multibyte character, the value of the macro EILSEQ is stored in errno, (size_t) (-1) is returned, and the conversion state is unspecified.
Remarks: Calls to c8rtomb with a null pointer argument for s may introduce a data race (16.4.6.10) with other calls to c8rtomb with a null pointer argument for s.
24 Containers library [containers]

24.1 General [containers.general]

1 This Clause describes components that C++ programs may use to organize collections of information.

2 The following subclauses describe container requirements, and components for sequence containers and associative containers, as summarized in Table 82.

Table 82: Containers library summary [tab:containers.summary]

24.2 Requirements [container.requirements]

24.2.1 Preamble [container.requirements.pre]

1 Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.

2 All of the complexity requirements in this Clause are stated solely in terms of the number of operations on the contained objects.

[Example 1: The copy constructor of type vector<vector<int>> has linear complexity, even though the complexity of copying each contained vector<int> is itself linear. — end example]

3 Allocator-aware containers (24.2.2.5) other than basic_string construct elements using the function allocator_traits<allocator_type>::rebind_traits<U>::construct and destroy elements using the function allocator_traits<allocator_type>::rebind_traits<U>::destroy (20.2.9.3), where U is either allocator_type::value_type or an internal type used by the container. These functions are called only for the container’s element type, not for internal types used by the container.

[Note 1: This means, for example, that a node-based container would need to construct nodes containing aligned buffers and call construct to place the element into the buffer. — end note]

24.2.2 General containers [container.gen.reqmts]

24.2.2.1 General [container.requirements.general]

1 In subclause 24.2.2,

(1.1) — X denotes a container class containing objects of type T,

(1.2) — a denotes a value of type X,

(1.3) — b and c denote values of type (possibly const) X,

(1.4) — i and j denote values of type (possibly const) X::iterator,

(1.5) — u denotes an identifier,

(1.6) — v denotes an lvalue of type (possibly const) X or an rvalue of type const X,

(1.7) — s and t denote non-const lvalues of type X, and

(1.8) — rv denotes a non-const rvalue of type X.

24.2.2.2 Containers [container.reqmts]

1 A type X meets the container requirements if the following types, statements, and expressions are well-formed and have the specified semantics.
typedef X::value_type
   Result: T

   Preconditions: T is Cpp17Erasable from X (see 24.2.2.5, below).

typedef X::reference
   Result: T

typedef X::const_reference
   Result: const T

typedef X::iterator
   Result: A type that meets the forward iterator requirements (25.3.5.5) with value type T. The type
   X::iterator is convertible to X::const_iterator.

typedef X::const_iterator
   Result: A type that meets the requirements of a constant iterator and those of a forward iterator with
   value type T.

typedef X::difference_type
   Result: A signed integer type, identical to the difference type of X::iterator and X::const_iterator.

typedef X::size_type
   Result: An unsigned integer type that can represent any non-negative value of X::difference_type.

X u;
X u = X();
   Postconditions: u.empty()

   Complexity: Constant.

X u(v);
X u = v;
   Preconditions: T is Cpp17CopyInsertable into X (see below).
   Postconditions: u == v.
   Complexity: Linear.

X u(rv);
X u = rv;
   Postconditions: u is equal to the value that rv had before this construction.
   Complexity: Linear for array and constant for all other standard containers.

t = v;
   Result: Xk.
   Postconditions: t == v.
   Complexity: Linear.

t = rv
   Result: Xk.
   Effects: All existing elements of t are either move assigned to or destroyed.
   Postconditions: If t and rv do not refer to the same object, t is equal to the value that rv had before
   this assignment.
   Complexity: Linear.

a.~X()
   Result: void.
   Effects: Destroys every element of a; any memory obtained is deallocated.
Complexity: Linear.

    b.begin()
    Result: iterator; const_iterator for constant b.
    Returns: An iterator referring to the first element in the container.
    Complexity: Constant.

b.end()
    Result: iterator; const_iterator for constant b.
    Returns: An iterator which is the past-the-end value for the container.
    Complexity: Constant.

b.cbegin()
    Result: const_iterator.
    Returns: const_cast<X const&>(b).begin()
    Complexity: Constant.

b.cend()
    Result: const_iterator.
    Returns: const_cast<X const&>(b).end()
    Complexity: Constant.

i <=> j
    Result: strong_ordering.
    Constraints: X::iterator meets the random access iterator requirements.
    Complexity: Constant.

c == b
    Preconditions: T meets the Cpp17EqualityComparable requirements.
    Result: bool.
    Returns: equal(c.begin(), c.end(), b.begin(), b.end())
    [Note 1: The algorithm equal is defined in 27.6.13. — end note]
    Complexity: Constant if c.size() != b.size(), linear otherwise.
    Remarks: == is an equivalence relation.

c != b
    Effects: Equivalent to !(c == b).

t.swap(s)
    Result: void.
    Effects: Exchanges the contents of t and s.
    Complexity: Linear for array and constant for all other standard containers.

swap(t, s)
    Effects: Equivalent to t.swap(s).

c.size()
    Result: size_type.
    Returns: distance(c.begin(), c.end()), i.e., the number of elements in the container.
    Complexity: Constant.
    Remarks: The number of elements is defined by the rules of constructors, inserts, and erases.
c.max_size()

Result: size_type.

Returns: distance(begin(), end()) for the largest possible container.

Complexity: Constant.

c.empty()

Result: bool.

Returns: c.begin() == c.end()

Complexity: Constant.

Remarks: If the container is empty, then c.empty() is true.

In the expressions

i == j
i != j
i < j
i <= j
i >= j
i > j
i <=> j
i - j

where i and j denote objects of a container’s iterator type, either or both may be replaced by an object of the container’s const_iterator type referring to the same element with no change in semantics.

Unless otherwise specified, all containers defined in this Clause obtain memory using an allocator (see 16.4.4.6).

[Note 2: In particular, containers and iterators do not store references to allocated elements other than through the allocator’s pointer type, i.e., as objects of type P or pointer_traits<P>::template rebind<unspecified>, where P is allocator_traits<allocator_type>::pointer. — end note]

Copy constructors for these container types obtain an allocator by calling allocator_traits<allocator_type>::select_on_container_copy_construction on the allocator belonging to the container being copied. Move constructors obtain an allocator by move construction from the allocator belonging to the container being moved. Such move construction of the allocator shall not exit via an exception. All other constructors for these container types take a const allocator_type& argument.

[Note 3: If an invocation of a constructor uses the default value of an optional allocator argument, then the allocator type must support value-initialization. — end note]

A copy of this allocator is used for any memory allocation and element construction performed, by these constructors and by all member functions, during the lifetime of each container object or until the allocator is replaced. The allocator may be replaced only via assignment or swap(). Allocator replacement is performed by copy assignment, move assignment, or swapping of the allocator only if

(64.1) allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value,

(64.2) allocator_traits<allocator_type>::propagate_on_container_move_assignment::value, or

(64.3) allocator_traits<allocator_type>::propagate_on_container_swap::value

is true within the implementation of the corresponding container operation. In all container types defined in this Clause, the member get_allocator() returns a copy of the allocator used to construct the container or, if that allocator has been replaced, a copy of the most recent replacement.

The expression a.swap(b), for containers a and b of a standard container type other than array, shall exchange the values of a and b without invoking any move, copy, or swap operations on the individual container elements. Any Compare, Pred, or Hash types belonging to a and b shall meet the Cpp17Swappable requirements and shall be exchanged by calling swap as described in 16.4.4.3. If allocator_traits<allocator_type>::propagate_on_container_swap::value is true, then allocator_type shall meet the Cpp17Swappable requirements and the allocators of a and b shall also be exchanged by calling swap as described in 16.4.4.3. Otherwise, the allocators shall not be swapped, and the behavior is undefined unless a.get_allocator() == b.get_allocator(). Every iterator referring to an element in one container before the swap shall refer to the same element in the other container after the swap. It is unspecified whether an iterator with value a.end() before the swap will have value b.end() after the swap.
A contiguous container is a container whose member types iterator and const_iterator meet the Cpp17RandomAccessIterator requirements (25.3.5.7) and model contiguous_iterator (25.3.4.14).

24.2.2.3 Reversible container requirements

A type X meets the reversible container requirements if X meets the container requirements, the iterator type of X belongs to the bidirectional or random access iterator categories (25.3), and the following types and expressions are well-formed and have the specified semantics.

typename X::reverse_iterator

Result: The type reverse_iterator<X::iterator>, an iterator type whose value type is T.

typename X::const_reverse_iterator

Result: The type reverse_iterator<X::const_iterator>, a constant iterator type whose value type is T.

a.rbegin()

Result: reverse_iterator; const_reverse_iterator for constant a.

Returns: reverse_iterator(end())

Complexity: Constant.

a.rend()

Result: reverse_iterator; const_reverse_iterator for constant a.

Returns: reverse_iterator(begin())

Complexity: Constant.

a.crbegin()

Result: const_reverse_iterator.

Returns: const_cast<X const&>(a).rbegin()

Complexity: Constant.

a.crend()

Result: const_reverse_iterator.

Returns: const_cast<X const&>(a).rend()

Complexity: Constant.

Unless otherwise specified (see 24.2.7.2, 24.2.8.2, 24.3.8.4, and 24.3.11.5) all container types defined in this Clause meet the following additional requirements:

(16.1) — If an exception is thrown by an insert() or emplace() function while inserting a single element, that function has no effects.

(16.2) — If an exception is thrown by a push_back(), push_front(), emplace_back(), or emplace_front() function, that function has no effects.

(16.3) — No erase(), clear(), pop_back() or pop_front() function throws an exception.

(16.4) — No copy constructor or assignment operator of a returned iterator throws an exception.

(16.5) — No swap() function throws an exception.

(16.6) — No swap() function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped.

[Note 1: The end() iterator does not refer to any element, so it can be invalidated. — end note]

Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

24.2.2.4 Optional container requirements

The following operations are provided for some types of containers but not others. Those containers for which the listed operations are provided shall implement the semantics as described unless otherwise stated. If the
iterators passed to `lexicographical_compare_three_way` meet the `constexpr` iterator requirements (25.3.1) then the operations described below are implemented by `constexpr` functions.

\[ a \lessgtr b \]

**Result:** `synth-three-way-result<X::value_type>`.

**Preconditions:** Either `<<` is defined for values of type (possibly const) `T`, or `<` is defined for values of type (possibly const) `T` and `<` is a total ordering relationship.

**Returns:** `lexicographical_compare_three_way(a.begin(), a.end(), b.begin(), b.end(), synth-three-way)`

*Note 1:* The algorithm `lexicographical_compare_three_way` is defined in Clause 27. — end note

**Complexity:** Linear.

### 24.2.2.5 Allocator-aware containers

All of the containers defined in Clause 24 and in 23.4.3 except `array` meet the additional requirements of an `allocator-aware container`, as described below.

Given an allocator type `A` and given a container type `X` having a `value_type` identical to `T` and an `allocator_type` identical to `allocator_traits<A>::rebind_alloc<T>` and given an lvalue `m` of type `A`, a pointer `p` of type `T*`, an expression `v` of type `T` or `const T`, and an rvalue `rv` of type `T`, the following terms are defined. If `X` is not allocator-aware or is a specialization of `basic_string`, the terms below are defined as if `A` were `allocator<T>` — no allocator object needs to be created and user specializations of `allocator<T>` are not instantiated:

1. **T is Cpp17DefaultInsertable into X** means that the following expression is well-formed:
   ```cpp
   allocator_traits<A>::construct(m, p)
   ```

2. **An element of X is default-inserted** if it is initialized by evaluation of the expression
   ```cpp
   allocator_traits<A>::construct(m, p)
   ```
   where `p` is the address of the uninitialized storage for the element allocated within `X`.

3. **T is Cpp17MoveInsertable into X** means that the following expression is well-formed:
   ```cpp
   allocator_traits<A>::construct(m, p, rv)
   ```
   and its evaluation causes the following postcondition to hold: The value of `*p` is equivalent to the value of `rv` before the evaluation.

   *Note 1:* `rv` remains a valid object. Its state is unspecified — end note

4. **T is Cpp17CopyInsertable into X** means that, in addition to T being Cpp17MoveInsertable into X, the following expression is well-formed:
   ```cpp
   allocator_traits<A>::construct(m, p, v)
   ```
   and its evaluation causes the following postcondition to hold: The value of `v` is unchanged and is equivalent to `*p`.

5. **T is Cpp17EmplaceConstructible into X from args**, for zero or more arguments `args`, means that the following expression is well-formed:
   ```cpp
   allocator_traits<A>::construct(m, p, args)
   ```

   *Note 2:* A container calls `allocator_traits<A>::construct(m, p, args)` to construct an element at `p` using `args`, with `m == get_allocator()`. The default `construct` in `allocator` will call `::new((void*)p) T(args)`, but specialized allocators can choose a different definition. — end note

The following exposition-only concept is used in the definition of containers:

```cpp
template<class R, class T>
concept container-compatible-range = // exposition only
   ranges::input_range<R> && convertible_to<ranges::range_reference_t<R>, T>;
```

In this subclause,

1. **X denotes an allocator-aware container class with a value_type of T using an allocator of type A,**
— u denotes a variable,
— a and b denote non-const lvalues of type X,
— c denotes an lvalue of type const X,
— t denotes an lvalue or a const rvalue of type X,
— rv denotes a non-const rvalue of type X, and
— m is a value of type A.

A type X meets the allocator-aware container requirements if X meets the container requirements and the following types, statements, and expressions are well-formed and have the specified semantics.

typename X::allocator_type

Result: A

Preconditions: allocator_type::value_type is the same as X::value_type.

complexity: Constant.

X u;
X u = X();

Preconditions: A meets the Cpp17DefaultConstructible requirements.

Postconditions: u.empty() returns true, u.get_allocator() == A().

Complexity: Constant.

X u(m);

Postconditions: u.empty() returns true, u.get_allocator() == m.

Complexity: Constant.

X u(t, m);

Preconditions: T is Cpp17CopyInsertable into X.

Postconditions: u == t, u.get_allocator() == m

Complexity: Linear.

X u(rv);

Postconditions: u has the same elements as rv had before this construction; the value of u.get_allocator() is the same as the value of rv.get_allocator() before this construction.

Complexity: Constant if m == rv.get_allocator(), otherwise linear.

a = t

Result: X&.

Preconditions: T is Cpp17CopyInsertable into X and Cpp17CopyAssignable.

Postconditions: a == t is true.

Complexity: Linear.

a = rv

Result: X&.
Preconditions: If `allocator_traits<allocator_type>::propagate_on_container_move_assign::value` is `false`, `T` is `Cpp17MoveInsertable` into `X` and `Cpp17MoveAssignable`.

Effects: All existing elements of `a` are either move assigned to or destroyed.

Postconditions: If `a` and `rv` do not refer to the same object, `a` is equal to the value that `rv` had before this assignment.

Complexity: Linear.

```
void a.swap(b)
```

Effects: Exchanges the contents of `a` and `b`.

Complexity: Constant.

The behavior of certain container member functions and deduction guides depends on whether types qualify as input iterators or allocators. The extent to which an implementation determines that a type cannot be an input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators. Likewise, the extent to which an implementation determines that a type cannot be an allocator is unspecified, except that as a minimum a type `A` shall not qualify as an allocator unless it meets both of the following conditions:

1. The `qualified-id A::value_type` is valid and denotes a type (13.10.3).
2. The expression `declval<A&>().allocate(size_t{}` is well-formed when treated as an unevaluated operand.

### 24.2.3 Container data races

For purposes of avoiding data races (16.4.6.10), implementations shall consider the following functions to be `const`:

- `begin`, `end`, `rbegin`, `rend`, `front`, `back`, `data`, `find`, `lower_bound`, `upper_bound`, `equal_range`, `at`
- and, except in associative or unordered associative containers, `operator[]`

Notwithstanding 16.4.6.10, implementations are required to avoid data races when the contents of the contained object in different elements in the same container, excepting `vector<bool>`, are modified concurrently.

[Note 1: For a `vector<int> x` with a size greater than one, `x[1] = 5` and `*x.begin() = 10` can be executed concurrently without a data race, but `x[0] = 5` and `*x.begin() = 10` executed concurrently can result in a data race. As an exception to the general rule, for a `vector<bool> y`, `y[0] = true` can race with `y[1] = true`. — end note]

### 24.2.4 Sequence containers

A sequence container organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides four basic kinds of sequence containers: `vector`, `forward_list`, `list`, and `deque`. In addition, `array` is provided as a sequence container which provides limited sequence operations because it has a fixed number of elements. The library also provides container adaptors that make it easy to construct abstract data types, such as `stacks`, `queues`, `flat_maps`, `flat_multimaps`, `flat_sets`, or `flat_multisets`, out of the basic sequence container kinds (or out of other program-defined sequence containers).

[Note 1: The sequence containers offer the programmer different complexity trade-offs. `vector` is appropriate in most circumstances. `array` has a fixed size known during translation. `list` or `forward_list` support frequent insertions and deletions from the middle of the sequence. `deque` supports efficient insertions and deletions taking place at the beginning or at the end of the sequence. When choosing a container, remember `vector` is best; leave a comment to explain if you choose from the rest! — end note]

In this subclause,

1. `X` denotes a sequence container class,
2. `a` denotes a value of type `X` containing elements of type `T`,
3. `u` denotes the name of a variable being declared,
4. `A` denotes `X::allocator_type` if the `qualified-id X::allocator_type` is valid and denotes a type (13.10.3) and `allocator<T>` if it doesn’t,
5. `i` and `j` denote iterators that meet the `Cpp17InputIterator` requirements and refer to elements implicitly convertible to `value_type`,
6. `[i, j)` denotes a valid range,
rg denotes a value of a type \( R \) that models container-compatible-range<\( T \>.

il designates an object of type initializer_list<value_type>.

\( n \) denotes a value of type \( X::size_type \).

\( p \) denotes a valid constant iterator to \( a \).

\( q \) denotes a valid dereferenceable constant iterator to \( a \).

\( [q_1, q_2) \) denotes a valid range of constant iterators in \( a \).

\( t \) denotes an lvalue or a const rvalue of \( X::value_type \) and

\( rv \) denotes a non-const rvalue of \( X::value_type \).

\( Args \) denotes a template parameter pack;

\( args \) denotes a function parameter pack with the pattern \( Args&& \).

4 The complexities of the expressions are sequence dependent.

A type \( X \) meets the sequence container requirements if \( X \) meets the container requirements and the following statements and expressions are well-formed and have the specified semantics.

\[ X u(n, t); \]

Preconditions: \( T \) is Cpp17CopyInsertable into \( X \).

Effects: Constructs a sequence container with \( n \) copies of \( t \).

Postconditions: \( \text{distance}(u.begin(), u.end()) == n \) is true.

\[ X u(i, j); \]

Preconditions: \( T \) is Cpp17EmplaceConstructible into \( X \) from \( *i \).

For vector, if the iterator does not meet the Cpp17ForwardIterator requirements (25.3.5.5), \( T \) is also Cpp17MoveInsertable into \( X \).

Effects: Constructs a sequence container equal to the range \( [i, j) \). Each iterator in the range \( [i,j) \) is dereferenced exactly once.

Postconditions: \( \text{distance}(u.begin(), u.end()) == \text{distance}(i, j) \) is true.

\[ X(from\_range, rg) \]

Preconditions: \( T \) is Cpp17EmplaceConstructible into \( X \) from \( *ranges::begin(rg) \).

For vector, if \( R \) models neither ranges::sized_range nor ranges::forward_range, \( T \) is also Cpp17MoveInsertable into \( X \).

Effects: Constructs a sequence container equal to the range \( rg \).

Each iterator in the range \( rg \) is dereferenced exactly once.

Postconditions: \( \text{distance}(begin(), end()) == \text{ranges::distance}(rg) \) is true.

\[ X(il) \]

Effects: Equivalent to \( X(il.begin(), il.end()) \).

\[ a = il \]

Result: \( Xk \).

Preconditions: \( T \) is Cpp17CopyInsertable into \( X \) and Cpp17CopyAssignable.

Effects: Assigns the range \( [il.begin(), il.end()) \) into \( a \). All existing elements of \( a \) are either assigned to or destroyed.

Returns: \( *this \).

\[ a.\text{emplace}(p, args) \]

Result: iterator.

Preconditions: \( T \) is Cpp17EmplaceConstructible into \( X \) from \( args \). For vector and deque, \( T \) is also Cpp17MoveInsertable into \( X \) and Cpp17MoveAssignible.

Effects: Inserts an object of type \( T \) constructed with std::forward<Args>(args)... before \( p \).

[Note 2: \( args \) can directly or indirectly refer to a value in \( a \). — end note]
Returns: An iterator that points to the new element constructed from \texttt{args} into \texttt{a}.

\begin{verbatim}
a.insert(p, t)
\end{verbatim}

\textbf{Result:} iterator.

\textbf{Preconditions:} \texttt{T} is \texttt{Cpp17CopyInsertable} into \texttt{X}. For \texttt{vector} and \texttt{deque}, \texttt{T} is also \texttt{Cpp17CopyAssignable}.

\textbf{Effects:} Inserts a copy of \texttt{t} before \texttt{p}.

\textbf{Returns:} An iterator that points to the copy of \texttt{t} inserted into \texttt{a}.

\begin{verbatim}
a.insert(p, rv)
\end{verbatim}

\textbf{Result:} iterator.

\textbf{Preconditions:} \texttt{T} is \texttt{Cpp17MoveInsertable} into \texttt{X}. For \texttt{vector} and \texttt{deque}, \texttt{T} is also \texttt{Cpp17MoveAssignable}.

\textbf{Effects:} Inserts a copy of \texttt{rv} before \texttt{p}.

\textbf{Returns:} An iterator that points to the copy of \texttt{rv} inserted into \texttt{a}.

\begin{verbatim}
a.insert(p, n, t)
\end{verbatim}

\textbf{Result:} iterator.

\textbf{Preconditions:} \texttt{T} is \texttt{Cpp17CopyInsertable} into \texttt{X} and \texttt{Cpp17CopyAssignable}.

\textbf{Effects:} Inserts \texttt{n} copies of \texttt{t} before \texttt{p}.

\textbf{Returns:} An iterator that points to the copy of the first element inserted into \texttt{a}, or \texttt{p} if \texttt{n} == 0.

\begin{verbatim}
a.insert(p, i, j)
\end{verbatim}

\textbf{Result:} iterator.

\textbf{Preconditions:} \texttt{T} is \texttt{Cpp17EmplaceConstructible} into \texttt{X} from \texttt{*i}. For \texttt{vector} and \texttt{deque}, \texttt{T} is also \texttt{Cpp17MoveInsertable} into \texttt{X}, and \texttt{T} meets the \texttt{Cpp17MoveConstructible}, \texttt{Cpp17MoveAssignable}, and \texttt{Cpp17Swappable} (16.4.4.3) requirements. Neither \texttt{i} nor \texttt{j} are iterators into \texttt{a}.

\textbf{Effects:} Inserts copies of elements in \([i, j)\) before \texttt{p}. Each iterator in the range \([i, j)\) shall be dereferenced exactly once.

\textbf{Returns:} An iterator that points to the copy of the first element inserted into \texttt{a}, or \texttt{p} if \texttt{i} == \texttt{j}.

\begin{verbatim}
a.insert_range(p, rg)
\end{verbatim}

\textbf{Result:} iterator.

\textbf{Preconditions:} \texttt{T} is \texttt{Cpp17EmplaceConstructible} into \texttt{X} from \texttt{*ranges::begin(rg)}. For \texttt{vector} and \texttt{deque}, \texttt{T} is also \texttt{Cpp17MoveInsertable} into \texttt{X}, and \texttt{T} meets the \texttt{Cpp17MoveConstructible}, \texttt{Cpp17MoveAssignable}, and \texttt{Cpp17Swappable} (16.4.4.3) requirements. \texttt{rg} and \texttt{a} do not overlap.

\textbf{Effects:} Inserts copies of elements in \texttt{rg} before \texttt{p}. Each iterator in the range \texttt{rg} is dereferenced exactly once.

\textbf{Returns:} An iterator that points to the copy of the first element inserted into \texttt{a}, or \texttt{p} if \texttt{rg} is empty.

\begin{verbatim}
a.insert(p, il)
\end{verbatim}

\textbf{Effects:} Equivalent to \texttt{a.insert(p, il.begin(), il.end())}.

\textbf{a.erase(q)}

\textbf{Result:} iterator.

\textbf{Preconditions:} For \texttt{vector} and \texttt{deque}, \texttt{T} is \texttt{Cpp17MoveAssignable}.

\textbf{Effects:} Erases the element pointed to by \texttt{q}.

\textbf{Returns:} An iterator that points to the element immediately following \texttt{q} prior to the element being erased. If no such element exists, \texttt{a.end()} is returned.

\textbf{a.erase(q1, q2)}

\textbf{Result:} iterator.

\textbf{Preconditions:} For \texttt{vector} and \texttt{deque}, \texttt{T} is \texttt{Cpp17MoveAssignable}. 

§ 24.2.4
Effects: Erases the elements in the range \([q_1, q_2)\).

Returns: An iterator that points to the element pointed to by \(q_2\) prior to any elements being erased. If no such element exists, \(a\.end()\) is returned.

\(a\.clear()\)

Result: void

Effects: Destroys all elements in \(a\). Invalidates all references, pointers, and iterators referring to the elements of \(a\) and may invalidate the past-the-end iterator.

Postconditions: \(a\.empty()\) is true.

Complexity: Linear.

\(a\.assign(i, j)\)

Result: void

Preconditions: \(T\) is \(\text{Cpp17EmplaceConstructible}\) into \(X\) from \(*i\) and assignable from \(*i\). For \(\text{vector}\), if the iterator does not meet the forward iterator requirements (25.3.5.5), \(T\) is also \(\text{Cpp17MoveInsertable}\) into \(X\). Neither \(i\) nor \(j\) are iterators into \(a\).

Effects: Replaces elements in \(a\) with a copy of \([i, j)\). Invalidates all references, pointers and iterators referring to the elements of \(a\). For \(\text{vector}\) and \(\text{deque}\), also invalidates the past-the-end iterator. Each iterator in the range \([i, j)\) is dereferenced exactly once.

\(a\.assign\_range(rg)\)

Result: void

Mandates: assignable_from\(<T&, \text{ranges::range\_reference}_t<R\>>&\) is modeled.

Preconditions: \(T\) is \(\text{Cpp17EmplaceConstructible}\) into \(X\) from \(*\text{ranges::begin}(rg)\). For \(\text{vector}\), if \(R\) models neither \(\text{ranges::sized\_range}\) nor \(\text{ranges::forward\_range}\), \(T\) is also \(\text{Cpp17MoveInsertable}\) into \(X\). \(rg\) and \(a\) do not overlap.

Effects: Replaces elements in \(a\) with a copy of each element in \(rg\). Invalidates all references, pointers, and iterators referring to the elements of \(a\). For \(\text{vector}\) and \(\text{deque}\), also invalidates the past-the-end iterator. Each iterator in the range \(rg\) is dereferenced exactly once.

\(a\.assign(il)\)

Effects: Equivalent to \(a\.assign(il\.begin(), il\.end())\).

\(a\.assign(n, t)\)

Result: void

Preconditions: \(T\) is \(\text{Cpp17CopyInsertable}\) into \(X\) and \(\text{Cpp17CopyAssignable}\). \(t\) is not a reference into \(a\).

Effects: Replaces elements in \(a\) with \(n\) copies of \(t\). Invalidates all references, pointers and iterators referring to the elements of \(a\). For \(\text{vector}\) and \(\text{deque}\), also invalidates the past-the-end iterator.

For every sequence container defined in this Clause and in Clause 23:

\(\text{(68.1)}\)

— If the constructor

\[
\text{template<class InputIterator>}
X(InputIterator first, InputIterator last, 
\text{const allocator\_type}\& alloc = allocator\_type());
\]

is called with a type \(\text{InputIterator}\) that does not qualify as an input iterator, then the constructor shall not participate in overload resolution.

\(\text{(68.2)}\)

— If the member functions of the forms:

\[
\text{template<class InputIterator>}
\text{return\_type } F(\text{const\_iterator } p, 
\text{InputIterator } first, \text{InputIterator } last); \quad \text{// such as insert}
\]

\[
\text{template<class InputIterator>}
\text{return\_type } F(\text{InputIterator } first, \text{InputIterator } last); \quad \text{// such as append, assign}
\]
template<class InputIterator>

return-type F(const_iterator i1, const_iterator i2,
              InputIterator first, InputIterator last); // such as replace

are called with a type InputIterator that does not qualify as an input iterator, then these functions
shall not participate in overload resolution.

— A deduction guide for a sequence container shall not participate in overload resolution if it has an
InputIterator template parameter and a type that does not qualify as an input iterator is deduced
for that parameter, or if it has an Allocator template parameter and a type that does not qualify as
an allocator is deduced for that parameter.

The following operations are provided for some types of sequence containers but not others. Operations other
than prepend_range and append_range are implemented so as to take amortized constant time.

a.front()

Result: reference; const_reference for constant a.

Returns: *a.begin()

Remarks: Required for basic_string, array, deque, forward_list, list, and vector.

a.back()

Result: reference; const_reference for constant a.

Effects: Equivalent to:

auto tmp = a.end();
--tmp;
return *tmp;

Remarks: Required for basic_string, array, deque, list, and vector.

a.emplace_front(args)

Result: reference

Preconditions: T is Cpp17EmplaceConstructible into X from args.

Effects: Prepends an object of type T constructed with std::forward<Args>(args)...

Returns: a.front().

Remarks: Required for deque, forward_list, and list.

a.emplace_back(args)

Result: reference

Preconditions: T is Cpp17EmplaceConstructible into X from args. For vector, T is also Cpp17MoveIns-
sertable into X.

Effects: Appends an object of type T constructed with std::forward<Args>(args)....

Returns: a.back().

Remarks: Required for deque, list, and vector.

a.push_front(t)

Result: void

Preconditions: T is Cpp17CopyInsertable into X.

Effects: Prepends a copy of t.

Remarks: Required for deque, forward_list, and list.

a.push_front(rv)

Result: void

Preconditions: T is Cpp17MoveInsertable into X.

Effects: Prepends a copy of rv.

Remarks: Required for deque, forward_list, and list.
a.prepend_range(rg)

Result: void

Preconditions: T is Cpp17EmplaceConstructible into X from *ranges::begin(rg). For deque, T is also Cpp17MoveInsertable into X, and T meets the Cpp17MoveConstructible, Cpp17MoveAssignable, and Cpp17Swappable (16.4.4.3) requirements.

Effects: Inserts copies of elements in rg before begin(). Each iterator in the range rg is dereferenced exactly once.

[Note 3: The order of elements in rg is not reversed. —end note]

Remarks: Required for deque, forward_list, and list.

a.push_back(t)

Result: void

Preconditions: T is Cpp17CopyInsertable into X.

Effects: Appends a copy of t.

Remarks: Required for basic_string, deque, list, and vector.

a.push_back(rv)

Result: void

Preconditions: T is Cpp17MoveInsertable into X.

Effects: Appends a copy of rv.

Remarks: Required for basic_string, deque, list, and vector.

a.append_range(rg)

Result: void

Preconditions: T is Cpp17EmplaceConstructible into X from *ranges::begin(rg). For vector, T is also Cpp17MoveInsertable into X.

Effects: Inserts copies of elements in rg before end(). Each iterator in the range rg is dereferenced exactly once.

Remarks: Required for deque, list, and vector.

a.pop_front()

Result: void

Preconditions: a.empty() is false.

Effects: Destroys the first element.

Remarks: Required for deque, forward_list, and list.

a.pop_back()

Result: void

Preconditions: a.empty() is false.

Effects: Destroys the last element.

Remarks: Required for basic_string, deque, list, and vector.

a[n]

Result: reference; const_reference for constant a

Returns: *(a.begin() + n)

Remarks: Required for basic_string, array, deque, and vector.

a.at(n)

Result: reference; const_reference for constant a

Returns: *(a.begin() + n)
Throws: `out_of_range` if \( n \geq a.\text{size}() \).

Remarks: Required for `basic_string`, `array`, `deque`, and `vector`.

### 24.2.5 Node handles

#### 24.2.5.1 Overview

A *node handle* is an object that accepts ownership of a single element from an associative container (24.2.7) or an unordered associative container (24.2.8). It may be used to transfer that ownership to another container with compatible nodes. Containers with compatible nodes have the same node handle type. Elements may be transferred in either direction between container types in the same row of Table 83.

**Table 83: Container types with compatible nodes**

<table>
<thead>
<tr>
<th>Container Type 1</th>
<th>Container Type 2</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>map&lt;K, T, C1, A&gt;</code></td>
<td><code>map&lt;K, T, C2, A&gt;</code></td>

</tbody>
</table>

2 If a node handle is not empty, then it contains an allocator that is equal to the allocator of the container when the element was extracted. If a node handle is empty, it contains no allocator.

3 Class `node-handle` is for exposition only.

4 If a user-defined specialization of `pair` exists for `pair<const Key, T>` or `pair<Key, T>`, where `Key` is the container’s `key_type` and `T` is the container’s `mapped_type`, the behavior of operations involving node handles is undefined.

```cpp
template<
    unspecified
>
class node-handle {
public:
    // These type declarations are described in 24.2.7 and 24.2.8.
    using value_type = see below; // not present for map containers
    using key_type = see below;   // not present for set containers
    using mapped_type = see below; // not present for set containers
    using allocator_type = see below;

private:
    using container_node_type = unspecified; // exposition only
    using ator_traits = allocator_traits<allocator_type>; // exposition only

    typename ator_traits::template
        rebind_traits<container_node_type>::pointer ptr_; // exposition only
    optional<allocator_type> alloc_; // exposition only

public:
    // 24.2.5.2, constructors, copy, and assignment
    constexpr node-handle() noexcept : ptr_(), alloc_() {} 
    node-handle(node-handle&&) noexcept;
    node-handle& operator=(node-handle&&);

    // 24.2.5.3, destructor
    ~node-handle();

    // 24.2.5.4, observers
    value_type& value() const; // not present for map containers
    key_type& key() const;     // not present for set containers
    mapped_type& mapped() const; // not present for set containers
```
allocator_type get_allocator() const;
explicit operator bool() const noexcept;
[[nodiscard]] bool empty() const noexcept;

// 24.2.5.5, modifiers
void swap(node-handle&&)
  noexcept(ator_traits::propagate_on_container_swap::value ||
  ator_traits::is_always_equal::value);

friend void swap(node-handle x, node-handle y) noexcept(noexcept(x.swap(y))) {
    x.swap(y);
}

24.2.5.2 Constructors, copy, and assignment

node-handle(node-handle&& nh) noexcept;

  Effects: Constructs a node-handle object initializing ptr_ with nh.ptr_. Move constructs alloc_ with
  nh.alloc_. Assigns nullptr to nh.ptr_ and assigns nullopt to nh.alloc_.

  Preconditions: Either !alloc_ or ator_traits::propagate_on_container_move_assignment::value is true, or alloc_ == nh.alloc_.

  Effects:
  (3.1) — If ptr_ != nullptr, destroys the value_type subobject in the container_node_type object
          pointed to by ptr_ by calling ator_traits::destroy, then deallocates ptr_ by calling ator_->
          traits::template rebind_traits<container_node_type>::deallocate.
  (3.2) — Assigns nh.ptr_ to ptr_.
  (3.3) — If !alloc_ or ator_traits::propagate_on_container_move_assignment::value is true,
          move assigns nh.alloc_ to alloc_.
  (3.4) — Assigns nullptr to nh.ptr_ and assigns nullopt to nh.alloc_.

  Returns: *this.

  Throws: Nothing.

24.2.5.3 Destructor

~node-handle();

  Effects: If ptr_ != nullptr, destroys the value_type subobject in the container_node_type object
  pointed to by ptr_ by calling ator_traits::destroy, then deallocates ptr_ by calling ator_->
  traits::template rebind_traits<container_node_type>::deallocate.

24.2.5.4 Observers

value_type& value() const;

  Preconditions: empty() == false.

  Returns: A reference to the value_type subobject in the container_node_type object pointed to by
  ptr_.

  Throws: Nothing.

key_type& key() const;

  Preconditions: empty() == false.

  Returns: A non-const reference to the key_type member of the value_type subobject in the contain-
  er_node_type object pointed to by ptr_.

  Throws: Nothing.

  Remarks: Modifying the key through the returned reference is permitted.
mapped_type& mapped() const;  
Preconditions: empty() == false.

Returns: A reference to the mapped_type member of the value_type subobject in the container_node_type object pointed to by ptr_.

Throws: Nothing.

allocator_type get_allocator() const;
Preconditions: empty() == false.

Returns: *alloc_.

Throws: Nothing.

explicit operator bool() const noexcept;

Returns: ptr_ != nullptr.

[[nodiscard]] bool empty() const noexcept;

Returns: ptr_ == nullptr.

24.2.5.5 Modifiers [container.node.modifiers]

void swap(node-handle& nh)  
noexcept(ator_traits::propagate_on_container_swap::value ||  
ator_traits::is_always_equal::value);

Preconditions: !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap::value is true, or alloc_ == nh.alloc_.

Effects: Calls swap(ptr_, nh.ptr_). If !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap::value is true calls swap(alloc_, nh.alloc_).

24.2.6 Insert return type [container.insert.return]

The associative containers with unique keys and the unordered containers with unique keys have a member function insert that returns a nested type insert_return_type. That return type is a specialization of the template specified in this subclause.

template<class Iterator, class NodeType>  
struct insert_return_type  
{  
  Iterator position;  
  bool inserted;  
  NodeType node;  
};

The name insert-return-type is exposition only. insert-return-type has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

24.2.7 Associative containers [associative.reqmts]

24.2.7.1 General [associative.reqmts.general]

Associative containers provide fast retrieval of data based on keys. The library provides four basic kinds of associative containers: set, multiset, map and multimap. The library also provides container adaptors that make it easy to construct abstract data types, such as flat_maps, flat_multimaps, flat_sets, or flat_multisets, out of the basic sequence container kinds (or out of other program-defined sequence containers).

Each associative container is parameterized on Key and an ordering relation Compare that induces a strict weak ordering (27.8) on elements of Key. In addition, map and multimap associate an arbitrary mapped type T with the Key. The object of type Compare is called the comparison object of a container.

The phrase “equivalence of keys” means the equivalence relation imposed by the comparison object. That is, two keys k1 and k2 are considered to be equivalent if for the comparison object comp, comp(k1, k2) == false && comp(k2, k1) == false.
An associative container supports unique keys if it may contain at most one element for each key. Otherwise, it supports equivalent keys. The set and map classes support unique keys; the multiset and multimap classes support equivalent keys. For multiset and multimap, insert, emplace, and erase preserve the relative ordering of equivalent elements.

For set and multiset the value type is the same as the key type. For map and multimap it is equal to \( \text{pair<const Key, T>} \).

iterator of an associative container is of the bidirectional iterator category. For associative containers where the value type is the same as the key type, both iterator and const_iterator are constant iterators. It is unspecified whether or not iterator and const_iterator are the same type.

In this subclause,

1. \( X \) denotes an associative container class,
2. \( a \) denotes a value of type \( X \),
3. \( a2 \) denotes a value of a type with nodes compatible with type \( X \) (Table 83),
4. \( b \) denotes a value or type \( X \) or const \( X \),
5. \( u \) denotes the name of a variable being declared,
6. \( \text{a_uniq} \) denotes a value of type \( X \) when \( X \) supports unique keys,
7. \( \text{a_eq} \) denotes a value of type \( X \) when \( X \) supports multiple keys,
8. \( \text{a_tran} \) denotes a value of type \( X \) or const \( X \) when the qualified-id \( X::\text{key_compare}::\text{is_transparent} \) is valid and denotes a type (13.10.3),
9. \( i \) and \( j \) meet the Cpp17InputIterator requirements and refer to elements implicitly convertible to value_type,
10. \( [i, j) \) denotes a valid range,
11. \( \text{rg} \) denotes a value of a type \( R \) that models container-compatible-range<value_type>,
12. \( p \) denotes a valid constant iterator to \( a \),
13. \( q \) denotes a valid dereferenceable constant iterator to \( a \),
14. \( r \) denotes a valid dereferenceable iterator to \( a \),
15. \( [q1, q2) \) denotes a valid range of constant iterators in \( a \),
16. \( \text{il} \) designates an object of type initializer_list<value_type>,
17. \( t \) denotes a value of type \( X::\text{value_type}, \)
18. \( k \) denotes a value of type \( X::\text{key_type}, \) and
19. \( c \) denotes a value of type \( X::\text{key_compare} \) or const \( X::\text{key_compare} \);
20. \( kl \) is a value such that \( a \) is partitioned (27.8) with respect to \( c(x, k1) \), with \( x \) the key value of \( e \) and \( e \) in \( a \);
21. \( ku \) is a value such that \( a \) is partitioned with respect to !\( c(ku, x) \), with \( x \) the key value of \( e \) and \( e \) in \( a \);
22. \( ke \) is a value such that \( a \) is partitioned with respect to \( c(x, ke) \) and !\( c(ke, x) \), with \( c(x, ke) \) implying !\( c(ke, x) \) and with \( x \) the key value of \( e \) and \( e \) in \( a \);
23. \( kx \) is a value such that
   - \( a \) is partitioned with respect to \( c(x, kx) \) and !\( c(kx, x) \), with \( c(x, kx) \) implying !\( c(kx, x) \) and with \( x \) the key value of \( e \) and \( e \) in \( a \), and
   - \( kx \) is not convertible to either iterator or const_iterator; and
24. \( A \) denotes the storage allocator used by \( X \), if any, or allocator<\( X::\text{value_type} > \) otherwise.

[Note 1: This is not necessarily the same as the result of \( k1 == k2 \). —end note]

For any two keys \( k1 \) and \( k2 \) in the same container, calling \( \text{comp}(k1, k2) \) shall always return the same value.

[Note 2: iterator and const_iterator have identical semantics in this case, and iterator is convertible to const_iterator. Users can avoid violating the one-definition rule by always using const_iterator in their function parameter lists. —end note]
© ISO/IEC N4944

(7.25) — \( m \) denotes an allocator of a type convertible to \( A \), and \( \text{nh} \) denotes a non-const rvalue of type \( X::\text{node}_-\text{type} \).

8 A type \( X \) meets the associative container requirements if \( X \) meets all the requirements of an allocator-aware container (24.2.2.1) and the following types, statements, and expressions are well-formed and have the specified semantics, except that for \( \text{map} \) and \( \text{multimap} \), the requirements placed on \( \text{value_type} \) in 24.2.2.5 apply instead to \( \text{key_type} \) and \( \text{mapped_type} \).

[Note 3: For example, in some cases \( \text{key_type} \) and \( \text{mapped_type} \) are required to be \( \text{Cpp17CopyAssignable} \) even though the associated \( \text{value_type} \), \( \text{pair<const key_type, mapped_type>} \), is not \( \text{Cpp17CopyAssignable} \). — end note]

\[
\begin{align*}
\text{typename } X::\text{key_type} & \quad \text{Result: Key.} \\

\text{Complexity: Constant.} \]
X u = X(); 
X u; 
Preconditions: key_compare meets the Cpp17DefaultConstructible requirements. 
Effects: Constructs an empty container. Uses Compare() as a comparison object. 
Complexity: Constant. 
X(i, j, c) 
Preconditions: value_type is Cpp17EmplaceConstructible into X from *i. 
Effects: Constructs an empty container and inserts elements from the range \([i, j)\) into it; uses \( c \) as a comparison object. 
Complexity: \( N \log N \) in general, where \( N \) has the value distance(i, j); linear if \([i, j)\) is sorted with respect to value_comp(). 
X(i, j) 
Preconditions: key_compare meets the Cpp17DefaultConstructible requirements. value_type is Cpp17EmplaceConstructible into X from *i. 
Effects: Constructs an empty container and inserts elements from the range \([i, j)\) into it; uses Compare() as a comparison object. 

§ 24.2.7.1
Complexity: \( N \log N \) in general, where \( N \) has the value \( \text{distance}(i, j) \); linear if \([i, j]\) is sorted with respect to \( \text{value\_comp()} \).

\( X(\text{from\_range}, \text{rg}, c) \)

- **Preconditions:** \( \text{value\_type} \) is \( \text{Cpp17\Emplace\Constructible} \) into \( X \) from \( \text{*ranges::begin(rg)} \).
- **Effects:** Constructs an empty container and inserts each element from \( \text{rg} \) into it. Uses \( c \) as the comparison object.
- **Complexity:** \( N \log N \) in general, where \( N \) has the value \( \text{ranges::distance(rg)} \); linear if \( \text{rg} \) is sorted with respect to \( \text{value\_comp()} \).

\( X(\text{from\_range}, \text{rg}) \)

- **Preconditions:** \( \text{key\_compare} \) meets the \( \text{Cpp17\Default\Constructible} \) requirements. \( \text{value\_type} \) is \( \text{Cpp17\Emplace\Constructible} \) into \( X \) from \( \text{*ranges::begin(rg)} \).
- **Effects:** Constructs an empty container and inserts each element from \( \text{rg} \) into it. Uses \( \text{Compare()} \) as the comparison object.
- **Complexity:** Same as \( X(\text{from\_range}, \text{rg}, c) \).

\( X(\text{il}, c) \)

- **Effects:** Equivalent to \( X(\text{il\_begin()}, \text{il\_end()}, c) \).

\( X(\text{il}) \)

- **Effects:** Equivalent to \( X(\text{il\_begin()}, \text{il\_end()}) \).

\( a = \text{il} \)

- **Result:** \( X\& \)
- **Preconditions:** \( \text{value\_type} \) is \( \text{Cpp17\Copy\Insertable} \) into \( X \) and \( \text{Cpp17\Copy\Assignable} \).
- **Effects:** Assigns the range \([\text{il\_begin()}, \text{il\_end()}]\) into \( a \). All existing elements of \( a \) are either assigned to or destroyed.
- **Complexity:** \( N \log N \) in general, where \( N \) has the value \( \text{il\_size()} + \text{a\_size()} \); linear if \([\text{il\_begin()}, \text{il\_end()}]\) is sorted with respect to \( \text{value\_comp()} \).

\( b.\text{key\_comp()} \)

- **Result:** \( X::\text{key\_compare} \)
- **Returns:** The comparison object out of which \( b \) was constructed.
- **Complexity:** Constant.

\( b.\text{value\_comp()} \)

- **Result:** \( X::\text{value\_compare} \)
- **Returns:** An object of \( \text{value\_compare} \) constructed out of the comparison object.
- **Complexity:** Constant.

\( a\\_uniq.\text{emplace(args)} \)

- **Result:** \( \text{pair<iterator, bool>} \)
- **Preconditions:** \( \text{value\_type} \) is \( \text{Cpp17\Emplace\Constructible} \) into \( X \) from \( \text{args} \).
- **Effects:** Inserts a \( \text{value\_type} \) object \( t \) constructed with \( \text{std::forward<Arg>s>(args)} \) if and only if there is no element in the container with key equivalent to the key of \( t \).
- **Returns:** The \( \text{bool} \) component of the returned pair is \( \text{true} \) if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of \( t \).
- **Complexity:** Logarithmic.

\( a\_eq.\text{emplace(args)} \)

- **Result:** \( \text{iterator} \)
- **Preconditions:** \( \text{value\_type} \) is \( \text{Cpp17\Emplace\Constructible} \) into \( X \) from \( \text{args} \).
Effects: Inserts a value_type object \( t \) constructed with `std::forward<Args>(args)`... If a range containing elements equivalent to \( t \) exists in \( \text{a}_\text{eq} \), \( t \) is inserted at the end of that range.

Returns: An iterator pointing to the newly inserted element.

Complexity: Logarithmic.

```cpp
a.emplace_hint(p, args)
```

Result: iterator

Effects: Equivalent to `a.emplace(std::forward<Args>(args))`, except that the element is inserted as close as possible to the position just prior to \( p \).

Returns: An iterator pointing to the element with the key equivalent to the newly inserted element.

Complexity: Logarithmic in general, but amortized constant if the element is inserted right before \( p \).

```cpp
a_unique.insert(t)
```

Result: pair<iterator, bool>

Preconditions: If \( t \) is a non-const rvalue, value_type is `Cpp17MoveInsertable` into \( X \); otherwise, value_type is `Cpp17CopyInsertable` into \( X \).

Effects: Inserts \( t \) if and only if there is no element in the container with key equivalent to the key of \( t \).

Returns: The bool component of the returned pair is true if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of \( t \).

Complexity: Logarithmic.

```cpp
a_eq.insert(t)
```

Result: iterator

Preconditions: If \( t \) is a non-const rvalue, value_type is `Cpp17MoveInsertable` into \( X \); otherwise, value_type is `Cpp17CopyInsertable` into \( X \).

Effects: Inserts \( t \) and returns the iterator pointing to the newly inserted element. If a range containing elements equivalent to \( t \) exists in \( \text{a}_\text{eq} \), \( t \) is inserted at the end of that range.

Complexity: Logarithmic.

```cpp
a.insert(p, t)
```

Result: iterator

Preconditions: If \( t \) is a non-const rvalue, value_type is `Cpp17MoveInsertable` into \( X \); otherwise, value_type is `Cpp17CopyInsertable` into \( X \).

Effects: Inserts \( t \) if and only if there is no element with key equivalent to the key of \( t \) in containers with unique keys; always inserts \( t \) in containers with equivalent keys. \( t \) is inserted as close as possible to the position just prior to \( p \).

Returns: An iterator pointing to the element with key equivalent to the key of \( t \).

Complexity: Logarithmic in general, but amortized constant if \( t \) is inserted right before \( p \).

```cpp
a.insert(i, j)
```

Result: void

Preconditions: value_type is `Cpp17EmplaceConstructible` into \( X \) from \( *i \). Neither \( i \) nor \( j \) are iterators into \( a \).

Effects: Inserts each element from the range \([i, j])\) if and only if there is no element with key equivalent to the key of that element in containers with unique keys; always inserts that element in containers with equivalent keys.

Complexity: \( N \log(a.size()) + N \), where \( N \) has the value `distance(i, j)`.

```cpp
a.insert_range(rg)
```

Result: void
Preconditions: `value_type` is `Cpp17EmplaceConstructible` into `X` from `ranges::begin(rg)`. `rg` and `a` do not overlap.

Effects: Inserts each element from `rg` if and only if there is no element with key equivalent to the key of that element in containers with unique keys; always inserts that element in containers with equivalent keys.

Complexity: `N \log(a.size() + N)`, where `N` has the value `ranges::distance(rg)`.

```cpp
a.insert(il)
```

Effects: Equivalent to `a.insert(il.begin(), il.end())`.

```cpp
a_uniq.insert(nh)
```

**Result:** `insert_return_type`

Preconditions: `nh` is empty or `a_uniq.get_allocator() == nh.get_allocator()` is true.

Effects: If `nh` is empty, has no effect. Otherwise, inserts the element owned by `nh` if and only if there is no element in the container with a key equivalent to `nh.key()`.

Returns: If `nh` is empty, `inserted` is `false`, `position` is `end()`, and `node` is empty. Otherwise if the insertion took place, `inserted` is `true`, `position` points to the inserted element, and `node` is empty; if the insertion failed, `inserted` is `false`, `node` has the previous value of `nh`, and `position` points to an element with a key equivalent to `nh.key()`.

Complexity: Logarithmic.

```cpp
a_eq.insert(nh)
```

**Result:** `iterator`

Preconditions: `nh` is empty or `a_eq.get_allocator() == nh.get_allocator()` is true.

Effects: If `nh` is empty, has no effect and returns `a_eq.end()`. Otherwise, inserts the element owned by `nh` and returns an iterator pointing to the newly inserted element. If a range containing elements with keys equivalent to `nh.key()` exists in `a_eq`, the element is inserted at the end of that range.

Postconditions: `nh` is empty.

Complexity: Logarithmic.

```cpp
a.insert(p, nh)
```

**Result:** `iterator`

Preconditions: `nh` is empty or `a.get_allocator() == nh.get_allocator()` is true.

Effects: If `nh` is empty, has no effect and returns `a.end()`. Otherwise, inserts the element owned by `nh` if and only if there is no element with key equivalent to `nh.key()` in containers with unique keys; always inserts the element owned by `nh` in containers with equivalent keys. The element is inserted as close as possible to the position just prior to `p`.

Postconditions: `nh` is empty if insertion succeeds, unchanged if insertion fails.

Returns: An iterator pointing to the element with key equivalent to `nh.key()`.

Complexity: Asymptotically optimal (amortized constant if the element is inserted right before `p`).

```cpp
a.extract(k)
```

**Result:** `node_type`

Effects: Removes the first element in the container with key equivalent to `k`.

Returns: A `node_type` owning the element if found, otherwise an empty `node_type`.

Complexity: `\log(a.size())`

```cpp
a_tran.extract(kx)
```

**Result:** `node_type`

Effects: Removes the first element in the container with key `r` such that `!c(r, kx) && !c(kx, r)` is true.
Returns: A node_type owning the element if found, otherwise an empty node_type.

Complexity: \( \log(a\text{.}\text{transf}\text{.}\text{size()}) \)

\( a\text{.}\text{extract(q)} \)

Result: node_type

Effects: Removes the element pointed to by q.

Returns: A node_type owning that element.

Complexity: Amortized constant.

\( a\text{.}\text{merge(a2)} \)

Result: void

Preconditions: \( a\text{.}\text{get}\text{.}\text{allocator()} == a2\text{.}\text{get}\text{.}\text{allocator()} \).

Effects: Attempts to extract each element in a2 and insert it into a using the comparison object of a.
In containers with unique keys, if there is an element in a with key equivalent to the key of an element from a2, then that element is not extracted from a2.

Postconditions: Pointers and references to the transferred elements of a2 refer to those same elements but as members of a. Iterators referring to the transferred elements will continue to refer to their elements, but they now behave as iterators into a, not into a2.

Throws: Nothing unless the comparison object throws.

Complexity: \( N \log(a\text{.}\text{size()}) + N \), where \( N \) has the value a2\text{.}size().

\( a\text{.}\text{erase(k)} \)

Result: size_type

Effects: Erases all elements in the container with key equivalent to k.

Returns: The number of erased elements.

Complexity: \( \log(a\text{.}\text{size()}) + a\text{.}\text{count(k)} \)

\( a\text{.}\text{transf}\text{.}\text{erase(kx)} \)

Result: size_type

Effects: Erases all elements in the container with key r such that \( !c(r, kx) \&\& !c(kx, r) \) is true.

Returns: The number of erased elements.

Complexity: \( \log(a\text{.}\text{transf}\text{.}\text{size()}) + a\text{.}\text{transf}\text{.}\text{count(kx)} \)

\( a\text{.}\text{erase(q)} \)

Result: iterator

Effects: Erases the element pointed to by q.

Returns: An iterator pointing to the element immediately following q prior to the element being erased.
If no such element exists, returns a.end().

Complexity: Amortized constant.

\( a\text{.}\text{erase(r)} \)

Result: iterator

Effects: Erases the element pointed to by r.

Returns: An iterator pointing to the element immediately following r prior to the element being erased.
If no such element exists, returns a.end().

Complexity: Amortized constant.

\( a\text{.}\text{erase(q1, q2)} \)

Result: iterator

Effects: Erases all the elements in the range \( [q1, q2) \).
Returns: An iterator pointing to the element pointed to by q2 prior to any elements being erased. If no such element exists, a.end() is returned.

Complexity: \( \log(a.size()) + N \), where \( N \) has the value distance(q1, q2).

\( \text{a.clear()} \)

Effects: Equivalent to a.erase(a.begin(), a.end()).

Postconditions: a.empty() is true.

Complexity: Linear in a.size().

\( \text{b.find}(k) \)

Result: iterator; const_iterator for constant b.

Returns: An iterator pointing to an element with the key equivalent to k, or b.end() if such an element is not found.

Complexity: Logarithmic.

\( \text{a_tran.find}(ke) \)

Result: iterator; const_iterator for constant a_tran.

Returns: An iterator pointing to an element with key r such that \(!c(r, ke) \&\& c(ke, r)\) is true, or a_tran.end() if such an element is not found.

Complexity: Logarithmic.

\( \text{b.count}(k) \)

Result: size_type

Returns: The number of elements with key equivalent to k.

Complexity: \( \log(b.size()) + b.count(k) \)

\( \text{a_tran.count}(ke) \)

Result: size_type

Returns: The number of elements with key r such that \(!c(r, ke) \&\& c(ke, r)\).

Complexity: \( \log(a_tran.size()) + a_tran.count(ke) \)

\( \text{b.contains}(k) \)

Result: bool

Effects: Equivalent to: return b.find(k) != b.end();

\( \text{a_tran.contains}(ke) \)

Result: bool

Effects: Equivalent to: return a_tran.find(ke) != a_tran.end();

\( \text{b.lower_bound}(k) \)

Result: iterator; const_iterator for constant b.

Returns: An iterator pointing to the first element with key not less than k, or b.end() if such an element is not found.

Complexity: Logarithmic.

\( \text{a_tran.lower_bound}(kl) \)

Result: iterator; const_iterator for constant a_tran.

Returns: An iterator pointing to the first element with key r such that \(!c(r, kl)\), or a_tran.end() if such an element is not found.

Complexity: Logarithmic.
b.upper_bound(k)

Result: iterator; const_iterator for constant b.

Returns: An iterator pointing to the first element with key greater than k, or b.end() if such an element is not found.

Complexity: Logarithmic,

a_tran.upper_bound(ku)

Result: iterator; const_iterator for constant a_tran.

Returns: An iterator pointing to the first element with key r such that c(ku, r), or a_tran.end() if such an element is not found.

Complexity: Logarithmic.

b.equal_range(k)

Result: pair<iterator, iterator>; pair<const_iterator, const_iterator> for constant b.

Effects: Equivalent to: return make_pair(b.lower_bound(k), b.upper_bound(k));

Complexity: Logarithmic.

a_tran.equal_range(ke)

Result: pair<iterator, iterator>; pair<const_iterator, const_iterator> for constant a_tran.

Effects: Equivalent to: return make_pair(a_tran.lower_bound(ke), a_tran.upper_bound(ke));

Complexity: Logarithmic.

The insert, insert_range, and emplace members shall not affect the validity of iterators and references to the container, and the erase members shall invalidate only iterators and references to the erased elements.

The extract members invalidate only iterators to the removed element; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a node_type is undefined behavior. References and pointers to an element obtained while it is owned by a node_type are invalidated if the element is successfully inserted.

The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators i and j such that distance from i to j is positive, the following condition holds:

value_comp(*j, *i) == false

For associative containers with unique keys the stronger condition holds:

value_comp(*i, *j) != false

When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, through either a copy constructor or an assignment operator, the target container shall then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.

The member function templates find, count, contains, lower_bound, upper_bound, equal_range, erase, and extract shall not participate in overload resolution unless the qualified-id Compare::is_transparent is valid and denotes a type (13.10.3). Additionally, the member function templates extract and erase shall not participate in overload resolution if is_convertible_v<K&&, iterator> || is_convertible_v<K&&, const_iterator> is true, where K is the type substituted as the first template argument.

A deduction guide for an associative container shall not participate in overload resolution if any of the following are true:

(181.1) — It has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

(181.2) — It has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.
Unordered associative containers conform to the requirements for Containers (24.2), except that the expressions $a == b$ and $a != b$ have different semantics than for the other container types.

### 24.2.7.2 Exception safety guarantees

1. For associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container’s `Compare` object (if any).
2. For associative containers, if an exception is thrown by any operation from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.
3. For associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container’s `Compare` object (if any).

### 24.2.8 Unordered associative containers

#### 24.2.8.1 General

Unordered associative containers provide an ability for fast retrieval of data based on keys. The worst-case complexity for most operations is linear, but the average case is much faster. The library provides four unordered associative containers: `unordered_set`, `unordered_map`, `unordered_multiset`, and `unordered_multimap`.

Unordered associative containers conform to the requirements for Containers (24.2), except that the expressions $a == b$ and $a != b$ have different semantics than for the other container types.

Each unordered associative container is parameterized by `Key`, by a function object type `Hash` that meets the C++17Hash requirements (16.4.4.5) and acts as a hash function for argument values of type `Key`, and by a binary predicate `Pred` that induces an equivalence relation on values of type `Key`. Additionally, `unordered_map` and `unordered_multimap` associate an arbitrary `mapped type T` with the `Key`.

The container’s object of type `Hash` — denoted by `hash` — is called the hash function of the container. The container’s object of type `Pred` — denoted by `pred` — is called the key equality predicate of the container.

Two values $k_1$ and $k_2$ are considered equivalent if the container’s key equality predicate `pred(k1, k2)` is valid and returns `true` when passed those values. If $k_1$ and $k_2$ are equivalent, the container’s hash function shall return the same value for both.

[Note 1: Thus, when an unordered associative container is instantiated with a non-default `Pred` parameter it usually needs a non-default `Hash` parameter as well. — end note]

For any two keys $k_1$ and $k_2$ in the same container, calling `pred(k1, k2)` shall always return the same value. For any key $k$ in a container, calling `hash(k)` shall always return the same value.

An unordered associative container supports unique keys if it may contain at most one element for each key. Otherwise, it supports equivalent keys. `unordered_set` and `unordered_map` support unique keys. `unordered_multiset` and `unordered_multimap` support equivalent keys. In containers that support equivalent keys, elements with equivalent keys are adjacent to each other in the iteration order of the container. Thus, although the absolute order of elements in an unordered container is not specified, its elements are grouped into equivalent-key groups such that all elements of each group have equivalent keys. Mutating operations on unordered containers shall preserve the relative order of elements within each equivalent-key group unless otherwise specified.

For `unordered_set` and `unordered_multiset` the value type is the same as the key type. For `unordered_map` and `unordered_multimap` it is `pair<const Key, T>`.

For unordered containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type.

[Note 2: `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists. — end note]

The elements of an unordered associative container are organized into buckets. Keys with the same hash code appear in the same bucket. The number of buckets is automatically increased as elements are added to an unordered associative container, so that the average number of elements per bucket is kept below a bound. Rehashing invalidates iterators, changes ordering between elements, and changes which buckets elements appear in, but does not invalidate pointers or references to elements. For `unordered_multiset` and `unordered_multimap`, rehashing preserves the relative ordering of equivalent elements.
In this subclause,

— X denotes an unordered associative container class,
— a denotes a value of type X,
— a2 denotes a value of a type with nodes compatible with type X (Table 83),
— b denotes a value of type X or const X,
— a_uniq denotes a value of type X when X supports unique keys,
— a_eq denotes a value of type X when X supports equivalent keys,
— a_tran denotes a value of type X or const X when the qualified-ids X::key_equal::is_transparent
  and X::hasher::is_transparent are both valid and denote types (13.10.3),
— i and j denote input iterators that refer to value_type,
— [i, j) denotes a valid range,
— rg denotes a value of a type R that models container-compatible-range<value_type>,
— p and q2 denote valid constant iterators to a,
— q and q1 denote valid dereferenceable constant iterators to a,
— r denotes a valid dereferenceable iterator to a,
— [q1, q2) denotes a valid range in a,
— il denotes a value of type initializer_list<value_type>,
— t denotes a value of type value_type,
— k denotes a value of type key_type,
— hf denotes a value of type hasher or const hasher,
— eq denotes a value of type key_equal or const key_equal,
— ke is a value such that
  — eq(r1, ke) == eq(ke, r1),
  — hf(r1) == hf(ke) if eq(r1, ke) is true, and
  — if any two of eq(r1, ke), eq(r2, ke), and eq(r1, r2) are true, then all three are true,
where r1 and r2 are keys of elements in a_tran,
— kx is a value such that
  — eq(r1, kx) == eq(kx, r1),
  — hf(r1) == hf(kx) if eq(r1, kx) is true,
  — if any two of eq(r1, kx), eq(r2, kx), and eq(r1, r2) are true, then all three are true, and
  — kx is not convertible to either iterator or const_iterator,
where r1 and r2 are keys of elements in a_tran,
— n denotes a value of type size_type,
— z denotes a value of type float, and
— nh denotes an rvalue of type X::node_type.

A type X meets the unordered associative container requirements if X meets all the requirements of an allocator-aware container (24.2.2.1) and the following types, statements, and expressions are well-formed and have the specified semantics, except that for unordered_map and unordered_multimap, the requirements placed on value_type in 24.2.2.5 apply instead to key_type and mapped_type.

[Note 3: For example, key_type and mapped_type are sometimes required to be Cpp17CopyAssignable even though the associated value_type, pair<const key_type, mapped_type>, is not Cpp17CopyAssignable. — end note]
typename X::mapped_type
   
   Result: T.
   
   Remarks: For unordered_map and unordered_multimap only.

typename X::value_type
   
   Result: Key for unordered_set and unordered_multiset only; pair<const Key, T> for unordered_map and unordered_multimap only.
   
   Preconditions: value_type is Cpp17Erasable from X.

typename X::hasher
   
   Result: Hash.
   
   Preconditions: Hash is a unary function object type such that the expression hf(k) has type size_t.

typename X::key_equal
   
   Result: Pred.
   
   Preconditions: Pred meets the Cpp17CopyConstructible requirements. Pred is a binary predicate that takes two arguments of type Key. Pred is an equivalence relation.

typename X::local_iterator
   
   Result: An iterator type whose category, value type, difference type, and pointer and reference types are the same as X::iterator's.

   [Note 4: A local_iterator object can be used to iterate through a single bucket, but cannot be used to iterate across buckets. — end note]

typename X::const_local_iterator
   
   Result: An iterator type whose category, value type, difference type, and pointer and reference types are the same as X::const_iterator's.

   [Note 5: A const_local_iterator object can be used to iterate through a single bucket, but cannot be used to iterate across buckets. — end note]

typename X::node_type
   
   Result: A specialization of a node-handle class template (24.2.5), such that the public nested types are the same types as the corresponding types in X.

   X(n, hf, eq)
   
   Effects: Constructs an empty container with at least n buckets, using hf as the hash function and eq as the key equality predicate.
   
   Complexity: \( \Theta(n) \)

   X(n, hf)
   
   Preconditions: key_equal meets the Cpp17DefaultConstructible requirements.
   
   Effects: Constructs an empty container with at least n buckets, using hf as the hash function and key_equal() as the key equality predicate.
   
   Complexity: \( \Theta(n) \)

   X(n)
   
   Preconditions: hasher and key_equal meet the Cpp17DefaultConstructible requirements.
   
   Effects: Constructs an empty container with at least n buckets, using hasher() as the hash function and key_equal() as the key equality predicate.
   
   Complexity: \( \Theta(n) \)

   X a = X();
   X a;
   
   Preconditions: hasher and key_equal meet the Cpp17DefaultConstructible requirements.
Effects: Constructs an empty container with an unspecified number of buckets, using hasher() as the hash function and key_equal() as the key equality predicate.

Complexity: Constant.

\( X(i, j, n, hf, eq) \)

Preconditions: value_type is Cpp17EmplaceConstructible into \( X \) from \(*i\).

Effects: Constructs an empty container with at least \( n \) buckets, using hf as the hash function and eq as the key equality predicate, and inserts elements from \([i, j]\) into it.

Complexity: Average case \( \Theta(N) \) \((N \text{ is distance}(i, j))\), worst case \( \Theta(N^2) \).

\( X(i, j, n) \)

Preconditions: key_equal meets the Cpp17DefaultConstructible requirements. value_type is Cpp17EmplaceConstructible into \( X \) from \(*i\).

Effects: Constructs an empty container with at least \( n \) buckets, using hf as the hash function and key_equal() as the key equality predicate, and inserts elements from \([i, j]\) into it.

Complexity: Average case \( \Theta(N) \) \((N \text{ is distance}(i, j))\), worst case \( \Theta(N^2) \).

\( X(i, j) \)

Preconditions: hasher and key_equal meet the Cpp17DefaultConstructible requirements. value_type is Cpp17EmplaceConstructible into \( X \) from \(*i\).

Effects: Constructs an empty container with an unspecified number of buckets, using hasher() as the hash function and key_equal() as the key equality predicate, and inserts elements from \([i, j]\) into it.

Complexity: Average case \( \Theta(N) \) \((N \text{ is distance}(i, j))\), worst case \( \Theta(N^2) \).

\( X(\text{from range}, \text{rg}, n, hf, eq) \)

Preconditions: value_type is Cpp17EmplaceConstructible into \( X \) from \(*\text{ranges::begin}(\text{rg})\).

Effects: Constructs an empty container with at least \( n \) buckets, using hf as the hash function and eq as the key equality predicate, and inserts elements from \( \text{rg} \) into it.

Complexity: Average case \( \Theta(N) \) \((N \text{ is ranges::distance}(\text{rg}))\), worst case \( \Theta(N^2) \).

\( X(\text{from range}, \text{rg}, n, hf) \)

Preconditions: key_equal meets the Cpp17DefaultConstructible requirements. value_type is Cpp17EmplaceConstructible into \( X \) from \(*\text{ranges::begin}(\text{rg})\).

Effects: Constructs an empty container with at least \( n \) buckets, using hf as the hash function and key_equal() as the key equality predicate, and inserts elements from \( \text{rg} \) into it.

Complexity: Average case \( \Theta(N) \) \((N \text{ is ranges::distance}(\text{rg}))\), worst case \( \Theta(N^2) \).

\( X(\text{from range}, \text{rg}, n) \)

Preconditions: hasher and key_equal meet the Cpp17DefaultConstructible requirements. value_type is Cpp17EmplaceConstructible into \( X \) from \(*\text{ranges::begin}(\text{rg})\).

Effects: Constructs an empty container with at least \( n \) buckets, using hasher() as the hash function and key_equal() as the key equality predicate, and inserts elements from \( \text{rg} \) into it.

Complexity: Average case \( \Theta(N) \) \((N \text{ is ranges::distance}(\text{rg}))\), worst case \( \Theta(N^2) \).
X(from_range, rg)

Preconditions: hasher and key_equal meet the Cpp17DefaultConstructible requirements. value_type is Cpp17EmplaceConstructible into X from *ranges::begin(rg).

Effects: Constructs an empty container with an unspecified number of buckets, using hasher() as the hash function and key_equal() as the key equality predicate, and inserts elements from rg into it.

Complexity: Average case $O(N)$ ($N$ is ranges::distance(rg)), worst case $O(N^2)$.

X(il)

Effects: Equivalent to X(il.begin(), il.end()).

X(il, n)

Effects: Equivalent to X(il.begin(), il.end(), n).

X(il, n, hf)

Effects: Equivalent to X(il.begin(), il.end(), n, hf).

X(il, n, hf, eq)

Effects: Equivalent to X(il.begin(), il.end(), n, hf, eq).

X(b)

Effects: In addition to the container requirements (24.2.2.1), copies the hash function, predicate, and maximum load factor.

Complexity: Average case linear in b.size(), worst case quadratic.

a = b

Result: X&

Effects: In addition to the container requirements, copies the hash function, predicate, and maximum load factor.

Complexity: Average case linear in b.size(), worst case quadratic.

a = il

Result: X&

Preconditions: value_type is Cpp17CopyInsertable into X and Cpp17CopyAssignable.

Effects: Assigns the range [il.begin(), il.end()) into a. All existing elements of a are either assigned to or destroyed.

Complexity: Average case linear in il.size(), worst case quadratic.

b.hash_function()

Result: hasher

Returns: b’s hash function.

Complexity: Constant.

b.key_eq()

Result: key_equal

Returns: b’s key equality predicate.

Complexity: Constant.

a_uniq.emplace(args)

Result: pair<iterator, bool>

Preconditions: value_type is Cpp17EmplaceConstructible into X from args.

Effects: Inserts a value_type object t constructed with std::forward<Args>(args)... if and only if there is no element in the container with key equivalent to the key of t.
Returns: The bool component of the returned pair is true if and only if the insertion takes place, and the iterator component of the pair points to the element with key equivalent to the key of t.

Complexity: Average case $O(1)$, worst case $O(a_{uniq}.size())$.

\texttt{a_eq.emplace(args)}

Result: iterator

Preconditions: value\_type is Cpp17EmplaceConstructible into X from args.

Effects: Inserts a value\_type object t constructed with std::forward<Args>(args)....

Returns: An iterator pointing to the newly inserted element.

Complexity: Average case $O(1)$, worst case $O(a_{eq}.size())$.

\texttt{a.insert(i, j)}

Result: void

Preconditions: value\_type is Cpp17EmplaceConstructible into X from *i. Neither i nor j are iterators into a.
Effects: Equivalent to `a.insert(t)` for each element in `[i,j)`.

Complexity: Average case \( \Theta(N) \), where \( N \) is `distance(i, j)`, worst case \( \Theta(N(a.size() + 1)) \).

\( a.insert\_range(rg) \)

Result: `void`

Preconditions: `value_type` is `Cpp17EmplaceConstructible` into \( X \) from `ranges::begin(rg)`. \( rg \) and \( a \) do not overlap.

Effects: Equivalent to `a.insert(t)` for each element \( t \) in \( rg \).

Complexity: Average case \( \Theta(N) \), where \( N \) is `ranges::distance(rg)`, worst case \( \Theta(N(a.size() + 1)) \).

\( a.insert(il) \)

Effects: Equivalent to `a.insert(il.begin(), il.end())`.

\( a\_uniq.insert(nh) \)

Result: `insert\_return\_type`

Preconditions: \( nh \) is empty or `a\_uniq.get\_allocator() == nh.get\_allocator()` is true.

Effects: If \( nh \) is empty, has no effect. Otherwise, inserts the element owned by \( nh \) if and only if there is no element in the container with a key equivalent to `nh.key()`.

Postconditions: If \( nh \) is empty, `inserted` is `false`, `position` is `end()`, and `node` is empty. Otherwise if the insertion took place, `inserted` is `true`, `position` points to the inserted element, and `node` is empty; if the insertion failed, `inserted` is `false`, `node` has the previous value of `nh`, and `position` points to an element with a key equivalent to `nh.key()`.

Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a\_uniq.size()) \).

\( a\_eq.insert(nh) \)

Result: `iterator`

Preconditions: \( nh \) is empty or `a\_eq.get\_allocator() == nh.get\_allocator()` is true.

Effects: If \( nh \) is empty, has no effect and returns `a\_eq.end()`. Otherwise, inserts the element owned by \( nh \) and returns an iterator pointing to the newly inserted element.

Postconditions: \( nh \) is empty.

Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a\_eq.size()) \).

\( a.insert(q, nh) \)

Result: `iterator`

Preconditions: \( nh \) is empty or `a\_get\_allocator() == nh\_get\_allocator()` is true.

Effects: If \( nh \) is empty, has no effect and returns `a\_end()`. Otherwise, inserts the element owned by \( nh \) if and only if there is no element with key equivalent to \( nh\_key() \) in containers with unique keys; always inserts the element owned by \( nh \) in containers with equivalent keys. The iterator \( q \) is a hint pointing to where the search should start. Implementations are permitted to ignore the hint.

Postconditions: \( nh \) is empty if insertion succeeds, unchanged if insertion fails.

Returns: An iterator pointing to the element with key equivalent to `nh.key()`.

Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a.size()) \).

\( a.extract(k) \)

Result: `node_type`

Effects: Removes an element in the container with key equivalent to \( k \).

Returns: A `node_type` owning the element if found, otherwise an empty `node_type`.

Complexity: Average case \( \Theta(1) \), worst case \( \Theta(a.size()) \).

\( a\_\_trans.extract(kx) \)

Result: `node_type`
Effects: Removes an element in the container with key equivalent to kx.

Returns: A node_type owning the element if found, otherwise an empty node_type.

Complexity: Average case $O(1)$, worst case $O(a\_tran\_size())$.

a.extract(q)

Result: node_type

Effects: Removes the element pointed to by q.

Returns: A node_type owning that element.

Complexity: Average case $O(1)$, worst case $O(a\_size())$.

a.merge(a2)

Result: void

Preconditions: a.get_allocator() == a2.get_allocator().

Effects: Attempts to extract each element in a2 and insert it into a using the hash function and key equality predicate of a. In containers with unique keys, if there is an element in a with key equivalent to the key of an element from a2, then that element is not extracted from a2.

Postconditions: Pointers and references to the transferred elements of a2 refer to those same elements but as members of a. Iterators referring to the transferred elements and all iterators referring to a will be invalidated, but iterators to elements remaining in a2 will remain valid.

Complexity: Average case $O(N)$, where N is a2.size(), worst case $O(N\ast a\_size() + N)$.

a.erase(k)

Result: size_type

Effects: Erases all elements with key equivalent to k.

Returns: The number of elements erased.

Complexity: Average case $O(a\_count(k))$, worst case $O(a\_size())$.

a_tran.erase(kx)

Result: size_type

Effects: Erases all elements with key equivalent to kx.

Returns: The number of elements erased.

Complexity: Average case $O(a\_tran\_count(kx))$, worst case $O(a\_tran\_size())$.

a.erase(q)

Result: iterator

Effects: Erases the element pointed to by q.

Returns: The iterator immediately following q prior to the erasure.

Complexity: Average case $O(1)$, worst case $O(a\_size())$.

a.erase(r)

Result: iterator

Effects: Erases the element pointed to by r.

Returns: The iterator immediately following r prior to the erasure.

Complexity: Average case $O(1)$, worst case $O(a\_size())$.

a.erase(q1, q2)

Result: iterator

Effects: Erases all elements in the range [q1, q2).

Returns: The iterator immediately following the erased elements prior to the erasure.

Complexity: Average case linear in distance(q1, q2), worst case $O(a\_size())$. 

§ 24.2.8.1
a.clear()

  \textit{Result:} void
  
  \textit{Effects:} Erases all elements in the container.
  
  \textit{Postconditions:} \texttt{a.empty()} is true.
  
  \textit{Complexity:} Linear in \texttt{a.size()}.  

\newpage

b.find(k)

  \textit{Result:} \texttt{iterator}; \texttt{const_iterator} for constant \texttt{b}.
  
  \textit{Returns:} An iterator pointing to an element with key equivalent to \texttt{k}, or \texttt{b.end()} if no such element exists.
  
  \textit{Complexity:} Average case $\Theta(1)$, worst case $\Theta(b.size())$.  

a_tran.find(ke)

  \textit{Result:} \texttt{iterator}; \texttt{const_iterator} for constant \texttt{a_tran}.
  
  \textit{Returns:} An iterator pointing to an element with key equivalent to \texttt{ke}, or \texttt{a_tran.end()} if no such element exists.
  
  \textit{Complexity:} Average case $\Theta(1)$, worst case $\Theta(a_tran.size())$.  

b.count(k)

  \textit{Result:} \texttt{size_type}  
  
  \textit{Returns:} The number of elements with key equivalent to \texttt{k}.
  
  \textit{Complexity:} Average case $\Theta(b.count(k))$, worst case $\Theta(b.size())$.  

a_tran.count(ke)

  \textit{Result:} \texttt{size_type}  
  
  \textit{Returns:} The number of elements with key equivalent to \texttt{ke}.
  
  \textit{Complexity:} Average case $\Theta(a_tran.count(ke))$, worst case $\Theta(a_tran.size())$.  

b.contains(k)

  \textit{Effects:} Equivalent to \texttt{b.find(k) \neq b.end()}.  

a_tran.contains(ke)

  \textit{Effects:} Equivalent to \texttt{a_tran.find(ke) \neq a_tran.end()}.  

b.equal_range(k)

  \textit{Result:} \texttt{pair<iterator, iterator>; pair<const_iterator, const_iterator>} for constant \texttt{b}.
  
  \textit{Returns:} A range containing all elements with keys equivalent to \texttt{k}. Returns \texttt{make_pair(b.end(), b.end())} if no such elements exist.
  
  \textit{Complexity:} Average case $\Theta(b.count(k))$, worst case $\Theta(b.size())$.  

a_tran.equal_range(ke)

  \textit{Result:} \texttt{pair<iterator, iterator>; pair<const_iterator, const_iterator>} for constant \texttt{a_tran}.
  
  \textit{Returns:} A range containing all elements with keys equivalent to \texttt{ke}. Returns \texttt{make_pair(a_tran.end(), a_tran.end())} if no such elements exist.
  
  \textit{Complexity:} Average case $\Theta(a_tran.count(ke))$, worst case $\Theta(a_tran.size())$.  

b.bucket_count()

  \textit{Result:} \texttt{size_type}  
  
  \textit{Returns:} The number of buckets that \texttt{b} contains.
  
  \textit{Complexity:} Constant.
b.max_bucket_count()

    Result: size_type
    Returns: An upper bound on the number of buckets that b can ever contain.
    Complexity: Constant.

b.bucket(k)

    Result: size_type
    Preconditions: b.bucket_count() > 0.
    Returns: The index of the bucket in which elements with keys equivalent to k would be found, if any such element existed. The return value is in the range [0, b.bucket_count()).
    Complexity: Constant.

b.bucket_size(n)

    Result: size_type
    Preconditions: n shall be in the range [0, b.bucket_count()).
    Returns: The number of elements in the n\textsuperscript{th} bucket.
    Complexity: \(O(b.bucket\_size(n))\)

b.begin(n)

    Result: local_iterator; const_local_iterator for constant b.
    Preconditions: n is in the range [0, b.bucket_count()).
    Returns: An iterator referring to the first element in the bucket. If the bucket is empty, then b.begin(n) == b.end(n).
    Complexity: Constant.

b.end(n)

    Result: local_iterator; const_local_iterator for constant b.
    Preconditions: n is in the range [0, b.bucket_count()).
    Returns: An iterator which is the past-the-end value for the bucket.
    Complexity: Constant.

b.cbegin(n)

    Result: const_local_iterator
    Preconditions: n shall be in the range [0, b.bucket_count()).
    Returns: An iterator referring to the first element in the bucket. If the bucket is empty, then b.cbegin(n) == b.cend(n).
    Complexity: Constant.

b.cend(n)

    Result: const_local_iterator
    Preconditions: n is in the range [0, b.bucket_count()).
    Returns: An iterator which is the past-the-end value for the bucket.
    Complexity: Constant.

b.load_factor()

    Result: float
    Returns: The average number of elements per bucket.
    Complexity: Constant.
b.max_load_factor()

Result: float

Returns: A positive number that the container attempts to keep the load factor less than or equal to. The container automatically increases the number of buckets as necessary to keep the load factor below this number.

Complexity: Constant.

a.max_load_factor(z)

Result: void

Preconditions: z is positive. May change the container’s maximum load factor, using z as a hint.

Complexity: Constant.

a.rehash(n)

Result: void

Postconditions: a.bucket_count() >= a.size() / a.max_load_factor() and a.bucket_count() > n.

Complexity: Average case linear in a.size(), worst case quadratic.

a.reserve(n)

Effects: Equivalent to a.rehash(ceil(n / a.max_load_factor())).

Two unordered containers a and b compare equal if a.size() == b.size() and, for every equivalent-key group [Ea1, Ea2] obtained from a.equal_range(Ea1), there exists an equivalent-key group [Eb1, Eb2] obtained from b.equal_range(Ea1), such that is_permutation(Ea1, Ea2, Eb1, Eb2) returns true. For unordered_set and unordered_map, the complexity of operator== (i.e., the number of calls to the == operator of the value_type, to the predicate returned by key_eq(), and to the hasher returned by hash_function()) is proportional to N in the average case and to N^2 in the worst case, where N is a.size(). For unordered_multiset and unordered_multimap, the complexity of operator== is proportional to \( \sum E_i^2 \) in the average case and to N^2 in the worst case, where N is a.size(), and E_i is the size of the i^th equivalent-key group in a. However, if the respective elements of each corresponding pair of equivalent-key groups Eu and Eb are arranged in the same order (as is commonly the case, e.g., if a and b are unmodified copies of the same container), then the average-case complexity for unordered_multiset and unordered_multimap becomes proportional to N (but worst-case complexity remains \( O(N^2) \), e.g., for a pathologically bad hash function).

The behavior of a program that uses operator== or operator!= on unordered containers is undefined unless the Pred function object has the same behavior for both containers and the equality comparison function for Key is a refinement\(^\text{209}\) of the partition into equivalent-key groups produced by Pred.

The iterator types iterator and const_iterator of an unordered associative container are of at least the forward iterator category. For unordered associative containers where the key type and value type are the same, both iterator and const_iterator are constant iterators.

The insert, insert_range, and emplace members shall not affect the validity of references to container elements, but may invalidate all iterators to the container. The erase members shall invalidate only iterators and references to the erased elements, and preserve the relative order of the elements that are not erased.

The insert, insert_range, and emplace members shall not affect the validity of iterators if \((N+n) \leq z \times B\), where N is the number of elements in the container prior to the insert operation, n is the number of elements inserted, B is the container’s bucket count, and z is the container’s maximum load factor.

The extract members invalidate only iterators to the removed element, and preserve the relative order of the elements that are not erased; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a node_type is undefined behavior. References and pointers to an element obtained while it is owned by a node_type are invalidated if the element is successfully inserted.

The member function templates find, count, equal_range, contains, extract, and erase shall not participate in overload resolution unless the qualified-ids Pred::is_transparent and Hash::is_transparent are both valid and denote types (13.10.3). Additionally, the member function templates extract and erase

\(^{209}\) Equality comparison is a refinement of partitioning if no two objects that compare equal fall into different partitions.
shall not participate in overload resolution if \texttt{is\_convertible\_v<K&&, iterator> || is\_convertible\_v<K&&, const\_iterator>} is true, where \(K\) is the type substituted as the first template argument.

A deduction guide for an unordered associative container shall not participate in overload resolution if any of the following are true:

1. (243.1) It has an \texttt{InputIterator} template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
2. (243.2) It has an \texttt{Allocator} template parameter and a type that does not qualify as an allocator is deduced for that parameter.
3. (243.3) It has a \texttt{Hash} template parameter and an integral type or a type that qualifies as an allocator is deduced for that parameter.
4. (243.4) It has a \texttt{Pred} template parameter and a type that qualifies as an allocator is deduced for that parameter.

### 24.2.8.2 Exception safety guarantees

For unordered associative containers, no \texttt{clear()} function throws an exception. \texttt{erase(k)} does not throw an exception unless that exception is thrown by the container’s \texttt{Hash} or \texttt{Pred} object (if any).

For unordered associative containers, if an exception is thrown by any operation other than the container’s hash function from within an \texttt{insert} or \texttt{emplace} function inserting a single element, the insertion has no effect.

For unordered associative containers, no \texttt{swap} function throws an exception unless that exception is thrown by the swap of the container’s \texttt{Hash} or \texttt{Pred} object (if any).

For unordered associative containers, if an exception is thrown from within a \texttt{rehash()} function other than by the container’s hash function or comparison function, the \texttt{rehash()} function has no effect.

### 24.3 Sequence containers

#### 24.3.1 In general

The headers \texttt{<array> (24.3.2), <deque> (24.3.3), <forward\_list> (24.3.4), <list> (24.3.5), and <vector> (24.3.6) define class templates that meet the requirements for sequence containers.

The following exposition-only alias template may appear in deduction guides for sequence containers:

```cpp
template<class InputIterator>
using iter\_value\_type = typename iterator\_traits<InputIterator>::value\_type; // exposition only
```

#### 24.3.2 Header \texttt{<array>} synopsis

```cpp
#include <compare> // see 17.11.1
#include <initializer\_list> // see 17.10.2

namespace std {
    // 24.3.7, class template array
    template<class T, size\_t N> struct array;

    template<class T, size\_t N>
    constexpr bool operator==(const array<T, N>& x, const array<T, N>& y);

    template<class T, size\_t N>
    constexpr synth\_three\_way\_result<T>
    operator<||(const array<T, N>& x, const array<T, N>& y);

    // 24.3.7.4, specialized algorithms
    template<class T, size\_t N>
    constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));

    // 24.3.7.6, array creation functions
    template<class T, size\_t N>
    constexpr array<remove\_cv\_t<T>, N> to\_array(T (&a)[N]);

    template<class T, size\_t N>
    constexpr array<remove\_cv\_t<T>, N> to\_array(T (&a)[N]);

§ 24.3.2 908
// 24.3.7.7, tuple interface
template<class T> struct tuple_size;
template<size_t I, class T> struct tuple_element;
template<class T, size_t N> struct tuple_size<array<T, N>>;
template<size_t I, class T, size_t N> struct tuple_element<I, array<T, N>>;
template<size_t I, class T, size_t N> constexpr T& get(array<T, N>&) noexcept;
template<size_t I, class T, size_t N> constexpr T&& get(array<T, N>&&) noexcept;
template<size_t I, class T, size_t N> constexpr const T& get(const array<T, N>&) noexcept;
template<size_t I, class T, size_t N> constexpr const T&& get(const array<T, N>&&) noexcept;
}

24.3.3 Header <deque> synopsis

#include <compare> // see 17.11.1
#include <initializer_list> // see 17.10.2
namespace std {

// 24.3.8, class template
deque
template<class T, class Allocator = allocator<T>> class deque;

constexpr const_reference back() const;
constexpr T * data() noexcept;
constexpr const T * data() const noexcept;

};

template<class T, class... U>
array(T, U...) -> array<T, 1 + sizeof...(U)>;

24.3.7.2 Constructors, copy, and assignment

The conditions for an aggregate (9.4.2) shall be met. Class array relies on the implicitly-declared special
member functions (11.4.5.2, 11.4.7, 11.4.5.3) to conform to the container requirements table in 24.2. In
addition to the requirements specified in the container requirements table, the implicit move constructor
and move assignment operator for array require that T be Cpp17MoveConstructible or Cpp17MoveAssignable,
respectively.

Mandates: (is_same_v<T, U> && ...) is true.
24.3.7.3 Member functions

```cpp
constexpr size_type size() const noexcept;
```

Returns: N.

```cpp
constexpr T* data() noexcept;
constexpr const T* data() const noexcept;
```

Returns: A pointer such that [data(), data() + size()) is a valid range. For a non-empty array, data() == addressof(front()).

```cpp
constexpr void fill(const T& u);
```

Effects: As if by fill_n(begin(), N, u).

```cpp
constexpr void swap(array& y) noexcept(is_nothrow_swappable_v<T>);
```

Effects: Equivalent to swap_ranges(begin(), end(), y.begin()).

[Note 1: Unlike the swap function for other containers, array::swap takes linear time, can exit via an exception, and does not cause iterators to become associated with the other container. — end note]

24.3.7.4 Specialized algorithms

```cpp
template<class T, size_t N>
constexpr void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));
```

Constraints: N == 0 or is_swappable_v<T> is true.

Effects: As if by x.swap(y).

Complexity: Linear in N.

24.3.7.5 Zero-sized arrays

array shall provide support for the special case N == 0.

In the case that N == 0, begin() == end() == unique value. The return value of data() is unspecified.

The effect of calling front() or back() for a zero-sized array is undefined.

Member function swap() shall have a non-throwing exception specification.

24.3.7.6 Array creation functions

```cpp
template<class T, size_t N>
constexpr array<remove_cv_t<T>, N> to_array(T (&a)[N]);
```

Mandates: is_array_v<T> is false and is_constructible_v<T, T&> is true.

Preconditions: T meets the Cpp17CopyConstructible requirements.

Returns: {{ a[0], ..., a[N - 1] }}.

```cpp
template<class T, size_t N>
constexpr array<remove_cv_t<T>, N> to_array(T (&&a)[N]);
```

Mandates: is_array_v<T> is false and is_move_constructible_v<T> is true.

Preconditions: T meets the Cpp17MoveConstructible requirements.

Returns: {{ std::move(a[0]), ..., std::move(a[N - 1]) }}.

24.3.7.7 Tuple interface

```cpp
template<class T, size_t N>
struct tuple_size<array<T, N>> : integral_constant<size_t, N> { }; 
```

```cpp
template<size_t I, class T, size_t N>
struct tuple_element<I, array<T, N>> {
    using type = T;
};
```

Mandates: I < N is true.
template<size_t I, class T, size_t N>
constexpr T& get(array<T, N>& a) noexcept;

template<size_t I, class T, size_t N>
constexpr T&& get(array<T, N>&& a) noexcept;

template<size_t I, class T, size_t N>
constexpr const T& get(const array<T, N>& a) noexcept;

template<size_t I, class T, size_t N>
constexpr const T&& get(const array<T, N>&& a) noexcept;

Mandates: \( I < N \) is true.

Returns: A reference to the \( I \)th element of \( a \), where indexing is zero-based.

24.3.8 Class template deque

24.3.8.1 Overview

A deque is a sequence container that supports random access iterators (25.3.5.7). In addition, it supports constant time insert and erase operations at the beginning or the end; insert and erase in the middle take linear time. That is, a deque is especially optimized for pushing and popping elements at the beginning and end. Storage management is handled automatically.

A deque meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of a sequence container, including the optional sequence container requirements (24.2.4). Descriptions are provided here only for operations on deque that are not described in one of these tables or for operations where there is additional semantic information.

namespace std {
    template<class T, class Allocator = allocator<T>>
    class deque {
        public:
            // types
            using value_type = T;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 24.2
            using difference_type = implementation-defined; // see 24.2
            using iterator = implementation-defined; // see 24.2
            using const_iterator = implementation-defined; // see 24.2
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::reverse_iterator<const_iterator>;

            // 24.3.8.2 construct/copy/destroy
            deque() : deque(Allocator()) { }
            explicit deque(const Allocator&);
            explicit deque(size_type n, const Allocator& = Allocator());
            deque(size_type n, const T& value, const Allocator& = Allocator());
            template<class InputIterator>

iterator insert(const_iterator position, initializer_list<T>);
void pop_front();
void pop_back();

§ 24.3.8.1
24.3.8.2 Constructors, copy, and assignment

```cpp
explicit deque(const Allocator&);
```

**Effects:** Constructs an empty `deque`, using the specified allocator.

**Complexity:** Constant.

```cpp
explicit deque(size_type n, const Allocator& = Allocator());
```

**Preconditions:** `T` is `Cpp17DefaultInsertable` into `*this`.

**Effects:** Constructs a `deque` with `n` default-inserted elements using the specified allocator.

**Complexity:** Linear in `n`.

```cpp
deque(size_type n, const T& value, const Allocator& = Allocator());
```

**Preconditions:** `T` is `Cpp17CopyInsertable` into `*this`.

**Effects:** Constructs a `deque` with `n` copies of `value`, using the specified allocator.

**Complexity:** Linear in `n`.

```cpp
template<class InputIterator, class Allocator = allocator<
    iter-value-type<InputIterator>>
deque(InputIterator, InputIterator, Allocator = Allocator());
```

**Effects:** Constructs a `deque` equal to the range `[first, last)`, using the specified allocator.

**Complexity:** Linear in `distance(first, last)`.

```cpp
template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>
deque(from_range_t, R&&, Allocator = Allocator());
```

**Effects:** Constructs a `deque` with the elements of the range `rg`, using the specified allocator.

**Complexity:** Linear in `ranges::distance(rg)`.

24.3.8.3 Capacity

```cpp
void resize(size_type sz);
```

**Preconditions:** `T` is `Cpp17MoveInsertable` and `Cpp17DefaultInsertable` into `*this`.

**Effects:** If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` default-inserted elements to the sequence.

```cpp
void resize(size_type sz, const T& c);
```

**Preconditions:** `T` is `Cpp17CopyInsertable` into `*this`.

**Effects:** If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` copies of `c` to the sequence.

```cpp
void shrink_to_fit();
```

**Preconditions:** `T` is `Cpp17MoveInsertable` into `*this`.
Effects: shrink_to_fit is a non-binding request to reduce memory use but does not change the size of the sequence.

[Note 1: The request is non-binding to allow latitude for implementation-specific optimizations. — end note]

If the size is equal to the old capacity, or if an exception is thrown other than by the move constructor of a non-Cpp17CopyInsertable T, then there are no effects.

Complexity: If the size is not equal to the old capacity, linear in the size of the sequence; otherwise constant.

Remarks: If the size is not equal to the old capacity, then invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

24.3.8.4 Modifiers

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);

template<class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);

template<container-compatible-range <T> R>
iterator insert_range(const_iterator position, R&& rg);

iterator insert(const_iterator position, initializer_list<T>);

template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);

void push_front(const T& x);
void push_front(T&& x);

template<container-compatible-range <T> R>
void prepend_range(R&& rg);

void push_back(const T& x);
void push_back(T&& x);

template<container-compatible-range <T> R>
void append_range(R&& rg);

1 Effects: An insertion in the middle of the deque invalidates all the iterators and references to elements of the deque. An insertion at either end of the deque invalidates all the iterators to the deque, but has no effect on the validity of references to elements of the deque.

Complexity: The complexity is linear in the number of elements inserted plus the lesser of the distances to the beginning and end of the deque. Inserting a single element at either the beginning or end of a deque always takes constant time and causes a single call to a constructor of T.

Remarks: If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of T there are no effects. If an exception is thrown while inserting a single element at either end, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-Cpp17CopyInsertable T, the effects are unspecified.

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_front();
void pop_back();

4 Effects: An erase operation that erases the last element of a deque invalidates only the past-the-end iterator and all iterators and references to the erased elements. An erase operation that erases the first element of a deque but not the last element invalidates only iterators and references to the erased elements. An erase operation that erases neither the first element nor the last element of a deque invalidates the past-the-end iterator and all iterators and references to all the elements of the deque.

[Note 1: pop_front and pop_back are erase operations. — end note]

Throws: Nothing unless an exception is thrown by the assignment operator of T.

Complexity: The number of calls to the destructor of T is the same as the number of elements erased, but the number of calls to the assignment operator of T is no more than the lesser of the number of elements before the erased elements and the number of elements after the erased elements.
24.3.8.5 Erasure

template<class T, class Allocator, class U>
typename deque<T, Allocator>::size_type
erase(deque<T, Allocator>& c, const U& value);

Effects: Equivalent to:
 auto it = remove(c.begin(), c.end(), value);
 auto r = distance(it, c.end());
 c.erase(it, c.end());
 return r;

template<class T, class Allocator, class Predicate>
typename deque<T, Allocator>::size_type
erase_if(deque<T, Allocator>& c, Predicate pred);

Effects: Equivalent to:
 auto it = remove_if(c.begin(), c.end(), pred);
 auto r = distance(it, c.end());
 c.erase(it, c.end());
 return r;

24.3.9 Class template forward_list

24.3.9.1 Overview

A forward_list is a container that supports forward iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Fast random access to list elements is not supported.

[Note 1: It is intended that forward_list have zero space or time overhead relative to a hand-written C-style singly linked list. Features that would conflict with that goal have been omitted. — end note]

A forward_list meets all of the requirements of a container (24.2.2.2), except that the size() member function is not provided and operator== has linear complexity. A forward_list also meets all of the requirements for an allocator-aware container (24.2.2.5). In addition, a forward_list provides the assign member functions and several of the optional sequence container requirements (24.2.4). Descriptions are provided here only for operations on forward_list that are not described in that table or for operations where there is additional semantic information.

[Note 2: Modifying any list requires access to the element preceding the first element of interest, but in a forward_list there is no constant-time way to access a preceding element. For this reason, erase_after and splice_after take fully-open ranges, not semi-open ranges. — end note]

namespace std {
 template<class T, class Allocator = allocator<T>>
 class forward_list {
 public:
  // types
  using value_type = T;
  using allocator_type = Allocator;

void reverse() noexcept;

};

template<class InputIterator, class Allocator = allocator<
                    iter_value_type<InputIterator>>>  
forward_list(InputIterator, InputIterator, Allocator = Allocator())
                    -> forward_list<
                    iter_value_type<InputIterator>, Allocator>;

template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>  
forward_list(from_range_t, R&&, Allocator = Allocator())
                    -> forward_list<ranges::range_value_t<R>, Allocator>;

4 An incomplete type T may be used when instantiating forward_list if the allocator meets the allocator completeness requirements (16.4.4.6.2). T shall be complete before any member of the resulting specialization of forward_list is referenced.

24.3.9.2 Constructors, copy, and assignment
[forward.list.cons]

explicit forward_list(const Allocator&);

Effects: Constructs an empty forward_list object using the specified allocator.
Complexity: Constant.

explicit forward_list(size_type n, const Allocator& = Allocator());

Preconditions: T is Cpp17DefaultInsertable into *this.

Effects: Constructs a forward_list object with n default-inserted elements using the specified allocator.
Complexity: Linear in n.

forward_list(size_type n, const T& value, const Allocator& = Allocator());

Preconditions: T is Cpp17CopyInsertable into *this.

Effects: Constructs a forward_list object with n copies of value using the specified allocator.
Complexity: Linear in n.
template<class InputIterator>
    forward_list(InputIterator first, InputIterator last, const Allocator& = Allocator());

    Effects: Constructs a forward_list object equal to the range [first, last).

    Complexity: Linear in distance(first, last).

template<container-compatible-range<T> R>
    forward_list(from_range_t, R&& rg, const Allocator& = Allocator());

    Effects: Constructs a forward_list object with the elements of the range rg.

    Complexity: Linear in ranges::distance(rg).

24.3.9.3 Iterators

    iterator before_begin() noexcept;
    const_iterator before_begin() const noexcept;
    const_iterator cbefore_begin() const noexcept;

    Effects: cbefore_begin() is equivalent to const_cast<forward_list const&>(*this).before_begin().

    Returns: A non-dereferenceable iterator that, when incremented, is equal to the iterator returned by begin().

    Remarks: before_begin() == end() shall equal false.

24.3.9.4 Element access

    reference front();
    const_reference front() const;

    Returns: *begin()

24.3.9.5 Modifiers

    template<class... Args> reference emplace_front(Args&&... args);

    Effects: Inserts an object of type value_type constructed with
    value_type(std::forward<Args>(args)... ) at the beginning of the list.

    void push_front(const T& x);
    void push_front(T&& x);

    Effects: Inserts a copy of x at the beginning of the list.

    template<container-compatible-range<T> R>
        void prepend_range(R&& rg);

    Effects: Inserts a copy of each element of rg at the beginning of the list.

    [Note 1: The order of elements is not reversed. — end note]

    void pop_front();

    Effects: As if by erase_after(before_begin()).

    iterator insert_after(const_iterator position, const T& x);

    Preconditions: T is Cpp17CopyInsertable into forward_list. position is before_begin() or is a
dereferenceable iterator in the range [begin(), end()).

    Effects: Inserts a copy of x after position.

    Returns: An iterator pointing to the copy of x.
iterator insert_after(const_iterator position, T& x);

**Preconditions:** T is `Cpp17MoveInsertable` into `forward_list`. position is before `begin()` or is a dereferenceable iterator in the range `[begin(), end())`.

**Effects:** Inserts a copy of x after position.

**Returns:** An iterator pointing to the copy of x.

iterator insert_after(const_iterator position, size_type n, const T& x);

**Preconditions:** T is `Cpp17CopyInsertable` into `forward_list`. position is before `begin()` or is a dereferenceable iterator in the range `[begin(), end())`.

**Effects:** Inserts n copies of x after position.

**Returns:** An iterator pointing to the last inserted copy of x, or position if n == 0 is true.

```cpp
template<class InputIterator>
iterator insert_after(const_iterator position, InputIterator first, InputIterator last);
```

**Preconditions:** T is `Cpp17EmplaceConstructible` into `forward_list` from `*first`. position is before `begin()` or is a dereferenceable iterator in the range `[begin(), end())`. Neither first nor last are iterators in *this.

**Effects:** Inserts copies of elements in `[first, last)` after position.

**Returns:** An iterator pointing to the last inserted element, or position if first == last is true.

```cpp
template<container-compatible-range<T> R>
iterator insert_range_after(const_iterator position, R&& rg);
```

**Preconditions:** T is `Cpp17EmplaceConstructible` into `forward_list` from `*ranges::begin(rg)`. position is before `begin()` or is a dereferenceable iterator in the range `[begin(), end())`. rg and *this do not overlap.

**Effects:** Inserts copies of elements in the range rg after position.

**Returns:** An iterator pointing to the last inserted element, or position if rg is empty.

```cpp
iterator insert_after(const_iterator position, initializer_list<T> il);
```

**Effects:** Equivalent to: return insert_after(position, il.begin(), il.end());

```cpp
template<class... Args>
iterator emplace_after(const_iterator position, Args&&... args);
```

**Preconditions:** T is `Cpp17EmplaceConstructible` into `forward_list` from `std::forward<Args>(args)`. position is before `begin()` or is a dereferenceable iterator in the range `[begin(), end())`.

**Effects:** Inserts an object of type `value_type` direct-non-list-initialized with `std::forward<Args>(args)`... after position.

**Returns:** An iterator pointing to the new object.

```cpp
iterator erase_after(const_iterator position);
```

**Preconditions:** The iterator following position is dereferenceable.

**Effects:** Erases the element pointed to by the iterator following position.

**Returns:** An iterator pointing to the element following the one that was erased, or end() if no such element exists.

**Throws:** Nothing.

```cpp
iterator erase_after(const_iterator position, const_iterator last);
```

**Preconditions:** All iterators in the range (position, last) are dereferenceable.

**Effects:** Erases the elements in the range (position, last).

**Returns:** last.

**Throws:** Nothing.
void resize(size_type sz);

**Preconditions:** T is Cpp17DefaultInsertable into *this.

**Effects:** If sz < distance(begin(), end()), erases the last distance(begin(), end()) - sz elements from the list. Otherwise, inserts sz - distance(begin(), end()) default-inserted elements at the end of the list.

void resize(size_type sz, const value_type& c);

**Preconditions:** T is Cpp17CopyInsertable into *this.

**Effects:** If sz < distance(begin(), end()), erases the last distance(begin(), end()) - sz elements from the list. Otherwise, inserts sz - distance(begin(), end()) copies of c at the end of the list.

void clear() noexcept;

**Effects:** Erases all elements in the range [begin(), end()).

**Remarks:** Does not invalidate past-the-end iterators.

### 24.3.9.6 Operations

[forward.list.ops]

In this subclause, arguments for a template parameter named Predicate or BinaryPredicate shall meet the corresponding requirements in 27.2. The semantics of i + n, where i is an iterator into the list and n is an integer, are the same as those of next(i, n). The expression i - n, where i is an iterator into the list and n is an integer, means an iterator j such that j + n == i is true. For merge and sort, the definitions and requirements in 27.8 apply.

void splice_after(const_iterator position, forward_list& x);
void splice_after(const_iterator position, forward_list&& x);

**Preconditions:** position is before_begin() or is a dereferenceable iterator in the range [begin(), end()). get_allocator() == x.get_allocator() is true. addressof(x) != this is true.

**Effects:** Inserts the contents of x after position, and x becomes empty. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

**Throws:** Nothing.

**Complexity:** \(O(distance(x.begin(), x.end()))\)

void splice_after(const_iterator position, forward_list& x, const_iterator i);
void splice_after(const_iterator position, forward_list&& x, const_iterator i);

**Preconditions:** position is before_begin() or is a dereferenceable iterator in the range [begin(), end()). The iterator following i is a dereferenceable iterator in x. get_allocator() == x.get_allocator() is true.

**Effects:** Inserts the element following i into *this, following position, and removes it from x. The result is unchanged if position == i or position == ++i. Pointers and references to ++i continue to refer to the same element but as a member of *this. Iterators to ++i continue to refer to the same element, but now behave as iterators into *this, not into x.

**Throws:** Nothing.

**Complexity:** \(O(1)\)

void splice_after(const_iterator position, forward_list& x, const_iterator first, const_iterator last);
void splice_after(const_iterator position, forward_list&& x, const_iterator first, const_iterator last);

**Preconditions:** position is before_begin() or is a dereferenceable iterator in the range [begin(), end()). (first, last) is a valid range in x, and all iterators in the range (first, last) are dereferenceable. position is not an iterator in the range (first, last). get_allocator() == x.get_allocator() is true.

§ 24.3.9.6 923
Effects: Inserts elements in the range \((\text{first}, \text{last})\) after \text{position} and removes the elements from \text{x}. Pointers and references to the moved elements of \text{x} now refer to those same elements but as members of \(*\text{this}\). Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into \(*\text{this}\), not into \text{x}.

Complexity: \(O(\text{distance(\text{first}, \text{last})})\)

\[
\text{size_type \text{remove(const T& value);}}
\]
\[
\text{template<class Predicate> size_type \text{remove_if(Predicate \text{pred});}}
\]

Effects: Erases all the elements in the list referred to by a list iterator \text{i} for which the following conditions hold: \(*\text{i} == \text{value}\) (for \text{remove()}), \text{pred(*i)} is \text{true} (for \text{remove_if()}). Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the equality comparison or the predicate.

Complexity: Exactly \text{distance(begin(), end())} applications of the corresponding predicate.

Remarks: Stable (16.4.6.8).

\[
\text{size_type \text{unique();}}
\]
\[
\text{template<class BinaryPredicate> size_type \text{unique(BinaryPredicate binary_pred);} \]

Let \text{binary_pred} be \text{equal_to<>\{\}} for the first overload.

Preconditions: \text{binary_pred} is an equivalence relation.

Effects: Erases all but the first element from every consecutive group of equivalent elements. That is, for a nonempty list, erases all elements referred to by the iterator \text{i} in the range \([\text{begin()} + 1, \text{end()}]\) for which \text{binary_pred(*i, *(i - 1))} is \text{true}. Invalidates only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the predicate.

Complexity: If \text{empty()} is \text{false}, exactly \text{distance(begin(), end())} - 1 applications of the corresponding predicate, otherwise no applications of the predicate.

\[
\text{void \text{merge(forward_list& x);} \}
\]
\[
\text{void \text{merge(forward_list&& x);} \}
\]
\[
\text{template<class Compare> void \text{merge(forward_list& x, Compare \text{comp};}} \}
\]
\[
\text{template<class Compare> void \text{merge(forward_list&& x, Compare \text{comp);}} \}
\]

Let \text{comp} be \text{less<>} for the first two overloads.

Preconditions: \(*\text{this} and \text{x are both sorted with respect to the comparator \text{comp}}, and \text{get_allocator()} == \text{x.get_allocator()}\) is \text{true}.

Effects: If \text{addressof(\text{x}) == this}, there are no effects. Otherwise, merges the two sorted ranges \([\text{begin()}, \text{end()}]\) and \([\text{x.begin()}, \text{x.end()}]\). The result is a range that is sorted with respect to the comparator \text{comp}. Pointers and references to the moved elements of \text{x} now refer to those same elements but as members of \(*\text{this}\). Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into \(*\text{this}, not into \text{x}.

Complexity: At most \text{distance(begin(), end())} + \text{distance(x.begin(), x.end())} - 1 comparisons if \text{addressof(\text{x}) != this}; otherwise, no comparisons are performed.

Remarks: Stable (16.4.6.8). If \text{addressof(\text{x}) != this, \text{x is empty after the merge. No elements are copied by this operation. If an exception is thrown other than by a comparison, there are no effects.}

\[
\text{void \text{sort();}} \}
\]
\[
\text{template<class Compare> void \text{sort(Compare \text{comp);}} \}
\]

Effects: Sorts the list according to the \text{operator<} or the \text{comp} function object. If an exception is thrown, the order of the elements in \(*\text{this} is unspecified. Does not affect the validity of iterators and references.

Complexity: Approximately \(N \log N\) comparisons, where \(N\) is \text{distance(begin(), end())}.

Remarks: Stable (16.4.6.8).
void reverse() noexcept;

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

24.3.9.7 Erasure

template<class T, class Allocator, class U>
    typename forward_list<T, Allocator>::size_type
erase(forward_list<T, Allocator>& c, const U& value);

Effects: Equivalent to: return erase_if(c, [&]{auto& elem { return elem == value; } });

template<class T, class Allocator, class Predicate>
    typename forward_list<T, Allocator>::size_type
erase_if(forward_list<T, Allocator>& c, Predicate pred);

Effects: Equivalent to: return c.remove_if(pred);

24.3.10 Class template list

24.3.10.1 Overview

A list is a sequence container that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Unlike vectors (24.3.11) and deques (24.3.8), fast random access to list elements is not supported, but many algorithms only need sequential access anyway.

A list meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of a sequence container, including most of the optional sequence container requirements (24.2.4). The exceptions are the operator[] and at member functions, which are not provided. Descriptions are provided here only for operations on list that are not described in one of these tables or for operations where there is additional semantic information.

namespace std {
    template<class T, class Allocator = allocator<T>>
    class list {
        public:
            // types
            using value_type = T;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 24.2
            using difference_type = implementation-defined; // see 24.2
            using iterator = implementation-defined; // see 24.2
            using const_iterator = implementation-defined; // see 24.2
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::reverse_iterator<const_iterator>;

            // 24.3.10.2, construct/copy/destroy
            list() : list(Allocator()) {} }
            explicit list(const Allocator&);
            explicit list(size_type n, const Allocator& = Allocator());
            list(size_type n, const T& value, const Allocator& = Allocator());
            template<class InputIterator>
                list(InputIterator first, InputIterator last, const Allocator& = Allocator());
            template<Container-compatible-range<T> R>
                list(from_range_t, R&& rg, const Allocator& = Allocator());
            list(const list& x);
            list(list&& x);
            list(const list&, const type_identity_t<Allocator>&);

210) These member functions are only provided by containers whose iterators are random access iterators.

iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    iterator insert(const_iterator position, InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
    iterator insert_range(const_iterator position, R&& rg);
iterator erase(const_iterator position);
iterator erase(const_iterator position, const_iterator last);
void swap(list&) noexcept(allocator_traits<Allocator>::is_always_equal::value);
void clear() noexcept;

// 24.3.10.5, list operations
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);
void splice(const_iterator position, list& x, const_iterator first, const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);

size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);
size_type unique();
template<class BinaryPredicate>
    size_type unique(BinaryPredicate binary_pred);

void merge(list& x);
void merge(list&& x);
template<class Compare>
    void merge(list& x, Compare comp);
template<class Compare>
    void merge(list&& x, Compare comp);

void sort();
template<class Compare>
    void sort(Compare comp);

void reverse() noexcept;
};

3 An incomplete type T may be used when instantiating list if the allocator meets the allocator completeness requirements (16.4.4.6.2). T shall be complete before any member of the resulting specialization of list is referenced.

24.3.10.2 Constructors, copy, and assignment

```cpp
explicit list(const Allocator&);
```  
1 Effects: Constructs an empty list, using the specified allocator.

```cpp
Complexity: Constant.
```

```cpp
explicit list(size_type n, const Allocator& = Allocator());
```  
3 Preconditions: T is Cpp17DefaultInsertable into *this.

```cpp
Effects: Constructs a list with n default-inserted elements using the specified allocator.
```

```cpp
Complexity: Linear in n.
```

```cpp
list(size_type n, const T& value, const Allocator& = Allocator());
```  
6 Preconditions: T is Cpp17CopyInsertable into *this.

```cpp
Effects: Constructs a list with n copies of value, using the specified allocator.
```
8  Complexity: Linear in n.

template<class InputIterator>
list(InputIterator first, InputIterator last, const Allocator& = Allocator());

9  Effects: Constructs a list equal to the range [first,last).

Complexity: Linear in distance(first, last).

template<container-compatible-range<T> R>
list(from_range_t, R&& rg, const Allocator& = Allocator());

11  Effects: Constructs a list object with the elements of the range rg.

Complexity: Linear in ranges::distance(rg).

24.3.10.3 Capacity [list.capacity]

void resize(size_type sz);

1  Preconditions: T is Cpp17DefaultInsertable into *this.

2  Effects: If size() < sz, appends sz - size() default-inserted elements to the sequence. If sz <=
size(), equivalent to:

list<T>::iterator it = begin();
advance(it, sz);
erase(it, end());

void resize(size_type sz, const T& c);

3  Preconditions: T is Cpp17CopyInsertable into *this.

4  Effects: As if by:

if (sz > size())
  insert(end(), sz-size(), c);
else if (sz < size()) {
  iterator i = begin();
  advance(i, sz);
  erase(i, end());
} else
  // do nothing

24.3.10.4 Modifiers [list.modifiers]

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
iterator insert(const_iterator position, InputIterator first,
    InputIterator last);
template<container-compatible-range<T> R>
iterator insert_range(const_iterator position, R&& rg);
iterator insert(const_iterator position, initializer_list<T>);
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
template<container-compatible-range<T> R>
void prepend_range(R&& rg);
void push_back(const T& x);
void push_back(T&& x);
template<container-compatible-range<T> R>
void append_range(R&& rg);

1  Complexity: Insertion of a single element into a list takes constant time and exactly one call to a
constructor of T. Insertion of multiple elements into a list is linear in the number of elements inserted,
and the number of calls to the copy constructor or move constructor of \( T \) is exactly equal to the number of elements inserted.

**Remarks**: Does not affect the validity of iterators and references. If an exception is thrown there are no effects.

```cpp
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
```

```cpp
void pop_front();
void pop_back();
void clear() noexcept;
```

**Effects**: Invalidates only the iterators and references to the erased elements.

**Throws**: Nothing.

**Complexity**: Erasing a single element is a constant time operation with a single call to the destructor of \( T \). Erasing a range in a list is linear time in the size of the range and the number of calls to the destructor of type \( T \) is exactly equal to the size of the range.

### 24.3.10.5 Operations

Since lists allow fast insertion and erasing from the middle of a list, certain operations are provided specifically for them. As specified in 16.4.4.6, the requirements in this Clause apply only to lists whose allocators compare equal.

**splice** provides three splice operations that destructively move elements from one list to another. The behavior of splice operations is undefined if \( \text{get_allocator}() \neq x.\text{get_allocator}() \).

```cpp
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);
```

**Preconditions**: \( \text{addressof}(x) \neq \text{this} \) is true.

**Effects**: Inserts the contents of \( x \) before \( \text{position} \) and \( x \) becomes empty. Pointers and references to the moved elements of \( x \) now refer to those same elements but as members of \( \ast\text{this} \). Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into \( \ast\text{this}, \) not into \( x \).

**Throws**: Nothing.

**Complexity**: Constant time.

```cpp
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);
```

**Preconditions**: \( i \) is a valid dereferenceable iterator of \( x \).

**Effects**: Inserts an element pointed to by \( i \) from list \( x \) before \( \text{position} \) and removes the element from \( x \). The result is unchanged if \( \text{position} \neq i \) or \( \text{position} \neq ++i \). Pointers and references to \( \ast i \) continue to refer to this same element but as a member of \( \ast\text{this} \). Iterators to \( \ast i \) (including \( i \) itself) continue to refer to the same element, but now behave as iterators into \( \ast\text{this}, \) not into \( x \).

**Throws**: Nothing.

**Complexity**: Constant time.

```cpp
void splice(const_iterator position, list& x, const_iterator first, const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);
```

**Preconditions**: \( \text{[first, last)} \) is a valid range in \( x \). \( \text{position} \) is not an iterator in the range \( \text{[first, last)} \).

**Effects**: Inserts elements in the range \( \text{[first, last)} \) before \( \text{position} \) and removes the elements from \( x \). Pointers and references to the moved elements of \( x \) now refer to those same elements but as members...
of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

**Throws:** Nothing.

**Complexity:** Constant time if addressof(x) == this; otherwise, linear time.

```cpp
size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);
```

**Effects:** Erases all the elements in the list referred to by a list iterator i for which the following conditions hold: *i == value, pred(*i) != false. Invalidates only the iterators and references to the erased elements.

**Returns:** The number of elements erased.

**Throws:** Nothing unless an exception is thrown by *i == value or pred(*i) != false.

**Complexity:** Exactly size() applications of the corresponding predicate.

**Remarks:** Stable (16.4.6.8).

```cpp
size_type unique();
template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);
```

Let binary_pred be equal_to<>{} for the first overload.

**Preconditions:** binary_pred is an equivalence relation.

**Effects:** Erases all but the first element from every consecutive group of equivalent elements. That is, for a nonempty list, erases all elements referred to by the iterator i in the range [begin() + 1, end()) for which binary_pred(*i, *(i - 1)) is true. Invalidates only the iterators and references to the erased elements.

**Returns:** The number of elements erased.

**Throws:** Nothing unless an exception is thrown by the predicate.

**Complexity:** If empty() is false, exactly size() - 1 applications of the corresponding predicate, otherwise no applications of the predicate.

```cpp
void merge(list& x);
void merge(list&& x);
template<class Compare> void merge(list& x, Compare comp);
template<class Compare> void merge(list&& x, Compare comp);
```

Let comp be less<> for the first two overloads.

**Preconditions:** *this and x are both sorted with respect to the comparator comp, and get_allocator() == x.get_allocator() is true.

**Effects:** If addressof(x) == this, there are no effects. Otherwise, merges the two sorted ranges [begin(), end()) and [x.begin(), x.end()). The result is a range that is sorted with respect to the comparator comp. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

**Complexity:** At most size() + x.size() - 1 comparisons if addressof(x) != this; otherwise, no comparisons are performed.

**Remarks:** Stable (16.4.6.8). If addressof(x) != this, x is empty after the merge. No elements are copied by this operation. If an exception is thrown other than by a comparison there are no effects.

```cpp
void reverse() noexcept;
```

**Effects:** Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

**Complexity:** Linear time.

```cpp
void sort();
```
template<class Compare> void sort(Compare comp);

Effects: Sorts the list according to the operator< or a Compare function object. If an exception is thrown, the order of the elements in \*this is unspecified. Does not affect the validity of iterators and references.

Complexity: Approximately \(N \log N\) comparisons, where \(N = \text{size()}\).

Remarks: Stable (16.4.6.8).

24.3.10.6 Erasure

\[\text{list.\text{erase}}\]

\begin{verbatim}
template<class T, class Allocator, class U>
  typename list<T, Allocator>::size_type
  erase(list<T, Allocator>& c, const U& value);
\end{verbatim}

Effects: Equivalent to: return erase_if(c, [&](auto& elem) { return elem == value; });

\begin{verbatim}
template<class T, class Allocator, class Predicate>
  typename list<T, Allocator>::size_type
  erase_if(list<T, Allocator>& c, Predicate pred);
\end{verbatim}

Effects: Equivalent to: return c.remove_if(pred);

24.3.11 Class template vector

24.3.11.1 Overview

A vector is a sequence container that supports (amortized) constant time insert and erase operations at the end; insert and erase in the middle take linear time. Storage management is handled automatically, though hints can be given to improve efficiency.

A vector meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), of a sequence container, including most of the optional sequence container requirements (24.2.4), and, for an element type other than bool, of a contiguous container (24.2.2.2). The exceptions are the push_front, prepend_range, pop_front, and emplace_front member functions, which are not provided. Descriptions are provided here only for operations on vector that are not described in one of these tables or for operations where there is additional semantic information.

The types iterator and const_iterator meet the constexpr iterator requirements (25.3.1).

namespace std {
  template<class T, class Allocator = allocator<T>>
  class vector {
    public:
      // types
      using value_type = T;
      using allocator_type = Allocator;
      using pointer = typename allocator_traits<Allocator>::pointer;
      using const_pointer = typename allocator_traits<Allocator>::const_pointer;

    noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
        allocator_traits<Allocator>::is_always_equal::value);
constexpr void clear() noexcept;
};

template<class InputIterator, class Allocator = allocator<
iter-value-type<InputIterator>>>
vector(InputIterator, InputIterator, Allocator = Allocator())
    -> vector<iter-value-type<InputIterator>, Allocator>;
template<ranges::input_range R, class Allocator = allocator<ranges::range_value_t<R>>>
vector(from_range_t, R&&, Allocator = Allocator())
    -> vector<ranges::range_value_t<R>, Allocator>;

An incomplete type T may be used when instantiating vector if the allocator meets the allocator completeness requirements (16.4.4.6.2). T shall be complete before any member of the resulting specialization of vector is referenced.

24.3.11.2 Constructors

constexpr explicit vector(const Allocator&) noexcept;

   Effects: Constructs an empty vector, using the specified allocator.

   Complexity: Constant.

constexpr explicit vector(size_type n, const Allocator& = Allocator());

   Preconditions: T is Cpp17DefaultInsertable into *this.

   Effects: Constructs a vector with n default-inserted elements using the specified allocator.

   Complexity: Linear in n.

constexpr vector(size_type n, const T& value,
    const Allocator& = Allocator());

   Preconditions: T is Cpp17CopyInsertable into *this.

   Effects: Constructs a vector with n copies of value, using the specified allocator.

   Complexity: Linear in n.

template<class InputIterator>
constexpr vector(InputIterator first, InputIterator last,
    const Allocator& = Allocator());

   Effects: Constructs a vector equal to the range [first, last), using the specified allocator.

   Complexity: Makes only N calls to the copy constructor of T (where N is the distance between first and last) and no reallocations if iterators first and last are of forward, bidirectional, or random access categories. It makes order N calls to the copy constructor of T and order \log N reallocations if they are just input iterators.

template<container-compatible-range<T> R>
constexpr vector(from_range_t, R&& rg, const Allocator& = Allocator());

   Effects: Constructs a vector object with the elements of the range rg, using the specified allocator.
Complexity: Initializes exactly \( N \) elements from the results of dereferencing successive iterators of \( rg \), where \( N \) is \texttt{ranges::distance}(rg). Performs no reallocations if \( R \) models \texttt{ranges::forward_range} or \texttt{ranges::sized_range}; otherwise, performs order \( \log N \) reallocations and order \( N \) calls to the copy or move constructor of \( T \).

24.3.11.3 Capacity

```cpp
constexpr size_type capacity() const noexcept;
```

Returns: The total number of elements that the vector can hold without requiring reallocation.

Complexity: Constant time.

