Working Draft, Standard for Programming Language C++

Note: this is an early draft. It’s known to be incomplet and incorrekt, and it has lots of bad formatting.
## Contents

- **Foreword** x
- **1 Scope** 1
- **2 Normative references** 2
- **3 Terms and definitions** 3
- **4 General principles** 10
  - 4.1 Implementation compliance 10
  - 4.2 Structure of this document 11
  - 4.3 Syntax notation 12
- **5 Lexical conventions** 13
  - 5.1 Separate translation 13
  - 5.2 Phases of translation 13
  - 5.3 Character sets 14
  - 5.4 Preprocessing tokens 17
  - 5.5 Alternative tokens 18
  - 5.6 Tokens 18
  - 5.7 Comments 18
  - 5.8 Header names 18
  - 5.9 Preprocessing numbers 19
  - 5.10 Identifiers 19
  - 5.11 Keywords 20
  - 5.12 Operators and punctuators 20
  - 5.13 Literals 21
- **6 Basics** 32
  - 6.1 Preamble 32
  - 6.2 Declarations and definitions 33
  - 6.3 One-definition rule 34
  - 6.4 Scope 39
  - 6.5 Name lookup 44
  - 6.6 Program and linkage 57
  - 6.7 Memory and objects 61
  - 6.8 Types 74
  - 6.9 Program execution 82
- **7 Expressions** 94
  - 7.1 Preamble 94
  - 7.2 Properties of expressions 95
  - 7.3 Standard conversions 98
  - 7.4 Usual arithmetic conversions 103
  - 7.5 Primary expressions 103
  - 7.6 Compound expressions 122
  - 7.7 Constant expressions 154
- **8 Statements** 163
  - 8.1 Preamble 163
  - 8.2 Label 164
  - 8.3 Expression statement 164
  - 8.4 Compound statement or block 164
  - 8.5 Selection statements 164

Foreword

[This page is intentionally left blank.]
1 Scope

This document specifies requirements for implementations of the C++ programming language. The first such requirement is that they implement the language, so this document also defines C++. Other requirements and relaxations of the first requirement appear at various places within this document.

C++ is a general purpose programming language based on the C programming language as described in ISO/IEC 9899:2018 *Programming languages — C* (hereinafter referred to as the *C standard*). C++ provides many facilities beyond those provided by C, including additional data types, classes, templates, exceptions, namespaces, operator overloading, function name overloading, references, free store management operators, and additional library facilities.
2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

(1.1) ISO/IEC 2382, Information technology — Vocabulary

(1.2) ISO 8601:2004, Data elements and interchange formats — Information interchange — Representation of dates and times

(1.3) ISO/IEC 9899:2018, Programming languages — C

(1.4) ISO/IEC/IEEE 9945:2009, Information Technology — Portable Operating System Interface (POSIX)

(1.5) ISO/IEC/IEEE 9945:2009/Cor 1:2013, Information Technology — Portable Operating System Interface (POSIX), Technical Corrigendum 1

(1.6) ISO/IEC/IEEE 9945:2009/Cor 2:2017, Information Technology — Portable Operating System Interface (POSIX), Technical Corrigendum 2

(1.7) ISO/IEC/IEEE 60559:2020, Information technology — Microprocessor Systems — Floating-Point arithmetic

(1.8) ISO 80000-2:2009, Quantities and units — Part 2: Mathematical signs and symbols to be used in the natural sciences and technology

The library described in ISO/IEC 9899:2018, Clause 7, is hereinafter called the C standard library.

The operating system interface described in ISO/IEC 9945:2009 is hereinafter called POSIX.

The ECMAScript Language Specification described in Standard Ecma-262 is hereinafter called ECMA-262.
3 Terms and definitions [intro.defs]

For the purposes of this document, the terms and definitions given in ISO/IEC 2382, the terms, definitions, and symbols given in ISO 80000-2:2009, and the following apply.

ISO and IEC maintain terminology databases for use in standardization at the following addresses:

— ISO Online browsing platform: available at https://www.iso.org/obp

— IEC Electropedia: available at https://www.electropedia.org/

Terms that are used only in a small portion of this document are defined where they are used and italicized where they are defined.

3.1 access [defs.access]

(execution-time action) read or modify the value of an object

[Note 1 to entry: Only gvalues of scalar type can be used to access objects. Reads of scalar objects are described in 7.3.2 and modifications of scalar objects are described in 7.6.19, 7.6.1.6, and 7.6.2.3. Attempts to read or modify an object of class type typically invoke a constructor (11.4.5) or assignment operator (11.4.6); such invocations do not themselves constitute accesses, although they may involve accesses of scalar subobjects. — end note]

3.2 arbitrary-positional stream [defs.arbitrary.stream]

(library) stream that can seek to any integral position within the length of the stream

[Note 1 to entry: Every arbitrary-positional stream is also a repositionable stream (3.48). — end note]

3.3 argument [defs.argument]

(function call expression) expression in the comma-separated list bounded by the parentheses

3.4 argument [defs.argument.macro]

(function-like macro) sequence of preprocessing tokens in the comma-separated list bounded by the parentheses

3.5 argument [defs.argument.throw]

(throw expression) operand of throw

3.6 argument [defs.argument.temp]

(template instantiation) constant-expression, type-id, or id-expression in the comma-separated list bounded by the angle brackets

3.7 block [defs.block]

(execution) wait for some condition (other than for the implementation to execute the execution steps of the thread of execution) to be satisfied before continuing execution past the blocking operation

3.8 block [defs.block.stmt]

(statement) compound statement

3.9 character [defs.character]

(library) object which, when treated sequentially, can represent text

[Note 1 to entry: The term does not mean only char, char8_t, char16_t, char32_t, and wchar_t objects (6.8.2), but any value that can be represented by a type that provides the definitions specified in Clause 23, Clause 30, Clause 31, or Clause 22. — end note]
3.10 character container type
(library) class or a type used to represent a character

[Note 1 to entry: It is used for one of the template parameters of the string, iostream, and regular expression class
templates. — end note]

3.11 collating element
sequence of one or more characters within the current locale that collate as if they were a single character

3.12 component
(library) group of library entities directly related as members, parameters, or return types

[Note 1 to entry: For example, the class template basic_string and the non-member function templates that operate
on strings are referred to as the string component. — end note]

3.13 conditionally-supported
program construct that an implementation is not required to support

[Note 1 to entry: Each implementation documents all conditionally-supported constructs that it does not support.
— end note]

3.14 constant subexpression
expression whose evaluation as subexpression of a conditional-expression CE would not prevent CE from being
a core constant expression

3.15 deadlock
(library) situation wherein one or more threads are unable to continue execution because each is blocked
waiting for one or more of the others to satisfy some condition

3.16 default behavior
(library implementation) specific behavior provided by the implementation, within the scope of the required
behavior

3.17 diagnostic message
message belonging to an implementation-defined subset of the implementation’s output messages

3.18 direct-non-list-initialization
direct-initialization that is not list-initialization

3.19 dynamic type
(glvalue) type of the most derived object to which the glvalue refers

[Example 1: If a pointer (9.3.4.2) p whose static type is “pointer to class B” is pointing to an object of class D, derived
from B (11.7), the dynamic type of the expression *p is “D”. References (9.3.4.3) are treated similarly. — end example]

3.20 dynamic type
(prvalue) static type of the prvalue expression
3.21 expression-equivalent
(library) expressions that all have the same effects, either are all potentially-throwing or are all not potentially-throwing, and either are all constant subexpressions or are all not constant subexpressions

[Example 1: For a value \( x \) of type \( \text{int} \) and a function \( f \) that accepts integer arguments, the expressions \( f(x + 2) \), \( f(2 + x) \), and \( f(1 + x + 1) \) are expression-equivalent. — end example]

3.22 finite state machine
(regular expression) unspecified data structure that is used to represent a regular expression, and which permits efficient matches against the regular expression to be obtained

3.23 format specifier
(regular expression) sequence of one or more characters that is to be replaced with some part of a regular expression match

3.24 handler function
(library) non-reserved function whose definition may be provided by a C++ program

[Note 1 to entry: A C++ program may designate a handler function at various points in its execution by supplying a pointer to the function when calling any of the library functions that install handler functions (Clause 17). — end note]

3.25 ill-formed program
program that is not well-formed (3.68)

3.26 implementation-defined behavior
behavior, for a well-formed program construct and correct data, that depends on the implementation and that each implementation documents

3.27 implementation-defined strict total order over pointers
(library) implementation-defined strict total ordering over all pointer values such that the ordering is consistent with the partial order imposed by the builtin operators \(<\), \(>\), \(<=\), \(>=\), and \(<>\)

3.28 implementation limits
restrictions imposed upon programs by the implementation

3.29 iostream class templates
(library) templates that are declared in header \(<\text{iosfwd}>\) and take two template arguments

[Note 1 to entry: The arguments are named \(\text{charT} \) and \(\text{traits} \). The argument \(\text{charT} \) is a character container class, and the argument \(\text{traits} \) is a class which defines additional characteristics and functions of the character type represented by \(\text{charT} \) necessary to implement the iostream class templates. — end note]

3.30 locale-specific behavior
behavior that depends on local conventions of nationality, culture, and language that each implementation documents

3.31 matched
(regular expression) condition when a sequence of zero or more characters correspond to a sequence of characters defined by the pattern
3.32 modifier function
(library) class member function other than a constructor, assignment operator, or destructor that alters the state of an object of the class.

3.33 move assignment
(library) assignment of an rvalue of some object type to a modifiable lvalue of the same type.

3.34 move construction
(library) direct-initialization of an object of some type with an rvalue of the same type.

3.35 non-constant library call
invocation of a library function that, as part of evaluating any expression E, prevents E from being a core constant expression.

3.36 NTCTS
(library) sequence of values that have character type that precede the terminating null character type value charT()

3.37 observer function
(library) class member function that accesses the state of an object of the class but does not alter that state.
[Note 1 to entry: Observer functions are specified as const member functions. — end note]

3.38 parameter
(function or catch clause) object or reference declared as part of a function declaration or definition or in the catch clause of an exception handler that acquires a value on entry to the function or handler.

3.39 parameter
(function-like macro) identifier from the comma-separated list bounded by the parentheses immediately following the macro name.

3.40 parameter
(template) member of a template-parameter-list.

3.41 primary equivalence class
(regular expression) set of one or more characters which share the same primary sort key: that is the sort key weighting that depends only upon character shape, and not accents, case, or locale specific tailorings.

3.42 program-defined specialization
(library) explicit template specialization or partial specialization that is not part of the C++ standard library and not defined by the implementation.

3.43 program-defined type
(library) non-closure class type or enumeration type that is not part of the C++ standard library and not defined by the implementation, or a closure type of a non-implementation-provided lambda expression, or an instantiation of a program-defined specialization.
[Note 1 to entry: Types defined by the implementation include extensions (4.1) and internal types used by the library. — end note]
3.44 projection
(library) transformation that an algorithm applies before inspecting the values of elements

Example 1:
```cpp
std::pair<int, std::string_view> pairs[] = {{2, "foo"}, {1, "bar"}, {0, "baz"}};
std::ranges::sort(pairs, std::ranges::less{}, [] (auto const& p) { return p.first; });
```
sorts the pairs in increasing order of their first members:

```cpp
{{0, "baz"}, {1, "bar"}, {2, "foo"}}
```
— end example

3.45 referenceable type
(type that is either an object type, a function type that does not have cv-qualifiers or a ref-qualifier, or a reference type

[Note 1 to entry: The term describes a type to which a reference can be created, including reference types. — end note]

3.46 regular expression
(pattern that selects specific strings from a set of character strings

3.47 replacement function
(library) non-reserved function whose definition is provided by a C++ program

[Note 1 to entry: Only one definition for such a function is in effect for the duration of the program’s execution, as the result of creating the program (5.2) and resolving the definitions of all translation units (6.6). — end note]

3.48 repositional stream
(library) stream that can seek to a position that was previously encountered

3.49 required behavior
(library) description of replacement function and handler function semantics applicable to both the behavior provided by the implementation and the behavior of any such function definition in the program

[Note 1 to entry: If such a function defined in a C++ program fails to meet the required behavior when it executes, the behavior is undefined. — end note]

3.50 reserved function
(library) function, specified as part of the C++ standard library, that is defined by the implementation

[Note 1 to entry: If a C++ program provides a definition for any reserved function, the results are undefined. — end note]

3.51 signature
(name, parameter-type-list, and enclosing namespace

[Note 1 to entry: Signatures are used as a basis for name mangling and linking. — end note]

3.52 signature
(non-template friend function with trailing requires-clause) name, parameter-type-list, enclosing class, and trailing requires-clause

3.53 signature
(function template) name, parameter-type-list, enclosing namespace, return type, signature of the template-head, and trailing requires-clause (if any)
3.54 [defs.signature.templ.friend]
signature
(friend function template with constraint involving enclosing template parameters) name, parameter-type-list, return type, enclosing class, signature of the template-head, and trailing requires-clause (if any)

3.55 [defs.signature.spec]
signature
(function template specialization) signature of the template of which it is a specialization and its template arguments (whether explicitly specified or deduced)

3.56 [defs.signature.member]
signature
(class member function) name, parameter-type-list, class of which the function is a member, cv-qualifiers (if any), ref-qualifier (if any), and trailing requires-clause (if any)

3.57 [defs.signature.member.templ]
signature
(class member function template) name, parameter-type-list, class of which the function is a member, cv-qualifiers (if any), ref-qualifier (if any), return type (if any), signature of the template-head, and trailing requires-clause (if any)

3.58 [defs.signature.member.spec]
signature
(class member function template specialization) signature of the member function template of which it is a specialization and its template arguments (whether explicitly specified or deduced)

3.59 [defs.signature.template.head]
signature
(template-head) template parameter list, excluding template parameter names and default arguments, and requires-clause (if any)

3.60 [defs.stable]
stable algorithm
(library) algorithm that preserves, as appropriate to the particular algorithm, the order of elements

[Note 1 to entry: Requirements for stable algorithms are given in 16.4.6.8. — end note]

3.61 [defs.static.type]
static type
type of an expression resulting from analysis of the program without considering execution semantics

[Note 1 to entry: The static type of an expression depends only on the form of the program in which the expression appears, and does not change while the program is executing. — end note]

3.62 [defs.regex.subexpression]
sub-expression
(regular expression) subset of a regular expression that has been marked by parentheses

3.63 [defs.traits]
traits class
(library) class that encapsulates a set of types and functions necessary for class templates and function templates to manipulate objects of types for which they are instantiated

3.64 [defs.unblock]
unblock
satisfy a condition that one or more blocked threads of execution are waiting for
3.65 undefined behavior
behavior for which this document imposes no requirements

[Note 1 to entry: Undefined behavior may be expected when this document omits any explicit definition of behavior
or when a program uses an erroneous construct or erroneous data. Permissible undefined behavior ranges from
ignoring the situation completely with unpredictable results, to behaving during translation or program execution in
a documented manner characteristic of the environment (with or without the issuance of a diagnostic message), to
terminating a translation or execution (with the issuance of a diagnostic message). Many erroneous program constructs
do not engender undefined behavior; they are required to be diagnosed. Evaluation of a constant expression (7.7)
never exhibits behavior explicitly specified as undefined in Clause 4 through Clause 15. — end note]

3.66 unspecified behavior
behavior, for a well-formed program construct and correct data, that depends on the implementation

[Note 1 to entry: The implementation is not required to document which behavior occurs. The range of possible
behaviors is usually delineated by this document. — end note]

3.67 valid but unspecified state
〈library〉 value of an object that is not specified except that the object’s invariants are met and operations on
the object behave as specified for its type

[Example 1: If an object x of type std::vector<int> is in a valid but unspecified state, x.empty() can be called
unconditionally, and x.front() can be called only if x.empty() returns false. — end example]

3.68 well-formed program
C++ program constructed according to the syntax and semantic rules
4 General principles

4.1 Implementation compliance

4.1.1 General

1 The set of diagnosable rules consists of all syntactic and semantic rules in this document except for those rules containing an explicit notation that “no diagnostic is required” or which are described as resulting in “undefined behavior”.

2 Although this document states only requirements on C++ implementations, those requirements are often easier to understand if they are phrased as requirements on programs, parts of programs, or execution of programs. Such requirements have the following meaning:

(2.1) — If a program contains no violations of the rules in Clause 5 through Clause 33 and Annex D, a conforming implementation shall, within its resource limits as described in Annex B, accept and correctly execute that program.

(2.2) — If a program contains a violation of a rule for which no diagnostic is required, this document places no requirement on implementations with respect to that program.

(2.3) — Otherwise, if a program contains a violation of any diagnosable rule or an occurrence of a construct described in this document as “conditionally-supported” when the implementation does not support that construct, a conforming implementation shall issue at least one diagnostic message.

[Note 1: During template argument deduction and substitution, certain constructs that in other contexts require a diagnostic are treated differently; see 13.10.3. — end note]

Furthermore, a conforming implementation

(2.4) — shall not accept a preprocessing translation unit containing a \#error preprocessing directive (15.8),

(2.5) — shall issue at least one diagnostic message for each \#warning or \#error preprocessing directive not following a \#error preprocessing directive in a preprocessing translation unit, and

(2.6) — shall not accept a translation unit with a static_assert-declaration that fails (9.1).

3 For classes and class templates, the library Clauses specify partial definitions. Private members (11.8) are not specified, but each implementation shall supply them to complete the definitions according to the description in the library Clauses.

4 For functions, function templates, objects, and values, the library Clauses specify declarations. Implementations shall supply definitions consistent with the descriptions in the library Clauses.

5 A C++ translation unit (5.2) obtains access to the names defined in the library by including the appropriate standard library header or importing the appropriate standard library named header unit (16.4.3.2).

6 The templates, classes, functions, and objects in the library have external linkage (6.6). The implementation provides definitions for standard library entities, as necessary, while combining translation units to form a complete C++ program (5.2).

7 Two kinds of implementations are defined: a hosted implementation and a freestanding implementation. A freestanding implementation is one in which execution may take place without the benefit of an operating system. A hosted implementation supports all the facilities described in this document, while a freestanding implementation supports the entire C++ language described in Clause 5 through Clause 15 and the subset of the library facilities described in 16.4.2.5.

8 A conforming implementation may have extensions (including additional library functions), provided they do not alter the behavior of any well-formed program. Implementations are required to diagnose programs that use such extensions that are ill-formed according to this document. Having done so, however, they can compile and execute such programs.

9 Each implementation shall include documentation that identifies all conditionally-supported constructs that it does not support and defines all locale-specific characteristics.5

4) “Correct execution” can include undefined behavior, depending on the data being processed; see Clause 3 and 6.9.1.

5) This documentation also defines implementation-defined behavior; see 4.1.2.
4.1.2 Abstract machine

The semantic descriptions in this document define a parameterized nondeterministic abstract machine. This document places no requirement on the structure of conforming implementations. In particular, they need not copy or emulate the structure of the abstract machine. Rather, conforming implementations are required to emulate (only) the observable behavior of the abstract machine as explained below.\(^6\)

Certain aspects and operations of the abstract machine are described in this document as implementation-defined (for example, \texttt{sizeof(int)}). These constitute the parameters of the abstract machine. Each implementation shall include documentation describing its characteristics and behavior in these respects.\(^7\) Such documentation shall define the instance of the abstract machine that corresponds to that implementation (referred to as the “corresponding instance” below).

Certain other aspects and operations of the abstract machine are described in this document as unspecified (for example, order of evaluation of arguments in a function call (7.6.1.3)). Where possible, this document defines a set of allowable behaviors. These define the nondeterministic aspects of the abstract machine. An instance of the abstract machine can thus have more than one possible execution for a given program and a given input.

Certain other operations are described in this document as undefined (for example, the effect of attempting to modify a \texttt{const} object).

\[\text{Note 1: This document imposes no requirements on the behavior of programs that contain undefined behavior.}\]

A conforming implementation executing a well-formed program shall produce the same observable behavior as one of the possible executions of the corresponding instance of the abstract machine with the same program and the same input. However, if any such execution contains an undefined operation, this document places no requirement on the implementation executing that program with that input (not even with regard to operations preceding the first undefined operation).

The least requirements on a conforming implementation are:

\begin{itemize}
  \item \texttt{Accesses through volatile glvalues are evaluated strictly according to the rules of the abstract machine.}
  \item \texttt{At program termination, all data written into files shall be identical to one of the possible results that execution of the program according to the abstract semantics would have produced.}
  \item \texttt{The input and output dynamics of interactive devices shall take place in such a fashion that prompting output is actually delivered before a program waits for input. What constitutes an interactive device is implementation-defined.}
\end{itemize}

These collectively are referred to as the \textit{observable behavior} of the program.

\[\text{Note 2: More stringent correspondences between abstract and actual semantics can be defined by each implementation.}\]

4.2 Structure of this document

Clause 5 through Clause 15 describe the C++ programming language. That description includes detailed syntactic specifications in a form described in 4.3. For convenience, Annex A repeats all such syntactic specifications.

Clause 17 through Clause 33 and Annex D (the \textit{library clauses}) describe the C++ standard library. That description includes detailed descriptions of the entities and macros that constitute the library, in a form described in Clause 16.

Annex B recommends lower bounds on the capacity of conforming implementations.

Annex C summarizes the evolution of C++ since its first published description, and explains in detail the differences between C++ and C. Certain features of C++ exist solely for compatibility purposes; Annex D describes those features.

\[\text{Note 6: This provision is sometimes called the “as-if” rule, because an implementation is free to disregard any requirement of this document as long as the result is as if the requirement had been obeyed, as far as can be determined from the observable behavior of the program. For instance, an actual implementation need not evaluate part of an expression if it can deduce that its value is not used and that no side effects affecting the observable behavior of the program are produced.}\]

\[\text{Note 7: This documentation also includes conditionally-supported constructs and locale-specific behavior. See 4.1.1.}\]
4.3 Syntax notation

1 In the syntax notation used in this document, syntactic categories are indicated by *italic* type, and literal words and characters in *constant width* type. Alternatives are listed on separate lines except in a few cases where a long set of alternatives is marked by the phrase “one of”. If the text of an alternative is too long to fit on a line, the text is continued on subsequent lines indented from the first one. An optional terminal or non-terminal symbol is indicated by the subscript “opt”, so

\[
\{ \text{expression}_{\text{opt}} \}
\]

indicates an optional expression enclosed in braces.

2 Names for syntactic categories have generally been chosen according to the following rules:

(2.1) — *X-name* is a use of an identifier in a context that determines its meaning (e.g., *class-name*, *typedef-name*).

(2.2) — *X-id* is an identifier with no context-dependent meaning (e.g., *qualified-id*).

(2.3) — *X-seq* is one or more *X*s without intervening delimiters (e.g., *declaration-seq* is a sequence of declarations).

(2.4) — *X-list* is one or more *X*s separated by intervening commas (e.g., *identifier-list* is a sequence of identifiers separated by commas).
5 Lexical conventions

5.1 Separate translation

The text of the program is kept in units called source files in this document. A source file together with all the headers (16.4.2.3) and source files included (15.3) via the preprocessing directive #include, less any source lines skipped by any of the conditional inclusion (15.2) preprocessing directives, is called a preprocessing translation unit.

[Note 1: A C++ program need not all be translated at the same time. — end note]

The separate translation units of a program communicate (6.6) by (for example) calls to functions whose identifiers have external or module linkage, manipulation of objects whose identifiers have external or module linkage, or manipulation of data files. Translation units can be separately translated and then later linked to produce an executable program (6.6). — end note]

5.2 Phases of translation

The precedence among the syntax rules of translation is specified by the following phases.

1. An implementation shall support input files that are a sequence of UTF-8 code units (UTF-8 files). It may also support an implementation-defined set of other kinds of input files, and, if so, the kind of an input file is determined in an implementation-defined manner that includes a means of designating input files as UTF-8 files, independent of their content.

[Note 1: In other words, recognizing the U+FEFF BYTE ORDER MARK is not sufficient. — end note]

If an input file is determined to be a UTF-8 file, then it shall be a well-formed UTF-8 code unit sequence and it is decoded to produce a sequence of Unicode scalar values. A sequence of translation character set elements is then formed by mapping each Unicode scalar value to the corresponding translation character set element. In the resulting sequence, each pair of characters in the input sequence consisting of U+000D CARRIAGE RETURN followed by U+000A LINE FEED, as well as each U+000D CARRIAGE RETURN not immediately followed by a U+000A LINE FEED, is replaced by a single new-line character. For any other kind of input file supported by the implementation, characters are mapped, in an implementation-defined manner, to a sequence of translation character set elements (5.3), representing end-of-line indicators as new-line characters.

2. If the first translation character is U+FEFF BYTE ORDER MARK, it is deleted. Each sequence of a backslash character (\) immediately followed by zero or more whitespace characters other than new-line followed by a new-line character is deleted, splicing physical source lines to form logical source lines. Only the last backslash on any physical source line shall be eligible for being part of such a splice. Except for splices reverted in a raw string literal, if a splice results in a character sequence that matches the syntax of a universal-character-name, the behavior is undefined. A source file that is not empty and that does not end in a new-line character, or that ends in a splice, shall be processed as if an additional new-line character were appended to the file.

3. The source file is decomposed into preprocessing tokens (5.4) and sequences of whitespace characters (including comments). A source file shall not end in a partial preprocessing token or in a partial comment. Each comment is replaced by one space character. New-line characters are retained. Whether each nonempty sequence of whitespace characters other than new-line is retained or replaced by one space character is unspecified. As characters from the source file are consumed to form the next preprocessing token (i.e., not being consumed as part of a comment or other forms of whitespace), except when matching a c-char-sequence, s-char-sequence, r-char-sequence, h-char-sequence, or q-char-sequence, universal-character-names are recognized and replaced by the designated element of the translation character set. The process of dividing a source file’s characters into preprocessing tokens is context-dependent.

8) Implementations behave as if these separate phases occur, although in practice different phases can be folded together.

9) A partial preprocessing token would arise from a source file ending in the first portion of a multi-character token that requires a terminating sequence of characters, such as a header-name that is missing the closing * or >. A partial comment would arise from a source file ending with an unclosed /* comment.
4. Preprocessing directives are executed, macro invocations are expanded, and _Pragma unary operator expressions are executed. A #include preprocessing directive causes the named header or source file to be processed from phase 1 through phase 4, recursively. All preprocessing directives are then deleted.

5. For a sequence of two or more adjacent string-literal tokens, a common encoding-prefix is determined as specified in 5.13.5. Each such string-literal token is then considered to have that common encoding-prefix.

6. Adjacent string-literal tokens are concatenated (5.13.5).

7. Whitespace characters separating tokens are no longer significant. Each preprocessing token is converted into a token (5.6). The resulting tokens constitute a translation unit and are syntactically and semantically analyzed and translated.

8. Translated translation units and instantiation units are combined as follows:

9. All external entity references are resolved. Library components are linked to satisfy external references to entities not defined in the current translation. All such translator output is collected into a program image which contains information needed for execution in its execution environment.

5.3 Character sets

The translation character set consists of the following elements:

1. Each abstract character assigned a code point in the Unicode codespace, and
2. A distinct character for each Unicode scalar value not assigned to an abstract character.

The basic character set is a subset of the translation character set, consisting of 96 characters as specified in Table 1.

The universal-character-name construct provides a way to name other characters.

n-char: one of

any member of the translation character set except the U+007D RIGHT CURLY BRACKET or new-line character

n-char-sequence:

n-char

n-char-sequence n-char

named-universal-character:
\N{ n-char-sequence }

hex-quad:
hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit

simple-hexadecimal-digit-sequence:
hexadecimal-digit
simple-hexadecimal-digit-sequence hexadecimal-digit

universal-character-name:
\u hex-quad
\U hex-quad hex-quad
\u{ simple-hexadecimal-digit-sequence }

designates the character in the translation character set whose Unicode scalar value is the hexadecimal number represented by the sequence of hexadecimal-digits in the universal-character-name. The program is ill-formed if that number is not a Unicode scalar value.

4 A universal-character-name of the form \u hex-quad, \U hex-quad hex-quad, or \u{simple-hexadecimal-digit-sequence} designates the character in the translation character set whose Unicode scalar value is the hexadecimal number represented by the sequence of hexadecimal-digits in the universal-character-name. The program is ill-formed if that number is not a Unicode scalar value.

5 A universal-character-name that is a named-universal-character designates the corresponding character in the Unicode Standard (chapter 4.8 Name) if the n-char-sequence is equal to its character name or to one of its character name aliases of type “control”, “correction”, or “alternate”; otherwise, the program is ill-formed.

[Note 3: These aliases are listed in the Unicode Character Database’s NameAliases.txt. None of these names or aliases have leading or trailing spaces. — end note]

6 If a universal-character-name outside the c-char-sequence, s-char-sequence, or r-char-sequence of a character-literal or string-literal (in either case, including within a user-defined-literal) corresponds to a control character or to a character in the basic character set, the program is ill-formed.

[Note 4: A sequence of characters resembling a universal-character-name in an r-char-sequence (5.13.5) does not form a universal-character-name. — end note]

7 The basic literal character set consists of all characters of the basic character set, plus the control characters specified in Table 2.

8 A code unit is an integer value of character type (6.8.2). Characters in a character-literal other than a multicharacter or non-encodable character literal or in a string-literal are encoded as a sequence of one or more code units, as determined by the encoding-prefix (5.13.3, 5.13.5); this is termed the respective literal encoding. The ordinary literal encoding is the encoding applied to an ordinary character or string literal. The wide literal encoding is the encoding applied to a wide character or string literal.

9 A literal encoding or a locale-specific encoding of one of the execution character sets (16.3.3.3.4) encodes each element of the basic literal character set as a single code unit with non-negative value, distinct from the code unit for any other such element.

[Note 5: A character not in the basic literal character set can be encoded with more than one code unit; the value of such a code unit can be the same as that of a code unit for an element of the basic literal character set. — end note]

The U+0000 NULL character is encoded as the value 0. No other element of the translation character set is encoded with a code unit of value 0. The code unit value of each decimal digit character after the digit 0 (U+0030) shall be one greater than the value of the previous. The ordinary and wide literal encodings are otherwise implementation-defined. For a UTF-8, UTF-16, or UTF-32 literal, the Unicode scalar value corresponding to each character of the translation character set is encoded as specified in the Unicode Standard for the respective Unicode encoding form.
5.4 Preprocessing tokens

preprocessing-token:
  header-name
  import-keyword
  module-keyword
  export-keyword
  identifier
  pp-number
  character-literal
  user-defined-character-literal
  string-literal
  user-defined-string-literal
  preprocessing-op-or-punc
  each non-whitespace character that cannot be one of the above

1 Each preprocessing token that is converted to a token (5.6) shall have the lexical form of a keyword, an identifier, a literal, or an operator or punctuator.

2 A preprocessing token is the minimal lexical element of the language in translation phases 3 through 6. In this document, glyphs are used to identify elements of the basic character set (5.3). The categories of preprocessing token are: header names, placeholder tokens produced by preprocessing import and module directives (import-keyword, module-keyword, and export-keyword), identifiers, preprocessing numbers, character literals (including user-defined character literals), string literals (including user-defined string literals), preprocessing operators and punctuators, and single non-whitespace characters that do not lexically match the other preprocessing token categories. If a U+0027 APOSTROPHE or a U+0022 QUOTATION MARK character matches the last category, the behavior is undefined. If any character not in the basic character set matches the last category, the program is ill-formed. Preprocessing tokens can be separated by whitespace; this consists of comments (5.7), or whitespace characters (U+0020 SPACE, U+0009 CHARACTER TABULATION, new-line, U+000B LINE TABULATION, and U+000C FORM FEED), or both. As described in Clause 15, in certain circumstances during translation phase 4, whitespace (or the absence thereof) serves as more than preprocessing token separation. Whitespace can appear within a preprocessing token only as part of a header name or between the quotation characters in a character literal or string literal.

3 If the input stream has been parsed into preprocessing tokens up to a given character:

(3.1) — If the next character begins a sequence of characters that could be the prefix and initial double quote of a raw string literal, such as R", the next preprocessing token shall be a raw string literal. Between the initial and final double quote characters of the raw string, any transformations performed in phase 2 (line splicing) are reverted; this reversion shall apply before any d-char, r-char, or delimiting parenthesis is identified. The raw string literal is defined as the shortest sequence of characters that matches the raw-string pattern

  encoding-prefixopt R raw-string

(3.2) — Otherwise, if the next three characters are <:: and the subsequent character is neither : nor >, the < is treated as a preprocessing token by itself and not as the first character of the alternative token <:.

(3.3) — Otherwise, the next preprocessing token is the longest sequence of characters that could constitute a preprocessing token, even if that would cause further lexical analysis to fail, except that a header-name (5.8) is only formed

(3.3.1) — after the include or import preprocessing token in an #include (15.3) or import (15.5) directive, or

(3.3.2) — within a has-include-expression.

[Example 1:]  
#define R "x"
const char* s = R"y";  // ill-formed raw string, not "x" "y"
— end example]

4 The import-keyword is produced by processing an import directive (15.5), the module-keyword is produced by preprocessing a module directive (15.4), and the export-keyword is produced by preprocessing either of the previous two directives.

[Note 1: None has any observable spelling. — end note]
Example 2: The program fragment 0xe+foo is parsed as a preprocessing number token (one that is not a valid integer-literal or floating-point-literal token), even though a parse as three preprocessing tokens 0xe, +, and foo can produce a valid expression (for example, if foo is a macro defined as 1). Similarly, the program fragment 1E1 is parsed as a preprocessing number (one that is a valid floating-point-literal token), whether or not E is a macro name. — end example

Example 3: The program fragment x+++++y is parsed as x ++ ++ + y, which, if x and y have integral types, violates a constraint on increment operators, even though the parse x ++ + ++ y can yield a correct expression. — end example

5.5 Alternative tokens

Alternative token representations are provided for some operators and punctuators. Alternative token representations are provided for some operators and punctuators. In all respects of the language, each alternative token behaves the same, respectively, as its primary token, except for its spelling.

Table 3: Alternative tokens

5.6 Tokens

token: identifier keyword literal operator-or-punctuator

There are five kinds of tokens: identifiers, keywords, literals, operators, and other separators. Blanks, horizontal and vertical tabs, newlines, formfeeds, and comments (collectively, “whitespace”), as described below, are ignored except as they serve to separate tokens. [Note 1: Some whitespace is required to separate otherwise adjacent identifiers, keywords, numeric literals, and alternative tokens containing alphabetic characters. — end note]

5.7 Comments

The characters /* start a comment, which terminates with the characters */. These comments do not nest. The characters // start a comment, which terminates immediately before the next new-line character. If there is a form-feed or a vertical-tab character in such a comment, only whitespace characters shall appear between it and the new-line that terminates the comment; no diagnostic is required. [Note 1: The comment characters //, /*, and */ have no special meaning within a // comment and are treated just like other characters. Similarly, the comment characters // and */ have no special meaning within a /* comment. — end note]

5.8 Header names

header-name: < h-char-sequence > * q-char-sequence *
The sequences in both forms of header-names are mapped in an implementation-defined manner to headers or to external source file names as specified in 15.3.

1 [Note 1: Header name preprocessing tokens only appear within a #include preprocessing directive, a __has_include preprocessing expression, or after certain occurrences of an import token (see 5.4). — end note]

The appearance of either of the characters ' or \ or of either of the character sequences */ or // in a q-char-sequence or an h-char-sequence is conditionally-supported with implementation-defined semantics, as is the appearance of the character " in an h-char-sequence. 13

5.9 Preprocessing numbers  [lex.pppnumber]

\[ p\mathrm{p-number}: \]
\[ \text{digit} \]
\[ . \text{digit} \]
\[ \text{pp-number identifier-continue} \]
\[ \text{pp-number } \text{digit} \]
\[ \text{pp-number } \text{nondigit} \]
\[ \text{pp-number } \text{e sign} \]
\[ \text{pp-number } \text{E sign} \]
\[ \text{pp-number } \text{p sign} \]
\[ \text{pp-number } \text{P sign} \]
\[ \text{pp-number } . \]

1 Preprocessing number tokens lexically include all integer-literal tokens (5.13.2) and all floating-point-literal tokens (5.13.4).

2 A preprocessing number does not have a type or a value; it acquires both after a successful conversion to an integer-literal token or a floating-point-literal token.

5.10 Identifiers  [lex.name]

\[ \text{identifier}: \]
\[ \text{identifier-start} \]
\[ \text{identifier identifier-continue} \]

\[ \text{identifier-start}: \]
\[ \text{nondigit} \]
\[ \text{an element of the translation character set with the Unicode property XID_Start} \]

\[ \text{identifier-continue}: \]
\[ \text{digit} \]
\[ \text{nondigit} \]
\[ \text{an element of the translation character set with the Unicode property XID_Continue} \]

\[ \text{nondigit}: \text{one of} \]
\[ a \; b \; c \; d \; e \; f \; g \; h \; i \; j \; k \; l \; m \]
\[ n \; o \; p \; q \; r \; s \; t \; u \; v \; w \; x \; y \; z \]
\[ A \; B \; C \; D \; E \; F \; G \; I \; J \; K \; L \; M \]
\[ N \; O \; P \; Q \; R \; S \; T \; U \; V \; W \; X \; Y \; Z \; _ \]

\[ \text{digit}: \text{one of} \]
\[ 0 \; 1 \; 2 \; 3 \; 4 \; 5 \; 6 \; 7 \; 8 \; 9 \]

13) Thus, a sequence of characters that resembles an escape sequence can result in an error, be interpreted as the character corresponding to the escape sequence, or have a completely different meaning, depending on the implementation.

§ 5.10
The program is ill-formed if an _identifier_ does not conform to Normalization Form C as specified in the Unicode Standard.

**Note 2:** Identifiers are case-sensitive. — end note

**Note 3:** In translation phase 4, _identifier_ also includes those _preprocessing-tokens_ (5.4) differentiated as keywords (5.11) in the later translation phase 7 (5.6). — end note

1 The identifiers in Table 4 have a special meaning when appearing in a certain context. When referred to in the grammar, these identifiers are used explicitly rather than using the _identifier_ grammar production. Unless otherwise specified, any ambiguity as to whether a given _identifier_ has a special meaning is resolved to interpret the token as a regular _identifier_.

Table 4: Identifiers with special meaning

<table>
<thead>
<tr>
<th>final</th>
<th>import</th>
<th>module</th>
<th>override</th>
</tr>
</thead>
</table>

3 In addition, some identifiers appearing as a _token_ or _preprocessing-token_ are reserved for use by C++ implementations and shall not be used otherwise; no diagnostic is required.

(3.1) — Each identifier that contains a double underscore `__` or begins with an underscore followed by an uppercase letter is reserved to the implementation for any use.

(3.2) — Each identifier that begins with an underscore is reserved to the implementation for use as a name in the global namespace.

5.11 Keywords

`keyword`: any identifier listed in Table 5

`import-keyword` `module-keyword` `export-keyword`

1 The identifiers shown in Table 5 are reserved for use as keywords (that is, they are unconditionally treated as keywords in phase 7) except in an _attribute-token_ (9.12.1).

**Note 1:** The _register_ keyword is unused but is reserved for future use. — end note

2 Furthermore, the alternative representations shown in Table 6 for certain operators and punctuators (5.5) are reserved and shall not be used otherwise.

5.12 Operators and punctuators

`preprocessing-op-or-punc:` `preprocessing-operator` `operator-or-punctuator`

`preprocessing-operator`: one of `#` `##` `%` `%:%`

1 The lexical representation of C++ programs includes a number of preprocessing tokens that are used in the syntax of the preprocessor or are converted into tokens for operators and punctuators:

---

14) On systems in which linkers cannot accept extended characters, an encoding of the _universal-character-name_ can be used in forming valid external identifiers. For example, some otherwise unused character or sequence of characters can be used to encode the `\u` in a _universal-character-name_. Extended characters can produce a long external identifier, but C++ does not place a translation limit on significant characters for external identifiers.
Table 5: Keywords  [tab:lex.key]

| alignas | constinit | false | public | true   |
| alignof | const_cast | float | register | try    |
| asm     | continue | for | reinterpret_cast | typedef |
| auto    | co_await | friend | requires | typeid |
| bool    | co_return | goto | return | typename |
| break   | co_yield | if | short | union |
| case    | decением | inline | signed | unsigned |
| catch   | default | int | sizeof | using |
| char    | delete | long | static | virtual |
| char8_t | do | mutable | static_assert | void |
| char16_t | double | namespace | static_cast | volatile |
| char32_t | dynamic_cast | new | struct | wchar_t |
| class   | else | noexcept | switch | while |
| concept | enum | nullptr | template | |
| const   | explicit | operator | this | |
| consteval | export | private | thread_local | |
| constexpr | extern | protected | throw | |

Table 6: Alternative representations  [tab:lex.key.digraph]

<table>
<thead>
<tr>
<th>and</th>
<th>and_eq</th>
<th>bitand</th>
<th>bitor</th>
<th>compl</th>
<th>not</th>
</tr>
</thead>
<tbody>
<tr>
<td>not_eq</td>
<td>or</td>
<td>or_eq</td>
<td>xor</td>
<td>xor_eq</td>
<td></td>
</tr>
</tbody>
</table>

Each `operator-or-punctuator` is converted to a single token in translation phase 7 (5.2).

5.13 Literals  [lex.literal]

5.13.1 Kinds of literals  [lex.literal.kinds]

There are several kinds of literals.\footnote{The term “literal” generally designates, in this document, those tokens that are called “constants” in ISO C.}

---

§ 5.13.2 Integer literals  [lex.icon]

integer-literal:
- binary-literal integer-suffix\textsubscript{opt}
- octal-literal integer-suffix\textsubscript{opt}
- decimal-literal integer-suffix\textsubscript{opt}
- hexadecimal-literal integer-suffix\textsubscript{opt}

\footnote{The term “literal” generally designates, in this document, those tokens that are called “constants” in ISO C.}
binary-literal:
  0b binary-digit
  0B binary-digit
binary-literal ’opt binary-digit

octal-literal:
  0
  octal-literal ’opt octal-digit

decimal-literal:
  nonzero-digit
  decimal-literal ’opt digit

decimal-literal:
  hexadecimal-prefix hexadecimal-digit-sequence
  hexadecimal-prefix hexadecimal-digit-sequence ’opt hexadecimal-digit

hexadecimal-digit: one of
  0 1

octal-digit: one of
  0 1 2 3 4 5 6 7

nonzero-digit: one of
  1 2 3 4 5 6 7 8 9

hexadecimal-prefix: one of
  0x 0X

hexadecimal-digit-sequence:
  hexadecimal-digit
  hexadecimal-digit-sequence ’opt hexadecimal-digit

hexadecimal-digit: one of
  0 1 2 3 4 5 6 7 8 9
  a b c d e f
  A B C D E F

integer-suffix:
  unsigned-suffix long-suffixopt
  unsigned-suffix long-long-suffixopt
  unsigned-suffix size-suffixopt
  long-suffix unsigned-suffixopt
  long-long-suffix unsigned-suffixopt
  size-suffix unsigned-suffixopt

unsigned-suffix: one of
  u U

long-suffix: one of
  l L

long-long-suffix: one of
  ll LL

size-suffix: one of
  z Z

1 In an integer-literal, the sequence of binary-digits, octal-digits, digits, or hexadecimal-digits is interpreted as a base N integer as shown in table Table 7; the lexically first digit of the sequence of digits is the most significant.

[Note 1: The prefix and any optional separating single quotes are ignored when determining the value. — end note]

Table 7: Base of integer-literals [tab:lex.icon.base]

<table>
<thead>
<tr>
<th>Kind of integer-literal</th>
<th>base N</th>
</tr>
</thead>
<tbody>
<tr>
<td>binary-literal</td>
<td>2</td>
</tr>
<tr>
<td>octal-literal</td>
<td>8</td>
</tr>
<tr>
<td>decimal-literal</td>
<td>10</td>
</tr>
<tr>
<td>hexadecimal-literal</td>
<td>16</td>
</tr>
</tbody>
</table>

2 The hexadecimal-digits a through f and A through F have decimal values ten through fifteen.
The type of an integer-literal is the first type in the list in Table 8 corresponding to its optional integer-suffix in which its value can be represented.

3

Table 8: Types of integer-literals

<table>
<thead>
<tr>

<td>unsigned long int</td>
</tr>
<tr>
<td>ll or LL</td>
<td>long long int</td>
<td>long long int</td>
</tr>
<tr>
<td></td>
<td>unsigned long int</td>
<td>unsigned long int</td>
</tr>
<tr>
<td></td>
<td>unsigned long long int</td>
<td>unsigned long long int</td>
</tr>
<tr>
<td>z or Z</td>
<td>the signed integer type corresponding to std::size_t (17.2.4)</td>
<td>the signed integer type corresponding to std::size_t</td>
</tr>
<tr>
<td></td>
<td>std::size_t</td>
<td>std::size_t</td>
</tr>
</tbody>
</table>

4 If an integer-literal cannot be represented by any type in its list and an extended integer type (6.8.2) can represent its value, it may have that extended integer type. If all of the types in the list for the integer-literal are signed, the extended integer type shall be signed. If all of the types in the list for the integer-literal are unsigned, the extended integer type shall be unsigned. If the list contains both signed and unsigned types, the extended integer type may be signed or unsigned. A program is ill-formed if one of its translation units contains an integer-literal that cannot be represented by any of the allowed types.

5.13.3 Character literals

character-literal:
  encoding-prefix<sup>opt</sup> <sup>1</sup> c-char-sequence <sup>1</sup>

encoding-prefix: one of
  u8 u U L

c-char-sequence:
  c-char
  c-char-sequence c-char

c-char:
  basic-c-char
  escape-sequence
  universal-character-name

basic-c-char:
  any member of the translation character set except the U+0027 APOSTROPHE,
  U+005C REVERSE SOLIDUS, or new-line character

§ 5.13.3
escape-sequence:
  simple-escape-sequence
  numeric-escape-sequence
  conditional-escape-sequence

simple-escape-sequence:
  \ simple-escape-sequence-char

simple-escape-sequence-char: one of
  ' " ? \ a b f n r t v

numeric-escape-sequence:
  octal-escape-sequence
  hexadecimal-escape-sequence

simple-octal-digit-sequence:
  octal-digit
  simple-octal-digit-sequence octal-digit

octal-escape-sequence:
  \ octal-digit
  \ octal-digit octal-digit
  \ octal-digit octal-digit octal-digit
  \o{ simple-octal-digit-sequence }

hexadecimal-escape-sequence:
  \x simple-hexadecimal-digit-sequence
  \x{ simple-hexadecimal-digit-sequence }

conditional-escape-sequence:
  \ conditional-escape-sequence-char

conditional-escape-sequence-char:
  any member of the basic character set that is not an octal-digit, a simple-escape-sequence-char, or the characters N, o, u, U, or x

1 A non-encodable character literal is a character-literal whose c-char-sequence consists of a single c-char that is not a numeric-escape-sequence and that specifies a character that either lacks representation in the literal’s associated character encoding or that cannot be encoded as a single code unit. A multicharacter literal is a character-literal whose c-char-sequence consists of more than one c-char. The encoding-prefix of a non-encodable character literal or a multicharacter literal shall be absent. Such character-literals are conditionally-supported.

2 The kind of a character-literal, its type, and its associated character encoding (5.3) are determined by its encoding-prefix and its c-char-sequence as defined by Table 9. The special cases for non-encodable character literals and multicharacter literals take precedence over the base kind.

[Note 1: The associated character encoding for ordinary character literals determines encodability, but does not determine the value of non-encodable ordinary character literals or ordinary multicharacter literals. The examples in Table 9 for non-encodable ordinary character literals assume that the specified character lacks representation in the ordinary literal encoding or that encoding the character would require more than one code unit. — end note]

Table 9: Character literals [tab:lex.ccon.literal]

<table>
<thead>
<tr>
<th>Encoding prefix</th>
<th>Kind</th>
<th>Type</th>
<th>Associated character encoding</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>ordinary character literal</td>
<td>char</td>

<td>ordinary multicharacter literal</td>
<td>int</td>
<td>encoding</td>
<td>'abcd'</td>
</tr>
<tr>
<td>L</td>
<td>wide character literal</td>
<td>wchar_t</td>
<td>wide literal encoding</td>
<td>L'w'</td>
</tr>
<tr>
<td>u8</td>
<td>UTF-8 character literal</td>
<td>char8_t</td>
<td>UTF-8</td>
<td>u8'x'</td>
</tr>
<tr>
<td>u</td>
<td>UTF-16 character literal</td>
<td>char16_t</td>
<td>UTF-16</td>
<td>u'y'</td>
</tr>
<tr>
<td>U</td>
<td>UTF-32 character literal</td>
<td>char32_t</td>
<td>UTF-32</td>
<td>U'z'</td>
</tr>
</tbody>
</table>

3 In translation phase 4, the value of a character-literal is determined using the range of representable values of the character-literal’s type in translation phase 7. A non-encodable character literal or a multicharacter literal has an implementation-defined value. The value of any other kind of character-literal is determined as follows:
(3.1) — A character-literal with a c-char-sequence consisting of a single basic-c-char, simple-escape-sequence, or universal-character-name is the code unit value of the specified character as encoded in the literal’s associated character encoding.

[Note 2: If the specified character lacks representation in the literal’s associated character encoding or if it cannot be encoded as a single code unit, then the literal is a non-encodable character literal. — end note]

(3.2) — A character-literal with a c-char-sequence consisting of a single numeric-escape-sequence has a value as follows:

(3.2.1) — Let \( v \) be the integer value represented by the octal number comprising the sequence of octal-digits in an octal-escape-sequence or by the hexadecimal number comprising the sequence of hexadecimal-digits in a hexadecimal-escape-sequence.

(3.2.2) — If \( v \) does not exceed the range of representable values of the character-literal’s type, then the value is \( v \).

(3.2.3) — Otherwise, if the character-literal’s encoding-prefix is absent or \( L \), and \( v \) does not exceed the range of representable values of the corresponding unsigned type for the underlying type of the character-literal’s type \( T \) that is congruent to \( v \) modulo \( 2^N \), where \( N \) is the width of \( T \).

(3.2.4) — Otherwise, the character-literal is ill-formed.

(3.3) — A character-literal with a c-char-sequence consisting of a single conditional-escape-sequence is conditionally-supported and has an implementation-defined value.

4 The character specified by a simple-escape-sequence is specified in Table 10.

[Note 3: Using an escape sequence for a question mark is supported for compatibility with ISO C++ 2014 and ISO C. — end note]

5.13.4 Floating-point literals

floating-point-literal:
  decimal-floating-point-literal
  hexadecimal-floating-point-literal

decimal-floating-point-literal:
  fractional-constant exponent-part_{opt} floating-point-suffix_{opt}
  digit-sequence exponent-part floating-point-suffix_{opt}

hexadecimal-floating-point-literal:
  hexadecimal-prefix hexadecimal-fractional-constant binary-exponent-part floating-point-suffix_{opt}

fractional-constant:
  digit-sequence_{opt} . digit-sequence
  digit-sequence

hexadecimal-fractional-constant:
  hexadecimal-digit-sequence_{opt} . hexadecimal-digit-sequence
  hexadecimal-digit-sequence

§ 5.13.4
The type of a floating-point-literal (6.8.2, 6.8.3) is determined by its floating-point-suffix as specified in Table 11.

Table 11: Types of floating-point-literals

<table>
<thead>
<tr>
<th>floating-point-suffix</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>double</td>
</tr>
<tr>
<td>f or F</td>
<td>float</td>
</tr>
<tr>
<td>l or L</td>
<td>long double</td>
</tr>
<tr>
<td>f16 or F16</td>
<td>std::float16_t</td>
</tr>
<tr>
<td>f32 or F32</td>
<td>std::float32_t</td>
</tr>
<tr>
<td>f64 or F64</td>
<td>std::float64_t</td>
</tr>
<tr>
<td>f128 or F128</td>
<td>std::float128_t</td>
</tr>
<tr>
<td>bf16 or BF16</td>
<td>std::bfloat16_t</td>
</tr>
</tbody>
</table>

The significand of a floating-point-literal is the fractional-constant or digit-sequence of a decimal-floating-point-literal or the hexadecimal-fractional-constant or hexadecimal-digit-sequence of a hexadecimal-floating-point-literal. In the significand, the sequence of digits or hexadecimal-digits and optional period are interpreted as a base N real number s, where N is 10 for a decimal-floating-point-literal and 16 for a hexadecimal-floating-point-literal.

If an exponent-part or binary-exponent-part is present, the exponent e of the floating-point-literal is the result of interpreting the sequence of an optional sign and the digits as a base 10 integer. Otherwise, the exponent e is 0. The scaled value of the literal is \( s \times 10^e \) for a decimal-floating-point-literal and \( s \times 2^e \) for a hexadecimal-floating-point-literal.

If the scaled value is not in the range of representable values for its type, the program is ill-formed. Otherwise, the value of a floating-point-literal is the scaled value if representable, else the larger or smaller representable value nearest the scaled value, chosen in an implementation-defined manner.

5.13.5 String literals
basic-s-char:
  any member of the translation character set except the U+0022 QUOTATION MARK, U+005C REVERSE SOLIDUS, or new-line character

raw-string:
  " d-char-sequence_opt ( r-char-sequence_opt ) d-char-sequence_opt "

r-char-sequence:
  r-char
  r-char-sequence r-char

r-char:
  any member of the translation character set, except a U+0029 RIGHT PARENTHESES followed by the initial d-char-sequence (which may be empty) followed by a U+0022 QUOTATION MARK

d-char-sequence:
  d-char
  d-char-sequence d-char

d-char:
  any member of the basic character set except:
  U+0020 SPACE, U+0028 LEFT PARENTHESES, U+0029 RIGHT PARENTHESES, U+005C REVERSE SOLIDUS,
  U+0009 CHARACTER TABULATION, U+000B LINE TABULATION, U+000C FORM FEED, and new-line

1 The kind of a string-literal, its type, and its associated character encoding (5.3) are determined by its encoding prefix and sequence of s-chars or r-chars as defined by Table 12 where \(n\) is the number of encoded code units as described below.

Table 12: String literals

<table>
<thead>
<tr>
<th>Encoding prefix</th>
<th>Kind</th>
<th>Type</th>
<th>Associated character encoding</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>ordinary string literal</td>
<td>array of (n)</td>
<td>ordinary literal</td>
<td>&quot;ordinary string&quot;</td>
</tr>
<tr>
<td>L</td>
<td>wide string literal</td>
<td>array of (n)</td>
<td>wide literal</td>
<td>L&quot;wide string&quot;</td>
</tr>
<tr>
<td>u8</td>
<td>UTF-8 string literal</td>
<td>array of (n)</td>
<td>UTF-8</td>
<td>u8&quot;UTF-8 string&quot;</td>
</tr>
<tr>
<td>u</td>
<td>UTF-16 string literal</td>
<td>array of (n)</td>
<td>UTF-16</td>
<td>u&quot;UTF-16 string&quot;</td>
</tr>
<tr>
<td>U</td>
<td>UTF-32 string literal</td>
<td>array of (n)</td>
<td>UTF-32</td>
<td>U&quot;UTF-32 string&quot;</td>
</tr>
</tbody>
</table>

2 A string-literal that has an R in the prefix is a raw string literal. The d-char-sequence serves as a delimiter. The terminating d-char-sequence of a raw-string is the same sequence of characters as the initial d-char-sequence. A d-char-sequence shall consist of at most 16 characters.

3 [Note 1: The characters ‘(‘ and ‘)’ are permitted in a raw-string. Thus, R"delimiter((a|b))delimiter" is equivalent to "(a|b)". — end note]

4 [Note 2: A source-file new-line in a raw string literal results in a new-line in the resulting execution string literal. Assuming no whitespace at the beginning of lines in the following example, the assert will succeed:

```c
const char* p = R"(a\n b
c)";
assert(std::strcmp(p, "a\nb\nc") == 0);
```

— end note]

5 [Example 1: The raw string

R"a( ">

)0"
is equivalent to "\n\\\n\\n^x". The raw string
\[
R^* (x = \"^y\")^* 
\]
is equivalent to "x = \"^y\\n\\n^x". — end example]  

6 Ordinary string literals and UTF-8 string literals are also referred to as narrow string literals.  

7 The common encoding-prefix for a sequence of adjacent string-literals is determined pairwise as follows: If two string-literals have the same encoding-prefix, the common encoding-prefix is that encoding-prefix. If one string-literal has no encoding-prefix, the common encoding-prefix is that of the other string-literal. Any other combinations are ill-formed.  

[Note 3: A string-literal’s rawness has no effect on the determination of the common encoding-prefix. — end note]  

8 In translation phase 6 (5.2), adjacent string-literals are concatenated. The lexical structure and grouping of the contents of the individual string-literals is retained.  

[Example 2:  
"\xA" "B"  
represents the code unit ’\xA’ and the character ’B’ after concatenation (and not the single code unit ’\xAB’). Similarly,  
\[
R^*(\u0000) = "41" 
\]
represents six characters, starting with a backslash and ending with the digit 1 (and not the single character ’A’ specified by a universal-character-name).  

Table 13 has some examples of valid concatenations. — end example]  

<table>
<thead>

<td></td>
<td></td>
</tr>
</tbody>
</table>

9 Evaluating a string-literal results in a string literal object with static storage duration (6.7.5). Whether all string-literals are distinct (that is, are stored in nonoverlapping objects) and whether successive evaluations of a string-literal yield the same or a different object is unspecified.  

[Note 4: The effect of attempting to modify a string literal object is undefined. — end note]  

10 String literal objects are initialized with the sequence of code unit values corresponding to the string-literal’s sequence of s-chars (originally from non-raw string literals) and r-chars (originally from raw string literals), plus a terminating null character, in order as follows:  

(10.1) — The sequence of characters denoted by each contiguous sequence of basic-s-chars, r-chars, simple-escape-sequences (5.13.3), and universal-character-names (5.3) is encoded to a code unit sequence using the string-literal’s associated character encoding. If a character lacks representation in the associated character encoding, then the string-literal is conditionally-supported and an implementation-defined code unit sequence is encoded.  

[Note 5: No character lacks representation in any Unicode encoding form. — end note]  

When encoding a stateful character encoding, implementations should encode the first such sequence beginning with the initial encoding state and encode subsequent sequences beginning with the final encoding state of the prior sequence.  

[Note 6: The encoded code unit sequence can differ from the sequence of code units that would be obtained by encoding each character independently. — end note]  

(10.2) — Each numeric-escape-sequence (5.13.3) contributes a single code unit with a value as follows:  

(10.2.1) — Let \( v \) be the integer value represented by the octal number comprising the sequence of octal-digits in an octal-escape-sequence or by the hexadecimal number comprising the sequence of hexadecimal-digits in a hexadecimal-escape-sequence.  

(10.2.2) — If \( v \) does not exceed the range of representable values of the string-literal’s array element type, then the value is \( v \).
Otherwise, if the string-literal’s encoding-prefix is absent or L, and v does not exceed the range of representable values of the corresponding unsigned type for the underlying type of the string-literal’s array element type, then the value is the unique value of the string-literal’s array element type T that is congruent to v modulo $2^N$, where N is the width of T.

— Otherwise, the string-literal is ill-formed.

When encoding a stateful character encoding, these sequences should have no effect on encoding state.

Each conditional-escape-sequence (5.13.3) contributes an implementation-defined code unit sequence. When encoding a stateful character encoding, it is implementation-defined what effect these sequences have on encoding state.

### 5.13.6 Boolean literals

```plaintext
boolean-literal:
  false
  true
```

The Boolean literals are the keywords `false` and `true`. Such literals have type `bool`.

### 5.13.7 Pointer literals

```plaintext
pointer-literal:
  nullptr
```

The pointer literal is the keyword `nullptr`. It has type `std::nullptr_t`.

[Note 1: `std::nullptr_t` is a distinct type that is neither a pointer type nor a pointer-to-member type; rather, a prvalue of this type is a null pointer constant and can be converted to a null pointer value or null member pointer value. See 7.3.12 and 7.3.13. — end note]

### 5.13.8 User-defined literals

```plaintext
user-defined-literal:
  user-defined-integer-literal
  user-defined-floating-point-literal
  user-defined-string-literal
  user-defined-character-literal

user-defined-integer-literal:
  decimal-literal ud-suffix
  octal-literal ud-suffix
  hexadecimal-literal ud-suffix
  binary-literal ud-suffix

user-defined-floating-point-literal:
  fractional-constant exponent-part opt ud-suffix
  digit-sequence exponent-part ud-suffix
  hexadecimal-prefix hexadecimal-fractional-constant binary-exponent-part ud-suffix
  hexadecimal-prefix hexadecimal-digit-sequence binary-exponent-part ud-suffix

user-defined-string-literal:
  string-literal ud-suffix

user-defined-character-literal:
  character-literal ud-suffix

ud-suffix:
  identifier
```

If a token matches both `user-defined-literal` and another literal kind, it is treated as the latter.

[Example 1: `123_km` is a `user-defined-literal`, but `12LL` is an `integer-literal`. — end example]

The syntactic non-terminal preceding the `ud-suffix` in a `user-defined-literal` is taken to be the longest sequence of characters that could match that non-terminal.

A `user-defined-literal` is treated as a call to a literal operator or literal operator template (12.6). To determine the form of this call for a given `user-defined-literal` L with `ud-suffix` X, first let S be the set of declarations found by unqualified lookup for the `literal-operator-id` whose literal suffix identifier is X (6.5.3). S shall not be empty.
If \( L \) is a user-defined-integer-literal, let \( n \) be the literal without its ud-suffix. If \( S \) contains a literal operator with parameter type \texttt{unsigned long long}, the literal \( L \) is treated as a call of the form
\[
\text{operator } "X(\text{nULL})"
\]
Otherwise, \( S \) shall contain a raw literal operator or a numeric literal operator template (12.6) but not both. If \( S \) contains a raw literal operator, the literal \( L \) is treated as a call of the form
\[
\text{operator } "X("n")"
\]
Otherwise \((S \text{ contains a numeric literal operator template})\), \( L \) is treated as a call of the form
\[
\text{operator } "X<\text{c}_1, \text{c}_2, \ldots \text{c}_k>()
\]
where \( n \) is the source character sequence \( \text{c}_1\text{c}_2...\text{c}_k \).

[Note 1: The sequence \( \text{c}_1\text{c}_2...\text{c}_k \) can only contain characters from the basic character set. — end note]

4 If \( L \) is a user-defined-floating-point-literal, let \( f \) be the literal without its ud-suffix. If \( S \) contains a literal operator with parameter type \texttt{long double}, the literal \( L \) is treated as a call of the form
\[
\text{operator } "X(\text{fL})"
\]
Otherwise, \( S \) shall contain a raw literal operator or a numeric literal operator template (12.6) but not both. If \( S \) contains a raw literal operator, the literal \( L \) is treated as a call of the form
\[
\text{operator } "X("f")"
\]
Otherwise \((S \text{ contains a numeric literal operator template})\), \( L \) is treated as a call of the form
\[
\text{operator } "X<\text{c}_1, \text{c}_2, \ldots \text{c}_k>()
\]
where \( f \) is the source character sequence \( \text{c}_1\text{c}_2...\text{c}_k \).

[Note 2: The sequence \( \text{c}_1\text{c}_2...\text{c}_k \) can only contain characters from the basic character set. — end note]

5 If \( L \) is a user-defined-string-literal, let \( \text{str} \) be the literal without its ud-suffix and let \( \text{len} \) be the number of code units in \( \text{str} \) (i.e., its length excluding the terminating null character). If \( S \) contains a literal operator template with a non-type template parameter for which \( \text{str} \) is a well-formed template-argument, the literal \( L \) is treated as a call of the form
\[
\text{operator } "X<\text{str}>()"
\]
Otherwise, the literal \( L \) is treated as a call of the form
\[
\text{operator } "X(\text{str}, \text{len})"
\]

6 If \( L \) is a user-defined-character-literal, let \( \text{ch} \) be the literal without its ud-suffix. \( S \) shall contain a literal operator (12.6) whose only parameter has the type of \( \text{ch} \) and the literal \( L \) is treated as a call of the form
\[
\text{operator } "X(\text{ch})"
\]

[Example 2:
\[
\text{long double } \text{operator } "._w(\text{long double});
\text{std::string } \text{operator } "._w(\text{const char16_t*}, \text{std::size_t});
\text{unsigned } \text{operator } "._w(\text{const char*});
\]
\]
\[
\text{int main()} \{ \text{ \}
\text{1.2}_w; \text{ // calls operator } "._w(\text{1.2L})"
\text{u"one"}_w; \text{ // calls operator } "._w(u"one", 3)
\text{12}_w; \text{ // calls operator } "._w("12")"
\text{"two"}_w; \text{ // error: no applicable literal operator}
\}
\]

—end example]

In translation phase 6 (5.2), adjacent string-literals are concatenated and user-defined-string-literals are considered string-literals for that purpose. During concatenation, ud-suffixes are removed and ignored and the concatenation process occurs as described in 5.13.5. At the end of phase 6, if a string-literal is the result of a concatenation involving at least one user-defined-string-literal, all the participating user-defined-string-literals shall have the same ud-suffix and that suffix is applied to the result of the concatenation.

[Example 3:
\[
\text{int main()} \{ \text{ \}
\text{L"A" } "B" "C"_x; \text{ // OK, same as L"ABC"_x}
\text{"P"_x } "Q" "R"_y; \text{ // error: two different ud-suffixes}
\}
\]

§ 5.13.8
6 Basics

6.1 Preamble

[Note 1: This Clause presents the basic concepts of the C++ language. It explains the difference between an object and a name and how they relate to the value categories for expressions. It introduces the concepts of a declaration and a definition and presents C++’s notion of type, scope, linkage, and storage duration. The mechanisms for starting and terminating a program are discussed. Finally, this Clause presents the fundamental types of the language and lists the ways of constructing compound types from these. — end note]

[Note 2: This Clause does not cover concepts that affect only a single part of the language. Such concepts are discussed in the relevant Clauses. — end note]

An entity is a value, object, reference, structured binding, function, enumerator, type, class member, bit-field, template, template specialization, namespace, or pack.

A name is an identifier (5.10), operator-function-id (12.4), literal-operator-id (12.6), or conversion-function-id (11.4.8.3).

Every name is introduced by a declaration, which is a

- name-declaration, block-declaration, or member-declaration (9.1, 11.4),
- init-declarator (9.3),
- identifier in a structured binding declaration (9.6),
- init-capture (7.5.5.3),
- condition with a declarator (8.1),
- member-declarator (11.4),
- using-declarator (9.9),
- parameter-declaration (9.3.4.6),
- type-parameter (13.2),
- elaborated-type-specifier that introduces a name (9.2.9.4),
- class-specifier (11.1),
- enum-specifier or enumerator-definition (9.7.1),
- exception-declaration (14.1), or
- implicit declaration of an injected-class-name (11.1).

[Note 3: The interpretation of a for-range-declaration produces one or more of the above (8.6.5). — end note]

An entity E is denoted by the name (if any) that is introduced by a declaration of E or by a typedef-name introduced by a declaration specifying E.

A variable is introduced by the declaration of a reference other than a non-static data member or of an object. The variable’s name, if any, denotes the reference or object.

A local entity is a variable with automatic storage duration (6.7.5.4), a structured binding (9.6) whose corresponding variable is such an entity, or the this object (7.5.2).

Some names denote types or templates. In general, whenever a name is encountered it is necessary to determine whether that name denotes one of these entities before continuing to parse the program that contains it. The process that determines this is called name lookup (6.5).

Two names are the same if

- they are identifiers composed of the same character sequence, or
- they are operator-function-ids formed with the same operator, or
- they are conversion-function-ids formed with equivalent (13.7.7.2) types, or
- they are literal-operator-ids (12.6) formed with the same literal suffix identifier.
A name used in more than one translation unit can potentially refer to the same entity in these translation units depending on the linkage (6.6) of the name specified in each translation unit.

### 6.2 Declarations and definitions

A declaration (Clause 9) may (re)introduce one or more names and/or entities into a translation unit. If so, the declaration specifies the interpretation and semantic properties of these names. A declaration of an entity or `typedef-name X` is a redeclaration of `X` if another declaration of `X` is reachable from it (10.7). A declaration may also have effects including:

1. A static assertion (9.1),
2. Controlling template instantiation (13.9.3),
3. Guiding template argument deduction for constructors (13.7.2.3),
4. Use of attributes (9.12), and

Each entity declared by a declaration is also defined by that declaration unless:

1. It declares a function without specifying the function’s body (9.5),
2. It contains the `extern` specifier (9.2.2) or a `linkage-specification` (9.11) and neither an `initializer` nor a `function-body`,
3. It declares a non-inline static data member in a class definition (11.4, 11.4.9),
4. It declares a static data member outside a class definition and the variable was defined within the class with the `constexpr` specifier (this usage is deprecated; see D.6),
5. It is an `elaborated-type-specifier` (11.3),
6. It is an `opaque-enum-declaration` (9.7.1),
7. It is a `template-parameter` (13.2),
8. It is a `parameter-declaration` (9.3.4.6) in a function declarator that is not the declarator of a `function-definition`,
9. It is a `typedef` declaration (9.2.4),
10. It is an `alias-declaration` (9.2.4),
11. It is a `using-declaration` (9.9),
12. It is a `deduction-guide` (13.7.2.3),
13. It is a `static_assert-declaration` (9.1),
14. It is an `attribute-declaration` (9.1),
15. It is an `empty-declaration` (9.1),
16. It is a `using-directive` (9.8.4),
17. It is a `using-enum-declaration` (9.7.2),
18. It is a `template-declaration` (13.1) whose `template-head` is not followed by either a `concept-definition` or a declaration that defines a function, a class, a variable, or a static data member,
19. It is an explicit instantiation declaration (13.9.3), or
20. It is an explicit specialization (13.9.4) whose declaration is not a definition.

A declaration is said to be a definition of each entity that it defines.

### Example 1:

All but one of the following are definitions:

```c
int a;
extern const int c = 1; // defines a
int f(int x) { return x+a; } // defines f and defines x
struct S { int a; int b; }; // defines S, S::a, and S::b
struct X {
    int x;              // defines X
    // defines non-static data member x
```
static int y; // declares static data member y
X(): x(0) {} // defines a constructor of X
);
int X::y = 1; // defines X::y
enum { up, down }; // defines up and down
namespace N { int d; } // defines N and N::d
namespace N1 = N; // defines N1
X anX; // defines anX

whereas these are just declarations:

extern int a; // declares a
extern const int c; // declares c
int f(int); // declares f
struct S; // declares S
typedef int Int; // declares Int
extern X anotherX; // declares anotherX
using N::d; // declares d
—end example

3 [Note 1: In some circumstances, C++ implementations implicitly define the default constructor (11.4.5.2), copy constructor, move constructor (11.4.5.3), copy assignment operator, move assignment operator (11.4.6), or destructor (11.4.7) member functions. —end note]

[Example 2: Given

#include <string>

struct C {
    std::string s; // std::string is the standard library class (23.4)
};

int main() {
    C a;
    C b = a;
    b = a;
}

the implementation will implicitly define functions to make the definition of C equivalent to

struct C {
    std::string s;
    C() : s() {} // C() : s() {}  
    C(const C& x) : s(x.s) {} // C(const C& x) : s(x.s) {}
    C(C&& x) : s(static_cast<std::string&&>(x.s)) {} // C(C&& x) : s(static_cast<std::string&&>(x.s)) {}
    // : s(std::move(x.s)) {} // C(C&& x) : s(static_cast<std::string&&>(x.s)) {} // C(C&& x) : s(static_cast<std::string&&>(x.s)) {}
    C& operator=(const C& x) { s = x.s; return *this; }
    C& operator=(C&& x) { s = static_cast<std::string&&>(x.s); return *this; }
    // { s = std::move(x.s); return *this; }
    ~C() {} // C(C&& x) : s(static_cast<std::string&&>(x.s)); return *this; }
};
—end example]

4 [Note 2: A class name can also be implicitly declared by an elaborated-type-specifier (9.2.9.4). —end note]

5 In the definition of an object, the type of that object shall not be an incomplete type (6.8.1), an abstract class type (11.7.4), or a (possibly multi-dimensional) array thereof.

6.3 One-definition rule [basic.def.odr]

Each of the following is termed a definable item:

(1.1) — a class type (Clause 11),
(1.2) — an enumeration type (9.7.1),
(1.3) — a function (9.3.4.6),
(1.4) — a variable (6.1),
(1.5) — a templated entity (13.1),

§ 6.3 34
No translation unit shall contain more than one definition of any definable item.

An expression or conversion is potentially evaluated unless it is an unevaluated operand, a subexpression thereof, or a conversion in an initialization or conversion sequence in such a context. The set of potential results of an expression \( E \) is defined as follows:

1. If \( E \) is an \textit{id-expression} \( (7.5.4) \), the set contains only \( E \).
2. If \( E \) is a subscripting operation \( (7.6.1.2) \) with an array operand, the set contains the potential results of that operand.
3. If \( E \) is a class member access expression \( (7.6.1.5) \) of the form \( E_1.template\text{opt} E_2 \) naming a non-static data member, the set contains the potential results of \( E_1 \).
4. If \( E \) is a class member access expression naming a static data member, the set contains the \textit{id-expression} designating the data member.
5. If \( E \) is a pointer-to-member expression \( (7.6.4) \) of the form \( E_1.\star E_2 \), the set contains the potential results of \( E_1 \).
6. If \( E \) has the form \( (E_1) \), the set contains the potential results of \( E_1 \).
7. If \( E \) is a glvalue conditional expression \( (7.6.16) \), the set is the union of the sets of potential results of the second and third operands.
8. If \( E \) is a comma expression \( (7.6.20) \), the set contains the potential results of the right operand.
9. Otherwise, the set is empty.

[Note 1: This set is a (possibly-empty) set of \textit{id-expressions}, each of which is either \( E \) or a subexpression of \( E \).]

[Example 1: In the following example, the set of potential results of the initializer of \( n \) contains the first \( S::x \) subexpression, but not the second \( S::x \) subexpression.

```cpp
struct S { static const int x = 0; }
const int &f(const int &r);
int n = b ? (1, S::x) // S::x is not odr-used here
       : f(S::x); // S::x is odr-used here, so a definition is required
```

—end example—

—end note—

A function is named by an expression or conversion as follows:

1. A function is named by an expression or conversion if it is the selected member of an overload set \( (6.5, 12.2, 12.3) \) in an overload resolution performed as part of forming that expression or conversion, unless it is a pure virtual function and either the expression is not an \textit{id-expression} naming the function with an explicitly qualified name or the expression forms a pointer to member \( (7.6.2.2) \).

[Note 2: This covers taking the address of functions \( (7.3.4, 7.6.2.2) \), calls to named functions \( (7.6.1.3) \), operator overloading (Clause 12), user-defined conversions \( (11.4.8.3) \), allocation functions for \textit{new-expressions} \( (7.6.2.8) \), as well as non-default initialization \( (9.4) \). A constructor selected to copy or move an object of class type is considered to be named by an expression or conversion even if the call is actually elided by the implementation \( (11.9.6) \).]

—end note—

2. A deallocation function for a class is named by a \textit{new-expression} if it is the single matching deallocation function for the allocation function selected by overload resolution, as specified in \( 7.6.2.8 \).

3. A deallocation function for a class is named by a \textit{delete-expression} if it is the selected usual deallocation function as specified in \( 7.6.2.9 \) and \( 11.4.11 \).

A variable is named by an expression if the expression is an \textit{id-expression} that denotes it. A variable \( x \) that is named by a potentially-evaluated expression \( E \) is \textit{odr-used} by \( E \) unless

1. \( x \) is a reference that is usable in constant expressions \( (7.7) \), or
2. \( x \) is a variable of non-reference type that is usable in constant expressions and has no mutable subobjects, and \( E \) is an element of the set of potential results of an expression of non-volatile-qualified non-class type to which the lvalue-to-rvalue conversion \( (7.3.2) \) is applied, or
x is a variable of non-reference type, and \( E \) is an element of the set of potential results of a discarded-value expression (7.2.3) to which the lvalue-to-rvalue conversion is not applied.

A structured binding is odr-used if it appears as a potentially-evaluated expression.

\*this is odr-used if this appears as a potentially-evaluated expression (including as the result of the implicit transformation in the body of a non-static member function (11.4.3)).

A virtual member function is odr-used if it is not pure. A function is odr-used if it is named by a potentially-evaluated expression or conversion. A non-placement allocation or deallocation function for a class is odr-used by the definition of a constructor of that class. A non-placement deallocation function for a class is odr-used by the definition of the destructor of that class, or by being selected by the lookup at the point of definition of a virtual destructor (11.4.7). An assignment operator function in a class is odr-used by an implicitly-defined copy-assignment or move-assignment function for another class as specified in 11.4.6. A constructor for a class is odr-used as specified in 9.4. A destructor for a class is odr-used if it is potentially invoked (11.4.7).

A local entity (6.1) is odr-usable in a scope (6.4.1) if:

- either the local entity is not \*this, or an enclosing class or non-lambda function parameter scope exists and, if the innermost such scope is a function parameter scope, it corresponds to a non-static member function, and
- for each intervening scope (6.4.1) between the point at which the entity is introduced and the scope (where \*this is considered to be introduced within the innermost enclosing class or non-lambda function definition scope), either:
  - the intervening scope is a block scope, or
  - the intervening scope is the function parameter scope of a lambda-expression that has a simple-capture naming the entity or has a capture-default, and the block scope of the lambda-expression is also an intervening scope.

If a local entity is odr-used in a scope in which it is not odr-usable, the program is ill-formed.

Every program shall contain at least one definition of every function or variable that is odr-used in that program outside of a discarded statement (8.5.2); no diagnostic required. The definition can appear explicitly in the program, it can be found in the standard or a user-defined library, or (when appropriate) it is implicitly defined (see 11.4.5.2, 11.4.5.3, 11.4.7, and 11.4.6).

An implementation is not required to call allocation and deallocation functions from constructors or destructors; however, this is a permissible implementation technique.
A definition domain is a private-module-fragment or the portion of a translation unit excluding its private-module-fragment (if any). A definition of an inline function or variable shall be reachable from the end of every definition domain in which it is odr-used outside of a discarded statement.

A definition of a class shall be reachable in every context in which the class is used in a way that requires the class type to be complete.

[Example 4: The following complete translation unit is well-formed, even though it never defines X:

```c
struct X; // declare X as a struct type
struct X* x1; // use X in pointer formation
X* x2; // use X in pointer formation
```
—end example]

[Note 3: The rules for declarations and expressions describe in which contexts complete class types are required. A class type \( T \) must be complete if:

1. an object of type \( T \) is defined (6.2), or
2. a non-static class data member of type \( T \) is declared (11.4), or
3. \( T \) is used as the allocated type or array element type in a new-expression (7.6.2.8), or
4. an lvalue-to-rvalue conversion is applied to a glvalue referring to an object of type \( T \) (7.3.2), or
5. an expression is converted (either implicitly or explicitly) to type \( T \) (7.3, 7.6.1.4, 7.6.1.7, 7.6.1.9, 7.6.3), or
6. an expression that is not a null pointer constant, and has type other than cv void*, is converted to the type pointer to \( T \) or reference to \( T \) using a standard conversion (7.3), a dynamic_cast (7.6.1.7) or a static_cast (7.6.1.9), or
7. a class member access operator is applied to an expression of type \( T \) (7.6.1.5), or
8. the typeid operator (7.6.1.8) or the sizeof operator (7.6.2.5) is applied to an operand of type \( T \), or
9. a function with a return type or argument type of type \( T \) is defined (6.2) or called (7.6.1.3), or
10. a class with a base class of type \( T \) is defined (11.7), or
11. an lvalue of type \( T \) is assigned to (7.6.19), or
12. the type \( T \) is the subject of an alignof expression (7.6.2.6), or
13. an exception-declaration has type \( T \), reference to \( T \), or pointer to \( T \) (14.4).
—end note]

For any definable item \( D \) with definitions in multiple translation units,

1. if \( D \) is a non-inline non-templated function or variable, or
2. if the definitions in different translation units do not satisfy the following requirements, the program is ill-formed; a diagnostic is required only if the definable item is attached to a named module and a prior definition is reachable at the point where a later definition occurs. Given such an item, for all definitions of \( D \), or, if \( D \) is an unnamed enumeration, for all definitions of \( D \) that are reachable at any given program point, the following requirements shall be satisfied.

1. Each such definition shall not be attached to a named module (10.1).
2. Each such definition shall consist of the same sequence of tokens, where the definition of a closure type is considered to consist of the sequence of tokens of the corresponding lambda-expression.
3. In each such definition, corresponding names, looked up according to 6.5, shall refer to the same entity, after overload resolution (12.2) and after matching of partial template specialization (13.10.4), except that a name can refer to

   1. a non-volatile const object with internal or no linkage if the object
      1. has the same literal type in all definitions of \( D \),
      2. is initialized with a constant expression (7.7),
      3. is not odr-used in any definition of \( D \), and
      4. has the same value in all definitions of \( D \),
   or
   2. a reference with internal or no linkage initialized with a constant expression such that the reference refers to the same entity in all definitions of \( D \).
In each such definition, except within the default arguments and default template arguments of D, corresponding lambda-expressions shall have the same closure type (see below).

— In each such definition, corresponding entities shall have the same language linkage.

— In each such definition, const objects with static or thread storage duration shall be constant-initialized if the object is constant-initialized in any such definition.

— In each such definition, corresponding manifestly constant-evaluated expressions that are not value-dependent shall have the same value (7.7, 13.8.3.4).

— In each such definition, the overloaded operators referred to, the implicit calls to conversion functions, constructors, operator new functions and operator delete functions, shall refer to the same function.

— In each such definition, a default argument used by an (implicit or explicit) function call or a default template argument used by an (implicit or explicit) template-id or simple-template-id is treated as if its token sequence were present in the definition of D; that is, the default argument or default template argument is subject to the requirements described in this paragraph (recursively).

— If D is a class with an implicitly-declared constructor (11.4.5.2, 11.4.5.3), it is as if the constructor was implicitly defined in every translation unit where it is odr-used, and the implicit definition in every translation unit shall call the same constructor for a subobject of D.

[Example 5:

// translation unit 1:
struct X {
    X(int, int);
    X(int, int, int);
};
X::X(int, int = 0) { }
class D {
    X x = 0;
};
D d1;  // X(int, int) called by D()

// translation unit 2:
struct X {
    X(int, int);
    X(int, int, int);
};
X::X(int, int = 0, int = 0) { }
class D {
    X x = 0;
};
D d2;  // X(int, int, int) called by D();
// D()'s implicit definition violates the ODR

— end example]

(14.13)  — If D is a class with a defaulted three-way comparison operator function (11.10.3), it is as if the operator was implicitly defined in every translation unit where it is odr-used, and the implicit definition in every translation unit shall call the same comparison operators for each subobject of D.

15 If D is a template and is defined in more than one translation unit, then the preceding requirements shall apply both to names from the template’s enclosing scope used in the template definition, and also to dependent names at the point of instantiation (13.8.3). These requirements also apply to corresponding entities defined within each definition of D (including the closure types of lambda-expressions, but excluding entities defined within default arguments or default template arguments of either D or an entity not defined within D). For each such entity and for D itself, the behavior is as if there is a single entity with a single definition, including in the application of these requirements to other entities.

[Note 4: The entity is still declared in multiple translation units, and 6.6 still applies to these declarations. In particular, lambda-expressions (7.5.5) appearing in the type of D can result in the different declarations having distinct types, and lambda-expressions appearing in a default argument of D might still denote different types in different translation units. — end note]

16 [Example 6:
inline void f(bool cond, void (*p)()) {
    if (cond) f(false, []());
}
inline void g(bool cond, void (*p)() = []()) {
    if (cond) g(false);
}
struct X {
    void h(bool cond, void (*p)() = []()) {
        if (cond) h(false);
    }
};

If the definition of \( f \) appears in multiple translation units, the behavior of the program is as if there is only one definition of \( f \). If the definition of \( g \) appears in multiple translation units, the program is ill-formed (no diagnostic required) because each such definition uses a default argument that refers to a distinct \( \lambda \)-expression closure type. The definition of \( X \) can appear in multiple translation units of a valid program; the \( \lambda \)-expressions defined within the default argument of \( X::h \) within the definition of \( X \) denote the same closure type in each translation unit. — end example

17 If, at any point in the program, there is more than one reachable unnamed enumeration definition in the same scope that have the same first enumerator name and do not have typedef names for linkage purposes (9.7.1), those unnamed enumeration types shall be the same; no diagnostic required.

6.4 Scope

6.4.1 General

The declarations in a program appear in a number of scopes that are in general discontiguous. The global scope contains the entire program; every other scope \( S \) is introduced by a declaration, parameter-declaration-clause, statement, or handler (as described in the following subclauses of 6.4) appearing in another scope which thereby contains \( S \). An enclosing scope at a program point is any scope that contains it; the smallest such scope is said to be the immediate scope at that point. A scope intervenes between a program point \( P \) and a scope \( S \) (that does not contain \( P \)) if it is or contains \( S \) but does not contain \( P \).

Unless otherwise specified:

(2.1) — The smallest scope that contains a scope \( S \) is the parent scope of \( S \).
(2.2) — No two declarations (re)introduce the same entity.
(2.3) — A declaration inhabits the immediate scope at its locus (6.4.2).
(2.4) — A declaration’s target scope is the scope it inhabits.
(2.5) — Any names (re)introduced by a declaration are bound to it in its target scope.

An entity belongs to a scope \( S \) if \( S \) is the target scope of a declaration of the entity.

[Note 1: Special cases include that:

(2.6) — Template parameter scopes are parents only to other template parameter scopes (6.4.9).
(2.7) — Corresponding declarations with appropriate linkage declare the same entity (6.6).
(2.8) — The declaration in a template-declaration inhabits the same scope as the template-declaration.
(2.9) — Friend declarations and declarations of qualified names and template specializations do not bind names (9.3.4); those with qualified names target a specified scope, and other friend declarations and certain elaborated-type-specifiers (9.2.9.4) target a larger enclosing scope.
(2.10) — Block-scope extern declarations target a larger enclosing scope but bind a name in their immediate scope.
(2.11) — The names of unscoped enumerators are bound in the two innermost enclosing scopes (9.7.1).
(2.12) — A class’s name is also bound in its own scope (11.1).
(2.13) — The names of the members of an anonymous union are bound in the union’s parent scope (11.5.2).
— end note]

(3.1) — exactly one is an implicit object member function with no ref-qualifier and the types of their object parameters (9.3.4.6), after removing top-level references, are the same, or
(3.2) — their object parameters have the same type.
Two non-static member function templates have corresponding object parameters if:

(3.3) exactly one is an implicit object member function with no ref-qualifier and the types of their object parameters, after removing any references, are equivalent, or

(3.4) the types of their object parameters are equivalent.

Two function templates have corresponding signatures if their template-parameter-lists have the same length, their corresponding template-parameters are equivalent, they have equivalent non-object-parameter-type-lists and return types (if any), and, if both are non-static members, they have corresponding object parameters.

Two declarations correspond if they (re)introduce the same name, both declare constructors, or both declare destructors, unless

(4.1) either is a using-declarator, or

(4.2) one declares a type (not a typedef-name) and the other declares a variable, non-static data member other than of an anonymous union (11.5.2), enumerator, function, or function template, or

(4.3) each declares a function or function template, except when

(4.3.1) both declare functions with the same non-object-parameter-type-list, equivalent (13.7.7.2) trailing requires-clauses (if any, except as specified in 13.7.5), and, if both are non-static members, they have corresponding object parameters, or

(4.3.2) both declare function templates with corresponding signatures and equivalent template-heads and trailing requires-clauses (if any).

[Note 2: Declarations can correspond even if neither binds a name.]

[Example 1:

```c
struct A {
  friend void f();  // #1
};
struct B {
  friend void f() {} // corresponds to, and defines, #1
};
```

—end example]

[Example 2:

```c
typedef int Int;
enum E : int { a }
void f(int);   // #1
void f(Int) {} // defines #1
void f(E) {}   // OK, another overload

struct X {
  static void f();  // error: redeclaration
  void f() const;
  void g();        // OK
  void g() const;
  void g() &;      // error: redeclaration

  void h(this X&, int);
  void h(Int) &&;   // OK, another overload
  void j(this const X&);
  void j() const &;
  void k();
  void k(this X&);  // error: redeclaration
};
```

—end example]

Two declarations potentially conflict if they correspond and cause their shared name to denote different entities (6.6). The program is ill-formed if, in any scope, a name is bound to two declarations that potentially conflict and one precedes the other (6.5).

---

18) An implicit object parameter (12.2.2) is not part of the parameter-type-list.
[Note 3: Overload resolution can consider potentially conflicting declarations found in multiple scopes (e.g., via using-directives or for operator functions), in which case it is often ambiguous. — end note]

[Example 3:

```cpp
void f() {
    int x, y;
    void x(); // error: different entity for x
    int y;  // error: redefinition
}
enum { f };  // error: different entity for ::f
namespace A {}
namespace B = A;
namespace B = A; // OK, no effect
namespace B = B; // OK, no effect
namespace A = B;  // OK, no effect
namespace B {} // error: different entity for B
```
— end example]

6 A declaration is nominable in a class, class template, or namespace E at a point P if it precedes P, it does not inhabit a block scope, and its target scope is the scope associated with E or, if E is a namespace, any element of the inline namespace set of E (9.8.2).

[Example 4:

```cpp
namespace A {
    void f() {void g();}
    inline namespace B {
        struct S {
            friend void h();
            static int i;
        };
    }
}
```
At the end of this example, the declarations of f, B, S, and h are nominable in A, but those of g and i are not. — end example]

7 When instantiating a templated entity (13.1), any scope S introduced by any part of the template definition is considered to be introduced by the instantiated entity and to contain the instantiations of any declarations that inhabit S.

6.4.2 Point of declaration [basic.scope.pdecl]

1 The locus of a declaration (6.1) that is a declarator is immediately after the complete declarator (9.3).

[Example 1:

```cpp
unsigned char x = 12;
{ unsigned char x = x; }
```
Here, the initialization of the second x has undefined behavior, because the initializer accesses the second x outside its lifetime (6.7.3). — end example]

2 [Note 1: A name from an outer scope remains visible up to the locus of the declaration that hides it.

[Example 2:

```cpp
const int i = 2;
{ int i[1]; }
```
declares a block-scope array of two integers. — end example]

— end note]

3 The locus of a class-specifier is immediately after the identifier or simple-template-id (if any) in its class-head (11.1). The locus of an enum-specifier is immediately after its enum-head; the locus of an opaque-enum-declaration is immediately after it (9.7.1). The locus of an alias-declaration is immediately after it.

4 The locus of a using-declarator that does not name a constructor is immediately after the using-declarator (9.9).

5 The locus of an enumerator-definition is immediately after it.

[Example 3:
const int x = 12;
{ enum { x = x }; }

Here, the enumerator \( x \) is initialized with the value of the constant \( x \), namely 12. — end example

[Note 2: After the declaration of a class member, the member name can be found in the scope of its class even if the class is an incomplete class.

Example 4:

```c
struct X {
    enum E { z = 16 };
    int b[X::z];  // OK
};
— end example]
— end note]

7 The locus of an elaborated-type-specifier that is a declaration (9.2.9.4) is immediately after it.

8 The locus of an injected-class-name declaration (11.1) is immediately following the opening brace of the class definition.

9 The locus of the implicit declaration of a function-local predefined variable (9.5.1) is immediately before the function-body of its function’s definition.

10 The locus of the declaration of a structured binding (9.6) is immediately after the identifier-list of the structured binding declaration.

11 The locus of a for-range-declaration of a range-based for statement (8.6.5) is immediately after the for-range-initializer.

12 The locus of a template-parameter is immediately after it.

Example 5:

typedef unsigned char T;
template<class T = T>
    N = 0> struct A { };
— end example]
— end note]

13 The locus of a concept-definition is immediately after its concept-name (13.7.9).

[Note 3: The constraint-expression cannot use the concept-name. — end note]

14 The locus of a namespace-definition with an identifier is immediately after the identifier.

[Note 4: An identifier is invented for an unnamed-namespace-definition (9.8.2.2). — end note]

15 [Note 5: Friend declarations can introduce functions or classes that belong to the nearest enclosing namespace or block scope, but they do not bind names anywhere (11.8.4). Function declarations at block scope and variable declarations with the extern specifier at block scope declare entities that belong to the nearest enclosing namespace, but they do not bind names in it. — end note]

16 [Note 6: For point of instantiation of a template, see 13.8.4.1. — end note]

### 6.4.3 Block scope

Each

1. selection or iteration statement (8.5, 8.6),
2. substatement of such a statement,
3. handler (14.1), or
4. compound statement (8.4) that is not the compound-statement of a handler introduces a block scope that includes that statement or handler.

[Note 1: A substatement that is also a block has only one scope. — end note]

A variable that belongs to a block scope is a block variable.

Example 1:

```c
int i = 42;
```
int a[10];
for (int i = 0; i < 10; i++)
a[i] = i;
int j = i;        // j = 42
—end example]  
2 If a declaration whose target scope is the block scope $S$ of a
(2.1) — compound-statement of a lambda-expression, function-body, or function-try-block,
(2.2) — substatement of a selection or iteration statement that is not itself a selection or iteration statement, or
(2.3) — handler of a function-try-block
potentially conflicts with a declaration whose target scope is the parent scope of $S$, the program is ill-formed.
[Example 2:
if (int x = f()) {
  int x;      // error: redeclaration of x
} else {
  int x;      // error: redeclaration of x
}  
—end example]  
6.4.4 Function parameter scope  [basic.scope.param]  
A parameter-declaration-clause $P$ introduces a function parameter scope that includes $P$.
[Note 1: A function parameter cannot be used for its value within the parameter-declaration-clause (9.3.4.7). — end note]  
(1.1) — If $P$ is associated with a declarator and is preceded by a (possibly-parenthesized) noptr-declarator of the
form declarator-id attribute-specifier-seq_opt, its scope extends to the end of the nearest enclosing init-declarator,
member-declarator, declarator of a parameter-declaration or a nodeclspec-function-declaration,
or function-definition, but does not include the locus of the associated declarator.
[Note 2: In this case, $P$ declares the parameters of a function (or a function or template parameter declared
with function type). A member function’s parameter scope is nested within its class’s scope. — end note]  
(1.2) — If $P$ is associated with a lambda-declarator, its scope extends to the end of the compound-statement in the
lambda-expression.
(1.3) — If $P$ is associated with a requirement-parameter-list, its scope extends to the end of the requirement-body
of the requires-expression.
(1.4) — If $P$ is associated with a deduction-guide, its scope extends to the end of the deduction-guide.
6.4.5 Lambda scope  [basic.scope.lambda]  
A lambda-expression $E$ introduces a lambda scope that starts immediately after the lambda-introducer of $E$
and extends to the end of the compound-statement of $E$.
6.4.6 Namespace scope  [basic.scope.namespace]  
Any namespace-definition for a namespace $N$ introduces a namespace scope that includes the namespace-body
for every namespace-definition for $N$. For each non-friend redeclaration or specialization whose target scope is
or is contained by the scope, the portion after the declarator-id, class-head-name, or enum-head-name is also
included in the scope. The global scope is the namespace scope of the global namespace (9.8).
[Example 1:
namespace Q {
  namespace V { void f(); }
  void V::f() {       // in the scope of V
    void h();         // declares Q::V::h
  }
}  
—end example]
6.4.7 Class scope

Any declaration of a class or class template \( \mathcal{C} \) introduces a class scope that includes the member-specification of the class-specifier for \( \mathcal{C} \) (if any). For each non-friend redeclaration or specialization whose target scope is or is contained by the scope, the portion after the declarator-id, class-head-name, or enum-head-name is also included in the scope.

[Note 1: Lookup from a program point before the class-specifier of a class will find no bindings in the class scope.]

[Example 1:

```cpp
template<class D>
struct B {
    D::type x; // #1
};

struct A { using type = int; };
struct C : A, B<C> {}; // error at #1: C::type not found
```

—end example]

6.4.8 Enumeration scope

Any declaration of an enumeration \( \mathcal{E} \) introduces an enumeration scope that includes the enumerator-list of the enum-specifier for \( \mathcal{E} \) (if any).

6.4.9 Template parameter scope

Each template template-parameter introduces a template parameter scope that includes the template-head of the template-parameter.

Each template-declaration \( \mathcal{D} \) introduces a template parameter scope that extends from the beginning of its template-parameter-list to the end of the template-declaration. Any declaration outside the template-parameter-list that would inhabit that scope instead inhabits the same scope as \( \mathcal{D} \). The parent scope of any scope \( \mathcal{S} \) that is not a template parameter scope is the smallest scope that contains \( \mathcal{S} \) and is not a template parameter scope.

[Note 1: Therefore, only template parameters belong to a template parameter scope, and only template parameter scopes have a template parameter scope as a parent scope. —end note]

6.5 Name lookup

6.5.1 General

The name lookup rules apply uniformly to all names (including typedef-names (9.2.4), namespace-names (9.8), and class-names (11.3)) wherever the grammar allows such names in the context discussed by a particular rule. Name lookup associates the use of a name with a set of declarations (6.2) of that name. Unless otherwise specified, the program is ill-formed if no declarations are found. If the declarations found by name lookup all denote functions or function templates, the declarations are said to form an overload set. Otherwise, if the declarations found by name lookup do not all denote the same entity, they are ambiguous and the program is ill-formed. Overload resolution (12.2, 12.3) takes place after name lookup has succeeded. The access rules (11.8) are considered only once name lookup and function overload resolution (if applicable) have succeeded. Only after name lookup, function overload resolution (if applicable) and access checking have succeeded are the semantic properties introduced by the declarations used in further processing.

A program point \( P \) is said to follow any declaration in the same translation unit whose locus (6.4.2) is before \( P \).

[Note 1: The declaration might appear in a scope that does not contain \( P \). —end note]

A declaration \( X \) precedes a program point \( P \) in a translation unit \( L \) if \( P \) follows \( X \), \( X \) inhabits a class scope and is reachable from \( P \), or else \( X \) appears in a translation unit \( D \) and

1. \( P \) follows a module-import-declaration or module-declaration that imports \( D \) (directly or indirectly), and
2. \( X \) appears after the module-declaration in \( D \) (if any) and before the private-module-fragment in \( D \) (if any), and
3. either \( X \) is exported or else \( D \) and \( L \) are part of the same module and \( X \) does not inhabit a namespace with internal linkage or declare a name with internal linkage.
[Note 2: Names declared by a using-declaration have no linkage. — end note]

[Note 3: A module-import-declaration imports both the named translation unit(s) and any modules named by exported module-import-declarations within them, recursively.

[Example 1:

Translation unit #1:

```cpp
export module Q;
export int sq(int i) { return i*i; }
```  

Translation unit #2:

```cpp
export module R;
export import Q;
```  

Translation unit #3:

```cpp
import R;
int main() { return sq(9); }  // OK, sq from module Q
```  

— end example]

— end note]

3 A single search in a scope $S$ for a name $N$ from a program point $P$ finds all declarations that precede $P$ to which any name that is the same as $N$ (6.1) is bound in $S$. If any such declaration is a using-declaration whose terminal name (7.5.4.2) is not dependent (13.8.3.2), it is replaced by the declarations named by the using-declaration (9.9).

4 In certain contexts, only certain kinds of declarations are included. After any such restriction, any declarations of classes or enumerations are discarded if any other declarations are found.

[Note 4: A type (but not a typedef-name or template) is therefore hidden by any other entity in its scope. — end note]

However, if a lookup is type-only, only declarations of types and templates whose specializations are types are considered; furthermore, if declarations of a typedef-name and of the type to which it refers are found, the declaration of the typedef-name is discarded instead of the type declaration.

6.5.2 Member name lookup

1 A search in a scope $X$ for a name $M$ from a program point $P$ is a single search in $X$ for $M$ from $P$ unless $X$ is the scope of a class or class template $T$, in which case the following steps define the result of the search.

[Note 1: The result differs only if $M$ is a conversion-function-id or if the single search would find nothing. — end note]

2 The lookup set for a name $N$ in a class or class template $C$, called $S(N,C)$, consists of two component sets: the declaration set, a set of members named $N$; and the subobject set, a set of subobjects where declarations of these members were found (possibly via using-declarations). In the declaration set, type declarations (including injected-class-names) are replaced by the types they designate. $S(N,C)$ is calculated as follows:

The declaration set is the result of a single search in the scope of $C$ for $N$ from immediately after the class-specifier of $C$ if $P$ is in a complete-class context of $C$ or from $P$ otherwise. If the resulting declaration set is not empty, the subobject set contains $C$ itself, and calculation is complete.

Otherwise (i.e., $C$ does not contain a declaration of $N$ or the resulting declaration set is empty), $S(N,C)$ is initially empty. Calculate the lookup set for $N$ in each direct non-dependent (13.8.3.2) base class subobject $B_i$, and merge each such lookup set $S(N,B_i)$ in turn into $S(N,C)$.

[Note 2: If $C$ is incomplete, only base classes whose base-specifier appears before $P$ are considered. If $C$ is an instantiated class, its base classes are not dependent. — end note]

The following steps define the result of merging lookup set $S(N,B_i)$ into the intermediate $S(N,C)$:

(5.1) — If each of the subobject members of $S(N,B_i)$ is a base class subobject of at least one of the subobject members of $S(N,C)$, or if $S(N,B_i)$ is empty, $S(N,C)$ is unchanged and the merge is complete. Conversely, if each of the subobject members of $S(N,C)$ is a base class subobject of at least one of the subobject members of $S(N,B_i)$, or if $S(N,C)$ is empty, the new $S(N,C)$ is a copy of $S(N,B_i)$.

(5.2) — Otherwise, if the declaration sets of $S(N,B_i)$ and $S(N,C)$ differ, the merge is ambiguous: the new $S(N,C)$ is a lookup set with an invalid declaration set and the union of the subobject sets. In subsequent merges, an invalid declaration set is considered different from any other.

§ 6.5.2 45
Otherwise, the new \( S(N, C) \) is a lookup set with the shared set of declarations and the union of the subobject sets.

6 The result of the search is the declaration set of \( S(M, T) \). If it is an invalid set, the program is ill-formed. If it differs from the result of a search in \( T \) for \( M \) in a complete-class context (11.4) of \( T \), the program is ill-formed, no diagnostic required.

**Example 1:**

```c
struct A { int x; };  // S(x,A) = { { A::x }, { A } }
struct B { float x; };  // S(x,B) = { { B::x }, { B } }
struct C: public A, public B { };  // S(x,C) = { invalid, { A in C, B in C } }
struct D: public virtual C { };  // S(x,D) = S(x,C)
struct E: public virtual C { char x; };  // S(x,E) = { { E::x }, { E } }
struct F: public D, public E { };  // S(x,F) = S(x,E)
int main() {
    F f;
    f.x = 0;  // OK, lookup finds E::x
    return 0;
}
```

\( S(x,F) \) is unambiguous because the \( A \) and \( B \) base class subobjects of \( D \) are also base class subobjects of \( E \), so \( S(x,D) \) is discarded in the first merge step.

7 If \( M \) is a non-dependent conversion-function-id, conversion function templates that are members of \( T \) are considered. For each such template \( F \), the lookup set \( S(t,T) \) is constructed, considering a function template declaration to have the name \( t \) only if it corresponds to a declaration of \( F \) (6.4.1). The members of the declaration set of each such lookup set, which shall not be an invalid set, are included in the result.

**Note 3:** Overload resolution will discard those that cannot convert to the type specified by \( N \) (13.10.4). —end note

**Note 4:** A static member, a nested type or an enumerator defined in a base class \( T \) can unambiguously be found even if an object has more than one base class subobject of type \( T \). Two base class subobjects share the non-static member subobjects of their common virtual base classes. —end note

**Example 2:**

```c
struct V { int v; }
struct A {  
    int a;
    static int s;
    enum { e };  
};
struct B : A, virtual V { }
struct C : A, virtual V { }
struct D : B, C { }

void f(D* pd) {
    pd->v++;  // OK, only one v (virtual)
    pd->s++;  // OK, only one s (static)
    int i = pd->e;  // OK, only one e (enumerator)
    pd->a++;  // error: ambiguous: two a's in D
}
```

—end example

**Note 5:** When virtual base classes are used, a hidden declaration can be reached along a path through the subobject lattice that does not pass through the hiding declaration. This is not an ambiguity. The identical use with non-virtual base classes is an ambiguity; in that case there is no unique instance of the name that hides all the others. —end note

**Example 3:**

```c
struct V { int f(); int x; }
struct W { int g(); int y; }
struct B : virtual V, W {  
    int f(); int x;
    int g(); int y;
};
struct C : virtual V, W { }
```

§ 6.5.2 46
struct D : B, C { void glorp(); };

![Diagram of class hierarchy](image.png)

Figure 1: Name lookup  [fig:class.lookup]

As illustrated in Figure 1, the names declared in V and the left-hand instance of W are hidden by those in B, but the names declared in the right-hand instance of W are not hidden at all.

```cpp
void D::glorp() {
    x++; // OK, B::x hides V::x
    f();  // OK, B::f() hides V::f()
    y++; // error: B::y and C's W::y
    g(); // error: B::g() and C's W::g()
}
```

—end example—

10 An explicit or implicit conversion from a pointer to or an expression designating an object of a derived class to a pointer or reference to one of its base classes shall unambiguously refer to a unique object representing the base class.