```cpp
constexpr void reserve(size_type n);
```

Preconditions: \( T \) is \texttt{Cpp17MoveInsertable} into *this.

Effects: A directive that informs a vector of a planned change in size, so that it can manage the storage allocation accordingly. After \texttt{reserve()}, \texttt{capacity()} is greater or equal to the argument of \texttt{reserve} if reallocation happens; and equal to the previous value of \texttt{capacity()} otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of \texttt{reserve}(). If an exception is thrown other than by the move constructor of a non-\texttt{Cpp17CopyInsertable} type, there are no effects.

Throws: \texttt{length_error} if \( n > \texttt{max_size()} \).

Complexity: It does not change the size of the sequence and takes at most linear time in the size of the sequence.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence, as well as the past-the-end iterator.

[Note 1: If no reallocation happens, they remain valid. — end note]

No reallocation shall take place during insertions that happen after a call to \texttt{reserve()} until an insertion would make the size of the vector greater than the value of \texttt{capacity()}.

```cpp
constexpr void shrink_to_fit();
```

Preconditions: \( T \) is \texttt{Cpp17MoveInsertable} into *this.

Effects: \texttt{shrink_to_fit} is a non-binding request to reduce \texttt{capacity()} to \texttt{size()}.

[Note 2: The request is non-binding to allow latitude for implementation-specific optimizations. — end note]

It does not increase \texttt{capacity()}, but may reduce \texttt{capacity()} by causing reallocation. If an exception is thrown other than by the move constructor of a non-\texttt{Cpp17CopyInsertable} \( T \) there are no effects.

Complexity: If reallocation happens, linear in the size of the sequence.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator.

[Note 3: If no reallocation happens, they remain valid. — end note]

```cpp
constexpr void swap(vector& x)
    noexcept(algorithm_traits<Algorithm>::propagate_on_container_swap::value ||
             algorithm_traits<Algorithm>::is_always_equal::value);
```

Effects: Exchanges the contents and \texttt{capacity()} of *this with that of \( x \).

Complexity: Constant time.

```cpp
constexpr void resize(size_type sz);
```

Preconditions: \( T \) is \texttt{Cpp17MoveInsertable} and \texttt{Cpp17DefaultInsertable} into *this.

Effects: If \( sz < \texttt{size()} \), erases the last \( \texttt{size()} - sz \) elements from the sequence. Otherwise, appends \( sz - \texttt{size()} \) default-inserted elements to the sequence.

Remarks: If an exception is thrown other than by the move constructor of a non-\texttt{Cpp17CopyInsertable} \( T \) there are no effects.

\footnote{\texttt{reserve()} uses \texttt{Allocator::allocate()} which can throw an appropriate exception.}
constexpr void resize(size_type sz, const T& c);

Preconditions: T is Cpp17CopyInsertable into *this.

Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends
sz - size() copies of c to the sequence.

Remarks: If an exception is thrown there are no effects.

### 24.3.11.4 Data

```cpp
constexpr T* data() noexcept;
constexpr const T* data() const noexcept;
```

Returns: A pointer such that [data(), data() + size()) is a valid range. For a non-empty vector,
data() == addressof(front()).

Complexity: Constant time.

### 24.3.11.5 Modifiers

```cpp
constexpr iterator insert(const_iterator position, const T& x);
constexpr iterator insert(const_iterator position, T&& x);
c templ ene class InputIterator>
  constexpr iterator insert(const_iterator position, InputIterator first, InputIterator last);
template<container-compatible-range<T> R>
  constexpr iterator insert_range(const_iterator position, R&& rg);
c templ ene class InputIterator>
  constexpr iterator insert(const_iterator position, initializer_list<T>);
```

Effects: Invalidates iterators and references at or after the point of the erase.

Throws: Nothing unless an exception is thrown by the assignment operator or move assignment operator of T.

Complexity: The destructor of T is called the number of times equal to the number of the elements erased, but the assignment operator of T is called the number of times equal to the number of elements in the vector after the erased elements.

### 24.3.11.6 Erasure

```cpp
template<class T, class Allocator, class U>
  constexpr typename vector<T, Allocator>::size_type
      erase(vector<T, Allocator>& c, const U& value);
```

Effects: Equivalent to:
auto it = remove(c.begin(), c.end(), value);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;

template<class T, class Allocator, class Predicate>
constexpr typename vector<T, Allocator>::size_type
erase_if(vector<T, Allocator>& c, Predicate pred);

Effects: Equivalent to:
auto it = remove_if(c.begin(), c.end(), pred);
auto r = distance(it, c.end());
c.erase(it, c.end());
return r;

24.3.12 Specialization of vector for bool [vector.bool]
24.3.12.1 Partial class template specialization vector<bool, Allocator> [vector.bool.pspc]

To optimize space allocation, a partial specialization of vector for bool elements is provided:

namespace std {
    template<class Allocator>
    class vector<bool, Allocator> {
    public:
      // types
      using value_type = bool;
      using allocator_type = Allocator;
      using pointer = implementation-defined;
      using const_pointer = implementation-defined;
      using const_reference = bool;
      using size_type = implementation-defined;
      using difference_type = implementation-defined;
      using iterator = implementation-defined;
      using const_iterator = implementation-defined;
      using reverse_iterator = std::reverse_iterator<iterator>;
      using const_reverse_iterator = std::reverse_iterator<const_iterator>;

      // bit reference
      class reference {
        friend class vector;
        constexpr reference() noexcept;
        public:
          constexpr reference(const reference&) = default;
          constexpr ~reference();
          constexpr operator bool() const noexcept;
          constexpr reference& operator=(bool x) noexcept;
          constexpr reference& operator=(const reference& x) noexcept;
          constexpr const reference& operator=(bool x) const noexcept;
          constexpr void flip() noexcept; // flips the bit
      };

      // construct/copy/destroy
      constexpr vector() noexcept(noexcept(Allocator())) : vector(Allocator()) {} 
      constexpr explicit vector(const Allocator&) noexcept;
      constexpr explicit vector(size_type n, const Allocator& = Allocator());
      constexpr vector(size_type n, const bool& value, const Allocator& = Allocator());
      template<class InputIterator>
      constexpr vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
      template<container-compatible-range<br> R>
      constexpr vector(from_range_t, R&& rg, const Allocator& = Allocator());
      constexpr vector(const vector&) noexcept;
      constexpr vector(vector&&) noexcept;
      constexpr vector(const vector&, const type_identity_t<Allocator>&);
      constexpr vector(vector&&, const type_identity_t<Allocator>&);
    };

§ 24.3.12.1
constexpr vector(initializer_list<bool>, const Allocator& = Allocator());
constexpr ~vector();
constexpr vector& operator=(const vector& x);
constexpr vector& operator=(vector&& x)
    noexcept(algorithm_traits<Allocator>::propagate_on_container_move_assignment::value ||

constexpr const_reference back() const;

// modifiers
template<class... Args> constexpr reference emplace_back(Args&&... args);
constexpr void push_back(const bool& x);
template<container-compatible-range<bool> R>
constexpr void append_range(R&& rg);
constexpr void pop_back();
template<class... Args> constexpr iterator emplace(const_iterator position, Args&&... args);
constexpr iterator insert(const_iterator position, const bool& x);
constexpr iterator insert(const_iterator position, size_type n, const bool& x);
template<class InputIterator>
constexpr iterator insert(const_iterator position,
    InputIterator first, InputIterator last);
template<container-compatible-range<bool> R>
constexpr iterator insert_range(const_iterator position, R&& rg);
constexpr iterator insert(const_iterator position, initializer_list<bool> il);
constexpr iterator erase(const_iterator position);
constexpr iterator erase(const_iterator first, const_iterator last);
constexpr void swap(vector&&) noexcept(algorithm_traits<Allocator>::propagate_on_container_swap::value || 
    algorithm_traits<Allocator>::is_always_equal::value);
static constexpr void swap(reference x, reference y) noexcept;
constexpr void flip() noexcept; // flips all bits
constexpr void clear() noexcept;
};

2 Unless described below, all operations have the same requirements and semantics as the primary vector template, except that operations dealing with the bool value type map to bit values in the container storage and algorithm_traits::construct (20.2.9.3) is not used to construct these values.

3 There is no requirement that the data be stored as a contiguous allocation of bool values. A space-optimized representation of bits is recommended instead.

4 reference is a class that simulates the behavior of references of a single bit in vector<bool>. The conversion function returns true when the bit is set, and false otherwise. The assignment operators set the bit when the argument is (convertible to) true and clear it otherwise. flip reverses the state of the bit.

customexpr void flip() noexcept;

5 Effects: Replaces each element in the container with its complement.

static constexpr void swap(reference x, reference y) noexcept;

6 Effects: Exchanges the contents of x and y as if by:
    bool b = x;
    x = y;
    y = b;

template<class Allocator> struct hash<vector<bool, Allocator>>;

7 The specialization is enabled (22.10.19).

template<class T>
customexpr bool is-vector-bool-reference = see below;

8 The expression is-vector-bool-reference<T> is true if T denotes the type vector<bool, Alloc>::reference for some type Alloc and vector<bool, Alloc> is not a program-defined specialization.

24.3.12.2 Formatter specialization for vector<bool> [vector.bool.fmt]

namespace std {
    template<class T, class charT>
        requires is-vector-bool-reference<T>
    struct formatter<T, charT> {
        private:
            formatter<bool, charT> underlying_; // exposition only

        public:
            template<class ParseContext>
                constexpr typename ParseContext::iterator
                    parse(ParseContext& ctx);

            template<class FormatContext>
                typename FormatContext::iterator
                    format(const T& ref, FormatContext& ctx) const;
        };
    }

template<class ParseContext>
    constexpr typename ParseContext::iterator
        parse(ParseContext& ctx);

1 Equivalent to: return underlying_.parse(ctx);
template<class FormatContext>
typename FormatContext::iterator
    format(const T& ref, FormatContext& ctx) const;

Equivalent to: return underlying_.format(ref, ctx);

24.4  Associative containers

24.4.1 In general

The header <map> defines the class templates map and multimap; the header <set> defines the class templates set and multiset.

The following exposition-only alias templates may appear in deduction guides for associative containers:

```cpp
template<class InputIterator>
    using iter-value-type = typename iterator_traits<InputIterator>::value_type;  // exposition only

template<class InputIterator>
    using iter-key-type = remove_const_t<
        tuple_element_t<0,
            iter-value-type<InputIterator>>>;  // exposition only

template<class InputIterator>
    using iter-mapped-type =
        tuple_element_t<1,
            iter-value-type<InputIterator>>;  // exposition only

template<class InputIterator>
    using iter-to-alloc-type = pair<
        add_const_t<
            tuple_element_t<0,
                iter-value-type<InputIterator>>>,
        tuple_element_t<1,
            iter-value-type<InputIterator>>>;  // exposition only

template<ranges::input_range Range>
    using range-key-type =
        remove_const_t<typename ranges::range_value_t<Range>::first_type>;  // exposition only

template<ranges::input_range Range>
    using range-mapped-type = typename ranges::range_value_t<Range>::second_type;  // exposition only

template<ranges::input_range Range>
    using range-to-alloc-type =
        pair<add_const_t<typename ranges::range_value_t<Range>::first_type>,
            typename ranges::range_value_t<Range>::second_type>;  // exposition only
```

24.4.2 Header <map> synopsis

```cpp
#include <compare>  // see 17.11.1
#include <initializer_list>  // see 17.10.2

namespace std {
    // 24.4.4, class template map
    template<class Key, class T, class Compare = less<Key>,
        class Allocator = allocator<pair<const Key, T>>>
        class map;

    template<class Key, class T, class Compare, class Allocator>
        bool operator==(const map<Key, T, Compare, Allocator>& x,
            const map<Key, T, Compare, Allocator>& y);

    template<class Key, class T, class Compare, class Allocator>
        synth-three-way-result<pair<const Key, T>>
            operator<=>(const map<Key, T, Compare, Allocator>& x,
                const map<Key, T, Compare, Allocator>& y);

    template<class Key, class T, class Compare, class Allocator>
        void swap(map<Key, T, Compare, Allocator>& x,
            map<Key, T, Compare, Allocator>& y);

    // 24.4.4.5, erasure for map
    template<class Key, class T, class Compare, class Allocator, class Predicate>
        typename map<Key, T, Compare, Allocator>::size_type
            erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);
```
24.4.5, class template multimap

```cpp
template<class Key, class T, class Compare = less<Key>,
    class Allocator = allocator<pair<const Key, T>>>
class multimap;
```

```cpp
template<class Key, class T, class Compare, class Allocator>
bool operator==(const multimap<Key, T, Compare, Allocator>& x,
    const multimap<Key, T, Compare, Allocator>& y);
```

```cpp
template<class Key, class T, class Compare, class Allocator>
synth-three-way-result<pair<const Key, T>>
operator<=>(const multimap<Key, T, Compare, Allocator>& x,
    const multimap<Key, T, Compare, Allocator>& y);
```

```cpp
template<class Key, class T, class Compare, class Allocator>
void swap(multimap<Key, T, Compare, Allocator>& x,
    multimap<Key, T, Compare, Allocator>& y)
    noexcept(noexcept(x.swap(y)));  
```

24.4.5.4, erasure for multimap

```cpp
namespace pmr {
    template<class Key, class T, class Compare = less<Key>>
    using map = std::map<Key, T, Compare,
            polymorphic_allocator<pair<const Key, T>>;

    template<class Key, class T, class Compare = less<Key>>
    using multimap = std::multimap<Key, T, Compare,
            polymorphic_allocator<pair<const Key, T>>;
}
```
template<class Key, class Compare, class Allocator>
bool operator==(const multiset<Key, Compare, Allocator>& x,
    const multiset<Key, Compare, Allocator>& y);

template<class Key, class Compare, class Allocator>
synth-three-way-result<Key> operator<=>(const multiset<Key, Compare, Allocator>& x,
    const multiset<Key, Compare, Allocator>& y);

template<class Key, class Compare, class Allocator>
void swap(multiset<Key, Compare, Allocator>& x,
    multiset<Key, Compare, Allocator>& y)
    noexcept(noexcept(x.swap(y)));

// 24.4.7.3, erasure for multiset
template<class Key, class Compare, class Allocator, class Predicate>
    typename multiset<Key, Compare, Allocator>::size_type
    erase_if(multiset<Key, Compare, Allocator>& c, Predicate pred);

namespace pmr {
    template<class Key, class Compare = less<Key>>
        set<Key, Compare, polymorphic_allocator<Key>>
    template<class Key, class Compare = less<Key>>
        multiset<Key, Compare, polymorphic_allocator<Key>>
} namespace std {
    template<class Key, class T, class Compare = less<Key>,
        class Allocator = allocator<pair<const Key, T>>>

§ 24.4.4.1
24.4.4.2 Constructors, copy, and assignment

```
explicit map(const Compare& comp, const Allocator& = Allocator());
```

**Effects:** Constructs an empty `map` using the specified comparison object and allocator.

**Complexity:** Constant.

```
template<class InputIterator>
map(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());
```

**Effects:** Constructs an empty `map` using the specified comparison object and allocator, and inserts elements from the range `[first, last)`.

**Complexity:** Linear in \(N\) if the range `[first, last)` is already sorted with respect to `comp` and otherwise \(N \log N\), where \(N\) is `last - first`.

```
template<container-compatible-range<value_type> R>
map(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());
```

**Effects:** Constructs an empty `map` using the specified comparison object and allocator, and inserts elements from the range `rg`.

**Complexity:** Linear in \(N\) if `rg` is already sorted with respect to `comp` and otherwise \(N \log N\), where \(N\) is `ranges::distance(rg)`.

24.4.4.3 Element access

```
mapped_type& operator[](const key_type& x);
```

**Effects:** Equivalent to: \(\text{return try\_emplace(x).first->second;}\)

```
mapped_type& operator[](key_type&& x);
```

**Effects:** Equivalent to: \(\text{return try\_emplace(std::move(x)).first->second;}\)

```
mapped_type& at(const key_type& x);
const mapped_type& at(const key_type& x) const;
```

**Returns:** A reference to the `mapped_type` corresponding to `x` in `*this`.

**Throws:** An exception object of type `out_of_range` if no such element is present.

**Complexity:** Logarithmic.

24.4.4.4 Modifiers

```
template<class P>
pair<iterator, bool> insert(P&& x);
template<class P>
iterator insert(const_iterator position, P&& x);
```

**Constraints:** `is_constructible_v<value_type, P&&>` is `true`.

**Effects:** The first form is equivalent to `return emplace(std::forward<P>(x)).first->second;`. The second form is equivalent to `return emplace_hint(position, std::forward<P>(x)).`.

```
template<class... Args>
pair<iterator, bool> try_emplace(const key_type& k, Args&... args);
template<class... Args>
iterator try_emplace(const_iterator hint, const key_type& k, Args&... args);
```

**Preconditions:** `value_type` is `Cpp17EmplaceConstructible` into `map` from `piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...)`.

**Effects:** If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...)`.

**Returns:** In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.

**Complexity:** The same as `emplace` and `emplace_hint`, respectively.
template<class... Args>
  pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);

template<class... Args>
  iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);

Preconditions: value_type is C++17EmplaceConstructible into map from piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
  pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);

template<class M>
  iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.

Preconditions: value_type is C++17EmplaceConstructible into map from k, std::forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with k, std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
  pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);

template<class M>
  iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.

Preconditions: value_type is C++17EmplaceConstructible into map from std::move(k), std::forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with std::move(k), std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

### 24.4.4.5 Erasure

```
template<class Key, class T, class Compare, class Allocator, class Predicate>
  typename map<Key, T, Compare, Allocator>::size_type
  erase_if(map<Key, T, Compare, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:
```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```
24.4.5 Class template multimap

24.4.5.1 Overview

A multimap is an associative container that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type T based on the keys. The multimap class supports bidirectional iterators.

A multimap meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of an associative container (24.2.7). A multimap also provides most operations described in 24.2.7 for equal keys. This means that a multimap supports the a_eq operations in 24.2.7 but not the a_uniq operations. For a multimap<Key,T> the key_type is Key and the value_type is pair<const Key,T>. Descriptions are provided here only for operations on multimap that are not described in one of those tables or for operations where there is additional semantic information.

namespace std {

-> multimap<Key, T, less<Key>, Allocator>;

24.4.5.2 Constructors
[multimap.cons]

explicit multimap(const Compare& comp, const Allocator& = Allocator());

1 Effects: Constructs an empty multimap using the specified comparison object and allocator.
2 Complexity: Constant.

template<class InputIterator>
multimap(InputIterator first, InputIterator last,
const Compare& comp = Compare(),
const Allocator& = Allocator());

3 Effects: Constructs an empty multimap using the specified comparison object and allocator, and inserts elements from the range [first, last).
4 Complexity: Linear in \( N \) if the range [first, last) is already sorted with respect to \( \text{comp} \) and otherwise \( N \log N \), where \( N = \text{last} - \text{first} \).

template<
container-compatible-range<value_type> R>
multimap(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());

5 Effects: Constructs an empty multimap using the specified comparison object and allocator, and inserts elements from the range \( \text{rg} \).
6 Complexity: Linear in \( N \) if \( \text{rg} \) is already sorted with respect to \( \text{comp} \) and otherwise \( N \log N \), where \( N = \text{ranges::distance(rg)} \).

24.4.5.3 Modifiers
[multimap.modifiers]

template<class P> iterator insert(P&& x);
template<class P> iterator insert(const_iterator position, P&& x);

1 Constraints: is_constructible_v<value_type, P&&> is true.
2 Effects: The first form is equivalent to return emplace(std::forward<P>(x)). The second form is equivalent to return emplace_hint(position, std::forward<P>(x)).

24.4.5.4 Erasure
[multimap.erasure]

template<class Key, class T, class Compare, class Allocator, class Predicate>
typename multimap<Key, T, Compare, Allocator>::size_type
erase_if(multimap<Key, T, Compare, Allocator>& c, Predicate pred);

1 Effects: Equivalent to:
   auto original_size = c.size();
   for (auto i = c.begin(), last = c.end(); i != last; ) {
      if (pred(*i)) {
         i = c.erase(i);
      } else {
         auto new_size = c.size();
         if (new_size < original_size) {
            // Handle underflow
         } else { // Handle overflow
            // Handle overflow
         }
      }
   }

§ 24.4.5.4
24.4.6.1 Overview

A `set` is an associative container that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of the keys themselves. The `set` class supports bidirectional iterators.

A `set` meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of an associative container (24.2.7). A `set` also provides most operations described in 24.2.7 for unique keys. This means that a `set` supports the `a_uniq` operations in 24.2.7 but not the `a_eq` operations. For a `set<Key>` both the `key_type` and `value_type` are `Key`. Descriptions are provided here only for operations on `set` that are not described in one of these tables and for operations where there is additional semantic information.

namespace std {
    template<class Key, class Compare = less<Key>,
            class Allocator = allocator<Key>>

}

### 24.4.6.2 Constructors, copy, and assignment

```cpp
explicit set(const Compare& comp, const Allocator& = Allocator());
```

1. **Effects**: Constructs an empty set using the specified comparison object and allocator.
2. **Complexity**: Constant.

```cpp
template<class InputIterator>
set(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());
```

3. **Effects**: Constructs an empty set using the specified comparison object and allocator, and inserts elements from the range `[first, last)`.
4. **Complexity**: Linear in \( N \) if the range `[first, last)` is already sorted with respect to \( \text{comp} \) and otherwise \( N \log N \), where \( N \) is \( \text{last - first} \).

```cpp
template<container-compatible-range<value_type> R>
set(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());
```

5. **Effects**: Constructs an empty set using the specified comparison object and allocator, and inserts elements from the range \( \text{rg} \).
6. **Complexity**: Linear in \( N \) if \( \text{rg} \) is already sorted with respect to \( \text{comp} \) and otherwise \( N \log N \), where \( N \) is \( \text{ranges::distance(rg)} \).

### 24.4.6.3 Erasure

```cpp
template<class Key, class Compare, class Allocator, class Predicate>
type_name set<Key, Compare, Allocator>::-size_type
    erase_if(set<Key, Compare, Allocator>& c, Predicate pred);
```

1. **Effects**: Equivalent to:
   ```cpp
   auto original_size = c.size();
   for (auto i = c.begin(), last = c.end(); i != last; ) {
       if (pred(*i)) {
           i = c.erase(i);
       } else {
           ++i;
       }
   }
   return original_size - c.size();
   ```

### 24.4.7 Class template multiset

#### 24.4.7.1 Overview

A **multiset** is an associative container that supports equivalent keys (i.e., possibly contains multiple copies of the same key value) and provides for fast retrieval of the keys themselves. The **multiset** class supports bidirectional iterators.

A **multiset** meets all of the requirements of a container (24.2.2.2), of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), of an associative container (24.2.7). **multiset** also provides most operations described in 24.2.7 for duplicate keys. This means that a **multiset** supports the `a_eq` operations in 24.2.7 but not the `a_uniq` operations. For a **multiset<Key>** both the `key_type` and `value_type` are `Key`. Descriptions are provided here only for operations on **multiset** that are not described in one of these tables and for operations where there is additional semantic information.

```cpp
namespace std {
    template<class Key, class Compare = less<Key>,
        class Allocator = allocator<Key>>
    class multiset {
        public:
            // types
            using key_type = Key;
```
using key_compare = Compare;

§ 24.4.7.2 957

24.4.7.2 Constructors

explicit multiset(const Compare& comp, const Allocator& = Allocator());

Effects: Constructs an empty multiset using the specified comparison object and allocator.

Complexity: Constant.

template<class InputIterator>
multiset(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty multiset using the specified comparison object and allocator, and inserts
elements from the range [first, last).

Complexity: Linear in $N$ if the range [first, last) is already sorted with respect to comp and otherwise
$N \log N$, where $N$ is last - first.

template<container-compatible-range<value_type> R>
multiset(from_range_t, R&& rg, const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty multiset using the specified comparison object and allocator, and inserts
elements from the range rg.
Complexity: Linear in $N$ if $rg$ is already sorted with respect to $\text{comp}$ and otherwise $N \log N$, where $N$ is $\text{ranges::distance}(rg)$.

24.4.7.3 Erasure

```cpp
template<class Key, class Compare, class Allocator, class Predicate>
typename multiset<Key, Compare, Allocator>::size_type
erase_if(multiset<Key, Compare, Allocator>& c, Predicate pred);
```

Effects: Equivalent to:
```
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
```

24.5 Unordered associative containers

24.5.1 In general

The header `<unordered_map>` defines the class templates `unordered_map` and `unordered_multimap`; the header `<unordered_set>` defines the class templates `unordered_set` and `unordered_multiset`.

The exposition-only alias templates `iter-value-type`, `iter-key-type`, `iter-mapped-type`, `iter-to-alloc-type`, `range-key-type`, `range-mapped-type`, and `range-to-alloc-type` defined in 24.4.1 may appear in deduction guides for unordered containers.

24.5.2 Header `<unordered_map>` synopsis

```cpp
#include <compare>         // see 17.11.1
#include <initializer_list> // see 17.10.2

namespace std {
  // 24.5.4, class template unordered_map
  template<class Key, class T, class Hash = hash<Key>,
           class Pred = equal_to<Key>,
           class Alloc = allocator<pair<const Key, T>>>
  class unordered_map;

  // 24.5.5, class template unordered_multimap
  template<class Key, class T, class Hash = hash<Key>,
           class Pred = equal_to<Key>,
           class Alloc = allocator<pair<const Key, T>>>
  class unordered_multimap;

  template<class Key, class T, class Hash, class Pred, class Alloc>
  bool operator==(const unordered_map<Key, T, Hash, Pred, Alloc>& a,
                  const unordered_map<Key, T, Hash, Pred, Alloc>& b);

  template<class Key, class T, class Hash, class Pred, class Alloc>

    polymorphic_allocator<Key>>;
}

24.5.4  Class template unordered_map

24.5.4.1  Overview

1 An unordered_map is an unordered associative container that supports unique keys (an unordered_map contains at most one of each key value) and that associates values of another type mapped_type with the keys. The unordered_map supports forward iterators.

2 An unordered_map meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), and of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_map supports the \texttt{a uniq} operations in that table, not the \texttt{a eq} operations. For an unordered_map\langle Key, T\rangle the key_type is Key, the mapped_type is T, and the value_type is pair<const Key, T>.

3 Subclause 24.5.4 only describes operations on unordered_map that are not described in one of the requirement tables, or for which there is additional semantic information.

namespace std {
  template<class Key,
    class T,
    class Hash = hash<Key>,
    class Pred = equal_to<Key>,
    class Allocator = allocator<pair<const Key, T>>>
  class unordered_map {
    public:
      // types
      using key_type = Key;
      using mapped_type = T;
      using value_type = pair<const Key, T>;

template<
class Key, class T, class Allocator>
unordered_map(initializer_list<pair<Key, T>>, Allocator)
  -> unordered_map<Key, T, hash<Key>, equal_to<Key>, Allocator>;

§ 24.5.4.1
template<class Key, class T, class Hash, class Allocator>  
unordered_map(initializer_list<pair<Key, T>>, typename see below::size_type, Hash,  
Allocator)  
-> unordered_map<Key, T, Hash, equal_to<Key>, Allocator>;  

A size_type parameter type in an unordered_map deduction guide refers to the size_type member type of the type deduced by the deduction guide.

24.5.4.2 Constructors  

unordered_map() : unordered_map(size_type(see below)) {}  
explicit unordered_map(size_type n,  
const hasher& hf = hasher(),  
const key_equal& eql = key_equal(),  
const allocator_type& a = allocator_type());  

Effects: Constructs an empty unordered_map using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.

template<class InputIterator>  
unordered_map(InputIterator f, InputIterator l,  
size_type n = see below,  
const hasher& hf = hasher(),  
const key_equal& eql = key_equal(),  
const allocator_type& a = allocator_type());  

template<container-compatible-range<value_type> R>  
unordered_map(from_range_t, R& rg,  
size_type n = see below,  
const hasher& hf = hasher(),  
const key_equal& eql = key_equal(),  
const allocator_type& a = allocator_type());  

Effects: Constructs an empty unordered_map using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l), rg, or il, respectively. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

24.5.4.3 Element access  
mapped_type& operator[](const key_type& k);  

Effects: Equivalent to: return try_emplace(k).first->second;

mapped_type& operator[](key_type&& k);  

Effects: Equivalent to: return try_emplace(std::move(k)).first->second;

mapped_type& at(const key_type& k);  
const mapped_type& at(const key_type& k) const;  

Returns: A reference to x.second, where x is the (unique) element whose key is equivalent to k.

Throws: An exception object of type out_of_range if no such element is present.

24.5.4.4 Modifiers  

template<class P>  
pair<iterator, bool> insert(P&& obj);  

Constraints: is_constructible_v<value_type, P&&> is true.
Effects: Equivalent to: return emplace(std::forward<P>(obj));

template<class P>
iterator insert(const_iterator hint, P&& obj);

Constraints: is_constructible_v<value_type, P&&> is true.
Effects: Equivalent to: return emplace_hint(hint, std::forward<P>(obj));

template<class... Args>
pair<iterator, bool> try_emplace(const_iterator hint, const key_type& k, Args&&... args);

Preconditions: value_type is Cpp17EmplaceConstructible into unordered_map from piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).
Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).
Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.
Complexity: The same as emplace and emplace_hint, respectively.

template<class... Args>
pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);

Preconditions: value_type is Cpp17EmplaceConstructible into unordered_map from piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).
Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).
Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.
Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.
Preconditions: value_type is Cpp17EmplaceConstructible into unordered_map from m, std::forward<M>(obj).
Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with std::forward<M>(obj).
Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.
Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

Mandates: is_assignable_v<mapped_type&, M&&> is true.
Preconditions: value_type is Cpp17EmplaceConstructible into unordered_map from std::move(k), std::forward<M>(obj).
Effects: Equivalent to: return emplace(std::forward<P>(obj));

§ 24.5.4.4 966
Effects: If the map already contains an element e whose key is equivalent to k, assigns \( \text{std::forward<M>(obj)} \) to e.second. Otherwise inserts an object of type value_type constructed with \( \text{std::move(k), std::forward<M>(obj)} \).

Returns: In the first overload, the bool component of the returned pair is \text{true} if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

24.5.4.5 Erasure

```cpp
template<class K, class T, class H, class P, class A, class Predicate>
typename unordered_map<K, T, H, P, A>::size_type
erase_if(unordered_map<K, T, H, P, A>& c, Predicate pred);
```

Effects: Equivalent to:

```cpp
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
} return original_size - c.size();
```

24.5.5 Class template unordered_multimap

### 24.5.5.1 Overview

An unordered_multimap is an unordered associative container that supports equivalent keys (an instance of unordered_multimap may contain multiple copies of each key value) and that associates values of another type mapped_type with the keys. The unordered_multimap class supports forward iterators.

An unordered_multimap meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), and of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for equivalent keys; that is, an unordered_multimap supports the \text{a_eq} operations in that table, not the \text{a_uniq} operations. For an unordered_multimap\(\text{<Key, T>}\) the key_type is Key, the mapped_type is T, and the value_type is \text{pair<const Key, T>}.

Subclause 24.5.5 only describes operations on unordered_multimap that are not described in one of the requirement tables, or for which there is additional semantic information.

```cpp
namespace std {
    template<class Key, class T, class Hash = hash<Key>,
    class Pred = equal_to<Key>,
    class Allocator = allocator<pair<const Key, T>>>
    class unordered_multimap {
    public:
        // types
        using key_type = Key;
        using mapped_type = T;
        using value_type = pair<const Key, T>;
        using hasher = Hash;
        using key_equal = Pred;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 24.2
        using difference_type = implementation-defined; // see 24.2
        using iterator = implementation-defined; // see 24.2
        using const_iterator = implementation-defined; // see 24.2
```
using local_iterator = implementation-defined; // see 24.2
using const_local_iterator = implementation-defined; // see 24.2
using node_type = unspecified;

    -> unordered_multimap<Key, T, hash<Key>, equal_to<Key>, Allocator>;

24.5.5.2 Constructors

unordered_multimap() : unordered_multimap(size_type(see below)) {}  
explicit unordered_multimap(size_type n,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

1 Effects: Constructs an empty unordered_multimap using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

2 Complexity: Constant.

template<
    class InputIterator>
unordered_multimap(InputIterator f, InputIterator l,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

§ 24.5.5.2
template<container-compatible-range<value_type> R>
unordered_multimap(from_range_t, R&& rg,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
unordered_multimap(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

**Effects**: Constructs an empty unordered_multimap using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f,l), rg, or il, respectively. max_load_factor() returns 1.0.

**Complexity**: Average case linear, worst case quadratic.

### 24.5.5.3 Modifiers

```
template<class P>
iterator insert(P&& obj);
```

**Constraints**: is_constructible_v<value_type, P&&> is true.

**Effects**: Equivalent to: return emplace(std::forward<P>(obj));

```
template<class P>
iterator insert(const_iterator hint, P&& obj);
```

**Constraints**: is_constructible_v<value_type, P&&> is true.

**Effects**: Equivalent to: return emplace_hint(hint, std::forward<P>(obj));

### 24.5.5.4 Erasure

```
template<class K, class T, class H, class P, class A, class Predicate>
typename unordered_multimap<K, T, H, P, A>::size_type
erase_if(unordered_multimap<K, T, H, P, A>& c, Predicate pred);
```

**Effects**: Equivalent to:

```cpp
type original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
    if (pred(*i)) {
        i = c.erase(i);
    } else {
        ++i;
    }
}
return original_size - c.size();
```

### 24.5.6 Class template unordered_set

#### 24.5.6.1 Overview

An unordered_set is an unordered associative container that supports unique keys (an unordered_set contains at most one of each key value) and in which the elements’ keys are the elements themselves. The unordered_set class supports forward iterators.

An unordered_set meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_set supports the a_uniq operations in that table, not the a_eq operations. For an unordered_set<Key> the key_type and the value_type are both Key. The iterator and const_iterator types are both constant iterator types. It is unspecified whether they are the same type.

Subclause 24.5.6 only describes operations on unordered_set that are not described in one of the requirement tables, or for which there is additional semantic information.

void reserve(size_type n);
};
A size_type parameter type in an unordered_set deduction guide refers to the size_type member type of the type deduced by the deduction guide.

### 24.5.6.2 Constructors

unordered_set() : unordered_set(size_type(see below)) { }

### Effects

Constructs an empty unordered_set using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is
implementation-defined. \texttt{max\_load\_factor()} returns 1.0.

\textbf{Complexity:} Constant.

\begin{verbatim}
template<class InputIterator>
unordered_set(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
\end{verbatim}

\begin{verbatim}
template<container-compatible-range<value_type> R>
unordered_multiset(from_range_t, R&& rg,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
\end{verbatim}

\begin{verbatim}
unordered_set(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
\end{verbatim}

\textbf{Effects:} Constructs an empty \texttt{unordered\_set} using the specified hash function, key equality predicate, and allocator, and using at least \(n\) buckets. If \(n\) is not provided, the number of buckets is implementation-defined. Then inserts elements from the range \([f, l)\), \(rg\), or \(il\), respectively. \texttt{max\_load\_factor()} returns 1.0.

\textbf{Complexity:} Average case linear, worst case quadratic.

\section{24.5.6.3 Erasure}

\begin{verbatim}
template<class K, class H, class P, class A, class Predicate>
typename unordered_set<K, H, P, A>::size_type
erase_if(unordered_set<K, H, P, A>& c, Predicate pred);
\end{verbatim}

\textbf{Effects:} Equivalent to:

\begin{verbatim}
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();
\end{verbatim}

\section{24.5.7 Class template \texttt{unordered\_multiset}}

\subsection{24.5.7.1 Overview}

An \texttt{unordered\_multiset} is an unordered associative container that supports equivalent keys (an instance of \texttt{unordered\_multiset} may contain multiple copies of the same key value) and in which each element’s key is the element itself. The \texttt{unordered\_multiset} class supports forward iterators.

An \texttt{unordered\_multiset} meets all of the requirements of a container (24.2.2.2), of an allocator-aware container (24.2.2.5), and of an unordered associative container (24.2.8). It provides the operations described in the preceding requirements table for equivalent keys; that is, an \texttt{unordered\_multiset} supports the \texttt{a\_eq} operations in that table, not the \texttt{a\_uniq} operations. For an \texttt{unordered\_multiset<Key>} the \texttt{key\_type} and the \texttt{value\_type} are both \texttt{Key}. The \texttt{iterator} and \texttt{const\_iterator} types are both constant iterator types. It is unspecified whether they are the same type.

Subclause 24.5.7 only describes operations on \texttt{unordered\_multiset} that are not described in one of the tables, or for which there is additional semantic information.

A size_type parameter type in an unordered_multiset deduction guide refers to the size_type member type of the type deduced by the deduction guide.

24.5.7.2 Constructors [unord.multiset.cnstr]

unordered_multiset() : unordered_multiset(size_type(see below)) { }
explicit unordered_multiset(size_type n,  
const hasher& hf = hasher(),  
const key_equal& eql = key_equal(),  
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.
template<class InputIterator>
unordered_multiset(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

template<
container-compatible-range<
value_type> R>
unordered_multiset(from_range_t, R&& rg, 
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

unordered_multiset(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l), rg, or il, respectively. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

24.5.7.3 Erasure
[unord.multiset.erease]

template<class K, class H, class P, class A, class Predicate>
typename unordered_multiset<K, H, P, A>::size_type
erase_if(unordered_multiset<K, H, P, A>& c, Predicate pred);

Effects: Equivalent to:
auto original_size = c.size();
for (auto i = c.begin(), last = c.end(); i != last; ) {
  if (pred(*i)) {
    i = c.erase(i);
  } else {
    ++i;
  }
}
return original_size - c.size();

24.6 Container adaptors
[container.adaptors]

24.6.1 In general
[container.adaptors.general]

The headers <queue>, <stack>, <flat_map>, and <flat_set> define the container adaptors queue and priority_queue, stack, flat_map and flat_multimap, and flat_set and flat_multiset, respectively.

Each container adaptor takes one or more template parameters named Container, KeyContainer, or MappedContainer that denote the types of containers that the container adaptor adapts. Each container adaptor has at least one constructor that takes a reference argument to one or more such template parameters. For each constructor reference argument to a container C, the constructor copies the container into the container adaptor. If C takes an allocator, then a compatible allocator may be passed in to the adaptor’s constructor. Otherwise, normal copy or move construction is used for the container argument. For the container adaptors that take a single container template parameter Container, the first template parameter T of the container adaptor shall denote the same type as Container::value_type.

For container adaptors, no swap function throws an exception unless that exception is thrown by the swap of the adaptor’s Container, KeyContainer, MappedContainer, or Compare object (if any).

A constructor template of a container adaptor shall not participate in overload resolution if it has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
For container adaptors that have them, the \texttt{insert}, \texttt{emplace}, and \texttt{erase} members affect the validity of iterators, references, and pointers to the adaptor’s container(s) in the same way that the containers’ respective \texttt{insert}, \texttt{emplace}, and \texttt{erase} members do.

[Example 1: A call to \texttt{flat\_map\langle Key, T\rangle::insert} can invalidate all iterators to the \texttt{flat\_map}. — end example]

A deduction guide for a container adaptor shall not participate in overload resolution if any of the following are true:

\begin{enumerate}
\item It has an \texttt{InputIterator} template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
\item It has a \texttt{Compare} template parameter and a type that qualifies as an allocator is deduced for that parameter.
\item It has a \texttt{Container}, \texttt{KeyContainer}, or \texttt{MappedContainer} template parameter and a type that qualifies as an allocator is deduced for that parameter.
\item It has no \texttt{Container}, \texttt{KeyContainer}, or \texttt{MappedContainer} template parameter, and it has an \texttt{Allocator} template parameter, and a type that does not qualify as an allocator is deduced for that parameter.
\item It has both \texttt{Container} and \texttt{Allocator} template parameters, and \texttt{uses\_allocator\_v<Container, Allocator>} is false.
\item It has both \texttt{KeyContainer} and \texttt{Allocator} template parameters, and \texttt{uses\_allocator\_v<KeyContainer, Allocator>} is false.
\item It has both \texttt{KeyContainer} and \texttt{Compare} template parameters, and
\begin{verbatim}
is_invocable_v<const Compare&,
    const typename KeyContainer::value_type&,
    const typename KeyContainer::value_type&>
\end{verbatim}
is not a valid expression or is \texttt{false}.
\item It has both \texttt{MappedContainer} and \texttt{Allocator} template parameters, and \texttt{uses\_allocator\_v<MappedContainer, Allocator>} is false.
\end{enumerate}

The exposition-only alias template \texttt{iter\_value\_type} defined in 24.3.1 and the exposition-only alias templates \texttt{iter\_key\_type}, \texttt{iter\_mapped\_type}, \texttt{range\_key\_type}, and \texttt{range\_mapped\_type} defined in 24.4.1 may appear in deduction guides for container adaptors.

The following exposition-only alias template may appear in deduction guides for container adaptors:

\begin{verbatim}
template<class Allocator, class T>
    using alloc\_rebind = // exposition only
        typename allocator_traits<Allocator>::template rebind\_alloc<T>;
\end{verbatim}

24.6.6.1 Class template queue

24.6.6.1 Definition

Any sequence container supporting operations \texttt{front()}, \texttt{back()}, \texttt{push\_back()} and \texttt{pop\_front()} can be used to instantiate \texttt{queue}. In particular, \texttt{list} (24.3.10) and \texttt{deque} (24.3.8) can be used.

```cpp
namespace std {
    template<class T, class Container = deque<T>>
    class queue {
        using value_type = typename Container::value_type;
        using reference = typename Container::reference;
        using const_reference = typename Container::const_reference;
        using size_type = typename Container::size_type;
        using container_type = Container;

        protected:
            Container c;

        public:
            queue() : queue(Container()) {}
            explicit queue(const Container&);
            explicit queue(Container&&);
            template<class InputIterator> queue(InputIterator first, InputIterator last);
            template<container-compatible-range<T> R> queue(from_range_t, R&& rg);
            template<class Alloc> explicit queue(const Alloc&);
            template<class Alloc> queue(const Container&, const Alloc&);
            template<class Alloc> queue(Container&&, const Alloc&);
            template<class Alloc> queue(const queue&, const Alloc&);
            template<class Alloc> queue(queue&&, const Alloc&);
            template<class InputIterator, class Alloc> queue(InputIterator first, InputIterator last, const Alloc&);
            template<container-compatible-range<T> R, class Alloc> queue(from_range_t, R&& rg, const Alloc&);

            [[nodiscard]] bool empty() const { return c.empty(); }
            size_type size() const { return c.size(); }
            reference front() { return c.front(); }
            const_reference front() const { return c.front(); }
            reference back() { return c.back(); }
            const_reference back() const { return c.back(); }
            void push(const value_type& x) { c.push_back(x); }
            void push(value_type&& x) { c.push_back(std::move(x)); }
            template<container-compatible-range<T> R> void push_range(R&& rg);
            template<class... Args> decltype(auto) emplace(Args&&... args)
            {
                using std::swap
                { using std::swap; swap(c, q.c); }
            }
            void swap(queue& q) noexcept(is_nothrow_swappable_v<Container>)
            {
                using std::swap
                { using std::swap; swap(c, q.c); }
            }

        template<class Container>
            queue(Container) -> queue<typename Container::value_type, Container>;

        template<class InputIterator>
            queue(InputIterator, InputIterator) -> queue<typename InputIterator::value-type<InputIterator>>;
```
template<ranges::input_range R> 
queue(from_range_t, R&&) -> queue<ranges::range_value_t<R>>; 

template<class Container, class Allocator> 
queue(Container, Allocator) -> queue<typename Container::value_type, Container>; 

template<class InputIterator, class Allocator> 
queue(InputIterator, InputIterator, Allocator) 
   -> queue<iter-value-type<InputIterator>, deque<iter-value-type<InputIterator>, 
           Allocator>>; 

template<ranges::input_range R, class Allocator> 
queue(from_range_t, R&&, Allocator) 
   -> queue<ranges::range_value_t<R>, deque<ranges::range_value_t<R>, Allocator>>; 

template<class T, class Container, class Alloc> 
struct uses_allocator<queue<T, Container>, Alloc> : uses_allocator<Container, Alloc>::type { }; 

24.6.6.2 Constructors [queue.cons] 

explicit queue(const Container& cont); 
1 Effects: Initializes c with cont. 

explicit queue(Container&& cont); 
2 Effects: Initializes c with std::move(cont). 

template<class InputIterator> 
queue(InputIterator first, InputIterator last); 
3 Effects: Initializes c with first as the first argument and last as the second argument. 

template<container-compatible-range<T> R> 
queue(from_range_t, R&& rg); 
4 Effects: Initializes c with ranges::to<Container>(std::forward<R>(rg)). 

24.6.6.3 Constructors with allocators [queue.cons.alloc] 

If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution. 

template<class Alloc> explicit queue(const Alloc& a); 
1 Effects: Initializes c with a. 

template<class Alloc> queue(const container_type& cont, const Alloc& a); 
2 Effects: Initializes c with cont as the first argument and a as the second argument. 

template<class Alloc> queue(container_type& cont, const Alloc& a); 
3 Effects: Initializes c with std::move(cont) as the first argument and a as the second argument. 

template<class Alloc> queue(const queue& q, const Alloc& a); 
4 Effects: Initializes c with q.c as the first argument and a as the second argument. 

template<class Alloc> queue(queue&& q, const Alloc& a); 
5 Effects: Initializes c with std::move(q.c) as the first argument and a as the second argument. 

template<class InputIterator, class Alloc> 
queue(InputIterator first, InputIterator last, const Alloc& alloc); 
7 Effects: Initializes c with first as the first argument, last as the second argument, and alloc as the third argument. 

§ 24.6.6.3
template<container-compatible-range<T> R, class Alloc>
queue(from_range_t, R&& rg, const Alloc& a);

Effects: Initializes c with ranges::to(Container)(std::forward<R>(rg), a).

### 24.6.6.4 Modifiers

template<container-compatible-range<T> R>
void push_range(R&& rg);

Effects: Equivalent to c.append_range(std::forward<R>(rg)) if that is a valid expression, otherwise ranges::copy(rg, back_inserter(c)).

### 24.6.6.5 Operators

#### template<class T, class Container>
bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c == y.c.

#### template<class T, class Container>
bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c != y.c.

#### template<class T, class Container>
bool operator< (const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c < y.c.

#### template<class T, class Container>
bool operator> (const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c > y.c.

#### template<class T, class Container>
bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c <= y.c.

#### template<class T, class Container>
bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c >= y.c.

#### template<class T, three_way_comparable Container>
compare_three_way_result_t<Container>
operator<=>(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c <=> y.c.

### 24.6.6.6 Specialized algorithms

template<class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));

Constraints: is_swappable_v<Container> is true.

Effects: As if by x.swap(y).

### 24.6.7 Class template priority_queue

#### 24.6.7.1 Overview

Any sequence container with random access iterator and supporting operations front(), push_back() and pop_back() can be used to instantiate priority_queue. In particular, vector (24.3.11) and deque (24.3.8) can be used. Instantiating priority_queue also involves supplying a function or function object for making priority comparisons; the library assumes that the function or function object defines a strict weak ordering (27.8).
namespace std {
    template<class T, class Container = vector<T>,
       class Compare = less<typename Container::value_type>>
    class priority_queue {
public:
    using value_type = typename Container::value_type;
    using reference = typename Container::reference;
    using const_reference = typename Container::const_reference;
    using size_type = typename Container::size_type;
    using container_type = Container;
    using value_compare = Compare;
    protected:
        Container c;
        Compare comp;

public:
    priority_queue() : priority_queue(Compare()) {}  
    explicit priority_queue(const Compare& x) : priority_queue(x, Container()) {}  
    priority_queue(const Compare& x, const Container&);  
    priority_queue(const Compare& x, Container&&);  
    template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, const Compare& x = Compare());  
    template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, const Compare& x, 
                   const Container&);  
    template<class InputIterator>

             && is_nothrow_swappable_v<Compare>))  
          { using std::swap; swap(c, q.c); swap(comp, q.comp); }
    };

§ 24.6.7.1
989
template<class Compare, class Container>
    priority_queue(Compare, Container)
    -> priority_queue<typename Container::value_type, Container, Compare>;

template<class InputIterator,
    class Compare = less<iter_value_type<InputIterator>>,
    class Container = vector<iter_value_type<InputIterator>>>
    priority_queue(InputIterator, InputIterator, Compare = Compare(), Container = Container())
    -> priority_queue<typename InputIterator::value_type, InputIterator, Compare>;

template<ranges::input_range R, class Compare = less<ranges::range_value_t<R>>,
    class Container = vector<ranges::range_value_t<R>>> priority_queue(from_range_t, R&&, Compare = Compare())
    -> priority_queue<ranges::range_value_t<R>, vector<ranges::range_value_t<R>>, Compare>;

template<class Compare, class Container, class Allocator>
    priority_queue(Compare, Container, Allocator)
    -> priority_queue<typename Container::value_type, Container, Compare>;

template<class InputIterator, class Allocator>
    priority_queue(InputIterator, InputIterator, Allocator)
    -> priority_queue<iter_value_type<InputIterator>, vector<iter_value_type<InputIterator>, Allocator>,
                            less<iter_value_type<InputIterator>>, Compare>;

template<class InputIterator, class Compare, class Allocator>
    priority_queue(InputIterator, InputIterator, Compare, Allocator)
    -> priority_queue<iter_value_type<InputIterator>, vector<iter_value_type<InputIterator>, Allocator>, Compare>;

template<class InputIterator, class Compare, class Container, class Allocator>
    priority_queue(InputIterator, InputIterator, Compare, Container, Allocator)
    -> priority_queue<typename Container::value_type, Container, Compare>;

template<ranges::input_range R, class Compare, class Allocator>
    priority_queue(from_range_t, R&&, Compare, Allocator)
    -> priority_queue<ranges::range_value_t<R>, vector<ranges::range_value_t<R>, Allocator>,
                            Compare>;

// no equality is provided

24.6.7.2 Constructors
[priqueue.cons]

priority_queue(const Compare& x, const Container& y);
    priority_queue(const Compare& x, Container&& y);

1. Preconditions: x defines a strict weak ordering (27.8).

2. Effects: Initializes comp with x and c with y (copy constructing or move constructing as appropriate); calls make_heap(c.begin(), c.end(), comp).

template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, const Compare& x = Compare());

3. Preconditions: x defines a strict weak ordering (27.8).

4. Effects: Initializes c with first as the first argument and last as the second argument, and initializes comp with x; then calls make_heap(c.begin(), c.end(), comp).
template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, const Compare& x, const Container& y);
template<class InputIterator>
    priority_queue(InputIterator first, InputIterator last, const Compare& x, Container&& y);

    Preconditions: x defines a strict weak ordering (27.8).
    Effects: Initializes \( c \) with \( x \) and \( c \) with \( y \) (copy constructing or move constructing as appropriate); calls \( c.insert(c.end(), \text{first}, \text{last}) \) and finally calls \( \text{make_heap}(c.begin(), c.end(), \text{comp}) \).

template<container-compatible-range<T> R>
    priority_queue(from_range_t, R&& rg, const Compare& x = Compare());

    Preconditions: x defines a strict weak ordering (27.8).
    Effects: Initializes \( c \) with \( x \) with \( \text{ranges::to<Container>(std::forward<R>(rg))} \) and finally calls \( \text{make_heap}(c.begin(), c.end(), \text{comp}) \).

24.6.7.3 Constructors with allocators

If \text{uses_allocator_v<container_type, Alloc>} is \text{false} the constructors in this subclause shall not participate in overload resolution.

template<class Alloc> explicit priority_queue(const Alloc& a);

    Effects: Initializes \( c \) with \( a \) and value-initializes \( \text{comp} \).

template<class Alloc> priority_queue(const Compare& compare, const Alloc& a);

    Effects: Initializes \( c \) with \( a \) and initializes \( \text{comp} \) with \( \text{compare} \).

template<class Alloc>
    priority_queue(const Compare& compare, const Container& cont, const Alloc& a);

    Effects: Initializes \( c \) with \( \text{cont} \) as the first argument and \( a \) as the second argument, and initializes \( \text{comp} \) with \( \text{compare} \); calls \( \text{make_heap}(c.begin(), c.end(), \text{comp}) \).

template<class Alloc>
    priority_queue(const Compare& compare, Container&& cont, const Alloc& a);

    Effects: Initializes \( c \) with \( \text{std::move(cont)} \) as the first argument and \( a \) as the second argument, and initializes \( \text{comp} \) with \( \text{compare} \); calls \( \text{make_heap}(c.begin(), c.end(), \text{comp}) \).

template<class Alloc>
    priority_queue(const priority_queue& q, const Alloc& a);

    Effects: Initializes \( c \) with \( q.c \) as the first argument and \( a \) as the second argument, and initializes \( \text{comp} \) with \( q.\text{comp} \).

template<class Alloc>
    priority_queue(priority_queue&& q, const Alloc& a);

    Effects: Initializes \( c \) with \( \text{std::move(q.c)} \) as the first argument and \( a \) as the second argument, and initializes \( \text{comp} \) with \( \text{std::move(q.\text{comp})} \).

24.6.7.3.991
template<class InputIterator, class Alloc>
priority_queue(InputIterator first, InputIterator last, const Compare& compare, Container&& cont, const Alloc& a);

Effects: Initializes c with std::move(cont) as the first argument and a as the second argument, and initializes comp with compare; calls c.insert(c.end(), first, last); and finally calls make_heap(c.begin(), c.end(), comp).

template<container-compatible-range<T> R, class Alloc>
priority_queue(from_range_t, R&& rg, const Compare& compare, const Alloc& a);

Effects: Initializes comp with compare and c with ranges::to<Container>(std::forward<R>(rg), a); calls make_heap(c.begin(), c.end(), comp).

template<container-compatible-range<T> R, class Alloc>
priority_queue(from_range_t, R&& rg, const Alloc& a);

Effects: Initializes c with ranges::to<Container>(std::forward<R>(rg), a); calls make_heap(c.begin(), c.end(), comp).

24.6.7.4 Members [pqueue.members]

void push(const value_type& x);

Effects: As if by:
c.push_back(x);
push_heap(c.begin(), c.end(), comp);

void push(value_type&& x);

Effects: As if by:
c.push_back(std::move(x));
push_heap(c.begin(), c.end(), comp);

template<container-compatible-range<T> R>
void push_range(R&& rg);

Effects: Inserts all elements of rg in c via c.append_range(std::forward<R>(rg)) if that is a valid expression, or ranges::copy(rg, back_inserter(c)) otherwise. Then restores the heap property as if by make_heap(c.begin(), c.end(), comp).

Postconditions: is_heap(c.begin(), c.end(), comp) is true.

template<class... Args> void emplace(Args&&... args);

Effects: As if by:
c.emplace_back(std::forward<Args>(args)...);
push_heap(c.begin(), c.end(), comp);

void pop();

Effects: As if by:
pop_heap(c.begin(), c.end(), comp);
c.pop_back();

24.6.7.5 Specialized algorithms [pqueue.special]

template<class T, class Container, class Compare>
void swap(priority_queue<T, Container, Compare>& x, priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));

Constraints: is_swappable_v<Container> is true and is_swappable_v<Compare> is true.

Effects: As if by x.swap(y).

24.6.8 Class template stack [stack]

24.6.8.1 General [stack.general]

Any sequence container supporting operations back(), push_back() and pop_back() can be used to instantiate stack. In particular, vector (24.3.11), list (24.3.10) and deque (24.3.8) can be used.
24.6.8.2 Definition

```cpp
namespace std {
    template<class T, class Container = deque<T>>
    class stack {
        public:
            using value_type = typename Container::value_type;
            using reference = typename Container::reference;
            using const_reference = typename Container::const_reference;
            using size_type = typename Container::size_type;
            using container_type = Container;

        protected:
            Container c;

        public:
            stack() : stack(Container()) {}
            explicit stack(const Container&);
            explicit stack(Container&&);
            template<class InputIterator> stack(InputIterator first, InputIterator last);
            template<container-compatible-range<T> R> stack(from_range_t, R&& rg);
            template<class Alloc> explicit stack(const Alloc&);
            template<class Alloc> stack(const Container&, const Alloc&);
            template<class Alloc> stack(Container&&, const Alloc&);
            template<class Alloc> stack(const stack&, const Alloc&);
            template<class Alloc> stack(stack&&, const Alloc&);
            template<class InputIterator, class Alloc>
            stack(InputIterator first, InputIterator last, const Alloc&);
            template<container-compatible-range<T> R, class Alloc>
            stack(from_range_t, R&& rg, const Alloc&);

            [[nodiscard]] bool empty() const { return c.empty(); }
            size_type size() const { return c.size(); }
            reference top() { return c.back(); }
            const_reference top() const { return c.back(); }
            void push(const value_type& x) { c.push_back(x); }
            void push(value_type&& x) { c.push_back(std::move(x)); }
            template<container-compatible-range<T> R>
            void push_range(R&& rg);
            template<class... Args>
            decltype(auto) emplace(Args&&... args) { return c.emplace_back(std::forward<Args>(args)...); }
            void pop() { c.pop_back(); }
            void swap(stack& s) noexcept(is_nothrow_swappable_v<Container>) { using std::swap; swap(c, s.c); }
    }

    template<class Container>
    stack(Container) -> stack<typename Container::value_type, Container>;

    template<class InputIterator>
    stack(InputIterator, InputIterator) -> stack<iter-value-type<InputIterator>>;

    template<ranges::input_range R>
    stack(from_range_t, R&) -> stack<ranges::range_value_t<R>>;

    template<class Container, class Allocator>
    stack(Container, Allocator) -> stack<typename Container::value_type, Container>;

    template<class InputIterator, class Allocator>
    stack(InputIterator, InputIterator, Allocator) ->
    stack<iter-value-type<InputIterator>, deque<iter-value-type<InputIterator>>, Allocator>>;
```
template<ranges::input_range R, class Allocator>
stack(from_range_t, R&&, Allocator)
  -> stack<ranges::range_value_t<R>, deque<ranges::range_value_t<R>, Allocator>>;

template<class T, class Container, class Alloc>
struct uses_allocator<stack<T, Container>, Alloc>
  : uses_allocator<Container, Alloc>::type { }
;

24.6.8.3 Constructors

explicit stack(const Container& cont);

  Effects: Initializes c with cont.

explicit stack(Container&& cont);

  Effects: Initializes c with std::move(cont).

template<class InputIterator>
stack(InputIterator first, InputIterator last);

  Effects: Initializes c with first as the first argument and last as the second argument.

template<container-compatible-range<T> R>
stack(from_range_t, R&& rg);

  Effects: Initializes c with ranges::to<Container>(std::forward<R>(rg)).

24.6.8.4 Constructors with allocators

If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution.

template<class Alloc> explicit stack(const Alloc& a);

  Effects: Initializes c with a.

template<class Alloc> stack(const container_type& cont, const Alloc& a);

  Effects: Initializes c with cont as the first argument and a as the second argument.

template<class Alloc> stack(container_type&& cont, const Alloc& a);

  Effects: Initializes c with std::move(cont) as the first argument and a as the second argument.

template<class Alloc> stack(const stack& s, const Alloc& a);

  Effects: Initializes c with s.c as the first argument and a as the second argument.

template<class Alloc> stack(stack&& s, const Alloc& a);

  Effects: Initializes c with std::move(s.c) as the first argument and a as the second argument.

template<class InputIterator, class Alloc>
stack(InputIterator first, InputIterator last, const Alloc& alloc);

  Effects: Initializes c with first as the first argument, last as the second argument, and alloc as the third argument.

template<container-compatible-range<T> R, class Alloc>
stack(from_range_t, R&& rg, const Alloc& a);

  Effects: Initializes c with ranges::to<Container>(std::forward<R>(rg), a).

24.6.8.5 Modifiers

template<container-compatible-range<T> R>
void push_range(R&& rg);

  Effects: Equivalent to c.append_range(std::forward<R>(rg)) if that is a valid expression, otherwise ranges::copy(rg, back_inserter(c)).
24.6.8.6 Operators

```c
template<class T, class Container>
bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c == y.c.
```

```c
template<class T, class Container>
bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c != y.c.
```

```c
template<class T, class Container>
bool operator<(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c < y.c.
```

```c
template<class T, class Container>
bool operator>(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c > y.c.
```

```c
template<class T, class Container>
bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c <= y.c.
```

```c
template<class T, class Container>
bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c >= y.c.
```

```c
template<class T, three_way_comparable Container>
compare_three_way_result_t<Container>
operator<=>(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c <=> y.c.
```

24.6.8.7 Specialized algorithms

```c
template<class T, class Container>
void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));
Constraints: is_swappable_v<Container> is true.
Effects: As if by x.swap(y).
```

24.6.9 Class template flat_map

24.6.9.1 Overview

A flat_map is a container adaptor that provides an associative container interface that supports unique keys (i.e., contains at most one of each key value) and provides for fast retrieval of values of another type T based on the keys. flat_map supports iterators that meet the Cpp17InputIterator requirements and model the random_access_iterator concept (25.3.4.13).

A flat_map meets all of the requirements of a container (24.2.2.2) and of a reversible container (24.2.2.3), plus the optional container requirements (24.2.2.4). flat_map meets the requirements of an associative container (24.2.7), except that:

1. it does not meet the requirements related to node handles (24.2.5),
2. it does not meet the requirements related to iterator invalidation, and
3. the time complexity of the operations that insert or erase a single element from the map is linear, including the ones that take an insertion position iterator.

[Note 1: A flat_map does not meet the additional requirements of an allocator-aware container (24.2.2.5). — end note]

A flat_map also provides most operations described in 24.2.7 for unique keys. This means that a flat_map supports the a_uniq operations in 24.2.7 but not the a_eq operations. For a flat_map<Key, T> the key_type is Key and the value_type is pair<Key, T>.
4 Descriptions are provided here only for operations on flat_map that are not described in one of those sets of requirements or for operations where there is additional semantic information.

5 A flat_map maintains the following invariants:

(5.1) it contains the same number of keys and values;
(5.2) the keys are sorted with respect to the comparison object; and
(5.3) the value at offset off within the value container is the value associated with the key at offset off within the key container.

6 If any member function in 24.6.9.2 exits via an exception the invariants are restored.

[Note 2: This can result in the flat_map being emptied. — end note]

7 Any type C that meets the sequence container requirements (24.2.4) can be used to instantiate flat_map, as long as C::iterator meets the Cpp17RandomAccessIterator requirements and invocations of member functions C::size and C::max_size do not exit via an exception. In particular, vector (24.3.11) and deque (24.3.8) can be used.

[Note 3: vector<bool> is not a sequence container. — end note]

8 The program is ill-formed if Key is not the same type as KeyContainer::value_type or T is not the same type as MappedContainer::value_type.

9 The effect of calling a constructor that takes both key_container_type and mapped_container_type arguments with containers of different sizes is undefined.

10 The effect of calling a constructor or member function that takes a sorted_unique_t argument with a container, containers, or range that is not sorted with respect to key_comp(), or that contains equal elements, is undefined.

24.6.9.2 Definition

namespace std {
    template<class Key, class T, class Compare = less<Key>,

class Allocator& a);

1 The member type containers has the data members and special members specified above. It has no base
classes or members other than those specified.

24.6.9.3 Constructors [flat.map.cons]

flat_map(key_container_type key_cont, mapped_container_type mapped_cont,
const key_compare& comp = key_compare());

Effects: Initializes c.keys with std::move(key_cont), c.values with std::move(mapped_cont), and
compare with comp; sorts the range [begin(), end()) with respect to value_comp(); and finally erases
the duplicate elements as if by:

auto zv = ranges::zip_view(c.keys, c.values);
auto it = ranges::unique(zv, key_equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());

Complexity: Linear in N if the container arguments are already sorted with respect to value_comp()
and otherwise N log N, where N is the value of key_cont.size() before this call.

template<class Allocator>
flat_map(const key_container_type& key_cont, const mapped_container_type& mapped_cont,
const Allocator& a);
template<class Allocator>
flat_map(const key_container_type& key_cont, const mapped_container_type& mapped_cont,
const key_compare& comp, const Allocator& a);

Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

Effects: Equivalent to flat_map(key_cont, mapped_cont) and flat_map(key_cont, mapped_cont, comp), respectively, except that c.keys and c.values are constructed with uses-allocator construction (20.2.8.2).

Complexity: Same as flat_map(key_cont, mapped_cont) and flat_map(key_cont, mapped_cont, comp), respectively.

flat_map(sorted_unique_t, key_container_type key_cont, mapped_container_type mapped_cont,
const key_compare& comp = key_compare());

Effects: Initializes c.keys with std::move(key_cont), c.values with std::move(mapped_cont), and compare with comp.

Complexity: Constant.

template<class Allocator>
flat_map(sorted_unique_t s, const key_container_type& key_cont,
const mapped_container_type& mapped_cont, const Allocator& a);

Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

Effects: Equivalent to flat_map(s, key_cont, mapped_cont) and flat_map(s, key_cont, mapped_cont, comp), respectively, except that c.keys and c.values are constructed with uses-allocator construction (20.2.8.2).

Complexity: Linear.

template<class Allocator>
flat_map(const key_compare& comp, const Allocator& a);

template<class InputIterator, class Allocator>
flat_map(InputIterator first, InputIterator last, const key_compare& comp, const Allocator& a);

template<class InputIterator, class Allocator>
flat_map(sorted_unique_t, InputIterator first, InputIterator last, const key_compare& comp, const Allocator& a);

template<class Allocator>
flat_map(initializer_list<value_type> il, const key_compare& comp, const Allocator& a);

template<class Allocator>
flat_map(sorted_unique_t, initializer_list<value_type> il, const Allocator& a);

Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.
24.6.9.4 Capacity

size_type size() const noexcept;

Returns: c.keys.size().

size_type max_size() const noexcept;

Returns: min<
size_type>(c.keys.max_size(), c.values.max_size()).

24.6.9.5 Access

mapped_type& operator[](const key_type& x);

Effects: Equivalent to: return try_emplace(x).first->second;

mapped_type& operator[](key_type&& x);

Effects: Equivalent to: return try_emplace(std::move(x)).first->second;

template<class K> mapped_type& operator[](K&& x);

Constraints: The qualified-id Compare::is_transparent is valid and denotes a type.

Effects: Equivalent to: return try_emplace(std::forward<K>(x)).first->second;

mapped_type& at(const key_type& x);

Returns: A reference to the mapped_type corresponding to x in *this.

Throws: An exception object of type out_of_range if no such element is present.

Complexity: Logarithmic.

template<class K> mapped_type& at(const K& x);

template<class K> const mapped_type& at(const K& x) const;

Constraints: The qualified-id Compare::is_transparent is valid and denotes a type.

Preconditions: The expression find(x) is well-formed and has well-defined behavior.

Returns: A reference to the mapped_type corresponding to x in *this.

Throws: An exception object of type out_of_range if no such element is present.

Complexity: Logarithmic.

24.6.9.6 Modifiers

template<class... Args> pair<iterator, bool> emplace(Args&&... args);

Constraints: is_constructible_v<pair<key_type, mapped_type>, Arg...> is true.

Effects: Initializes an object t of type pair<key_type, mapped_type> with std::forward<Args>(args)...; if the map already contains an element whose key is equivalent to t.first, *this is unchanged. Otherwise, equivalent to:

auto key_it = ranges::upper_bound(c.keys, t.first, compare);
auto value_it = c.values.begin() + distance(c.keys.begin(), key_it);
c.keys.insert(key_it, std::move(t.first));
c.values.insert(value_it, std::move(t.second));

Returns: The bool component of the returned pair is true if and only if the insertion took place, and the iterator component of the pair points to the element with key equivalent to t.first.

template<class P> pair<iterator, bool> insert(P&& x);

template<class P> iterator insert(const_iterator position, P&& x);

Constraints: is_constructible_v<pair<key_type, mapped_type>, P> is true.

Effects: The first form is equivalent to return emplace(std::forward<P>(x));. The second form is equivalent to return emplace_hint(position, std::forward<P>(x));.
```cpp
template<class InputIterator>
void insert(InputIterator first, InputIterator last);

Effects: Adds elements to c as if by:
for (; first != last; ++first) {
    value_type value = *first;
    c.keys.insert(c.keys.end(), std::move(value.first));
    c.values.insert(c.values.end(), std::move(value.second));
}

Then, sorts the range of newly inserted elements with respect to value_comp(); merges the resulting
sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases
the duplicate elements as if by:
auto zv = ranges::zip_view(c.keys, c.values);
auto it = ranges::unique(zv, key_equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());

Complexity: \(N + M \log M\), where \(N\) is size(c) before the operation and \(M\) is distance(first, last).

Remarks: Since this operation performs an in-place merge, it may allocate memory.
```

```cpp
template<class InputIterator>
void insert(sorted_unique_t, InputIterator first, InputIterator last);

Effects: Adds elements to c as if by:
for (; first != last; ++first) {
    value_type value = *first;
    c.keys.insert(c.keys.end(), std::move(value.first));
    c.values.insert(c.values.end(), std::move(value.second));
}

Then, merges the sorted range of newly added elements and the sorted range of pre-existing elements
into a single sorted range; and finally erases the duplicate elements as if by:
auto zv = ranges::zip_view(c.keys, c.values);
auto it = ranges::unique(zv, key_equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());

Complexity: Linear in \(N\), where \(N\) is size(c) after the operation.

Remarks: Since this operation performs an in-place merge, it may allocate memory.
```

```cpp
template<container-compatible-range<value_type> R>
void insert_range(R&& rg);

Effects: Adds elements to c as if by:
for (const auto& e : rg) {
    c.keys.insert(c.keys.end(), e.first);
    c.values.insert(c.values.end(), e.second);
}

Then, sorts the range of newly inserted elements with respect to value_comp(); merges the resulting
sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases
the duplicate elements as if by:
auto zv = ranges::zip_view(c.keys, c.values);
auto it = ranges::unique(zv, key_equiv(compare)).begin();
auto dist = distance(zv.begin(), it);
c.keys.erase(c.keys.begin() + dist, c.keys.end());
c.values.erase(c.values.begin() + dist, c.values.end());

Complexity: \(N + M \log M\), where \(N\) is size(c) before the operation and \(M\) is ranges::distance(rg).

Remarks: Since this operation performs an in-place merge, it may allocate memory.
```
template<class... Args>
pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);

template<class... Args>
pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);

template<class... Args>
iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);

template<class... Args>
iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);

Constraints: is_constructible_v<mapped_type, Args...> is true.

Effects: If the map already contains an element whose key is equivalent to k, *this and args... are unchanged. Otherwise equivalent to:

auto key_it = ranges::upper_bound(c.keys, k, compare);
auto value_it = c.values.begin() + distance(c.keys.begin(), key_it);
c.keys.insert(key_it, std::forward<decltype(k)>(k));
c.values.emplace(value_it, std::forward<Args>(args)...);

Returns: In the first two overloads, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace for the first two overloads, and the same as emplace_hint for the last two overloads.

template<class K, class... Args>
pair<iterator, bool> try_emplace(K&& k, Args&&... args);

template<class K, class... Args>
iterator try_emplace(const_iterator hint, K&& k, Args&&... args);

Constraints:

— The qualified-id Compare::is_transparent is valid and denotes a type.
— is_constructible_v<key_type, K> is true.
— is_constructible_v<mapped_type, Args...> is true.
— For the first overload, is_convertible_v<K&&, const_iterator> and is_convertible_v<K&&, iterator> are both false.

Preconditions: The conversion from k into key_type constructs an object u, for which find(k) == find(u) is true.

Effects: If the map already contains an element whose key is equivalent to k, *this and args... are unchanged. Otherwise equivalent to:

auto key_it = ranges::upper_bound(c.keys, k, compare);
auto value_it = c.values.begin() + distance(c.keys.begin(), key_it);
c.keys.emplace(key_it, std::forward<K>(k));
c.values.emplace(value_it, std::forward<Args>(args)...);

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template<class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);

template<class M>
pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);

template<class M>
iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

Constraints: isAssignable_v<mapped_type&, M> is true and is_constructible_v<mapped_type, M> is true.

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise, equivalent to

try_emplace(std::forward<decltype(k)>(k), std::forward<M>(obj))
for the first two overloads or
  try_emplace_hint(hint, std::forward<decltype(k)>(k), std::forward<M>(obj))
for the last two overloads.

Returns: In the first two overloads, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace for the first two overloads and the same as emplace_hint for the last two overloads.

template<class K, class M>
pair<iterator, bool> insert_or_assign(K&& k, M&& obj);
template<class K, class M>
iterator insert_or_assign(const_iterator hint, K&& k, M&& obj);

Constraints:
(28.1) — The qualified-id Compare::is_transparent is valid and denotes a type.
(28.2) — is_constructible_v<key_type, K> is true.
(28.3) — is_assignable_v<mapped_type&, M> is true.
(28.4) — is_constructible_v<mapped_type, M> is true.

Preconditions: The conversion from k into key_type constructs an object u, for which find(k) == find(u) is true.

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise, equivalent to
  try_emplace(std::forward<decltype(k)>(k), std::forward<M>(obj))
for the first overload or
  try_emplace_hint(hint, std::forward<decltype(k)>(k), std::forward<M>(obj))
for the second overload.

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

void swap(flat_map& y) noexcept;

Effects: Equivalent to:
  ranges::swap(compare, y.compare);
  ranges::swap(c.keys, y.c.keys);
  ranges::swap(c.values, y.c.values);

containers extract() &&;

Postconditions: *this is emptied, even if the function exits via an exception.

Returns: std::move(c).

void replace(key_container_type&& key_cont, mapped_container_type&& mapped_cont);

Preconditions: key_cont.size() == mapped_cont.size() is true, the elements of key_cont are sorted with respect to compare, and key_cont contains no equal elements.

Effects: Equivalent to:
  c.keys = std::move(key_cont);
  c.values = std::move(mapped_cont);

24.6.9.7 Erasure

template<class Key, class T, class Compare, class KeyContainer, class MappedContainer, class Predicate>
typename flat_map<Key, T, Compare, KeyContainer, MappedContainer>::size_type
erase_if(flat_map<Key, T, Compare, KeyContainer, MappedContainer>& c, Predicate pred);

Preconditions: Key and T meet the Cpp17MoveAssignable requirements.
Effects: Let $E$ be $\text{bool(pred(pair<const Key&, const T&>(e)))}$. Erases all elements $e$ in $c$ for which $E$ holds.

Returns: The number of elements erased.

Complexity: Exactly $c\cdot \text{size()}$ applications of the predicate.

Remarks: Stable (16.4.6.8). If an invocation of erase_if exits via an exception, $c$ is in a valid but unspecified state (3.67).

[Note 1: $c$ still meets its invariants, but can be empty. — end note]

24.6.10 Class template flat_multimap [flat.multimap]

24.6.10.1 Overview [flat.multimap.overview]

A flat_multimap is a container adaptor that provides an associative container interface that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type $T$ based on the keys. flat_multimap supports iterators that meet the Cpp17InputIterator requirements and model the random_access_iterator concept (25.3.4.13).

A flat_multimap meets all of the requirements for a container (24.2.2.2) and for a reversible container (24.2.2.3), plus the optional container requirements (24.2.2.4). flat_multimap meets the requirements of an associative container (24.2.7), except that:

(2.1) — it does not meet the requirements related to node handles (24.2.5),
(2.2) — it does not meet the requirements related to iterator invalidation, and
(2.3) — the time complexity of the operations that insert or erase a single element from the map is linear, including the ones that take an insertion position iterator.

[Note 1: A flat_multimap does not meet the additional requirements of an allocator-aware container (24.2.2.5). — end note]

A flat_multimap also provides most operations described in 24.2.7 for equal keys. This means that a flat_multimap supports the a_eq operations in 24.2.7 but not the a_uniq operations. For a flat_multimap<Key, T> the key_type is Key and the value_type is pair<Key, T>.

Except as otherwise noted, operations on flat_multimap are equivalent to those of flat_map, except that flat_multimap operations do not remove or replace elements with equal keys.

[Example 1: flat_multimap constructors and emplace do not erase non-unique elements after sorting them. — end example]

A flat_multimap maintains the following invariants:

(5.1) — it contains the same number of keys and values;
(5.2) — the keys are sorted with respect to the comparison object; and
(5.3) — the value at offset $off$ within the value container is the value associated with the key at offset $off$ within the key container.

If any member function in 24.6.10.2 exits via an exception, the invariants are restored.

[Note 2: This can result in the flat_multimap being emptied. — end note]

Any type $C$ that meets the sequence container requirements (24.2.4) can be used to instantiate flat_multimap, as long as $C::\text{iterator}$ meets the Cpp17RandomAccessIterator requirements and invocations of member functions $C::\text{size}$ and $C::\text{max_size}$ do not exit via an exception. In particular, vector (24.3.11) and deque (24.3.8) can be used.

[Note 3: vector<bool> is not a sequence container. — end note]

The program is ill-formed if $Key$ is not the same type as KeyContainer::value_type or $T$ is not the same type as MappedContainer::value_type.

The effect of calling a constructor that takes both key_container_type and mapped_container_type arguments with containers of different sizes is undefined.

The effect of calling a constructor or member function that takes a sorted_equivalent_t argument with a container, containers, or range that are not sorted with respect to key_comp() is undefined.

24.6.10.3 Constructors

```cpp
flat_multimap(key_container_type key_cont, mapped_container_type mapped_cont,
const key_compare& comp = key_compare());
```

1 Effects: Initializes `c.keys` with `std::move(key_cont)`, `c.values` with `std::move(mapped_cont)`, and `compare` with `comp`; sorts the range `[begin(), end())` with respect to `value_comp()`.

2 Complexity: Linear in \( N \) if the container arguments are already sorted with respect to `value_comp()` and otherwise \( N \log N \), where \( N \) is the value of `key_cont.size()` before this call.
template<class Allocator>
flat_multimap(const key_container_type& key_cont, const mapped_container_type& mapped_cont,
const Allocator& a);

template<class Allocator>
flat_multimap(const key_container_type& key_cont, const mapped_container_type& mapped_cont,
const Allocator& a);

Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

Effects: Equivalent to flat_multimap(key_cont, mapped_cont) and flat_multimap(key_cont, mapped_cont, comp), respectively, except that c.keys and c.values are constructed with uses-allocator construction (20.2.8.2).

Complexity: Same as flat_multimap(key_cont, mapped_cont) and flat_multimap(key_cont, mapped_cont, comp), respectively.

flat_multimap(sorted_equivalent_t, key_container_type key_cont, mapped_container_type mapped_cont,
const Allocator& a);

Effects: Initializes c.keys with std::move(key_cont), c.values with std::move(mapped_cont), and compare with comp.

Complexity: Constant.

template<class Allocator>
flat_multimap(sorted_equivalent_t s, const key_container_type& key_cont,
const mapped_container_type& mapped_cont, const Allocator& a);

Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<mapped_container_type, Allocator> is true.

Effects: Equivalent to flat_multimap(s, key_cont, mapped_cont) and flat_multimap(s, key_cont, mapped_cont, comp), respectively, except that c.keys and c.values are constructed with uses-allocator construction (20.2.8.2).

Complexity: Linear.

§ 24.6.10.3
template<class Allocator>
  flat_multimap(sorted_equivalent_t, initializer_list<value_type> il, const Allocator& a);

  Constraints: uses_allocator_v<key_container_type, Allocator> is true and uses_allocator_v<
mapped_container_type, Allocator> is true.

  Effects: Equivalent to the corresponding non-allocator constructors except that c.keys and c.values
  are constructed with uses-allocator construction (20.2.8.2).

24.6.10.4 Erasure

template<class Key, class T, class Compare, class KeyContainer, class MappedContainer,
  class Predicate>
  typename flat_multimap<Key, T, Compare, KeyContainer, MappedContainer>::size_type
  erase_if(flat_multimap<Key, T, Compare, KeyContainer, MappedContainer>& c, Predicate pred);

  Preconditions: Key and T meet the Cpp17MoveAssignable requirements.

  Effects: Let E be bool(pred(pair<const Key&, const T&>(e))). Erases all elements e in c for
  which E holds.

  Returns: The number of elements erased.

  Complexity: Exactly c.size() applications of the predicate.

  Remarks: Stable (16.4.6.8). If an invocation of erase_if exits via an exception, c is in a valid but
  unspecified state (3.67).

  [Note 1: c still meets its invariants, but can be empty.  — end note]

24.6.11 Class template flat_set

24.6.11.1 Overview

A flat_set is a container adaptor that provides an associative container interface that supports unique keys
(i.e., contains at most one of each key value) and provides for fast retrieval of the keys themselves. flat_set
supports iterators that model the random_access_iterator concept (25.3.4.13).

A flat_set meets all of the requirements for a container (24.2.2.2) and for a reversible container (24.2.2.3),
plus the optional container requirements (24.2.2.4). flat_set meets the requirements of an associative
container (24.2.7), except that:

(2.1)  — it does not meet the requirements related to node handles (24.2.5.1),

(2.2)  — it does not meet the requirements related to iterator invalidation, and

(2.3)  — the time complexity of the operations that insert or erase a single element from the set is linear,
  including the ones that take an insertion position iterator.

  [Note 1: A flat_set does not meet the additional requirements of an allocator-aware container, as described in
  24.2.2.5.  — end note]

A flat_set also provides most operations described in 24.2.7 for unique keys. This means that a flat_set
supports the a_uniq operations in 24.2.7 but not the a_eq operations. For a flat_set<Key>, both the
key_type and value_type are Key.

Descriptions are provided here only for operations on flat_set that are not described in one of those sets of
requirements or for operations where there is additional semantic information.

A flat_set maintains the invariant that the keys are sorted with respect to the comparison object.

If any member function in 24.6.11.2 exits via an exception, the invariant is restored.

[Note 2: This can result in the flat_set's being emptied.  — end note]

Any sequence container (24.2.4) supporting Cpp17RandomAccessIterator can be used to instantiate flat_set.
In particular, vector (24.3.11) and deque (24.3.8) can be used.

[Note 3: vector<bool> is not a sequence container.  — end note]

The program is ill-formed if Key is not the same type as KeyContainer::value_type.

The effect of calling a constructor or member function that takes a sorted_unique_t argument with a range
that is not sorted with respect to key_comp(), or that contains equal elements, is undefined.

24.6.11.3 Constructors

explicit flat_set(container_type cont, const key_compare& comp = key_compare());
1 Effects: Initializes c with std::move(cont) and compare with comp, sorts the range [begin(), end()) with respect to compare, and finally erases all but the first element from each group of consecutive equivalent elements.
2 Complexity: Linear in N if cont is sorted with respect to compare and otherwise N log N, where N is the value of cont.size() before this call.

template<class Allocator>
flat_set(const container_type& cont, const Allocator& a);

template<class Allocator>
flat_set(const container_type& cont, const key_compare& comp, const Allocator& a);
3 Constraints: uses_allocator_v<container_type, Allocator> is true.
4 Effects: Equivalent to flat_set(cont) and flat_set(cont, comp), respectively, except that c is constructed with uses-allocator construction (20.2.8.2).
5 Complexity: Same as flat_set(cont) and flat_set(cont, comp), respectively.

template<class Allocator>
flat_set(sorted_unique_t s, const container_type& cont, const Allocator& a);
6 Constraints: uses_allocator_v<container_type, Allocator> is true.
7 Effects: Equivalent to flat_set(s, cont) and flat_set(s, cont, comp), respectively, except that c is constructed with uses-allocator construction (20.2.8.2).
8 Complexity: Linear.

template<class Allocator>
flat_set(const key_compare& comp, const Allocator& a);

§ 24.6.11.3 1019
Effects: Equivalent to the corresponding non-allocator constructors except that \( c \) is constructed with uses-allocator construction (20.2.8.2).

### 24.6.11.4 Modifiers

#### [flat.set.modifiers]

```cpp
template<class K> pair<iterator, bool> insert(K&& x);
template<class K> iterator insert(const_iterator hint, K&& x);
```

**Constraints:** The qualified-id `Compare::is_transparent` is valid and denotes a type. `is_constructible_v<value_type, K>` is true.

**Preconditions:** The conversion from \( x \) into `value_type` constructs an object \( u \), for which `find(x) == find(u)` is true.

**Effects:** If the set already contains an element equivalent to \( x \), `*this` and \( x \) are unchanged. Otherwise, inserts a new element as if by `emplace(std::forward<K>(x))`.

**Returns:** In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the element whose key is equivalent to \( x \).

```cpp
template<class InputIterator>
void insert(InputIterator first, InputIterator last);
```

**Effects:** Adds elements to \( c \) as if by:

```cpp
    c.insert(c.end(), first, last);
```

Then, sorts the range of newly inserted elements with respect to `compare`; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases all but the first element from each group of consecutive equivalent elements.

**Complexity:** \( N + M \log M \), where \( N \) is `size()` before the operation and \( M \) is `distance(first, last)`.

**Remarks:** Since this operation performs an in-place merge, it may allocate memory.

```cpp
template<class InputIterator>
void insert(sorted_unique_t, InputIterator first, InputIterator last);
```

**Effects:** Equivalent to `insert(first, last)`.

**Complexity:** Linear.

```cpp
template<container-compatible-range<value_type> R>
void insert_range(R&& rg);
```

**Effects:** Adds elements to \( c \) as if by:

```cpp
    for (const auto& e : rg) {
        c.insert(c.end(), e);
    }
```

Then, sorts the range of newly inserted elements with respect to `compare`; merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range; and finally erases all but the first element from each group of consecutive equivalent elements.

**Complexity:** \( N + M \log M \), where \( N \) is `size()` before the operation and \( M \) is `distance(first, last)`.

**Remarks:** Since this operation performs an in-place merge, it may allocate memory.

```cpp
void swap(flat_set& y) noexcept;
```

**Effects:** Equivalent to:

```cpp
    ranges::swap(compare, y.compare);
    ranges::swap(c, y.c);
```

**Postconditions:** `*this` is emptied, even if the function exits via an exception.

**Returns:** `std::move(c)`.
void replace(container_type&& cont);

Preconditions: The elements of cont are sorted with respect to compare, and cont contains no equal elements.

Effects: Equivalent to: c = std::move(cont);

24.6.11.5 Erasure

template<class Key, class Compare = less<Key>, class KeyContainer = vector<Key>>
        typename flat_set<Key, Compare, KeyContainer>::size_type
    erase_if(flat_set<Key, Compare, KeyContainer>& c, Predicate pred);

Preconditions: Key meets the Cpp17MoveAssignable requirements.
Effects: Let E be bool(pred(as_const(e))). Erases all elements e in c for which E holds.
Returns: The number of elements erased.
Complexity: Exactly c.size() applications of the predicate.
Remarks: Stable (16.4.6.8). If an invocation of erase_if exits via an exception, c is in a valid but unspecified state (3.67).
[Note 1: c still meets its invariants, but can be empty. — end note]

24.6.12 Class template flat_multiset

24.6.12.1 Overview

A flat Multiset is a container adaptor that provides an associative container interface that supports equivalent keys (i.e., possibly containing multiple copies of the same key value) and provides for fast retrieval of the keys themselves. flat_multiset supports iterators that model the random_access_iterator concept (25.3.4.13).

A flat_multiset meets all of the requirements for a container (24.2.2.2) and for a reversible container (24.2.2.3), plus the optional container requirements (24.2.2.4). flat_multiset meets the requirements of an associative container (24.2.7), except that:

(2.1) — it does not meet the requirements related to node handles (24.2.5.1),
(2.2) — it does not meet the requirements related to iterator invalidation, and
(2.3) — the time complexity of the operations that insert or erase a single element from the set is linear, including the ones that take an insertion position iterator.

[Note 1: A flat_multiset does not meet the additional requirements of an allocator-aware container, as described in 24.2.2.5. — end note]

A flat_multiset also provides most operations described in 24.2.7 for equal keys. This means that a flat_multiset supports the a_eq operations in 24.2.7 but not the a_uniq operations. For a flat_multiset<Key>, both the key_type and value_type are Key.

Descriptions are provided here only for operations on flat_multiset that are not described in one of the general sections or for operations where there is additional semantic information.

A flat_multiset maintains the invariant that the keys are sorted with respect to the comparison object.

If any member function in 24.6.12.2 exits via an exception, the invariant is restored.

[Note 2: This can result in the flat_multiset’s being emptied. — end note]

Any sequence container (24.2.4) supporting Cpp17RandomAccessIterator can be used to instantiate flat_multiset. In particular, vector (24.3.11) and deque (24.3.8) can be used.

[Note 3: vector<bool> is not a sequence container. — end note]

The program is ill-formed if Key is not the same type as KeyContainer::value_type.

The effect of calling a constructor or member function that takes a sorted_equivalent_t argument with a range that is not sorted with respect to key_comp() is undefined.

struct uses_allocator<flat_multiset<Key, Compare, KeyContainer>, Allocator> 
  : bool_constant<uses_allocator_v<KeyContainer, Allocator>> { }; 
}
24.6.12.3 Constructors

```cpp
explicit flat_multiset(container_type cont, const key_compare& comp = key_compare());
```

**Effects:** Initializes `c` with `std::move(cont)` and `compare` with `comp`, and sorts the range `[begin(), end())` with respect to `compare`.

**Complexity:** Linear in \( N \) if `cont` is sorted with respect to `compare` and otherwise \( N \log N \), where \( N \) is the value of `cont.size()` before this call.

```cpp
template<class Allocator>
flat_multiset(const container_type& cont, const Allocator& a);
```

**Constraints:** `uses_allocator_v<container_type, Allocator>` is true.

**Effects:** Equivalent to `flat_multiset(cont)` and `flat_multiset(cont, comp)`, respectively, except that `c` is constructed with uses-allocator construction (20.2.8.2).

**Complexity:** Same as `flat_multiset(cont)` and `flat_multiset(cont, comp)`, respectively.

```cpp
template<class Allocator>
flat_multiset(sorted_equivalent_t s, const container_type& cont, const Allocator& a);
```

**Constraints:** `uses_allocator_v<container_type, Allocator>` is true.

**Effects:** Equivalent to `flat_multiset(s, cont)` and `flat_multiset(s, cont, comp)`, respectively, except that `c` is constructed with uses-allocator construction (20.2.8.2).

**Complexity:** Linear.
### 24.6.12.4 Modifiers

**template<class... Arg> iterator emplace(Arg&&... args);**

Constraints: is_constructible_v<value_type, Arg...> is true.

Effects: First, initializes an object t of type value_type with std::forward<Arg>(args)..., then inserts t as if by:

```cpp
c.auto it = ranges::upper_bound(c, t, compare);
c.insert(it, std::move(t));
```

Returns: An iterator that points to the inserted element.

```cpp
template<class InputIterator>
void insert(InputIterator first, InputIterator last);
```

Effects: Adds elements to c as if by:

```cpp
c.insert(c.end(), first, last);
```

Then, sorts the range of newly inserted elements with respect to compare, and merges the resulting sorted range and the sorted range of pre-existing elements into a single sorted range.

Complexity: \(N + M \log M\), where \(N\) is size() before the operation and \(M\) is distance(first, last).

Remarks: Since this operation performs an in-place merge, it may allocate memory.

```cpp
template<class InputIterator>
void insert(sorted_equivalent_t, InputIterator first, InputIterator last);
```

Effects: Equivalent to insert(first, last).

Complexity: Linear.

```cpp
void swap(flat_multiset& y) noexcept;
```

Effects: Equivalent to:

```cpp
ranges::swap(compare, y.compare);
ranges::swap(c, y.c);
```

```cpp
container_type extract() &&;
```

Postconditions: *this is emptied, even if the function exits via an exception.

Returns: std::move(c).

```cpp
void replace(container_type&& cont);
```

Preconditions: The elements of cont are sorted with respect to compare.

Effects: Equivalent to: \(c = \text{std::move}(\text{cont})\).

### 24.6.12.5 Erasure

**template<class Key, class Compare, class KeyContainer, class Predicate>**

```cpp
typename flat_multiset<Key, Compare, KeyContainer>::size_type
erase_if(flat_multiset<Key, Compare, KeyContainer>& c, Predicate pred);
```

Preconditions: Key meets the Cpp17MoveAssignable requirements.

Effects: Let \(E\) be bool(pred(as_const(e))). Erases all elements e in c for which \(E\) holds.

Returns: The number of elements erased.

Complexity: Exactly c.size() applications of the predicate.

Remarks: Stable (16.4.6.8). If an invocation of erase_if exits via an exception, c is in a valid but unspecified state (3.67).

[Note 1: c still meets its invariants, but can be empty. — end note]

### 24.6.13 Container adaptors formatting

For each of queue, priority_queue, and stack, the library provides the following formatter specialization where **adaptor-type** is the name of the template:
namespace std {
    template<class charT, class T, formattable<charT> Container, class... U>
    struct formatter<adaptor-type<T, Container, U...>, charT> {
        private:
            using maybe-const-container = // exposition only
                fmt-maybe-const<Container, charT>;
            using maybe-const-adaptor = // exposition only
                maybe-const<is_const_v<maybe-const-container> ,
                    adaptor-type<T, Container, U...>>;
            formatter<ranges::ref_view<maybe-const-container>, charT> underlying_; // exposition only
        public:
            template<class ParseContext>
            constexpr typename ParseContext::iterator
            parse(ParseContext& ctx);
            template<class FormatContext>
            typename FormatContext::iterator
            format(maybe-const-adaptor r, FormatContext& ctx) const;
    }

    template<class ParseContext>
    constexpr typename ParseContext::iterator
    parse(ParseContext& ctx);

    template<class FormatContext>
    typename FormatContext::iterator
    format(maybe-const-adaptor r, FormatContext& ctx) const;

24.7.2.2 Class template `span` [views.span]

24.7.2.2.1 Overview [span.overview]

1 A `span` is a view over a contiguous sequence of objects, the storage of which is owned by some other object.

2 All member functions of `span` have constant time complexity.

```cpp
namespace std {
    template<class ElementType, size_t Extent = dynamic_extent>
    class span {
    public:
        // constants and types
        using element_type = ElementType;
        using value_type = remove_cv_t<ElementType>;
        using size_type = size_t;
        using difference_type = ptrdiff_t;
        using pointer = element_type*;
        using const_pointer = const element_type*;
        using reference = element_type&;
        using const_reference = const element_type&;
        using iterator = implementation-defined; // see 24.7.2.2.7
        using const_iterator = std::const_iterator<iterator>;
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::const_iterator<reverse_iterator>;
        static constexpr size_type extent = Extent;

        // 24.7.2.2.2, constructors, copy, and assignment
        constexpr span() noexcept;
        template<class It>
        constexpr explicit(extent != dynamic_extent) span(It first, size_type count);
        template<class It, class End>
        constexpr explicit(extent != dynamic_extent) span(It first, End last);
        template<size_t N>
        constexpr span(type_identity_t<element_type> (&arr)[N]) noexcept;
        template<class T, size_t N>
        constexpr span(array<T, N>& arr) noexcept;
        template<class T, size_t N>
        constexpr span(const array<T, N>& arr) noexcept;
        template<class R>
        constexpr explicit(extent != dynamic_extent) span(R&& r);
        constexpr span(const span& other) noexcept = default;
        template<class OtherElementType, size_t OtherExtent>
        constexpr explicit(see below) span(const span<OtherElementType, OtherExtent>& s) noexcept;

        ~span() noexcept = default;
        constexpr span& operator=(const span& other) noexcept = default;

private:
    pointer data_;    // exposition only
    size_type size_;  // exposition only
};

template<class It, class EndOrSize>
span(It, EndOrSize) -> span<remove_reference_t<iter_reference_t<It>>>

template<class T, size_t N>
span(T (&)[N]) -> span<T, N>

template<class T, size_t N>
span(array<T, N>&) -> span<T, N>

template<class T, size_t N>
span(const array<T, N>&) -> span<const T, N>

template<class R>
span(R&&) -> span<remove_reference_t<ranges::range_reference_t<R>>>

span<ElementType, Extent> is a trivially copyable type (6.8.1).

ElementType is required to be a complete object type that is not an abstract class type.

24.7.2.2.2 Constructors, copy, and assignment [span.cons]

constexpr span() noexcept;

Constraints: Extent == dynamic_extent || Extent == 0 is true.

Postconditions: size() == 0 && data() == nullptr.

template<class It>
constexpr explicit(extent != dynamic_extent) span(It first, size_type count);

Constraints: Let U be remove_reference_t<iter_reference_t<It>>.

(3.1) It satisfies contiguous_iterator.
(3.2) is_convertible_v<U(*)[], element_type(*)[]> is true.

[Note 1: The intent is to allow only qualification conversions of the iterator reference type to element_type.
—end note]

Preconditions:
(4.1) [first, first + count) is a valid range.
(4.2) It models contiguous_iterator.
(4.3) If extent is not equal to dynamic_extent, then count is equal to extent.

Effects: Initializes data_ with to_address(first) and size_ with count.

Throws: Nothing.

template<class It, class End>
constexpr explicit(extent != dynamic_extent) span(It first, End last);

Constraints: Let U be remove_reference_t<iter_reference_t<It>>.
(7.1) — \text{is\_convertible\_v}\langle\text{U(*)[]}, \text{element\_type(*)[]}\rangle \text{ is true.} \\
[\text{Note 2: The intent is to allow only qualification conversions of the iterator reference type to element\_type.} \\
\text{— end note}]

(7.2) — It satisfies contiguous\_iterator.

(7.3) — End satisfies sized\_sentinel\_for\langle\text{It}\rangle.

(7.4) — \text{is\_convertible\_v}\langle\text{End, size\_t}\rangle \text{ is false.}

Preconditions:

(8.1) — If extent is not equal to dynamic\_extent, then last – first is equal to extent.

(8.2) — [first, last) is a valid range.

(8.3) — It models contiguous\_iterator.

(8.4) — End models sized\_sentinel\_for\langle\text{It}\rangle.

Effects: Initializes data\_ with to\_address(first) and size\_ with last – first.

Throws: When and what last – first throws.

template\langle\text{size\_t N}\rangle \text{ constexpr span(\text{type\_identity\_t<\text{element\_type}}\rangle (&\text{arr}[N]) \text{ noexcept;}}

template\langle\text{class T, size\_t N}\rangle \text{ constexpr span(\text{array<T, N>& arr}) \text{ noexcept;}}

template\langle\text{class T, size\_t N}\rangle \text{ constexpr span(\text{const array<T, N>& arr}) \text{ noexcept;}}

Constraints: Let U be remove\_pointer\_t\langle\text{decltype(data(arr))}\rangle.

(11.1) — ext == dynamic\_extent || N == extent is true, and

(11.2) — \text{is\_convertible\_v}\langle\text{U(*)[]}, \text{element\_type(*)[]}\rangle \text{ is true.} \\
[\text{Note 3: The intent is to allow only qualification conversions of the array element type to element\_type.} \\
\text{— end note}]

Effects: Constructs a span that is a view over the supplied array.

[Note 4: type\_identity\_t affects class template argument deduction. — end note]

Postconditions: size\_() == N && data\_() == data(arr) is true.

template\langle\text{class R}\rangle \text{ constexpr explicit(extend \(!=\) dynamic\_extent) span(R&\& r);}

Constraints: Let U be remove\_reference\_t\langle\text{ranges::range\_reference\_t<R}\rangle.

(14.1) — R satisfies ranges::contiguous\_range and ranges::sized\_range.

(14.2) — Either R satisfies ranges::borrowed\_range or is\_constant\_v<element\_type> is true.

(14.3) — remove\_cvref\_t<R> is not a specialization of span.

(14.4) — remove\_cvref\_t<R> is not a specialization of array.

(14.5) — \text{is\_array\_v}\langle\text{remove\_cvref\_t<R}\rangle is false.

(14.6) — \text{is\_convertible\_v}\langle\text{U(*)[]}, \text{element\_type(*)[]}\rangle \text{ is true.} \\
[\text{Note 5: The intent is to allow only qualification conversions of the range reference type to element\_type.} \\
\text{— end note}]

Preconditions:

(15.1) — If extent is not equal to dynamic\_extent, then ranges::size(r) is equal to extent.

(15.2) — R models ranges::contiguous\_range and ranges::sized\_range.

(15.3) — If is\_constant\_v<element\_type> is false, R models ranges::borrowed\_range.

Effects: Initializes data\_ with ranges::data(r) and size\_ with ranges::size(r).

Throws: What and when ranges::data(r) and ranges::size(r) throw.

constexpr span(const span& other) noexcept = default;

Postconditions: other.size\_() == size\_() \&\& other.data\_() == data\_().

template\langle\text{class Other\_Element\_Type, size\_t Other\_Extent}\rangle 
constexpr explicit(see below) span(const span<Other\_Element\_Type, Other\_Extent>& s) \text{ noexcept;}

Constraints:
— extent == dynamic_extent || OtherExtent == dynamic_extent || extent == OtherExtent is true, and

— is_convertible_v<OtherElementType(*)[], element_type(*)[]> is true.

[Note 6: The intent is to allow only qualification conversions of the OtherElementType to element_type. — end note]

Preconditions: If extent is not equal to dynamic_extent, then s.size() is equal to extent.
Effects: Constructs a span that is a view over the range [s.data(), s.data() + s.size()).
Postconditions: size() == s.size() && data() == s.data().
Remarks: The expression inside explicit is equivalent to:
extent != dynamic_extent && OtherExtent == dynamic_extent

constexpr span& operator=(const span& other) noexcept = default;
Postconditions: size() == other.size() && data() == other.data().

24.7.2.2.3 Deduction guides [span.deduct]

template<class It, class EndOrSize>
span(It, EndOrSize) -> span<remove_reference_t<iter_reference_t<It>>>;
Constraints: It satisfies contiguous_iterator.

template<class R>
span(R&&) -> span<remove_reference_t<ranges::range_reference_t<R>>>;
Constraints: R satisfies ranges::contiguous_range.

24.7.2.2.4 Subviews [span.sub]

template<size_t Count> constexpr span<element_type, Count> first() const;
Mandates: Count <= Extent is true.
Preconditions: Count <= size() is true.
Effects: Equivalent to: return R{data(), Count}; where R is the return type.

template<size_t Count> constexpr span<element_type, Count> last() const;
Mandates: Count <= Extent is true.
Preconditions: Count <= size() is true.
Effects: Equivalent to: return R{data() + (size() - Count), Count}; where R is the return type.

template<size_t Offset, size_t Count = dynamic_extent>
constexpr span<element_type, see below> subspan() const;
Mandates:
Offset <= Extent && (Count == dynamic_extent || Count <= Extent - Offset)
is true.
Preconditions:
Offset <= size() && (Count == dynamic_extent || Count <= size() - Offset)
is true.
Effects: Equivalent to:
return span<ElementType, see below>(
    data() + Offset, Count != dynamic_extent ? Count : size() - Offset);
Remarks: The second template argument of the returned span type is:
Count != dynamic_extent ? Count
    : (Extent != dynamic_extent ? Extent - Offset
   : dynamic_extent)
constexpr span<element_type, dynamic_extent> first(size_type count) const;

**Preconditions**: count \(\leq\) size() is true.

**Effects**: Equivalent to: return {data(), count};

constexpr span<element_type, dynamic_extent> last(size_type count) const;

**Preconditions**: count \(\leq\) size() is true.

**Effects**: Equivalent to: return {data() + (size() - count), count};

constexpr span<element_type, dynamic_extent> subspan(
    size_type offset, size_type count = dynamic_extent) const;

**Preconditions**:
    offset \(\leq\) size() && (count == dynamic_extent || count \(\leq\) size() - offset)

**Effects**: Equivalent to:
    return {data() + offset, count == dynamic_extent ? size() - offset : count};

### 24.7.2.2.5 Observers

```cpp
constexpr size_type size() const noexcept;  
**Effects**: Equivalent to: return size_;  
```

```cpp
constexpr size_type size_bytes() const noexcept;  
**Effects**: Equivalent to: return size() * sizeof(element_type);  
```

```cpp
[[nodiscard]] constexpr bool empty() const noexcept;  
**Effects**: Equivalent to: return size() == 0;  
```

### 24.7.2.2.6 Element access

```cpp
constexpr reference operator[](size_type idx) const;  
**Preconditions**: idx < size() is true.  
**Effects**: Equivalent to: return *(data() + idx);  
```

```cpp
constexpr reference front() const;  
**Preconditions**: empty() is false.  
**Effects**: Equivalent to: return *data();  
```

```cpp
constexpr reference back() const;  
**Preconditions**: empty() is false.  
**Effects**: Equivalent to: return *(data() + (size() - 1));  
```

```cpp
constexpr pointer data() const noexcept;  
**Effects**: Equivalent to: return data_;  
```

### 24.7.2.2.7 Iterator support

```cpp
using iterator = implementation-defined;  
```

The type models contiguous_iterator (25.3.4.14), meets the Cpp17RandomAccessIterator requirements (25.3.5.7), and meets the requirements for constexpr iterators (25.3.1), whose value type is value_type and whose reference type is reference.

All requirements on container iterators (24.2.2.2) apply to span::iterator as well.

```cpp
constexpr iterator begin() const noexcept;  
**Returns**: An iterator referring to the first element in the span. If empty() is true, then it returns the same value as end().  
```
constexpr iterator end() const noexcept;

Returns: An iterator which is the past-the-end value.

constexpr reverse_iterator rbegin() const noexcept;

Effects: Equivalent to: return reverse_iterator(end());

constexpr reverse_iterator rend() const noexcept;

Effects: Equivalent to: return reverse_iterator(begin());

24.7.2.3 Views of object representation

template<class ElementType, size_t Extent>
span<const byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
as_bytes(span<ElementType, Extent> s) noexcept;

Effects: Equivalent to: return R{reinterpret_cast<const byte*>(s.data()), s.size_bytes()};
where R is the return type.

template<class ElementType, size_t Extent>
span<byte, Extent == dynamic_extent ? dynamic_extent : sizeof(ElementType) * Extent>
as_writable_bytes(span<ElementType, Extent> s) noexcept;

Constraints: is_const_v<ElementType> is false.

Effects: Equivalent to: return R{reinterpret_cast<byte*>(s.data()), s.size_bytes()}; where R is the return type.

24.7.3 Multidimensional access

24.7.3.1 Overview

A multidimensional index space is a Cartesian product of integer intervals. Each interval can be represented by
a half-open range \([L_i, U_i)\), where \(L_i\) and \(U_i\) are the lower and upper bounds of the \(i^{th}\) dimension. The rank of
a multidimensional index space is the number of intervals it represents. The size of a multidimensional index
space is the product of \(U_i - L_i\) for each dimension \(i\) if its rank is greater than 0, and 1 otherwise.

An integer \(r\) is a rank index of an index space \(S\) if \(r\) is in the range \([0, \text{rank of } S)\).

A pack of integers \(\text{idx}\) is a multidimensional index in a multidimensional index space \(S\) (or representation thereof) if both of the following are true:

- (3.1) \(\text{sizeof...}(\text{idx})\) is equal to the rank of \(S\), and
- (3.2) for every rank index \(i\) of \(S\), the \(i^{th}\) value of \(\text{idx}\) is an integer in the interval \([L_i, U_i)\) of \(S\).

24.7.3.2 Header <mdspan> synopsis

24.7.3.3 Class template extents

24.7.3.3.1 Overview

The class template extents represents a multidimensional index space of rank equal to sizeof...(Extents). In subclause (24.7), extents is used synonymously with multidimensional index space.

namespace std {
    template<class IndexType, size_t... Extents>
    class extents {
        public:
            using index_type = IndexType;
            using size_type = make_unsigned_t<index_type>;
            using rank_type = size_t;

            // 24.7.3.3.4, observers of the multidimensional index space
            static constexpr rank_type rank() noexcept { return sizeof...(Extents); }
            static constexpr rank_type rank_dynamic() noexcept { return
            dynamic_index(rank()); }
            static constexpr size_t static_extent(rank_type) noexcept;
            constexpr index_type extent(rank_type) const noexcept;

            // 24.7.3.3.3, constructors
            constexpr extents() noexcept = default;
            template<class OtherIndexType, size_t... OtherExtents>
            constexpr explicit(extents(const extents<OtherIndexType, OtherExtents...>&) noexcept;
            template<class... OtherIndexTypes>
            constexpr explicit(extents(OtherIndexTypes...) noexcept;
            template<class OtherIndexType, size_t N>
            constexpr explicit(N != rank_dynamic())
            extents(span<OtherIndexType, N>) noexcept;
            template<class OtherIndexType, size_t N>
            constexpr explicit(N != rank_dynamic())
            extents(const array<OtherIndexType, N>&) noexcept;

            // 24.7.3.3.5, comparison operators
            friend constexpr bool operator==(const extents&, const extents<OtherIndexType, OtherExtents...>&) noexcept;

            // 24.7.3.3.2, exposition-only helpers
            constexpr size_t fwd_prod_of_extents(rank_type) const noexcept; // exposition only
            constexpr size_t rev_prod_of_extents(rank_type) const noexcept; // exposition only
            template<class OtherIndexType>
            static constexpr auto index_cast(OtherIndexType&&) noexcept;

            private:
                static constexpr rank_type dynamic_index(rank_type) noexcept; // exposition only
                static constexpr rank_type dynamic_index_inv(rank_type) noexcept; // exposition only
                array<index_type, rank_dynamic()> dynamic_extents{}; // exposition only
        }
    }
}

template<class... Integrals>
explicit extents(Integrals...) -> see below;

1 Mandates:
   (1.1) — IndexType is a signed or unsigned integer type, and
Each element of Extents is either equal to dynamic_extent, or is representable as a value of type IndexType.

2   Each specialization of extents models regular and is trivially copyable.

3   Let $E_r$ be the $r^{th}$ element of Extents. $E_r$ is a dynamic extent if it is equal to dynamic_extent, otherwise $E_r$ is a static extent. Let $D_r$ be the value of $\text{dynamic-extents}[\text{dynamic-index}(r)]$ if $E_r$ is a dynamic extent, otherwise $E_r$.

4   The $r^{th}$ interval of the multidimensional index space represented by an extents object is $[0, D_r)$.

### 24.7.3.3.2 Exposition-only helpers

[mdspan.extents.expo]

```cpp
static constexpr rank_type dynamic-index(rank_type i) noexcept;
```

1  Preconditions: $i \leq rank()$ is true.

2  Returns: The number of $E_r$ with $r < i$ for which $E_r$ is a dynamic extent.

```cpp
static constexpr rank_type dynamic-index-inv(rank_type i) noexcept;
```

3  Preconditions: $i < rank_{\text{dynamic}}()$ is true.

4  Returns: The minimum value of $r$ such that $\text{dynamic-index}(r + 1) == i + 1$ is true.

```cpp
constexpr size_t fwd-prod-of-extents(rank_type i) const noexcept;
```

5  Preconditions: $i \leq rank()$ is true.

6  Returns: If $i > 0$ is true, the product of $\text{extent}(k)$ for all $k$ in the range $[0, i)$, otherwise 1.

```cpp
constexpr size_t rev-prod-of-extents(rank_type i) const noexcept;
```

7  Preconditions: $i < rank()$ is true.

8  Returns: If $i + 1 < rank()$ is true, the product of $\text{extent}(k)$ for all $k$ in the range $[i + 1, rank()$, otherwise 1.

```cpp
template<class OtherIndexType>
static constexpr auto index-cast(OtherIndexType&& i) noexcept;
```

9  Effects:

- If OtherIndexType is an integral type other than bool, then equivalent to return i;,

- otherwise, equivalent to return static_cast<index_type>(i);

[Note 1: This function will always return an integral type other than bool. Since this function’s call sites are constrained on convertibility of OtherIndexType to index_type, integer-class types can use the static_cast branch without loss of precision. ]

### 24.7.3.3.3 Constructors

[mdspan.extents.cons]

```cpp
template<class OtherIndexType, size_t... OtherExtents>
constexpr explicit(const extents<OtherIndexType, OtherExtents...>& other) noexcept;
```

1  Constraints:

- sizeof...(OtherExtents) == rank() is true.

- (($\text{OtherExtents} == \text{dynamic_extent} || \text{Extents} == \text{dynamic_extent} || \text{OtherExtents} == \text{Extents} && ...) is true.

2  Preconditions:

- other.extent($r$) equals $E_r$ for each $r$ for which $E_r$ is a static extent, and

- either

- sizeof...(OtherExtents) is zero, or

- other.extent($r$) is representable as a value of type index_type for every rank index $r$ of other.
Postconditions: *this == other is true.

Remarks: The expression inside explicit is equivalent to:

\[
((\text{Extents} != \text{dynamic_extent}) \&\& (\text{OtherExtents} == \text{dynamic_extent})) || \ldots ||
\text{(numeric_limits<index_type>::max() < numeric_limits<OtherIndexType>::max())}
\]

```cpp
template<class... OtherIndexTypes>
constexpr explicit extents(OtherIndexTypes... exts) noexcept;
```

Let \( N \) be \(
\text{sizeof...(OtherIndexTypes)}, \) and let \( \text{exts\_arr} \) be \( \text{array<index_type, N>\{static\_cast<index_type>(std::move(exts))\ldots\}} \).

Constraints:

(6.1) \( \text{(is\_convertible_v<OtherIndexTypes, index\_type> \&\& \ldots)} \) is true,

(6.2) \( \text{(is\_nothrow\_constructible_v<index\_type, OtherIndexTypes> \&\& \ldots)} \) is true, and

(6.3) \( N == \text{rank\_dynamic()} \| N == \text{rank()} \) is true.

[Note 1: One can construct extents from just dynamic extents, which are all the values getting stored, or from all the extents with a precondition. —end note]

Preconditions:

(7.1) If \( N != \text{rank\_dynamic()} \) is true, \( \text{exts\_arr}[r] \) equals \( E_r \) for each \( r \) for which \( E_r \) is a static extent, and

(7.2) either

(7.2.1) \( \text{sizeof...(exts)} == 0 \) is true, or

(7.2.2) each element of \( \text{exts} \) is nonnegative and is representable as a value of type \( \text{index\_type} \).

Postconditions: *this == extents(exts\_arr) is true.

```cpp
template<class OtherIndexType, size_t N>
constexpr explicit extents(span<OtherIndexType, N> exts) noexcept;
```

```cpp
template<class OtherIndexType, size_t N>
constexpr explicit extents(const array<OtherIndexType, N>& exts) noexcept;
```

Constraints:

(9.1) \( \text{is\_convertible_v<const OtherIndexType&, index\_type> is true}, \)

(9.2) \( \text{is\_nothrow\_constructible_v<index\_type, const OtherIndexType&> is true, and} \)

(9.3) \( N == \text{rank\_dynamic()} \| N == \text{rank()} \) is true.

Preconditions:

(10.1) If \( N != \text{rank\_dynamic()} \) is true, \( \text{exts}[r] \) equals \( E_r \) for each \( r \) for which \( E_r \) is a static extent, and

(10.2) either

(10.2.1) \( N \) is zero, or

(10.2.2) \( \text{exts}[r] \) is nonnegative and is representable as a value of type \( \text{index\_type} \) for every rank index \( r \).

Effects:

(11.1) If \( N \) equals \( \text{dynamic\_rank()} \), for all \( d \) in the range \([0, \text{rank\_dynamic()}), \) direct-non-list-initializes \( \text{dynamic\_extents}[d] \) with \( \text{as\_const(exts}[d]) \).

(11.2) Otherwise, for all \( d \) in the range \([0, \text{rank\_dynamic()}), \) direct-non-list-initializes \( \text{dynamic\_extents}[d] \) with \( \text{as\_const(exts}[\text{dynamic\_index\_inv}(d)]) \).

```cpp
template<class... Integrals>
explicit extents(Integrals...) -> see below;
```

Constraints: \( \text{(is\_convertible_v<Integrals, size_t> \&\& \ldots)} \) is true.

Remarks: The deduced type is \( \text{dextents<size_t, sizeof...(Integrals)>} \).
24.7.3.3.4 Observers of the multidimensional index space

static constexpr size_t static_extent(rank_type i) noexcept;

Preconditions: i < rank() is true.

Returns: \( E_i \).

constexpr index_type extent(rank_type i) const noexcept;

Preconditions: i < rank() is true.

Returns: \( D_i \).

24.7.3.3.5 Comparison operators

template<class OtherIndexType, size_t... OtherExtents>
friend constexpr bool operator==(const extents& lhs, const extents<OtherIndexType, OtherExtents...>& rhs) noexcept;

Returns: true if \( \text{lhs.rank()} \) equals \( \text{rhs.rank()} \) and if \( \text{lhs.extent(r)} \) equals \( \text{rhs.extent(r)} \) for every rank index \( r \) of \( \text{rhs} \), otherwise false.

24.7.3.3.6 Alias template dextents

template<class IndexType, size_t Rank>
using dextents = see below;

Result: A type \( E \) that is a specialization of extents such that \( E::\text{rank()} \) == Rank && \( E::\text{rank()} \) == \( E::\text{rank\_dynamic()} \) is true, and \( E::\text{index\_type} \) denotes IndexType.

24.7.3.4 Layout mapping

24.7.3.4.1 General

In subclauses 24.7.3.4.2 and 24.7.3.4.3:

(1.1) \( M \) denotes a layout mapping class.
(1.2) \( m \) denotes a (possibly const) value of type \( M \).
(1.3) \( i \) and \( j \) are packs of (possibly const) integers that are multidimensional indices in \( m.\text{extents()} \) (24.7.3.1). [Note 1: The type of each element of the packs can be a different integer type. — end note]
(1.4) \( r \) is a (possibly const) rank index of \( \text{typename } M::\text{extents\_type} \).
(1.5) \( d_r \) is a pack of (possibly const) integers for which \( \text{sizeof...(d_r)} == M::\text{extents\_type::rank()} \) is true, the \( r \)th element is equal to 1, and all other elements are equal to 0.

In subclauses 24.7.3.4.2 through 24.7.3.4.7, let \( \text{is-mapping-of} \) be the exposition-only variable template defined as follows:

template<class Layout, class Mapping>
constexpr bool is-mapping-of = // exposition only
is_same_v<typename Layout::template mapping<typename Mapping::extents_type>, Mapping>;

24.7.3.4.2 Requirements

A type \( M \) meets the layout mapping requirements if

(1.1) \( M \) models copyable and equality_comparable,
(1.2) \( \text{is_nothrow\_move\_constructible\_v<}\langle M \rangle \) is true,
(1.3) \( \text{is_nothrow\_move\_assignable\_v<}\langle M \rangle \) is true,
(1.4) \( \text{is_nothrow\_swappable\_v<}\langle M \rangle \) is true, and
(1.5) the following types and expressions are well-formed and have the specified semantics.

\( \text{typename } M::\text{extents\_type} \)

Result: A type that is a specialization of extents.

\( \text{typename } M::\text{index\_type} \)

Result: \( \text{typename } M::\text{extents\_type::index\_type} \).
typedef M::rank_type
Result: typedef M::extents_type::rank_type.

typedef M::layout_type
Result: A type MP that meets the layout mapping policy requirements (24.7.3.4.3) and for which
is-mapping-of<MP, M> is true.

m.extents()
Result: const typename M::extents_type&
m(i...)
Result: typename M::index_type
Returns: A nonnegative integer less than numeric_limits<typename M::index_type>::max() and
less than or equal to numeric_limits<size_t>::max().
m(i...) == m(static_cast<typename M::index_type>(i)...)  
Result: bool
Returns: true

m.required_span_size()
Result: typename M::index_type
Returns: If the size of the multidimensional index space m.extents() is 0, then 0, else 1 plus the
maximum value of m(i...) for all i.

m.is_unique()
Result: bool
Returns: true only if for every i and j where (i != j || ...) is true, m(i...) ! = m(j...) is true.
[Note 1: A mapping can return false even if the condition is met. For certain layouts, it is possibly not feasible
to determine efficiently whether the layout is unique. — end note]  
m.is_exhaustive()
Result: bool
Returns: true only if for all k in the range [0, m.required_span_size()) there exists an i such that
m(i...) equals k.
[Note 2: A mapping can return false even if the condition is met. For certain layouts, it is possibly not feasible
to determine efficiently whether the layout is exhaustive. — end note]

m.is_strided()
Result: bool
Returns: true only if for every rank index r of m.extents() there exists an integer s_r such that, for all
i where (i + d_r) is a multidimensional index in m.extents() (24.7.3.1), m((i + d_r)...) - m(i...) equals s_r.
[Note 3: This implies that for a strided layout m(i_0,...,i_k) = m(0,...,0) + i_0 \times s_0 + \cdots + i_k \times s_k. — end note]
[Note 4: A mapping can return false even if the condition is met. For certain layouts, it is possibly not feasible
to determine efficiently whether the layout is strided. — end note]

m.stride(r)
Preconditions: m.is_strided() is true.
Result: typename M::index_type
Returns: s_r as defined in m.is_strided() above.

M::is_always_unique()
Result: A constant expression (7.7) of type bool.
Returns: true only if `m.is_unique()` is true for all possible objects `m` of type `M`.

[Note 5: A mapping can return false even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is unique. — end note]

`M::is_always_exhaustive()`

Result: A constant expression (7.7) of type bool.

Returns: true only if `m.is_exhaustive()` is true for all possible objects `m` of type `M`.

[Note 6: A mapping can return false even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is exhaustive. — end note]

`M::is_always_strided()`

Result: A constant expression (7.7) of type bool.

Returns: true only if `m.is_strided()` is true for all possible objects `m` of type `M`.

[Note 7: A mapping can return false even if the above condition is met. For certain layout mappings, it is possibly not feasible to determine whether every instance is strided. — end note]

### 24.7.3.4.3 Layout mapping policy requirements

A type `MP` meets the **layout mapping policy** requirements if for a type `E` that is a specialization of `extents`, `MP::mapping<E>` is valid and denotes a type `X` that meets the layout mapping requirements (24.7.3.4.2), and for which the qualified-id `X::layout_type` is valid and denotes the type `MP` and the qualified-id `X::extents_type` denotes `E`.

### 24.7.3.4.4 Layout mapping policies

**namespace std {**

```cpp
struct layout_left {
    template<class Extents>
    class mapping;
};

struct layout_right {
    template<class Extents>
    class mapping;
};

struct layout_stride {
    template<class Extents>
    class mapping;
};
```

**}**

1 Each of `layout_left`, `layout_right`, and `layout_stride` meets the layout mapping policy requirements and is a trivial type.

### 24.7.3.4.5 Class template `layout_left::mapping`

**namespace std {**

```cpp
template<class Extents>
class layout_left::mapping {
public:
    using extents_type = Extents;
    using index_type = typename extents_type::index_type;
    using size_type = typename extents_type::size_type;
    using rank_type = typename extents_type::rank_type;
    using layout_type = layout_left;

    // 24.7.3.4.5.2, constructors
    constexpr mapping() noexcept = default;
    constexpr mapping(const mapping&) noexcept = default;
    constexpr mapping(const extents_type&) noexcept;
```

**}**

§ 24.7.3.4.5 1040
template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const mapping<OtherExtents>&) noexcept;

template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const layout_right::mapping<OtherExtents>&) noexcept;

template<class OtherExtents>
constexpr explicit(extents_type::rank() > 0)
    mapping(const layout_stride::mapping<OtherExtents>&);

constexpr mapping& operator=(const mapping&) noexcept = default;

// 24.7.3.4.5.3, observers
constexpr const extents_type& extents() const noexcept { return extents_; }

constexpr index_type required_span_size() const noexcept;

template<class... Indices>
constexpr index_type operator()(Indices...) const noexcept;

static constexpr bool is_always_unique() noexcept { return true; }
static constexpr bool is_always_exhaustive() noexcept { return true; }
static constexpr bool is_always_strided() noexcept { return true; }
static constexpr bool is_unique() noexcept { return true; }
static constexpr bool is_exhaustive() noexcept { return true; }
static constexpr bool is_strided() noexcept { return true; }

constexpr index_type stride(rank_type) const noexcept;

template<class OtherExtents>
friend constexpr bool operator==(const mapping&, const mapping<OtherExtents>&) noexcept;

private:
    extents_type extents_;  // exposition only
};

2 If Extents is not a specialization of extents, then the program is ill-formed.

3 layout_left::mapping<E> is a trivially copyable type that models regular for each E.

4 Mandates: If Extents::rank_dynamic() == 0 is true, then the size of the multidimensional index space Extents() is representable as a value of type typename Extents::index_type.

### 24.7.3.4.5.2 Constructors [mdspan.layout.left.cons]

constexpr mapping(const extents_type& e) noexcept;

1 **Preconditions:** The size of the multidimensional index space e is representable as a value of type index_type (6.8.2).

2 **Effects:** Direct-non-list-initializes extents_ with e.

template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const mapping<OtherExtents>&& other) noexcept;

3 **Constraints:** is_constructible_v<extents_type, OtherExtents> is true.

4 **Preconditions:** other.required_span_size() is representable as a value of type index_type (6.8.2).

5 **Effects:** Direct-non-list-initializes extents_ with other.extents().

template<class OtherExents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
    mapping(const layout_right::mapping<OtherExtents>& other) noexcept;

6 **Constraints:**
© ISO/IEC N4944

§ 24.7.3.4.5.3 Observers [mdspan.layout.left.obs]

```cpp
template<class... Indices>
constexpr index_type required_span_size() const noexcept {
    return (static_cast<index_type>(i) * stride(P)) + ... + 0;
}
```

4 Returns: extents().fwd-prod-of-extents(i).

### Preconditions
- extents_type::rank() > 0 is true.
- i < extents_type::rank() is true.

6 Preconditions: i < extents_type::rank() is true.

7 Effects: Direct-Non-list-initializes extents_ with other.extents().

24.7.3.4.6 Class template layout_right::mapping [mdspan.layout.right]

24.7.3.4.6.1 Overview [mdspan.layout.right.overview]

layout_right provides a layout mapping where the rightmost extent is stride 1, and strides increase right-to-left as the product of extents.