```cpp
Example 4:
struct V { }
struct A { }
struct B : A, virtual V { }
struct C : A, virtual V { }
struct D : B, C { }

void g() {
    D d;
    B* pb = &d;
    A* pa = &d;  // error: ambiguous: C's A or B's A?
    V* pv = &d;  // OK, only one V subobject
}
```

—end example—

11 [Note 6: Even if the result of name lookup is unambiguous, use of a name found in multiple subobjects might still be ambiguous (7.3.13, 7.6.1.5, 11.8.3). — end note]

```cpp
Example 5:
struct B1 {
    void f();
    static void f(int);
    int i;
};
struct B2 {
    void f(double);
};
struct I1: B1 { }
struct I2: B1 { }
struct D: I1, I2, B2 {
    using B1::f;
    using B2::f;
    void g() {
        f(); // Ambiguous conversion of this
        f(0); // Unambiguous (static)
    }
}
```

§ 6.5.2
6.5.3 Unqualified name lookup

1 A using-directive is active in a scope S at a program point P if it precedes P and inhabits either S or the scope of a namespace nominated by a using-directive that is active in S at P.

2 An unqualified search in a scope S from a program point P includes the results of searches from P in

(2.1) — S, and

(2.2) — for any scope U that contains P and is or is contained by S, each namespace contained by S that is nominated by a using-directive that is active in U at P.

If no declarations are found, the results of the unqualified search are the results of an unqualified search in the parent scope of S, if any, from P.

[Note 1: When a class scope is searched, the scopes of its base classes are also searched (6.5.2). If it inherits from a single base, it is as if the scope of the base immediately contains the scope of the derived class. Template parameter scopes that are associated with one scope in the chain of parents are also considered (13.8.2). — end note]

3 Unqualified name lookup from a program point performs an unqualified search in its immediate scope.

4 An unqualified name is a name that does not immediately follow a nested-name-specifier or the . or -> in a class member access expression (7.6.1.5), possibly after a template keyword or ~. Unless otherwise specified, such a name undergoes unqualified name lookup from the point where it appears.

5 An unqualified name that is a component name (7.5.4.2) of a type-specifier or ptr-operator of a conversion-type-id is looked up in the same fashion as the conversion-function-id in which it appears. If that lookup finds nothing, it undergoes unqualified name lookup; in each case, only names that denote types or templates whose specializations are types are considered.

[Example 1:

```cpp
class X, class T
int g() {
  using U = U2;
  X().operator U T::*(); // #1, searches for T in the scope of X first
  X().operator U decltype(T())::*(); // #2
  return 0;
}

int x = g<B, T2>(); // #1 calls B::operator U1 T1::*
  // #2 calls B::operator U1 T2::*
```

—end example]

6 In a friend declaration declarator whose declarator-id is a qualified-id whose lookup context (6.5.5) is a class or namespace S, lookup for an unqualified name that appears after the declarator-id performs a search in the scope associated with S. If that lookup finds nothing, it undergoes unqualified name lookup.

[Example 2:

```cpp
f(0.0);  // Unambiguous (only one B2)
int B1::* mpB1 = &D::i;  // Unambiguous
int D::* mpD = &D::i;  // Ambiguous conversion
```
using I = int;
using D = double;
namespace A {
    inline namespace N {using C = char;}
    using F = float;
    void f(I);
    void f(D);
    void f(C);
    void f(F);
}
struct X0 {using F = float;};
struct W {
    using D = void;
    struct X : X0 {
        void g(I);
        void g(::D);
        void g(F);
    };
};
namespace B {
typedef short I, F;
class Y {
    friend void A::f(I);
    // error: no void A::f(short)
    friend void A::f(D);
    // OK
    friend void A::f(C);
    // error: A::N::C not found
    friend void A::f(F);
    // OK
    friend void W::X::g(I);
    // error: no void X::g(short)
    friend void W::X::g(D);
    // OK
    friend void W::X::g(F);
    // OK
};
—end example]

6.5.4 Argument-dependent name lookup [basic.lookup.argdep]

1 When the postfix-expression in a function call (7.6.1.3) is an unqualified-id, and unqualified lookup (6.5.3) for
the name in the unqualified-id does not find any
   — declaration of a class member, or
   — function declaration inhabiting a block scope, or
   — declaration not of a function or function template
then lookup for the name also includes the result of argument-dependent lookup in a set of associated
namespaces that depends on the types of the arguments (and for template template arguments, the namespace
of the template argument), as specified below.

[Example 1:]
namespace N {
    struct S {
        void f(S);
    }

    void g() {
        N::S s;
        f(s);
        // OK, calls N::f
        (f)(s);
        // error: N::f not considered; parentheses prevent argument-dependent lookup
    }
—end example]

2 [Note 1: For purposes of determining (during parsing) whether an expression is a postfix-expression for a function call,
the usual name lookup rules apply. In some cases a name followed by < is treated as a template-name even though
name lookup did not find a template-name (see 13.3). For example,

int h;
void g();

§ 6.5.4
namespace N {
  struct A {}
  template <class T> int f(T);
  template <class T> int g(T);
  template <class T> int h(T);
}

int x = f<N::A>(N::A()); // OK, lookup of f finds nothing, f treated as template name
int y = g<N::A>(N::A()); // OK, lookup of g finds a function, g treated as template name
int z = h<N::A>(N::A()); // error: h does not begin a template-id

The rules have no effect on the syntactic interpretation of an expression. For example,

typedef int f;
namespace N {
  struct A {
    friend void f(A &);
    operator int();
    void g(A a) {
      int i = f(a); // f is the typedef, not the friend function: equivalent to int(a)
    }
  }
};

Because the expression is not a function call, argument-dependent name lookup does not apply and the friend function f is not found. — end note]  

For each argument type \( T \) in the function call, there is a set of zero or more associated entities to be considered. The set of entities is determined entirely by the types of the function arguments (and any template template arguments). Any typedef-names and using-declarations used to specify the types do not contribute to this set. The set of entities is determined in the following way:

1. If \( T \) is a fundamental type, its associated set of entities is empty.
2. If \( T \) is a class type (including unions), its associated entities are: the class itself; the class of which it is a member, if any; and its direct and indirect base classes. Furthermore, if \( T \) is a class template specialization, its associated entities also include: the entities associated with the types of the template arguments provided for template type parameters; the templates used as template template arguments; and the classes of which any member templates used as template template arguments are members.
   [Note 2: Non-type template arguments do not contribute to the set of associated entities. — end note]
3. If \( T \) is an enumeration type, its associated entities are \( T \) and, if it is a class member, the member’s class.
4. If \( T \) is a pointer to \( U \) or an array of \( U \), its associated entities are those associated with \( U \).
5. If \( T \) is a function type, its associated entities are those associated with the function parameter types and those associated with the return type.
6. If \( T \) is a pointer to a member function of a class \( X \), its associated entities are those associated with the function parameter types and return type, together with those associated with \( X \).
7. If \( T \) is a pointer to a data member of class \( X \), its associated entities are those associated with the member type together with those associated with \( X \).

In addition, if the argument is an overload set or the address of such a set, its associated entities are the union of those associated with each of the members of the set, i.e., the entities associated with its parameter types and return type. Additionally, if the aforementioned overload set is named with a template-id, its associated entities also include its template template-arguments and those associated with its type template-arguments.

The associated namespaces for a call are the innermost enclosing non-inline namespaces for its associated entities as well as every element of the inline namespace set (9.8.2) of those namespaces. Argument-dependent lookup finds all declarations of functions and function templates that

1. are found by a search of any associated namespace, or
2. are declared as a friend (11.8.4) of any class with a reachable definition in the set of associated entities, or

§ 6.5.4
are exported, are attached to a named module $M$ (10.2), do not appear in the translation unit containing the point of the lookup, and have the same innermost enclosing non-inline namespace scope as a declaration of an associated entity attached to $M$ (6.6).

If the lookup is for a dependent name (13.8.3, 13.8.4.2), the above lookup is also performed from each point in the instantiation context (10.6) of the lookup, additionally ignoring any declaration that appears in another translation unit, is attached to the global module, and is either discarded (10.4) or has internal linkage.

Example 2:

Translation unit #1:

```plaintext
export module M;
namespace R {
    export struct X {}
    export void f(X);
}
namespace S {
    export void f(R::X, R::X);
}
```

Translation unit #2:

```plaintext
export module N;
import M;
export R::X make();
namespace R { static int g(X); }
export template<typename T, typename U> void apply(T t, U u) {
    f(t, u);
    g(t);
}
```

Translation unit #3:

```plaintext
module Q;
import N;
namespace S {
    struct Z { template<typename T> operator T(); }
}
```

```plaintext
void test() {
    auto x = make();  // OK, decltype(x) is R::X in module M
    R::f(x);          // error: R and R::f are not visible here
    f(x);            // OK, calls R::f from interface of M
    f(x, S::Z());    // error: S::f in module M not considered
    apply(x, S::Z()); // error: S::f is visible in instantiation context, but
                        // even though S is an associated namespace
    // error: R::g has internal linkage and cannot be used outside TU #2
}
```

Example 3:

```plaintext
namespace NS {
    class T { }
    void f(T);
    void g(T, int);
}
NS::T parm;
void g(NS::T, float);
int main() {
    f(parm);         // OK, calls NS::f
    extern void g(NS::T, float);
    g(parm, 1);      // OK, calls g(NS::T, float)
}
```

Note 3: The associated namespace can include namespaces already considered by ordinary unqualified lookup. — end note

Example 3:
6.5.5 Qualified name lookup

6.5.5.1 General

1 Lookup of an identifier followed by a :: scope resolution operator considers only namespaces, types, and templates whose specializations are types. If a name, template-id, or decltype-specifier is followed by a ::, it shall designate a namespace, class, enumeration, or dependent type, and the :: is never interpreted as a complete nested-name-specifier.

[Example 1:

```cpp
class A {
public:
    static int n;
};
int main() {
    int A;
    A::n = 42; // OK
    A b; // error: A does not name a type
}
template<int> struct B : A {};
namespace N {
    template<int> void B();
    int f() {
        return B<0>::n; // error: N::B<0> is not a type
    }
}
```

—end example]

2 A member-qualified name is the (unique) component name (7.5.4.2), if any, of

(2.1) — an unqualified-id or

(2.2) — a nested-name-specifier of the form type-name :: or namespace-name ::

in the id-expression of a class member access expression (7.6.1.5). A qualified name is

(2.3) — a member-qualified name or

(2.4) — the terminal name of

(2.4.1) — a qualified-id,

(2.4.2) — a using-declarator,

(2.4.3) — a typename-specifier,

(2.4.4) — a qualified-namespace-specifier, or

(2.4.5) — a nested-name-specifier, elaborated-type-specifier, or class-or-decltype that has a nested-name-specifier (7.5.4.3).

The lookup context of a member-qualified name is the type of its associated object expression (considered dependent if the object expression is type-dependent). The lookup context of any other qualified name is the type, template, or namespace nominated by the preceding nested-name-specifier.

[Note 1: When parsing a class member access, the name following the -> or . is a qualified name even though it is not yet known of which kind. —end note]

[Example 2: In

```cpp
N::C::m.Base::f()
```

Base is a member-qualified name; the other qualified names are C, m, and f. —end example]

3 Qualified name lookup in a class, namespace, or enumeration performs a search of the scope associated with it (6.5.2) except as specified below. Unless otherwise specified, a qualified name undergoes qualified name lookup in its lookup context from the point where it appears unless the lookup context either is dependent and is not the current instantiation (13.8.3.2) or is not a class or class template. If nothing is found by qualified lookup for a member-qualified name that is the terminal name (7.5.4.2) of a nested-name-specifier and is not dependent, it undergoes unqualified lookup.

[Note 2: During lookup for a template specialization, no names are dependent. —end note]
[Example 3:

```cpp
int f();
struct A {
    int B, C;
    template<int> using D = void;
    using T = void;
    void f();
};
using B = A;
template<int> using C = A;
template<int> using D = A;
template<int> using X = A;
template<class T>
void g(T *p) {
    p->X<0>::f();  // error: A::X not found in ((p->X) < 0) > ::f()
    p->template X<0>::f();  // OK, ::X found in definition context
    p->B::f();   // OK, non-type A::B ignored
    p->template C<0>::f();  // error: A::C is not a template
    p->template D<0>::f();  // error: A::D<0> is not a class type
    p->T::f();   // error: A::T is not a class type
}
template void g(A*);
—end example]
```

§ 6.5.5.1 53

(4.1) — If a qualified name \( Q \) follows a \(~\)

(4.2) — Otherwise, its nested-name-specifier \( N \) shall nominate a type. If \( N \) has another nested-name-specifier \( S \), \( Q \) is looked up as if its lookup context were that nominated by \( S \).

(4.3) — Otherwise, if the terminal name of \( N \) is a member-qualified name \( M \), \( Q \) is looked up as if \(~Q\) appeared in place of \( M \) (as above).

(4.4) — Otherwise, \( Q \) undergoes unqualified lookup.

(4.5) — Each lookup for \( Q \) considers only types (if \( Q \) is not followed by a \(<\)) and templates whose specializations are types. If it finds nothing or is ambiguous, it is discarded.

(4.6) — The type-name that is or contains \( Q \) shall refer to its (original) lookup context (ignoring cv-qualification) under the interpretation established by at least one (successful) lookup performed.

[Example 4:

```cpp
struct C {
    typedef int I;
};
typedef int I1, I2;
extern int* p;
extern int* q;
void f() {
    p->C::I::~I();  // I is looked up in the scope of C
    q->I1::~I2();   // I2 is found by unqualified lookup
}
struct A {
    ~A();
};
typedef A AB;
int main() {
    AB* p;
    p->AB::~AB();  // explicitly calls the destructor for A
}
—end example]
```
6.5.5.2 Class members

In a lookup for a qualified name \( N \) whose lookup context is a class \( C \) in which function names are not ignored,\(^1\)

1. if the search finds the injected-class-name of \( C \) (11.1), or
2. if \( N \) is dependent and is the terminal name of a using-declarator (9.9) that names a constructor, \( N \) is instead considered to name the constructor of class \( C \). Such a constructor name shall be used only in the declarator-id of a (friend) declaration of a constructor or in a using-declaration.

[Example 1:
```
struct A { A(); };
struct B: public A { B(); };
A::A() { }
B::B() { }
B::A ba; // object of type A
A::A a; // error: A::A is not a type name
struct A::A a2; // object of type A
```
—end example]

6.5.5.3 Namespace members

Qualified name lookup in a namespace \( N \) additionally searches every element of the inline namespace set of \( N \) (9.8.2). If nothing is found, the results of the lookup are the results of qualified name lookup in each namespace nominated by a using-directive that precedes the point of the lookup and inhabits \( N \) or an element of \( N \)'s inline namespace set.

[Note 1: If a using-directive refers to a namespace that has already been considered, it does not affect the result. —end note]

[Example 1:
```
int x;
namespace Y {
    void f(float);
    void h(int);
}
namespace Z {
    void h(double);
}
namespace A {
    using namespace Y;
    void f(int);
    void g(int);
    int i;
}
namespace B {
    using namespace Z;
    void f(char);
    int i;
}
namespace AB {
    using namespace A;
    using namespace B;
    void g();
}
```

\(^1\) Lookups in which function names are ignored include names appearing in a nested-name-specifier, an elaborated-type-specifier, or a base-specifier.
void h()
{
    AB::g(); // g is declared directly in AB, therefore S is {AB::g()} and AB::g() is chosen
    AB::f(1); // f is not declared directly in AB so the rules are applied recursively to A and B;
    // namespace Y is not searched and Y::f(float) is not considered;
    // S is {A::f(int), B::f(char)} and overload resolution chooses A::f(int)
    AB::f('c'); // as above but resolution chooses B::f(char)
    AB::x++; // x is not declared directly in AB, and is not declared in A or B, so the rules
    // are applied recursively to Y and Z, S is {} so the program is ill-formed
    AB::i++; // i is not declared directly in AB so the rules are applied recursively to A and B,
    // S is {A::i, B::i} so the use is ambiguous and the program is ill-formed
    AB::h(16.8); // h is not declared directly in AB and not declared directly in A or B so the rules
    // are applied recursively to Y and Z, S is {Y::h(int), Z::h(double)} and
    // overload resolution chooses Z::h(double)
}

—end example]

[Note 2: The same declaration found more than once is not an ambiguity (because it is still a unique declaration).

Example 2:

namespace A {
    int a;
}

namespace B {
    using namespace A;
}

namespace C {
    using namespace A;
}

namespace BC {
    using namespace B;
    using namespace C;
}

void f()
{
    BC::a++; // OK, S is {A::a, A::a}
}

namespace D {
    using A::a;
}

namespace BD {
    using namespace B;
    using namespace D;
}

void g()
{
    BD::a++; // OK, S is {A::a, A::a}
}

—end example]

—end note]
**Example 3:** Because each referenced namespace is searched at most once, the following is well-defined:

```cpp
namespace B {
    int b;
}

namespace A {
    using namespace B;
    int a;
}

namespace B {
    using namespace A;
}

void f() {
    A::a++;
    // OK, a declared directly in A, S is {A::a}
    B::a++;
    // OK, both A and B searched (once), S is {A::a}
    A::b++;
    // OK, both A and B searched (once), S is {B::b}
    B::b++;
    // OK, b declared directly in B, S is {B::b}
}
```

—end example

**Note 3:** Class and enumeration declarations are not discarded because of other declarations found in other searches.

—end note

**Example 4:**

```cpp
namespace A {
    struct x { };
    int x;
    int y;
}

namespace B {
    struct y { };
}

namespace C {
    using namespace A;
    using namespace B;
    int i = C::x;
    // OK, A::x (of type int)
    int j = C::y;
    // ambiguous, A::y or B::y
}
```

—end example

### 6.5.6 Elaborated type specifiers

1. If the `class-key` or `enum` keyword in an *elaborated-type-specifier* is followed by an *identifier* that is not followed by `::`, lookup for the *identifier* is type-only (6.5.1).

   [Note 1: In general, the recognition of an *elaborated-type-specifier* depends on the following tokens. If the *identifier* is followed by `::`, see 6.5.5. —end note]

2. If the terminal name of the *elaborated-type-specifier* is a qualified name, lookup for it is type-only. If the name lookup does not find a previously declared *type-name*, the *elaborated-type-specifier* is ill-formed.

   [Example 1:

   ```cpp
   struct Node {
       struct Node* Next;
       // OK, refers to injected-class-name Node
       struct Data* Data;
       // OK, declares type Data at global scope and member Data
   };

   struct Data {
       struct Node* Node;
       // OK, refers to Node at global scope
       friend struct ::Glob;
       // error: Glob is not declared, cannot introduce a qualified type (9.2.9.4)
   }
   ```

§ 6.5.6
friend struct Glob;  // OK, refers to (as yet) undeclared Glob at global scope.
/* ... */
);

struct Base {
    struct Data;  // OK, declares nested Data
    struct ::Data* thatData;  // OK, refers to ::Data
    struct Base::Data* thisData;  // OK, refers to nested Data
    friend class ::Data;  // OK, global Data is a friend
    friend class Data;  // OK, nested Data is a friend
    struct Data { /* ... */ };  // Defines nested Data
};

struct Data;  // OK, redeclares Data at global scope
struct ::Data;  // error: cannot introduce a qualified type (9.2.9.4)
struct Base::Data;  // error: cannot introduce a qualified type (9.2.9.4)
struct Base::Datum;  // error: Datum undefined
struct Base::Data* pBase;  // OK, refers to nested Data

—end example

6.5.7 Using-directives and namespace aliases

In a using-directive or namespace-alias-definition, during the lookup for a namespace-name or for a name in a nested-name-specifier only namespace names are considered.

6.6 Program and linkage

A program consists of one or more translation units (5.1) linked together. A translation unit consists of a sequence of declarations.

translation-unit:
declaration-seqopt
global-module-fragmentopt module-declaration declaration-seqopt private-module-fragmentopt

A name is said to have linkage when it can denote the same object, reference, function, type, template, namespace or value as a name introduced by a declaration in another scope:

1. When a name has external linkage, the entity it denotes can be referred to by names from scopes of other translation units or from other scopes of the same translation unit.
2. When a name has module linkage, the entity it denotes can be referred to by names from other scopes of the same module unit (10.1) or from scopes of other module units of that same module.
3. When a name has internal linkage, the entity it denotes can be referred to by names from other scopes in the same translation unit.
4. When a name has no linkage, the entity it denotes cannot be referred to by names from other scopes.

The name of an entity that belongs to a namespace scope (6.4.6) has internal linkage if it is the name of:

1. a variable, variable template, function, or function template that is explicitly declared static; or
2. a non-template variable of non-volatile const-qualified type, unless
   1. it is declared in the purview of a module interface unit (outside the private-module-fragment, if any) or module partition, or
   2. it is explicitly declared extern, or
   3. it is inline, or
   4. it was previously declared and the prior declaration did not have internal linkage; or
3. a data member of an anonymous union.

[Note 1: An instantiated variable template that has const-qualified type can have external or module linkage, even if not declared extern. — end note]

An unnamed namespace or a namespace declared directly or indirectly within an unnamed namespace has internal linkage. All other namespaces have external linkage. The name of an entity that belongs to a namespace scope that has not been given internal linkage above and that is the name of:

1. a variable; or

§ 6.6 57
(4.2) — a function; or
(4.3) — a named class (11.1), or an unnamed class defined in a typedef declaration in which the class has the typedef name for linkage purposes (9.2.4); or
(4.4) — a named enumeration (9.7.1), or an unnamed enumeration defined in a typedef declaration in which the enumeration has the typedef name for linkage purposes (9.2.4); or
(4.5) — an unnamed enumeration that has an enumerator as a name for linkage purposes (9.7.1); or
(4.6) — a template
has its linkage determined as follows:
(4.7) — if the enclosing namespace has internal linkage, the name has internal linkage;
(4.8) — otherwise, if the declaration of the name is attached to a named module (10.1) and is not exported (10.2), the name has module linkage;
(4.9) — otherwise, the name has external linkage.

5 In addition, a member function, a static data member, a named class or enumeration that inhabits a class scope, or an unnamed class or enumeration defined in a typedef declaration that inhabits a class scope such that the class or enumeration has the typedef name for linkage purposes (9.2.4), has the same linkage, if any, as the name of the class of which it is a member.

6 [Example 1:

```c
static void f();
extern "C" void h();
static int i = 0;  // #1
void q() {
    extern void f();  // internal linkage
    extern void g();  // :g, external linkage
    extern void h();  // C language linkage
    int i;            // #2: i has no linkage
    {
        extern void f();  // internal linkage
        extern int i;    // #3: internal linkage
    }
}
```

Even though the declaration at line #2 hides the declaration at line #1, the declaration at line #3 still redeclares #1 and receives internal linkage. — end example]

7 Names not covered by these rules have no linkage. Moreover, except as noted, a name declared at block scope (6.4.3) has no linkage.

8 Two declarations of entities declare the same entity if, considering declarations of unnamed types to introduce their names for linkage purposes, if any (9.2.4, 9.7.1), they correspond (6.4.1), have the same target scope that is not a function or template parameter scope, and either

(8.1) — they appear in the same translation unit, or
(8.2) — they both declare names with module linkage and are attached to the same module, or
(8.3) — they both declare names with external linkage.

[Note 2: There are other circumstances in which declarations declare the same entity (9.11, 13.6, 13.7.6). — end note]

9 If a declaration $H$ that declares a name with internal linkage precedes a declaration $D$ in another translation unit $U$ and would declare the same entity as $D$ if it appeared in $U$, the program is ill-formed.

[Note 3: Such an $H$ can appear only in a header unit. — end note]

10 If two declarations of an entity are attached to different modules, the program is ill-formed; no diagnostic is required if neither is reachable from the other.

[Example 2:

```
decls.h";
int f();          // #1, attached to the global module
int g();         // #2, attached to the global module
```
Module interface of $M$:

```c
module;
#include "decls.h"
export module $M$;
export using ::f; // OK, does not declare an entity, exports #1
int g(); // error: matches #2, but attached to $M$
export int h(); // #3
export int k(); // #4
```

Other translation unit:

```c
import $M$;
static int h(); // error: matches #3
int k(); // error: matches #4
```

As a consequence of these rules, all declarations of an entity are attached to the same module; the entity is said to be attached to that module.

For any two declarations of an entity $E$:

11.1 — If one declares $E$ to be a variable or function, the other shall declare $E$ as one of the same type.

11.2 — If one declares $E$ to be an enumerator, the other shall do so.

11.3 — If one declares $E$ to be a namespace, the other shall do so.

11.4 — If one declares $E$ to be a type, the other shall declare $E$ to be a type of the same kind (9.2.9.4).

11.5 — If one declares $E$ to be a class template, the other shall do so with the same kind and an equivalent template-head (13.7.7.2).

[Note 4: The declarations can supply different default template arguments. — end note]

11.6 — If one declares $E$ to be a function template or a (partial specialization of a) variable template, the other shall declare $E$ to be one with an equivalent template-head and type.

11.7 — If one declares $E$ to be an alias template, the other shall declare $E$ to be one with an equivalent template-head and defining-type-id.

11.8 — If one declares $E$ to be a concept, the other shall do so.

Types are compared after all adjustments of types (during which typedefs (9.2.4) are replaced by their definitions); declarations for an array object can specify array types that differ by the presence or absence of a major array bound (9.3.4.5). No diagnostic is required if neither declaration is reachable from the other.

[Example 3:

```c
int f(int x, int x); // error: different entities for x
void g(); // #1
void g(int); // OK, different entity from #1
int g(); // error: same entity as #1 with different type
void h(); // #2
namespace h {} // error: same entity as #2, but not a function
```

— end example]

Note 5: Linkage to non-C++ declarations can be achieved using a linkage-specification (9.11). — end note]

A declaration $D$ names an entity $E$ if

13.1 — $D$ contains a lambda-expression whose closure type is $E$.

13.2 — $E$ is not a function or function template and $D$ contains an id-expression, type-specifier, nested-name-specifier, template-name, or concept-name denoting $E$, or

13.3 — $E$ is a function or function template and $D$ contains an expression that names $E$ (6.3) or an id-expression that refers to a set of overloads that contains $E$.

[Note 6: Non-dependent names in an instantiated declaration do not refer to a set of overloads (13.8). — end note]

A declaration is an exposure if it either names a TU-local entity (defined below), ignoring
the function-body for a non-inline function or function template (but not the deduced return type for a (possibly instantiated) definition of a function with a declared return type that uses a placeholder type (9.2.9.6)),

— the initializer for a variable or variable template (but not the variable's type),

— friend declarations in a class definition, and

— any reference to a non-volatile const object or reference with internal or no linkage initialized with a constant expression that is not an odr-use (6.3),

or defines a constexpr variable initialized to a TU-local value (defined below).

[Note 7: An inline function template can be an exposure even though certain explicit specializations of it would be usable in other translation units. — end note]

An entity is TU-local if it is

— a type, function, variable, or template that

— has a name with internal linkage, or

— does not have a name with linkage and is declared, or introduced by a lambda-expression, within the definition of a TU-local entity,

— a type with no name that is defined outside a class-specifier, function body, or initializer or is introduced by a defining-type-specifier that is used to declare only TU-local entities,

— a specialization of a TU-local template,

— a specialization of a template with any TU-local template argument, or

— a specialization of a template whose (possibly instantiated) declaration is an exposure.

[Note 8: A specialization can be produced by implicit or explicit instantiation. — end note]

A value or object is TU-local if either

— it is, or is a pointer to, a TU-local function or the object associated with a TU-local variable, or

— it is an object of class or array type and any of its subobjects or any of the objects or functions to which its non-static data members of reference type refer is TU-local and is usable in constant expressions.

If a (possibly instantiated) declaration of, or a deduction guide for, a non-TU-local entity in a module interface unit (outside the private-module-fragment, if any) or module partition (10.1) is an exposure, the program is ill-formed. Such a declaration in any other context is deprecated (D.7).

If a declaration that appears in one translation unit names a TU-local entity declared in another translation unit that is not a header unit, the program is ill-formed. A declaration instantiated for a template specialization (13.9) appears at the point of instantiation of the specialization (13.8.4.1).

[Example 4:]

Translation unit #1:

```c
export module A;
static void f() {}  // error: is an exposure of f
inline void it() { f(); }  // error: is an exposure of f
static inline void its() { f(); }  // OK
template<int> void g() { its(); }  // OK
template void g<0>();
dcltype(f) *fp;  // error: f (though not its type) is TU-local
auto &fr = f;  // OK
constexpr auto &fr2 = fr;  // error: is an exposure of f
constexpr static auto fp2 = fr;  // OK

struct S { void (&ref)(); } s{f};  // OK, value is TU-local
constexpr extern struct W { S &s; } wrap{s};  // OK, value is not TU-local

static auto x = []{f();};  // OK
auto x2 = x;  // error: the closure type is TU-local
int y = ([](f());){,0};  // error: the closure type is not TU-local
int y2 = (x,0);  // OK
```
6.7 Memory and objects

6.7.1 Memory model

The fundamental storage unit in the C++ memory model is the byte. A byte is at least large enough to contain the ordinary literal encoding of any element of the basic literal character set (5.3) and the eight-bit code units of the Unicode UTF-8 encoding form and is composed of a contiguous sequence of bits, the number of which is implementation-defined. The least significant bit is called the low-order bit; the most significant bit is called the high-order bit. The memory available to a C++ program consists of one or more sequences of contiguous bytes. Every byte has a unique address.

A memory location is either an object of scalar type that is not a bit-field or a maximal sequence of adjacent bit-fields all having nonzero width.

Two or more threads of execution can access separate memory locations without interfering with each other.

Example 1: A class declared as

```cpp
struct {
  char a;
  int b:5,
    c:11,
    :0,
  d:8;
  struct {int ee:8;} e;
};
```

contains four separate memory locations: The member `a` and bit-fields `d` and `e.ee` are each separate memory locations, and can be modified concurrently without interfering with each other. The bit-fields `b` and `c` together constitute the fourth memory location. The bit-fields `b` and `c` cannot be concurrently modified, but `b` and `a`, for example, can be.

---

20) Unicode® is a registered trademark of Unicode, Inc. This information is given for the convenience of users of this document and does not constitute an endorsement by ISO or IEC of this product.

21) The number of bits in a byte is reported by the macro `CHAR_BIT` in the header `<climits>` (17.3.6).
6.7.2 Object model

The constructs in a C++ program create, destroy, refer to, access, and manipulate objects. An object is created by a definition (6.2), by a new-expression (7.6.2.8), by an operation that implicitly creates objects (see below), when implicitly changing the active member of a union (11.5), or when a temporary object is created (7.3.5, 6.7.7). An object occupies a region of storage in its period of construction (11.9.5), throughout its lifetime (6.7.3), and in its period of destruction (11.9.5).

[Note 1: A function is not an object, regardless of whether or not it occupies storage in the way that objects do. —end note]

The properties of an object are determined when the object is created. An object can have a name (6.1). An object has a storage duration (6.7.5) which influences its lifetime (6.7.3). An object has a type (6.8).

[Note 2: Some objects are polymorphic (11.7.3); the implementation generates information associated with each such object that makes it possible to determine that object’s type during program execution. —end note]

Objects can contain other objects, called subobjects. A subobject can be a member subobject (11.4), a base class subobject (11.7), or an array element. An object that is not a subobject of any other object is called a complete object. If an object is created in storage associated with a member subobject or array element e (which may or may not be within its lifetime), the created object is a subobject of e’s containing object if:

1. the lifetime of e’s containing object has begun and not ended, and
2. the storage for the new object exactly overlays the storage location associated with e, and
3. the new object is of the same type as e (ignoring cv-qualification).

If a complete object is created (7.6.2.8) in storage associated with another object e of type “array of N unsigned char” or of type “array of N std::byte” (17.2.1), that array provides storage for the created object if:

1. the lifetime of e has begun and not ended, and
2. the storage for the new object fits entirely within e, and
3. there is no array object that satisfies these constraints nested within e.

[Note 3: If that portion of the array previously provided storage for another object, the lifetime of that object ends because its storage was reused (6.7.3). —end note]

Example 1:

```cpp
template<typename ...T>
struct AlignedUnion {
    alignas(T...) unsigned char data[max(sizeof(T)...)];
};

int f() {
    AlignedUnion<int, char> au;
    int *p = new (au.data) int;  // OK, au.data provides storage
    char *c = new (au.data) char();  // OK, ends lifetime of *p
    char *d = new (au.data + 1) char();  // OK
    return *c + *d;
}

struct A { unsigned char a[32]; };  // a provides storage for *b
struct B { unsigned char b[16]; };  // b->b does not provide storage for *p (directly).
A a;
B *b = new (a.a + 8) B;  // a.a provides storage for *b
int *p = new (b->b + 4) int;  // b->b provides storage for *p
// but *p is nested within a (see below)
```

An object a is nested within another object b if:

1. a is a subobject of b, or
2. b provides storage for a, or
3. there exists an object c where a is nested within c, and c is nested within b.

For every object x, there is some object called the complete object of x, determined as follows:
If \( x \) is a complete object, then the complete object of \( x \) is itself.

Otherwise, the complete object of \( x \) is the complete object of the (unique) object that contains \( x \).

If a complete object, a member subobject, or an array element is of class type, its type is considered the most derived class, to distinguish it from the class type of any base class subobject; an object of a most derived class type or of a non-class type is called a most derived object.

A potentially-overlapping subobject is either:

- a base class subobject, or
- a non-static data member declared with the \texttt{no_unique_address} attribute (9.12.11).

An object has nonzero size if it

- is not a potentially-overlapping subobject, or
- is not of class type, or
- is of a class type with virtual member functions or virtual base classes, or
- has subobjects of nonzero size or unnamed bit-fields of nonzero length.

Otherwise, if the object is a base class subobject of a standard-layout class type with no non-static data members, it has zero size. Otherwise, the circumstances under which the object has zero size are implementation-defined. Unless it is a bit-field (11.4.10), an object with nonzero size shall occupy one or more bytes of storage, including every byte that is occupied in full or in part by any of its subobjects. An object of trivially copyable or standard-layout type (6.8.1) shall occupy contiguous bytes of storage.

Unless an object is a bit-field or a subobject of zero size, the address of that object is the address of the first byte it occupies. Two objects with overlapping lifetimes that are not bit-fields may have the same address if one is nested within the other, or if at least one is a subobject of zero size and they are of different types; otherwise, they have distinct addresses and occupy disjoint bytes of storage.

```c
Example 2:
static const char test1 = 'x';
static const char test2 = 'x';
const bool b = &test1 != &test2; // always true
@end example
```

The address of a non-bit-field subobject of zero size is the address of an unspecified byte of storage occupied by the complete object of that subobject.

Some operations are described as implicitly creating objects within a specified region of storage. For each operation that is specified as implicitly creating objects, that operation implicitly creates and starts the lifetime of zero or more objects of implicit-lifetime types (6.8.1) in its specified region of storage if doing so would result in the program having defined behavior. If no such set of objects would give the program defined behavior, the behavior of the program is undefined. If multiple such sets of objects would give the program defined behavior, it is unspecified which such set of objects is created.

```c
Note 4: Such operations do not start the lifetimes of subobjects of such objects that are not themselves of implicit-lifetime types. —end note
```

Further, after implicitly creating objects within a specified region of storage, some operations are described as producing a pointer to a suitable created object. These operations select one of the implicitly-created objects whose address is the address of the start of the region of storage, and produce a pointer value that points to that object, if that value would result in the program having defined behavior. If no such pointer value would give the program defined behavior, the behavior of the program is undefined. If multiple such pointer values would give the program defined behavior, it is unspecified which such pointer value is produced.

```c
Example 3:
#include <cstdlib>
struct X { int a, b; }
X *make_x() {
    // The call to \texttt{std::malloc} implicitly creates an object of type X
    // and its subobjects a and b, and returns a pointer to that X object
    // (or an object that is pointer-interconvertible (6.8.4) with it),
    X *x = (X *)\texttt{std::malloc} (sizeof(X));
    x->a = 1;
    x->b = 2;
    return x;
}
```

22) Under the “as-if” rule an implementation is allowed to store two objects at the same machine address or not store an object at all if the program cannot observe the difference (6.9.1).
An operation that begins the lifetime of an array of `unsigned char` or `std::byte` implicitly creates objects within the region of storage occupied by the array.

[Note 5: The array object provides storage for these objects. — end note]

Any implicit or explicit invocation of a function named `operator new` or `operator new[]` implicitly creates objects in the returned region of storage and returns a pointer to a suitable created object.

[Note 6: Some functions in the C++ standard library implicitly create objects (20.2.6, 20.2.9.3, 20.2.12, 23.5.3, 22.15.3). — end note]

### 6.7.3 Lifetime

The lifetime of an object or reference is a runtime property of the object or reference. A variable is said to have **vacuous initialization** if it is default-initialized and, if it is of class type or a (possibly multi-dimensional) array thereof, that class type has a trivial default constructor. The lifetime of an object of type `T` begins when:

1. storage with the proper alignment and size for type `T` is obtained, and
2. its initialization (if any) is complete (including vacuous initialization) (9.4),

except that if the object is a union member or subobject thereof, its lifetime only begins if that union member is the initialized member in the union (9.4.2, 11.9.3), or as described in 11.5, 11.4.5.3, and 11.4.6, and except as described in 20.2.10.2. The lifetime of an object `o` of type `T` ends when:

1. if `T` is a non-class type, the object is destroyed, or
2. if `T` is a class type, the destructor call starts, or
3. the storage which the object occupies is released, or is reused by an object that is not nested within `o` (6.7.2).

The lifetime of a reference begins when its initialization is complete. The lifetime of a reference ends as if it were a scalar object requiring storage.

[Note 1: 11.9.3 describes the lifetime of base and member subobjects. — end note]

The properties ascribed to objects and references throughout this document apply for a given object or reference only during its lifetime.

[Note 2: In particular, before the lifetime of an object starts and after its lifetime ends there are significant restrictions on the use of the object, as described below, in 11.9.3, and in 11.9.5. Also, the behavior of an object under construction and destruction can differ from the behavior of an object whose lifetime has started and not ended. 11.9.3 and 11.9.5 describe the behavior of an object during its periods of construction and destruction. — end note]

A program may end the lifetime of an object of class type without invoking the destructor, by reusing or releasing the storage as described above.

[Note 3: A `delete-expression` (7.6.2.9) invokes the destructor prior to releasing the storage. — end note]

In this case, the destructor is not implicitly invoked.

[Note 4: The correct behavior of a program often depends on the destructor being invoked for each object of class type. — end note]

Before the lifetime of an object has started but after the storage which the object will occupy has been allocated or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any pointer that represents the address of the storage location where the object will be or was located may be used but only in limited ways. For an object under construction or destruction, see 11.9.5. Otherwise, such a pointer refers to allocated storage (6.7.5.5.2), and using the pointer as if the
pointer were of type \texttt{void*} is well-defined. Indirection through such a pointer is permitted but the resulting value may only be used in limited ways, as described below. The program has undefined behavior if:

1. the pointer is used as the operand of a \texttt{delete-expression},
2. the pointer is used to access a non-static data member or call a non-static member function of the object, or
3. the pointer is implicitly converted (7.3.12) to a pointer to a virtual base class, or
4. the pointer is used as the operand of a \texttt{static_cast} (7.6.1.9), except when the conversion is to pointer to \texttt{cv void}, or to pointer to \texttt{cv void} and subsequently to pointer to \texttt{cv char}, \texttt{cv unsigned char}, or \texttt{cv std::byte} (17.2.1), or
5. the pointer is used as the operand of a \texttt{dynamic_cast} (7.6.1.7).

\begin{example}
\begin{verbatim}
#include <cstdlib>

struct B {
  virtual void f();
  void mutate();
  virtual ~B();
};

struct D1 : B { void f(); }
struct D2 : B { void f(); }

void B::mutate() {
  new (this) D2;  // reuses storage — ends the lifetime of *this
  f();            // undefined behavior
  \ldots = this;  // OK, this points to valid memory
}

void g() {
  void* p = std::malloc(sizeof(D1) + sizeof(D2));
  B* pb = new (p) D1;
  \*pb;
  // OK, pb points to valid memory
  void* q = pb;
  // OK, pb points to valid memory
  \*pb->f();
  // undefined behavior: lifetime of \*pb has ended
}
\end{verbatim}
\end{example}

Similarly, before the lifetime of an object has started but after the storage which the object will occupy has been allocated or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any gvalue that refers to the original object may be used but only in limited ways. For an object under construction or destruction, see 11.9.5. Otherwise, such a gvalue refers to allocated storage (6.7.5.5.2), and using the properties of the gvalue that do not depend on its value is well-defined. The program has undefined behavior if:

1. the gvalue is used to access the object, or
2. the gvalue is used to call a non-static member function of the object, or
3. the gvalue is bound to a reference to a virtual base class (9.4.4), or
4. the gvalue is used as the operand of a \texttt{dynamic_cast} (7.6.1.7) or as the operand of \texttt{typeid}.

If, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, a new object is created at the storage location which the original object occupied, a pointer that pointed to the original object, a reference that referred to the original object, or the name of the original object will automatically refer to the new object and, once the lifetime of the new object has started, can be used to manipulate the new object, if the original object is transparently replaceable (see below) by the new object. An object \(o_1\) is \textit{transparently replaceable} by an object \(o_2\) if:

1. the storage that \(o_2\) occupies exactly overlays the storage that \(o_1\) occupied, and
2. \(o_1\) and \(o_2\) are of the same type (ignoring the top-level cv-qualifiers), and
— $o_1$ is not a const, complete object, and
— neither $o_1$ nor $o_2$ is a potentially-overlapping subobject (6.7.2), and
— either $o_1$ and $o_2$ are both complete objects, or $o_1$ and $o_2$ are direct subobjects of objects $p_1$ and $p_2$, respectively, and $p_1$ is transparently replaceable by $p_2$.

[Example 2:

```cpp
struct C {
  int i;
  void f();
  const C& operator=( const C& );
};

const C& C::operator=( const C& other) {
  if ( this != &other ) {
    this->~C(); // lifetime of *this ends
    new (this) C(other); // new object of type C created
    f(); // well-defined
  }
  return *this;
}

C c1;
C c2;
c1 = c2; // well-defined
c1.f(); // well-defined; c1 refers to a new object of type C

-end example]

[Note 5: If these conditions are not met, a pointer to the new object can be obtained from a pointer that represents the address of its storage by calling `std::launder` (17.6.5). — end note]

If a program ends the lifetime of an object of type $T$ with static (6.7.5.2), thread (6.7.5.3), or automatic (6.7.5.4) storage duration and if $T$ has a non-trivial destructor, and another object of the original type does not occupy that same storage location when the implicit destructor call takes place, the behavior of the program is undefined. This is true even if the block is exited with an exception.

[Example 3:

```cpp
class T { }; /* end example]

class B { /* undefined behavior at block exit
  void h() {
    B b;
    new (&b) T;
  }
}

 /* end example]

Creating a new object within the storage that a const, complete object with static, thread, or automatic storage duration occupies, or within the storage that such a const object used to occupy before its lifetime ended, results in undefined behavior.

[Example 4:

```cpp
struct B { /* end example]
  B();
  ~B();
};

const B b;

24) That is, an object for which a destructor will be called implicitly—upon exit from the block for an object with automatic storage duration, upon exit from the thread for an object with thread storage duration, or upon exit from the program for an object with static storage duration.
void h() {
  b..B();
  new (const_cast<B*>(\&b)) const B;  // undefined behavior
}

In this subclause, “before” and “after” refer to the “happens before” relation (6.9.2).

[Note 6: Therefore, undefined behavior results if an object that is being constructed in one thread is referenced from
another thread without adequate synchronization. — end note]

6.7.4 Indeterminate values

1 When storage for an object with automatic or dynamic storage duration is obtained, the object has an
indeterminate value, and if no initialization is performed for the object, that object retains an indeterminate
value until that value is replaced (7.6.19).

[Note 1: Objects with static or thread storage duration are zero-initialized, see 6.9.3.2. — end note]

2 If an indeterminate value is produced by an evaluation, the behavior is undefined except in the following
cases:

(2.1) — If an indeterminate value of unsigned ordinary character type (6.8.2) or std::byte type (17.2.1) is
produced by the evaluation of:

(2.1.1) — the second or third operand of a conditional expression (7.6.16),
(2.1.2) — the right operand of a comma expression (7.6.20),
(2.1.3) — the operand of a cast or conversion (7.3.9, 7.6.1.4, 7.6.1.9, 7.6.3) to an unsigned ordinary character
type or std::byte type (17.2.1), or
(2.1.4) — a discarded-value expression (7.2.3),
then the result of the operation is an indeterminate value.

(2.2) — If an indeterminate value of unsigned ordinary character type or std::byte type is produced by the
evaluation of the right operand of a simple assignment operator (7.6.19) whose first operand is an lvalue
of unsigned ordinary character type or std::byte type, an indeterminate value replaces the value
of the object referred to by the left operand.

(2.3) — If an indeterminate value of unsigned ordinary character type is produced by the evaluation of the
initialization expression when initializing an object of unsigned ordinary character type, that object
is initialized to an indeterminate value.

(2.4) — If an indeterminate value of unsigned ordinary character type or std::byte type is produced by the
evaluation of the initialization expression when initializing an object of std::byte type, that object
is initialized to an indeterminate value.

[Example 1:

int f(bool b) {
  unsigned char c;
  unsigned char d = c;  // OK, d has an indeterminate value
  int e = d;  // undefined behavior
  return b ? d : 0;  // undefined behavior if b is true
}

— end example]

6.7.5 Storage duration

6.7.5.1 General

1 The storage duration is the property of an object that defines the minimum potential lifetime of the storage
containing the object. The storage duration is determined by the construct used to create the object and is
one of the following:

(1.1) — static storage duration
(1.2) — thread storage duration
(1.3) — automatic storage duration
(1.4) — dynamic storage duration
Static, thread, and automatic storage durations are associated with objects introduced by declarations (6.2) and implicitly created by the implementation (6.7.7). The dynamic storage duration is associated with objects created by a `new-expression` (7.6.2.8).

The storage duration categories apply to references as well.

When the end of the duration of a region of storage is reached, the values of all pointers representing the address of any part of that region of storage become invalid pointer values (6.8.4). Indirection through an invalid pointer value and passing an invalid pointer value to a deallocation function have undefined behavior. Any other use of an invalid pointer value has implementation-defined behavior.

6.7.5.2 Static storage duration [basic.stc.static]

1 All variables which

(1.1) — do not have thread storage duration and

(1.2) — belong to a namespace scope (6.4.6) or are first declared with the `static` or `extern` keywords (9.2.2) have static storage duration. The storage for these entities lasts for the duration of the program (6.9.3.2, 6.9.3.4).

2 If a variable with static storage duration has initialization or a destructor with side effects, it shall not be eliminated even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in 11.9.6.

3 [Note 1: The keyword `static` can be used to declare a block variable (6.4.3) with static storage duration; 8.8 and 6.9.3.4 describe the initialization and destruction of such variables. The keyword `static` applied to a class data member in a class definition gives the data member static storage duration (11.4.9.3). — end note]

6.7.5.3 Thread storage duration [basic.stc.thread]

1 All variables declared with the `thread_local` keyword have thread storage duration. The storage for these entities lasts for the duration of the thread in which they are created. There is a distinct object or reference per thread, and use of the declared name refers to the entity associated with the current thread.

2 [Note 1: A variable with thread storage duration is initialized as specified in 6.9.3.2, 6.9.3.3, and 8.8 and, if constructed, is destroyed on thread exit (6.9.3.4). — end note]

6.7.5.4 Automatic storage duration [basic.stc.auto]

1 Variables that belong to a block or parameter scope and are not explicitly declared `static`, `thread_local`, or `extern` have automatic storage duration. The storage for these entities lasts until the block in which they are created exits.

2 [Note 1: These variables are initialized and destroyed as described in 8.8. — end note]

3 If a variable with automatic storage duration has initialization or a destructor with side effects, an implementation shall not destroy it before the end of its block nor eliminate it as an optimization, even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in 11.9.6.

6.7.5.5 Dynamic storage duration [basic.stc.dynamic]

6.7.5.5.1 General [basic.stc.dynamic.general]

1 Objects can be created dynamically during program execution (6.9.1), using `new-expressions` (7.6.2.8), and destroyed using `delete-expressions` (7.6.2.9). A C++ implementation provides access to, and management of, dynamic storage via the global allocation functions `operator new` and `operator new[]` and the global deallocation functions `operator delete` and `operator delete[]`.

[Note 1: The non-allocating forms described in 17.6.3.4 do not perform allocation or deallocation. — end note]

2 The library provides default definitions for the global allocation and deallocation functions. Some global allocation and deallocation functions are replaceable (10.1); these are attached to the global module (10.1). A C++ program shall provide at most one definition of a replaceable allocation or deallocation function. Any such function definition replaces the default version provided in the library (16.4.5.6). The following allocation and deallocation functions (17.6) are implicitly declared in global scope in each translation unit of a program.

```cpp
[[nodiscard]] void* operator new(std::size_t);
[[nodiscard]] void* operator new(std::size_t, std::align_val_t);
```

25) Some implementations might define that copying an invalid pointer value causes a system-generated runtime fault.
These implicit declarations introduce only the function names `operator new`, `operator new[]`, `operator delete`, and `operator delete[]`.

[Note 2: The implicit declarations do not introduce the names `std`, `std::size_t`, `std::align_val_t`, or any other names that the library uses to declare these names. Thus, a `new-expression`, `delete-expression`, or function call that refers to one of these functions without importing or including the header `<new>` (17.6.2) or importing a C++ library module (16.4.2.4) is well-formed. However, referring to `std` or `std::size_t` or `std::align_val_t` is ill-formed unless a standard library declaration (17.2.1, 17.6.2, 16.4.2.4) of that name precedes (6.5.1) the use of that name. — end note]

Allocation and/or deallocation functions may also be declared and defined for any class (11.4.11).

3 If the behavior of an allocation or deallocation function does not satisfy the semantic constraints specified in 6.7.5.5.2 and 6.7.5.5.3, the behavior is undefined.

6.7.5.5.2 Allocation functions

1 An allocation function that is not a class member function shall belong to the global scope and not have a name with internal linkage. The return type shall be `void*`. The first parameter shall have type `std::size_t` (17.2). The first parameter shall not have an associated default argument (9.3.4.7). The value of the first parameter is interpreted as the requested size of the allocation. An allocation function can be a function template. Such a template shall declare its return type and first parameter as specified above (that is, template parameter types shall not be used in the return type and first parameter type). Allocation function templates shall have two or more parameters.

2 An allocation function attempts to allocate the requested amount of storage. If it is successful, it returns the address of the start of a block of storage whose length in bytes is at least as large as the requested size. The order, contiguity, and initial value of storage allocated by successive calls to an allocation function are unspecified. Even if the size of the space requested is zero, the request can fail. If the request succeeds, the value returned by a replaceable allocation function is a non-null pointer value (6.8.4) p0 different from any previously returned value p1, unless that value p1 was subsequently passed to a replaceable deallocation function. Furthermore, for the library allocation functions in 17.6.3.2 and 17.6.3.3, p0 represents the address of a block of storage disjoint from the storage for any other object accessible to the caller. The effect of indirection through a pointer returned from a request for zero size is undefined.26

3 For an allocation function other than a reserved placement allocation function (17.6.3.4), the pointer returned on a successful call shall represent the address of storage that is aligned as follows:

(3.1) — If the allocation function takes an argument of type `std::align_val_t`, the storage will have the alignment specified by the value of this argument.

(3.2) — Otherwise, if the allocation function is named `operator new[]`, the storage is aligned for any object that does not have new-extended alignment (6.7.6) and is no larger than the requested size.

(3.3) — Otherwise, the storage is aligned for any object that does not have new-extended alignment and is of the requested size.

4 An allocation function that fails to allocate storage can invoke the currently installed new-handler function (17.6.4.3), if any.

[Note 1: A program-supplied allocation function can obtain the address of the currently installed `new_handler` using the `std::get_new_handler` function (17.6.4.5). — end note]

26) The intent is to have `operator new()` implementable by calling `std::malloc()` or `std::calloc()`, so the rules are substantially the same. C++ differs from C in requiring a zero request to return a non-null pointer.
An allocation function that has a non-throwing exception specification (14.5) indicates failure by returning a null pointer value. Any other allocation function never returns a null pointer value and indicates failure only by throwing an exception (14.2) of a type that would match a handler (14.4) of type `std::bad_alloc` (17.6.4.1).

A global allocation function is only called as the result of a new expression (7.6.2.8), or called directly using the function call syntax (7.6.1.3), or called indirectly to allocate storage for a coroutine state (9.5.4), or called indirectly through calls to the functions in the C++ standard library.

[Note 2: In particular, a global allocation function is not called to allocate storage for objects with static storage duration (6.7.5.2), for objects or references with thread storage duration (6.7.5.3), for objects of type `std::type_info` (7.6.1.8), or for an exception object (14.2). — end note]

### 6.7.5.5.3 Deallocation functions [basic.stc.dynamic.deallocation]

1 A deallocation function that is not a class member function shall belong to the global scope and not have a name with internal linkage.

2 A deallocation function is a *destroying operator delete* if it has at least two parameters and its second parameter is of type `std::destroying_delete_t`. A destroying operator delete shall be a class member function named `operator delete`.

[Note 1: Array deletion cannot use a destroying operator delete. — end note]

3 Each deallocation function shall return `void`. If the function is a destroying operator delete declared in class type `C`, the type of its first parameter shall be `C*`; otherwise, the type of its first parameter shall be `void*`. A deallocation function may have more than one parameter. A usual deallocation function is a deallocation function whose parameters after the first are

   (3.1) — optionally, a parameter of type `std::destroying_delete_t`, then
   (3.2) — optionally, a parameter of type `std::size_t`, then
   (3.3) — optionally, a parameter of type `std::align_val_t`.

A destroying operator delete shall be a usual deallocation function. A deallocation function may be an instance of a function template. Neither the first parameter nor the return type shall depend on a template parameter. A deallocation function template shall have two or more function parameters. A template instance is never a usual deallocation function, regardless of its signature.

4 If a deallocation function terminates by throwing an exception, the behavior is undefined. The value of the first argument supplied to a deallocation function may be a null pointer value; if so, and if the deallocation function is one supplied in the standard library, the call has no effect.

5 If the argument given to a deallocation function in the standard library is a pointer that is not the null pointer value (6.8.4), the deallocation function shall deallocate the storage referenced by the pointer, ending the duration of the region of storage.

### 6.7.5.6 Duration of subobjects [basic.stc.inherit]

1 The storage duration of subobjects and reference members is that of their complete object (6.7.2).

### 6.7.6 Alignment [basic.align]

1 Object types have *alignment requirements* (6.8.2, 6.8.4) which place restrictions on the addresses at which an object of that type may be allocated. An alignment is an implementation-defined integer value representing the number of bytes between successive addresses at which a given object can be allocated. An object type imposes an alignment requirement on every object of that type; stricter alignment can be requested using the alignment specifier (9.12.2).

2 A *fundamental alignment* is represented by an alignment less than or equal to the greatest alignment supported by the implementation in all contexts, which is equal to `alignof(std::max_align_t)` (17.2). The alignment required for a type may be different when it is used as the type of a complete object and when it is used as the type of a subobject.