```cpp
namespace std {
    template<class Extents>
    class layout_right::mapping {
        public:
            using extents_type = Extents;
            using index_type = typename extents_type::index_type;
            using size_type = typename extents_type::size_type;
        }
    }
}
using rank_type = typename extents_type::rank_type;
using layout_type = layout_right;

// 24.7.3.4.6.2, constructors
constexpr mapping() noexcept = default;
constexpr mapping(const mapping&) noexcept = default;
constexpr mapping(const extents_type&) noexcept;
template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
  mapping(const mapping<OtherExtents>&) noexcept;
template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
  mapping(const layout_left::mapping<OtherExtents>&) noexcept;
template<class OtherExtents>
constexpr explicit(rank_type::rank() > 0)
  mapping(const layout_stride::mapping<OtherExtents>&) noexcept;
constexpr mapping& operator=(const mapping&) noexcept = default;

// 24.7.3.4.6.3, observers
constexpr const extents_type& extents() const noexcept { return extents_; }
constexpr index_type required_span_size() const noexcept;
template<class... Indices>
constexpr index_type operator()(Indices...) const noexcept;
static constexpr bool is_always_unique() noexcept { return true; }
static constexpr bool is_always_exhaustive() noexcept { return true; }
static constexpr bool is_always_strided() noexcept { return true; }
static constexpr bool is_unique() noexcept { return true; }
static constexpr bool is_exhaustive() noexcept { return true; }
static constexpr bool is_strided() noexcept { return true; }
constexpr index_type stride(rank_type) const noexcept;
template<class OtherExtents>
friend constexpr bool operator==(const mapping&, const mapping<OtherExtents>&) noexcept;

private:
  extents_type extents_; // exposition only
};

2 If Extents is not a specialization of extents, then the program is ill-formed.
3 layout_right::mapping<E> is a trivially copyable type that models regular for each E.
4 Mandates: If Extents::rank_dynamic() == 0 is true, then the size of the multidimensional index space Extents() is representable as a value of type typename Extents::index_type.
Effects: Direct-list-initializes `extents_` with `other.extents()`.

```cpp
template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
mapping(const layout_left::mapping<OtherExtents>& other) noexcept;
```

Constraints:
- `extents_type::rank() <= 1` is true, and
- `is_constructible_v<extents_type, OtherExtents>` is true.

Preconditions: `other.required_span_size()` is representable as a value of type `index_type (6.8.2)`.

Effects: Direct-non-list-initializes `extents_` with `other.extents()`.

```cpp
template<class OtherExtents>
constexpr explicit(!is_convertible_v<OtherExtents, extents_type>)
mapping(const layout_stride::mapping<OtherExtents>& other) noexcept;
```

Constraints: `is_constructible_v<extents_type, OtherExtents>` is true.

Preconditions:
- If `extents_type::rank() > 0` is true, then for all `r` in the range `[0, extents_type::rank())`, `other.stride(r)` equals `extents().rev-prod-of-extents(r)`.
- `other.required_span_size()` is representable as a value of type `index_type (6.8.2)`.

Effects: Direct-non-list-initializes `extents_` with `other.extents()`.

### 24.7.3.4.6.3 Observers

```cpp
index_type required_span_size() const noexcept;
```

Returns: `extents().fwd-prod-of-extents(extents_type::rank())`.

```cpp
template<class... Indices>
constexpr index_type operator()(Indices... i) const noexcept;
```

Constraints:
- `sizeof...(Indices) == extents_type::rank()` is true,
- `(is_convertible_v<Indices, index_type> && ...)` is true, and
- `(is_nothrow_constructible_v<index_type, Indices> && ...)` is true.

Preconditions: `extents_type::index-cast(i)` is a multidimensional index in `extents_ (24.7.3.1)`.

Effects: Let `P` be a parameter pack such that

- `(is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>)` is true. Equivalent to:

  ```cpp
  return ((static_cast<index_type>(i) * stride(P)) + ... + 0);
  ```

```cpp
constexpr index_type stride(rank_type i) const noexcept;
```

Constraints: `extents_type::rank() > 0` is true.

Preconditions: `i < extents_type::rank()` is true.

Returns: `extents().rev-prod-of-extents(i)`.

### 24.7.3.4.7 Class template layout_stride::mapping

Overview

`layout_stride` provides a layout mapping where the strides are user-defined.
namespace std {
    template<class Extents>
    class layout_stride::mapping {
        public:
            using extents_type = Extents;
            using index_type = typename extents_type::index_type;
            using size_type = typename extents_type::size_type;
            using rank_type = typename extents_type::rank_type;
            using layout_type = layout_stride;

            private:
                static constexpr rank_type rank_ = extents_type::rank();  // exposition only

                public:
                    // 24.7.3.4.7.3, constructors
                    constexpr mapping() noexcept;
                    constexpr mapping(const mapping&) noexcept = default;
                    template<class OtherIndexType>
                        constexpr mapping(const extents_type&, span<OtherIndexType,
                            rank_>) noexcept;
                    template<class OtherIndexType>
                        constexpr mapping(const extents_type&, const array<OtherIndexType,
                            rank_>&) noexcept;
                    template<class StridedLayoutMapping>
                        constexpr explicit(mapping(const StridedLayoutMapping&) noexcept;

                    constexpr mapping& operator=(const mapping&) noexcept = default;

                    // 24.7.3.4.7.4, observers
                    constexpr const extents_type& extents() const noexcept { return extents_; }
                    constexpr array<index_type,
                        rank_> strides() const noexcept { return strides_; }

                    constexpr index_type required_span_size() const noexcept;
                    template<class... Indices>
                        constexpr index_type operator()(Indices...) const noexcept;

                    static constexpr bool is_always_unique() noexcept { return true; }
                    static constexpr bool is_always_exhaustive() noexcept { return false; }
                    static constexpr bool is_always_strided() noexcept { return true; }

                    constexpr bool is_exhaustive() const noexcept;
                    static constexpr bool is_strided() noexcept { return true; }

                    constexpr index_type stride(rank_type i) const noexcept { return strides_[i]; }

                    template<class OtherMapping>
                        friend constexpr bool operator==(const mapping&, const OtherMapping&) noexcept;

                private:
                    extents_type extents_;  // exposition only
                    array<index_type, rank_> strides_;  // exposition only
                };
    };

2 If Extents is not a specialization of extents, then the program is ill-formed.

3 layout_stride::mapping<E> is a trivially copyable type that models regular for each E.

4 Mandates: If Extents::rank_dynamic() == 0 is true, then the size of the multidimensional index space Extents() is representable as a value of type typename Extents::index_type.

24.7.3.4.7.2 Exposition-only helpers [mdspan.layout.stride.expo]

1 Let REQUIRED-SIZE(e, strides) be:

\[(1.1) \quad 1, \text{ if } e.\text{rank}() == 0 \text{ is true,} \]
© ISO/IEC N4944

24.7.3.4.7.3 Constructors

constexpr mapping() noexcept;

Preconditions: layout_right::mapping<extents_type>().required_span_size() is representable
as a value of type index_type (6.8.2).

Effects: Direct-non-list-initializes extents_ with extents_type(), and for all d in the range
[0, rank_), direct-non-list-initializes strides_[d] with layout_right::mapping<extents_type>().stride(d).

template<class OtherIndexType>
constexpr mapping(const extents_type& e, span<OtherIndexType, rank_> s) noexcept;
template<class OtherIndexType>
constexpr mapping(const extents_type& e, const array<OtherIndexType, rank_>& s) noexcept;

Constraints:

(3.1) — is_convertible_v<const OtherIndexType&, index_type> is true, and
(3.2) — is_nothrow_constructible_v<index_type, const OtherIndexType&> is true.

Preconditions:

(4.1) — s[i] > 0 is true for all i in the range [0, rank_).
(4.2) — REQUIRED-SPAN-SIZE(e, s) is representable as a value of type index_type (6.8.2).
(4.3) — If rank_ is greater than 0, then there exists a permutation P of the integers in the range
[0, rank_), such that s[P[i]] >= s[P[i-1]] * e.extent(P[i-1]) is true for all i in the range [1, rank_),
where P is the i-th element of P.

[Note 1: For layout_stride, this condition is necessary and sufficient for is_unique() to be true. — end
note]

Effects: Direct-non-list-initializes extents_ with e, and for all d in the range [0, rank_),
direct-non-list-initializes strides_[d] with as_const(s[d]).
template<class StridedLayoutMapping>
constexpr explicit(see below)
    mapping(const StridedLayoutMapping& other) noexcept;

Constraints:

(6.1)  — layout-mapping-alike<StridedLayoutMapping> is satisfied.
(6.2)  — is_constructible_v<extents_type, typename StridedLayoutMapping::extents_type> is true.
(6.3)  — StridedLayoutMapping::is_always_unique() is true.
(6.4)  — StridedLayoutMapping::is_always_strided() is true.

Preconditions:

(7.1)  — StridedLayoutMapping meets the layout mapping requirements (24.7.3.4.3),
(7.2)  — other.stride(r) > 0 is true for every rank index r of extents(),
(7.3)  — other.required_span_size() is representable as a value of type index_type (6.8.2), and
(7.4)  — OFFSET(other) == 0 is true.

Effects: Direct-non-list-initializes extents_ with other.extents(), and for all d in the range [0, rank_),
direct-non-list-initializes strides_[d] with other.stride(d).

Remarks: The expression inside explicit is equivalent to:

!is_convertible_v<typename StridedLayoutMapping::extents_type, extents_type> &&
(is-mapping-of<layout_left, LayoutStrideMapping> ||
is-mapping-of<layout_right, LayoutStrideMapping> ||
is-mapping-of<layout_stride, LayoutStrideMapping>)

24.7.3.4.7.4 Observers

constexpr index_type required_span_size() const noexcept;

Returns: REQUIRED-SPAN-SIZE(extents(), strides_).

template<class... Indices>
constexpr index_type operator()(Indices... i) const noexcept;

Constraints:

(2.1)  — sizeof...(Indices) == rank_ is true,
(2.2)  — (is_convertible_v<Indices, index_type> && ...) is true, and
(2.3)  — (is_nothrow_constructible_v<index_type, Indices> && ...) is true.

Preconditions: extents_type::index-cast(i) is a multidimensional index in extents_ (24.7.3.1).

Effects: Let P be a parameter pack such that

is_same_v<index_sequence_for<Indices...>, index_sequence<P...>>

is true. Equivalent to:

return ((static_cast<index_type>(i) * stride(P)) + ... + 0);

constexpr bool is_exhaustive() const noexcept;

Returns:

(5.1)  — true if rank_ is 0.
(5.2)  — Otherwise, true if there is a permutation P of the integers in the range [0, rank_) such that
    stride(p_0) equals 1, and stride(p_i) equals stride(p_{i−1}) * extents_.extent(p_{i−1}) for i in
    the range [1, rank_), where p_i is the i\textsuperscript{th} element of P.
(5.3)  — Otherwise, false.

template<class OtherMapping>
friend constexpr bool operator==(const mapping& x, const OtherMapping& y) noexcept;

Constraints:

(6.1)  — layout-mapping-alike<OtherMapping> is satisfied.
Preconditions: OtherMapping meets the layout mapping requirements (24.7.3.4.3).

Returns: true if x.extents() == y.extents() is true, OFFSET(y) == 0 is true, and each of x.stride(r) == y.stride(r) is true for r in the range [0, x.extents().rank()). Otherwise, false.

24.7.3.5 Accessor policy

24.7.3.5.1 General

An accessor policy defines types and operations by which a reference to a single object is created from an abstract data handle to a number of such objects and an index.

A range of indices [0, N) is an accessible range of a given data handle and an accessor if, for each i in the range, the accessor policy’s access function produces a valid reference to an object.

In subclause 24.7.3.5.2,

(3.1) A denotes an accessor policy.
(3.2) a denotes a value of type A or const A.
(3.3) p denotes a value of type A::data_handle_type or const A::data_handle_type.
[Note 1: The type A::data_handle_type need not be dereferenceable. — end note]
(3.4) n, i, and j each denote values of type size_t.

24.7.3.5.2 Requirements

A type A meets the accessor policy requirements if

(1.1) A models copyable,
(1.2) is_nothrow_move_constructible_v<A> is true,
(1.3) is_nothrow_move_assignable_v<A> is true,
(1.4) is_nothrow_swappable_v<A> is true, and
(1.5) the following types and expressions are well-formed and have the specified semantics.

typename A::element_type

Result: A complete object type that is not an abstract class type.

typename A::data_handle_type

Result: A type that models copyable, and for which is_nothrow_move_constructible_v<A::data_handle_type> is true, is_nothrow_move_assignable_v<A::data_handle_type> is true, and is_nothrow_swappable_v<A::data_handle_type> is true.
[Note 1: The type of data_handle_type need not be element_type*. — end note]

typename A::reference

Result: A type that models common_reference_with<A::reference&, A::element_type&>.
[Note 2: The type of reference need not be element_type&. — end note]

typename A::offset_policy

Result: A type OP such that:

OP meets the accessor policy requirements,
constructible_from<OP, const A&> is modeled, and
is_same_v<typename OP::element_type, typename A::element_type> is true.

a.access(p, i)

Result: A::reference

Remarks: The expression is equality preserving.
[Note 3: Concrete accessor policies can impose preconditions for their access function. However, they might not. For example, an accessor where \( p \) is \( \text{span}<A::\text{element_type}, \text{dynamic_extent}> \) and \( \text{access}(p, i) \) returns \( p[i \mod p.size()] \) does not need to impose a precondition on \( i \). — end note]

\[
a\text{offset}(p, i)
\]

9

**Result:** \( A::\text{offset_policy}::\text{data_handle_type} \)

10

**Returns:** \( q \) such that for \( b \) being \( A::\text{offset_policy}(a) \), and any integer \( n \) for which \( [0,n) \) is an accessible range of \( p \) and \( a \):

10.1

\( [0,n-i) \) is an accessible range of \( q \) and \( b \); and

10.2

\( b\text{.access}(q, j) \) provides access to the same element as \( a\text{.access}(p, i+j) \), for every \( j \) in the range \( [0,n-i) \).

11

**Remarks:** The expression is equality-preserving.

### 24.7.3.5.3 Class template default_accessor

#### 24.7.3.5.3.1 Overview

namespace std {
    template<class ElementType>
    struct default_accessor {
        using offset_policy = default_accessor;
        using element_type = ElementType;
        using reference = ElementType&;
        using data_handle_type = ElementType*;

        constexpr default_accessor() noexcept = default;
        template<class OtherElementType>
        constexpr default_accessor(default_accessor<OtherElementType>) noexcept;[
        constexpr reference access(data_handle_type p, size_t i) const noexcept;
        constexpr data_handle_type offset(data_handle_type p, size_t i) const noexcept;
    };
}

**default_accessor** meets the accessor policy requirements.

2

**ElementType** is required to be a complete object type that is neither an abstract class type nor an array type.

3

Each specialization of **default_accessor** is a trivially copyable type that models semiregular.

4

\( [0,n) \) is an accessible range for an object \( p \) of type \( \text{data_handle_type} \) and an object of type **default_accessor** if and only if \( [p, p+n) \) is a valid range.

### 24.7.3.5.3.2 Members

Template:

\[
\text{template}<\text{class OtherElementType}>
\text{constexpr default_accessor}(<\text{default_accessor}<\text{OtherElementType}>) \text{ noexcept} \{\}
\]

1

**Constraints:** \( \text{is_convertible_v<OtherElementType(*)[]}, \text{element_type(*)[]}> \) is true.

**Effects:** Equivalent to: return \( p[i] \);

\[
\text{constexpr data_handle_type offset(data_handle_type p, size_t i) const noexcept;}
\]

2

**Effects:** Equivalent to: return \( p + i \);

### 24.7.3.6 Class template mdspan

#### 24.7.3.6.1 Overview

\( \text{mdspan} \) is a view of a multidimensional array of elements.

namespace std {
    template<class ElementType, class Extents, class LayoutPolicy = layout_right, class AccessorPolicy = default_accessor<ElementType>>
    class mdspan {
        public:
            using extents_type = Extents;

        
§ 24.7.3.6.1 1049
using layout_type = LayoutPolicy;
using accessor_type = AccessorPolicy;
using mapping_type = typename layout_type::template mapping<extents_type>;
using element_type = ElementType;
using value_type = remove_cv_t<element_type>;
using index_type = typename extents_type::index_type;
using size_type = typename extents_type::size_type;
using rank_type = typename extents_type::rank_type;
using data_handle_type = typename accessor_type::data_handle_type;
using reference = typename accessor_type::reference;

static constexpr rank_type rank() noexcept { return extents_type::rank(); }
static constexpr rank_type rank_dynamic() noexcept { return extents_type::rank_dynamic(); }
static constexpr size_t static_extent(rank_type r) noexcept
    { return extents_type::static_extent(r); }
constexpr index_type extent(rank_type r) const noexcept { return extents().extent(r); }

// 24.7.3.6.2, constructors
constexpr mdspan();
constexpr mdspan(const mdspan& rhs) = default;
constexpr mdspan(mdspan&& rhs) = default;

    template<class... OtherIndexTypes>
    constexpr explicit mdspan(data_handle_type ptr, OtherIndexTypes... exts);
    template<class OtherIndexType, size_t N>
    constexpr explicit(N != rank_dynamic())
        mdspan(data_handle_type p, span<OtherIndexType, N> exts);
    template<class OtherIndexType, size_t N>
    constexpr explicit(N != rank_dynamic())

    { return map_.is_exhaustive(); }
constexpr bool is_strided() const
    { return map_.is_strided(); }
constexpr index_type stride(rank_type r) const
    { return map_.stride(r); }

private:
    accessor_type acc_;         // exposition only
    mapping_type map_;          // exposition only
    data_handle_type ptr_;      // exposition only
};

template<class CArray>
    requires(is_array_v<CArray> && rank_v<CArray> == 1)
mdspan(CArray&)
    -> mdspan<remove_all_extents_t<CArray>, extents<size_t, extent_v<CArray, 0>>>

template<class Pointer>
    requires(is_pointer_v<remove_reference_t<Pointer>>)
mdspan(Pointer&)
    -> mdspan<remove_pointer_t<remove_reference_t<Pointer>>, extents<size_t>>

template<class ElementType, class... Integrals>
    requires((is_convertible_v<Integrals, size_t> && ...) && sizeof...(Integrals) > 0)
explicit mdspan(ElementType*, Integrals...)
    -> mdspan<ElementType, dextents<size_t, sizeof...(Integrals)>>

template<class ElementType, class OtherIndexType, size_t N>
mdspan(ElementType*, span<OtherIndexType, N>)
    -> mdspan<ElementType, dextents<size_t, N>>

template<class ElementType, class OtherIndexType, size_t N>
mdspan(ElementType*, const array<OtherIndexType, N>&)
    -> mdspan<ElementType, const array<OtherIndexType, N>>&

template<class ElementType, class IndexType, size_t... ExtentsPack>
mdspan(ElementType*, const extents<IndexType, ExtentsPack...>&)
    -> mdspan<ElementType, extents<IndexType, ExtentsPack...>>&

template<class ElementType, class MappingType>
mdspan(ElementType*, const MappingType&)
    -> mdspan<ElementType, typename MappingType::extents_type,
                 typename MappingType::layout_type>

template<class MappingType, class AccessorType>
mdspan(const typename AccessorType::data_handle_type&, const MappingType&,
        const AccessorType&)
    -> mdspan<typename AccessorType::element_type, typename MappingType::extents_type,
                 typename MappingType::layout_type, AccessorType>;

2 mandates:
(2.1) ElementType is a complete object type that is neither an abstract class type nor an array type,
(2.2) Extents is a specialization of extents, and
(2.3) is_same_v<ElementType, typename AccessorPolicy::element_type> is true.
LayoutPolicy shall meet the layout mapping policy requirements (24.7.3.4.3), and AccessorPolicy shall meet the accessor policy requirements (24.7.3.5.2).

Each specialization MDS of mdspan models copyable and

(4.1)  is_nothrow_move_constructible_v<MDS> is true,
(4.2)  is_nothrow_move_assignable_v<MDS> is true, and
(4.3)  is_nothrow_swappable_v<MDS> is true.

A specialization of mdspan is a trivially copyable type if its accessor_type, mapping_type, and data_handle_type are trivially copyable types.

### 24.7.3.6.2 Constructors

**constexpr mdspan();**

Constraints:

(1.1)  rank_dynamic() > 0 is true.
(1.2)  is_default_constructible_v<data_handle_type> is true.
(1.3)  is_default_constructible_v<mapping_type> is true.
(1.4)  is_default_constructible_v<accessor_type> is true.

Preconditions: [0, map_.required_span_size()) is an accessible range of ptr_ and acc_ for the values of map_ and acc_ after the invocation of this constructor.

Effects: Value-initializes ptr_, map_, and acc_.

```
template<class... OtherIndexTypes>
constexpr explicit mdspan(data_handle_type p, OtherIndexTypes... exts);
```

Let N be sizeof...(OtherIndexTypes).

Constraints:

(5.1)  (is_convertible_v<OtherIndexTypes, index_type> && ...) is true,
(5.2)  (is_nothrow_constructible<index_type, OtherIndexTypes> && ...) is true,
(5.3)  N == rank() || N == rank_dynamic() is true,
(5.4)  is_constructible_v<mapping_type, extents_type> is true, and
(5.5)  is_default_constructible_v<accessor_type> is true.

Preconditions: [0, map_.required_span_size()) is an accessible range of p and acc_ for the values of map_ and acc_ after the invocation of this constructor.

Effects:

(7.1)  Direct-non-list-initializes ptr_ with std::move(p),
(7.2)  direct-non-list-initializes map_ with extents_type(static_cast<index_type>(std::move(exts))...), and
(7.3)  value-initializes acc_.

```
template<class OtherIndexType, size_t N>
constexpr explicit(N != rank_dynamic()) mdspan(data_handle_type p, span<OtherIndexType, N> exts);
template<class OtherIndexType, size_t N>
constexpr explicit(N != rank_dynamic()) mdspan(data_handle_type p, const array<OtherIndexType, N>& exts);
```

Constraints:

(8.1)  is_convertible_v<const OtherIndexType&, index_type> is true,
(8.2)  (is_nothrow_constructible<index_type, const OtherIndexType&> && ...) is true,
(8.3)  N == rank() || N == rank_dynamic() is true,
(8.4)  is_constructible_v<mapping_type, extents_type> is true, and
(8.5)  is_default_constructible_v<accessor_type> is true.
Preconditions: \([0, \text{map:]_.required\_span\_size()}\) is an accessible range of \(p\) and \(\text{acc}_.\) for the values of \(\text{map}\) and \(\text{acc}\) after the invocation of this constructor.

Effects:

(10.1) Direct-list-initializes \(\text{ptr}\) with \(\text{std::move}(p)\),
(10.2) direct-non-list-initializes \(\text{map}\) with \(\text{extents\_type}(\text{exts})\), and
(10.3) value-initializes \(\text{acc}\).

```constexpr mdspan(data\_handle\_type p, const extents\_type& ext);```

Constraints:

(11.1) \(\text{is\_constructible\_v<mapping\_type, const extents\_type&>}\) is true, and
(11.2) \(\text{is\_default\_constructible\_v<accessor\_type>}\) is true.

Preconditions: \([0, \text{map:]_.required\_span\_size()}\) is an accessible range of \(p\) and \(\text{acc}_.\) for the values of \(\text{map}\) and \(\text{acc}\) after the invocation of this constructor.

Effects:

(13.1) Direct-list-initializes \(\text{ptr}\) with \(\text{std::move}(p)\),
(13.2) direct-non-list-initializes \(\text{map}\) with \(\text{ext}\), and
(13.3) value-initializes \(\text{acc}\).

```constexpr mdspan(data\_handle\_type p, const mapping\_type\& m);```

Constraints: \(\text{is\_default\_constructible\_v<accessor\_type>}\) is true.

Preconditions: \([0, \text{m:]_.required\_span\_size()}\) is an accessible range of \(p\) and \(\text{acc}_.\) for the value of \(\text{acc}\) after the invocation of this constructor.

Effects:

(16.1) Direct-list-initializes \(\text{ptr}\) with \(\text{std::move}(p)\),
(16.2) direct-non-list-initializes \(\text{map}\) with \(\text{m}\), and
(16.3) value-initializes \(\text{acc}\).

```constexpr mdspan(data\_handle\_type p, const mapping\_type\& m, const accessor\_type\& a);```

Preconditions: \([0, \text{m:]_.required\_span\_size()}\) is an accessible range of \(p\) and \(a\).

Effects:

(18.1) Direct-list-initializes \(\text{ptr}\) with \(\text{std::move}(p)\),
(18.2) direct-non-list-initializes \(\text{map}\) with \(\text{m}\), and
(18.3) direct-non-list-initializes \(\text{acc}\) with \(\text{a}\).

```template<class OtherElementType, class OtherExtents, class OtherLayoutPolicy, class OtherAccessor> constexpr explicit(see below) mdspan(const mdspan<OtherElementType, OtherExtents, OtherLayoutPolicy, OtherAccessor>& other);```

Constraints:

(19.1) \(\text{is\_constructible\_v<mapping\_type, const OtherLayoutPolicy::template mapping<OtherExtents>>&}\) is true, and
(19.2) \(\text{is\_constructible\_v<accessor\_type, const OtherAccessor&>}\) is true.

Mandates:

(20.1) \(\text{is\_constructible\_v<data\_handle\_type, const OtherAccessor::data\_handle\_type&}>\) is true, and
(20.2) \(\text{is\_constructible\_v<extents\_type, OtherExtents>>}\) is true.

Preconditions:
For each rank index $r$ of extents_type, static_extent(r) == dynamic_extent || staticExtent(r) == other.extent(r) is true.

$[0, map_.required_span_size())$ is an accessible range of $ptr_*$ and $acc_*$ for values of $ptr_*$, $map_*$, and $acc_*$ after the invocation of this constructor.

**Effects:**
- Direct-non-list-initializes $ptr_*$ with other.$ptr_*$,
- direct-non-list-initializes $map_*$ with other.$map_*$, and
- direct-non-list-initializes $acc_*$ with other.$acc_*$.

**Remarks:** The expression inside explicit is equivalent to:

$!is_convertible_v<const OtherLayoutPolicy::template mapping<OtherExtents>&, mapping_type>
|| !is_convertible_v<const OtherAccessor&, accessor_type>$

### 24.7.3.6.3 Members

```cpp
template<class... OtherIndexTypes>
constexpr reference operator[](OtherIndexTypes... indices) const;

1 Constraints:
1.1 (is_convertible_v<OtherIndexTypes, index_type> && ...) is true,
1.2 (is_nothrow_constructible_v<index_type, OtherIndexTypes> && ...) is true, and
1.3 sizeof...(OtherIndexTypes) == rank() is true.

2 Let I be extents_type::index_cast(std::move(indices)).
3 Preconditions: I is a multidimensional index in extents().
[Note 1: This implies that map_(I) < map_.required_span_size() is true. — end note]
4 Effects: Equivalent to:
   return acc_.access(ptr_, map_(static_cast<index_type>(std::move(indices))...));

template<class OtherIndexType>
constexpr reference operator[](span<OtherIndexType, rank()> indices) const;

5 Constraints:
5.1 is_convertible_v<const OtherIndexType&, index_type> is true, and
5.2 is_nothrow_constructible_v<index_type, const OtherIndexType&> is true.
6 Effects: Let $P$ be a parameter pack such that
   is_same_v<make_index_sequence<rank()>, index_sequence<P...>>
   is true. Equivalent to:
   return operator[](as_const(indices[P])...);

constexpr size_type size() const noexcept;
7 Preconditions: The size of the multidimensional index space extents() is representable as a value of
type size_type (6.8.2).
8 Returns: extents().fwd-prod-of-extents(rank()).

[[nodiscard]] constexpr bool empty() const noexcept;
9 Returns: true if the size of the multidimensional index space extents() is 0, otherwise false.

friend constexpr void swap(mdspan& x, mdspan& y) noexcept;
10 Effects: Equivalent to:
   swap(x.$ptr_*$, y.$ptr_*$);
   swap(x.$map_*$, y.$map_*$);
   swap(x.$acc_*$, y.$acc_*$);
```

§ 24.7.3.6.3 1054
25 Iterators library

25.1 General

This Clause describes components that C++ programs may use to perform iterations over containers (Clause 24), streams (31.7), stream buffers (31.6), and other ranges (Clause 26).

The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators, and stream iterators, as summarized in Table 84.

Table 84: Iterators library summary

§ 25.2 1062
25.3 Iterator requirements

25.3.1 In general

Iterators are a generalization of pointers that allow a C++ program to work with different data structures (for example, containers and ranges) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterators. An input iterator \( i \) supports the expression \( \*i \), resulting in a value of some object type \( T \), called the value type of the iterator. An output iterator \( i \) has a non-empty set of types that are indirectly writable to the iterator; for each such type \( T \), the expression \( \*i = o \) is valid where \( o \) is a value of type \( T \). For every iterator type \( X \), there is a corresponding signed integer-like type (25.3.4.4) called the difference type of the iterator.

Since iterators are an abstraction of pointers, their semantics are a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This document defines six categories of iterators, according to the operations defined on them: **input iterators**, **output iterators**, **forward iterators**, **bidirectional iterators**, **random access iterators**, and **contiguous iterators**, as shown in Table 85.

Table 85: Relations among iterator categories

<th>Contiguous</th>
<th>Random Access</th>
<th>Bidirectional</th>
<th>Forward</th>
<th>Input</th>
<th>Output</th>
</tr>
</thead>
</table>

The six categories of iterators correspond to the iterator concepts

- input_iterator (25.3.4.9),
- output_iterator (25.3.4.10),
- forward_iterator (25.3.4.11),
- bidirectional_iterator (25.3.4.12),
- random_access_iterator (25.3.4.13), and
- contiguous_iterator (25.3.4.14),

respectively. The generic term iterator refers to any type that models the input_or_output_iterator concept (25.3.4.6).

Forward iterators meet all the requirements of input iterators and can be used whenever an input iterator is specified; Bidirectional iterators also meet all the requirements of forward iterators and can be used whenever a forward iterator is specified; Random access iterators also meet all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified; Contiguous iterators also meet all the requirements of random access iterators and can be used whenever a random access iterator is specified.

Iterators that further meet the requirements of output iterators are called mutable iterators. Nonmutable iterators are referred to as constant iterators.

In addition to the requirements in this subclause, the nested typedef-names specified in 25.3.2.3 shall be provided for the iterator type.

[Note 1: Either the iterator type must provide the typedef-names directly (in which case iterator_traits pick them up automatically), or an iterator_traits specialization must provide them. —end note]

Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type there is an iterator value that points past the last element of a corresponding sequence. Such a value is called a past-the-end value. Values of an iterator \( i \) for which the expression \( \*i \) is defined are called dereferenceable. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any sequence. Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value,
the assignment of a non-singular value to an iterator that holds a singular value, and, for iterators that meet the Cpp17DefaultConstructible requirements, using a value-initialized iterator as the source of a copy or move operation.

[Note 2: This guarantee is not offered for default-initialization, although the distinction only matters for types with trivial default constructors such as pointers or aggregates holding pointers. — end note]

In these cases the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.

Most of the library’s algorithmic templates that operate on data structures have interfaces that use ranges. A range is an iterator and a sentinel that designate the beginning and end of the computation, or an iterator and a count that designate the beginning and the number of elements to which the computation is to be applied.\[213\]

An iterator and a sentinel denoting a range are comparable. A range [i, s] is empty if i == s; otherwise, [i, s] refers to the elements in the data structure starting with the element pointed to by i and up to but not including the element, if any, pointed to by the first iterator j such that j == s.

A sentinel s is called reachable from an iterator i if and only if there is a finite sequence of applications of the expression ++i that makes i == s. If s is reachable from i, [i, s] denotes a valid range.

A counted range i + [0, n) is empty if n == 0; otherwise, i + [0, n) refers to the n elements in the data structure starting with the element pointed to by i and up to but not including the element, if any, pointed to by the result of n applications of ++i. A counted range i + [0, n) is valid if and only if n == 0; or n is positive, i is dereferenceable, and ++i + [0, −−n) is valid.

The result of the application of library functions to invalid ranges is undefined.

All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables and concept definitions for the iterators do not specify complexity.

Destruction of a non-forward iterator may invalidate pointers and references previously obtained from that iterator.

An invalid iterator is an iterator that may be singular.\[214\]

Iterators are called constexpr iterators if all operations provided to meet iterator category requirements are constexpr functions.

[Note 3: For example, the types “pointer to int” and reverse_iterator<int*> are constexpr iterators. — end note]

25.3.2 Associated types

25.3.2.1 Incrementable traits

To implement algorithms only in terms of incrementable types, it is often necessary to determine the difference type that corresponds to a particular incrementable type. Accordingly, it is required that if WI is the name of a type that models the weakly_incrementable concept (25.3.4.4), the type

    iter_difference_t<WI>

be defined as the incrementable type’s difference type.

```cpp
namespace std {
    template<class> struct incrementable_traits { };

    template<class T>
    requires is_object_v<T>
    struct incrementable_traits<T> { 
        using difference_type = ptrdiff_t;
    };

    template<class I>
    struct incrementable_traits<const I>
        : incrementable_traits<I> { }; 

213) The sentinel denoting the end of a range can have the same type as the iterator denoting the beginning of the range, or a different type.
214) This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.
template<class T>
    requires requires { typename T::difference_type; }
struct incrementable_traits<T> {
    using difference_type = typename T::difference_type;
};

template<class T>
    requires (!requires { typename T::difference_type; } &&
      requires(const T& a, const T& b) { { a - b } -> integral; })
struct incrementable_traits<T> {
    using difference_type = make_signed_t<decltype(declval<T>() - declval<T>())>;
};

template<class T>
    using iter_difference_t = see below;

Let $R_I$ be remove_cvref_t$I$. The type iter_difference_t$I$ denotes

1. \begin{equation}
   \text{incrementable_traits}<R_I>::\text{difference_type}
   \end{equation}
   if iterator_traits$<R_I>$ names a specialization generated from the primary template, and

2. \begin{equation}
   \text{iterator_traits}<R_I>::\text{difference_type}
   \end{equation}
   otherwise.

Users may specialize \text{incrementable_traits} on program-defined types.

25.3.2.2 Indirectly readable traits \[\text{readable.traits}\]

To implement algorithms only in terms of indirectly readable types, it is often necessary to determine the value type that corresponds to a particular indirectly readable type. Accordingly, it is required that if $R$ is the name of a type that models the \text{indirectly_readable} concept (25.3.4.2), the type

iter_value_t$<R>$

be defined as the indirectly readable type’s value type.

template<class> struct cond-value-type { }; // exposition only

struct cond-value-type<T> {
    using value_type = remove_cv_t<T>;
};

class T
    concept has-member-value-type = requires { typename T::value_type; }; // exposition only

template<class T>
    concept has-member-element-type = requires { typename T::element_type; }; // exposition only

template<class R>
    struct indirectly_readable_traits { 
        using value_type = remove_cv_t<remove_extent_t<R>>;
    };

template<class I>
    requires is_array_v<I>
struct indirectly_readable_traits<I> {
    using value_type = remove_cv_t<remove_extent_t<I>>;
};

template<class I>
    struct indirectly_readable_traits<const I> : indirectly_readable_traits<I> { 
    };

template<class T>
    struct indirectly_readable_traits<has-member-value_type T>
    : indirectly_readable_traits<T> {
    };

§ 25.3.2.2 1065
2 Let $R_I$ be $\text{remove_cvref}_t\langle I \rangle$. The type $\text{iter\_value\_t}_t\langle I \rangle$ denotes

\begin{enumerate}
\item[(2.1)] $\text{indirectly\_readable\_traits}\langle R_I \rangle::\text{value\_type}$ if $\text{iterator\_traits}\langle R_I \rangle$ names a specialization generated from the primary template, and
\item[(2.2)] $\text{iterator\_traits}\langle R_I \rangle::\text{value\_type}$ otherwise.
\end{enumerate}

3 Class template $\text{indirectly\_readable\_traits}$ may be specialized on program-defined types.

[Note 1: Some legacy output iterators define a nested type named $\text{value\_type}$ that is an alias for $\text{void}$. These types are not \text{indirectly\_readable} and have no associated value types. — end note]

[Note 2: Smart pointers like $\text{shared\_ptr<int>}$ are \text{indirectly\_readable} and have an associated value type, but a smart pointer like $\text{shared\_ptr<void>}$ is not \text{indirectly\_readable} and has no associated value type. — end note]

25.3.2.3 Iterator traits

To implement algorithms only in terms of iterators, it is sometimes necessary to determine the iterator category that corresponds to a particular iterator type. Accordingly, it is required that if $I$ is the type of an iterator, the type $\text{iterator\_traits}\langle I \rangle::\text{iterator\_category}$ be defined as the iterator's iterator category. In addition, the types

\begin{align*}
\text{iterator\_traits}\langle I \rangle::\text{pointer} \\
\text{iterator\_traits}\langle I \rangle::\text{reference}
\end{align*}

shall be defined as the iterator's pointer and reference types; that is, for an iterator object $a$ of class type, the same type as $\text{decltype}(a.\text{operator->}())$ and $\text{decltype}(\ast a)$, respectively. The type $\text{iterator\_-traits}\langle I \rangle::\text{pointer}$ shall be $\text{void}$ for an iterator of class type $I$ that does not support $\text{operator->}$. Additionally, in the case of an output iterator, the types

\begin{align*}
\text{iterator\_traits}\langle I \rangle::\text{value\_type} \\
\text{iterator\_traits}\langle I \rangle::\text{difference\_type} \\
\text{iterator\_traits}\langle I \rangle::\text{reference}
\end{align*}

may be defined as $\text{void}$.

The definitions in this subclause make use of the following exposition-only concepts:

\begin{align*}
\text{template<class I> \\
concept \text{cpp17\_-iterator} = \\
\quad \text{requires}(I i) \{} \\
\quad \{ *i \} \to \text{can\_-reference}; \\
\quad \{ ++i \} \to \text{same\_as}<I&>; \\
\quad \{ *i++] \to \text{can\_-reference}; \\
\quad \} \&\& \text{copyable}<I>;
\end{align*}

\begin{align*}
\text{template<class I> \\
concept \text{cpp17\_-input\_-iterator} = \\
\quad \text{cpp17\_-iterator}\langle I \rangle \&\& \text{equality\_comparable}\langle I \rangle \&\& \text{requires}(I i) \{} \\
\quad \text{typename incrementable\_traits}\langle I \rangle::\text{difference\_type}; \\
\quad \text{typename indirectly\_readable\_traits}\langle I \rangle::\text{value\_type}; \\
\quad \text{typename common\_reference\_t}<\text{iter\_reference\_t}\langle I \rangle\&\&, \\
\quad \text{typename indirectly\_readable\_traits}\langle I \rangle::\text{value\_type}\};
\end{align*}
typedef typename common_reference_t<decltype(*i++)&&, typename indirectly_readable_traits<I>::value_type&>
requires signed_integral<typename incrementable_traits<I>::difference_type>
{};

template<class I>
concept cpp17-forward_iterator =
cpp17-input_iterator<I> && constructible_from<I> &&
is_reference_v<iter_reference_t<I>> &&
same_as<remove_cvref_t<iter_reference_t<I>>>,
typeinfo indirectly_readable_traits<I>::value_type &&
requires(I i) {
    { i++ } -> convertible_to<const I&>;
    { *i++ } -> same_as<iter_reference_t<I>>;
};

template<class I>
concept cpp17-bidirectional_iterator =
cpp17-forward_iterator<I> && requires(I i) {
    { --i } -> same_as<I&>;
    { i-- } -> convertible_to<const I&>;
    { ++i } -> same_as<iter_reference_t<I>>;
};

template<class I>
concept cpp17-random-access_iterator =
cpp17-bidirectional_iterator<I> && totally_ordered<I> &&
requires(I i, typename incrementable_traits<I>::difference_type n) {
    { i += n } -> same_as<I&>;
    { i -= n } -> same_as<I&>;
    { i + n } -> same_as<I&>;
    { n + i } -> same_as<I&>;
    { i - n } -> same_as<I&>;
    { i - i } -> same_as<decay_t(n)>
    { i[n] } -> convertible_to<iter_reference_t<I>>;
};

3 The members of a specialization iterator_traits<I> generated from the iterator_traits primary template are computed as follows:

(3.1) — If I has valid (13.10.3) member types difference_type, value_type, reference, and iterator_category, then iterator_traits<I> has the following publicly accessible members:

using iterator_category = typename I::iterator_category;
using value_type = typename I::value_type;
using difference_type = typename I::difference_type;
using pointer = see below;
using reference = typename I::reference;

If the qualified-id I::pointer is valid and denotes a type, then iterator_traits<I>::pointer names that type; otherwise, it names void.

(3.2) — Otherwise, if I satisfies the exposition-only concept cpp17-input_iterator, iterator_traits<I> has the following publicly accessible members:

using iterator_category = see below;
using value_type = typename indirectly_readable_traits<I>::value_type;
using difference_type = typename incrementable_traits<I>::difference_type;
using pointer = see below;
using reference = see below;

(3.2.1) — If the qualified-id I::pointer is valid and denotes a type, pointer names that type. Otherwise, if decltype(declval<I&>().operator->()) is well-formed, then pointer names that type. Otherwise, pointer names void.

(3.2.2) — If the qualified-id I::reference is valid and denotes a type, reference names that type. Otherwise, reference names iter_reference_t<I>.
If the qualified-id `I::iterator_category` is valid and denotes a type, `iterator_category` names that type. Otherwise, `iterator_category` names:

- random_access_iterator_tag if I satisfies `cpp17-random-access-iterator`, or otherwise
- bidirectional_iterator_tag if I satisfies `cpp17-bidirectional-iterator`, or otherwise
- forward_iterator_tag if I satisfies `cpp17-forward-iterator`, or otherwise
- input_iterator_tag.

— Otherwise, if I satisfies the exposition-only concept `cpp17-iterator`, then `iterator_traits<I>` has the following publicly accessible members:

- using iterator_category = output_iterator_tag;
- using value_type = void;
- using difference_type = see below;
- using pointer = void;
- using reference = void;

If the qualified-id `incrementable_traits<I>::difference_type` is valid and denotes a type, then `difference_type` names that type; otherwise, it names `void`.

— Otherwise, `iterator_traits<I>` has no members by any of the above names.

Explicit or partial specializations of `iterator_traits` may have a member type `iterator_concept` that is used to indicate conformance to the iterator concepts (25.3.4).

[Example 1: To indicate conformance to the `input_iterator` concept but a lack of conformance to the `Cpp17InputIterator` requirements (25.3.5.3), an `iterator_traits` specialization might have `iterator_concept` denote `input_iterator_tag` but not define `iterator_category`. — end example]

`iterator_traits` is specialized for pointers as

```
namespace std {
    template<class T>
    requires is_object_v<T>
    struct iterator_traits<T*> {  
        using iterator_concept = contiguous_iterator_tag;
        using iterator_category = random_access_iterator_tag;
        using value_type = remove_cv_t<T>;
        using difference_type = ptrdiff_t;
        using pointer = T*;
        using reference = T&;
    };
}
```

[Example 2: To implement a generic `reverse` function, a C++ program can do the following:

```
template<class BI>
void reverse(BI first, BI last) {
    typename iterator_traits<BI>::difference_type n = distance(first, last);
    --n;
    while(n > 0) {
        typename iterator_traits<BI>::value_type tmp = *first;
        *first++ = *--last;
        *last = tmp;
        n -= 2;
    }
}
```

— end example]

25.3.3 Customization point objects  

25.3.3.1 ranges::iter_move
****(1.1) iter_move(E), if E has class or enumeration type and iter_move(E) is a well-formed expression when treated as an unevaluated operand, where the meaning of iter_move is established as-if by performing argument-dependent lookup only (6.5.4).

(1.2) Otherwise, if the expression *E is well-formed:

(1.2.1) if *E is an lvalue, std::move(*E);

(1.2.2) otherwise, *E.

(1.3) Otherwise, ranges::iter_move(E) is ill-formed.

[Note 1: This case can result in substitution failure when ranges::iter_move(E) appears in the immediate context of a template instantiation. — end note]

2 If ranges::iter_move(E) is not equal to *E, the program is ill-formed, no diagnostic required.

25.3.3.2 ranges::iter_swap

The name ranges::iter_swap denotes a customization point object (16.3.3.5) that exchanges the values (18.4.9) denoted by its arguments.

Let iter-exchange-move be the exposition-only function:

```cpp
#include <iterator_traits>

template<class X, class Y>
const expr iter_value_t<X> iter-exchange-move(X&& x, Y&& y)
noexcept(noexcept(iter_value_t<X>(iter_move(x))) &&
noexcept(*x = iter_move(y)));
```

3 Effects: Equivalent to:

```cpp
iter_value_t<X> old_value(iter_move(x));
*x = iter_move(y);
return old_value;
```

4 The expression ranges::iter_swap(E1, E2) for subexpressions E1 and E2 is expression-equivalent to:

(4.1) (void)iter_swap(E1, E2), if either E1 or E2 has class or enumeration type and iter_swap(E1, E2) is a well-formed expression with overload resolution performed in a context that includes the declaration

```cpp
template<class I1, class I2>
void iter_swap(I1, I2) = delete;
```

and does not include a declaration of ranges::iter_swap. If the function selected by overload resolution does not exchange the values denoted by E1 and E2, the program is ill-formed, no diagnostic required.

[Note 1: This precludes calling unconstrained std::iter_swap. When the deleted overload is viable, program-defined overloads need to be more specialized (13.7.7.3) to be selected. — end note]

(4.2) Otherwise, if the types of E1 and E2 each model indirectly_readable, and if the reference types of E1 and E2 model swappable_with (18.4.9), then ranges::swap(*E1, *E2).

(4.3) Otherwise, if the types T1 and T2 of E1 and E2 model indirectly_movable_storable<T1, T2> and indirectly_movable_storable<T2, T1>, then (void)(*E1 = iter-exchange-move(E2, E1)), except that E1 is evaluated only once.

(4.4) Otherwise, ranges::iter_swap(E1, E2) is ill-formed.

[Note 2: This case can result in substitution failure when ranges::iter_swap(E1, E2) appears in the immediate context of a template instantiation. — end note]

25.3.4 Iterator concepts

25.3.4.1 General

For a type I, let ITER_TRAITS(I) denote the type I if iterator_traits<I> names a specialization generated from the primary template. Otherwise, ITER_TRAITS(I) denotes iterator_traits<I>.

(1.1) If the qualified-id ITER_TRAITS(I)::iterator_concept is valid and names a type, then ITER_CONCEPT(I) denotes that type.

(1.2) Otherwise, if the qualified-id ITER_TRAITS(I)::iterator_category is valid and names a type, then ITER_CONCEPT(I) denotes that type.

(1.3) Otherwise, if iterator_traits<I> names a specialization generated from the primary template, then ITER_CONCEPT(I) denotes random_access_iterator_tag.
— Otherwise, \texttt{ITER\_CONCEPT(I)} does not denote a type.

\[ \text{Example 1:} \]

```cpp
struct I {
    using value_type = int;
    using difference_type = int;

    int operator*() const;
    I& operator++();
    I operator++(int);
    I& operator--();
    I operator--(int);

    bool operator==(I) const;
};
```

\texttt{iterator\_traits}\texttt{<I>::iterator\_category} denotes \texttt{input\_iterator\_tag}, and \texttt{ITER\_CONCEPT(I)} denotes \texttt{random\_-access\_iterator\_tag}. — end example]

### 25.3.4.2 Concept indirectly\_readable

Types that are indirectly readable by applying \texttt{operator*} model the indirectly\_readable concept, including pointers, smart pointers, and iterators.

```cpp
template<class In>
concept indirectly\_readable\_impl =
    requires(const In in) {
        typename iter\_value\_t<In>;
        typename iter\_reference\_t<In>;
        typename iter\_rvalue\_reference\_t<In>;
        { *in } -> same\_as<iter\_reference\_t<In>>;
        { ranges::iter\_move(in) } -> same\_as<iter\_rvalue\_reference\_t<In>>;
    } &&
    common\_reference\_with<iter\_reference\_t<In>>&,& iter\_value\_t<In>&& &
    common\_reference\_with<iter\_reference\_t<In>>&,& iter\_rvalue\_reference\_t<In>&& &
    common\_reference\_with<iter\_rvalue\_reference\_t<In>>&,& const iter\_value\_t<In>&;
}
```

```cpp
template<class In>
concept indirectly\_readable =
    indirectly\_readable\_impl<remove\_cvref\_t<In>>;
```

2 Given a value \texttt{i} of type \texttt{I}, \texttt{I} models indirectly\_readable only if the expression \texttt{*i} is equality-preserving.

### 25.3.4.3 Concept indirectly\_writable

The indirectly\_writable concept specifies the requirements for writing a value into an iterator’s referenced object.

```cpp
template<class Out, class T>
concept indirectly\_writable =
    requires(Out&& o, T&& t) {
        *o = std::forward<T>(t); // not required to be equality-preserving
        *std::forward<Out>(o) = std::forward<T>(t); // not required to be equality-preserving
        const\_cast<const iter\_reference\_t<Out>&>(*o) =
            std::forward<T>(t); // not required to be equality-preserving
        const\_cast<const iter\_reference\_t<Out>&>(*std::forward<Out>(o)) =
            std::forward<T>(t); // not required to be equality-preserving
    };
```

2 Let \texttt{E} be an expression such that \texttt{decltype((E))} is \texttt{T}, and let \texttt{o} be a dereferenceable object of type \texttt{Out}. \texttt{Out} and \texttt{T} model indirectly\_writable<\texttt{Out}, \texttt{T}> only if

\[ (2.1) \]

If \texttt{Out} and \texttt{T} model indirectly\_readable<\texttt{Out}>&& same\_as<iter\_value\_t<\texttt{Out}>, decay\_t<T>>, then \texttt{*o} after any above assignment is equal to the value of \texttt{E} before the assignment.

3 After evaluating any above assignment expression, \texttt{o} is not required to be dereferenceable.

4 If \texttt{E} is an xvalue (7.2.1), the resulting state of the object it denotes is valid but unspecified (16.4.6.15).
Expressions of integer-class type are explicitly convertible to any integer-like type, and implicitly convertible to any integral type that permit rvalue assignment but do not also permit const rvalue assignment. Consequently, an iterator type \( I \) that returns \( std::string \) by value does not model indirectly_writable<\( I \), \( std::string \)>.

---

**25.3.4.4 Concept weakly_incrementable**

The weakly_incrementable concept specifies the requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are not required to be equality-preserving, nor is the type required to be equality_comparable.

```cpp
template<class I>
constexpr bool is-integer-like = see below; // exposition only

template<class I>
constexpr bool is-signed-integer-like = see below; // exposition only

template<class I>
concept weakly_incrementable = movable<I> && requires(I i) {
  typename iter_difference_t<I>;
  requires is-signed-integer-like<iter_difference_t<I>>;
  { ++i } -> same_as<I&>; // not required to be equality-preserving
  i++; // not required to be equality-preserving
};
```

A type \( I \) is an integer-class type if it is in a set of implementation-defined types that behave as integer types do, as defined below.

---

### Note 1

An integer-class type is not necessarily a class type. —end note

---

The range of representable values of an integer-class type is the continuous set of values over which it is defined. For any integer-class type, its range of representable values is either \(-2^{N-1} \) to \(2^{N-1} - 1 \) (inclusive) for some integer \( N \), in which case it is a signed-integral-class type, or \(0\) to \(2^N - 1 \) (inclusive) for some integer \( N \), in which case it is an unsigned-integral-class type. In both cases, \( N \) is called the width of the integer-class type. The width of an integer-class type is greater than that of every integral type of the same signedness.

---

A type \( I \) other than \( cv \) bool is integer-like if it models integral<\( I \)> or if it is an integer-class type. An integer-like type \( I \) is signed-integral-like if it models signed_integral<\( I \)> or if it is a signed-integral-class type. An integer-like type \( I \) is unsigned-integral-like if it models unsigned_integral<\( I \)> or if it is an unsigned-integral-class type.

---

For every integer-class type \( I \), let \( B(I) \) be a unique hypothetical extended integer type of the same signedness with the same width (6.8.2) as \( I \).

---

### Note 2

The corresponding hypothetical specialization numeric_limits<\( B(I) \)> meets the requirements on numeric_limits specializations for integral types (17.3.5). —end note

For every integral type \( J \), let \( B(J) \) be the same type as \( J \).

---

Expressions of integer-class type are explicitly convertible to any integer-like type, and implicitly convertible to any integral type of equal or greater width and the same signedness. Expressions of integral type are both implicitly and explicitly convertible to any integer-class type. Conversions between integral and integer-class types and between two integer-class types do not exit via an exception. The result of such a conversion is the unique value of the destination type that is congruent to the source modulo \( 2^N \), where \( N \) is the width of the destination type.

---

Let \( a \) be an object of integer-class type \( I \), let \( b \) be an object of integer-like type \( I2 \) such that the expression \( b \) is implicitly convertible to \( I \), let \( x \) and \( y \) be, respectively, objects of type \( B(I) \) and \( B(I2) \) as described above that represent the same values as \( a \) and \( b \), and let \( c \) be an lvalue of any integral type.

---

(7.1) — The expressions \( a++ \) and \( a-- \) shall be prvalues of type \( I \) whose values are equal to that of \( a \) prior to the evaluation of the expressions. The expression \( a++ \) shall modify the value of \( a \) by adding 1 to it. The expression \( a-- \) shall modify the value of \( a \) by subtracting 1 from it.
The expressions \(++a, --a\), and \&a shall be expression-equivalent to \(a += 1\), \(a -= 1\), and \text{addressof}(a), respectively.

For every unary-operator \(\&\) other than \&\& for which the expression \&x is well-formed, \&a shall also be well-formed and have the same value, effects, and value category as \&x. If \&x has type bool, so too does \&a; if \&x has type B(I), then \&a has type I.

For every assignment operator \(\&=\) for which c \(\&= x\) is well-formed, c \(\&= a\) shall also be well-formed and shall have the same value and effects as c \(\&= x\). The expression c \(\&= a\) shall be an lvalue referring to c.

For every assignment operator \(\&=\) for which x \(\&= y\) is well-formed, a \(\&= b\) shall also be well-formed and shall have the same effects as x \(\&= y\), except that the value that would be stored into x is stored into a. The expression a \(\&= b\) shall be an lvalue referring to a.

For every non-assignment binary operator \(\&\) for which x \(\&\ y\) and y \(\&\ x\) are well-formed, a \(\&\ b\) and b \(\&\ a\) shall also be well-formed and shall have the same value, effects, and value category as x \(\&\ y\) and y \(\&\ x\), respectively. If x \(\&\ y\) or y \(\&\ x\) has type B(I), then a \(\&\ b\) or b \(\&\ a\), respectively, has type I; if x \(\&\ y\) or y \(\&\ x\) has type B(I2), then a \(\&\ b\) or b \(\&\ a\), respectively, has type I2; if x \(\&\ y\) or y \(\&\ x\) has any other type, then a \(\&\ b\) or b \(\&\ a\), respectively, has that type.

An expression \(E\) of integer-class type \(I\) is contextually convertible to bool as if by bool\(E \neq I(0)\).

All integer-class types model regular (18.6) and three_way_comparable<\strong_ordering> (17.11.4).

A value-initialized object of integer-class type has value 0.

For every (possibly cv-qualified) integer-class type \(I\), \text{numeric_limits}<I> is specialized such that each static data member \(m\) has the same value as numeric_limits<B(I)>::\(m\), and each static member function \(f\) returns \(\text{numeric_limits}<B(I)>::f()\).

For any two integer-like types \(I1\) and \(I2\), at least one of which is an integer-class type, common_type_t<I1, I2> denotes an integer-class type whose width is not less than that of \(I1\) or \(I2\). If both \(I1\) and \(I2\) are signed-integer-like types, then common_type_t<I1, I2> is also a signed-integer-like type.

\text{is-integer-like}<I> is \text{true} if and only if \(I\) is an integer-like type. \text{is-signed-integer-like}<I> is \text{true} if and only if \(I\) is a signed-integer-like type.

Let \(i\) be an object of type \(I\). When \(i\) is in the domain of both pre- and post-increment, \(i\) is said to be \text{incrementable}. \(I\) models weakly_incrementable<I> only if

\(i++\) and \(++i\) have the same domain.

If \(i\) is incrementable, then both \(i++\) and \(++i\) advance \(i\) to the next element.

If \(i\) is incrementable, then \text{addressof}(++i) is equal to \text{addressof}(i).

\text{Recommended practice}: The implementaton of an algorithm on a weakly incrementable type should never attempt to pass through the same incrementable value twice; such an algorithm should be a single-pass algorithm.

\text{Note 3}: For weakly_incrementable types, \(a\) equals \(b\) does not imply that \(++a\) equals \(++b\). (Equality does not guarantee the substitution property or referential transparency.) Such algorithms can be used with istreams as the source of the input data through the istream_iterator class template. \text{end note}]

\textbf{25.3.4.5 Concept incrementable}

The \text{incrementable} concept specifies requirements on types that can be incremented with the pre- and post-increment operators. The increment operations are required to be equality-preserving, and the type is required to be \text{equality_comparable}.

\text{Note 1}: This supersedes the annotations on the increment expressions in the definition of weakly_incrementable.

\text{end note}]

```c++
template<class I>
concept weakly_incrementable =
  regular<I> & &
  requires(I i) {
  { i++ } -> same_as<I>;
  }
```
Let \(a\) and \(b\) be incrementable objects of type \(I\). \(I\) models incrementable only if

\[
(2.1) \quad \text{If } \text{bool}(a == b) \text{ then } \text{bool}(a++ == b).
\]

\[
(2.2) \quad \text{If } \text{bool}(a == b) \text{ then } \text{bool}((\text{void})a++, a) == ++b).
\]

[Note 2: The requirement that \(a\) equals \(b\) implies \(++a\) equals \(++b\) (which is not true for weakly incrementable types) allows the use of multi-pass one-directional algorithms with types that model incrementable. — end note]

### 25.3.4.6 Concept input_or_output_iterator

The `input_or_output_iterator` concept forms the basis of the iterator concept taxonomy; every iterator models `input_or_output_iterator`. This concept specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to compare iterators with sentinels (25.3.4.7), to read (25.3.4.9), or write (25.3.4.10) values, or to provide a richer set of iterator movements (25.3.4.11, 25.3.4.12, 25.3.4.13).

```cpp
template<class I>  
concept input_or_output_iterator =  
  requires(I i) {  
    {*i} -> can-reference;  
  } &&  
  weakly_incrementable<I>;  
```

[Note 1: Unlike the `Cpp17Iterator` requirements, the `input_or_output_iterator` concept does not require copyability. — end note]

### 25.3.4.7 Concept sentinel_for

The `sentinel_for` concept specifies the relationship between an `input_or_output_iterator` type and a `semiregular` type whose values denote a range.

```cpp
template<class S, class I>  
concept sentinel_for =  
  semiregular<S> &&  
  input_or_output_iterator<I> &&  
  weakly-equality-comparable-with<S, I>;  
```

Let \(s\) and \(i\) be values of type \(S\) and \(I\) such that \([i, s)\) denotes a range. Types \(S\) and \(I\) model `sentinel_for<S, I>` only if

\[
(2.1) \quad \text{if } N \text{ is representable by } \text{iter_difference_t}<I>, \text{then } s - i \text{ is well-defined and equals } N.
\]

\[
(2.2) \quad \text{if } -N \text{ is representable by } \text{iter_difference_t}<I>, \text{then } i - s \text{ is well-defined and equals } -N.
\]

### 25.3.4.8 Concept sized_sentinel_for

The `sized_sentinel_for` concept specifies requirements on an `input_or_output_iterator` type \(I\) and a corresponding `sentinel_for<I>` that allow the use of the `-` operator to compute the distance between them in constant time.

```cpp
template<class S, class I>  
concept sized_sentinel_for =  
  sentinel_for<S, I> &&  
  !disable_sized_sentinel_for<remove_cv_t<S>, remove_cv_t<I>> &&  
  requires(const I& i, const S& s) {  
    { s - i } -> same_as<iter_difference_t<I>>;  
    { i - s } -> same_as<iter_difference_t<I>>;  
  };
```

Let \(i\) be an iterator of type \(I\), and \(s\) a sentinel of type \(S\) such that \([i, s)\) denotes a range. Let \(N\) be the smallest number of applications of \(++i\) necessary to make \(\text{bool}(i == s)\) be `true`. \(S\) and \(I\) model `sized_sentinel_for<S, I>` only if

\[
(2.1) \quad \text{if } N \text{ is representable by } \text{iter_difference_t}<I>, \text{then } s - i \text{ is well-defined and equals } N.
\]

\[
(2.2) \quad \text{if } -N \text{ is representable by } \text{iter_difference_t}<I>, \text{then } i - s \text{ is well-defined and equals } -N.
\]
template<class S, class I>
constexpr bool disable_sized_sentinel_for = false;

Remarks: Pursuant to 16.4.5.2.1, users may specialize disable_sized_sentinel_for for cv-unqualified non-array object types S and I if S and/or I is a program-defined type. Such specializations shall be usable in constant expressions (7.7) and have type const bool.

[Note 1: disable_sized_sentinel_for allows use of sentinels and iterators with the library that satisfy but do not in fact model sized_sentinel_for. — end note]

[Example 1: The sized_sentinel_for concept is modeled by pairs of random_access_iterators (25.3.4.13) and by counted iterators and their sentinels (25.5.7.1). — end example]

25.3.4.9 Concept input_iterator

The input_iterator concept defines requirements for a type whose referenced values can be read (from the requirement for indirectly_readable (25.3.4.2)) and which can be both pre- and post-incremented.

[Note 1: Unlike the Cpp17InputIterator requirements (25.3.5.3), the input_iterator concept does not need equality comparison since iterators are typically compared to sentinels. — end note]

```
template<class I>
concept input_iterator =
    input_or_output_iterator<I> &&
    indirectly_readable<I> &&
    requires { typename ITER_CONCEPT(I); } &&
    derived_from<ITER_CONCEPT(I), input_iterator_tag>;
```

25.3.4.10 Concept output_iterator

The output_iterator concept defines requirements for a type that can be used to write values (from the requirement for indirectly_writable (25.3.4.3)) and which can be both pre- and post-incremented.

[Note 1: Output iterators are not required to model equality_comparable. — end note]

```
template<class I, class T>
concept output_iterator =
    input_or_output_iterator<I> &&
    indirectly_writable<I, T> &&
    requires(I i, T&& t) {
        *i++ = std::forward<T>(t); // not required to be equality-preserving
    }
```

Let E be an expression such that decltype((E)) is T, and let i be a dereferenceable object of type I. I and T model output_iterator<I, T> only if *i++ = E; has effects equivalent to:

*++i;

Recommended practice: The implementation of an algorithm on output iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single-pass algorithm.

25.3.4.11 Concept forward_iterator

The forward_iterator concept adds copyability, equality comparison, and the multi-pass guarantee, specified below.

```
template<class I>
concept forward_iterator =
    input_iterator<I> &&
    derived_from<ITER_CONCEPT(I), forward_iterator_tag> &&
    incrementable<I> &&
    sentinel_for<I, I>;
```

The domain of == for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators of the same type may be compared and shall compare equal to other value-initialized iterators of the same type.

[Note 1: Value-initialized iterators behave as if they refer past the end of the same empty sequence. — end note]

Pointers and references obtained from a forward iterator into a range [i, s) shall remain valid while [i, s) continues to denote a range.

Two dereferenceable iterators a and b of type X offer the multi-pass guarantee if:
— \( a \equiv b \) implies ++\( a \equiv ++b \) and

the expression \( ((\text{void})[X x\{++x;\}](a), \ast a) \) is equivalent to the expression \( \ast a \).

[Note 2: The requirement that \( a \equiv b \) implies ++\( a \equiv ++b \) and the removal of the restrictions on the number of assignments through a mutable iterator (which applies to output iterators) allow the use of multi-pass one-directional algorithms with forward iterators. — end note]

25.3.4.12 Concept bidirectional_iterator

The \texttt{bidirectional\_iterator} concept adds the ability to move an iterator backward as well as forward.

```cpp
template<class I>
concept bidirectional\_iterator =
    forward\_iterator\!<I> \&\&
    derived\_from\<\text{ITER\_CONCEPT}(I), bidirectional\_iterator\_tag> \&\&
    requires(I i) {
        { --i } -> same\_as\<!\&I>;
        { i-- } -> same\_as\!<I>;
    };
```

A bidirectional iterator \( r \) is decrementable if and only if there exists some \( q \) such that ++\( q \equiv r \). Decrementable iterators \( r \) shall be in the domain of the expressions \( --r \) and \( r-- \).

Let \( a \) and \( b \) be equal objects of type \( I \). \( I \) models \texttt{bidirectional\_iterator} only if:

- If \( a \) and \( b \) are decrementable, then all of the following are true:
  - \( \text{addressof}(-a) \equiv \text{addressof}(a) \)
  - \( \text{bool}(a-- \equiv b) \)
  - after evaluating both \( a-- \) and \( --b \), \( \text{bool}(a \equiv b) \) is still true
  - \( \text{bool}(++(-a) \equiv b) \)
- If \( a \) and \( b \) are incrementable, then \( \text{bool}(-(-++a) \equiv b) \).

25.3.4.13 Concept random_access_iterator

The \texttt{random\_access\_iterator} concept adds support for constant-time advancement with \( +=, +, -=, \) and \(- \), as well as the computation of distance in constant time with \(- \). Random access iterators also support array notation via subscripting.

```cpp
template<class I>
concept random\_access\_iterator =
    bidirectional\_iterator\!<I> \&\&
    derived\_from\<\text{ITER\_CONCEPT}(I), random\_access\_iterator\_tag> \&\&
    totally\_ordered\!<I> \&\&
    sized\_sentinel\_for\!<I, I> \&\&
    requires(I i, const I j, const iter\_difference\_t\!<I> n) {
        { i += n } -> same\_as\!<I>;
        { j + n } -> same\_as\!<I>;
        { n + j } -> same\_as\!<I>;
        { i -= n } -> same\_as\!<I>;
        { n - j } -> same\_as\!<I>;
        { j[n] } -> same\_as\!<\text{iter\_reference\_t\!<I>}>;
    };
```

Let \( a \) and \( b \) be valid iterators of type \( I \) such that \( b \) is reachable from \( a \) after \( n \) applications of ++\( a \), let \( D \) be \texttt{iter\_difference\_t\!<I>}\), and let \( n \) denote a value of type \( D \). \( I \) models \texttt{random\_access\_iterator} only if

- \( (a += n) \) is equal to \( b \).
- \( \text{addressof}(a += n) \) is equal to \( \text{addressof}(a) \).
- \( (a + n) \) is equal to \( (a += n) \).
- For any two positive values \( x \) and \( y \) of type \( D \), if \( (a + D(x + y)) \) is valid, then \( (a + D(x + y)) \) is equal to \((a + x) + y)\).
- \( (a + D(0)) \) is equal to \( a \).
- If \( (a + D(n - 1)) \) is valid, then \( (a + n) \) is equal to \( [] \{I c\{ return ++c; \}(a + D(n - 1)) \)
© ISO/IEC

— (b += D(-n)) is equal to a.
— (b -= n) is equal to a.
— addressof(b -= n) is equal to addressof(b).
— (b - n) is equal to (b -= n).
— If b is dereferenceable, then a[n] is valid and is equal to *b.
— bool(a <= b) is true.

25.3.4.14 Concept contiguous_iterator

The contiguous_iterator concept provides a guarantee that the denoted elements are stored contiguously in memory.

```cpp
template<class I>
concept contiguous_iterator =
    random_access_iterator<I> &&
    derived_from<ITER_CONCEPT(I), contiguous_iterator_tag> &&
    is_lvalue_reference_v<iter_reference_t<I>> &&
    same_as<iter_value_t<I>, remove_cvref_t<iter_reference_t<I>>> &&
    requires(const I& i) {
        to_address(i) -> same_as<add_pointer_t<iter_reference_t<I>>;}
```

Let a and b be dereferenceable iterators and c be a non-dereferenceable iterator of type I such that b is reachable from a and c is reachable from b, and let D be iter_difference_t<I>. The type I models contiguous_iterator only if

---

25.3.5 C++17 iterator requirements

25.3.5.1 General

A type X meets the Cpp17Iterator requirements if:

---

25.3.5.3 Input iterators

A class or pointer type X meets the requirements of an input iterator for the value type T if X meets the Cpp17Iterator (25.3.5.2) and Cpp17EqualityComparable (Table 28) requirements and the expressions in Table 87 are valid and have the indicated semantics.

---

\[25.3.5.3\]

---

§ 25.3.5.3
requirements on the domain of `==` for the iterator values it uses. These requirements can be inferred from
the uses that algorithm makes of `==` and `!=`.

[Example 1: The call `find(a,b,x)` is defined only if the value of `a` has the property `p` defined as follows: `b` has property `p` and a value `i` has property `p` if `*i==x` or if `*i!=x` and `++i` has property `p`]. — end example]

---

3 Recommended practice: The implementation of an algorithm on input iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single pass algorithm.
[Note 1: For input iterators, a == b does not imply ++a == ++b. (Equality does not guarantee the substitution property or referential transparency.) Value type T is not required to be a Cpp17CopyAssignable type (Table 34). Such an algorithm can be used with istreams as the source of the input data through the istream_iterator class template. — end note]

25.3.5.4 Output iterators

A class or pointer type X meets the requirements of an output iterator if X meets the Cpp17Iterator requirements (25.3.5.2) and the expressions in Table 88 are valid and have the indicated semantics.

Table 88: Cpp17OutputIterator requirements (in addition to Cpp17Iterator)  

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>*r = o</td>
<td>result is not used</td>
<td>Remarks: After this operation r is not required to be dereferenceable.</td>
<td>Postconditions: r is incrementable.</td>
</tr>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td>addressof(r) == addressof(++r). Remarks: After this operation r is not required to be dereferenceable.</td>
<td>Postconditions: r is incrementable.</td>
</tr>
<tr>
<td>r++</td>
<td>convertible to const X&amp;</td>
<td>{ X tmp = r; ++r; return tmp; }</td>
<td>Remarks: After this operation r is not required to be dereferenceable.</td>
</tr>
<tr>
<td>*r++ = o</td>
<td>result is not used</td>
<td>Remarks: After this operation r is not required to be dereferenceable.</td>
<td>Postconditions: r is incrementable.</td>
</tr>
</tbody>
</table>

2 Recommended practice: The implementation of an algorithm on output iterators should never attempt to pass through the same iterator twice; such an algorithm should be a single-pass algorithm.

[Note 1: The only valid use of an operator* is on the left side of the assignment statement. Assignment through the same value of the iterator happens only once. Equality and inequality are not necessarily defined. — end note]

25.3.5.5 Forward iterators

A class or pointer type X meets the requirements of a forward iterator if

(1.1) — X meets the Cpp17InputIterator requirements (25.3.5.3),
(1.2) — X meets the Cpp17DefaultConstructible requirements (16.4.4.2),
(1.3) — if X is a mutable iterator, reference is a reference to T; if X is a constant iterator, reference is a reference to const T,
(1.4) — the expressions in Table 89 are valid and have the indicated semantics, and
(1.5) — objects of type X offer the multi-pass guarantee, described below.

The domain of == for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators may be compared and shall compare equal to other value-initialized iterators of the same type.

[Note 1: Value-initialized iterators behave as if they refer past the end of the same empty sequence. — end note]
Two dereferenceable iterators $a$ and $b$ of type $X$ offer the multi-pass guarantee if:

(3.1) $a == b$ implies $++a == ++b$ and

(3.2) $X$ is a pointer type or the expression $(\text{void})++X(a)$, $*a$ is equivalent to the expression $*a$.

[Note 2: The requirement that $a == b$ implies $++a == ++b$ (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through a mutable iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators. — end note]

Table 89: Cpp17ForwardIterator requirements (in addition to Cpp17InputIterator) [tab:forwarditerator]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>$r++$</td>
<td>convertible to</td>
<td>${ X \ tmp = r;$</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$X &amp;$</td>
<td>$++r;$</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>$\text{return } tmp;$</td>
<td></td>
</tr>
<tr>
<td>$*r++$</td>
<td>reference</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If $a$ and $b$ are equal, then either $a$ and $b$ are both dereferenceable or else neither is dereferenceable.

If $a$ and $b$ are both dereferenceable, then $a == b$ if and only if $*a$ and $*b$ are bound to the same object.

25.3.5.6 Bidirectional iterators [bidirectional.iterators]

A class or pointer type $X$ meets the requirements of a bidirectional iterator if, in addition to meeting the Cpp17ForwardIterator requirements, the following expressions are valid as shown in Table 90.

Table 90: Cpp17BidirectionalIterator requirements (in addition to Cpp17ForwardIterator) [tab:bidirectionaliterator]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>$--r$</td>
<td>$X &amp;$</td>
<td>$Preconditions:$ there exists $s$ such that $r == ++s$. $Postconditions:$ $r$ is dereferenceable. $--(++r) == r$. $--r == --s$ implies $r == s$. $\text{addressof}(r) == \text{addressof}(--r)$.</td>
<td></td>
</tr>
<tr>
<td>$r--$</td>
<td>convertible to ${ X \ tmp = r;$</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>$X &amp;$</td>
<td>$--r;$</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>$\text{return } tmp;$</td>
<td></td>
</tr>
<tr>
<td>$*r--$</td>
<td>reference</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

[Note 1: Bidirectional iterators allow algorithms to move iterators backward as well as forward. — end note]

25.3.5.7 Random access iterators [random.access.iterators]

A class or pointer type $X$ meets the requirements of a random access iterator if, in addition to meeting the Cpp17BidirectionalIterator requirements, the following expressions are valid as shown in Table 91.
Table 91: `Cpp17RandomAccessIterator` requirements (in addition to `Cpp17BidirectionalIterator`)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>

<tr>
<td><code>a &gt;= b</code></td>
<td><code>decltype(a &gt;= b) models boolean-test-able</code></td>
<td><code>!(a &lt; b)</code></td>
<td></td>
</tr>
<tr>
<td><code>a &lt;= b</code></td>
<td><code>decltype(a &lt;= b) models boolean-test-able</code></td>
<td><code>!(a &gt; b)</code></td>
<td></td>
</tr>
</tbody>
</table>

25.3.6 Indirect callable requirements

25.3.6.1 General

There are several concepts that group requirements of algorithms that take callable objects (22.10.3) as arguments.

25.3.6.2 Indirect callable traits

To implement algorithms taking projections, it is necessary to determine the projected type of an iterator’s value type. For the exposition-only alias template `indirect-value-t`, `indirect-value-t<T>` denotes

(1.1) `invoke_result_t<Proj&, indirect-value-t<T>>` if `T` names `projected<I, Proj>`, and

(1.2) `iter_value_t<T>&` otherwise.
The indirect callable concepts are used to constrain those algorithms that accept callable objects (22.10.3) as arguments.

```cpp
namespace std {
    template<class F, class I>
    concept indirectly_unary_invocable =
        indirectly_readable<I> &&
        copy_constructible<F> &&
        invocable<F&, indirect_value_t<I>[]> &&
        invocable<F&, iter_reference_t<I>> &&
        invocable<F&, iter_common_reference_t<I>> &&
        common_reference_with<
            invoke_result_t<F&>, indirect_value_t<I>,
            invoke_result_t<F&>, iter_reference_t<I>>;

    template<class F, class I>
    concept indirectly_regular_unary_invocable =
        indirectly_readable<I> &&
        copy_constructible<F> &&
        regular_invocable<F&, indirect_value_t<I>[]> &&
        regular_invocable<F&, iter_reference_t<I>> &&
        regular_invocable<F&, iter_common_reference_t<I>> &&
        common_reference_with<
            invoke_result_t<F&>, indirect_value_t<I>,
            invoke_result_t<F&>, iter_reference_t<I>>;

    template<class F, class I1, class I2>
    concept indirect_binary_predicate =
        indirectly_readable<I1> && indirectly_readable<I2> &&
        copy_constructible<F> &&
        predicate<F&, indirect_value_t<I1>, indirect_value_t<I2>> &&
        predicate<F&, indirect_value_t<I1>, iter_reference_t<I2>> &&
        predicate<F&, iter_reference_t<I1>, indirect_value_t<I2>> &&
        predicate<F&, iter_reference_t<I1>, iter_reference_t<I2>> &&
        predicate<F&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;

    template<class F, class I1, class I2 = I1>
    concept indirect_equivalence_relation =
        indirectly_readable<I1> && indirectly_readable<I2> &&
        copy_constructible<F> &&
        equivalence_relation<F&, indirect_value_t<I1>, indirect_value_t<I2>> &&
        equivalence_relation<F&, indirect_value_t<I1>, iter_reference_t<I2>> &&
        equivalence_relation<F&, iter_reference_t<I1>, indirect_value_t<I2>[]> &&
        equivalence_relation<F&, iter_reference_t<I1>, iter_reference_t<I2>> &&
        equivalence_relation<F&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;

    template<class F, class I1, class I2 = I1>
    concept indirect_strict_weak_order =
        indirectly_readable<I1> && indirectly_readable<I2> &&
        copy_constructible<F> &&
        strict_weak_order<F&, indirect_value_t<I1>, indirect_value_t<I2>> &&
        strict_weak_order<F&, indirect_value_t<I1>, iter_reference_t<I2>> &&
        strict_weak_order<F&, iter_reference_t<I1>, indirect_value_t<I2>> &&
        strict_weak_order<F&, iter_reference_t<I1>, iter_reference_t<I2>> &&
        strict_weak_order<F&, iter_common_reference_t<I1>, iter_common_reference_t<I2>>;
}
```
Class template `projected` is used to constrain algorithms that accept callable objects and projections (3.44). It combines an indirectly_readable type `I` and a callable object type `Proj` into a new indirectly_readable type whose reference type is the result of applying `Proj` to the iter_reference_t of `I`.

```cpp
namespace std {
    template<indirectly_readable I, indirectly_regular_unary_invocable<I> Proj>
    struct projected {
        using value_type = remove_cvref_t<indirect_result_t<Proj&, I>>;
        indirect_result_t<Proj&, I> operator*() const;  // not defined
    };

    template<weakly_incrementable I, class Proj>
    struct incrementable_traits<projected<I, Proj>> {
        using difference_type = iter_difference_t<I>;
    };
}
```

25.3.7 Common algorithm requirements

25.3.7.1 General

There are several additional iterator concepts that are commonly applied to families of algorithms. These group together iterator requirements of algorithm families. There are three relational concepts that specify how element values are transferred between indirectly_readable and indirectly_writable types: indirectly_movable, indirectly_copyable, and indirectly_swappable. There are three relational concepts for rearrangements: permutable, mergeable, and sortable. There is one relational concept for comparing values from different sequences: indirectlyComparable.

[Note 1: The ranges::less function object type used in the concepts below imposes constraints on the concepts’ arguments in addition to those that appear in the concepts’ bodies (22.10.9). — end note]

25.3.7.2 Concept indirectly_movable

The indirectly_movable concept specifies the relationship between an indirectly_readable type and an indirectly_writable type between which values may be moved.

```cpp
template<class In, class Out>
concept indirectly_movable =
    indirectly_readable<In> &&
    indirectly_writable<Out, iter_rvalue_reference_t<In>>;
```

The indirectly_movable_storable concept augments indirectly_movable with additional requirements enabling the transfer to be performed through an intermediate object of the indirectly_readable type’s value type.

```cpp
template<class In, class Out>
concept indirectly_movable_storable =
    indirectly_movable<In, Out> &&
    indirectly_writable<Out, iter_value_t<In>> &&
    movable<iter_value_t<In>> &&
    constructible_from<iter_value_t<In>, iter_rvalue_reference_t<In>> &&
    assignable_from<iter_value_t<In>&, iter_rvalue_reference_t<In>>;
```

Let `i` be a dereferenceable value of type `In`. In and `Out` model indirectly_movable_storable<In, Out> only if after the initialization of the object `obj` in

```
iter_value_t<In> obj(ranges::iter_move(i));
```

`obj` is equal to the value previously denoted by `*i`. If `iter_rvalue_reference_t<In>` is an rvalue reference type, the resulting state of the value denoted by `*i` is valid but unspecified (16.4.6.15).

25.3.7.3 Concept indirectly_copyable

The indirectly_copyable concept specifies the relationship between an indirectly_readable type and an indirectly_writable type between which values may be copied.

```cpp
template<class In, class Out>
concept indirectly_copyable =
    indirectly_readable<In> &&
    indirectly_writable<Out, iter_rvalue_reference_t<In>>;
```
The *indirectly_copyable_storable* concept augments *indirectly_copyable* with additional requirements enabling the transfer to be performed through an intermediate object of the *indirectly_readable* type’s value type. It also requires the capability to make copies of values.

```cpp
template<class In, class Out>
concept indirectly_copyable_storable =
    indirectly_copyable<In, Out> &&
    indirectly_writable<Out, iter_value_t<In>>,
    indirectly_writable<Out, const iter_value_t<In>>,
    indirectly_writable<Out, iter_value_t<In> &>,
    indirectly_writable<Out, const iter_value_t<In> &>,
    copyable<iter_value_t<In>>,
    constructible_from<iter_value_t<In>>, iter_reference_t<In>>,
    assignable_from<iter_value_t<In>>, iter_reference_t<In>>;
```

Let \(i\) be a dereferenceable value of type \(\text{In}\). \(\text{In}\) and \(\text{Out}\) model *indirectly_copyable_storable* only if after the initialization of the object \(\text{obj}\) in

```cpp
iter_value_t<\text{In}> \text{obj}(*\text{i});
```

\(\text{obj}\) is equal to the value previously denoted by \(*\text{i}\). If \(\text{iter_reference_t}<\text{In}\) is an rvalue reference type, the resulting state of the value denoted by \(*\text{i}\) is valid but unspecified (16.4.6.15).

### 25.3.7.4 Concept indirectly_swappable

[alg.req.ind.swap]

The *indirectly_swappable* concept specifies a swappable relationship between the values referenced by two *indirectly_readable* types.

```cpp
template<class I1, class I2 = I1>
concept indirectly_swappable =
    indirectly_readable<I1> && indirectly_readable<I2> &&
    requires(const I1 i1, const I2 i2) {
        ranges::iter_swap(i1, i1);
        ranges::iter_swap(i2, i2);
        ranges::iter_swap(i1, i2);
        ranges::iter_swap(i2, i1);
    };
```

### 25.3.7.5 Concept indirectly_comparable

[alg.req.ind.cmp]

The *indirectly_comparable* concept specifies the common requirements of algorithms that compare values from two different sequences.

```cpp
template<class I1, class I2, class R, class P1 = identity,
        class P2 = identity>
concept indirectly_comparable =
    indirect_binary_predicate<R, projected<I1, P1>, projected<I2, P2>>;
```

### 25.3.7.6 Concept permutable

[alg.req.permutable]

The *permutable* concept specifies the common requirements of algorithms that reorder elements in place by moving or swapping them.

```cpp
template<class I>
concept permutable =
    forward_iterator<I> &&
    indirectly_movable_storable<I, I> &&
    indirectly_swappable<I, I>;
```

### 25.3.7.7 Concept mergeable

[alg.req.mergeable]

The *mergeable* concept specifies the requirements of algorithms that merge sorted sequences into an output sequence by copying elements.
template<class I1, class I2, class Out, class R = ranges::less,
    class P1 = identity, class P2 = identity>
concept mergeable =
    input_iterator<I1> &&
    input_iterator<I2> &&
    weakly_incrementable<Out> &&
    indirectly_copyable<I1, Out> &&
    indirectly_copyable<I2, Out> &&
    indirect_strict_weak_order<R, projected<I1, P1>, projected<I2, P2>>;

25.3.7.8 Concept sortable
[alg.req.sortable]
The sortable concept specifies the common requirements of algorithms that permute sequences into ordered
sequences (e.g., sort).

```cpp
template<class I, class R = ranges::less, class P = identity>
concept sortable =
    permutable<I> &&
    indirect_strict_weak_order<R, projected<I, P>>;
```

25.4 Iterator primitives
[iterator.primitives]
25.4.1 General
[iterator.primitives.general]

To simplify the use of iterators, the library provides several classes and functions.

25.4.2 Standard iterator tags
[std.iterator.tags]

It is often desirable for a function template specialization to find out what is the most specific category
of its iterator argument, so that the function can select the most efficient algorithm at compile
time. To facilitate this, the library introduces category tag classes which are used as compile time tags
for algorithm selection. They are: output_iterator_tag, input_iterator_tag, forward_iterator_tag,
bidirectional_iterator_tag, random_access_iterator_tag, and contiguous_iterator_tag. For every
iterator of type I, iterator_traits<I>::iterator_category shall be defined to be a category tag that
describes the iterator’s behavior. Additionally, iterator_traits<I>::iterator_concept may be used to
indicate conformance to the iterator concepts (25.3.4).

```cpp
namespace std {
    struct output_iterator_tag { };
    struct input_iterator_tag { };
    struct forward_iterator_tag: public input_iterator_tag { };
    struct bidirectional_iterator_tag: public forward_iterator_tag { };
    struct random_access_iterator_tag: public bidirectional_iterator_tag { };
    struct contiguous_iterator_tag: public random_access_iterator_tag { };
}
```

2 [Example 1]: A program-defined iterator BinaryTreeIterator can be included into the bidirectional iterator category
by specializing the iterator_traits template:

```cpp
template<class T> struct iterator_traits<BinaryTreeIterator<T>> {
    using iterator_category = bidirectional_iterator_tag;
    using difference_type = ptrdiff_t;
    using value_type = T;
    using pointer = T*;
    using reference = T&;
};
```

— end example]

3 [Example 2]: If evolve() is well-defined for bidirectional iterators, but can be implemented more efficiently for random
access iterators, then the implementation is as follows:

```cpp
template<class BidirectionalIterator>
inline void
evolve(BidirectionalIterator first, BidirectionalIterator last) {
    evolve(first, last,
        typename iterator_traits<BidirectionalIterator>::iterator_category());
}
```
template<class BidirectionalIterator>
void evolve(BidirectionalIterator first, BidirectionalIterator last, bidirectional_iterator_tag) {
  // more generic, but less efficient algorithm
}

template<class RandomAccessIterator>
void evolve(RandomAccessIterator first, RandomAccessIterator last, random_access_iterator_tag) {
  // more efficient, but less generic algorithm
} — end example]

25.4.3 Iterator operations [iterator.operations]

1 Since only random access iterators provide + and − operators, the library provides two function templates advance and distance. These function templates use + and − for random access iterators (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use ++ to provide linear time implementations.

template<class InputIterator, class Distance>
constexpr void advance(InputIterator& i, Distance n);

2 Preconditions: n is negative only for bidirectional iterators.

3 Effects: Increments i by n if n is non-negative, and decrements i by −n otherwise.

template<class InputIterator>
constexpr typename iterator_traits<InputIterator>::difference_type
distance(InputIterator first, InputIterator last);

4 Preconditions: last is reachable from first, or InputIterator meets the Cpp17RandomAccessIterator requirements and first is reachable from last.

5 Effects: If InputIterator meets the Cpp17RandomAccessIterator requirements, returns (last − first); otherwise, increments first until last is reached and returns the number of increments.

template<class InputIterator>
constexpr InputIterator next(InputIterator x, typename iterator_traits<InputIterator>::difference_type n = 1);

6 Effects: Equivalent to: advance(x, n); return x;

template<class BidirectionalIterator>
constexpr BidirectionalIterator prev(BidirectionalIterator x, typename iterator_traits<BidirectionalIterator>::difference_type n = 1);

7 Effects: Equivalent to: advance(x, −n); return x;

25.4.4 Range iterator operations [range.iter.ops]

25.4.4.1 General [range.ops.general]

1 The library includes the function templates ranges::advance, ranges::distance, ranges::next, and ranges::prev to manipulate iterators. These operations adapt to the set of operators provided by each iterator category to provide the most efficient implementation possible for a concrete iterator type.

[Example 1: ranges::advance uses the + operator to move a random_access_iterator forward n steps in constant time. For an iterator type that does not model random_access_iterator, ranges::advance instead performs n individual increments with the ++ operator. — end example]

2 The function templates defined in 25.4.4 are not found by argument-dependent name lookup (6.5.4). When found by unqualified (6.5.3) name lookup for the postfix-expression in a function call (7.6.1.3), they inhibit argument-dependent name lookup.

[Example 2:
  void foo() {
    using namespace std::ranges;
    std::vector<int> vec{1,2,3};
  }]
The function call expression at #1 invokes std::ranges::distance, not std::distance, despite that (a) the iterator type returned from begin(vec) and end(vec) may be associated with namespace std and (b) std::distance is more specialized (13.7.7.3) than std::ranges::distance since the former requires its first two parameters to have the same type. — end example]

The number and order of deducible template parameters for the function templates defined in 25.4.4 is unspecified, except where explicitly stated otherwise.

25.4.4.2 ranges::advance

```cpp
template<input_or_output_iterator I>
constexpr void ranges::advance(I& i, iter_difference_t<I> n);
```

1 Preconditions: If I does not model bidirectional_iterator, n is not negative.
2 Effects:
(2.1) — If I models random_access_iterator, equivalent to i += n.
(2.2) — Otherwise, if n is non-negative, increments i by n.
(2.3) — Otherwise, decrements i by -n.

```cpp
template<input_or_output_iterator I, sentinel_for<I> S>
constexpr void ranges::advance(I& i, S bound);
```

3 Preconditions: Either assignable_from<I&, S> || sized_sentinel_for<S, I> is modeled, or [i, bound] denotes a range.
4 Effects:
(4.1) — If I and S model assignable_from<I&, S>, equivalent to i = std::move(bound).
(4.2) — Otherwise, if S and I model sized_sentinel_for<S, I>, equivalent to ranges::advance(i, bound - i).
(4.3) — Otherwise, while bool(i != bound) is true, increments i.

```cpp
template<input_or_output_iterator I, sentinel_for<I> S>
constexpr iter_difference_t<I> ranges::advance(I& i, iter_difference_t<I> n, S bound);
```

5 Preconditions: If n > 0, [i, bound] denotes a range. If n == 0, [i, bound) or [bound, i) denotes a range. If n < 0, [bound, i) denotes a range, I models bidirectional_iterator, and I and S model same_as<I, S>.
6 Effects:
(6.1) — If S and I model sized_sentinel_for<S, I>:
(6.1.1) — If |n| ≥ |bound - i|, equivalent to ranges::advance(i, bound).
(6.1.2) — Otherwise, equivalent to ranges::advance(i, n).
(6.2) — Otherwise,
(6.2.1) — if n is non-negative, while bool(i != bound) is true, increments i but at most n times.
(6.2.2) — Otherwise, while bool(i != bound) is true, decrements i but at most -n times.
7 Returns: n - M, where M is the difference between the ending and starting positions of i.

25.4.4.3 ranges::distance

```cpp
template<class I, sentinel_for<I> S>
requires (!sized_sentinel_for<S, I>)
constexpr iter_difference_t<I> ranges::distance(I first, S last);
```

1 Preconditions: [first, last) denotes a range.
2 Effects: Increments first until last is reached and returns the number of increments.
template<class I, sized_sentinel_for<decay_t<I>> S>
constexpr iter_difference_t<decay_t<I>> ranges::distance(I&& first, S last);

Effects: Equivalent to: return last - static_cast<const decay_t<I>&>(first);

Effects: Equivalent to: return ranges::distance(r);

Effects: Equivalent to: ranges::distance ranges::begin(r), ranges::end(r));

25.4.4.4 ranges::next

Effects: Equivalent to: ++x; return x;

Effects: Equivalent to: ranges::advance(x, n); return x;

Effects: Equivalent to: ranges::advance(x, n, S bound));

Effects: Equivalent to: ranges::advance(x, n, S bound);

25.5 Iterator adaptors

25.5.1 Reverse iterators

25.5.1.1 General

Class template reverse_iterator is an iterator adaptator that iterates from the end of the sequence defined by its underlying iterator to the beginning of that sequence.

25.5.1.2 Class template reverse_iterator

namespace std {
template<class I, sized_sentinel_for<decay_t<I>> S>
class reverse_iterator {
public:
  using iterator_type = I;
  using iterator_concept = see below;
  using iterator_category = see below;
  using value_type = iter_value_t<I>;
  using difference_type = iter_difference_t<I>;
}
using pointer = typename iterator_traits<Iterator>::pointer;
using reference = iter_reference_t<Iterator>;

constexpr reverse_iterator();
constexpr explicit reverse_iterator(Iterator x);
template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);
template<class U> constexpr reverse_iterator& operator=(const reverse_iterator<U>& u);

constexpr Iterator base() const;
constexpr reference operator*() const;
constexpr pointer operator->() const requires see below;
constexpr reverse_iterator& operator++();
constexpr reverse_iterator operator++(int);
constexpr reverse_iterator& operator--();
constexpr reverse_iterator operator--(int);
constexpr reverse_iterator operator+(difference_type n) const;
constexpr reverse_iterator& operator+=(difference_type n);
constexpr reverse_iterator operator-(difference_type n) const;
constexpr reverse_iterator& operator-=(difference_type n);
constexpr unspecified operator[](difference_type n) const;

friend constexpr iter_rvalue_reference_t<Iterator> iter_move(const reverse_iterator& i) noexcept(see below);
template<indirectly_swappable<Iterator> Iterator2>
friend constexpr void iter_swap(const reverse_iterator& x,
const reverse_iterator<Iterator2>& y) noexcept(see below);

protected:
  Iterator current;
};

1 The member typedef-name iterator_concept denotes
  — random_access_iterator_tag if Iterator models random_access_iterator, and
  — bidirectional_iterator_tag otherwise.

2 The member typedef-name iterator_category denotes
  — random_access_iterator_tag if the type iterator_traits<Iterator>::iterator_category models
derived_from<random_access_iterator_tag>, and
  — iterator_traits<Iterator>::iterator_category otherwise.

### 25.5.1.3 Requirements [reverse.iter.requirements]

1 The template parameter Iterator shall either meet the requirements of a Cpp17BidirectionalIterator (25.3.5.6)
or model bidirectional_iterator (25.3.4.12).

2 Additionally, Iterator shall either meet the requirements of a Cpp17RandomAccessIterator (25.3.5.7) or
model random_access_iterator (25.3.4.13) if the definitions of any of the members
  — operator+, operator-, operator+=, operator-= (25.5.1.7), or
  — operator[] (25.5.1.6),
or the non-member operators (25.5.1.8)
  — operator<, operator>, operator<=, operator>=, operator-, or operator+ (25.5.1.9)
are instantiated (13.9.2).

### 25.5.1.4 Construction and assignment [reverse.iter.cons]

constexpr reverse_iterator();

1 Effects: Value-initializes current. Iterator operations applied to the resulting iterator have defined
behavior if and only if the corresponding operations are defined on a value-initialized iterator of type `Iterator`.

```cpp
constexpr explicit reverse_iterator(Iterator x);
```

**Effects:** Initializes `current` with `x`.

```cpp
template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);
```

**Constraints:** `is_same_v<U, Iterator>` is false and `const U&` models `convertible_to<Iterator>`.

**Effects:** Initializes `current` with `u.current`.

```cpp
template<class U>
constexpr reverse_iterator& operator=(const reverse_iterator<U>& u);
```

**Constraints:** `is_same_v<U, Iterator>` is false, `const U&` models `convertible_to<Iterator>`, and `assignable_from<Iterator&, const U&>` is modeled.

**Effects:** Assigns `u.current` to `current`.

**Returns:** `*this`.

### 25.5.1.5 Conversion

```cpp
constexpr Iterator base() const;
```

**Returns:** `current`.

### 25.5.1.6 Element access

```cpp
constexpr reference operator*() const;
```

**Effects:** As if by:

```cpp
Iterator tmp = current;
return *--tmp;
```

```cpp
constexpr pointer operator->() const
```

**requires (is_pointer_v<Iterator> || requires(const Iterator i) { i.operator->(); });
```

**Effects:**

1. If `Iterator` is a pointer type, equivalent to: `return prev(current);`
2. Otherwise, equivalent to: `return prev(current).operator->();`

```cpp
constexpr unspecified operator[](difference_type n) const;
```

**Returns:** `current[-n-1]`.

### 25.5.1.7 Navigation

```cpp
constexpr reverse_iterator operator+(difference_type n) const;
```

**Returns:** `reverse_iterator(current-n)`.

```cpp
constexpr reverse_iterator operator-(difference_type n) const;
```

**Returns:** `reverse_iterator(current+n)`.

```cpp
constexpr reverse_iterator& operator++();
```

**Effects:** As if by: `--current`.

**Returns:** `*this`.

```cpp
constexpr reverse_iterator operator++(int);
```

**Effects:** As if by:

```cpp
reverse_iterator tmp = *this;
--current;
return tmp;
```
constexpr reverse_iterator& operator--();

Effects: As if by ++current.

Returns: *this.

constexpr reverse_iterator operator--(int);

Effects: As if by:
    reverse_iterator tmp = *this;
    ++current;
    return tmp;

constexpr reverse_iterator& operator+=(difference_type n);

Effects: As if by: current -= n;

Returns: *this.

constexpr reverse_iterator& operator-=(difference_type n);

Effects: As if by: current += n;

Returns: *this.

25.5.1.8 Comparisons

template<class Iterator1, class Iterator2>
constexpr bool operator==(const reverse_iterator<Iterator1>& x,
const reverse_iterator<Iterator2>& y);

Constraints: x.base() == y.base() is well-formed and convertible to bool.

Returns: x.base() == y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator!=(const reverse_iterator<Iterator1>& x,
const reverse_iterator<Iterator2>& y);

Constraints: x.base() != y.base() is well-formed and convertible to bool.

Returns: x.base() != y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator<(const reverse_iterator<Iterator1>& x,
const reverse_iterator<Iterator2>& y);

Constraints: x.base() < y.base() is well-formed and convertible to bool.

Returns: x.base() < y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator>(const reverse_iterator<Iterator1>& x,
const reverse_iterator<Iterator2>& y);

Constraints: x.base() > y.base() is well-formed and convertible to bool.

Returns: x.base() > y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator<=(const reverse_iterator<Iterator1>& x,
const reverse_iterator<Iterator2>& y);

Constraints: x.base() >= y.base() is well-formed and convertible to bool.

Returns: x.base() >= y.base().
template<class Iterator1, class Iterator2>
constexpr bool operator>=(
  const reverse_iterator<Iterator1>& x,
  const reverse_iterator<Iterator2>& y);

Constraints: x.base() <= y.base() is well-formed and convertible to bool.

Returns: x.base() <= y.base().

template<class Iterator1, three_way_comparable_with<Iterator1> Iterator2>
constexpr compare_three_way_result_t<Iterator1, Iterator2>
operator<=>(const reverse_iterator<Iterator1>& x,
  const reverse_iterator<Iterator2>& y);

Returns: y.base() <=> x.base().

[Note 1: The argument order in the Returns: element is reversed because this is a reverse iterator. — end note]

25.5.1.9 Non-member functions [reverse.iter.nonmember]

template<class Iterator1, class Iterator2>
constexpr auto operator-(
  const reverse_iterator<Iterator1>& x,
  const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());

Returns: y.base() - x.base().

template<class Iterator>
constexpr reverse_iterator<Iterator> operator+(
  iter_difference_t<Iterator> n,
  const reverse_iterator<Iterator>& x);

Returns: reverse_iterator<Iterator>(x.base() - n).

friend constexpr iter_rvalue_reference_t<Iterator>
iter_move(const reverse_iterator& i) noexcept;

Effects: Equivalent to:
  auto tmp = i.base();
  return ranges::iter_move(--tmp);

Remarks: The exception specification is equivalent to:
  is_nothrow_copy_constructible_v<Iterator> &&
  noexcept(ranges::iter_move(--declval<Iterator&>()))

friend constexpr void
iter_swap(const reverse_iterator& x,
  const reverse_iterator<Iterator2>& y) noexcept;

Effects: Equivalent to:
  auto xtmp = x.base();
  auto ytmp = y.base();
  ranges::iter_swap(--xtmp, --ytmp);

Remarks: The exception specification is equivalent to:
  is_nothrow_copy_constructible_v<Iterator> &&
  is_nothrow_copy_constructible_v<Iterator2> &&
  noexcept(ranges::iter_swap(--declval<Iterator&>()), --declval<Iterator2&>()))

template<class Iterator>
constexpr reverse_iterator<Iterator> make_reverse_iterator(Iterator i);

Returns: reverse_iterator<Iterator>(i).

25.5.2 Insert iterators [insert.iterators]

25.5.2.1 General [insert.iterators.general]

1 To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called insert iterators, are provided in the library. With regular iterator classes,
while (first != last) *result++ = *first++;

causes a range \([\text{first, last}]\) to be copied into a range starting with result. The same code with result being an insert iterator will insert corresponding elements into the container. This device allows all of the copying algorithms in the library to work in the \(\text{insert mode}\) instead of the \(\text{regular overwrite mode}\).

An insert iterator is constructed from a container and possibly one of its iterators pointing to where insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators meet the requirements of output iterators. \(\text{operator}\*\) returns the insert iterator itself. The assignment \(\text{operator=}(\text{const } T& \ x)\) is defined on insert iterators to allow writing into them, it inserts \(\ x\) right before where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the container where the insertion takes place. \(\text{back_insert_iterator}\) inserts elements at the end of a container, \(\text{front_insert_iterator}\) inserts elements at the beginning of a container, and \(\text{insert_iterator}\) inserts elements where the iterator points to in a container. \(\text{back_inserter}, \text{front_inserter}, \text{and inserter}\) are three functions making the insert iterators out of a container.

25.5.2.2 Class template \(\text{back_insert_iterator}\)

```cpp
namespace std {
    template<class Container>
    class back_insert_iterator {
    protected:
        Container* container;

    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
        using difference_type = ptrdiff_t;
        using pointer = void;
        using reference = void;
        using container_type = Container;

        constexpr explicit back_insert_iterator(Container& x);
        constexpr back_insert_iterator& operator=(const typename Container::value_type& value);
        constexpr back_insert_iterator& operator=(typename Container::value_type&& value);
        constexpr back_insert_iterator& operator*();
        constexpr back_insert_iterator& operator++();
        constexpr back_insert_iterator operator++(int);
    };
}
```

25.5.2.2.1 Operations

| `constexpr explicit back_insert_iterator(Container& x);` | 1 |
| `Effects: Initializes `container with addressof(x).` |
| `constexpr back_insert_iterator& operator=(const typename Container::value_type& value);` | 2 |
| `Effects: As if by: container->push_back(value);` |
| `Returns: *this.` |
| `constexpr back_insert_iterator& operator=(typename Container::value_type&& value);` | 4 |
| `Effects: As if by: container->push_back(std::move(value));` |
| `Returns: *this.` |
| `constexpr back_insert_iterator& operator*();` | 6 |
| `Returns: *this.` |
| `constexpr back_insert_iterator& operator++();` |
| `constexpr back_insert_iterator& operator++(int);` |
| `Returns: *this.` | 7 |
25.5.2.2  back_inserter

```cpp
template<class Container>
constexpr back_insert_iterator<Container> back_inserter(Container& x);
```

1 Returns: back_insert_iterator<Container>(x).

25.5.2.3  Class template front_insert_iterator

```cpp
namespace std {
    template<class Container>
    class front_insert_iterator {
        protected:
            Container* container;

        public:
            using iterator_category = output_iterator_tag;
            using value_type = void;
            using difference_type = ptrdiff_t;
            using pointer = void;
            using reference = void;
            using container_type = Container;

            constexpr explicit front_insert_iterator(Container& x);
            constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
            constexpr front_insert_iterator& operator=(typename Container::value_type&& value);
            constexpr front_insert_iterator& operator*();
            constexpr front_insert_iterator& operator++();
            constexpr front_insert_iterator operator++(int);
    };
}
```

25.5.2.3.1  Operations

```cpp
constexpr explicit front_insert_iterator(Container& x);
```

1 Effects: Initializes container with addressof(x).

```cpp
constexpr front_insert_iterator& operator=(const typename Container::value_type& value);
```

2 Effects: As if by: container->push_front(value);

3 Returns: *this.

```cpp
constexpr front_insert_iterator& operator=(typename Container::value_type&& value);
```

4 Effects: As if by: container->push_front(std::move(value));

5 Returns: *this.

```cpp
constexpr front_insert_iterator& operator*();
```

6 Returns: *this.

```cpp
constexpr front_insert_iterator& operator++();
```

7 Returns: *this.

25.5.2.3.2  front_inserter

```cpp
template<class Container>
constexpr front_insert_iterator<Container> front_inserter(Container& x);
```

1 Returns: front_insert_iterator<Container>(x).
25.5.2.4 Class template insert_iterator

namespace std {
    template<class Container>
    class insert_iterator {
    protected:
        Container* container;
        ranges::iterator_t<Container> iter;

    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
        using difference_type = ptrdiff_t;
        using pointer = void;
        using reference = void;
        using container_type = Container;

        constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
        constexpr insert_iterator& operator=(const typename Container::value_type& value);
        constexpr insert_iterator& operator=(typename Container::value_type&& value);
        constexpr insert_iterator& operator*();
        constexpr insert_iterator& operator++();
        constexpr insert_iterator& operator++(int);
    };
}

25.5.2.4.1 Operations

constexpr insert_iterator(Container& x, ranges::iterator_t<Container> i);
1 Effects: Initializes container with addressof(x) and iter with i.

constexpr insert_iterator& operator=(const typename Container::value_type& value);
2 Effects: As if by:
    iter = container->insert(iter, value);
    ++iter;
3 Returns: *this.

constexpr insert_iterator& operator=(typename Container::value_type&& value);
4 Effects: As if by:
    iter = container->insert(iter, std::move(value));
    ++iter;
5 Returns: *this.

constexpr insert_iterator& operator*();
6 Returns: *this.

constexpr insert_iterator& operator++();
7 constexpr insert_iterator& operator++(int);

25.5.2.4.2 inserter

template<class Container>
constexpr insert_iterator<Container>
    inserter(Container& x, ranges::iterator_t<Container> i);
1 Returns: insert_iterator<Container>(x, i).
### 25.5.3 Constant iterators and sentinels

#### 25.5.3.1 General

Class template `basic_const_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator’s indirection operator to a type such that the adapted iterator is a constant iterator (25.3). Some generic algorithms can be called with constant iterators to avoid mutation.

Specializations of `basic_const_iterator` are constant iterators.

#### 25.5.3.2 Alias templates

```cpp
template<indirectly_readable It>
  using iter_const_reference_t =
    common_reference_t<const iter_value_t<It>&&, iter_reference_t<It>>;

template<class It>
  concept constant_iterator =
    // exposition only
    input_iterator<It> && same_as<iter_const_reference_t<It>, iter_reference_t<It>>;

template<input_iterator I>
  using const_iterator = see below;
```

Result: If `I` models `constant_iterator`, `I`. Otherwise, `basic_const_iterator<I>`.

```cpp
template<semiregular S>
  using const_sentinel = see below;
```

Result: If `S` models `input_iterator`, `const_iterator<S>`. Otherwise, `S`.

#### 25.5.3.3 Class template `basic_const_iterator`

```cpp
namespace std {
  template<class I>
    concept not-a-const_iterator = see below; // exposition only

  template<indirectly_readable I>
    using iter_const_rvalue_reference_t =
      // exposition only
      common_reference_t<const iter_value_t<I>&&, iter_rvalue_reference_t<I>>;

  template<input_iterator Iterator>
    class basic_const_iterator {
    private:
      Iterator current_ = Iterator(); // exposition only
      using reference = iter_const_reference_t<Iterator>; // exposition only
      using rvalue_reference =
        iter_const_rvalue_reference_t<Iterator>;

    public:
      using iterator_concept = see below;
      using iterator_category = see below; // not always present
      using value_type = iter_value_t<Iterator>;
      using difference_type = iter_difference_t<Iterator>;
      basic_const_iterator() requires default_initializable<Iterator> = default;
      constexpr basic_const_iterator(Iterator current);
      template<convertible_to<Iterator> U>
        constexpr basic_const_iterator(basic_const_iterator<U> current);
      template<different-from<basic_const_iterator> T>
        requires convertible_to<T, Iterator>
        constexpr basic_const_iterator(T&& current);

      constexpr const Iteratork& base() const & noexcept;
      constexpr Iterator base() &&;
      constexpr reference operator*() const;
    }
}
```

§ 25.5.3.3
constexpr const auto* operator->() const
requires is_lvalue_reference_v<iter_reference_t<Iterator>> &&
    same_as<remove_cvref_t<iter_reference_t<Iterator>>, value_type>;

constexpr basic_const_iterator& operator++();
constexpr void operator++(int);
constexpr basic_const_iterator operator++(int) requires forward_iterator<Iterator>;

constexpr basic_const_iterator& operator--() requires bidirectional_iterator<Iterator>;
constexpr basic_const_iterator operator--(int) requires bidirectional_iterator<Iterator>;

constexpr basic_const_iterator& operator+=(difference_type n)
requires random_access_iterator<Iterator>;
constexpr basic_const_iterator& operator-=(difference_type n)
requires random_access_iterator<Iterator>;

constexpr reference operator[](difference_type n) const
requires random_access_iterator<Iterator>;

template<sentinel_for<Iterator> S>
constexpr bool operator==(const S& s) const;
constexpr bool operator<(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;
constexpr bool operator>(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;
constexpr bool operator<=(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;
constexpr bool operator>=(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;

constexpr auto operator<=>(const basic_const_iterator& y) const
requires random_access_iterator<Iterator> && three_way_comparable<Iterator>;

template<different_from<basic_const_iterator> I>
constexpr bool operator<(const I& y) const
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
constexpr bool operator>(const I& y) const
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
constexpr bool operator<=(const I& y) const
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
constexpr bool operator>=(const I& y) const
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<not_a_const_iterator I>
friend constexpr bool operator<(const I& x, const basic_const_iterator& y)
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
friend constexpr bool operator>(const I& x, const basic_const_iterator& y)
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
friend constexpr bool operator<=(const I& x, const basic_const_iterator& y)
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
friend constexpr bool operator>=(const I& x, const basic_const_iterator& y)
requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
friend constexpr basic_const_iterator operator+=(const basic_const_iterator& i, difference_type n)
  requires random_access_iterator<Iterator>;
friend constexpr basic_const_iterator operator+=(difference_type n, const basic_const_iterator& i)
  requires random_access_iterator<Iterator>;
friend constexpr basic_const_iterator operator-(const basic_const_iterator& i, difference_type n)
  requires random_access_iterator<Iterator>;
template<sized_sentinel_for<Iterator> S>
  constexpr difference_type operator-(const S& y) const;
template<not-a-const-iterator S>
  requires sized_sentinel_for<S, Iterator>
  friend constexpr difference_type operator-(const S& x, const basic_const_iterator& y);
friend constexpr rvalue_reference iter_move(const basic_const_iterator& i)
  noexcept(noexcept(static_cast<rvalue_reference>(ranges::iter_move(i.current_))))
  { return static_cast<rvalue_reference>(ranges::iter_move(i.current_)); }
};

1 Given some type I, the concept not-a-const-iterator is defined as false if I is a specialization of basic_const_iterator and true otherwise.

25.5.3.4 Member types

basic_const_iterator<Iterator>::iterator_concept is defined as follows:

(1.1) — If Iterator models contiguous_iterator, then iterator_concept denotes contiguous_iterator_tag.
(1.2) — Otherwise, if Iterator models random_access_iterator, then iterator_concept denotes random_access_iterator_tag.
(1.3) — Otherwise, if Iterator models bidirectional_iterator, then iterator_concept denotes bidirectional_iterator_tag.
(1.4) — Otherwise, if Iterator models forward_iterator, then iterator_concept denotes forward_iterator_tag.
(1.5) — Otherwise, iterator_concept denotes input_iterator_tag.

2 The member typedef-name iterator_category is defined if and only if Iterator models forward_iterator. In that case, basic_const_iterator<Iterator>::iterator_category denotes the type iterator_traits<Iterator>::iterator_category.

25.5.3.5 Operations

constexpr basic_const_iterator(Iterator current);

Effects: Initializes current_ with std::move(current).

template<convertible_to<Iterator> U>
constexpr basic_const_iterator(basic_const_iterator<U> current);

Effects: Initializes current_ with std::move(current.current_).

template<different-from<basic_const_iterator> T>
requires convertible_to<T, Iterator>
constexpr basic_const_iterator(T&& current);

Effects: Initializes current_ with std::forward<T>(current).

constexpr const Iterator& base() const & noexcept;

Effects: Equivalent to: return current_;

constexpr Iterator base() &&;

Effects: Equivalent to: return std::move(current_);
constexpr reference operator*() const;

Effects: Equivalent to: return static_cast<reference>(*current_);

constexpr const auto* operator->() const requires is_lvalue_reference_v<iter_reference_t<Iterator>> && same_as<remove_cvref_t<iter_reference_t<Iterator>>, value_type>;

Returns: If Iterator models contiguous_iterator, to_address(current_); otherwise, address-of(*current_).

constexpr basic_const_iterator& operator++();

Effects: Equivalent to:
++current_; return *this;

constexpr void operator++(int);

Effects: Equivalent to: ++current_;

constexpr basic_const_iterator operator++(int) requires forward_iterator<Iterator>;

Effects: Equivalent to:
auto tmp = *this;
++*this;
return tmp;

constexpr basic_const_iterator& operator--() requires bidirectional_iterator<Iterator>;

Effects: Equivalent to:
--current_; return *this;

constexpr basic_const_iterator operator--(int) requires bidirectional_iterator<Iterator>;

Effects: Equivalent to:
auto tmp = *this;
--*this;
return tmp;

constexpr basic_const_iterator& operator+=(difference_type n) requires random_access_iterator<Iterator>;
constexpr basic_const_iterator& operator-=(difference_type n) requires random_access_iterator<Iterator>;

Let op be the operator.

Effects: Equivalent to:
current_ op n;
return *this;

constexpr reference operator[](difference_type n) const requires random_access_iterator<Iterator>

Effects: Equivalent to: return static_cast<reference>(current_[n]);

template<sentinel_for<Iterator> S>
constexpr bool operator==(const S& s) const;

Effects: Equivalent to: return current_ == s;

caseexpr bool operator<(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;
caseexpr bool operator>(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;
caseexpr bool operator<=(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;
caseexpr bool operator>=(const basic_const_iterator& y) const
requires random_access_iterator<Iterator>;

§ 25.5.3.5
constexpr auto operator<=>(const basic_const_iterator& y) const
    requires random_access_iterator<Iterator> && three_way_comparable<Iterator>;

Let \( \text{op} \) be the operator.

**Effects:** Equivalent to: \( \text{return current_ op y.current_} \);

```cpp
template<\text{different-from}<\text{basic_const_iterator}> I>
constexpr bool operator<(const I& y) const
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<\text{different-from}<\text{basic_const_iterator}> I>
constexpr bool operator>(const I& y) const
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<\text{different-from}<\text{basic_const_iterator}> I>
constexpr bool operator<=(const I& y) const
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<\text{different-from}<\text{basic_const_iterator}> I>
constexpr bool operator>=(const I& y) const
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I> &&
        three_way_comparable_with<Iterator, I>;
```

Let \( \text{op} \) be the operator.

**Effects:** Equivalent to: \( \text{return current_ op y} \);

```cpp
template<\text{not-a-const-iterator} I>
friend constexpr bool operator<(const I& x, const basic_const_iterator& y)
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<\text{not-a-const-iterator} I>
friend constexpr bool operator>(const I& x, const basic_const_iterator& y)
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<\text{not-a-const-iterator} I>
friend constexpr bool operator<=(const I& x, const basic_const_iterator& y)
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;

template<\text{not-a-const-iterator} I>
friend constexpr bool operator>=(const I& x, const basic_const_iterator& y)
    requires random_access_iterator<Iterator> && totally_ordered_with<Iterator, I>;
```

Returns: Equivalent to: \( \text{return x op y.current_} \);

```cpp
friend constexpr basic_const_iterator operator+(const basic_const_iterator& i, difference_type n)
    requires random_access_iterator<Iterator>;

friend constexpr basic_const_iterator operator+(difference_type n, const basic_const_iterator& i)
    requires random_access_iterator<Iterator>;
```

**Effects:** Equivalent to: \( \text{return basic_const_iterator(i.current_ + n)} \);

```cpp
friend constexpr basic_const_iterator operator-(const basic_const_iterator& i, difference_type n)
    requires random_access_iterator<Iterator>;
```

**Effects:** Equivalent to: \( \text{return basic_const_iterator(i.current_ - n)} \);

```cpp
template<\text{sized_sentinel_for}<\text{Iterator}> S>
constexpr difference_type operator-(const S& y) const;
```

**Effects:** Equivalent to: \( \text{return current_ - y} \);

```cpp
template<\text{not-a-const-iterator} S>
requires sized_sentinel_for<S, Iterator>
friend constexpr difference_type operator-(const S& x, const basic_const_iterator& y);
```

**Effects:** Equivalent to: \( \text{return x - y.current_} \);
25.5.4 Move iterators and sentinels

25.5.4.1 General

Class template move_iterator is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator’s indirection operator to an rvalue. Some generic algorithms can be called with move iterators to replace copying with moving.

[Example 1:

```cpp
list<string> s;
// populate the list s
vector<string> v1(s.begin(), s.end());  // copies strings into v1
vector<string> v2(make_move_iterator(s.begin()), make_move_iterator(s.end()));  // moves strings into v2
```
—end example]

25.5.4.2 Class template move_iterator

```cpp
namespace std {
    template<class Iterator>
    class move_iterator {
    public:
        using iterator_type = Iterator;
        using iterator_concept = see below;
        using iterator_category = see below;  // not always present
        using value_type = iter_value_t<Iterator>;
        using difference_type = iter_difference_t<Iterator>;
        using pointer = Iterator;
        using reference = iter_rvalue_reference_t<Iterator>;

        constexpr move_iterator();
        constexpr explicit move_iterator(Iterator i);
        template<class U> constexpr move_iterator(const move_iterator<U>& u);
        template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);
        constexpr const Iterator& base() const & noexcept;
        constexpr Iterator base() &&;
        constexpr reference operator*() const;
        constexpr move_iterator& operator++();
        constexpr auto operator++(int);
        constexpr move_iterator& operator--();
        constexpr move_iterator operator--(int);
        constexpr move_iterator operator+(difference_type n) const;
        constexpr move_iterator& operator+=(difference_type n);
        constexpr move_iterator operator-(difference_type n) const;
        constexpr move_iterator& operator-=(difference_type n);
        constexpr reference operator[](difference_type n) const;

        template<sentinel_for<Iterator> S>
        friend constexpr bool operator==(const move_iterator& x, const move_sentinel<S>& y);
        template<sized_sentinel_for<Iterator> S>
        friend constexpr iter_difference_t<Iterator> operator-(const move_sentinel<S>& x, const move_iterator& y);
        template<sized_sentinel_for<Iterator> S>
        friend constexpr iter_difference_t<Iterator> operator-(const move_iterator& x, const move_sentinel<S>& y);
        friend constexpr iter_rvalue_reference_t<Iterator> iter_move(const move_iterator& i)
            noexcept(noexcept(ranges::iter_move(i.current)));

    };
}
```

§ 25.5.4.2 1100
The member typedef-name `iterator_concept` is defined as follows:

1. If `Iterator` models `random_access_iterator`, then `iterator_concept` denotes `random_access_iterator_tag`.
2. Otherwise, if `Iterator` models `bidirectional_iterator`, then `iterator_concept` denotes `bidirectional_iterator_tag`.
3. Otherwise, if `Iterator` models `forward_iterator`, then `iterator_concept` denotes `forward_iterator_tag`.
4. Otherwise, `iterator_concept` denotes `input_iterator_tag`.

The member typedef-name `iterator_category` is defined if and only if the `qualified-id iterator_traits<Iterator>::iterator_category` is valid and denotes a type. In that case, `iterator_category` denotes

1. `random_access_iterator_tag` if the type `iterator_traits<Iterator>::iterator_category` models derived from `random_access_iterator_tag`, and
2. `iterator_traits<Iterator>::iterator_category` otherwise.

### 25.5.4.3 Requirements

The template parameter `Iterator` shall either meet the `Cpp17InputIterator` requirements (25.3.5.3) or model `input_iterator` (25.3.4.9). Additionally, if any of the bidirectional traversal functions are instantiated, the template parameter shall either meet the `Cpp17BidirectionalIterator` requirements (25.3.5.6) or model `bidirectional_iterator` (25.3.4.12). If any of the random access traversal functions are instantiated, the template parameter shall either meet the `Cpp17RandomAccessIterator` requirements (25.3.5.7) or model `random_access_iterator` (25.3.4.13).

### 25.5.4.4 Construction and assignment

```cpp
constexpr move_iterator();
```

Effects: Value-initializes `current`.

```cpp
constexpr explicit move_iterator(Iterator i);
```

Effects: Initializes `current` with `std::move(i)`.

```cpp
template<class U> constexpr move_iterator(const move_iterator<U>& u);
```

Constraints: `is_same_v<U, Iterator>` is false and `const U&` models `convertible_to<Iterator>`.

Effects: Initializes `current` with `u.current`.

```cpp
template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);
```

Constraints: `is_same_v<U, Iterator>` is false, `const U&` models `convertible_to<Iterator>`, and `assignable_from<Iterator&, const U&>` is modeled.

Effects: Assigns `u.current` to `current`.

Returns: `*this`.

### 25.5.4.5 Conversion

```cpp
constexpr const Iterator& base() const & noexcept;
```

Returns: `current`.

```cpp
constexpr Iterator base() &&;
```

Returns: `std::move(current)`.
25.5.4.6 Element access

constexpr reference operator*() const;
  Effects: Equivalent to: return ranges::iter_move(current);
constexpr reference operator[](difference_type n) const;
  Effects: Equivalent to: return ranges::iter_move(current + n);

25.5.4.7 Navigation

constexpr move_iterator& operator++();
  Effects: As if by ++current.
  Returns: *this.
constexpr auto operator++(int);
  Effects: If Iterator models forward_iterator, equivalent to:
          move_iterator tmp = *this;
          ++current;
          return tmp;
  Otherwise, equivalent to ++current.
constexpr move_iterator& operator--();
  Effects: As if by --current.
  Returns: *this.
constexpr move_iterator operator--(int);
  Effects: As if by:
          move_iterator tmp = *this;
          --current;
          return tmp;
constexpr move_iterator operator+(difference_type n) const;
  Returns: move_iterator(current + n).
constexpr move_iterator& operator+=(difference_type n);
  Effects: As if by:
          current += n;
  Returns: *this.
constexpr move_iterator operator-(difference_type n) const;
  Returns: move_iterator(current - n).
constexpr move_iterator& operator-=(difference_type n);
  Effects: As if by: current -= n;
  Returns: *this.

25.5.4.8 Comparisons

template<class Iterator1, class Iterator2>
  constexpr bool operator==(const move_iterator<Iterator1>& x,
                            const move_iterator<Iterator2>& y);
template<sentinel_for<Iterator> S>
  friend constexpr bool operator==(const move_iterator& x,
                                   const move_sentinel<S>& y);
  Constraints: x.base() == y.base() is well-formed and convertible to bool.
  Returns: x.base() == y.base().
template<class Iterator1, class Iterator2>
constexpr bool operator<(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: x.base() < y.base() is well-formed and convertible to bool.
Returns: x.base() < y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator<=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: y.base() < x.base() is well-formed and convertible to bool.
Returns: !(y < x).

template<class Iterator1, class Iterator2>
constexpr bool operator>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: y.base() < x.base() is well-formed and convertible to bool.
Returns: y < x.

template<class Iterator1, class Iterator2>
constexpr bool operator>=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Constraints: x.base() < y.base() is well-formed and convertible to bool.
Returns: !(x < y).

template<class Iterator1, class Iterator2>
constexpr bool operator<=>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Returns: x.base() <=> y.base().

25.5.4.9 Non-member functions

template<class Iterator1, class Iterator2>
constexpr auto operator-(
  const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y) -> decltype(x.base() - y.base());

template<sized_sentinel_for<Iterator> S>
friend constexpr iter_difference_t<Iterator> operator-(
  const move_sentinel<S>& x, const move_iterator& y);

template<sized_sentinel_for<Iterator> S>
friend constexpr iter_difference_t<Iterator> operator-(
  const move_iterator& x, const move_sentinel<S>& y);

Returns: x.base() - y.base().

template<class Iterator>
constexpr move_iterator<Iterator>
operator+(iter_difference_t<Iterator> n, const move_iterator<Iterator>& x);

Constraints: x.base() + n is well-formed and has type Iterator.
Returns: x + n.

friend constexpr iter_rvalue_reference_t<Iterator>
iter_move(const move_iterator& i)
noexcept(noexcept(ranges::iter_move(i.current)));

Effects: Equivalent to: return ranges::iter_move(i.current);

template<indirectly_swappable<Iterator> Iterator2>
friend constexpr void
iter_swap(const move_iterator& x, const move_iterator<Iterator2>& y)
noexcept(noexcept(ranges::iter_swap(x.current, y.current)));

Effects: Equivalent to: ranges::iter_swap(x.current, y.current).
template<class Iterator>
constexpr move_iterator<Iterator> make_move_iterator(Iterator i);

Returns: move_iterator<Iterator>(std::move(i)).

25.5.4.10 Class template move_sentinel

Class template move_sentinel is a sentinel adaptor useful for denoting ranges together with move_iterator. When an input iterator type I and sentinel type S model sentinel_for<S, I>, move_sentinel<S> and move_iterator<I> model sentinel_for<move_sentinel<S>, move_iterator<I>> as well.

[Example 1: A move_if algorithm is easily implemented with copy_if using move_iterator and move_sentinel:

```cpp
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, indirect_unary_predicate<I> Pred>
requires indirectly_movable<I, O>
void move_if(I first, S last, O out, Pred pred) {
    ranges::copy_if(move_iterator<I>{std::move(first)}, move_sentinel<S>{last}, std::move(out), pred);
}
```
—end example]

namespace std {
    template<semiregular S>
    class move_sentinel {
    public:
        constexpr move_sentinel();
        constexpr explicit move_sentinel(S s);
        template<class S2>
        requires convertible_to<const S2&, S>
        constexpr move_sentinel(const move_sentinel<S2>& s);
        template<class S2>
        requires assignable_from<S&, const S2&>
        constexpr move_sentinel& operator=(const move_sentinel<S2>& s);

        constexpr S base() const;
    private:
        S last;           // exposition only
    }
}

25.5.4.11 Operations

constexpr move_sentinel();

Effects: Value-initializes last. If is_trivially_default_constructible_v<S> is true, then this constructor is a constexpr constructor.

constexpr explicit move_sentinel(S s);

Effects: Initializes last with std::move(s).

template<class S2>
requires convertible_to<const S2&, S>
constexpr move_sentinel(const move_sentinel<S2>& s);

Effects: Initializes last with s.last.

template<class S2>
requires assignable_from<S&, const S2&>
constexpr move_sentinel& operator=(const move_sentinel<S2>& s);

Effects: Equivalent to: last = s.last; return *this;

constexpr S base() const;

Returns: last.
25.5.5 Common iterators

25.5.5.1 Class template common_iterator

Class template common_iterator is an iterator/sentinel adaptor that is capable of representing a non-common range of elements (where the types of the iterator and sentinel differ) as a common range (where they are the same). It does this by holding either an iterator or a sentinel, and implementing the equality comparison operators appropriately.

[Note 1: The common_iterator type is useful for interfacing with legacy code that expects the begin and end of a range to have the same type. — end note]

Example 1:

```cpp
template<class ForwardIterator>
void fun(ForwardIterator begin, ForwardIterator end);

list<int> s;
// populate the list s
using CI = common_iterator<counted_iterator<list<int>::iterator>, default_sentinel_t>;
// call fun on a range of 10 ints
fun(CI(counted_iterator(s.begin(), 10)), CI(default_sentinel_t));
```

namespace std {
    template<input_or_output_iterator I, sentinel_for<I> S>
    requires (!same_as<I, S> && copyable<I>)
    class common_iterator {
    public:
        constexpr common_iterator() requires default_initializable<I> = default;
        constexpr common_iterator(I i);
        constexpr common_iterator(S s);
        template<class I2, class S2>
        requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
        constexpr common_iterator(const common_iterator<I2, S2>& x);
        template<class I2, class S2>
        requires convertible_to<const I2&, I> && convertible_to<const S2&, S> &&
        assignable_from<I&, const I2&> && assignable_from<S&, const S2&>
        constexpr common_iterator& operator=(const common_iterator<I2, S2>& x);
        constexpr decltype(auto) operator*();
        constexpr decltype(auto) operator*() const
        requires dereferenceable<const I>;
        constexpr auto operator->() const
        requires see below;
        constexpr common_iterator& operator++();
        constexpr decltype(auto) operator++(int);
        template<class I2, sentinel_for<I> S2>
        requires sentinel_for<S, I2>
        friend constexpr bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);
        template<class I2, sentinel_for<I> S2>
        requires sentinel_for<S, I2> && equality_comparable_with<I, I2>
        friend constexpr bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);
        template<sized_sentinel_for<I> I2, sized_sentinel_for<I> S2>
        requires sized_sentinel_for<S, I2>
        friend constexpr iter_difference_t<I2> operator-(
        const common_iterator& x, const common_iterator<I2, S2>& y);
        friend constexpr iter_rvalue_reference_t<I> iter_move(const common_iterator& i)
        noexcept(noexcept(ranges::iter_move(declval<const I&>())))
        requires input_iterator<I>;
    }
```cpp
template<indirectly_swappable<I> I2, class S2>
friend constexpr void iter_swap(const common_iterator& x, const common_iterator<I2, S2>& y)
    noexcept(noexcept(ranges::iter_swap(declval<const I&>(), declval<const I2&>()));

private:
    variant<I, S> v_; // exposition only
};

template<class I, class S>
struct incrementable_traits<common_iterator<I, S>> {
    using difference_type = iter_difference_t<I>;
};

template<input_iterator I, class S>
struct iterator_traits<common_iterator<I, S>> {
    using iterator_concept = see below;
    using iterator_category = see below;
    using value_type = iter_value_t<I>;
    using difference_type = iter_difference_t<I>;
    using pointer = see below;
    using reference = iter_reference_t<I>;
};

25.5.5.2 Associated types

The nested typedef-names of the specialization of iterator_traits for common_iterator<I, S> are defined as follows.

(1.1) — iterator_concept denotes forward_iterator_tag if I models forward_iterator; otherwise it denotes input_iterator_tag.

(1.2) — iterator_category denotes forward_iterator_tag if the qualified-id iterator_traits<I>::iterator_category is valid and denotes a type that models derived_from<forward_iterator_tag>; otherwise it denotes input_iterator_tag.

(1.3) — Let a denote an lvalue of type const common_iterator<I, S>. If the expression a.operator->() is well-formed, then pointer denotes decltype(a.operator->()). Otherwise, pointer denotes void.

25.5.5.3 Constructors and conversions

constexpr common_iterator(I i);

Effects: Initializes v_ as if by v_{in_place_type<I>, std::move(i)}.

constexpr common_iterator(S s);

Effects: Initializes v_ as if by v_{in_place_type<S>, std::move(s)}.

template<class I2, class S2>
requires convertible_to<const I2&, I> && convertible_to<const S2&, S>
constexpr common_iterator(const common_iterator<I2, S2>& x);

Preconditions: x.v_.valueless_by_exception() is false.

Effects: Initializes v_ as if by v_{in_place_index<i>, get<i>(x.v_)}, where i is x.v_.index().

template<class I2, class S2>
requires convertible_to<const I2&, I> && convertible_to<const S2&, S> && assignable_from<I, const I2&> && assignable_from<S, const S2&>
constexpr common_iterator& operator=(const common_iterator<I2, S2>& x);

Preconditions: x.v_.valueless_by_exception() is false.

Effects: Equivalent to:

(6.1) — If v_.index() == x.v_.index(), then get<i>(v_) = get<i>(x.v_).

(6.2) — Otherwise, v_.emplace<i>(get<i>(x.v_)).

§ 25.5.5.3
""
where \( i \) is \( \text{x.v_.index()} \).

**Returns:** *this

### 25.5.5.4 Accessors

```c++
constexpr decltype(auto) operator*();
constexpr decltype(auto) operator*() const
    requires dereferenceable<\&\& \text{I}>
1  // Preconditions: holds_alternative<\&\& \text{I}>(\text{v}_\_\_) is true.
2  // Effects: Equivalent to: return *\text{get}<\&\& \text{I}>(\text{v}_\_\_);

constexpr auto operator->() const
    requires see below;
3  // Preconditions: holds_alternative<\&\& \text{I}>(\text{v}_\_\_) is true.
4  // Effects:
5     (5.1) If \text{I} is a pointer type or if the expression \text{get}<\&\& \text{I}>(\text{v}_\_\_).operator->() is well-formed, equivalent to:
      return \text{get}<\&\& \text{I}>(\text{v}_\_\_);
(5.2) Otherwise, if \text{iter_reference_t<\&\& \text{I}}> is a reference type, equivalent to:
      auto&& tmp = *\text{get}<\&\& \text{I}>(\text{v}_\_\_);
      return addressof(tmp);
(5.3) Otherwise, equivalent to: return \text{proxy}(*\text{get}<\&\& \text{I}>(\text{v}_\_\_)); where \text{proxy} is the exposition-only class:

        class proxy {
            \text{iter_value_t<\&\& \text{I}}> keep_; 
            constexpr proxy(\text{iter_reference_t<\&\& \text{I>>}}&& x)
                : keep_(std::move(x)) {}
            public:
                constexpr \&\& \text{iter_value_t<\&\& \text{I}}> operator->() const noexcept {
                    return addressof(keep_);}
        };
```

### 25.5.5.5 Navigation

```c++
constexpr common_iterator& operator++();
1  // Preconditions: holds_alternative<\&\& \text{I}>(\text{v}_\_\_) is true.
2  // Effects: Equivalent to ++\text{get}<\&\& \text{I}>(\text{v}_\_\_).
3  // Returns: *this.

constexpr decltype(auto) operator++(int);
4  // Preconditions: holds_alternative<\&\& \text{I}>(\text{v}_\_\_) is true.
5  // Effects: If \text{I} models forward_iterator, equivalent to:
      common_iterator tmp = *this;
      +++this;
      return tmp;
Otherwise, if requires(I& i) { { *i++ } \rightarrow \text{can-reference}; } is true or
      indirectly_readable<\&\& \text{I>>} && constructible_from<\text{iter_value_t<\&\& \text{I}}>, \text{iter_reference_t<\&\& \text{I}}>&&
      move_constructible<\text{iter_value_t<\&\& \text{I}}}>
is false, equivalent to:
      return \text{get}<\&\& \text{I}>(\text{v}_\_\_++);
```
Otherwise, equivalent to:

```cpp
postfix-proxy p(**this);
++*this;
return p;
```

where `postfix-proxy` is the exposition-only class:

```cpp
class postfix-proxy {
  iter_value_t<I> keep_;
  constexpr postfix-proxy(iter_reference_t<I>&& x)
      : keep_(std::forward<iter_reference_t<I>>(x)) {} 
  public:
    constexpr const iter_value_t<I>& operator*() const noexcept {
      return keep_;
    }
};
```

### 25.5.5.6 Comparisons

```cpp
template<class I2, sentinel_for<I> S2>
requires sentinel_for<S, I2>
friend constexpr bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);
```

1. **Preconditions**: `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each false.
2. **Returns**: true if `i == j`, and otherwise `get<i>(x.v_) == get<j>(y.v_)`, where `i` is `x.v_.index()` and `j` is `y.v_.index()`.

```cpp
template<class I2, sentinel_for<I> S2>
requires sentinel_for<S, I2> && equality_comparable_with<I, I2>
friend constexpr bool operator==(const common_iterator& x, const common_iterator<I2, S2>& y);
```

3. **Preconditions**: `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each false.
4. **Returns**: true if `i` and `j` are each 1, and otherwise `get<i>(x.v_) == get<j>(y.v_)`, where `i` is `x.v_.index()` and `j` is `y.v_.index()`.

```cpp
template<sized_sentinel_for<I> I2, sized_sentinel_for<I> S2>
requires sized_sentinel_for<S, I2>
friend constexpr iter_difference_t<I2> operator-(const common_iterator& x, const common_iterator<I2, S2>& y);
```

5. **Preconditions**: `x.v_.valueless_by_exception()` and `y.v_.valueless_by_exception()` are each false.
6. **Returns**: `0` if `i` and `j` are each 1, and otherwise `get<i>(x.v_) - get<j>(y.v_)`, where `i` is `x.v_.index()` and `j` is `y.v_.index()`.

### 25.5.5.7 Customizations

```cpp
friend constexpr iter_rvalue_reference_t<I> iter_move(const common_iterator& i)
  noexcept(noexcept(ranges::iter_move(declval<const I&>())))
  requires input_iterator<I>;
```

1. **Preconditions**: `holds_alternative<I>(i.v_)` is true.
2. **Effects**: Equivalent to: `return ranges::iter_move(get<I>(i.v_));`

```cpp
template<indirectly_swappable<I> I2, class S2>
friend constexpr void iter_swap(const common_iterator& x, const common_iterator<I2, S2>& y)
  noexcept(noexcept(ranges::iter_swap(declval<const I&>(), declval<const I2&>())))
  requires input_iterator<I>;
```

3. **Preconditions**: `holds_alternative<I>(x.v_)` and `holds_alternative<I2>(y.v_)` are each true.
4. **Effects**: Equivalent to `ranges::iter_swap(get<I>(x.v_), get<I2>(y.v_));`

§ 25.5.5.7
25.5.6 Default sentinel

namespace std {
  struct default_sentinel_t {};
}

Class `default_sentinel_t` is an empty type used to denote the end of a range. It can be used together with iterator types that know the bound of their range (e.g., `counted_iterator` (25.5.7.1)).

25.5.7 Counted iterators

25.5.7.1 Class template `counted_iterator`  

Class template `counted_iterator` is an iterator adaptor with the same behavior as the underlying iterator except that it keeps track of the distance to the end of its range. It can be used together with `default_sentinel` in calls to generic algorithms to operate on a range of \( N \) elements starting at a given position without needing to know the end position a priori.

[Example 1:]

```cpp
list<string> s;
// populate the list s with at least 10 strings
vector<string> v;
// copies 10 strings into v:
ranges::copy(counted_iterator(s.begin(), 10), default_sentinel, back_inserter(v));
--end example
```

Two values \( i_1 \) and \( i_2 \) of types `counted_iterator<I1>` and `counted_iterator<I2>` refer to elements of the same sequence if and only if there exists some integer \( n \) such that \( \text{next}(i_1.\text{base}(), i_1.\text{count()} + n) \) and \( \text{next}(i_2.\text{base}(), i_2.\text{count()} + n) \) refer to the same (possibly past-the-end) element.

namespace std {
  template<input_or_output_iterator I>
  class counted_iterator {
  public:
    using iterator_type = I;
    using value_type = iter_value_t<I>;
    // present only
    // if I models indirectly_readable
    using difference_type = iter_difference_t<I>;
    using iterator_concept = typename I::iterator_concept;
    // present only
    // if the qualified-id I::iterator_concept is valid and denotes a type
    using iterator_category = typename I::iterator_category;
    // present only
    // if the qualified-id I::iterator_category is valid and denotes a type
    constexpr counted_iterator() requires default_initializable<I> = default;
    constexpr counted_iterator(I x, iter_difference_t<I> n);
    template<class I2>
    requires convertible_to<const I2&, I>
    constexpr counted_iterator(const counted_iterator<I2>& x);
    template<class I2>
    requires assignable_from<I&, const I2&>
    constexpr counted_iterator& operator=(const counted_iterator<I2>& x);
    constexpr const I& base() const & noexcept;
    constexpr I base() &&;
    constexpr iter_difference_t<I> count() const noexcept;
    constexpr decltype(auto) operator*();
    constexpr decltype(auto) operator*() const requires dereferenceable<const I>;
    constexpr auto operator->() const noexcept requires contiguous_iterator<I>;
    constexpr counted_iterator& operator++();
    constexpr decltype(auto) operator++(int);
    constexpr counted_iterator operator++(int) requires forward_iterator<I>;
  };
```
constexpr counted_iterator& operator--() requires bidirectional_iterator<I>;
constexpr counted_iterator operator--(int) requires bidirectional_iterator<I>;

constexpr counted_iterator operator+(iter_difference_t<I> n) const requires random_access_iterator<I>;
friend constexpr counted_iterator operator+(iter_difference_t<I> n, const counted_iterator& x) requires random_access_iterator<I>;
constexpr counted_iterator& operator+=(iter_difference_t<I> n) requires random_access_iterator<I>;

private:
    I current = I(); // exposition only
    iter_difference_t<I> length = 0; // exposition only
};

template<input_iterator I>
requires same_as<ITER_TRAITS(I), iterator_traits<I>> // see 25.3.4.1
struct iterator_traits<counted_iterator<I>> : iterator_traits<I> {
    using pointer = conditional_t<contiguous_iterator<I>, add_pointer_t<iter_reference_t<I>>, void>;
};

25.5.7.2 Constructors and conversions [counted.iter.const]
constexpr counted_iterator(I i, iter_difference_t<I> n);

1 Preconditions: n >= 0.
2 Effects: Initializes current with std::move(i) and length with n.
template<class I2>
requires convertible_to<const I2&, I>
constexpr counted_iterator(const counted_iterator<I2>& x);

Effects: Initializes current with x.current and length with x.length.

template<class I2>
requires assignable_from<I&, const I2&>
constexpr counted_iterator& operator=(const counted_iterator<I2>& x);

Effects: Assigns x.current to current and x.length to length.

Returns: *this.

25.5.7.3 Accessors

constexpr const I& base() const & noexcept;

Effects: Equivalent to: return current;

constexpr I base() &&;

Returns: std::move(current).

constexpr iter_difference_t<I> count() const noexcept;

Effects: Equivalent to: return length;

25.5.7.4 Element access

constexpr decltype(auto) operator*();
constexpr decltype(auto) operator*() const
requires dereferenceable<const I>;

Preconditions: length > 0 is true.

Effects: Equivalent to: return *current;

constexpr auto operator->() const noexcept
requires contiguous_iterator<I>;

Effects: Equivalent to: return to_address(current);

constexpr decltype(auto) operator[](iter_difference_t<I> n) const
requires random_access_iterator<I>;

Preconditions: n < length.

Effects: Equivalent to: return current[n];

25.5.7.5 Navigation

constexpr counted_iterator& operator++();

Preconditions: length > 0.

Effects: Equivalent to:
++current;
--length;
return *this;

constexpr decltype(auto) operator++(int);

Preconditions: length > 0.

Effects: Equivalent to:
--length;
try { return current++; } 
catch(...) { ++length; throw; }

constexpr counted_iterator operator++(int)
requires forward_iterator<I>;

Effects: Equivalent to:

Preconditions: n <= length.

Effects: Equivalent to:
current += n;
length -= n;
return *this;

constexpr counted_iterator operator-(iter_difference_t<I> n) const requires random_access_iterator<I>;

Effects: Equivalent to: return counted_iterator(current - n, length + n);

template<common_with<I> I2>
friend constexpr iter_difference_t<I2> operator-(
const counted_iterator& x, const counted_iterator<I2>& y);

Preconditions: x and y refer to elements of the same sequence (25.5.7.1).

Effects: Equivalent to: return y.length - x.length;

friend constexpr iter_difference_t<I> operator-(
const counted_iterator& x, default_sentinel_t);

Effects: Equivalent to: return -x.length;

friend constexpr iter_difference_t<I> operator-(
default_sentinel_t, const counted_iterator& y);

Effects: Equivalent to: return y.length;

constexpr counted_iterator& operator-(iter_difference_t<I> n) const requires random_access_iterator<I>;

Preconditions: -n <= length.

Effects: Equivalent to:
current -= n;
length += n;
return *this;

25.5.7.6 Comparisons

template<common_with<I> I2>
friend constexpr bool operator==(const counted_iterator& x, const counted_iterator<I2>& y);

1 Preconditions: x and y refer to elements of the same sequence (25.5.7.1).
2 Effects: Equivalent to: return x.length == y.length;

friend constexpr bool operator==(const counted_iterator& x, default_sentinel_t);

3 Effects: Equivalent to: return x.length == 0;

25.5.7.7 Customizations

friend constexpr iter_rvalue_reference_t<I>
iter_move(const counted_iterator& i)
noexcept(noexcept(ranges::iter_move(i.current)))
requires input_iterator<I>;

1 Preconditions: i.length > 0 is true.
2 Effects: Equivalent to: return ranges::iter_move(i.current);

template<indirectly_swappable<I> I2>
friend constexpr void
iter_swap(const counted_iterator& x, const counted_iterator<I2>& y)
noexcept(noexcept(ranges::iter_swap(x.current, y.current)));

3 Preconditions: Both x.length > 0 and y.length > 0 are true.
4 Effects: Equivalent to ranges::iter_swap(x.current, y.current).

25.5.8 Unreachable sentinel

Class unreachable_sentinel_t can be used with any weakly_incrementable type to denote the “upper bound” of an unbounded interval.

2 [Example 1]:

char* p;
// set p to point to a character buffer containing newlines
char* nl = find(p, unreachable_sentinel, 'n');

Provided a newline character really exists in the buffer, the use of unreachable_sentinel above potentially makes the call to find more efficient since the loop test against the sentinel does not require a conditional branch. — end example

namespace std {
struct unreachable_sentinel_t {
  template<weakly_incrementable I> friend constexpr bool operator==(unreachable_sentinel_t, const I&) noexcept { return false; }
};
}
25.6 Stream iterators

25.6.1 General

To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

[Example 1:

```cpp
partial_sum(istream_iterator<double, char>(cin),
            istream_iterator<double, char>(),
            ostream_iterator<double, char>(cout, "\n"));
```

reads a file containing floating-point numbers from `cin`, and prints the partial sums onto `cout`. — end example]

25.6.2 Class template istream_iterator

25.6.2.1 General

The class template `istream_iterator` is an input iterator (25.3.5.3) that reads successive elements from the input stream for which it was constructed.

```cpp
namespace std {
    template<class T, class charT = char, class traits = char_traits<charT>,
             class Distance = ptrdiff_t>
    class istream_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type = T;
        using difference_type = Distance;
        using pointer = const T*;
        using reference = const T&;
        using char_type = charT;
        using traits_type = traits;
        using istream_type = basic_istream<charT, traits>;

        constexpr istream_iterator();
        constexpr istream_iterator(default_sentinel_t);
        istream_iterator(istream_type& s);
        constexpr istream_iterator(const istream_iterator& x) noexcept (see below);
        ~istream_iterator() = default;
        istream_iterator& operator=(const istream_iterator&);laus;

        const T& operator*() const;
        const T* operator->() const;
        istream_iterator& operator++();
        istream_iterator operator++(int);

        friend bool operator==(const istream_iterator& i, default_sentinel_t);
    private:
        basic_istream<charT,traits>* in_stream; // exposition only
        T value; // exposition only
    };
}
```

The type `T` shall meet the `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, and `Cpp17CopyAssignable` requirements.

25.6.2.2 Constructors and destructor

```cpp
constexpr istream_iterator();
constexpr istream_iterator(default_sentinel_t);
```

Effects: Constructs the end-of-stream iterator, value-initializing `value`.

Postconditions: `in_stream == nullptr` is true.

Remarks: If the initializer `T()` in the declaration `auto x = T();` is a constant initializer (7.7), then these constructors are `constexpr` constructors.
istream_iterator(istream_type& s);

Effects: Initializes in_stream with addressof(s), value-initializes value, and then calls operator++().

constexpr istream_iterator(const istream_iterator& x) noexcept(see below);

Effects: Initializes in_stream with x.in_stream and initializes value with x.value.

Remarks: An invocation of this constructor may be used in a core constant expression if and only if the initialization of value from x.value is a constant subexpression (3.14). The exception specification is equivalent to is_nothrow_copy_constructible_v<T>.

istream_iterator() = default;

Remarks: If is_trivially_destructible_v<T> is true, then this destructor is trivial.

25.6.2.3 Operations

const T& operator*() const;

Preconditions: in_stream != nullptr is true.

Returns: value.

const T* operator->() const;

Preconditions: in_stream != nullptr is true.

Returns: addressof(value).

istream_iterator& operator++();

Preconditions: in_stream != nullptr is true.

Effects: Equivalent to:

if (!(*in_stream >> value))
in_stream = nullptr;

Returns: *this.

istream_iterator operator++(int);

Preconditions: in_stream != nullptr is true.

Effects: Equivalent to:

istream_iterator tmp = *this;
++*this;
return tmp;

template<class T, class charT, class traits, class Distance>
bool operator==(const istream_iterator<T,charT,traits,Distance>& x, const istream_iterator<T,charT,traits,Distance>& y);

Returns: x.in_stream == y.in_stream.

friend bool operator==(const istream_iterator& i, default_sentinel_t);

Returns: !i.in_stream.

25.6.3 Class template ostream_iterator

25.6.3.1 General

ostream_iterator writes (using operator<<) successive elements onto the output stream from which it was constructed. If it was constructed with charT* as a constructor argument, this string, called a delimiter string, is written to the stream after every T is written.

namespace std {
  template<class T, class charT = char, class traits = char_traits<charT>>
  class ostream_iterator {
    public:
      using iterator_category = output_iterator_tag;
      using value_type = void;
      using difference_type = ptrdiff_t;
  }
using pointer = void;
using reference = void;
using char_type = charT;
using traits_type = traits;
using ostream_type = basic_ostream<charT,traits>;

ostream_iterator(ostream_type& s);
ostream_iterator(ostream_type& s, const charT* delimiter);
ostream_iterator(const ostream_iterator& x);
~ostream_iterator();
ostream_iterator& operator=(const ostream_iterator&);
ostream_iterator& operator=(const T& value);
ostream_iterator& operator*();
ostream_iterator& operator++();
ostream_iterator& operator++(int);

private:
  basic_ostream<charT,traits>* out_stream;     // exposition only
  const charT* delim;                          // exposition only
};

25.6.3.2 Constructors and destructor [ostream.iterator.cons.des]

ostream_iterator(ostream_type& s);
1 Effects: Initializes out_stream with addressof(s) and delim with nullptr.

ostream_iterator(ostream_type& s, const charT* delimiter);
2 Effects: Initializes out_stream with addressof(s) and delim with delimiter.

25.6.3.3 Operations [ostream.iterator.ops]

ostream_iterator& operator=(const T& value);
1 Effects: As if by:
  *out_stream << value;
  if (delim)
    *out_stream << delim;
  return *this;

ostream_iterator& operator*();
2 Returns: *this.

ostream_iterator& operator++();
ostream_iterator& operator++(int);
3 Returns: *this.

25.6.4 Class template istreambuf_iterator [istreambuf.iterator]

25.6.4.1 General [istreambuf.iterator.general]

The class template istreambuf_iterator defines an input iterator (25.3.5.3) that reads successive characters from the streambuf for which it was constructed. operator* provides access to the current input character, if any. Each time operator++ is evaluated, the iterator advances to the next input character. If the end of stream is reached (streambuf_type::sgetc() returns traits::eof()), the iterator becomes equal to the end-of-stream iterator value. The default constructor istreambuf_iterator() and the constructor istreambuf_iterator(nullptr) both construct an end-of-stream iterator object suitable for use as an end-of-range. All specializations of istreambuf_iterator shall have a trivial copy constructor, a constexpr default constructor, and a trivial destructor.

2 The result of operator*() on an end-of-stream iterator is undefined. For any other iterator value a char_type value is returned. It is impossible to assign a character via an input iterator.
namespace std {

    template<class charT, class traits = char_traits<charT>>
    class istreambuf_iterator {
      public:
        using iterator_category = input_iterator_tag;
        using value_type = charT;
        using difference_type = typename traits::off_type;
        using pointer = unspecified;
        using reference = charT;
        using char_type = charT;
        using traits_type = traits;
        using int_type = typename traits::int_type;
        using streambuf_type = basic_streambuf<charT,traits>;
        using istream_type = basic_istream<charT,traits>;

        template<>
        struct proxy { // exposition only
            charT keep_;            // exposition only
        };

        // 25.6.4.2, class istreambuf_iterator::proxy
        class proxy;             // exposition only

        constexpr istreambuf_iterator() noexcept;
        constexpr istreambuf_iterator(default_sentinel_t) noexcept;
        istreambuf_iterator(const istreambuf_iterator&) noexcept = default;
        ~istreambuf_iterator() = default;
        istreambuf_iterator(istream_type& s) noexcept;
        istreambuf_iterator(streambuf_type* s) noexcept;
        istreambuf_iterator(const proxy& p) noexcept;
        istreambuf_iterator& operator=(const istreambuf_iterator&) noexcept = default;
        charT operator*() const;
        istreambuf_iterator& operator++();
        proxy operator++(int);
        bool equal(const istreambuf_iterator& b) const;

        friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);

      private:
        streambuf_type* sbuf_;   // exposition only
    };

    25.6.4.3 Constructors [istreambuf.iterator.cons]
    For each istreambuf_iterator constructor in this subclause, an end-of-stream iterator is constructed if and only if the exposition-only member sbuf_ is initialized with a null pointer value.

    constexpr istreambuf_iterator() noexcept;

};
constexpr istreambuf_iterator(default_sentinel_t) noexcept;  

Effects: Initializes sbuf_ with nullptr.

istreambuf_iterator(istream_type& s) noexcept;  

Effects: Initializes sbuf_ with s.rdbuf().

istreambuf_iterator(streambuf_type* s) noexcept;  

Effects: Initializes sbuf_ with s.

istreambuf_iterator(const proxy& p) noexcept;  

Effects: Initializes sbuf_ with p.sbuf_.

25.6.4.4 Operations [istreambuf.iterator.ops]

cartT operator*() const;  

Returns: The character obtained via the streambuf member sbuf_->sgetc().

istreambuf_iterator& operator++();  

Effects: As if by sbuf_->sbumpc().

Returns: *this.

proxy operator++(int);  

Returns: proxy(sbuf_->sbumpc(), sbuf_).

bool equal(const istreambuf_iterator& b) const;  

Returns: true if and only if both iterators are at end-of-stream, or neither is at end-of-stream, regardless of what streambuf object they use.

template<class charT, class traits>  

bool operator==(const istreambuf_iterator<charT,traits>& a,  

const istreambuf_iterator<charT,traits>& b);  

Returns: a.equal(b).

friend bool operator==(const istreambuf_iterator& i, default_sentinel_t s);  

Returns: i.equal(s).

25.6.5 Class template ostreambuf_iterator [ostreambuf.iterator]

25.6.5.1 General [ostreambuf.iterator.general]

The class template ostreambuf_iterator writes successive characters onto the output stream from which it was constructed.

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class ostreambuf_iterator {
        public:
            using iterator_category = output_iterator_tag;
            using value_type = void;
            using difference_type = ptrdiff_t;
            using pointer = void;
            using reference = void;
            using char_type = charT;
            using traits_type = traits;
            using streambuf_type = basic_streambuf<charT,traits>;
            using ostream_type = basic_ostream<charT,traits>;

            ostreambuf_iterator(ostream_type& s) noexcept;
            ostreambuf_iterator(streambuf_type* s) noexcept;
            ostreambuf_iterator& operator=(charT c);
25.6.5.2 Constructors [ostreambuf.iter.cons]

ostreambuf_iterator(ostream_type& s) noexcept;

1 Preconditions: s.rdbuf() is not a null pointer.

2 Effects: Initializes sbuf_ with s.rdbuf().

ostreambuf_iterator(streambuf_type* s) noexcept;

3 Preconditions: s is not a null pointer.

4 Effects: Initializes sbuf_ with s.

25.6.5.3 Operations [ostreambuf.iter.ops]

ostreambuf_iterator& operator=(charT c);

1 Effects: If failed() yields false, calls sbuf_->sputc(c); otherwise has no effect.

2 Returns: *this.

ostreambuf_iterator& operator*();

3 Returns: *this.

ostreambuf_iterator& operator++();

4 Returns: *this.

ostreambuf_iterator& operator++(int);

5 Returns: *this.

bool failed() const noexcept;

5 Returns: true if in any prior use of member operator=, the call to sbuf_->sputc() returned traits::eof(); or false otherwise.

25.7 Range access [iterator.range]

In addition to being available via inclusion of the <iterator> header, the function templates in 25.7 are available when any of the following headers are included: <array> (24.3.2), <deque> (24.3.3), <forward_list> (24.3.4), <list> (24.3.5), <map> (24.4.3), <regex> (32.3), <set> (24.4.3), <span> (24.7.2.1), <string> (23.4.2), <string_view> (23.3.2), <unordered_map> (24.5.2), <unordered_set> (24.5.3), and <vector> (24.3.6).

template<class C> constexpr auto begin(C& c) -> decltype(c.begin());

2 Returns: c.begin().

template<class C> constexpr auto begin(const C& c) -> decltype(c.begin());

2 Returns: c.begin().

template<class C> constexpr auto end(C& c) -> decltype(c.end());

3 Returns: c.end().

template<class C> constexpr auto end(const C& c) -> decltype(c.end());

3 Returns: c.end().

template<class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept;

4 Returns: array.

template<class T, size_t N> constexpr T* end(T (&array)[N]) noexcept;

4 Returns: array + N.
template<class C> constexpr auto cbegin(const C& c) noexcept(noexcept(std::begin(c)))
   -> decltype(std::begin(c));

Returns: std::begin(c).

template<class C> constexpr auto cend(const C& c) noexcept(noexcept(std::end(c)))
   -> decltype(std::end(c));

Returns: std::end(c).

template<class C> constexpr auto rbegin(C& c) -> decltype(c.rbegin());
template<class C> constexpr auto rbegin(const C& c) -> decltype(c.rbegin());

Returns: c.rbegin().

template<class C> constexpr auto rend(C& c) -> decltype(c.rend());
template<class C> constexpr auto rend(const C& c) -> decltype(c.rend());

Returns: c.rend().

template<class T, size_t N> constexpr reverse_iterator<T*> rbegin(T (&array)[N]);

Returns: reverse_iterator<T*>(array + N).

template<class T, size_t N> constexpr reverse_iterator<T*> rend(T (&array)[N]);

Returns: reverse_iterator<T*>(array).

template<class E> constexpr reverse_iterator<const E*> rbegin(const E* il);

Returns: reverse_iterator<const E*>(il.end()).

template<class E> constexpr reverse_iterator<const E*> rend(const E* il);

Returns: reverse_iterator<const E*>(il.begin()).

template<class C> constexpr auto crbegin(const C& c) -> decltype(std::rbegin(c));

Returns: std::rbegin(c).

template<class C> constexpr auto crend(const C& c) -> decltype(std::rend(c));

Returns: std::rend(c).

template<class C> constexpr auto size(const C& c) -> decltype(c.size());

Returns: c.size().

template<class C> constexpr auto ssize(const C& c)
   -> common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>;

Effects: Equivalent to:
   return static_cast<common_type_t<ptrdiff_t, make_signed_t<decltype(c.size())>>>(c.size());

template<class T, ptrdiff_t N> constexpr ptrdiff_t ssize(const T (&array)[N]) noexcept;

Returns: N.

template<class C> constexpr auto data(C& c) -> decltype(c.data());
template<class C> constexpr auto data(const C& c) -> decltype(c.data());

Returns: c.data().

template<class T, size_t N> constexpr T* data(T (&array)[N]) noexcept;

Returns: array.

template<class E> constexpr const E* data(initializer_list<E> il) noexcept;

Returns: il.begin().

§ 25.7 1121
26  Ranges library

26.1  General

This Clause describes components for dealing with ranges of elements.

The following subclauses describe range and view requirements, and components for range primitives and range generators as summarized in Table 92.

Table 92: Ranges library summary

§ 26.2
Within this Clause, for an integer-like type \( X \) (25.3.4.4), \( \text{make-unsigned-like-}t<X> \) denotes \( \text{make_unsigned-_t}<X> \) if \( X \) is an integer type; otherwise, it denotes a corresponding unspecified unsigned-integer-like type of the same width as \( X \). For an expression \( x \) of type \( X \), \( \text{to-unsigned-like}(x) \) is \( x \) explicitly converted to \( \text{make-unsigned-like-}t<X> \).
Also within this Clause, `make-signed-like-t<X>` for an integer-like type `X` denotes `make_signed_t<X>` if `X` is an integer type; otherwise, it denotes a corresponding unspecified signed-integer-like type of the same width as `X`.

### 26.3 Range access

#### 26.3.1 General

In addition to being available via inclusion of the `<ranges>` header, the customization point objects in 26.3 are available when `<iterator>` (25.2) is included.

Within 26.3, the `reified object` of a subexpression `E` denotes

1. the same object as `E` if `E` is a glvalue, or
2. the result of applying the temporary materialization conversion (7.3.5) to `E` otherwise.

### 26.3.2 `ranges::begin`

The name `ranges::begin` denotes a customization point object (16.3.3.3.5).

Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

1. If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::begin(E)` is ill-formed.
2. Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::begin(E)` is ill-formed with no diagnostic required.
3. Otherwise, if `T` is an array type, `ranges::begin(E)` is expression-equivalent to `t + 0`.
4. Otherwise, if `auto(t.begin())` is a valid expression whose type models `input_or_output_iterator`, then `ranges::begin(E)` is expression-equivalent to `auto(t.begin())`.
5. Otherwise, if `T` is a class or an enumeration type and `auto(begin(t))` is a valid expression whose type models `input_or_output_iterator` where the meaning of `begin` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::begin(E)` is expression-equivalent to that expression.
6. Otherwise, `ranges::begin(E)` is ill-formed.

[Note 1: Diagnosable ill-formed cases above result in substitution failure when `ranges::begin(E)` appears in the immediate context of a template instantiation. — end note]

[Note 2: Whenever `ranges::begin(E)` is a valid expression, its type models `input_or_output_iterator`. — end note]

### 26.3.3 `ranges::end`

The name `ranges::end` denotes a customization point object (16.3.3.3.5).

Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

1. If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::end(E)` is ill-formed.
2. Otherwise, if `T` is an array type (9.3.4.5) and `remove_all_extents_t<T>` is an incomplete type, `ranges::end(E)` is ill-formed with no diagnostic required.
3. Otherwise, if `T` is an array, `ranges::end(E)` is expression-equivalent to `t + extent_v<T>`.
4. Otherwise, if `auto(t.end())` is a valid expression whose type models `sentinel_for<iterator_t<T>>` then `ranges::end(E)` is expression-equivalent to `auto(t.end())`.
5. Otherwise, if `T` is a class or an enumeration type and `auto(end(t))` is a valid expression whose type models `sentinel_for<iterator_t<T>>` where the meaning of `end` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::end(E)` is expression-equivalent to that expression.
6. Otherwise, `ranges::end(E)` is ill-formed.

[Note 1: Diagnosable ill-formed cases above result in substitution failure when `ranges::end(E)` appears in the immediate context of a template instantiation. — end note]

[Note 2: Whenever `ranges::end(E)` is a valid expression, the types `S` and `I` of `ranges::end(E)` and `ranges::begin(E)` model `sentinel_for<S, I>`. — end note]
26.3.4 ranges::cbegin

The name ranges::cbegin denotes a customization point object (16.3.3.3.5). Given a subexpression \( E \) with type \( T \), let \( t \) be an lvalue that denotes the reified object for \( E \). Then:

1. If \( E \) is an rvalue and enable_borrowed_range<remove_cv_t<T>> is false, ranges::cbegin(\( E \)) is ill-formed.
2. Otherwise, let \( U \) be ranges::begin(possibly-const-range(t)). ranges::cbegin(\( E \)) is expression-equivalent to const_iterator<decltype(U)>\( (U) \).

[Note 1: Whenever ranges::cbegin(\( E \)) is a valid expression, its type models input_or_output_iterator and constant_iterator. — end note]

26.3.5 ranges::cend

The name ranges::cend denotes a customization point object (16.3.3.3.5). Given a subexpression \( E \) with type \( T \), let \( t \) be an lvalue that denotes the reified object for \( E \). Then:

1. If \( E \) is an rvalue and enable_borrowed_range<remove_cv_t<T>> is false, ranges::cend(\( E \)) is ill-formed.
2. Otherwise, let \( U \) be ranges::end(possibly-const-range(t)). ranges::cend(\( E \)) is expression-equivalent to const_sentinel<decltype(U)>\( (U) \).

[Note 1: Whenever ranges::cend(\( E \)) is a valid expression, its type models input_or_output_iterator and sentinel_for<\( E \), I>. If \( S \) models input_iterator, then \( S \) also models constant_iterator. — end note]

26.3.6 ranges::rbegin

The name ranges::rbegin denotes a customization point object (16.3.3.3.5).

1. Given a subexpression \( E \) with type \( T \), let \( t \) be an lvalue that denotes the reified object for \( E \). Then:
2. If \( E \) is an rvalue and enable_borrowed_range<remove_cv_t<T>> is false, ranges::rbegin(\( E \)) is ill-formed.
3. Otherwise, if \( T \) is an array type (9.3.4.5) and remove_all_extents_t\( <T> \) is an incomplete type, ranges::rbegin(\( E \)) is ill-formed with no diagnostic required.
4. Otherwise, if auto(\( t\).rbegin()) is a valid expression whose type models input_or_output_iterator, ranges::rbegin(\( E \)) is expression-equivalent to auto(\( t\).rbegin()).
5. Otherwise, if \( T \) is a class or enumeration type and auto(rbegin(\( t\))) is a valid expression whose type models input_or_output_iterator where the meaning of rbegin is established as-if by performing argument-dependent lookup only (6.5.4), then ranges::rbegin(\( E \)) is expression-equivalent to that expression.
6. Otherwise, ranges::rbegin(\( E \)) is ill-formed.

[Note 1: Diagnosable ill-formed cases above result in substitution failure when ranges::rbegin(\( E \)) appears in the immediate context of a template instantiation. — end note]

26.3.7 ranges::rend

The name ranges::rend denotes a customization point object (16.3.3.3.5).

1. Given a subexpression \( E \) with type \( T \), let \( t \) be an lvalue that denotes the reified object for \( E \). Then:
2. If \( E \) is an rvalue and enable_borrowed_range<remove_cv_t<T>> is false, ranges::rend(\( E \)) is ill-formed.
3. Otherwise, if \( T \) is an array type (9.3.4.5) and remove_all_extents_t\( <T> \) is an incomplete type, ranges::rend(\( E \)) is ill-formed with no diagnostic required.
4. Otherwise, if auto(\( t\).rend()) is a valid expression whose type models sentinel_for<decltype(ranges::rbegin(\( E \))) then ranges::rend(\( E \)) is expression-equivalent to auto(\( t\).rend())).

§ 26.3.7
— Otherwise, if $T$ is a class or enumeration type and `auto(rend(t))` is a valid expression whose type models `sentinel_for<decltype(ranges::begin(E))>` where the meaning of `rend` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::rend(E)` is expression-equivalent to that expression.

— Otherwise, if both `ranges::begin(t)` and `ranges::end(t)` are valid expressions of the same type which models `bidirectional_iterator` (25.3.4.12), then `ranges::rend(E)` is expression-equivalent to `make_reverse_iterator(ranges::begin(t))`.

— Otherwise, `ranges::rend(E)` is ill-formed.

3 [Note 1: Diagnosable ill-formed cases above result in substitution failure when `ranges::rend(E)` appears in the immediate context of a template instantiation. —end note]

4 [Note 2: Whenever `ranges::rend(E)` is a valid expression, the types $S$ and $I$ of the expressions `ranges::rend(E)` and `ranges::begin(E)` model `sentinel_for<S, I>`. —end note]

### 26.3.8 `ranges::crbegin`

The name `ranges::crbegin` denotes a customization point object (16.3.3.3.5). Given a subexpression $E$ with type $T$, let $t$ be an lvalue that denotes the reified object for $E$. Then:

— If $E$ is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::crbegin(E)` is ill-formed.

— Otherwise, let $U$ be `ranges::begin(possibly-const-range(t))`. `ranges::crbegin(E)` is expression-equivalent to `const_iterator<decltype(U)>(U)`.

2 [Note 1: Whenever `ranges::crbegin(E)` is a valid expression, its type models `input_or_output_iterator` and `constant_iterator`. —end note]

### 26.3.9 `ranges::crend`

The name `ranges::crend` denotes a customization point object (16.3.3.3.5). Given a subexpression $E$ with type $T$, let $t$ be an lvalue that denotes the reified object for $E$. Then:

— If $E$ is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::crend(E)` is ill-formed.

— Otherwise, let $U$ be `ranges::rend(possibly-const-range(t))`. `ranges::crend(E)` is expression-equivalent to `const_sentinel<decltype(U)>(U)`.

2 [Note 1: Whenever `ranges::crend(E)` is a valid expression, the types $S$ and $I$ of the expressions `ranges::crend(E)` and `ranges::crbegin(E)` model `sentinel_for<S, I>`. If $S$ models `input_iterator`, then $S$ also models `constant_iterator`. —end note]

### 26.3.10 `ranges::size`

The name `ranges::size` denotes a customization point object (16.3.3.3.5).

2 Given a subexpression $E$ with type $T$, let $t$ be an lvalue that denotes the reified object for $E$. Then:

— If $T$ is an array of unknown bound (9.3.4.5), `ranges::size(E)` is ill-formed.

— Otherwise, if $T$ is an array type, `ranges::size(E)` is expression-equivalent to `auto(extent_v<T>)`.

— Otherwise, if `disable_sized_range<remove_cv_t<T>>` is false and `auto(t.size())` is a valid expression of integer-like type (25.3.4.4), `ranges::size(E)` is expression-equivalent to `auto(t.size())`.

— Otherwise, if $T$ is a class or enumeration type, `disable_sized_range<remove_cv_t<T>>` is false and `auto(size(t))` is a valid expression of integer-like type where the meaning of `size` is established as-if by performing argument-dependent lookup only (6.5.4), then `ranges::size(E)` is expression-equivalent to that expression.

— Otherwise, if `to_unsigned-like(ranges::end(t) - ranges::begin(t))` (26.2) is a valid expression and the types $I$ and $S$ of `ranges::begin(t)` and `ranges::end(t)` (respectively) model both `sized_sentinel_for<S, I>` (25.3.4.8) and `forward_iterator<I>`, then `ranges::size(E)` is expression-equivalent to `to_unsigned-like(ranges::end(t) - ranges::begin(t))`.

— Otherwise, `ranges::size(E)` is ill-formed.

3 [Note 1: Diagnosable ill-formed cases above result in substitution failure when `ranges::size(E)` appears in the immediate context of a template instantiation. —end note]
[Note 2: Whenever `ranges::size(E)` is a valid expression, its type is integer-like. — end note]

26.3.11 ranges::ssize

The name `ranges::ssize` denotes a customization point object (16.3.3.3.5).

Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. If `ranges::size(t)` is ill-formed, `ranges::ssize(E)` is ill-formed. Otherwise let `D` be `make_signed-like-t<decltype(ranges::size(t))>`, or `ptrdiff_t` if it is wider than that type; `ranges::ssize(E)` is expression-equivalent to `static_cast<D>(ranges::size(t))`.

26.3.12 ranges::empty

The name `ranges::empty` denotes a customization point object (16.3.3.3.5).

Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

- (2.1) If `T` is an array of unknown bound (9.3.4.5), `ranges::empty(E)` is ill-formed.
- (2.2) Otherwise, if `bool(t.empty())` is a valid expression, `ranges::empty(E)` is expression-equivalent to `bool(t.empty())`.
- (2.3) Otherwise, if `(ranges::size(t) == 0)` is a valid expression, `ranges::empty(E)` is expression-equivalent to `(ranges::size(t) == 0)`.
- (2.4) Otherwise, if `bool(ranges::begin(t) == ranges::end(t))` is a valid expression and the type of `ranges::begin(t)` models `forward_iterator`, `ranges::empty(E)` is expression-equivalent to `bool(ranges::begin(t) == ranges::end(t))`.
- (2.5) Otherwise, `ranges::empty(E)` is ill-formed.

[Note 1: Diagnosable ill-formed cases above result in substitution failure when `ranges::empty(E)` appears in the immediate context of a template instantiation. — end note]

[Note 2: Whenever `ranges::empty(E)` is a valid expression, it has type `bool`. — end note]

26.3.13 ranges::data

The name `ranges::data` denotes a customization point object (16.3.3.3.5).

Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

- (1.1) If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::data(E)` is ill-formed.
- (1.2) Otherwise, `ranges::data(E)` is expression-equivalent to `as_const-pointer(ranges::data(possibly_const-range(t)))`.

[Note 1: Diagnosable ill-formed cases above result in substitution failure when `ranges::data(E)` appears in the immediate context of a template instantiation. — end note]

[Note 2: Whenever `ranges::data(E)` is a valid expression, it has pointer to object type. — end note]

26.3.14 ranges::cdata

template<class T>
constexpr auto as-const-pointer(const T* p) { return p; } // exposition only

The name `ranges::cdata` denotes a customization point object (16.3.3.3.5). Given a subexpression `E` with type `T`, let `t` be an lvalue that denotes the reified object for `E`. Then:

- (1.1) If `E` is an rvalue and `enable_borrowed_range<remove_cv_t<T>>` is false, `ranges::cdata(E)` is ill-formed.
- (1.2) Otherwise, `ranges::cdata(E)` is expression-equivalent to `as-const-pointer(ranges::data(possibly-const-range(t)))`.

[Note 1: Whenever `ranges::cdata(E)` is a valid expression, it has pointer to constant object type. — end note]
26.4 Range requirements [range.req]

26.4.1 General [range.req.general]

1 Ranges are an abstraction that allows a C++ program to operate on elements of data structures uniformly. Calling `ranges::begin` on a range returns an object whose type models `input_or_output_iterator` (25.3.4.6). Calling `ranges::end` on a range returns an object whose type `S`, together with the type `I` of the object returned by `ranges::begin`, models `sentinel_for<S, I>`. The library formalizes the interfaces, semantics, and complexity of ranges to enable algorithms and range adaptors that work efficiently on different types of sequences.

2 The `range` concept requires that `ranges::begin` and `ranges::end` return an iterator and a sentinel, respectively. The `sized_range` concept refines `range` with the requirement that `ranges::size` be amortized $O(1)$.

3 Several refinements of `range` group requirements that arise frequently in concepts and algorithms. Common ranges are ranges for which `ranges::begin` and `ranges::end` return objects of the same type. Random access ranges are ranges for which `ranges::begin` returns a type that models `random_access_iterator` (25.3.4.13). (Contiguous, bidirectional, forward, input, and output ranges are defined similarly.) Viewable ranges can be converted to views.

26.4.2 Ranges [range.range]

1 The `range` concept defines the requirements of a type that allows iteration over its elements by providing an iterator and sentinel that denote the elements of the range.

```cpp
template<class T>
concept range =
    requires(T& t) {
        ranges::begin(t); // sometimes equality-preserving (see below)
        ranges::end(t);
    };
```

2 The required expressions `ranges::begin(t)` and `ranges::end(t)` of the `range` concept do not require implicit expression variations (18.2).

3 Given an expression `t` such that `decltype((t))` is `T&`, `T` models `range` only if
   (3.1) `[ranges::begin(t), ranges::end(t)]` denotes a range (25.3.1),
   (3.2) both `ranges::begin(t)` and `ranges::end(t)` are amortized constant time and non-modifying, and
   (3.3) if the type of `ranges::begin(t)` models `forward_iterator`, `ranges::begin(t)` is equality-preserving.

4 [Note 1: Equality preservation of both `ranges::begin` and `ranges::end` enables passing a range whose iterator type models `forward_iterator` to multiple algorithms and making multiple passes over the range by repeated calls to `ranges::begin` and `ranges::end`. Since `ranges::begin` is not required to be equality-preserving when the return type does not model `forward_iterator`, it is possible for repeated calls to not return equal values or to not be well-defined. — end note]

```cpp
template<class T>
concept borrowed_range =
    range<T> && (is_lvalue_reference_v<T> || enable_borrowed_range<remove_cvref_t<T>>);
```

5 Let `U` be `remove_reference_t<T>` if `T` is an rvalue reference type, and `T` otherwise. Given a variable `u` of type `U`, `T` models `borrowed_range` only if the validity of iterators obtained from `u` is not tied to the lifetime of that variable.

6 [Note 2: Since the validity of iterators is not tied to the lifetime of a variable whose type models `borrowed_range`, a function with a parameter of such a type can return iterators obtained from it without danger of dangling. — end note]

```cpp
template<class>
constexpr bool enable_borrowed_range = false;
```

7 **Remarks:** Pursuant to 16.4.5.2.1, users may specialize `enable_borrowed_range` for cv-unqualified program-defined types. Such specializations shall be usable in constant expressions (7.7) and have type `const bool`.

§ 26.4.2 1135
[Example 1: Each specialization $S$ of class template `subrange` (26.5.4) models `borrowed_range` because

(8.1) — `enable_borrowed_range<S>` is specialized to have the value `true`, and

(8.2) — $S$’s iterators do not have validity tied to the lifetime of an $S$ object because they are “borrowed” from some other range.

— end example]

26.4.3 Sized ranges

The `sized_range` concept refines `range` with the requirement that the number of elements in the range can be determined in amortized constant time using `ranges::size`.

```cpp
template<class T>
concept sized_range =
    range<T> && requires(T& t) { ranges::size(t); };
```

Given an lvalue `t` of type `remove_reference_t<T>`, `T` models `sized_range` only if

(2.1) — `ranges::size(t)` is amortized $O(1)$, does not modify `t`, and is equal to `ranges::distance(ranges::begin(t), ranges::end(t))`, and

(2.2) — if `iterator_t<T>` models `forward_iterator`, `ranges::size(t)` is well-defined regardless of the evaluation of `ranges::begin(t)`.

[Note 1: `ranges::size(t)` is otherwise not required to be well-defined after evaluating `ranges::begin(t)`. For example, it is possible for `ranges::size(t)` to be well-defined for a `sized_range` whose iterator type does not model `forward_iterator` only if evaluated before the first call to `ranges::begin(t)`. — end note]

```cpp
template<class>
constexpr bool disable_sized_range = false;
```

Remarks: Pursuant to 16.4.5.2.1, users may specialize `disable_sized_range` for cv-unqualified program-defined types. Such specializations shall be usable in constant expressions (7.7) and have type `const bool`.

[Note 2: `disable_sized_range` allows use of range types with the library that satisfy but do not in fact model `sized_range`. — end note]

26.4.4 Views

The `view` concept specifies the requirements of a `range` type that has the semantic properties below, which make it suitable for use in constructing range adaptor pipelines (26.7).

```cpp
template<class T>
concept view =
    range<T> && movable<T> && enable_view<T>;
```

`T` models `view` only if:

(2.1) — `T` has $O(1)$ move construction; and

(2.2) — move assignment of an object of type `T` is no more complex than destruction followed by move construction; and

(2.3) — if $N$ copies and/or moves are made from an object of type `T` that contained $M$ elements, then those $N$ objects have $O(N + M)$ destruction; and

(2.4) — `copy_constructible<T>` is `false`, or `T` has $O(1)$ copy construction; and

(2.5) — `copyable<T>` is `false`, or copy assignment of an object of type `T` is no more complex than destruction followed by copy construction.

[Note 1: The constraints on copying and moving imply that a moved-from object of type `T` has $O(1)$ destruction. — end note]

[Example 1: Examples of views are:

(4.1) — A `range` type that wraps a pair of iterators.

(4.2) — A `range` type that holds its elements by `shared_ptr` and shares ownership with all its copies.

(4.3) — A `range` type that generates its elements on demand.]
A container such as `vector<string>` does not meet the semantic requirements of `view` since copying the container copies all of the elements, which cannot be done in constant time. — end example]

Since the difference between `range` and `view` is largely semantic, the two are differentiated with the help of `enable_view`.

```cpp
template<class T>
constexpr bool is-derived-from-view-interface = see below; // exposition only
```

For a type `T`, `is-derived-from-view-interface` is true if and only if `T` has exactly one public base class `view_interface<U>` for some type `U` and `T` has no base classes of type `view_interface<V>` for any other type `V`.

Remarks: Pursuant to 16.4.5.2.1, users may specialize `enable_view` to `true` for cv-unqualified program-defined types which model `view`, and `false` for types which do not. Such specializations shall be usable in constant expressions (7.7) and have type `constexpr bool`.

### 26.4.5 Other range refinements

The `output_range` concept specifies requirements of a `range` type for which `ranges::begin` returns a model of `output_iterator` (25.3.4.10). `input_range`, `forward_range`, `bidirectional_range`, and `random_access_range` are defined similarly.

```cpp
template<class R, class T>
concept output_range =
    range<R> && output_iterator<iterator_t<R>, T>;
```

```cpp
template<class T>
concept input_range =
    range<T> && input_iterator<iterator_t<T>>;
```

```cpp
template<class T>
concept forward_range =
    input_range<T> && forward_iterator<iterator_t<T>>;
```

```cpp
template<class T>
concept bidirectional_range =
    forward_range<T> && bidirectional_iterator<iterator_t<T>>;
```

```cpp
template<class T>
concept random_access_range =
    bidirectional_range<T> && random_access_iterator<iterator_t<T>>;
```

`contiguous_range` additionally requires that the `ranges::data` customization point object (26.3.13) is usable with the range.

```cpp
template<class T>
concept contiguous_range =
    random_access_range<T> && contiguous_iterator<iterator_t<T>> 
    && requires(T& t) {
        { ranges::data(t) } -> same_as<add_pointer_t<range_reference_t<T>>};
    };
```

Given an expression `t` such that `decltype((t))` is `T&`, `T` models `contiguous_range` only if `to_address(ranges::begin(t)) == ranges::data(t)` is true.

The `common_range` concept specifies requirements of a `range` type for which `ranges::begin` and `ranges::end` return objects of the same type.

[Example 1: The standard containers (Clause 24) model `common_range`. — end example]

```cpp
template<class T>
concept common_range =
    range<T> && same_as<iterator_t<T>>, sentinel_t<T>>;
```
The `viewable_range` concept specifies the requirements of a `range` type that can be converted to a view safely.

```cpp
template<class T>
concept viewable_range =
    range<T> &&
    ((view<remove_cvref_t<T>>, T> ||
      (!view<remove_cvref_t<T>> &&
        (is_lvalue_reference_v<T> || (movable<remove_reference_t<T>>, &isinitializer_list<T>))));
```

The `constant_range` concept specifies the requirements of a `range` type whose elements are not modifiable.

```cpp
template<class T>
concept constant_range =
    input_range<T> &&
    constant_iterator<iterator_t<T>>;
```

### 26.5 Range utilities

#### 26.5.1 General

The components in 26.5 are general utilities for representing and manipulating ranges.

#### 26.5.2 Helper concepts

Many of the types in subclause 26.5 are specified in terms of the following exposition-only concepts:

```cpp
template<class R>
concept simple_view =
    view<R> && range<const R> &&
    same_as<iterator_t<R>, iterator_t<const R>> &&
    same_as<sentinel_t<R>, sentinel_t<const R>>;
```

```cpp
template<class I>
concept has_arrow =
    input_iterator<I> && (is_pointer_v<I> || requires(I i) { i.operator->(); });
```

```cpp
template<class T, class U>
concept different_from =
    !same_as<remove_cvref_t<T>, remove_cvref_t<U>>;
```

```cpp
template<class R>
concept range-with-movable-references =
    input_range<R> && move_constructible<range_reference_t<R>>, &isinitializer_list<R>>;
```

### 26.5.3 View interface

#### 26.5.3.1 General

The class template `view_interface` is a helper for defining view-like types that offer a container-like interface. It is parameterized with the type that is derived from it.

```cpp
namespace std::ranges {
    template<class D>
    requires is_class_v<D> && same_as<D, remove_cv_t<D>>
    class view_interface {
        private:
            constexpr D& derived() noexcept {
                return static_cast<D&>(*this);
            }
            constexpr const D& derived() const noexcept {
                return static_cast<const D&>(*this);
            }
    }
} // namespace std::ranges
```
public:

cconstexpr bool empty() requires sized_range<D> || forward_range<D> {
    if constexpr (sized_range<D>)
        return ranges::size(derived()) == 0;
    else
        return ranges::begin(derived()) == ranges::end(derived());
}
cconstexpr bool empty() const requires sized_range<const D> || forward_range<const D> {
    if constexpr (sized_range<const D>)
        return ranges::size(derived()) == 0;
    else
        return ranges::begin(derived()) == ranges::end(derived());
}
cconstexpr auto cbegin() requires input_range<D> {
    return ranges::cbegin(derived());
}
cconstexpr auto cbegin() const requires input_range<const D> {
    return ranges::cbegin(derived());
}
cconstexpr auto cend() requires input_range<D> {
    return ranges::cend(derived());
}
cconstexpr auto cend() const requires input_range<const D> {
    return ranges::cend(derived());
}
cconstexpr explicit operator bool() requires requires { ranges::empty(derived()); } {
    return !ranges::empty(derived());
}
cconstexpr explicit operator bool() const requires requires { ranges::empty(derived()); } {
    return !ranges::empty(derived());
}
cconstexpr auto data() requires contiguous_iterator<iterator_t<D>> {
    return to_address(ranges::begin(derived()));
}
cconstexpr auto data() const requires range<const D> && contiguous_iterator<iterator_t<const D>> {
    return to_address(ranges::begin(derived()));
}
cconstexpr auto size() requires forward_range<D> &&
    sized_sentinel_for<sentinel_t<D>, iterator_t<D>> {
    return to_unsigned_like(ranges::end(derived()) - ranges::begin(derived()));
}
cconstexpr auto size() const requires forward_range<const D> &&
    sized_sentinel_for<sentinel_t<const D>, iterator_t<const D>> {
    return to_unsigned_like(ranges::end(derived()) - ranges::begin(derived()));
}
cconstexpr decltype(auto) front() requires forward_range<D>;
cconstexpr decltype(auto) front() const requires forward_range<const D>;
cconstexpr decltype(auto) back() requires bidirectional_range<D> && common_range<D>;
cconstexpr decltype(auto) back() const requires bidirectional_range<const D> && common_range<const D>;

template<random_access_range R = D>
cconstexpr decltype(auto) operator[](range_difference_t<R> n) {
    return ranges::begin(derived())[n];
}
The template parameter \( D \) for \texttt{view\_interface} may be an incomplete type. Before any member of the resulting specialization of \texttt{view\_interface} other than special member functions is referenced, \( D \) shall be complete, and model both \texttt{derived\_from<view\_interface<D>>>} and \texttt{view}.

### 26.5.3.2 Members

- \texttt{constexpr decltype(auto) front() requires forward\_range<D>;
  constexpr decltype(auto) front() const requires forward\_range<const D>;
}

  1. **Preconditions:** \(!empty() \) is true.
  2. **Effects:** Equivalent to: \( \text{return *ranges::begin(derived());} \)

- \texttt{constexpr decltype(auto) back() requires bidirectional\_range<D> \&\& common\_range<D>;
  constexpr decltype(auto) back() const
  requires bidirectional\_range<const D> \&\& common\_range<const D>;
}

  1. **Preconditions:** \(!empty() \) is true.
  2. **Effects:** Equivalent to: \( \text{return *ranges::prev(ranges::end(derived()));} \)

### 26.5.4 Sub-ranges

#### 26.5.4.1 General

The \texttt{subrange} class template combines together an iterator and a sentinel into a single object that models the \texttt{view} concept. Additionally, it models the \texttt{sized\_range} concept when the final template parameter is \texttt{subrange\_kind::sized}.

```cpp
namespace std::ranges {
  template<class From, class To>
  concept uses\-nonqualification\-pointer\-conversion = // exposition only
    is\_pointer\_v<From> \&\& is\_pointer\_v<To> \&\&
    !convertible\_to<remove\_pointer\_t<From>(*)[], remove\_pointer\_t<To>(*)[]>;

  template<class From, class To>
  concept convertible\-to\-non\-slicing = // exposition only
    convertible\_to<From, To> \&\&
    !uses\-nonqualification\-pointer\-conversion<decay\_t<From>, decay\_t<To>>;

  template<class T, class U, class V>
  concept pair\-like\-convertible\-from = // exposition only
    !range<T> \&\& !is\_reference\_v<T> \&\& pair\-like<T> \&\&
    constructible\_from<T, U, V> \&\&
    convertible\-to\-non\-slicing<U, tuple\_element\_t<0, T>>, tuple\_element\_t<1, T>> \&\&
    convertible\_to<V, tuple\_element\_t<1, T>>;

  template<input\_or\_output\_iterator I, sentinel\_for<I> S = I, subrange\_kind K =
    sized\_sentinel\_for<S, I> \? subrange\_kind::sized : subrange\_kind::unsized>
    requires (K == subrange\_kind::sized || !sized\_sentinel\_for<S, I>)
  class subrange : public view\_interface<subrange<I, S, K>> {  
    private:
      static constexpr bool StoreSize = // exposition only
        K == subrange\_kind::sized \&\& !sized\_sentinel\_for<S, I>;
      I begin_ = I();       // exposition only
      S end_ = S();         // exposition only
      make\-unsigned\_like\_t<iter\_difference\_t<I>> size_ = 0;    // exposition only; present only
      if StoreSize is true
    
      public:
        subrange() requires default\_initializable<I> = default;

        constexpr subrange(convertible\-to\-non\-slicing<I> auto i, S s)
          requires (!StoreSize);

§ 26.5.4.1 1140
```
**26.5.4.2 Constructors and conversions**

```cpp
constexpr subrange(convertible-to-non-slicing<I> auto i, S s, 
    make-unsigned-like-t<iter_difference_t<I>> n)
    requires (K == subrange_kind::sized);
```

1. **Preconditions:** \([i, s)\) is a valid range.
2. **Effects:** Initializes `begin_` with `std::move(i)` and `end_` with `s`. 

---

© ISO/IEC  
N4944
constexpr subrange(convertible-to-non-slicing<I> auto i, S s, make-unsigned-like-t<iter_difference_t<I>> n) requires (K == subrange_kind::sized);

3 Preconditions: [i, s) is a valid range, and n == to-unsigned-like(ranges::distance(i, s)) is true.

4 Effects: Initializes begin_ with std::move(i) and end_ with s. If StoreSize is true, initializes size_ with n.

[Note 1: Accepting the length of the range and storing it to later return from size() enables subrange to model sized_range even when it stores an iterator and sentinel that do not model sized_sentinel_for. — end note]

template<different-from<subrange> R>
requires borrowed_range<R> &&
convertible-to-non-slicing<iterator_t<R>, I> &&
convertible_to<sentinel_t<R>, S>
constexpr subrange(R&& r) requires (!StoreSize || sized_range<R>);

6 Effects: Equivalent to:
— (6.1) If StoreSize is true, subrange(r, static_cast<decltype(size_>>(ranges::size(r))).
— (6.2) Otherwise, subrange(ranges::begin(r), ranges::end(r)).

template<different-from<subrange> PairLike>
requires pair-like-convertible-from<PairLike, const I&, const S&>
constexpr operator PairLike() const;

7 Effects: Equivalent to: return PairLike(begin_, end_);

26.5.4.3 Accessors

constexpr I begin() const requires copyable<I>;
1 Effects: Equivalent to: return begin_;

[[nodiscard]] constexpr I begin() requires (!copyable<I>);
2 Effects: Equivalent to: return std::move(begin_);

constexpr S end() const;
3 Effects: Equivalent to: return end_;

constexpr bool empty() const;
4 Effects: Equivalent to: return begin_ == end_;

constexpr make-unsigned-like-t<iter_difference_t<I>> size() const requires (K == subrange_kind::sized);
5 Effects:
— (5.1) If StoreSize is true, equivalent to: return size_;
— (5.2) Otherwise, equivalent to: return to-unsigned-like(end_ - begin_);

[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) const &
requires forward_iterator<I>;
6 Effects: Equivalent to:
auto tmp = *this;
tmp.advance(n);
return tmp;

[[nodiscard]] constexpr subrange next(iter_difference_t<I> n = 1) &&;
7 Effects: Equivalent to:
advance(n);
return std::move(*this);
[[nodiscard]] constexpr subrange prev(iter_difference_t<I> n = 1) const
requires bidirectional_iterator<I>;

Effects: Equivalent to:
    auto tmp = *this;
    tmp.advance(-n);
    return tmp;

constexpr subrange& advance(iter_difference_t<I> n);

Effects: Equivalent to:
    if constexpr (bidirectional_iterator<I>) {
        if (n < 0) {
            ranges::advance(begin_, n);
            if constexpr (StoreSize)
                size_ += to_unsigned_like(-n);
        return *this;
      }
      auto d = n - ranges::advance(begin_, n, end_);
    if constexpr (StoreSize)
        size_ -= to_unsigned_like(d);
    return *this;

template<
    size_t N,
    class I, class S, subrange_kind K>
requires ((N == 0 && copyable<I>) || N == 1
constexpr auto get(const subrange<I, S, K>& r);

template<
    size_t N,
    class I, class S, subrange_kind K>
requires (N < 2)
constexpr auto get(subrange<I, S, K>&& r);

Effects: Equivalent to:
    if constexpr (N == 0)
        return r.begin();
    else
        return r.end();

26.5.5  Dangling iterator handling  [range.dangling]

The type dangling is used together with the template aliases borrowed_iterator_t and borrowed_subrange_t. When an algorithm that typically returns an iterator into, or a subrange of, a range argument is called with an rvalue range argument that does not model borrowed_range (26.4.2), the return value possibly refers to a range whose lifetime has ended. In such cases, the type dangling is returned instead of an iterator or subrange.

namespace std::ranges {
    struct dangling {
        constexpr dangling() noexcept = default;
        constexpr dangling(auto&&...) noexcept {}
    };
}

[Example 1:

vector<int> f();
auto result1 = ranges::find(f(), 42); // #1
static_assert(same_as<decltype(result1), ranges::dangling>);
auto vec = f();
auto result2 = ranges::find(vec, 42); // #2
static_assert(same_as<decltype(result2), vector<int>::iterator>);
auto result3 = ranges::find(ranges::subrange{vec}, 42); // #3
static_assert(same_as<decltype(result3), vector<int>::iterator>);

The call to ranges::find at #1 returns ranges::dangling since f() is an rvalue vector; it is possible for the vector to be destroyed before a returned iterator is dereferenced. However, the calls at #2 and #3 both return iterators since the lvalue vec and specializations of subrange model borrowed_range. — end example]
For a type $R$ that models `range`:

(3.1) if $R$ models `borrowed_range`, then `borrowed_iterator_t<R>` denotes `iterator_t<R>`, and `borrowed_subrange_t<R>` denotes `subrange<iterator_t<R>>`; 

(3.2) otherwise, both `borrowed_iterator_t<R>` and `borrowed_subrange_t<R>` denote `dangling`.

### 26.5.6 Class template `elements_of`

Specializations of `elements_of` encapsulate a range and act as a tag in overload sets to disambiguate when a range should be treated as a sequence rather than a single value.

*Example 1:*

```cpp
template<bool YieldElements>
generator<any> f(ranges::input_range auto&& r) {
    if constexpr (YieldElements)
        co_yield ranges::elements_of(r); // yield each element of r
    else
        co_yield r; // yield r as a single value
}
```

```
namespace std::ranges {
    template<range R, class Allocator = allocator<byte>>
    struct elements_of {
        [[no_unique_address]] R range;
        [[no_unique_address]] Allocator allocator = Allocator();
    };
    template<class R, class Allocator = allocator<byte>>
    elements_of(R&&, Allocator = Allocator()) -> elements_of<R&&, Allocator>;
}
```

### 26.5.7 Range conversions

#### 26.5.7.1 General

The range conversion functions construct an object (usually a container) from a range, by using a constructor taking a range, a `from_range_t` tagged constructor, or a constructor taking a pair of iterators, or by inserting each element of the range into the default-constructed object.

`ranges::to` is applied recursively, allowing the conversion of a range of ranges.

*Example 1:*

```cpp
string_view str = "the quick brown fox";
auto words = views::split(str, ' ') | to<vector<string>>();
// words is vector<string>"the", "quick", "brown", "fox"
```

Let `reservable-container` be defined as follows:

```cpp
template<class Container>
constexpr bool reservable-container = // exposition only
    sized_range<Container> &&
    requires(Container& c, range_size_t<Container> n) {
        c.reserve(n);
        { c.capacity() } -> same_as<decltype(n)>;
        { c.max_size() } -> same_as<decltype(n)>;
    };
```

Let `container-insertable` be defined as follows:

```cpp
template<class Container, class Ref>
constexpr bool container-insertable = // exposition only
    requires(Container& c, Ref&& ref) {
        requires (requires { c.push_back(std::forward<Ref>(ref)); }) ||
            requires { c.insert(c.end(), std::forward<Ref>(ref)); });
    };
```
Let \texttt{container-inserter} be defined as follows:

```cpp
template<class Ref, class Container>
constexpr auto container-inserter(Container& c) { 
    // exposition only
    if constexpr (requires { c.push_back(declval<Ref>()); })
        return back_inserter(c);
    else
        return inserter(c, c.end());
}
```

### 26.5.7.2 \texttt{ranges::to}

```
template<class C, input_range R, class... Args>
constexpr C to(R&& r, Args&&... args);
```

1. **Mandates**: \(C\) is a cv-unqualified class type.

2. **Returns**: An object of type \(C\) constructed from the elements of \(r\) in the following manner:

   (2.1) — If \(C\) does not satisfy \textit{input_range} or \textit{convertible_to<range_reference_t<R>, range_value_t<C>}, \textit{range_value_t<C>} is true:

   (2.1.1) — If \textit{constructible_from<C, R, Args...>} is true:

   \(C(\text{std::forward}(R)(r), \text{std::forward}(\text{Args})(\text{args})...)\)

   (2.1.2) — Otherwise, if \textit{constructible_from<C, from_range_t, R, Args...>} is true:

   \(C(\text{from_range}, \text{std::forward}(R)(r), \text{std::forward}(\text{Args})(\text{args})...)\)

   (2.1.3) — Otherwise, if

   (2.1.3.1) — \textit{common_range<R>} is true,

   (2.1.3.2) — the \textit{qualified-id} \textit{iterator_traits<iterator_t<R>>::iterator_category} is valid and
denotes a type that models \textit{derived_from<input_iterator_tag>}, and

   (2.1.3.3) — \textit{constructible_from<C, iterator_t<R>, sentinel_t<R>, Args...>} is true:

   \(C(\text{ranges::begin}(r), \text{ranges::end}(r), \text{std::forward}(\text{Args})(\text{args})...)\)

   (2.1.4) — Otherwise, if

   (2.1.4.1) — \textit{constructible_from<C, Args...>} is true, and

   (2.1.4.2) — \textit{container-insertable<C, range_reference_t<R>}} is true:

   \(C(c(\text{std::forward}(\text{Args})(\text{args})...));\)

   if \textit{constexpr} \(\text{sizeof}(\text{range_size_t<C>})\) \textit{C.reserve}\(\text{static_cast<range_size_t<C>>(ranges::size(r))}\);

   \(\text{ranges::copy}(r, \text{container-inserter<range_reference_t<R>>>(c))}\)

   (2.2) — Otherwise, if \textit{input_range<range_reference_t<R>}} is true:

   \(\text{to<C>(r | views::transform([](auto&& elem) { \n        return to<range_value_t<C>>(\text{std::forward<decltype(elem>>(elem)); \n    })}, \text{std::forward}(\text{Args})(\text{args})...);}\)

   (2.3) — Otherwise, the program is ill-formed.

```

### 26.5.7.2 Let \texttt{input_iterator} be an exposition-only type:

```cpp
struct input_iterator { 
    // exposition only
    using iterator_category = input_iterator_tag;
    using value_type = range_value_t<R>;
    using difference_type = ptrdiff_t;
    using pointer = add_pointer_t<range_reference_t<R>>;
    using reference = range_reference_t<R>;
    reference operator*() const;
    pointer operator->() const;
    input_iterator& operator++();
    input_iterator operator++(int);
};
```
bool operator==(const input_iterator&) const;
};

[Note 1: input_iterator meets the syntactic requirements of Cpp17InputIterator. — end note]

Let \texttt{DEDUCE_EXPR} be defined as follows:

(4.1) \quad \text{C(declval<R>(), declval<Args>()...)} \quad \text{if that is a valid expression,}

(4.2) \quad \text{otherwise, C(from_range, declval<R>(), declval<Args>()...)} \quad \text{if that is a valid expression,}

(4.3) \quad \text{otherwise,}

\text{C(declval<input_iterator>(), declval<input_iterator>(), declval<Args>()...)}

\text{if that is a valid expression,}

(4.4) \quad \text{otherwise, the program is ill-formed.}

\textbf{Returns:} \texttt{to<decltype(DEDUCE_EXPR>>(std::forward<R>(r), std::forward<Args>(args)...)}.

\subsection*{26.5.7.3 \texttt{ranges::to} adaptors}

\begin{verbatim}
template<class C, class... Args> requires (!view<C>)
constexpr auto to(Args&&... args);
\end{verbatim}

\begin{verbatim}
template<template<class...> class C, class... Args>
constexpr auto to(Args&&... args);
\end{verbatim}

\textbf{Mandates:} For the first overload, \texttt{C} is a cv-unqualified class type.

\textbf{Returns:} A range adaptor closure object (26.7.2) \texttt{f} that is a perfect forwarding call wrapper (22.10.4) with the following properties:

(2.1) \quad \text{It has no target object.}

(2.2) \quad \text{Its bound argument entities \texttt{bound_args} consist of objects of types decay_t<Args>... direct-}

\text{non-list-initialized with std::forward<Args>(args)..., respectively.}

(2.3) \quad \text{Its call pattern is to\texttt{<C>(r, bound_args...), where} r \text{is the argument used in a function call}

\text{expression of} f.}

\section*{26.6 Range factories}

\subsection*{26.6.1 General}

Subclause 26.6 defines range factories, which are utilities to create a view.

\subsection*{26.6.2 Empty view}

\subsection*{26.6.2.1 Overview}

\textbf{Example 1:}

\begin{verbatim}
auto e = views::empty<int>;
static_assert(ranges::empty(e));
static_assert(0 == e.size());
\end{verbatim}

\section*{26.6.2.2 Class template \texttt{empty_view}}

\begin{verbatim}
namespace std::ranges {
    template<class T>
    requires is_object_v<T>
    class empty_view : public view_interface<empty_view<T>> {
        public:
            static constexpr T* begin() noexcept { return nullptr; }
            static constexpr T* end() noexcept { return nullptr; }
            static constexpr T* data() noexcept { return nullptr; }
            static constexpr size_t size() noexcept { return 0; }
            static constexpr bool empty() noexcept { return true; }
    };
}
\end{verbatim}
26.6.3 Single view

26.6.3.1 Overview

`single_view` produces a view that contains exactly one element of a specified value.

The name `views::single` denotes a customization point object (16.3.3.5). Given a subexpression E, the expression `views::single(E)` is expression-equivalent to `single_view<decay_t<decltype((E))>>>(E)`.

[Example 1:

```cpp
define i : views::single(4)
    cout << i; // prints 4
—end example]

26.6.3.2 Class template single_view

```cpp
define std::ranges {
    template<move_constructible T>
    class single_view : public view_interface<single_view<T>> {
        private:
            movable-box<T> value_; // exposition only (see 26.7.3)
        public:
            single_view() requires default_initializable<T> = default;
            constexpr explicit single_view(const T& t) requires copy_constructible<T>;
            constexpr explicit single_view(T&& t);
        template<class... Args>
            requires constructible_from<T, Args...>
            constexpr explicit single_view(in_place_t, Args&&... args);
            constexpr T* begin() noexcept;
            constexpr const T* begin() const noexcept;
            constexpr T* end() noexcept;
            constexpr const T* end() const noexcept;
            static constexpr size_t size() noexcept;
            constexpr T* data() noexcept;
            constexpr const T* data() const noexcept;
    }
    template<class T>
        single_view(T) -> single_view<T>;
}
```

`constexpr explicit single_view(const T& t) requires copy_constructible<T>;`

*Effects:* Initializes `value_` with `t`.

`constexpr explicit single_view(T&& t);`

*Effects:* Initializes `value_` with `std::move(t)`.

`template<class... Args>
    requires constructible_from<T, Args...>
    constexpr explicit single_view(in_place_t, Args&&... args);`

*Effects:* Initializes `value_` as if by `value_ {in_place, std::forward<Args>(args)...}`.

`constexpr T* begin() noexcept;`

*Effects:* Equivalent to: return `data()`.

`constexpr T* end() noexcept;`

*Effects:* Equivalent to: return `data() + 1`.

`static constexpr size_t size() noexcept;`

*Effects:* Equivalent to: return 1;
constexpr T* data() noexcept;
constexpr const T* data() const noexcept;

Effects: Equivalent to: return value_.operator->();

26.6.4 Iota view

26.6.4.1 Overview

iota_view generates a sequence of elements by repeatedly incrementing an initial value.

The name views::iota denotes a customization point object (16.3.3.3.5). Given subexpressions E and F, the expressions views::iota(E) and views::iota(E, F) are expression-equivalent to iota_view(E) and iota_view(E, F), respectively.

[Example 1:
 for (int i : views::iota(1, 10))
  cout << i << ' '; // prints 1 2 3 4 5 6 7 8 9
 — end example]

26.6.4.2 Class template iota_view

namespace std::ranges {
  template<class I>
  concept decrementable = see below; // exposition only

template<class I>
  concept advanceable = see below; // exposition only

  template<weakly_incrementable W, semiregular Bound = unreachable_sentinel_t>
  requires weakly-equality-comparable-with<W, Bound> && copyable<W>
class iota_view : public view_interface<iota_view<W, Bound>> {
private:
  // 26.6.4.3, class iota_view::iterator
  struct iterator; // exposition only

  // 26.6.4.4, class iota_view::sentinel
  struct sentinel; // exposition only

  W value_ = W(); // exposition only
  Bound bound_ = Bound(); // exposition only

public:
  iota_view() requires default_initializable<W> = default;
  constexpr explicit iota_view(W value);
  constexpr explicit iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);
  constexpr explicit iota_view(iterator first, see below last);

  constexpr iterator begin() const;
  constexpr auto end() const requires same_as<W, Bound>;

  constexpr iterator end() const requires same_as<W, Bound>;

  constexpr auto size() const requires see below;
};

  template<class W, class Bound>
  requires (!is-integer-like<W> || !is-integer-like<Bound> ||
            (is-signed-integer-like<W> == is-signed-integer-like<Bound>))
  iota_view(W, Bound) -> iota_view<W, Bound>;
}

Let IOTA-DIFF-T(W) be defined as follows:

(1.1)  — If W is not an integral type, or if it is an integral type and sizeof(iter_difference_t<W>) is greater than sizeof(W), then IOTA-DIFF-T(W) denotes iter_difference_t<W>.

(1.2)  — Otherwise, IOTA-DIFF-T(W) is a signed integer type of width greater than the width of W if such a type exists.
— Otherwise, \texttt{IOTA-DIFF-T(W)} is an unspecified signed-integer-like type (25.3.4.4) of width not less than the width of \texttt{W}.

\textit{Note 1:} It is unspecified whether this type satisfies \texttt{weakly_incrementable}. \textit{— end note}

The exposition-only \texttt{decrementable} concept is equivalent to:

\begin{verbatim}
template<class I>
concept decrementable = // exposition only
incrementable<I> && requires(I i) {
    { --i } -> same_as<I&>;
    { i-- } -> same_as<I>;
};
\end{verbatim}

When an object is in the domain of both pre- and post-decrement, the object is said to be \texttt{decrementable}.

Let \(a\) and \(b\) be equal objects of type \(I\). \(I\) models \texttt{decrementable} only if

\begin{enumerate}
\item If \(a\) and \(b\) are decrementable, then the following are all true:
\begin{enumerate}
\item \texttt{addressof(--a) == addressof(a)}
\item \texttt{bool(a-- == b)}
\item \texttt{bool((((void)a--) a) == --b)}
\item \texttt{bool(+(--a) == b)}.
\end{enumerate}
\end{enumerate}

The exposition-only \texttt{advanceable} concept is equivalent to:

\begin{verbatim}
template<class I>
concept advanceable = // exposition only
decrementable<I> && totally_ordered<I> && requires(I i, const I j, const IOTA-DIFF-T(I) n) {
    { i += n } -> same_as<I&>;
    { i -= n } -> same_as<I&>;
    I(j + n);
    I(n + j);
    I(j - n);
    { j - j } -> convertible_to<IOTA-DIFF-T(I)>;
};
\end{verbatim}

Let \(D\) be \texttt{IOTA-DIFF-T(I)}. Let \(a\) and \(b\) be objects of type \(I\) such that \(b\) is reachable from \(a\) after \(n\) applications of \(+a\), for some value \(n\) of type \(D\). \(I\) models \texttt{advanceable} only if

\begin{enumerate}
\item \texttt{a += n} is equal to \(b\).
\item \texttt{addressof(a += n)} is equal to \texttt{addressof(a)}.
\item \texttt{I(a + n)} is equal to \texttt{(a += n)}.
\item For any two positive values \(x\) and \(y\) of type \(D\), if \(I(a + D(x + y))\) is well-defined, then \(I(a + D(x + y))\) is equal to \(I(I(a + x) + y)\).
\item \texttt{I(a + D(0))} is equal to \(a\).
\item If \(I(a + D(n - 1))\) is well-defined, then \(I(a + n)\) is equal to \[I(I c) \{ \text{return } ++c; \}(I(a + D(n - 1)))\].
\item \texttt{(b += -n)} is equal to \(a\).
\item \texttt{(b -= n)} is equal to \(a\).
\item \texttt{addressof(b -= n)} is equal to \texttt{addressof(b)}.
\item \texttt{I(b - n)} is equal to \texttt{(b -= n)}.
\item \texttt{D(b - a)} is equal to \(n\).
\item \texttt{D(a - b)} is equal to \(D(-n)\).
\item \texttt{bool(a <= b)} is true.
\end{enumerate}
constexpr explicit iota_view(W value);

Preconditions: Bound denotes unreachable_sentinel_t or Bound() is reachable from value. When W and Bound model totally_ordered_with, then bool(value <= Bound()) is true.

Effects: Initializes value_ with value.

castexpr explicit iota_view(type_identity_t<W> value, type_identity_t<Bound> bound);

Preconditions: Bound denotes unreachable_sentinel_t or bound is reachable from value. When W and Bound model totally_ordered_with, then bool(value <= bound) is true.

Effects: Initializes value_ with value and bound_ with bound.

castexpr explicit iota_view(iterator first, see below last);

Effects: Equivalent to:

(10.1) — If same_as<W, Bound> is true, iota_view(first.value_, last.value_).
(10.2) — Otherwise, if Bound denotes unreachable_sentinel_t, iota_view(first.value_, last).
(10.3) — Otherwise, iota_view(first.value_, last.bound_).

Remarks: The type of last is:

(11.1) — If same_as<W, Bound> is true, iterator.
(11.2) — Otherwise, if Bound denotes unreachable_sentinel_t, Bound.
(11.3) — Otherwise, sentinel.

castexpr iterator begin() const;

Effects: Equivalent to: return iterator{value_};

castexpr auto end() const;

Effects: Equivalent to:

if constexpr (same_as<Bound, unreachable_sentinel_t>)
   return unreachable_sentinel;
else
   return sentinel{bound_};

castexpr iterator end() const requires same_as<W, Bound>;

Effects: Equivalent to: return iterator{bound_};

castexpr auto size() const requires see below;

Effects: Equivalent to:

   if constexpr (is-integer-like<W> && is-integer-like<Bound>)
      return (value_ < 0)  
        ? ((bound_ < 0)
           ? to-unsigned-like(-value_) - to-unsigned-like(-bound_)
           : to-unsigned-like(bound_) + to-unsigned-like(-value_))
        : to-unsigned-like(bound_) - to-unsigned-like(value_);
   else
      return to-unsigned-like(bound_ - value_);

Remarks: The expression in the requires-clause is equivalent to:

   (same_as<W, Bound> && advanceable<W>) || (is-integer-like<W> && is-integer-like<Bound>) ||
   sized_sentinel_for<Bound, W>

26.6.4.3 Class iota_view::iterator [range.iota.iterator]

namespace std::ranges {
   template<weakly_incrementable W, semiregular Bound>
      requires weakly-equality-comparable-with<W, Bound> && copyable<W>
   struct iota_view<W, Bound>::iterator {
      private:
         W value_ = W();  // exposition only
public:
using iterator_concept = see below;  // present only if W models incrementable and
using iterator_category = input_iterator_tag;  // IOTA-DIFF-T(W) is an integral type

using value_type = W;
using difference_type = IOTA-DIFF-T(W);

iterator() requires default_initializable<W> = default;
constexpr explicit iterator(W value);

constexpr W operator*() const noexcept(is_nothrow_copy_constructible_v<W>);
constexpr iterator& operator++()
constexpr void operator++(int);
constexpr iterator operator++(int) requires incrementable<W>;
constexpr iterator operator++(int) requires decrementable<W>;
constexpr iterator& operator+(difference_type n) requires advanceable<W>;
constexpr iterator& operator-(difference_type n) requires advanceable<W>;
constexpr W operator[](difference_type n) const requires advanceable<W>;

friend constexpr bool operator==(const iterator& x, const iterator& y) requires equality_comparable<W>;
friend constexpr bool operator<(const iterator& x, const iterator& y) requires totally_ordered<W>;
friend constexpr bool operator>(const iterator& x, const iterator& y) requires totally_ordered<W>;
friend constexpr bool operator<=(const iterator& x, const iterator& y) requires totally_ordered<W>;
friend constexpr bool operator>=(const iterator& x, const iterator& y) requires totally_ordered<W>;
friend constexpr auto operator<=>(const iterator& x, const iterator& y) requires totally_ordered<W> && three_way_comparable<W>;

friend constexpr iterator operator-(iterator i, difference_type n) requires advanceable<W>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y) requires advanceable<W>;

1 iterator::iterator_concept is defined as follows:

(1.1) — If W models advanceable, then iterator_concept is random_access_iterator_tag.
(1.2) — Otherwise, if W models decrementable, then iterator_concept is bidirectional_iterator_tag.
(1.3) — Otherwise, if W models incrementable, then iterator_concept is forward_iterator_tag.
(1.4) — Otherwise, iterator_concept is input_iterator_tag.

2 [Note 1: Overloads for iter_move and iter_swap are omitted intentionally. — end note]

constexpr explicit iterator(W value);

3 Effects: Initializes value with value.
constexpr W operator*() const noexcept(is_nothrow_copy_constructible_v<W>);

Effects: Equivalent to: return value_;  

[Note 2: The noexcept clause is needed by the default iter_move implementation. — end note]

constexpr iterator& operator++();

Effects: Equivalent to:
    ++value_;  
    return *this;

constexpr void operator++(int);

Effects: Equivalent to +++this.

constexpr iterator& operator+=(difference_type n) requires advanceable<W>;

Effects: Equivalent to:
    if constexpr (is-integer-like<W> && !is-signed-integer-like<W>) {
        if (n >= difference_type(0))
            value_ += static_cast<W>(n);
        else
            value_ -= static_cast<W>(-n);
    } else {
        value_ += n;
    }
    return *this;

constexpr iterator& operator-=(difference_type n) requires advanceable<W>;

Effects: Equivalent to:
    if constexpr (is-integer-like<W> && !is-signed-integer-like<W>) {
        if (n >= difference_type(0))
            value_ -= static_cast<W>(n);

    Effects: Equivalent to: return x.value_ <=> y.value_;
friend constexpr iterator operator+(iterator i, difference_type n) 

    requires advanceable<W>;

    Effects: Equivalent to: 
    i += n;
    return i;
friend constexpr iterator operator+(difference_type n, iterator i) 

    requires advanceable<W>;

    Effects: Equivalent to: return i + n;
friend constexpr iterator operator-(iterator i, difference_type n) 

    requires advanceable<W>;

    Effects: Equivalent to: 
    i -= n;
    return i;
friend constexpr difference_type operator-(const iterator& x, const iterator& y) 

    requires advanceable<W>;

    Effects: Equivalent to: 
    using D = difference_type;
    if constexpr (is_integer_like<W>) {
        if constexpr (is_signed_integer_like<W>)
            return D(D(x.value_) - D(y.value_));
        else
            return (y.value_ > x.value_)  
                ? D(-D(y.value_ - x.value_))  
                : D(x.value_ - y.value_);  
    } else {
        return x.value_ - y.value_;
    }

26.6.4.4 Class iota_view::sentinel

namespace std::ranges {
    template<weakly_incrementable W, semiregular Bound>
    requires weakly-equality-comparable-with<W, Bound> && copyable<W>
    struct iota_view<W, Bound>::sentinel {
private:
    Bound bound_ = Bound(); // exposition only

public:
    sentinel() = default;
    constexpr explicit sentinel(Bound bound);

friend constexpr bool operator==(const iterator& x, const sentinel& y);
friend constexpr iter_difference_t<W> operator-(const iterator& x, const sentinel& y)
    requires sized_sentinel_for<Bound, W>;
friend constexpr iter_difference_t<W> operator-(const sentinel& x, const iterator& y)
    requires sized_sentinel_for<Bound, W>;
};

constexpr explicit sentinel(Bound bound);

Effects: Initializes bound_ with bound.

friend constexpr bool operator==(const iterator& x, const sentinel& y);
Effects: Equivalent to: return x.value_ == y.bound_;

friend constexpr iter_difference_t<W> operator-(const iterator& x, const sentinel& y)
    requires sized_sentinel_for<Bound, W>;
Effects: Equivalent to: return x.value_ - y.bound_;

friend constexpr iter_difference_t<W> operator-(const sentinel& x, const iterator& y)
    requires sized_sentinel_for<Bound, W>;
Effects: Equivalent to: return -(y - x);

26.6.5 Repeat view
26.6.5.1 Overview
repeat_view generates a sequence of elements by repeatedly producing the same value.

The name views::repeat denotes a customization point object (16.3.3.3.5). Given subexpressions E and F, the expressions views::repeat(E) and views::repeat(E, F) are expression-equivalent to repeat_view(E) and repeat_view(E, F), respectively.

[Example 1:
for (int i : views::repeat(17, 4))
cout << i << ' '; // prints 17 17 17 17
— end example]

26.6.5.2 Class template repeat_view
namespace std::ranges {
    template<class T>
    concept integer-like-with-usable-difference-type = // exposition only
        is-signed-integer-like<T> || (is-integer-like<T> && weakly_incrementable<T>);

    template<move_constructible T, semiregular Bound = unreachable_sentinel_t>
        requires (is_object_v<T> && same_as<T, remove_cv_t<T>> &&
            (integer-like-with-usable-difference-type<Bound> ||
                same_as<Bound, unreachable_sentinel_t>))
    class repeat_view : public view_interface<repeat_view<T, Bound>> {
private:
    // 26.6.5.3, class repeat_view::iterator
    struct iterator; // exposition only

    movable-box<T> value_; // exposition only, see 26.7.3
    Bound bound_ = Bound(); // exposition only

}
public:
    repeat_view() requires default_initializable<T> = default;

    constexpr explicit repeat_view(const T& value, Bound bound = Bound())
        requires copy_constructible<T>;
    constexpr explicit repeat_view(T&& value, Bound bound = Bound());
    template<class... TArgs, class... BoundArgs>
        requires constructible_from<T, TArgs...> &&
            constructible_from<Bound, BoundArgs...>
        constexpr explicit repeat_view(piecewise_construct_t,
            tuple<TArgs...> value_args, tuple<BoundArgs...> bound_args = tuple<{}>);

    constexpr_iterator begin() const;
    constexpr_iterator end() const requires (!same_as<Bound, unreachable_sentinel_t>);
    constexpr unreachable_sentinel_t end() const noexcept;
    constexpr auto size() const requires (!same_as<Bound, unreachable_sentinel_t>);
};

template<class T, class Bound>
    repeat_view(T, Bound) -> repeat_view<T, Bound>;

constexpr explicit repeat_view(const T& value, Bound bound = Bound())
    requires copy_constructible<T>;
1  Preconditions: If Bound is not reachable_sentinel_t, bound ≥ 0.
2  Effects: Initializes value_ with value and bound_ with bound.

constexpr explicit repeat_view(T&& value, Bound bound = Bound());
3  Preconditions: If Bound is not reachable_sentinel_t, bound ≥ 0.
4  Effects: Initializes value_ with std::move(value) and bound_ with bound.

template<class... TArgs, class... BoundArgs>
    requires constructible_from<T, TArgs...> &&
        constructible_from<Bound, BoundArgs...>
    constexpr explicit repeat_view(piecewise_construct_t,
        tuple<TArgs...> value_args, tuple<BoundArgs...> bound_args = tuple<{}>);
5  Effects: Initializes value_ with make_from_tuple<T>(std::move(value_args)) and initializes
        bound_ with make_from_tuple<Bound>(std::move(bound_args)). The behavior is undefined if Bound
        is not reachable_sentinel_t and bound_ is negative.

constexpr_iterator begin() const;
6  Effects: Equivalent to: return iterator(addressof(*value_));

constexpr_iterator end() const requires (!same_as<Bound, unreachable_sentinel_t>);
7  Effects: Equivalent to: return iterator(addressof(*value_), bound_);  

constexpr unreachable_sentinel_t end() const noexcept;
8  Effects: Equivalent to: return unreachable_sentinel;

constexpr auto size() const requires (!same_as<Bound, unreachable_sentinel_t>);
9  Effects: Equivalent to: return toUnsigned-like(bound_);

26.6.5.3 Class repeat_view::iterator [range.repeat.iterator]

namespace std::ranges {
    template<move_constructible T, semiregular Bound>
        requires (is_object_v<T> && same_as<T, remove_cv_t<T>> &&
            (integer-like-with-usable-difference-type<Bound> ||
            same_as<Bound, unreachable_sentinel_t>))
    class repeat_view<T, Bound>::iterator {
        private:
using index-type = conditional_t<same_as<Bound, unreachable_sentinel_t>, ptrdiff_t, Bound>;  // exposition only
const T* value_ = nullptr;  // exposition only
index-type current_ = index-type();  // exposition only

constexpr explicit iterator(const T* value, index-type b = index-type());  // exposition only

public:
using iterator_concept = random_access_iterator_tag;
using iterator_category = random_access_iterator_tag;
using value_type = T;
using difference_type = see below;

iterator() = default;

constexpr const T& operator*() const noexcept;

constexpr iterator& operator++();

constexpr iterator operator++(int);

constexpr iterator& operator--();

constexpr iterator operator--(int);

constexpr iterator& operator+=(difference_type n);

constexpr iterator& operator-=(difference_type n);

constexpr const T& operator[](difference_type n) const noexcept;

friend constexpr bool operator==(const iterator& x, const iterator& y);

friend constexpr auto operator<=>(const iterator& x, const iterator& y);

friend constexpr iterator operator+(int, iterator i);

friend constexpr iterator operator-(difference_type n, iterator i);

friend constexpr difference_type operator-(const iterator& x, const iterator& y);

If is-signed-integer-like<index-type> is true, the member typedef-name difference_type denotes index-type. Otherwise, it denotes IOTA-DIFF-T(index-type) (26.6.4.2).

constexpr explicit iterator(const T* value, index-type b = index-type());

Preconditions: If Bound is not unreachable_sentinel_t, b ≥ 0.

Effects: Initializes value_ with value and current_ with b.

constexpr const T& operator*() const noexcept;

Effects: Equivalent to: return *value_;

constexpr iterator& operator++();

Effects: Equivalent to:
++current_;  
return *this;

constexpr iterator& operator++(int);

Effects: Equivalent to:
auto tmp = *this;  
++this;  
return tmp;

constexpr iterator& operator--();

Preconditions: If Bound is not unreachable_sentinel_t, current_ > 0.

§ 26.6.5.3
Effects: Equivalent to:

```cpp
--current_; 
return *this;
```

constexpr iterator operator--(int);

Effects: Equivalent to:

```cpp
auto tmp = *this; 
--*this; 
return tmp;
```

constexpr iterator& operator+=(difference_type n);

Preconditions: If Bound is not unreachable_sentinel_t, current_ + n ≥ 0.

Effects: Equivalent to:

```cpp
current_ += n; 
return *this;
```

constexpr iterator& operator-=(difference_type n);

Preconditions: If Bound is not unreachable_sentinel_t, current_ - n ≥ 0.

Effects: Equivalent to:

```cpp
current_ -= n; 
return *this;
```

constexpr const T& operator[](difference_type n) const noexcept;

Effects: Equivalent to:

```cpp
return *(this + n);
```

friend constexpr bool operator==(const iterator& x, const iterator& y);

Effects: Equivalent to:

```cpp
x.current_ == y.current_; 
```

friend constexpr auto operator<=>(const iterator& x, const iterator& y);

Effects: Equivalent to:

```cpp
x.current_<=> y.current_; 
```

friend constexpr iterator operator+(iterator i, difference_type n);

friend constexpr iterator operator+(difference_type n, iterator i);

Effects: Equivalent to:

```cpp
i += n; 
return i;
```

friend constexpr iterator operator-(iterator i, difference_type n);

Effects: Equivalent to:

```cpp
i -= n; 
return i;
```

friend constexpr difference_type operator-(const iterator& x, const iterator& y);

Effects: Equivalent to:

```cpp
return static_cast<difference_type>(x.current_) - static_cast<difference_type>(y.current_); 
```

### 26.6.6 Istream view

#### 26.6.6.1 Overview

basic_istream_view models input_range and reads (using operator>>) successive elements from its corresponding input stream.

The name views::istream view denotes a customization point object (16.3.3.3.5). Given a type T and a subexpression E of type U, if U models derived_from<basic_istream<typename U::char_type, typename U::traits_type>>, then the expression views::istream_view<T>(E) is expression-equivalent to basic_istream_view<T, typename U::char_type, typename U::traits_type>(E); otherwise, views::istream_view<T>(E) is ill-formed.

[Example 1:...]

§ 26.6.6.1

1157
auto ints = istringstream("0 1 2 3 4");
ranges::copy(views::istream<int>(ints), ostream_iterator<int>{cout, "-"});
// prints 0-1-2-3-4-
— end example]

26.6.6.2 Class template basic_istream_view

```cpp
namespace std::ranges {
    template<class Val, class CharT, class Traits>
    concept stream-extractable = // exposition only
        requires(basic_istream<CharT, Traits>& is, Val& t) {
            is >> t;
        };

template<movable Val, class CharT, class Traits = char_traits<CharT>>
    requires default_initializable<Val> && stream-extractable<Val, CharT, Traits>
    class basic_istream_view : public view_interface<basic_istream_view<Val, CharT, Traits>> {
        public:
            constexpr explicit basic_istream_view(basic_istream<CharT, Traits>& stream);

            constexpr default_sentinel_t end() const noexcept;

        private:
            // 26.6.6.3, class basic_istream_view::iterator
            struct iterator;
            // exposition only
            basic_istream<CharT, Traits>* stream_; // exposition only
            Val value_ = Val(); // exposition only
        };

    constexpr explicit basic_istream_view(basic_istream<CharT, Traits>& stream);

    Effects: Initializes stream_ with addressof(stream).

    constexpr default_sentinel_t end() const noexcept;

    Effects: Equivalent to: return default_sentinel;
```

26.6.6.3 Class basic_istream_view::iterator

```cpp
namespace std::ranges {
    template<movable Val, class CharT, class Traits>
    requires default_initializable<Val> && stream-extractable<Val, CharT, Traits>
    class basic_istream_view<Val, CharT, Traits>::iterator {
        public:
            using iterator_concept = input_iterator_tag;
            using difference_type = ptrdiff_t;
            using value_type = Val;

            constexpr explicit iterator(basic_istream_view& parent) noexcept;

            iterator(const iterator&) = delete;
            iterator(iterator&&) = default;

            iterator& operator=(const iterator&) = delete;
            iterator& operator=(iterator&&) = default;

            iterator& operator++();
            void operator++(int);
```

§ 26.6.6.3 1158
Val& operator*() const;
friend bool operator==(const iterator& x, default_sentinel_t);

private:
    basic_istream_view* parent_;  // exposition only
};

constexpr explicit iterator(basic_istream_view& parent) noexcept;

Effects: Initializes parent_ with addressof(parent).

iterator& operator++();

Effects: Equivalent to:
    *parent_->stream_ >> parent_->value_;
    return *this;

void operator++(int);

Effects: Equivalent to: ++*this.

Val& operator*() const;

Effects: Equivalent to:
    return parent_->value_;

friend bool operator==(const iterator& x, default_sentinel_t);

Effects: Equivalent to: return !*x.

parent_->stream_;
The expression $C \mid D$ is well-formed if and only if the initializations of the state entities of $E$ are all well-formed.

Given an object $t$ of type $T$, where

1. $t$ is a unary function object that accepts a range argument,
2. $T$ models $\text{derived\_from}<\text{range\_adaptor\_closure}\langle T \rangle>$,
3. $T$ has no other base classes of type $\text{range\_adaptor\_closure}\langle U \rangle$ for any other type $U$, and
4. $T$ does not model $\text{range}$
then the implementation ensures that $t$ is a range adaptor closure object.

The template parameter $D$ for $\text{range\_adaptor\_closure}$ may be an incomplete type. If an expression of type $\text{cv} D$ is used as an operand to the $\mid$ operator, $D$ shall be complete and model $\text{derived\_from}<\text{range\_adaptor\_closure}\langle D \rangle>$. The behavior of an expression involving an object of type $\text{cv} D$ as an operand to the $\mid$ operator is undefined if overload resolution selects a program-defined operator function.

If an expression of type $\text{cv} U$ is used as an operand to the $\mid$ operator, where $U$ has a base class of type $\text{range\_adaptor\_closure}\langle T \rangle$ for some type $T$ other than $U$, the behavior is undefined.

The behavior of a program that adds a specialization for $\text{range\_adaptor\_closure}$ is undefined.

A range adaptor object is a customization point object (16.3.3.3.5) that accepts a viewable range as its first argument and returns a view.

If a range adaptor object accepts only one argument, then it is a range adaptor closure object.

If a range adaptor object adaptor accepts more than one argument, then let range be an expression such that $\text{decltype}((\text{range}))$ models viewable_range, let args... be arguments such that $\text{adaptor}($range$, \text{args}...)$ is a well-formed expression as specified in the rest of subclause 26.7, and let BoundArgs be a pack that denotes $\text{decay\_t}<\text{decltype}((\text{args}))>\ldots$. The expression $\text{adaptor}($args...$)$ produces a range adaptor closure object $f$ that is a perfect forwarding call wrapper (22.10.4) with the following properties:

1. Its target object is a copy of adaptor.
2. Its bound argument entities bound_args consist of objects of types BoundArgs... direct-non-list-initialized with std::forward<$\text{decltype}((\text{args}))>$,$\ldots$, respectively.
3. Its call pattern is $\text{adaptor}($r$, \text{bound\_args}...$), where $r$ is the argument used in a function call expression of $f$.

The expression $\text{adaptor}($args...$)$ is well-formed if and only if the initialization of the bound argument entities of the result, as specified above, are all well-formed.

### 26.7.3 Movable wrapper

Many types in this subclause are specified in terms of an exposition-only class template movable-box. movable-box$<$T$>$ behaves exactly like optional$<$T$>$ with the following differences:

1. movable-box$<$T$>$ constrains its type parameter T with move_constructible$<$T$>$ && is_object_v$<$T$>$.
2. The default constructor of movable-box$<$T$>$ is equivalent to:
   ```cpp
   constexpr movable-box() noexcept(is_nothrow_default_constructible_v<T>)
   requires default_initializable<T>
   : movable-box(in_place) {}
   ```
3. If copyable$<$T$>$ is not modeled, the copy assignment operator is equivalent to:
   ```cpp
   constexpr movable-box& operator=(const movable-box& that)
   noexcept(is_nothrow_copy_constructible_v<T>)
   requires copy_constructible<T>
   {
   if (this != addressof(that)) {
   if (that) emplace(*that);
   else reset();
   }
   return *this;
   }
   ```
4. If movable$<$T$>$ is not modeled, the move assignment operator is equivalent to:
```cpp
constexpr movable-box operator=(movable-box&& that) noexcept(is_nothrow_move_constructible_v<T>) {
    if (this != addressof(that)) {
        if (that) emplace(std::move(*that));
        else reset();
    }
    return *this;
}
```

2 **Recommended practice:**

(2.1) If `copy_constructible<T>` is true, `movable-box<T>` should store only a `T` if either `T` models `copyable`, or `is_nothrow_move_constructible_v<T> && is_nothrow_copy_constructible_v<T>` is true.

(2.2) Otherwise, `movable-box<T>` should store only a `T` if either `T` models `movable` or `is_nothrow_move_constructible_v<T>` is true.

### § 26.7.4 Non-propagating cache

1 Some types in subclause 26.7 are specified in terms of an exposition-only class template `non-propagating-cache`. `non-propagating-cache<T>` behaves exactly like `optional<T>` with the following differences:

(1.1) `non-propagating-cache<T>` constrains its type parameter `T` with `is_object_v<T>`.

(1.2) The copy constructor is equivalent to:

```cpp
constexpr non-propagating-cache(const non-propagating-cache&) noexcept {
}
```

(1.3) The move constructor is equivalent to:

```cpp
constexpr non-propagating-cache(non-propagating-cache&& other) noexcept {
    other.reset();
}
```

(1.4) The copy assignment operator is equivalent to:

```cpp
constexpr non-propagating-cache& operator=(const non-propagating-cache& other) noexcept {
    if (addressof(other) != this)
        reset();
    return *this;
}
```

(1.5) The move assignment operator is equivalent to:

```cpp
constexpr non-propagating-cache& operator=(non-propagating-cache&& other) noexcept {
    reset();
    other.reset();
    return *this;
}
```

(1.6) `non-propagating-cache<T>` has an additional member function template specified as follows:

```cpp
template<class I>
constexpr T& emplace-deref(const I& i);  // exposition only
```

*Mandates:* The declaration `T t(*i);` is well-formed for some invented variable `t`.

[Note 1: If `*i` is a prvalue of type `cv T`, there is no requirement that it is movable (9.4.1). — end note]

*Effects:* Calls `reset()`. Then direct-non-list-initializes the contained value with `*i`.

*Postconditions:* `*this` contains a value.

*Returns:* A reference to the new contained value.

*Throws:* Any exception thrown by the initialization of the contained value.

*Remarks:* If an exception is thrown during the initialization of `T`, `*this` does not contain a value, and the previous value (if any) has been destroyed.

2 [Note 2: `non-propagating-cache` enables an input view to temporarily cache values as it is iterated over. — end note]
26.7.5  Range adaptor helpers

```cpp
namespace std::ranges {
    template<class F, class Tuple>
    constexpr auto
tuple-transform(F&& f, Tuple&& t) { // exposition only
        return apply([&]<class... Ts>(Ts&&... elements) {
            return tuple<invoke_result_t<F&, Ts>...>(invoke(f, std::forward<Ts>(elements))...);
        }, std::forward<Tuple>(t));
    }

    template<class F, class Tuple>
    constexpr void
tuple-for-each(F&& f, Tuple&& t) { // exposition only
        apply([&]<class... Ts>(Ts&&... elements) {
            (static_cast<void>(invoke(f, std::forward<Ts>(elements))), ...);
        }, std::forward<Tuple>(t));
    }

    template<class T>
    constexpr T&
as-lvalue(T&& t) { // exposition only
        return static_cast<T&>(t);
    }
}
```

26.7.6  All view

26.7.6.1  General

1 views::all returns a view that includes all elements of its range argument.

2 The name views::all denotes a range adaptor object (26.7.2). Given a subexpression E, the expression
views::all(E) is expression-equivalent to:

(2.1) — decay-copy(E) if the decayed type of E models view.

(2.2) — Otherwise, ref_view(E) if that expression is well-formed.

(2.3) — Otherwise, owning_view(E).

26.7.6.2  Class template ref_view

1 ref_view is a view of the elements of some other range.

```cpp
namespace std::ranges {
    template<range R>
    requires is_object_v<R>
    class ref_view : public view_interface<ref_view<R>> {
        private:
        R* r_; // exposition only

        public:
        template<different-from<ref_view> T>
        requires see below
        constexpr ref_view(T&& t);

        constexpr R& base() const { return *r_; }

        constexpr iterator_t<R> begin() const { return ranges::begin(*r_); }
        constexpr sentinel_t<R> end() const { return ranges::end(*r_); }

        constexpr bool empty() const requires { ranges::empty(*r_); }
        { return ranges::empty(*r_); }

        constexpr auto size() const requires sized_range<R>
        { return ranges::size(*r_); }

        constexpr auto data() const requires contiguous_range<R>
        { return ranges::data(*r_); }
    };
```
template<class R>
    ref_view(R&) -> ref_view<R>;
}

template<different-from<ref_view> T>
requires see below
constexpr ref_view(T&& t);

Effects: Initializes r_ with addressof(static_cast<R&>(std::forward<T>(t))).

Remarks: Let FUN denote the exposition-only functions
    void FUN(R&);
    void FUN(R&&) = delete;

The expression in the requires-clause is equivalent to:
    convertible_to<T, R&> && requires { FUN(declval<T>()); }

26.7.6.3 Class template owning_view
[range.owning.view]

owning_view is a move-only view of the elements of some other range.

namespace std::ranges {
    template<range R>
    requires movable<R> && (!is-initializer-list<R>) // see 26.4.5
class owning_view : public view_interface<owning_view<R>> {
private:
    R r_ = R(); // exposition only

public:
    owning_view() requires default_initializable<R> = default;
    constexpr owning_view(R&& t);
    owning_view(owning_view&&) = default;
    owning_view& operator=(owning_view&&) = default;
    constexpr R& base() & noexcept { return r_; }
    constexpr const R& base() const & noexcept { return r_; }
    constexpr R&& base() && noexcept { return std::move(r_); }
    constexpr const R&& base() const && noexcept { return std::move(r_); }
    constexpr iterator_t<R> begin() { return ranges::begin(r_); }
    constexpr sentinel_t<R> end() { return ranges::end(r_); }
    constexpr auto begin() const requires range<const R> { return ranges::begin(r_); }
    constexpr auto end() const requires range<const R> { return ranges::end(r_); }
    constexpr bool empty() requires requires { ranges::empty(r_); } { return ranges::empty(r_); }
    constexpr bool empty() const requires requires { ranges::empty(r_); } { return ranges::empty(r_); }
    constexpr auto size() requires sized_range<R> { return ranges::size(r_); }
    constexpr auto size() const requires sized_range<const R> { return ranges::size(r_); }
    constexpr auto data() requires contiguous_range<R> { return ranges::data(r_); }
    constexpr auto data() const requires contiguous_range<const R> { return ranges::data(r_); }
};
constexpr owning_view(R&& t);

Effects: Initializes \( r_\) with \( \text{std::move}(t) \).

### 26.7.7 As rvalue view

#### 26.7.7.1 Overview

as\_rvalue\_view presents a view of an underlying sequence with the same behavior as the underlying sequence except that its elements are rvalues. Some generic algorithms can be called with an as\_rvalue\_view to replace copying with moving.

The name \( \text{views::as\_rvalue} \) denotes a range adaptor object (26.7.2). Let \( E \) be an expression and let \( T \) be \( \text{decltype((E))} \). The expression \( \text{views::as\_rvalue}(E) \) is expression-equivalent to:

1. \( \text{views::all}(E) \) if same\_as<range\_rvalue\_reference\_t<T>, range\_reference\_t<T>> is true.
2. Otherwise, as\_rvalue\_view\( (E) \).

**Example 1:**

```cpp
vector<string> words = {"the", "quick", "brown", "fox", "ate", "a", "pterodactyl"};
vector<string> new_words;
ranges::copy(words | views::as\_rvalue, back_inserter(new_words));
// moves each string from \( \text{words} \) into \( \text{new\_words} \)
```

#### 26.7.7.2 Class template as\_rvalue\_view

```cpp
namespace std::ranges {
    template<view V>
    requires input\_range<V>
    class as\_rvalue\_view : public view\_interface<as\_rvalue\_view\_V>> {
        V base_ = V(); // exposition only

        public:
        as\_rvalue\_view() requires default\_initializable<V> = default;
        constexpr explicit as\_rvalue\_view(V base);

        constexpr V base() const & requires copy\_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }

        constexpr auto begin() requires (!simple\_view<V>) {
            if constexpr (common\_range<V>) {
                return move\_iterator(ranges::begin(base_));
            } else {
                return move\_sentinel(ranges::end(base_));
            }
        }
        constexpr auto begin() const requires range<const V> {
            if constexpr (common\_range<const V>) {
                return move\_iterator(ranges::begin(base_));
            } else {
                return move\_sentinel(ranges::end(base_));
            }
        }
        constexpr auto end() requires (simple\_view<V>) {
            if constexpr (common\_range<V>) {
                return move\_iterator(ranges::end(base_));
            } else {
                return move\_sentinel(ranges::end(base_));
            }
        }
        constexpr auto end() const requires range<const V> {
            if constexpr (common\_range<const V>) {
                return move\_iterator(ranges::end(base_));
            } else {
                return move\_sentinel(ranges::end(base_));
            }
        }
        constexpr auto size() requires sized\_range<V> { return ranges::size(base_); }
        constexpr auto size() const requires sized\_range<const V> { return ranges::size(base_); }
    }
}
```

```cpp
template<class R>
as\_rvalue\_view(R&&) -> as\_rvalue\_view<views::all\_t<R>>;
```
constexpr explicit as_rvalue_view(V base);

**Effects:** Initializes \texttt{base} with \texttt{std::move(base)}.

### 26.7.8 Filter view

#### 26.7.8.1 Overview

\texttt{filter_view} presents a view of the elements of an underlying sequence that satisfy a predicate.