[Example 1:]

```c++
struct B { long double d; };
struct D : virtual B { char c; };
```

---

27) The global `operator delete(void*, std::size_t)` precludes use of an allocation function `void operator new(std::size_t, std::size_t)` as a placement allocation function (C.4.3).
When \( D \) is the type of a complete object, it will have a subobject of type \( B \), so it must be aligned appropriately for a \texttt{long double}. If \( D \) appears as a subobject of another object that also has \( B \) as a virtual base class, the \( B \) subobject might be part of a different subobject, reducing the alignment requirements on the \( D \) subobject. —end example

The result of the \texttt{alignof} operator reflects the alignment requirement of the type in the complete-object case.

An extended alignment is represented by an alignment greater than \texttt{alignof(std::max\_align\_t)}. It is implementation-defined whether any extended alignments are supported and the contexts in which they are supported (9.12.2). A type having an extended alignment requirement is an over-aligned type.

[Note 1: Every over-aligned type is or contains a class type to which extended alignment applies (possibly through a non-static data member). — end note]

A new-extended alignment is represented by an alignment greater than \texttt{__STDCPP\_DEFAULT\_NEW\_ALIGNMENT\_} (15.11).

Alignments are represented as values of the type \texttt{std::size\_t}. Valid alignments include only those values returned by an \texttt{alignof} expression for the fundamental types plus an additional implementation-defined set of values, which may be empty. Every alignment value shall be a non-negative integral power of two.

Alignments have an order from weaker to stronger or stricter alignments. Stricter alignments have larger alignment values. An address that satisfies an alignment requirement also satisfies any weaker valid alignment requirement.

The alignment requirement of a complete type can be queried using an \texttt{alignof} expression (7.6.2.6). Furthermore, the narrow character types (6.8.2) shall have the weakest alignment requirement.

[Note 2: This enables the ordinary character types to be used as the underlying type for an aligned memory area (9.12.2). —end note]

Comparing alignments is meaningful and provides the obvious results:

1. Two alignments are equal when their numeric values are equal.
2. Two alignments are different when their numeric values are not equal.
3. When an alignment is larger than another it represents a stricter alignment.

[Note 3: The runtime pointer alignment function (20.2.5) can be used to obtain an aligned pointer within a buffer; an alignment-specifier (9.12.2) can be used to align storage explicitly. —end note]

If a request for a specific extended alignment in a specific context is not supported by an implementation, the program is ill-formed.

### 6.7.7 Temporary objects

Temporary objects are created

1. when a prvalue is converted to an xvalue (7.3.5),
2. when needed by the implementation to pass or return an object of trivially copyable type (see below), and
3. when throwing an exception (14.2).

[Note 1: The lifetime of exception objects is described in 14.2. —end note]

Even when the creation of the temporary object is unevaluated (7.2.3), all the semantic restrictions shall be respected as if the temporary object had been created and later destroyed.

[Note 2: This includes accessibility (11.8) and whether it is deleted, for the constructor selected and for the destructor. However, in the special case of the operand of a \texttt{decltype-specifier} (9.2.9.5), no temporary is introduced, so the foregoing does not apply to such a prvalue. —end note]

The materialization of a temporary object is generally delayed as long as possible in order to avoid creating unnecessary temporary objects.

[Note 3: Temporary objects are materialized:

1. when binding a reference to a prvalue (9.4.4, 7.6.1.4, 7.6.1.7, 7.6.1.9, 7.6.1.11, 7.6.3),
2. when performing member access on a class prvalue (7.6.1.5, 7.6.4),
3. when performing an array-to-pointer conversion or subscripting on an array prvalue (7.3.3, 7.6.1.2),
4. when initializing an object of type \texttt{std::initializer\_list<T>} from a \texttt{braced-init-list} (9.4.5),
5. for certain unevaluated operands (7.6.1.8, 7.6.2.5), and]
(2.6) — when a prvalue that has type other than cv void appears as a discarded-value expression (7.2.3).

—end note

[Example 1: Consider the following code:

class X {
public:
    X(int);
    X(const X&);
    X& operator=(const X&);
    ~X();
};
class Y {
public:
    Y(int);
    Y(Y&&);
    ~Y();
};
X f(X);
Y g(Y);

void h() {
    X a(1);
    X b = f(X(2));
    Y c = g(Y(3));
    a = f(a);
}

X(2) is constructed in the space used to hold f()’s argument and Y(3) is constructed in the space used to hold g()’s argument. Likewise, f()’s result is constructed directly in b and g()’s result is constructed directly in c. On the other hand, the expression a = f(a) requires a temporary for the result of f(a), which is materialized so that the reference parameter of X::operator=(const X&) can bind to it. —end example]

3 When an object of class type X is passed to or returned from a function, if X has at least one eligible copy or move constructor (11.4.4), each such constructor is trivial, and the destructor of X is either trivial or deleted, implementations are permitted to create a temporary object to hold the function parameter or result object. The temporary object is constructed from the function argument or return value, respectively, and the function’s parameter or return object is initialized as if by using the eligible trivial constructor to copy the temporary (even if that constructor is inaccessible or would not be selected by overload resolution to perform a copy or move of the object).

[Note 4: This latitude is granted to allow objects of class type to be passed to or returned from functions in registers. —end note]

4 When an implementation introduces a temporary object of a class that has a non-trivial constructor (11.4.5.2, 11.4.5.3), it shall ensure that a constructor is called for the temporary object. Similarly, the destructor shall be called for a temporary with a non-trivial destructor (11.4.7). Temporary objects are destroyed as the last step in evaluating the full-expression (6.9.1) that (lexically) contains the point where they were created. This is true even if that evaluation ends in throwing an exception. The value computations and side effects of destroying a temporary object are associated only with the full-expression, not with any specific subexpression.

5 There are four contexts in which temporaries are destroyed at a different point than the end of the full-expression. The first context is when a default constructor is called to initialize an element of an array with no corresponding initializer (9.4). The second context is when a copy constructor is called to copy an element of an array while the entire array is copied (7.5.5.3, 11.4.5.3). In either case, if the constructor has one or more default arguments, the destruction of every temporary created in a default argument is sequenced before the construction of the next array element, if any.

6 The third context is when a reference binds to a temporary object.28 The temporary object to which the reference is bound or the temporary object that is the complete object of a subobject to which the reference

28) The same rules apply to initialization of an initializer_list object (9.4.5) with its underlying temporary array.
is bound persists for the lifetime of the reference if the glvalue to which the reference is bound was obtained through one of the following:

1. a temporary materialization conversion (7.3.5),
2. \( (\text{expression}) \), where \text{expression} is one of these expressions,
3. subcripting (7.6.1.2) of an array operand, where that operand is one of these expressions,
4. a class member access (7.6.1.5) using the . operator where the left operand is one of these expressions and the right operand designates a non-static data member of non-reference type,
5. a pointer-to-member operation (7.6.4) using the .* operator where the left operand is one of these expressions and the right operand is a pointer to data member of non-reference type,
6. a
   1. \text{const\_cast} (7.6.1.11),
   2. \text{static\_cast} (7.6.1.9),
   3. \text{dynamic\_cast} (7.6.1.7), or
   4. \text{reinterpret\_cast} (7.6.1.10)
   converting, without a user-defined conversion, a glvalue operand that is one of these expressions to a glvalue that refers to the object designated by the operand, or to its complete object or a subobject thereof,
7. a conditional expression (7.6.16) that is a glvalue where the second or third operand is one of these expressions, or
8. a comma expression (7.6.20) that is a glvalue where the right operand is one of these expressions.

\begin{example}
\begin{verbatim}
template<typename T> using id = T;

int i = 1;
int&& a = id<int[3]>{1, 2, 3}[i]; // temporary array has same lifetime as a
const int& b = static_cast<const int&>(0); // temporary int has same lifetime as b
int&& c = cond ? id<int[3]>{1, 2, 3}[i] : static_cast<int&&>(0); // exactly one of the two temporaries is lifetime-extended
\end{verbatim}
\end{example}

\begin{note}
An explicit type conversion (7.6.1.4, 7.6.3) is interpreted as a sequence of elementary casts, covered above.
\end{note}
\begin{example}
\begin{verbatim}
const int& x = (const int&)1; // temporary for value 1 has same lifetime as x
\end{verbatim}
\end{example}
\begin{note}
\end{note}
\begin{example}
\begin{verbatim}
struct S {
    const int& m;
};
const S& s = S{1}; // both S and int temporaries have lifetime of s
\end{verbatim}
\end{example}
\begin{note}
\end{note}

The exceptions to this lifetime rule are:

1. A temporary object bound to a reference parameter in a function call (7.6.1.3) persists until the completion of the full-expression containing the call.
2. A temporary object bound to a reference element of an aggregate of class type initialized from a parenthesized \text{expression-list} (9.4) persists until the completion of the full-expression containing the \text{expression-list}.

\section*{§ 6.7.7}
The lifetime of a temporary bound to the returned value in a function `return` statement (8.7.4) is not extended; the temporary is destroyed at the end of the full-expression in the `return` statement.

A temporary bound to a reference in a `new-initializer` (7.6.2.8) persists until the completion of the full-expression containing the `new-initializer`. [Note 7: This might introduce a dangling reference. — end note]

```
Example 5:
struct S { int mi; const std::pair<int,int>& mp; };
S a { 1, {2,3} };
S* p = new S{ 1, {2,3} };  // creates dangling reference
```

7 The fourth context is when a temporary object other than a function parameter object is created in the `for-range-initializer` of a range-based `for` statement. If such a temporary object would otherwise be destroyed at the end of the `for-range-initializer` full-expression, the object persists for the lifetime of the reference initialized by the `for-range-initializer`.

8 The destruction of a temporary whose lifetime is not extended beyond the full-expression in which it was created is sequenced before the destruction of every temporary which is constructed earlier in the same full-expression. If the lifetime of two or more temporaries with lifetimes extending beyond the full-expressions in which they were created ends at the same point, these temporaries are destroyed at that point in the reverse order of the completion of their construction. In addition, the destruction of such temporaries shall take into account the ordering of destruction of objects with static, thread, or automatic storage duration (6.7.5.2, 6.7.5.3, 6.7.5.4); that is, if `obj1` is an object with the same storage duration as the temporary and created before the temporary is created the temporary shall be destroyed before `obj1` is destroyed; if `obj2` is an object with the same storage duration as the temporary and created after the temporary is created the temporary shall be destroyed after `obj2` is destroyed.

```
Example 6:
struct S {
    S();
    S(int);
    friend S operator+(const S&, const S&);
    ~S();
};
S obj1;
const S& cr = S(16)+S(23);
S obj2;
```

7 The fourth context is when a temporary object other than a function parameter object is created in the `for-range-initializer` of a range-based `for` statement. If such a temporary object would otherwise be destroyed at the end of the `for-range-initializer` full-expression, the object persists for the lifetime of the reference initialized by the `for-range-initializer`.

For any object (other than a potentially-overlapping subobject) of trivially copyable type `T`, whether or not the object holds a valid value of type `T`, the underlying bytes (6.7.1) making up the object can be copied into an array of `char`, `unsigned char`, or `std::byte` (17.2.1).29 If the content of that array is copied back into the object, the object shall subsequently hold its original value.

```
Example 1:
```

---

29) By using, for example, the library functions (16.4.2.3) `std::memcpy` or `std::memmove`. 

§ 6.8.1 74
constexpr std::size_t N = sizeof(T);

char buf[N]; // obj initialized to its original value
T obj; // between these two calls to std::memcpy, obj might be modified
std::memcpy(buf, &obj, N); // at this point, each subobject of obj of scalar type holds its original value

--- end example

For two distinct objects obj1 and obj2 of trivially copyable type T, where neither obj1 nor obj2 is a potentially-overlapping subobject, if the underlying bytes (6.7.1) making up obj1 are copied into obj2, obj2 shall subsequently hold the same value as obj1.

[Example 2:

T* t1p;
T* t2p;
// provided that t2p points to an initialized object ...
std::memcpy(t1p, t2p, sizeof(T));
// at this point, every subobject of trivially copyable type in *t1p contains
// the same value as the corresponding subobject in *t2p

--- end example]

The object representation of an object of type T is the sequence of N unsigned char objects taken up by the object of type T, where N equals sizeof(T). The value representation of an object of type T is the set of bits that participate in representing a value of type T. Bits in the object representation that are not part of the value representation are padding bits. For trivially copyable types, the value representation is a set of bits in the object representation that determines a value, which is one discrete element of an implementation-defined set of values. 31

A class that has been declared but not defined, an enumeration type in certain contexts (9.7.1), or an array of unknown bound or of incomplete element type, is an incompletely-defined object type. 32 Incompletely-defined object types and cv void are incomplete types (6.8.2).

[Note 2: Objects cannot be defined to have an incomplete type (6.2). — end note]

A class type (such as “class X”) can be incomplete at one point in a translation unit and complete later on; the type “class X” is the same type at both points. The declared type of an array object can be an array of incomplete class type and therefore incomplete; if the class type is completed later on in the translation unit, the array type becomes complete; the array type at those two points is the same type. The declared type of an array object can be an array of unknown bound and therefore be incomplete at one point in a translation unit and complete later on; the array types at those two points (“array of unknown bound of T” and “array of N T”) are different types.

[Note 3: The type of a pointer or reference to array of unknown bound permanently points to or refers to an incomplete type. An array of unknown bound named by a typedef declaration permanently refers to an incomplete type. In either case, the array type cannot be completed. — end note]

[Example 3:

class X; // X is an incomplete type
extern X* xp; // xp is a pointer to an incomplete type
extern int arr[]; // the type of arr is incomplete
typedef int UNKA[]; // UNKA is an incomplete type
UNKA* arrp; // arrp is a pointer to an incomplete type
UNKA** arrpp;

void foo() {
    xp++; // error: X is incomplete
    arrp++; // error: incomplete type
    arrpp++; // OK, sizeof UNKA* is known
}

struct X { int i; }; // now X is a complete type
int arr[10]; // now the type of arr is complete

§ 6.8.1 75

30) By using, for example, the library functions (16.4.2.3) std::memcpy or std::memmove.
31) The intent is that the memory model of C++ is compatible with that of ISO/IEC 9899 Programming Language C.
32) The size and layout of an instance of an incompletely-defined object type is unknown.
void bar() {
    xp = &x;  // OK; type is “pointer to X”
    arrp = &arr;  // OK; qualification conversion (7.3.6)
    xp++;  // OK, X is complete
    arrp++;  // error: UNK can’t be completed
}

—end example

Note 4: The rules for declarations and expressions describe in which contexts incomplete types are prohibited. —end note

An object type is a (possibly cv-qualified) type that is not a function type, not a reference type, and not cv void.

Arithmetic types (6.8.2), enumeration types, pointer types, pointer-to-member types (6.8.4), std::nullptr_t, and cv-qualified (6.8.5) versions of these types are collectively called scalar types. Scalar types, trivially copyable class types (11.2), arrays of such types, and cv-qualified versions of these types are collectively called trivially copyable types. Scalar types, trivial class types (11.2), arrays of such types and cv-qualified versions of these types are collectively called trivial types. Scalar types, standard-layout class types (11.2), arrays of such types and cv-qualified versions of these types are collectively called standard-layout types. Scalar types, implicit-lifetime class types (11.2), array types, and cv-qualified versions of these types are collectively called implicit-lifetime types.

A type is a literal type if it is:

- cv void; or
- a scalar type; or
- a reference type; or
- an array of literal type; or
- a possibly cv-qualified class type (Clause 11) that has all of the following properties:
  - it has a constexpr destructor (9.2.6),
  - all of its non-static non-variant data members and base classes are of non-volatile literal types, and
  - it
    - is a closure type (7.5.5.2),
    - is an aggregate union type that has either no variant members or at least one variant member of non-volatile literal type,
    - is a non-union aggregate type for which each of its anonymous union members satisfies the above requirements for an aggregate union type, or
    - has at least one constexpr constructor or constructor template (possibly inherited (9.9) from a base class) that is not a copy or move constructor.

[Note 5: A literal type is one for which it might be possible to create an object within a constant expression. It is not a guarantee that it is possible to create such an object, nor is it a guarantee that any object of that type will be usable in a constant expression. —end note]

Two types cv1 T1 and cv2 T2 are layout-compatible types if T1 and T2 are the same type, layout-compatible enumerations (9.7.1), or layout-compatible standard-layout class types (11.4).

6.8.2 Fundamental types

There are five standard signed integer types: “signed char”, “short int”, “int”, “long int”, and “long long int”. In this list, each type provides at least as much storage as those preceding it in the list. There may also be implementation-defined extended signed integer types. The standard and extended signed integer types are collectively called signed integer types. The range of representable values for a signed integer type is $-2^{N-1}$ to $2^{N-1} - 1$ (inclusive), where $N$ is called the width of the type.

[Note 1: Plain ints are intended to have the natural width suggested by the architecture of the execution environment; the other signed integer types are provided to meet special needs. —end note]

For each of the standard signed integer types, there exists a corresponding (but different) standard unsigned integer type: “unsigned char”, “unsigned short int”, “unsigned int”, “unsigned long int”, “unsigned long long int”, “unsigned long long int”, “unsigned long long int”. 

§ 6.8.2 76
and “unsigned long long int”. Likewise, for each of the extended signed integer types, there exists a corresponding extended unsigned integer type. The standard and extended unsigned integer types are collectively called unsigned integer types. An unsigned integer type has the same width \(N\) as the corresponding signed integer type. The range of representable values for the unsigned type is \(0\) to \(2^N - 1\) (inclusive); arithmetic for the unsigned type is performed modulo \(2^N\).

[Note 2: Unsigned arithmetic does not overflow. Overflow for signed arithmetic yields undefined behavior (7.1). — end note]

An unsigned integer type has the same object representation, value representation, and alignment requirements (6.7.6) as the corresponding signed integer type. For each value \(x\) of a signed integer type, the value of the corresponding unsigned integer type congruent to \(x\) modulo \(2^N\) has the same value of corresponding bits in its value representation.\(^{33}\)

[Example 1: The value \(-1\) of a signed integer type has the same representation as the largest value of the corresponding unsigned type. — end example]

### Table 14: Minimum width

<table>
<thead>
<tr>
<th>Type</th>
<th>Minimum width (N)</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed char</td>
<td>8</td>
</tr>
<tr>
<td>short int</td>
<td>16</td>
</tr>
<tr>
<td>int</td>
<td>16</td>
</tr>
<tr>
<td>long int</td>
<td>32</td>
</tr>
<tr>
<td>long long int</td>
<td>64</td>
</tr>
</tbody>
</table>

The width of each signed integer type shall not be less than the values specified in Table 14. The value representation of a signed or unsigned integer type comprises \(N\) bits, where \(N\) is the respective width. Each set of values for any padding bits (6.8.1) in the object representation are alternative representations of the value specified by the value representation.

[Note 3: Padding bits have unspecified value, but cannot cause traps. In contrast, see ISO C 6.2.6.2. — end note]

[Note 4: The signed and unsigned integer types satisfy the constraints given in ISO C 5.2.4.2.1. — end note]

Except as specified above, the width of a signed or unsigned integer type is implementation-defined.

Each value \(x\) of an unsigned integer type with width \(N\) has a unique representation \(x = x_02^0 + x_12^1 + \ldots + x_{N-1}2^{N-1}\), where each coefficient \(x_i\) is either 0 or 1; this is called the base-2 representation of \(x\). The base-2 representation of a value of signed integer type is the base-2 representation of the congruent value of the corresponding unsigned integer type. The standard signed integer types and standard unsigned integer types are collectively called the standard integer types, and the extended signed integer types and extended unsigned integer types are collectively called the extended integer types.

A fundamental type specified to have a signed or unsigned integer type as its underlying type has the same object representation, value representation, alignment requirements (6.7.6), and range of representable values as the underlying type. Further, each value has the same representation in both types.

Type char is a distinct type that has an implementation-defined choice of “signed char” or “unsigned char” as its underlying type. The three types char, signed char, and unsigned char are collectively called ordinary character types. The ordinary character types and char8_t are collectively called narrow character types. For narrow character types, each possible bit pattern of the object representation represents a distinct value.

[Note 5: This requirement does not hold for other types. — end note]

[Note 6: A bit-field of narrow character type whose width is larger than the width of that type has padding bits; see 6.8.1. — end note]

Type wchar_t is a distinct type that has an implementation-defined signed or unsigned integer type as its underlying type.

Type char8_t denotes a distinct type whose underlying type is unsigned char. Types char16_t and char32_t denote distinct types whose underlying types are uint_least16_t and uint_least32_t, respectively, in <cstdint> (17.4.1).

\(^{33}\) This is also known as two’s complement representation.
Type bool is a distinct type that has the same object representation, value representation, and alignment requirements as an implementation-defined unsigned integer type. The values of type bool are true and false.

[Note 7: There are no signed, unsigned, short, or long bool types or values. — end note]

The types char, wchar_t, char8_t, char16_t, and char32_t are collectively called character types. The character types, bool, the signed and unsigned integer types, and cv-qualified versions (6.8.5) thereof, are collectively termed integral types. A synonym for integral type is integer type.

[Note 8: Enumerations (9.7.1) are not integral; however, unscoped enumerations can be promoted to integral types as specified in 7.3.7. — end note]

The three distinct types float, double, and long double can represent floating-point numbers. The type double provides at least as much precision as float, and the type long double provides at least as much precision as double. The set of values of the type float is a subset of the set of values of the type double; the set of values of the type double is a subset of the set of values of the type long double. The types float, double, and long double, and cv-qualified versions (6.8.5) thereof, are collectively termed standard floating-point types. An implementation may also provide additional types that represent floating-point values and define them (and cv-qualified versions thereof) to be extended floating-point types. The standard and extended floating-point types are collectively termed floating-point types.

[Note 9: Any additional implementation-specific types representing floating-point values that are not defined by the implementation to be extended floating-point types are not considered to be floating-point types, and this document imposes no requirements on them or their interactions with floating-point types. — end note]

Except as specified in 6.8.3, the object and value representations and accuracy of operations of floating-point types are implementation-defined.

Integral and floating-point types are collectively termed arithmetic types.

[Note 10: Properties of the arithmetic types, such as their minimum and maximum representable value, can be queried using the facilities in the standard library headers <limits> (17.3.3), <climits> (17.3.6), and <float> (17.3.7). — end note]

A type cv void is an incomplete type that cannot be completed; such a type has an empty set of values. It is used as the return type for functions that do not return a value. Any expression can be explicitly converted to type cv void (7.6.1.4, 7.6.1.9, 7.6.3). An expression of type cv void shall be used only as an expression statement (8.3), as an operand of a comma expression (7.6.20), as a second or third operand of ?: (7.6.16), as the operand of typeid, noexcept, or decltype, as the expression in a return statement (8.7.4) for a function with the return type cv void, or as the operand of an explicit conversion to type cv void.

A value of type std::nullptr_t is a null pointer constant (7.3.12). Such values participate in the pointer and pointer-to-member conversions (7.3.12, 7.3.13). sizeof(std::nullptr_t) shall be equal to sizeof(void*).

The types described in this subclause are called fundamental types.

[Note 11: Even if the implementation defines two or more fundamental types to have the same value representation, they are nevertheless different types. — end note]

### 6.8.3 Optional extended floating-point types

If the implementation supports an extended floating-point type (6.8.2) whose properties are specified by the ISO/IEC/IEEE 60559 floating-point interchange format binary16, then the typedef-name std::float16_t is defined in the header <stdfloat> (17.4.2) and names such a type, the macro __STDCPP_FLOAT16_T__ is defined (15.11), and the floating-point literal suffixes f16 and F16 are supported (5.13.4).

If the implementation supports an extended floating-point type whose properties are specified by the ISO/IEC/IEEE 60559 floating-point interchange format binary32, then the typedef-name std::float32_t is defined in the header <stdfloat> and names such a type, the macro __STDCPP_FLOAT32_T__ is defined, and the floating-point literal suffixes f32 and F32 are supported.

If the implementation supports an extended floating-point type whose properties are specified by the ISO/IEC/IEEE 60559 floating-point interchange format binary64, then the typedef-name std::float64_t is defined in the header <stdfloat> and names such a type, the macro __STDCPP_FLOAT64_T__ is defined, and the floating-point literal suffixes f64 and F64 are supported.

If the implementation supports an extended floating-point type whose properties are specified by the ISO/IEC/IEEE 60559 floating-point interchange format binary128, then the typedef-name std::float128_t
is defined in the header `<stdfloat>` and names such a type, the macro `__STDCPP_FLOAT128_T__` is defined, and the floating-point literal suffixes `f128` and `F128` are supported.

If the implementation supports an extended floating-point type with the properties, as specified by ISO/IEC/IEEE 60559, of radix \((b)\) of 2, storage width in bits \((k)\) of 16, precision in bits \((p)\) of 8, maximum exponent \((emax)\) of 127, and exponent field width in bits \((w)\) of 8, then the typedef-name `std::bfloat16_t` is defined in the header `<stdfloat>` and names such a type, the macro `__STDCPP_BFLOAT16_T__` is defined, and the floating-point literal suffixes `bf16` and `BF16` are supported.

[Note 1: A summary of the parameters for each type is given in Table 15. The precision \(p\) includes the implicit 1 bit at the beginning of the mantissa, so the storage used for the mantissa is \(p - 1\) bits. ISO/IEC/IEEE 60559 does not assign a name for a type having the parameters specified for `std::bfloat16_t`. — end note]

### Table 15: Properties of named extended floating-point types

<table>
<thead>
<tr>
<th>Parameter</th>
<th>float16_t</th>
<th>float32_t</th>
<th>float64_t</th>
<th>float128_t</th>
<th>bfloat16_t</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO/IEC/IEEE 60559 name</td>
<td>binary16</td>
<td>binary32</td>
<td>binary64</td>
<td>binary128</td>
<td></td>
</tr>
<tr>
<td>(k), storage width in bits</td>
<td>16</td>
<td>32</td>
<td>64</td>
<td>128</td>
<td>16</td>
</tr>
<tr>
<td>(p), precision in bits</td>
<td>11</td>
<td>24</td>
<td>53</td>
<td>113</td>
<td>8</td>

</tr>
</tbody>
</table>

Recommended practice: Any names that the implementation provides for the extended floating-point types described in this subsection that are in addition to the names defined in the `<stdfloat>` header should be chosen to increase compatibility and interoperability with the interchange types `_Float16`, `_Float32`, `_Float64`, and `_Float128` defined in ISO/IEC TS 18661-3 and with future versions of the C standard.

### 6.8.4 Compound types

Compound types can be constructed in the following ways:

1. **Arrays of objects** of a given type, 9.3.4.5;
2. **Functions**, which have parameters of given types and return `void` or references or objects of a given type, 9.3.4.6;
3. **Pointers to cv `void` or objects or functions** (including static members of classes) of a given type, 9.3.4.2;
4. **References** to objects or functions of a given type, 9.3.4.3. There are two types of references:
   1. **lvalue reference**
   2. **rvalue reference**
5. **Classes** containing a sequence of objects of various types (Clause 11), a set of types, enumerations and functions for manipulating these objects (11.4.2), and a set of restrictions on the access to these entities (11.8);
6. **Unions**, which are classes capable of containing objects of different types at different times, 11.5;
7. **Enumerations**, which comprise a set of named constant values, 9.7.1;
8. **Pointers to non-static class members**, which identify members of a given type within objects of a given class, 9.3.4.4. Pointers to data members and pointers to member functions are collectively called **pointer-to-member** types.

These methods of constructing types can be applied recursively; restrictions are mentioned in 9.3.4. Constructing a type such that the number of bytes in its object representation exceeds the maximum value representable in the type `std::size_t` (17.2) is ill-formed.

The type of a pointer to `cv void_t` or a pointer to an object type is called an **object pointer type**.

[Note 1: A pointer to `void` does not have a pointer-to-object type, however, because `void` is not an object type. — end note]

---

34) Static class members are objects or functions, and pointers to them are ordinary pointers to objects or functions.
The type of a pointer that can designate a function is called a *function pointer type*. A pointer to an object of type \( T \) is referred to as a “pointer to \( T \)”.

*Example 1*: A pointer to an object of type \( \text{int} \) is referred to as “pointer to \( \text{int} \)” and a pointer to an object of class \( \text{X} \) is called a “pointer to \( \text{X} \)”.

Except for pointers to static members, text referring to “pointers” does not apply to pointers to members. Pointers to incomplete types are allowed although there are restrictions on what can be done with them (6.7.6). Every value of pointer type is one of the following:

1. A *pointer* to an object or function (the pointer is said to *point* to the object or function), or
2. A *pointer past the end* of an object (7.6.6), or
3. The *null pointer value* for that type, or
4. An *invalid pointer value*.

A value of a pointer type that is a pointer to or past the end of an object represents the *address* of the first byte in memory (6.7.1) occupied by the object\(^{35}\) or the first byte in memory after the end of the storage occupied by the object, respectively.

*Note 2*: A pointer past the end of an object (7.6.6) is not considered to point to an unrelated object of the object’s type, even if the unrelated object is located at that address. A pointer value becomes invalid when the storage it denotes reaches the end of its storage duration; see 6.7.5. — *end note*

For purposes of pointer arithmetic (7.6.6) and comparison (7.6.9, 7.6.10), a pointer past the end of the last element of an array \( x \) of \( n \) elements is considered to be equivalent to a pointer to a hypothetical array element \( n \) of \( x \) and an object of type \( T \) that is not an array element is considered to belong to an array with one element of type \( T \). The value representation of pointer types is implementation-defined. Pointers to layout-compatible types shall have the same value representation and alignment requirements (6.7.6).

*Note 3*: Pointers to over-aligned types (6.7.6) have no special representation, but their range of valid values is restricted by the extended alignment requirement. — *end note*

Two objects \( a \) and \( b \) are *pointer-interconvertible* if:

1. They are the same object, or
2. One is a union object and the other is a non-static data member of that object (11.5), or
3. One is a standard-layout class object and the other is the first non-static data member of that object or any base class subobject of that object (11.4), or
4. There exists an object \( c \) such that \( a \) and \( c \) are pointer-interconvertible, and \( c \) and \( b \) are pointer-interconvertible.

If two objects are pointer-interconvertible, then they have the same address, and it is possible to obtain a pointer to one from a pointer to the other via a \textit{reinterpret_cast} (7.6.1.10).

*Note 4*: An array object and its first element are not pointer-interconvertible, even though they have the same address. — *end note*

A byte of storage \( b \) is *reachable through* a pointer value that points to an object \( x \) if there is an object \( y \), pointer-interconvertible with \( x \), such that \( b \) is within the storage occupied by \( y \), or the immediately-enclosing array object if \( y \) is an array element.

A pointer to \textit{cv void} can be used to point to objects of unknown type. Such a pointer shall be able to hold any object pointer. An object of type “pointer to \textit{cv void}” shall have the same representation and alignment requirements as an object of type “pointer to \textit{cv char}”.

### 6.8.5 CV-qualifiers

Each type other than a function or reference type is part of a group of four distinct, but related, types: a \textit{cv-unqualified} version, a \textit{const-qualified} version, a \textit{volatile-qualified} version, and a \textit{const-volatile-qualified} version. The types in each such group shall have the same representation and alignment requirements (6.7.6).\(^{36}\) A function or reference type is always \textit{cv-unqualified}.

1. A \textit{const object} is an object of type \textit{const T} or a non-mutable subobject of a \textit{const object}.

\(^{35}\) For an object that is not within its lifetime, this is the first byte in memory that it will occupy or used to occupy.

\(^{36}\) The same representation and alignment requirements are meant to imply interchangeability as arguments to functions, return values from functions, and non-static data members of unions.
A **volatile object** is an object of type `volatile T` or a subobject of a volatile object.

A **const volatile object** is an object of type `const volatile T`, a non-mutable subobject of a const volatile object, a const subobject of a volatile object, or a non-mutable volatile subobject of a const object.

[Note 1: The type of an object (6.7.2) includes the cv-qualifiers specified in the *decl-specifier-seq* (9.2), *declarator* (9.3), *type-id* (9.3.2), or *new-type-id* (7.6.2.8) when the object is created. — end note]

2 Except for array types, a compound type (6.8.4) is not cv-qualified by the cv-qualifiers (if any) of the types from which it is compounded.

3 An array type whose elements are cv-qualified is also considered to have the same cv-qualifications as its elements.

[Note 2: Cv-qualifiers applied to an array type attach to the underlying element type, so the notation “cv T”, where T is an array type, refers to an array whose elements are so-qualified (9.3.4.5). — end note]

[Example 1:]  
```c
typedef char CA[5];
typedef const char CC;
CC arr1[5] = { 0 };
const CA arr2 = { 0 };
```

The type of both `arr1` and `arr2` is “array of 5 const char”, and the array type is considered to be const-qualified. — end example]

[Note 3: See 9.3.4.6 and 12.2.2 regarding function types that have cv-qualifiers. — end note]

4 There is a partial ordering on cv-qualifiers, so that a type can be said to be **more cv-qualified** than another. Table 16 shows the relations that constitute this ordering.

```
<table>
<thead>
<tr>
<th></th>
<th>no cv-qualifier</th>
<th>const</th>
</tr>
</thead>
<tbody>
<tr>
<td>no cv-qualifier</td>
<td>&lt;</td>
<td>volatile</td>
</tr>
<tr>
<td>no cv-qualifier</td>
<td>&lt;</td>
<td>const volatile</td>
</tr>
<tr>
<td></td>
<td>const</td>
<td>volatile</td>
</tr>
<tr>
<td>volatile</td>
<td>&lt;</td>
<td>volatile</td>
</tr>
</tbody>
</table>
```

6 In this document, the notation `cv` (or `cv1`, `cv2`, etc.), used in the description of types, represents an arbitrary set of cv-qualifiers, i.e., one of `{const}`, `{volatile}`, `{const, volatile}`, or the empty set. For a type `cv T`, the **top-level cv-qualifiers** of that type are those denoted by `cv`.

[Example 2: The type corresponding to the *type-id* `const int` has no top-level cv-qualifiers. The type corresponding to the *type-id* `volatile int * const` has the top-level cv-qualifier `const`. For a class type `C`, the type corresponding to the *type-id* `void (C::* volatile)(int) const` has the top-level cv-qualifier `volatile`. — end example]

### 6.8.6 Conversion ranks

1 Every integer type has an **integer conversion rank** defined as follows:

[conv.rank]

(1.1) — No two signed integer types other than `char` and `signed char` (if `char` is signed) have the same rank, even if they have the same representation.

(1.2) — The rank of a signed integer type is greater than the rank of any signed integer type with a smaller width.

(1.3) — The rank of `long long int` is greater than the rank of `long int`, which is greater than the rank of `int`, which is greater than the rank of `short int`, which is greater than the rank of `signed char`.

(1.4) — The rank of any unsigned integer type equals the rank of the corresponding signed integer type.

(1.5) — The rank of any standard integer type is greater than the rank of any extended integer type with the same width.

(1.6) — The rank of `char` equals the rank of `signed char` and `unsigned char`.

(1.7) — The rank of `bool` is less than the rank of all standard integer types.

(1.8) — The ranks of `char8_t`, `char16_t`, `char32_t`, and `wchar_t` equal the ranks of their underlying types (6.8.2).
The rank of any extended signed integer type relative to another extended signed integer type with the same width is implementation-defined, but still subject to the other rules for determining the integer conversion rank.

For all integer types T1, T2, and T3, if T1 has greater rank than T2 and T2 has greater rank than T3, then T1 has greater rank than T3.

[Note 1: The integer conversion rank is used in the definition of the integral promotions (7.3.7) and the usual arithmetic conversions (7.4). — end note]

Every floating-point type has a floating-point conversion rank defined as follows:

The rank of a floating point type T is greater than the rank of any floating-point type whose set of values is a proper subset of the set of values of T.

The rank of long double is greater than the rank of double, which is greater than the rank of float.

Two extended floating-point types with the same set of values have equal ranks.

An extended floating-point type with the same set of values as exactly one cv-unqualified standard floating-point type has a rank equal to the rank of that standard floating-point type.

An extended floating-point type with the same set of values as more than one cv-unqualified standard floating-point type has a rank equal to the rank of double.

[Note 2: The conversion ranks of floating-point types T1 and T2 are unordered if the set of values of T1 is neither a subset nor a superset of the set of values of T2. This can happen when one type has both a larger range and a lower precision than the other. — end note]

Floating-point types that have equal floating-point conversion ranks are ordered by floating-point conversion subrank. The subrank forms a total order among types with equal ranks. The types std::float16_t, std::float32_t, std::float64_t, and std::float128_t have a greater conversion subrank than any standard floating-point type with equal conversion rank. Otherwise, the conversion subrank order is implementation-defined.

[Note 3: The floating-point conversion rank and subrank are used in the definition of the usual arithmetic conversions (7.4). — end note]

6.9 Program execution

6.9.1 Sequential execution

An instance of each object with automatic storage duration (6.7.5.4) is associated with each entry into its block. Such an object exists and retains its last-stored value during the execution of the block and while the block is suspended (by a call of a function, suspension of a coroutine (7.6.2.4), or receipt of a signal).

A constituent expression is defined as follows:

The constituent expression of an expression is that expression.

The constituent expression of a conversion is the corresponding implicit function call, if any, or the converted expression otherwise.

The constituent expressions of a braced-init-list or of a (possibly parenthesized) expression-list are the constituent expressions of the elements of the respective list.

The constituent expressions of a brace-or-equal-initializer of the form = initializer-clause are the constituent expressions of the initializer-clause.

[Example 1:]

```c
struct A { int x; }
struct B { int y; struct A a; }
B b = { 5, { 1+1 } };  
```

The constituent expressions of the initializer used for the initialization of b are 5 and 1+1. — end example]

The immediate subexpressions of an expression E are

— the constituent expressions of E’s operands (7.2),
— any function call that E implicitly invokes,
— if E is a lambda-expression (7.5.5), the initialization of the entities captured by copy and the constituent expressions of the initializer of the init-captures,
§ 6.9.1 83

(3.4) — if \( E \) is a function call (7.6.1.3) or implicitly invokes a function, the constituent expressions of each default argument (9.3.4.7) used in the call, or

(3.5) — if \( E \) creates an aggregate object (9.4.2), the constituent expressions of each default member initializer (11.4) used in the initialization.

A subexpression of an expression \( E \) is an immediate subexpression of \( E \) or a subexpression of an immediate subexpression of \( E \).

[Note 1: Expressions appearing in the compound-statement of a lambda-expression are not subexpressions of the lambda-expression. — end note]

The potentially-evaluated subexpressions of an expression, conversion, or initializer \( E \) are

(4.1) — the constituent expressions of \( E \) and

(4.2) — the subexpressions thereof that are not subexpressions of a nested unevaluated operand (7.2.3).

A full-expression is

(5.1) — an unevaluated operand (7.2.3),

(5.2) — a constant-expression (7.7),

(5.3) — an immediate invocation (7.7),

(5.4) — an init-declarator (9.3) or a mem-initializer (11.9.3), including the constituent expressions of the initializer,

(5.5) — an invocation of a destructor generated at the end of the lifetime of an object other than a temporary object (6.7.7) whose lifetime has not been extended, or

(5.6) — an expression that is not a subexpression of another expression and that is not otherwise part of a full-expression.

If a language construct is defined to produce an implicit call of a function, a use of the language construct is considered to be an expression for the purposes of this definition. Conversions applied to the result of an expression in order to satisfy the requirements of the language construct in which the expression appears are also considered to be part of the full-expression. For an initializer, performing the initialization of the entity (including evaluating default member initializers of an aggregate) is also considered part of the full-expression.

[Example 2:

```c
struct S {
    S(int i): I(i) { }
    // full-expression is initialization of I
    int& v() { return I; }
    ~S() noexcept(false) { }
private:
    int I;
};

S s1(1);
// full-expression comprises call of S::S(int)
void f() {
    S s2 = 2;
    // full-expression comprises call of S::S(int)
    if (S(3).v())
        // full-expression includes lvalue-to-rvalue and int to bool conversions,
        // performed before temporary is deleted at end of full-expression
    }
    bool b = noexcept(S());
    // exception specification of destructor of S considered for noexcept

    // full-expression is destruction of s2 at end of block
}
struct B {
    B(S = S(0));
};
B b[2] = { B(), B() };
// full-expression is the entire initialization
// including the destruction of temporaries

— end example]

[Note 2: The evaluation of a full-expression can include the evaluation of subexpressions that are not lexically part of the full-expression. For example, subexpressions involved in evaluating default arguments (9.3.4.7) are considered to be created in the expression that calls the function, not the expression that defines the default argument. — end note]
Reading an object designated by a volatile glvalue (7.2.1), modifying an object, calling a library I/O function, or calling a function that does any of those operations are all side effects, which are changes in the state of the execution environment. Evaluation of an expression (or a subexpression) in general includes both value computations (including determining the identity of an object for glvalue evaluation and fetching a value previously assigned to an object for prvalue evaluation) and initiation of side effects. When a call to a library I/O function returns or an access through a volatile glvalue is evaluated the side effect is considered complete, even though some external actions implied by the call (such as the I/O itself) or by the volatile access may not have completed yet.

Sequenced before is an asymmetric, transitive, pair-wise relation between evaluations executed by a single thread (6.9.2), which induces a partial order among those evaluations. Given any two evaluations A and B, if A is sequenced before B (or, equivalently, B is sequenced after A), then the execution of A shall precede the execution of B. If A is not sequenced before B and B is not sequenced before A, then A and B are unsequenced.

Evaluations A and B are indeterminately sequenced when either A is sequenced before B or B is sequenced before A, but it is unspecified which.

Every value computation and side effect associated with a full-expression is sequenced before every value computation and side effect associated with the next full-expression to be evaluated.

Except where noted, evaluations of operands of individual operators and of subexpressions of individual expressions are unsequenced.

The value computations of the operands of an operator are sequenced before the value computation of the result of the operator. If a side effect on a memory location (6.7.1) is unsequenced relative to either another side effect on the same memory location or a value computation using the value of any object in the same memory location, and they are not potentially concurrent (6.9.2), the behavior is undefined.

When invoking a function (whether or not the function is inline), every argument expression and the postfix expression designating the called function are sequenced before every expression or statement in the body of the called function. For each function invocation or evaluation of an await-expression F, each evaluation that does not occur within F but is evaluated on the same thread and as part of the same signal handler (if any) is either sequenced before all evaluations that occur within F or sequenced after all evaluations that occur within F. If F invokes or resumes a coroutine (7.6.2.4), only evaluations subsequent to the previous suspension (if any) and prior to the next suspension (if any) are considered to occur within F.

Several contexts in C++ cause evaluation of a function call, even though no corresponding function call syntax appears in the translation unit.

[Note 3: The execution of unsequenced evaluations can overlap. — end note] Evaluations A and B are indeterminately sequenced when either A is sequenced before B or B is sequenced before A, but it is unspecified which.

[Note 4: Indeterminately sequenced evaluations cannot overlap, but either can be executed first. — end note] An expression X is said to be sequenced before an expression Y if every value computation and every side effect associated with the expression X is sequenced before every value computation and every side effect associated with the expression Y.

Every value computation and side effect associated with a full-expression is sequenced before every value computation and side effect associated with the next full-expression to be evaluated.

Except where noted, evaluations of operands of individual operators and of subexpressions of individual expressions are unsequenced.

[Note 5: In an expression that is evaluated more than once during the execution of a program, unsequenced and indeterminately sequenced evaluations of its subexpressions need not be performed consistently in different evaluations. — end note] The value computations of the operands of an operator are sequenced before the value computation of the result of the operator. If a side effect on a memory location (6.7.1) is unsequenced relative to either another side effect on the same memory location or a value computation using the value of any object in the same memory location, and they are not potentially concurrent (6.9.2), the behavior is undefined.

[Note 6: The next subclause imposes similar, but more complex restrictions on potentially concurrent computations. — end note] [Example 3:

```c
void g(int i) {
    i = 7, i++, i++;
    // i becomes 9
    i = i++ + 1;
    // the value of i is incremented
    i = i++ + 1;
    // undefined behavior
    i = i + 1;
    // the value of i is incremented
}
—end example]
```

When invoking a function (whether or not the function is inline), every argument expression and the postfix expression designating the called function are sequenced before every expression or statement in the body of the called function. For each function invocation or evaluation of an await-expression F, each evaluation that does not occur within F but is evaluated on the same thread and as part of the same signal handler (if any) is either sequenced before all evaluations that occur within F or sequenced after all evaluations that occur within F. If F invokes or resumes a coroutine (7.6.2.4), only evaluations subsequent to the previous suspension (if any) and prior to the next suspension (if any) are considered to occur within F.

Several contexts in C++ cause evaluation of a function call, even though no corresponding function call syntax appears in the translation unit.

37) As specified in 6.7.7, after a full-expression is evaluated, a sequence of zero or more invocations of destructor functions for temporary objects takes place, usually in reverse order of the construction of each temporary object.

38) In other words, function executions do not interleave with each other.
Example 4: Evaluation of a new-expression invokes one or more allocation and constructor functions; see 7.6.2.8. For another example, invocation of a conversion function (11.4.8.3) can arise in contexts in which no function call syntax appears. — end example

The sequencing constraints on the execution of the called function (as described above) are features of the function calls as evaluated, regardless of the syntax of the expression that calls the function.

If a signal handler is executed as a result of a call to the std::raise function, then the execution of the handler is sequenced after the invocation of the std::raise function and before its return.

[Note 7: When a signal is received for another reason, the execution of the signal handler is usually unsequenced with respect to the rest of the program. — end note]

6.9.2 Multi-threaded executions and data races

6.9.2.1 General

A thread of execution (also known as a thread) is a single flow of control within a program, including the initial invocation of a specific top-level function, and recursively including every function invocation subsequently executed by the thread.

[Note 1: When one thread creates another, the initial call to the top-level function of the new thread is executed by the new thread, not by the creating thread. — end note]

Every thread in a program can potentially access every object and function in a program. Under a hosted implementation, a C++ program can have more than one thread running concurrently. The execution of each thread proceeds as defined by the remainder of this document. The execution of the entire program consists of an execution of all of its threads.

[Note 2: Usually the execution can be viewed as an interleaving of all its threads. However, some kinds of atomic operations, for example, allow executions inconsistent with a simple interleaving, as described below. — end note]

Under a freestanding implementation, it is implementation-defined whether a program can have more than one thread of execution.

For a signal handler that is not executed as a result of a call to the std::raise function, it is unspecified which thread of execution contains the signal handler invocation.

6.9.2.2 Data races

The value of an object visible to a thread \( T \) at a particular point is the initial value of the object, a value assigned to the object by \( T \), or a value assigned to the object by another thread, according to the rules below.

[Note 1: In some cases, there might instead be undefined behavior. Much of this subclause is motivated by the desire to support atomic operations with explicit and detailed visibility constraints. However, it also implicitly supports a simpler view for more restricted programs. — end note]

Two expression evaluations conflict if one of them modifies a memory location (6.7.1) and the other one reads or modifies the same memory location.

The library defines a number of atomic operations (33.5) and operations on mutexes (Clause 33) that are specially identified as synchronization operations. These operations play a special role in making assignments in one thread visible to another. A synchronization operation on one or more memory locations is either a consume operation, an acquire operation, a release operation, or both an acquire and release operation. A synchronization operation without an associated memory location is a fence and can be either an acquire fence, a release fence, or both an acquire and release fence. In addition, there are relaxed atomic operations, which are not synchronization operations, and atomic read-modify-write operations, which have special characteristics.

[Note 2: For example, a call that acquires a mutex will perform an acquire operation on the locations comprising the mutex. Correspondingly, a call that releases the same mutex will perform a release operation on those same locations. Informally, performing a release operation on \( A \) forces prior side effects on other memory locations to become visible to other threads that later perform a consume or an acquire operation on \( A \). "Relaxed" atomic operations are not synchronization operations even though, like synchronization operations, they cannot contribute to data races. — end note]

An object with automatic or thread storage duration (6.7.5) is associated with one specific thread, and can be accessed by a different thread only indirectly through a pointer or reference (6.8.4).
All modifications to a particular atomic object $M$ occur in some particular total order, called the \textit{modification order} of $M$.

[Note 3: There is a separate order for each atomic object. There is no requirement that these can be combined into a single total order for all objects. In general this will be impossible since different threads can observe modifications to different objects in inconsistent orders. — \textit{end note}]

4 A \textit{release sequence} headed by a release operation $A$ on an atomic object $M$ is a maximal contiguous sub-sequence of side effects in the modification order of $M$, where the first operation is $A$, and every subsequent operation is an atomic read-modify-write operation.

5 Certain library calls \textit{synchronize with} other library calls performed by another thread. For example, an atomic store-release synchronizes with a load-acquire that takes its value from the store (33.5.4).

[Note 4: Except in the specified cases, reading a later value does not necessarily ensure visibility as described below. Such a requirement would sometimes interfere with efficient implementation. — \textit{end note}]

6 An evaluation $A$ \textit{carries a dependency to} an evaluation $B$ if

\begin{enumerate}[\hfill (7.1)]
\item the value of $A$ is used as an operand of $B$, unless:
\begin{enumerate}[\hfill (7.1.1)]
\item $B$ is an invocation of any specialization of \texttt{std::kill dependency} (33.5.4), or
\item $A$ is the left operand of a built-in logical \texttt{AND} (\texttt{&&}, see 7.6.14) or logical \texttt{OR} (11, see 7.6.15) operator, or
\end{enumerate}
\begin{enumerate}[\hfill (7.1.2)]
\item $A$ is the left operand of a conditional (\texttt{?;}, see 7.6.16) operator, or
\end{enumerate}
\begin{enumerate}[\hfill (7.1.3)]
\item $A$ is the left operand of the built-in comma (\texttt{,}) operator (7.6.20);
\end{enumerate}
\end{enumerate}

or

\begin{enumerate}[\hfill (7.2)]
\item $A$ writes a scalar object or bit-field $M$, $B$ reads the value written by $A$ from $M$, and $A$ is sequenced before $B$, or
\item for some evaluation $X$, $A$ carries a dependency to $X$, and $X$ carries a dependency to $B$.
\end{enumerate}

[Note 6: “Carries a dependency to” is a subset of “is sequenced before”, and is similarly strictly intra-thread. — \textit{end note}]

8 An evaluation $A$ is \textit{dependency-ordered before} an evaluation $B$ if

\begin{enumerate}[\hfill (8.1)]
\item $A$ performs a release operation on an atomic object $M$, and, in another thread, $B$ performs a consume operation on $M$ and reads the value written by $A$, or
\item for some evaluation $X$, $A$ is dependency-ordered before $X$ and $X$ carries a dependency to $B$.
\end{enumerate}

[Note 7: The relation “is dependency-ordered before” is analogous to “synchronizes with”, but uses release/consume in place of release/acquire. — \textit{end note}]

9 An evaluation $A$ \textit{inter-thread happens before} an evaluation $B$ if

\begin{enumerate}[\hfill (9.1)]
\item $A$ synchronizes with $B$, or
\item $A$ is dependency-ordered before $B$, or
\item for some evaluation $X$
\begin{enumerate}[\hfill (9.3.1)]
\item $A$ synchronizes with $X$ and $X$ is sequenced before $B$, or
\item $A$ is sequenced before $X$ and $X$ inter-thread happens before $B$, or
\item $A$ inter-thread happens before $X$ and $X$ inter-thread happens before $B$.
\end{enumerate}
\end{enumerate}

[Note 8: The “inter-thread happens before” relation describes arbitrary concatenations of “sequenced before”, “synchronizes with” and “dependency-ordered before” relationships, with two exceptions. The first exception is that a concatenation is not permitted to end with “dependency-ordered before” followed by “sequenced before”. The reason for this limitation is that a consume operation participating in a “dependency-ordered before” relationship provides ordering only with respect to operations to which this consume operation actually carries a dependency. The reason that this limitation applies only to the end of such a concatenation is that any subsequent release operation will provide the required ordering for a prior consume operation. The second exception is that a concatenation is not permitted to consist entirely of “sequenced before”. The reasons for this limitation are (1) to permit “inter-thread happens before” to be transitively closed and (2) the “happens before” relation, defined below, provides for relationships consisting entirely of “sequenced before”. — \textit{end note}]

\section*{§ 6.9.2.2}
An evaluation $A$ \textit{happens before} an evaluation $B$ (or, equivalently, $B$ \textit{happens after} $A$) if:

1. $A$ is sequenced before $B$, or
2. $A$ inter-thread happens before $B$.

The implementation shall ensure that no program execution demonstrates a cycle in the “happens before” relation.

[Note 9: This cycle would otherwise be possible only through the use of consume operations. — end note]

An evaluation $A$ \textit{simply happens before} an evaluation $B$ if either

1. $A$ is sequenced before $B$, or
2. $A$ synchronizes with $B$, or
3. $A$ simply happens before $X$ and $X$ simply happens before $B$.

[Note 10: In the absence of consume operations, the happens before and simply happens before relations are identical. — end note]

An evaluation $A$ \textit{strongly happens before} an evaluation $D$ if, either

1. $A$ is sequenced before $D$, or
2. $A$ synchronizes with $D$, and both $A$ and $D$ are sequentially consistent atomic operations (33.5.4), or
3. there are evaluations $B$ and $C$ such that $A$ is sequenced before $B$, $B$ simply happens before $C$, and $C$ is sequenced before $D$, or
4. there is an evaluation $B$ such that $A$ strongly happens before $B$, and $B$ strongly happens before $D$.

[Note 11: Informally, if $A$ strongly happens before $B$, then $A$ appears to be evaluated before $B$ in all contexts. Strongly happens before excludes consume operations. — end note]

A \textit{visible side effect} $A$ on a scalar object or bit-field $M$ with respect to a value computation $B$ of $M$ satisfies the conditions:

1. $A$ happens before $B$ and
2. there is no other side effect $X$ to $M$ such that $A$ happens before $X$ and $X$ happens before $B$.

The value of a non-atomic scalar object or bit-field $M$, as determined by evaluation $B$, shall be the value stored by the visible side effect $A$.

[Note 12: If there is ambiguity about which side effect to a non-atomic object or bit-field is visible, then the behavior is either unspecified or undefined. — end note]

[Note 13: This states that operations on ordinary objects are not visibly reordered. This is not actually detectable without data races, but it is necessary to ensure that data races, as defined below, and with suitable restrictions on the use of atomics, correspond to data races in a simple interleaved (sequentially consistent) execution. — end note]

The value of an atomic object $M$, as determined by evaluation $B$, shall be the value stored by some side effect $A$ that modifies $M$, where $B$ does not happen before $A$.

[Note 14: The set of such side effects is also restricted by the rest of the rules described here, and in particular, by the coherence requirements below. — end note]

If an operation $A$ that modifies an atomic object $M$ happens before an operation $B$ that modifies $M$, then $A$ shall be earlier than $B$ in the modification order of $M$.

[Note 15: This requirement is known as write-write coherence. — end note]

If a value computation $A$ of an atomic object $M$ happens before a value computation $B$ of $M$, and $A$ takes its value from a side effect $X$ on $M$, then the value computed by $B$ shall either be the value stored by $X$ or the value stored by a side effect $Y$ on $M$, where $Y$ follows $X$ in the modification order of $M$.

[Note 16: This requirement is known as read-read coherence. — end note]

If a value computation $A$ of an atomic object $M$ happens before an operation $B$ that modifies $M$, then $A$ shall take its value from a side effect $X$ on $M$, where $X$ precedes $B$ in the modification order of $M$.

[Note 17: This requirement is known as read-write coherence. — end note]

If a side effect $X$ on an atomic object $M$ happens before a value computation $B$ of $M$, then the evaluation $B$ shall take its value from $X$ or from a side effect $Y$ that follows $X$ in the modification order of $M$.

[Note 18: This requirement is known as write-read coherence. — end note]
Two actions are potentially concurrent if
(21.1) — they are performed by different threads, or
(21.2) — they are unsequenced, at least one is performed by a signal handler, and they are not both performed
by the same signal handler invocation.

The execution of a program contains a data race if it contains two potentially concurrent conflicting actions,
at least one of which is not atomic, and neither happens before the other, except for the special case for
signal handlers described below. Any such data race results in undefined behavior.

[Note 19: The four preceding coherence requirements effectively disallow compiler reordering of atomic operations
to a single object, even if both operations are relaxed loads. This effectively makes the cache coherence guarantee
provided by most hardware available to C++ atomic operations. — end note]

[Note 20: The value observed by a load of an atomic depends on the “happens before” relation, which depends on the
values observed by loads of atomics. The intended reading is that there must exist an association of atomic loads with
modifications they observe that, together with suitably chosen modification orders and the “happens before” relation
derived as described above, satisfy the resulting constraints as imposed here. — end note]

Two accesses to the same object of type volatile std::sig_atomic_t do not result in a data race if
both occur in the same thread, even if one or more occurs in a signal handler. For each signal handler
invocation, evaluations performed by the thread invoking a signal handler can be divided into two groups
A and B, such that no evaluations in B happen before evaluations in A, and the evaluations of such volatile
std::sig_atomic_t objects take values as though all evaluations in A happened before the execution of the
signal handler and the execution of the signal handler happened before all evaluations in B.

[Note 21: It can be shown that programs that correctly use mutexes and memory_order::seq_cst operations to
prevent all data races and use no other synchronization operations behave as if the operations executed by their
constituent threads were simply interleaved, with each value computation of an object being taken from the last side
effect on that object in that interleaving. This is normally referred to as “sequential consistency”. However, this applies
only to data-race-free programs, and data-race-free programs cannot observe most program transformations that do
not change single-threaded program semantics. In fact, most single-threaded program transformations continue to be
allowed, since any program that behaves differently as a result has undefined behavior. — end note]

Two accesses to the same object of type volatile std::sig_atomic_t do not result in a data race if
both occur in the same thread, even if one or more occurs in a signal handler. For each signal handler
invocation, evaluations performed by the thread invoking a signal handler can be divided into two groups
A and B, such that no evaluations in B happen before evaluations in A, and the evaluations of such volatile
std::sig_atomic_t objects take values as though all evaluations in A happened before the execution of the
signal handler and the execution of the signal handler happened before all evaluations in B.

[Note 22: Compiler transformations that introduce assignments to a potentially shared memory location that would
not be modified by the abstract machine are generally precluded by this document, since such an assignment might
overwrite another assignment by a different thread in cases in which an abstract machine execution would not have
encountered a data race. This includes implementations of data member assignment that overwrite adjacent members
in separate memory locations. Reordering of atomic loads in cases in which the atomics in question might alias is also
generally precluded, since this could violate the coherence rules. — end note]

[Note 23: Transformations that introduce a speculative read of a potentially shared memory location might not
preserve the semantics of the C++ program as defined in this document, since they potentially introduce a data
race. However, they are typically valid in the context of an optimizing compiler that targets a specific machine with
well-defined semantics for data races. They would be invalid for a hypothetical machine that is not tolerant of races
or provides hardware race detection. — end note]

6.9.2.3 Forward progress

The implementation may assume that any thread will eventually do one of the following:

(1.1) — terminate,
(1.2) — make a call to a library I/O function,
(1.3) — perform an access through a volatile global value, or
(1.4) — perform a synchronization operation or an atomic operation.

[Note 1: This is intended to allow compiler transformations such as removal of empty loops, even when termination
cannot be proven. — end note]

Executions of atomic functions that are either defined to be lock-free (33.5.10) or indicated as lock-free (33.5.5)
are lock-free executions.

(2.1) — If there is only one thread that is not blocked (3.7) in a standard library function, a lock-free execution
in that thread shall complete.

[Note 2: Concurrently executing threads might prevent progress of a lock-free execution. For example, this
situation can occur with load-locked store-conditional implementations. This property is sometimes termed
obstruction-free. — end note]
When one or more lock-free executions run concurrently, at least one should complete.

[Note 3: It is difficult for some implementations to provide absolute guarantees to this effect, since repeated and particularly inopportune interference from other threads could prevent forward progress, e.g., by repeatedly stealing a cache line for unrelated purposes between load-locked and store-conditional instructions. For implementations that follow this recommendation and ensure that such effects cannot indefinitely delay progress under expected operating conditions, such anomalies can therefore safely be ignored by programmers. Outside this document, this property is sometimes termed lock-free. — end note]

During the execution of a thread of execution, each of the following is termed an execution step:

1. termination of the thread of execution,
2. performing an access through a volatile glvalue, or
3. completion of a call to a library I/O function, a synchronization operation, or an atomic operation.

An invocation of a standard library function that blocks (3.7) is considered to continuously execute execution steps while waiting for the condition that it blocks on to be satisfied.

[Example 1: A library I/O function that blocks until the I/O operation is complete can be considered to continuously check whether the operation is complete. Each such check consists of one or more execution steps, for example using observable behavior of the abstract machine. — end example]

[Note 4: Because of this and the preceding requirement regarding what threads of execution have to perform eventually, it follows that no thread of execution can execute forever without an execution step occurring. — end note]

A thread of execution makes progress when an execution step occurs or a lock-free execution does not complete because there are other concurrent threads that are not blocked in a standard library function (see above).

For a thread of execution providing concurrent forward progress guarantees, the implementation ensures that the thread will eventually make progress for as long as it has not terminated.

[Note 5: This is required regardless of whether or not other threads of execution (if any) have been or are making progress. To eventually fulfill this requirement means that this will happen in an unspecified but finite amount of time. — end note]

It is implementation-defined whether the implementation-created thread of execution that executes main (6.9.3.1) and the threads of execution created by std::thread (33.4.3) or std::jthread (33.4.4) provide concurrent forward progress guarantees. General-purpose implementations should provide these guarantees.

For a thread of execution providing parallel forward progress guarantees, the implementation is not required to ensure that the thread will eventually make progress if it has not yet executed any execution step; once this thread has executed a step, it provides concurrent forward progress guarantees.

[Note 6: This does not specify a requirement for when to start this thread of execution, which will typically be specified by the entity that creates this thread of execution. For example, a thread of execution that provides concurrent forward progress guarantees and executes tasks from a set of tasks in an arbitrary order, one after the other, satisfies the requirements of parallel forward progress for these tasks. — end note]

For a thread of execution providing weakly parallel forward progress guarantees, the implementation does not ensure that the thread will eventually make progress.

[Note 7: Threads of execution providing weakly parallel forward progress guarantees cannot be expected to make progress regardless of whether other threads make progress or not; however, blocking with forward progress guarantee delegation, as defined below, can be used to ensure that such threads of execution make progress eventually. — end note]

Concurrent forward progress guarantees are stronger than parallel forward progress guarantees, which in turn are stronger than weakly parallel forward progress guarantees.

[Note 8: For example, some kinds of synchronization between threads of execution might only make progress if the respective threads of execution provide parallel forward progress guarantees, but will fail to make progress under weakly parallel guarantees. — end note]

When a thread of execution P is specified to block with forward progress guarantee delegation on the completion of a set S of threads of execution, then throughout the whole time of P being blocked on S, the implementation shall ensure that the forward progress guarantees provided by at least one thread of execution in S is at least as strong as P’s forward progress guarantees.

[Note 9: It is unspecified which thread or threads of execution in S are chosen and for which number of execution steps. The strengthening is not permanent and not necessarily in place for the rest of the lifetime of the affected thread of execution. As long as P is blocked, the implementation has to eventually select and potentially strengthen a thread of execution in S. — end note]
Once a thread of execution in $S$ terminates, it is removed from $S$. Once $S$ is empty, $P$ is unblocked.

15 *Note 10*: A thread of execution $B$ thus can temporarily provide an effectively stronger forward progress guarantee for a certain amount of time, due to a second thread of execution $A$ being blocked on it with forward progress guarantee delegation. In turn, if $B$ then blocks with forward progress guarantee delegation on $C$, this can also temporarily provide a stronger forward progress guarantee to $C$. — *end note*

16 *Note 11*: If all threads of execution in $S$ finish executing (e.g., they terminate and do not use blocking synchronization incorrectly), then $P$’s execution of the operation that blocks with forward progress guarantee delegation will not result in $P$’s progress guarantee being effectively weakened. — *end note*

17 *Note 12*: This does not remove any constraints regarding blocking synchronization for threads of execution providing parallel or weakly parallel forward progress guarantees because the implementation is not required to strengthen a particular thread of execution whose too-weak progress guarantee is preventing overall progress. — *end note*

18 An implementation should ensure that the last value (in modification order) assigned by an atomic or synchronization operation will become visible to all other threads in a finite period of time.

### 6.9.3 Start and termination

#### 6.9.3.1 main function

A program shall contain exactly one function called `main` that belongs to the global scope. Executing a program starts a main thread of execution (6.9.2, 33.4) in which the `main` function is invoked. It is implementation-defined whether a program in a freestanding environment is required to define a `main` function.

*Note 1*: In a freestanding environment, startup and termination is implementation-defined; startup contains the execution of constructors for non-local objects with static storage duration; termination contains the execution of destructors for objects with static storage duration. — *end note*

2 An implementation shall not predefined the `main` function. Its type shall have C++ language linkage and it shall have a declared return type of type `int`, but otherwise its type is implementation-defined. An implementation shall allow both

(2.1) — a function of () returning `int` and

(2.2) — a function of (`int`, pointer to pointer to `char`) returning `int` as the type of `main` (9.3.4.6). In the latter form, for purposes of exposition, the first function parameter is called `argc` and the second function parameter is called `argv`, where `argc` shall be the number of arguments passed to the program from the environment in which the program is run. If `argc` is nonzero these arguments shall be supplied in `argv[0]` through `argv[argc-1]` as pointers to the initial characters of null-terminated multibyte strings (`ntmbss`) (16.3.3.4.3) and `argv[0]` shall be the pointer to the initial character of a `ntmbs` that represents the name used to invoke the program or "". The value of `argc` shall be non-negative. The value of `argv[argc]` shall be 0.

*Recommended practice*: Any further (optional) parameters should be added after `argv`.

3 The function `main` shall not be used within a program. The linkage (6.6) of `main` is implementation-defined. A program that defines `main` as deleted or that declares `main` to be `inline`, `static`, `constexpr`, or `consteval` is ill-formed. The function `main` shall not be a coroutine (9.5.4). The `main` function shall not be declared with a `linkage-specification` (9.11). A program that declares

(3.1) — a variable `main` that belongs to the global scope, or

(3.2) — a function `main` that belongs to the global scope and is attached to a named module, or

(3.3) — a function template `main` that belongs to the global scope, or

(3.4) — an entity named `main` with C language linkage (in any namespace)

is ill-formed. The name `main` is not otherwise reserved.

*Example 1*: Member functions, classes, and enumerations can be called `main`, as can entities in other namespaces. — *end example*

4 Terminating the program without leaving the current block (e.g., by calling the function `std::exit(int)` (17.5)) does not destroy any objects with automatic storage duration (11.4.7). If `std::exit` is invoked during the destruction of an object with static or thread storage duration, the program has undefined behavior.

5 A `return` statement (8.7.4) in `main` has the effect of leaving the main function (destroying any objects with automatic storage duration) and calling `std::exit` with the return value as the argument. If control flows
off the end of the compound-statement of main, the effect is equivalent to a return with operand 0 (see also 14.4).

6.9.3.2 Static initialization

Variables with static storage duration are initialized as a consequence of program initiation. Variables with thread storage duration are initialized as a consequence of thread execution. Within each of these phases of initiation, initialization occurs as follows.

1 Constant initialization is performed if a variable or temporary object with static or thread storage duration is constant-initialized (7.7). If constant initialization is not performed, a variable with static storage duration (6.7.5.2) or thread storage duration (6.7.5.3) is zero-initialized (9.4). Together, zero-initialization and constant initialization are called static initialization; all other initialization is dynamic initialization. All static initialization strongly happens before (6.9.2.2) any dynamic initialization.

[Note 1: The dynamic initialization of non-block variables is described in 6.9.3.3; that of static block variables is described in 8.8. — end note]

2 An implementation is permitted to perform the initialization of a variable with static or thread storage duration as a static initialization even if such initialization is not required to be done statically, provided that

- the dynamic version of the initialization does not change the value of any other object of static or thread storage duration prior to its initialization, and
- the static version of the initialization produces the same value in the initialized variable as would be produced by the dynamic initialization if all variables not required to be initialized statically were initialized dynamically.

[Note 2: As a consequence, if the initialization of an object obj1 refers to an object obj2 potentially requiring dynamic initialization and defined later in the same translation unit, it is unspecified whether the value of obj2 used will be the value of the fully initialized obj2 (because obj2 was statically initialized) or will be the value of obj2 merely zero-initialized. For example,

```c
inline double fd() { return 1.0; }
extern double d1;
double d2 = d1; // unspecified:
    // either statically initialized to 0.0 or
    // dynamically initialized to 0.0 if d1 is
    // dynamically initialized, or 1.0 otherwise
double d1 = fd(); // either initialized statically or dynamically to 1.0
```

— end note]

6.9.3.3 Dynamic initialization of non-block variables

Dynamic initialization of a non-block variable with static storage duration is unordered if the variable is an implicitly or explicitly instantiated specialization, is partially-ordered if the variable is an inline variable that is not an implicitly or explicitly instantiated specialization, and otherwise is ordered.

[Note 1: A non-inline explicit specialization of a templated variable has ordered initialization. — end note]

2 A declaration D is appearance-ordered before a declaration E if

- D appears in the same translation unit as E, or
- the translation unit containing E has an interface dependency on the translation unit containing D, in either case prior to E.

3 Dynamic initialization of non-block variables V and W with static storage duration are ordered as follows:

- If V and W have ordered initialization and the definition of V is appearance-ordered before the definition of W, or if V has partially-ordered initialization, W does not have unordered initialization, and for every definition E of W there exists a definition D of V such that D is appearance-ordered before E, then

- if the program does not start a thread (6.9.2) other than the main thread (6.9.3.1) or V and W have ordered initialization and they are defined in the same translation unit, the initialization of V is sequenced before the initialization of W;

- otherwise, the initialization of V strongly happens before the initialization of W.

§ 6.9.3.3
— Otherwise, if the program starts a thread other than the main thread before either \( V \) or \( W \) is initialized, it is unspecified in which threads the initializations of \( V \) and \( W \) occur; the initializations are unsequenced if they occur in the same thread.

— Otherwise, the initializations of \( V \) and \( W \) are indeterminately sequenced.

[Note 2: This definition permits initialization of a sequence of ordered variables concurrently with another sequence. — end note]

A **non-initialization odr-use** is an odr-use (6.3) not caused directly or indirectly by the initialization of a non-block static or thread storage duration variable.

It is implementation-defined whether the dynamic initialization of a non-block non-inline variable with static storage duration is sequenced before the first statement of `main` or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of any non-inline function or non-inline variable defined in the same translation unit as the variable to be initialized. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

**Recommended practice:** An implementation should choose such points in a way that allows the programmer to avoid deadlocks.

**Example 1:**

```c
// - File 1 -
#include "a.h"
#include "b.h"
B b;
A::A() {
  b.Use();
}

// - File 2 -
#include "a.h"
A a;

// - File 3 -
#include "a.h"
#include "b.h"
extern A a;
extern B b;

int main() {
  a.Use();
  b.Use();
}
```

It is implementation-defined whether either \( a \) or \( b \) is initialized before `main` is entered or whether the initializations are delayed until \( a \) is first odr-used in `main`. In particular, if \( a \) is initialized before `main` is entered, it is not guaranteed that \( b \) will be initialized before it is odr-used by the initialization of \( a \), that is, before `A::A` is called. If, however, \( a \) is initialized at some point after the first statement of `main`, \( b \) will be initialized prior to its use in `A::A`. — *end example*

It is implementation-defined whether the dynamic initialization of a non-block inline variable with static storage duration is sequenced before the first statement of `main` or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of that variable. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

It is implementation-defined whether the dynamic initialization of a non-block non-inline variable with thread storage duration is sequenced before the first statement of the initial function of a thread or is deferred. If it is deferred, the initialization associated with the entity for thread \( t \) is sequenced before the first non-initialization odr-use by \( t \) of any non-inline variable with thread storage duration defined in the same translation unit as the variable to be initialized. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

If the initialization of a non-block variable with static or thread storage duration exits via an exception, the function `std::terminate` is called (14.6.2).

---

40) A non-block variable with static storage duration having initialization with side effects is initialized in this case, even if it is not itself odr-used (6.3, 6.7.5.2).
6.9.3.4 Termination  [basic.start.term]

1 Constructed objects (9.4) with static storage duration are destroyed and functions registered with std::atexit are called as part of a call to std::exit (17.5). The call to std::exit is sequenced before the destructions and the registered functions.

[Note 1: Returning from main invokes std::exit (6.9.3.1). — end note]

2 Constructed objects with thread storage duration within a given thread are destroyed as a result of returning from the initial function of that thread and as a result of that thread calling std::exit. The destruction of all constructed objects with thread storage duration within that thread strongly happens before destroying any object with static storage duration.

3 If the completion of the constructor or dynamic initialization of an object with static storage duration strongly happens before that of another, the completion of the destructor of the second is sequenced before the initiation of the destructor of the first. If the completion of the constructor or dynamic initialization of an object with thread storage duration is sequenced before that of another, the completion of the destructor of the second is sequenced before the initiation of the destructor of the first. If an object is initialized statically, the object is destroyed in the same order as if the object was dynamically initialized. For an object of array or class type, all subobjects of that object are destroyed before any block variable with static storage duration initialized during the construction of the subobjects is destroyed. If the destruction of an object with static or thread storage duration exits via an exception, the function std::terminate is called (14.6.2).

4 If a function contains a block variable of static or thread storage duration that has been destroyed and the function is called during the destruction of an object with static or thread storage duration, the program has undefined behavior if the flow of control passes through the definition of the previously destroyed block variable.

[Note 2: Likewise, the behavior is undefined if the block variable is used indirectly (e.g., through a pointer) after its destruction. — end note]

5 If the completion of the initialization of an object with static storage duration strongly happens before a call to std::atexit (see <cstdlib>, 17.5), the call to the function passed to std::atexit is sequenced before the call to the destructor for the object. If a call to std::atexit strongly happens before the completion of the initialization of an object with static storage duration, the call to the destructor for the object is sequenced before the call to the function passed to std::atexit. If a call to std::atexit strongly happens before another call to std::atexit, the call to the function passed to the second std::atexit call is sequenced before the call to the function passed to the first std::atexit call.

6 If there is a use of a standard library object or function not permitted within signal handlers (17.13) that does not happen before (6.9.2) completion of destruction of objects with static storage duration and execution of std::atexit registered functions (17.5), the program has undefined behavior.

[Note 3: If there is a use of an object with static storage duration that does not happen before the object’s destruction, the program has undefined behavior. Terminating every thread before a call to std::exit or the exit from main is sufficient, but not necessary, to satisfy these requirements. These requirements permit thread managers as static-storage-duration objects. — end note]

7 Calling the function std::abort() declared in <cstdlib> (17.2.2) terminates the program without executing any destructors and without calling the functions passed to std::atexit() or std::at_quick_exit().
7 Expressions

7.1 Preamble

[Note 1: Clause 7 defines the syntax, order of evaluation, and meaning of expressions. An expression is a sequence of operators and operands that specifies a computation. An expression can result in a value and can cause side effects. — end note]

[Note 2: Operators can be overloaded, that is, given meaning when applied to expressions of class type (Clause 11) or enumeration type (9.7.1). Uses of overloaded operators are transformed into function calls as described in 12.4. Overloaded operators obey the rules for syntax and evaluation order specified in 7.6, but the requirements of operand type and value category are replaced by the rules for function call. Relations between operators, such as \(a++\) meaning \(a=a+1\), are not guaranteed for overloaded operators (12.4). — end note]

Subclause 7.6 defines the effects of operators when applied to types for which they have not been overloaded. Operator overloading shall not modify the rules for the built-in operators, that is, for operators applied to types for which they are defined by this Standard. However, these built-in operators participate in overload resolution, and as part of that process user-defined conversions will be considered where necessary to convert the operands to types appropriate for the built-in operator. If a built-in operator is selected, such conversions will be applied to the operands before the operation is considered further according to the rules in subclause 7.6; see 12.2.2.3, 12.5.

If during the evaluation of an expression, the result is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

[Note 3: Treatment of division by zero, forming a remainder using a zero divisor, and all floating-point exceptions varies among machines, and is sometimes adjustable by a library function. — end note]

[Note 4: The implementation can regroup operators according to the usual mathematical rules only where the operators really are associative or commutative. For example, in the following fragment

```c
int a, b;
/* ... */
a = a + 32760 + b + 5;
```

the expression statement behaves exactly the same as

```
a = (((a + 32760) + b) + 5);
```

due to the associativity and precedence of these operators. Thus, the result of the sum \((a + 32760)\) is next added to \(b\), and that result is then added to 5 which results in the value assigned to \(a\). On a machine in which overflows produce an exception and in which the range of values representable by an `int` is \([-32768, +32767]\), the implementation cannot rewrite this expression as

```
a = ((a + b) + 32765);
```

since if the values for \(a\) and \(b\) were, respectively, −32754 and −15, the sum \(a + b\) would produce an exception while the original expression would not; nor can the expression be rewritten as either

```
a = ((a + 32765) + b);
```
or

```
a = (a + (b + 32765));
```

since the values for \(a\) and \(b\) might have been, respectively, 4 and −8 or −17 and 12. However on a machine in which overflows do not produce an exception and in which the results of overflows are reversible, the above expression statement can be rewritten by the implementation in any of the above ways because the same result will occur. — end note]

The values of the floating-point operands and the results of floating-point expressions may be represented in greater precision and range than that required by the type; the types are not changed thereby.

41) The precedence of operators is not directly specified, but it can be derived from the syntax.
42) Overloaded operators are never assumed to be associative or commutative.
43) The cast and assignment operators must still perform their specific conversions as described in 7.6.1.4, 7.6.3, 7.6.1.9 and 7.6.19.
7.2 Properties of expressions

7.2.1 Value category

Expressions are categorized according to the taxonomy in Figure 2.

Figure 2: Expression category taxonomy — end note

(1.1) — A glvalue is an expression whose evaluation determines the identity of an object or function.

(1.2) — A prvalue is an expression whose evaluation initializes an object or computes the value of an operand of an operator, as specified by the context in which it appears, or an expression that has type cv void.

(1.3) — An xvalue is a glvalue that denotes an object whose resources can be reused (usually because it is near the end of its lifetime).

(1.4) — An lvalue is a glvalue that is not an xvalue.

(1.5) — An rvalue is a prvalue or an xvalue.

2 Every expression belongs to exactly one of the fundamental classifications in this taxonomy: lvalue, xvalue, or prvalue. This property of an expression is called its value category.

[Note 1: The discussion of each built-in operator in 7.6 indicates the category of the value it yields and the value categories of the operands it expects. For example, the built-in assignment operators expect that the left operand is an lvalue and that the right operand is a prvalue and yield an lvalue as the result. User-defined operators are functions, and the categories of values they expect and yield are determined by their parameter and return types. — end note]

(2) [Note 2: Historically, lvalues and rvalues were so-called because they could appear on the left- and right-hand side of an assignment (although this is no longer generally true); glvalues are “generalized” lvalues, prvalues are “pure” rvalues, and xvalues are “eXpiring” lvalues. Despite their names, these terms classify expressions, not values. — end note]

(3) [Note 3: An expression is an xvalue if it is:

(4.1) — a move-eligible id-expression (7.5.4.2),

(4.2) — the result of calling a function, whether implicitly or explicitly, whose return type is an rvalue reference to object type (7.6.1.3),

(4.3) — a cast to an rvalue reference to object type (7.6.1.4, 7.6.1.7, 7.6.1.9, 7.6.1.10, 7.6.1.11, 7.6.3),

(4.4) — a subscripting operation with an xvalue array operand (7.6.1.2),

(4.5) — a class member access expression designating a non-static data member of non-reference type in which the object expression is an xvalue (7.6.1.5), or

(4.6) — a .• pointer-to-member expression in which the first operand is an xvalue and the second operand is a pointer to data member (7.6.4).

In general, the effect of this rule is that named rvalue references are treated as lvalues and unnamed rvalue references to objects are treated as xvalues; rvalue references to functions are treated as lvalues whether named or not. — end note]

[Example 1:

```cpp
struct A {
    int m;
};

&A&& operator+(A, A);
&A&& f();

A a;
&A&& ar = static_cast&A&&>(a);
```]
The expressions $f()$, $f().m$, `static_cast<A&&>(a)`, and $a + a$ are xvalues. The expression `ar` is an lvalue. — end example

5 The result of a glvalue is the entity denoted by the expression. The result of a prvalue is the value that the expression stores into its context; a prvalue that has type `cv void` has no result. A prvalue whose result is the value $V$ is sometimes said to have or name the value $V$. The result object of a prvalue is the object initialized by the prvalue; a non-discarded prvalue that is used to compute the value of an operand of a built-in operator or a prvalue that has type `cv void` has no result object.

[Note 4: Except when the prvalue is the operand of a `decltype-specifier`, a prvalue of class or array type always has a result object. For a discarded prvalue that has type other than `cv void`, a temporary object is materialized; see 7.2.3. — end note]

6 Whenever a glvalue appears as an operand of an operator that expects a prvalue for that operand, the lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), or function-to-pointer (7.3.4) standard conversions are applied to convert the expression to a prvalue.

[Note 5: An attempt to bind an rvalue reference to an lvalue is not such a context; see 9.4.4. — end note]

[Note 6: Because cv-qualifiers are removed from the type of an expression of non-class type when the expression is converted to a prvalue, an lvalue of type `const int` can, for example, be used where a prvalue of type `int` is required. — end note]

7 Whenever a prvalue appears as an operand of an operator that expects a glvalue for that operand, the temporary materialization conversion (7.3.5) is applied to convert the expression to an xvalue.

8 The discussion of reference initialization in 9.4.4 and of temporaries in 6.7.7 indicates the behavior of lvalues and rvalues in other significant contexts.

9 Unless otherwise indicated (9.2.9.5), a prvalue shall always have complete type or the `void` type; if it has a class type or (possibly multi-dimensional) array of class type, that class shall not be an abstract class (11.7.4). A glvalue shall not have type `cv void`.

[Note 8: A glvalue can have complete or incomplete non-`void` type. Class and array prvalues can have cv-qualified types; other prvalues always have cv-unqualified types. See 7.2.2. — end note]

An lvalue is modifiable unless its type is const-qualified or is a function type.

[Note 9: A program that attempts to modify an object through a nonmodifiable lvalue or through an rvalue is ill-formed (7.6.19, 7.6.1.6, 7.6.2.3). — end note]

11 If a program attempts to access (3.1) the stored value of an object through a glvalue whose type is not similar (7.3.6) to one of the following types the behavior is undefined:44

(11.1) — the dynamic type of the object,

(11.2) — a type that is the signed or unsigned type corresponding to the dynamic type of the object, or

(11.3) — a char, unsigned char, or `std::byte` type.

If a program invokes a defaulted copy/move constructor or copy/move assignment operator for a union of type $U$ with a glvalue argument that does not denote an object of type `cv U` within its lifetime, the behavior is undefined.

[Note 10: In C, an entire object of structure type can be accessed, e.g., using assignment. By contrast, C++ has no notion of accessing an object of class type through an lvalue of class type. — end note]

### 7.2.2 Type

If an expression initially has the type “reference to T” (9.3.4.3, 9.4.4), the type is adjusted to T prior to any further analysis. The expression designates the object or function denoted by the reference, and the expression is an lvalue or an xvalue, depending on the expression.

[Note 1: Before the lifetime of the reference has started or after it has ended, the behavior is undefined (see 6.7.3). — end note]

If a prvalue initially has the type “$cv T$”, where T is a cv-unqualified non-class, non-array type, the type of the expression is adjusted to T prior to any further analysis.

44) The intent of this list is to specify those circumstances in which an object can or cannot be aliased.
The composite pointer type of two operands \( p_1 \) and \( p_2 \) having types \( T_1 \) and \( T_2 \), respectively, where at least one is a pointer or pointer-to-member type or `std::nullptr_t`, is:

- if both \( p_1 \) and \( p_2 \) are null pointer constants, `std::nullptr_t`; 
- if either \( p_1 \) or \( p_2 \) is a null pointer constant, \( T_2 \) or \( T_1 \), respectively;
- if \( T_1 \) or \( T_2 \) is "pointer to cv1 void" and the other type is "pointer to cv2 T", where \( T \) is an object type or `void`, "pointer to cv12 void", where \( cv12 \) is the union of \( cv1 \) and \( cv2 \);
- if \( T_1 \) or \( T_2 \) is "pointer to noexcept function" and the other type is "pointer to function", where the function types are otherwise the same, "pointer to function";
- if \( T_1 \) is "pointer to cv1 C1" and \( T_2 \) is "pointer to cv2 C2", where \( C1 \) is reference-related to \( C2 \) or \( C2 \) is reference-related to \( C1 \) (9.4.4), the qualification-combined type (7.3.6) of \( T_1 \) and \( T_2 \) or the qualification-combined type of \( T_2 \) and \( T_1 \), respectively;
- if \( T_1 \) or \( T_2 \) is "pointer to member of \( C1 \) of type function", the other type is "pointer to member of \( C2 \) of type noexcept function", and \( C1 \) is reference-related to \( C2 \) or \( C2 \) is reference-related to \( C1 \) (9.4.4), where the function types are otherwise the same, "pointer to member of \( C2 \) of type function" or "pointer to member of \( C1 \) of type function", respectively;
- if \( T_1 \) is "pointer to member of \( C1 \) of type cv1 U" and \( T_2 \) is "pointer to member of \( C2 \) of type cv2 U", for some non-function type \( U \), where \( C1 \) is reference-related to \( C2 \) or \( C2 \) is reference-related to \( C1 \) (9.4.4), the qualification-combined type of \( T_2 \) and \( T_1 \) or the qualification-combined type of \( T_1 \) and \( T_2 \), respectively;
- if \( T_1 \) and \( T_2 \) are similar types (7.3.6), the qualification-combined type of \( T_1 \) and \( T_2 \);
- otherwise, a program that necessitates the determination of a composite pointer type is ill-formed.

Example 1:
```c
typedef void *p;
typedef const int *q;
typedef int **pi;
typedef const int **pci;
```

The composite pointer type of \( p \) and \( q \) is "pointer to const void"; the composite pointer type of \( pi \) and \( pci \) is "pointer to const pointer to const int". — end example]

7.2.3 Context dependence

In some contexts, unevaluated operands appear (7.5.7, 7.6.1.8, 7.6.2.5, 7.6.2.7, 9.2.9.5, 13.1, 13.7.9). An unevaluated operand is not evaluated.

[Note 1: In an unevaluated operand, a non-static class member can be named (7.5.4) and naming of objects or functions does not, by itself, require that a definition be provided (6.3). An unevaluated operand is considered a full-expression (6.9.1). — end note]

In some contexts, an expression only appears for its side effects. Such an expression is called a discarded-value expression. The array-to-pointer (7.3.3) and function-to-pointer (7.3.4) standard conversions are not applied. The lvalue-to-rvalue conversion (7.3.2) is applied if and only if the expression is a glvalue of volatile-qualified type and it is one of the following:

- ( expression ), where expression is one of these expressions,
- id-expression (7.5.4),
- subscripting (7.6.1.2),
- class member access (7.6.1.5),
- indirection (7.6.2.2),
- pointer-to-member operation (7.6.4),
- conditional expression (7.6.16) where both the second and the third operands are one of these expressions, or
- comma expression (7.6.20) where the right operand is one of these expressions.

[Note 2: Using an overloaded operator causes a function call; the above covers only operators with built-in meaning. — end note]

The temporary materialization conversion (7.3.5) is applied if the (possibly converted) expression is a prvalue of object type.
[Note 3: If the original expression is an lvalue of class type, it must have a volatile copy constructor to initialize the temporary object that is the result object of the temporary materialization conversion. — end note]

The expression is evaluated and its result (if any) is discarded.

7.3 Standard conversions

7.3.1 General

Standard conversions are implicit conversions with built-in meaning. 7.3 enumerates the full set of such conversions. A standard conversion sequence is a sequence of standard conversions in the following order:

(1) Zero or one conversion from the following set: lvalue-to-rvalue conversion, array-to-pointer conversion, and function-to-pointer conversion.

(2) Zero or one conversion from the following set: integral promotions, floating-point promotion, integral conversions, floating-point conversions, floating-integral conversions, pointer conversions, pointer-to-member conversions, and boolean conversions.

(3) Zero or one function pointer conversion.

(4) Zero or one qualification conversion.

[Note 1: A standard conversion sequence can be empty, i.e., it can consist of no conversions. — end note]

A standard conversion sequence will be applied to an expression if necessary to convert it to a required destination type.

2 [Note 2: Expressions with a given type will be implicitly converted to other types in several contexts:

(1) When used as operands of operators. The operator’s requirements for its operands dictate the destination type (7.6).

(2) When used in the condition of an if statement (8.5.2) or iteration statement (8.6). The destination type is bool.

(3) When used in the expression of a switch statement (8.5.3). The destination type is integral.

(4) When used as the source expression for an initialization (which includes use as an argument in a function call and use as the expression in a return statement). The type of the entity being initialized is (generally) the destination type. See 9.4, 9.4.4. — end note]

An expression $E$ can be implicitly converted to a type $T$ if and only if the declaration $T \ t = E$; is well-formed, for some invented temporary variable $t$ (9.4).

4 Certain language constructs require that an expression be converted to a Boolean value. An expression $E$ appearing in such a context is said to be contextually converted to bool and is well-formed if and only if the declaration bool $t(E)$; is well-formed, for some invented temporary variable $t$ (9.4).

5 Certain language constructs require conversion to a value having one of a specified set of types appropriate to the construct. An expression $E$ of class type $C$ appearing in such a context is said to be contextually implicitly converted to a specified type $T$ and is well-formed if and only if $E$ can be implicitly converted to a type $T$ that is determined as follows: $C$ is searched for non-explicit conversion functions whose return type is cv $T$ or reference to cv $T$ such that $T$ is allowed by the context. There shall be exactly one such $T$.

6 The effect of any implicit conversion is the same as performing the corresponding declaration and initialization and then using the temporary variable as the result of the conversion. The result is an lvalue if $T$ is an lvalue reference type or an rvalue reference to function type (9.3.4.3), an xvalue if $T$ is an rvalue reference to object type, and a prvalue otherwise. The expression $E$ is used as a glvalue if and only if the initialization uses it as a glvalue.

[Note 3: For class types, user-defined conversions are considered as well; see 11.4.8. In general, an implicit conversion sequence (12.2.4.2) consists of a standard conversion sequence followed by a user-defined conversion followed by another standard conversion sequence. — end note]

8 [Note 4: There are some contexts where certain conversions are suppressed. For example, the lvalue-to-rvalue conversion is not done on the operand of the unary & operator. Specific exceptions are given in the descriptions of those operators and contexts. — end note]
7.3.2 Lvalue-to-rvalue conversion

A glvalue (7.2.1) of a non-function, non-array type \( T \) can be converted to a prvalue.\(^{45} \) If \( T \) is an incomplete type, a program that necessitates this conversion is ill-formed. If \( T \) is a non-class type, the type of the prvalue is the cv-unqualified version of \( T \). Otherwise, the type of the prvalue is \( T \).\(^{46} \)

When an lvalue-to-rvalue conversion is applied to an expression \( E \), and either

1. \( E \) is not potentially evaluated, or
2. the evaluation of \( E \) results in the evaluation of a member \( E_x \) of the set of potential results of \( E \), and \( E_x \) names a variable \( x \) that is not odr-used by \( E_x \) (6.3),

the value contained in the referenced object is not accessed.

[Example 1:

```cpp
struct S { int n; }
auto f() {
    S x { 1 };
    constexpr S y { 2 };
    return [&](bool b) { return (b ? y : x).n; };
}
auto g = f();
int m = g(false); // undefined behavior: access of x.n outside its lifetime
int n = g(true);  // OK, does not access y.n
```
—end example]

3 The result of the conversion is determined according to the following rules:

1. If \( T \) is \( \text{cv std::nullptr_t} \), the result is a null pointer constant (7.3.12).

   [Note 1: Since the conversion does not access the object to which the glvalue refers, there is no side effect even if \( T \) is volatile-qualified (6.9.1), and the glvalue can refer to an inactive member of a union (11.5). —end note]

2. Otherwise, if \( T \) has a class type, the conversion copy-initializes the result object from the glvalue.

3. Otherwise, if the object to which the glvalue refers contains an invalid pointer value (6.7.5.5.3), the behavior is implementation-defined.

4. Otherwise, the object indicated by the glvalue is read (3.1), and the value contained in the object is the prvalue result.

   [Note 2: See also 7.2.1. —end note]

7.3.3 Array-to-pointer conversion

An lvalue or rvalue of type “array of \( N T \)” or “array of unknown bound of \( T \)” can be converted to a prvalue of type “pointer to \( T \)”. The temporary materialization conversion (7.3.5) is applied. The result is a pointer to the first element of the array.

7.3.4 Function-to-pointer conversion

An lvalue of function type \( T \) can be converted to a prvalue of type “pointer to \( T \)”. The result is a pointer to the function.\(^{47} \)

7.3.5 Temporary materialization conversion

A prvalue of type \( T \) can be converted to an xvalue of type \( T \). This conversion initializes a temporary object (6.7.7) of type \( T \) from the prvalue by evaluating the prvalue with the temporary object as its result object, and produces an xvalue denoting the temporary object. \( T \) shall be a complete type.

[Note 1: If \( T \) is a class type (or array thereof), it must have an accessible and non-deleted destructor; see 11.4.7. —end note]

---

\(^{45} \) For historical reasons, this conversion is called the “lvalue-to-rvalue” conversion, even though that name does not accurately reflect the taxonomy of expressions described in 7.2.1.

\(^{46} \) In C++ class and array prvalues can have cv-qualified types. This differs from ISO C, in which non-lvalues never have cv-qualified types.

\(^{47} \) This conversion never applies to non-static member functions because an lvalue that refers to a non-static member function cannot be obtained.
7.3.6 Qualification conversions

A qualification-decomposition of a type \( T \) is a sequence of \( cv_i \) and \( P_i \) such that \( T \) is

\[
\text{“} cv_0 \ P_0 \ cv_1 \ P_1 \ \cdots \ cv_{n-1} \ P_{n-1} \ cv_n \ U \text{” for } n \geq 0,
\]

where each \( cv_i \) is a set of cv-qualifiers (6.8.5), and each \( P_i \) is “pointer to” (9.3.4.2), “pointer to member of class \( C_i \) of type” (9.3.4.4), “array of \( N_i \),” or “array of unknown bound of” (9.3.4.5). If \( P_i \) designates an array, the cv-qualifiers \( cv_{i+1} \) on the element type are also taken as the cv-qualifiers \( cv_i \) of the array.

Example 1: The type denoted by the type-id const int ** has three qualification-decompositions, taking \( U \) as “int”, as “pointer to const int”, and as “pointer to pointer to const int”. — end example

The \( n \)-tuple of cv-qualifiers after the first one in the longest qualification-decomposition of \( T \), that is, \( cv_1, cv_2, \ldots, cv_n \), is called the cv-qualification signature of \( T \).

Two types \( T_1 \) and \( T_2 \) are similar if they have qualification-decompositions with the same \( n \) such that corresponding \( P_i \) components are either the same or one is “array of \( N_i \),” and the other is “array of unknown bound of”, and the types denoted by \( U \) are the same.

The qualification-combined type of two types \( T_1 \) and \( T_2 \) is the type \( T_3 \) similar to \( T_1 \) whose qualification-decomposition is such that:

\[
\text{(3.1) — for every } i > 0, \ cv_i^1 \text{ is the union of } cv_i^1 \text{ and } cv_i^2,
\]

\[
\text{(3.2) — if either } P_i^1 \text{ or } P_i^2 \text{ is “array of unknown bound of”, } P_i^3 \text{ is “array of unknown bound of”, otherwise it is } P_i^1, \text{ and}
\]

\[
\text{(3.3) — if the resulting } cv_i^3 \text{ is different from } cv_i^1 \text{ or } cv_i^2, \text{ or the resulting } P_i^3 \text{ is different from } P_i^1 \text{ or } P_i^2, \text{ then}
\]

\[
\text{const is added to every } cv_k^3 \text{ for } 0 < k < i,
\]

where \( cv_i^1 \) and \( P_i^j \) are the components of the qualification-decomposition of \( T_j \). A prvalue of type \( T_1 \) can be converted to type \( T_2 \) if the qualification-combined type of \( T_1 \) and \( T_2 \) is \( T_2 \).

Note 1: If a program could assign a pointer of type \( T^* \) to a pointer of type const \( T^* \) (that is, if line #1 below were allowed), a program could inadvertently modify a const object (as it is done on line #2). For example,

```c
int main() {
    const char c = 'c';
    char* pc;
    const char** pcc = &pc;       // #1: not allowed
    *pcc = &c;
    *pc = 'C';                     // #2: modifies a const object
}
```

— end note

Note 2: Given similar types \( T_1 \) and \( T_2 \), this construction ensures that both can be converted to the qualification-combined type of \( T_1 \) and \( T_2 \). — end note

Note 3: A prvalue of type “pointer to cv1 T” can be converted to a prvalue of type “pointer to cv2 T” if “cv2 T” is more cv-qualified than “cv1 T”. A prvalue of type “pointer to member of X of type cv1 T” can be converted to a prvalue of type “pointer to member of X of type cv2 T” if “cv2 T” is more cv-qualified than “cv1 T”. — end note

Note 4: Function types (including those used in pointer-to-member-function types) are never cv-qualified (9.3.4.6). — end note

7.3.7 Integral promotions

A prvalue of an integer type other than bool, char8_t, char16_t, char32_t, or wchar_t whose integer conversion rank (6.8.6) is less than the rank of int can be converted to a prvalue of type int if int can represent all the values of the source type; otherwise, the source prvalue can be converted to a prvalue of type unsigned int.

A prvalue of type char8_t, char16_t, char32_t, or wchar_t (6.8.2) can be converted to a prvalue of the first of the following types that can represent all the values of its underlying type: int, unsigned int, long int, unsigned long int, long long int, or unsigned long long int. If none of these types in that list can
represent all the values of its underlying type, a prvalue of type char8_t, char16_t, char32_t, or wchar_t can be converted to a prvalue of its underlying type.

A prvalue of an unscoped enumeration type whose underlying type is not fixed can be converted to a prvalue of the first of the following types that can represent all the values of the enumeration (9.7.1): int, unsigned int, long int, unsigned long int, or unsigned long long int. If none of the types in that list can represent all the values of the enumeration, a prvalue of an unscoped enumeration type can be converted to a prvalue of the extended integer type with lowest integer conversion rank (6.8.6) greater than the rank of long long in which all the values of the enumeration can be represented. If there are two such extended types, the signed one is chosen.

A prvalue of an unscoped enumeration type whose underlying type is fixed (9.7.1) can be converted to a prvalue of its underlying type. Moreover, if integral promotion can be applied to its underlying type, a prvalue of an unscoped enumeration type whose underlying type is fixed can also be converted to a prvalue of the promoted underlying type.

A prvalue for an integral bit-field (11.4.10) can be converted to a prvalue of type int if int can represent all the values of the bit-field; otherwise, it can be converted to unsigned int if unsigned int can represent all the values of the bit-field. If the bit-field is larger yet, no integral promotion applies to it. If the bit-field has enumeration type, it is treated as any other value of that type for promotion purposes.

A prvalue of type bool can be converted to a prvalue of type int, with false becoming zero and true becoming one.

These conversions are called integral promotions.

7.3.8 Floating-point promotion

A prvalue of type float can be converted to a prvalue of type double. The value is unchanged.

This conversion is called floating-point promotion.

7.3.9 Integral conversions

A prvalue of an integer type can be converted to a prvalue of another integer type. A prvalue of an unscoped enumeration type can be converted to a prvalue of an integer type.

If the destination type is bool, see 7.3.15. If the source type is bool, the value false is converted to zero and the value true is converted to one.

Otherwise, the result is the unique value of the destination type that is congruent to the source integer modulo 2^N, where N is the width of the destination type.

The conversions allowed as integral promotions are excluded from the set of integral conversions.

7.3.10 Floating-point conversions

A prvalue of floating-point type can be converted to a prvalue of another floating-point type with a greater or equal conversion rank (6.8.6). A prvalue of standard floating-point type can be converted to a prvalue of another standard floating-point type.

If the source value can be exactly represented in the destination type, the result of the conversion is that exact representation. If the source value is between two adjacent destination values, the result of the conversion is an implementation-defined choice of either of those values. Otherwise, the behavior is undefined.

The conversions allowed as floating-point promotions are excluded from the set of floating-point conversions.

7.3.11 Floating-integral conversions

A prvalue of a floating-point type can be converted to a prvalue of an integer type. The conversion truncates; that is, the fractional part is discarded. The behavior is undefined if the truncated value cannot be represented in the destination type.

[Note 1: If the destination type is bool, see 7.3.15. — end note]

A prvalue of an integer type or of an unscoped enumeration type can be converted to a prvalue of a floating-point type. The result is exact if possible. If the value being converted is in the range of values that can be represented but the value cannot be represented exactly, it is an implementation-defined choice of either the next lower or higher representable value.

§ 7.3.11
[Note 2: Loss of precision occurs if the integral value cannot be represented exactly as a value of the floating-point type. — end note]

If the value being converted is outside the range of values that can be represented, the behavior is undefined. If the source type is bool, the value false is converted to zero and the value true is converted to one.

7.3.12 Pointer conversions

A null pointer constant is an integer literal (5.13.2) with value zero or a prvalue of type std::nullptr_t. A null pointer constant can be converted to a pointer type; the result is the null pointer value of that type (6.8.4) and is distinguishable from every other value of object pointer or function pointer type. Such a conversion is called a null pointer conversion. Two null pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to cv-qualified type is a single conversion, and not the sequence of a pointer conversion followed by a qualification conversion (7.3.6). A null pointer constant of integral type can be converted to a prvalue of type std::nullptr_t.

[Note 1: The resulting prvalue is not a null pointer value. — end note]

A prvalue of type “pointer to cv T”, where T is an object type, can be converted to a prvalue of type “pointer to cv void”. The pointer value (6.8.4) is unchanged by this conversion.

A prvalue of type “pointer to cv D”, where D is a complete class type, can be converted to a prvalue of type “pointer to cv B”, where B is a base class (11.7) of D. If B is an inaccessible (11.8) or ambiguous (6.5.2) base class of D, a program that necessitates this conversion is ill-formed. The result of the conversion refers to the base class subobject of the derived class object. The null pointer value is converted to the null pointer value of the destination type.

7.3.13 Pointer-to-member conversions

A null pointer constant (7.3.12) can be converted to a pointer-to-member type; the result is the null member pointer value of that type and is distinguishable from any pointer to member not created from a null pointer constant. Such a conversion is called a null member pointer conversion. Two null member pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to member of cv-qualified type is a single conversion, and not the sequence of a pointer-to-member conversion followed by a qualification conversion (7.3.6).

A prvalue of type “pointer to member of B of type cv T”, where B is a class type, can be converted to a prvalue of type “pointer to member of D of type cv T”, where D is a complete class derived (11.7) from B. If B is an inaccessible (11.8), ambiguous (6.5.2), or virtual (11.7.2) base class of D, or a base class of a virtual base class of D, a program that necessitates this conversion is ill-formed. The result of the conversion refers to the same member as the pointer to member before the conversion took place, but it refers to the base class member as if it were a member of the derived class. The result refers to the member in D’s instance of B. Since the result has type “pointer to member of D of type cv T”, indirection through it with a D object is valid. The result is the same as if indirecting through the pointer to member of B with the B subobject of D. The null member pointer value is converted to the null member pointer value of the destination type.

7.3.14 Function pointer conversions

A prvalue of type “pointer to noexcept function” can be converted to a prvalue of type “pointer to function”. The result is a pointer to the function. A prvalue of type “pointer to member of type noexcept function” can be converted to a prvalue of type “pointer to member of type function”. The result designates the member function.

[Example 1:]

```c++
void (*p)();
void (**pp)() noexcept = &p;  // error: cannot convert to pointer to noexcept function

struct S { typedef void (*p)(); operator p(); float i; };  // S::operator p() = &S::p
void (*q)() noexcept = &S::i;  // error: cannot convert to pointer to noexcept function

-- end example
```

48) The rule for conversion of pointers to members (from pointer to member of base to pointer to member of derived) appears inverted compared to the rule for pointers to objects (from pointer to derived to pointer to base) (7.3.12, 11.7). This inversion is necessary to ensure type safety. Note that a pointer to member is not an object pointer or a function pointer and the rules for conversions of such pointers do not apply to pointers to members. In particular, a pointer to member cannot be converted to a void*.

§ 7.3.14
7.3.15 Boolean conversions

A prvalue of arithmetic, unscoped enumeration, pointer, or pointer-to-member type can be converted to a prvalue of type bool. A zero value, null pointer value, or null member pointer value is converted to false; any other value is converted to true.

7.4 Usual arithmetic conversions

Many binary operators that expect operands of arithmetic or enumeration type cause conversions and yield result types in a similar way. The purpose is to yield a common type, which is also the type of the result. This pattern is called the usual arithmetic conversions, which are defined as follows:

1. If either operand is of scoped enumeration type (9.7.1), no conversions are performed; if the other operand does not have the same type, the expression is ill-formed.
2. Otherwise, if either operand is of floating-point type, the following rules are applied:
   1.1. If both operands have the same type, no further conversion is needed.
   1.2. Otherwise, if one of the operands is of a non-floating-point type, that operand is converted to the type of the operand with the floating-point type.
   1.3. Otherwise, the expression is ill-formed.
3. Otherwise, each operand is converted to a common type C. The integral promotion rules (7.3.7) are used to determine a type T1 and type T2 for each operand. Then the following rules are applied to determine C:
   1.1. If T1 and T2 are the same type, C is that type.
   1.2. Otherwise, if T1 and T2 are both signed integer types or are both unsigned integer types, C is the type with greater rank.
   1.3. Otherwise, let U be the unsigned integer type and S be the signed integer type.
      1.3.1. If U has rank greater than or equal to the rank of S, C is U.
      1.3.2. Otherwise, if S can represent all of the values of U, C is S.
      1.3.3. Otherwise, C is the unsigned integer type corresponding to S.

If one operand is of enumeration type and the other operand is of a different enumeration type or a floating-point type, this behavior is deprecated (D.2).

7.5 Primary expressions

7.5.1 Literals

The type of a literal is determined based on its form as specified in 5.13. A string-literal is an lvalue designating a corresponding string literal object (5.13.5), a user-defined-literal has the same value category as the corresponding operator call expression described in 5.13.8, and any other literal is a prvalue.

49) As a consequence, operands of type bool, char8_t, char16_t, char32_t, wchar_t, or of enumeration type are converted to some integral type.
7.5.2 This

The keyword `this` names a pointer to the object for which an implicit object member function (11.4.3) is invoked or a non-static data member’s initializer (11.4) is evaluated.

The current class at a program point is the class associated with the innermost class scope containing that point.

[Note 1: A lambda-expression does not introduce a class scope. — end note]

If a declaration declares a member function or member function template of a class X, the expression `this` is a prvalue of type “pointer to cv-qualifier-seq X” wherever X is the current class between the optional cv-qualifier-seq and the end of the function-definition, member-declarator, or declarator. It shall not appear within the declaration of either a static member function or an explicit object member function of the current class (although its type and value category are defined within such member functions as they are within an implicit object member function).

[Note 2: This is because declaration matching does not occur until the complete declarator is known. — end note]

[Note 3: In a trailing-return-type, the class being defined is not required to be complete for purposes of class member access (7.6.1.5). Class members declared later are not visible.

[Example 1:
```cpp
struct A {
    char g();
    template<class T> auto f(T t) -> decltype(t + g())
    { return t + g(); }  
};
```  
—end example]

—end note]

Otherwise, if a member-declarator declares a non-static data member (11.4) of a class X, the expression `this` is a prvalue of type “pointer to X” wherever X is the current class within the optional default member initializer (11.4).

The expression `this` shall not appear in any other context.

[Example 2:
```cpp
class Outer {
    int a[sizeof(*this)];                   // error: not inside a member function
    unsigned int sz = sizeof(*this);       // OK, in default member initializer

    void f() {
        int b[sizeof(*this)];               // OK

        struct Inner {
            int c[sizeof(*this)];            // error: not inside a member function of Inner
        }
    }
};
```  
—end example]

7.5.3 Parentheses

A parenthesized expression (E) is a primary expression whose type, result, and value category are identical to those of E. The parenthesized expression can be used in exactly the same contexts as those where E can be used, and with the same meaning, except as otherwise indicated.

7.5.4 Names

7.5.4.1 General

An id-expression is a restricted form of a primary-expression.

[Note 1: An id-expression can appear after . and -> operators (7.6.1.5). — end note]
2 If an id-expression \( E \) denotes a member \( M \) of an anonymous union (11.5.2) \( U \):

(2.1) — If \( U \) is a non-static data member, \( E \) refers to \( M \) as a member of the lookup context of the terminal name of \( E \) (after any transformation to a class member access expression (11.4.3)).

[Example 1: \( o.x \) is interpreted as \( o.u.x \), where \( u \) names the anonymous union member. — end example]

(2.2) — Otherwise, \( E \) is interpreted as a class member access (7.6.1.5) that designates the member subobject \( M \) of the anonymous union variable for \( U \).

[Note 2: Under this interpretation, \( E \) no longer denotes a non-static data member. — end note]

[Example 2: \( N::x \) is interpreted as \( N::u.x \), where \( u \) names the anonymous union variable. — end example]

3 An id-expression that denotes a non-static data member or implicit object member function of a class can only be used:

(3.1) — as part of a class member access (7.6.1.5) in which the object expression refers to the member’s class or a class derived from that class, or

(3.2) — to form a pointer to member (7.6.2.2), or

(3.3) — if that id-expression denotes a non-static data member and it appears in an unevaluated operand.

[Example 3:

```c
struct S {
    int m;
};
int i = sizeof(S::m); // OK
int j = sizeof(S::m + 42); // OK
```

— end example]

4 For an id-expression that denotes an overload set, overload resolution is performed to select a unique function (12.2, 12.3).

[Note 3: A program cannot refer to a function with a trailing requires-clause whose constraint-expression is not satisfied, because such functions are never selected by overload resolution.

[Example 4:

```c
template<typename T> struct A {
    static void f(int) requires false;
};

void g() {
    A<int>::f(0); // error: cannot call f
    void (*p1)(int) = A<int>::f; // error: cannot take the address of f
    decltype(A<int>::f)* p2 = nullptr; // error: the type decltype(A<int>::f) is invalid
}
```

In each case, the constraints of \( f \) are not satisfied. In the declaration of \( p2 \), those constraints are required to be satisfied even though \( f \) is an unevaluated operand (7.2.3). — end example]

— end note]

7.5.4.2 Unqualified names [expr.prim.id.unqual]

unqualified-id:

identifier
operator-function-id
conversion-function-id
literal-operator-id
~ type-name
~ decltype-specifier
template-id

1 An identifier is only an id-expression if it has been suitably declared (Clause 9) or if it appears as part of a declarator-id (9.3). An identifier that names a coroutine parameter refers to the copy of the parameter (9.5.4).

[Note 1: For operator-function-ids, see 12.4; for conversion-function-ids, see 11.4.8.3; for literal-operator-ids, see 12.6; for template-ids, see 13.3. A type-name or decltype-specifier prefixed by ~ denotes the destructor of the type so named; 50) This also applies when the object expression is an implicit \(*this\) (11.4.3).]
see 7.5.4.4. Within the definition of a non-static member function, an identifier that names a non-static member is transformed to a class member access expression (11.4.3). — end note

2 A component name of an unqualified-id \( U \) is

\[
\begin{align*}
\text{—} (2.1) & \quad U \text{ if it is a name or} \\
\text{—} (2.2) & \quad \text{the component name of the template-id or type-name of } U, \text{ if any.}
\end{align*}
\]

[Note 2: Other constructs that contain names to look up can have several component names (7.5.4.3, 9.2.9.3, 9.2.9.4, 9.3.4.4, 9.9, 13.2, 13.3, 13.8). — end note]

The terminal name of a construct is the component name of that construct that appears lexically last.

3 The result is the entity denoted by the unqualified-id (6.5.3). If the unqualified-id appears in a lambda-expression at program point \( P \) and the entity is a local entity (6.1) or a variable declared by an init-capture (7.5.5.3), then let \( S \) be the compound-statement of the innermost enclosing lambda-expression of \( P \). If naming the entity from outside of an unevaluated operand within \( S \) would refer to an entity captured by copy in some intervening lambda-expression, then let \( E \) be the innermost such lambda-expression.

\[
\begin{align*}
\text{—} (3.1) & \quad \text{If there is such a lambda-expression and if } P \text{ is in } E \text{'s function parameter scope but not its parameter-declaration-clause, then the type of the expression is the type of a class member access expression (7.6.1.5) naming the non-static data member that would be declared for such a capture in the object parameter (9.3.4.6) of the function call operator of } E. \\
\text{—} (3.2) & \quad \text{Otherwise (if there is no such lambda-expression or if } P \text{ either precedes } E \text{'s function parameter scope or is in } E \text{'s parameter-declaration-clause), the type of the expression is the type of the result.}
\end{align*}
\]

[Note 3: If \( E \) is not declared mutable, the type of such an identifier will typically be const qualified. — end note]

[Note 4: If the entity is a template parameter object for a template parameter of type \( T \) (13.2), the type of the expression is \( \text{const } T \). — end note]

[Note 5: The type will be adjusted as described in 7.2.2 if it is cv-qualified or is a reference type. — end note]

The expression is an xvalue if it is move-eligible (see below); an lvalue if the entity is a function, variable, structured binding (9.6), data member, or template parameter object; and a prvalue otherwise (7.2.1); it is a bit-field if the identifier designates a bit-field.

**Example 1:**

```c
void f() {
  float x, &r = x;

  [=] () -> decltype((x)) {} // lambda returns float const& because this lambda is not mutable and 
  // x is an lvalue
  decltype(x) y1; // y1 has type float
  decltype((x)) y2 = y1; // y2 has type float const&
  decltype(r) r1 = y1; // r1 has type float&
  decltype((r)) r2 = y2; // r2 has type float const&
  return y2;
}

[=] (decltype((x)) y) {
  decltype((x)) z = y; // OK, y has type float&, z has type float const&
};

[=] (decltype((x)) y) {}; // OK, lambda takes a parameter of type float const&

[=] (decltype((x)) y) {
  decltype((x)) z = y; // OK, y has type int&, z has type int const&
};

} — end example]
```

4 An implicitly movable entity is a variable of automatic storage duration that is either a non-volatile object or an rvalue reference to a non-volatile object type. In the following contexts, an id-expression is move-eligible:
(4.1) — If the id-expression (possibly parenthesized) is the operand of a return (8.7.4) or co_return (8.7.5) statement, and names an implicitly movable entity declared in the body or parameter-declaration-clause of the innermost enclosing function or lambda-expression, or

(4.2) — if the id-expression (possibly parenthesized) is the operand of a throw-expression (7.6.18), and names an implicitly movable entity that belongs to a scope that does not contain the compound-statement of the innermost lambda-expression, try-block, or function-try-block (if any) whose compound-statement or ctor-initializer contains the throw-expression.

7.5.4.3 Qualified names [expr.prim.id.qual]

qualified-id:
  nested-name-specifier template_opt unqualified-id

nested-name-specifier:
  ::
    type-name ::
    namespace-name ::
    decltype-specifier ::
    nested-name-specifier identifier ::
    nested-name-specifier template_opt simple-template-id ::

1 The component names of a qualified-id are those of its nested-name-specifier and unqualified-id. The component names of a nested-name-specifier are its identifier (if any) and those of its type-name, namespace-name, simple-template-id, and/or nested-name-specifier.

2 A nested-name-specifier is declarative if it is part of
   (2.1) — a class-head-name,
   (2.2) — an enum-head-name,
   (2.3) — a qualified-id that is the id-expression of a declarator-id, or
   (2.4) — a declarative nested-name-specifier.

   A declarative nested-name-specifier shall not have a decltype-specifier. A declaration that uses a declarative nested-name-specifier shall be a friend declaration or inhabit a scope that contains the entity being redeclared or specialized.

3 The nested-name-specifier :: nominates the global namespace. A nested-name-specifier with a decltype-specifier nominates the type denoted by the decltype-specifier, which shall be a class or enumeration type. If a nested-name-specifier N is declarative and has a simple-template-id with a template argument list A that involves a template parameter, let T be the template nominated by N without A. T shall be a class template.

   (3.1) — If A is the template argument list (13.4) of the corresponding template-head H (13.7.3), N nominates the primary template of T; H shall be equivalent to the template-head of T (13.7.7.2).
   (3.2) — Otherwise, N nominates the partial specialization (13.7.6) of T whose template argument list is equivalent to A (13.7.7.2); the program is ill-formed if no such partial specialization exists.

Any other nested-name-specifier nominates the entity denoted by its type-name, namespace-name, identifier, or simple-template-id. If the nested-name-specifier is not declarative, the entity shall not be a template.

4 A qualified-id shall not be of the form nested-name-specifier template_opt ~ decltype-specifier nor of the form decltype-specifier :: ~ type-name.

5 The result of a qualified-id Q is the entity it denotes (6.5.5). The type of the expression is the type of the result. The result is an lvalue if the member is
   (5.1) — a function other than a non-static member function,
   (5.2) — a non-static member function if Q is the operand of a unary & operator,
   (5.3) — a variable,
   (5.4) — a structured binding (9.6), or
   (5.5) — a data member,

   and a prvalue otherwise.
7.5.4.4 Destruction

An id-expression that denotes the destructor of a type T names the destructor of T if T is a class type (11.4.7), otherwise the id-expression is said to name a pseudo-destructor.

If the id-expression names a pseudo-destructor, T shall be a scalar type and the id-expression shall appear as the right operand of a class member access (7.6.1.5) that forms the postfix-expression of a function call (7.6.1.3).

[Note 1: Such a call ends the lifetime of the object (7.6.1.3, 6.7.3). — end note]

Example 1:

```cpp
struct C {};
void f() {
    C * pc = new C;
    pc->C::~C2();  // OK, destroys *pc
    C().C::~C();  // undefined behavior: temporary of type C destroyed twice
    using T = int;
    0.T::~T();    // OK, no effect
    0.T::~T();    // error: 0.T is a user-defined-floating-point-literal (5.13.8)
}
```

—end example—

7.5.5 Lambda expressions

7.5.5.1 General

A lambda-expression provides a concise way to create a simple function object.

Example 1:

```cpp
#include <algorithm>
#include <cmath>
void abssort(float* x, unsigned N) {
    std::sort(x, x + N, [](float a, float b) { return std::abs(a) < std::abs(b); });
}
```

—end example—

A lambda-expression is a prvalue whose result object is called the closure object.

[Note 1: A closure object behaves like a function object (22.10). — end note]

An ambiguity can arise because a requires-clause can end in an attribute-specifier-seq, which collides with the attribute-specifier-seq in lambda-expression. In such cases, any attributes are treated as attribute-specifier-seq in lambda-expression.
A lambda-specifier-seq shall contain at most one of each lambda-specifier and shall not contain both constexpr and consteval. If the lambda-declarator contains an explicit object parameter (9.3.4.6), then no lambda-specifier in the lambda-specifier-seq shall be mutable or static. The lambda-specifier-seq shall not contain both mutable and static. If the lambda-specifier-seq contains static, there shall be no lambda-capture.

If a lambda-declarator does not include a parameter-declaration-clause, it is as if () were inserted at the start of the lambda-declarator. If the lambda-declarator does not include a trailing-return-type, it is considered to be -> auto.

A lambda is a generic lambda if the lambda-expression has any generic parameter type placeholders (9.2.9.6), or if the lambda has a template-parameter-list.

The closure type is declared in the smallest block scope, class scope, or namespace scope that contains the corresponding lambda-expression, whose properties are described below.

The closure type is not an aggregate type (9.4.2). An implementation may define the closure type differently from what is described below provided this does not alter the observable behavior of the program other than by changing:

- (2.1) the size and/or alignment of the closure type,
- (2.2) whether the closure type is trivially copyable (11.2), or
- (2.3) whether the closure type is a standard-layout class (11.2).

An implementation shall not add members of rvalue reference type to the closure type.

The closure type for a lambda-expression has a public inline function call operator (for a non-generic lambda) or function call operator template (for a generic lambda) (12.4.4) whose parameters and return type are described by the lambda-expression’s parameter-declaration-clause and trailing-return-type respectively, and whose template-parameter-list consists of the specified template-parameter-list, if any. The requires-clause of the function call operator template is the requires-clause immediately following < template-parameter-list >, if any. The trailing requires-clause of the function call operator or operator template is the requires-clause of the lambda-declarator, if any.

The function call operator template for a generic lambda can be an abbreviated function template (9.3.4.6).

Example 1:

```cpp
auto glambda = [] (auto a, auto&& b) { return a < b; };
bool b = glambda(3, 3.14);  // OK
```
auto vglambda = [] (auto printer) {
    return [=] (auto&& ... ts) {
        printer(std::forward<decltype(ts)>(ts)...);
        return [=] () {
            printer(ts ...);
        };
    };

    auto p = vglambda( [](auto v1, auto v2, auto v3) {
        std::cout << v1 << v2 << v3;
    } );
    auto q = p(1, 'a', 3.14);
    // OK, outputs 1a3.14
    q();
    // OK, outputs 1a3.14

    auto fact = [] (this auto self, int n) -> int {
        return (n <= 1) ? 1 : n * self(n-1);
    };
    std::cout << fact(5);  // OK, outputs 120
    return; // OK, defines a function

    // Example 2:
    struct C {
      template <typename T>
        C(T);
    };
    void func(int i) {
      int x = [=] (this auto&&) { return i; }();  // OK
      int y = [=] (this C) { return i; }();    // error
      int z = [] (this C) { return 42; }();  // OK
    }
    // Example 2:

    // Example 3:
    auto ID = [] (auto a) { return a; };  // OK
    static_assert(ID(3) == 3);
    struct NonLiteral {
      NonLiteral(int n) : n(n) { }
      int n;
    };
    static_assert(ID(NonLiteral{3}).n == 3);  // error

4 Given a lambda with a lambda-capture, the type of the explicit object parameter, if any, of the lambda’s function call operator (possibly instantiated from a function call operator template) shall be either:

(4.1) the closure type,
(4.2) a class type derived from the closure type, or
(4.3) a reference to a possibly cv-qualified such type.

[Example 2]:
struct C {
  template <typename T>
    C(T);
};
void func(int i) {
  int x = [=] (this auto&&) { return i; }();  // OK
  int y = [=] (this C) { return i; }();    // error
  int z = [] (this C) { return 42; }();  // OK
}

5 The function call operator or operator template is a static member function or static member function template (11.4.9.2) if the lambda-expression’s parameter-declaration-clause is followed by static. Otherwise, it is a non-static member function or member function template (11.4.3) that is declared const (11.4.3) if and only if the lambda-expression’s parameter-declaration-clause is not followed by mutable and the lambda-declaration does not contain an explicit object parameter. It is neither virtual nor declared volatile. Any noexcept-specifier specified on a lambda-expression applies to the corresponding function call operator or operator template. An attribute-specifier-seq in a lambda-declarator appertains to the type of the corresponding function call operator or operator template. An attribute-specifier-seq in a lambda-expression preceding a lambda-declarator appertains to the corresponding function call operator or operator template. The function call operator or any given operator template specialization is a constexpr function if either the corresponding lambda-expression’s parameter-declaration-clause is followed by constexpr or consteval, or it is constexpr-suitable (9.2.6). It is an immediate function (9.2.6) if the corresponding lambda-expression’s parameter-declaration-clause is followed by consteval.

[Example 3]:
auto ID = [] (auto a) { return a; };  // OK
static_assert(ID(3) == 3);

struct NonLiteral {
  NonLiteral(int n) : n(n) { }
  int n;
};
static_assert(ID(NonLiteral{3}).n == 3);  // error
Example 4:

```cpp
class auto monoid = [] (auto v) { return [=] { return v; }; };
class auto add = [] (auto m1) constexpr {
    auto ret = m1();
    return [=] (auto m2) mutable {
        auto m1val = m1();
        auto plus = [=] (auto m2val) mutable constexpr {
            return m1val += m2val;
        };
        ret = plus(m2());
        return monoid(ret);
    };
};
class constexpr auto zero = monoid(0);
class constexpr auto one = monoid(1);
static_assert(add(one)(zero)() == one()); // OK

// Since `two` below is not declared `constexpr`, an evaluation of its `constexpr` member function call operator
// cannot perform an `value-to-value` conversion on one of its subobjects (that represents its capture)
// in a constant expression.
auto two = monoid(2);
assert(two() == 2); // OK, not a constant expression.
static_assert(add(one)(one)() == two()); // error: `two()` is not a constant expression
static_assert(add(one)(one)() == monoid(2)()); // OK
```

--- end example

Note 3: The function call operator or operator template can be constrained (13.5.3) by a type-constraint (13.2), a requires-clause (13.1), or a trailing requires-clause (9.3).

Example 5:

```cpp
template <typename T> concept C1 = /* ... */;
template <std::size_t N> concept C2 = /* ... */;
template <typename A, typename B> concept C3 = /* ... */;

auto f = []<typename T1, C1 T2> requires C2<sizeof(T1) + sizeof(T2)>
             (T1 a1, T1 b1, T2 a2, auto a3, auto a4) requires C3<decltype(a4), T2> {
    // `T2` is constrained by a type-constraint.
    // `T1` and `T2` are constrained by a requires-clause, and
    // `T2` and the type of `a4` are constrained by a trailing requires-clause.
};
```

--- end example

--- end note

The closure type for a non-generic lambda-expression with no lambda-capture whose constraints (if any) are satisfied has a conversion function to pointer to function with C++ language linkage (9.11) having the same parameter and return types as the closure type's function call operator. The conversion is to “pointer to noexcept function” if the function call operator has a non-throwing exception specification. If the function call operator is a static member function, then the value returned by this conversion function is the address of the function call operator. Otherwise, the value returned by this conversion function is the address of a function F that, when invoked, has the same effect as invoking the closure type's function call operator on a default-constructed instance of the closure type. F is a constexpr function if the function call operator is a constexpr function and is an immediate function if the function call operator is an immediate function.

For a generic lambda with no lambda-capture, the closure type has a conversion function template to pointer to function. The conversion function template has the same invented template parameter list, and the pointer to function has the same parameter types, as the function call operator template. The return type of the pointer to function shall behave as if it were a decltype-specifier denoting the return type of the corresponding function call operator template specialization.

Note 4: If the generic lambda has no trailing-return-type or the trailing-return-type contains a placeholder type, return type deduction of the corresponding function call operator template specialization has to be done. The corresponding specialization is that instantiation of the function call operator template with the same template arguments as those deduced for the conversion function template. Consider the following:
auto glambda = [](auto a) { return a; };
int (*fp)(int) = glambda;

The behavior of the conversion function of `glambda` above is like that of the following conversion function:

```cpp
struct Closure {
    template<class T> auto operator()(T t) const { /* ... */ }
    template<class T> static auto lambda_call_operator_invoker(T a) {
        // forwards execution to operator()(a) and therefore has
        // the same return type deduced
        /* ... */
    }
    template<class T> using fptr_t = decltype(lambda_call_operator_invoker(declval<T>())) (*)(T);
    template<class T> operator fptr_t<T>() const { return &lambda_call_operator_invoker; }
};
```

—end note

**Example 6**:

```cpp
void f1(int (*)(int)) { }
void f2(char (*)(int)) { }
void g(int (*)(int)) { } // #1
void g(char (*)(char)) { } // #2
void h(int (*)(int)) { } // #3
void h(char (*)(int)) { } // #4

auto glambda = [](auto a) { return a; };
f1(glambda); // OK
f2(glambda); // error: ID is not convertible
g(glambda); // error: ambiguous
h(glambda); // OK, calls #3 since it is convertible from ID
int& (*fpi)(int*) = [](auto* a) -> auto& { return *a; }; // OK
```

—end example

11 If the function call operator template is a static member function template, then the value returned by any given specialization of this conversion function template is the address of the corresponding function call operator template specialization. Otherwise, the value returned by any given specialization of this conversion function template is the address of a function `F` that, when invoked, has the same effect as invoking the generic lambda’s corresponding function call operator template specialization on a default-constructed instance of the closure type. `F` is a constexpr function if the corresponding specialization is a constexpr function and `F` is an immediate function if the function call operator template specialization is an immediate function.

[Note 5: This will result in the implicit instantiation of the generic lambda's body. The instantiated generic lambda's return type and parameter types are required to match the return type and parameter types of the pointer to function. —end note]

**Example 7**:

```cpp
auto GL = [](auto a) { std::cout << a; return a; };
int (*GL_int)(int) = GL; // OK, through conversion function template
GL_int(3); // OK, same as GL(3)
```

—end example

12 The conversion function or conversion function template is public, constexpr, non-virtual, non-explicit, const, and has a non-throwing exception specification (14.5).

**Example 8**:

```cpp
auto Fwd = [](int (*fp)(int), auto a) { return fp(a); };
auto C = [](auto a) { return a; };
static_assert(Fwd(C, 3) == 3); // OK
```
The `lambda-expression`'s compound-statement yields the function-body (9.5.3) of the function call operator, but it is not within the scope of the closure type.

```cpp
Example 9:
struct S1 {
    int x, y;
    int operator()(int);
    void f() {
        [=]() -> int {
            return operator()(this->x + y);  // equivalent to S1::operator()(this->x + (*this).y)
            // this has type S1*
        };
    }
};
```

Further, a variable `__func__` is implicitly defined at the beginning of the compound-statement of the `lambda-expression`, with semantics as described in 9.5.1.

The closure type associated with a `lambda-expression` has no default constructor if the `lambda-expression` has a `lambda-capture` and a defaulted default constructor otherwise. It has a defaulted copy constructor and a defaulted move constructor (11.4.5.3). It has a deleted copy assignment operator if the `lambda-expression` has a `lambda-capture` and defaulted copy and move assignment operators otherwise (11.4.6).

[Note 6: These special member functions are implicitly defined as usual, which can result in them being defined as deleted. — end note]

The closure type associated with a `lambda-expression` has an implicitly-declared destructor (11.4.7).

A member of a closure type shall not be explicitly instantiated (13.9.3), explicitly specialized (13.9.4), or named in a friend declaration (11.8.4).

7.5.5.3 Captures

```
lambda-capture: capture-default
    capture-list
    capture-default , capture-list

capture-default:
    &

capture-list:
    capture
    capture-list , capture

capture:
    simple-capture
    init-capture

simple-capture:
    identifier ... opt
    & identifier ... opt
    this
    * this

init-capture:
    ... opt identifier initializer
    & ... opt identifier initializer
```

The body of a `lambda-expression` may refer to local entities of enclosing block scopes by capturing those entities, as described below.
If a lambda-capture includes a capture-default that is &k, no identifier in a simple-capture of that lambda-capture shall be preceded by &k. If a lambda-capture includes a capture-default that is =, each simple-capture of that lambda-capture shall be of the form "&k identifier ...opt", "this", or "* this".

[Note 1: The form [&,this] is redundant but accepted for compatibility with ISO C++ 2014. — end note]

Ignoring appearances in initializers of init-captures, an identifier or this shall not appear more than once in a lambda-capture.

[Example 1:

```cpp
struct S2 { void f(int i); }
void S2::f(int i) {
  [&i]{ } // OK
  [&i, i]{ }; // OK, equivalent to [&i]
  [=, *this]{ } // OK
  [=, this]{ }; // OK, equivalent to [=]
  [i, i]{ }; // error: i repeated
  [this, *this]{ }; // error: this appears twice
}

— end example]

3 A lambda-expression shall not have a capture-default or simple-capture in its lambda-introducer unless its innermost enclosing scope is a block scope (6.4.3) or it appears within a default member initializer and its innermost enclosing scope is the corresponding class scope (6.4.7).

4 The identifier in a simple-capture shall denote a local entity (6.5.3, 6.1). The simple-captures this and *this denote the local entity *this. An entity that is designated by a simple-capture is said to be explicitly captured.

5 If an identifier in a capture appears as the declarator-id of a parameter of the lambda-declarator’s parameter-declaration-clause or as the name of a template parameter of the lambda-expression’s template-parameter-list, the program is ill-formed.

[Example 2:

```cpp
void f() {
  int x = 0;
  auto g = [x](int x) { return 0; }; // error: parameter and capture have the same name
  auto h = [y = 0]<typename y>(y) { return 0; }; // error: template parameter and capture have the same name
}

— end example]

6 An init-capture inhabits the lambda scope (6.4.5) of the lambda-expression. An init-capture without ellipsis behaves as if it declares and explicitly captures a variable of the form “auto init-capture ;”, except that:

(6.1) — if the capture is by copy (see below), the non-static data member declared for the capture and the variable are treated as two different ways of referring to the same object, which has the lifetime of the non-static data member, and no additional copy and destruction is performed, and

(6.2) — if the capture is by reference, the variable’s lifetime ends when the closure object’s lifetime ends.

[Note 2: This enables an init-capture like “x = std::move(x)”; the second “x” must bind to a declaration in the surrounding context. — end note]

[Example 3:

```cpp
int x = 4;
auto y = [&x = x, x = x+1]()->int {
  r += 2;
  return x+2;
}(); // Updates ::x to 6, and initializes y to 7.

auto z = [a = 42](int a) { return 1; }; // error: parameter and conceptual local variable have the same name
auto counter = [i=0]() mutable -> decltype(i) { // OK, returns int
  return i++;
};

§ 7.5.5.3 114
For the purposes of lambda capture, an expression potentially references local entities as follows:

(7.1) An id-expression that names a local entity potentially references that entity; an id-expression that names one or more non-static class members and does not form a pointer to member (7.6.2.2) potentially references *this.

[Note 3: This occurs even if overload resolution selects a static member function for the id-expression. — end note]

(7.2) A this expression potentially references *this.

(7.3) A lambda-expression potentially references the local entities named by its simple-captures.

If an expression potentially references a local entity within a scope in which it is odr-usable (6.3), and the expression would be potentially evaluated if the effect of any enclosing typeid expressions (7.6.1.8) were ignored, the entity is said to be implicitly captured by each intervening lambda-expression with an associated capture-default that does not explicitly capture it. The implicit capture of *this is deprecated when the capture-default is =; see D.3.

[Example 4:

```cpp
void f(int, const int (&)[2] = {}); // #1
void f(const int &, const int (&)[1]); // #2
void test() {
    const int x = 17;
    auto g = [](auto a) {
        f(x); // OK, calls #1, does not capture x
    };
    auto g1 = [=](auto a) {
        f(x); // OK, calls #1, captures x
    };
    auto g2 = [=](auto a) {
        int selector[sizeof(a) == 1 ? 1 : 2]{};
        f(x, selector); // OK, captures x, can call #1 or #2
    };
    auto g3 = [=](auto a) {
        typeid(a + x); // captures x regardless of whether a + x is an unevaluated operand
    };
}
```

Within g1, an implementation can optimize away the capture of x as it is not odr-used. — end example]

[Note 4: The set of captured entities is determined syntactically, and entities are implicitly captured even if the expression denoting a local entity is within a discarded statement (8.5.2).

[Example 5:

```cpp
template<bool B>
void f(int n) {
    [=](auto a) {
        if constexpr (B && sizeof(a) > 4) {
            (void)n; // captures n regardless of the value of B and sizeof(int)
        }
    }(0);
}
```

— end example]

— end note]

8 An entity is captured if it is captured explicitly or implicitly. An entity captured by a lambda-expression is odr-used (6.3) by the lambda-expression.

[Note 5: As a consequence, if a lambda-expression explicitly captures an entity that is not odr-usable, the program is ill-formed (6.3). — end note]

[Example 6:
void f1(int i) {
    int const N = 20;
    auto m1 = [=]{
        int const M = 30;
        auto m2 = [=]{
            int x[N][M];
            x[0][0] = i;
            // OK, i is explicitly captured by m2 and implicitly captured by m1
        };
    };
}

struct s1 {
    int f;
    void work(int n) {
        int m = n*n;
        int j = 40;
        auto m3 = [this,m] {
            auto m4 = [&j] {
                int x = n;
                x *= m;
                x *= i;
                x += f;
                // OK, this captured implicitly by m4 and explicitly by m3
            };
        };
    }
};

struct s2 {
    double ohseven = .007;
    auto f() {
        return [this] {
            return [*this] {
                return ohseven;
            };
        }();
    }
    auto g() {
        return [] {
            return [*this] { };
        }();
    }
};

—end example

[Note 6: Because local entities are not odr-usable within a default argument (6.3), a lambda-expression appearing in a default argument cannot implicitly or explicitly capture any local entity. Such a lambda-expression can still have an init-capture if any full-expression in its initializer satisfies the constraints of an expression appearing in a default argument (9.3.4.7). —end note]

Example 7:
void f2() {
    int i = 1;
    void g1(int = ([i]{ return i; })()); // error
    void g2(int = ([i]{ return 0; })()); // error
    void g3(int = ([i]{ return i; })()); // error
    void g4(int = ([i]{ return 0; })()); // OK
    void g5(int = ([i]{ return sizeof i; })()); // OK
    void g6(int = ([i=1]{ return x; })()); // OK
    void g7(int = ([i=1]{ return x; })()); // error
}

—end example

10 An entity is captured by copy if

— it is implicitly captured, the capture-default is =, and the captured entity is not *this, or
it is explicitly captured with a capture that is not of the form `this`, `&identifier`, or `&identifier initializer`.

For each entity captured by copy, an unnamed non-static data member is declared in the closure type. The declaration order of these members is unspecified. The type of such a data member is the referenced type if the entity is a reference to an object, an lvalue reference to the referenced function type if the entity is a reference to a function, or the type of the corresponding captured entity otherwise. A member of an anonymous union shall not be captured by copy.

Every `id-expression` within the `compound-statement` of a `lambda-expression` that is an odr-use (6.3) of an entity captured by copy is transformed into an access to the corresponding unnamed data member of the closure type.

[Note 7: An `id-expression` that is not an odr-use refers to the original entity, never to a member of the closure type. However, such an `id-expression` can still cause the implicit capture of the entity. — end note]

If `*this` is captured by copy, each expression that odr-uses `*this` is transformed to instead refer to the corresponding unnamed data member of the closure type.

```
Example 8:

    void f(const int*);
    void g() {
      const int N = 10;
      [=] {
        int arr[N]; // OK, not an odr-use, refers to automatic variable
        f(&N);     // OK, causes N to be captured; &N points to
                    // the corresponding member of the closure type
      };
    }

    — end example]
```

An entity is captured by reference if it is implicitly or explicitly captured but not captured by copy. It is unspecified whether additional unnamed non-static data members are declared in the closure type for entities captured by reference. If declared, such non-static data members shall be of literal type.

```
Example 9:

    // The inner closure type must be a literal type regardless of how reference captures are represented.
    static_assert([](int n) { return [&n] { return ++n; }(); } (3) == 4);

    — end example]
```

A bit-field or a member of an anonymous union shall not be captured by reference.

An `id-expression` within the `compound-statement` of a `lambda-expression` that is an odr-use of a reference captured by reference refers to the entity to which the captured reference is bound and not to the captured reference.

[Note 8: The validity of such captures is determined by the lifetime of the object to which the reference refers, not by the lifetime of the reference itself. — end note]

```
Example 10:

    auto h(int &r) {
      return [&] {
        ++r;     // Valid after h returns if the lifetime of the
                  // object to which r is bound has not ended
      };
    }

    — end example]
```

If a `lambda-expression` `m2` captures an entity and that entity is captured by an immediately enclosing `lambda-expression` `m1`, then `m2`s capture is transformed as follows:

1. If `m1` captures the entity by copy, `m2` captures the corresponding non-static data member of `m1`’s closure type; if `m1` is not mutable, the non-static data member is considered to be const-qualified.
2. If `m1` captures the entity by reference, `m2` captures the same entity captured by `m1`.

```
Example 11: The nested lambda-expressions and invocations below will output 123234.

    int a = 1, b = 1, c = 1;
```
auto m1 = [a, &b, &c]() mutable {
    auto m2 = [a, b, &c]() mutable {
        std::cout << a << b << c;
        a = 4; b = 4; c = 4;
    };
    a = 3; b = 3; c = 3;
    m2();
    a = 2; b = 2; c = 2;
    m1();
    std::cout << a << b << c;
— end example]
15 When the lambda-expression is evaluated, the entities that are captured by copy are used to direct-initialize each corresponding non-static data member of the resulting closure object, and the non-static data members corresponding to the init-captures are initialized as indicated by the corresponding initializer (which may be copy- or direct-initialization). (For array members, the array elements are direct-initialized in increasing subscript order.) These initializations are performed in the (unspecified) order in which the non-static data members are declared.
[Note 9: This ensures that the destructions will occur in the reverse order of the constructions. — end note]
16 [Note 10: If a non-reference entity is implicitly or explicitly captured by reference, invoking the function call operator of the corresponding lambda-expression after the lifetime of the entity has ended is likely to result in undefined behavior. — end note]
17 A simple-capture containing an ellipsis is a pack expansion (13.7.4). An init-capture containing an ellipsis is a pack expansion that declares an init-capture pack (13.7.4).
[Example 12:
    template<class... Args>
    void f(Args... args) {
        auto lm = [&args...] { return g(args...); };
        lm();

        auto lm2 = [...xs=std::move(args)] { return g(xs...); };
        lm2();
    }
— end example]

7.5.6 Fold expressions
[expr.prim.fold]
1 A fold expression performs a fold of a pack (13.7.4) over a binary operator.

fold-expression:
    ( cast-expression fold-operator ... )
( .... fold-operator cast-expression )
( cast-expression fold-operator ... fold-operator cast-expression )

fold-operator: one of
+ - * / % ^ & | << >>
+= -= *= /= %= ^= &= |= <<= >>= =
== != < > <= >= && || , .* ->*

2 An expression of the form ( ... op e) where op is a fold-operator is called a unary left fold. An expression of the form ( e op ... ) where op is a fold-operator is called a unary right fold. Unary left folds and unary right folds are collectively called unary folds. In a unary fold, the cast-expression shall contain an unexpanded pack (13.7.4).

3 An expression of the form ( e1 op1 ... op2 e2) where op1 and op2 are fold-operators is called a binary fold. In a binary fold, op1 and op2 shall be the same fold-operator, and either e1 shall contain an unexpanded pack or e2 shall contain an unexpanded pack, but not both. If e2 contains an unexpanded pack, the expression is called a binary left fold. If e1 contains an unexpanded pack, the expression is called a binary right fold.
[Example 1:
template<typename ...Args>
bool f(Args ...args) {
    return (true && ... && args); // OK
}

template<typename ...Args>
bool f(Args ...args) {
    return (args + ... + args); // error: both operands contain unexpanded packs
}

7.5.7 Requires expressions

7.5.7.1 General

A requires-expression provides a concise way to express requirements on template arguments that can be checked by name lookup (6.5) or by checking properties of types and expressions.

requires-expression:
  requires requirement-parameter-list_opt requirement-body

requirement-parameter-list:
  ( parameter-declaration-clause )

requirement-body:
  { requirement-seq }

requirement-seq:
  requirement
  requirement requirement-seq

requirement:
  simple-requirement
  type-requirement
  compound-requirement
  nested-requirement

A requires-expression is a prvalue of type bool whose value is described below. Expressions appearing within a requirement-body are unevaluated operands (7.2.3).

[Example 1: A common use of requires-expressions is to define requirements in concepts such as the one below:

template<typename T>
concept R = requires (T i) {
    typename T::type;
    *(i) -> std::convertible_to<const typename T::type&>;
};

A requires-expression can also be used in a requires-clause (13.1) as a way of writing ad hoc constraints on template arguments such as the one below:

template<typename T>
requires requires (T x) { x + x; }
T add(T a, T b) { return a + b; }

The first requires introduces the requires-clause, and the second introduces the requires-expression. — end example]

A requires-expression may introduce local parameters using a parameter-declaration-clause (9.3.4.6). A local parameter of a requires-expression shall not have a default argument. These parameters have no linkage, storage, or lifetime; they are only used as notation for the purpose of defining requirements. The parameter-declaration-clause of a requirement-parameter-list shall not terminate with an ellipsis.

[Example 2:

template<typename T>
concept C = requires(T t, ...) { // error: terminates with an ellipsis
    t;
};
— end example]

The substitution of template arguments into a requires-expression may result in the formation of invalid types or expressions in its requirements or the violation of the semantic constraints of those requirements. In
such cases, the `requires-expression` evaluates to `false`; it does not cause the program to be ill-formed. The substitution and semantic constraint checking proceeds in lexical order and stops when a condition that determines the result of the `requires-expression` is encountered. If substitution (if any) and semantic constraint checking succeed, the `requires-expression` evaluates to `true`.

[Note 1: If a `requires-expression` contains invalid types or expressions in its `requirements`, and it does not appear within the declaration of a templated entity, then the program is ill-formed. — end note]

If the substitution of template arguments into a `requirement` would always result in a substitution failure, the program is ill-formed; no diagnostic required.

[Example 3:
```cpp
template<typename T> concept C =
requires {
    new int[~(int)sizeof(T)];    // ill-formed, no diagnostic required
};
```
—end example]

### 7.5.7.2 Simple requirements

```
expression ;
```

1 A `simple-requirement` asserts the validity of an `expression`.

[Note 1: The enclosing `requires-expression` will evaluate to `false` if substitution of template arguments into the `expression` fails. The expression is an unevaluated operand (7.2.3). — end note]

[Example 1:
```cpp
template<typename T> concept C =
requires (T a, T b) {
    a + b;    // C<T> is true if a + b is a valid expression
};
```
—end example]

2 A `requirement` that starts with a `requires` token is never interpreted as a `simple-requirement`.

[Note 2: This simplifies distinguishing between a `simple-requirement` and a `nested-requirement`. — end note]

### 7.5.7.3 Type requirements

```
type-requirement:
    typename nested-name-specifier_opt type-name ;
```

1 A `type-requirement` asserts the validity of a type.

[Note 1: The enclosing `requires-expression` will evaluate to `false` if substitution of template arguments fails. — end note]

[Example 1:
```cpp
template<typename T, typename T::type = 0> struct S;
template<typename T> using Ref = T&;
template<typename T> concept C = requires {
    typename T::inner;    // required nested member name
    typename S<T>;        // required valid (13.3) template-id;
    typename Ref<T>;      // fails if T::type does not exist as a type to which 0 can be implicitly converted
};
```
—end example]

2 A `type-requirement` that names a class template specialization does not require that type to be complete (6.8.1).

### 7.5.7.4 Compound requirements

```
compound-requirement:
    { expression } noexcept_opt return-type-requirement_opt ;
    return-type-requirement:
        -> type-constraint
```
A compound-requirement asserts properties of the expression $E$. Substitution of template arguments (if any) and verification of semantic properties proceed in the following order:

1. Substitution of template arguments (if any) into the expression is performed.

2. If the `noexcept` specifier is present, $E$ shall not be a potentially-throwing expression (14.5).

3. If the `return-type-requirement` is present, then:
   - (1.3.1) Substitution of template arguments (if any) into the `return-type-requirement` is performed.
   - (1.3.2) The immediately-declared constraint (13.2) of the type-constraint for `decltype((E))` shall be satisfied.

[Example 1: Given concepts $C$ and $D$,
```
requires {
    { E1 } -> C;
    { E2 } -> D<A_1, \ldots, A_n>;
};
```

is equivalent to
```
requires {
    E1; requires C<decltype((E1))>;
    E2; requires D<decltype((E2)), A_1, \ldots, A_n>;
};
```

(including in the case where $n$ is zero). — end example]

[Example 2:]
```
template<typename T> concept C1 = requires(T x) {
    {x++};
};
```
The compound-requirement in C1 requires that $x++$ is a valid expression. It is equivalent to the simple-requirement $x++$:
```
template<typename T> concept C2 = requires(T x) {
    requires C<decltype (+t)>
};
```
The compound-requirement in C2 requires that $*x$ is a valid expression, that $\text{typename } T::inner$ is a valid type, and that $\text{std::same_as<decltype(*x), typename } T::inner>$ is satisfied.
```
template<typename T> concept C3 = requires(T x) {
    requires(T x) {
        {g(x)} noexcept;
    };
};
```
The compound-requirement in C3 requires that $g(x)$ is a valid expression and that $g(x)$ is non-throwing. — end example]

### 7.5.7.5 Nested requirements

A nested-requirement can be used to specify additional constraints in terms of local parameters. The constraint-expression shall be satisfied (13.5.3) by the substituted template arguments, if any. Substitution of template arguments into a nested-requirement does not result in substitution into the constraint-expression other than as specified in 13.5.2.

[Example 1:]
```
template<typename U> concept C = sizeof(U) == 1;
```
```
template<typename T> concept D = requires (T t) {
    requires C<decltype (+t)>;
};
```
$D<T>$ is satisfied if $\text{sizeof(decltype (*t)) == 1}$ (13.5.2.3). — end example]
7.6 Compound expressions

7.6.1 Postfix expressions

7.6.1.1 General

1 Postfix expressions group left-to-right.

\[
\text{postfix-expression}:
\begin{align*}
\text{primary-expression} \\
\text{postfix-expression} \ [ \text{expression-list}_{\text{opt}} ] \\
\text{postfix-expression} \ ( \text{expression-list}_{\text{opt}} ) \\
\text{simple-type-specifier} \ ( \text{expression-list}_{\text{opt}} ) \\
\text{typename-specifier} \ ( \text{expression-list}_{\text{opt}} ) \\
\text{simple-type-specifier} \ \text{braced-init-list} \\
\text{typename-specifier} \ \text{braced-init-list} \\
\text{postfix-expression} \ \text{template}_{\text{opt}} \ \text{id-expression} \\
\text{postfix-expression} \ \text{\textrightarrow} \ \text{template}_{\text{opt}} \ \text{id-expression} \\
\text{postfix-expression} \ \\ \\
\text{dynamic_cast} < \text{type-id} > ( \text{expression} ) \\
\text{static_cast} < \text{type-id} > ( \text{expression} ) \\
\text{reinterpret_cast} < \text{type-id} > ( \text{expression} ) \\
\text{const_cast} < \text{type-id} > ( \text{expression} ) \\
\text{typeid} ( \text{expression} ) \\
\text{typeid} ( \text{type-id} )
\end{align*}
\]

expression-list:

\[
\begin{align*}
\text{initializer-list}
\end{align*}
\]

2 [Note 1: The \textgreater token following the \textit{type-id} in a \texttt{dynamic_cast}, \texttt{static_cast}, \texttt{reinterpret_cast}, or \texttt{const_cast} can be the product of replacing a \texttt{\textgreater\textgreater} token by two consecutive \texttt{\textgreater} tokens (13.3). — end note]

7.6.1.2 Subscripting

1 A \textit{subscript expression} is a postfix expression followed by square brackets containing a possibly empty, comma-separated list of \texttt{initializer-clauses} that constitute the arguments to the subscript operator. The postfix-expression and the initialization of the object parameter of any applicable subscript operator function is sequenced before each expression in the expression-list and also before any default argument. The initialization of a non-object parameter of a subscript operator function \texttt{S} (12.4.5), including every associated value computation and side effect, is indeterminately sequenced with respect to that of any other non-object parameter of \texttt{S}.

2 With the built-in subscript operator, an expression-list shall be present, consisting of a single \texttt{assignment-expression}. One of the expressions shall be a glvalue of type “array of \texttt{T}” or a prvalue of type “pointer to \texttt{T}” and the other shall be a prvalue of unscoped enumeration or integral type. The result is of type “\texttt{T}”. The type “\texttt{T}” shall be a completely-defined object type.51 The expression \texttt{E1[E2]} is identical (by definition) to \texttt{*((E1)+(E2))}, except that in the case of an array operand, the result is an lvalue if that operand is an lvalue and an xvalue otherwise.

3 [Note 1: Despite its asymmetric appearance, subscripting is a commutative operation except for sequencing. See 7.6.2 and 7.6.6 for details of \texttt{*} and \texttt{+} and 9.3.4.5 for details of array types. — end note]

7.6.1.3 Function call

1 A \textit{function call} is a postfix expression followed by parentheses containing a possibly empty, comma-separated list of \texttt{initializer-clauses} which constitute the arguments to the function.

[Note 1: If the postfix expression is a function or member function name, the appropriate function and the validity of the call are determined according to the rules in 12.2. — end note]

The postfix expression shall have function type or function pointer type. For a call to a non-member function or to a static member function, the postfix expression shall either be an lvalue that refers to a function (in which case the function-to-pointer standard conversion (7.3.4) is suppressed on the postfix expression), or have function pointer type.

2 If the selected function is non-virtual, or if the \textit{id-expression} in the class member access expression is a \textit{qualified-id}, that function is called. Otherwise, its final overrider (11.7.3) in the dynamic type of the object expression is called; such a call is referred to as a \textit{virtual function call}.

51) This is true even if the subscript operator is used in the following common idiom: \texttt{&x[0]}. 

§ 7.6.1.3
[Note 2: The dynamic type is the type of the object referred to by the current value of the object expression. 11.9.5 describes the behavior of virtual function calls when the object expression refers to an object under construction or destruction. — end note]

3 [Note 3: If a function or member function name is used, and name lookup (6.5) does not find a declaration of that name, the program is ill-formed. No function is implicitly declared by such a call. — end note]

4 If the postfix-expression names a destructor or pseudo-destructor (7.5.4.4), the type of the function call expression is void; otherwise, the type of the function call expression is the return type of the statically chosen function (i.e., ignoring the virtual keyword), even if the type of the function actually called is different. If the postfix-expression names a pseudo-destructor (in which case the postfix-expression is a possibly-parenthesized class member access), the function call destroys the object of scalar type denoted by the object expression of the class member access (7.6.1.5, 6.7.3).

5 Calling a function through an expression whose function type $E$ is different from the function type $F$ of the called function’s definition results in undefined behavior unless the type “pointer to $F$” can be converted to the type “pointer to $E$” via a function pointer conversion (7.3.14).

[Note 4: The exception applies when the expression has the type of a potentially-throwing function, but the called function has a non-throwing exception specification, and the function types are otherwise the same. — end note]

6 When a function is called, each parameter (9.3.4.6) is initialized (9.4, 11.4.5.3) with its corresponding argument. If the function is an explicit object member function and there is an implied object argument (12.2.2.2.2), the list of provided arguments is preceded by the implied object argument for the purposes of this correspondence. If there is no corresponding argument, the default argument for the parameter is used.

[Example 1:

```cpp
template<typename ...T> int f(int n = 0, T ...t);
int x = f<int>();
// error: no argument for second function parameter
```

—end example]
If the function is an implicit object member function, the this parameter of the function (7.5.2) is initialized with a pointer to the object of the call, converted as if by an explicit type conversion (7.6.3).

[Note 5: There is no access or ambiguity checking on this conversion; the access checking and disambiguation are done as part of the (possibly implicit) class member access operator. See 6.5.2, 11.8.3, and 7.6.1.5. — end note]
When a function is called, the type of any parameter shall not be a class type that is either incomplete or abstract.

[Note 6: This still allows a parameter to be a pointer or reference to such a type. However, it prevents a passed-by-value parameter to have an incomplete or abstract class type. — end note]
It is implementation-defined whether the lifetime of a parameter ends when the function in which it is defined returns or at the end of the enclosing full-expression. The initialization and destruction of each parameter occurs within the context of the calling function.

[Example 2: The access of the constructor, conversion functions or destructor is checked at the point of call in the calling function. If a constructor or destructor for a function parameter throws an exception, the search for a handler starts in the calling function; in particular, if the function called has a function-try-block (14.1) with a handler that can handle the exception, this handler is not considered. — end example]

7 The postfix-expression is sequenced before each expression in the expression-list and any default argument. The initialization of a parameter, including every associated value computation and side effect, is indeterminately sequenced with respect to that of any other parameter.

[Note 7: All side effects of argument evaluations are sequenced before the function is entered (see 6.9.1). — end note]

[Example 3:

```cpp
void f() {
    std::string s = "but I have heard it works even if you don't believe in it";
    s.replace(0, 4, "").replace(s.find("even"), 4, "only").replace(s.find(" don't"), 6, "");
    assert(s == "I have heard it works only if you believe in it"); // OK
}
```

—end example]

[Note 8: If an operator function is invoked using operator notation, argument evaluation is sequenced as specified for the built-in operator; see 12.2.2.3. — end note]

[Example 4:}
struct S {
    S(int);
};
int operator<<(S, int);
int i, j;
int x = S(i=1) << (i=2);
int y = operator<<(S(j=1), j=2);

After performing the initializations, the value of \( i \) is 2 (see 7.6.7), but it is unspecified whether the value of \( j \) is 1 or 2. —end example

The result of a function call is the result of the possibly-converted operand of the return statement (8.7.4) that transferred control out of the called function (if any), except in a virtual function call if the return type of the final overrider is different from the return type of the statically chosen function, the value returned from the final overrider is converted to the return type of the statically chosen function.

[Note 9: A function can change the values of its non-const parameters, but these changes cannot affect the values of the arguments except where a parameter is of a reference type (9.3.4.3); if the reference is to a const-qualified type, const_cast is required to be used to cast away the constness in order to modify the argument’s value. Where a parameter is of const reference type a temporary object is introduced if needed (9.2.9, 5.13, 5.13.5, 9.3.4.5, 6.7.7). In addition, it is possible to modify the values of non-constant objects through pointer parameters. —end note]

A function can be declared to accept fewer arguments (by declaring default arguments (9.3.4.7)) or more arguments (by using the ellipsis, ..., or a function parameter pack (9.3.4.6)) than the number of parameters in the function definition (9.5).

[Note 10: This implies that, except where the ellipsis (...) or a function parameter pack is used, a parameter is available for each argument. —end note]

When there is no parameter for a given argument, the argument is passed in such a way that the receiving function can obtain the value of the argument by invoking va_arg (17.13).

[Note 11: This paragraph does not apply to arguments passed to a function parameter pack. Function parameter packs are expanded during template instantiation (13.7.4), thus each such argument has a corresponding parameter when a function template specialization is actually called. —end note]

The lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the argument expression. An argument that has type cv std::nullptr_t is converted to type void* (7.3.12). After these conversions, if the argument does not have arithmetic, enumeration, pointer, pointer-to-member, or class type, the program is ill-formed. Passing a potentially-evaluated argument of a scoped enumeration type or of a class type (Clause 11) having an eligible non-trivial copy constructor, an eligible non-trivial move constructor, or a non-trivial destructor (11.4.4), with no corresponding parameter, is conditionally-supported with implementation-defined semantics. If the argument has integral or enumeration type that is subject to the integral promotions (7.3.7), or a floating-point type that is subject to the floating-point promotion (7.3.8), the value of the argument is converted to the promoted type before the call. These promotions are referred to as the default argument promotions.

Recursive calls are permitted, except to the main function (6.9.3.1).

A function call is an lvalue if the result type is an lvalue reference type or an rvalue reference to function type, an xvalue if the result type is an rvalue reference to object type, and a prvalue otherwise.

7.6.1.4 Explicit type conversion (functional notation) [expr.type.conv]

A simple-type-specifier (9.2.9.3) or typename-specifier (13.8) followed by a parenthesized optional expression-list or by a braced-init-list (the initializer) constructs a value of the specified type given the initializer. If the type is a placeholder for a deduced class type, it is replaced by the return type of the function selected by overload resolution for class template deduction (12.2.2.9) for the remainder of this subclause. Otherwise, if the type contains a placeholder type, it is replaced by the type determined by placeholder type deduction (9.2.9.6.2).

[Example 1:

```c
struct A {}
void f(A&); // #1
void f(A&&); // #2
A& g();
void h() {
    f(g()); // calls #1
    f(A(g())); // calls #2 with a temporary object
```]
f(auto(g())); // calls #2 with a temporary object

— end example

2 If the initializer is a parenthesized single expression, the type conversion expression is equivalent to the corresponding cast expression (7.6.3). Otherwise, if the type is cv void and the initializer is () or {} (after pack expansion, if any), the expression is a prvalue of type void that performs no initialization. Otherwise, the expression is a prvalue of the specified type whose result object is direct-initialized (9.4) with the initializer. If the initializer is a parenthesized optional expression-list, the specified type shall not be an array type.

7.6.1.5 Class member access [expr.ref]

A postfix expression followed by a dot . or an arrow ->, optionally followed by the keyword template, and then followed by an id-expression, is a postfix expression. The postfix expression before the dot or arrow is evaluated, the result of that evaluation, together with the id-expression, determines the result of the entire postfix expression.

[Note 1: If the keyword template is used, the following unqualified name is considered to refer to a template (13.3). If a simple-template-id results and is followed by a ::, the id-expression is a qualified-id. — end note]

2 For the first option (dot) the first expression shall be a glvalue. For the second option (arrow) the first expression shall be a prvalue having pointer type. The expression E1->E2 is converted to the equivalent form *(E1).E2; the remainder of 7.6.1.5 will address only the first option (dot).