1. The name \texttt{views::filter} denotes a range adaptor object (26.7.2). Given subexpressions \texttt{E} and \texttt{P}, the expression \texttt{views::filter(E, P)} is expression-equivalent to \texttt{filter_view(E, P)}.

2. **Example 1:**

   ```cpp
tvector<int> is{ 0, 1, 2, 3, 4, 5, 6 };  
auto evens = views::filter(is, [](int i) { return 0 == i % 2; });  
for (int i : evens)  
  cout << i << ' '; // prints 0 2 4 6
   
   —end example
```

### 26.7.8.2 Class template \texttt{filter_view}

```cpp
namespace std::ranges {
  template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
  requires view<V> && is_object_v<Pred>
  class filter_view : public view_interface<filter_view<V, Pred>> {
    private:
      V base_ = V();                      // exposition only
      movable_box<Pred> pred_;           // exposition only
    
    // 26.7.8.3, class filter_view::iterator
    class iterator;
  
    // 26.7.8.4, class filter_view::sentinel
    class sentinel;
  public:
    filter_view() requires default_initializable<V> && default_initializable<Pred> = default;
    constexpr explicit filter_view(V base, Pred pred);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr const Pred& pred() const;

    constexpr iterator begin();
    constexpr auto end() {
      if constexpr (common_range<V>)
        return iterator(*this, ranges::end(base_));
      else
        return sentinel(*this);
    }
  }

template<class R, class Pred>
  filter_view(R&&, Pred) -> filter_view<views::all_t<R>, Pred>;
}
```

```cpp
constexpr explicit filter_view(V base, Pred pred);

**Effects:** Initializes \texttt{base} with \texttt{std::move(base)} and initializes \texttt{pred} with \texttt{std::move(pred)}.

```cpp
constexpr const Pred& pred() const;

**Effects:** Equivalent to: return \texttt{*pred};
```
constexpr iterator begin();

3   Preconditions: pred_.has_value() is true.
4   Returns: {*this, ranges::find_if(base_, ref(*pred_))}.
5   Remarks: In order to provide the amortized constant time complexity required by the range concept when filter_view models forward_range, this function caches the result within the filter_view for use on subsequent calls.

26.7.8.3 Class filter_view::iterator

namespace std::ranges {
    template<input_range V, indirect_unary_predicate<iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
    class filter_view<V, Pred>::::iterator {
        private:
            iterator_t<V> current_ = iterator_t<V>(); // exposition only
            filter_view* parent_ = nullptr; // exposition only
        public:
            using iterator_concept = see below;
            using iterator_category = see below; // not always present
            using value_type = range_value_t<V>;
            using difference_type = range_difference_t<V>;
            iterator() requires default_initializable<iterator_t<V>> = default;
            constexpr iterator(filter_view& parent, iterator_t<V> current);
            constexpr const iterator_t<V>& base() const & noexcept;
            constexpr iterator_t<V> base() &&;
            constexpr range_reference_t<V> operator*() const;
            constexpr iterator_t<V> operator->() const requires has-arrow<iterator_t<V>> && copyable<iterator_t<V>>;
            constexpr iterator& operator++();
            constexpr void operator++(int);
            constexpr iterator operator++(int) requires forward_range<V>;
            constexpr iterator& operator--() requires bidirectional_range<V>;
            constexpr iterator operator--(int) requires bidirectional_range<V>;
            friend constexpr bool operator==(const iterator& x, const iterator& y)
                requires equality_comparable<iterator_t<V>>;
            friend constexpr range_rvalue_reference_t<V> iter_move(const iterator& i)
                noexcept(noexcept(ranges::iter_move(i.current_)));
            friend constexpr void iter_swap(const iterator& x, const iterator& y)
                noexcept(noexcept(ranges::iter_swap(x.current_, y.current_)))
                requires indirectly_swappable<iterator_t<V>>;
        }
    }

1 Modification of the element a filter_view::iterator denotes is permitted, but results in undefined behavior if the resulting value does not satisfy the filter predicate.

2 iterator::iterator_concept is defined as follows:

(2.1) — If V models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.

(2.2) — Otherwise, if V models forward_range, then iterator_concept denotes forward_iterator_tag.

(2.3) — Otherwise, iterator_concept denotes input_iterator_tag.

3 The member typedef-name iterator_category is defined if and only if V models forward_range. In that case, iterator::iterator_category is defined as follows:

(3.1) — Let C denote the type iterator_traits<iterator_t<V>>::iterator_category.
If \( C \) models `derived_from<bidirectional_iterator_tag>`, then `iterator_category` denotes `bidirectional_iterator_tag`.

Otherwise, if \( C \) models `derived_from<forward_iterator_tag>`, then `iterator_category` denotes `forward_iterator_tag`.

Otherwise, `iterator_category` denotes \( C \).

```cpp
cconstexpr iterator(filter_view& parent, iterator_t<V> current);
```

**Effects:** Initializes `current_` with `std::move(current)` and `parent_` with `addressof(parent)`.

```cpp
cconstexpr const iterator_t<V>& base() const & noexcept;
```

**Effects:** Equivalent to: `return current_`;

```cpp
cconstexpr iterator_t<V> base() &&;
```

**Effects:** Equivalent to: `return std::move(current_)`;

```cpp
cconstexpr range_reference_t<V> operator*() const;
```

**Effects:** Equivalent to: `return *current_`;

```cpp
cconstexpr iterator_t<V> operator->() const
requires has-arrow<iterator_t<V>> & copyable<iterator_t<V>>;
```

**Effects:** Equivalent to: `return current_`;

```cpp
cconstexpr iterator& operator++();
```

**Effects:** Equivalent to:

```cpp
current_ = ranges::find_if(std::move(++current_), ranges::end(parent_->base_),
ref(*parent_->pred_));
```

`return *this;`

```cpp
cconstexpr void operator++(int);
```

**Effects:** Equivalent to: `++*this`.

```cpp
cconstexpr iterator operator++(int) requires forward_range<V>;
```

**Effects:** Equivalent to:

```cpp
auto tmp = *this;
++*this;
return tmp;
```

```cpp
cconstexpr iterator& operator--() requires bidirectional_range<V>;
```

**Effects:** Equivalent to:

```cpp
do
--current_;
while (!invoke(*parent_->pred_, *current_));
```

`return *this;`

```cpp
cconstexpr iterator operator--(int) requires bidirectional_range<V>;
```

**Effects:** Equivalent to:

```cpp
auto tmp = *this;
--*this;
return tmp;
```

friend constexpr bool operator==(const iterator& x, const iterator& y)
requires equality_comparable<iterator_t<V>>;

**Effects:** Equivalent to: `return x.current_ == y.current_`;

friend constexpr range_rvalue_reference_t<V> iter_move(const iterator& i)
noexcept(noexcept(ranges::iter_move(i.current_)));

**Effects:** Equivalent to: `return ranges::iter_move(i.current_);`
friend constexpr void iter_swap(const iterator& x, const iterator& y) noexcept(noexcept(ranges::iter_swap(x.current_, y.current_))) requires indirectly_swappable<iterator_t<V>>;

**Effects:** Equivalent to ranges::iter_swap(x.current_, y.current_).

### 26.7.8.4 Class filter_view::sentinel

```cpp
namespace std::ranges {
    template<input_range V, indirect Unary Predicate iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
    class filter_view<V, Pred>::sentinel {
        private:
            sentinel_t<V> end_ = sentinel_t<V>(); // exposition only

        public:
            sentinel() = default;
            constexpr explicit sentinel(filter_view& parent);
            constexpr sentinel_t<V> base() const;

            friend constexpr bool operator==(const iterator& x, const sentinel& y);
    };
}
```

**Effects:**

1. Initializes `end_` with ranges::end(parent.base_).

2. `sentinel_t<V>` function returns `end_`.

3. `operator==(const iterator& x, const sentinel& y)`.

### 26.7.9 Transform view

#### 26.7.9.2 Class template transform_view

```cpp
namespace std::ranges {
    template<input_range V, move_constructible F>
    requires view<V> && is_object_v<F> &&
        regular_invocable<F&, range_reference_t<V>> &&
        can-reference<invoke_result_t<F&, range_reference_t<V>>>
    class transform_view : public view_interface<transform_view<V, F>> {
        private:
            // 26.7.9.3, class template transform_view::iterator
            template<bool> struct iterator;
            // exposition only

            // 26.7.9.4, class template transform_view::sentinel
            template<bool> struct sentinel;
            // exposition only
    }
}
```

## Example 1:

```cpp
template<
    input_range V,
    move_constructible F>
    requires view<V> && is_object_v<F> &&
        regular_invocable<F&, range_reference_t<V>> &&
        can-reference<invoke_result_t<F&, range_reference_t<V>>>

    class transform_view : public view_interface<transform_view<V, F>> {
        private:
            // 26.7.9.3, class template transform_view::iterator
            template<bool> struct iterator;
            // exposition only

            // 26.7.9.4, class template transform_view::sentinel
            template<bool> struct sentinel;
            // exposition only
```
V base_ = V(); // exposition only
movable-box<F> fun_; // exposition only

public:
    transform_view() requires default_initializable<V> && default_initializable<F> = default;
    constexpr explicit transform_view(V base, F fun);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr iterator<false> begin();
    constexpr iterator<true> begin() const
        requires range<const V> &&
            regular_invocable<const F& , range_reference_t<const V>>;

    constexpr sentinel<false> end();
    constexpr iterator<false> end() requires common_range<V>;
    constexpr iterator<true> end() const
        requires range<const V> &&
            regular_invocable<const F& , range_reference_t<const V>>;

    constexpr auto size() requires sized_range<V> { return ranges::size(base_); }
    constexpr auto size() const requires sized_range<const V>
        { return ranges::size(base_); }
};

template<class R, class F>
    transform_view(R&&, F) -> transform_view<views::all_t<R>, F>;

constexpr explicit transform_view(V base, F fun);

1. Effects: Initializes base_ with std::move(base) and fun_ with std::move(fun).

2. Effects: Equivalent to:

   return iterator<false>{*this, ranges::begin(base_)};

3. Effects: Equivalent to:

   return iterator<true>{*this, ranges::begin(base_)};

4. Effects: Equivalent to:

   return sentinel<false>{ranges::end(base_)};

5. Effects: Equivalent to:

   return iterator<false>{*this, ranges::end(base_)};

6. Effects: Equivalent to:

   return sentinel<true>{ranges::end(base_)};
constexpr iterator<true> end() const
  requires common_range<const V> &&
    regular_invocable<const F&, range_reference_t<const V>>;

Effects: Equivalent to:

return iterator<true>(*this, ranges::end(base_));

26.7.9.3 Class template transform_view::iterator

namespace std::ranges {
  template<input_range V, move_constructible F>
    requires view<V> && is_object_v<F> &&
      regular_invocable<F&, range_reference_t<V>> &&
        can_reference<invoke_result_t<F&, range_reference_t<V>>>;
  template<bool Const>
    class transform_view<V, F>::iterator {
  private:
    using Parent = maybe-const<Const, transform_view>; // exposition only
    using Base = maybe-const<Const, V>; // exposition only
    iterator_t<Base> current_ = iterator_t<Base>(); // exposition only
    Parent* parent_ = nullptr; // exposition only
  public:
    using iterator_concept = see below;
    using iterator_category = see below; // not always present
    using value_type =
      remove_cvref_t<invoke_result_t<maybe-const<Const, F>&, range_reference_t<Base>>; // exposition only
    using difference_type = range_difference_t<Base>;
    iterator() requires default_initializable<iterator_t<Base>> = default;
    constexpr iterator(Parent& parent, iterator_t<Base> current);
    constexpr iterator(iterator<!Const> i)
      requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
    constexpr const iterator_t<Base>& base() const & noexcept;
    constexpr iterator_t<Base>& base() &&;
    constexpr decltype(auto) operator*() const
      noexcept(noexcept(invoke(*parent_->fun_, *current_))) {
      return invoke(*parent_->fun_, *current_);
    }
    constexpr iterator& operator++();
    constexpr void operator++(int);
    constexpr iterator& operator++(int) requires forward_range<Base>;
    constexpr iterator& operator--() requires bidirectional_range<Base>;
    constexpr iterator& operator--(int) requires bidirectional_range<Base>;
    constexpr iterator& operator+=(difference_type n)
      requires random_access_range<Base>;
    constexpr iterator& operator-=(difference_type n)
      requires random_access_range<Base>;
    constexpr decltype(auto) operator[](difference_type n) const
      requires random_access_range<Base> {
      return invoke(*parent_->fun_, current_[n]);
    }
    friend constexpr bool operator==(const iterator& x, const iterator& y)
      requires equality_comparable<iterator_t<Base>>;
    friend constexpr bool operator<(const iterator& x, const iterator& y)
      requires random_access_range<Base>;
  }
}
friend constexpr bool operator>(const iterator & x, const iterator & y)  
requires random_access_range<Base>;
friend constexpr bool operator<=(const iterator & x, const iterator & y)  
requires random_access_range<Base>;
friend constexpr bool operator>=(const iterator & x, const iterator & y)  
requires random_access_range<Base>;
friend constexpr auto operator<=>(const iterator & x, const iterator & y)  
requires random_access_range<Base> && three_way_comparable<iterator_t<Base>>;
friend constexpr iterator operator+(iterator i, difference_type n)  
requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, iterator i)  
requires random_access_range<Base>;
friend constexpr iterator operator-(iterator i, difference_type n)  
requires random_access_range<Base>;
friend constexpr difference_type operator-(const iterator & x, const iterator & y)  
requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;

iterator::iterator_concept is defined as follows:

1. If Base models random_access_range, then iterator_concept denotes random_access_iterator_tag.
2. Otherwise, if Base models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.
3. Otherwise, if Base models forward_range, then iterator_concept denotes forward_iterator_tag.
4. Otherwise, iterator_concept denotes input_iterator_tag.

The member typedef-name iterator_category is defined if and only if Base models forward_range. In that case, iterator::iterator_category is defined as follows: Let C denote the type iterator_traits<iterator_t<Base>>::iterator_category.

- If is_reference_v<invoke_result_t<maybe-const<Const, F>&, range_reference_t<Base>>> is true, then
  - if C models derived_from<contiguous_iterator_tag>, iterator_category denotes random_access_iterator_tag;
  - otherwise, iterator_category denotes C.
- Otherwise, iterator_category denotes input_iterator_tag.

constexpr iterator (Parent & parent, iterator_t<Base> current);
Effects: Initializes current_ with std::move(current) and parent_ with addressof(parent).

constexpr iterator (iterator<!Const> i)  
requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
Effects: Initializes current_ with std::move(i.current_) and parent_ with i.parent_.

constexpr const iterator_t<Base> & base() const & noexcept;  
Effects: Equivalent to: return current_;

26.7.10 Take view

26.7.10.1 Overview

The name `views::take` denotes a range adaptor object (26.7.2). Let E and F be expressions, let T be remove_cvref_t<decltype((E))>, and let D be range_difference_t<decltype((E))>. If decltype((F)) does not model convertible_to<D>, `views::take(E, F)` is ill-formed. Otherwise, the expression `views::take(E, F)` is expression-equivalent to:

1. If T is a specialization of empty_view (26.6.2.2), then `((void)F, decay-copy(E))`, except that the evaluations of E and F are indeterminately sequenced.

2. Otherwise, if T models random_access_range and sized_range and is a specialization of span (24.7.2.2), basic_string_view (23.3), or subrange (26.5.4), then U(ranges::begin(E), ranges::begin(E) + std::min<D>(ranges::distance(E), F)), except that E is evaluated only once, where U is a type determined as follows:

   3.1. If T is a specialization of span, then U is `span<typename T::element_type>);
   3.2. Otherwise, if T is a specialization of basic_string_view, then U is T;
   3.3. Otherwise, T is a specialization of subrange, and U is `subrange<iterator_t<T>>`;

3. Otherwise, if T is a specialization of iota_view (26.6.4.2) that models random_access_range and sized_range, then iota_view(*ranges::begin(E), *(ranges::begin(E) + std::min<D>(ranges::distance(E), F))), except that E is evaluated only once.

4. Otherwise, if T is a specialization of repeat_view (26.6.5.2):

   4.1. If T models sized_range, then
   `views::repeat(*E.value_, std::min<D>(ranges::distance(E), F))`
   except that E is evaluated only once;
   4.2. Otherwise, `views::repeat(*E.value_, static_cast<D>(F))`.

5. Otherwise, `take_view(E, F)`.

3 [Example 1:

```cpp
vector<int> is{0,1,2,3,4,5,6,7,8,9};
for (int i : is | views::take(5))
    cout << i << ' '; // prints 0 1 2 3 4
```

end example]

26.7.10.2 Class template take_view

```cpp
namespace std::ranges {
    template<V>
    class take_view : public view_interface<take_view<V>> { 
    private:
```
V base_ = V(); // exposition only
range_difference_t<V> count_ = 0; // exposition only

// 26.7.10.3, class template take_view::sentinel
template<bool> class sentinel; // exposition only

public:
take_view() requires default_initializable<V> = default;
constexpr explicit take_view(V base, range_difference_t<V> count);

constexpr V base() const & requires copy_constructible<V> { return base_; } 
constexpr V base() && { return std::move(base_); } 

constexpr auto begin() requires (!simple_view<V>) {
    if constexpr (sized_range<V>) {
        return ranges::begin(base_);
    } else {

§ 26.7.11.3 1178
26.7.12 Drop view

26.7.12.1 Overview

`drop_view` produces a view excluding the first \( N \) elements from another view, or an empty range if the adapted view contains fewer than \( N \) elements.

The name `views::drop` denotes a range adaptor object (26.7.2). Let \( E \) and \( F \) be expressions, let \( T \) be `remove_cvref_t<\text{decltype}(E)>`, and let \( D \) be `range_difference_t<\text{decltype}(E)>`. If `decltype(F)` does not model `convertible_to<D>`, `views::drop(E, F)` is ill-formed. Otherwise, the expression `views::drop(E, F)` is expression-equivalent to:

1. If \( T \) is a specialization of `empty_view` (26.6.2.2), then `((void)F, \text{decay-copy}(E))`, except that the evaluations of \( E \) and \( F \) are indeterminately sequenced.
2. Otherwise, if \( T \) models `random_access_range` and `sized_range` and is
   1. a specialization of `span` (24.7.2.2),
   2. a specialization of `basic_string_view` (23.3),
   3. a specialization of `iota_view` (26.6.4.2), or
   4. a specialization of `subrange` (26.5.4) where \( T::\text{StoreSize} \) is false, then \( U(\text{ranges::begin}(E) + \text{std::min}<D>(\text{ranges::distance}(E), F), \text{ranges::end}(E)) \), except that \( E \) is evaluated only once, where \( U \) is `span<typename T::element_type>` if \( T \) is a specialization of `span` and \( T \) otherwise.
3. Otherwise, if \( T \) is a specialization of `subrange` (26.5.4) that models `random_access_range` and `sized_range`, then \( V(\text{ranges::begin}(E) + \text{std::min}<D>(\text{ranges::distance}(E), F), \text{ranges::end}(E), \text{to-unsigned-like}(\text{ranges::distance}(E) - \text{std::min}<D>(\text{ranges::distance}(E), F))) \), except that \( E \) and \( F \) are each evaluated only once.
4. Otherwise, if \( T \) is a specialization of `repeat_view` (26.6.5.2):
   1. if \( T \) models `sized_range`, then `views::repeat(*E.value_, \text{ranges::distance}(E) - \text{std::min}<D>(\text{ranges::distance}(E), F))` except that \( E \) is evaluated only once;
   2. otherwise, `((void)F, \text{decay-copy}(E))`, except that the evaluations of \( E \) and \( F \) are indeterminately sequenced.
5. Otherwise, `drop_view(E, F).

[Example 1:
```cpp
class drop_view : public view_interface<drop_view<V>> { public:
    drop_view() requires default_initializable<V> = default;
    constexpr explicit drop_view(V base, range_difference_t<V> count) {
        constexpr auto begin() requires (!simple_view<V> &&
            random_access_range<const V> && sized_range<const V>) {
            constexpr auto begin() const
                requires random_access_range<const V> && sized_range<const V>;
```}

26.7.12.2 Class template drop_view

```cpp
namespace std::ranges {
    template<typename V>
    class drop_view : public view_interface<drop_view<V>> {
        public:
            drop_view() requires default_initializable<V> = default;
            constexpr explicit drop_view(V base, range_difference_t<V> count) {
                constexpr V base() const & requires copy_constructible<V> { return base_; }
                constexpr V base() && { return std::move(base_); }

                constexpr auto begin() requires (!simple_view<V> &&
                    random_access_range<const V> && sized_range<const V>) {
                    constexpr auto begin() const
                        requires random_access_range<const V> && sized_range<const V>;
```
constexpr auto end() requires (! simple-view<V>)
{ return ranges::end(base_); }

constexpr auto end() const requires range<const V>
{ return ranges::end(base_); }

constexpr auto size() requires sized_range<V> {
    const auto s = ranges::size(base_);
    const auto c = static_cast<decltype(s)>(count_);
    return s < c ? 0 : s - c;
}

constexpr auto size() const requires sized_range<const V> {
    const auto s = ranges::size(base_);
    const auto c = static_cast<decltype(s)>(count_);
    return s < c ? 0 : s - c;
}

private:
V base_ = V(); // exposition only
range_difference_t<V> count_ = 0; // exposition only
};

template<class R>
drop_view(R&&, range_difference_t<R>) -> drop_view<views::all_t<R>>;

constexpr explicit drop_view(V base, range_difference_t<V> count);

Preconditions: count >= 0 is true.
Effects: Initializes base_ with std::move(base) and count_ with count.

constexpr auto begin() requires (! (simple-view<V> && random_access_range<const V> && sized_range<const V>) && sized_range<V>);
constexpr auto begin() const requires random_access_range<const V> && sized_range<const V>;

Returns: ranges::next(ranges::begin(base_), count_, ranges::end(base_)).
Remarks: In order to provide the amortized constant-time complexity required by the range concept when drop_view models forward_range, the first overload caches the result within the drop_view for use on subsequent calls.

[Note 1: Without this, applying a reverse_view over a drop_view would have quadratic iteration complexity. —end note]

26.7.13 Drop while view

26.7.13.1 Overview

Given a unary predicate pred and a view r, drop_while_view produces a view of the range [ranges::find_if_not(r, pred), ranges::end(r)].

The name views::drop_while denotes a range adaptor object (26.7.2). Given subexpressions E and F, the expression views::drop_while(E, F) is expression-equivalent to drop_while_view(E, F).

[Example 1:]
constexpr auto source = " \t \t \t hello there"sv;
auto is_invisible = [](const auto x) { return x == ' ' || x == '\' \t'; };
auto skip_ws = views::drop_while(source, is_invisible);
for (auto c : skip_ws) {
    cout << c; // prints hello there with no leading space
}
—end example]
26.7.13.2 Class template drop_while_view

```cpp
namespace std::ranges {
    template<view V, class Pred>
    requires input_range<V> && is_object_v<Pred> &&
    indirect_unary_predicate<const Pred, iterator_t<V>>
    class drop_while_view : public view_interface<drop_while_view<V, Pred>> {
    public:
        drop_while_view() requires default_initializable<V> && default_initializable<Pred> = default;
        constexpr explicit drop_while_view(V base, Pred pred);
        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }
        constexpr const Pred& pred() const;
        constexpr auto begin();
        constexpr auto end() { return ranges::end(base_); }
    private:
        V base_ = V(); // exposition only
        movable-box<Pred> pred_; // exposition only
    }; // exposition only

template<class R, class Pred>
drop_while_view(R&&, Pred) -> drop_while_view<views::all_t<R>, Pred>;
}
```

**Effects:** Initializes `base_` with `std::move(base)` and `pred_` with `std::move(pred)`.

**Preconditions:** `pred_.has_value()` is true.

**Remarks:** In order to provide the amortized constant-time complexity required by the range concept when `drop_while_view` models `forward_range`, the first call caches the result within the `drop_while_view` for use on subsequent calls.

[Note 1: Without this, applying a `reverse_view` over a `drop_while_view` would have quadratic iteration complexity. —end note]

26.7.14 Join view

26.7.14.1 Overview

**join_view** flattens a view of ranges into a view.

The name `views::join` denotes a range adaptor object (26.7.2). Given a subexpression `E`, the expression `views::join(E)` is expression-equivalent to `join_view<views::all_t<decltype((E))>>{E}`.

[Example 1:

```cpp
vector<string> ss{"hello", " ", "world", "!"};
for (char ch : ss | views::join) cout << ch; // prints hello world!
```
—end example]

26.7.14.2 Class template join_view

```cpp
namespace std::ranges {
    template<input_range V>
    requires view<V> && input_range<range_reference_t<V>>
```
class join_view : public view_interface<join_view<V>> {
private:
    using InnerRng = range_reference_t<V>; // exposition only

    // 26.7.14.3, class template join_view::iterator
    template<bool Const>
    struct iterator; // exposition only

    // 26.7.14.4, class template join_view::sentinel
    template<bool Const>
    struct sentinel; // exposition only

    V base_ = V(); // exposition only

    non-propagating-cache<iterator_t<V>> outer_; // exposition only, present only
    non-propagating-cache<remove_cv_t<InnerRng>> inner_; // exposition only, present only

public:
    join_view() requires default_initializable<V> = default;
    constexpr explicit join_view(V base);

    constexpr V base() const & requires copy_constructible<V> { return base_; }
    constexpr V base() && { return std::move(base_); }

    constexpr auto begin() { return iterator<false>{*this}; }
    constexpr auto begin() const requires forward_range<const V> && is_reference_v<range_reference_t<const V>> && input_range<range_reference_t<const V>> { return iterator<true>{*this}; }

    constexpr auto end() { return sentinel<simple-view<V>>{*this}; }
    constexpr auto end() const requires forward_range<const V> && is_reference_v<range_reference_t<const V>> && input_range<range_reference_t<const V>> { return sentinel<true>{*this}; }
};
namespace std::ranges {
    template<input_range V> requires view<V> && input_range<range_reference_t<V>>

            OuterIter outer_ = OuterIter(); // exposition only, present only
            optional<InnerIter> inner_; // exposition only
            Parent* parent_ = nullptr; // exposition only
           constexpr void satisfy(); // exposition only
            constexpr OuterIter& outer(); // exposition only
            constexpr const OuterIter& outer() const; // exposition only

            constexpr iterator(Parent& parent, OuterIter outer) requires forward_range<Base>; // exposition only
            constexpr explicit iterator(Parent& parent) requires (!forward_range<Base>); // exposition only

        public:
            using iterator_concept = see below;
            using iterator_category = see below; // not always present
            using value_type = range_value_t<range_reference_t<Base>>;
            using difference_type = see below;
            iterator() = default;
            constexpr iterator(iterator<!Const> i) requires Const &&
                convertible_to<iterator_t<V>, OuterIter> &&
                convertible_to<iterator_t<InnerRng>, InnerIter>;
            constexpr decltype(auto) operator*() const { return **inner_; }
            constexpr InnerIter operator->() const
                requires has_arrow<InnerIter> && copyable<InnerIter>;
            constexpr iterator& operator++();
            constexpr void operator++(int);
            constexpr iterator operator++(int) requires ref_is_glvalue && forward_range<Base> &&
                forward_range<range_reference_t<Base>>;
        }
    }
}

§ 26.7.14.3 1183
constexpr iterator & operator--()
requires ref-is-glvalue && bidirectional_range<Base> &&
        common_range<range_reference_t<Base>>;

constexpr iterator operator--(int)
requires ref-is-glvalue && bidirectional_range<Base> &&
        common_range<range_reference_t<Base>>;

friend constexpr bool operator==(const iterator & x, const iterator & y)
requires ref-is-glvalue && forward_range<Base> &&
        equality_comparable<iterator_t<range_reference_t<Base>>>;

friend constexpr decltype(auto) iter_move(const iterator & i)
noexcept(noexcept(ranges::iter_move(*i.inner_))) {
    return ranges::iter_move(*i.inner_);
}

friend constexpr void iter_swap(const iterator & x, const iterator & y)
noexcept(noexcept(ranges::iter_swap(*x.inner_, *y.inner_)))
requires indirectly_swappable<InnerIter>;

1 iterator::iterator_concept is defined as follows:

(1.1) — If ref-is-glvalue is true, Base models bidirectional_range, and
        range_reference_t<Base> models both bidirectional_range and
        common_range, then iterator_concept denotes bidirectional_iterator_tag.

(1.2) — Otherwise, if ref-is-glvalue is true and Base and range_reference_t<Base>
        each model forward_range, then iterator_concept denotes forward_iterator_tag.

(1.3) — Otherwise, iterator_concept denotes input_iterator_tag.

2 The member typedef-name iterator_category is defined if and only if ref-is-glvalue
        is true, Base models forward_range, and range_reference_t<Base> models forward_range.
        In that case, iterator::iterator_category is defined as follows:

(2.1) — Let OUTERC denote iterator_traits<iterator_t<Base>>::iterator_category, and let INNERC
        denote iterator_traits<iterator_t<range_reference_t<Base>>>::iterator_category.

(2.2) — If OUTERC and INNERC each model derived_from<bidirectional_iterator_tag> and
        range_reference_t<Base> models common_range, iterator_category denotes bidirectional_iterator_tag.

(2.3) — Otherwise, if OUTERC and INNERC each model derived_from<forward_iterator_tag>, iterator_category
denotes forward_iterator_tag.

(2.4) — Otherwise, iterator_category denotes input_iterator_tag.

3 iterator::difference_type denotes the type:

    common_type_t<
        range_difference_t<Base>,
        range_difference_t<range_reference_t<Base>>>

4 join_view iterators use the satisfy function to skip over empty inner ranges.

constexpr OuterIter & outer();
constexpr const OuterIter & outer() const;

5 Returns: outer_ if Base models forward_range; otherwise, *parent_ -> outer_.

constexpr void satisfy();

6 Effects: Equivalent to:

    auto update_inner = [this](const iterator_t<Base> & x) -> auto& {
        if constexpr (ref-is-glvalue)  // *x is a reference

§ 26.7.14.3 1184
return *x;
else
    return parent_\rightarrow inner_.emplace-deref(x);
};

for (; outer() != ranges::end(parent_\rightarrow base_); ++outer()) {
    auto&& inner = update_inner(outer());

26.7.15 Join with view

26.7.15.1 Overview

join_with_view takes a view and a delimiter, and flattens the view, inserting every element of the delimiter in between elements of the view. The delimiter can be a single element or a view of elements.

The name views::join_with denotes a range adaptor object (26.7.2). Given subexpressions E and F, the expression views::join_with(E, F) is expression-equivalent to join_with_view(E, F).

[Example 1:
    vector<string> vs = {"the", "quick", "brown", "fox"};
    for (char c : vs | views::join_with(‘-‘)) {
        cout << c;
    }
    // The above prints the-quick-brown-fox
    —end example]

26.7.15.2 Class template join_with_view

    friend constexpr bool operator==(const iterator& x, const iterator& y) requires ref_is_glvalue && forward_range<Base> &&
                                      equality_comparable<InnerIter>;
    } // namespace std::ranges

§ 26.7.15.3
friend constexpr decltype(auto) iter_move(const iterator x) {
    using rvalue_reference = common_reference_t<
        iter_rvalue_reference_t<InnerIter>,
        iter_rvalue_reference_t<PatternIter>>;
    return visit<rvalue_reference>(ranges::iter_move, x.inner_it_);
}

friend constexpr void iter_swap(const iterator x, const iterator y)
requires indirectly_swappable<InnerIter, PatternIter> {
    visit(ranges::iter_swap, x.inner_it_, y.inner_it_);
}

iterator::iterator_concept is defined as follows:

(1.1) — If ref-is-glvalue is true, Base models bidirectional_range, and InnerBase and PatternBase each model bidirectional_common, then iterator_concept denotes bidirectional_iterator_tag.

(1.2) — Otherwise, if ref-is-glvalue is true and Base and InnerBase each model forward_range, then iterator_concept denotes forward_iterator_tag.

(1.3) — Otherwise, iterator_concept denotes input_iterator_tag.

The member typedef-name iterator_category is defined if and only if ref-is-glvalue is true, and Base and InnerBase each model forward_range. In that case, iterator::iterator_category is defined as follows:

(2.1) — Let OUTERC denote iterator_traits<OuterIter>::iterator_category, let INNERC denote iterator_traits<InnerIter>::iterator_category, and let PATTERNC denote iterator_traits<PatternIter>::iterator_category.

(2.2) — If
    is_reference_v<common_reference_t<
        iter_reference_t<InnerIter>,
        iter_reference_t<PatternIter>>> is false,
    iterator_category denotes input_iterator_tag.

(2.3) — Otherwise, if OUTERC, INNERC, and PATTERNC each model derived_from<bidirectional_iterator_category> and InnerBase and PatternBase each model common_range, iterator_category denotes bidirectional_iterator_tag.

(2.4) — Otherwise, if OUTERC, INNERC, and PATTERNC each model derived_from<forward_iterator_tag>, iterator_category denotes forward_iterator_tag.

(2.5) — Otherwise, iterator_category denotes input_iterator_tag.

iterator::value_type denotes the type:
    common_type_t<
        iter_value_t<InnerIter>,
        iter_value_t<PatternIter>>

iterator::difference_type denotes the type:
    common_type_t<
        iter_difference_t<OuterIter>,
        iter_difference_t<InnerIter>,
        iter_difference_t<PatternIter>>

constexpr OuterIter& outer();
constexpr const OuterIter& outer() const;

Returns: outer_it_ if Base models forward_range; otherwise, *parent_->outer_it_.

constexpr auto& update-inner();

Effects: Equivalent to:
    if constexpr (ref-is-glvalue)
        return as-lvalue(*outer());
    else
        return parent_->inner_.emplace_deref(outer());

§ 26.7.15.3 1190
constexpr auto& get-inner();

Effects: Equivalent to:
if constexpr (ref-is-glvalue)
  return as-lvalue(*outer());
else
  return *parent_->inner_;
constexpr void satisfy();

Effects: Equivalent to:
while (true) {
  if (inner_it_.index() == 0) {
    if (std::get<0>(inner_it_) != ranges::end(parent_->pattern_))
      break;
    inner_it_.emplace<1>(ranges::begin(update-inner()));
  } else {
    if (std::get<1>(inner_it_) != ranges::end(get-inner()))
      break;
    if (++outer() == ranges::end(parent_->base_)) {
      if constexpr (ref-is-glvalue)
        inner_it_.emplace<0>();
      break;
    }
    inner_it_.emplace<0>(ranges::begin(parent_->pattern_));
  }
}

[Note 1: join_with_view iterators use the satisfy function to skip over empty inner ranges. — end note]

constexpr iterator(Parent& parent, OuterIter outer)
  requires forward_range<Base>;
constexpr explicit iterator(Parent& parent)
  requires (!forward_range<Base>);

Effects: Initializes parent_ with addressof(parent). For the first overload, also initializes outer_it_ with std::move(outer). Then, equivalent to:
if (outer() != ranges::end(parent_->base_)) {
  inner_it_.emplace<1>(ranges::begin(update-inner()));
satisfy();
}

constexpr iterator(iterator<!Const> i)
  requires Const && convertible_to<iterator_t<OuterIter>, OuterIter> &&
  convertible_to<iterator_t<InnerRng>, InnerIter> &&
  convertible_to<iterator_t<Pattern>, PatternIter>;

Effects: Initializes outer_it_ with std::move(i.outer_it_) and parent_ with i.parent_. Then, equivalent to:
if (i.outer_it_.index() == 0)
  inner_it_.emplace<0>(std::get<0>(std::move(i.inner_it_)));
else
  inner_it_.emplace<1>(std::get<1>(std::move(i.inner_it_)));

[Note 2: Const can only be true when Base models forward_range. — end note]

castexpr decltype(auto) operator*() const;

Effects: Equivalent to:
using reference =
  common_reference_t<iter_reference_t<InnerIter>, iter_reference_t<PatternIter>>;
return visit([](auto& it) -> reference { return *it; }, inner_it_);

castexpr iterator& operator++();

Effects: Equivalent to:
visit([](auto& it) { ++it; }, inner_it_);
```cpp
satisfy();
return *this;

constexpr void operator++(int);

Effects: Equivalent to +++this.

constexpr iterator operator++(int)
requires ref-is-glvalue & forward_iterator<OuterIter> & forward_iterator<InnerIter>;

Effects: Equivalent to:
iterator tmp = *this;
+++this;
return tmp;

constexpr iterator& operator--()
requires ref-is-glvalue & bidirectional_range<Base> &
bidirectional-common<InnerBase> & bidirectional-common<PatternBase>;

Effects: Equivalent to:
if (outer_it_ == ranges::end(parent_->base_)) {
    auto& inner = *--outer_it_;  
    inner_it_.emplace<1>(ranges::end(inner));
}
while (true) {
    if (inner_it_.index() == 0) {
        auto it = std::get<0>(inner_it_);
        if (it == ranges::begin(parent_->pattern_)) {
            auto& inner = *--outer_it_;  
            inner_it_.emplace<1>(ranges::end(inner));
        } else {
            break;
        }
    } else {
        auto it = std::get<1>(inner_it_);
        auto& inner = *outer_it_;  
        if (it == ranges::begin(inner)) {
            inner_it_.emplace<0>(ranges::end(parent_->pattern_));
        } else {
            break;
        }
    }
    visit([](auto& it){ --it; }, inner_it_);
return *this;
}

friend constexpr bool operator==(const iterator& x, const iterator& y)
requires ref-is-glvalue & forward_range<Base> &
equality_comparable<InnerIter>;

Effects: Equivalent to:
iterator tmp = *this;
--*this;
return tmp;
```

26.7.15.4 Class template join_with_view::sentinel

```cpp
namespace std::ranges {
    template<input_range V, forward_range Pattern>
```
requires view<V> && input_range<range_reference_t<V>>
&& view<Pattern> && compatible-joinable-ranges<range_reference_t<V>, Pattern>

template<Bool Const>
class join_with_view<V, Pattern>::sentinel {
  using Parent = maybe-const<Const, join_with_view>; // exposition only
  using Base = maybe-const<Const, V>;
  // exposition only
  sentinel_t<Base> end_ = sentinel_t<Base>();
  // exposition only

  constexpr explicit sentinel(Parent& parent);
  // exposition only

  public:
    sentinel() = default;
    constexpr sentinel(sentinel<!Const> s)
      requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
      // exposition only

    template<Bool OtherConst>
    requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
    friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
    // exposition only

  constexpr explicit sentinel(Parent& parent);

  Effects: Initializes end_ with ranges::end(parent.base_).

  constexpr sentinel(sentinel<!Const> s)
      requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
    Effects: Initializes end_ with std::move(s.end_).

  template<Bool OtherConst>
      requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
      friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
    Effects: Equivalent to: return x.outer() == y.end_;

26.7.16 Lazy split view

26.7.16.1 Overview

The name views::lazy_split denotes a range adaptor object (26.7.2). Given subexpressions E and F, the expression views::lazy_split(E, F) is expression-equivalent to lazy_split_view(E, F).

[Example 1:

```c
string str{"the quick brown fox"};
for (auto word : str | views::lazy_split(' ')) {
  for (char ch : word)
    cout << ch;
  cout << '*';
}
// The above prints the*quick*brown*fox*
```
—end example]

26.7.16.2 Class template lazy_split_view

```c
namespace std::ranges {
  template<auto> struct require-constant;
  // exposition only

  template<class R>
  concept tiny-range =
      sized_range<R> &&
      requires { typename require-constant<remove_reference_t<R>::size>(); } &&
      (remove_reference_t<R>::size() <= 1);

  § 26.7.16.2 1193
```
template<input_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
    indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to> &&
    (forward_range<V> || tiny-range<Pattern>)
class lazy_split_view : public view_interface<lazy_split_view<V, Pattern>> {
    private:
    V base_ = V(); // exposition only
    Pattern pattern_ = Pattern(); // exposition only
    non-propagating-cache<iterator_t<V>> current_; // exposition only, present only
    // if forward_range<V> is false
    // 26.7.16.3, class template lazy_split_view::outer_iterator
    template<bool> struct outer_iterator;
    // exposition only
    // 26.7.16.5, class template lazy_split_view::inner_iterator
    template<bool> struct inner_iterator;
    // exposition only

class lazy_split_view() {

                }
            
            // 26.7.16.4.1, struct lazy_split_view::outer-iterator::operator*()
            using value_type = range_difference_t<Base>;  

            // 26.7.16.4.2, struct lazy_split_view::outer-iterator::operator++()  

            // 26.7.16.4.3, struct lazy_split_view::outer-iterator::operator++(int)  

        }
    }  
}
friend constexpr bool operator==(const outer-iterator& x, const outer-iterator& y) 
requires forward_range<Base>;

friend constexpr bool operator==(const outer-iterator& x, default_sentinel_t);
);

1 Many of the specifications in 26.7.16 refer to the notional member current of outer-iterator. current is 
equivalent to current_ if V models forward_range, and *parent_→current_ otherwise.

costexpr explicit outer-iterator(Parent& parent) 
requires (!forward_range<Base>);

2 Effects: Initializes parent_ with addressof(parent).

costexpr outer-iterator(Parent& parent, iterator_t<Base> current) 
requires forward_range<Base>;

3 Effects: Initializes parent_ with addressof(parent) and current_ with std::move(current).

costexpr outer-iterator(!Const> i) 
requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;

4 Effects: Initializes parent_ with i, parent_ and current_ with std::move(i.current_).

costexpr value_type operator*() const;

5 Effects: Equivalent to: return value_type(*this);

costexpr outer-iterator& operator++();

6 Effects: Equivalent to:
    const auto end = ranges::end(parent_→base_); 
    if (current == end) {

Effects: Equivalent to ranges::iter_swap(x.i_.current, y.i_.current).

26.7.17 Split view [range.split]

26.7.17.1 Overview [range.split.overview]

split_view takes a view and a delimiter, and splits the view into subranges on the delimiter. The delimiter can be a single element or a view of elements.

The name views::split denotes a range adaptor object (26.7.2). Given subexpressions E and F, the expression views::split(E, F) is expression-equivalent to split_view(E, F).

[Example 1:]

    string str{"the quick brown fox"};
    for (auto word : views::split(str, ' ')) {
        cout << string_view(word) << '*';
    }
    // The above prints the*quick*brown*fox*

—end example]

26.7.17.2 Class template split_view [range.split.view]

namespace std::ranges {

    template<forward_range V, forward_range Pattern>
    requires view<V> && view<Pattern> &&
        indirectly_comparable<iterator_t<V>, iterator_t<Pattern>, ranges::equal_to>
    class split_view : public view_interface<split_view<V, Pattern>> {

    private:
        V base_ = V(); // exposition only
        Pattern pattern_ = Pattern(); // exposition only

    // 26.7.17.3, class split_view::iterator
    struct iterator;

    // 26.7.17.4, class split_view::sentinel
    struct sentinel;

    public:
        split_view()
            requires default_initializable<V> && default_initializable<Pattern> = default;
            constexpr explicit split_view(V base, Pattern pattern);

    template<forward_range R>
    requires constructible_from<V, views::all_t<R>> &&
        constructible_from<Pattern, single_view<range_value_t<R>>>
    constexpr explicit split_view(R&& r, range_value_t<R> e);

§ 26.7.17.2 1199
constexpr V base() const & requires copy_constructible<V> { return base_; }
constexpr V base() && { return std::move(base_); }

constexpr iterator begin();
constexpr auto end() {
  if constexpr (common_range<V>) {
    return iterator{*this, ranges::end(base_), {}};
  } else {
    return sentinel{*this};
  }
}

constexpr subrange<iterator_t<V>> find-next(iterator_t<V>); // exposition only

template<class R, class P>
split_view(R&&, P&&) -> split_view<views::all_t<R>, views::all_t<P>>;

template<forward_range R>
split_view(R&&, range_value_t<R>)
  -> split_view<views::all_t<R>, single_view<range_value_t<R>>;}

constexpr explicit split_view(V base, Pattern pattern);

Effects: Initializes base_ with std::move(base), and pattern_ with std::move(pattern).

template<forward_range R>
requires constructible_from<V, views::all_t<R>> &&
constructible_from<Pattern, single_view<range_value_t<R>>>
constexpr explicit split_view(R&& r, range_value_t<R> e);

Effects: Initializes base_ with views::all(std::forward<R>(r)), and pattern_ with views::
single(std::move(e)).

constexpr iterator begin();
Returns: {*this, ranges::begin(base_), find-next(ranges::begin(base_))}.

Remarks: In order to provide the amortized constant time complexity required by the range concept,
this function caches the result within the split_view for use on subsequent calls.

constexpr subrange<iterator_t<V>> find-next(iterator_t<V> it);

Effects: Equivalent to:

auto [b, e] = ranges::search(subrange(it, ranges::end(base_), pattern_);
if (b != ranges::end(base_) && ranges::empty(pattern_;) {
  ++b;
  ++e;
}
return {b, e};

                return ranges::size(base_);
            }

    };

    template<class R>
    common_view(R&&) -> common_view<views::all_t<R>>;

    constexpr explicit common_view(V base);
    
    Effects: Initializes base_ with std::move(base).

}
26.7.20 Reverse view

26.7.20.1 Overview

reverse_view takes a bidirectional view and produces another view that iterates the same elements in reverse order.

The name views::reverse denotes a range adaptor object (26.7.2). Given a subexpression E, the expression views::reverse(E) is expression-equivalent to:

1. If the type of E is a (possibly cv-qualified) specialization of reverse_view, equivalent to E.base().
2. Otherwise, if the type of E is cv subrange<reverse_iterator<I>, reverse_iterator<I>, K> for some iterator type I and value K of type subrange_kind,
   a. if K is subrange_kind::sized, equivalent to:
      subrange<I, I, K>(E.end().base(), E.begin().base(), E.size())
   b. otherwise, equivalent to:
      subrange<I, I, K>(E.end().base(), E.begin().base())

However, in either case E is evaluated only once.

Example 1:
vector<int> is {0,1,2,3,4};
for (int i : is | views::reverse)
    cout << i << " "; // prints 4 3 2 1 0

26.7.20.2 Class template reverse_view

namespace std::ranges {
    template<class V>
    requires bidirectional_range<V>
    class reverse_view : public view_interface<reverse_view<V>> {
        private:
            V base_ = V(); // exposition only

        public:
            reverse_view() requires default_initializable<V> = default;

            constexpr explicit reverse_view(V r);

            constexpr V base() const & requires copy_constructible<V> { return base_; }
            constexpr V base() && { return std::move(base_); }

            constexpr reverse_iterator<iterator_t<V>> begin();
            constexpr auto begin() const requires common_range<const V>;

            constexpr auto end() const requires common_range<const V>;

            constexpr auto size() requires sized_range<V> {
                return ranges::size(base_);
            }

            constexpr auto size() const requires sized_range<const V> {
                return ranges::size(base_);
            }
    };

    template<class R>
    reverse_view(R&&) -> reverse_view<views::all_t<R>>;
}
constexpr explicit reverse_view(V base);

    Effects: Initializes base_ with std::move(base).

constexpr reverse_iterator<iterator_t<V>> begin();

    Returns:
    
    make_reverse_iterator(ranges::next(ranges::begin(base_), ranges::end(base_)))

    Remarks: In order to provide the amortized constant time complexity required by the range concept, this function caches the result within the reverse_view for use on subsequent calls.

constexpr reverse_iterator<iterator_t<V>> begin() requires common_range<V>;  
constexpr auto begin() const requires common_range<const V>;

    Effects: Equivalent to: return make_reverse_iterator(ranges::end(base_));

constexpr reverse_iterator<iterator_t<V>> end();

constexpr auto end() const requires common_range<const V>;

    Effects: Equivalent to: return make_reverse_iterator(ranges::begin(base_));

26.7.21 As const view

26.7.21.1 Overview

as_const_view presents a view of an underlying sequence as constant. That is, the elements of an as_const_view cannot be modified.

[Example 1]:

```cpp
template<constant_range R>
void cant_touch_this(R&&);

vector<char> hammer = {'m', 'c'};
span<char> beat = hammer;
cant_touch_this(views::as_const(beat)); // will not modify the elements of hammer
```

26.7.21.2 Class template as_const_view

namespace std::ranges {

    template<view V>
    class as_const_view : public view_interface<as_const_view<V>> {
        V base_ = V(); // exposition only

    public:
        as_const_view() requires default_initializable<V> = default;
        constexpr explicit as_const_view(V base) = default;

        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }

    };

} // namespace std::ranges
constexpr auto begin() requires (!simple-view<V>) { return ranges::cbegin(base_); }
constexpr auto begin() const requires range<const V> { return ranges::cbegin(base_); }
constexpr auto end() requires (!simple-view<V>) { return ranges::cend(base_); }
constexpr auto end() const requires range<const V> { return ranges::cend(base_); }
constexpr auto size() requires sized_range<V> { return ranges::size(base_); }
constexpr auto size() const requires sized_range<const V> { return ranges::size(base_); }
};

```cpp
template<class R>
as_const_view(R&&) -> as_const_view<views::all_t<R>>;
```

constexpr explicit as_const_view(V base);

Effects: Initializes base_ with std::move(base).

### 26.7.22 Elements view

#### 26.7.22.1 Overview

`elements_view` takes a view of tuple-like values and a size_t, and produces a view with a value-type of the N\textsuperscript{th} element of the adapted view’s value-type.

The name `views::elements<N>` denotes a range adaptor object (26.7.2). Given a subexpression E and constant expression N, the expression `views::elements<N>(E)` is expression-equivalent to `elements_view<views::all_t<decltype((E))>, N>{E}`.

**Example 1:**
```cpp
auto historical_figures = map{
    pair("Lovelace"sv, 1815),
    {"Turing"sv, 1912},
    {"Babbage"sv, 1791},
    {"Hamilton"sv, 1936}
};

auto names = historical_figures | views::elements<0>;
for (auto&& name : names) {
    cout << name << ' '; // prints Babbage Hamilton Lovelace Turing
}
```

**Example 2:**
```cpp
auto birth_years = historical_figures | views::elements<1>;
for (auto& born : birth_years) {
    cout << born << ' '; // prints 1791 1936 1815 1912
}
```

**Example 3:**
```cpp
auto is_even = [](const auto x) { return x % 2 == 0; };
cout << ranges::count_if(historical_figures | views::values, is_even); // prints 2
```

#### 3 keys_view

`keys_view` is an alias for `elements_view<R, 0>`, and is useful for extracting keys from associative containers.

**Example 2:**
```cpp
auto names = historical_figures | views::keys;
for (auto& name : names) {
    cout << name << ' '; // prints Babbage Hamilton Lovelace Turing
}
```

#### 4 values_view

`values_view` is an alias for `elements_view<R, 1>`, and is useful for extracting values from associative containers.

**Example 3:**
```cpp
auto is_even = [] (const auto x) { return x % 2 == 0; };
cout << ranges::count_if(historical_figures | views::values, is_even); // prints 2
```
26.7.22.2 Class template `elements_view`

```cpp
namespace std::ranges {
    template<class T, size_t N>
    concept has-tuple-element = // exposition only
        tuple-like<T> && N < tuple_size_v<T>;

    template<class T, size_t N>
    concept returnable-element = // exposition only
        is_reference_v<T> || move_constructible<tuple_element_t<N, T>>;

§ 26.7.22.3
friend constexpr difference_type operator-(const iterator& x, const iterator& y)  
  requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;  
};

The member typedef-name iterator_concept is defined as follows:

— If Base models random_access_range, then iterator_concept denotes random_access_iterator_tag.

— Otherwise, if Base models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.

— Otherwise, if Base models forward_range, then iterator_concept denotes forward_iterator_tag.

— Otherwise, iterator_concept denotes input_iterator_tag.

The member typedef-name iterator_category is defined if and only if Base models forward_range. In that case, iterator_category is defined as follows: Let C denote the type iterator_traits<iterator_t<Base>>::iterator_category.

— If std::get<N>(*current_) is an rvalue, iterator_category denotes input_iterator_tag.

— Otherwise, if C models derived_from<random_access_iterator_tag>, iterator_category denotes random_access_iterator_tag.

— Otherwise, iterator_category denotes C.

static constexpr decltype(auto) get-element(const iterator_t<Base>& i);

Effects: Equivalent to:

if constexpr (is_reference_v<range_reference_t<Base>>) {

26.7.23 Enumerate view

26.7.23.1 Overview

enumerate_view is a view whose elements represent both the position and value from a sequence of elements.

The name views::enumerate denotes a range adaptor object. Given a subexpression E, the expression views::enumerate(E) is expression-equivalent to enumerate_view<views::all_t<decltype((E))>>(E).

[Example 1:
vector<int> vec{ 1, 2, 3 };  // begin example
for (auto [index, value] : views::enumerate(vec))
  cout << index << ":" << value << ' ' << std::flush;  // prints 0:1 1:2 2:3
—end example]

26.7.23.2 Class template enumerate_view

namespace std::ranges {
template<view V>
requires range-with-movable-references<V>
class enumerate_view : public view_interface<enumerate_view<V>> {
  V base_ = V();  // exposition only

  // 26.7.23.3, class template enumerate_view::iterator
template<bool Const>
class iterator;
  // exposition only

  // 26.7.23.4, class template enumerate_view::sentinel
template<bool Const>
class sentinel;
  // exposition only

public:
constexpr enumerate_view() requires default_initializable<V> = default;
constexpr explicit enumerate_view(V base);

      if constexpr (!zip-is-common<const Views> && ...) {
        return sentinel<true>(tuple-transform(ranges::end, views_);
      } else if constexpr ((random_access_range<const Views> && ...) {
        return begin() + iter_difference_t<iterator<true>>(size());
      } else {
        return iterator<true>(tuple-transform(ranges::end, views_);
      }
    }
}
Two `zip_view` objects have the same underlying sequence if and only if the corresponding elements of `views_` are equal (18.2) and have the same underlying sequence.

[Note 1: In particular, comparison of iterators obtained from `zip_view` objects that do not have the same underlying sequence is not required to produce meaningful results (25.3.4.11). — end note]
constexpr iterator& operator+=(difference_type x)
requires all-random-access<Const, Views...>;
constexpr iterator& operator-=(difference_type x)
requires all-random-access<Const, Views...>;
constexpr auto operator[](difference_type n) const
requires all-random-access<Const, Views...>;
friend constexpr bool operator==(const iterator& x, const iterator& y)
requires (equality_comparable<iterator_t<maybe-const<Const, Views>>> && ...);

requires (indirectly_swappable<iterator_t<maybe-const<Const, Views>>> && ...);
};
}

1 iterator::iterator_concept is defined as follows:

(1.1) — If all-random-access<Const, Views...> is modeled, then iterator_concept denotes random_access_iterator_tag.
(1.2) — Otherwise, if all-bidirectional<Const, Views...> is modeled, then iterator_concept denotes bidirectional_iterator_tag.
(1.3) — Otherwise, if all-forward<Const, Views...> is modeled, then iterator_concept denotes forward_iterator_tag.
(1.4) — Otherwise, iterator_concept denotes input_iterator_tag.

2 iterator::iterator_category is present if and only if all-forward<Const, Views...> is modeled.

3 If the invocation of any non-const member function of iterator exits via an exception, the iterator acquires a singular value.

constexpr explicit iterator(tuplet<iterator_t<maybe-const<Const, Views>>>...) current);

4 Effects: Initializes current_ with std::move(current).

constexpr iterator(iterator<Const& i)
requires Const && (convertible_to<iterator_t<Views>, iterator_t<const Views>> && ...);

5 Effects: Initializes current_ with std::move(i.current_).

constexpr auto operator*() const;

6 Effects: Equivalent to:

    return tuple-transform([](auto& i) -> decltype(auto) { return *i; }, current_);

constexpr iterator& operator++();

7 Effects: Equivalent to:

    tuple-for-each([](auto& i) { ++i; }, current_);
    return *this;
constexpr void operator++(int);

Effects: Equivalent to `*++this`.

constexpr iterator operator++(int) requires all-forward<Const, Views...>;

Effects: Equivalent to:

```
auto tmp = *this;
++*this;
return tmp;
```

constexpr iterator& operator--() requires all-bidirectional<Const, Views...>;

Effects: Equivalent to:

```
tuple-for-each([&]<class I>(I& i) { --i; }, current_);
return *this;
```

constexpr iterator operator--(int) requires all-bidirectional<Const, Views...>;

Effects: Equivalent to:

```
auto tmp = *this;
--*this;
return tmp;
```

constexpr iterator& operator+=(difference_type x) requires all-random-access<Const, Views...>;

Effects: Equivalent to:

```
tuple-for-each([&]<class I>(I& i) { i += iter_difference_t<I>(x); }, current_);
return *this;
```

constexpr iterator& operator-=(difference_type x) requires all-random-access<Const, Views...>;

Effects: Equivalent to:

```
tuple-for-each([&]<class I>(I& i) { i -= iter_difference_t<I>(x); }, current_);
return *this;
```

constexpr auto operator[](difference_type n) const requires all-random-access<Const, Views...>;

Effects: Equivalent to:

```
return tuple-transform([&]<class I>(I& i) -> decltype(auto) {
    return i[iter_difference_t<I>(n)];
}, current_);
```

friend constexpr bool operator==(const iterator& x, const iterator& y)
requires (equality_comparable<iterator_t<maybe-const<Const, Views>>> && ...);

Returns:

- x.current_ == y.current_ if all-bidirectional<Const, Views...> is true.
- Otherwise, true if there exists an integer 0 ≤ i < sizeof...(Views) such that bool(std::get<i>(x.current_) == std::get<i>(y.current_)) is true.

[Note 1: This allows zip_view to model common_range when all constituent views model common_range.]

- Otherwise, false.

friend constexpr auto operator<>(const iterator& x, const iterator& y)
requires all-random-access<Const, Views...>;

Returns: x.current_ < op y.current_.

friend constexpr iterator operator+(const iterator& i, difference_type n)
requires all-random-access<Const, Views...>;
friend constexpr iterator operator+(difference_type n, const iterator& i) 17
    requires all-random-access<Const, Views...>;

    Effects: Equivalent to:
    auto r = i;
    r += n;
    return r;

friend constexpr iterator operator-(const iterator& i, difference_type n) 18
    requires all-random-access<Const, Views...>;

    Effects: Equivalent to:
    auto r = i;
    r -= n;
    return r;

friend constexpr difference_type operator-(const iterator& x, const iterator& y) 19
    requires (sized_sentinel_for<iterator_t<maybe-const<Const, Views>>,
        iterator_t<maybe-const<Const, Views>>> && ...);

    Let DIST(i) be difference_type(std::get<i>(x.current_) - std::get<i>(y.current_)).

    Returns: The value with the smallest absolute value among DIST(n) for all integers 0 ≤ n < sizeof...(Views).

friend constexpr auto iter_move(const iterator& i) noexcept(see below); 21

    Effects: Equivalent to:
    return tuple-transform(ranges::iter_move, i.current_);

    Remarks: The exception specification is equivalent to:
    (noexcept(ranges::iter_move(declval<Const iterator_t<maybe-const<Const,
        Views>>> & )) && ...) &&
    (is_nothrow_move_constructible_v<range_rvalue_reference_t<maybe-const<
        Const, Views>>> && ...)

friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below) 23
    requires (indirectly_swappable<iterator_t<maybe-const<Const, Views>>,
        iterator_t<maybe-const<OtherConst, Views>>> && ...);

    Effects: For every integer 0 ≤ i < sizeof...(Views), performs:
    ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_))

    Remarks: The exception specification is equivalent to the logical AND of the following expressions:
    noexcept(ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_)))
for every integer 0 ≤ i < sizeof...(Views).

26.7.24.4  Class template zip_view::sentinel [range.zip.sentinel]

namespace std::ranges {
    template<input_range... Views>
        requires (view<Views> && ...) && (sizeof...(Views) > 0)
    template<Bool Const>
    class zip_view<Views...>::sentinel {
        tuple<sentinel_t<maybe-const<Const, Views>>, end_;  // exposition only
    contextexpr explicit sentinel(tuple<sentinel_t<maybe-const<Const, Views>>, end_);  // exposition only

public:
    sentinel() = default;
    constexpr sentinel(sentinel<!Const> i) 24
        requires Const && (convertible_to<sentinel_t<Views>, sentinel_t<const Views>> && ...);

    template<OtherConst>
    requires (sentinel_for<sentinel_t<maybe-const<Const, Views>>,
        iterator_t<maybe-const<OtherConst, Views>>> && ...)
    friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);
template<bool OtherConst>
    requires (sized_sentinel_for<sentinel_t<\maybe-const<Const, Views>>, iterator_t<\maybe-const<OtherConst, Views>>> && ...) 
friend constexpr common_type_t<range_difference_t<\maybe-const<OtherConst, Views>>...> 
    operator-(const iterator<\OtherConst>& x, const sentinel& y);

template<bool OtherConst>
    requires (sized_sentinel_for<sentinel_t<\maybe-const<Const, Views>>, iterator_t<\maybe-const<OtherConst, Views>>> && ...) 
friend constexpr common_type_t<range_difference_t<\maybe-const<OtherConst, Views>>...> 
    operator-(const sentinel& y, const iterator<\OtherConst>& x);

constexpr explicit sentinel(tuple<sentinel_t<\maybe-const<Const, Views>>>...> end);

Effects: Initializes end_ with end.

constexpr sentinel(sential<!Const> i)
    requires Const && (convertible_to<sentinel_t<Views>, sentinel_t<const Views>> && ...);

Effects: Initializes end_ with std::move(i.end_).

template<bool OtherConst>
    requires (sized_sentinel_for<sentinel_t<\maybe-const<Const, Views>>, iterator_t<\maybe-const<OtherConst, Views>>> && ...) 
friend constexpr bool operator==(const iterator<\OtherConst>& x, const sentinel& y);

Effects: Returns true if there exists an integer 0 ≤ i < sizeof...(Views) such that 
bool(std::get<i>(x.current_) == std::get<i>(y.end_)) is true. Otherwise, false.

template<bool OtherConst>
    requires (sized_sentinel_for<sentinel_t<\maybe-const<Const, Views>>, iterator_t<\maybe-const<OtherConst, Views>>> && ...) 
friend constexpr common_type_t<range_difference_t<\maybe-const<OtherConst, Views>>...> 
    operator-(const iterator<\OtherConst>& x, const sentinel& y);

Effects: Equivalent to return -(x - y);

26.7.25 Zip transform view

26.7.25.1 Overview

zip_transform_view takes an invocable object and any number of views and produces a view whose 
Mth element is the result of applying the invocable object to the Mth elements of all views.

The name views::zip_transform denotes a customization point object (16.3.3.3.5). Let F be a subexpression, 
and let Es... be a pack of subexpressions.

(2.1) If Es is an empty pack, let FD be decay_t<decltype((F))>.

(2.1.1) If move_constructible<FD> && regular_invocable<FD&> is false, or if decay_t<invoke_- 
result_t<FD&>> is not an object type, views::zip_transform(F, Es...) is ill-formed.

(2.1.2) Otherwise, the expression views::zip_transform(F, Es...) is expression-equivalent to 
((void)F, auto(views::empty<decay_t<invoke_result_t<FD&>>>))

(2.2) Otherwise, the expression views::zip_transform(F, Es...) is expression-equivalent to zip_trans-
form_view(F, Es...).
[Example 1]
vector v1 = {1, 2};
vector v2 = {4, 5, 6};

for (auto i : views::zip_transform(plus(), v1, v2)) {
  cout << i << ' ';  // prints 5 7
}
—end example

26.7.25.2 Class template zip_transform_view

namespace std::ranges {
  template<move_constructible F, input_range... Views>
  requires (view<Views> && ...) && (sizeof...(Views) > 0) && is_object_v<F> &&
  regular_invocable<F&, range_reference_t<Views>>, ...> &
  can_reference<invoke_result_t<F&, range_reference_t<Views>>, ...>>
  class zip_transform_view : public view_interface<zip_transform_view<F, Views>>, ...> {

requires random_access_range<Base>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y)  
requires sized_sentinel_for<ziperator<Const>, ziperator<Const>>;
};
}

1 The member typedef-name iterator::iterator_category is defined if and only if Base models forward_range. In that case, iterator::iterator_category is defined as follows:

(1.1) — If

invoke_result_t<maybe-const<Const, F>&, range_reference_t<maybe-const<Const, Views>>&>...

is not a reference, iterator_category denotes input_iterator_tag.

(1.2) — Otherwise, let Cs denote the pack of types iterator_traits<iterator_t<maybe-const<Const, Views>>>::iterator_category...

(1.2.1) — If (derived_from<Cs, random_access_iterator_tag> && ...) is true, iterator_category denotes random_access_iterator_tag.
(1.2.2) — Otherwise, if (derived_from<Cs, bidirectional_iterator_tag> && ...) is true, iterator_category denotes bidirectional_iterator_tag.
(1.2.3) — Otherwise, if (derived_from<Cs, forward_iterator_tag> && ...) is true, iterator_category denotes forward_iterator_tag.
(1.2.4) — Otherwise, iterator_category denotes input_iterator_tag.

constexpr iterator(Parent& parent, ziperator<Const> inner);
2 Effects: Initializes parent_ with addressof(parent) and inner_ with std::move(inner).

constexpr iterator(iterator<Const> i)  
requires Const && convertible_to<ziperator<false>, ziperator<Const>>;
3 Effects: Initializes parent_ with i.parent_ and inner_ with std::move(i.inner_).

constexpr decltype(auto) operator*() const noexcept(see below);
4 Effects: Equivalent to:

return apply([&](const auto&... iters) -> decltype(auto) {
    return invoke(*parent_->fun_, *iters...);
}, inner_.current_);

Remarks: Let Is be the pack 0, 1, ..., (sizeof...(Views)-1). The exception specification is equivalent to: noexcept(invoke(*parent_->fun_, *std::get<Is>(inner_.current_))...)).

constexpr iterator& operator++();
6 Effects: Equivalent to:

++inner_;  
return *this;

constexpr void operator++(int);
7 Effects: Equivalent to: ++*this.

constexpr iterator operator++(int) requires forward_range<Base>;
8 Effects: Equivalent to:

auto tmp = *this;  
++*this;  
return tmp;
constexpr iterator operator--() requires bidirectional_range<Base>;

**Effects:** Equivalent to:

```
--inner_;  
return *this;
```

constexpr iterator operator--(int) requires bidirectional_range<Base>;

**Effects:** Equivalent to:

```
auto tmp = *this;  
--*this;  
return tmp;
```

constexpr iterator& operator+=(difference_type x) requires random_access_range<Base>;

**Effects:** Equivalent to:

```
inner_ += x;  
return *this;
```

constexpr iterator& operator-=(difference_type x) requires random_access_range<Base>;

**Effects:** Equivalent to:

```
inner_ -= x;  
return *this;
```

constexpr decltype(auto) operator[](difference_type n) const requires random_access_range<Base>;

**Effects:** Equivalent to:

```
return apply([&]<class... Is>(const Is&... iters) -> decltype(auto) {
  return invoke(*parent_->fun_, iters[iter_difference_t<Is>(n)]...);
}, inner_.current_);
```

friend constexpr bool operator==(const iterator& x, const iterator& y) requires equality_comparable<ziperator<Const>>;

friend constexpr auto operator<=>(const iterator& x, const iterator& y) requires random_access_range<Base>;

**Effects:** Equivalent to:

```
return x.inner_ op y.inner_;  
```

friend constexpr iterator operator+(const iterator& i, difference_type n) requires random_access_range<Base>;

friend constexpr iterator operator+(difference_type n, const iterator& i) requires random_access_range<Base>;

**Effects:** Equivalent to:

```
return iterator(*i.parent_, i.inner_ + n);
```

friend constexpr iterator operator-(const iterator& i, difference_type n) requires random_access_range<Base>;

**Effects:** Equivalent to:

```
return iterator(*i.parent_, i.inner_ - n);
```

friend constexpr difference_type operator-(const iterator& x, const iterator& y) requires sized_sentinel_for<ziperator<Const>, ziterator<Const>>;

**Effects:** Equivalent to:

```
return x.inner_ - y.inner_;  
```

26.7.25.4 Class template zip_transform_view::sentinel

```cpp
namespace std::ranges {
    template<move_constructible F, input_range... Views>
    requires (view<View>... & & (sizeof...(View) > 0) & is_object_v<F> &
        regular_invocable<F, range_reference_t<View>...> &
        can_reference<invoke_result_t<F, range_reference_t<View>...>>
    template<bool Const>
    class zip_transform_view<F, Views...>::sentinel {

§ 26.7.25.4
sentinel<Const> inner_; // exposition only
constexpr explicit sentinel(sentinel<Const> inner); // exposition only

public:
    sentinel() = default;

    }
} // namespace std::ranges

§ 26.7.26.3 1229
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
   requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;

friend constexpr auto iter_move(const iterator& i) noexcept(see below);
friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
   requires indirectly_swappable<iterator_t<Base>>;

};

iterator::iterator_concept is defined as follows:
(1.1) — If Base models random_access_range, then iterator_concept denotes random_access_iterator_tag.
(1.2) — Otherwise, if Base models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.
(1.3) — Otherwise, iterator_concept denotes forward_iterator_tag.

1 If the invocation of any non-const member function of iterator exits via an exception, the iterator
   acquires a singular value.

constexpr iterator( iterator_t<Base> first, sentinel_t<Base> last);
3 Postconditions: current_ [0] == first is true, and for every integer 1 ≤ i < N, current_[i] ==
   ranges::next(current_[i-1], 1, last) is true.

constexpr iterator(as-sentinel, iterator_t<Base> first, iterator_t<Base> last);
4 Postconditions: If Base does not model bidirectional_range, each element of current_ is equal to
   last. Otherwise, current_[N-1] == last is true, and for every integer 0 ≤ i < (N-1), current_[i] ==
   ranges::prev(current_[i+1], 1, first) is true.

constexpr iterator( iterator<!Const> i)
   requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
5 Effects: Initializes each element of current_ with the corresponding element of i.current_ as an
   xvalue.

constexpr auto operator*() const;
6 Effects: Equivalent to:
   return tuple-transform([](auto& i) -> decltype(auto) { return *i; }, current_);

constexpr iterator& operator++();
7 Preconditions: current_.back() is incrementable.
8 Postconditions: Each element of current_ is equal to ranges::next(i), where i is the value of that
   element before the call.
9 Returns: *this.

constexpr iterator& operator++(int);
10 Effects: Equivalent to:
   auto tmp = *this;
   ***this;
   return tmp;

constexpr iterator& operator--() requires bidirectional_range<Base>;
11 Preconditions: current_.front() is decreementable.
12 Postconditions: Each element of current_ is equal to ranges::prev(i), where i is the value of that
   element before the call.
13 Returns: *this.

constexpr iterator& operator--(int) requires bidirectional_range<Base>;
14 Effects: Equivalent to:

§ 26.7.26.3
auto tmp = *this;
  --*this;
  return tmp;

constexpr iterator& operator+=(difference_type x)
  requires random_access_range<Base>;

  Preconditions: current_.back() + x has well-defined behavior.
  Postconditions: Each element of current_ is equal to i + x, where i is the value of that element
  before the call.

  Returns: *this.

constexpr iterator& operator-=(difference_type x)
  requires random_access_range<Base>;

  Preconditions: current_.front() - x has well-defined behavior.
  Postconditions: Each element of current_ is equal to i - x, where i is the value of that element
  before the call.

  Returns: *this.

constexpr auto operator[](difference_type n) const
  requires random_access_range<Base>;

  Effects: Equivalent to:
    return tuple-transform([&](auto& i) -> decltype(auto) { return i[n]; }, current_);

friend constexpr bool operator==(const iterator& x, const iterator& y);

friend constexpr bool operator<(const iterator& x, const iterator& y)
  requires random_access_range<Base>;

friend constexpr bool operator>(const iterator& x, const iterator& y)
  requires random_access_range<Base>;

friend constexpr bool operator<=(const iterator& x, const iterator& y)
  requires random_access_range<Base>;

friend constexpr bool operator>=(const iterator& x, const iterator& y)
  requires random_access_range<Base>;

friend constexpr auto operator<=>(const iterator& x, const iterator& y)
  requires random_access_range<Base> &&
  three_way_comparable<iterator_t<Base>>;

friend constexpr iterator operator+(const iterator& i, difference_type n)
  requires random_access_range<Base>;

friend constexpr iterator operator+(difference_type n, const iterator& i)
  requires random_access_range<Base>;

  Effects: Equivalent to:
    auto r = i;
    r += n;
    return r;
friend constexpr iterator operator-(const iterator& i, difference_type n)
    requires random_access_range<Base>;

Effects: Equivalent to:
    auto r = i;
    r -= n;
    return r;

friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base> >;

Effects: Equivalent to:
    return x.current_.back() - y.current_.back();

friend constexpr auto iter_move(const iterator& i) noexcept;

Effects: Equivalent to:
    return tuple-transform(ranges::iter_move, i.current_);

Remarks: The exception specification is equivalent to:
    noexcept(ranges::iter_move(declval<const iterator_t<Base>&>()) &&
        is_nothrow_move_constructible_v<range_rvalue_reference_t<Base>>)

friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept;

Preconditions: None of the iterators in l.current_ is equal to an iterator in r.current_.

Effects: For every integer \(0 \leq i < N\), performs ranges::iter_swap(l.current_[i], r.current_[i]).

Remarks: The exception specification is equivalent to:
    noexcept(ranges::iter_swap(declval<iterator_t<Base>>(), declval<iterator_t<Base>>()))

26.7.26.4 Class template adjacent_view::sentinel
    [range.adjacent.sentinel]

namespace std::ranges {
    template<forward_range V, size_t N>
        requires view<V> && (N > 0)
    template<bool Const>

        friend constexpr range_difference_t<maybe-const<OtherConst, V>>
            operator-(const iterator<OtherConst>& x, const sentinel& y);

    };

    constexpr explicit sentinel(sentinel_t<Base> end);

    Effects: Initializes end_ with end.
constexpr sentinel(sentinel<sentinel<!Const> i)
    requires Const && convertible_to<sentinel_t<V>, sentinel_t<Base>>;

Effects: Initializes end_ with std::move(i.end_).

template<bool OtherConst>
    requires sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr bool operator==(const iterator<OtherConst>& x, const sentinel& y);

Effects: Equivalent to: return x.current_.back() == y.end;

template<bool OtherConst>
    requires sized_sentinel_for<sentinel_t<Base>, iterator_t<maybe-const<OtherConst, V>>>
friend constexpr range_difference_t<maybe-const<OtherConst, V>>
operator-(const sentinel& y, const iterator<OtherConst>& x);

Effects: Equivalent to: return y.end_ - x.current_.back();

26.7.27 Adjacent transform view

26.7.27.1 Overview

adjacent_transform_view takes an invocable object and a view and produces a view whose \(M\)th element is the result of applying the invocable object to the \(M\)th through \((M + N - 1)\)th elements of the original view. If the original view has fewer than \(N\) elements, the resulting view is empty.

The name \(\text{views::adjacent_transform}<N>\) denotes a range adaptor object (26.7.2). Given subexpressions \(E\) and \(F\) and a constant expression \(N\):

\[\text{(2.1)} \quad \text{If } N \text{ is equal to } 0, \text{ views::adjacent_transform}<N>(E, F) \text{ is expression-equivalent to } ((\text{void})E, \text{ views::zip_transform}(F)), \text{ except that the evaluations of } E \text{ and } F \text{ are indeterminately sequenced.}\]
\[\text{(2.2)} \quad \text{Otherwise, the expression } \text{views::adjacent_transform}<N>(E, F) \text{ is expression-equivalent to adjacent_transform_view<views::all_t<decay_t<(E)>>, decay_t<decltype((F))>>, N>(E, F).}\]

[Example 1:]

```cpp
vector v = {1, 2, 3, 4};
for (auto i : v | views::adjacent_transform<2>(std::multiplies())) {
    cout << i << ' '; // prints 2 6 12
}
```

—end example]
public:
adjacent_transform_view() = default;
constexpr explicit adjacent_transform_view(V base, F fun);

constexpr V base() const & requires copy_constructible<InnerView> { return inner_.base(); }
constexpr V base() && { return std::move(inner_.base()); }

constexpr auto begin() { return iterator<false>(*this, inner_.begin()); }
constexpr auto begin() const requires range<const InnerView> && regular_invocable<const F&, REPEAT(range_reference_t<const V>, N)...> { return iterator<true>(*this, inner_.begin()); }

constexpr auto end() { if constexpr (common_range<InnerView>) { return iterator<false>(*this, inner_.end()); } else { return sentinel<false>(inner_.end()); } }
constexpr auto end() const requires range<const InnerView> && regular_invocable<const F&, REPEAT(range_reference_t<const V>, N)...> { if constexpr (common_range<const InnerView>) { return iterator<true>(*this, inner_.end()); } else { return sentinel<true>(inner_.end()); } }

constexpr auto size() requires sized_range<InnerView> { return inner_.size(); }
constexpr auto size() const requires sized_range<const InnerView> { return inner_.size(); }

constexpr explicit adjacent_transform_view(V base, F fun);

Effects: Initializes fun_ with std::move(fun) and inner_ with std::move(base).

26.7.27.3 Class template adjacent_transform_view::iterator
[range.adjacent.transform.iterator]
namespace std::ranges {
  template<forward_range V, move_constructible F, size_t N>
  requires view<V> && (N > 0) && is_object_v<F> &&
  regular_invocable<F&, REPEAT(range_reference_t<V>, N)...> &&
  can_reference<invoke_result_t<F&>, REPEAT(range_reference_t<V>, N)...>>
  template<bool Const>
  class adjacent_transform_view<V, F, N>::iterator {
    using Parent = maybe-const<Const, adjacent_transform_view>;
    using Base = maybe-const<Const, V>;
    Parent* parent_ = nullptr;
  }
};
The member typedef-name iterator::iterator_category is defined as follows:

1. If invoke_result_t<maybe-const<Const, F>&, REPEAT(range_reference_t<Base>, N)...> is not a reference, iterator_category denotes input_iterator_tag.
2. Otherwise, let C denote the type iterator_traits<iterator_t<Base>>::iterator_category.
   1. If derived_from<C, random_access_iterator_tag> is true, iterator_category denotes random_access_iterator_tag.
   2. Otherwise, if derived_from<C, bidirectional_iterator_tag> is true, iterator_category denotes bidirectional_iterator_tag.
   3. Otherwise, if derived_from<C, forward_iterator_tag> is true, iterator_category denotes forward_iterator_tag.
   4. Otherwise, iterator_category denotes input_iterator_tag.
constexpr iterator (Parent & parent, inner_iterator<Const> inner);

2 Effects: Initializes parent_ with addressof(parent) and inner_ with std::move(inner).

constexpr iterator (iterator<!Const> i)
requires Const && convertible_to<inner_iterator<false>>, inner_iterator<Const>>;
3 Effects: Initializes parent_ with i.parent_ and inner_ with std::move(i.inner_).

constexpr decltype(auto) operator*() const noexcept;
4 Effects: Equivalent to:
return apply([&](const auto&... iters) -> decltype(auto) {
    return invoke(*parent_->fun_, *iters...);
}, inner_.current_);

Remarks: Let Is be the pack 0, 1, ..., (N-1). The exception specification is equivalent to:
noexcept(invoke(*parent_->fun_, std::get<Is>(inner_.current...)...))

operator-(const iterator<OtherConst>& x, const sentinel& y);

Effects: Equivalent to return x.inner_ - y.inner_

26.7.28 Chunk view

chunk_view takes a view and a number \(N\) and produces a range of views that are \(N\)-sized non-overlapping successive chunks of the elements of the original view, in order. The last view in the range can have fewer than \(N\) elements.

The name views::chunk denotes a range adaptor object (26.7.2). Given subexpressions \(E\) and \(N\), the expression views::chunk(E, N) is expression-equivalent to chunk_view(E, N).

[Example 1:

vector v = {1, 2, 3, 4, 5};

for (auto r : v | views::chunk(2)) {
    cout << '[';
    auto sep = " ";
    for (auto i : r) {
        cout << sep << i;
        sep = ", ";
    }
    cout << "] ";
}
// The above prints [1, 2] [3, 4] [5]
— end example]

26.7.28.2 Class template chunk_view for input ranges

namespace std::ranges {
    template<class I>
    constexpr I div ceil(I num, I denom) {
        // exposition only
        I r = num / denom;
        if (num % denom)
            ++r;
        return r;
    }

template<class V>
requires input_range<V>
    class chunk_view : public view_interface<chunk_view<V>> {
    V base_; // exposition only
    range_difference_t<V> n_; // exposition only
    range_difference_t<V> remainder_ = 0; // exposition only
    non-propagating-cache<iterator_t<V>> current_; // exposition only
}
// 26.7.28.3, class chunk_view::outer-iterator
class outer-iterator;  // exposition only

// 26.7.28.5, class chunk_view::inner-iterator
class inner-iterator;  // exposition only

public:

};

1 iterator::iterator_concept is defined as follows:

(1.1) — If Base models random_access_range, then iterator_concept denotes random_access_iterator_tag.
(1.2) Otherwise, if `Base` models `bidirectional_range`, then `iterator_concept` denotes `bidirectional_iterator_tag`.

(1.3) Otherwise, `iterator_concept` denotes `forward_iterator_tag`.

```cpp
constexpr iterator(Parent* parent, iterator_t<Base> current, range_difference_t<Base> missing = 0);
```

**Effects**: Initializes `current_` with `current`, `end_` with `ranges::end(parent->base_)`, `n_` with `parent->n_`, and `missing_` with `missing`.

```cpp
constexpr iterator(decltype(i) i) requires Const && convertible_to<iterator_t<V>, iterator_t<Base>> && convertible_to<sentinel_t<V>, sentinel_t<Base>>;
```

**Effects**: Initializes `current_` with `std::move(i.current_)`, `end_` with `std::move(i.end_)`, `n_` with `i.n_`, and `missing_` with `i.missing_`.

```cpp
constexpr iterator_t<Base> base() const;
```

**Returns**: `current_`.

```cpp
constexpr value_type operator*() const;
```

**Preconditions**: `current_ != end_` is true.

```cpp
constexpr iterator operator++();
```

**Preconditions**: `current_ != end_` is true.

**Effects**: Equivalent to:

- `missing_ = ranges::advance(current_, n_, end_);
- return *this;`

```cpp
constexpr iterator operator++(int);
```

**Effects**: Equivalent to:

- `auto tmp = *this;
- ++*this;
- return tmp;`

```cpp
constexpr iterator operator--() requires bidirectional_range<Base>;
```

**Effects**: Equivalent to:

- `ranges::advance(current_, missing_ - n_);
- missing_ = 0;
- return *this;`

```cpp
constexpr iterator operator--(int) requires bidirectional_range<Base>;
```

**Effects**: Equivalent to:

- `auto tmp = *this;
- --*this;
- return tmp;`

```cpp
constexpr iterator& operator+=(difference_type x) requires random_access_range<Base>;
```

**Preconditions**: If `x` is positive, `ranges::distance(current_, end_) > n_ * (x - 1)` is true.

[Note 1: If `x` is negative, the Effects paragraph implies a precondition. — end note]

**Effects**: Equivalent to:

- if `(x > 0)` {
  - `ranges::advance(current_, n_ * (x - 1));
  - missing_ = ranges::advance(current_, n_, end_);`
- } else if `(x < 0)` {
  - `ranges::advance(current_, n_ * x + missing_);`
constexpr iterator& operator=(difference_type x)
    requires random_access_range<Base>;
14
    Effects: Equivalent to: return *this += -x;

constexpr value_type operator[](difference_type n) const
    requires random_access_range<Base>;
15
    Returns: *(this + n).

friend constexpr bool operator==(const iterator& x, const iterator& y);
16
    Returns: x.current_ == y.current_.

friend constexpr bool operator==(const iterator& x, default_sentinel_t);
17
    Returns: x.current_ == x.end_.

friend constexpr bool operator<(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
18
    Effects: Equivalent to: return y < x;

friend constexpr bool operator>(const iterator& x, const iterator& y)
    requires random_access_range<Base>;
19
    Effects: Equivalent to: return x < y;

friend constexpr auto operator<=>(const iterator& x, const iterator& y)
    requires random_access_range<Base> &&
    three_way_comparable<iterator_t<Base>>;
20
    Returns: x.current_ <=> y.current_.

    requires random_access_range<Base>;
friend constexpr iterator operator+(difference_type n, const iterator& i)
    requires random_access_range<Base>;
21
    Effects: Equivalent to:
    auto r = i;
    r += n;
    return r;

friend constexpr operator-(const iterator& i, difference_type n)
    requires random_access_range<Base>;
22
    Effects: Equivalent to:
    auto r = i;
    r -= n;
    return r;

friend constexpr difference_type operator-(const iterator& x, const iterator& y)
    requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;
23
    Returns: (x.current_ - y.current_ + x.missing_ - y.missing_) / x.m_.
friend constexpr difference_type operator-(default_sentinel_t y, const iterator& x)  
requires sized_sentinel_for<sentinel_t<Base>, iterator_t<Base>>;

Returns: $\text{div-ceil}(x.\text{end_} - x.\text{current_}, x.\text{n_})$.

friend constexpr difference_type operator-(const iterator& x, default_sentinel_t y)  
requires sized_sentinel_for<sentinel_t<Base>, iterator_t<Base>>;

Effects: Equivalent to: return -(y - x);

### 26.7.29 Slide view

#### 26.7.29.1 Overview

slide_view takes a view and a number $N$ and produces a view whose $M^{th}$ element is a view over the $M^{th}$ through $(M + N - 1)^{th}$ elements of the original view. If the original view has fewer than $N$ elements, the resulting view is empty.

The name views::slide denotes a range adaptor object (26.7.2). Given subexpressions $E$ and $N$, the expression views::slide($E$, $N$) is expression-equivalent to slide_view($E$, $N$).

**Example 1:**
```cpp
vector v = {1, 2, 3, 4};
for (auto i : v | views::slide(2)) {
    cout << 'i' << i[0] << 'j' << i[1] << 'k' << i[2] << 'l' << i[3] << 'm';  // prints [1, 2] [2, 3] [3, 4]
}
```

--- end example

#### 26.7.29.2 Class template slide_view

namespace std::ranges {

concept slide-caches-nothing = random_access_range<V> && sized_range<V>; // exposition only

concept slide-caches-last =  
!slide-caches-nothing && bidirectional_range<V> && common_range<V>; // exposition only

concept slide-caches-first =  
!slide-caches-nothing && !slide-caches-last; // exposition only

template<forward_range V>
requires view<V>
class slide_view : public view_interface<slide_view<V>> {  
    V base_;  // exposition only
    range_difference_t<V> n_;  // exposition only

    // 26.7.29.3, class template slide_view::iterator
    template<bool> class iterator;  // exposition only

    // 26.7.29.4, class slide_view::sentinel
    class sentinel;  // exposition only

public:
    constexpr explicit slide_view(V base, range_difference_t<V> n);

cconstexpr V base() const & requires copy_constructible<V> { return base_; }  
cconstexpr V base() && { return std::move(base_); }

cconstexpr auto begin()  
requires (!view<V> && slide-caches-nothing<const V>);

cconstexpr auto begin() const requires slide-caches-nothing<const V>;

cconstexpr auto end()  
requires (!view<V> && slide-caches-nothing<const V>);
```
constexpr auto end() const requires `slide-caches-nothing<const V>`;
constexpr auto size() requires `sized_range<V>`;
constexpr auto size() const requires `sized_range<const V>`;

```

 template<class R>
 slide_view(R&&, range_difference_t<R>) -> slide_view<views::all_t<R>>;

```

constexpr explicit slide_view(V base, range_difference_t<V> n);

1 Preconditions: n > 0 is true.
2 Effects: Initializes `base_` with std::move(base) and `n_` with n.
3
4 Remarks: In order to provide the amortized constant-time complexity required by the range concept, this function caches the result within the `slide_view` for use on subsequent calls when V models `slide-caches-first`.

```
constexpr auto begin() const requires `slide-caches-nothing<const V>`;
returns: iterator<true>(ranges::begin(base_), n_).
```

6 Remarks: In order to provide the amortized constant-time complexity required by the range concept, this function caches the result within the `slide_view` for use on subsequent calls when V models `slide-caches-last`.

```
constexpr auto end() const requires `slide-caches-nothing<const V>`;
returns: begin() + range_difference_t<const V>(size()).
```

8 Effects: Equivalent to:
   auto sz = ranges::distance(base_) - n_ + 1;
   if (sz < 0) sz = 0;
   return to_unsigned_like(sz);

26.7.29.3 Class template slide_view::iterator

§ 26.7.29.3

N4944

1249
iterator::iterator_concept is defined as follows:

1. If `Base` models `random_access_range`, then `iterator_concept` denotes `random_access_iterator_tag`.
2. Otherwise, if `Base` models `bidirectional_range`, then `iterator_concept` denotes `bidirectional_iterator_tag`.
3. Otherwise, `iterator_concept` denotes `forward_iterator_tag`.

If the invocation of any non-const member function of `iterator` exits via an exception, the `iterator` acquires a singular value.

```cpp
constexpr iterator(iterator_t<Base> current, range_difference_t<Base> n)
    requires (!slide-caches-first<Base>);
Effects: Initializes `current_` with `current` and `n_` with `n`.
```

```cpp
constexpr iterator(iterator_t<Base> current, iterator_t<Base> last_ele,
    range_difference_t<Base> n)
    requires slide-caches-first<Base>;
Effects: Initializes `current_` with `current`, `last_ele_` with `last_ele`, and `n_` with `n`.
```

```cpp
constexpr iterator(!Const i)
    requires Const && convertible_to<iterator_t<V>, iterator_t<Base>>;
Effects: Initializes `current_` with `std::move(i.current_)` and `n_` with `i.n_`.
[Note 1: `iterator<true>` can only be formed when `Base` models `slide-caches-nothing`, in which case `last_ele_` is not present. — end note]
```

```cpp
constexpr auto operator*() const;
Returns: views::counted(`current_`, `n_`).
```

```cpp
constexpr iterator& operator++();
Preconditions: `current_` and `last_ele_` (if present) are incrementable.
Postconditions: `current_` and `last_ele_` (if present) are each equal to `ranges::next(i)`, where `i` is the value of that data member before the call.
Returns: *this.
```

```cpp
constexpr iterator operator++(int);
Effects: Equivalent to:
    auto tmp = *this;
    ++*this;
    return tmp;
```

```cpp
constexpr iterator& operator--() requires bidirectional_range<Base>;
Preconditions: `current_` and `last_ele_` (if present) are decrementable.
Postconditions: `current_` and `last_ele_` (if present) are each equal to `ranges::prev(i)`, where `i` is the value of that data member before the call.
Returns: *this.
```

```cpp
constexpr iterator operator--(int) requires bidirectional_range<Base>;
Effects: Equivalent to:
    auto tmp = *this;
    --*this;
    return tmp;
```
constexpr iterator +=(difference_type x)
requires random_access_range<Base>;

Preconditions: current_ + x and last_ele_ + x (if last_ele_ is present) have well-defined behavior.
Postconditions: current_ and last_ele_ (if present) are each equal to i + x, where i is the value of that data member before the call.
Returns: *this.

constexpr iterator -= (difference_type x)
requires random_access_range<Base>;

Preconditions: current_ - x and last_ele_ - x (if last_ele_ is present) have well-defined behavior.
Postconditions: current_ and last_ele_ (if present) are each equal to i - x, where i is the value of that data member before the call.
Returns: *this.

constexpr auto operator[](difference_type n) const
requires random_access_range<Base>;

Effects: Equivalent to: return views::counted(current_ + n, n_);

friend constexpr bool operator==(const iterator& x, const iterator& y);

Returns: If last_ele_ is present, x.last_ele_ == y.last_ele_; otherwise, x.current_ == y.current_.

friend constexpr bool operator<(const iterator& x, const iterator& y)
requires random_access_range<Base>;

Returns: x.current_ < y.current_.

friend constexpr bool operator<=(const iterator& x, const iterator& y)
requires random_access_range<Base>;

Effects: Equivalent to: return !(y < x);

friend constexpr auto operator<=>(const iterator& x, const iterator& y)
requires random_access_range<Base> &&
three_way_comparable<iterator_t<Base>>;

Returns: x.current_ <=> y.current_.

friend constexpr iterator operator+(const iterator& i, difference_type n)
requires random_access_range<Base>;

friend constexpr iterator operator+(difference_type n, const iterator& i)
requires random_access_range<Base>;

Effects: Equivalent to:
auto r = i;
  r += n;
  return r;

friend constexpr iterator operator-(const iterator& i, difference_type n)
requires random_access_range<Base>;

Effects: Equivalent to:
auto r = i;
  r -= n;
  return r;
friend constexpr difference_type operator-(const iterator&amp; x, const iterator&amp; y)
    requires sized_sentinel_for<iterator_t<Base>, iterator_t<Base>>;

30    Returns: If \texttt{last\_ele\_} is present, \texttt{x.last\_ele\_} - \texttt{y.last\_ele\_}; otherwise, \texttt{x.current\_} - \texttt{y.current\_}.

26.7.29.4 Class \texttt{slide\_view::sentinel}\hspace{1em}[range.slide.sentinel]

namespace std::ranges {
    template<forward_range V>
    requires view<V>
    class slide_view<V>::sentinel {
        sentinel_t<V> end_ = sentinel_t<V>(); // exposition only
        constexpr explicit sentinel(sentinel_t<V> end); // exposition only

        public:
            sentinel() = default;

            friend constexpr explicit sentinel(sentinel_t<V> end);

            friend constexpr bool operator==(const iterator<false>& x, const sentinel& y);

            friend constexpr range_difference_t<V> operator-(const iterator<false>& x, const sentinel& y)
                requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;

            friend constexpr range_difference_t<V> operator-(const sentinel& y, const iterator<false>& x)
                requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;
    }
}

1 \textbf{[Note 1: sentinel is used only when \texttt{slide\_caches\_first\langle V\rangle} is true. — end note]}

constexpr explicit sentinel(sentinel_t<V> end);

2 Effects: Initializes \texttt{end\_} with \texttt{end}.

friend constexpr range_difference_t<V> operator-(const iterator<false>& x, const sentinel& y)
    requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;

3 Returns: \texttt{x.last\_ele\_} == \texttt{y.end\_}.

friend constexpr range_difference_t<V> operator-(const sentinel& y, const iterator<false>& x)
    requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;

4 Returns: \texttt{x.last\_ele\_} - \texttt{y.end\_}.

friend constexpr range_difference_t<V> operator-(const iterator<false>& x, const sentinel& y)
    requires sized_sentinel_for<sentinel_t<V>, iterator_t<V>>;

5 Returns: \texttt{y.end\_} - \texttt{x.last\_ele\_}.

26.7.30 Chunk by view\hspace{1em}[range.chunk.by]

26.7.30.1 Overview\hspace{1em}[range.chunk.by.overview]

\texttt{chunk\_by\_view} takes a view and a predicate, and splits the view into \texttt{subranges} between each pair of adjacent elements for which the predicate returns \texttt{false}.

The name \texttt{views::chunk\_by} denotes a range adaptor object (26.7.2). Given subexpressions \texttt{E} and \texttt{F}, the expression \texttt{views::chunk\_by\langle E, F\rangle} is expression-equivalent to \texttt{chunk\_by\_view\langle E, F\rangle}.

\textbf{[Example 1:]}

```cpp
vector v = {1, 2, 2, 3, 0, 4, 5, 2};

for (auto r : v | views::chunk_by(ranges::less_equal{})) {
    cout << '[';
    auto sep = "";
    for (auto i : r) {
        cout << sep << i;
```
namespace std::ranges {
    template<forward_range V, indirect_binary_predicate<iterator_t<V>, iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
    class chunk_by_view : public view_interface<chunk_by_view<V, Pred>> {
        V base_;  // exposition only
        movable-box<Pred> pred_;  // exposition only
        // 26.7.30.3, class chunk_by_view::iterator
        class iterator;  // exposition only

    public:
        chunk_by_view() requires default_initializable<V> && default_initializable<Pred> = default;
        constexpr explicit chunk_by_view(V base, Pred pred);
        constexpr V base() const & requires copy_constructible<V> { return base_; }
        constexpr V base() && { return std::move(base_); }
        constexpr const Pred& pred() const;
        constexpr iterator begin();
        constexpr auto end();
        constexpr iterator_t<V> find-next(iterator_t<V>);
        // exposition only
        constexpr iterator_t<V> find-prev(iterator_t<V>)
            requires bidirectional_range<V>;
    };

template<class R, class Pred>
    chunk_by_view(R&&, Pred) -> chunk_by_view<views::all_t<R>, Pred>;
}

constexpr explicit chunk_by_view(V base, Pred pred);

1. **Effects**: Initializes `base_` with `std::move(base)` and `pred_` with `std::move(pred)`.
2. **Effects**: Equivalent to: `return *pred_;`
3. **Preconditions**: `pred_.has_value()` is true.
4. **Returns**: `iterator(*this, ranges::begin(base_), find-next(ranges::begin(base_)))`.
5. **Remarks**: In order to provide the amortized constant-time complexity required by the `range` concept, this function caches the result within the `chunk_by_view` for use on subsequent calls.
6. **Effects**: Equivalent to:
   ```cpp
   if constexpr (common_range<V>) {
       return iterator(*this, ranges::end(base_), ranges::end(base_));
   } else {
       return default_sentinel;
   }
   ```
constexpr iterator_t<V> find-next(iterator_t<V> current);

Preconditions: pred_.has_value() is true.

Returns:

ranges::next(ranges::adjacent_find(current, ranges::end(base_), not_fn(ref(*pred_))),
1, ranges::end(base_))

constexpr iterator_t<V> find-prev(iterator_t<V> current) requires bidirectional_range<V>;

Preconditions:

(9.1) current is not equal to ranges::begin(base_).
(9.2) pred_.has_value() is true.

Returns: An iterator i in the range [ranges::begin(base_), current) such that:

(10.1) ranges::adjacent_find(i, current, not_fn(*pred_)) is equal to current; and
(10.2) if i is not equal to ranges::begin(base_), then bool(invoke(*pred_, *ranges::prev(i), *i)) is false.

26.7.30.3 Class chunk_by_view::iterator

namespace std::ranges {
    template<forward_range V, indirect_binary_predicate<iterator_t<V>, iterator_t<V>> Pred>
    requires view<V> && is_object_v<Pred>
    class chunk_by_view<V, Pred>::iterator {
        chunk_by_view* parent_ = nullptr; // exposition only
        iterator_t<V> current_ = iterator_t<V>(); // exposition only
        iterator_t<V> next_ = iterator_t<V>(); // exposition only

        constexpr iterator(chunk_by_view& parent, iterator_t<V> current,
            iterator_t<V> next); // exposition only

        public:
            using value_type = subrange<iterator_t<V>>;
            using difference_type = range_difference_t<V>;
            using iterator_category = input_iterator_tag;
            using iterator_concept = see below;

            iterator() = default;

            constexpr value_type operator*() const;
            constexpr iterator& operator++();
            constexpr iterator operator++(int);
            constexpr iterator& operator--() requires bidirectional_range<V>;
            constexpr iterator operator--(int) requires bidirectional_range<V>;

            friend constexpr bool operator==(const iterator& x, const iterator& y);
            friend constexpr bool operator==(const iterator& x, default_sentinel_t);
    }
}

1 iterator::iterator_concept is defined as follows:

(1.1) If V models bidirectional_range, then iterator_concept denotes bidirectional_iterator_tag.
(1.2) Otherwise, iterator_concept denotes forward_iterator_tag.

constexpr iterator(chunk_by_view& parent, iterator_t<V> current, iterator_t<V> next);

Effects: Initializes parent_ with addressof(parent), current_ with current, and next_ with next.

constexpr value_type operator*() const;

Preconditions: current_ is not equal to next_.

Returns: subrange(current_, next_).
constexpr iterator& operator++();

Preconditions: current_ is not equal to next_.

Effects: Equivalent to:

current_ = next_;  
next_ = parent_->find-next(current_);  
return *this;

constexpr iterator operator++(int);

Effects: Equivalent to:

auto tmp = *this;  
++*this;  
return tmp;

constexpr iterator& operator--() requires bidirectional_range<V>;

Effects: Equivalent to:

next_ = current_;  
current_ = parent_->find-prev(next_);  
return *this;

constexpr iterator operator--(int) requires bidirectional_range<V>;

Effects: Equivalent to:

auto tmp = *this;  
--*this;  
return tmp;

friend constexpr bool operator==(const iterator& x, const iterator& y);

Returns: x.current_ == y.current_.

friend constexpr bool operator==(const iterator& x, default_sentinel_t);

Returns: x.current_ == x.next_.

26.7.31 Stride view

26.7.31.1 Overview

stride_view presents a view of an underlying sequence, advancing over n elements at a time, as opposed to the usual single-step succession.

The name views::stride denotes a range adaptor object (26.7.2). Given subexpressions E and N, the expression views::stride(E, N) is expression-equivalent to stride_view(E, N).

[Example 1]

auto input = views::iota(0, 12) | views::stride(3);  
ranges::copy(input, ostream_iterator<int>(cout, " "));  // prints 0 3 6 9  
ranges::copy(input | views::reverse, ostream_iterator<int>(cout, " "));  // prints 9 6 3 0

—end example

26.7.31.2 Class template stride_view

noexcept(noexcept(ranges::iter_swap(x.current_, y.current_)))
requires indirectly_swappable<iterator_t<Base>>;

Effects: Equivalent to: ranges::iter_swap(x.current_, y.current_);

26.7.32 Cartesian product view

26.7.32.1 Overview

cartesian_product_view takes any non-zero number of ranges n and produces a view of tuples calculated by the n-ary cartesian product of the provided ranges.

The name views::cartesian_product denotes a customization point object (16.3.3.5). Given a pack of subexpressions Es, the expression views::cartesian_product(Es...) is expression-equivalent to

(2.1) — views::single(tuple()) if Es is an empty pack,
(2.2) — otherwise, cartesian_product_view<views::all_t<decltype((Es))>...>(Es...).

Example 1:
vector<int> v { 0, 1, 2 };
for (auto&& [a, b, c] : views::cartesian_product(v, v, v)) {
    cout << a << ' ' << b << ' ' << c << '\n';
}

// The above prints
// 0 0 0
// 0 0 1
// 0 0 2
// 0 1 0
// 0 1 1
// ...

—end example]  

26.7.32.2 Class template cartesian_product_view

```cpp
namespace std::ranges {
    template<bool Const, class First, class... Vs>
    concept cartesian-product-is-random-access = // exposition only
        (random_access_range<maybe-const<Const, First>> && ...
         && random_access_range<maybe-const<Const, Vs>>
         && sized_range<maybe-const<Const, Vs>>);

template<class R>
    concept cartesian-product-common-arg = // exposition only
        common_range<R> || (sized_range<R> && random_access_range<R>);

constexpr iterator<true> begin() const
  requires (range<const First> && ... && range<const Vs>);

constexpr iterator<false> end()
  requires (((simple_view<First> || ... || simple_view<Vs>)
             && cartesian_product_is_common<First, Vs...>);
constexpr iterator<true> end() const
  requires cartesian_product_is_common<const First, const Vs...>;
constexpr default_sentinel_t end() const noexcept;

constexpr see below size()
  requires cartesian_product_is_sized<First, Vs...>;
constexpr see below size() const
  requires cartesian_product_is_sized<const First, const Vs...>;

};

template<class... Vs>
cartesian_product_view(Vs&&...) -> cartesian_product_view<all_t<Vs>...>;

1 Effects: Initializes bases_ with std::move(first_base), std::move(bases)....

constexpr iterator<false> begin()
  requires (!simple_view<First> || ... || !simple_view<Vs>);
2 Effects: Equivalent to:
  return iterator<false>(*this, tuple-transform(ranges::begin, bases_));
constexpr iterator<true> begin() const
  requires (range<const First> && ... && range<const Vs>);
3 Effects: Equivalent to:
  return iterator<true>(*this, tuple-transform(ranges::begin, bases_));
constexpr iterator<false> end()
  requires ((simple_view<First> || ... || simple_view<Vs>)
             && cartesian_product_is_common<First, Vs...>);
4 Let:
   — is-const be true for the const-qualified overload, and false otherwise;
   — is-empty be true if the expression ranges::empty(rng) is true for any rng among the underlying ranges except the first one and false otherwise; and
   — begin-or-first-end(rng) be expression-equivalent to is-empty ? ranges::begin(rng) : cartesian_common_arg_end(rng) if rng is the first underlying range and ranges::begin(rng) otherwise.
5 Effects: Equivalent to:
   iterator<is-const> it(*this, tuple-transform(
      [](auto& rng){ return begin-or-first-end(rng); }, bases_));
   return it;

constexpr default_sentinel_t end() const noexcept;
6 Returns: default_sentinel.
The return type is an implementation-defined unsigned-integer-like type.

**Recommended practice:** The return type should be the smallest unsigned-integer-like type that is sufficiently wide to store the product of the maximum sizes of all the underlying ranges, if such a type exists.

Let $p$ be the product of the sizes of all the ranges in `bases_`.

**Preconditions:** $p$ can be represented by the return type.

**Returns:** $p$.

### 26.7.32.3 Class template `cartesian_product_view::iterator` [range.cartesian.iterator]

```cpp
namespace std::ranges {
    template<input_range First, forward_range... Vs>
        requires (view<First> && ... && view<Vs>)
    template<bool Const>
        class cartesian_product_view<First, Vs...>::iterator {
        public:
            using iterator_category = input_iterator_tag;
            using iterator_concept = see below;
            using value_type = tuple<range_value_t<
                maybe-const<Const, First>>,
                range_value_t<maybe-const<Const, Vs>>...>;
            using reference = tuple<range_reference_t<
                maybe-const<Const, First>>,
                range_reference_t<maybe-const<Const, Vs>>...>;
            using difference_type = see below;
            iterator() = default;
            constexpr iterator(iterator<!Const> i) requires Const &&
                (convertible_to<iterator_t<First>, iterator_t<const First>> &&
                ... && convertible_to<iterator_t<Vs>, iterator_t<const Vs>>);
            constexpr auto operator*() const;
            constexpr iterator& operator++();
            constexpr void operator++(int);
            constexpr iterator& operator++(int) requires forward_range<maybe-const<Const, First>>;
            constexpr iterator& operator--();
            constexpr iterator& operator--(int) requires cartesian-product-is-bidirectional<Const, First, Vs...>;
            constexpr iterator& operator+=(difference_type x) requires cartesian-product-is-random-access<Const, First, Vs...>;
            constexpr iterator& operator-=(difference_type x) requires cartesian-product-is-random-access<Const, First, Vs...>;
            constexpr reference operator[](difference_type n) const requires cartesian-product-is-random-access<Const, First, Vs...>;
            friend constexpr bool operator==(const iterator& x, const iterator& y) requires equality_comparable<iterator_t<maybe-const<Const, First>>>
            friend constexpr bool operator==(const iterator& x, default_sentinel_t);
            friend constexpr auto operator<=>(const iterator& x, const iterator& y) requires all-random-access<Const, First, Vs...>;
            friend constexpr iterator operator+(const iterator& x, difference_type y) requires cartesian-product-is-random-access<Const, First, Vs...>;
```

§ 26.7.32.3 1263
friend constexpr iterator operator+(difference_type x, const iterator& y)  
requires cartesian-product-is-random-access<Const, First, Vs...>;
friend constexpr iterator operator-(const iterator& x, difference_type y)  
requires cartesian-product-is-random-access<Const, First, Vs...>;
friend constexpr difference_type operator-(const iterator& x, const iterator& y)  
requires cartesian-is-sized-sentinel<Const, iterator_t, First, Vs...>;
friend constexpr difference_type operator-(const iterator& i, default_sentinel_t)  
requires cartesian-is-sized-sentinel<Const, sentinel_t, First, Vs...>;
friend constexpr difference_type operator-(default_sentinel_t, const iterator& i)  
requires cartesian-is-sized-sentinel<Const, sentinel_t, First, Vs...>;
friend constexpr auto iter_move(const iterator& i) noexcept(see below);
friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)  
requires (indirectly_swappable<iterator_t<maybe-const<Const, First>>> && ... &&  
indirectly_swappable<iterator_t<maybe-const<Const, Vs>>>);

private:
using Parent = maybe-const<Const, cartesian_product_view>;  
// exposition only
Parent* parent_ = nullptr;  
// exposition only
tuple<iterator_t<maybe-const<Const, First>>,  
iterator_t<maybe-const<Const, Vs>>...> current_;  
// exposition only
template<size_t N = sizeof...(Vs)>  
constexpr void next();  
// exposition only
template<size_t N = sizeof...(Vs)>  
constexpr void prev();  
// exposition only
template<class Tuple>  
constexpr difference_type distance-from(const Tuple& t) const;  
// exposition only
iterator(Parent& parent, tuple<iterator_t<maybe-const<Const, First>>,  
iterator_t<maybe-const<Const, Vs>>...> current);  
// exposition only
};

1 iterator::iterator_concept is defined as follows:
(1.1) If cartesian-product-is-random-access<Const, First, Vs...> is modeled, then iterator_concept  
denotes random_access_iterator_tag.
(1.2) Otherwise, if cartesian-product-is-bidirectional<Const, First, Vs...> is modeled, then iterator_concept  
denotes bidirectional_iterator_tag.
(1.3) Otherwise, if maybe-const<Const, First> models forward_range, then iterator_concept denotes  
forward_iterator_tag.
(1.4) Otherwise, iterator_concept denotes input_iterator_tag.

2 iterator::difference_type is an implementation-defined signed-integer-like type.

3 Recommended practice: iterator::difference_type should be the smallest signed-integer-like type that is  
sufficiently wide to store the product of the maximum sizes of all underlying ranges if such a type exists.

4 template<size_t N = sizeof...(Vs)>  
constexpr void next();

5 Effects: Equivalent to:
auto& it = std::get<N>(current_);  
+it;
if constexpr (N > 0) {
  if (it == ranges::end(std::get<N>(parent_->bases_))) {
    it = ranges::begin(std::get<N>(parent_->bases_));
    next<N - 1>();
  } else {
    ++it;
  }
}
template<
    size_t N = sizeof...(Vs)>
constexpr void prev();

Effects: Equivalent to:

auto& it = std::get<N>(current_);
if constexpr (N > 0) {
    if (it == ranges::begin(std::get<N>(parent_->bases_))) {
        it = cartesian-common-arg-end(std::get<N>(parent_->bases_));
    }
    prev<N - 1>();
}
--it;

template<class Tuple>
constexpr difference_type distance-from(const Tuple& t) const;

Let:

1. scaled-size(N) be the product of static_cast<
   difference_type>(ranges::size(std::get<N>(parent_->bases_)))
   and scaled-size(N + 1) if N ≤ sizeof...(Vs), otherwise static_cast<
   difference_type>(1);
2. scaled-distance(N) be the product of static_cast<
   difference_type>(std::get<N>(current_) - std::get<N>(t))
   and scaled-size(N + 1); and
3. scaled-sum be the sum of scaled-distance(N) for every integer
   0 ≤ N ≤ sizeof...(Vs).

Preconditions: scaled-sum can be represented by difference_type.

Returns: scaled-sum.

constexpr iterator(Parent& parent, tuple<iterator_t<
maybe-const<Const, First>>,
iterator_t<maybe-const<Const, Vs>>...> current);

Effects: Initializes parent_ with addressof(parent) and current_ with
std::move(current).

constexpr iterator(iterator<!Const> i) requires Const &&
(convertible_to<iterator_t<First>, iterator_t<const First>> &&
... && convertible_to<iterator_t<Vs>, iterator_t<const Vs>>);

Effects: Initializes parent_ with i.parent_ and current_ with
std::move(i.current_).

constexpr auto operator*() const;

Effects: Equivalent to:

return tuple-transform([](auto& i) -> decltype(auto) { return *i; }, current_);

constexpr iterator& operator++();

Effects: Equivalent to:

next();
return *this;

constexpr void operator++(int);

Effects: Equivalent to +++this.

constexpr iterator operator++(int) requires forward_range<maybe-const<Const, First>>;

Effects: Equivalent to:

auto tmp = *this;
++this;
return tmp;

constexpr iterator& operator--() requires cartesian-product-is-bidirectional<Const, First, Vs...>;

Effects: Equivalent to:
prev();
return *this;

constexpr iterator operator--(int)
requires cartesian-product-is-bidirectional<Const, First, Vs...>;

Effects: Equivalent to:
auto tmp = *this;
--*this;
return tmp;

constexpr iterator& operator+=(difference_type x)
requires cartesian-product-is-random-access<Const, First, Vs...>;

Let orig be the value of *this before the call.
Let ret be:

(18.1) If x > 0, the value of *this had next been called x times.
(18.2) Otherwise, if x < 0, the value of *this had prev been called -x times.
(18.3) Otherwise, orig.

Preconditions: x is in the range [ranges::distance(*this, ranges::begin(*parent_)),
ranges::distance(*this, ranges::end(*parent_))].

Effects: Sets the value of *this to ret.

Returns: *this.

Complexity: Constant.

constexpr iterator& operator-=(difference_type x)
requires cartesian-product-is-random-access<Const, First, Vs...>;

Effects: Equivalent to:
*this += -x;
return *this;

constexpr reference operator[](difference_type n) const
requires cartesian-product-is-random-access<Const, First, Vs...>;

Effects: Equivalent to: return *((*this) + n);

friend constexpr bool operator==(const iterator& x, const iterator& y)
requires equality_comparable<iterator_t<maybe-const<Const, First>>>

Effects: Equivalent to: return x.current_ == y.current_;

friend constexpr bool operator==(const iterator& x, default_sentinel_t);

Returns: true if std::get<i>(x.current_) == ranges::end(std::get<i>(x.parent_)->bases_))
is true for any integer 0 ≤ i ≤ sizeof...(Vs); otherwise, false.

friend constexpr auto operator<=>(const iterator& x, const iterator& y)
requires all-random-access<Const, First, Vs...>;

Effects: Equivalent to: return x.current_ <=> y.current_;

friend constexpr iterator operator+(const iterator& x, difference_type y)
requires cartesian-product-is-random-access<Const, First, Vs...>;

Effects: Equivalent to: return iterator(x) += y;

friend constexpr iterator operator+(difference_type x, const iterator& y)
requires cartesian-product-is-random-access<Const, First, Vs...>;

Effects: Equivalent to: return iterator(x) += y;

friend constexpr iterator operator-(const iterator& x, difference_type y)
requires cartesian-product-is-random-access<Const, First, Vs...>;

Effects: Equivalent to: return iterator(x) -= y;
friend constexpr difference_type operator-(const iterator& x, const iterator& y)
requires cartesian-is-sized-sentinel<Const, iterator_t, First, Vs...>;

Effects: Equivalent to: return x.distance-from(y.current_);

friend constexpr difference_type operator-(const iterator& i, default_sentinel_t)
requires cartesian-is-sized-sentinel<Const, sentinel_t, First, Vs...>;

Let end-tuple be an object of a type that is a specialization of tuple, such that:

(32.1) std::get<0>(end-tuple) has the same value as ranges::end(std::get<0>(i.parent_->bases_));
(32.2) std::get<N>(end-tuple) has the same value as ranges::begin(std::get<N>(i.parent_->bases_)) for every integer \(1 \leq N \leq \text{sizeof...(Vs)}.\)

Effects: Equivalent to: return i.distance-from(end-tuple);

friend constexpr auto iter_move(const iterator& i) noexcept(see below);

Effects: Equivalent to: return tuple-transform(ranges::iter_move, i.current_);

Remarks: The exception specification is equivalent to the logical AND of the following expressions:

(36.1) noexcept(ranges::iter_move(std::get<i>(i.current_))) for every integer \(0 \leq N \leq \text{sizeof...(Vs)},\)
(36.2) is_nothrow_move_constructible_v<range_rvalue_reference_t<maybe-const<Const, T>>> for every type \(T\) in First, Vs...

friend constexpr void iter_swap(const iterator& l, const iterator& r) noexcept(see below)
requires (indirectly_swappable<iterator_t<maybe-const<Const, First>>> && ... && indirectly_swappable<iterator_t<maybe-const<Const, Vs>>>);

Effects: For every integer \(0 \leq i \leq \text{sizeof...(Vs)},\) performs:

ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_))

Remarks: The exception specification is equivalent to the logical AND of the following expressions:

(38.1) noexcept(ranges::iter_swap(std::get<i>(l.current_), std::get<i>(r.current_))) for every integer \(0 \leq i \leq \text{sizeof...(Vs)}.\)

26.8 Range generators

26.8.1 Overview

Class template generator presents a view of the elements yielded by the evaluation of a coroutine.

A generator generates a sequence of elements by repeatedly resuming the coroutine from which it was returned. Elements of the sequence are produced by the coroutine each time a co_yield statement is evaluated. When the co_yield statement is of the form co_yield elements_of(r), each element of the range r is successively produced as an element of the sequence.

[Example 1:

```cpp
generator<int> ints(int start = 0) {
    while (true)
        co_yield start++;
}

void f() {
    for (auto i : ints() | views::take(3))
        cout << i << ' '; // prints 0 1 2
}

-- end example]

§ 26.8.1 1267
26.8.2 Header <generator> synopsis

```cpp
namespace std {
    // 26.8.3, class template generator
    template<class Ref, class V = void, class Allocator = void>
    class generator;

    namespace pnr {
        template<class R, class V = void>
        using generator = std::generator<R, V, polymorphic_allocator>>;
    }
}
```

26.8.3 Class template generator

```cpp
namespace std {
    template<class Ref, class V = void, class Allocator = void>
    class generator : public ranges::view_interface<generator<Ref, V, Allocator>> {
        private:
            using value = conditional_t<is_void_v<V>, remove_cvref_t<Ref>, V>; // exposition only
            using reference = conditional_t<is_void_v<V>, Ref&&, Ref>; // exposition only

            // 26.8.6, class generator::iterator
            class iterator; // exposition only

        public:
            using yielded =
                conditional_t<is_reference_v<
                reference>, reference, const reference&>;

            // 26.8.5, class generator::promise_type
            class promise_type;

            generator(const generator&) = delete;
            generator(generator&& other) noexcept;
            ~generator();
            generator& operator=(generator other) noexcept;
            iterator begin();
            default_sentinel_t end() const noexcept;

        private:
            coroutine_handle<promise_type> coroutine_ = nullptr; // exposition only
            unique_ptr<stack<coroutine_handle<> active_; // exposition only
        }
    }
```

1 **Mandates:**

1.1 If Allocator is not void, allocator_traits<Allocator>::pointer is a pointer type.
1.2 value is a cv-unqualified object type.
1.3 reference is either a reference type, or a cv-unqualified object type that models copy_constructible.
1.4 Let RRef denote remove_reference_t<reference>&& if reference is a reference type, and reference otherwise. Each of:
   1.4.1 common_reference_with<reference&&, value&>,
   1.4.2 common_reference_with<reference&&, RRef&&>, and
   1.4.3 common_reference_with<RRef&&, const value&>

is modeled.

[Note 1: These requirements ensure the exposition-only iterator type can model indirectly_readable and thus input_iterator. — end note]
If `Allocator` is not void, it shall meet the `Cpp17Allocator` requirements.

Specializations of `generator` model `view` and `input_range`.

The behavior of a program that adds a specialization for `generator` is undefined.

### 26.8.4 Members

```cpp
26.8.4 Members
[coro.generator.members]

generator(generator&& other) noexcept;
1
  Effects: Initializes `coroutine_` with exchange(other.coroutine_, {}) and `active_` with exchange(
other.active_, nullptr).
2
  [Note 1: Iterators previously obtained from `other` are not invalidated; they become iterators into `*this`. — end
  note]

~generator();
3
  Effects: Equivalent to:
         if (coroutine_) {
           coroutine_.destroy();
         }
4
  [Note 2: Ownership of recursively yielded generators is held in awaitable objects in the coroutine frame of the
  yielding generator, so destroying the root generator effectively destroys the entire stack of yielded generators.
  — end note]

generator& operator=(generator other) noexcept;
5
  Effects: Equivalent to:
         swap(coroutine_, other.coroutine_);
         swap(active_, other.active_);
6
  Returns: `*this`.
7
  [Note 3: Iterators previously obtained from `other` are not invalidated; they become iterators into `*this`. — end
  note]

iterator begin();
8
  Preconditions: `coroutine_` refers to a coroutine suspended at its initial suspend point (9.5.4).
9
  Effects: Pushes `coroutine_` into `*active_`, then evaluates `coroutine_.resume()`.
10
  Returns: An `iterator` object whose member `coroutine_` refers to the same coroutine as does `coroutine_`.
11
  [Note 4: A program that calls `begin` more than once on the same generator has undefined behavior. — end
  note]

default_sentinel_t end() const noexcept;
12
  Returns: `default_sentinel`.
```

### 26.8.5 Class `generator::promise_type`

```cpp
namespace std {
  template<class Ref, class V, class Allocator>
  class generator<Ref, V, Allocator>::promise_type {
    public:
      generator get_return_object() noexcept;

      suspend_always initial_suspend() const noexcept { return {}; }
      auto final_suspend() noexcept;

      suspend_always yield_value(yielded val) noexcept;
      auto yield_value(const remove_reference_t<yielded>& lval)
      requires is_rvalue_reference_v<yielded> &&
                    constructible_from<remove_cvref_t<yielded>, const remove_reference_t<yielded> &>;
```
template<class R2, class V2, class Alloc2, class Unused>
requires same_as<typename generator<R2, V2, Alloc2>::yielded, yielded>
    auto yield_value(ranges::elements_of<generator<R2, V2, Alloc2>&&, Unused> g) noexcept;

template<ranges::input_range R, class Alloc>
requires convertible_to<ranges::range_reference_t<R>, yielded>
    auto yield_value(ranges::elements_of<R, Alloc> r) noexcept;

void await_transform() = delete;
void return_void() const noexcept {};
void unhandled_exception();

void* operator new(size_t size)
requires same_as<Allocator, void> || default_initializable<Allocator>;

template<class Alloc, class... Args>
requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
    void* operator new(size_t size, allocator_arg_t, const Alloc& alloc, const Args&...);

template<class This, class Alloc, class... Args>
requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
    void* operator new(size_t size, const This&, allocator_arg_t, const Alloc& alloc,
                        const Args&...);

void operator delete(void* pointer, size_t size) noexcept;

private:
    add_pointer_t<yielded> value_ = nullptr; // exposition only
    exception_ptr except_; // exposition only
};

generator get_return_object() noexcept;

auto final_suspend() noexcept;

Preconditions: A handle referring to the coroutine whose promise object is *this is at the top of
    *active of some generator object x. This function is called by that coroutine upon reaching its final
    suspend point (9.5.4).