3 Abbreviating postfix-expression.id-expression as E1.E2, E1 is called the object expression. If the object expression is of scalar type, E2 shall name the pseudo-destructor of that same type (ignoring cv-qualifications) and E1.E2 is a prvalue of type “function of () returning void”.

[Note 2: This value can only be used for a notional function call (7.5.4.4). — end note]

4 Otherwise, the object expression shall be of class type. The class expression shall be complete unless the class member access appears in the definition of that class.

[Note 3: The program is ill-formed if the result differs from that when the class is complete (6.5.2). — end note]

[Note 4: 6.5.5 describes how names are looked up after the . and -> operators. — end note]

5 If E2 is a bit-field, E1.E2 is a bit-field. The type and value category of E1.E2 are determined as follows. In the remainder of 7.6.1.5, cq represents either const or the absence of const and vq represents either volatile or the absence of volatile. cv represents an arbitrary set of cv-qualifiers, as defined in 6.8.5.

6 If E2 is declared to have type “reference to T”, then E1.E2 is an lvalue of type T. If E2 is a static data member, E1.E2 designates the object or function to which the reference is bound, otherwise E1.E2 designates the object or function to which the corresponding reference member of E1 is bound. Otherwise, one of the following rules applies.

(6.1) — If E2 is a static data member and the type of E2 is T, then E1.E2 is an lvalue; the expression designates the named member of the class. The type of E1.E2 is T.

(6.2) — If E2 is a non-static data member and the type of E1 is “cq1 vq1 X”, and the type of E2 is “cq2 vq2 T”, the expression designates the corresponding member subobject of the object designated by the first expression. If E1 is an lvalue, then E1.E2 is an lvalue; otherwise E1.E2 is an xvalue. Let the notation vq12 stand for the “union” of vq1 and vq2; that is, if vq1 or vq2 is volatile, then vq12 is volatile. Similarly, let the notation cq12 stand for the “union” of cq1 and cq2; that is, if cq1 or cq2 is const, then cq12 is const. If E2 is declared to be a mutable member, then the type of E1.E2 is “vq12 T”. If E2 is not declared to be a mutable member, then the type of E1.E2 is “cq12 vq12 T”.

(6.3) — If E2 is an overload set, function overload resolution (12.2) is used to select the function to which E2 refers. The type of E1.E2 is the type of E2 and E1.E2 refers to the function referred to by E2.

(6.3.1) — If E2 refers to a static member function, E1.E2 is an lvalue.

(6.3.2) — Otherwise (when E2 refers to a non-static member function), E1.E2 is a prvalue. The expression can be used only as the left-hand operand of a member function call (11.4.2).

[Note 5: Any redundant set of parentheses surrounding the expression is ignored (7.5.3). — end note]

52) If the class member access expression is evaluated, the subexpression evaluation happens even if the result is unnecessary to determine the value of the entire postfix expression, for example if the id-expression denotes a static member.

53) Note that *(E1)) is an lvalue.
If \( E_2 \) is a nested type, the expression \( E_1.E_2 \) is ill-formed.

If \( E_2 \) is a member enumerator and the type of \( E_2 \) is \( T \), the expression \( E_1.E_2 \) is a prvalue of type \( T \) whose value is the value of the enumerator.

If \( E_2 \) is a non-static member, the program is ill-formed if the class of which \( E_2 \) is directly a member is an ambiguous base (6.5.2) of the naming class (11.8.3) of \( E_2 \).

[Note 6: The program is also ill-formed if the naming class is an ambiguous base of the class type of the object expression; see 11.8.3. — end note]

If \( E_2 \) is a non-static member and the result of \( E_1 \) is an object whose type is not similar (7.3.6) to the type of \( E_1 \), the behavior is undefined.

[Example 1:

```c
struct A { int i; }
struct B { int j; }
struct D : A, B {}
void f() {
    D d;
    static_cast<B&>(d).j; // OK, object expression designates the B subobject of d
    reinterpret_cast<B&>(d).j; // undefined behavior
}
```

— end example]

### 7.6.1.6 Increment and decrement

The value of a postfix ++ expression is the value of its operand.

[Note 1: The value obtained is a copy of the original value. — end note]

The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than \( cv\ )bool, or a pointer to a complete object type. An operand with volatile-qualified type is deprecated; see D.5. The value of the operand object is modified (3.1) by adding 1 to it. The value computation of the ++ expression is sequenced before the modification of the operand object. With respect to an indeterminately-sequenced function call, the operation of postfix ++ is a single evaluation.

[Note 2: Therefore, a function call cannot intervene between the lvalue-to-rvalue conversion and the side effect associated with any single postfix ++ operator. — end note]

The result is a prvalue. The type of the result is the cv-unqualified version of the type of the operand. If the operand is a bit-field that cannot represent the incremented value, the resulting value of the bit-field is implementation-defined. See also 7.6.6 and 7.6.19.

The operand of postfix -- is decremented analogously to the postfix ++ operator.

[Note 3: For prefix increment and decrement, see 7.6.2.3. — end note]

### 7.6.1.7 Dynamic cast

The result of the expression `dynamic_cast<T>(v)` is the result of converting the expression \( v \) to type \( T \). \( T \) shall be a pointer or reference to a complete class type, or “pointer to \( cv\ ) void”. The dynamic_cast operator shall not cast away constness (7.6.1.11).

If \( T \) is a pointer type, \( v \) shall be a prvalue of a pointer to complete class type, and the result is a prvalue of type \( T \). If \( T \) is an lvalue reference type, \( v \) shall be an lvalue of a complete class type, and the result is an lvalue of the type referred to by \( T \). If \( T \) is an rvalue reference type, \( v \) shall be a glvalue having a complete class type, and the result is an xvalue of the type referred to by \( T \).

If the type of \( v \) is the same as \( T \) (ignoring cv-qualifications), the result is \( v \) (converted if necessary).

If \( T \) is “pointer to \( cv1\ ) B” and \( v \) has type “pointer to \( cv2\ ) D” such that \( B \) is a base class of \( D \), the result is a pointer to the unique \( B \) subobject of the \( D \) object pointed to by \( v \), or a null pointer value if \( v \) is a null pointer value. Similarly, if \( T \) is “reference to \( cv1\ ) B” and \( v \) has type \( cv2\ ) D \) such that \( B \) is a base class of \( D \), the result is the unique \( B \) subobject of the \( D \) object referred to by \( v \). In both the pointer and reference cases, the program is ill-formed if \( B \) is an inaccessible or ambiguous base class of \( D \).

[Example 1:

```c
struct B { };
```

54) The most derived object (6.7.2) pointed or referred to by \( v \) can contain other \( B \) objects as base classes, but these are ignored.
struct D : B { }
void foo(D* dp) {
    B* bp = dynamic_cast<B*>(dp); // equivalent to B* bp = dp;
}
—end example]

Otherwise, v shall be a pointer to or a glvalue of a polymorphic type (11.7.3).

If v is a null pointer value, the result is a null pointer value.

If T is “pointer to cv void”, then the result is a pointer to the most derived object pointed to by v. Otherwise, a runtime check is applied to see if the object pointed or referred to by v can be converted to the type pointed or referred to by T.

Let C be the class type to which T points or refers. The runtime check logically executes as follows:

— (8.1) If, in the most derived object pointed (referred) to by v, v points (refers) to a public base class subobject of a C object, and if only one object of type C is derived from the subobject pointed (referred) to by v the result points (refers) to that C object.

— (8.2) Otherwise, if v points (refers) to a public base class subobject of the most derived object, and the type of the most derived object has a base class, of type C, that is unambiguous and public, the result points (refers) to the C subobject of the most derived object.

— (8.3) Otherwise, the runtime check fails.

The value of a failed cast to pointer type is the null pointer value of the required result type. A failed cast to reference type throws an exception (14.2) of a type that would match a handler (14.4) of type std::bad_cast (17.7.4).

[Example 2:

class A { virtual void f(); };  
class B { virtual void g(); };  
class D : public virtual A, private B { };  
void g() {
    D d;
    B* bp = (B*)&d; // cast needed to break protection
    A* ap = &d;  // public derivation, no cast needed
    D& dr = dynamic_cast<D&>(bp);  // fails
    ap = dynamic_cast<A*>(bp); // fails
    bp = dynamic_cast<B*>(ap);  // fails
    ap = dynamic_cast<A&>(&d); // succeeds
    bp = dynamic_cast<B&>(&d);  // ill-formed (not a runtime check)
}

class E : public D, public B { };  
class F : public E, public D { };  
void h() {
    F f;
    A* ap = &f;  // succeeds: finds unique A
    D* dp = dynamic_cast<D*>(ap); // fails: yields null; f has two D subobjects
    E* ep = (E*)ap;  // error: cast from virtual base
    E* ep1 = dynamic_cast<E*>(ap); // succeeds
}
—end example]

[Note 1: Subclause 11.9.5 describes the behavior of a dynamic_cast applied to an object under construction or destruction. — end note]

7.6.1.8 Type identification [expr.typeid]

The result of a typeid expression is an lvalue of static type const std::type_info (17.7.3) and dynamic type const std::type_info or const name where name is an implementation-defined class publicly derived from std::type_info which preserves the behavior described in 17.7.3. The lifetime of the object referred to by the lvalue extends to the end of the program. Whether or not the destructor is called for the std::type_info object at the end of the program is unspecified.

55) The recommended name for such a class is extended_type_info.
2 If the type of the expression or type-id operand is a (possibly cv-qualified) class type or a reference to (possibly cv-qualified) class type, that class shall be completely defined.

3 When typeid is applied to a glvalue whose type is a polymorphic class type (11.7.3), the result refers to a std::type_info object representing the type of the most derived object (6.7.2) (that is, the dynamic type) to which the glvalue refers. If the glvalue is obtained by applying the unary * operator to a pointer and the pointer is a null pointer value (6.8.4), the typeid expression throws an exception (14.2) of a type that would match a handler of type std::bad_typeid exception (17.7.5).

4 When typeid is applied to an expression other than a glvalue of a polymorphic class type, the result refers to a std::type_info object representing the static type of the expression. Lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) conversions are not applied to the expression. If the expression is a prvalue, the temporary materialization conversion (7.3.5) is applied. The expression is an unevaluated operand (7.2.3).

5 When typeid is applied to a type-id, the result refers to a std::type_info object representing the type of the type-id. If the type of the type-id is a reference to a possibly cv-qualified type, the result of the typeid expression refers to a std::type_info object representing the cv-unqualified referenced type.

[Note 1: The type-id cannot denote a function type with a cv-qualifier-seq or a ref-qualifier (9.3.4.6). — end note]

6 If the type of the expression or type-id is a cv-qualified type, the result of the typeid expression refers to a std::type_info object representing the cv-unqualified referenced type.

[Example 1:]
```
class D { /* ... */ };  
D d1;  
const D d2;  

typeid(d1) == typeid(d2);  // yields true  
typeid(D) == typeid(const D);  // yields true  
typeid(D) == typeid(d2);  // yields true  
typeid(D) == typeid(const D&);  // yields true  

—end example]
```

7 The type std::type_info (17.7.3) is not predefined; if a standard library declaration (17.7.2, 16.4.2.4) of std::type_info does not precede (6.5.1) a typeid expression, the program is ill-formed.

8 [Note 2: Subclause 11.9.5 describes the behavior of typeid applied to an object under construction or destruction. — end note]

7.6.1.9 Static cast [expr.static.cast]

1 The result of the expression static_cast<T>(v) is the result of converting the expression v to type T. If T is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue. The static_cast operator shall not cast away constness (7.6.1.11).

2 An lvalue of type “cv1 B”, where B is a class type, can be cast to type “reference to cv2 D”, where D is a class derived (11.7) from B, if cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If B is a virtual base class of D or a base class of a virtual base class of D, or if no valid standard conversion from “pointer to D” to “pointer to B” exists (7.3.12), the program is ill-formed. An xvalue of type “cv1 B” can be cast to type “rvalue reference to cv2 D” with the same constraints as for an lvalue of type “cv1 B”. If the object of type “cv1 B” is actually a base class subobject of an object of type D, the result refers to the enclosing object of type D. Otherwise, the behavior is undefined.

[Example 1:]
```
struct B { };  
struct D : public B { };  
D d;  
B &br = d;  

static_cast<D&>(br);  // produces lvalue denoting the original d object  

—end example]
```

56) If p is an expression of pointer type, then *p, (*p), (*p), ((*p)), and so on all meet this requirement.
An lvalue of type \( T_1 \) can be cast to type “rvalue reference to \( T_2 \)” if \( T_2 \) is reference-compatible with \( T_1 \) (9.4.4). If the value is not a bit-field, the result refers to the object or the specified base class subobject thereof; otherwise, the lvalue-to-rvalue conversion (7.3.2) is applied to the bit-field and the resulting prvalue is used as the operand of the \texttt{static\_cast} for the remainder of this subclause. If \( T_2 \) is an inaccessible (11.8) or ambiguous (6.5.2) base class of \( T_1 \), a program that necessitates such a cast is ill-formed.

An expression \( E \) can be explicitly converted to a type \( T \) if there is an implicit conversion sequence (12.2.4.2) from \( E \) to \( T \), if overload resolution for a direct-initialization (9.4) of an object or reference of type \( T \) from \( E \) would find at least one viable function (12.2.3), or if \( T \) is an aggregate type (9.4.2) having a first element \( x \) and there is an implicit conversion sequence from \( E \) to the type of \( x \). If \( T \) is a reference type, the effect is the same as performing the declaration and initialization

\[
T t(E);
\]

for some invented temporary variable \( t \) (9.4) and then using the temporary variable as the result of the conversion. Otherwise, the result object is direct-initialized from \( E \).

\[\text{Note 1: The conversion is ill-formed when attempting to convert an expression of class type to an inaccessible or ambiguous base class. — end note}\]

\[\text{Note 2: If } T \text{ is “array of unknown bound of } U \text{”, this direct-initialization defines the type of the expression as } U[1]. — end note\]

Otherwise, the \texttt{static\_cast} shall perform one of the conversions listed below. No other conversion shall be performed explicitly using a \texttt{static\_cast}.

Any expression can be explicitly converted to type \textit{cv void}, in which case the operand is a discarded-value expression (7.2).

\[\text{Note 3: Such a } \texttt{static\_cast} \text{ has no result as it is a prvalue of type } \textit{void}; \text{ see 7.2.1. — end note}\]

\[\text{Note 4: However, if the value is in a temporary object (6.7.7), the destructor for that object is not executed until the usual time, and the value of the object is preserved for the purpose of executing the destructor. — end note}\]

The inverse of any standard conversion sequence (7.3) not containing an lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), function-to-pointer (7.3.4), null pointer (7.3.12), null member pointer (7.3.13), boolean (7.3.15), or function pointer (7.3.14) conversion, can be performed explicitly using \texttt{static\_cast}. A program is ill-formed if it uses \texttt{static\_cast} to perform the inverse of an ill-formed standard conversion sequence.

\[\text{Example 2:}\]

\begin{verbatim}
struct B { }
struct D : private B { }
void f() {
    static_cast<D*>(0); // error: B is a private base of D
    static_cast<int B::*>(0); // error: B is a private base of D
}
\end{verbatim}

\[\text{—end example}\]

The lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) conversions are applied to the operand. Such a \texttt{static\_cast} is subject to the restriction that the explicit conversion does not cast away constness (7.6.1.11), and the following additional rules for specific cases:

A value of a scoped enumeration type (9.7.1) can be explicitly converted to an integral type; the result is the same as that of converting to the enumeration’s underlying type and then to the destination type. A value of a scoped enumeration type can also be explicitly converted to a floating-point type; the result is the same as that of converting from the original value to the floating-point type.

A value of integral or enumeration type can be explicitly converted to a complete enumeration type. If the enumeration type has a fixed underlying type, the value is first converted to that type by integral promotion (7.3.7) or integral conversion (7.3.9), if necessary, and then to the enumeration type. If the enumeration type does not have a fixed underlying type, the value is unchanged if the original value is within the range of the enumeration values (9.7.1), and otherwise, the behavior is undefined. A value of floating-point type can also be explicitly converted to an enumeration type. The resulting value is the same as converting the original value to the underlying type of the enumeration (7.3.11), and subsequently to the enumeration type.

A prvalue of floating-point type can be explicitly converted to any other floating-point type. If the source value can be exactly represented in the destination type, the result of the conversion has that exact
A prvalue of type “pointer to cv1 B”, where B is a class type, can be converted to a prvalue of type “pointer to cv2 D”, where D is a complete class derived (11.7) from B, if cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If B is a virtual base class of D or a base class of a virtual base class of D, or if no valid standard conversion from “pointer to D” to “pointer to B” exists (7.3.12), the program is ill-formed. The null pointer value (6.8.4) is converted to the null pointer value of the destination type. If the prvalue of type “pointer to cv1 B” points to a B that is actually a base class subobject of an object of type D, the resulting pointer points to the enclosing object of type D. Otherwise, the behavior is undefined.

A prvalue of type “pointer to member of D of type cv1 T” can be converted to a prvalue of type “pointer to member of B of type cv2 T”, where D is a complete class type and B is a base class (11.7) of D, if cv2 is the same cv-qualification as, or greater cv-qualification than, cv1.

[Note 5: Function types (including those used in pointer-to-member-function types) are never cv-qualified (9.3.4.6). —end note]

If no valid standard conversion from “pointer to member of B of type T” to “pointer to member of D of type T” exists (7.3.13), the program is ill-formed. The null member pointer value (7.3.13) is converted to the null member pointer value of the destination type. If class B contains the original member, or is a base or derived class of the class containing the original member, the resulting pointer to member points to the original member. Otherwise, the behavior is undefined.

[Note 6: Although class B need not contain the original member, the dynamic type of the object with which indirection through the pointer to member is performed must contain the original member; see 7.6.4. —end note]

A prvalue of type “pointer to cv1 void” can be converted to a prvalue of type “pointer to cv2 T”, where T is an object type and cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If the original pointer value represents the address A of a byte in memory and A does not satisfy the alignment requirement of T, then the resulting pointer value is unspecified. Otherwise, if the original pointer value points to an object a, and there is an object b of type similar to T that is pointer-interconvertible (6.8.4) with a, the result is a pointer to b. Otherwise, the pointer value is unchanged by the conversion.

[Example 3:
   T* p1 = new T;
   const T* p2 = static_cast<const T*>(static_cast<void*>(p1));
   bool b = p1 == p2; // b will have the value true.
   —end example]

7.6.1.10 Reinterpret cast

The result of the expression reinterpret_cast<T>(v) is the result of converting the expression v to type T. If T is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue and the lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the expression v. Conversions that can be performed explicitly using reinterpret_cast are listed below. No other conversion can be performed explicitly using reinterpret_cast.

The reinterpret_cast operator shall not cast away constness (7.6.1.11). An expression of integral, enumeration, pointer, or pointer-to-member type can be explicitly converted to its own type; such a cast yields the value of its operand.

[Note 1: The mapping performed by reinterpret_cast might, or might not, produce a representation different from the original value. —end note]

A pointer can be explicitly converted to any integral type large enough to hold all values of its type. The mapping function is implementation-defined.

[Note 2: It is intended to be unsurprising to those who know the addressing structure of the underlying machine. —end note]

A value of type std::nullptr_t can be converted to an integral type; the conversion has the same meaning and validity as a conversion of (void*)0 to the integral type.

[Note 3: A reinterpret_cast cannot be used to convert a value of any type to the type std::nullptr_t. —end note]
A value of integral type or enumeration type can be explicitly converted to a pointer. A pointer converted to an integer of sufficient size (if any such exists on the implementation) and back to the same pointer type will have its original value; mappings between pointers and integers are otherwise implementation-defined.

A function pointer can be explicitly converted to a function pointer of a different type.

[Note 4: The effect of calling a function through a pointer to a function type (9.3.4.6) that is not the same as the type used in the definition of the function is undefined (7.6.1.3). — end note] Except that converting a prvalue of type “pointer to T1” to the type “pointer to T2” (where T1 and T2 are function types) and back to its original type yields the original pointer value, the result of such a pointer conversion is unspecified.

[Note 5: See also 7.3.12 for more details of pointer conversions. — end note]

An object pointer can be explicitly converted to an object pointer of a different type. When a prvalue v of object pointer type is converted to the object pointer type “pointer to cv T”, the result is static_cast<cv T*>(static_cast<cv void*>(v)).

[Note 6: Converting a pointer of type “pointer to T1” that points to an object of type T1 to the type “pointer to T2” (where T2 is an object type and the alignment requirements of T2 are no stricter than those of T1) and back to its original type yields the original pointer value. — end note]

Converting a function pointer to an object pointer type or vice versa is conditionally-supported. The meaning of such a conversion is implementation-defined, except that if an implementation supports conversions in both directions, converting a prvalue of one type to the other type and back, possibly with different cv-qualification, shall yield the original pointer value.

The null pointer value (6.8.4) is converted to the null pointer value of the destination type.

[Note 7: A null pointer constant of type std::nullptr_t cannot be converted to a pointer type, and a null pointer constant of integral type is not necessarily converted to a null pointer value. — end note]

A prvalue of type “pointer to member of X of type T1” can be explicitly converted to a prvalue of a different type “pointer to member of Y of type T2” if T1 and T2 are both function types or both object types. The null member pointer value (7.3.13) is converted to the null member pointer value of the destination type. The result of this conversion is unspecified, except in the following cases:

(10.1) Converting a prvalue of type “pointer to member function” to a different pointer-to-member-function type and back to its original type yields the original pointer-to-member value.

(10.2) Converting a prvalue of type “pointer to data member of X of type T1” to the type “pointer to data member of Y of type T2” (where the alignment requirements of T2 are no stricter than those of T1) and back to its original type yields the original pointer-to-member value.

A glvalue of type T1, designating an object x, can be cast to the type “reference to T2” if an expression of type “pointer to T1” can be explicitly converted to the type “pointer to T2” using a reinterpret_cast. The result is that of reinterpret_cast<T2*>(p) where p is a pointer to x of type “pointer to T1”. No temporary is created, no copy is made, and no constructors (11.4.5) or conversion functions (11.4.8) are called.

7.6.1.11 Const cast

The result of the expression const_cast<T>(v) is of type T. If T is an lvalue reference to object type, the result is an lvalue; if T is an rvalue reference to object type, the result is an rvalue; otherwise, the result is a prvalue and the lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the expression v. Conversions that can be performed explicitly using const_cast are listed below. No other conversion shall be performed explicitly using const_cast.

[Note 1: Subject to the restrictions in this subclause, an expression can be cast to its own type using a const_cast operator. — end note]

For two similar types T1 and T2 (7.3.6), a prvalue of type T1 may be explicitly converted to the type T2 using a const_cast if, considering the qualification-decompositions of both types, each Pi is the same as Pj for all i. The result of a const_cast refers to the original entity.

57 The types can have different cv-qualifiers, subject to the overall restriction that a reinterpret_cast cannot cast away constness.

58 T1 and T2 can have different cv-qualifiers, subject to the overall restriction that a reinterpret_cast cannot cast away constness.

59 This is sometimes referred to as a type pun when the result refers to the same object as the source glvalue.
*Example 1:*

```c
typedef int *A[3]; // array of 3 pointer to int
typedef const int *const CA[3]; // array of 3 const pointer to const int

CA &&r = A{}; // OK, reference binds to temporary array object
// after qualification conversion to type CA
A &&r1 = const_cast<A>(CA{}); // error: temporary array decayed to pointer
A &&r2 = const_cast<A&&>(CA{}); // OK
```

--- end example

For two object types $T_1$ and $T_2$, if a pointer to $T_1$ can be explicitly converted to the type “pointer to $T_2$” using a `const_cast`, then the following conversions can also be made:

1. an lvalue of type $T_1$ can be explicitly converted to an lvalue of type $T_2$ using the cast `const_cast<T2&>`;
2. a glvalue of type $T_1$ can be explicitly converted to an xvalue of type $T_2$ using the cast `const_cast<T2&&>`; and
3. if $T_1$ is a class type, a prvalue of type $T_1$ can be explicitly converted to an xvalue of type $T_2$ using the cast `const_cast<T2&&>`.

The result of a reference `const_cast` refers to the original object if the operand is a glvalue and to the result of applying the temporary materialization conversion (7.3.5) otherwise.

A null pointer value (6.8.4) is converted to the null pointer value of the destination type. The null member pointer value (7.3.13) is converted to the null member pointer value of the destination type.

[Note 2: Depending on the type of the object, a write operation through the pointer, lvalue or pointer to data member resulting from a `const_cast` that casts away a const-qualifier can produce undefined behavior (9.2.9.2). —end note]

A conversion from a type $T_1$ to a type $T_2$ *casts away constness* if $T_1$ and $T_2$ are different, there is a qualification-decomposition (7.3.6) of $T_1$ yielding $n$ such that $T_2$ has a qualification-decomposition of the form

$$cv^2_0 P^2_0 cv^2_1 P^2_1 \cdots cv^2_{n-1} P^2_{n-1} cv^2_n \cup_2,$$

and there is no qualification conversion that converts $T_1$ to

$$cv^2_0 P^1_0 cv^2_1 P^1_1 \cdots cv^2_{n-1} P^1_{n-1} cv^2_n \cup_1.$$

Casting from an lvalue of type $T_1$ to an lvalue of type $T_2$ using an lvalue reference cast or casting from an expression of type $T_1$ to an xvalue of type $T_2$ using an rvalue reference cast casts away constness if a cast from a prvalue of type “pointer to $T_1$” to the type “pointer to $T_2$” casts away constness.

[Note 3: Some conversions which involve only changes in cv-qualification cannot be done using `const_cast`. For instance, conversions between pointers to functions are not covered because such conversions lead to values whose use causes undefined behavior. For the same reasons, conversions between pointers to member functions, and in particular, the conversion from a pointer to a const member function to a pointer to a non-const member function, are not covered. —end note]

### 7.6.2 Unary expressions

#### 7.6.2.1 General

Expressions with unary operators group right-to-left.

---

60) `const_cast` is not limited to conversions that cast away a const-qualifier.
unary-expression:
  postfix-expression
  unary-operator cast-expression
  ++ cast-expression
  -- cast-expression
  await-expression
  sizeof unary-expression
  sizeof (( type-id )
  sizeof ... ( identifier )
  alignof (( type-id )
  noexcept-expression
  new-expression
  delete-expression

unary-operator: one of
  * & + - ! ~

7.6.2.2 Unary operators

1 The unary * operator performs indirection. Its operand shall be a prvalue of type “pointer to T”, where T is an object or function type. The operator yields an lvalue of type T denoting the object or function to which the operand points.

[Note 1: Indirection through a pointer to an incomplete type (other than cv void) is valid. The lvalue thus obtained can be used in limited ways (to initialize a reference, for example); this lvalue must not be converted to a prvalue, see 7.3.2. — end note]

2 Each of the following unary operators yields a prvalue.

3 The operand of the unary & operator shall be an lvalue of some type T. The result is a prvalue.

(3.1) — If the operand is a qualified-id naming a non-static or variant member m of some class C, other than an explicit object member function, the result has type “pointer to member of class C of type T” and designates C::m.

(3.2) — Otherwise, the result has type “pointer to T” and points to the designated object (6.7.1) or function (6.8.4). If the operand names an explicit object member function (9.3.4.6), the operand shall be a qualified-id.

[Note 2: In particular, taking the address of a variable of type “cv T” yields a pointer of type “pointer to cv T”. — end note]

[Example 1:
  struct A { int i; };
  struct B : A { };...
  &B::i ... // has type int A::*
  int a;
  int* p1 = &a;
  int* p2 = p1 + 1; // defined behavior
  bool b = p2 > p1; // defined behavior, with value true
  — end example]

[Note 3: A pointer to member formed from a mutable non-static data member (9.2.2) does not reflect the mutable specifier associated with the non-static data member. — end note]

4 A pointer to member is only formed when an explicit & is used and its operand is a qualified-id not enclosed in parentheses.

[Note 4: That is, the expression & (qualified-id), where the qualified-id is enclosed in parentheses, does not form an expression of type “pointer to member”. Neither does qualified-id, because there is no implicit conversion from a qualified-id for a non-static member function to the type “pointer to member function” as there is from an lvalue of function type to the type “pointer to function” (7.3.4). Nor is & unqualified-id a pointer to member, even within the scope of the unqualified-id’s class. — end note]

5 If & is applied to an lvalue of incomplete class type and the complete type declares operator&( ), it is unspecified whether the operator has the built-in meaning or the operator function is called. The operand of & shall not be a bit-field.

[Note 5: The address of an overload set (Clause 12) can be taken only in a context that uniquely determines which function is referred to (see 12.3). Since the context can affect whether the operand is a static or non-static member

§ 7.6.2.2
function, the context can also affect whether the expression has type “pointer to function” or “pointer to member function”. —end note]

7 The operand of the unary + operator shall have arithmetic, unscoped enumeration, or pointer type and the result is the value of the argument. Integral promotion is performed on integral or enumeration operands. The type of the result is the type of the promoted operand.

8 The operand of the unary - operator shall have arithmetic or unscoped enumeration type and the result is the negative of its operand. Integral promotion is performed on integral or enumeration operands. The negative of an unsigned quantity is computed by subtracting its value from \(2^n\), where \(n\) is the number of bits in the promoted operand. The type of the result is the type of the promoted operand.

[Note 6: The result is the two’s complement of the operand (where operand and result are considered as unsigned). —end note]

9 The operand of the logical negation operator \(!\) is contextually converted to \(\text{bool}\) (7.3); its value is \text{true} if the converted operand is \text{false} and \text{false} otherwise. The type of the result is \(\text{bool}\).

10 The operand of the \(-\) operator shall have integral or unscoped enumeration type. Integral promotions are performed. The type of the result is the type of the promoted operand. Given the coefficients \(x_i\) of the base-2 representation (6.8.2) of the promoted operand \(x\), the coefficient \(r_i\) of the base-2 representation of the result \(r\) is 1 if \(x_i\) is 0, and 0 otherwise.

[Note 7: The result is the ones’ complement of the operand (where operand and result are considered as unsigned). —end note]

There is an ambiguity in the grammar when \(-\) is followed by a \text{name} or \text{decltype-specifier}. The ambiguity is resolved by treating \(-\) as the operator rather than as the start of an \text{unqualified-id} naming a destructor.

[Note 8: Because the grammar does not permit an operator to follow the \_. \(-\) tokens, a \(-\) followed by a \text{name} or \text{decltype-specifier} in a member access expression or \text{qualified-id} is unambiguously parsed as a destructor name. —end note]

7.6.2.3 Increment and decrement [expr.pre.incr]

1 The operand of prefix \(\text{++}\) is modified (3.1) by adding 1. The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than \(\text{cv bool}\), or a pointer to a completely-defined object type. An operand with volatile-qualified type is deprecated; see D.5. The result is the updated operand; it is an lvalue, and it is a bit-field if the operand is a bit-field. The expression \(\text{++x}\) is equivalent to \(\text{x+=1}\).

[Note 1: See the discussions of addition (7.6.6) and assignment operators (7.6.19) for information on conversions. —end note]

2 The operand of prefix \(\text{--}\) is modified (3.1) by subtracting 1. The requirements on the operand of prefix \(\text{--}\) and the properties of its result are otherwise the same as those of prefix \(\text{++}\).

[Note 2: For postfix increment and decrement, see 7.6.1.6. —end note]

7.6.2.4 Await [expr.await]

1 The \text{co\_await} expression is used to suspend evaluation of a coroutine (9.5.4) while awaiting completion of the computation represented by the operand expression.

\[
\text{await-expression}:
\text{co\_await cast\_expression}
\]

2 An \text{await-expression} shall appear only in a potentially-evaluated expression within the \text{compound-statement} of a \text{function-body} outside of a \text{handler} (14.1). In a \text{declaration-statement} or in the \text{simple-declaration} (if any) of an \text{init-statement}, an \text{await-expression} shall appear only in an \text{initializer} of that \text{declaration-statement} or \text{simple-declaration}. An \text{await-expression} shall not appear in a default argument (9.3.4.7). An \text{await-expression} shall not appear in the initializer of a block variable with static or thread storage duration. A context within a function where an \text{await-expression} can appear is called a \text{suspension context} of the function.

3 Evaluation of an \text{await-expression} involves the following auxiliary types, expressions, and objects:

(3.1) \(p\) is an lvalue naming the promise object (9.5.4) of the enclosing coroutine and \(P\) is the type of that object.

(3.2) Unless the \text{await-expression} was implicitly produced by a \text{yield-expression} (7.6.17), an initial await expression, or a final await expression (9.5.4), a search is performed for the name \text{await\_transform} in the scope of \(P\) (6.5.2). If this search is performed and finds at least one declaration, then \(a\) is \(p\).\text{await\_transform}(...); otherwise, \(a\) is the \text{cast\_expression}.
(3.3) — $o$ is determined by enumerating the applicable `operator co_await` functions for an argument $a$ (12.2.2.3), and choosing the best one through overload resolution (12.2). If overload resolution is ambiguous, the program is ill-formed. If no viable functions are found, $o$ is $a$. Otherwise, $o$ is a call to the selected function with the argument $a$. If $o$ would be a prvalue, the temporary materialization conversion (7.3.5) is applied.

(3.4) — $e$ is a lvalue referring to the result of evaluating the (possibly-converted) $o$.

(3.5) — $h$ is an object of type `std::coroutine_handle<P>` referring to the enclosing coroutine.

(3.6) — `await-ready` is the expression $e$.`await_ready()`, contextually converted to `bool`.

(3.7) — `await-suspend` is the expression $e$.`await_suspend(h)`, which shall be a prvalue of type `void`, `bool`, or `std::coroutine_handle<Z>` for some type $Z$.

(3.8) — `await-resume` is the expression $e$.`await_resume()`.

The `await-expression` has the same type and value category as the `await-resume` expression.

The `await-expression` evaluates the (possibly-converted) $o$ expression and the `await-ready` expression, then:

(5.1) — If the result of `await-ready` is `false`, the coroutine is considered suspended. Then:

(5.1.1) — If the type of `await-suspend` is `std::coroutine_handle<Z>`, `await-suspend.resume()` is evaluated.

[Note 1: This resumes the coroutine referred to by the result of `await-suspend`. Any number of coroutines can be successively resumed in this fashion, eventually returning control flow to the current coroutine caller or resumer (9.5.4). — end note]

(5.1.2) — Otherwise, if the type of `await-suspend` is `bool`, `await-suspend` is evaluated, and the coroutine is resumed if the result is `false`.

(5.1.3) — Otherwise, `await-suspend` is evaluated.

If the evaluation of `await-suspend` exits via an exception, the exception is caught, the coroutine is resumed, and the exception is immediately rethrown (14.2). Otherwise, control flow returns to the current coroutine caller or resumer (9.5.4) without exiting any scopes (8.7). The point in the coroutine immediately prior to control returning to its caller or resumer is a coroutine suspend point.

(5.2) — If the result of `await-ready` is `true`, or when the coroutine is resumed other than by rethrowing an exception from `await-suspend`, the `await-resume` expression is evaluated, and its result is the result of the `await-expression`.

[Note 2: With respect to sequencing, an `await-expression` is indivisible (6.9.1). — end note]

Example 1:

```cpp
template <typename T>
struct my_future {
    /* ... */
    bool await_ready();
    void await_suspend(std::coroutine_handle<>);
    T await_resume();
};

template <class Rep, class Period>
auto operator co_await(std::chrono::duration<Rep, Period> d) {
    struct awaiter {
        std::chrono::system_clock::duration duration;
        /* ... */
        awaiter(std::chrono::system_clock::duration d) : duration(d) {} //
        bool await_ready() const { return duration.count() <= 0; }
        void await_resume() {}
        void await_suspend(std::coroutine_handle<> h) { /* ... */ }
    };
    return awaiter(d);
}

using namespace std::chrono;

my_future<int> h();
```
```cpp
my_future<void> g() {
    std::cout << "just about to go to sleep...\n";
    co_await 10ms;
    std::cout << "resumed\n";
    co_await h();
}

auto f(int x = co_await h());  // error: await-expression outside of function suspension context
int a[] = { co_await h() };       // error: await-expression outside of function suspension context

7.6.2.5 sizeof [expr.sizeof]
1 The `sizeof` operator yields the number of bytes occupied by a non-potentially-overlapping object of the type of its operand. The operand is either an expression, which is an unevaluated operand (7.2.3), or a parenthesized `type-id`. The `sizeof` operator shall not be applied to an expression that has function or incomplete type, to the parenthesized name of such types, or to a glvalue that designates a bit-field. The result of `sizeof` applied to any of the narrow character types is 1. The result of `sizeof` applied to any other fundamental type (6.8.2) is implementation-defined.

[Note 1: In particular, the values of `sizeof(bool)`, `sizeof(char16_t)`, `sizeof(char32_t)`, and `sizeof(wchar_t)` are implementation-defined. — end note]

[Note 2: See 6.7.1 for the definition of byte and 6.8.1 for the definition of object representation. — end note]

2 When applied to a reference type, the result is the size of the referenced type. When applied to a class, the result is the number of bytes in an object of that class including any padding required for placing objects of that type in an array. The result of applying `sizeof` to a potentially-overlapping subobject is the size of the type, not the size of the subobject. When applied to an array, the result is the total number of bytes in the array. This implies that the size of an array of `n` elements is `n` times the size of an element.

3 The `sizeof` operator yields the number of elements in the pack (13.7.4). A `sizeof`... expression is a pack expansion (13.7.4).

[Example 1:
```cpp
template<class... Types>
struct count {
    static const std::size_t value = sizeof...(Types);
};
```
— end example]

5 The result of `sizeof` and `sizeof`... is a prvalue of type `std::size_t`.

[Note 3: A `sizeof` expression is an integral constant expression (7.7). The type `std::size_t` is defined in the standard header `<cstddef>` (17.2.1, 17.2.4). — end note]

7.6.2.6 Alignof [expr.alignof]
1 An `alignof` expression yields the alignment requirement of its operand type. The operand shall be a `type-id` representing a complete object type, or an array thereof, or a reference to one of those types.

2 The result is a prvalue of type `std::size_t`.

[Note 1: An `alignof` expression is an integral constant expression (7.7). The type `std::size_t` is defined in the standard header `<cstddef>` (17.2.1, 17.2.4). — end note]

3 When `alignof` is applied to a reference type, the result is the alignment of the referenced type. When `alignof` is applied to an array type, the result is the alignment of the element type.

[61] `sizeof(bool)` is not required to be 1.
[62] The actual size of a potentially-overlapping subobject can be less than the result of applying `sizeof` to the subobject, due to virtual base classes and less strict padding requirements on potentially-overlapping subobjects.

§ 7.6.2.6
7.6.2.7 noexcept operator

The noexcept operator determines whether the evaluation of its operand, which is an unevaluated operand (7.2.3), can throw an exception (14.2).

noexcept-expression:
   noexcept ( expression )

2 The result of the noexcept operator is a prvalue of type bool.
[Note 1: A noexcept-expression is an integral constant expression (7.7). — end note]
3 The result of the noexcept operator is true unless the expression is potentially-throwing (14.5).

7.6.2.8 New

The new-expression attempts to create an object of the type-id (9.3.2) or new-type-id to which it is applied. The type of that object is the allocated type. This type shall be a complete object type (6.8.1), but not an abstract class type (11.7.4) or array thereof (6.7.2).
[Note 1: Because references are not objects, references cannot be created by new-expressions. — end note]
[Note 2: The type-id can be a cv-qualified type, in which case the object created by the new-expression has a cv-qualified type. — end note]

new-expression:
::\texttt{opt} new-placement\texttt{opt} new-type-id new-initializer\texttt{opt}
::\texttt{opt} new-placement\texttt{opt} ( type-id ) new-initializer\texttt{opt}

new-placement:
( expression-list )

new-type-id:
type-specifier-seq new-declarator\texttt{opt}

new-declarator:
ptr-operator new-declarator\texttt{opt}
noptr-new-declarator

noptr-new-declarator:
{ expression\texttt{opt} } attribute-specifier-seq\texttt{opt}
noptr-new-declarator [ constant-expression ] attribute-specifier-seq\texttt{opt}

new-initializer:
( expression-list\texttt{opt} ) braced-init-list

2 If a placeholder type (9.2.9.6) appears in the type-specifier-seq of a new-type-id or type-id of a new-expression, the allocated type is deduced as follows: Let init be the new-initializer, if any, and T be the new-type-id or type-id of the new-expression, then the allocated type is the type deduced for the variable x in the invented declaration (9.2.9.6):

\begin{verbatim}
T x init;
\end{verbatim}

[Example 1:
new auto(1); // allocated type is int
auto x = new auto('a'); // allocated type is char, x is of type char*

template<class T> struct A { A(T, T); };  
auto y = new A(1, 2); // allocated type is A<int>

— end example]

3 The new-type-id in a new-expression is the longest possible sequence of new-declarators.
[Note 3: This prevents ambiguities between the declarator operators \texttt{k, kk, *}, and \texttt{[]} and their expression counterparts. — end note]

[Example 2:
new int * i; // syntax error: parsed as (new int*) i, not as (new int)*i

The * is the pointer declarator and not the multiplication operator. — end example]

4 [Note 4: Parentheses in a new-type-id of a new-expression can have surprising effects.

[Example 3:
new int(*[10])(); // error

§ 7.6.2.8]
is ill-formed because the binding is

\[
\text{(new int) (*[10])();} \quad // \text{error}
\]

Instead, the explicitly parenthesized version of the `new` operator can be used to create objects of compound types (6.8.4):

\[
\text{new (int (*[10])());}
\]

allocates an array of 10 pointers to functions (taking no argument and returning `int`). —end example]

—end note]

5 The attribute-specifier-seq in a `noptr-new-declarator` appertains to the associated array type.

6 Every `constant-expression` in a `noptr-new-declarator` shall be converted to a constant expression (7.7) of type `std::size_t` and its value shall be greater than zero.

[Example 4: Given the definition `int n = 42`, `new float[n][5]` is well-formed (because `n` is the expression of a `noptr-new-declarator`), but `new float[5][n]` is ill-formed (because `n` is not a constant expression). —end example]

7 If the `type-id` or `new-type-id` denotes an array type of unknown bound (9.3.4.5), the `new-initializer` shall not be omitted; the allocated object is an array with `n` elements, where `n` is determined from the number of initial elements supplied in the `new-initializer` (9.4.2, 9.4.3).

8 If the `expression` in a `noptr-new-declarator` is present, it is implicitly converted to `std::size_t`. The `expression` is erroneous if:

- the `expression` is of non-class type and its value before converting to `std::size_t` is less than zero;
- the `expression` is of class type and its value before application of the second standard conversion (12.2.4.2.3) is less than zero;
- its value is such that the size of the allocated object would exceed the implementation-defined limit (Annex B); or
- the `new-initializer` is a `braced-init-list` and the number of array elements for which initializers are provided (including the terminating `\0` in a `string-literal` (5.13.5)) exceeds the number of elements to initialize.

If the `expression` is erroneous after converting to `std::size_t`:

- if the `expression` is a potentially-evaluated core constant expression, the program is ill-formed;
- otherwise, an allocation function is not called; instead

- if the allocation function that would have been called has a non-throwing exception specification (14.5), the value of the `new-expression` is the null pointer value of the required result type;
- otherwise, the `new-expression` terminates by throwing an exception of a type that would match a handler (14.4) of type `std::bad_array_new_length` (17.6.4.2).

When the value of the `expression` is zero, the allocation function is called to allocate an array with no elements.

9 Objects created by a `new-expression` have dynamic storage duration (6.7.5.5).

[Note 5: The lifetime of such an object is not necessarily restricted to the scope in which it is created. —end note]

10 When the allocated type is “array of N T” (that is, the `noptr-new-declarator` syntax is used or the `new-type-id` or `type-id` denotes an array type), the `new-expression` yields a prvalue of type “pointer to T” that points to the initial element (if any) of the array. Otherwise, let T be the allocated type; the `new-expression` is a prvalue of type “pointer to T” that points to the object created.

[Note 6: Both `new int` and `new int[10]` have type `int*` and the type of `new int[1][10]` is `int (*)[10]`. —end note]

11 A `new-expression` may obtain storage for the object by calling an allocation function (6.7.5.5.2). If the `new-expression` terminates by throwing an exception, it may release storage by calling a deallocation function (6.7.5.5.3). If the allocated type is a non-array type, the allocation function’s name is `operator new` and the deallocation function’s name is `operator delete`. If the allocated type is an array type, the allocation function’s name is `operator new[]` and the deallocation function’s name is `operator delete[]`

[Note 7: An implementation is required to provide default definitions for the global allocation functions (6.7.5.5, 17.6.3.2, 17.6.3.3). A C++ program can provide alternative definitions of these functions (16.4.5.6) and/or class-specific versions (11.4.11). The set of allocation and deallocation functions that can be called by a `new-expression` can include functions that do not perform allocation or deallocation; for example, see 17.6.3.4. —end note]

63) If the conversion function returns a signed integer type, the second standard conversion converts to the unsigned type `std::size_t` and thus thwarts any attempt to detect a negative value afterwards.

§ 7.6.2.8 138
If the new-expression does not begin with a unary :: operator and the allocated type is a class type T or array thereof, a search is performed for the allocation function's name in the scope of T (6.5.2). Otherwise, or if nothing is found, the allocation function’s name is looked up by searching for it in the global scope.

An implementation is allowed to omit a call to a replaceable global allocation function (17.6.3.2, 17.6.3.3). When it does so, the storage is instead provided by the implementation or provided by extending the allocation of another new-expression.

During an evaluation of a constant expression, a call to an allocation function is always omitted.

[Note 8: Only new-expressions that would otherwise result in a call to a replaceable global allocation function can be evaluated in constant expressions (7.7). — end note]

The implementation may extend the allocation of a new-expression e1 to provide storage for a new-expression e2 if the following would be true were the allocation not extended:

1. The evaluation of e1 is sequenced before the evaluation of e2, and
2. e2 is evaluated whenever e1 obtains storage, and
3. both e1 and e2 invoke the same replaceable global allocation function, and
4. if the allocation function invoked by e1 and e2 is throwing, any exceptions thrown in the evaluation of either e1 or e2 would be first caught in the same handler, and
5. the pointer values produced by e1 and e2 are operands to evaluated delete-expressions, and
6. the evaluation of e2 is sequenced before the evaluation of the delete-expression whose operand is the pointer value produced by e1.

[Example 5:]

```cpp
void can_merge(int x) {
  // These allocations are safe for merging:
  std::unique_ptr<char[]> a(new (std::nothrow) char[8]);
  std::unique_ptr<char[]> b(new (std::nothrow) char[8]);
  std::unique_ptr<char[]> c(new (std::nothrow) char[x]);

  g(a.get(), b.get(), c.get());
}

void cannot_merge(int x) {
  std::unique_ptr<char[]> a(new char[8]);
  try {
    // Merging this allocation would change its catch handler.
    std::unique_ptr<char[]> b(new char[x]);
  } catch (const std::bad_alloc& e) {
    std::cerr << "Allocation failed: " << e.what() << std::endl;
    throw;
  }
}
```

When a new-expression calls an allocation function and that allocation has not been extended, the new-expression passes the amount of space requested to the allocation function as the first argument of type std::size_t. That argument shall be no less than the size of the object being created; it may be greater than the size of the object being created only if the object is an array and the allocation function is not a non-allocating form (17.6.3.4). For arrays of char, unsigned char, and std::byte, the difference between the result of the new-expression and the address returned by the allocation function shall be an integral multiple of the strictest fundamental alignment requirement (6.7.6) of any object type whose size is no greater than the size of the array being created.

[Note 9: Because allocation functions are assumed to return pointers to storage that is appropriately aligned for objects of any type with fundamental alignment, this constraint on array allocation overhead permits the common idiom of allocating character arrays into which objects of other types will later be placed. — end note]

When a new-expression calls an allocation function and that allocation has been extended, the size argument to the allocation call shall be no greater than the sum of the sizes for the omitted calls as specified above, plus the size for the extended call had it not been extended, plus any padding necessary to align the allocated objects within the allocated memory.
The new-placement syntax is used to supply additional arguments to an allocation function; such an expression is called a placement new-expression.

Overload resolution is performed on a function call created by assembling an argument list. The first argument is the amount of space requested, and has type std::size_t. If the type of the allocated object has new-extended alignment, the next argument is the type’s alignment, and has type std::align_val_t. If the new-placement syntax is used, the initializer-clauses in its expression-list are the succeeding arguments. If no matching function is found then

1. if the allocated object type has new-extended alignment, the alignment argument is removed from the argument list;
2. otherwise, an argument that is the type’s alignment and has type std::align_val_t is added into the argument list immediately after the first argument;

and then overload resolution is performed again.

Example 6:

1. new T results in one of the following calls:
   - operator new(sizeof(T))
   - operator new(sizeof(T), std::align_val_t(alignof(T)))
2. new(2,f) T results in one of the following calls:
   - operator new(sizeof(T), 2, f)
   - operator new(sizeof(T), std::align_val_t(alignof(T)), 2, f)
3. new T[5] results in one of the following calls:
   - operator new[](sizeof(T) + 5 + x)
   - operator new[](sizeof(T) + 5 + x, std::align_val_t(alignof(T)))
4. new(2,f) T[5] results in one of the following calls:
   - operator new[](sizeof(T) + 5 + x, 2, f)
   - operator new[](sizeof(T) + 5 + x, std::align_val_t(alignof(T)), 2, f)

Here, each instance of x is a non-negative unspecified value representing array allocation overhead; the result of the new-expression will be offset by this amount from the value returned by operator new[]. This overhead may be applied in all array new-expressions, including those referencing a placement allocation function, except when referencing the library function operator new[](std::size_t, void*). The amount of overhead may vary from one invocation of new to another. —end example

Note 10: Unless an allocation function has a non-throwing exception specification (14.5), it indicates failure to allocate storage by throwing a std::bad_alloc exception (6.7.5.5.2, Clause 14, 17.6.4.1); it returns a non-null pointer otherwise. If the allocation function has a non-throwing exception specification, it returns null to indicate failure to allocate storage and a non-null pointer otherwise. —end note

If the allocation function is a non-allocating form (17.6.3.4) that returns null, the behavior is undefined. Otherwise, if the allocation function returns null, initialization shall not be done, the deallocation function shall not be called, and the value of the new-expression shall be null.

Note 11: When the allocation function returns a value other than null, it must be a pointer to a block of storage in which space for the object has been reserved. The block of storage is assumed to be appropriately aligned and of the requested size. The address of the created object will not necessarily be the same as that of the block if the object is an array. —end note

A new-expression that creates an object of type T initializes that object as follows:

1. If the new-initializer is omitted, the object is default-initialized (9.4).
   - [Note 12: If no initialization is performed, the object has an indeterminate value. —end note]
2. Otherwise, the new-initializer is interpreted according to the initialization rules of 9.4 for direct-initialization.

The invocation of the allocation function is sequenced before the evaluations of expressions in the new-initializer. Initialization of the allocated object is sequenced before the value computation of the new-expression.

If the new-expression creates an object or an array of objects of class type, access and ambiguity control are done for the allocation function, the deallocation function (6.7.5.5.3), and the constructor (11.4.5) selected for the initialization (if any). If the new-expression creates an array of objects of class type, the destructor is potentially invoked (11.4.7).
If any part of the object initialization described above terminates by throwing an exception and a suitable deallocation function can be found, the deallocation function is called to free the memory in which the object was being constructed, after which the exception continues to propagate in the context of the new-expression. If no unambiguous matching deallocation function can be found, propagating the exception does not cause the object’s memory to be freed.

[Note 13: This is appropriate when the called allocation function does not allocate memory; otherwise, it is likely to result in a memory leak. —end note]

If the new-expression does not begin with a unary :: operator and the allocated type is a class type T or an array thereof, a search is performed for the deallocation function’s name in the scope of T. Otherwise, or if nothing is found, the deallocation function’s name is looked up by searching for it in the global scope.

A declaration of a placement deallocation function matches the declaration of a placement allocation function if it has the same number of parameters and, after parameter transformations (9.3.4.6), all parameter types except the first are identical. If the lookup finds a single matching deallocation function, that function will be called; otherwise, no deallocation function will be called. If the lookup finds a usual deallocation function and that function, considered as a placement deallocation function, would have been selected as a match for the allocation function, the program is ill-formed. For a non-placement allocation function, the normal deallocation function lookup is used to find the matching deallocation function (7.6.2.9).

[Example 7:

```cpp
struct S {
  // Placement allocation function:
  static void* operator new(std::size_t, std::size_t);

  // Usual (non-placement) deallocation function:
  static void operator delete(void*, std::size_t);
};

S* p = new (0) S; // error: non-placement deallocation function matches placement allocation function

end example]

If a new-expression calls a deallocation function, it passes the value returned from the allocation function call as the first argument of type void*. If a placement deallocation function is called, it is passed the same additional arguments as were passed to the placement allocation function, that is, the same arguments as those specified with the new-placement syntax. If the implementation is allowed to introduce a temporary object or make a copy of any argument as part of the call to the allocation function, it is unspecified whether the same object is used in the call to both the allocation and deallocation functions.

7.6.2.9 Delete [expr.delete]

The delete-expression operator destroys a most derived object (6.7.2) or array created by a new-expression.

delete-expression:
  ::opt delete cast-expression
  ::opt delete [ ] cast-expression

The first alternative is a single-object delete expression, and the second is an array delete expression. Whenever the delete keyword is immediately followed by empty square brackets, it shall be interpreted as the second alternative. The operand shall be of pointer to object type or of class type. If of class type, the operand is contextually implicitly converted (7.3) to a pointer to object type. The delete-expression has type void.