Returns: An awaitable object of unspecified type (7.6.2.4) whose member functions arrange for the
    calling coroutine to be suspended, pop the coroutine handle from the top of *x.active_, and resume
    execution of the coroutine referred to by x.active_->top() if *x.active_ is not empty. If it is empty,
    control flow returns to the current coroutine caller or resumer (9.5.4).

suspend_always yield_value(yielded val) noexcept;

Effects: Equivalent to value_ = addressof(val).

Returns: {}.

auto yield_value(const remove_reference_t<yielded>& lval)
requires is_rvalue_reference_v<yielded> &&
    constructible_from<remove_cvref_t<yielded>, const remove_reference_t<yielded>&>;

Preconditions: A handle referring to the coroutine whose promise object is *this is at the top of
    *active of some generator object.

Returns: An awaitable object of an unspecified type (7.6.2.4) that stores an object of type remove_-
    cvref_t<yielded> direct-non-list-initialized with lval, whose member functions arrange for value_ to
    point to that stored object and then suspend the coroutine.

Throws: Any exception thrown by the initialization of the stored object.

§ 26.8.5
Remarks: A yield-expression that calls this function has type void (7.6.17).

```
template<class R2, class V2, class Alloc2, class Unused>
requires same_as<typename generator<R2, V2, Alloc2>::yielded, yielded>
auto yield_value(ranges::elements_of<generator<R2, V2, Alloc2>&&, Unused> g) noexcept;
```

Preconditions: A handle referring to the coroutine whose promise object is *this is at the top of *active_of some generator object x. The coroutine referred to by g.range.coroutine_ is suspended at its initial suspend point.

Returns: An awaitable object of an unspecified type (7.6.2.4) into which g.range is moved, whose member await_ready returns false, whose member await_suspend pushes g.range.coroutine_ into *x.active_ and resumes execution of the coroutine referred to by g.range.coroutine_, and whose member await_resume evaluates rethrow_exception(except_) if bool(except_) is true. If bool(except_) is false, the await_resume member has no effects.

Remarks: A yield-expression that calls this function has type void (7.6.17).

```
template<ranges::input_range R, class Alloc>
requires convertible_to<ranges::range_reference_t<R>, yielded>
auto yield_value(ranges::elements_of<R, Alloc> r) noexcept;
```

Effects: Equivalent to:
```
auto nested = [] (allocator_arg_t, Alloc, ranges::iterator_t<R> i, ranges::sentinel_t<R> s)
    -> generator<yielded, ranges::range_value_t<R>, Alloc>
    {
        for (; i != s; ++i) {
            co_yield static_cast<yielded>(*i);
        }
    };
return yield_value(ranges::elements_of(nested(
    allocator_arg, r.allocator, ranges::begin(r.range), ranges::end(r.range))));
```

[Note 1: A yield-expression that calls this function has type void (7.6.17). — end note]

void unhandled_exception();

Preconditions: A handle referring to the coroutine whose promise object is *this is at the top of *active_of some generator object x.

Effects: If the handle referring to the coroutine whose promise object is *this is the sole element of *x.active_, equivalent to throw, otherwise, assigns current_exception() to except_.

void* operator new(size_t size)
requires same_as<Allocator, void> || default_initializable<Allocator>;

template<class Alloc, class... Args>
requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
void* operator new(size_t size, allocator_arg_t, const Alloc& alloc, const Args&...);

template<class This, class Alloc, class... Args>
requires same_as<Allocator, void> || convertible_to<const Alloc&, Allocator>
void* operator new(size_t size, const This&, allocator_arg_t, const Alloc& alloc, const Args&...);

Let A be
(17.1) — Allocator, if it is not void,
(17.2) — Alloc for the overloads with a template parameter Alloc, or
(17.3) — allocator<void> otherwise.

Let B be allocator_traits<A>::template rebind_alloc<U> where U is an unspecified type whose size and alignment are both __STDCPP_DEFAULT_NEW_ALIGNMENT__

Mandates: allocator_traits<B>::pointer is a pointer type.

Effects: Initializes an allocator b of type B with A(alloc), for the overloads with a function parameter alloc, and with A() otherwise. Uses b to allocate storage for the smallest array of U sufficient to
provide storage for a coroutine state of size \texttt{size}, and unspecified additional state necessary to ensure that \texttt{operator delete} can later deallocate this memory block with an allocator equal to \texttt{b}.

\begin{verbatim}
Returns: A pointer to the allocated storage.
void operator delete(void* pointer, size_t size) noexcept;
\end{verbatim}

\textit{Preconditions:} \texttt{pointer} was returned from an invocation of one of the above overloads of \texttt{operator new} with a \texttt{size} argument equal to \texttt{size}.

\textit{Effects:} Deallocates the storage pointed to by \texttt{pointer} using an allocator equivalent to that used to allocate it.

### 26.8.6 Class \texttt{generator::iterator}

```cpp
namespace std {
    template<class Ref, class V, class Allocator>
    class generator<Ref, V, Allocator>::::iterator {
public:
        using value_type = value;
        using difference_type = ptrdiff_t;

        iterator(iterator&& other) noexcept;
        iterator& operator=(iterator&& other) noexcept;
        reference operator*() const noexcept(is_nothrow_copy_constructible_v<reference>);
        iterator& operator++();
        void operator++(int);
        friend bool operator==(const iterator& i, default_sentinel_t);

    private:
        coroutine_handle<promise_type> coroutine_; // exposition only
    }
}
```

\textit{iterator(iterator&& other) noexcept;}

\textit{Effects:} Initializes \texttt{coroutine_} with \texttt{exchange(other.coroutine_, {})}.

\textit{iterator& operator=(iterator&& other) noexcept;}

\textit{Effects:} Equivalent to \texttt{coroutine_ = exchange(other.coroutine_, {})}.

\textit{Returns: *this.}

\textit{reference operator*() const noexcept(is_nothrow_copy_constructible_v<reference>);}

\textit{Preconditions:} For some \texttt{generator} object \texttt{x}, \texttt{coroutine_} is in \texttt{*x.active_} and \texttt{x.active_-top()} refers to a suspended coroutine with promise object \texttt{p}.

\textit{Effects:} Equivalent to: \texttt{return static_cast<reference>(*p.value_);}

\textit{iterator& operator++();}

\textit{Preconditions:} For some \texttt{generator} object \texttt{x}, \texttt{coroutine_} is in \texttt{*x.active_}.

\textit{Effects:} Equivalent to \texttt{x.active_-top().resume()}. 

\textit{Returns: *this.}

\textit{void operator++(int);}

\textit{Effects:} Equivalent to \texttt{***this.}

\textit{friend bool operator==(const iterator& i, default_sentinel_t);}

\textit{Effects:} Equivalent to: \texttt{return i.coroutine_.done();}

\section*{§ 26.8.6 1272}
27 Algorithms library

27.1 General

This Clause describes components that C++ programs may use to perform algorithmic operations on containers (Clause 24) and other sequences.

The following subclauses describe components for non-modifying sequence operations, mutating sequence operations, sorting and related operations, and algorithms from the ISO C library, as summarized in Table 93.

Table 93: Algorithms library summary

27.2 Algorithms requirements

All of the algorithms are separated from the particular implementations of data structures and are parameterized by iterator types. Because of this, they can work with program-defined data structures, as long as these data structures have iterator types satisfying the assumptions on the algorithms.

The entities defined in the std::ranges namespace in this Clause are not found by argument-dependent name lookup (6.5.4). When found by unqualified (6.5.3) name lookup for the postfix-expression in a function call (7.6.1.3), they inhibit argument-dependent name lookup.

Example 1:

```cpp
void foo() {
    using namespace std::ranges;
    std::vector<int> vec{1,2,3};
    find(begin(vec), end(vec), 2);  // #1
}
```

The function call expression at #1 invokes std::ranges::find, not std::find, despite that (a) the iterator type returned from begin(vec) and end(vec) may be associated with namespace std and (b) std::find is more specialized (13.7.7.3) than std::ranges::find since the former requires its first two parameters to have the same type. — end example

For purposes of determining the existence of data races, algorithms shall not modify objects referenced through an iterator argument unless the specification requires such modification.

Throughout this Clause, where the template parameters are not constrained, the names of template parameters are used to express type requirements.

(4.1) — If an algorithm’s Effects element specifies that a value pointed to by any iterator passed as an argument is modified, then the type of that argument shall meet the requirements of a mutable iterator (25.3).

(4.2) — If an algorithm’s template parameter is named InputIterator, InputIterator1, or InputIterator2, the template argument shall meet the Cpp17InputIterator requirements (25.3.5.3).

(4.3) — If an algorithm’s template parameter is named OutputIterator, OutputIterator1, or OutputIterator2, the template argument shall meet the Cpp17OutputIterator requirements (25.3.5.4).

(4.4) — If an algorithm’s template parameter is named ForwardIterator, ForwardIterator1, ForwardIterator2, or NoThrowForwardIterator, the template argument shall meet the Cpp17ForwardIterator requirements (25.3.5.5).
requirements (25.3.5.5) if it is required to be a mutable iterator, or model forward iterator (25.3.4.11) otherwise.

(4.5)  If an algorithm’s template parameter is named NoThrowForwardIterator, the template argument is also required to have the property that no exceptions are thrown from increment, assignment, or comparison of, or indirectation through, valid iterators.

(4.6)  If an algorithm’s template parameter is named BidirectionalIterator, BidirectionalIterator1, or BidirectionalIterator2, the template argument shall meet the Cpp17BidirectionalIterator requirements (25.3.5.6) if it is required to be a mutable iterator, or model bidirectional_iterator (25.3.4.12) otherwise.

(4.7)  If an algorithm’s template parameter is named RandomAccessIterator, RandomAccessIterator1, or RandomAccessIterator2, the template argument shall meet the Cpp17RandomAccessIterator requirements (25.3.5.7) if it is required to be a mutable iterator, or model random_access_iterator (25.3.4.13) otherwise.

[Note 1: These requirements do not affect iterator arguments that are constrained, for which iterator category and mutability requirements are expressed explicitly. — end note]

5 Both in-place and copying versions are provided for certain algorithms.215 When such a version is provided for algorithm it is called algorithm_copy. Algorithms that take predicates end with the suffix _if (which follows the suffix _copy).

6 When not otherwise constrained, the Predicate parameter is used whenever an algorithm expects a function object (22.10) that, when applied to the result of dereferencing the corresponding iterator, returns a value testable as true. If an algorithm takes Predicate pred as its argument and first as its iterator argument with value type T, the expression pred(*first) shall be well-formed and the type decltype(pred(*first)) shall model boolean-testable (18.5.2). The function object pred shall not apply any non-constant function through its argument. Given a glvalue u of type (possibly const) T that designates the same object as *first, pred(u) shall be a valid expression that is equal to pred(*first).

7 When not otherwise constrained, the BinaryPredicate parameter is used whenever an algorithm expects a function object that, when applied to the result of dereferencing two corresponding iterators or to dereferencing an iterator and type T when T is part of the signature, returns a value testable as true. If an algorithm takes BinaryPredicate binary_pred as its argument and first1 and first2 as its iterator arguments with respective value types T1 and T2, the expression binary_pred(*first1, *first2) shall be well-formed and the type decltype(binary_pred(*first1, *first2)) shall model boolean-testable. Unless otherwise specified, BinaryPredicate always takes the first iterator’s value_type as its first argument, that is, in those cases when T value is part of the signature, the expression binary_pred(*first1, value) shall be well-formed and the type decltype(binary_pred(*first1, value)) shall model boolean-testable. binary_pred shall not apply any non-constant function through any of its arguments. Given a glvalue u of type (possibly const) T1 that designates the same object as *first1, and a glvalue v of type (possibly const) T2 that designates the same object as *first2, binary_pred(u, *first2), binary_pred(*first1, v), and binary_pred(u, v) shall each be a valid expression that is equal to binary_pred(*first1, *first2), and binary_pred(u, value) shall be a valid expression that is equal to binary_pred(*first1, value).

8 The parameters UnaryOperation, BinaryOperation, BinaryOperation1, and BinaryOperation2 are used whenever an algorithm expects a function object (22.10).

[Note 2: Unless otherwise specified, algorithms that take function objects as arguments can copy those function objects freely. If object identity is important, a wrapper class that points to a non-copied implementation object such as reference_wrapper<T> (22.10.6), or some equivalent solution, can be used. — end note]

9 When the description of an algorithm gives an expression such as *first == value for a condition, the expression shall evaluate to either true or false in boolean contexts.

10 In the description of the algorithms, operator + is used for some of the iterator categories for which it does not have to be defined. In these cases the semantics of a + n are the same as those of

auto tmp = a;
for (; n < 0; ++n) --tmp;
for (; n > 0; --n) ++tmp;
return tmp;

215 The decision whether to include a copying version was usually based on complexity considerations. When the cost of doing the operation dominates the cost of copy, the copying version is not included. For example, sort_copy is not included because the cost of sorting is much more significant, and users can invoke copy followed by sort.
Similarly, operator - is used for some combinations of iterators and sentinel types for which it does not have to be defined. If \([a, b)\) denotes a range, the semantics of \(b - a\) in these cases are the same as those of

\[
\text{iter_difference_t<decltype(a)>} \ n = 0;
\text{for (auto tmp = a; tmp != b; ++tmp) ++n;}
\text{return n;}
\]

and if \([b, a)\) denotes a range, the same as those of

\[
\text{iter_difference_t<decltype(b)>} \ n = 0;
\text{for (auto tmp = b; tmp != a; ++tmp) --n;}
\text{return n;}
\]

12 In the description of the algorithms, given an iterator \(a\) whose difference type is \(D\), and an expression \(n\) of integer-like type other than \(cv D\), the semantics of \(a + n\) and \(a - n\) are, respectively, those of \(a + D(n)\) and \(a - D(n)\).

13 In the description of algorithm return values, a sentinel value \(s\) denoting the end of a range \([i, s)\) is sometimes returned where an iterator is expected. In these cases, the semantics are as if the sentinel is converted into an iterator using \(\text{ranges::next}(i, s)\).

14 Overloads of algorithms that take \textit{range} arguments (26.4.2) behave as if they are implemented by calling \(\text{ranges::begin}\) and \(\text{ranges::end}\) on the \textit{range}(s) and dispatching to the overload in namespace \textit{ranges} that takes separate iterator and sentinel arguments.

The well-formedness and behavior of a call to an algorithm with an explicitly-specified template argument list is unspecified, except where explicitly stated otherwise.

[Note 3: Consequently, an implementation can declare an algorithm with different template parameters than those presented. — end note]

27.3 Parallel algorithms

27.3.1 Preamble

Subclause 27.3 describes components that C++ programs may use to perform operations on containers and other sequences in parallel.

A parallel algorithm is a function template listed in this document with a template parameter named ExecutionPolicy.

Parallel algorithms access objects indirectly accessible via their arguments by invoking the following functions:

1. All operations of the categories of the iterators that the algorithm is instantiated with.
2. Operations on those sequence elements that are required by its specification.
3. User-provided function objects to be applied during the execution of the algorithm, if required by the specification.
4. Operations on those function objects required by the specification.

[Note 1: See 27.2. — end note]

These functions are herein called \textit{element access functions}.

[Example 1: The \texttt{sort} function may invoke the following element access functions:

1. Operations of the random-access iterator of the actual template argument (as per 25.3.5.7), as implied by the name of the template parameter \texttt{RandomAccessIterator}.
2. The \texttt{swap} function on the elements of the sequence (as per the preconditions specified in 27.8.2.1).
3. The user-provided \texttt{Compare} function object.

— end example]

A standard library function is \textit{vectorization-unsafe} if it is specified to synchronize with another function invocation, or another function invocation is specified to synchronize with it, and if it is not a memory allocation or deallocation function.

[Note 2: Implementations must ensure that internal synchronization inside standard library functions does not prevent forward progress when those functions are executed by threads of execution with weakly parallel forward progress guarantees. — end note]

[Example 2:

\[
\text{int x = 0;}
\]]
```cpp
std::mutex m;
void f() {
    int a[] = {1,2};
    std::for_each(std::execution::par_unseq, std::begin(a), std::end(a), [&](int) {
        std::lock_guard<mutex> guard(m);
        // incorrect: lock_guard constructor calls m.lock()
        ++x;
    });
}
```

The above program may result in two consecutive calls to `m.lock()` on the same thread of execution (which may deadlock), because the applications of the function object are not guaranteed to run on different threads of execution.

— end example

### 27.3.2 Requirements on user-provided function objects [algorithms.parallel.user]

1. Unless otherwise specified, function objects passed into parallel algorithms as objects of type `Predicate`, `BinaryPredicate`, `Compare`, `UnaryOperation`, `BinaryOperation`, `BinaryOperation1`, `BinaryOperation2`, and the operators used by the analogous overloads to these parallel algorithms that are formed by an invocation with the specified default predicate or operation (where applicable) shall not directly or indirectly modify objects via their arguments, nor shall they rely on the identity of the provided objects.

### 27.3.3 Effect of execution policies on algorithm execution [algorithms.parallel.exec]

1. Parallel algorithms have template parameters named `ExecutionPolicy (22.12)` which describe the manner in which the execution of these algorithms may be parallelized and the manner in which they apply the element access functions.

2. If an object is modified by an element access function, the algorithm will perform no other unsynchronized accesses to that object. The modifying element access functions are those which are specified as modifying the object.

   [Note 1: For example, `swap`, `+`, `->`, `@=`, and assignments modify the object. For the assignment and `@=` operators, only the left argument is modified. — end note]

3. Unless otherwise stated, implementations may make arbitrary copies of elements (with type `T`) from sequences where `is_trivially_copy_constructible_v<T>` and `is_trivially_destructible_v<T>` are `true`.

   [Note 2: This implies that user-supplied function objects cannot rely on object identity of arguments for such input sequences. If object identity of the arguments to these function objects is important, a wrapping iterator that returns a non-copied implementation object such as `reference_wrapper<T>` (22.10.6), or some equivalent solution, can be used. — end note]

4. The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::sequenced_policy` all occur in the calling thread of execution.

   [Note 3: The invocations are not interleaved; see 6.9.1. — end note]

5. The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::unsequenced_policy` are permitted to execute in an unordered fashion in the calling thread of execution, unsequenced with respect to one another in the calling thread of execution.

   [Note 4: This means that multiple function object invocations can be interleaved on a single thread of execution, which overrides the usual guarantee from 6.9.1 that function executions do not overlap with one another. — end note]

6. The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::parallel_policy` are permitted to execute either in the invoking thread of execution or in a thread of execution implicitly created by the library to support parallel algorithm execution. If the threads of execution created by `thread (33.4.3)` or `jthread (33.4.4)` provide concurrent forward progress guarantees (6.9.2.3), then a thread of execution implicitly created by the library will provide parallel forward progress guarantees; otherwise, the provided forward progress guarantee is implementation-defined. Any such invocations executing in the same thread of execution are indeterminately sequenced with respect to each other.

   [Note 5: Because `execution::unsequenced_policy` allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock. — end note]

   [Note 6: It is the caller’s responsibility to ensure that the invocation does not introduce data races or deadlocks. — end note]
Example 1:

```cpp
int a[] = {0, 1};
std::vector<int> v;
std::for_each(std::execution::par, std::begin(a), std::end(a), [&] (int i) {
  v.push_back(i * 2 + 1);  // incorrect: data race
});
```

The program above has a data race because of the unsynchronized access to the container `v`. — end example

Example 2:

```cpp
std::atomic<int> x{0};
int a[] = {1, 2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&] (int) {
  x.fetch_add(1, std::memory_order::relaxed);
  // spin wait for another iteration to change the value of x
  while (x.load(std::memory_order::relaxed) == 1) { }  // incorrect: assumes execution order
});
```

The above example depends on the order of execution of the iterations, and will not terminate if both iterations are executed sequentially on the same thread of execution. — end example

Example 3:

```cpp
int x = 0;
std::mutex m;
int a[] = {1, 2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&] (int) {
  std::lock_guard<mutex> guard(m);
  ++x;
});
```

The above example synchronizes access to object `x` ensuring that it is incremented correctly. — end example

The invocations of element access functions in parallel algorithms invoked with an execution policy object of type `execution::parallel_unsequenced_policy` are permitted to execute in an unordered fashion in unspecified threads of execution, and unsequenced with respect to one another within each thread of execution. These threads of execution are either the invoking thread of execution or threads of execution implicitly created by the library; the latter will provide weakly parallel forward progress guarantees.

[Note 7: This means that multiple function object invocations can be interleaved on a single thread of execution, which overrides the usual guarantee from 6.9.1 that function executions do not overlap with one another. — end note]

The behavior of a program is undefined if it invokes a vectorization-unsafe standard library function from user code called from an `execution::parallel_unsequenced_policy` algorithm.

[Note 8: Because `execution::parallel_unsequenced_policy` allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock. — end note]

[Note 9: The semantics of invocation with `execution::unsequenced_policy`, `execution::parallel_policy`, or `execution::parallel_unsequenced_policy` allow the implementation to fall back to sequential execution if the system cannot parallelize an algorithm invocation, e.g., due to lack of resources. — end note]

If an invocation of a parallel algorithm uses threads of execution implicitly created by the library, then the invoking thread of execution will either

9.1 temporarily block with forward progress guarantee delegation (6.9.2.3) on the completion of these library-managed threads of execution, or

9.2 eventually execute an element access function;

the thread of execution will continue to do so until the algorithm is finished.

[Note 10: In blocking with forward progress guarantee delegation in this context, a thread of execution created by the library is considered to have finished execution as soon as it has finished the execution of the particular element access function that the invoking thread of execution logically depends on. — end note]

The semantics of parallel algorithms invoked with an execution policy object of implementation-defined type are implementation-defined.
27.3.4 Parallel algorithm exceptions

1 During the execution of a parallel algorithm, if temporary memory resources are required for parallelization and none are available, the algorithm throws a bad_alloc exception.

2 During the execution of a parallel algorithm, if the invocation of an element access function exits via an uncaught exception, the behavior is determined by the ExecutionPolicy.

27.3.5 ExecutionPolicy algorithm overloads

1 Parallel algorithms are algorithm overloads. Each parallel algorithm overload has an additional template type parameter named ExecutionPolicy, which is the first template parameter. Additionally, each parallel algorithm overload has an additional function parameter of type ExecutionPolicy&&, which is the first function parameter.

[Note 1: Not all algorithms have parallel algorithm overloads. — end note]

2 Unless otherwise specified, the semantics of ExecutionPolicy algorithm overloads are identical to their overloads without.

3 Unless otherwise specified, the complexity requirements of ExecutionPolicy algorithm overloads are relaxed from the complexity requirements of the overloads without as follows: when the guarantee says “at most expr” or “exactly expr” and does not specify the number of assignments or swaps, and expr is not already expressed with $\mathcal{O}()$ notation, the complexity of the algorithm shall be $\mathcal{O}(expr)$.

4 Parallel algorithms shall not participate in overload resolution unless is_execution_policy_v<remove_cvref_t<ExecutionPolicy>> is true.

27.6 Non-modifying sequence operations

27.6.1 All of

\begin{align}
\text{template<} & \text{class InputIterator, class Predicate>} \\
& \quad \text{constexpr bool all_of(InputIterator first, InputIterator last, Predicate pred);} \\
\text{template<} & \text{class ExecutionPolicy, class ForwardIterator, class Predicate>} \\
& \quad \text{bool all_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,} \\
& \quad \text{Predicate pred);} \\
\text{template<} & \text{input_iterator I, sentinel_for<I> S, class Proj = identity,} \\
& \quad \text{indirect_unary_predicate<projected<I, Proj>> Pred>} \\
& \quad \text{constexpr bool ranges::all_of(I first, S last, Pred pred, Proj proj = {});} \\
\text{template<} & \text{input_range R, class Proj = identity,} \\
& \quad \text{indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>} \\
& \quad \text{constexpr bool ranges::all_of(R&& r, Pred pred, Proj proj = {});} \\
\end{align}

\begin{enumerate}
\item Let E be:
\begin{align}
\text{pred} (*i) \quad \text{for the overloads in namespace std; } \\
\text{invoke(pred, invoke(proj, *i))} \quad \text{for the overloads in namespace ranges.}
\end{align}
\item Returns: \text{false} if E is \text{false} for some iterator i in the range \([\text{first, last})\), and \text{true} otherwise.
\item Complexity: At most \text{last} - \text{first} applications of the predicate and any projection.
\end{enumerate}
27.6.2 Any of [alg.any.of]

```cpp
template<class InputIterator, class Predicate>
constexpr bool any_of(InputIterator first, InputIterator last, Predicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool any_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);
```

```cpp
template<input_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr bool ranges::any_of(I first, S last, Pred pred, Proj proj = {});
```

```cpp
template<input_range R, class Proj = identity,
indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::any_of(R&& r, Pred pred, Proj proj = {});
```

1 Let $E$ be:
2
1.1 $\text{pred}(\ast i)$ for the overloads in namespace `std`;
2.2 $\text{invoke(pred, invoke(proj, \ast i))}$ for the overloads in namespace `ranges`.

2 Returns: true if $E$ is true for some iterator $i$ in the range `[first, last)`, and false otherwise.

3 Complexity: At most last - first applications of the predicate and any projection.

27.6.3 None of [alg.none.of]

```cpp
template<class InputIterator, class Predicate>
constexpr bool none_of(InputIterator first, InputIterator last, Predicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool none_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);
```

```cpp
template<input_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr bool ranges::none_of(I first, S last, Pred pred, Proj proj = {});
```

```cpp
template<input_range R, class Proj = identity,
indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr bool ranges::none_of(R&& r, Pred pred, Proj proj = {});
```

1 Let $E$ be:
2
1.1 $\text{pred}(\ast i)$ for the overloads in namespace `std`;
2.2 $\text{invoke(pred, invoke(proj, \ast i))}$ for the overloads in namespace `ranges`.

2 Returns: false if $E$ is true for some iterator $i$ in the range `[first, last)`, and true otherwise.

3 Complexity: At most last - first applications of the predicate and any projection.

27.6.4 Contains [alg.contains]

```cpp
template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*>constexpr bool ranges::contains(I first, S last, const T& value, Proj proj = {});
```

```cpp
template<input_range R, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*>constexpr bool ranges::contains(R&& r, const T& value, Proj proj = {});
```

1 Returns: `ranges::find(std::move(first), last, value, proj) != last`.

```cpp
template<forward_iterator I1, sentinel_for<I1> S1,
forward_iterator I2, sentinel_for<I2> S2,
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>constexpr bool ranges::contains_subrange(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
```

```cpp
template<forward_range R1, forward_range R2,
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>constexpr bool ranges::contains_subrange(R1&& r1, R2&& r2, Pred pred = {}),
```
Returns: first2 == last2 || !ranges::search(first1, last1, first2, last2, pred, proj1, proj2).empty().

27.6.5 For each

```cpp
template<class InputIterator, class Function>
constexpr Function for_each(InputIterator first, InputIterator last, Function f);
```

Preconditions: Function meets the \texttt{Cpp17MoveConstructible} requirements (Table 31).

[Note 1: Function need not meet the requirements of \texttt{Cpp17CopyConstructible} (Table 32). — end note]

Effects: Applies f to the result of dereferencing every iterator in the range \([\text{first}, \text{last})\), starting from first and proceeding to last - 1.

[Note 2: If the type of \texttt{first} meets the requirements of a mutable iterator, f can apply non-constant functions through the dereferenced iterator. — end note]

Returns: f.

Complexity: Applies f exactly \(\text{last} - \text{first}\) times.

Remarks: If f returns a result, the result is ignored.

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Function>
void for_each(ExecutionPolicy&& exec,
             ForwardIterator first, ForwardIterator last,
             Function f);
```

Preconditions: Function meets the \texttt{Cpp17CopyConstructible} requirements.

Effects: Applies f to the result of dereferencing every iterator in the range \([\text{first}, \text{last})\).

[Note 3: If the type of \texttt{first} meets the requirements of a mutable iterator, f can apply non-constant functions through the dereferenced iterator. — end note]

Complexity: Applies f exactly \(\text{last} - \text{first}\) times.

Remarks: If f returns a result, the result is ignored. Implementations do not have the freedom granted under 27.3.3 to make arbitrary copies of elements from the input sequence.

[Note 4: Does not return a copy of its Function parameter, since parallelization often does not permit efficient state accumulation. — end note]

```cpp
template<input_iterator I, sentinel_for<I> S, class Proj = identity,
          indirectly_unary_invocable<projected<I, Proj>> Fun>
constexpr ranges::for_each_result<I, Fun>
ranges::for_each(I first, S last, Fun f, Proj proj = {});
```

Effects: Calls \texttt{invoke(f, invoke(proj, \*i))} for every iterator i in the range \([\text{first}, \text{last})\), starting from first and proceeding to last - 1.

[Note 5: If the result of \texttt{invoke(proj, \*i)} is a mutable reference, f can apply non-constant functions. — end note]

Returns: \{last, std::move(f)\}.

Complexity: Applies f and proj exactly \(\text{last} - \text{first}\) times.

Remarks: If f returns a result, the result is ignored.

[Note 6: The overloads in namespace ranges require \texttt{Fun} to model \texttt{copy_constructible}. — end note]

```cpp
template<class InputIterator, class Size, class Function>
constexpr InputIterator for_each_n(InputIterator first, Size n, Function f);
```

Mandates: The type \texttt{Size} is convertible to an integral type (7.3.9, 11.4.8).

Preconditions: \(n >= 0\) is true. Function meets the \texttt{Cpp17MoveConstructible} requirements.

[Note 7: Function need not meet the requirements of \texttt{Cpp17CopyConstructible}. — end note]
Effects: Applies f to the result of dereferencing every iterator in the range [first, first + n) in order.
[Note 8: If the type of first meets the requirements of a mutable iterator, f can apply non-constant functions through the dereferenced iterator. — end note]

Returns: first + n.

Remarks: If f returns a result, the result is ignored.

template<class ExecutionPolicy, class ForwardIterator, class Size, class Function>
ForwardIterator for_each_n(ExecutionPolicy&& exec, ForwardIterator first, Size n, 
Function f);

Mandates: The type Size is convertible to an integral type (7.3.9, 11.4.8).

Preconditions: n >= 0 is true. Function meets the Cpp17CopyConstructible requirements.

Effects: Applies f to the result of dereferencing every iterator in the range [first, first + n).
[Note 9: If the type of first meets the requirements of a mutable iterator, f can apply non-constant functions through the dereferenced iterator. — end note]

Returns: first + n.

Remarks: If f returns a result, the result is ignored. Implementations do not have the freedom granted under 27.3.3 to make arbitrary copies of elements from the input sequence.

template<input_iterator I, class Proj = identity, 
indirectly_unary_invocable<projected<I, Proj>> Fun>
constexpr ranges::for_each_n_result<I, Fun>
ranges::for_each_n(I first, iter_difference_t<I> n, Fun f, Proj proj = {});

Preconditions: n >= 0 is true.

Effects: Calls invoke(f, invoke(proj, *i)) for every iterator i in the range [first, first + n) in order.
[Note 10: If the result of invoke(proj, *i) is a mutable reference, f can apply non-constant functions. — end note]

Returns: {first + n, std::move(f)}.

Remarks: If f returns a result, the result is ignored.

[Note 11: The overload in namespace ranges requires Fun to model copy_constructible. — end note]
Let $E$ be:

1. $\*i == \text{value}$ for \text{find};
2. $\text{pred}(\*i) \neq \text{false}$ for \text{find_if};
3. $\text{bool}(\text{invoke} (\text{proj}, \*i)) == \text{false}$ for \text{find_if_not};
4. $\text{bool}(\text{invoke} (\text{proj}, \*i))$ for \text{ranges::find};
5. $\text{bool}(\text{invoke} (\text{proj}, \*i)))$ for \text{ranges::find_if};
6. $\text{bool}(\text{invoke} (\text{proj}, \*i)))$ for \text{ranges::find_if_not}.

Returns: The first iterator $i$ in the range $[\text{first}, \text{last})$ for which $E$ is true. Returns last if no such iterator is found.

Complexity: At most $\text{last} - \text{first}$ applications of the corresponding predicate and any projection.
27.6.8 Find end

```cpp
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator1
find_end(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
find_end(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);
```

```cpp
template<class ForwardIterator1, class ForwardIterator2,
class BinaryPredicate>
constexpr ForwardIterator1
find_end(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryPredicate>
ForwardIterator1
find_end(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);
```

```cpp
template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2,
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr subrange<I1>
find_end(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});
```

```cpp
template<forward_range R1, forward_range R2,
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_subrange_t<R1>
find_end(R1&& r1, R2&& r2, Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});
```

Let:

1. `pred` be `equal_to{}` for the overloads with no parameter `pred`;
2. `E` be:
   1. `pred(*((i + n), *(first2 + n)))` for the overloads in namespace `std`;
   2. `invoke(pred, invoke(proj1, *(i + n)), invoke(proj2, *(first2 + n)))` for the overloads in namespace `ranges`;
3. `i` be `last1` if `[first2, last2)` is empty, or if `(last2 - first2) > (last1 - first1)` is true, or if there is no iterator in the range `[first1, last1 - (last2 - first2))` such that for every non-negative integer `n < (last2 - first2)`, `E` is true. Otherwise `i` is the last such iterator in `[first1, last1 - (last2 - first2))`.

Returns:

1. `i` for the overloads in namespace `std`.
2. `{i, i + (i == last1 ? 0 : last2 - first2)}` for the overloads in namespace `ranges`.

Complexity: At most `(last2 - first2) * (last1 - first1 - (last2 - first2) + 1)` applications of the corresponding predicate and any projections.

27.6.9 Find first

```cpp
template<class InputIterator, class ForwardIterator>
constexpr InputIterator
find_first_of(InputIterator first1, InputIterator last1,
ForwardIterator first2, ForwardIterator last2);
```

```cpp
template<class ExecutionPolicy, class InputIterator, class ForwardIterator>
InputIterator
find_first_of(InputIterator first1, InputIterator last1,
ExecutionPolicy&& exec,
ForwardIterator first2, ForwardIterator last2);
```

```cpp
template<class InputIterator, class ForwardIterator,
class BinaryPredicate>
InputIterator
find_first_of(InputIterator first1, InputIterator last1,
ForwardIterator first2, ForwardIterator last2,
BinaryPredicate pred);
```

```cpp
template<class ExecutionPolicy, class InputIterator, class ForwardIterator,
class BinaryPredicate>
InputIterator
find_first_of(ExecutionPolicy&& exec,
InputIterator first1, InputIterator last1,
ForwardIterator first2, ForwardIterator last2,
BinaryPredicate pred);
```

Let:

1. `pred` be `equal_to{}` for the overloads with no parameter `pred`;
2. `E` be:
   1. `pred(*((i + n), *(first2 + n)))` for the overloads in namespace `std`;
   2. `invoke(pred, invoke(proj1, *(i + n)), invoke(proj2, *(first2 + n)))` for the overloads in namespace `ranges`;
3. `i` be `last1` if `[first2, last2)` is empty, or if `(last2 - first2) > (last1 - first1)` is true, or if there is no iterator in the range `[first1, last1 - (last2 - first2))` such that for every non-negative integer `n < (last2 - first2)`, `E` is true. Otherwise `i` is the last such iterator in `[first1, last1 - (last2 - first2))`.

Returns:

1. `i` for the overloads in namespace `std`.
2. `{i, i + (i == last1 ? 0 : last2 - first2)}` for the overloads in namespace `ranges`.

Complexity: At most `(last2 - first2) * (last1 - first1 - (last2 - first2) + 1)` applications of the corresponding predicate and any projections.
ForwardIterator first2, ForwardIterator last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
find_first_of(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator, class ForwardIterator,
class BinaryPredicate>
constexpr InputIterator
find_first_of(InputIterator first1, InputIterator last1,
ForwardIterator first2, ForwardIterator last2,
BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryPredicate>
ForwardIterator1
find_first_of(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);

template<input_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2,
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr I1
ranges::find_first_of(I1 first1, S1 last1, I2 first2, S2 last2,
Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, forward_range R2,
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_iterator_t<R1>
ranges::find_first_of(R1&& r1, R2&& r2,
Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

Let \( E \) be:

\[
\begin{align*}
(1.1) & \quad \ast i == \ast j \quad \text{for the overloads with no parameter \( \text{pred} \);} \\
(1.2) & \quad \text{pred}(\ast i, \ast j) \neq \text{false} \quad \text{for the overloads with a parameter \( \text{pred} \) and no parameter \( \text{proj1} \);} \\
(1.3) & \quad \text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj1}, \ast i), \text{invoke}(\text{proj2}, \ast j))) \quad \text{for the overloads with parameters \( \text{pred} \) and \( \text{proj1} \) .}
\end{align*}
\]

**Effects:** Finds an element that matches one of a set of values.

**Returns:** The first iterator \( i \) in the range \([\text{first1}, \text{last1}]\) such that for some iterator \( j \) in the range \([\text{first2}, \text{last2}]\) \( E \) holds. Returns \( \text{last1} \) if \([\text{first2}, \text{last2}]\) is empty or if no such iterator is found.

**Complexity:** At most \((\text{last1}-\text{first1}) \times (\text{last2}-\text{first2})\) applications of the corresponding predicate and any projections.

### 27.6.10 Adjacent find

template<class ForwardIterator>
constexpr ForwardIterator
adjacent_find(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
adjacent_find(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
constexpr ForwardIterator
adjacent_find(ForwardIterator first, ForwardIterator last,
BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
ForwardIterator
adjacent_find(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
BinaryPredicate pred);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_binary_predicate<projected<I, Proj>,
projected<I, Proj>> Pred = ranges::equal_to>
constexpr I ranges::adjacent_find(I first, S last, Proj proj = {});

template<input_iterator I, sentinel_for<I> S, class Proj = identity,
indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr I ranges::adjacent_find(I first, S last, Proj proj = {});

Let \( E \) be:

\[
\begin{align*}
\text{(1.1)} & \quad i \equiv *(i + 1) \text{ for the overloads with no parameter } \text{pred}; \\
\text{(1.2)} & \quad \text{proj}(*i, *(i + 1)) \neq \text{false} \text{ for the overloads with a parameter } \text{pred} \text{ and no parameter } \text{proj}; \\
\text{(1.3)} & \quad \text{bool}(<\text{proj}, \text{proj}(\text{proj}, *i), \text{proj}(\text{proj}, *(i + 1)))) \text{ for the overloads with both paramters } \text{pred} \text{ and } \text{proj}.
\end{align*}
\]

Returns: The first iterator \( i \) such that both \( i \) and \( i + 1 \) are in the range \([\text{first}, \text{last})\) for which \( E \) holds. Returns last if no such iterator is found.

Complexity: For the overloads with no ExecutionPolicy, exactly

\[\min((i - \text{first}) + 1, \text{(last} - \text{first}) - 1)\]

applications of the corresponding predicate, where \( i \) is adjacent_find's return value. For the overloads with an ExecutionPolicy, \( \Theta(\text{last} - \text{first}) \) applications of the corresponding predicate, and no more than twice as many applications of any projection.

### 27.6.11 Count

```cpp
template<class InputIterator, class T>
constexpr typename iterator_traits<InputIterator>::difference_type
count(InputIterator first, InputIterator last, const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>
typename iterator_traits<ForwardIterator>::difference_type
count(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last, const T& value);

template<class InputIterator, class Predicate>
constexpr typename iterator_traits<InputIterator>::difference_type
count_if(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
typename iterator_traits<ForwardIterator>::difference_type
count_if(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last, Predicate pred);

template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T*> 
constexpr iter_difference_t<I>
ranges::count(I first, S last, const T& value, Proj proj = {});

template<input_range R, class T, class Proj = identity>
requires indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T*> 
constexpr range_difference_t<R>
ranges::count(R&& r, const T& value, Proj proj = {});

template<input_iterator I, sentinel_for<I> S, class T, class Proj = identity,
indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr iter_difference_t<I>
ranges::count_if(I first, S last, Pred pred, Proj proj = {});
```
template<input_range R, class Proj = identity, indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
constexpr range_difference_t<R>
ranges::count_if(R&& r, Pred pred, Proj proj = {});

1
Let $E$ be:

1.1 $*i == \text{value}$ for the overloads with no parameter $\text{pred}$ or $\text{proj}$;

1.2 $\text{pred}(\text{*i}) != false$ for the overloads with a parameter $\text{pred}$ but no parameter $\text{proj}$;

1.3 $\text{invoke} (\text{proj}, *i) == \text{value}$ for the overloads with a parameter $\text{proj}$ but no parameter $\text{pred}$;

1.4 $\text{bool} (\text{invoke} (\text{pred}, \text{invoke} (\text{proj}, *i)))$ for the overloads with both parameters $\text{proj}$ and $\text{pred}$.

2 **Effects:** Returns the number of iterators $i$ in the range $[\text{first}, \text{last})$ for which $E$ holds.

3 **Complexity:** Exactly $\text{last} - \text{first}$ applications of the corresponding predicate and any projection.

### 27.6.12 Mismatch

```
§ 27.6.12 1327
```
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, 
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr ranges::mismatch_result<I1, I2>
ranges::mismatch(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});
template<input_range R1, input_range R2, 
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr ranges::mismatch_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
ranges::mismatch(R1&& r1, R2&& r2, Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

1 Let last2 be first2 + (last1 - first1) for the overloads with no parameter last2 or r2.

2 Let E be:

(2.1)   !(*(first1 + n) == *(first2 + n)) for the overloads with no parameter pred;

(2.2)   pred(*(first1 + n), *(first2 + n)) == false for the overloads with a parameter pred and
        no parameter proj1;

(2.3)   !invoke(pred, invoke(proj1, *(first1 + n)), invoke(proj2, *(first2 + n))) for the
        overloads with both parameters pred and proj1.

3 Let N be min(last1 - first1, last2 - first2).

4 Returns: { first1 + n, first2 + n }, where n is the smallest integer in [0, N) such that E holds,
or N if no such integer exists.

5 Complexity: At most N applications of the corresponding predicate and any projections.

27.6.13 Equal

[alg.equal]

template<class InputIterator1, class InputIterator2>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2);

template<class InputIterator1, class InputIterator2, 
class BinaryPredicate>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, BinaryPredicate pred);

template<class InputIterator1, class InputIterator2>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2, 
class BinaryPredicate>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2, 
                        BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr bool ranges::equal(I1 first1, S1 last1, I2 first2, S2 last2,
Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, class Pred = ranges::equal_to,
class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<input_iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr bool ranges::equal(R1&& r1, R2&& r2, Pred pred = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

Let:

(1.1) last2 be first2 + (last1 - first1) for the overloads with no parameter last2 or r2;
(1.2) pred be equal_to{} for the overloads with no parameter pred;
(1.3) E be:

(1.3.1) pred(*i, *(first2 + (i - first1))) for the overloads with no parameter proj1;
(1.3.2) invoke(pred, invoke(proj1, *i), invoke(proj2, *(first2 + (i - first1)))) for
the overloads with parameter proj1.

Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if E holds
for every iterator i in the range [first1, last1). Otherwise, returns false.

Complexity:

(3.1) the types of first1, last1, first2, and last2 meet the Cpp17RandomAccessIterator requirements
(25.3.5.7) and last1 - first1 != last2 - first2 for the overloads in namespace std;
(3.2) the types of first1, last1, first2, and last2 pairwise model sized_sentinel_for (25.3.4.8)
and last1 - first1 != last2 - first2 for the first overload in namespace ranges,
(3.3) R1 and R2 each model sized_range and ranges::distance(r1) != ranges::distance(r2) for
the second overload in namespace ranges,
then no applications of the corresponding predicate and each projection; otherwise,

(3.4) For the overloads with no ExecutionPolicy, at most min(last1 - first1, last2 - first2)
applications of the corresponding predicate and any projections.
(3.5) For the overloads with an ExecutionPolicy, O(min(last1 - first1, last2 - first2)) appli-
cations of the corresponding predicate.

27.6.14 Is permutation

template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2);

template<class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, BinaryPredicate pred);

template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);

Let last2 be first2 + (last1 - first1) for the overloads with no parameter named last2, and let pred be equal_to{} for the overloads with no parameter pred.

**Mandates:** ForwardIterator1 and ForwardIterator2 have the same value type.

** Preconditions:** The comparison function is an equivalence relation.

**Returns:** If last1 - first1 != last2 - first2, return false. Otherwise return true if there exists a permutation of the elements in the range [first2, last2), beginning with ForwardIterator2 begin, such that equal(first1, last1, begin, pred) returns true; otherwise, returns false.

**Complexity:** No applications of the corresponding predicate if ForwardIterator1 and ForwardIterator2 meet the requirements of random access iterators and last1 - first1 != last2 - first2. Otherwise, exactly last1 - first1 applications of the corresponding predicate if equal(first1, last1, first2, last2, pred) would return true; otherwise, at worst $O(N^2)$, where $N$ has the value last1 - first1.

```cpp
template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2, class Proj1 = identity, class Proj2 = identity, indirect_equivalence_relation<projected<I1, Proj1>, projected<I2, Proj2>> Pred = ranges::equal_to>
constexpr bool ranges::is_permutation(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
```

**Returns:** If last1 - first1 != last2 - first2, return false. Otherwise return true if there exists a permutation of the elements in the range [first2, last2), bounded by [pfirst, plast), such that ranges::equal(first1, last1, pfirst, plast, pred, proj1, proj2) returns true; otherwise, returns false.

**Complexity:** No applications of the corresponding predicate and projections if:

- for the first overload,
  - S1 and I1 model sized_sentinel_for<S1, I1>,
  - S2 and I2 model sized_sentinel_for<S2, I2>, and
  - last1 - first1 != last2 - first2;
- for the second overload, R1 and R2 each model sized_range, and ranges::distance(r1) != ranges::distance(r2).

Otherwise, exactly last1 - first1 applications of the corresponding predicate and projections if ranges::equal(first1, last1, first2, last2, pred, proj1, proj2) would return true; otherwise, at worst $O(N^2)$, where $N$ has the value last1 - first1.

### 27.6.15 Search

```cpp
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator1 search(ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1 search(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2);
```
template<class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
constexpr ForwardIterator1
suyểnx<ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, BinaryPredicate pred>;

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
ForwardIterator1
search<ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, BinaryPredicate pred>;

1. **Returns**: The first iterator i in the range \([first1, last1 - (last2 - first2))\) such that for every non-negative integer \(n\) less than \(last2 - first2\) the following corresponding conditions hold: \(*(i + n) == *(first2 + n), pred(*i + n, *(first2 + n)) != false\). Returns `first1` if \([first2, last2)\) is empty, otherwise returns `last1` if no such iterator is found.

2. **Complexity**: At most \((last1 - first1) \times (last2 - first2)\) applications of the corresponding predicate.

template<forward_iterator I1, sentinel_for<I1> S1, forward_iterator I2, sentinel_for<I2> S2, class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<I1, I2, Pred, Proj1, Proj2>
constexpr subrange<I1>
ranges::search(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<forward_range R1, forward_range R2, class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
requires indirectly_comparable<iterator_t<R1>, iterator_t<R2>, Pred, Proj1, Proj2>
constexpr borrowed_subrange_t<R1>
ranges::search(R1&& r1, R2&& r2, Pred pred = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

3. **Returns**: 
   \(\{i, i + (last2 - first2)\}\), where \(i\) is the first iterator in the range \([first1, last1 - (last2 - first2))\) such that for every non-negative integer \(n\) less than \(last2 - first2\) the condition 
   \(bool(invoke(pred, invoke(proj1, *(i + n)), invoke(proj2, *(first2 + n))))\)
   is true.

4. **Complexity**: At most \((last1 - first1) \times (last2 - first2)\) applications of the corresponding predicate and projections.

template<class ForwardIterator, class Size, class T>
constexpr ForwardIterator
search_n(ForwardIterator first, ForwardIterator last, Size count, const T& value);

template<class ExecutionPolicy, class ForwardIterator, class Size, class T>
ForwardIterator
search_n(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Size count, const T& value);

template<class ForwardIterator, class Size, class T, class BinaryPredicate>
constexpr ForwardIterator
search_n(ForwardIterator first, ForwardIterator last, Size count, const T& value, BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator, class Size, class T, class BinaryPredicate>
ForwardIterator
    search_n(ExecutionPolicy&& exec,
             ForwardIterator first, ForwardIterator last,
             Size count, const T& value,
             BinaryPredicate pred);

Mandates: The type Size is convertible to an integral type (7.3.9, 11.4.8).

Returns: The first iterator i in the range [first, last - count) such that for every non-negative integer n less than count the following corresponding conditions hold: *(i + n) == value, pred(*(i + n), value) != false. Returns last if no such iterator is found.

Complexity: At most last - first applications of the corresponding predicate.

template<forward_iterator I, sentinel_for<I> S, class T, class Pred = ranges::equal_to, class Proj = identity>
constexpr subrange<I>
    ranges::search_n(I first, S last, iter_difference_t<I> count, const T& value, Pred pred = {}, Proj proj = {});

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
           class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
    constexpr bool ranges::starts_with(I1 first1, S1 last1, I2 first2, S2 last2, Pred pred = {},
                                         Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, class Pred = ranges::equal_to, class Proj1 = identity, class Proj2 = identity>
    constexpr bool ranges::starts_with(R1&& r1, R2&& r2, Pred pred = {},
                                         Proj1 proj1 = {}, Proj2 proj2 = {});

Returns: ranges::mismatch(std::move(first1), last1, std::move(first2), last2, pred, proj1, proj2).in2 == last2

27.6.16 Starts with [alg.starts.with]

27.6.17 Ends with [alg.ends.with]
Let \( N_1 \) be \( \text{last1} - \text{first1} \) and \( N_2 \) be \( \text{last2} - \text{first2} \).

Returns: \( \text{false} \) if \( N_1 < N_2 \), otherwise

\[
\text{ranges::equal(std::move(first1) + (N1 - N2), last1, std::move(first2), last2, pred, proj1, proj2)}
\]

Let \( N_1 \) be \( \text{ranges::distance(r1)} \) and \( N_2 \) be \( \text{ranges::distance(r2)} \).

Returns: \( \text{false} \) if \( N_1 < N_2 \), otherwise

\[
\text{ranges::equal(ranges::drop_view(ranges::ref_view(r1), N1 - N2), r2, pred, proj1, proj2)}
\]

27.6.18 Fold

\[
\text{template<input_iterator I, sentinel_for<I> S, class T, indirectly-binary-left-foldable<T, I> F>}
\]

\[
\text{constexpr auto ranges::fold_left(I first, S last, T init, F f);} \tag{1}
\]

Returns:

\[
\text{ranges::fold_left_with_iter(std::move(first), last, std::move(init), f).value}
\]

\[
\text{template<input_iterator I, sentinel_for<I> S, indirectly-binary-left-foldable<iter_value_t<I>, I> F>}
\]

\[
\text{constexpr auto ranges::fold_left_first(I first, S last, F f);} \tag{2}
\]

Effects: Equivalent to:

\[
\text{using U = decay_t<invoke_result_t<F&> , iter_reference_t<I>>;}
\]

\[
\text{if (first == last)}
\]

\[
\text{return U(std::move(init)) ;}
\]

\[
\text{I tail = ranges::next(first, last);}
\]

\[
\text{U accum = invoke(f, *--tail, std::move(init));}
\]

\[
\text{while (first != tail)}
\]

\[
\text{accum = invoke(f, *--tail, std::move(accum));}
\]

\[
\text{return accum;}
\]

Effects: Equivalent to:

\[
\text{using U = decay_t<invoke_result_t<F&> , range_reference_t<R>>;}
\]

\[
\text{if (first == last)}
\]

\[
\text{return U(std::move(init));}
\]

\[
\text{R tail = ranges::next(first, last);}
\]

\[
\text{U accum = invoke(f, *--tail, std::move(init));}
\]

\[
\text{while (first != tail)}
\]

\[
\text{accum = invoke(f, *--tail, std::move(accum));}
\]

\[
\text{return accum;}
\]

\[
\text{template<bidirectional_iterator I, sentinel_for<I> S, class T, indirectly-binary-right-foldable<T, I> F>}
\]

\[
\text{constexpr auto ranges::fold_right(I first, S last, T init, F f);} \tag{3}
\]

\[
\text{template<bidirectional_range R, class T, indirectly-binary-right-foldable<range_value_t<R>, iterator_t<R>> F>}
\]

\[
\text{constexpr auto ranges::fold_right_last(R&& r, T init, F f);} \tag{4}
\]

\[
\text{template<bidirectional_iterator I, sentinel_for<I> S, indirectly-binary-right-foldable<iter_value_t<I>, I> F>}
\]

\[
\text{constexpr auto ranges::fold_right_first(I first, S last, F f);} \tag{5}
\]

\[
\text{template<bidirectional_range R, indirectly-binary-right-foldable<range_value_t<R>, range_reference_t<R>> F>}
\]

\[
\text{constexpr auto ranges::fold_right_last(R&& r, F f);} \tag{6}
\]

\[
\text{template<bidirectional_iterator I, sentinel_for<I> S, indirectly-binary-right-foldable<iter_value_t<I>, I> F>}
\]

\[
\text{constexpr auto ranges::fold_right_first_with_iter(std::move(first), last, f).value}
\]

\[
\text{template<bidirectional_iterator I, sentinel_for<I> S, indirectly-binary-right-foldable<range_value_t<R>, iterator_t<R>> F>}
\]

\[
\text{constexpr auto ranges::fold_right_last_with_iter(std::move(first), last, f).value}
\]
constexpr auto ranges::fold_right_last(R&& r, F f);

Let U be decltype(ranges::fold_right(first, last, iter_value_t<I>(*first), f)).

**Effects**: Equivalent to:

```cpp
if (first == last)
    return optional<U>();
I tail = ranges::prev(ranges::next(first, std::move(last)));
return optional<U>(in_place,
    ranges::fold_right(std::move(first), tail, iter_value_t<I>(*tail), std::move(f)));
```

**Remarks**: The return type is `fold_left_with_iter_result<I, U>` for the first overload and `fold_left_with_iter_result<borrowed_iterator_t<R>, U>` for the second overload.

Let U be decay_t<invoke_result_t<F&, T, iter_reference_t<I>>>.

**Effects**: Equivalent to:

```cpp
if (first == last)
    return {std::move(first), U(std::move(init))};
U accum = invoke(f, std::move(init), *first);
for (++first; first != last; ++first)
    accum = invoke(f, std::move(accum), *first);
return {std::move(first), std::move(accum)};
```

**Remarks**: The return type is `fold_left_with_iter_result<I, U>` for the first overload and `fold_left_with_iter_result<borrowed_iterator_t<R>, U>` for the second overload.

---

### 27.7 Mutating sequence operations

#### 27.7.1 Copy

```cpp
template<class InputIterator, class OutputIterator>
constexpr OutputIterator copy(InputIterator first, InputIterator last, OutputIterator result);
```

```cpp
template<input_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr ranges::copy_result<I, O> ranges::copy(I first, S last, O result);
```
```
template<input_range R, weakly_incrementable O>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::copy_result<borrowed_iterator_t<R>, O> ranges::copy(R&& r, O result);

Let \( N \) be \( \text{last} - \text{first} \).

**Preconditions:** \( \text{result} \) is not in the range \([\text{first}, \text{last})\).

**Effects:** Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result}, \text{result} + N)\) starting from \(\text{first}\) and proceeding to \(\text{last}\). For each non-negative integer \( n < N \), performs \( \ast(\text{result} + n) = \ast(\text{first} + n) \).

**Returns:**
- \( \text{result} + N \) for the overload in namespace \text{std}.
- \( \{\text{last}, \text{result} + N\} \) for the overload in namespace \text{ranges}.

**Complexity:** Exactly \( N \) assignments.

```
Let $E$ be:

- $\text{(15.1)} \quad \text{bool(pred(*i))}$
- $\text{(15.2)} \quad \text{bool(invoke(pred, invoke(proj, *i)))}$

and $N$ be the number of iterators $i$ in the range $[\text{first}, \text{last})$ for which the condition $E$ holds.

Preconditions: The ranges $[\text{first}, \text{last})$ and $[\text{result}, \text{result} + (\text{last} - \text{first}))$ do not overlap.

[Note 1: For the overload with an ExecutionPolicy, there might be a performance cost if $\text{iterator_traits<ForwardIterator1>::value_type}$ is not $\text{Cpp17MoveConstructible}$ (Table 31). — end note]

Effects: Copies all of the elements referred to by the iterator $i$ in the range $[\text{first}, \text{last})$ for which $E$ is true.

Returns:

- $\text{(18.1)} \quad \text{result + N}$
- $\text{(18.2)} \quad \{\text{last}, \text{result + N}\}$

Complexity: Exactly $\text{last} - \text{first}$ applications of the corresponding predicate and any projection.

Remarks: Stable (16.4.6.8).

---

27.7.2 Move

template<class InputIterator, class OutputIterator>
constexpr OutputIterator move(InputIterator first, InputIterator last, OutputIterator result);

---

216) $\text{copy_backward}$ can be used instead of $\text{copy}$ when last is in the range $[\text{result} - N, \text{result})$. 
Let $E$ be

- std::move(*(first + $n$)) for the overload in namespace std;
- ranges::iter_move(first + $n$) for the overloads in namespace ranges.

Let $N$ be last - first.

**Preconditions:** result is not in the range [first,last).

**Effects:** Moves elements in the range [first,last) into the range [result,result + $N$) starting from first and proceeding to last. For each non-negative integer $n < N$, performs *(result + $n$) = $E$.

**Returns:**

- result + $N$ for the overload in namespace std.
- {last, result + $N$} for the overloads in namespace ranges.

**Complexity:** Exactly $N$ assignments.

Let $E$ be

- std::move(*(last - $n$)) for the overload in namespace std;
- ranges::iter_move(last - $n$) for the overloads in namespace ranges.

Let $N$ be last - first.

**Preconditions:** The ranges [first,last) and [result,result + $N$) do not overlap.

**Effects:** Moves elements in the range [first,last) into the range [result,result + $N$). For each non-negative integer $n < N$, performs *(result + $n$) = std::move(*(first + $n$)).

**Returns:** result + $N$.

**Complexity:** Exactly $N$ assignments.
Returns:

- result - N for the overload in namespace std.
- \{last, result - N\} for the overloads in namespace ranges.

Complexity: Exactly N assignments.

27.7.3 Swap

```cpp
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator2
swap_ranges(ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
swap_ranges(ExecutionPolicy&& exec,
            ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2);
```

```cpp
template<input_iterator I1, sentinel_for<I1> S1,
          input_iterator I2, sentinel_for<I2> S2>
requires indirectly_swappable<I1, I2>
constexpr ranges::swap_ranges_result<I1, I2>
ranges::swap_ranges(I1 first1, S1 last1, I2 first2, S2 last2);
```

```cpp
template<input_range R1, input_range R2>
requires indirectly_swappable<iterator_t<R1>, iterator_t<R2>>
constexpr ranges::swap_ranges_result<borrowed_iterator_t<R1>,
borrowed_iterator_t<R2>>
ranges::swap_ranges(R1&& r1, R2&& r2);
```

Let:

1. last2 be first2 + (last1 - first1) for the overloads with no parameter named last2;
2. M be min(last1 - first1, last2 - first2).

Preconditions: The two ranges [first1, last1) and [first2, last2) do not overlap. For the overloads in namespace std, *(first1 + n) is swappable with (16.4.4.3) *(first2 + n).

Effects: For each non-negative integer n < M performs:

1. swap(*(first1 + n), *(first2 + n)) for the overloads in namespace std;
2. ranges::iter_swap(first1 + n, first2 + n) for the overloads in namespace ranges.

Returns:

1. last2 for the overloads in namespace std.
2. \{first1 + M, first2 + M\} for the overloads in namespace ranges.

Complexity: Exactly M swaps.

```cpp
template<class ForwardIterator1, class ForwardIterator2>
constexpr void iter_swap(ForwardIterator1 a, ForwardIterator2 b);
```

Preconditions: a and b are dereferenceable. *a is swappable with (16.4.4.3) *b.

Effects: As if by swap(*a, *b).

27.7.4 Transform

```cpp
template<class InputIterator, class OutputIterator,
         class UnaryOperation>
constexpr OutputIterator
transform(InputIterator first1, InputIterator last1,
          OutputIterator result, UnaryOperation op);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class UnaryOperation>
ForwardIterator2
transform(ExecutionPolicy&& exec,
          ForwardIterator1 first1, ForwardIterator1 last1,
          ForwardIterator2 result, UnaryOperation op);
```
template<class InputIterator1, class InputIterator2, 
  class OutputIterator, class BinaryOperation>
constexpr OutputIterator
transform(InputIterator1 first1, InputIterator1 last1, 
  InputIterator2 first2, OutputIterator result, 
  BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
  class ForwardIterator, class BinaryOperation>
ForwardIterator
transform(ExecutionPolicy&& exec, 
  ForwardIterator1 first1, ForwardIterator1 last1, 
  ForwardIterator2 first2, ForwardIterator result, 
  BinaryOperation binary_op);

template<input_iterator I, sentinel_for<I> S, weakly_incrementable 0, 
  copy_constructible F, class Proj = identity>
requires indirectly_writable<0, indirect_result_t<F&>, projected<I, Proj>>
constexpr ranges::unary_transform_result<I, O>
ranges::transform(I first1, S last1, O result, F op, Proj proj = {});

template<input_range R, weakly_incrementable 0, copy_constructible F, 
  class Proj = identity>
requires indirectly_writable<0, indirect_result_t<F&>, projected<iterator_t<R>, Proj>>
constexpr ranges::unary_transform_result<borrowed_iterator_t<R>, O>
ranges::transform(R&& r1, O result, F op, Proj proj = {});

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, 
  weakly_incrementable 0, copy_constructible F, class Proj1 = identity, 
  class Proj2 = identity>
requires indirectly_writable<0, indirect_result_t<F&>, projected<I1, Proj1>, 
  projected<I2, Proj2>>
constexpr ranges::binary_transform_result<I1, I2, O>
ranges::transform(I1 first1, S1 last1, I2 first2, S2 last2, O result, 
  F binary_op, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable 0, 
  copy_constructible F, class Proj1 = identity, class Proj2 = identity>
requires indirectly_writable<0, indirect_result_t<F&>, projected<iterator_t<R1>, Proj1>, 
  projected<iterator_t<R2>, Proj2>>
constexpr ranges::binary_transform_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
ranges::transform(R1&& r1, R2&& r2, O result, 
  F binary_op, Proj1 proj1 = {}, Proj2 proj2 = {});

Let:

1. last2 be first2 + (last1 - first1) for the overloads with parameter first2 but no parameter last2;
2. N be last1 - first1 for unary transforms, or min(last1 - first1, last2 - first2) for binary transforms;
3. E be
   1. op(*(first1 + (i - result))) for unary transforms defined in namespace std;
   2. binary_op(*(first1 + (i - result)), *(first2 + (i - result))) for binary transforms defined in namespace std;
   3. invoke(op, invoke(proj, *(first1 + (i - result)))) for unary transforms defined in namespace ranges;
   4. invoke(binary_op, invoke(proj1, *(first1 + (i - result))), invoke(proj2, 
      *(first2 + (i - result)))) for binary transforms defined in namespace ranges.

Preconditions: op and binary_op do not invalidate iterators or subranges, nor modify elements in the ranges
--- [result, result + N]. \( ^{218} \)

**Effects:** Assigns through every iterator \( i \) in the range \([result, result + N)\) a new corresponding value equal to \( E \).

**Returns:**

---

- \( result + N \) for the overloads defined in namespace `std`.
- \( \{first1 + N, result + N\} \) for unary transforms defined in namespace `ranges`.
- \( \{first1 + N, first2 + N, result + N\} \) for binary transforms defined in namespace `ranges`.

**Complexity:** Exactly \( N \) applications of \( \text{op} \) or \( \text{binary_op} \), and any projections. This requirement also applies to the overload with an `ExecutionPolicy`.

**Remarks:** \( result \) may be equal to \( first1 \) or \( first2 \).

### 27.7.5 Replace

```
template<class ForwardIterator, class T>
constexpr void replace(ForwardIterator first, ForwardIterator last,
                       const T& old_value, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator, class T>
void replace(ExecutionPolicy&& exec,
             ForwardIterator first, ForwardIterator last,
             const T& old_value, const T& new_value);

template<class ForwardIterator, class Predicate, class T>
constexpr void replace_if(ForwardIterator first, ForwardIterator last,
                           Predicate pred, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator, class Predicate, class T>
void replace_if(ExecutionPolicy&& exec,
                ForwardIterator first, ForwardIterator last,
                Predicate pred, const T& new_value);
```

```
template<input_iterator I, sentinel_for<I> S, class T1, class T2, class Proj = identity>
requires indirectly_writable<I, const T2&> &&
     indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T1*>
constexpr I
    ranges::replace(I first, S last, const T1& old_value, const T2& new_value, Proj proj = {});

template<input_range R, class T1, class T2, class Proj = identity>
requires indirectly_writable<iterator_t<R>, const T2&> &&
     indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T1*>
constexpr borrowed_iterator_t<R>
    ranges::replace(R&& r, const T1& old_value, const T2& new_value, Proj proj = {});
```

**Remarks:**

- Let \( E \) be
  - bool(*i == old_value) for `replace`;
  - bool(pred(*i)) for `replace_if`;
  - bool(invoke(proj, *i) == old_value) for `ranges::replace`;
  - bool(invoke(pred, invoke(proj, *i))) for `ranges::replace_if`.

---

\( ^{218} \) The use of fully closed ranges is intentional.
**Mandates:** `new_value` is writable (25.3.1) to `first`.

**Effects:** Substitutes elements referred by the iterator `i` in the range `[first, last)` with `new_value`, when `E` is true.

**Returns:** `last` for the overloads in namespace `ranges`.

**Complexity:** Exactly `last - first` applications of the corresponding predicate and any projection.

```cpp
template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
replace_copy(InputIterator first, InputIterator last,
              OutputIterator result,
              const T& old_value, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
ForwardIterator2
replace_copy(ExecutionPolicy&& exec,
              ForwardIterator1 first, ForwardIterator1 last,
              ForwardIterator2 result,
              const T& old_value, const T& new_value);

template<class InputIterator, class OutputIterator, class Predicate, class T>
constexpr OutputIterator
replace_copy_if(InputIterator first, InputIterator last,
                OutputIterator result,
                Predicate pred, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class Predicate, class T>
ForwardIterator2
replace_copy_if(ExecutionPolicy&& exec,
                ForwardIterator1 first, ForwardIterator1 last,
                ForwardIterator2 result,
                Predicate pred, const T& new_value);

template<input_iterator I, sentinel_for<I> S, class T1, class T2, output_iterator<const T2&> O,
           class Proj = identity>
requires indirectly_copyable<I, O> &&
  indirect_binary_predicate<ranges::equal_to, projected<I, Proj>, const T1*>;

constexpr ranges::replace_copy_result<I, O>
ranges::replace_copy(I first, S last, O result, const T1& old_value, const T2& new_value,
                     Proj proj = {});

template<input_range R, class T1, class T2, output_iterator<const T2&> O,
           class Proj = identity>
requires indirectly_copyable<iterator_t<R>, O> &&
  indirect_binary_predicate<ranges::equal_to, projected<iterator_t<R>, Proj>, const T1*>;

constexpr ranges::replace_copy_result<borrowed_iterator_t<R>, O>
ranges::replace_copy(R&& r, O result, const T1& old_value, const T2& new_value,
                     Proj proj = {});

template<input_iterator I, sentinel_for<I> S, class T, output_iterator<const T&> O,
           class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>;

constexpr ranges::replace_copy_if_result<I, O>
ranges::replace_copy_if(I first, S last, O result, Pred pred, const T& new_value,
                        Proj proj = {});

template<input_range R, class T, output_iterator<const T&> O, class Proj = identity,
           indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires indirectly_copyable<iterator_t<R>, O>;

constexpr ranges::replace_copy_if_result<borrowed_iterator_t<R>, O>
ranges::replace_copy_if(R&& r, O result, Pred pred, const T& new_value,
                      Proj proj = {});

Let `E` be

(6.1) `bool(*(first + (i - result)) == old_value)` for `replace_copy`;

(6.2) `bool(pred(*(first + (i - result))))` for `replace_copy_if`;

§ 27.7.5
Mandates: The results of the expressions \(*first\) and \(\text{new\_value}\) are writable (25.3.1) to \(\text{result}\).

Preconditions: The ranges \([first, last)\) and \([result, result + (last - first))\) do not overlap.

Effects: Assigns through every iterator \(i\) in the range \([result, result + (last - first))\) a new corresponding value

\[ \begin{align*}
    & \text{— } \text{new\_value if } E \text{ is true or } \\
    & \text{— } \text{*(first + (i - result)) otherwise.}
\end{align*} \]

Returns:

\[ \begin{align*}
    & \text{— result + (last - first) for the overloads in namespace std.} \\
    & \text{— } \{\text{last, result + (last - first)}\} \text{ for the overloads in namespace } \text{ranges.}
\end{align*} \]

Complexity: Exactly \((last - first)\) applications of the corresponding predicate and any projection.

### 27.7.6 Fill

\[ \text{alg.fill} \]

\[
\begin{align*}
\text{template<class ForwardIterator, class T>} & \quad \text{constexpr void fill(ForwardIterator first, ForwardIterator last, const T& value);} \\
\text{template<class ExecutionPolicy, class ForwardIterator, class T>} & \quad \text{void fill(ExecutionPolicy&& exec,} \\
& \text{ForwardIterator first, ForwardIterator last, const T& value);} \\
\text{template<class OutputIterator, class Size, class T>} & \quad \text{constexpr OutputIterator fill_n(OutputIterator first, Size n, const T& value);} \\
\text{template<class ExecutionPolicy, class ForwardIterator, class Size, class T>} & \quad \text{ForwardIterator fill_n(ExecutionPolicy&& exec,} \\
& \text{ForwardIterator first, Size n, const T& value);} \\
\text{template<class T, output_iterator<const T&> O, sentinel_for<O> S>} & \quad \text{constexpr O ranges::fill(O first, S last, const T& value);} \\
\text{template<class T, output_range<const T&> R>} & \quad \text{constexpr borrowed_iterator_t<R> ranges::fill(R& r, const T& value);} \\
\text{template<class T, output_iterator<const T&> O>} & \quad \text{constexpr O ranges::fill_n(O first, iter_difference_t<O> n, const T& value);} \\
\end{align*} \]

Let \(N\) be \(\max(0, n)\) for the \(\text{fill\_n}\) algorithms, and \((last - first)\) for the \(\text{fill}\) algorithms.

Mandates: The expression \(\text{value}\) is writable (25.3.1) to the output iterator. The type \(\text{Size}\) is convertible to an integral type (7.3.9, 11.4.8).

Effects: Assigns \(\text{value}\) through all the iterators in the range \([first, first + N)\).

Returns: \(\text{first + N}\).

Complexity: Exactly \(N\) assignments.

### 27.7.7 Generate

\[ \text{alg.generate} \]

\[
\begin{align*}
\text{template<class ForwardIterator, class Generator>} & \quad \text{constexpr void generate(ForwardIterator first, ForwardIterator last, Generator gen);} \\
\text{template<class ExecutionPolicy, class ForwardIterator, class Generator>} & \quad \text{void generate(ExecutionPolicy&& exec,} \\
& \text{ForwardIterator first, ForwardIterator last, Generator gen);} \\
\text{template<class OutputIterator, class Size, class Generator>} & \quad \text{constexpr OutputIterator generate_n(OutputIterator first, Size n, Generator gen);} \\
\text{template<class ExecutionPolicy, class ForwardIterator, class Size, class Generator>} & \quad \text{ForwardIterator generate_n(ExecutionPolicy&& exec,} \\
& \text{ForwardIterator first, Size n, Generator gen);} \\
\end{align*} \]

§ 27.7.7
template<input_or_output_iterator O, sentinel_for<O> S, copy_constructible F>
requires invocable<F&> && indirectly_writable<O, invoke_result_t<F&>>
constexpr O ranges::generate(O first, S last, F gen);

template<class R, copy_constructible F>
requires invocable<F&> && output_range<R, invoke_result_t<F&>>
constexpr borrowed_iterator_t<R> ranges::generate(R&& r, F gen);

template<input_or_output_iterator O, copy_constructible F>
requires invocable<F&> && indirectly_writable<O, invoke_result_t<F&>>
constexpr O ranges::generate_n(O first, iter_difference_t<O> n, F gen);

Let N be max(0,n) for the generate_n algorithms, and last - first for the generate algorithms.

Mandates: Size is convertible to an integral type (7.3.9, 11.4.8).

Effects: Assigns the result of successive evaluations of gen() through each iterator in the range
[first,first + N).

Returns: first + N.

Complexity: Exactly N evaluations of gen() and assignments.

27.7.8 Remove

[alg.remove]

template<class ForwardIterator, class T>
constexpr ForwardIterator remove(ForwardIterator first, ForwardIterator last,
const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>
ForwardIterator remove(ExecutionPolicy&& exec,
FirstIterator first, ForwardIterator last,
const T& value);

template<class ForwardIterator, class Predicate>
constexpr ForwardIterator remove_if(ForwardIterator first, ForwardIterator last,
Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator remove_if(ExecutionPolicy&& exec,
FirstIterator first, ForwardIterator last,
Predicate pred);

Let E be
(1.1) bool(*i == value) for remove;
(1.2) bool(pred(*i)) for remove_if;
(1.3) bool(invoke(proj, *i) == value) for ranges::remove;
(1.4) bool(invoke(pred, invoke(proj, *i))) for ranges::remove_if.

Preconditions: For the algorithms in namespace std, the type of *first meets the Cpp17MoveAssignable
requirements (Table 33).
Effects: Eliminates all the elements referred to by iterator \( i \) in the range \([\text{first}, \text{last})\) for which \( E \) holds.

Returns: Let \( j \) be the end of the resulting range. Returns:

- \( j \) for the overloads in namespace \textit{std}.
- \( \{j, \text{last}\} \) for the overloads in namespace \textit{ranges}.

Complexity: Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate and any projection.

Remarks: Stable (16.4.6.8).

[Note 1: Each element in the range \([\text{ret}, \text{last})\), where \text{ret} is the returned value, has a valid but unspecified state, because the algorithms can eliminate elements by moving from elements that were originally in that range. — end note]

```cpp
template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
remove_copy(InputIterator first, InputIterator last,
OutputIterator result, const T& value);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class T>
ForwardIterator2
remove_copy(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, const T& value);

template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator
remove_copy_if(InputIterator first, InputIterator last,
OutputIterator result, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class Predicate>
ForwardIterator2
remove_copy_if(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, Predicate pred);

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class T,
class Proj = identity>
requires indirectly_copyable<I, O> &&
indirect_binary_predicate ranges::equal_to, projected<I, Proj>, const T>>
constexpr ranges::remove_copy_result<I, O>
ranges::remove_copy(I first, S last, O result, const T& value, Proj proj = {});

template<input_range R, weakly_incrementable O, class T, class Proj = identity>
requires indirectly_copyable<iterator_t<R>, O> &&
indirect_binary_predicate ranges::equal_to, projected<iterator_t<R>, Proj>, const T>>
constexpr ranges::remove_copy_result<borrowed_iterator_t<R>, O>
ranges::remove_copy(R&& r, O result, const T& value, Proj proj = {});

template<input_iterator I, sentinel_for<I> S, weakly_incrementable O,
class Proj = identity, indirect_unary_predicate projected<I, Proj>> Pred>
requires indirectly_copyable<I, O>
constexpr ranges::remove_copy_if_result<I, O>
ranges::remove_copy_if(I first, S last, O result, Pred pred, Proj proj = {});

template<input_range R, weakly_incrementable O, class Proj = identity,
indirect_unary_predicate projected<iterator_t<R>>, Proj>> Pred>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::remove_copy_if_result<borrowed_iterator_t<R>, O>
ranges::remove_copy_if(R&& r, O result, Pred pred, Proj proj = {});

Let \( E \) be

- \( \text{bool}(*i == \text{value}) \) for remove_copy;
- \( \text{bool}(\text{pred}(*i)) \) for remove_copy_if;
- \( \text{bool}(\text{invoke}(\text{proj}, *i) == \text{value}) \) for ranges::remove_copy;
- \( \text{bool}(\text{invoke}(\text{pred}, \text{invoke}(\text{proj}, *i))) \) for ranges::remove_copy_if.

§ 27.7.8 1344
Let \( N \) be the number of elements in \([\text{first}, \text{last})\) for which \( E \) is false.

**Mandates:** *first* is writable (25.3.1) to result.

**Preconditions:** The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) do not overlap.

[Note 2: For the overloads with an ExecutionPolicy, there might be a performance cost if iterator_traits<ForwardIterator>::value_type does not meet the Cpp17MoveConstructible (Table 31) requirements. —end note]

**Effects:** Copies all the elements referred to by the iterator \( i \) in the range \([\text{first}, \text{last})\) for which \( E \) is false.

**Returns:**

1. \( \text{result} + N \), for the algorithms in namespace std.
2. \( \{\text{last}, \text{result} + N\} \), for the algorithms in namespace ranges.

**Complexity:** Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate and any projection.

**Remarks:** Stable (16.4.6.8).

### 27.7.9 Unique

[alg.unique]

```cpp
template<class ForwardIterator>
constexpr ForwardIterator unique(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator unique(ExecutionPolicy&& exec,
                        ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
constexpr ForwardIterator unique(ForwardIterator first, ForwardIterator last,
                                 BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
ForwardIterator unique(ExecutionPolicy&& exec,
                        ForwardIterator first, ForwardIterator last,
                        BinaryPredicate pred);

template<permutable I, sentinel_for<I> S, class Proj = identity,
         indirect_equivalence_relation<projected<I, Proj>> C = ranges::equal_to>
constexpr subrange<I> ranges::unique(I first, S last, C comp = {}, Proj proj = {});

template<forward_range R, class Proj = identity,
         indirect_equivalence_relation<projected<iterator_t<R>, Proj>> C = ranges::equal_to>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R>
ranges::unique(R&& r, C comp = {}, Proj proj = {});
```

1. Let \( \text{pred} \) be equal_to{} for the overloads with no parameter \( \text{pred} \), and let \( E \) be
   
   1.1. \( \text{bool}(\text{pred}(\*(i - 1), \*i)) \) for the overloads in namespace std;
   
   1.2. \( \text{bool}((\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, \*(i - 1)), \text{invoke}(\text{proj}, \*i))) \) for the overloads in namespace ranges.

2. **Preconditions:** For the overloads in namespace std, \( \text{pred} \) is an equivalence relation and the type of *first* meets the Cpp17MoveAssignable requirements (Table 33).

3. **Effects:** For a nonempty range, eliminates all but the first element from every consecutive group of equivalent elements referred to by the iterator \( i \) in the range \([\text{first} + 1, \text{last})\) for which \( E \) is true.

4. **Returns:** Let \( j \) be the end of the resulting range. Returns:
   
   4.1. \( j \) for the overloads in namespace std.
   
   4.2. \( \{j, \text{last}\} \) for the overloads in namespace ranges.

5. **Complexity:** For nonempty ranges, exactly \( (\text{last} - \text{first}) - 1 \) applications of the corresponding predicate and no more than twice as many applications of any projection.
Let \( \text{pred} \) be \( \text{equal\_to}() \) for the overloads in namespace \( \text{std} \) with no parameter \( \text{pred} \), and let \( E \) be

(6.1) \( \text{bool}(\text{pred}(*i, *(i - 1))) \) for the overloads in namespace \( \text{std} \);

(6.2) \( \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, *i), \text{invoke}(\text{proj}, *(i - 1)))) \) for the overloads in namespace \( \text{ranges} \).

**Mandates:** \( \ast\text{first} \) is writable (25.3.1) to \( \text{result} \).

**Preconditions:**

(8.1) The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result}+(\text{last}-\text{first}))\) do not overlap.

(8.2) For the overloads in namespace \( \text{std} \):

(8.2.1) The comparison function is an equivalence relation.

(8.2.2) For the overloads with no \( \text{ExecutionPolicy} \), let \( T \) be the value type of \( \text{InputIterator} \). If \( \text{InputIterator} \) models \( \text{forward\_iterator} \) (25.3.4.11), then there are no additional requirements for \( T \). Otherwise, if \( \text{OutputIterator} \) meets the \( \text{Cpp17ForwardIterator} \) requirements and its value type is the same as \( T \), then \( T \) meets the \( \text{Cpp17CopyAssignable} \) (Table 34) requirements. Otherwise, \( T \) meets both the \( \text{Cpp17CopyConstructible} \) (Table 32) and \( \text{Cpp17CopyAssignable} \) requirements.

[Note 1: For the overloads with an \( \text{ExecutionPolicy} \), there might be a performance cost if the value type of \( \text{ForwardIterator1} \) does not meet both the \( \text{Cpp17CopyConstructible} \) and \( \text{Cpp17CopyAssignable} \) requirements. — end note]

**Effects:** Copies only the first element from every consecutive group of equal elements referred to by the iterator \( i \) in the range \([\text{first}, \text{last})\) for which \( E \) holds.

**Returns:**

(10.1) \( \text{result} + N \) for the overloads in namespace \( \text{std} \).
27.7.10 Reverse [alg.reverse]

template<class BidirectionalIterator>
constexpr void reverse(BidirectionalIterator first, BidirectionalIterator last);

template<class ExecutionPolicy, class BidirectionalIterator>
void reverse(ExecutionPolicy&& exec,
            BidirectionalIterator first, BidirectionalIterator last);

template<bidirectional_iterator I, sentinel_for<I> S>
requires permutable<I>
constexpr I ranges::reverse(I first, S last);

template<bidirectional_range R>
requires permutable<iterator_t<R>>
constexpr borrowed_iterator_t<R> ranges::reverse(R&& r);

Preconditions: For the overloads in namespace std, BidirectionalIterator meets the Cpp17Value-
Swappable requirements (16.4.4.3).

Effects: For each non-negative integer $i < (\text{last} - \text{first}) / 2$, applies std::iter_swap, or ranges::
iter_swap for the overloads in namespace ranges, to all pairs of iterators first + i, (last - i) - i.

Returns: last for the overloads in namespace ranges.

Complexity: Exactly $(\text{last} - \text{first})/2$ swaps.

template<class BidirectionalIterator, class OutputIterator>
constexpr OutputIterator
reverse_copy(BidirectionalIterator first, BidirectionalIterator last,
             OutputIterator result);

template<class ExecutionPolicy, class BidirectionalIterator, class ForwardIterator>
ForwardIterator
reverse_copy(ExecutionPolicy&& exec,
             BidirectionalIterator first, BidirectionalIterator last,
             ForwardIterator result);

template<bidirectional_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr ranges::reverse_copy_result<I, O>
ranges::reverse_copy(I first, S last, O result);

template<bidirectional_range R, weakly_incrementable O>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::reverse_copy_result<borrowed_iterator_t<R>, O>
ranges::reverse_copy(R&& r, O result);

Let $N$ be last - first.

Preconditions: The ranges $[\text{first}, \text{last})$ and $[\text{result}, \text{result} + N)$ do not overlap.

Effects: Copies the range $[\text{first}, \text{last})$ to the range $[\text{result}, \text{result} + N)$ such that for every non-
negative integer $i < N$ the following assignment takes place: $*(\text{result} + N - 1 - i) = *(\text{first} + i)$.

Returns:

— result + N for the overloads in namespace std.

— $\{\text{last}, \text{result} + N\}$ for the overloads in namespace ranges.

Complexity: Exactly $N$ assignments.

27.7.11 Rotate [alg.rotate]

template<class ForwardIterator>
constexpr ForwardIterator
§ 27.7.11 1347
rotate(ForwardIterator first, ForwardIterator middle, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
rotate(ExecutionPolicy&& exec,
       ForwardIterator first, ForwardIterator middle, ForwardIterator last);

template<permutable I, sentinel_for<I> S>
constexpr subrange<I> ranges::rotate(I first, I middle, S last);

1 Preconditions: [first, middle) and [middle, last) are valid ranges. For the overloads in namespace std, ForwardIterator meets the Cpp17ValueSwappable requirements (16.4.1.3), and the type of *first meets the Cpp17MoveConstructible (Table 31) and Cpp17MoveAssignable (Table 33) requirements.

2 Effects: For each non-negative integer i < (last - first), places the element from the position first + i into position first + (i + (last - middle)) % (last - first).

[Note 1: This is a left rotate. — end note]

3 Returns:

(3.1) — first + (last - middle) for the overloads in namespace std.

(3.2) — {first + (last - middle), last} for the overload in namespace ranges.

4 Complexity: At most last - first swaps.

template<forward_range R>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R> ranges::rotate(R&& r, iterator_t<R> middle);

5 Effects: Equivalent to: return ranges::rotate(ranges::begin(r), middle, ranges::end(r));

template<class ForwardIterator, class OutputIterator>
constexpr OutputIterator
rotate_copy(ForwardIterator first, ForwardIterator middle, ForwardIterator last,
            OutputIterator result);

6 template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
rotate_copy(ExecutionPolicy&& exec,
            ForwardIterator1 first, ForwardIterator1 middle, ForwardIterator1 last,
            ForwardIterator2 result);

7 template<forward_iterator I, sentinel_for<I> S, weakly_incrementable O>
requires indirectly_copyable<I, O>
constexpr ranges::rotate_copy_result<I, O>
ranges::rotate_copy(I first, I middle, S last, O result);

8 Let N = last - first.

7 Preconditions: [first, middle) and [middle, last) are valid ranges. The ranges [first, last) and [result, result + N) do not overlap.

8 Effects: Copies the range [first, last) to the range [result, result + N) such that for each non-negative integer i < N the following assignment takes place: *(result + i) = *(first + (i + (middle - first)) % N).

9 Returns:

(9.1) — result + N for the overloads in namespace std.

(9.2) — {last, result + N} for the overload in namespace ranges.

10 Complexity: Exactly N assignments.

template<forward_range R, weakly_incrementable O>
requires indirectly_copyable<iterator_t<R>, O>
constexpr ranges::rotate_copy_result<borrowed_iterator_t<R>, O>
ranges::rotate_copy(R&& r, iterator_t<R> middle, O result);

11 Effects: Equivalent to:

return ranges::rotate_copy(ranges::begin(r), middle, ranges::end(r), std::move(result));
27.7.12 Sample

\[ \text{SampleIter} \text{Iterator sample(PopulationIter first, PopulationIter last, SampleIter out, Distance n, UniformRandomBitGenerator& g);} \]

\[ \text{template<input_iterator I, sentinel_for<I> S, weakly_incrementable O, class Gen> requires (forward_iterator<I> || random_access_iterator<O>) && indirectly_copyable<I, O> && uniform_random_bit_generator<remove_reference_t<Gen>> O ranges::sample(I first, S last, O out, iter_difference_t<I> n, Gen& g);} \]

\[ \text{template<input_range R, weakly_incrementable O, class Gen> requires (forward_range<R> || random_access_iterator<O>) && indirectly_copyable<iterator_t<R>, O> && uniform_random_bit_generator<remove_reference_t<Gen>> O ranges::sample(R&& r, O out, range_difference_t<R> n, Gen& g);} \]

1 **Mandates:** For the overload in namespace std, Distance is an integer type and **first** is writable (25.3.1) to out.

2 **Preconditions:** out is not in the range \([first, last)\). For the overload in namespace std:

(2.1) — PopulationIterator meets the Cpp17InputIterator requirements (25.3.5.3).

(2.2) — SampleIterator meets the Cpp17OutputIterator requirements (25.3.5.4).

(2.3) — SampleIterator meets the Cpp17RandomAccessIterator requirements (25.3.5.7) unless PopulationIterator models forward_iterator (25.3.4.11).

(2.4) — remove_reference_t<UniformRandomBitGenerator> meets the requirements of a uniform random bit generator type (28.5.3.3).

3 **Effects:** Copies \(\min(last - first, n)\) elements (the sample) from \([first, last)\) (the population) to out such that each possible sample has equal probability of appearance.

[Note 1: Algorithms that obtain such effects include selection sampling and reservoir sampling. — end note]

4 **Returns:** The end of the resulting sample range.

5 **Complexity:** \(\Theta(last - first)\).

6 **Remarks:**

(6.1) — For the overload in namespace std, stable if and only if PopulationIterator models forward_iterator. For the first overload in namespace ranges, stable if and only if I models forward_iterator.

(6.2) — To the extent that the implementation of this function makes use of random numbers, the object g serves as the implementation’s source of randomness.

27.7.13 Shuffle

\[ \text{void shuffle(RandomAccessIter first, RandomAccessIter last, UniformRandomBitGenerator& g);} \]

\[ \text{template<random_access_iterator I, sentinel_for<I> S, class Gen> requires permutatable<I> && uniform_random_bit_generator<remove_reference_t<Gen>> I ranges::shuffle(I first, S last, Gen& g);} \]

\[ \text{template<random_access_range R, class Gen> requires permutatable<iterator_t<R>> && uniform_random_bit_generator<remove_reference_t<Gen>> borrowed_iterator_t<R> ranges::shuffle(R&& r, Gen& g);} \]

1 **Preconditions:** For the overload in namespace std:

(1.1) — RandomAccessIterator meets the Cpp17ValueSwappable requirements (16.4.4.3).
The type `remove_reference_t<UniformRandomBitGenerator>` meets the uniform random bit generator (28.5.3.3) requirements.

**Effects:** Permutates the elements in the range `[first, last)` such that each possible permutation of those elements has equal probability of appearance.

**Returns:** `last` for the overloads in namespace `ranges`.

**Complexity:** Exactly `(last - first) - 1` swaps.

**Remarks:** To the extent that the implementation of this function makes use of random numbers, the object referenced by `g` shall serve as the implementation’s source of randomness.

### 27.7.14 Shift

**Template declarations:**

```cpp
template<class ForwardIterator>
constexpr ForwardIterator
shift_left(ForwardIterator first, ForwardIterator last,
          typename iterator_traits<ForwardIterator>::difference_type n);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
shift_left(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
          typename iterator_traits<ForwardIterator>::difference_type n);

template<permutable I, sentinel_for<I> S>
constexpr subrange<I> ranges::shift_left(I first, S last, iter_difference_t<I> n);

template<forward_range R>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R> ranges::shift_left(R&& r, range_difference_t<R> n);
```

**Preconditions:** `n >= 0` is true. For the overloads in namespace `std`, the type of `*first` meets the `Cpp17MoveAssignable` requirements.

**Effects:** If `n == 0` or `n >= last - first`, does nothing. Otherwise, moves the element from position `first + n + i` into position `first + i` for each non-negative integer `i < (last - first) - n`. For the overloads without an `ExecutionPolicy` template parameter, does so in order starting from `i = 0` and proceeding to `i = (last - first) - n - 1`.

**Returns:** Let `NEW_LAST` be `first + (last - first - n)` if `n < last - first`, otherwise `first`.

**Complexity:** At most `(last - first) - n` assignments.

```cpp
template<class ForwardIterator>
constexpr ForwardIterator
shift_right(ForwardIterator first, ForwardIterator last,
            typename iterator_traits<ForwardIterator>::difference_type n);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
shift_right(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
            typename iterator_traits<ForwardIterator>::difference_type n);

template<permutable I, sentinel_for<I> S>
constexpr subrange<I> ranges::shift_right(I first, S last, iter_difference_t<I> n);

template<forward_range R>
requires permutable<iterator_t<R>>
constexpr borrowed_subrange_t<R> ranges::shift_right(R&& r, range_difference_t<R> n);
```

**Preconditions:** `n >= 0` is true. For the overloads in namespace `std`, the type of `*first` meets the `Cpp17MoveAssignable` requirements, and `ForwardIterator` meets the `Cpp17BidirectionalIterator` requirements (25.3.5.6) or the `Cpp17ValueSwappable` requirements.

**Effects:** If `n == 0` or `n >= last - first`, does nothing. Otherwise, moves the element from position `first + i` into position `first + n + i` for each non-negative integer `i < (last - first) - n`. Does so in order starting from `i = (last - first) - n - 1` and proceeding to `i = 0` if:
— for the overload in namespace std without an ExecutionPolicy template parameter, ForwardIterator meets the Cpp17BidirectionalIterator requirements,

— for the overloads in namespace ranges, I models bidirectional_iterator.

Returns: Let NEW_FIRST be first + n if n < last - first, otherwise last.

NEW_FIRST for the overloads in namespace std.

NEW_FIRST, last} for the overloads in namespace ranges.

Complexity: At most (last - first) - n assignments or swaps.

27.8 Sorting and related operations

27.8.1 General

The operations in 27.8 defined directly in namespace std have two versions: one that takes a function object of type Compare and one that uses an operator<.

Compare is a function object type (22.10) that meets the requirements for a template parameter named BinaryPredicate (27.2). The return value of the function call operation applied to an object of type Compare, when converted to bool, yields true if the first argument of the call is less than the second, and false otherwise. Compare comp is used throughout for algorithms assuming an ordering relation.

For all algorithms that take Compare, there is a version that uses operator< instead. That is, comp(*i, *j) != false defaults to *i < *j != false. For algorithms other than those described in 27.8.4, comp shall induce a strict weak ordering on the values.

The term strict refers to the requirement of an irreflexive relation (!comp(x, x) for all x), and the term weak to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define equiv(a, b) as !comp(a, b) && !comp(b, a), then the requirements are that comp and equiv both be transitive relations:

— comp(a, b) && comp(b, c) implies comp(a, c)
— equiv(a, b) && equiv(b, c) implies equiv(a, c)

[Note 1: Under these conditions, it can be shown that]
— equiv is an equivalence relation,
— comp induces a well-defined relation on the equivalence classes determined by equiv, and
— the induced relation is a strict total ordering.

—end note]

A sequence is sorted with respect to a comp and proj for a comparator and projection comp and proj if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence,

bool(invoke(comp, invoke(proj, *(i + n)), invoke(proj, *i)))

is false.

A sequence is sorted with respect to a comparator comp for a comparator comp if it is sorted with respect to comp and identity{} (the identity projection).

A sequence [start, finish) is partitioned with respect to an expression f(e) if there exists an integer n such that for all 0 <= i < (finish - start), f(*((start + i))) is true if and only if i < n.

In the descriptions of the functions that deal with ordering relationships we frequently use a notion of equivalence to describe concepts such as stability. The equivalence to which we refer is not necessarily an operator==, but an equivalence relation induced by the strict weak ordering. That is, two elements a and b are considered equivalent if and only if !(a < b) && !(b < a).

27.8.2 Sorting

27.8.2.1 sort

template<class RandomAccessIterator>
constexpr void sort(RandomAccessIterator first, RandomAccessIterator last);
template<class ExecutionPolicy, class RandomAccessIterator>
void sort(ExecutionPolicy&& exec,
          RandomAccessIterator first, RandomAccessIterator last);
Let \( \text{comp} \) be \( \text{less}() \) and \( \text{proj} \) be \( \text{identity}() \) for the overloads with no parameters by those names.

Preconditions: For the overloads in namespace \( \text{std} \), \( \text{RandomAccessIterator} \) meets the \text{Cpp17Value-Swappable} requirements (16.4.4.3) and the type of \( \ast \text{first} \) meets the \text{Cpp17MoveConstructible} (Table 31) and \text{Cpp17MoveAssignable} (Table 33) requirements.

Effects: Sorts the elements in the range \([\text{first}, \text{last})\) with respect to \( \text{comp} \) and \( \text{proj} \).

Returns: last for the overloads in namespace \( \text{ranges} \).

Complexity: Let \( N \) be \( \text{last} - \text{first} \). \( \Theta(N \log N) \) comparisons and projections.
Remarks: Stable (16.4.6.8).

27.8.2.3 partial_sort

\begin{verbatim}
template<class RandomAccessIterator>
constexpr void partial_sort(RandomAccessIterator first,
RandomAccessIterator middle,
RandomAccessIterator last);
template<class ExecutionPolicy, class RandomAccessIterator>
void partial_sort(ExecutionPolicy&& exec,
RandomAccessIterator first,
RandomAccessIterator middle,
RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void partial_sort(RandomAccessIterator first,
RandomAccessIterator middle,
RandomAccessIterator last,
Compare comp);
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void partial_sort(ExecutionPolicy&& exec,
RandomAccessIterator first,
RandomAccessIterator middle,
RandomAccessIterator last,
Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::partial_sort(I first, I middle, S last, Comp comp = {}, Proj proj = {});
\end{verbatim}

\begin{enumerate}
\item Let \texttt{comp} be \texttt{less{}} and \texttt{proj} be \texttt{identity{}} for the overloads with no parameters by those names.
\item Preconditions: \texttt{[first, middle)} and \texttt{[middle, last)} are valid ranges. For the overloads in namespace \texttt{std}, \texttt{RandomAccessIterator} meets the Cpp17ValueSwappable requirements (16.4.4.3) and the type of \texttt{*first} meets the Cpp17MoveConstructible (Table 31) and Cpp17MoveAssignable (Table 33) requirements.
\item Effects: Places the first \texttt{middle - first} elements from the range \texttt{[first, last)} as sorted with respect to \texttt{comp} and \texttt{proj} into the range \texttt{[first, middle)}. The rest of the elements in the range \texttt{[middle, last)} are placed in an unspecified order.
\item Returns: \texttt{last} for the overload in namespace \texttt{ranges}.
\item Complexity: Approximately \((last - first) \cdot \log(middle - first)\) comparisons, and twice as many projections.
\end{enumerate}

\begin{verbatim}
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::partial_sort(R&& r, iterator_t<R> middle, Comp comp = {}, Proj proj = {});
\end{verbatim}

\begin{enumerate}
\item Equivalent to:
\begin{verbatim}
return ranges::partial_sort(ranges::begin(r), middle, ranges::end(r), comp, proj);
\end{verbatim}
\end{enumerate}

27.8.2.4 partial_sort_copy

\begin{verbatim}
template<class InputIterator, class RandomAccessIterator>
constexpr RandomAccessIterator
partial_sort_copy(InputIterator first, InputIterator last,
RandomAccessIterator result_first,
RandomAccessIterator result_last);
template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator>
RandomAccessIterator
partial_sort_copy(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
RandomAccessIterator result_first,
\end{verbatim}
RandomAccessIterator result_last);

template<class InputIterator, class RandomAccessIterator>
constexpr RandomAccessIterator
partial_sort_copy(InputIterator first, InputIterator last,
RandomAccessIterator result_first,
RandomAccessIterator result_last,
Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator>
RandomAccessIterator
partial_sort_copy(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
RandomAccessIterator result_first,
RandomAccessIterator result_last,
Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, random_access_iterator I2, sentinel_for<I2> S2,
class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires indirectly_copyable<I1, I2> && sortable<I1, Comp, Proj2> &&
indirect_strict_weak_order<Comp, projected<I1, Proj1>, projected<I2, Proj2>>
constexpr ranges::partial_sort_copy_result<I1, I2>
ranges::partial_sort_copy(I1 first, S1 last, I2 result_first, S2 result_last,
Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, random_access_range R2, class Comp = ranges::less,
class Proj1 = identity, class Proj2 = identity>
requires indirectly_copyable<iterator_t<R1>, iterator_t<R2>>, sortable<iterator_t<R2>, Comp, Proj2> &&
indirect_strict_weak_order<Comp, projected<iterator_t<R1>, Proj1>,
projected<iterator_t<R2>, Proj2>>
constexpr ranges::partial_sort_copy_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>>
ranges::partial_sort_copy(R1&& r, R2&& result_r, Comp comp = {},
Proj1 proj1 = {}, Proj2 proj2 = {});

Let \( N \) be \( \min(last - first, result_last - result_first) \). Let \( \text{comp} \) be \( \text{less}{} \), and \( \text{proj1} \) and \( \text{proj2} \) be \( \text{identity}{} \) for the overloads with no parameters by those names.

Mandates: For the overloads in namespace \( \text{std} \), the expression \( *\text{first} \) is writable (25.3.1) to \( \text{result} - \text{first} \).

Preconditions: For the overloads in namespace \( \text{std} \), \( \text{RandomAccessIterator} \) meets the \( \text{Cpp17ValueSwappable} \) requirements (16.4.4.3), the type of \( *\text{result_first} \) meets the \( \text{Cpp17MoveConstructible} \) (Table 31) and \( \text{Cpp17MoveAssignable} \) (Table 33) requirements.

For iterators \( a1 \) and \( b1 \) in \( [\text{first}, \text{last}) \), and iterators \( x2 \) and \( y2 \) in \( [\text{result_first}, \text{result_last}) \), after evaluating the assignment \( *y2 = *b1 \), let \( E \) be the value of

\[
\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj1}, *a1), \text{invoke}(\text{proj2}, *y2))).
\]

Then, after evaluating the assignment \( *x2 = *a1 \), \( E \) is equal to

\[
\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj2}, *x2), \text{invoke}(\text{proj2}, *y2))).
\]

[Note 1: Writing a value from the input range into the output range does not affect how it is ordered by \( \text{comp} \) and \( \text{proj1} \) or \( \text{proj2} \). — end note]

Effects: Places the first \( N \) elements as sorted with respect to \( \text{comp} \) and \( \text{proj2} \) into the range \( [\text{result} - \text{first}, \text{result_first} + N) \).

Returns:

\( \text{result_first} + N \) for the overloads in namespace \( \text{std} \).

\{last, result_first + N\} for the overloads in namespace \( \text{ranges} \).

Complexity: Approximately \( (\text{last} - \text{first}) \times \log N \) comparisons, and twice as many projections.
27.8.2.5 `is_sorted`

```cpp
template<class ForwardIterator>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last);
```

**Effects:** Equivalent to: return is_sorted_until(first, last) == last;

```cpp
template<class ExecutionPolicy, class ForwardIterator>
bool is_sorted(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last);
```

**Effects:** Equivalent to:
```
return is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last) == last;
```

```cpp
template<class ForwardIterator, class Compare>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last, Compare comp);
```

**Effects:** Equivalent to:
```
return is_sorted_until(first, last, comp) == last;
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Compare>
bool is_sorted(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Compare comp);
```

**Effects:** Equivalent to:
```
return is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last;
```

```cpp
template<forward_iterator I, sentinel_for<I> S, class Proj = identity, indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::is_sorted_until(I first, S last, Comp comp = {}, Proj proj = {});
```

**Effects:** Equivalent to: return ranges::is_sorted_until(first, last, comp, proj) == last;

```cpp
template<class ForwardIterator>
constexpr ForwardIterator is_sorted_until(ForwardIterator first, ForwardIterator last);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator is_sorted_until(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last);
```

```cpp
template<class ForwardIterator, class Compare>
constexpr ForwardIterator is_sorted_until(ForwardIterator first, ForwardIterator last, Compare comp);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator is_sorted_until(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Compare comp);
```

```cpp
template<forward_iterator I, sentinel_for<I> S, class Proj = identity, indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::is_sorted_until(I first, S last, Comp comp = {}, Proj proj = {});
```

**Let comp be `less{}` and proj be `identity{}` for the overloads with no parameters by those names.**

**Returns:** The last iterator i in [first, last] for which the range [first, i) is sorted with respect to comp and proj.
Complexity: Linear.

27.8.3 Nth element

```cpp
template<class RandomAccessIterator>
constexpr void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
                            RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void nth_element(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator nth,
                 RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
                            RandomAccessIterator last, Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void nth_element(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator nth,
                 RandomAccessIterator last, Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
         class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
    ranges::nth_element(I first, I nth, S last, Comp comp = {}, Proj proj = {});
```

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

Preconditions: `[first, nth)` and `[nth, last)` are valid ranges. For the overloads in namespace `std`, `RandomAccessIterator` meets the `Cpp17ValueSwappable` requirements (16.4.4.3), and the type of *first* meets the `Cpp17MoveConstructible` (Table 31) and `Cpp17MoveAssignable` (Table 33) requirements.

Effects: After `nth_element` the element in the position pointed to by `nth` is the element that would be in that position if the whole range were sorted with respect to `comp` and `proj`, unless `nth == last`. Also for every iterator `i` in the range `[first, nth)` and every iterator `j` in the range `[nth, last)` it holds that: `bool(invoke(comp, invoke(proj, *j), invoke(proj, *i)))` is false.

Returns: `last` for the overload in namespace `ranges`.

Complexity: For the overloads with no `ExecutionPolicy`, linear on average. For the overloads with an `ExecutionPolicy`, $\Theta(N)$ applications of the predicate, and $\Theta(N \log N)$ swaps, where $N = \text{last} - \text{first}$.

```cpp
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
    ranges::nth_element(R&& r, iterator_t<R> nth, Comp comp = {}, Proj proj = {});
```

Effects: Equivalent to:
```
return ranges::nth_element(ranges::begin(r), nth, ranges::end(r), comp, proj);
```

27.8.4 Binary search

27.8.4.1 General

All of the algorithms in 27.8.4 are versions of binary search and assume that the sequence being searched is partitioned with respect to an expression formed by binding the search key to an argument of the comparison function. They work on non-random access iterators minimizing the number of comparisons, which will be logarithmic for all types of iterators. They are especially appropriate for random access iterators, because these algorithms do a logarithmic number of steps through the data structure. For non-random access iterators they execute a linear number of steps.

27.8.4.2 lower_bound

```cpp
template<class ForwardIterator, class T>
constexpr ForwardIterator
    lower_bound(ForwardIterator first, ForwardIterator last, T key);
```
lower_bound(ForwardIterator first, ForwardIterator last, 
const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr ForwardIterator
lower_bound(ForwardIterator first, ForwardIterator last, 
const T& value, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity, 
indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::lower_bound(I first, S last, const T& value, Comp comp = {}, 
Proj proj = {});

template<forward_range R, class T, class Proj = identity, 
indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R>
ranges::lower_bound(R&& r, const T& value, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for overloads with no parameters by those names.

Preconditions: The elements e of [first, last) are partitioned with respect to the expression 
bool(invoke(comp, invoke(proj, e), value)).

Returns: The furthermost iterator i in the range [first, last] such that for every iterator j in the 
range [first, i), bool(invoke(comp, invoke(proj, *j), value)) is true.

Complexity: At most log₂(last - first) + Θ(1) comparisons and projections.

27.8.4.3 upper_bound [upper.bound]

template<class ForwardIterator, class T>
constexpr ForwardIterator
upper_bound(ForwardIterator first, ForwardIterator last, 
const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr ForwardIterator
upper_bound(ForwardIterator first, ForwardIterator last, 
const T& value, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity, 
indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::upper_bound(I first, S last, const T& value, Comp comp = {}, 
Proj proj = {});

template<forward_range R, class T, class Proj = identity, 
indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R>
ranges::upper_bound(R&& r, const T& value, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for overloads with no parameters by those names.

Preconditions: The elements e of [first, last) are partitioned with respect to the expression 
!bool(invoke(comp, value, invoke(proj, e))).

Returns: The furthermost iterator i in the range [first, last] such that for every iterator j in the 
range [first, i), !bool(invoke(comp, value, invoke(proj, *j))) is true.

Complexity: At most log₂(last - first) + Θ(1) comparisons and projections.

27.8.4.4 equal_range [equal.range]

template<class ForwardIterator, class T>
constexpr pair<ForwardIterator, ForwardIterator>
equal_range(ForwardIterator first, 
ForwardIterator last, const T& value);
template<class ForwardIterator, class T, class Compare>
constexpr pair<ForwardIterator, ForwardIterator>
equal_range(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity, indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr subrange<I>
ranges::equal_range(I first, S last, const T& value, Comp comp = {}, Proj proj = {});

template<forward_range R, class T, class Proj = identity, indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_subrange_t<R>
ranges::equal_range(R&& r, const T& value, Comp comp = {}, Proj proj = {});

1 Let comp be less{} and proj be identity{} for overloads with no parameters by those names.

2 Preconditions: The elements e of [first, last) are partitioned with respect to the expressions
   bool(invoke(comp, invoke(proj, e), value)) and !bool(invoke(comp, value, invoke(proj, e))). Also, for all elements e of [first, last), bool(comp(e, value)) implies !bool(comp(value, e)) for the overloads in namespace std.

3 Returns:
   • For the overloads in namespace std:
     {lower_bound(first, last, value, comp),
      upper_bound(first, last, value, comp)}
   • For the overloads in namespace ranges:
     {ranges::lower_bound(first, last, value, comp, proj),
      ranges::upper_bound(first, last, value, comp, proj)}

4 Complexity: At most $2 \times \log_2 (\text{last} - \text{first}) + O(1)$ comparisons and projections.

27.8.4.5 binary_search

template<class ForwardIterator, class T>
constexpr bool
binary_search(ForwardIterator first, ForwardIterator last, const T& value);

template<class ForwardIterator, class T, class Compare>
constexpr bool
binary_search(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class T, class Proj = identity, indirect_strict_weak_order<const T*, projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::binary_search(I first, S last, const T& value, Comp comp = {}, Proj proj = {});

template<forward_range R, class T, class Proj = identity, indirect_strict_weak_order<const T*, projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr bool ranges::binary_search(R&& r, const T& value, Comp comp = {}, Proj proj = {});

1 Let comp be less{} and proj be identity{} for overloads with no parameters by those names.

2 Preconditions: The elements e of [first, last) are partitioned with respect to the expressions
   bool(invoke(comp, invoke(proj, e), value)) and !bool(invoke(comp, value, invoke(proj, e))). Also, for all elements e of [first, last), bool(comp(e, value)) implies !bool(comp(value, e)) for the overloads in namespace std.

3 Returns: true if and only if for some iterator i in the range [first, last), !bool(invoke(comp, invoke(proj, *i), value)) && !bool(invoke(comp, value, invoke(proj, *i))) is true.

4 Complexity: At most $\log_2 (\text{last} - \text{first}) + O(1)$ comparisons and projections.
### 27.8.5 Partitions

**template<class InputIterator, class Predicate>**

```cpp
constexpr bool is_partitioned(InputIterator first, InputIterator last, Predicate pred);
```

**template<class ExecutionPolicy, class ForwardIterator, class Predicate>**

```cpp
bool is_partitioned(ExecutionPolicy&& exec,
                    ForwardIterator first, ForwardIterator last, Predicate pred);
```

**template<input_iterator I, sentinel_for<I> S, class Proj = identity,
             indirect_unary_predicate<projected<I, Proj>> Pred>**

```cpp
constexpr bool ranges::is_partitioned(I first, S last, Pred pred, Proj proj = {});
```

**template<input_range R, class Proj = identity,
            indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>**

```cpp
constexpr bool ranges::is_partitioned(R&& r, Pred pred, Proj proj = {});
```

1. Let `proj` be `identity{}` for the overloads with no parameter named `proj`.
2. **Returns:** true if and only if the elements `e` of `[first, last)` are partitioned with respect to the expression `bool(invoke(pred, invoke(proj, e)))`.
3. **Complexity:** Linear. At most `last - first` applications of `pred` and `proj`.

**template<class ForwardIterator, class Predicate>**

```cpp
constexpr ForwardIterator partition(ForwardIterator first, ForwardIterator last, Predicate pred);
```

**template<class ExecutionPolicy, class ForwardIterator, class Predicate>**

```cpp
ForwardIterator partition(ExecutionPolicy&& exec,
                          ForwardIterator first, ForwardIterator last, Predicate pred);
```

**template<permutable I, sentinel_for<I> S, class Proj = identity,
           indirect_unary_predicate<projected<I, Proj>> Pred>**

```cpp
constexpr subrange<I>
ranges::partition(I first, S last, Pred pred, Proj proj = {});
```

**template<forward_range R, class Proj = identity,
           indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>**

```cpp
requires permutable<iterator_t<R>>
ranges::partition(R&& r, Pred pred, Proj proj = {});
```

4. Let `proj` be `identity{}` for the overloads with no parameter named `proj` and let `E(x)` be `bool(invoke(pred, invoke(proj, x)))`.
5. **Preconditions:** For the overloads in namespace std, `ForwardIterator` meets the `Cpp17ValueSwappable` requirements (16.4.4.3).
6. **Effects:** Places all the elements `e` in `[first, last)` that satisfy `E(e)` before all the elements that do not.
7. **Returns:** Let `i` be an iterator such that `E(*j)` is true for every iterator `j` in `[first, i)` and false for every iterator `j` in `[i, last)`. Returns:
   - `i` for the overloads in namespace std.
   - `{i, last}` for the overloads in namespace `ranges`.
8. **Complexity:** Let `N = last - first`:
   - For the overload with no `ExecutionPolicy`, exactly `N` applications of the predicate and projection. At most `N/2` swaps if the type of `first` meets the `Cpp17BidirectionalIterator` requirements for the overloads in namespace std or models `bidirectional_iterator` for the overloads in namespace `ranges`, and at most `N` swaps otherwise.
   - For the overload with an `ExecutionPolicy`, `O(N log N)` swaps and `O(N)` applications of the predicate.

**template<class BidirectionalIterator, class Predicate>**

```cpp
BidirectionalIterator stable_partition(BidirectionalIterator first, BidirectionalIterator last, Predicate pred);
```

§ 27.8.5
template<class ExecutionPolicy, class BidirectionalIterator, class Predicate>
BidirectionalIterator
stable_partition(ExecutionPolicy&& exec,
    BidirectionalIterator first, BidirectionalIterator last, Predicate pred);

template<bidirectional_iterator I, sentinel_for<I> S, class Proj = identity,
    indirect_unary_predicate<projected<I, Proj>> Pred>
requires permutable<I>
 subrange<I> ranges::stable_partition(I first, S last, Pred pred, Proj proj = {});

template<bidirectional_range R, class Proj = identity,
    indirect_unary_predicate<projected<iterator_t<R>, Proj>> Pred>
requires permutable<iterator_t<R>>
borrowed_subrange_t<R> ranges::stable_partition(R&& r, Pred pred, Proj proj = {});

Let proj be identity{} for the overloads with no parameter named proj and let $E(x)$ be
bool(invoke(pred, invoke(proj, x))).

Preconditions: For the overloads in namespace std, BidirectionalIterator meets the
Cpp17Value-Swappable requirements (16.4.4.3) and the type of *first meets the
Cpp17MoveConstructible (Table 31) and Cpp17MoveAssignable (Table 33) requirements.

Effects: Places all the elements $e$ in [first, last) that satisfy $E(e)$ before all the elements that do not.
The relative order of the elements in both groups is preserved.

Returns: Let $i$ be an iterator such that for every iterator $j$ in [first, i), $E(*j)$ is true, and for every iterator $j$ in the range [i, last), $E(*j)$ is false. Returns:

(12.1) $i$ for the overloads in namespace std.
(12.2) {i, last} for the overloads in namespace ranges.

Complexity: Let $N = last - first$:

(13.1) For the overloads with no ExecutionPolicy, at most $N \log_2 N$ swaps, but only $O(N)$ swaps if
there is enough extra memory. Exactly $N$ applications of the predicate and projection.

(13.2) For the overload with an ExecutionPolicy, $O(N \log N)$ swaps and $O(N)$ applications of the
predicate.

Mandates: For the overloads with no parameter named proj and let $E(x)$ be bool(invoke(
pred, invoke(proj, x))).

Mandates: For the overloads in namespace std, the expression *first is writable (25.3.1) to out_true
and out_false.
Preconditions: The input range and output ranges do not overlap.

[Note 1: For the overload with an ExecutionPolicy, there might be a performance cost if `first`'s value type does not meet the `Cpp17CopyConstructible` requirements. — end note]

Effects: For each iterator `i` in `[first, last)`, copies `*i` to the output range beginning with `out_true` if `E(*i)` is `true`, or to the output range beginning with `out_false` otherwise.

Returns: Let `o1` be the end of the output range beginning at `out_true`, and `o2` the end of the output range beginning at `out_false`. Returns

- `{o1, o2}` for the overloads in namespace `std`.
- `{last, o1, o2}` for the overloads in namespace `ranges`.

Complexity: Exactly last - first applications of `pred` and `proj`.

template<class ForwardIterator, class Predicate>
constexpr ForwardIterator
partition_point(ForwardIterator first, ForwardIterator last, Predicate pred);

template<class I, sentinel_for<I> S, class Proj = identity, indirect_unary_predicate<projected<I, Proj>> Pred>
constexpr I ranges::partition_point(I first, S last, Pred pred, Proj proj = {});

template<class R, class Proj = identity, indirect_unary_predicate<iterator_t<R>, Proj>>
constexpr borrowed_iterator_t<R> ranges::partition_point(R&& r, Pred pred, Proj proj = {});

Preconditions: The elements `e` of `[first, last)` are partitioned with respect to `E(e)`.

Returns: An iterator `mid` such that `E(*i)` is `true` for all iterators `i` in `[first, mid)`, and `false` for all iterators `i` in `[mid, last)`. Complexity: \(O(\log(last - first))\) applications of `pred` and `proj`.

### 27.8.6 Merge

```cpp
template<class InputIterator1, class InputIterator2, class OutputIterator>
constexpr OutputIterator
merge(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator>
ForwardIterator
merge(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result);

template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>
constexpr OutputIterator
merge(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare>
ForwardIterator
merge(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result, Compare comp);
```
template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::merge_result<I1, I2, O>
ranges::merge(I1 first1, S1 last1, I2 first2, S2 last2, O result, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::merge_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
ranges::merge(R1&& r1, R2&& r2, O result, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

Let \( N \) be \((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})\). Let \( \text{comp} \) be \( \text{less}\{\} \), \( \text{proj1} \) be \( \text{identity}\{\} \), and \( \text{proj2} \) be \( \text{identity}\{\} \), for the overloads with no parameters by those names.

Preconditions: The ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) are sorted with respect to \( \text{comp} \) and \( \text{proj1} \) or \( \text{proj2} \), respectively. The resulting range does not overlap with either of the original ranges.

Effects: Copies all the elements of the two ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) into the range \([\text{result}, \text{result_last})\), where \( \text{result_last} = \text{result} + N \). If an element \( a \) precedes \( b \) in an input range, \( a \) is copied into the output range before \( b \). If \( e1 \) is an element of \([\text{first1}, \text{last1})\) and \( e2 \) of \([\text{first2}, \text{last2})\), \( e2 \) is copied into the output range before \( e1 \) if and only if \( \text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj2}, e2), \text{invoke}(\text{proj1}, e1))) \) is true.

Returns:

\(\text{(4.1)}\) — \(\text{result_last}\) for the overloads in namespace \(\text{std}\).
\(\text{(4.2)}\) — \(\{\text{last1}, \text{last2}, \text{result_last}\}\) for the overloads in namespace \(\text{ranges}\).

Complexity:

\(\text{(5.1)}\) — For the overloads with no \(\text{ExecutionPolicy}\), at most \(N - 1\) comparisons and applications of each projection.
\(\text{(5.2)}\) — For the overloads with an \(\text{ExecutionPolicy}\), \(O(N)\) comparisons.

Remarks: Stable (16.4.6.8).

template<class BidirectionalIterator>
void inplace_merge(BidirectionalIterator first, BidirectionalIterator middle, BidirectionalIterator last);

template<class ExecutionPolicy, class BidirectionalIterator>
void inplace_merge(ExecutionPolicy&& exec, BidirectionalIterator first, BidirectionalIterator middle, BidirectionalIterator last);

template<class BidirectionalIterator, class Compare>
void inplace_merge(BidirectionalIterator first, BidirectionalIterator middle, BidirectionalIterator last, Compare comp);

template<class ExecutionPolicy, class BidirectionalIterator, class Compare>
void inplace_merge(ExecutionPolicy&& exec, BidirectionalIterator first, BidirectionalIterator middle, BidirectionalIterator last, Compare comp);

template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less, class Proj = identity>
requires sortable<I, Comp, Proj>
I ranges::inplace_merge(I first, I middle, S last, Comp comp = {}, Proj proj = {});

Let \( \text{comp} \) be \( \text{less}\{\} \) and \( \text{proj} \) be \( \text{identity}\{\} \) for the overloads with no parameters by those names.
Preconditions: \([\text{first}, \text{middle})\) and \([\text{middle}, \text{last})\) are valid ranges sorted with respect to \(\text{comp}\) and \(\text{proj}\). For the overloads in namespace \text{std}, \text{BidirectionalIterator} meets the \text{Cpp17ValueSwappable} requirements (16.4.4.3) and the type of *first meets the \text{Cpp17MoveConstructible} (Table 31) and \text{Cpp17MoveAssignable} (Table 33) requirements.

Effects: Merges two sorted consecutive ranges \([\text{first}, \text{middle})\) and \([\text{middle}, \text{last})\), putting the result of the merge into the range \([\text{first}, \text{last})\). The resulting range is sorted with respect to \(\text{comp}\) and \(\text{proj}\).

Returns: last for the overload in namespace \text{ranges}.

Complexity: Let \(N = \text{last} - \text{first}\):

\[\begin{align}
N - 1 \\
O(N \log N)
\end{align}\]

In either case, twice as many projections as comparisons.

Remarks: Stable (16.4.6.8).

\[
\text{template<bidirectional_range } R, \text{ class Comp } = \text{ranges::less}, \text{ class Proj } = \text{identity}> \\
\text{requires sortable<iterator_t<R>, Comp, Proj>} \\
\text{borrowed_iterator_t<R> ranges::inplace_merge}(R&& r, iterator_t<R> middle, Comp comp = {}, Proj proj = {});
\]

Effects: Equivalent to:

\[
\text{return ranges::inplace_merge(ranges::begin(r), middle, ranges::end(r), comp, proj);}\
\]

27.8.7 Set operations on sorted structures [alg.set.operations]

27.8.7.1 General [alg.set.operations.general]

Subclause 27.8.7 defines all the basic set operations on sorted structures. They also work with multisets (24.4.7) containing multiple copies of equivalent elements. The semantics of the set operations are generalized to multisets in a standard way by defining \text{set_union} to contain the maximum number of occurrences of every element, \text{set_intersection} to contain the minimum, and so on.

27.8.7.2 includes [includes]

\[
\text{template<class InputIterator1, class InputIterator2>} \\
\text{constexpr bool includes(InputIterator1 first1, InputIterator1 last1,} \\
\text{InputIterator2 first2, InputIterator2 last2);} \\
\text{template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>} \\
\text{bool includes(ExecutionPolicy&& exec,} \\
\text{ForwardIterator1 first1, ForwardIterator1 last1,} \\
\text{ForwardIterator2 first2, ForwardIterator2 last2);} \\
\]

\[
\text{template<class InputIterator1, class InputIterator2, class Compare>} \\
\text{constexpr bool includes(InputIterator1 first1, InputIterator1 last1,} \\
\text{InputIterator2 first2, InputIterator2 last2,} \\
\text{Compare comp);} \\
\text{template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare>} \\
\text{bool includes(ExecutionPolicy&& exec,} \\
\text{ForwardIterator1 first1, ForwardIterator1 last1,} \\
\text{ForwardIterator2 first2, ForwardIterator2 last2,} \\
\text{Compare comp);} \\
\]

\[
\text{template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,} \\
\text{class Proj1 = identity, class Proj2 = identity,} \\
\text{indirect_strict_weak_order<projected<I1, Proj1>,} \\
\text{projected<I2, Proj2>> Comp = ranges::less>} \\
\text{constexpr bool ranges::includes(I1 first1, S1 last1, I2 first2, S2 last2, Comp comp = {};} \\
\text{Proj1 proj1 = {};} \\
\text{Proj2 proj2 = {});} \\
\text{template<input_range R1, input_range R2, class Proj1 = identity,} \\
\text{class Proj2 = identity,} \\
\text{indirect_strict_weak_order<projected<input_iterator_t<R1>, Proj1>,} \\
\text{projected<input_iterator_t<R2>, Proj2>> Comp = ranges::less>} \\
\text{constexpr bool ranges::includes(R1&& r1, R2&& r2, Comp comp = {})}\
\]
Let $comp$ be $\text{less}()$, $proj_1$ be $\text{identity}()$, and $proj_2$ be $\text{identity}()$, for the overloads with no parameters by those names.

**Preconditions:** The ranges $[\text{first}_1, \text{last}_1)$ and $[\text{first}_2, \text{last}_2)$ are sorted with respect to $comp$ and $proj_1$ or $proj_2$, respectively.

**Returns:** $true$ if and only if $[\text{first}_2, \text{last}_2)$ is a subsequence of $[\text{first}_1, \text{last}_1)$.

[Note 1: A sequence $S$ is a subsequence of another sequence $T$ if $S$ can be obtained from $T$ by removing some, all, or none of $T$'s elements and keeping the remaining elements in the same order. — end note]

**Complexity:** At most $2 \times ((\text{last}_1 - \text{first}_1) + (\text{last}_2 - \text{first}_2)) - 1$ comparisons and applications of each projection.

27.8.7.3 set_union

template<class InputIterator1, class InputIterator2, class OutputIterator>
constexpr OutputIterator
set_union(InputIterator1 first1, InputIterator1 last1,
  InputIterator2 first2, InputIterator2 last2,
  OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
  class ForwardIterator>
ForwardIterator
set_union(ExecutionPolicy&& exec,
  ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2, ForwardIterator2 last2,
  ForwardIterator result);

template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>
constexpr OutputIterator
set_union(InputIterator1 first1, InputIterator1 last1,
  InputIterator2 first2, InputIterator2 last2,
  OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
  class ForwardIterator, class Compare>
ForwardIterator
set_union(ExecutionPolicy&& exec,
  ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2, ForwardIterator2 last2,
  ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
  weakly_incrementable O, class Comp = ranges::less,
  class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O>
constexpr ranges::set_union_result<I1, I2, O>
ranges::set_union(I1 first1, S1 last1, I2 first2, S2 last2, O result, Comp comp = {},
  Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O,
  class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<input_iterator_t<R1>, input_iterator_t<R2>, O,
  ranges::set_union_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
ranges::set_union(R1&& r1, R2&& r2, O result, Comp comp = {},
  Proj1 proj1 = {}, Proj2 proj2 = {});

Let $comp$ be $\text{less}()$, and $proj_1$ and $proj_2$ be $\text{identity}()$ for the overloads with no parameters by those names.

**Preconditions:** The ranges $[\text{first}_1, \text{last}_1)$ and $[\text{first}_2, \text{last}_2)$ are sorted with respect to $comp$ and $proj_1$ or $proj_2$, respectively. The resulting range does not overlap with either of the original ranges.

**Effects:** Constructs a sorted union of the elements from the two ranges; that is, the set of elements that are present in one or both of the ranges.

**Returns:** Let $\text{result} \_\text{last}$ be the end of the constructed range. Returns
result_last for the overloads in namespace std.

{last1, last2, result_last} for the overloads in namespace ranges.

Complexity: At most $2 \ast ((last1 - first1) + (last2 - first2)) - 1$ comparisons and applications of each projection.

Remarks: Stable (16.4.6.8). If [first1, last1) contains $m$ elements that are equivalent to each other and [first2, last2) contains $n$ elements that are equivalent to them, then all $m$ elements from the first range are copied to the output range, in order, and then the final max($n - m, 0$) elements from the second range are copied to the output range, in order.

27.8.7.4 set_intersection

template<class InputIterator1, class InputIterator2, class OutputIterator>
constexpr OutputIterator set_intersection(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator>
ForwardIterator set_intersection(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result);

template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>
constexpr OutputIterator set_intersection(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator, class Compare>
ForwardIterator set_intersection(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<I1, I2, O, Comp, Proj1, Proj2>
constexpr ranges::set_intersection_result<I1, I2, O>
ranges::set_intersection(I1 first1, S1 last1, I2 first2, S2 last2, O result, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O, class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity>
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2>
constexpr ranges::set_intersection_result<borrowed_iterator_t<R1>, borrowed_iterator_t<R2>, O>
ranges::set_intersection(R1&& r1, R2&& r2, O result, Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

Let comp be less{}, and proj1 and proj2 be identity{} for the overloads with no parameters by those names.

Preconditions: The ranges [first1, last1) and [first2, last2) are sorted with respect to comp and proj1 or proj2, respectively. The resulting range does not overlap with either of the original ranges.

Effects: Constructs a sorted intersection of the elements from the two ranges; that is, the set of elements that are present in both of the ranges.

Returns: Let result_last be the end of the constructed range. Returns

— result_last for the overloads in namespace std.
— \{last1, last2, result_last\} for the overloads in namespace ranges.

5  Complexity: At most \(2 \times ((last1 - first1) + (last2 - first2)) - 1\) comparisons and applications of each projection.

6  Remarks: Stable (16.4.6.8). If \([first1, last1)\) contains \(m\) elements that are equivalent to each other and \([first2, last2)\) contains \(n\) elements that are equivalent to them, the first \(\min(m, n)\) elements are copied from the first range to the output range, in order.

27.8.7.5  set_difference

\begin{verbatim}
template<class InputIterator1, class InputIterator2, 
          class OutputIterator> 
constexpr OutputIterator 
set_difference(InputIterator1 first1, InputIterator1 last1, 
              InputIterator2 first2, InputIterator2 last2, 
              OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
          class ForwardIterator> 
ForwardIterator 
set_difference(ExecutionPolicy&& exec, 
              ForwardIterator1 first1, ForwardIterator1 last1, 
              ForwardIterator2 first2, ForwardIterator2 last2, 
              ForwardIterator result);

template<class InputIterator1, class InputIterator2, 
          class OutputIterator, class Compare> 
constexpr OutputIterator 
set_difference(InputIterator1 first1, InputIterator1 last1, 
              InputIterator2 first2, InputIterator2 last2, 
              OutputIterator result, Compare comp);

template<class ExecutionPolicy&& exec, 
          class ForwardIterator1, class ForwardIterator2, class ForwardIterator, 
          class Compare> 
ForwardIterator 
set_difference(ExecutionPolicy&& exec, 
              ForwardIterator1 first1, ForwardIterator1 last1, 
              ForwardIterator2 first2, ForwardIterator2 last2, 
              ForwardIterator result, Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2, 
           weakly_incrementable O, class Comp = ranges::less, 
           class Proj1 = identity, class Proj2 = identity> 
requires mergeable<I1, I2, O, Comp, Proj1, Proj2> 
constexpr ranges::set_difference_result<I1, O> 
    ranges::set_difference(I1 first1, S1 last1, I2 first2, S2 last2, O result, 
                           Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, weakly_incrementable O, 
           class Comp = ranges::less, class Proj1 = identity, class Proj2 = identity> 
requires mergeable<iterator_t<R1>, iterator_t<R2>, O, Comp, Proj1, Proj2> 
constexpr ranges::set_difference_result<borrowed_iterator_t<R1>, O> 
    ranges::set_difference(R1&& r1, R2&& r2, O result, 
                          Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});
\end{verbatim}

1  Let \(\text{comp}\) be \{\} and \(\text{proj1}\) and \(\text{proj2}\) be \{\} for the overloads with no parameters by those names.

2  Preconditions: The ranges \([first1, last1)\) and \([first2, last2)\) are sorted with respect to \(\text{comp}\) and \(\text{proj1}\) or \(\text{proj2}\), respectively. The resulting range does not overlap with either of the original ranges.

3  Effects: Copies the elements of the range \([first1, last1)\) which are not present in the range \([first2, last2)\) to the range beginning at \(\text{result}\). The elements in the constructed range are sorted.

4  Returns: Let \(\text{result}_\text{last}\) be the end of the constructed range. Returns

\begin{verbatim}
— \(\text{result}_\text{last}\) for the overloads in namespace std.
— \{last1, result_last\} for the overloads in namespace ranges.
\end{verbatim}
Complexity: At most $2 \times ((\text{last}_1 - \text{first}_1) + (\text{last}_2 - \text{first}_2)) - 1$ comparisons and applications of each projection.

Remarks: If \([\text{first}_1, \text{last}_1]\) contains \(m\) elements that are equivalent to each other and \([\text{first}_2, \text{last}_2]\) contains \(n\) elements that are equivalent to them, the last \(\max(m - n, 0)\) elements from \([\text{first}_1, \text{last}_1]\) are copied to the output range, in order.

27.8.7.6 set_symmetric_difference

```
set_symmetric_difference(InputIterator1 first1, InputIterator1 last1,
                          InputIterator2 first2, InputIterator2 last2,
                          OutputIterator result);
```

Preconditions: The ranges \([\text{first}_1, \text{last}_1]\) and \([\text{first}_2, \text{last}_2]\) are sorted with respect to \text{comp} and \text{proj}_1 or \text{proj}_2, respectively. The resulting range does not overlap with either of the original ranges.

Effects: Copies the elements of the range \([\text{first}_1, \text{last}_1]\) that are not present in the range \([\text{first}_2, \text{last}_2]\), and the elements of the range \([\text{first}_2, \text{last}_2]\) that are not present in the range \([\text{first}_1, \text{last}_1]\) to the range beginning at \text{result}. The elements in the constructed range are sorted.

Returns: Let \text{result}_{last} be the end of the constructed range. Returns

\[\text{result}_{last}\] for the overloads in namespace std.
— \{last1, last2, result_last\} for the overloads in namespace ranges.

Complexity: At most \(2 \times ((last1 - first1) + (last2 - first2)) - 1\) comparisons and applications of each projection.

Remarks: Stable (16.4.6.8). If \([first1, last1]\) contains \(m\) elements that are equivalent to each other and \([first2, last2]\) contains \(n\) elements that are equivalent to them, then \(|m - n|\) of those elements shall be copied to the output range: the last \(m - n\) of these elements from \([first1, last1]\) if \(m > n\), and the last \(n - m\) of these elements from \([first2, last2]\) if \(m < n\). In either case, the elements are copied in order.

### 27.8.8 Heap operations

#### 27.8.8.1 General

A random access range \([a, b)\) is a heap with respect to \(\text{comp}\) and \(\text{proj}\) for a comparator and projection \(\text{comp}\) and \(\text{proj}\) if its elements are organized such that:

1. With \(N = b - a\), for all \(0 < i < N\), \(\text{bool}(\text{invoke}(\text{comp}, \text{invoke}(\text{proj}, a[\lfloor \frac{i}{2} \rfloor])), \text{invoke}(\text{proj}, a[i]))\) is false.
2. \(*a\) may be removed by \(\text{pop_heap}\), or a new element added by \(\text{push_heap}\), in \(O(\log N)\) time.

These properties make heaps useful as priority queues.

\(\text{make_heap}\) converts a range into a heap and \(\text{sort_heap}\) turns a heap into a sorted sequence.

#### 27.8.8.2 push_heap

```
template<class RandomAccessIterator>
constexpr void push_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```
template<class RandomAccessIterator, class Compare>
constexpr void push_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

```
template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less, class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr I
ranges::push_heap(I first, S last, Comp comp = {}, Proj proj = {});
```

```
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::push_heap(R&& r, Comp comp = {}, Proj proj = {});
```

Let \(\text{comp}\) be \(\text{less}\) and \(\text{proj}\) be \(\text{identity}\) for the overloads with no parameters by those names.

Preconditions: The range \([\text{first}, \text{last} - 1)\) is a valid heap with respect to \(\text{comp}\) and \(\text{proj}\). For the overloads in namespace \(\text{std}\), \(\text{RandomAccessIterator}\) meets the \(\text{Cpp17ValueSwappable}\) requirements (16.4.4.3) and the type of \(*\text{first}\) meets the \(\text{Cpp17MoveConstructible}\) requirements (Table 31) and the \(\text{Cpp17MoveAssignable}\) requirements (Table 33).

Effects: Places the value in the location \(\text{last} - 1\) into the resulting heap \([\text{first}, \text{last})\).

Returns: \(\text{last}\) for the overloads in namespace \(\text{ranges}\).

Complexity: At most \(\log(\text{last} - \text{first})\) comparisons and twice as many projections.

#### 27.8.8.3 pop_heap

```
template<class RandomAccessIterator>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```
template<class RandomAccessIterator, class Compare>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```
template<random_access_iterator I, sentinel_for<I> S, class Comp = ranges::less,
class Proj = identity>
constexpr I
ranges::pop_heap(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R>
ranges::pop_heap(R&& r, Comp comp = {}, Proj proj = {});

Let \texttt{comp} be \texttt{less{}} and \texttt{proj} be \texttt{identity{}} for the overloads with no parameters by those names.

Preconditions: The range \( [\texttt{first}, \texttt{last}) \) is a valid non-empty heap with respect to \texttt{comp} and \texttt{proj}. For the overloads in namespace \texttt{std}, \texttt{RandomAccessIterator} meets the \texttt{Cpp17ValueSwappable} requirements (16.4.4.3) and the type of \*\texttt{first} meets the \texttt{Cpp17MoveConstructible} (Table 31) and \texttt{Cpp17MoveAssignable} (Table 33) requirements.

Effects: Swaps the value in the location \texttt{first} with the value in the location \texttt{last - 1} and makes \( [\texttt{first}, \texttt{last} - 1) \) into a heap with respect to \texttt{comp} and \texttt{proj}.

Returns: \texttt{last} for the overloads in namespace \texttt{ranges}.

Complexity: At most \( 2\log(last - first) \) comparisons and twice as many projections.

### 27.8.8.4 make_heap

```cpp
template<class RandomAccessIterator>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last,
Compare comp);
```

Let \texttt{comp} be \texttt{less{}} and \texttt{proj} be \texttt{identity{}} for the overloads with no parameters by those names.

Preconditions: For the overloads in namespace \texttt{std}, \texttt{RandomAccessIterator} meets the \texttt{Cpp17ValueSwappable} requirements (16.4.4.3) and the type of \*\texttt{first} meets the \texttt{Cpp17MoveConstructible} (Table 31) and \texttt{Cpp17MoveAssignable} (Table 33) requirements.

Effects: Constructs a heap with respect to \texttt{comp} and \texttt{proj} out of the range \( [\texttt{first}, \texttt{last}) \).

Returns: \texttt{last} for the overloads in namespace \texttt{ranges}.

Complexity: At most \( 3(last - first) \) comparisons and twice as many projections.

### 27.8.8.5 sort_heap

```cpp
template<class RandomAccessIterator>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last,
Compare comp);
```

§ 27.8.8.5 1369
template<random_access_range R, class Comp = ranges::less, class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr borrowed_iterator_t<R> ranges::sort_heap(R&& r, Comp comp = {}, Proj proj = {});

Let `comp` be `less{}` and `proj` be `identity{}` for the overloads with no parameters by those names.

**Preconditions:** The range `[first, last)` is a valid heap with respect to `comp` and `proj`. For the overloads in namespace `std`, `RandomAccessIterator` meets the `Cpp17ValueSwappable` requirements (16.4.4.3) and the type of `*first` meets the `Cpp17MoveConstructible` (Table 31) and `Cpp17MoveAssignable` (Table 33) requirements.

**Effects:** Sorts elements in the heap `[first, last)` with respect to `comp` and `proj`.

**Returns:** last for the overloads in namespace `ranges`.

**Complexity:** At most $2N \log N$ comparisons, where $N = last - first$, and twice as many projections.

### 27.8.8.6 `is_heap`

```
template<class RandomAccessIterator>
constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last);
```

**Effects:** Equivalent to: return `is_heap_until(first, last) == last;`

```
template<class ExecutionPolicy, class RandomAccessIterator>
bool is_heap(ExecutionPolicy&& exec,
             RandomAccessIterator first, RandomAccessIterator last);
```

**Effects:** Equivalent to:
```
return is_heap_until(std::forward<ExecutionPolicy>(exec), first, last) == last;
```

```
template<class RandomAccessIterator, class Compare>
constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last,
                        Compare comp);
```

**Effects:** Equivalent to:
```
return is_heap_until(first, last, comp) == last;
```

```
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
bool is_heap(ExecutionPolicy&& exec,
             RandomAccessIterator first, RandomAccessIterator last,
             Compare comp);
```

**Effects:** Equivalent to:
```
return is_heap_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last;
```

```
template<random_access_iterator I, sentinel_for<I> S, class Proj = identity,
          indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr bool ranges::is_heap(I first, S last, Comp comp = {}, Proj proj = {});
```

```
template<random_access_range R, class Proj = identity,
          indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr bool ranges::is_heap(R&& r, Comp comp = {}, Proj proj = {});
```

**Effects:** Equivalent to: return `ranges::is_heap_until(first, last, comp, proj) == last;`

```
template<class RandomAccessIterator>
constexpr RandomAccessIterator
is_heap_until(RandomAccessIterator first, RandomAccessIterator last);
```

```
template<class ExecutionPolicy, class RandomAccessIterator>
RandomAccessIterator
is_heap_until(ExecutionPolicy&& exec,
              RandomAccessIterator first, RandomAccessIterator last);
```

```
template<class RandomAccessIterator, class Compare>
constexpr RandomAccessIterator
is_heap_until(RandomAccessIterator first, RandomAccessIterator last,
              Compare comp);
```
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
RandomAccessIterator
is_heap_until(ExecutionPolicy&& exec, 
    RandomAccessIterator first, RandomAccessIterator last, 
    Compare comp);

template<random_access_iterator I, sentinel_for<I> S, class Proj = identity, 
    indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::is_heap_until(I first, S last, Comp comp = {}, Proj proj = {});

template<random_access_range R, class Proj = identity, 
    indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr borrowed_iterator_t<R>
ranges::is_heap_until(R&& r, Comp comp = {}, Proj proj = {});

Let \( \text{comp} \) be \( \text{less}{} \) and \( \text{proj} \) be \( \text{identity}{} \) for the overloads with no parameters by those names.

Returns: The last iterator \( i \) in \([\text{first}, \text{last}]\) for which the range \([\text{first}, i)\) is a heap with respect to \( \text{comp} \) and \( \text{proj} \).

Complexity: Linear.

27.8.9 Minimum and maximum

\[\text{alg.min.max}\]

template<class T>
constexpr T min(const T& a, const T& b);

template<class T, class Compare>
constexpr const T& min(const T& a, const T& b, Compare comp);

Let \( \text{comp} \) be \( \text{less}{} \) and \( \text{proj} \) be \( \text{identity}{} \) for the overloads with no parameters by those names.

Preconditions: For the first form, \( T \) meets the \( \text{Cpp17LessThanComparable} \) requirements (Table 29).

Returns: The smaller value. Returns the first argument when the arguments are equivalent.

Complexity: Exactly one comparison and two applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter \( T \) of the overloads in namespace \( \text{std} \).

template<class T>
constexpr T min(initializer_list<T> r);

template<class T, class Compare>
constexpr T min(initializer_list<T> r, Compare comp);

Preconditions: \( \text{ranges::distance}(r) > 0 \). For the overloads in namespace \( \text{std} \), \( T \) meets the \( \text{Cpp17CopyConstructible} \) requirements. For the first form, \( T \) meets the \( \text{Cpp17LessThanComparable} \) requirements (Table 29).

Returns: The smallest value in the input range. Returns a copy of the leftmost element when several elements are equivalent to the smallest.

Complexity: Exactly \( \text{ranges::distance}(r) - 1 \) comparisons and twice as many applications of the projection, if any.

Remarks: An invocation may explicitly specify an argument for the template parameter \( T \) of the overloads in namespace \( \text{std} \).
template<class T>
constexpr const T& max(const T& a, const T& b);

template<class T, class Compare>
constexpr const T& max(const T& a, const T& b, Compare comp);

template<class T, class Proj = identity,
indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr const T& ranges::max(const T& a, const T& b, Comp comp = {}, Proj proj = {});

Preconditions: For the first form, T meets the Cpp17LessThanComparable requirements (Table 29).
Returns: The larger value. Returns the first argument when the arguments are equivalent.
Complexity: Exactly one comparison and two applications of the projection, if any.
Remarks: An invocation may explicitly specify an argument for the template parameter T of the
overloads in namespace std.

template<class T>
constexpr T max(initializer_list<T> r);

template<class T, class Compare>
constexpr T max(initializer_list<T> r, Compare comp);

template<copyable T, class Proj = identity,
indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr T ranges::max(initializer_list<T> r, Comp comp = {}, Proj proj = {});

Preconditions: ranges::distance(r) > 0. For the overloads in namespace std, T meets the Cpp17-
CopyConstructible requirements. For the first form, T meets the Cpp17LessThanComparable requirements
(Table 29).
Returns: The largest value in the input range. Returns a copy of the leftmost element when several
elements are equivalent to the largest.
Complexity: Exactly ranges::distance(r) - 1 comparisons and twice as many applications of the
projection, if any.
Remarks: An invocation may explicitly specify an argument for the template parameter T of the
overloads in namespace std.

template<class T>
constexpr pair<const T&, const T&> minmax(const T& a, const T& b);

template<class T, class Compare>
constexpr pair<const T&, const T&> minmax(const T& a, const T& b, Compare comp);

template<class T, class Proj = identity,
indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr ranges::minmax_result<const T&>
ranges::minmax(const T& a, const T& b, Comp comp = {}, Proj proj = {});

Preconditions: For the first form, T meets the Cpp17LessThanComparable requirements (Table 29).
Returns: {b, a} if b is smaller than a, and {a, b} otherwise.
Complexity: Exactly one comparison and two applications of the projection, if any.
Remarks: An invocation may explicitly specify an argument for the template parameter T of the
overloads in namespace std.

template<class T>
constexpr pair<T, T> minmax(initializer_list<T> t);

template<class T, class Compare>
constexpr pair<T, T> minmax(initializer_list<T> t, Compare comp);
template<copyable T, class Proj = identity,
    indirect_strict_weak_order<projected<const T*, Proj>> Comp = ranges::less>
constexpr ranges::minmax_result<T>
ranges::minmax(initializer_list<T> r, Comp comp = {}, Proj proj = {});

template<input_range R, class Proj = identity,
    indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
requires indirectly_copyable_storable<iterator_t<R>, range_value_t<R>>
constexpr ranges::minmax_result<range_value_t<R>>
ranges::minmax(R&& r, Comp comp = {}, Proj proj = {});

21 Preconditions: ranges::distance(r) > 0. For the overloads in namespace std, T meets the Cpp17-
CopyConstructible requirements. For the first form, type T meets the Cpp17LessThanComparable
requirements (Table 29).

22 Returns: Let X be the return type. Returns X{x, y}, where x is a copy of the leftmost element with
the smallest value and y a copy of the rightmost element with the largest value in the input range.

23 Complexity: At most (3/2)ranges::distance(r) applications of the corresponding predicate and twice
as many applications of the projection, if any.

24 Remarks: An invocation may explicitly specify an argument for the template parameter T of the
overloads in namespace std.

template<class ForwardIterator>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator min_element(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last,
    Compare comp);

template<class ForwardIterator, class Compare>
ForwardIterator min_element(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
    indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::min_element(I first, S last, Comp comp = {}, Proj proj = {});

template<forward_range R, class Proj = identity,
    indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
ranges::min_element(R&& r, Comp comp = {}, Proj proj = {});

25 Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

26 Returns: The first iterator i in the range [first, last) such that for every iterator j in the range
[first, last),
bool:invoke(comp, invoke(proj, *j), invoke(proj, *i)))
is false. Returns last if first == last.

27 Complexity: Exactly max(last - first - 1, 0) comparisons and twice as many projections.
Compare comp);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
    indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::max_element(I first, S last, Comp comp = {}, Proj proj = {});

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
    indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr I ranges::max_element(I first, S last, Comp comp = {}, Proj proj = {});

Let comp be less{} and proj be identity{} for the overloads with no parameters by those names.

Returns: The first iterator i in the range [first, last) such that for every iterator j in the range
[first, last),

bool:invoke(comp, invoke(proj, *i), invoke(proj, *j))

is false. Returns last if first == last.

Complexity: Exactly max(last - first - 1, 0) comparisons and twice as many projections.

template<class ForwardIterator>
constexpr pair<ForwardIterator, ForwardIterator>
minmax_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
pair<ForwardIterator, ForwardIterator>
minmax_element(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr pair<ForwardIterator, ForwardIterator>
minmax_element(ForwardIterator first, ForwardIterator last, Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
pair<ForwardIterator, ForwardIterator>
minmax_element(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Compare comp);

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
    indirect_strict_weak_order<projected<I, Proj>> Comp = ranges::less>
constexpr ranges::minmax_element_result<I>
ranges::minmax_element(I first, S last, Comp comp = {}, Proj proj = {});

template<forward_iterator I, sentinel_for<I> S, class Proj = identity,
    indirect_strict_weak_order<projected<iterator_t<R>, Proj>> Comp = ranges::less>
constexpr ranges::minmax_element_result<borrowed_iterator_t<R>>
ranges::minmax_element(R&& r, Comp comp = {}, Proj proj = {});

Returns: {first, first} if [first, last) is empty, otherwise {m, M}, where m is the first iterator in
[first, last) such that no iterator in the range refers to a smaller element, and where M is the last
iterator in [first, last) such that no iterator in the range refers to a larger element.

Complexity: Let N be last - first. At most max(\lfloor \frac{3}{2} (N - 1) \rfloor, 0) comparisons and twice as many
applications of the projection, if any.

27.8.10 Bounded value

template<class T>
constexpr const T& clamp(const T& v, const T& lo, const T& hi);

template<class T, class Compare>
constexpr const T& clamp(const T& v, const T& lo, const T& hi, Compare comp);

template<class T, class Proj = identity,
    indirect_strict_weak_order<projected<T*, Proj>> Comp = ranges::less>
constexpr const T&
ranges::clamp(const T& v, const T& lo, const T& hi, Comp comp = {}, Proj proj = {});

Let comp be less{} for the overloads with no parameter comp, and let proj be identity{} for the
overloads with no parameter proj.

219] This behavior intentionally differs from max_element.
Preconditions: bool(invoke(comp, invoke(proj, hi), invoke(proj, lo))) is false. For the first form, type T meets the Cpp17LessThanComparable requirements (Table 29).

Returns: lo if bool(invoke(comp, invoke(proj, v), invoke(proj, lo))) is true, hi if bool(invoke(comp, invoke(proj, hi), invoke(proj, v))) is true, otherwise v.

[Note 1: If NaN is avoided, T can be a floating-point type. —end note]

Complexity: At most two comparisons and three applications of the projection.

27.8.11 Lexicographical comparison

```cpp
template<class InputIterator1, class InputIterator2>
constexpr bool
lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool
lexicographical_compare(ExecutionPolicy&& exec,
                        ForwardIterator1 first1, ForwardIterator1 last1,
                        ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2, class Compare>
constexpr bool
lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
                        InputIterator2 first2, InputIterator2 last2,
                        Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class Compare>
bool
lexicographical_compare(ExecutionPolicy&& exec,
                        ForwardIterator1 first1, ForwardIterator1 last1,
                        ForwardIterator2 first2, ForwardIterator2 last2,
                        Compare comp);

template<input_iterator I1, sentinel_for<I1> S1, input_iterator I2, sentinel_for<I2> S2,
class Proj1 = identity, class Proj2 = identity,
indirect_strict_weak_order<projected<I1, Proj1>,
projected<I2, Proj2>> Comp = ranges::less>
constexpr bool
ranges::lexicographical_compare(I1 first1, S1 last1, I2 first2, S2 last2,
Comp comp = {}, Proj1 proj1 = {}, Proj2 proj2 = {});

template<input_range R1, input_range R2, class Proj1 = identity,
class Proj2 = identity,
indirect_strict_weak_order<projected<iterator_t<R1>, Proj1>,
projected<iterator_t<R2>, Proj2>> Comp = ranges::less>
constexpr bool
ranges::lexicographical_compare(R1&& r1, R2&& r2, Comp comp = {},
Proj1 proj1 = {}, Proj2 proj2 = {});
```

Returns: true if and only if the sequence of elements defined by the range [first1, last1) is lexicographically less than the sequence of elements defined by the range [first2, last2).

Complexity: At most 2 min(last1 - first1, last2 - first2) applications of the corresponding comparison and each projection, if any.

Remarks: If two sequences have the same number of elements and their corresponding elements (if any) are equivalent, then neither sequence is lexicographically less than the other. If one sequence is a proper prefix of the other, then the shorter sequence is lexicographically less than the longer sequence. Otherwise, the lexicographical comparison of the sequences yields the same result as the comparison of the first corresponding pair of elements that are not equivalent.

[Example 1: ranges::lexicographical_compare(I1, I2, S1, S2, Comp, Proj1, Proj2) can be implemented as:

```cpp
for ( ; first1 != last1 && first2 != last2 ; ++first1, (void) ++first2) {
    if (invoke(comp, invoke(proj1, *first1), invoke(proj2, *first2))) return true;
```
if (invoke(comp, invoke(proj2, *first2), invoke(proj1, *first1))) return false;
}
return first1 == last1 && first2 != last2;
—end example

[Note 1: An empty sequence is lexicographically less than any non-empty sequence, but not less than any empty sequence. — end note]

### 27.8.12 Three-way comparison algorithms

```cpp
template<class InputIterator1, class InputIterator2, class Cmp>
constexpr auto
lexicographical_compare_three_way(InputIterator1 b1, InputIterator1 e1,
InputIterator2 b2, InputIterator2 e2,
Cmp comp)
-> decltype(comp(*b1, *b2));
```

Let \(N\) be \(\min(e1 - b1, e2 - b2)\). Let \(E(n)\) be \(comp(*(b1 + n), *(b2 + n))\).

**Mandates:** decltype(comp(*b1, *b2)) is a comparison category type.

**Returns:** \(E(i)\), where \(i\) is the smallest integer in \([0, N)\) such that \(E(i) != 0\) is true, or \((e1 - b1) <=> (e2 - b2)\) if no such integer exists.

**Complexity:** At most \(N\) applications of \(comp\).

```cpp
template<class InputIterator1, class InputIterator2>
constexpr auto
lexicographical_compare_three_way(InputIterator1 b1, InputIterator1 e1,
InputIterator2 b2, InputIterator2 e2);
```

**Effects:** Equivalent to:

```cpp
return lexicographical_compare_three_way(b1, e1, b2, e2, compare_three_way());
```

### 27.8.13 Permutation generators

```cpp
template<class BidirectionalIterator>
constexpr bool next_permutation(BidirectionalIterator first,
BidirectionalIterator last);
```

```cpp
template<class BidirectionalIterator, class Compare>
constexpr bool next_permutation(BidirectionalIterator first,
BidirectionalIterator last, Compare comp);
```

```cpp
template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less,
class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr ranges::next_permutation_result<I>
ranges::next_permutation(I first, S last, Comp comp = {}, Proj proj = {});
```

```cpp
template<bidirectional_range R, class Comp = ranges::less,
class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr ranges::next_permutation_result<borrowed_iterator_t<R>>
ranges::next_permutation(R&& r, Comp comp = {}, Proj proj = {});
```

Let \(comp\) be \(less()\) and \(proj\) be \(identity()\) for overloads with no parameters by those names.

**Preconditions:** For the overloads in namespace \(std\), \(BidirectionalIterator\) meets the \(Cpp17Value-Swappable\) requirements (16.4.4.3).

**Effects:** Takes a sequence defined by the range \([\text{first}, \text{last})\) and transforms it into the next permutation. The next permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to \(comp\) and \(proj\). If no such permutation exists, transforms the sequence into the first permutation; that is, the ascendingly-sorted one.

**Returns:** \(let \(B\) be true if a next permutation was found and otherwise false.\) Returns:

(4.1) \(B\) for the overloads in namespace \(std\).

(4.2) \{ \text{last, } B \} for the overloads in namespace \(ranges\).
Complexity: At most \((last - first) / 2\) swaps.

```cpp
template<class BidirectionalIterator>
constexpr bool prev_permutation(BidirectionalIterator first,
                                 BidirectionalIterator last);
```

```cpp
template<class BidirectionalIterator, class Compare>
constexpr bool prev_permutation(BidirectionalIterator first,
                                 BidirectionalIterator last, Compare comp);
```

```cpp
template<bidirectional_iterator I, sentinel_for<I> S, class Comp = ranges::less,
class Proj = identity>
requires sortable<I, Comp, Proj>
constexpr ranges::prev_permutation_result<I>
ranges::prev_permutation(I first, S last, Comp comp = {}, Proj proj = {});
```

```cpp
template<bidirectional_range R, class Comp = ranges::less,
class Proj = identity>
requires sortable<iterator_t<R>, Comp, Proj>
constexpr ranges::prev_permutation_result<borrowed_iterator_t<R>>
ranges::prev_permutation(R&& r, Comp comp = {}, Proj proj = {});
```

Let \(comp\) be \(\text{less}\{\}\) and \(proj\) be \(\text{identity}\{\}\) for overloads with no parameters by those names.

Preconditions: For the overloads in namespace \(\text{std}\), \(\text{BidirectionalIterator}\) meets the \(\text{Cpp17ValueSwappable}\) requirements (16.4.4.3).

Effects: Takes a sequence defined by the range \([\text{first}, \text{last})\) and transforms it into the previous permutation. The previous permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to \(comp\) and \(proj\). If no such permutation exists, transforms the sequence into the last permutation; that is, the descendingly-sorted one.

Returns: Let \(B\) be \(\text{true}\) if a previous permutation was found and otherwise \(\text{false}\). Returns:

- \(B\) for the overloads in namespace \(\text{std}\).
- \(\{ \text{last}, \text{B} \}\) for the overloads in namespace \(\text{ranges}\).

Complexity: At most \((last - first) / 2\) swaps.

27.9 Header <numeric> synopsis

```cpp
namespace std {
    // 27.10.3, accumulate
    template<class InputIterator, class T>
    constexpr T accumulate(InputIterator first, InputIterator last, T init);
    template<class InputIterator, class T, class BinaryOperation>
    constexpr T accumulate(InputIterator first, InputIterator last, T init,
                            BinaryOperation binary_op);

    // 27.10.4, reduce

    using iota_result = out_value_result<O, T>;

    template<input_or_output_iterator O, sentinel_for<O> S, weakly_incrementable T>
    requires indirectly_writable<O, const T&>
    constexpr iota_result<O, T> iota(O first, S last, T value);

    template<weakly_incrementable T, output_range<const T&> R>
    constexpr iota_result<borrowed_iterator_t<R>, T> iota(R&& r, T value);
}

// 27.10.14, greatest common divisor
template<class M, class N>
    constexpr common_type_t<M, N> gcd(M m, N n);

// 27.10.15, least common multiple
template<class M, class N>
    constexpr common_type_t<M, N> lcm(M m, N n);
// 27.10.16, midpoint

template<class T>
    constexpr T midpoint(T a, T b) noexcept;

template<class T>
    constexpr T* midpoint(T* a, T* b);

27.10 Generalized numeric operations [numeric.ops]

27.10.1 General [numeric.ops.general]

1 [Note 1: The use of closed ranges as well as semi-open ranges to specify requirements throughout 27.10 is intentional. —end note]

27.10.2 Definitions [numerics.defns]

1 Define GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aN) as follows:

   (1.1) a1 when N is 1, otherwise

   (1.2) op(GENERALIZED_NONCOMMUTATIVE_SUM(op, a1, ..., aK),
                                                    GENERALIZED_NONCOMMUTATIVE_SUM(op, aM, ..., aN)) for any K where 1 < K + 1 = M ≤ N.

2 Define GENERALIZED_SUM(op, a1, ..., aN) as GENERALIZED_NONCOMMUTATIVE_SUM(op, b1, ..., bN), where b1, ..., bN may be any permutation of a1, ..., aN.

27.10.3 Accumulate [accumulate]

template<class InputIterator, class T>
    constexpr T accumulate(InputIterator first, InputIterator last, T init);

template<class InputIterator, class T, class BinaryOperation>
    constexpr T accumulate(InputIterator first, InputIterator last, T init,
                              BinaryOperation binary_op);

1 Preconditions: T meets the Cpp17CopyConstructible (Table 32) and Cpp17CopyAssignable (Table 34) requirements. In the range [first, last], binary_op neither modifies elements nor invalidates iterators or subranges.220

2 Effects: Computes its result by initializing the accumulator acc with the initial value init and then modifies it with acc = std::move(acc) + *i or acc = binary_op(std::move(acc), *i) for every iterator i in the range [first, last) in order.221

27.10.4 Reduce [reduce]

template<class InputIterator>
    constexpr typename iterator_traits<InputIterator>::value_type
        reduce(InputIterator first, InputIterator last);

template<class ExecutionPolicy, class ForwardIterator>
    typename iterator_traits<ForwardIterator>::value_type
        reduce(ExecutionPolicy&& exec,
                  ForwardIterator first, ForwardIterator last);

2 Effects: Equivalent to:

    return reduce(std::forward<ExecutionPolicy>(exec), first, last,
                                  typename iterator_traits<ForwardIterator>::value_type());

template<class InputIterator, class T>
    constexpr T reduce(InputIterator first, InputIterator last, T init);

3 Effects: Equivalent to:

    return reduce(first, last, init, plus<>());

220) The use of fully closed ranges is intentional.
221) accumulate is similar to the APL reduction operator and Common Lisp reduce function, but it avoids the difficulty of defining the result of reduction on an empty sequence by always requiring an initial value.
27.10.5 Inner product

template<class ExecutionPolicy, class ForwardIterator, class T>
T reduce(ExecutionPolicy&& exec,
        ForwardIterator first, ForwardIterator last, T init);

Effects: Equivalent to:

        return reduce(std::forward<ExecutionPolicy>(exec), first, last, init, plus<>());

template<class InputIterator, class T, class BinaryOperation>
constexpr T reduce(InputIterator first, InputIterator last, T init,
                    BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator, class T, class BinaryOperation>
T reduce(ExecutionPolicy&& exec,
         ForwardIterator first, ForwardIterator last, T init,
         BinaryOperation binary_op);

Mandates: All of

(5.1)    — binary_op(init, *first),
(5.2)    — binary_op(*first, init),
(5.3)    — binary_op(init, init), and
(5.4)    — binary_op(*first, *first)

are convertible to T.

Preconditions:

(6.1)    — T meets the Cpp17MoveConstructible (Table 31) requirements.
(6.2)    — binary_op neither invalidates iterators or subranges, nor modifies elements in the range [first, last].

Returns: GENERALIZED_SUM(binary_op, init, *i, ...) for every i in [first, last).

Complexity: $O((last - first))$ applications of binary_op.

[Note 1: The difference between reduce and accumulate is that reduce applies binary_op in an unspecified order, which yields a nondeterministic result for non-associative or non-commutative binary_op such as floating-point addition. —end note]

27.10.6 Transform reduce

template<class InputIterator1, class InputIterator2, class T>
constexpr T transform_reduce(InputIterator1 first1, InputIterator1 last1,
                              InputIterator2 first2, T init);

Effects: Equivalent to:

222) The use of fully closed ranges is intentional.
return transform_reduce(first1, last1, first2, init, plus<>(), multiplies<>());

template<class ExecutionPolicy,
    class ForwardIterator1, class ForwardIterator2, class T>
T transform_reduce(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2,
    T init);  

Effects: Equivalent to:
return transform_reduce(std::forward<ExecutionPolicy>(exec),
    first1, last1, first2, init, plus<>(), multiplies<>());

template<class InputIterator1, class InputIterator2, class T,
    class BinaryOperation1, class BinaryOperation2>
constexpr T transform_reduce(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2,
    T init,
    BinaryOperation1 binary_op1,
    BinaryOperation2 binary_op2);

template<class ExecutionPolicy,
    class ForwardIterator1, class ForwardIterator2, class T,
    class BinaryOperation1, class BinaryOperation2>
T transform_reduce(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2,
    T init,
    BinaryOperation1 binary_op1,
    BinaryOperation2 binary_op2);

Mandates: All of
(3.1) — binary_op1(init, init),
(3.2) — binary_op1(init, binary_op2(*first1, *first2)),
(3.3) — binary_op1(binary_op2(*first1, *first2), init), and
(3.4) — binary_op1(binary_op2(*first1, *first2), binary_op2(*first1, *first2))
are convertible to T.

Preconditions:
(4.1) — T meets the Cpp17MoveConstructible (Table 31) requirements.
(4.2) — Neither binary_op1 nor binary_op2 invalidates subranges, nor modifies elements in the ranges
[first1, last1] and [first2, first2 + (last1 - first1)].

Returns:
GENERALIZED_SUM(binary_op1, init, binary_op2(*i, *(first2 + (i - first1))), ...)
for every iterator i in [first1, last1].

Complexity: $O((last1 - first1)$ applications each of binary_op1 and binary_op2.

template<class InputIterator, class T,
    class BinaryOperation, class UnaryOperation>
constexpr T transform_reduce(InputIterator first, InputIterator last, T init,
    BinaryOperation binary_op, UnaryOperation unary_op);

template<class ExecutionPolicy,
    class ForwardIterator, class T,
    class BinaryOperation, class UnaryOperation>
T transform_reduce(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    T init, BinaryOperation binary_op, UnaryOperation unary_op);

Mandates: All of
(7.1) — binary_op1(init, init),
(7.2) — binary_op1(init, unary_op(*first)),

§ 27.10.6 1383
— binary_op(unary_op(*first), init), and

— binary_op(unary_op(*first), unary_op(*first))

are convertible to T.

8

Preconditions:

(8.1) — T meets the Cpp17MoveConstructible (Table 31) requirements.

(8.2) — Neither unary_op nor binary_op invalidates subranges, nor modifies elements in the range [first, last].

9

Returns:

GENERALIZED_SUM(binary_op, init, unary_op(*i), ...)

for every iterator i in [first, last).

Complexity: \( \Theta(l - f) \) applications each of unary_op and binary_op.

[Note 1: transform_reduce does not apply unary_op to init. — end note]

27.10.7 Partial sum

template<class InputIterator, class OutputIterator>
constexpr OutputIterator
partial_sum(InputIterator first, InputIterator last,
OutputIterator result);

template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator
partial_sum(InputIterator first, InputIterator last,
OutputIterator result, BinaryOperation binary_op);

1

Mandates: InputIterator's value type is constructible from *first. The result of the expression std::move(acc) + *i or binary_op(std::move(acc), *i) is implicitly convertible to InputIterator's value type. acc is writable (25.3.1) to result.

2

Preconditions: In the ranges [first, last] and [result, result + (last - first)] binary_op neither modifies elements nor invalidates iterators or subranges.

3

Effects: For a non-empty range, the function creates an accumulator acc whose type is InputIterator's value type, initializes it with *first, and assigns the result to *result. For every iterator i in [first + 1, last) in order, acc is then modified by acc = std::move(acc) + *i or acc = binary_op(std::move(acc), *i) and the result is assigned to *(result + (i - first)).

4

Returns: result + (last - first).

Complexity: Exactly (last - first) - 1 applications of the binary operation.

Remarks: result may be equal to first.

27.10.8 Exclusive scan

template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
exclusive_scan(InputIterator first, InputIterator last,
OutputIterator result, T init);

1

Effects: Equivalent to:

return exclusive_scan(first, last, result, init, plus<>());

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
ForwardIterator2
exclusive_scan(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, T init);

2

Effects: Equivalent to:

return exclusive_scan(std::forward<ExecutionPolicy>(exec),
first, last, result, init, plus<>());

223) The use of fully closed ranges is intentional.
template<class InputIterator, class OutputIterator, class T, class BinaryOperation>
constexpr OutputIterator
exclusive_scan(InputIterator first, InputIterator last,
OutputIterator result, T init, BinaryOperation binary_op);

template<class ExecutionPolicy,
class ForwardIterator1, class ForwardIterator2, class T, class BinaryOperation>
ForwardIterator2
exclusive_scan(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, T init, BinaryOperation binary_op);

Mandates: All of
(3.1)  — binary_op(init, init),
(3.2)  — binary_op(init, *first), and
(3.3)  — binary_op(*first, *first)
are convertible to T.

Preconditions:
(4.1)  — T meets the Cpp17MoveConstructible (Table 31) requirements.
(4.2)  — binary_op neither invalidates iterators or subranges, nor modifies elements in the ranges [first, last] or [result.result + (last - first)].

Effects: For each integer K in [0, last - first) assigns through result + K the value of:

\[
\text{GENERALIZED\_NONCOMMUTATIVE\_SUM} \left( \text{binary\_op}, \text{init}, *(\text{first} + 0), *(\text{first} + 1), \ldots, *(\text{first} + K - 1) \right)
\]

Returns: The end of the resulting range beginning at result.

Complexity: \(O(last - first)\) applications of binary_op.

Remarks: result may be equal to first.

[Note 1: The difference between exclusive_scan and inclusive_scan is that exclusive_scan excludes the \(i^{th}\) input element from the \(i^{th}\) sum. If binary_op is not mathematically associative, the behavior of exclusive_scan can be nondeterministic. — end note]

27.10.9 Inclusive scan

template<class InputIterator, class OutputIterator>
constexpr OutputIterator
inclusive_scan(InputIterator first, InputIterator last,
OutputIterator result);

Effects: Equivalent to:
return inclusive_scan(first, last, result, plus<>());

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
inclusive_scan(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result);

Effects: Equivalent to:
return inclusive_scan(std::forward<ExecutionPolicy>(exec), first, last, result, plus<>());

template<class InputIterator, class OutputIterator, class BinaryOperation>
constexpr OutputIterator
inclusive_scan(InputIterator first, InputIterator last,
OutputIterator result, BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryOperation>
ForwardIterator2
inclusive_scan(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, BinaryOperation binary_op);
Let $U$ be the value type of `decltype(first)`.

**Mandates:** If `init` is provided, all of

1. $\text{binary\_op}(\text{init}, \text{init})$,
2. $\text{binary\_op}(\text{init}, \*\text{first})$, and
3. $\text{binary\_op}(\*\text{first}, \*\text{first})$

are convertible to $T$; otherwise, $\text{binary\_op}(\*\text{first}, \*\text{first})$ is convertible to $U$.

**Preconditions:**

1. If `init` is provided, $T$ meets the \texttt{Cpp17MoveConstructible} (Table 31) requirements; otherwise, $U$ meets the \texttt{Cpp17MoveConstructible} requirements.
2. $\text{binary\_op}$ neither invalidates iterators or subranges, nor modifies elements in the ranges $[\text{first}, \text{last}]$ or $[\text{result}, \text{result} + (\text{last} - \text{first})]$.

**Effects:** For each integer $k$ in $[0, \text{last} - \text{first})$ assigns through $\text{result} + k$ the value of

1. $\texttt{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{binary\_op}, \text{init}, \*\text{first} + 0, \*\text{first} + 1, \ldots, \*\text{first} + k)$

if `init` is provided, or

2. $\texttt{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{binary\_op}, \*\text{first} + 0, \*\text{first} + 1, \ldots, \*\text{first} + k)$

otherwise.

**Returns:** The end of the resulting range beginning at $\text{result}$.

**Complexity:** $O(\text{last} - \text{first})$ applications of $\text{binary\_op}$.

**Remarks:** $\text{result}$ may be equal to $\text{first}$.

\[\text{Note 1: The difference between exclusive\_scan and inclusive\_scan is that inclusive\_scan includes the } i\text{th input element in the } i\text{th sum. If } \text{binary\_op} \text{ is not mathematically associative, the behavior of inclusive\_scan can be nondeterministic.} \quad \text{— end note}\]

### 27.10.10 Transform exclusive scan

**Mandates:** All of

1. $\text{binary\_op}(\text{init}, \text{init})$,
2. $\text{binary\_op}(\text{init}, \text{unary\_op}(\*\text{first}))$, and

**Returns:** The end of the resulting range beginning at $\text{result}$.

**Complexity:** $O(\text{last} - \text{first})$ applications of $\text{binary\_op}$.
binary_op(unary_op(*first), unary_op(*first)) are convertible to T.

Preconditions:

1. T meets the Cpp17MoveConstructible (Table 31) requirements.
2. Neither unary_op nor binary_op invalidates iterators or subranges, nor modifies elements in the ranges [first, last] or [result, result + (last - first)].

Effects: For each integer K in [0, last - first) assigns through result + K the value of:

\[
\text{GENERALIZED_NONCOMMUTATIVE_SUM} \\
\text{binary_op, init,} \\
\text{unary_op(*first + 0), unary_op(*first + 1), \ldots, unary_op(*first + K - 1))}
\]

Returns: The end of the resulting range beginning at result.

Complexity: \(O(last - first)\) applications each of unary_op and binary_op.

Remarks: result may be equal to first.

[Note 1: The difference between transform_exclusive_scan and transform_inclusive_scan is that transform_exclusive_scan excludes the \(i\)th input element from the \(i\)th sum. If binary_op is not mathematically associative, the behavior of transform_exclusive_scan can be nondeterministic. transform_exclusive_scan does not apply unary_op to init. — end note]

§ 27.10.11 Transform inclusive scan

```cpp
template<class InputIterator, class OutputIterator, 
class BinaryOperation, class UnaryOperation>
constexpr OutputIterator transform_inclusive_scan(InputIterator first, InputIterator last,
OutputIterator result,
BinaryOperation binary_op, UnaryOperation unary_op);

template<class ExecutionPolicy, 
class ForwardIterator1, class ForwardIterator2, 
class BinaryOperation, class UnaryOperation>
ForwardIterator2 transform_inclusive_scan(ExecutionPolicy&& exec, 
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result,
BinaryOperation binary_op, UnaryOperation unary_op);

template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator transform_inclusive_scan(InputIterator first, InputIterator last,
OutputIterator result,
BinaryOperation binary_op, UnaryOperation unary_op, T init);

template<class ExecutionPolicy, 
class ForwardIterator1, class ForwardIterator2, 
class BinaryOperation, class UnaryOperation, class T>
ForwardIterator2 transform_inclusive_scan(ExecutionPolicy&& exec, 
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result,
BinaryOperation binary_op, UnaryOperation unary_op, T init);
```

Let U be the value type of decltype(first).

Mandates: If init is provided, all of

1. — binary_op(init, init),
2. — binary_op(init, unary_op(*first)), and
3. — binary_op(unary_op(*first), unary_op(*first))
are convertible to \( T \); otherwise, \( \text{binary\_op(\text{unary\_op(*first)}, \text{unary\_op(*first)})} \) is convertible to \( U \).

**Preconditions:**

1. If \( \text{init} \) is provided, \( T \) meets the \textit{Cpp17MoveConstructible} (Table 31) requirements; otherwise, \( U \) meets the \textit{Cpp17MoveConstructible} requirements.
2. Neither \( \text{unary\_op} \) nor \( \text{binary\_op} \) invalidates iterators or subranges, nor modifies elements in the ranges \([\text{first}, \text{last}]\) or \([\text{result}, \text{result} + (\text{last} - \text{first})]\).

**Effects:** For each integer \( K \) in \([0, \text{last} - \text{first})\) assigns through \( \text{result} + K \) the value of

1. \( \textit{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{binary\_op, init,}
   \text{unary\_op(*(first + 0)), unary\_op(*(first + 1)), ..., unary\_op(*(first + K)))} \)
   if \( \text{init} \) is provided, or
2. \( \textit{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{binary\_op,}
   \text{unary\_op(*(first + 0)), unary\_op(*(first + 1)), ..., unary\_op(*(first + K)))} \)
   otherwise.

**Returns:** The end of the resulting range beginning at \( \text{result} \).

**Complexity:** \( \Theta(\text{last} - \text{first}) \) applications each of \( \text{unary\_op} \) and \( \text{binary\_op} \).

**Remarks:** \( \text{result} \) may be equal to \( \text{first} \).

[Note 1: The difference between \textit{transform\_exclusive\_scan} and \textit{transform\_inclusive\_scan} is that \textit{transform\_inclusive\_scan} includes the \( i \)th input element in the \( i \)th sum. If \( \text{binary\_op} \) is not mathematically associative, the behavior of \textit{transform\_inclusive\_scan} can be nondeterministic. \textit{transform\_inclusive\_scan} does not apply \( \text{unary\_op} \) to \( \text{init} \). — end note]

### 27.10.12 Adjacent difference

**template<class InputIterator, class OutputIterator>**

\[
\text{constexpr OutputIterator}\]

\[
\text{adjacent\_difference(InputIterator first, InputIterator last, OutputIterator result);}\]

**template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>**

\[
\text{ForwardIterator2}\]

\[
\text{adjacent\_difference(ExecutionPolicy&& exec, ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result);}\]

**template<class InputIterator, class OutputIterator, class BinaryOperation>**

\[
\text{constexpr OutputIterator}\]

\[
\text{adjacent\_difference(InputIterator first, InputIterator last, OutputIterator result, BinaryOperation binary\_op);}\]

**template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryOperation>**

\[
\text{ForwardIterator2}\]

\[
\text{adjacent\_difference(ExecutionPolicy&& exec, ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result, BinaryOperation binary\_op);}\]

Let \( T \) be the value type of \texttt{decltype(first)}. For the overloads that do not take an argument \( \text{binary\_op} \), let \( \text{binary\_op} \) be an lvalue that denotes an object of type \texttt{minus<>.}

**Mandates:**

1. For the overloads with no \textit{ExecutionPolicy}, \( T \) is constructible from \( *\text{first}.\ acc \) (defined below) is writable (25.3.1) to the \( \text{result} \) output iterator. The result of the expression \( \text{binary\_op(val, std::move(acc))} \) is writable to \( \text{result} \).
2. For the overloads with an \textit{ExecutionPolicy}, the result of the expressions \( \text{binary\_op(*first, *first)} \) and \( *\text{first} \) are writable to \( \text{result} \).

**Preconditions:**
— For the overloads with no ExecutionPolicy, T meets the Cpp17MoveAssignable (Table 33) requirements.

— For all overloads, in the ranges [first, last] and [result.result + (last - first)], binary-op neither modifies elements nor invalidates iterators or subranges.

Effects: For the overloads with no ExecutionPolicy and a non-empty range, the function creates an accumulator acc of type T, initializes it with *first, and assigns the result to *result. For every iterator i in [first + 1, last) in order, creates an object val whose type is T, initializes it with *i, computes binary_op(val, std::move(acc)), assigns the result to *(result + (i - first)), and move assigns from val to acc.

For the overloads with an ExecutionPolicy and a non-empty range, performs *result = *first. Then, for every d in [1, last - first - 1], performs *(result + d) = binary_op(*(first + d), *(first + (d - 1))).

Returns: result + (last - first).

Complexity: Exactly (last - first) - 1 applications of the binary operation.

Remarks: For the overloads with an ExecutionPolicy, the ranges [first, last) and [result.result + (last - first)] shall not overlap.

27.10.13 Iota [numeric.iota]

template<class ForwardIterator, class T>
constexpr void iota(ForwardIterator first, ForwardIterator last, T value);

Mandates: T is convertible to ForwardIterator's value type. The expression ++val, where val has type T, is well-formed.

Effects: For each element referred to by the iterator i in the range [first, last), assigns *i = value and increments value as if by ++value.

Complexity: Exactly last - first increments and assignments.

template<input_or_output_iterator O, sentinel_for<O> S, weakly_incrementable T>
requires indirectly_writable<O, const T&>
constexpr ranges::iota_result<O, T> ranges::iota(O first, S last, T value);

template<weakly_incrementable T, output_range<const T&> R>
constexpr ranges::iota_result<borrowed_iterator_t<R>, T> ranges::iota(R&& r, T value);

Effects: Equivalent to:
while (first != last) {
  *first = as_const(value);
  ++first;
  ++value;
}
return {std::move(first), std::move(value)};

27.10.14 Greatest common divisor [numeric.ops.gcd]

template<class M, class N>
constexpr common_type_t<M, N> gcd(M m, N n);

Mandates: M and N both are integer types other than cv bool.

Preconditions: |m| and |n| are representable as a value of common_type_t<M, N>.

[Note 1: These requirements ensure, for example, that gcd(m, m) = |m| is representable as a value of type M. — end note]

Returns: Zero when m and n are both zero. Otherwise, returns the greatest common divisor of |m| and |n|.

Throws: Nothing.

224) The use of fully closed ranges is intentional.
27.10.15 Least common multiple

```cpp
template<class M, class N>
constexpr common_type_t<M, N> lcm(M m, N n);
```

1. **Mandates**: \( M \) and \( N \) both are integer types other than \( cv \) \( bool \).
2. **Preconditions**: \(|m| \) and \(|n| \) are representable as a value of \( common_type_t<M, N> \). The least common multiple of \(|m| \) and \(|n| \) is representable as a value of type \( common_type_t<M, N> \).
3. **Returns**: Zero when either \( m \) or \( n \) is zero. Otherwise, returns the least common multiple of \(|m| \) and \(|n| \).
4. **Throws**: Nothing.

27.10.16 Midpoint

```cpp
template<class T>
constexpr T midpoint(T a, T b) noexcept;
```

1. **Constraints**: \( T \) is an arithmetic type other than \( bool \).
2. **Returns**: Half the sum of \( a \) and \( b \). If \( T \) is an integer type and the sum is odd, the result is rounded towards \( a \).
3. **Remarks**: No overflow occurs. If \( T \) is a floating-point type, at most one inexact operation occurs.

```cpp
template<class T>
constexpr T* midpoint(T* a, T* b);
```

1. **Constraints**: \( T \) is an object type.
2. **Mandates**: \( T \) is a complete type.
3. **Preconditions**: \( a \) and \( b \) point to, respectively, elements \( i \) and \( j \) of the same array object \( x \).

```
[Note 1: As specified in 6.8.4, an object that is not an array element is considered to belong to a single-element array for this purpose and a pointer past the last element of an array of \( n \) elements is considered to be equivalent to a pointer to a hypothetical array element \( n \) for this purpose. — end note]
```
4. **Returns**: A pointer to array element \( i + j \div 2 \) of \( x \), where the result of the division is truncated towards zero.

27.11 Specialized <memory> algorithms

27.11.1 General

The contents specified in 27.11 are declared in the header `<memory>` (20.2.2).

2. Unless otherwise specified, if an exception is thrown in the following algorithms, objects constructed by a placement `new-expression` (7.6.2.8) are destroyed in an unspecified order before allowing the exception to propagate.

3. Some algorithms specified in 27.11 make use of the exposition-only function `voidify`:

```cpp
template<class T>
constexpr void* voidify(T& obj) noexcept {
  return addressof(obj);
}
```

27.11.2 Special memory concepts

Some algorithms in this subclause are constrained with the following exposition-only concepts:

```cpp
template<class I>
concept nothrow-input-iterator = // exposition only
  input_iterator<I> &&
  is_lvalue_reference_v<iter_reference_t<I>> &&
  same_as<remove_cvref_t<iter_reference_t<I>>, iter_value_t<I>>;
```

2. A type \( I \) models `nothrow-input-iterator` only if no exceptions are thrown from increment, copy construction, move construction, copy assignment, move assignment, or indirection through valid iterators.

```
[Note 1: This concept allows some `input_iterator` (25.3.4.9) operations to throw exceptions. — end note]
```
template<class S, class I>
  concept noexcept sentinel for = sentinel_for<S, I>; // exposition only

Types S and I model noexcept sentinel for only if no exceptions are thrown from
copy construction, move construction, copy assignment, move assignment, or
comparisons between valid values of type I and S.

[Note 2: This concept allows some sentinel for (25.3.4.7) operations to throw exceptions. — end note]

template<class R>
  concept noexcept input range = // exposition only
  range<R> &&
  noexcept input iterator<iterator_t<R>> &&
  noexcept sentinel for<sentinel_t<R>, iterator_t<R>>;

A type R models noexcept input range only if no exceptions are thrown from calls to \[\text{ranges::begin} \quad \text{and} \quad \text{ranges::end}\] on an object of type R.

template<class I>
  concept noexcept forward iterator = // exposition only
  noexcept input iterator<I> &&
  forward_iterator<I> &&
  noexcept sentinel for<I, I>;

[Note 3: This concept allows some forward iterator (25.3.4.11) operations to throw exceptions. — end note]

template<class R>
  concept noexcept forward range = // exposition only
  noexcept input range<R> &&
  noexcept forward iterator<iterator_t<R>>;

27.11.3 uninitialized default construct [uninitialized.construct.default]

template<class NoThrowForwardIterator>
  void uninitialized default construct(NoThrowForwardIterator first, NoThrowForwardIterator last);

Effects: Equivalent to:

for (; first != last; ++first)
  ::new (voidify(*first))
  typename iterator_traits<NoThrowForwardIterator>::value_type;

namespace ranges {

  template<nothrow forward iterator I, noexcept sentinel for<I> S>
  requires default initializable<iter_value_t<I>>
  I uninitialized default construct(I first, S last);

  template<nothrow forward range R>
  requires default initializable<range_value_t<R>>
  borrowed_iterator_t<R> uninitialized default construct(R&& r);

}

Effects: Equivalent to:

for (; first != last; ++first)
  ::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>;
  return first;

template<class NoThrowForwardIterator, class Size>
  NoThrowForwardIterator uninitialized default construct_n(NoThrowForwardIterator first, Size n);

Effects: Equivalent to:

for (; n > 0; (void)+first, --n)
  ::new (voidify(*first))
  typename iterator_traits<NoThrowForwardIterator>::value_type;
  return first;

namespace ranges {

  template<nothrow forward iterator I>
  requires default initializable<iter_value_t<I>>
  I uninitialized default construct_n(I first, iter_difference_t<I> n);

  template<nothrow forward iterator I, noexcept sentinel for<I> S>
  requires default initializable<iter_value_t<I>>
  I uninitialized default construct_n(I first, S last);
Effects: Equivalent to:

```
return uninitialized_default_construct(counted_iterator(first, n),
    default_sentinel).base();
```

27.11.4 uninitialized_value_construct

```cpp
template<class NoThrowForwardIterator>
void uninitialized_value_construct(NoThrowForwardIterator first, NoThrowForwardIterator last);
```

1 Effects: Equivalent to:

```cpp
for (; first != last; ++first)
    ::new (voidify(*first))
        typename iterator_traits<NoThrowForwardIterator>::value_type();
```

namespace ranges {
    template<class NoThrowForwardIterator, class Size>
    requires default_initializable<iter_value_t<NoThrowForwardIterator>>
    NoThrowForwardIterator uninitialized_value_construct_n(NoThrowForwardIterator first, Size n);
}

3 Effects: Equivalent to:

```cpp
for (; n > 0; (void)++first, --n)
    ::new (voidify(*first))
        typename iterator_traits<NoThrowForwardIterator>::value_type();
return first;
```

namespace ranges {
    template<class NoThrowForwardIterator I, nothrow-sentinel-for<I> S>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_value_construct(I first, S last);
    template<class NoThrowForwardIterator R>
    requires default_initializable<range_value_t<R>>
    borrowed_iterator_t<R> uninitialized_value_construct(R&& r);
}

4 Effects: Equivalent to:

```
return uninitialized_value_construct(counted_iterator(first, n),
    default_sentinel).base();
```

27.11.5 uninitialized_copy

```cpp
template<class InputIterator, class NoThrowForwardIterator>
NoThrowForwardIterator uninitialized_copy(InputIterator first, InputIterator last,
    NoThrowForwardIterator result);
```

1 Preconditions: result + [0, (last - first)) does not overlap with [first, last).

2 Effects: Equivalent to:

```cpp
for (; first != last; ++result, (void) ++first)
    ::new (voidify(*result))
        typename iterator_traits<NoThrowForwardIterator>::value_type(*first);
```

3 Returns: result.
namespace ranges {
    template<input_iterator I, sentinel_for<I> S1,
             noexcept-forward_iterator O, noexcept-sentinel_for<O> S2>
    requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
    uninitialized_copy_result<I, O>
    uninitialized_copy(I ifirst, S1 ilast, O ofirst, S2 olast);

    template<input_range IR, noexcept-forward-range OR>
    requires constructible_from<range_value_t<OR>, range_reference_t<IR>>
    uninitialized_copy_result<borrowed_iterator_t<IR>, borrowed_iterator_t<OR>>
    uninitialized_copy(IR&& in_range, OR&& out_range);
}

4 Preconditions: [ofirst, olast) does not overlap with [ifirst, ilast).
5 Effects: Equivalent to:
   for (; ifirst != ilast && ofirst != olast; ++ofirst, (void)++ifirst)
     ::new (voidify(*ofirst)) remove_reference_t<iter_reference_t<O>>(*ifirst);
   return {std::move(ifirst), ofirst};

6 template<class InputIterator, class Size, class NoThrowForwardIterator>
   NoThrowForwardIterator uninitialized_copy_n(InputIterator first, Size n,
                                          NoThrowForwardIterator result);

6 Preconditions: result + [0, n) does not overlap with first + [0, n).
7 Effects: Equivalent to:
   for ( ; n > 0; ++result, (void) ++first, --n)
     ::new (voidify(*result))
     typename iterator_traits<NoThrowForwardIterator>::value_type(*first);
8 Returns: result.

namespace ranges {
    template<input_iterator I, noexcept-forward_iterator O, noexcept-sentinel_for<O> S>
    requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
    uninitialized_copy_n_result<I, O>
    uninitialized_copy_n(I ifirst, iter_difference_t<I> n, O ofirst, S olast);
}

9 Preconditions: [ofirst, olast) does not overlap with ifirst + [0, n).
10 Effects: Equivalent to:
    auto t = uninitialized_copy(counted_iterator(std::move(ifirst), n),
                                       default_sentinel, ofirst, olast);
    return {std::move(t.in).base(), t.out};

27.11.6 uninitialized_move

template<class InputIterator, class NoThrowForwardIterator>
   NoThrowForwardIterator uninitialized_move(InputIterator first, InputIterator last,
                                          NoThrowForwardIterator result);

1 Preconditions: result + [0, (last - first)) does not overlap with [first, last).
2 Effects: Equivalent to:
   for (; first != last; (void)++result, ++first)
     ::new (voidify(*result))
     typename iterator_traits<NoThrowForwardIterator>::value_type(std::move(*first));
   return result;

namespace ranges {
    template<input_iterator I, sentinel_for<I> S1,
             noexcept-forward_iterator O, noexcept-sentinel_for<O> S2>
    requires constructible_from<iter_value_t<O>, iter_rvalue_reference_t<I>>
    uninitialized_move_result<I, O>
    uninitialized_move(I ifirst, S1 ilast, O ofirst, S2 olast);
template<input_range IR, noexcept-forward-range OR>
requires constructible_from<range_value_t<OR>, range_rvalue_reference_t<IR>>
uninitialized_move_result<borrowed_iterator_t<IR>, borrowed_iterator_t<OR>>
uninitialized_move(IR&& in_range, OR&& out_range);

Preconditions: 
(ofirst, olast) does not overlap with (ifirst, ilast).

Effects: Equivalent to:
for (; ifirst != ilast && ofirst != olast; ++ofirst, (void)**ifirst)
::new (voidify(*ofirst))
remove_reference_t<iter_reference_t<O>>(ranges::iter_move(ifirst));

[Note 1: If an exception is thrown, some objects in the range [ifirst, ilast) are left in a valid, but unspecified state. — end note]

template<class InputIterator, class Size, class NoThrowForwardIterator>
pair<InputIterator, NoThrowForwardIterator>
uninitialized_move_n(InputIterator first, Size n, NoThrowForwardIterator result);

Preconditions: 
result + [0, n) does not overlap with first + [0, n).

Effects: Equivalent to:
for (; n > 0; ++result, (void) ++first, --n)
::new (voidify(*result))
typename iterator_traits<NoThrowForwardIterator>::value_type(std::move(*first));
return {first, result};

namespace ranges {

template<input_iterator I, noexcept-forward-iterator O, nothrow-sentinel-for<O> S>
requires constructible_from<iter_value_t<O>, iter_rvalue_reference_t<I>>
uninitialized_move_n_result<I, O>
uninitialized_move_n(I ifirst, iter_difference_t<I> n, O ofirst, S olast);
}

Preconditions: 
(ofirst, olast) does not overlap with ifirst + [0, n).

Effects: Equivalent to:
auto t = uninitialized_move(counted_iterator(std::move(ifirst), n),
default_sentinel, ofirst, olast);
return {std::move(t.in).base(), t.out};

[Note 2: If an exception is thrown, some objects in the range ifirst + [0, n) are left in a valid but unspecified state. — end note]

27.11.7 uninitialized_fill

template<class NoThrowForwardIterator, class T>
void uninitialized_fill(NoThrowForwardIterator first, NoThrowForwardIterator last, const T& x);

Effects: Equivalent to:
for (; first != last; ++first)
::new (voidify(*first))
typename iterator_traits<NoThrowForwardIterator>::value_type(x);

namespace ranges {

template<nothrow-forward-iterator I, nothrow-sentinel-for<I> S, class T>
requires constructible_from<iter_value_t<I>, iter_rvalue_reference_t<I>>
I uninitialized_fill(I ifirst, S last, const T& x);
template<nothrow-forward-range R, class T>
requires constructible_from<range_value_t<R>, const T&>
borrowed_iterator_t<R> uninitialized_fill(R&& r, const T& x);
}

Effects: Equivalent to:
for (; first != last; ++first)
::new (voidify(*first)) remove_reference_t<iter_reference_t<I>>(x);
template<class NoThrowForwardIterator, class Size, class T>
NoThrowForwardIterator uninitialized_fill_n(NoThrowForwardIterator first, Size n, const T& x);

Effects: Equivalent to:
   for (; n--; ++first)
       ::new (voidify(*first))
       typename iterator_traits<NoThrowForwardIterator>::value_type(x);
   return first;

namespace ranges {
  template<nothrow-forward-iterator I, class T>
  requires constructible_from<iter_value_t<I>, const T&>
  I uninitialized_fill_n(I first, iter_difference_t<I> n, const T& x);
}

Effects: Equivalent to:
   return uninitialized_fill(counted_iterator(first, n), default_sentinel, x).base();

27.11.8 construct_at

template<class T, class... Args>
constexpr T* construct_at(T* location, Args&&... args);

namespace ranges {
  template<class T, class... Args>
  constexpr T* construct_at(T* location, Args&&... args);
}

Constraints: The expression ::new (declval<void*>(())) T(declval<Args>(...) is well-formed when treated as an unevaluated operand (7.2.3).

Effects: Equivalent to:
   return ::new (voidify(*location)) T(std::forward<Args>(args)...);

27.11.9 destroy

template<class T>
constexpr void destroy_at(T* location);

namespace ranges {
  template<destructible T>
  constexpr void destroy_at(T* location) noexcept;
}

Effects:
(1.1) If T is an array type, equivalent to destroy(begin(*location), end(*location)).
(1.2) Otherwise, equivalent to location->~T().

template<class NoThrowForwardIterator>
constexpr void destroy(NoThrowForwardIterator first, NoThrowForwardIterator last);

Effects: Equivalent to:
   for (; first != last; ++first)
       destroy_at(addressof(*first));

namespace ranges {
  template<nothrow-input-iterator I, nothrow-sentinel-for<I> S>
  requires destructible<iter_value_t<I>>
  constexpr I destroy(I first, S last) noexcept;
  template<nothrow-input-range R>
  requires destructible<range_value_t<R>>
  constexpr borrowed_iterator_t<R> destroy(R&& r) noexcept;
}

Effects: Equivalent to:
for (; first != last; ++first)
    destroy_at(addressof(*first));
return first;

template<class NoThrowForwardIterator, class Size>
constexpr NoThrowForwardIterator destroy_n(NoThrowForwardIterator first, Size n);
4
  Effects: Equivalent to:
          for (; n > 0; (void)*first, --n)
            destroy_at(addressof(*first));
        return first;

namespace ranges {
    template<nothrow-input_iterator I>
    requires destructible<iter_value_t<I>>
    constexpr I destroy_n(I first, iter_difference_t<I> n) noexcept;
}
5
  Effects: Equivalent to:
          return destroy(counted_iterator(std::move(first), n), default_sentinel).base();

27.12 C library algorithms
[alg.c.library]
1 [Note 1: The header `<cstdlib>` (17.2.2) declares the functions described in this subclause. — end note]

void* bsearch(const void* key, const void* base, size_t nmemb, size_t size, c-compare-pred* compar);
void* bsearch(const void* key, const void* base, size_t nmemb, size_t size, compare-pred* compar);
void qsort(void* base, size_t nmemb, size_t size, c-compare-pred* compar);
void qsort(void* base, size_t nmemb, size_t size, compare-pred* compar);

2  Preconditions: For qsort, the objects in the array pointed to by base are of trivially copyable type.
3  Effects: These functions have the semantics specified in the C standard library.
4  Throws: Any exception thrown by compar (16.4.6.13).

See also: ISO C 7.22.5
28 Numerics library [numerals]

28.1 General [numerals.general]

This Clause describes components that C++ programs may use to perform seminumerical operations.

The following subclauses describe components for complex number types, random number generation, numeric (n-at-a-time) arrays, generalized numeric algorithms, and mathematical constants and functions for floating-point types, as summarized in Table 94.

Table 94: Numerics library summary [tab:numerals.summary]

<table>

</tbody>
</table>

28.2 Numeric type requirements [numeric.requirements]

The complex and valarray components are parameterized by the type of information they contain and manipulate. A C++ program shall instantiate these components only with a numeric type. A numeric type is a cv-unqualified object type T that meets the Cpp17DefaultConstructible, Cpp17CopyConstructible, Cpp17CopyAssignable, and Cpp17Destructible requirements (16.4.4.2).

If any operation on T throws an exception the effects are undefined.

In addition, many member and related functions of valarray<T> can be successfully instantiated and will exhibit well-defined behavior if and only if T meets additional requirements specified for each such member or related function.

[Example 1: It is valid to instantiate valarray<complex>, but operator() will not be successfully instantiated for valarray<complex> operands, since complex does not have any ordering operators. — end example]

28.3 The floating-point environment [cfenv]

28.3.1 Header <cfenv> synopsis [cfenv.syn]

#define FE_ALL_EXCEPT see below
#define FE_DIVBYZERO see below // optional
#define FE_INEXACT see below // optional
#define FE_INVALID see below // optional
#define FE_OVERFLOW see below // optional
#define FE_UNDERFLOW see below // optional
#define FE_DOWNWARD see below // optional
#define FE_TONEAREST see below // optional
#define FE_TOWARDZERO see below // optional
#define FE_UPWARD see below // optional

#define FE_DFL_ENV see below

namespace std {
    // types
    using fenv_t = object type;
    using fexcept_t = integer type;
}

225) In other words, value types. These include arithmetic types, pointers, the library class complex, and instantiations of valarray for value types.

§ 28.3.1 1397
1 The contents and meaning of the header `<cfenv>` are the same as the C standard library header `<fenv.h>`. [Note 1: This document does not require an implementation to support the FENV_ACCESS pragma; it is implementation-defined (15.9) whether the pragma is supported. As a consequence, it is implementation-defined whether these functions can be used to test floating-point status flags, set floating-point control modes, or run under non-default mode settings. If the pragma is used to enable control over the floating-point environment, this document does not specify the effect on floating-point evaluation in constant expressions. —end note]

SEE ALSO: ISO C 7.6

28.3.2 Threads

The floating-point environment has thread storage duration (6.7.5.3). The initial state for a thread’s floating-point environment is the state of the floating-point environment of the thread that constructs the corresponding thread object (33.4.3) or jthread object (33.4.4) at the time it constructed the object. [Note 1: That is, the child thread gets the floating-point state of the parent thread at the time of the child’s creation. —end note]

A separate floating-point environment is maintained for each thread. Each function accesses the environment corresponding to its calling thread.

28.4 Complex numbers

28.4.1 General

The header `<complex>` defines a class template, and numerous functions for representing and manipulating complex numbers.

The effect of instantiating the template `complex` for any type that is not a cv-unqualified floating-point type (6.8.2) is unspecified. Specializations of `complex` for cv-unqualified floating-point types are trivially-copyable literal types (6.8.1).

If the result of a function is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

If \( z \) is an lvalue of type `cv complex<T>` then:

1. the expression `reinterpret_cast<cv T(&)[2]>(z)` is well-formed,
2. `reinterpret_cast<cv T(&)[2]>(z)[0]` designates the real part of \( z \), and
3. `reinterpret_cast<cv T(&)[2]>(z)[1]` designates the imaginary part of \( z \).

Moreover, if \( a \) is an expression of type `cv complex<T> *` and the expression \( a[i] \) is well-defined for an integer expression \( i \), then:

1. `reinterpret_cast<cv T*>(a)[2*i]` designates the real part of \( a[i] \), and
2. `reinterpret_cast<cv T*>(a)[2*i + 1]` designates the imaginary part of \( a[i] \).

28.4.2 Header `<complex>` synopsis

```cpp
namespace std {
    // 28.4.3, class template complex
template<class T> class complex;
```
template<class T> constexpr complex<T> operator+(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator+(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator+(const T&, const complex<T>&);
template<class T> constexpr complex<T> operator-(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator-(const complex<T>&, const T&);

template<class T> complex<T> sqrt (const complex<T>&);
template<class T> complex<T> tan (const complex<T>&);
template<class T> complex<T> tanh (const complex<T>&);

// 28.4.10, complex literals
inline namespace literals {
inline namespace complex_literals {
    constexpr complex<long double> operator"il(long double);
    constexpr complex<long double> operator"il(unsigned long long);
    constexpr complex<double> operator"i(long double);
    constexpr complex<double> operator"i(unsigned long long);
    constexpr complex<float> operator"if(long double);
    constexpr complex<float> operator"if(unsigned long long);
}
}

28.4.3 Class template complex

namespace std {
    template<class T> class complex {
        public:
            using value_type = T;
            constexpr complex(const T& re = T(), const T& im = T());
            constexpr complex(const complex&) = default;
            template<class X> constexpr explicit(const complex<X>&);
            constexpr T real() const;
            constexpr void real(T);
            constexpr T imag() const;
            constexpr void imag(T);
            constexpr complex& operator= (const T&);
            constexpr complex& operator+=(const T&);
            constexpr complex& operator-=(const T&);
            constexpr complex& operator*=(const T&);
            constexpr complex& operator/=(const T&);
            template<class X> constexpr complex& operator= (const complex<X>&);
            template<class X> constexpr complex& operator+=(const complex<X>&);
            template<class X> constexpr complex& operator-=(const complex<X>&);
            template<class X> constexpr complex& operator*=(const complex<X>&);
            template<class X> constexpr complex& operator/=(const complex<X>&);
    };
}

1 The class complex describes an object that can store the Cartesian components, real() and imag(), of a complex number.

28.4.4 Member functions

constexpr complex(const T& re = T(), const T& im = T());
1 Postconditions: real() == re && imag() == im is true.

template<class X> constexpr explicit(const complex<X>& other);
2 Effects: Initializes the real part with other.real() and the imaginary part with other.imag().
3 Remarks: The expression inside explicit evaluates to false if and only if the floating-point conversion rank of T is greater than or equal to the floating-point conversion rank of X.

constexpr T real() const;
4 Returns: The value of the real component.
constexpr void real(T val);

Effects: Assigns val to the real component.

constexpr T imag() const;

Returns: The value of the imaginary component.

constexpr void imag(T val);

Effects: Assigns val to the imaginary component.

### 28.4.5 Member operators

```cpp
constexpr complex& operator+=(const T& rhs);

Effects: Adds the scalar value rhs to the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.

Returns: *this.
```

```cpp
constexpr complex& operator-=(const T& rhs);

Effects: Subtracts the scalar value rhs from the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.

Returns: *this.
```

```cpp
constexpr complex& operator*=(const T& rhs);

Effects: Multiplies the scalar value rhs by the complex value *this and stores the result in *this.

Returns: *this.
```

```cpp
constexpr complex& operator/=(const T& rhs);

Effects: Divides the scalar value rhs into the complex value *this and stores the result in *this.

Returns: *this.
```

```cpp
template<class X> constexpr complex& operator+=(const complex<X>& rhs);

Effects: Adds the complex value rhs to the complex value *this and stores the sum in *this.

Returns: *this.
```

```cpp
template<class X> constexpr complex& operator-=(const complex<X>& rhs);

Effects: Subtracts the complex value rhs from the complex value *this and stores the difference in *this.

Returns: *this.
```

```cpp
template<class X> constexpr complex& operator*=(const complex<X>& rhs);

Effects: Multiplies the complex value rhs by the complex value *this and stores the product in *this.

Returns: *this.
```

```cpp
template<class X> constexpr complex& operator/=(const complex<X>& rhs);

Effects: Divides the complex value rhs into the complex value *this and stores the quotient in *this.

Returns: *this.
```

### 28.4.6 Non-member operations

```cpp
template<class T> constexpr complex<T> operator+(const complex<T>& lhs);

Returns: complex<T>(lhs).
```

```cpp
template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const complex<T>& rhs);

template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const T& rhs);

template<class T> constexpr complex<T> operator+(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) += rhs.
```
template<class T> constexpr complex<T> operator-(const complex<T>& lhs);  
Returns: complex<T>(-lhs.real(), -lhs.imag()).

template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const complex<T>& rhs);  
Returns: complex<T>(lhs) -= rhs.

template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const T& rhs);  
Returns: complex<T>(lhs) *= rhs.

template<class T> constexpr bool operator==(const complex<T>& lhs, const complex<T>& rhs);  
Returns: lhs.real() == rhs.real() && lhs.imag() == rhs.imag().

template<class T> T real(const complex<T>& x);  
Returns: x.real().

template<class T> T imag(const complex<T>& x);  
Returns: x.imag().

template<class T> T abs(const complex<T>& x);  
Returns: The magnitude of x.

28.4.7 Value operations

[complex.value.ops]
template<class T> T arg(const complex<T>& x);

Returns: The phase angle of x, or $\text{atan2}(\text{imag}(x), \text{real}(x))$.

template<class T> constexpr T norm(const complex<T>& x);

Returns: The squared magnitude of x.

template<class T> constexpr complex<T> conj(const complex<T>& x);

Returns: The complex conjugate of x.

template<class T> complex<T> proj(const complex<T>& x);

Returns: The projection of x onto the Riemann sphere.

Remarks: Behaves the same as the C function cproj. See also: ISO C 7.3.9.5

template<class T> complex<T> polar(const T& rho, const T& theta = T());

Preconditions: rho is non-negative and non-NaN. theta is finite.

Returns: The complex value corresponding to a complex number whose magnitude is rho and whose
phase angle is theta.

28.4.8 Transcendentals

[complex.transcendentals]

template<class T> complex<T> acos(const complex<T>& x);

Returns: The complex arc cosine of x.

Remarks: Behaves the same as the C function cacos. See also: ISO C 7.3.5.1

template<class T> complex<T> asin(const complex<T>& x);

Returns: The complex arc sine of x.

Remarks: Behaves the same as the C function casin. See also: ISO C 7.3.5.2

template<class T> complex<T> atan(const complex<T>& x);

Returns: The complex arc tangent of x.

Remarks: Behaves the same as the C function catan. See also: ISO C 7.3.5.3

template<class T> complex<T> acosh(const complex<T>& x);

Returns: The complex arc hyperbolic cosine of x.

Remarks: Behaves the same as the C function cacosh. See also: ISO C 7.3.6.1

template<class T> complex<T> asinh(const complex<T>& x);

Returns: The complex arc hyperbolic sine of x.

Remarks: Behaves the same as the C function casinh. See also: ISO C 7.3.6.2

template<class T> complex<T> atanh(const complex<T>& x);

Returns: The complex arc hyperbolic tangent of x.

Remarks: Behaves the same as the C function catanh. See also: ISO C 7.3.6.3

template<class T> complex<T> cos(const complex<T>& x);

Returns: The complex cosine of x.

template<class T> complex<T> cosh(const complex<T>& x);

Returns: The complex hyperbolic cosine of x.

template<class T> complex<T> exp(const complex<T>& x);

Returns: The complex base-e exponential of x.

template<class T> complex<T> log(const complex<T>& x);

Returns: The complex natural (base-e) logarithm of x. For all x, $\text{imag}(\text{log}(x))$ lies in the interval $[-\pi, \pi]$. 

§ 28.4.8 1403
Note 1: The semantics of this function are intended to be the same in C++ as they are for clog in C. — end note

Remarks: The branch cuts are along the negative real axis.

\texttt{template<class T> complex\langle T\rangle\ \log10(const complex\langle T\rangle& \ x);}

Returns: The complex common (base-10) logarithm of \( x \), defined as \( \log(x) / \log(10) \).

Remarks: The branch cuts are along the negative real axis.

\texttt{template<class T> complex\langle T\rangle\ \pow(const complex\langle T\rangle& \ x, const complex\langle T\rangle& \ y);}
\texttt{template<class T> complex\langle T\rangle\ \pow(const complex\langle T\rangle& \ x, const T& \ y);}
\texttt{template<class T> complex\langle T\rangle\ \pow(const T& \ x, const complex\langle T\rangle& \ y);}

Returns: The complex power of base \( x \) raised to the \( y \)-th power, defined as \( \exp(y \times \log(x)) \). The value returned for \( \text{pow}(0, 0) \) is implementation-defined.

Remarks: The branch cuts are along the negative real axis.

\texttt{template<class T> complex\langle T\rangle\ \sin(const complex\langle T\rangle& \ x);} \texttt{template<class T> complex\langle T\rangle\ \sinh(const complex\langle T\rangle& \ x);} \texttt{template<class T> complex\langle T\rangle\ \sqrt{const complex\langle T\rangle& \ x);}

Returns: The complex sine of \( x \).

Returns: The complex hyperbolic sine of \( x \).

Returns: The complex square root of \( x \), in the range of the right half-plane.

Note 2: The semantics of this function are intended to be the same in C++ as they are for \texttt{csqrt} in C. — end note

Remarks: The branch cuts are along the negative real axis.

\texttt{template<class T> complex\langle T\rangle\ \tan(const complex\langle T\rangle& \ x);} \texttt{template<class T> complex\langle T\rangle\ \tanh(const complex\langle T\rangle& \ x);}\texttt{template<class T> complex\langle T\rangle\ \tan(const complex\langle T\rangle& \ x);}\texttt{template<class T> complex\langle T\rangle\ \tan(const complex\langle T\rangle& \ x);}\texttt{template<class T> complex\langle T\rangle\ \tan(const complex\langle T\rangle& \ x);}\texttt{template<class T> complex\langle T\rangle\ \tan(const complex\langle T\rangle& \ x);}

Returns: The complex hyperbolic tangent of \( x \).

28.4.9 Additional overloads [cmlxl.over]

The following function templates shall have additional overloads:

\begin{Verbatim}
arg \hspace{10pt} \texttt{norm}
conj \hspace{10pt} \texttt{proj}
imag \hspace{10pt} \texttt{real}
\end{Verbatim}

where \texttt{norm}, \texttt{conj}, \texttt{imag}, and \texttt{real} are \texttt{constexpr} overloads.

The additional overloads shall be sufficient to ensure:

\begin{itemize}
  \item[(2.1)] If the argument has a floating-point type \( T \), then it is effectively cast to \texttt{complex\langle T\rangle}.
  \item[(2.2)] Otherwise, if the argument has integer type, then it is effectively cast to \texttt{complex\langle double\rangle}.
\end{itemize}

Function template \texttt{pow} has additional overloads sufficient to ensure, for a call with one argument of type \texttt{complex\langle T1\rangle} and the other argument of type \( T2 \) or \texttt{complex\langle T2\rangle}, both arguments are effectively cast to \texttt{complex\langle common\_type\_t\langle T1, T2\rangle\rangle}. If \texttt{common\_type\_t\langle T1, T2\rangle} is not well-formed, then the program is ill-formed.

28.4.10 Suffixes for complex number literals [complex.literals]

This subclause describes literal suffixes for constructing complex number literals. The suffixes \texttt{i}, \texttt{il}, and \texttt{if} create complex numbers of the types \texttt{complex\langle double\rangle}, \texttt{complex\langle long\ double\rangle}, and \texttt{complex\langle float\rangle} respectively, with their imaginary part denoted by the given literal number and the real part being zero.

\begin{Verbatim}
constexpr\texttt{complex\langle long\ double\rangle}\ \operator\"il\text{(long\ double\ \ d)};\operator\"if\text{(unsigned\ long\ long\ \ d)};
\end{Verbatim}

Returns: \texttt{complex\langle long\ double\rangle\{0.0L, static\_cast\langle long\ double\rangle\text{(d)}\}}.
constexpr complex<double> operator"i(long double d);
constexpr complex<double> operator"i(unsigned long long d);

Returns: complex<double>{0.0, static_cast<double>(d)}.

constexpr complex<float> operator"if(long double d);
constexpr complex<float> operator"if(unsigned long long d);

Returns: complex<float>{0.0f, static_cast<float>(d)}.

28.5 Random number generation

28.5.1 General

Subclause 28.5 defines a facility for generating (pseudo-)random numbers.

In addition to a few utilities, four categories of entities are described: uniform random bit generators, random number engines, random number engine adaptors, and random number distributions. These categorizations are applicable to types that meet the corresponding requirements, to objects instantiated from such types, and to templates producing such types when instantiated.

[Note 1: These entities are specified in such a way as to permit the binding of any uniform random bit generator object as the argument to any random number distribution object, thus producing a zero-argument function object such as given by bind(d, e). — end note]

Each of the entities specified in 28.5 has an associated arithmetic type (6.8.2) identified as result_type. With T as the result_type thus associated with such an entity, that entity is characterized:

(3.1) — as boolean or equivalently as boolean-valued, if T is bool;
(3.2) — otherwise as integral or equivalently as integer-valued, if numeric_limits<T>::is_integer is true;
(3.3) — otherwise as floating-point or equivalently as real-valued.

If integer-valued, an entity may optionally be further characterized as signed or unsigned, according to numeric_limits<T>::is_signed.

Unless otherwise specified, all descriptions of calculations in 28.5 use mathematical real numbers.

Throughout 28.5, the operators bitand, bitor, and xor denote the respective conventional bitwise operations. Further:

(5.1) — the operator rshift denotes a bitwise right shift with zero-valued bits appearing in the high bits of the result, and
(5.2) — the operator lshift denotes a bitwise left shift with zero-valued bits appearing in the low bits of the result, and whose result is always taken modulo 2^w.

28.5.3 Requirements

28.5.3.1 General requirements

Throughout this subclause 28.5, the effect of instantiating a template:

(1.1) that has a template type parameter named Sseq is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of seed sequence (28.5.3.2).

(1.2) that has a template type parameter named URBG is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of uniform random bit generator (28.5.3.3).
(1.3) — that has a template type parameter named `Engine` is undefined unless the corresponding template argument is cv-unqualified and meets the requirements of random number engine (28.5.3.4).

(1.4) — that has a template type parameter named `RealType` is undefined unless the corresponding template argument is cv-unqualified and is one of `float`, `double`, or `long double`.

(1.5) — that has a template type parameter named `IntType` is undefined unless the corresponding template argument is cv-unqualified and is one of `short`, `int`, `long`, `long long`, `unsigned short`, `unsigned int`, `unsigned long`, or `unsigned long long`.

(1.6) — that has a template type parameter named `UIntType` is undefined unless the corresponding template argument is cv-unqualified and is one of `unsigned short`, `unsigned int`, `unsigned long`, or `unsigned long long`.

2 Throughout this subclause 28.5, phrases of the form “x is an iterator of a specific kind” shall be interpreted as equivalent to the more formal requirement that “x is a value of a type meeting the requirements of the specified iterator type”.

3 Throughout this subclause 28.5, any constructor that can be called with a single argument and that meets a requirement specified in this subclause shall be declared `explicit`.

28.5.3.2 Seed sequence requirements [rand.req.seedseq]

A seed sequence is an object that consumes a sequence of integer-valued data and produces a requested number of unsigned integer values $i$, $0 \leq i < 2^{32}$, based on the consumed data.

[Note 1: Such an object provides a mechanism to avoid replication of streams of random variates. This can be useful, for example, in applications requiring large numbers of random number engines. — end note]

A class $S$ meets the requirements of a seed sequence if the expressions shown in Table 95 are valid and have the indicated semantics, and if $S$ also meets all other requirements of this subclause 28.5.3.2. In that Table and throughout this subclause:

(2.1) — $T$ is the type named by $S$’s associated `result_type`;

(2.2) — $q$ is a value of type $S$ and $r$ is a value of type $S$ or `const S`;

(2.3) — $ib$ and $ie$ are input iterators with an unsigned integer `value_type` of at least 32 bits;

(2.4) — $rb$ and $re$ are mutable random access iterators with an unsigned integer `value_type` of at least 32 bits;

(2.5) — $ob$ is an output iterator; and

(2.6) — $il$ is a value of type `initializer_list<T>`.

<td>$O(r.size())$</td>
</tr>
</tbody>
</table>

### 28.5.3.3 Uniform random bit generator requirements

A uniform random bit generator $g$ of type $G$ is a function object returning unsigned integer values such that each value in the range of possible results has (ideally) equal probability of being returned.

[Note 1: The degree to which $g$'s results approximate the ideal is often determined statistically. — end note]

```cpp
template<class G>
concept uniform_random_bit_generator =
  invocable<G&> && unsigned_integral<invoke_result_t<G&>> &&
  requires {
    { G::min() } -> same_as<invoke_result_t<G&>>;
    { G::max() } -> same_as<invoke_result_t<G&>>;
    requires bool_constant<(G::min() < G::max())>::value;
  };
```

2. Let $g$ be an object of type $G$. $G$ models `uniform_random_bit_generator` only if

1. $G::min() \leq g()$,
2. $g() \leq G::max()$, and
3. $g()$ has amortized constant complexity.

A class $G$ meets the `uniform_random_bit_generator` requirements if $G$ models `uniform_random_bit_generator`, `invoke_result_t<G&>` is an unsigned integer type (6.8.2), and $G$ provides a nested `typedef-name result_type` that denotes the same type as `invoke_result_t<G&>`.

### 28.5.3.4 Random number engine requirements

A random number engine (commonly shortened to engine) $e$ of type $E$ is a uniform random bit generator that additionally meets the requirements (e.g., for seeding and for input/output) specified in this subclause.

At any given time, $e$ has a state $e_i$ for some integer $i \geq 0$. Upon construction, $e$ has an initial state $e_0$. An engine's state may be established via a constructor, a `seed` function, assignment, or a suitable `operator>>`

E's specification shall define:

1. the size of $E$'s state in multiples of the size of `result_type`, given as an integral constant expression;
2. the transition algorithm $TA$ by which $e$'s state $e_i$ is advanced to its successor state $e_{i+1}$; and
3. the generation algorithm $GA$ by which an engine's state is mapped to a value of type `result_type`. 

§ 28.5.3.4
A class $E$ that meets the requirements of a uniform random bit generator (28.5.3.3) also meets the requirements of a random number engine if the expressions shown in Table 96 are valid and have the indicated semantics, and if $E$ also meets all other requirements of this subclause 28.5.3.4. In that Table and throughout this subclause:

(4.1) $T$ is the type named by $E$’s associated result_type;
(4.2) $e$ is a value of $E$, $v$ is an lvalue of $E$, $x$ and $y$ are (possibly const) values of $E$;
(4.3) $z$ is a value of type unsigned long long;
(4.4) $q$ is an lvalue meeting the requirements of a seed sequence (28.5.3.2);
(4.5) $s$ is a value of $T$;
(4.6) $os$ is an lvalue of the type of some class template specialization basic_ostream<charT, traits> and
(4.7) $is$ is an lvalue of the type of some class template specialization basic_istream<charT, traits>;

where charT and traits are constrained according to Clause 23 and Clause 31.

<table>

<td>This operator is an equivalence relation. With $S_x$ and $S_y$ as the infinite sequences of values that would be generated by repeated future calls to $x()$ and $y()$, respectively, returns true if $S_x = S_y$; else returns false.</td>
<td>$O$(size of state)</td>
</tr>
<tr>
<td>$x != y$</td>
<td>bool</td>
<td>!(x == y).</td>
<td>$O$(size of state)</td>
</tr>
</tbody>
</table>

---

226) This constructor (as well as the subsequent corresponding seed() function) can be particularly useful to applications requiring a large number of independent random sequences.

227) This operation is common in user code, and can often be implemented in an engine-specific manner so as to provide significant performance improvements over an equivalent naive loop that makes $z$ consecutive calls $e()$. 

§ 28.5.3.4
Expression | Return type | Pre/post-condition | Complexity |
---|---|---|---|
\texttt{os} \texttt{\ll} \texttt{x} | reference to the type of \texttt{os} | With \texttt{os.fmtflags} set to \texttt{ios-} \texttt{base::dec}|ios_base::left and the fill character set to the space character, writes to \texttt{os} the textual representation of \(x\)'s current state. In the output, adjacent numbers are separated by one or more space characters. Postconditions: The \texttt{os.fmtflags} and fill character are unchanged. | \(O(\text{size of state})\) |
\texttt{is} \texttt{\gg} \texttt{v} | reference to the type of \texttt{is} | With \texttt{is.fmtflags} set to \texttt{ios_base::dec}, sets \(v\)'s state as determined by reading its textual representation from \texttt{is}. If bad input is encountered, ensures that \(v\)'s state is unchanged by the operation and calls \texttt{is.setstate(ios_-} \texttt{base::failbit)} (which may throw \texttt{ios_base::failure} (31.5.4.4)). If a textual representation written via \texttt{os} \texttt{\ll} \texttt{x} was subsequently read via \texttt{is} \texttt{\gg} \texttt{v}, then \(x == v\) provided that there have been no intervening invocations of \(x\) or of \(v\). Preconditions: \texttt{is} provides a textual representation that was previously written using an output stream whose imbued locale was the same as that of \texttt{is}, and whose type’s template specialization arguments \texttt{charT} and \texttt{traits} were respectively the same as those of \texttt{is}. Postconditions: The \texttt{is.fmtflags} are unchanged. | \(O(\text{size of state})\) |

5 E shall meet the \texttt{Cpp17CopyConstructible} (Table 32) and \texttt{Cpp17CopyAssignable} (Table 34) requirements. These operations shall each be of complexity no worse than \(O(\text{size of state})\).

28.5.3.5 Random number engine adaptor requirements \[\text{rand.req.adapt}\]

1 A random number engine adaptor (commonly shortened to adaptor) \texttt{a} of type \texttt{A} is a random number engine that takes values produced by some other random number engine, and applies an algorithm to those values in order to deliver a sequence of values with different randomness properties. An engine \texttt{b} of type \texttt{B} adapted in this way is termed a base engine in this context. The expression \texttt{a.base()} shall be valid and shall return a const reference to \(a\)'s base engine.

2 The requirements of a random number engine type shall be interpreted as follows with respect to a random number engine adaptor type.

\texttt{A::A();}

3 \textit{Effects}: The base engine is initialized as if by its default constructor.

\texttt{bool operator== (const A & a1, const A & a2);}  

4 \textit{Returns}: true if \texttt{a1}'s base engine is equal to \texttt{a2}'s base engine. Otherwise returns \texttt{false}.
A::A(result_type s);

Effects: The base engine is initialized with s.

template<class Sseq> A::A(Sseq& q);

Effects: The base engine is initialized with q.

void seed();

Effects: With b as the base engine, invokes b.seed().

void seed(result_type s);

Effects: With b as the base engine, invokes b.seed(s).

template<class Sseq> void seed(Sseq& q);

Effects: With b as the base engine, invokes b.seed(q).

A shall also meet the following additional requirements:

(10.1) — The complexity of each function shall not exceed the complexity of the corresponding function applied to the base engine.

(10.2) — The state of A shall include the state of its base engine. The size of A’s state shall be no less than the size of the base engine.

(10.3) — Copying A’s state (e.g., during copy construction or copy assignment) shall include copying the state of the base engine of A.

(10.4) — The textual representation of A shall include the textual representation of its base engine.

28.5.3.6 Random number distribution requirements [rand.req.dist]

A random number distribution (commonly shortened to distribution) d of type D is a function object returning values that are distributed according to an associated mathematical probability density function p(z) or according to an associated discrete probability function P(z_i). A distribution’s specification identifies its associated probability function p(z) or P(z_i).

An associated probability function is typically expressed using certain externally-supplied quantities known as the parameters of the distribution. Such distribution parameters are identified in this context by writing, for example, p(z | a, b) or P(z_i | a, b), to name specific parameters, or by writing, for example, p(z | {p}) or P(z_i | {p}), to denote a distribution’s parameters p taken as a whole.

A class D meets the requirements of a random number distribution if the expressions shown in Table 97 are valid and have the indicated semantics, and if D and its associated types also meet all other requirements of this subclause 28.5.3.6. In that Table and throughout this subclause,

(3.1) — T is the type named by D’s associated result_type;

(3.2) — P is the type named by D’s associated param_type;

(3.3) — d is a value of D, and x and y are (possibly const) values of D;

(3.4) — glb and lub are values of T respectively corresponding to the greatest lower bound and the least upper bound on the values potentially returned by d’s operator(), as determined by the current values of d’s parameters;

(3.5) — p is a (possibly const) value of P;

(3.6) — g, g1, and g2 are lvalues of a type meeting the requirements of a uniform random bit generator (28.5.3.3);

(3.7) — os is an lvalue of the type of some class template specialization basic_ostream<charT, traits>;

(3.8) — is is an lvalue of the type of some class template specialization basic_istream<charT, traits>;

where charT and traits are constrained according to Clause 23 and Clause 31.

<td></td>
</tr>
</tbody>
</table>

**Preconditions:** `is` provides a textual representation that was previously written using an `os` whose imbued locale and whose type's template specialization arguments `charT` and `traits` were the same as those of `is`.

**Postconditions:** The `is.fmtflags` are unchanged.

---

4. `D` shall meet the `Cpp17CopyConstructible` (Table 32) and `Cpp17CopyAssignable` (Table 34) requirements.

5. The sequence of numbers produced by repeated invocations of `d(g)` shall be independent of any invocation of `os << d` or of any `const` member function of `D` between any of the invocations of `d(g)`.

6. If a textual representation is written using `os << x` and that representation is restored into the same or a different object `y` of the same type using `is >> y`, repeated invocations of `y(g)` shall produce the same sequence of numbers as would repeated invocations of `x(g)`.

7. It is unspecified whether `D::param_type` is declared as a (nested) `class` or via a `typedef`. In this subclause 28.5, declarations of `D::param_type` are in the form of `typedef`s for convenience of exposition only.

8. `P` shall meet the `Cpp17CopyConstructible` (Table 32), `Cpp17CopyAssignable` (Table 34), and `Cpp17Equality-Comparable` (Table 28) requirements.

9. For each of the constructors of `D` taking arguments corresponding to parameters of the distribution, `P` shall have a corresponding constructor subject to the same requirements and taking arguments identical in number, type, and default values. Moreover, for each of the member functions of `D` that return values corresponding to parameters of the distribution, `P` shall have a corresponding member function with the identical name, type, and semantics.

10. `P` shall have a declaration of the form

    ```
    using distribution_type = D;
    ```

---

### 28.5.4 Random number engine class templates [rand.eng]

#### 28.5.4.1 General [rand.eng.general]

1. Each type instantiated from a class template specified in 28.5.4 meets the requirements of a random number engine (28.5.3.4) type.

2. Except where specified otherwise, the complexity of each function specified in 28.5.4 is constant.

3. Except where specified otherwise, no function described in 28.5.4 throws an exception.

4. Every function described in 28.5.4 that has a function parameter `q` of type `Sseq&` for a template type parameter named `Sseq` that is different from type `seed_seq` throws `what` and when the invocation of `q.generate` throws.

5. Descriptions are provided in 28.5.4 only for engine operations that are not described in 28.5.3.4 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.
6 Each template specified in 28.5.4 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

7 For every random number engine and for every random number engine adaptor X defined in 28.5.4 and in 28.5.5:

(7.1) — if the constructor

```cpp
    template<class Sseq> explicit X(Sseq& q);
```

is called with a type Sseq that does not qualify as a seed sequence, then this constructor shall not participate in overload resolution;

(7.2) — if the member function

```cpp
    template<class Sseq> void seed(Sseq& q);
```

is called with a type Sseq that does not qualify as a seed sequence, then this function shall not participate in overload resolution.

The extent to which an implementation determines that a type cannot be a seed sequence is unspecified, except that as a minimum a type shall not qualify as a seed sequence if it is implicitly convertible to X::result_type.

28.5.4.2 Class template linear_congruential_engine

A linear_congruential_engine random number engine produces unsigned integer random numbers. The state \(x_i\) of a linear_congruential_engine object \(x\) is of size 1 and consists of a single integer. The transition algorithm is a modular linear function of the form \(TA(x_i) = (a \cdot x_i + c) \mod m\); the generation algorithm is \(GA(x_i) = x_{i+1}\).

```cpp
namespace std {
    template<class UIntType, UIntType a, UIntType c, UIntType m>
    class linear_congruential_engine {
    public:
        // types
        using result_type = UIntType;

        // engine characteristics
        static constexpr result_type multiplier = a;
        static constexpr result_type increment = c;
        static constexpr result_type modulus = m;
        static constexpr result_type min() { return c == 0u ? 1u : 0u; }
        static constexpr result_type max() { return m - 1u; }
        static constexpr result_type default_seed = 1u;

        // constructors and seeding functions
        linear_congruential_engine() : linear_congruential_engine(default_seed) {} // explicit linear_congruential_engine(result_type s);
        template<class Sseq> explicit linear_congruential_engine(Sseq& q);
        void seed(result_type s = default_seed);
        template<class Sseq> void seed(Sseq& q);

        // equality operators
        friend bool operator==(const linear_congruential_engine& x, const linear_congruential_engine& y);

        // generating functions
        result_type operator()();
        void discard(unsigned long long z);

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const linear_congruential_engine& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, linear_congruential_engine& x);
    } // linear_congruential_engine
}; // namespace std
```
Let (3.2) Let (3.4) With (3.1) Concatenate the upper (2.2) The textual representation consists of the value of 4 The textual representation consists of the value of 3 If the template parameter \( m \) need not be representable as a value of type result_type. — end note 3 If the template parameter \( m \) is not 0, the following relations shall hold: \( a < m \) and \( c < m \). 4 The textual representation consists of the value of \( x \).

\[
\text{explicit linear_congruential_engine(result_type s);} \]

\[
\text{template<Sseq> explicit linear_congruential_engine(Sseq& q);} \]

Effects: If \( c \) mod \( m \) is 0 and \( s \) mod \( m \) is 0, sets the engine’s state to 1, otherwise sets the engine’s state to \( s \) mod \( m \).

### 28.5.4.3 Class template mersenne_twister_engine

A mersenne_twister_engine random number engine produces unsigned integer random numbers in the closed interval \([0, 2^w - 1]\). The state \( x \) of a mersenne_twister_engine object \( x \) is of size \( n \) and consists of a sequence \( X \) of \( n \) values of the type delivered by \( x \); all subscripts applied to \( X \) are to be taken modulo \( n \).

1 The transition algorithm employs a twisted generalized feedback shift register defined by shift values \( n \) and \( m \), a twist value \( r \), and a conditional xor-mask \( a \). To improve the uniformity of the result, the bits of the raw shift register are additionally tempered (i.e., scrambled) according to a bit-scrambling matrix defined by values \( u, d, s, b, t, c, \) and \( \ell \).

The state transition is performed as follows:

\[
\text{(2.1) — Concatenate the upper } w - r \text{ bits of } X_{i-n} \text{ with the lower } r \text{ bits of } X_{i+1-n} \text{ to obtain an unsigned integer value } Y. \]

\[
\text{(2.2) — With } \alpha = a \cdot (Y \text{ bitand } 1), \text{ set } X_i \text{ to } X_{i+m-n} \text{ xor } (Y \text{ rshift } 1) \text{ xor } \alpha. \]

The sequence \( X \) is initialized with the help of an initialization multiplier \( f \).

1 The generation algorithm determines the unsigned integer values \( z_1, z_2, z_3, z_4 \) as follows, then delivers \( z_4 \) as its result:

\[
\text{(3.1) — Let } z_1 = X_i \text{ xor } ((X_i \text{ rshift } u) \text{ bitand } d). \]

\[
\text{(3.2) — Let } z_2 = z_1 \text{ xor } ((z_1 \text{ lshift } w) \text{ bitand } b). \]

\[
\text{(3.3) — Let } z_3 = z_2 \text{ xor } ((z_2 \text{ lshift } t) \text{ bitand } c). \]

\[
\text{(3.4) — Let } z_4 = z_3 \text{ xor } (z_3 \text{ rshift } \ell). \]

namespace std {

\[
\text{template<UIntType, size_t w, size_t n, size_t m, size_t r,}
\]

\[
\text{UIntType a, size_t u, UIntType d, size_t s,}
\]

\[
\text{UIntType b, size_t t,}
\]

\[
\text{UIntType c, size_t l, UIntType f>}
\]

\text{class mersenne_twister_engine {

\text{public:

\text{ // types

\text{ using result_type = UIntType;}

\text{ // engine characteristics

\text{ static constexpr size_t word_size = w;}
\text{ static constexpr size_t state_size = n;}
\text{ static constexpr size_t shift_size = m;}
\text{ static constexpr size_t mask_bits = r;}}

\text{}}}
\text{}}}
static constexpr UIntType xor_mask = a;
static constexpr size_t tempering_u = u;
static constexpr UIntType tempering_d = d;
static constexpr size_t tempering_s = s;
static constexpr UIntType tempering_b = b;
static constexpr size_t tempering_t = t;
static constexpr UIntType tempering_c = c;
static constexpr size_t tempering_l = l;
static constexpr UIntType initialization_multiplier = f;

static constexpr result_type min() { return 0; }  
static constexpr result_type max() { return \(2^w - 1\); }  
static constexpr result_type default_seed = 5489u;

// constructors and seeding functions
mersenne_twister_engine() : mersenne_twister_engine(default_seed) {}  
explicit mersenne_twister_engine(result_type value);  
template<class Sseq> explicit mersenne_twister_engine(Sseq& q);

void seed(result_type value = default_seed);  
template<class Sseq> void seed(Sseq& q);

// equality operators  
friend bool operator==(const mersenne_twister_engine& x, const mersenne_twister_engine& y);

// generating functions
result_type operator()();  
void discard(unsigned long long z);

// inserters and extractors  
template<class charT, class traits>  
friend basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const mersenne_twister_engine& x);

template<class charT, class traits>  
friend basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, mersenne_twister_engine& x);

The following relations shall hold:  
0 < m, m <= n, 2u < w, r <= w, u <= w, s <= w, l <= w, w <= numeric_limits<UIntType>::digits, a <= (1u<<w) - 1u, b <= (1u<<w) - 1u, c <= (1u<<w) - 1u, d <= (1u<<w) - 1u, and f <= (1u<<w) - 1u.

The textual representation of \(x_i\) consists of the values of \(X_{i-n}, \ldots, X_{i-1}\), in that order.

\[ f \cdot (X_{i-1} \ xor \ (X_{i-1} \ rshift \ (w - 2))) + i \mod n \mod 2^w. \]

\(\text{Complexity: } \Theta(n)\).

template<class Sseq> explicit mersenne_twister_engine(Sseq& q);

Effects: With \(k = \lceil w/32 \rceil\) and \(a\) an array (or equivalent) of length \(n \cdot k\), invokes \(q\).generate\((a + 0, a + n \cdot k)\) and then, iteratively for \(i = -n, \ldots, -1\), sets \(X_i\) to \(\left(\sum_{j=0}^{k-1} a_{k(i+n)+j} \cdot 2^{32j}\right) \mod 2^w\). Finally, if the most significant \(w - r\) bits of \(X_{-n}\) are zero, and if each of the other resulting \(X_i\) is \(0\), changes \(X_{-n}\) to \(2^w - 1\).

### 28.5.4.4 Class template subtract_with_carry_engine

A `subtract_with_carry_engine` random number engine produces unsigned integer random numbers.

The state \(x_i\) of a `subtract_with_carry_engine` object \(x\) is of size \(\Theta(r)\), and consists of a sequence \(X\) of \(r\) integer values \(0 \leq X_i < m = 2^w\); all subscripts applied to \(X\) are to be taken modulo \(r\). The state \(x_i\) additionally consists of an integer \(c\) (known as the `carry`) whose value is either \(0\) or \(1\).

The state transition is performed as follows:
(3.1) Let \( Y = X_{i-s} - X_{i-r} - c \).
(3.2) Set \( X_i \) to \( y = Y \mod m \). Set \( c \) to 1 if \( Y < 0 \), otherwise set \( c \) to 0.

[Note 1: This algorithm corresponds to a modular linear function of the form \( TA(x_i) = (a \cdot x_i) \mod b \), where \( b \) is of the form \( m^r - m^s + 1 \) and \( a = b - (b - 1)/m \). — end note]

The generation algorithm is given by \( GA(x_i) = y \), where \( y \) is the value produced as a result of advancing the engine's state as described above.

```cpp
namespace std {
    template<class UIntType, size_t w, size_t s, size_t r>
    class subtract_with_carry_engine {
    public:
        // types
        using result_type = UIntType;

        // engine characteristics
        static constexpr size_t word_size = w;
        static constexpr size_t short_lag = s;
        static constexpr size_t long_lag = r;
        static constexpr result_type min() { return 0; }
        static constexpr result_type max() { return m - 1; }
        static constexpr result_type default_seed = 19780503u;

        // constructors and seeding functions
        explicit subtract_with_carry_engine(result_type value);
        template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
        void seed(result_type value = default_seed);
        template<class Sseq> void seed(Sseq& q);

        // equality operators
        friend bool operator==(const subtract_with_carry_engine& x,
                                const subtract_with_carry_engine& y);

        // generating functions
        result_type operator()();
        void discard(unsigned long long z);

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const subtract_with_carry_engine& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, subtract_with_carry_engine& x);
    }
}
```

5 The following relations shall hold: \( 0 < s, s < r, 0 < w, \) and \( w \leq \text{numeric\_limits<UIntType>::digits} \).

6 The textual representation consists of the values of \( X_{i-r}, \ldots, X_{i-1} \), in that order, followed by \( c \).

### Effects

- **Sets the values of** \( X_{i-r}, \ldots, X_{i-1} \), in that order, as specified below. If \( X_{i-1} \) is then 0, sets \( c \) to 1; otherwise sets \( c \) to 0.
- To set the values \( X_k \), first construct \( e \), a `linear_congruential_engine` object, as if by the following definition:
  - `linear_congruential_engine<result_type, 40014u, 0u, 2147483563u> e(value == 0u ? default_seed : value);`
- Then, to set each \( X_k \), obtain new values \( z_0, \ldots, z_{n-1} \) from \( n = \lceil w/32 \rceil \) successive invocations of \( e \). Set \( X_k \) to \( \left( \sum_{j=0}^{n-1} z_j \cdot 2^{32j} \right) \mod m \).

8 **Complexity:** Exactly \( n \cdot r \) invocations of \( e \).
template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);

Effects: With \( k = \lceil w/32 \rceil \) and \( a \) an array (or equivalent) of length \( r \cdot k \), invokes \( q.\text{generate}(a + 0, a + r \cdot k) \) and then, iteratively for \( i = -r, \ldots, -1 \), sets \( X_i \) to \( \left( \sum_{j=0}^{k-1} a_{k(i+r)+j} \cdot 2^{32j} \right) \mod m \). If \( X_{-1} \) is then 0, sets \( c \) to 1; otherwise sets \( c \) to 0.

28.5.5 Random number engine adaptor class templates

28.5.5.1 In general

1 Each type instantiated from a class template specified in this subclause 28.5.5 meets the requirements of a random number engine adaptor (28.5.3.5) type.

2 Except where specified otherwise, the complexity of each function specified in this subclause 28.5.5 is constant.

3 Except where specified otherwise, no function described in this subclause 28.5.5 throws an exception.

4 Every function described in this subclause 28.5.5 that has a function parameter \( q \) of type \( Sseq \& \) for a template type parameter named \( Sseq \) that is different from type \( seed_seq \) throws what and when the invocation of \( q.\text{generate} \) throws.

5 Descriptions are provided in this subclause 28.5.5 only for adaptor operations that are not described in subclause 28.5.3.5 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

6 Each template specified in this subclause 28.5.5 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

28.5.5.2 Class template discard_block_engine

1 A \( \text{discard\_block\_engine} \) random number engine adaptor produces random numbers selected from those produced by some base engine \( e \). The state \( x_i \) of a \( \text{discard\_block\_engine} \) engine adaptor object \( x \) consists of the state \( e_i \) of its base engine \( e \) and an additional integer \( n \). The size of the state is the size of \( e \)'s state plus 1.

2 The transition algorithm discards all but \( r > 0 \) values from each block of \( p \geq r \) values delivered by \( e \). The state transition is performed as follows: If \( n \geq r \), advance the state of \( e \) from \( e_i \) to \( e_{i+p-r} \) and set \( n \) to 0. In any case, then increment \( n \) and advance \( e \)'s then-current state \( e_j \) to \( e_{j+1} \).

3 The generation algorithm yields the value returned by the last invocation of \( e() \) while advancing \( e \)'s state as described above.

namespace std {
    template<class Engine, size_t p, size_t r>
    class discard_block_engine {
        public:
            // types
            using result_type = typename Engine::result_type;

            // engine characteristics
            static constexpr size_t block_size = p;
            static constexpr size_t used_block = r;
            static constexpr result_type min() { return Engine::min(); }
            static constexpr result_type max() { return Engine::max(); }

            // constructors and seeding functions
            discard_block_engine();
            explicit discard_block_engine(const Engine& e);
            explicit discard_block_engine(Engine&& e);
            explicit discard_block_engine(result_type s);
            template<class Sseq> explicit discard_block_engine(Sseq& q);
            void seed();
            void seed(result_type s);
            template<class Sseq> void seed(Sseq& q);

            // equality operators
            friend bool operator==(const discard_block_engine& x, const discard_block_engine& y);
    };
}
// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; }

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const discard_block_engine& x);

// exposition only
size_t n;

private:
Engine e;

4 The following relations shall hold: 0 < r and r <= p.
5 The textual representation consists of the textual representation of e followed by the value of n.
6 In addition to its behavior pursuant to subclause 28.5.3.5, each constructor that is not a copy constructor
sets n to 0.

28.5.5.3 Class template independent_bits_engine

An independent_bits_engine random number engine adaptor combines random numbers that are produced
by some base engine e, so as to produce random numbers with a specified number of bits w. The state x_i of
an independent_bits_engine engine adaptor object x consists of the state e_i of its base engine e; the size
of the state is the size of e’s state.

2 The transition and generation algorithms are described in terms of the following integral constants:

(2.1) — Let R = e.max() - e.min() + 1 and m = [log_2 R].
(2.2) — With n as determined below, let w_0 = [w/n], n_0 = n - w mod n, y_0 = 2^{w_0} \cdot R/2^{w_0}, and y_1 = 2^{w_0+1} \cdot R/2^{w_0+1}.
(2.3) — Let n = [w/m] if and only if the relation R - y_0 \leq [y_0/n] holds as a result. Otherwise let n = 1 + [w/m].

[Note 1: The relation w = n_0w_0 + (n - n_0)(w_0 + 1) always holds. — end note]

3 The transition algorithm is carried out by invoking e() as often as needed to obtain n_0 values less than
y_0 + e.min() and n - n_0 values less than y_1 + e.min().

4 The generation algorithm uses the values produced while advancing the state as described above to yield a
quantity S obtained as if by the following algorithm:

\[
S = 0;
\]
for (k = 0; k < n_0; k += 1) {
  \[
do u = e() - e.min(); \text{ while } (u \geq y_0);
  S = 2^{w_0} \cdot S + u \text{ mod } 2^{w_0};
  \]
}
for (k = n_0; k < n; k += 1) {
  \[
do u = e() - e.min(); \text{ while } (u \geq y_1);
  S = 2^{w_0+1} \cdot S + u \text{ mod } 2^{w_0+1};
  \]
}

template<class Engine, size_t w, class UIntType>
class independent_bits_engine {
public:
  // types
  using result_type = UIntType;

  // engine characteristics
  static constexpr result_type min() { return 0; }
}
static constexpr result_type max() { return 2^w - 1; }

// constructors and seeding functions
independent_bits_engine();
exlicit independent_bits_engine(const Engine& e);
exlicit independent_bits_engine(Engine&& e);
exlicit independent_bits_engine(result_type s);
template<class Sseq> explicit independent_bits_engine(Sseq& q);
void seed();
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);

// equality operators
friend bool operator==(const independent_bits_engine& x, const independent_bits_engine& y);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; }

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const independent_bits_engine& x);
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, independent_bits_engine& x);

private:
    Engine e; // exposition only
};

The following relations shall hold: 0 < w and w <= numeric_limits<result_type>::digits.
The textual representation consists of the textual representation of e.

28.5.5.4 Class template shuffle_order_engine

A shuffle_order_engine random number engine adaptor produces the same random numbers that are
produced by some base engine e, but delivers them in a different sequence. The state x of a
shuffle_order_engine engine adaptor object x consists of the state e, of its base engine e, an additional value Y
of the type delivered by e, and an additional sequence V of k values also of the type delivered by e. The size of
the state is the size of e’s state plus k + 1.

The transition algorithm permutes the values produced by e. The state transition is performed as follows:

(2.1)  — Calculate an integer \( j = \left\lfloor \frac{k(Y - e_{\text{min}})}{e_{\text{max}} - e_{\text{min}} + 1} \right\rfloor \).

(2.2)  — Set Y to \( V_j \) and then set \( V_j \) to e().

The generation algorithm yields the last value of Y produced while advancing e’s state as described above.

namespace std {
    template<class Engine, size_t k>
    class shuffle_order_engine {
    public:
    using result_type = typename Engine::result_type;

    // engine characteristics
    static constexpr size_t table_size = k;
    static constexpr result_type min() { return Engine::min(); }
    static constexpr result_type max() { return Engine::max(); }
}
// constructors and seeding functions
shuffle_order_engine();
explicit shuffle_order_engine(const Engine& e);
explicit shuffle_order_engine(Engine&& e);
explicit shuffle_order_engine(result_type s);
template<class Sseq> explicit shuffle_order_engine(Sseq& q);
void seed();
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);

// equality operators
friend bool operator==(const shuffle_order_engine& x, const shuffle_order_engine& y);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; }

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const shuffle_order_engine& x);
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, shuffle_order_engine& x);

private:
Engine e; // exposition only
result_type V[k]; // exposition only
result_type Y; // exposition only
};

The following relation shall hold: 0 < k.
The textual representation consists of the textual representation of e, followed by the k values of V, followed by the value of Y.
In addition to its behavior pursuant to subclause 28.5.3.5, each constructor that is not a copy constructor initializes V[0],...,V[k-1] and Y, in that order, with values returned by successive invocations of e().

28.5.6 Engines and engine adaptors with predefined parameters

using minstd_rand0 =
linear_congruential_engine<uint_fast32_t, 16'807, 0, 2'147'483'647>;

Required behavior: The 10000th consecutive invocation of a default-constructed object of type minstd_rand0 produces the value 1043618065.

using minstd_rand =
linear_congruential_engine<uint_fast32_t, 48'271, 0, 2'147'483'647>;

Required behavior: The 10000th consecutive invocation of a default-constructed object of type minstd_rand produces the value 399268537.

using mt19937 =
mersenne_twister_engine<uint_fast32_t, 32, 624, 397, 31,
0x9908'b0df, 11, 0xffff'ffff, 7, 0x9d2c'5680, 15, 0x806d'b1a2, 18, 1'812'433'253>;

Required behavior: The 10000th consecutive invocation of a default-constructed object of type mt19937 produces the value 4123659995.

using mt19937_64 =
mersenne_twister_engine<uint_fast64_t, 64, 312, 156, 31,
0xb502'6f5a'a966'19e8, 29, 0x5555'5555'5555'5555, 17,
4 Required behavior: The 10000\textsuperscript{th} consecutive invocation of a default-constructed object of type \texttt{mt19937-64} produces the value 9981545732273789042.

using \texttt{ranlux24\_base} =  
\begin{verbatim}
subtract\_with\_carry\_engine<\texttt{uint\_fast32\_t}, 24, 10, 24>;
\end{verbatim}
5 Required behavior: The 10000\textsuperscript{th} consecutive invocation of a default-constructed object of type \texttt{ranlux24\_base} produces the value 7937952.

using \texttt{ranlux48\_base} =  
\begin{verbatim}
subtract\_with\_carry\_engine<\texttt{uint\_fast64\_t}, 48, 5, 12>;
\end{verbatim}
6 Required behavior: The 10000\textsuperscript{th} consecutive invocation of a default-constructed object of type \texttt{ranlux48\_base} produces the value 61839128582725.

using \texttt{ranlux24} = \texttt{discard\_block\_engine<ranlux24\_base}, 223, 23>;
7 Required behavior: The 10000\textsuperscript{th} consecutive invocation of a default-constructed object of type \texttt{ranlux24} produces the value 9901578.

using \texttt{ranlux48} = \texttt{discard\_block\_engine<ranlux48\_base}, 389, 11>;
8 Required behavior: The 10000\textsuperscript{th} consecutive invocation of a default-constructed object of type \texttt{ranlux48} produces the value 249142670248501.

using \texttt{knuth\_b} = \texttt{shuffle\_order\_engine<minstd\_rand0, 256>};
9 Required behavior: The 10000\textsuperscript{th} consecutive invocation of a default-constructed object of type \texttt{knuth\_b} produces the value 1112339016.

using \texttt{default\_random\_engine} = \texttt{implementation\_defined};

Remarks: The choice of engine type named by this \texttt{typedef} is implementation-defined.

[Note 1: The implementation can select this type on the basis of performance, size, quality, or any combination of such factors, so as to provide at least acceptable engine behavior for relatively casual, inexpert, and/or lightweight use. Because different implementations can select different underlying engine types, code that uses this \texttt{typedef} need not generate identical sequences across implementations. — end note]

28.5.7 Class \texttt{random\_device}  \([\texttt{rand.device}]\)

1 A \texttt{random\_device} uniform random bit generator produces nondeterministic random numbers.

2 If implementation limitations prevent generating nondeterministic random numbers, the implementation may employ a random number engine.

```cpp
namespace std {
    class random_device {
        public:
            // types
            using result_type = unsigned int;

            // generator characteristics
            static constexpr result_type min() { return numeric_limits<result_type>::min(); }
            static constexpr result_type max() { return numeric_limits<result_type>::max(); }

            // constructors
            random_device() : random_device(implementation-defined) {}
            explicit random_device(const string& token);

            // generating functions
            result_type operator()();

            // property functions
            double entropy() const noexcept;

            // no copy functions
            random_device(const random_device&) = delete;
    }
}
```

\[28.5.7\]
void operator=(const random_device&) = delete;

explicit random_device(const string& token);

Throws: A value of an implementation-defined type derived from exception if the random_device cannot be initialized.

Remarks: The semantics of the token parameter and the token value used by the default constructor are implementation-defined.\(^{229}\)

double entropy() const noexcept;

Returns: If the implementation employs a random number engine, returns 0.0. Otherwise, returns an entropy estimate\(^{230}\) for the random numbers returned by operator(), in the range min() to log\(_2\)(max() + 1).

result_type operator()();

Returns: A nondeterministic random value, uniformly distributed between min() and max() (inclusive). It is implementation-defined how these values are generated.

Throws: A value of an implementation-defined type derived from exception if a random number cannot be obtained.

28.5.8 Utilities \([\text{rand.util}]\)

28.5.8.1 Class seed_seq \([\text{rand.util.seedseq}]\)

namespace std {
  class seed_seq {
    public:
      // types
      using result_type = uint_least32_t;

      // constructors
      seed_seq() noexcept;
      template<class T>
        seed_seq(initializer_list<T> il);
      template<class InputIterator>
        seed_seq(InputIterator begin, InputIterator end);

      // generating functions
      template<class RandomAccessIterator>
        void generate(RandomAccessIterator begin, RandomAccessIterator end);

      // property functions
      size_t size() const noexcept;
      template<class OutputIterator>
        void param(OutputIterator dest) const;

      // no copy functions
      seed_seq(const seed_seq&) = delete;
      void operator=(const seed_seq&) = delete;

    private:
      vector<result_type> v;     // exposition only
    }
  }

seed_seq() noexcept;

Postconditions: v.empty() is true.

\(^{229}\) The parameter is intended to allow an implementation to differentiate between different sources of randomness.

\(^{230}\) If a device has \(n\) states whose respective probabilities are \(P_0, \ldots, P_{n-1}\), the device entropy \(S\) is defined as

\[
S = -\sum_{i=0}^{n-1} P_i \cdot \log P_i.
\]
template<class T>
seed_seq(initializer_list<T> il);

Constraints: T is an integer type.
Effects: Same as seed_seq(il.begin(), il.end()).

template<class InputIterator>
seed_seq(InputIterator begin, InputIterator end);

Mandates: iterator_traits<InputIterator>::value_type is an integer type.
Preconditions: InputIterator meets the Cpp17InputIterator requirements (25.3.5.3).
Effects: Initializes v by the following algorithm:
for (InputIterator s = begin; s != end; ++s)
v.push_back((*s) % 32);

template<class RandomAccessIterator>
void generate(RandomAccessIterator begin, RandomAccessIterator end);

Mandates: iterator_traits<RandomAccessIterator>::value_type is an unsigned integer type capable of accommodating 32-bit quantities.
Preconditions: RandomAccessIterator meets the Cpp17RandomAccessIterator requirements (25.3.5.7) and the requirements of a mutable iterator.
Effects: Does nothing if begin == end. Otherwise, with s = v.size() and n = end - begin, fills the supplied range [begin, end) according to the following algorithm in which each operation is to be carried out modulo $2^{32}$, each indexing operator applied to begin is to be taken modulo n, and $T(x)$ is defined as $x\oplus(x\gg 27)$:

1. By way of initialization, set each element of the range to the value $0x8b8b8b8b$. Additionally, for use in subsequent steps, let $p = (n - t)/2$ and let $q = p + t$, where

   $t = (n \geq 623) \oplus 11 : (n \geq 68) \oplus 7 : (n \geq 39) \oplus 5 : (n \geq 7) \oplus 3 : (n - 1)/2$;

2. With m as the larger of s + 1 and n, transform the elements of the range: iteratively for $k = 0, \ldots, m - 1$, calculate values:

   \[
   \begin{align*}
   r_1 &= 1664525 \cdot T(begin[k] \oplus begin[k + p] \oplus begin[k - 1]) \\
   r_2 &= r_1 + \begin{cases}
   s & , k = 0 \\
   k \mod n + v[k - 1] & , 0 < k \leq s \\
   k \mod n & , s < k
   \end{cases}
   \end{align*}
   \]

   and, in order, increment begin[k + p] by $r_1$, increment begin[k + q] by $r_2$, and set begin[k] to $r_2$.

3. Transform the elements of the range again, beginning where the previous step ended: iteratively for $k = m, \ldots, m + n - 1$, calculate values:

   \[
   \begin{align*}
   r_3 &= 1566083941 \cdot T(begin[k] + begin[k + p] + begin[k - 1]) \\
   r_4 &= r_3 - (k \mod n)
   \end{align*}
   \]

   and, in order, update begin[k + p] by xoring it with $r_3$, update begin[k + q] by xoring it with $r_4$, and set begin[k] to $r_4$.

Throws: What and when RandomAccessIterator operations of begin and end throw.

size_t size() const noexcept;

Returns: The number of 32-bit units that would be returned by a call to param().
Complexity: Constant time.

template<class OutputIterator>
void param(OutputIterator dest) const;

Mandates: Values of type result_type are writable (25.3.1) to dest.
Preconditions: OutputIterator meets the Cpp17OutputIterator requirements (25.3.5.4).
Effects: Copies the sequence of prepared 32-bit units to the given destination, as if by executing the following statement:

```cpp
    copy(v.begin(), v.end(), dest);
```

Throws: What and when `OutputIterator` operations of `dest` throw.

28.5.8.2 Function template `generate_canonical`  

```cpp
template<class RealType, size_t bits, class URBG>
RealType generate_canonical(URBG& g);
```

Effects: Invokes `g()` `k` times to obtain values `g_0, .., g_{k-1}` respectively. Calculates a quantity

\[
S = \sum_{i=0}^{k-1} (g_i - g.\min()) \cdot R^i
\]

using arithmetic of type `RealType`.

Returns: `S/R^k`.

[Note 1: `0 \leq S/R^k < 1`. — end note]

Throws: What and when `g` throws.

Complexity: Exactly `k = \max(1, \lceil b/\log_2 R \rceil)` invocations of `g`, where `b \leq 2^{31}` is the lesser of `numeric_limits<RealType>::digits` and `bits`, and `R` is the value of `g.\max() - g.\min() + 1`.

[Note 2: If the values `g_i` produced by `g` are uniformly distributed, the instantiation’s results are distributed as uniformly as possible. Obtaining a value in this way can be a useful step in the process of transforming a value generated by a uniform random bit generator into a value that can be delivered by a random number distribution. — end note]

28.5.9 Random number distribution class templates

28.5.9.1 In general

Each type instantiated from a class template specified in this subclause 28.5.9 meets the requirements of a random number distribution (28.5.3.6) type.

Descriptions are provided in this subclause 28.5.9 only for distribution operations that are not described in 28.5.3.6 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

The algorithms for producing each of the specified distributions are implementation-defined.

The value of each probability density function `p(z)` and of each discrete probability function `P(z_i)` specified in this subclause is 0 everywhere outside its stated domain.

28.5.9.2 Uniform distributions

28.5.9.2.1 Class template `uniform_int_distribution`

A `uniform_int_distribution` random number distribution produces random integers `i`, `a \leq i \leq b`, distributed according to the constant discrete probability function

\[
P(i \mid a, b) = 1/(b - a + 1)
\]

namespace std {
    
    template<class IntType = int>
    class uniform_int_distribution {
    public:
        // types
        using result_type = IntType;
        using param_type = unspecified;
    }  

§ 28.5.9.2.1
// constructors and reset functions
uniform_int_distribution() : uniform_int_distribution(0) {}  
explicit uniform_int_distribution(IntType a, IntType b = numeric_limits<IntType>::max()); 
explicit uniform_int_distribution(const param_type& parm); 
void reset();

// equality operators
friend bool operator==(const uniform_int_distribution& x, const uniform_int_distribution& y);

// generating functions
template<class URBG>
result_type operator()(URBG& g);

// property functions
result_type a() const;
result_type b() const;

// inserters and extractors

explicit uniform_int_distribution(IntType a, IntType b = numeric_limits<IntType>::max());

2 Preconditions: a ≤ b.
3 Remarks: a and b correspond to the respective parameters of the distribution.

result_type a() const;
4 Returns: The value of the a parameter with which the object was constructed.

result_type b() const;
5 Returns: The value of the b parameter with which the object was constructed.

28.5.9.2.2 Class template uniform_real_distribution [rand.dist.uni.real]
1 A uniform_real_distribution random number distribution produces random numbers \(x, a ≤ x < b\), distributed according to the constant probability density function

\[ p(x | a, b) = \frac{1}{b - a} . \]

[Note 1: This implies that \(p(x | a, b)\) is undefined when \(a == b\). — end note]
namespace std {
    class bernoulli_distribution {
    public:
        // types
        using result_type = bool;
        using param_type = unspecified;

        // constructors and reset functions
        bernoulli_distribution() : bernoulli_distribution(0.5) {}
        explicit bernoulli_distribution(double p);
        explicit bernoulli_distribution(const param_type& parm);
        void reset();
    }
}

A bernoulli_distribution random number distribution produces bool values b distributed according to the discrete probability function

\[ P(b|p) = \begin{cases} 
    p & \text{if } b = \text{true}, \text{ or} \\
    1 - p & \text{if } b = \text{false}. 
\end{cases} \]

28.5.9.3 Bernoulli distributions

28.5.9.3.1 Class bernoulli_distribution

A bernoulli_distribution random number distribution produces bool values b distributed according to the discrete probability function

\[ P(b|p) = \begin{cases} 
    p & \text{if } b = \text{true}, \text{ or} \\
    1 - p & \text{if } b = \text{false}. 
\end{cases} \]
explicit bernoulli_distribution(double p);

Preconditions: 0 ≤ p ≤ 1.
Remarks: p corresponds to the parameter of the distribution.

double p() const;
Returns: The value of the p parameter with which the object was constructed.

28.5.9.3.2 Class template binomial_distribution

A binomial_distribution random number distribution produces integer values \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i | t, p) = \binom{t}{i} \cdot p^i \cdot (1 - p)^{t-i}.
\]

namespace std {
    template<class IntType = int>
    class binomial_distribution {
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructors and reset functions
    binomial_distribution() : binomial_distribution(t) {}  
    explicit binomial_distribution(IntType t, double p = 0.5);  
    explicit binomial_distribution(const param_type& parm);  
    void reset();

    // equality operators
    friend bool operator==(const binomial_distribution& x, const binomial_distribution& y);

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);
};

§ 28.5.9.3.2 1429
// property functions
IntType t() const;
double p() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const binomial_distribution& x);
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, binomial_distribution& x);

explicit binomial_distribution(IntType t, double p = 0.5);

2 Preconditions: $0 \leq p \leq 1$ and $0 \leq t$.
3 Remarks: $t$ and $p$ correspond to the respective parameters of the distribution.

IntType t() const;
4 Returns: The value of the $t$ parameter with which the object was constructed.

double p() const;
5 Returns: The value of the $p$ parameter with which the object was constructed.

28.5.9.3.3 Class template geometric_distribution
A geometric_distribution random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function

$$P(i | p) = p \cdot (1 - p)^i.$$
// inserters and extractors

template<class charT, class traits>
friend basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const geometric_distribution& x);

template<class charT, class traits>
friend basic_istream<charT, traits>&
    operator>>(basic_istream<charT, traits>& is, geometric_distribution& x);

explicit geometric_distribution(double p);

Preconditions: 0 < p < 1.

Remarks: p corresponds to the parameter of the distribution.

double p() const;

Returns: The value of the p parameter with which the object was constructed.

28.5.9.3.4 Class template negative_binomial_distribution [rand.dist.bern.negbin]

A negative_binomial_distribution random number distribution produces random integers \(i \geq 0\) distributed according to the discrete probability function

\[
P(i | k, p) = \frac{(k + i - 1)}{i} \cdot p^k \cdot (1 - p)^i.\]

[Note 1: This implies that \(P(i | k, p)\) is undefined when \(p == 1\). —end note]

namespace std {

template<class IntType = int>
    class negative_binomial_distribution {
        public:
            // types
            using result_type = IntType;
            using param_type = unspecified;

            // constructor and reset functions
            negative_binomial_distribution() : negative_binomial_distribution(1) {};
            explicit negative_binomial_distribution(IntType k, double p = 0.5);
            explicit negative_binomial_distribution(const param_type& parm);
            void reset();

            // equality operators
            friend bool operator==(const negative_binomial_distribution& x,
                const negative_binomial_distribution& y);

            // generating functions
            template<class URBG>
                result_type operator()(URBG& g);
            template<class URBG>
                result_type operator()(URBG& g, const param_type& parm);

            // property functions
            IntType k() const;
            double p() const;
            param_type param() const;
            void param(const param_type& parm);
            result_type min() const;
            result_type max() const;

            // inserters and extractors
            template<class charT, class traits>
                friend basic_ostream<charT, traits>&
                    operator<<(basic_ostream<charT, traits>& os, const negative_binomial_distribution& x);

    };

};
explicit negative_binomial_distribution(IntType k, double p = 0.5);

Preconditions: $0 < p \leq 1$ and $0 < k$.

Remarks: $k$ and $p$ correspond to the respective parameters of the distribution.

IntType k() const;

Returns: The value of the $k$ parameter with which the object was constructed.

double p() const;

Returns: The value of the $p$ parameter with which the object was constructed.

28.5.9.4 Poisson distributions

28.5.9.4.1 Class template poisson_distribution

A poisson_distribution random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function

$$P(i|\mu) = \frac{e^{-\mu} \mu^i}{i!}.$$ 

The distribution parameter $\mu$ is also known as this distribution’s mean.

template<class IntType = int>
class poisson_distribution
{
    public:
        // types
        using result_type = IntType;
        using param_type = unspecified;

        // constructors and reset functions
        poisson_distribution() : poisson_distribution(1.0) {}  
        explicit poisson_distribution(double mean);  
        explicit poisson_distribution(const param_type& parm);  
        void reset();

        // equality operators
        friend bool operator==(const poisson_distribution& x, const poisson_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        double mean() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>& os, const poisson_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
            operator>>(basic_istream<charT, traits>& is, poisson_distribution& x);
explicit poisson_distribution(double mean);

Preconditions: 0 < mean.
Remarks: mean corresponds to the parameter of the distribution.

double mean() const;
Returns: The value of the mean parameter with which the object was constructed.

28.5.9.4.2 Class template exponential_distribution [rand.dist.pois.exp]

An exponential_distribution random number distribution produces random numbers x > 0 distributed according to the probability density function

\[ p(x | \lambda) = \lambda e^{-\lambda x} \]

namespace std {

template<class RealType = double>
class exponential_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructors and reset functions
    exponential_distribution() : exponential_distribution(1.0) {}
    explicit exponential_distribution(RealType lambda);
    explicit exponential_distribution(const param_type& parm);
    void reset();

    // equality operators
    friend bool operator==(const exponential_distribution& x, const exponential_distribution& y);

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType lambda() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;

    // inserters and extractors
    template<class charT, class traits>
    friend basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const exponential_distribution& x);
    template<class charT, class traits>
    friend basic_istream<charT, traits>&
    operator>>(basic_istream<charT, traits>& is, exponential_distribution& x);
};

explicit exponential_distribution(RealType lambda);

Preconditions: 0 < lambda.
Remarks: lambda corresponds to the parameter of the distribution.

RealType lambda() const;
Returns: The value of the lambda parameter with which the object was constructed.
A \texttt{gamma\_distribution} random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x | \alpha, \beta) = \frac{e^{-x/\beta}}{\beta^\alpha \Gamma(\alpha)} \cdot x^{\alpha-1}.
\]

namespace std {
    template<class RealType = double>
    class gamma\_distribution {
    public:
        // types
        using result\_type = RealType;
        using param\_type = unspecified;
        // constructors and reset functions
        gamma\_distribution() : gamma\_distribution(1.0) {}
        explicit gamma\_distribution(RealType alpha, RealType beta = 1.0);
        explicit gamma\_distribution(const param\_type& parm);
        void reset();
        // equality operators
        friend bool operator==(const gamma\_distribution& x, const gamma\_distribution& y);
        // generating functions
        template<class URBG>
        result\_type operator()(URBG& g);
        template<class URBG>
        result\_type operator()(URBG& g, const param\_type& parm);
        // property functions
        RealType alpha() const;
        RealType beta() const;
        param\_type param() const;
        void param(const param\_type& parm);
        result\_type min() const;
        result\_type max() const;
        // inserters and extractors
        template<class charT, class traits>
        friend basic\_ostream\<charT, traits\>& operator<<\(\langle\langle\)basic\_ostream\<charT, traits\>& os, const gamma\_distribution& x);
        template<class charT, class traits>
        friend basic\_istream\<charT, traits\>& operator>>\(\rangle\rangle\)\(\langle\langle\)basic\_istream\<charT, traits\>& is, gamma\_distribution& x);
    };

    explicit gamma\_distribution(RealType alpha, RealType beta = 1.0);
}

\textbf{Preconditions:} 0 < \alpha and 0 < \beta.

\textbf{Remarks:} \alpha and \beta correspond to the parameters of the distribution.

RealType alpha() const;

\textbf{Returns:} The value of the \(\alpha\) parameter with which the object was constructed.

RealType beta() const;

\textbf{Returns:} The value of the \(\beta\) parameter with which the object was constructed.
A `weibull_distribution` random number distribution produces random numbers \( x \geq 0 \) distributed according to the probability density function

\[
p(x \mid a, b) = \frac{a}{b} \cdot \left(\frac{x}{b}\right)^{a-1} \cdot \exp\left(-\left(\frac{x}{b}\right)^a\right).
\]

```cpp
namespace std {
    template<class RealType = double>
    class weibull_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        weibull_distribution() : weibull_distribution(1.0) {}
        explicit weibull_distribution(RealType a, RealType b = 1.0);
        explicit weibull_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const weibull_distribution& x, const weibull_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType a() const;
        RealType b() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const weibull_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, weibull_distribution& x);
    }
}
```

**Preconditions:** \( 0 < a \) and \( 0 < b \).

**Remarks:** \( a \) and \( b \) correspond to the respective parameters of the distribution.

**Returns:** The value of the \( a \) parameter with which the object was constructed.

**Returns:** The value of the \( b \) parameter with which the object was constructed.
28.5.9.4.5 Class template extreme_value_distribution

An `extreme_value_distribution` random number distribution produces random numbers \( x \) distributed according to the probability density function\(^{232}\)

\[
p(x \mid a, b) = \frac{1}{b} \exp \left( \frac{a - x}{b} - \exp \left( \frac{a - x}{b} \right) \right).
\]

```cpp
namespace std {
    template<class RealType = double>
    class extreme_value_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        extreme_value_distribution() : extreme_value_distribution(0.0) {}
        explicit extreme_value_distribution(RealType a, RealType b = 1.0);
        explicit extreme_value_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const extreme_value_distribution& x, const extreme_value_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType a() const;
        RealType b() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const extreme_value_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, extreme_value_distribution& x);
    };
}
```

\(^{232}\) The distribution corresponding to this probability density function is also known (with a possible change of variable) as the Gumbel Type I, the log-Weibull, or the Fisher-Tippett Type I distribution.

---

2

Preconditions: \( 0 < b \).

3

Remarks: \( a \) and \( b \) correspond to the respective parameters of the distribution.

RealType a() const;

4

Returns: The value of the \( a \) parameter with which the object was constructed.

RealType b() const;

5

Returns: The value of the \( b \) parameter with which the object was constructed.
28.5.9.5 Normal distributions

28.5.9.5.1 Class template normal_distribution

A normal_distribution random number distribution produces random numbers $x$ distributed according to the probability density function

$$p(x | \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right).$$

The distribution parameters $\mu$ and $\sigma$ are also known as this distribution’s mean and standard deviation.

```cpp
namespace std {
  template<class RealType = double>
  class normal_distribution {
  public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructors and reset functions
    normal_distribution() : normal_distribution(0.0) {} // 
    explicit normal_distribution(RealType mean, RealType stddev = 1.0);
    explicit normal_distribution(const param_type& parm);
    void reset();

    // equality operators
    friend bool operator==(const normal_distribution& x, const normal_distribution& y);

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType mean() const;
    RealType stddev() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;

    // inserters and extractors
    template<class charT, class traits>
    friend basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const normal_distribution& x);
    template<class charT, class traits>
    friend basic_istream<charT, traits>&
    operator>>(basic_istream<charT, traits>& is, normal_distribution& x);
  }
}
```

explicit normal_distribution(RealType mean, RealType stddev = 1.0):

Preconditions: $0 < \text{stddev}$.

Remarks: mean and stddev correspond to the respective parameters of the distribution.

RealType mean() const;

Returns: The value of the mean parameter with which the object was constructed.

RealType stddev() const;

Returns: The value of the stddev parameter with which the object was constructed.
28.5.9.5.2 Class template lognormal_distribution  

A `lognormal_distribution` random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x | m, s) = \frac{1}{sx\sqrt{2\pi}} \cdot \exp\left( -\frac{(\ln x - m)^2}{2s^2} \right).
\]

namespace std {
    template<class RealType = double>
    class lognormal_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        lognormal_distribution() : lognormal_distribution(0.0) {}       
        explicit lognormal_distribution(RealType m, RealType s = 1.0);  
        explicit lognormal_distribution(const param_type& parm);      
        void reset();                                                  

        // equality operators
        friend bool operator==(const lognormal_distribution& x, const lognormal_distribution& y); 

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);                      
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm); 

        // property functions
        RealType m() const;  
        RealType s() const;  
        param_type param() const;                            
        void param(const param_type& parm);                 
        result_type min() const;                            
        result_type max() const;                            

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>& 
            operator<<<(basic_ostream<charT, traits>& os, const lognormal_distribution& x); 
        template<class charT, class traits>
        friend basic_istream<charT, traits>& 
            operator>>(basic_istream<charT, traits>& is, lognormal_distribution& x); 
    }

    explicit lognormal_distribution(RealType m, RealType s = 1.0); 

    // Preconditions: 0 < s. 
    // Remarks: m and s correspond to the respective parameters of the distribution. 
    RealType m() const;  
    Returns: The value of the m parameter with which the object was constructed. 
    RealType s() const;  
    Returns: The value of the s parameter with which the object was constructed. 
}
28.5.9.5.3 Class template chisq

A chisq random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x | \nu) = \frac{x^{(\nu/2)-1} e^{-x/2}}{\Gamma(\nu/2) 2^{\nu/2}}.
\]

namespace std {
    template<class RealType = double>
    class chisq {
        public:
            // types
            using result_type = RealType;
            using param_type = unspecified;

            // constructor and reset functions
            chisq() : chisq(1.0) {}  // default constructor
            explicit chisq(RealType n);  // constructor
            explicit chisq(const param_type& parm);
            void reset();

            // equality operators
            friend bool operator==(const chisq& x, const chisq& y);

            // generating functions
            template<class URBG>
            result_type operator()(URBG& g);
            template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

            // property functions
            RealType n() const;
            param_type param() const;
            void param(const param_type& parm);
            result_type min() const;
            result_type max() const;

            // inserters and extractors
            template<class charT, class traits>
            friend basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& os, const chisq& x);
            template<class charT, class traits>
            friend basic_istream<charT, traits>&
                operator>>(basic_istream<charT, traits>& is, chisq& x);
    };
}

explicit chisq(RealType n);

Preconditions: 0 < \( \nu \).
Remarks: \( \nu \) corresponds to the parameter of the distribution.

2

RealType n() const;

Returns: The value of the \( \nu \) parameter with which the object was constructed.

28.5.9.5.4 Class template cauchy

A cauchy random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x | a, b) = \left( \pi b \left( 1 + \left( \frac{x - a}{b} \right)^2 \right)^{-1} \right).
\]

§ 28.5.9.5.4
namespace std {
  template<class RealType = double>
  class cauchy_distribution {
    public:
    // types
    using result_type = RealType;
    using param_type = unspecified;
    // constructor and reset functions
    cauchy_distribution() : cauchy_distribution(0.0) {} explicit cauchy_distribution(RealType a, RealType b = 1.0);
    explicit cauchy_distribution(const param_type& parm);
    void reset();
    // equality operators
    friend bool operator==(const cauchy_distribution& x, const cauchy_distribution& y);
    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);
    // property functions
    RealType a() const;
    RealType b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
    // inserters and extractors
    template<class charT, class traits>
    friend basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const cauchy_distribution& x);
    template<class charT, class traits>
    friend basic_istream<charT, traits>&
    operator>>(basic_istream<charT, traits>& is, cauchy_distribution& x);
  }

explicit cauchy_distribution(RealType a, RealType b = 1.0);

# Preconditions: 0 < b.
# Remarks: a and b correspond to the respective parameters of the distribution.

RealType a() const;
# Returns: The value of the a parameter with which the object was constructed.

RealType b() const;
# Returns: The value of the b parameter with which the object was constructed.

## 28.5.9.5.5 Class template fisher_f_distribution

A fisher_f_distribution random number distribution produces random numbers \( x \geq 0 \) distributed according to the probability density function

\[
p(x | m, n) = \frac{\Gamma((m + n)/2)}{\Gamma(m/2) \Gamma(n/2)} \cdot \left(\frac{m}{n}\right)^{m/2} \cdot x^{(m/2)-1} \cdot \left(1 + \frac{m x}{n}\right)^{-(m+n)/2}.
\]
namespace std {
    template<class RealType = double>
    class fisher_f_distribution {
        public:
            // types
            using result_type = RealType;
            using param_type = unspecified;

            // constructor and reset functions
            fisher_f_distribution() : fisher_f_distribution(1.0) {};
            explicit fisher_f_distribution(RealType m, RealType n = 1.0);
            explicit fisher_f_distribution(const param_type& parm);
            void reset();

            // equality operators
            friend bool operator==(const fisher_f_distribution& x, const fisher_f_distribution& y);

            // generating functions
            template<class URBG>
            result_type operator()(URBG& g);
            template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

            // property functions
            RealType m() const;
            RealType n() const;
            param_type param() const;
            void param(const param_type& parm);
            result_type min() const;
            result_type max() const;

            // inserters and extractors
            template<class charT, class traits>
            friend basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>& os, const fisher_f_distribution& x);
            template<class charT, class traits>
            friend basic_istream<charT, traits>&
            operator>>(basic_istream<charT, traits>& is, fisher_f_distribution& x);
    }

    explicit fisher_f_distribution(RealType m, RealType n = 1);

    Preconditions: 0 < m and 0 < n.
    Remarks: m and n correspond to the respective parameters of the distribution.

    RealType m() const;

    Returns: The value of the m parameter with which the object was constructed.

    RealType n() const;

    Returns: The value of the n parameter with which the object was constructed.

28.5.9.5.6 Class template student_t_distribution [rand.dist.norm.t]

A student_t_distribution random number distribution produces random numbers x distributed according to the probability density function

\[ p(x \mid n) = \frac{1}{\sqrt{n \pi}} \cdot \frac{\Gamma((n + 1)/2)}{\Gamma(n/2)} \cdot \left(1 + \frac{x^2}{n}\right)^{-(n+1)/2}. \]
namespace std {
    template<class RealType = double>
    class student_t_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        student_t_distribution() : student_t_distribution(1.0) {};
        explicit student_t_distribution(RealType n);
        explicit student_t_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const student_t_distribution& x, const student_t_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType n() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
        friend basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const student_t_distribution& x);
        template<class charT, class traits>
        friend basic_istream<charT, traits>&
        operator>>(basic_istream<charT, traits>& is, student_t_distribution& x);
    };

explicit student_t_distribution(RealType n);

Preconditions: \(0 < n\).

Remarks: \(n\) corresponds to the parameter of the distribution.

RealType n() const;

Returns: The value of the \(n\) parameter with which the object was constructed.

28.5.9.6 Sampling distributions \[rand.dist.samp\]

28.5.9.6.1 Class template discrete_distribution \[rand.dist.samp.discrete\]

A discrete_distribution random number distribution produces random integers \(i, 0 \leq i < n\), distributed according to the discrete probability function

\[P(i | p_0, \ldots, p_{n-1}) = p_i.\]

2 Unless specified otherwise, the distribution parameters are calculated as: \(p_k = w_k / S\) for \(k = 0, \ldots, n-1\), in which the values \(w_k\), commonly known as the weights, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: \(0 < S = w_0 + \cdots + w_{n-1}\).
using result_type = IntType;
using param_type = unspecified;

discrete_distribution();
template<class InputIterator>
discrete_distribution(InputIterator firstW, InputIterator lastW);
discrete_distribution(initializer_list<double> wl);
template<class UnaryOperation>
discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);
explicit discrete_distribution(const param_type& parm);
void reset();

friend bool operator==(const discrete_distribution& x, const discrete_distribution& y);

template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

vector<double> probabilities() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const discrete_distribution& x);
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, discrete_distribution& x);

Effects: Constructs a discrete_distribution object with $n = 1$ and $p_0 = 1$.

[Note 1: Such an object will always deliver the value 0. —end note]
Effects: Constructs a `discrete_distribution` object with probabilities given by the formula above, using the following values: If $nw = 0$, let $w_0 = 1$. Otherwise, let $w_k = fw(x_{\min} + k \cdot \delta + \delta/2)$ for $k = 0, \ldots, n - 1$.

Complexity: The number of invocations of $fw$ does not exceed $n$.

```
vector<double> probabilities() const;
```

Returns: A `vector<double>` whose size member returns $n$ and whose operator[] member returns $p_k$ when invoked with argument $k$ for $k = 0, \ldots, n - 1$.

### 28.5.9.6.2 Class template `piecewise_constant_distribution`  

A `piecewise_constant_distribution` random number distribution produces random numbers $x$, $b_0 \leq x < b_n$, uniformly distributed over each subinterval $[b_i, b_{i+1})$ according to the probability density function

$$
p(x \mid b_0, \ldots, b_n, \rho_0, \ldots, \rho_{n-1}) = \rho_i, \text{ for } b_i \leq x < b_{i+1}.
$$

The $n + 1$ distribution parameters $b_i$, also known as this distribution’s interval boundaries, shall satisfy the relation $b_i < b_{i+1}$ for $i = 0, \ldots, n - 1$. Unless specified otherwise, the remaining $n$ distribution parameters are calculated as:

$$
\rho_k = \frac{w_k \cdot S \cdot (b_{k+1} - b_k)}{S} \quad \text{for } k = 0, \ldots, n - 1,
$$

in which the values $w_k$, commonly known as the weights, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: $0 < S = w_0 + \cdots + w_{n-1}$.

```cpp
namespace std {
    template<class RealType = double>
    class piecewise_constant_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        piecewise_constant_distribution();
        template<class InputIteratorB, class InputIteratorW>
        piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                        InputIteratorW firstW);
        template<class UnaryOperation>
        piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);
        template<class UnaryOperation>
        piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax,
                                        UnaryOperation fw);
        explicit piecewise_constant_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const piecewise_constant_distribution& x,
                               const piecewise_constant_distribution& y);

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        vector<result_type> intervals() const;
        vector<result_type> densities() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;
    }
}
```
// inserters and extractors
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_istream<charT, traits>& is, const piecewise_constant_distribution& x);

template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, piecewise_constant_distribution& x);

piecewise_constant_distribution();

Effects: Constructs a piecewise_constant_distribution object with n = 1, \( \rho_0 = 1, b_0 = 0 \), and \( b_1 = 1 \).

template<class InputIteratorB, class InputIteratorW>
piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
InputIteratorW firstW);

Mandates: Both of

\[\text{(4.1)}\] --- is_convertible_v<iterator_traits<InputIteratorB>::value_type, double>

\[\text{(4.2)}\] --- is_convertible_v<iterator_traits<InputIteratorW>::value_type, double>

are true.

Preconditions: InputIteratorB and InputIteratorW each meet the Cpp17InputIterator requirements (25.3.5.3). If firstB == lastB or ++firstB == lastB, let \( n = 1, w_0 = 1, b_0 = 0 \), and \( b_1 = 1 \). Otherwise, \([\text{firstB, lastB}]\) forms a sequence \( b \) of length \( n + 1 \), the length of the sequence \( w \) starting from firstW is at least \( n \), and any \( w_k \) for \( k \geq n \) are ignored by the distribution.

Effects: Constructs a piecewise_constant_distribution object with parameters as specified above.

template<class UnaryOperation>
piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);

Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true. 

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: If bl.size() < 2, let \( n = 1, w_0 = 1, b_0 = 0 \), and \( b_1 = 1 \). Otherwise, let \([\text{bl.begin()}, \text{bl.end()}]\) form a sequence \( b_0, \ldots, b_n \), and let \( w_k = \text{fw}((b_{k+1} + b_k)/2) \) for \( k = 0, \ldots, n-1 \).

Complexity: The number of invocations of \( \text{fw} \) does not exceed \( n \).

template<class UnaryOperation>
piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

Mandates: is_invocable_r_v<double, UnaryOperation&, double> is true.

Preconditions: If \( nw = 0 \), let \( n = 1 \), otherwise let \( n = nw \). The relation \( 0 < \delta = (xmax - xmin)/n \) holds.

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: Let \( b_k = xmin + k \cdot \delta \) for \( k = 0, \ldots, n \), and \( w_k = \text{fw}(b_k + \delta/2) \) for \( k = 0, \ldots, n-1 \).

Complexity: The number of invocations of \( \text{fw} \) does not exceed \( n \).

vector<result_type> intervals() const;

Returns: A vector<result_type> whose size member returns \( n + 1 \) and whose operator[] member returns \( b_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n \).

vector<result_type> densities() const;

Returns: A vector<result_type> whose size member returns \( n \) and whose operator[] member returns \( \rho_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n-1 \).

28.5.9.6.3 Class template piecewise_linear_distribution [rand.dist.samp.plinear]

A piecewise_linear_distribution random number distribution produces random numbers \( x, b_0 \leq x < b_n \), distributed over each subinterval \([b_k, b_{k+1}]\) according to the probability density function

\[ p(x \mid b_0, \ldots, b_n, \rho_0, \ldots, \rho_n) = \rho_i \cdot \frac{b_{k+1} - x}{b_{k+1} - b_i} + \rho_{i+1} \cdot \frac{x - b_i}{b_{i+1} - b_i}, \text{ for } b_i \leq x < b_{i+1}. \]
The \( n + 1 \) distribution parameters \( b_i \), also known as this distribution’s interval boundaries, shall satisfy the relation \( b_i < b_{i+1} \) for \( i = 0, \ldots, n - 1 \). Unless specified otherwise, the remaining \( n + 1 \) distribution parameters are calculated as \( \rho_k = w_k/S \) for \( k = 0, \ldots, n \), in which the values \( w_k \), commonly known as the weights at boundaries, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold:

\[
0 < S = \frac{1}{2} \sum_{k=0}^{n-1} (w_k + w_{k+1}) \cdot (b_{k+1} - b_k).
\]

```cpp
namespace std {
    template<class RealType = double>
    class piecewise_linear_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        piecewise_linear_distribution();
        template<class InputIteratorB, class InputIteratorW>
            piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                            InputIteratorW firstW);
        template<class UnaryOperation>
            piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);
        template<class UnaryOperation>
            piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
        explicit piecewise_linear_distribution(const param_type& parm);
        void reset();

        // equality operators
        friend bool operator==(const piecewise_linear_distribution& x,
                               const piecewise_linear_distribution& y);

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        vector<result_type> intervals() const;
        vector<result_type> densities() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;

        // inserters and extractors
        template<class charT, class traits>
            friend basic_ostream<charT, traits>& operator<<
                (basic_ostream<charT, traits>& os, const piecewise_linear_distribution& x);
        template<class charT, class traits>
            friend basic_istream<charT, traits>& operator>>
                (basic_istream<charT, traits>& is, piecewise_linear_distribution& x);
    }
}
```

Effects: Constructs a `piecewise_linear_distribution` object with \( n = 1 \), \( \rho_0 = \rho_1 = 1 \), \( b_0 = 0 \), and \( b_1 = 1 \).
piecewise_linear_distribution\(\langle\text{InputIteratorB}\text{, InputIteratorW}\rangle\) \[\text{Mandates: is_invocable\_r\_v}\langle\text{double}\text{, UnaryOperation}\&\text{, double}\rangle\text{ is true.}\]

\text{Preconditions: InputIteratorB and InputIteratorW each meet the Cpp17InputIterator requirements (25.3.5.3). If firstB == lastB or ++firstB == lastB, let } n = 1, \rho_0 = \rho_1 = 1, b_0 = 0, \text{ and } b_1 = 1. \text{ Otherwise, } \{\text{firstB, lastB}\}\text{ forms a sequence } b \text{ of length } n + 1, \text{ the length of the sequence } w \text{ starting from firstW is at least } n + 1, \text{ and any } w_k \text{ for } k \geq n + 1 \text{ are ignored by the distribution.}\]

\text{Effects: Constructs a piecewise\_linear\_distribution object with parameters as specified above.}\]

piecewise_linear_distribution\(\langle\text{initializer\_list}\langle\text{RealType}\rangle\text{ bl}\text{, UnaryOperation fw}\rangle\)

\[\text{Mandates: is_invocable\_r\_v}\langle\text{double}\text{, UnaryOperation}\&\text{, double}\rangle\text{ is true.}\]

\text{Effects: Constructs a piecewise\_linear\_distribution object with parameters taken or calculated from the following values: If bl.size() < 2, let } n = 1, \rho_0 = \rho_1 = 1, b_0 = 0, \text{ and } b_1 = 1. \text{ Otherwise, let } \{\text{bl.begin()}, \text{bl.end()}\}\text{ form a sequence } b_0,\ldots,b_n, \text{ and let } w_k = fw(b_k) \text{ for } k = 0,\ldots,n.\]

\text{Complexity: The number of invocations of fw does not exceed } n + 1.\]

\text{vector}\langle\text{result\_type}\rangle\text{ intervals() const; Returns: A vector}<\text{result\_type}>\text{ whose size member returns } n + 1 \text{ and whose operator\[] member returns } b_k \text{ when invoked with argument } k \text{ for } k = 0,\ldots,n.\]

\text{vector}\langle\text{result\_type}\rangle\text{ densities() const; Returns: A vector}<\text{result\_type}>\text{ whose size member returns } n \text{ and whose operator\[] member returns } p_k \text{ when invoked with argument } k \text{ for } k = 0,\ldots,n.\]

28.5.10 Low-quality random number generation \([\text{c.math.rand}]\)

\[\text{Note 1: The header <cstdlib> (17.2.2) declares the functions described in this subclause.} \quad \text{— end note}\]

int rand();
void srand(unsigned int seed);

\[\text{Effects: The rand and srand functions have the semantics specified in the C standard library.}\]

\[\text{Remarks: The implementation may specify that particular library functions may call rand. It is} \quad \text{implementation-defined whether the rand function may introduce data races (16.4.6.10).}\]

\[\text{Note 2: The other random number generation facilities in this document (28.5) are often preferable to rand,} \quad \text{because rand's underlying algorithm is unspecified. Use of rand therefore continues to be non-portable, with}\]

\[\text{unpredictable and oft-questionable quality and performance.} \quad \text{— end note}\]

template<class T> valarray<bool> operator>=(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<bool> operator>=(const typename valarray<T>::value_type&, const valarray<T>&);

template<class T> valarray<T> abs (const valarray<T>&);

// Other functions defined here...
The header `<valarray>` defines five class templates (`valarray`, `slice_array`, `gslice_array`, `mask_array`, and `indirect_array`), two classes (`slice` and `gslice`), and a series of related function templates for representing and manipulating arrays of values.

The `valarray` array classes are defined to be free of certain forms of aliasing, thus allowing operations on these classes to be optimized.

Any function returning a `valarray<T>` is permitted to return an object of another type, provided all the const member functions of `valarray<T>` are also applicable to this type. This return type shall not add more than two levels of template nesting over the most deeply nested argument type.

Implementations introducing such replacement types shall provide additional functions and operators as follows:

1. for every function taking a `const valarray<T>&` other than `begin` and `end` (28.6.10), identical functions taking the replacement types shall be added;

2. for every function taking two `const valarray<T>&` arguments, identical functions taking every combination of `const valarray<T>&` and replacement types shall be added.

In particular, an implementation shall allow a `valarray<T>` to be constructed from such replacement types and shall allow assignments and compound assignments of such types to `valarray<T>`, `slice_array<T>`, `gslice_array<T>`, `mask_array<T>` and `indirect_array<T>` objects.

These library functions are permitted to throw a `bad_alloc` (17.6.4.1) exception if there are not sufficient resources available to carry out the operation. Note that the exception is not mandated.

### 28.6.2 Class template valarray

#### 28.6.2.1 Overview

```cpp
namespace std {
    template<class T> class valarray {
    public:
        using value_type = T;

        // 28.6.2.2, construct/destroy
        valarray();
        explicit valarray(size_t);
        valarray(const T&, size_t);
        valarray(const T*, size_t);
        valarray(const valarray&);
        valarray(valarray&&) noexcept;
        valarray(const slice_array<T>&);
        valarray(const gslice_array<T>&);
        valarray(const mask_array<T>&);
        valarray(const indirect_array<T>&);
        valarray(initializer_list<T>);
        ~valarray();
    }
}
```

---

233) Annex B recommends a minimum number of recursively nested template instantiations. This requirement thus indirectly suggests a minimum allowable complexity for `valarray` expressions.
// 28.6.2.3, assignment
valarray& operator=(const valarray&);
valarray& operator=(valarray&&) noexcept;
valarray& operator=(initializer_list<T>);
valarray& operator=(const T&);
valarray& operator=(const slice_array<T>&);
valarray& operator=(const gslice_array<T>&);
valarray& operator=(const mask_array<T>&);
valarray& operator=(const indirect_array<T>&);

// 28.6.2.4, element access
const T& operator[](size_t) const;
T& operator[](size_t);

// 28.6.2.5, subset operations
valarray operator[](slice) const;
slice_array<T> operator[](slice);
valarray operator[](const gslice&) const;
gslice_array<T> operator[](const gslice&);
valarray operator[](const valarray<bool>&) const;
mask_array<T> operator[](const valarray<bool>&);
valarray operator[](const valarray<size_t>&) const;
indirect_array<T> operator[](const valarray<size_t>&);

// 28.6.2.6, unary operators
valarray operator+() const;
valarray operator-() const;
valarray operator~() const;
valarray<bool> operator!() const;

// 28.6.2.7, compound assignment
valarray& operator*=(const T&);
valarray& operator/=(const T&);
valarray& operator%=(const T&);
valarray& operator+=(const T&);
valarray& operator-=(const T&);
valarray& operator^=(const T&);
valarray& operator&=(const T&);
valarray& operator|=(const T&);
valarray& operator<<=(const T&);
valarray& operator>>=(const T&);
valarray& operator*=(const valarray&);
valarray& operator/=(const valarray&);
valarray& operator%=(const valarray&);
valarray& operator+=(const valarray&);
valarray& operator-=(const valarray&);
valarray& operator^=(const valarray&);
valarray& operator|=(const valarray&);
valarray& operator<<=(const valarray&);
valarray& operator>>=(const valarray&);

// 28.6.2.8, member functions
void swap(valarray&) noexcept;

size_t size() const;
T sum() const;
T min() const;
T max() const;

valarray shift (int) const;
valarray cshift(int) const;
valarray apply(T func(T)) const;
valarray apply(T func(const T&)) const;
void resize(size_t sz, T c = T());
};

template<class T, size_t cnt> valarray(const T(&)[cnt], size_t) -> valarray<T>;
}

The class template valarray<T> is a one-dimensional smart array, with elements numbered sequentially from zero. It is a representation of the mathematical concept of an ordered set of values. For convenience, an object of type valarray<T> is referred to as an “array” throughout the remainder of §28.6. The illusion of higher dimensionality may be produced by the familiar idiom of computed indices, together with the powerful subsetting capabilities provided by the generalized subscript operators.234

### 28.6.2.2 Constructors

#### [valarray.cons]

**valarray();**

**Effects:** Constructs a valarray that has zero length.235

**explicit valarray(size_t n);**

**Effects:** Constructs a valarray that has length n. Each element of the array is value-initialized (9.4).

**valarray(const T& v, size_t n);**

**Effects:** Constructs a valarray that has length n. Each element of the array is initialized with v.

**valarray(const T* p, size_t n);**

**Preconditions:** \([p, p + n)\) is a valid range.

**Effects:** Constructs a valarray that has length n. The values of the elements of the array are initialized with the first n values pointed to by the first argument.236

**valarray(const valarray& v);**

**Effects:** Constructs a valarray that has the same length as v. The elements are initialized with the values of the corresponding elements of v.237

**valarray(valarray&& v) noexcept;**

**Effects:** Constructs a valarray that has the same length as v. The elements are initialized with the values of the corresponding elements of v.

**Complexity:** Constant.

**valarray(initializer_list<T> il);**

**Effects:** Equivalent to valarray(il.begin(), il.size()).

**valarray(const slice_array<T>&);**

**valarray(const gslice_array<T>&);**

**valarray(const mask_array<T>&);**

**valarray(const indirect_array<T>&);**

These conversion constructors convert one of the four reference templates to a valarray.

**~valarray();**

**Effects:** The destructor is applied to every element of *this; an implementation may return all allocated memory.

---

234 The intent is to specify an array template that has the minimum functionality necessary to address aliasing ambiguities and the proliferation of temporary objects. Thus, the valarray template is neither a matrix class nor a field class. However, it is a very useful building block for designing such classes.

235 This default constructor is essential, since arrays of valarray can be useful. After initialization, the length of an empty array can be increased with the resize member function.

236 This constructor is the preferred method for converting a C array to a valarray object.

237 This copy constructor creates a distinct array rather than an alias. Implementations in which arrays share storage are permitted, but they would need to implement a copy-on-reference mechanism to ensure that arrays are conceptually distinct.
28.6.2.3 Assignment

valarray& operator=(const valarray& v);

Effects: Each element of the *this array is assigned the value of the corresponding element of v. If the length of v is not equal to the length of *this, resizes *this to make the two arrays the same length, as if by calling resize(v.size()), before performing the assignment.

Postconditions: size() == v.size().

Returns: *this.

valarray& operator=(valarray&& v) noexcept;

Effects: *this obtains the value of v. The value of v after the assignment is not specified.

Returns: *this.

Complexity: Linear.

valarray& operator=(initializer_list<T> il);

Effects: Equivalent to: return *this = valarray(il);

valarray& operator=(const T& v);

Effects: Assigns v to each element of *this.

Returns: *this.

valarray& operator=(const slice_array<T>&);
valarray& operator=(const gslice_array<T>&);
valarray& operator=(const mask_array<T>&);
valarray& operator=(const indirect_array<T>&);

Preconditions: The length of the array to which the argument refers equals size(). The value of an element in the left-hand side of a valarray assignment operator does not depend on the value of another element in that left-hand side.

These operators allow the results of a generalized subscripting operation to be assigned directly to a valarray.

28.6.2.4 Element access

const T& operator[](size_t n) const;
T& operator[](size_t n);

Preconditions: n < size() is true.

Returns: A reference to the corresponding element of the array.

[Note 1: The expression (a[i] = q, a[i]) == q evaluates to true for any non-constant valarray<T> a, any T q, and for any size_t i such that the value of i is less than the length of a. — end note]

Remarks: The expression addressof(a[i+j]) == addressof(a[i]) + j evaluates to true for all size_t i and size_t j such that i+j < a.size().

The expression addressof(a[i]) != addressof(b[j]) evaluates to true for any two arrays a and b and for any size_t i and size_t j such that i < a.size() and j < b.size().

[Note 2: This property indicates an absence of aliasing and can be used to advantage by optimizing compilers. Compilers can take advantage of inlining, constant propagation, loop fusion, tracking of pointers obtained from operator new, and other techniques to generate efficient valarrays. — end note]

The reference returned by the subscript operator for an array shall be valid until the member function resize(size_t, T) (28.6.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

28.6.2.5 Subset operations

The member operator[] is overloaded to provide several ways to select sequences of elements from among those controlled by *this. Each of these operations returns a subset of the array. The const-qualified versions return this subset as a new valarray object. The non-const versions return a class template object which has reference semantics to the original array, working in conjunction with various overloads of operator=
and other assigning operators to allow selective replacement (slicing) of the controlled sequence. In each case
the selected element(s) shall exist.

valarray operator[](slice slicearr) const;

2 Returns: A valarray containing those elements of the controlled sequence designated by slicearr.

[Example 1:
  const valarray<char> v0("abcdefghijklmnop", 16);
  // v0[slice(2, 5, 3)] returns valarray<char>("cfilo", 5)
  —end example]

slice_array<T> operator[](slice slicearr);

3 Returns: An object that holds references to elements of the controlled sequence selected by slicearr.

[Example 2:
  valarray<char> v0("abcdefghijklmnop", 16);
  valarray<char> v1("ABCDE", 5);
  v0[slice(2, 5, 3)] = v1;
  // v0 == valarray<char>("abAdeBghCjkDmnEp", 16);
  —end example]

valarray operator[](const gslice& gslicearr) const;

4 Returns: A valarray containing those elements of the controlled sequence designated by gslicearr.

[Example 3:
  const valarray<char> v0("abcdefghijklmnop", 16);
  const size_t lv[] = { 2, 3 };  // 7
  const size_t dv[] = { 7, 2 };
  const valarray<size_t> len(lv, 2), str(dv, 2);
  // v0[gslice(3, len, str)] returns
  // valarray<char>("dfhkmno", 6)
  —end example]

gslice_array<T> operator[](const gslice& gslicearr);

5 Returns: An object that holds references to elements of the controlled sequence selected by gslicearr.

[Example 4:
  valarray<char> v0("abcdefghijklmnop", 16);
  valarray<char> v1("ABCDEF", 6);
  const size_t lv[] = { 2, 3 };
  const size_t dv[] = { 7, 2 };
  const valarray<size_t> len(lv, 2), str(dv, 2);
  v0[gslice(3, len, str)] = v1;
  // v0 == valarray<char>("abcAeBgCijDlEnFp", 16)
  —end example]

valarray operator[](const valarray<bool>& boolarr) const;

6 Returns: A valarray containing those elements of the controlled sequence designated by boolarr.

[Example 5:
  const valarray<char> v0("abcdefghijklmnop", 16);
  const bool vb[] = { false, false, true, true, false, true };
  // v0[valarray<bool>(vb, 6)] returns
  // valarray<char>("cdf", 3)
  —end example]

mask_array<T> operator[](const valarray<bool>& boolarr);

7 Returns: An object that holds references to elements of the controlled sequence selected by boolarr.

[Example 6:
  valarray<char> v0("abcdefghijklmnop", 16);
valarray<char> v1("ABC", 3);
const bool vb[] = { false, false, true, true, false, true };
v0[valarray<bool>(vb, 6)] = v1;
// v0 == valarray<char>("mbABeGhijklmnop", 16)
— end example]

valarray operator[](const valarray<size_t>& indarr) const;

Returns: A valarray containing those elements of the controlled sequence designated by indarr.
[Example 7]:
const valarray<char> v0("abcdefghijklmnop", 16);
const size_t vi[] = { 7, 5, 2, 3, 8 };
// v0[valarray<size_t>(vi, 5)] returns
// valarray<char>("hfcdi", 5)
— end example]

indirect_array<T> operator[](const valarray<size_t>& indarr);

Returns: An object that holds references to elements of the controlled sequence selected by indarr.
[Example 8]:
valarray<char> v0("abcdefghijklmnop", 16);
valarray<char> v1("ABCDE", 5);
const size_t vi[] = { 7, 5, 2, 3, 8 };
v0[valarray<size_t>(vi, 5)] = v1;
// v0 == valarray<char>("mbCDeBgAEjklmnop", 16)
— end example]

28.6.2.6 Unary operators [valarray.unary]

valarray operator+() const;
valarray operator-() const;
valarray operator~() const;
valarray<bool> operator!() const;

Mandates: The indicated operator can be applied to operands of type T and returns a value of type T (bool for operator!) or which may be unambiguously implicitly converted to type T (bool for operator!).

Returns: A valarray whose length is size(). Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array.

28.6.2.7 Compound assignment [valarray.cassign]

valarray& operator==( const valarray& v);
valarray& operator!=( const valarray& v);
valarray& operator%( const valarray& v);
valarray& operator+=( const valarray& v);
valarray& operator-=( const valarray& v);
valarray& operator^=( const valarray& v);
valarray& operator&=( const valarray& v);
valarray& operator|=( const valarray& v);
valarray& operator<=(const valarray& v);
valarray& operator>=(const valarray& v);

Mandates: The indicated operator can be applied to two operands of type T.

Preconditions: size() == v.size() is true.
The value of an element in the left-hand side of a valarray compound assignment operator does not depend on the value of another element in that left hand side.

Effects: Each of these operators performs the indicated operation on each of the elements of *this and the corresponding element of v.

Returns: *this.
5 Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers.

valarray& operator**(const T& v);
valarray& operator/=(const T& v);
valarray& operator%=(const T& v);
valarray& operator+=(const T& v);
valarray& operator-=(const T& v);
valarray& operator^=(const T& v);
valarray& operator&=(const T& v);
valarray& operator|=(const T& v);
valarray& operator<<=(const T& v);
valarray& operator>>=(const T& v);

6 Mandates: The indicated operator can be applied to two operands of type T.

7 Effects: Each of these operators applies the indicated operation to each element of *this and v.

8 Returns: *this

9 Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers to the elements of the array.

28.6.2.8 Member functions

void swap(valarray& v) noexcept;

1 Effects: *this obtains the value of v. v obtains the value of *this.

2 Complexity: Constant.

size_t size() const;

3 Returns: The number of elements in the array.

4 Complexity: Constant time.

T sum() const;

5 Mandates: operator**= can be applied to operands of type T.

6 Preconditions: size() > 0 is true.

7 Returns: The sum of all the elements of the array. If the array has length 1, returns the value of element 0. Otherwise, the returned value is calculated by applying operator**= to a copy of an element of the array and all other elements of the array in an unspecified order.

T min() const;

8 Preconditions: size() > 0 is true.

9 Returns: The minimum value contained in *this. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

T max() const;

10 Preconditions: size() > 0 is true.

11 Returns: The maximum value contained in *this. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

valarray shift(int n) const;

12 Returns: A valarray of length size(), each of whose elements I is (*this)[I + n] if I + n is non-negative and less than size(), otherwise T().

[Note 1: If element zero is taken as the leftmost element, a positive value of n shifts the elements left n places, with zero fill. — end note]

[Example 1: If the argument has the value −2, the first two elements of the result will be value-initialized (9.4); the third element of the result will be assigned the value of the first element of *this; etc. — end example]
valarray cshift(int n) const;

Returns: A valarray of length size() that is a circular shift of *this. If element zero is taken as the leftmost element, a non-negative value of \( n \) shifts the elements circularly left \( n \) places and a negative value of \( n \) shifts the elements circularly right \(-n\) places.

valarray apply(T func(T)) const;
valarray apply(T func(const T&)) const;

Returns: A valarray whose length is size(). Each element of the returned array is assigned the value returned by applying the argument function to the corresponding element of *this.

void resize(size_t sz, T c = T());

Effects: Changes the length of the *this array to \( sz \) and then assigns to each element the value of the second argument. Resizing invalidates all pointers and references to elements in the array.

### 28.6.3 valarray non-member operations [valarray.nonmembers]

#### 28.6.3.1 Binary operators [valarray.binary]

<table>
<thead>
<tr>
<th>Template</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class ( T )&gt; valarray&lt;( T )&gt; operator* (const valarray&lt;( T &gt;)&amp;, const valarray&lt;( T &gt;)&amp;);</td>
<td>\n</td>
</tr>
</tbody>
</table>

1. **Mandates:** The indicated operator can be applied to operands of type \( T \) and returns a value of type \( T \) or which can be unambiguously implicitly converted to \( T \).

2. **Preconditions:** The argument arrays have the same length.

3. **Returns:** A valarray whose length is equal to the lengths of the argument arrays. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.
template<class T> valarray<T> operator& (const typename valarray<T>::value_type&, const valarray<T>&);

template<class T> valarray<T> operator| (const valarray<T>&, const typename valarray<T>::value_type&);

Mandates: The indicated operator can be applied to operands of type T and returns a value of type T or which can be unambiguously implicitly converted to T.

Returns: A valarray whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array argument and the non-array argument.

28.6.3.2 Logical operators [valarray.comparison]

template<class T> valarray<bool> operator==(const valarray<T>&, const valarray<T>&);

Mandates: The indicated operator can be applied to operands of type T and returns a value of type bool or which can be unambiguously implicitly converted to bool.

Preconditions: The two array arguments have the same length.

Returns: A valarray<bool> whose length is equal to the length of the array arguments. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.
template<class T> valarray<bool> operator&&(const valarray<T>&, const typename valarray<T>::value_type&);

Mandates: The indicated operator can be applied to operands of type T and returns a value of type bool or which can be unambiguously implicitly converted to bool.

Returns: A valarray<bool> whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array and the non-array argument.

28.6.3.3 Transcendentals [valarray.transcend]

template<class T> valarray<T> abs (const valarray<T>&);
template<class T> valarray<T> acos (const valarray<T>&);
template<class T> valarray<T> asin (const valarray<T>&);
template<class T> valarray<T> atan (const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> atan2(const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> cos (const valarray<T>&);
template<class T> valarray<T> cosh (const valarray<T>&);
template<class T> valarray<T> exp (const valarray<T>&);
template<class T> valarray<T> log (const valarray<T>&);
template<class T> valarray<T> log10(const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> pow (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> sin (const valarray<T>&);
template<class T> valarray<T> sinh (const valarray<T>&);
template<class T> valarray<T> sqrt (const valarray<T>&);
template<class T> valarray<T> tan (const valarray<T>&);
template<class T> valarray<T> tanh (const valarray<T>&);

Mandates: A unique function with the indicated name can be applied (unqualified) to an operand of type T. This function returns a value of type T or which can be unambiguously implicitly converted to type T.

28.6.3.4 Specialized algorithms [valarray.special]

template<class T> void swap(valarray<T>& x, valarray<T>& y) noexcept;

Effects: Equivalent to x.swap(y).

28.6.4 Class slice [class.slice]

28.6.4.1 Overview [class.slice.overview]

namespace std {
    class slice {
    public:
        slice();
        slice(size_t, size_t, size_t);
        slice(const slice&);

        size_t start() const;
        size_t size() const;
        size_t stride() const;

        friend bool operator==(const slice& x, const slice& y);
    };
}
The `slice` class represents a BLAS-like slice from an array. Such a slice is specified by a starting index, a length, and a stride.\textsuperscript{238}

### 28.6.4.2 Constructors

```
slice();
slice(size_t start, size_t length, size_t stride);
```

The default constructor is equivalent to `slice(0, 0, 0)`. A default constructor is provided only to permit the declaration of arrays of slices. The constructor with arguments for a slice takes a start, length, and stride parameter.

[Example 1: `slice(3, 8, 2)` constructs a slice which selects elements 3, 5, 7, ..., 17 from an array. — end example]

### 28.6.4.3 Access functions

```
size_t start() const;
size_t size() const;
size_t stride() const;
```

Returns: The start, length, or stride specified by a `slice` object.

Complexity: Constant time.

### 28.6.4.4 Operators

```
friend bool operator==(const slice& x, const slice& y);
```

Effects: Equivalent to:

```
return x.start() == y.start() && x.size() == y.size() && x.stride() == y.stride();
```

### 28.6.5 Class template `slice_array`

#### 28.6.5.1 Overview

```
namespace std {
    template<class T> class slice_array {
        using value_type = T;
        void operator= (const valarray<T>&) const;
        void operator*= (const valarray<T>&) const;
        void operator/= (const valarray<T>&) const;
        void operator%= (const valarray<T>&) const;
        void operator+= (const valarray<T>&) const;
        void operator-= (const valarray<T>&) const;
        void operator^= (const valarray<T>&) const;
        void operator&= (const valarray<T>&) const;
        void operator|= (const valarray<T>&) const;
        void operator<<=(const valarray<T>&) const;
        void operator>>=(const valarray<T>&) const;
        slice_array(const slice_array&);
        ~slice_array();
        const slice_array& operator=(const slice_array&) const;
        void operator=(const T&) const;
        slice_array() = delete; // as implied by declaring copy constructor above
    };
}
```

This template is a helper template used by the `slice` subscript operator.

```
slice_array<T> valarray<T>::operator[] (slice);
```

\textsuperscript{238} BLAS stands for Basic Linear Algebra Subprograms. C++ programs can instantiate this class. See, for example, Dongarra, Du Croz, Duff, and Hammerling: A set of Level 3 Basic Linear Algebra Subprograms; Technical Report MCS-P1-0888, Argonne National Laboratory (USA), Mathematics and Computer Science Division, August, 1988.
It has reference semantics to a subset of an array specified by a slice object.

[Example 1: The expression \(a\{\text{slice}(1, 5, 3)\} = b\); has the effect of assigning the elements of \(b\) to a slice of the elements in \(a\). For the slice shown, the elements selected from \(a\) are \(1, 4, \ldots, 13\). — end example]

### 28.6.5.2 Assignment

**slice.arr.assign**

```cpp
void operator=(const valarray<T>&) const;
const slice_array& operator=(const slice_array&) const;
```

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which the `slice_array` object refers.

### 28.6.5.3 Compound assignment

**slice.arr.comp.assign**

```cpp
void operator*=(const valarray<T>&) const;
void operator/=(const valarray<T>&) const;
void operator%=(const valarray<T>&) const;
void operator+=(const valarray<T>&) const;
void operator-=(const valarray<T>&) const;
void operator^=(const valarray<T>&) const;
void operator&=(const valarray<T>&) const;
void operator|=(const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
```

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `slice_array` object refers.

### 28.6.5.4 Fill function

**slice.arr.fill**

```cpp
void operator=(const T&) const;
```

1 This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `slice_array` object refers.

### 28.6.6 The gslice class

**class.gslice**

#### 28.6.6.1 Overview

```cpp
namespace std {
    class gslice {
        public:
            gslice();
            gslice(size_t s, const valarray<size_t>& l, const valarray<size_t>& d);

            size_t start() const;
            valarray<size_t> size() const;
            valarray<size_t> stride() const;
    };
}
```

1 This class represents a generalized slice out of an array. A `gslice` is defined by a starting offset \((s)\), a set of lengths \((l_j)\), and a set of strides \((d_j)\). The number of lengths shall equal the number of strides.

2 A `gslice` represents a mapping from a set of indices \((i_j)\), equal in number to the number of strides, to a single index \(k\). It is useful for building multidimensional array classes using the `valarray` template, which is one-dimensional. The set of one-dimensional index values specified by a `gslice` are

\[ k = s + \sum_{j} i_j d_j \]

where the multidimensional indices \(i_j\) range in value from 0 to \(l_j - 1\).

[Example 1: The `gslice` specification

```cpp
    start = 3
    length = {2, 4, 3}
    stride = {19, 4, 1}
```]
yields the sequence of one-dimensional indices

\[ k = 3 + (0, 1) \times 19 + (0, 1, 2, 3) \times 4 + (0, 1, 2) \times 1 \]

which are ordered as shown in the following table:

\[
(i_0, i_1, i_2, k) = \\
(0, 0, 0, 3), \\
(0, 0, 1, 4), \\
(0, 0, 2, 5), \\
(0, 1, 0, 7), \\
(0, 1, 1, 8), \\
(0, 1, 2, 9), \\
(0, 2, 0, 11), \\
(0, 2, 1, 12), \\
(0, 2, 2, 13), \\
(0, 3, 0, 15), \\
(0, 3, 1, 16), \\
(0, 3, 2, 17), \\
(1, 0, 0, 22), \\
(1, 0, 1, 23), \\
... \\
(1, 3, 2, 36)
\]

That is, the highest-ordered index turns fastest. —end example] 4

It is possible to have degenerate generalized slices in which an address is repeated.

[Example 2: If the stride parameters in the previous example are changed to \{1, 1, 1\}, the first few elements of the resulting sequence of indices will be

\[
(0, 0, 0, 3), \\
(0, 0, 1, 4), \\
(0, 0, 2, 5), \\
(0, 1, 0, 4), \\
(0, 1, 1, 5), \\
(0, 1, 2, 6), \\
... 
\]

—end example] 5

If a degenerate slice is used as the argument to the non-const version of \operator\[\] (const gslice&), the behavior is undefined.

### 28.6.6.2 Constructors

[gslice.cons]

gslice();
gslice(size_t start, const valarray&lt;size_t\>& lengths,
const valarray&lt;size_t\>& strides);

The default constructor is equivalent to gslice(0, valarray&lt;size_t\>(), valarray&lt;size_t\>()). The constructor with arguments builds a gslice based on a specification of start, lengths, and strides, as explained in the previous subclause.

### 28.6.6.3 Access functions

[gslice.access]

size_t start() const;
valarray&lt;size_t\> size() const;
valarray&lt;size_t\> stride() const;

Returns: The representation of the start, lengths, or strides specified for the gslice.

Complexity: start() is constant time. size() and stride() are linear in the number of strides.
28.6.7 Class template gslice_array

28.6.7.1 Overview

namespace std {
  template<class T> class gslice_array {
    public:
      using value_type = T;

      void operator= (const valarray<T>&) const;
      void operator*= (const valarray<T>&) const;
      void operator/= (const valarray<T>&) const;
      void operator%= (const valarray<T>&) const;
      void operator+= (const valarray<T>&) const;
      void operator-= (const valarray<T>&) const;
      void operator^= (const valarray<T>&) const;
      void operator&= (const valarray<T>&) const;
      void operator|= (const valarray<T>&) const;
      void operator<<=(const valarray<T>&) const;
      void operator>>=(const valarray<T>&) const;
      gslice_array(const gslice_array&);
      ~gslice_array();
      const gslice_array& operator=(const gslice_array&) const;
      void operator=(const T&) const;

      gslice_array() = delete; // as implied by declaring copy constructor above
  };
}

1 This template is a helper template used by the gslice subscript operator

```
gslice_array<T> valarray<T>::operator[](const gslice&);
```

2 It has reference semantics to a subset of an array specified by a gslice object. Thus, the expression

```
a[gslice(1, length, stride)] = b
```

has the effect of assigning the elements of b to a generalized slice of the elements in a.

28.6.7.2 Assignment

```
void operator=(const valarray<T>&) const;
const gslice_array& operator=(const gslice_array&) const;
```

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the valarray<T> object to which the gslice_array refers.

28.6.7.3 Compound assignment

```
void operator== (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;
```

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray<T> object to which the gslice_array refers.

28.6.7.4 Fill function

```
void operator=(const T&) const;
```

1 This function has reference semantics, assigning the value of its argument to the elements of the valarray<T> object to which the gslice_array object refers.
28.6.8 Class template mask_array

28.6.8.1 Overview

namespace std {
    template<class T> class mask_array {
    public:
        using value_type = T;

        void operator= (const valarray<T>&) const;
        void operator*= (const valarray<T>&) const;
        void operator/= (const valarray<T>&) const;
        void operator%= (const valarray<T>&) const;
        void operator+= (const valarray<T>&) const;
        void operator-= (const valarray<T>&) const;
        void operator^= (const valarray<T>&) const;
        void operator&= (const valarray<T>&) const;
        void operator|= (const valarray<T>&) const;
        void operator<<=(const valarray<T>&) const;
        void operator>>=(const valarray<T>&) const;

        mask_array(const mask_array&);
        ~mask_array();
        const mask_array& operator=(const mask_array&) const;
        void operator=(const T&) const;

        mask_array() = delete;  // as implied by declaring copy constructor above
    };
} // namespace std

1 This template is a helper template used by the mask subscript operator:

mask_array<T> valarray<T>::operator[](const valarray<bool>&);

2 It has reference semantics to a subset of an array specified by a boolean mask. Thus, the expression a[mask] = b; has the effect of assigning the elements of b to the masked elements in a (those for which the corresponding element in mask is true).

28.6.8.2 Assignment

void operator=(const valarray<T>&) const;
const mask_array& operator=(const mask_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the valarray<T> object to which the mask_array object refers.

28.6.8.3 Compound assignment

void operator== (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray<T> object to which the mask_array object refers.

28.6.8.4 Fill function

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the valarray<T> object to which the mask_array object refers.
28.6.9 Class template indirect_array

28.6.9.1 Overview

namespace std {
    template<class T> class indirect_array {
        public:
            using value_type = T;
            void operator= (const valarray<T>&) const;
            void operator*= (const valarray<T>&) const;
            void operator/= (const valarray<T>&) const;
            void operator%=(const valarray<T>&) const;
            void operator+=(const valarray<T>&) const;
            void operator-=(const valarray<T>&) const;
            void operator^=(const valarray<T>&) const;
            void operator&=(const valarray<T>&) const;
            void operator|=(const valarray<T>&) const;
            void operator<<=(const valarray<T>&) const;
            void operator>>=(const valarray<T>&) const;
            indirect_array(const indirect_array&);
            ~indirect_array();
            const indirect_array& operator=(const indirect_array&) const;
            void operator=(const T&) const;
        indirect_array() = delete;  // as implied by declaring copy constructor above
    };
}

1 This template is a helper template used by the indirect subscript operator

indirect_array<T> valarray<T>::operator[](const valarray<size_t>&);

2 It has reference semantics to a subset of an array specified by an indirect_array. Thus, the expression

   a[indirect] = b;

   has the effect of assigning the elements of b to the elements in a whose indices appear in indirect.

28.6.9.2 Assignment

void operator=(const valarray<T>&) const;
const indirect_array& operator=(const indirect_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array
   elements to selected elements of the valarray<T> object to which it refers.

2 If the indirect_array specifies an element in the valarray<T> object to which it refers more than
   once, the behavior is undefined.

3 [Example 1:]
   int addr[] = {2, 3, 1, 4, 4};
   valarray<size_t> indirect(addr, 5);
   valarray<double> a(0., 10), b(1., 5);
   a[indirect] = b;
   results in undefined behavior since element 4 is specified twice in the indirection. — end example]

28.6.9.3 Compound assignment

void operator== (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%=(const valarray<T>&) const;
void operator+=(const valarray<T>&) const;
void operator-=(const valarray<T>&) const;
void operator^=(const valarray<T>&) const;
void operator&=(const valarray<T>&) const;
void operator|=(const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;

§ 28.6.9.3
These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `indirect_array` object refers.

If the `indirect_array` specifies an element in the `valarray<T>` object to which it refers more than once, the behavior is undefined.

---

### 28.6.9.4 Fill function

```cpp
void operator=(const T&) const;
```

This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `indirect_array` object refers.

### 28.6.10 valarray range access

In the `begin` and `end` function templates that follow, `unspecified1` is a type that meets the requirements of a mutable `Cpp17RandomAccessIterator` (25.3.5.7) and models `contiguous_iterator` (25.3.4.14), whose `value_type` is the template parameter `T` and whose `reference` type is `T&`. `unspecified2` is a type that meets the requirements of a constant `Cpp17RandomAccessIterator` and models `contiguous_iterator`, whose `value_type` is the template parameter `T` and whose `reference` type is `const T&`.

The iterators returned by `begin` and `end` for an array are guaranteed to be valid until the member function `resize(size_t, T)` (28.6.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

```cpp
template<class T> unspecified1 begin(valarray<T>& v);
template<class T> unspecified2 begin(const valarray<T>& v);
```

Returns: An iterator referencing the first value in the array.

```cpp
template<class T> unspecified1 end(valarray<T>& v);
template<class T> unspecified2 end(const valarray<T>& v);
```

Returns: An iterator referencing one past the last value in the array.

The contents and meaning of the header `<math>` are the same as the C standard library header `<math.h>`, with the addition of a three-dimensional hypotenuse function (28.7.3), a linear interpolation function (28.7.4), and the mathematical special functions described in 28.7.6.

[Note 1: Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (16.2). — end note]

For each function with at least one parameter of type `floating-point-type`, the implementation provides an overload for each cv-unqualified floating-point type (6.8.2) where all uses of `floating-point-type` in the function signature are replaced with that floating-point type.

For each function with at least one parameter of type `floating-point-type` other than `abs`, the implementation also provides additional overloads sufficient to ensure that, if every argument corresponding to a `floating-point-type` parameter has arithmetic type, then every such argument is effectively cast to the floating-point type with the greatest floating-point conversion rank and greatest floating-point conversion subrank among the types of

1 The contents and meaning of the header `<math>` are the same as the C standard library header `<math.h>`, with the addition of a three-dimensional hypotenuse function (28.7.3), a linear interpolation function (28.7.4), and the mathematical special functions described in 28.7.6.

[Note 1: Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (16.2). — end note]

For each function with at least one parameter of type `floating-point-type`, the implementation provides an overload for each cv-unqualified floating-point type (6.8.2) where all uses of `floating-point-type` in the function signature are replaced with that floating-point type.

For each function with at least one parameter of type `floating-point-type` other than `abs`, the implementation also provides additional overloads sufficient to ensure that, if every argument corresponding to a `floating-point-type` parameter has arithmetic type, then every such argument is effectively cast to the floating-point type with the greatest floating-point conversion rank and greatest floating-point conversion subrank among the types of
all such arguments, where arguments of integer type are considered to have the same floating-point conversion rank as double. If no such floating-point type with the greatest rank and subrank exists, then overload resolution does not result in a usable candidate (12.2.1) from the overloads provided by the implementation.

An invocation of nexttoward is ill-formed if the argument corresponding to the floating-point-type parameter has extended floating-point type.

See also: ISO C 7.12

28.7.2 Absolute values [c.math.abs]

1 [Note 1: The headers <cstdlib> (17.2.2) and <cmath> (28.7.1) declare the functions described in this subclause. — end note]

constexpr int abs(int j);
constexpr long int abs(long int j);
constexpr long long int abs(long long int j);

2 Effects: These functions have the semantics specified in the C standard library for the functions abs, labs, and llabs, respectively.

3 Remarks: If abs is called with an argument of type X for which is_unsigned_v<X> is true and if X cannot be converted to int by integral promotion (7.3.7), the program is ill-formed.

[Note 2: Arguments that can be promoted to int are permitted for compatibility with C. — end note]

constexpr floating-point-type abs(floating-point-type x);

4 Returns: The absolute value of x.

See also: ISO C 7.12.7, 7.22.6.1

28.7.3 Three-dimensional hypotenuse [c.math.hypot3]

floating-point-type hypot(floating-point-type x, floating-point-type y, floating-point-type z);

1 Returns: \(\sqrt{x^2 + y^2 + z^2}\).

28.7.4 Linear interpolation [c.math.lerp]

constexpr floating-point-type lerp(floating-point-type a, floating-point-type b, floating-point-type t) noexcept;

1 Returns: \(a + t(b - a)\).

2 Remarks: Let \(r\) be the value returned. If isfinite(a) && isfinite(b), then:

(2.1) — If \(t == 0\), then \(r == a\).
(2.2) — If \(t == 1\), then \(r == b\).
(2.3) — If \(t >= 0 && t <= 1\), then isfinite(r).
(2.4) — If isfinite(t) && a == b, then \(r == a\).
(2.5) — If isfinite(t) || !isnan(t) && b-a != 0, then !isnan(r).

Let CMP(x,y) be 1 if \(x > y\), -1 if \(x < y\), and 0 otherwise. For any t1 and t2, the product of CMP(lerp(a, b, t2), lerp(a, b, t1)), CMP(t2, t1), and CMP(b, a) is non-negative.

28.7.5 Classification / comparison functions [c.math.fpclass]

The classification / comparison functions behave the same as the C macros with the corresponding names defined in the C standard library.

See also: ISO C 7.12.3, 7.12.4

28.7.6 Mathematical special functions [sf.cmath]

28.7.6.1 General [sf.cmath.general]

1 If any argument value to any of the functions specified in 28.7.6 is a NaN (Not a Number), the function shall return a NaN but it shall not report a domain error. Otherwise, the function shall report a domain error for just those argument values for which:

§ 28.7.6.1 1473
the function description’s *Returns*: element explicitly specifies a domain and those argument values fall outside the specified domain, or

— the corresponding mathematical function value has a nonzero imaginary component, or

— the corresponding mathematical function is not mathematically defined.  

Unless otherwise specified, each function is defined for all finite values, for negative infinity, and for positive infinity.

### 28.7.6.2 Associated Laguerre polynomials

```c
floating-point-type assoc_laguerre(unsigned n, unsigned m, floating-point-type x);
float assoc_laguerref(unsigned n, unsigned m, float x);
long double assoc_laguerrel(unsigned n, unsigned m, long double x);
```

1. **Effects**: These functions compute the associated Laguerre polynomials of their respective arguments \( n \), \( m \), and \( x \).

2. **Returns**:

   \[ L_m^n(x) = (-1)^m \frac{d^m}{dx^m} L_{n+m}(x) \], for \( x \geq 0 \),

   where \( n \) is \( n \), \( m \) is \( m \), and \( x \) is \( x \).

3. **Remarks**: The effect of calling each of these functions is implementation-defined if \( n \geq 128 \) or if \( m \geq 128 \).

### 28.7.6.3 Associated Legendre functions

```c
floating-point-type assoc_legendre(unsigned l, unsigned m, floating-point-type x);
float assoc_legendref(unsigned l, unsigned m, float x);
long double assoc_legendrel(unsigned l, unsigned m, long double x);
```

1. **Effects**: These functions compute the associated Legendre functions of their respective arguments \( l \), \( m \), and \( x \).

2. **Returns**:

   \[ P_m^l(x) = (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_l(x) \], for \(|x| \leq 1\),

   where \( l \) is \( l \), \( m \) is \( m \), and \( x \) is \( x \).

3. **Remarks**: The effect of calling each of these functions is implementation-defined if \( l \geq 128 \).

### 28.7.6.4 Beta function

```c
floating-point-type beta(floating-point-type x, floating-point-type y);
float betaf(float x, float y);
long double betal(long double x, long double y);
```

1. **Effects**: These functions compute the beta function of their respective arguments \( x \) and \( y \).

2. **Returns**:

   \[ B(x,y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)} \], for \( x > 0 \), \( y > 0 \),

   where \( x \) is \( x \) and \( y \) is \( y \).

### 28.7.6.5 Complete elliptic integral of the first kind

```c
floating-point-type comp_ellint_1(floating-point-type k);
float comp_ellint_1f(float k);
long double comp_ellint_1l(long double k);
```

1. **Effects**: These functions compute the complete elliptic integral of the first kind of their respective arguments \( k \).

2. **Returns**:

   \[ K(k) = F(k, \pi/2) \], for \(|k| \leq 1\),

   where \( k \) is \( k \).

---

239) A mathematical function is mathematically defined for a given set of argument values (a) if it is explicitly defined for that set of argument values, or (b) if its limiting value exists and does not depend on the direction of approach.
See also 28.7.6.12.

### 28.7.6.6 Complete elliptic integral of the second kind

*floating-point-type* `comp_ellint_2(float k);`
*float* `comp_ellint_2f(float k);`
*long double* `comp_ellint_2l(long double k);`

1. **Effects**: These functions compute the complete elliptic integral of the second kind of their respective arguments `k`.

2. **Returns**:
   \[ E(k) = E(k, \pi/2), \text{ for } |k| \leq 1, \]
   where `k` is `k`.

See also 28.7.6.13.

### 28.7.6.7 Complete elliptic integral of the third kind

*floating-point-type* `comp_ellint_3(float k, float nu);`
*float* `comp_ellint_3f(float k, float nu);`
*long double* `comp_ellint_3l(long double k, long double nu);`

1. **Effects**: These functions compute the complete elliptic integral of the third kind of their respective arguments `k` and `nu`.

2. **Returns**:
   \[ \Pi(\nu,k) = \Pi(\nu,k,\pi/2), \text{ for } |k| \leq 1, \]
   where `k` is `k` and `nu` is `nu`.

See also 28.7.6.14.

### 28.7.6.8 Regular modified cylindrical Bessel functions

*floating-point-type* `cyl_bessel_i(float nu, float x);`
*float* `cyl_bessel_if(float nu, float x);`
*long double* `cyl_bessel_il(long double nu, long double x);`

1. **Effects**: These functions compute the regular modified cylindrical Bessel functions of their respective arguments `nu` and `x`.

2. **Returns**:
   \[ I_{\nu}(x) = i^{-\nu}J_{\nu}(ix) = \sum_{k=0}^{\infty} \frac{(x/2)^{\nu+2k}}{k! \Gamma(\nu + k + 1)}, \text{ for } x \geq 0, \]
   where `nu` is `nu` and `x` is `x`.

3. **Remarks**: The effect of calling each of these functions is implementation-defined if `nu >= 128`.

See also 28.7.6.9.

### 28.7.6.9 Cylindrical Bessel functions of the first kind

*floating-point-type* `cyl_bessel_j(float nu, float x);`
*float* `cyl_bessel_jf(float nu, float x);`
*long double* `cyl_bessel_jl(long double nu, long double x);`

1. **Effects**: These functions compute the cylindrical Bessel functions of the first kind of their respective arguments `nu` and `x`.

2. **Returns**:
   \[ J_{\nu}(x) = \sum_{k=0}^{\infty} \frac{(-1)^k(x/2)^{\nu+2k}}{k! \Gamma(\nu + k + 1)}, \text{ for } x \geq 0, \]
   where `nu` is `nu` and `x` is `x`.

3. **Remarks**: The effect of calling each of these functions is implementation-defined if `nu >= 128`. 

§ 28.7.6.9
28.7.6.10 Irregular modified cylindrical Bessel functions

floating-point-type cyl_bessel_k(floating-point-type nu, floating-point-type x);
float cyl_bessel_kf(float nu, float x);
long double cyl_bessel_kl(long double nu, long double x);

Effects: These functions compute the irregular modified cylindrical Bessel functions of their respective arguments nu and x.

Returns:

\[ K_\nu(x) = \frac{\pi}{2} i^{\nu+1} (J_\nu(ix) + iN_\nu(ix)) = \begin{cases} \frac{\pi}{2} \left( \frac{1_{-\nu}(x) - 1_\nu(x)}{\sin \nu \pi} \right), & \text{for } x \geq 0 \text{ and non-integral } \nu \\ \lim_{\mu \to \nu} \frac{1_{-\nu}(x) - 1_\nu(x)}{\sin \mu \pi}, & \text{for } x \geq 0 \text{ and integral } \nu \end{cases} \]

where \( \nu \) is nu and \( x \) is x.

Remarks: The effect of calling each of these functions is implementation-defined if nu >= 128.

See also 28.7.6.8, 28.7.6.9, 28.7.6.11.

28.7.6.11 Cylindrical Neumann functions

floating-point-type cyl_neumann(floating-point-type nu, floating-point-type x);
float cyl_neumannf(float nu, float x);
long double cyl_neumannl(long double nu, long double x);

Effects: These functions compute the cylindrical Neumann functions, also known as the cylindrical Bessel functions of the second kind, of their respective arguments nu and x.

Returns:

\[ N_\nu(x) = \begin{cases} \frac{J_\nu(x) \cos \nu \pi - J_{-\nu}(x)}{\sin \nu \pi}, & \text{for } x \geq 0 \text{ and non-integral } \nu \\ \lim_{\mu \to \nu} \frac{J_\mu(x) \cos \mu \pi - J_{-\mu}(x)}{\sin \mu \pi}, & \text{for } x \geq 0 \text{ and integral } \nu \end{cases} \]

where \( \nu \) is nu and \( x \) is x.

Remarks: The effect of calling each of these functions is implementation-defined if nu >= 128.

See also 28.7.6.9.

28.7.6.12 Incomplete elliptic integral of the first kind

floating-point-type ellint_1(floating-point-type k, floating-point-type phi);
float ellint_1f(float k, float phi);
long double ellint_1l(long double k, long double phi);

Effects: These functions compute the incomplete elliptic integral of the first kind of their respective arguments k and phi (phi measured in radians).

Returns:

\[ F(k, \phi) = \int_0^\phi \frac{d\theta}{\sqrt{1 - k^2 \sin^2 \theta}}, \text{ for } |k| \leq 1, \]

where \( k \) is k and \( \phi \) is phi.

28.7.6.13 Incomplete elliptic integral of the second kind

floating-point-type ellint_2(floating-point-type k, floating-point-type phi);
float ellint_2f(float k, float phi);
long double ellint_2l(long double k, long double phi);

Effects: These functions compute the incomplete elliptic integral of the second kind of their respective arguments k and phi (phi measured in radians).

Returns:

\[ E(k, \phi) = \int_0^\phi \sqrt{1 - k^2 \sin^2 \theta} d\theta, \text{ for } |k| \leq 1, \]

where \( k \) is k and \( \phi \) is phi.
28.7.6.14 Incomplete elliptic integral of the third kind

\[ \text{ellint}_3(k, \nu, \phi) \]

These functions compute the incomplete elliptic integral of the third kind of their respective arguments \( k, \nu, \) and \( \phi \) (\( \phi \) measured in radians).

28.7.6.15 Exponential integral

\[ \text{expint}(x) \]

These functions compute the exponential integral of their respective arguments \( x \).

28.7.6.16 Hermite polynomials

\[ H_n(x) \]

These functions compute the Hermite polynomials of their respective arguments \( n \) and \( x \).

28.7.6.17 Laguerre polynomials

\[ L_n(x) \]

These functions compute the Laguerre polynomials of their respective arguments \( n \) and \( x \).

28.7.6.18 Legendre polynomials

\[ P_l(x) \]

These functions compute the Legendre polynomials of their respective arguments \( l \) and \( x \).
28.7.6.19 Riemann zeta function

```c
floating-point-type riemann_zeta(floating-point-type x);
float riemann_zetaf(float x);
long double riemann_zetal(long double x);
```

1. **Effects:** These functions compute the Riemann zeta function of their respective arguments \( x \).  
2. **Returns:**  
   \[
   \zeta(x) = \begin{cases} 
   \sum_{k=1}^{\infty} k^{-x}, & \text{for } x > 1 \\
   \frac{1}{1 - 2^{1-x}} \sum_{k=1}^{\infty} (-1)^{k-1} k^{-x}, & \text{for } 0 \leq x \leq 1 \\
   2^x \pi^{x-1} \sin\left(\frac{\pi x}{2}\right) \Gamma(1-x) \zeta(1-x), & \text{for } x < 0
   \end{cases}
   \]

   where \( x \) is \( x \).

28.7.6.20 Spherical Bessel functions of the first kind

```c
floating-point-type sph_bessel(unsigned n, floating-point-type x);
float sph_besself(unsigned n, float x);
long double sph_bessell(unsigned n, long double x);
```

1. **Effects:** These functions compute the spherical Bessel functions of the first kind of their respective arguments \( n \) and \( x \).  
2. **Returns:**  
   \[
   j_n(x) = \left(\frac{\pi}{2x}\right)^{1/2} J_{n+1/2}(x), \quad \text{for } x \geq 0,
   \]

   where \( n \) is \( n \) and \( x \) is \( x \).  
3. **Remarks:** The effect of calling each of these functions is implementation-defined if \( n \geq 128 \).  
4. See also 28.7.6.9.

28.7.6.21 Spherical associated Legendre functions

```c
floating-point-type sph_legendre(unsigned l, unsigned m, floating-point-type theta);
float sph_legendref(unsigned l, unsigned m, float theta);
long double sph_legendrel(unsigned l, unsigned m, long double theta);
```

1. **Effects:** These functions compute the spherical associated Legendre functions of their respective arguments \( l \), \( m \), and \( \theta \) (\( \theta \) measured in radians).  
2. **Returns:**  
   \[
   Y^m_l(\theta, 0)
   \]

   where  
   \[
   Y^m_l(\theta, \phi) = (-1)^m \left[ \frac{(2l+1)(l-m)!}{4\pi (l+m)!} \right]^{1/2} P^m_l(\cos \theta) e^{i m \phi}, \quad \text{for } |m| \leq l,
   \]

   and \( l \) is \( l \), \( m \) is \( m \), and \( \theta \) is \( \theta \).  
3. **Remarks:** The effect of calling each of these functions is implementation-defined if \( l \geq 128 \).  
4. See also 28.7.6.3.

28.7.6.22 Spherical Neumann functions

```c
floating-point-type sph_neumann(unsigned n, floating-point-type x);
float sph_neumannf(unsigned n, float x);
long double sph_neumannl(unsigned n, long double x);
```

1. **Effects:** These functions compute the spherical Neumann functions, also known as the spherical Bessel functions of the second kind, of their respective arguments \( n \) and \( x \).  
2. **Returns:**  
   \[
   n_n(x) = \left(\frac{\pi}{2x}\right)^{1/2} N_{n+1/2}(x), \quad \text{for } x \geq 0,
   \]

\[\text{§ 28.7.6.22}\]
where \(n\) is \(n\) and \(x\) is \(x\).

Remarks: The effect of calling each of these functions is implementation-defined if \(n >= 128\).

See also 28.7.6.11.

28.8 Numbers

28.8.1 Header <numbers> synopsis

```cpp
namespace std::numbers {
  template<class T> constexpr T e_v = unspecified;
  template<class T> constexpr T log2e_v = unspecified;
  template<class T> constexpr T log10e_v = unspecified;
  template<class T> constexpr T pi_v = unspecified;
  template<class T> constexpr T inv_pi_v = unspecified;
  template<class T> constexpr T inv_sqrtpi_v = unspecified;
  template<class T> constexpr T ln2_v = unspecified;
  template<class T> constexpr T ln10_v = unspecified;
  template<class T> constexpr T sqrt2_v = unspecified;
  template<class T> constexpr T sqrt3_v = unspecified;
  template<class T> constexpr T inv_sqrt3_v = unspecified;
  template<class T> constexpr T egamma_v = unspecified;
  template<class T> constexpr T phi_v = unspecified;

  template<floating_point T> constexpr T e_v<T> = see below;
  template<floating_point T> constexpr T log2e_v<T> = see below;
  template<floating_point T> constexpr T log10e_v<T> = see below;
  template<floating_point T> constexpr T pi_v<T> = see below;
  template<floating_point T> constexpr T inv_pi_v<T> = see below;
  template<floating_point T> constexpr T inv_sqrtpi_v<T> = see below;

  inline constexpr double egamma = egamma_v<double>;
  inline constexpr double phi = phi_v<double>;
}
```

28.8.2 Mathematical constants

1 The library-defined partial specializations of mathematical constant variable templates are initialized with the nearest representable values of \(e\), \(\log_2 e\), \(\log_{10} e\), \(\pi\), \(\frac{1}{\sqrt{2}}\), \(\frac{1}{\sqrt{3}}\), \(\ln 2\), \(\ln 10\), \(\sqrt{2}\), \(\sqrt{3}\), \(\frac{1}{\sqrt{2}}\), the Euler-Mascheroni \(\gamma\) constant, and the golden ratio \(\phi\) constant \(\frac{1 + \sqrt{5}}{2}\), respectively.

2 Pursuant to 16.4.5.2.1, a program may partially or explicitly specialize a mathematical constant variable template provided that the specialization depends on a program-defined type.

3 A program that instantiates a primary template of a mathematical constant variable template is ill-formed.
29 Time library

29.1 General

This Clause describes the chrono library (29.2) and various C functions (29.14) that provide generally useful time utilities, as summarized in Table 98.

29.3 **Cpp17Clock requirements**

1 A clock is a bundle consisting of a `duration`, a `time_point`, and a function `now()` to get the current `time_point`. The origin of the clock’s `time_point` is referred to as the clock’s `epoch`. A clock shall meet the requirements in Table 99.

2 In Table 99 C1 and C2 denote clock types. t1 and t2 are values returned by C1::now() where the call returning t1 happens before (6.9.2) the call returning t2 and both of these calls occur before C1::time_point::max().

[Note 1: This means C1 did not wrap around between t1 and t2. — end note]

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

3 [Note 2: The relative difference in durations between those reported by a given clock and the SI definition is a measure of the quality of implementation. — end note]

4 A type TC meets the `Cpp17TrivialClock` requirements if:

(4.1) TC meets the `Cpp17Clock` requirements,

(4.2) the types TC::rep, TC::duration, and TC::time_point meet the `Cpp17EqualityComparable` (Table 28) and `Cpp17LessThanComparable` (Table 29) and `Cpp17Swappable` (16.4.4.3) requirements and the requirements of numeric types (28.2),

[Note 3: This means, in particular, that operations on these types will not throw exceptions. — end note]

(4.3) the function TC::now() does not throw exceptions, and

(4.4) the type TC::time_point::clock meets the `Cpp17TrivialClock` requirements, recursively.
29.4 Time-related traits

29.4.1 `treat_as_floating_point`

```cpp
template<class Rep> struct treat_as_floating_point : is_floating_point<Rep> {);
```

The `duration` template uses the `treat_as_floating_point` trait to help determine if a `duration` object can be converted to another `duration` with a different tick period. If `treat_as_floating_point_v<Rep>` is `true`, then implicit conversions are allowed among `duration`s. Otherwise, the implicit convertibility depends on the tick periods of the `duration`s.

[Note 1: The intention of this trait is to indicate whether a given class behaves like a floating-point type, and thus allows division of one value by another with acceptable loss of precision. If `treat_as_floating_point_v<Rep>` is `false`, `Rep` will be treated as if it behaved like an integral type for the purpose of these conversions. — end note]

29.4.2 `duration_values`

```cpp
template<class Rep>
struct duration_values {
  public:
    static constexpr Rep zero() noexcept;
    static constexpr Rep min() noexcept;
    static constexpr Rep max() noexcept;
};
```

The `duration` template uses the `duration_values` trait to construct special values of the `duration`'s representation (`Rep`). This is done because the representation can be a class type with behavior that requires some other implementation to return these special values. In that case, the author of that class type should specialize `duration_values` to return the indicated values.

```cpp
class Rep;
```

1. Returns: `Rep(0)`.
   [Note 1: `Rep(0)` is specified instead of `Rep()` because `Rep()` can have some other meaning, such as an uninitialized value. — end note]

2. Remarks: The value returned shall be the additive identity.

```cpp
static constexpr Rep min() noexcept;
```

3. Remarks: The value returned shall compare less than or equal to `zero()`.

```cpp
static constexpr Rep max() noexcept;
```

5. Remarks: The value returned shall compare greater than `zero()`.

29.4.3 Specializations of `common_type`

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
struct common_type<chrono::duration<Rep1, Period1>, chrono::duration<Rep2, Period2>> {;
  using type = chrono::duration<common_type_t<Rep1, Rep2>, see below>;
};
```

1. The period of the `duration` indicated by this specialization of `common_type` is the greatest common divisor of `Period1` and `Period2`.

[Note 1: This can be computed by forming a ratio of the greatest common divisor of `Period1::num` and `Period2::num` and the least common multiple of `Period1::den` and `Period2::den`. — end note]

2. [Note 2: The typedef name `type` is a synonym for the `duration` with the largest tick period possible where both `duration` arguments will convert to it without requiring a division operation. The representation of this type is intended to be able to hold any value resulting from this conversion with no truncation error, although floating-point `duration`s can have round-off errors. — end note]

```cpp
template<class Clock, class Duration1, class Duration2>
struct common_type<chrono::time_point<Clock, Duration1>, chrono::time_point<Clock, Duration2>> {
  using type = chrono::time_point<Clock, common_type_t<Duration1, Duration2>};
```
The common type of two `time_point` types is a `time_point` with the same clock as the two types and the common type of their two durations.

### 29.4.4 Class template `is_clock`

```cpp
template<class T> struct is_clock;
```

`is_clock` is a `Cpp17UnaryTypeTrait` (21.3.2) with a base characteristic of `true_type` if `T` meets the `Cpp17Clock` requirements (29.3), otherwise `false_type`. For the purposes of the specification of this trait, the extent to which an implementation determines that a type cannot meet the `Cpp17Clock` requirements is unspecified, except that as a minimum a type `T` shall not qualify as a `Cpp17Clock` unless it meets all of the following conditions:

1. The qualified-ids `T::rep, T::period, T::duration, and T::time_point` are valid and each denotes a type (13.10.3),
2. The expression `T::is_steady` is well-formed when treated as an unevaluated operand (7.2.3),
3. The expression `T::now()` is well-formed when treated as an unevaluated operand.

The behavior of a program that adds specializations for `is_clock` is undefined.

### 29.5 Class template `duration`

#### 29.5.1 General

A `duration` type measures time between two points in time (`time_points`). A `duration` has a representation which holds a count of ticks and a tick period. The tick period is the amount of time which occurs from one tick to the next, in units of seconds. It is expressed as a rational constant using the template `ratio`.

```cpp
namespace std::chrono {
    template<class Rep, class Period = ratio<1>>
    class duration {
        using rep = Rep;
        using period = typename Period::type;

        private:
            rep rep_;  // exposition only

        public:
            // 29.5.2, construct/copy/destroy
            constexpr duration() = default;
            template<class Rep2>
                constexpr explicit duration(const Rep2& r);
            template<class Rep2, class Period2>
                constexpr duration(const duration<Rep2, Period2>& d);
            ~duration() = default;
            duration(const duration&) = default;
            duration& operator=(const duration&);

            // 29.5.3, observer
            constexpr rep count() const;

            // 29.5.4, arithmetic
            constexpr common_type_t<duration> operator+(const duration&) const;
            constexpr common_type_t<duration> operator-(const duration&) const;
            constexpr duration& operator++();
            constexpr duration& operator--();
            constexpr duration& operator+=(const duration& d);
            constexpr duration& operator-=(const duration& d);
```
constexpr duration& operator*=(const rep& rhs);
constexpr duration& operator/=(const rep& rhs);
constexpr duration& operator%=(const rep& rhs);
constexpr duration& operator%=(const duration& rhs);

// 29.5.5, special values
static constexpr duration zero() noexcept;
static constexpr duration min() noexcept;
static constexpr duration max() noexcept;
}

2 Rep shall be an arithmetic type or a class emulating an arithmetic type. If duration is instantiated with a duration type as the argument for the template parameter Rep, the program is ill-formed.

3 If Period is not a specialization of ratio, the program is ill-formed. If Period::num is not positive, the program is ill-formed.

4 Members of duration do not throw exceptions other than those thrown by the indicated operations on their representations.

5 The defaulted copy constructor of duration shall be a constexpr function if and only if the required initialization of the member rep_ for copy and move, respectively, would satisfy the requirements for a constexpr function.

6 [Example 1]:

duration<long, ratio<60>> d0; // holds a count of minutes using a long
duration<long, milli> d1; // holds a count of milliseconds using a long long
duration<double, ratio<1, 30>> d2; // holds a count with a tick period of 1/30 of a second
        // (30 Hz) using a double

— end example]

29.5.2 Constructors [time.duration.cons]

template<class Rep2>
constexpr explicit duration(const Rep2& r);

1 Constraints: is_convertible_v<const Rep2&, rep> is true and
(1.1) — treat_as_floating_point_v<rep> is true or
(1.2) — treat_as_floating_point_v<Rep2> is false.

[Example 1]:
duration<int, milli> d(3); // OK
duration<int, milli> d(3.5); // error

— end example]

2 Effects: Initializes rep_ with r.

template<class Rep2, class Period2>
constexpr duration(const duration<Rep2, Period2>& d);

3 Constraints: No overflow is induced in the conversion and treat_as_floating_point_v<rep> is true or both ratio_divide<Period2, period>::den is 1 and treat_as_floating_point_v<Rep2> is false.

[Note 1: This requirement prevents implicit truncation error when converting between integral-based duration types. Such a construction could easily lead to confusion about the value of the duration. — end note]

[Example 2]:
duration<int, milli> ms(3);
duration<int, micro> us = ms; // OK
duration<int, milli> ms2 = us; // error

— end example]

4 Effects: Initializes rep_ with duration_cast<duration>(d).count().
29.5.3 Observer

```cpp
constexpr rep count() const;
Returns: rep_.
```

29.5.4 Arithmetic

```cpp
constexpr common_type_t<duration> operator+(const duration& d);
Effects: Equivalent to: rep_ += d.count().
Returns: *this.
```

```cpp
constexpr common_type_t<duration> operator-(const duration& d);
Effects: Equivalent to: rep_ -= d.count().
Returns: *this.
```

```cpp
constexpr duration& operator*=(const rep& rhs);
Effects: Equivalent to: rep_ *= rhs.
Returns: *this.
```

```cpp
constexpr duration& operator/=(const rep& rhs);
Effects: Equivalent to: rep_ /= rhs.
Returns: *this.
```

```cpp
constexpr duration& operator%=(const rep& rhs);
Effects: Equivalent to: rep_ %= rhs.
Returns: *this.
```

```cpp
constexpr duration operator++(int);
Effects: Equivalent to: return duration(rep_++);
```

```cpp
constexpr duration operator--(int);
Effects: Equivalent to: return duration(rep_-);
```

```cpp
constexpr duration& operator+=(const duration& d);
Effects: Equivalent to: rep_ += d.count().
Returns: *this.
```

```cpp
constexpr duration operator-=(const duration& d);
Effects: Equivalent to: rep_ -= d.count().
Returns: *this.
```

```cpp
constexpr duration operator*=(const rep& rhs);
Effects: Equivalent to: rep_ *= rhs.
Returns: *this.
```

```cpp
constexpr duration operator/=(const rep& rhs);
Effects: Equivalent to: rep_ /= rhs.
Returns: *this.
```

```cpp
constexpr duration operator%=(const rep& rhs);
Effects: Equivalent to: rep_ %= rhs.
Returns: *this.
```

```cpp
constexpr duration operator%=(const duration& rhs);
Effects: Equivalent to: rep_ %= rhs.count().
Returns: *this.
```

29.5.5 Special values

```cpp
static constexpr duration zero() noexcept;
Returns: duration(duration_values<rep>::zero()).
```

§ 29.5.5
static constexpr duration min() noexcept;

Returns: duration(duration_values<rep>::min()).

static constexpr duration max() noexcept;

Returns: duration(duration_values<rep>::max()).

### 29.5.6 Non-member arithmetic

In the function descriptions that follow, unless stated otherwise, let \(CD\) represent the return type of the function.

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator+(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: CD(CD(lhs).count() + CD(rhs).count()).
```

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator-(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: CD(CD(lhs).count() - CD(rhs).count()).
```

```cpp
template<class Rep1, class Period, class Rep2>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator*(const duration<Rep1, Period>& d, const Rep2& s);

Constraints: is_convertible_v<const Rep2&, common_type_t<Rep1, Rep2>> is true.

Returns: CD(CD(d).count() * s).
```

```cpp
template<class Rep1, class Period, class Rep2>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator*(const Rep1& s, const duration<Rep2, Period>& d);

Constraints: is_convertible_v<const Rep1&, common_type_t<Rep1, Rep2>> is true.

Returns: d * s.
```

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator%(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: CD(CD(lhs).count() % CD(rhs).count()).
```

§ 29.5.6 1499
29.5.7 Comparisons

In the function descriptions that follow, \( \text{CT} \) represents \( \text{common\_type\_t}<A, B> \), where \( A \) and \( B \) are the types of the two arguments to the function.

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator==(const duration<Rep1, Period1>& lhs, 
const duration<Rep2, Period2>& rhs);
```

Returns: \( \text{CT}(\text{lhs}).\text{count}() == \text{CT}(\text{rhs}).\text{count}() \).

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<(const duration<Rep1, Period1>& lhs, 
const duration<Rep2, Period2>& rhs);
```

Returns: \( \text{CT}(\text{lhs}).\text{count}() < \text{CT}(\text{rhs}).\text{count}() \).

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>(const duration<Rep1, Period1>& lhs, 
const duration<Rep2, Period2>& rhs);
```

Returns: \( \text{rhs < lhs} \).

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<=(const duration<Rep1, Period1>& lhs, 
const duration<Rep2, Period2>& rhs);
```

Returns: \( \neg (\text{rhs < lhs}) \).

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>=(const duration<Rep1, Period1>& lhs, 
const duration<Rep2, Period2>& rhs);
```

Returns: \( \neg (\text{lhs < rhs}) \).

```cpp
template<class Rep1, class Period1, class Rep2, class Period2>
requires three\_way\_comparable<typename CT::rep>
constexpr auto operator<=>(const duration<Rep1, Period1>& lhs, 
const duration<Rep2, Period2>& rhs);
```

Returns: \( \text{CT}(\text{lhs}).\text{count}() \trianglerighteq \text{CT}(\text{rhs}).\text{count}() \).

29.5.8 Conversions

```cpp
template<class ToDuration, class Rep, class Period>
constexpr ToDuration duration\_cast(const duration<Rep, Period>& d);
```

Constraints: \( \text{ToDuration} \) is a specialization of \( \text{duration} \).

Returns: Let \( \text{CF} \) be \( \text{ratio\_divide<Period, typename ToDuration::period>} \), and \( \text{CR} \) be \( \text{common\_type<typename ToDuration::rep, Rep, intmax\_t::type>} \).  

(2.1) If \( \text{CF}::\text{num} == 1 \) and \( \text{CF}::\text{den} == 1 \), returns

\[ \text{ToDuration(static\_cast<typename ToDuration::type>(d.count()))} \]

(2.2) Otherwise, if \( \text{CF}::\text{num} != 1 \) and \( \text{CF}::\text{den} == 1 \), returns

\[ \text{ToDuration(static\_cast<typename ToDuration::type>(d.count()) * static\_cast<CR>(CF::num))} \]

(2.3) Otherwise, if \( \text{CF}::\text{num} == 1 \) and \( \text{CF}::\text{den} != 1 \), returns

\[ \text{ToDuration(static\_cast<typename ToDuration::type>(d.count()) / static\_cast<CR>(CF::den))} \]

(2.4) Otherwise, returns

\[ \text{ToDuration(static\_cast<typename ToDuration::type>(d.count()) * static\_cast<CR>(CF::num) / static\_cast<CR>(CF::den))} \]

[Note 1: This function does not use any implicit conversions; all conversions are done with \text{static\_cast}. It avoids multiplications and divisions when it is known at compile time that one or more arguments is 1. Intermediate computations are carried out in the widest representation and only converted to the destination representation at the final step. — end note]
template<class ToDuration, class Rep, class Period>
constexpr ToDuration floor(const duration<Rep, Period>& d);

Constraints: ToDuration is a specialization of duration.

Returns: The greatest result t representable in ToDuration for which t <= d.

template<class ToDuration, class Rep, class Period>
constexpr ToDuration ceil(const duration<Rep, Period>& d);

Constraints: ToDuration is a specialization of duration.

Returns: The least result t representable in ToDuration for which t >= d.

template<class ToDuration, class Rep, class Period>
constexpr ToDuration round(const duration<Rep, Period>& d);

Constraints: ToDuration is a specialization of duration and treat_as_floating_point_v<typename ToDuration::rep> is false.

Returns: The value of ToDuration that is closest to d. If there are two closest values, then return the value t for which t % 2 == 0.

### 29.5.9 Suffixes for duration literals

This subclause describes literal suffixes for constructing duration literals. The suffixes h, min, s, ms, us, ns denote duration values of the corresponding types hours, minutes, seconds, milliseconds, microseconds, and nanoseconds respectively if they are applied to integer-literals.

If any of these suffixes are applied to a floating-point-literal the result is a `chrono::duration` literal with an unspecified floating-point representation.

If any of these suffixes are applied to an integer-literal and the resulting `chrono::duration` value cannot be represented in the result type because of overflow, the program is ill-formed.

[Example 1: The following code shows some duration literals.

```cpp
using namespace std::chrono_literals;
auto constexpr aday=24h;
auto constexpr lesson=45min;
auto constexpr halfanhour=0.5h;
```

—end example]

>Returns: A duration literal representing hours hours.

Returns: A duration literal representing minutes minutes.

Returns: A duration literal representing sec seconds.

[Note 1: The same suffix s is used for `basic_string` but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. —end note]

Returns: A duration literal representing msec milliseconds.

Returns: A duration literal representing usec microseconds.

Returns: A duration literal representing nsec nanoseconds.
constexpr chrono::duration<unspecified, nano> operator"ns(long double nsec);

Returns: A duration literal representing nsec nanoseconds.

29.5.10 Algorithms

template<class Rep, class Period>
constexpr duration<Rep, Period> abs(duration<Rep, Period> d);

Constraints: numeric_limits<Rep>::is_signed is true.

Returns: If d >= d.zero(), return d, otherwise return -d.

29.5.11 I/O

template<class charT, class traits, class Rep, class Period>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const duration<Rep, Period>& d);

Effects: Inserts the duration d onto the stream os as if it were implemented as follows:

basic_ostringstream<charT, traits> s;
s.flags(os.flags());
s.imbue(os.getloc());
s.precision(os.precision());
s << d.count() << units-suffix;
return os << s.str();

where units-suffix depends on the type Period::type as follows:

(1.1) — If Period::type is atto, units-suffix is "as".
(1.2) — Otherwise, if Period::type is femto, units-suffix is "fs".
(1.3) — Otherwise, if Period::type is pico, units-suffix is "ps".
(1.4) — Otherwise, if Period::type is nano, units-suffix is "ns".
(1.5) — Otherwise, if Period::type is micro, it is implementation-defined whether units-suffix is "µs" ("\u00b5s") or "us".
(1.6) — Otherwise, if Period::type is milli, units-suffix is "ms".
(1.7) — Otherwise, if Period::type is centi, units-suffix is "cs".
(1.8) — Otherwise, if Period::type is deci, units-suffix is "ds".
(1.9) — Otherwise, if Period::type is ratio<1>, units-suffix is "s".
(1.10) — Otherwise, if Period::type is deci, units-suffix is "das".
(1.11) — Otherwise, if Period::type is hecto, units-suffix is "hs".
(1.12) — Otherwise, if Period::type is kilo, units-suffix is "ks".
(1.13) — Otherwise, if Period::type is mega, units-suffix is "Ms".
(1.14) — Otherwise, if Period::type is giga, units-suffix is "Gs".
(1.15) — Otherwise, if Period::type is tera, units-suffix is "Ts".
(1.16) — Otherwise, if Period::type is peta, units-suffix is "Ps".
(1.17) — Otherwise, if Period::type is exa, units-suffix is "Es".
(1.18) — Otherwise, if Period::type is ratio<60>, units-suffix is "min".
(1.19) — Otherwise, if Period::type is ratio<3600>, units-suffix is "h".
(1.20) — Otherwise, if Period::type is ratio<86400>, units-suffix is "d".
(1.21) — Otherwise, if Period::type::den == 1, units-suffix is "[num]s".
(1.22) — Otherwise, units-suffix is "[num/den]s".

In the list above, the use of num and den refers to the static data members of Period::type, which are converted to arrays of charT using a decimal conversion with no leading zeroes.

Returns: os.
template<class charT, class traits, class Rep, class Period, class Alloc = allocator<charT> >
basic_istream<charT, traits>&
    from_stream(basic_istream<charT, traits>& is, const charT* fmt,
                 duration<Rep, Period>& d,
                 basic_string<charT, traits, Alloc>* abbrev = nullptr,
                 minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the duration d using the format flags given in the
NTCTS fmt as specified in 29.13. If the parse fails to decode a valid duration, is.setstate(ios_base::failbit)
is called and d is not modified. If %Z is used and successfully parsed, that value will
be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully
parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

29.6 Class template time_point

29.6.1 General

namespace std::chrono {
    template<class Clock, class Duration = typename Clock::duration>
    class time_point {
        public:
            using clock = Clock;
            using duration = Duration;
            using rep = typename duration::rep;
            using period = typename duration::period;

        private:
            duration d_; // exposition only

        public:
            // 29.6.2, construct
            constexpr time_point(); // has value epoch
            constexpr explicit time_point(const duration& d); // same as time_point() + d
            template<class Duration2>
            constexpr time_point(const time_point<clock, Duration2>& t);

            // 29.6.3, observer
            constexpr duration time_since_epoch() const;

            // 29.6.4, arithmetic
            constexpr time_point& operator++();
            constexpr time_point operator++(int);
            constexpr time_point& operator--();
            constexpr time_point operator--(int);
            constexpr time_point& operator+=(const duration& d);
            constexpr time_point& operator-=(const duration& d);

            // 29.6.5, special values
            static constexpr time_point min() noexcept;
            static constexpr time_point max() noexcept;
    };
}

1 If Duration is not a specialization of duration, the program is ill-formed.

29.6.2 Constructors

constexpr time_point();

Effects: Initializes d_ with duration::zero(). Such a time_point object represents the epoch.

constexpr explicit time_point(const duration& d);

Effects: Initializes d_ with d. Such a time_point object represents the epoch + d.

§ 29.6.2 1503
```cpp
template<class Duration2>
constexpr time_point(const time_point<clock, Duration2>& t);

Constraints: is_convertible_v<Duration2, duration> is true.
Effects: Initializes d_ with t.time_since_epoch().

29.6.3 Observer

constexpr duration time_since_epoch() const;
Returns: d_.

29.6.4 Arithmetic

constexpr time_point& operator++();
Effects: Equivalent to: ++d_.
Returns: *this.

constexpr time_point operator++(int);
Effects: Equivalent to: return time_point{d_++};

constexpr time_point& operator--();
Effects: Equivalent to: --d_.
Returns: *this.

constexpr time_point operator--(int);
Effects: Equivalent to: return time_point{d_--};

constexpr time_point& operator+=(const duration& d);
Effects: Equivalent to: d_ += d.
Returns: *this.

constexpr time_point& operator-=(const duration& d);
Effects: Equivalent to: d_ -= d.
Returns: *this.

29.6.5 Special values

static constexpr time_point min() noexcept;
Returns: time_point(duration::min()).

static constexpr time_point max() noexcept;
Returns: time_point(duration::max()).

29.6.6 Non-member arithmetic

template<class Clock, class Duration1, class Rep2, class Period2>
constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>> operator+(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
Returns: CT(lhs.time_since_epoch() + rhs), where CT is the type of the return value.

template<class Rep1, class Period1, class Clock, class Duration2>
constexpr time_point<Clock, common_type_t<duration<Rep1, Period1>, Duration2>> operator+(const duration<Rep1, Period1>& lhs, const time_point<Clock, Duration2>& rhs);
Returns: rhs + lhs.

template<class Clock, class Duration1, class Rep2, class Period2>
constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>> operator-(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
Returns: CT(lhs.time_since_epoch() - rhs), where CT is the type of the return value.
```
template<class Clock, class Duration1, class Duration2>
constexpr common_type_t<Duration1, Duration2>
operator-(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

4 Returns: lhs.time_since_epoch() - rhs.time_since_epoch().

29.6.7 Comparisons

template<class Clock, class Duration1, class Duration2>
constexpr bool operator==(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

1 Returns: lhs.time_since_epoch() == rhs.time_since_epoch().

template<class Clock, class Duration1, class Duration2>
constexpr bool operator<(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

2 Returns: lhs.time_since_epoch() < rhs.time_since_epoch().

template<class Clock, class Duration1, class Duration2>
constexpr bool operator>(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

3 Returns: rhs < lhs.

template<class Clock, class Duration1, class Duration2>
constexpr bool operator<=(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

4 Returns: !(rhs < lhs).

template<class Clock, class Duration1, class Duration2>
constexpr bool operator>(=) (const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

5 Returns: !(lhs < rhs).

template<class Clock, class Duration1, class Duration2>
constexpr auto operator<=>(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

6 Returns: lhs.time_since_epoch() <=> rhs.time_since_epoch().

29.6.8 Conversions

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> time_point_cast(const time_point<Clock, Duration>& t);

1 Constraints: ToDuration is a specialization of duration.

2 Returns: time_point<Clock, ToDuration>(duration_cast<ToDuration>(t.time_since_epoch()))

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> floor(const time_point<Clock, Duration>& tp);

3 Constraints: ToDuration is a specialization of duration.

4 Returns: time_point<Clock, ToDuration>(floor<ToDuration>(tp.time_since_epoch()))

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> ceil(const time_point<Clock, Duration>& tp);

5 Constraints: ToDuration is a specialization of duration.

6 Returns: time_point<Clock, ToDuration>(ceil<ToDuration>(tp.time_since_epoch()))
template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> round(const time_point<Clock, Duration>& tp);

Constraints: ToDuration is a specialization of duration, and treat_as_floating_point_v<typename
ToDuration::rep> is false.

Returns: time_point<Clock, ToDuration>(round<ToDuration>(tp.time_since_epoch())).

29.7 Clocks

29.7.1 General

The types defined in 29.7 meet the Cpp17TrivialClock requirements (29.3) unless otherwise specified.

29.7.2 Class system_clock

29.7.2.1 Overview

namespace std::chrono {
    class system_clock {
        public:
            using rep = unspecified;
            using period = ratio<unspecified, unspecified>;
            using duration = chrono::duration<rep, period>;
            using time_point = chrono::time_point<system_clock>;
            static constexpr bool is_steady = unspecified;

            static time_point now() noexcept;

            // mapping to/from C type time_t
            static time_t to_time_t (const time_point& t) noexcept;
            static time_point from_time_t(time_t t) noexcept;
    };
}

Objects of type system_clock represent wall clock time from the system-wide realtime clock. Objects of type sys_time<Duration> measure time since 1970-01-01 00:00:00 UTC excluding leap seconds. This measure is commonly referred to as Unix time. This measure facilitates an efficient mapping between sys_time and calendar types (29.8).

Example 1:
sys_seconds{sys_days{1970y/January/1}}.time_since_epoch() is 0s.
sys_seconds{sys_days{2000y/January/1}}.time_since_epoch() is 946'684'800s, which is 10'957 * 86'400s.
—end example

29.7.2.2 Members

using system_clock::rep = unspecified;

[Note 1: This implies that rep is a signed type. —end note]

static time_t to_time_t(const time_point& t) noexcept;

Returns: A time_t object that represents the same point in time as t when both values are restricted to the coarser of the precisions of time_t and time_point. It is implementation-defined whether values are rounded or truncated to the required precision.

static time_point from_time_t(time_t t) noexcept;

Returns: A time_point object that represents the same point in time as t when both values are restricted to the coarser of the precisions of time_t and time_point. It is implementation-defined whether values are rounded or truncated to the required precision.

29.7.2.3 Non-member functions

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const sys_time<Duration>& tp);

Constraints: treat_asFloatingPoint<
<
typeName

Duration: rep

>
is

false,

and

Duration{1} < days{1}

is

true.

Effects: Equivalent to:

return os << format(os.getloc(), STATICALLY-WIDEN<charT>("{:L%F %T}

"), tp);

Example 1:

```cpp
cout << sys_seconds{0s} << '

'; // 1970-01-01 00:00:00
cout << sys_seconds{946'684'800s} << '

'; // 2000-01-01 00:00:00
cout << sys_seconds{946'688'523s} << '

'; // 2000-01-01 01:02:03
```

—end example

Effects:

os << year_month_day(dp).

Returns:

os.

template<class charT, class traits>

basic_ostream<charT, traits>&

operator<<(basic_ostream<charT, traits>& os, const sys_days& dp);

Effects:

os << year_month_day(dp).

Returns:

os.

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>

basic_istream<charT, traits>&

from_stream(basic_istream<charT, traits>& is, const charT* fmt, sys_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);

Effects:

Attempts to parse the input stream is into the sys_time tp using the format flags given in

the NTCTS fmt as specified in 29.13. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) is called and tp is not modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

Returns:

is.

29.7.3 Class utc_clock

29.7.3.1 Overview

namespace std::chrono {

class utc_clock {

public:

    using rep = a signed arithmetic type;
    using period = ratio<unspecified, unspecified>;
    using duration = chrono::duration<rep, period>;
    using time_point = chrono::time_point<utc_clock>;
    static constexpr bool is_steady = unspecified;

    static time_point now();

    template<class Duration>
    static sys_time<
<
<

common_type_t<Duration, seconds>>

to_sys(const utc_time<Duration>& t);

    template<class Duration>
    static utc_time<
<
<
<

common_type_t<Duration, seconds>>

from_sys(const sys_time<Duration>& t);
}

In contrast to sys_time, which does not take leap seconds into account, utc_clock and its associated
time_point, utc_time, count time, including leap seconds, since 1970-01-01 00:00:00 UTC.