If the operand has a class type, the operand is converted to a pointer type by calling the above-mentioned conversion function, and the converted operand is used in place of the original operand for the remainder of this subclause. In a single-object delete expression, the value of the operand of delete may be a null pointer value, a pointer value that resulted from a previous non-array new-expression, or a pointer to a base class subobject of an object created by such a new-expression. If not, the behavior is undefined. In an array delete expression, the value of the operand of delete may be a null pointer value or a pointer value that resulted

64) This can include evaluating a new-initializer and/or calling a constructor.

65) A lambda-expression with a lambda-introducer that consists of empty square brackets can follow the delete keyword if the lambda-expression is enclosed in parentheses.

66) This implies that an object cannot be deleted using a pointer of type void* because void is not an object type.
from a previous array new-expression whose allocation function was not a non-allocating form (17.6.3.4). 67 If not, the behavior is undefined.

[Note 1: This means that the syntax of the delete-expression must match the type of the object allocated by new, not the syntax of the new-expression. — end note]

[Note 2: A pointer to a const type can be the operand of a delete-expression; it is not necessary to cast away the constness (7.6.1.11) of the pointer expression before it is used as the operand of the delete-expression. — end note]

3 In a single-object delete expression, if the static type of the object to be deleted is not similar (7.3.6) to its dynamic type and the selected deallocation function (see below) is not a destroying operator delete, the static type shall be a base class of the dynamic type of the object to be deleted and the static type shall have a virtual destructor or the behavior is undefined. In an array delete expression, if the dynamic type of the object to be deleted is not similar to its static type, the behavior is undefined.

4 The cast-expression in a delete-expression shall be evaluated exactly once.

5 If the object being deleted has incomplete class type at the point of deletion and the complete class has a non-trivial destructor or a deallocation function, the behavior is undefined.

6 If the value of the operand of the delete-expression is not a null pointer value and the selected deallocation function (see below) is not a destroying operator delete, the delete-expression will invoke the destructor (if any) for the object or the elements of the array being deleted. In the case of an array, the elements will be destroyed in order of decreasing address (that is, in reverse order of the completion of their constructor; see 11.9.3).

7 If the value of the operand of the delete-expression is not a null pointer value, then:

(7.1) If the allocation call for the new-expression for the object to be deleted was not omitted and the allocation was not extended (7.6.2.8), the delete-expression shall call a deallocation function (6.7.5.5.3). The value returned from the allocation call of the new-expression shall be passed as the first argument to the deallocation function.

(7.2) Otherwise, if the allocation was extended or was provided by extending the allocation of another new-expression, and the delete-expression for every other pointer value produced by a new-expression that had storage provided by the extended new-expression has been evaluated, the delete-expression shall call a deallocation function. The value returned from the allocation call of the extended new-expression shall be passed as the first argument to the deallocation function.

(7.3) Otherwise, the delete-expression will not call a deallocation function.

[Note 3: The deallocation function is called regardless of whether the destructor for the object or some element of the array throws an exception. — end note]

If the value of the operand of the delete-expression is a null pointer value, it is unspecified whether a deallocation function will be called as described above.

8 If a deallocation function is called, it is operator delete for a single-object delete expression or operator delete[] for an array delete expression.

[Note 4: An implementation provides default definitions of the global deallocation functions (17.6.3.2, 17.6.3.3). A C++ program can provide alternative definitions of these functions (16.4.5.6), and/or class-specific versions (11.4.11). — end note]

9 If the keyword delete in a delete-expression is not preceded by the unary :: operator and the type of the operand is a pointer to a (possibly cv-qualified) class type T or (possibly multidimensional) array thereof:

(9.1) For a single-object delete expression, if the operand is a pointer to cv T and T has a virtual destructor, the deallocation function is the one selected at the point of definition of the dynamic type’s virtual destructor (11.4.7).

(9.2) Otherwise, a search is performed for the deallocation function’s name in the scope of T.

Otherwise, or if nothing is found, the deallocation function’s name is looked up by searching for it in the global scope. In any case, any declarations other than of usual deallocation functions (6.7.5.5.3) are discarded.

[Note 5: If only a placement deallocation function is found in a class, the program is ill-formed because the lookup set is empty (6.5). — end note]

67) For nonzero-length arrays, this is the same as a pointer to the first element of the array created by that new-expression. Zero-length arrays do not have a first element.
If more than one deallocation function is found, the function to be called is selected as follows:

— If any of the deallocation functions is a destroying operator delete, all deallocation functions that are not destroying operator deletes are eliminated from further consideration.

— If the type has new-extended alignment, a function with a parameter of type `std::align_val_t` is preferred; otherwise a function without such a parameter is preferred. If any preferred functions are found, all non-preferred functions are eliminated from further consideration.

— If exactly one function remains, that function is selected and the selection process terminates.

— If the deallocation functions belong to a class scope, the one without a parameter of type `std::size_t` is selected.

— If the type is complete and if, for an array delete expression only, the operand is a pointer to a class type with a non-trivial destructor or a (possibly multi-dimensional) array thereof, the function with a parameter of type `std::size_t` is selected.

— Otherwise, it is unspecified whether a deallocation function with a parameter of type `std::size_t` is selected.

For a single-object delete expression, the deleted object is the object \( A \) pointed to by the operand if the static type of \( A \) does not have a virtual destructor, and the most-derived object of \( A \) otherwise.

[Note 6: If the deallocation function is not a destroying operator delete and the deleted object is not the most derived object in the former case, the behavior is undefined, as stated above. — end note]

For an array delete expression, the deleted object is the array object. When a delete-expression is executed, the selected deallocation function shall be called with the address of the deleted object in a single-object delete expression, or the address of the deleted object suitably adjusted for the array allocation overhead (7.6.2.8) in an array delete expression, as its first argument.

[Note 7: Any cv-qualifiers in the type of the deleted object are ignored when forming this argument. — end note]

If a destroying operator delete is used, an unspecified value is passed as the argument corresponding to the parameter of type `std::destroying_delete_t`. If a deallocation function with a parameter of type `std::align_val_t` is used, the alignment of the type of the deleted object is passed as the corresponding argument. If a deallocation function with a parameter of type `std::size_t` is used, the size of the deleted object in a single-object delete expression, or of the array plus allocation overhead in an array delete expression, is passed as the corresponding argument.

[Note 8: If this results in a call to a replaceable deallocation function, and either the first argument was not the result of a prior call to a replaceable allocation function or the second or third argument was not the corresponding argument in said call, the behavior is undefined (17.6.3.2, 17.6.3.3). — end note]

Access and ambiguity control are done for both the deallocation function and the destructor (11.4.7, 11.4.11).

### 7.6.3 Explicit type conversion (cast notation)

The result of the expression (\( T \)) `cast-expression` is of type \( T \). The result is an lvalue if \( T \) is an lvalue reference type or an rvalue reference to function type and an xvalue if \( T \) is an rvalue reference to object type; otherwise the result is a prvalue.

[Note 1: If \( T \) is a non-class type that is cv-qualified, the cv-qualifiers are discarded when determining the type of the resulting prvalue; see 7.2. — end note]

An explicit type conversion can be expressed using functional notation (7.6.1.4), a type conversion operator (`dynamic_cast`, `static_cast`, `reinterpret_cast`, `const_cast`), or the `cast` notation.

`cast-expression:`

```plaintext```
unary-expression
(type-id) cast-expression
```

Any type conversion not mentioned below and not explicitly defined by the user (11.4.8) is ill-formed.

The conversions performed by

- a `const_cast` (7.6.1.11),
- a `static_cast` (7.6.1.9),
- a `static_cast` followed by a `const_cast`,
- a `reinterpret_cast` (7.6.1.10), or
— a reinterpret_cast followed by a const_cast,
can be performed using the cast notation of explicit type conversion. The same semantic restrictions
and behaviors apply, with the exception that in performing a static_cast in the following situations the
conversion is valid even if the base class is inaccessible:

— a pointer to an object of derived class type or an lvalue or rvalue of derived class type may be explicitly
converted to a pointer or reference to an unambiguous base class type, respectively;

— a pointer to member of derived class type may be explicitly converted to a pointer to member of an
unambiguous non-virtual base class type;

— a pointer to an object of an unambiguous non-virtual base class type, a glvalue of an unambiguous
non-virtual base class type, or a pointer to member of an unambiguous non-virtual base class type
may be explicitly converted to a pointer, a reference, or a pointer to member of a derived class type,
respectively.

If a conversion can be interpreted in more than one of the ways listed above, the interpretation that appears
first in the list is used, even if a cast resulting from that interpretation is ill-formed. If a conversion can be
interpreted in more than one way as a static_cast followed by a const_cast, the conversion is ill-formed.

[Example 1:

```cpp
struct A { }
struct I1 : A { }
struct I2 : A { }
struct D : I1, I2 { }
A* foo(D* p) {
    return (A*) (p);
} // ill-formed static_cast interpretation
```
—end example]

5 The operand of a cast using the cast notation can be a prvalue of type “pointer to incomplete class type”.
The destination type of a cast using the cast notation can be “pointer to incomplete class type”. If both the
operand and destination types are class types and one or both are incomplete, it is unspecified whether the
static_cast or the reinterpret_cast interpretation is used, even if there is an inheritance relationship
between the two classes.

[Note 2: For example, if the classes were defined later in the translation unit, a multi-pass compiler would be permitted
to interpret a cast between pointers to the classes as if the class types were complete at the point of the cast. — end note]

7.6.4 Pointer-to-member operators

1 The pointer-to-member operators \( \texttt{->}\star \) and \( \texttt{.}\star \) group left-to-right.

\[
\text{pm-expression}:
\begin{align*}
\text{cast-expression} \\
\text{pm-expression} \ \texttt{.}\star \text{cast-expression} \\
\text{pm-expression} \ \texttt{->}\star \text{cast-expression}
\end{align*}
\]

2 The binary operator \( \texttt{.}\star \) binds its second operand, which shall be of type “pointer to member of \( T \)” to its first
operand, which shall be a glvalue of class \( T \) or of a class of which \( T \) is an unambiguous and accessible base
class. The result is an object or a function of the type specified by the second operand.

3 The binary operator \( \texttt{->}\star \) binds its second operand, which shall be of type “pointer to member of \( T \)” to its first
operand, which shall be of type “pointer to \( U \)” where \( U \) is either \( T \) or a class of which \( T \) is an unambiguous
and accessible base class. The expression \( E1\rightarrow\star E2 \) is converted into the equivalent form \( \texttt{(*(E1))} .\star E2 \).

4 Abbreviating \( \text{pm-expression}.\star\text{cast-expression} \) as \( E1 .\star E2 \), \( E1 \) is called the object expression. If the result of \( E1 \)
is an object whose type is not similar to the type of \( E1 \), or whose most derived object does not contain the
member to which \( E2 \) refers, the behavior is undefined. The expression \( E1 \) is sequenced before the expression
\( E2 \).

5 The restrictions on cv-qualification, and the manner in which the cv-qualifiers of the operands are combined
to produce the cv-qualifiers of the result, are the same as the rules for \( E1 . E2 \) given in 7.6.1.5.

[Note 1: It is not possible to use a pointer to member that refers to a mutable member to modify a const class object.
For example,
struct S {
    S() : i(0) { }
    mutable int i;
};

void f()
{
    const S cs;
    int S::* pm = &S::i;  // pm refers to mutable member S::i
    cs.*pm = 88;         // error: cs is a const object
}
—end note]

If the result of .* or ->* is a function, then that result can be used only as the operand for the function call operator () .

[Example 1:
    (ptr_to_obj->*ptr_to_mfct)(10);
] calls the member function denoted by ptr_to_mfct for the object pointed to by ptr_to_obj. —end example]

In a .* expression whose object expression is an rvalue, the program is ill-formed if the second operand is a pointer to member function whose ref-qualifier is &, unless its cv-qualifier-seq is const. In a .* expression whose object expression is an lvalue, the program is ill-formed if the second operand is a pointer to member function whose ref-qualifier is &. The result of a .* expression whose second operand is a pointer to a data member is an lvalue if the first operand is an lvalue and an xvalue otherwise. The result of a .* expression whose second operand is a pointer to a member function is a prvalue. If the second operand is the null member pointer value (7.3.13), the behavior is undefined.

7.6.5 Multiplicative operators [expr.mul]

1 The multiplicative operators *, /, and % group left-to-right.

    multiplicative-expression:
    pm-expression
    pm-expression * pm-expression
    pm-expression / pm-expression
    pm-expression % pm-expression

2 The operands of * and / shall have arithmetic or unscoped enumeration type; the operands of % shall have integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed on the operands and determine the type of the result.

3 The binary * operator indicates multiplication.

4 The binary / operator yields the quotient, and the binary % operator yields the remainder from the division of the first expression by the second. If the second operand of / or % is zero the behavior is undefined. For integral operands the / operator yields the algebraic quotient with any fractional part discarded;68 if the quotient a/b is representable in the type of the result, (a/b)*b + a%b is equal to a; otherwise, the behavior of both a/b and a%b is undefined.

7.6.6 Additive operators [expr.add]

1 The additive operators + and - group left-to-right. The usual arithmetic conversions (7.4) are performed for operands of arithmetic or enumeration type.

    additive-expression:
    pm-expression
    additive-expression + multiplicative-expression
    additive-expression - multiplicative-expression

For addition, either both operands shall have arithmetic or unscoped enumeration type, or one operand shall be a pointer to a completely-defined object type and the other shall have integral or unscoped enumeration type.

2 For subtraction, one of the following shall hold:

   (2.1) — both operands have arithmetic or unscoped enumeration type; or

68) This is often called truncation towards zero.
© ISO/IEC N4944

(2.2) — both operands are pointers to cv-qualified or cv-unqualified versions of the same completely-defined object type; or

(2.3) — the left operand is a pointer to a completely-defined object type and the right operand has integral or unscoped enumeration type.

3 The result of the binary + operator is the sum of the operands. The result of the binary - operator is the difference resulting from the subtraction of the second operand from the first.

4 When an expression J that has integral type is added to or subtracted from an expression P of pointer type, the result has the type of P.

(4.1) — If P evaluates to a null pointer value and J evaluates to 0, the result is a null pointer value.

(4.2) — Otherwise, if P points to an array element i of an array object x with n elements (9.3.4.5),69 the expressions P + J and J + P (where J has the value j) point to the (possibly-hypothetical) array element i + j of x if 0 ≤ i + j ≤ n and the expression P - J points to the (possibly-hypothetical) array element i - j of x if 0 ≤ i - j ≤ n.

(4.3) — Otherwise, the behavior is undefined.

[Note 1: Adding a value other than 0 or 1 to a pointer to a base class subobject, a member subobject, or a complete object results in undefined behavior. — end note]

5 When two pointer expressions P and Q are subtracted, the type of the result is an implementation-defined signed integral type; this type shall be the same type that is defined as std::ptrdiff_t in the <cstddef> header (17.2.4).

(5.1) — If P and Q both evaluate to null pointer values, the result is 0.

(5.2) — Otherwise, if P and Q point to, respectively, array elements i and j of the same array object x, the expression P - Q has the value i - j.

(5.3) — Otherwise, the behavior is undefined.

[Note 2: If the value i - j is not in the range of representable values of type std::ptrdiff_t, the behavior is undefined. — end note]

6 For addition or subtraction, if the expressions P or Q have type “pointer to cv T”, where T and the array element type are not similar (7.3.6), the behavior is undefined.

[Example 1:

```c
int arr[5] = {1, 2, 3, 4, 5};
unsigned int *p = reinterpret_cast<unsigned int*>(arr + 1);
unsigned int k = *p; // OK, value of k is 2 (7.3.2)
unsigned int *q = p + 1; // undefined behavior: p points to an int, not an unsigned int object
```

—end example]

7.6.7 Shift operators [expr.shift]

1 The shift operators << and >> group left-to-right.

```
shift-expression:
  additive-expression
  shift-expression << additive-expression
  shift-expression >> additive-expression
```

The operands shall be of integral or unscoped enumeration type and integral promotions are performed. The type of the result is that of the promoted left operand. The behavior is undefined if the right operand is negative, or greater than or equal to the width of the promoted left operand.

2 The value of E1 << E2 is the unique value congruent to E1 × 2E2 modulo 2N, where N is the width of the type of the result.

[Note 1: E1 is left-shifted E2 bit positions; vacated bits are zero-filled. — end note]

3 The value of E1 >> E2 is E1/2E2, rounded down.

[Note 2: E1 is right-shifted E2 bit positions. Right-shift on signed integral types is an arithmetic right shift, which performs sign-extension. — end note]

69) As specified in 6.8.4, an object that is not an array element is considered to belong to a single-element array for this purpose and a pointer past the last element of an array of n elements is considered to be equivalent to a pointer to a hypothetical array element n for this purpose.

§ 7.6.7 146
The expression \( E_1 \) is sequenced before the expression \( E_2 \).

### 7.6.8 Three-way comparison operator

The three-way comparison operator groups left-to-right.

```plaintext
compare-expression:
  shift-expression
compare-expression <= shift-expression
```

1. The expression \( p \lll q \) is a prvalue indicating whether \( p \) is less than, equal to, greater than, or incomparable with \( q \).
2. If one of the operands is of type `bool` and the other is not, the program is ill-formed.
3. If both operands have arithmetic types, or one operand has integral type and the other operand has unscoped enumeration type, the usual arithmetic conversions (7.4) are applied to the operands. Then:
   - If a narrowing conversion (9.4.5) is required, other than from an integral type to a floating-point type, the program is ill-formed.
   - Otherwise, if the operands have integral type, the result is of type `std::strong_ordering`. The result is `std::strong_ordering::equal` if both operands are arithmetically equal, `std::strong_ordering::less` if the first operand is arithmetically less than the second operand, and `std::strong_ordering::greater` otherwise.
   - Otherwise, the operands have floating-point type, and the result is of type `std::partial_ordering`. The expression \( a \lll b \) yields `std::partial_ordering::less` if \( a \) is less than \( b \), `std::partial_ordering::greater` if \( a \) is greater than \( b \), `std::partial_ordering::equivalent` if \( a \) is equivalent to \( b \), and `std::partial_ordering::unordered` otherwise.
4. If both operands have the same enumeration type \( E \), the operator yields the result of converting the operands to the underlying type of \( E \) and applying \( \lll \) to the converted operands.
5. If at least one of the operands is of object pointer type and the other operand is of object pointer or array type, array-to-pointer conversions (7.3.3), pointer conversions (7.3.12), and qualification conversions (7.3.6) are performed on both operands to bring them to their composite pointer type (7.2.2). After the conversions, the operands shall have the same type.

### 7.6.9 Relational operators

The relational operators group left-to-right.

```plaintext
relational-expression:
  compare-expression
relational-expression < compare-expression
relational-expression <= compare-expression
relational-expression > compare-expression
relational-expression >= compare-expression
```

1. The relational operators group left-to-right.

[Example 1: \( a \lll b \lll c \) means \( (a \lll b) \lll c \) and not \( (a \lll b) \&\& (b \lll c) \). — end example]
The lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the operands. The comparison is deprecated if both operands were of array type prior to these conversions (D.4).

2 The converted operands shall have arithmetic, enumeration, or pointer type. The operators < (less than), > (greater than), <= (less than or equal to), and >= (greater than or equal to) all yield \textit{false} or \textit{true}. The type of the result is \textit{bool}.

3 The usual arithmetic conversions (7.4) are performed on operands of arithmetic or enumeration type. If both operands are pointers, pointer conversions (7.3.12) and qualification conversions (7.3.6) are performed to bring them to their composite pointer type (7.2.2). After conversions, the operands shall have the same type.

4 The result of comparing unequal pointers to objects\(^{70}\) is defined in terms of a partial order consistent with the following rules:

\begin{enumerate}[\item\quad(4.1)]
\item If two pointers point to different elements of the same array, or to subobjects thereof, the pointer to the element with the higher subscript is required to compare greater.
\item If two pointers point to different non-static data members of the same object, or to subobjects of such members, recursively, the pointer to the later declared member is required to compare greater provided neither member is a subobject of zero size and their class is not a union.
\item Otherwise, neither pointer is required to compare greater than the other.
\end{enumerate}

5 If two operands \(p\) and \(q\) compare equal (7.6.10), \(p\approx q\) and \(p\gg q\) both yield \textit{true} and \(p<q\) and \(p\gg q\) both yield \textit{false}. Otherwise, if a pointer to object \(p\) compares greater than a pointer \(q\), \(p\gg q\), \(p>q\), \(q<p\), and \(q\ll p\) all yield \textit{true} and \(p<q\), \(p<q\), \(q<q\), and \(q<p\) all yield \textit{false}. Otherwise, the result of each of the operators is unspecified.

\begin{note} A relational operator applied to unequal function pointers or to unequal pointers to \textit{void} yields an unspecified result. \end{note}

6 If both operands (after conversions) are of arithmetic or enumeration type, each of the operators shall yield \textit{true} if the specified relationship is true and \textit{false} if it is false.

### 7.6.10 Equality operators

\begin{verbatim}
equality-expression:
    relational-expression
    equality-expression == relational-expression
    equality-expression != relational-expression
\end{verbatim}

1 The \(==\) (equal to) and the \(!=\) (not equal to) operators group left-to-right. The lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the operands. The comparison is deprecated if both operands were of array type prior to these conversions (D.4).

2 The converted operands shall have arithmetic, enumeration, pointer, or pointer-to-member type, or type \textit{std::nullptr_t}. The operators \(==\) and \(!=\) both yield \textit{true} or \textit{false}, i.e., a result of type \textit{bool}. In each case below, the operands shall have the same type after the specified conversions have been applied.

3 If at least one of the operands is a pointer, pointer conversions (7.3.12), function pointer conversions (7.3.14), and qualification conversions (7.3.6) are performed on both operands to bring them to their composite pointer type (7.2.2). Comparing pointers is defined as follows:

\begin{enumerate}[\item\quad(3.1)]
\item If one pointer represents the address of a complete object, and another pointer represents the address one past the last element of a different complete object,\(^{71}\) the result of the comparison is unspecified.
\item Otherwise, if the pointers are both null, both point to the same function, or both represent the same address (6.8.4), they compare equal.
\item Otherwise, the pointers compare unequal.
\end{enumerate}

4 If at least one of the operands is a pointer to member, pointer-to-member conversions (7.3.13), function pointer conversions (7.3.14), and qualification conversions (7.3.6) are performed on both operands to bring them to their composite pointer type (7.2.2). Comparing pointers to members is defined as follows:

\begin{enumerate}[\item\quad(4.1)]
\item If two pointers to members are both the null member pointer value, they compare equal.
\end{enumerate}

\begin{note} As specified in 6.8.4, an object that is not an array element is considered to belong to a single-element array for this purpose and a pointer past the last element of an array of \(n\) elements is considered to be equivalent to a pointer to a hypothetical array element \(n\) for this purpose.\end{note}

\begin{note} As specified in 6.8.4, an object that is not an array element is considered to belong to a single-element array for this purpose.\end{note}

\[\text{§ 7.6.10}\]

N4944
(4.2) If only one of two pointers to members is the null member pointer value, they compare unequal.
(4.3) If either is a pointer to a virtual member function, the result is unspecified.
(4.4) If one refers to a member of class C1 and the other refers to a member of a different class C2, where neither is a base class of the other, the result is unspecified.

[Example 1:
  struct A {
    int x;
  };
  struct B : A { int x; };
  struct C : A { int x; };

  int A::*bx = (int(A::*))&B::x;
  int A::*cx = (int(A::*))&C::x;

  bool b1 = (bx == cx); // unspecified
  —end example]

(4.5) If both refer to (possibly different) members of the same union (11.5), they compare equal.
(4.6) Otherwise, two pointers to members compare equal if they would refer to the same member of the same most derived object (6.7.2) or the same subobject if indirection with a hypothetical object of the associated class type were performed, otherwise they compare unequal.

[Example 2:
  struct B {
    int f();
  };
  struct L : B { };
  struct R : B { };
  struct D : L, R { };

  int (B::*pb)() = &B::f;
  int (L::*pl)() = pb;
  int (R::*pr)() = pb;
  int (D::*pdl)() = pl;
  int (D::*pdr)() = pr;

  bool x = (pdl == pdr); // false
  bool y = (pb == pl); // true
  —end example]

5 Two operands of type std::nullptr_t or one operand of type std::nullptr_t and the other a null pointer constant compare equal.
6 If two operands compare equal, the result is true for the == operator and false for the != operator. If two operands compare unequal, the result is false for the == operator and true for the != operator. Otherwise, the result of each of the operators is unspecified.
7 If both operands are of arithmetic or enumeration type, the usual arithmetic conversions (7.4) are performed on both operands; each of the operators shall yield true if the specified relationship is true and false if it is false.

7.6.11 Bitwise AND operator

[expr.bit.and]

and-expression:
equality-expression
and-expression & equality-expression

1 The & operator groups left-to-right. The operands shall be of integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed. Given the coefficients x_i and y_i of the base-2 representation (6.8.2) of the converted operands x and y, the coefficient r_i of the base-2 representation of the result r is 1 if both x_i and y_i are 1, or 0 otherwise.
[Note 1: The result is the bitwise AND function of the operands. — end note]

7.6.12 Bitwise exclusive OR operator

[expr.xor]
exclusive-or-expression:
  and-expression
exclusive-or-expression ^ and-expression

1 The `^` operator groups left-to-right. The operands shall be of integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed. Given the coefficients $x_i$ and $y_i$ of the base-2 representation (6.8.2) of the converted operands $x$ and $y$, the coefficient $r_i$ of the base-2 representation of the result $r$ is 1 if either (but not both) of $x_i$ and $y_i$ is 1, and 0 otherwise.

[Note 1: The result is the bitwise exclusive OR function of the operands. — end note]

### 7.6.13 Bitwise inclusive OR operator

inclusive-or-expression:
  exclusive-or-expression
inclusive-or-expression | inclusive-or-expression

1 The `|` operator groups left-to-right. The operands shall be of integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed. Given the coefficients $x_i$ and $y_i$ of the base-2 representation (6.8.2) of the converted operands $x$ and $y$, the coefficient $r_i$ of the base-2 representation of the result $r$ is 1 if at least one of $x_i$ and $y_i$ is 1, and 0 otherwise.

[Note 1: The result is the bitwise inclusive OR function of the operands. — end note]

### 7.6.14 Logical AND operator

logical-and-expression:
  inclusive-or-expression
logical-and-expression && inclusive-or-expression

1 The `&&` operator groups left-to-right. The operands are both contextually converted to `bool` (7.3). The result is `true` if both operands are `true` and `false` otherwise. Unlike `&`, `&&` guarantees left-to-right evaluation: the second operand is not evaluated if the first operand is `false`.

2 The result is a `bool`. If the second expression is evaluated, the first expression is sequenced before the second expression (6.9.1).

### 7.6.15 Logical OR operator

logical-or-expression:
  logical-and-expression
logical-or-expression || logical-and-expression

1 The `||` operator groups left-to-right. The operands are both contextually converted to `bool` (7.3). The result is `true` if either of its operands is `true`, and `false` otherwise. Unlike `|`, `||` guarantees left-to-right evaluation; moreover, the second operand is not evaluated if the first operand evaluates to `true`.

2 The result is a `bool`. If the second expression is evaluated, the first expression is sequenced before the second expression (6.9.1).

### 7.6.16 Conditional operator

conditional-expression:
  logical-or-expression
conditional-expression ? expression : assignment-expression

1 Conditional expressions group right-to-left. The first expression is contextually converted to `bool` (7.3). It is evaluated and if it is `true`, the result of the conditional expression is the value of the second expression, otherwise that of the third expression. Only one of the second and third expressions is evaluated. The first expression is sequenced before the second or third expression (6.9.1).

2 If either the second or the third operand has type `void`, one of the following shall hold:

1. The second or the third operand (but not both) is a (possibly parenthesized) `throw-expression` (7.6.18); the result is of the type and value category of the other. The `conditional-expression` is a bit-field if that operand is a bit-field.

2. Both the second and the third operands have type `void`; the result is of type `void` and is a prvalue.

[Note 1: This includes the case where both operands are `throw-expressions`. — end note]
Otherwise, if the second and third operand are glvalue bit-fields of the same value category and of types \textit{cv1 T} and \textit{cv2 T}, respectively, the operands are considered to be of type \textit{cv T} for the remainder of this subclause, where \textit{cv} is the union of \textit{cv1} and \textit{cv2}.

Otherwise, if the second and third operand have different types and either has (possibly cv-qualified) class type, or if both are glvalues of the same value category and the same type except for cv-qualification, an attempt is made to form an implicit conversion sequence (12.2.4.2) from each of those operands to the type of the other.

[Note 2: Properties such as access, whether an operand is a bit-field, or whether a conversion function is deleted are ignored for that determination. — end note]

Attempts are made to form an implicit conversion sequence from an operand expression \textit{E1} of type \textit{T1} to a target type related to the type \textit{T2} of the operand expression \textit{E2} as follows:

\begin{enumerate}
\item If \textit{E2} is an lvalue, the target type is “lvalue reference to \textit{T2}”, but an implicit conversion sequence can only be formed if the reference would bind directly (9.4.4) to a glvalue.
\item If \textit{E2} is an xvalue, the target type is “rvalue reference to \textit{T2}”, but an implicit conversion sequence can only be formed if the reference would bind directly.
\item If \textit{E2} is a prvalue or if neither of the conversion sequences above can be formed and at least one of the operands has (possibly cv-qualified) class type:
  \begin{enumerate}
  \item if \textit{T1} and \textit{T2} are the same class type (ignoring cv-qualification) and \textit{T2} is at least as cv-qualified as \textit{T1}, the target type is \textit{T2},
  \item otherwise, if \textit{T2} is a base class of \textit{T1}, the target type is \textit{cv1 T2}, where \textit{cv1} denotes the cv-qualifiers of \textit{T1},
  \item otherwise, the target type is the type that \textit{E2} would have after applying the lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions.
  \end{enumerate}
\end{enumerate}

Using this process, it is determined whether an implicit conversion sequence can be formed from the second operand to the target type determined for the third operand, and vice versa. If both sequences can be formed, or one can be formed but it is the ambiguous conversion sequence, the program is ill-formed. If no conversion sequence can be formed, the operands are left unchanged and further checking is performed as described below. Otherwise, if exactly one conversion sequence can be formed, that conversion is applied to the chosen operand and the converted operand is used in place of the original operand for the remainder of this subclause.

[Note 3: The conversion might be ill-formed even if an implicit conversion sequence could be formed. — end note]

If the second and third operands are glvalues of the same value category and have the same type, the result is of that type and value category and it is a bit-field if the second or the third operand is a bit-field, or if both are bit-fields.

Otherwise, the result is a prvalue. If the second and third operands do not have the same type, and either has (possibly cv-qualified) class type, overload resolution is used to determine the conversions (if any) to be applied to the operands (12.2.2.3, 12.5). If the overload resolution fails, the program is ill-formed. Otherwise, the conversions thus determined are applied, and the converted operands are used in place of the original operands for the remainder of this subclause.

Lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are performed on the second and third operands. After those conversions, one of the following shall hold:

\begin{enumerate}
\item The second and third operands have the same type; the result is of that type and the result object is initialized using the selected operand.
\item The second and third operands have arithmetic or enumeration type; the usual arithmetic conversions (7.4) are performed to bring them to a common type, and the result is of that type.
\item One or both of the second and third operands have pointer type; pointer conversions (7.3.12), function pointer conversions (7.3.14), and qualification conversions (7.3.6) are performed to bring them to their composite pointer type (7.2.2). The result is of the composite pointer type.
\item One or both of the second and third operands have pointer-to-member type; pointer to member conversions (7.3.13), function pointer conversions (7.3.14), and qualification conversions (7.3.6) are performed to bring them to their composite pointer type (7.2.2). The result is of the composite pointer type.
\end{enumerate}

§ 7.6.16
Both the second and third operands have type `std::nullptr_t` or one has that type and the other is a null pointer constant. The result is of type `std::nullptr_t`.

### 7.6.17 Yielding a value

**yield-expression**

- `co_yield assignment-expression`
- `co_yield braced-init-list`

A *yield-expression* shall appear only within a suspension context of a function (7.6.2.4). Let `e` be the operand of the *yield-expression* and `p` be an lvalue naming the promise object of the enclosing coroutine (9.5.4), then the *yield-expression* is equivalent to the expression `co_await p.yield_value(e)`.

#### Example 1:

```cpp
template <typename T>
struct my_generator {
    struct promise_type {
        T current_value;
        /* ... */
        auto yield_value(T v) {
            current_value = std::move(v);
            return std::suspend_always{};
        }
    }
    struct iterator { /* ... */ };
    iterator begin();
    iterator end();
};

my_generator<pair<int,int>> g1() {
    for (int i = 0; i < 10; ++i) co_yield {i,i};
}
my_generator<pair<int,int>> g2() {
    for (int i = 0; i < 10; ++i) co_yield make_pair(i,i);
}

auto f(int x = co_yield 5);
// error: yield-expression outside of function suspension context
int a[] = { co_yield 1 };  // error: yield-expression outside of function suspension context

int main() {
    auto r1 = g1();
    auto r2 = g2();
    assert(std::equal(r1.begin(), r1.end(), r2.begin(), r2.end()));
}
```

### 7.6.18 Throwing an exception

**throw-expression**

- `throw assignment-expression`
- `throw opt`

1. A *throw-expression* is of type `void`.
2. Evaluating a *throw-expression* with an operand throws an exception (14.2); the type of the exception object is determined by removing any top-level `cv-qualifiers` from the static type of the operand and adjusting the type from “array of `T`” or function type `T` to “pointer to `T`”.
3. A *throw-expression* with no operand rethrows the currently handled exception (14.4). The exception is reactivated with the existing exception object; no new exception object is created. The exception is no longer considered to be caught.

#### Example 1: An exception handler that cannot completely handle the exception itself can be written like this:

```cpp
try {
    // ...
} catch (...) {
    // catch all exceptions
    // respond (partially) to exception
    throw;  // pass the exception to some other handler
```
If no exception is presently being handled, evaluating a throw-expression with no operand calls std::terminate() (14.6.2).

7.6.19 Assignment and compound assignment operators [expr.ass]

The assignment operator (=) and the compound assignment operators all group right-to-left. All require a modifiable lvalue as their left operand; their result is an lvalue of the type of the left operand, referring to the left operand. The result in all cases is a bit-field if the left operand is a bit-field. In all cases, the assignment is sequenced after the value computation of the right and left operands, and before the value computation of the assignment expression. The right operand is sequenced before the left operand. With respect to an indeterminately-sequenced function call, the operation of a compound assignment is a single evaluation.

[Note 1: Therefore, a function call cannot intervene between the lvalue-to-rvalue conversion and the side effect associated with any single compound assignment operator. — end note]

assignment-expression:
    conditional-expression
    yield-expression
    throw-expression
    logical-or-expression assignment-operator initializer-clause

assignment-operator: one of
    =  *= /= %= += -= >>= <<= &= ^= |=

In simple assignment (=), the object referred to by the left operand is modified (3.1) by replacing its value with the result of the right operand.

If the right operand is an expression, it is implicitly converted (7.3) to the cv-unqualified type of the left operand.

When the left operand of an assignment operator is a bit-field that cannot represent the value of the expression, the resulting value of the bit-field is implementation-defined.

An assignment whose left operand is of a volatile-qualified type is deprecated (D.5) unless the (possibly parenthesized) assignment is a discarded-value expression or an unevaluated operand (7.2.3).

The behavior of an expression of the form E1 op = E2 is equivalent to E1 = E1 op E2 except that E1 is evaluated only once.

[Note 2: The object designated by E1 is accessed twice. — end note]

For += and -=, E1 shall either have arithmetic type or be a pointer to a possibly cv-qualified completely-defined object type. In all other cases, E1 shall have arithmetic type.

If the value being stored in an object is read via another object that overlaps in any way the storage of the first object, then the overlap shall be exact and the two objects shall have the same type, otherwise the behavior is undefined.

[Note 3: This restriction applies to the relationship between the left and right sides of the assignment operation; it is not a statement about how the target of the assignment can be aliased in general. See 7.2.1. — end note]

A braced-init-list may appear on the right-hand side of

(8.1) — an assignment to a scalar, in which case the initializer list shall have at most a single element. The meaning of x = {v}, where T is the scalar type of the expression x, is that of x = T{v}. The meaning of x = {} is x = T{}.

(8.2) — an assignment to an object of class type, in which case the initializer list is passed as the argument to the assignment operator function selected by overload resolution (12.4.3.2, 12.2).

[Example 1:

```cpp
complex<double> z;
z = { 1,2 }; // meaning z.operator=((1,2))
z += { 1, 2 }; // meaning z.operator+=(1,2)
int a, b;
a = b = { 1 }; // meaning a=b=1;
a = { 1 } = b; // syntax error
```

— end example]
7.6.20  Comma operator

The comma operator groups left-to-right.

<expression>
  <assignment-expression>
  expression, <assignment-expression>
</expression>

A pair of expressions separated by a comma is evaluated left-to-right; the left expression is a discarded-value expression (7.2). The left expression is sequenced before the right expression (6.9.1). The type and value of the result are the type and value of the right operand; the result is of the same value category as its right operand, and is a bit-field if its right operand is a bit-field.

[Note 1: In contexts where the comma token is given special meaning (e.g., function calls (7.6.1.3), subscript expressions (7.6.1.2), lists of initializers (9.4), or template-argument-lists (13.3)), the comma operator as described in this subclause can appear only in parentheses.

[Example 1:
  \f(a, (t=3, t+2), c);
has three arguments, the second of which has the value 5. — end example]
— end note]

7.7  Constant expressions

Certain contexts require expressions that satisfy additional requirements as detailed in this subclause; other contexts have different semantics depending on whether or not an expression satisfies these requirements. Expressions that satisfy these requirements, assuming that copy elision (11.9.6) is not performed, are called constant expressions.

[Note 1: Constant expressions can be evaluated during translation. — end note]

<constant-expression>
  <conditional-expression>
</constant-expression>

2 A variable or temporary object \( o \) is constant-initialized if

(2.1) — either it has an initializer or its default-initialization results in some initialization being performed, and
(2.2) — the full-expression of its initialization is a constant expression when interpreted as a constant-expression, except that if \( o \) is an object, that full-expression may also invoke constexpr constructors for \( o \) and its subobjects even if those objects are of non-literal class types.

[Note 2: Such a class can have a non-trivial destructor. Within this evaluation, \( \text{std::is_constant_evaluated}() \) (21.3.11) returns \( \text{true} \). — end note]

3 A variable is potentially-constant if it is constexpr or it has reference or non-volatile const-qualified integral or enumeration type.

4 A constant-initialized potentially-constant variable \( V \) is usable in constant expressions at a point \( P \) if \( V \)'s initializing declaration \( D \) is reachable from \( P \) and

(4.1) — \( V \) is constexpr,
(4.2) — \( V \) is not initialized to a TU-local value, or
(4.3) — \( P \) is in the same translation unit as \( D \).

An object or reference is usable in constant expressions if it is

(4.4) — a variable that is usable in constant expressions, or
(4.5) — a template parameter object (13.2), or
(4.6) — a string literal object (5.13.5), or
(4.7) — a temporary object of non-volatile const-qualified literal type whose lifetime is extended (6.7.7) to that of a variable that is usable in constant expressions, or
(4.8) — a non-mutable subobject or reference member of any of the above.

5 An expression \( E \) is a core constant expression unless the evaluation of \( E \), following the rules of the abstract machine (6.9.1), would evaluate one of the following:

(5.1) — this (7.5.2), except
(5.1.1) — in a constexpr function (9.2.6) that is being evaluated as part of \( E \) or

§ 7.7
— when appearing as the postfix-expression of an implicit or explicit class member access expression (7.6.1.5);

— a control flow that passes through a declaration of a variable with static (6.7.5.2) or thread (6.7.5.3) storage duration, unless that variable is usable in constant expressions;

[Example 1:
```c
constexpr char test() {
    static const int x = 5;
    static constexpr char c[] = "Hello World";
    return *(c + x);
}
static_assert(' ' == test());
```
— end example]

— an invocation of a non-constexpr function;\(^{72}\)

— an invocation of an undefined constexpr function;

— an invocation of an instantiated constexpr function that is not constexpr-suitable;

— an invocation of a virtual function (11.7.3) for an object whose dynamic type is constexpr-unknown;

— an expression that would exceed the implementation-defined limits (see Annex B);

— an operation that would have undefined behavior as specified in Clause 4 through Clause 15, excluding 9.12.3;\(^ {73}\)

— an lvalue-to-rvalue conversion (7.3.2) unless it is applied to

— a non-volatile glvalue that refers to an object that is usable in constant expressions, or

— a non-volatile glvalue of literal type that refers to a non-volatile object whose lifetime began within the evaluation of \(E\);

— an lvalue-to-rvalue conversion that is applied to a glvalue that refers to a non-active member of a union or a subobject thereof;

— an lvalue-to-rvalue conversion that is applied to an object with an indeterminate value (6.7.4);

— an invocation of an implicitly-defined copy/move constructor or copy/move assignment operator for a union whose active member (if any) is mutable, unless the lifetime of the union object began within the evaluation of \(E\);

— in a lambda-expression, a reference to this or to a variable with automatic storage duration defined outside that lambda-expression, where the reference would be an odr-use (6.3, 7.5.5);

[Example 2:
```c
void g() {
    const int n = 0;
    [=] {
        constexpr int i = n; // OK, n is not odr-used here
        constexpr int j = *\&n; // error: \&n would be an odr-use of n
    };
}
```
— end example]

[Note 3: If the odr-use occurs in an invocation of a function call operator of a closure type, it no longer refers to this or to an enclosing automatic variable due to the transformation (7.5.5.3) of the id-expression into an access of the corresponding data member.

[Example 3:
```c
auto monad = [] (auto v) { return [=] { return v; }; }
auto bind = [] (auto m) {
    return [=] (auto fvm) { return fvm(m()); }
};
```

\(^ {72}\) Overload resolution (12.2) is applied as usual.

\(^ {73}\) This includes, for example, signed integer overflow (7.1), certain pointer arithmetic (7.6.6), division by zero (7.6.5), or certain shift operations (7.6.7).
// OK to capture objects with automatic storage duration created during constant expression evaluation.
static_assert(bind(monad(2))(monad)() == monad(2)());
— end example
— end note

(5.14) — a conversion from type cv void* to a pointer-to-object type;
(5.15) — a reinterpret_cast (7.6.1.10);
(5.16) — a modification of an object (7.6.19, 7.6.16, 7.6.2.3) unless it is applied to a non-volatile value of literal type that refers to a non-volatile object whose lifetime began within the evaluation of E;
(5.17) — an invocation of a destructor (11.4.7) or a function call whose postfix-expression names a pseudo-destructor (7.6.1.3), in either case for an object whose lifetime did not begin within the evaluation of E;
(5.18) — a new-expression (7.6.2.8), unless the selected allocation function is a replaceable global allocation function (17.6.3.2, 17.6.3.3) and the allocated storage is deallocated within the evaluation of E;
(5.19) — a delete-expression (7.6.2.9), unless it deallocates a region of storage allocated within the evaluation of E;
(5.20) — a call to an instance of std::allocator<T>::allocate (20.2.10.2), unless the allocated storage is deallocated within the evaluation of E;
(5.21) — a call to an instance of std::allocator<T>::deallocate (20.2.10.2), unless it deallocates a region of storage allocated within the evaluation of E;
(5.22) — an await-expression (7.6.2.4);
(5.23) — a yield-expression (7.6.17);
(5.24) — a three-way comparison (7.6.8), relational (7.6.9), or equality (7.6.10) operator where the result is unspecified;
(5.25) — a throw-expression (7.6.18);
(5.26) — a dynamic_cast (7.6.1.7) or typeid (7.6.1.8) expression on a glvalue that refers to an object whose dynamic type is constexpr-unknown or that would throw an exception;
(5.27) — an asm-declaration (9.10);
(5.28) — an invocation of the va_arg macro (17.13.2);
(5.29) — a non-constant library call (3.35); or
(5.30) — a goto statement (8.7.6).

It is unspecified whether E is a core constant expression if E satisfies the constraints of a core constant expression, but evaluation of E would evaluate

(5.31) — an operation that has undefined behavior as specified in Clause 16 through Clause 33,
(5.32) — an invocation of the va_start macro (17.13.2), or
(5.33) — a statement with an assumption (9.12.3) whose converted conditional-expression, if evaluated where the assumption appears, would not disqualify E from being a core constant expression and would not evaluate to true.

[Note 4: E is not disqualified from being a core constant expression if the hypothetical evaluation of the converted conditional-expression would disqualify E from being a core constant expression. — end note]

Example 4:

```cpp
int x; // not constant
struct A {
constexpr A(bool b) : m(b?42:x) {} };
int m;
constexpr int v = A(true).m; // OK, constructor call initializes m with the value 42
constexpr int w = A(false).m; // error: initializer for m is x, which is non-constant
constexpr int f1(int k) {
constexpr int x = k; // error: x is not initialized by a constant expression
```
// because lifetime of k began outside the initializer of x

constexpr int f2(int k) {
  int x = k; // OK, not required to be a constant expression
  return x; // because x is not constexpr
}

constexpr int incr(int &n) {
  return ++n;
}

constexpr int g(int k) {
  constexpr int x = incr(k); // error: incr(k) is not a core constant expression
  return x; // because lifetime of k began outside the expression incr(k)
}

constexpr int h(int k) {
  int x = incr(k); // OK, incr(k) is not required to be a core constant expression
  return x;
}

constexpr int y = h(1); // OK, initializes y with the value 2
// h(1) is a core constant expression because
// the lifetime of k begins inside h(1)

—end example—

6 For the purposes of determining whether an expression E is a core constant expression, the evaluation of the body of a member function of std::allocator<T> as defined in 20.2.10.2, where T is a literal type, is ignored. Similarly, the evaluation of the body of std::construct_at or std::ranges::construct_at is considered to include only the underlying constructor call if the first argument (of type T*) points to storage allocated with std::allocator<T> or to an object whose lifetime began within the evaluation of E.

7 For the purposes of determining whether E is a core constant expression, the evaluation of a call to a trivial copy/move constructor or copy/move assignment operator of a union is considered to copy/move the active member of the union, if any.

[Note 5: The copy/move of the active member is trivial. —end note]

8 During the evaluation of an expression E as a core constant expression, all id-expressions and uses of *this that refer to an object or reference whose lifetime did not begin with the evaluation of E are treated as referring to a specific instance of that object or reference whose lifetime and that of all subobjects (including all union members) includes the entire constant evaluation. For such an object that is not usable in constant expressions, the dynamic type of the object is constexpr-unknown. For such a reference that is not usable in constant expressions, the reference is treated as binding to an unspecified object of the referenced type whose lifetime and that of all subobjects includes the entire constant evaluation and whose dynamic type is constexpr-unknown.

[Example 5:

```cpp
template <typename T, size_t N>
constexpr size_t array_size(T (&)[N]) {
  return N;
}

void use_array(int const (&gold_medal_mel)[2]) {
  constexpr auto gold = array_size(gold_medal_mel); // OK
}

constexpr auto olympic_mile() {
  const int ledecky = 1500;
  return []{ return ledecky; }; // OK
}

static_assert(olympic_mile()() == 1500); // OK

struct Swim {
  constexpr int phelps() { return 28; }
```
virtual constexpr int lochte() { return 12; }
int coughlin = 12;
};

constexpr int how_many(Swim& swam) {
    Swim* p = &swam;
    return (p + 1 - 1)->phelps();
}

void splash(Swim& swam) {
    static_assert(swam.phelps() == 28);
    // OK
    static_assert((&swam)->phelps() == 28);
    // OK
    Swim* pswam = &swam;
    static_assert(pswam->phelps() == 28);
    // error: lvalue-to-rvalue conversion on a pointer
    // not usable in constant expressions
    static_assert(how_many(swam) == 28);
    // OK
    static_assert(Swim().lochte() == 12);
    // OK
    static_assert(swam.lochte() == 12);
    // error: invoking virtual function on reference
    // with constexpr-unknown dynamic type
    static_assert(swam.coughlin == 12);
    // error: lvalue-to-rvalue conversion on an object
    // not usable in constant expressions
}

extern Swim dc;
extern Swim& trident;

constexpr auto& sandeno = typeid(dc);
    // OK, can only be typeid(Swim)
constexpr auto& gallagher = typeid(trident);
    // error: constexpr-unknown dynamic type
—end example]  

An object \( a \) is said to have \textit{constant destruction} if:

9.1 — it is not of class type nor (possibly multi-dimensional) array thereof, or

9.2 — it is of class type or (possibly multi-dimensional) array thereof, that class type has a constexpr destructor, and for a hypothetical expression \( E \) whose only effect is to destroy \( a \), \( E \) would be a core constant expression if the lifetime of \( a \) and its non-mutable subobjects (but not its mutable subobjects) were considered to start within \( E \).

10 An \textit{integral constant expression} is an expression of integral or unscoped enumeration type, implicitly converted to a prvalue, where the converted expression is a core constant expression.
[Note 6: Such expressions can be used as bit-field lengths (11.4.10), as enumerator initializers if the underlying type is not fixed (9.7.1), and as alignments (9.12.2). — end note]

11 If an expression of literal class type is used in a context where an integral constant expression is required, then that expression is contextually implicitly converted (7.3) to an integral or unscoped enumeration type and the selected conversion function shall be \textit{constexpr}.

[Example 6:

    struct A {
        constexpr A(int i) : val(i) { }
        constexpr operator int() const { return val; }
        constexpr operator long() const { return 42; }
    private:
        int val;
    }
    constexpr A a = alignof(int);
    alignas(a) int n;
    // error: ambiguous conversion
    struct B { int n : a; };  // error: ambiguous conversion
—end example]

12 A \textit{converted constant expression} of type \( T \) is an expression, implicitly converted to type \( T \), where the converted expression is a constant expression and the implicit conversion sequence contains only

12.1 — user-defined conversions,
— lvalue-to-rvalue conversions (7.3.2),
— array-to-pointer conversions (7.3.3),
— function-to-pointer conversions (7.3.4),
— qualification conversions (7.3.6),
— integral promotions (7.3.7),
— integral conversions (7.3.9) other than narrowing conversions (9.4.5),
— null pointer conversions (7.3.12) from `std::nullptr_t`,
— null member pointer conversions (7.3.13) from `std::nullptr_t`, and
— function pointer conversions (7.3.14),
and where the reference binding (if any) binds directly.

[Note 7: Such expressions can be used in `new` expressions (7.6.2.8), as case expressions (8.5.3), as enumerator initializers if the underlying type is fixed (9.7.1), as array bounds (9.3.4.5), and as non-type template arguments (13.4). — end note]

A contextually converted constant expression of type `bool` is an expression, contextually converted to `bool` (7.3), where the converted expression is a constant expression and the conversion sequence contains only the conversions above.

A constant expression is either a glvalue core constant expression that refers to an entity that is a permitted result of a constant expression (as defined below), or a prvalue core constant expression whose value satisfies the following constraints:

— if the value is an object of class type, each non-static data member of reference type refers to an entity that is a permitted result of a constant expression,
— if the value is an object of scalar type, it does not have an indeterminate value (6.7.4),
— if the value is of pointer type, it contains the address of an object with static storage duration, the address past the end of such an object (7.6.6), the address of a non-immediate function, or a null pointer value,
— if the value is of pointer-to-member-function type, it does not designate an immediate function, and
— if the value is an object of class or array type, each subobject satisfies these constraints for the value.

An entity is a permitted result of a constant expression if it is an object with static storage duration that either is not a temporary object or is a temporary object whose value satisfies the above constraints, or if it is a non-immediate function.

[Note 8: A glvalue core constant expression that either refers to or points to an unspecified object is not a constant expression. — end note]

[Example 7:
```c
consteval int f() { return 42; }
consteval auto g() { return f; }
consteval int h(int (*p)() = g()) { return p(); }
constexpr int r = h();   // OK
constexpr auto e = g();  // error: a pointer to an immediate function is not a permitted result of a constant expression
```
— end example]

Recommended practice: Implementations should provide consistent results of floating-point evaluations, irrespective of whether the evaluation is performed during translation or during program execution.

[Note 9: Since this document imposes no restrictions on the accuracy of floating-point operations, it is unspecified whether the evaluation of a floating-point expression during translation yields the same result as the evaluation of the same expression (or the same operations on the same values) during program execution.

[Example 8:
```c
bool f() {
    char array[1 + int(1 + 0.2 - 0.1 - 0.1)];   // Must be evaluated during translation
    int size = 1 + int(1 + 0.2 - 0.1 - 0.1);    // May be evaluated at runtime
    return sizeof(array) == size;
}
```

§ 7.7 159
It is unspecified whether the value of \( f() \) will be true or false. — end example]
— end note]

15 An expression or conversion is in an immediate function context if it is potentially evaluated and either:
\(15.1\) — its innermost enclosing non-block scope is a function parameter scope of an immediate function,
\(15.2\) — it is a subexpression of a manifestly constant-evaluated expression or conversion, or
\(15.3\) — its enclosing statement is enclosed (8.1) by the compound-statement of a consteval if statement (8.5.2).

An invocation is an immediate invocation if it is a potentially-evaluated explicit or implicit invocation of an immediate function and is not in an immediate function context. An aggregate initialization is an immediate invocation if it evaluates a default member initializer that has a subexpression that is an immediate-escalating expression.

16 An expression or conversion is immediate-escalating if it is not initially in an immediate function context and it is either
\(16.1\) — a potentially-evaluated id-expression that denotes an immediate function that is not a subexpression of an immediate invocation, or
\(16.2\) — an immediate invocation that is not a constant expression and is not a subexpression of an immediate invocation.

17 An immediate-escalating function is
\(17.1\) — the call operator of a lambda that is not declared with the constexpr specifier,
\(17.2\) — a defaulted special member function that is not declared with the constexpr specifier, or
\(17.3\) — a function that results from the instantiation of a templated entity defined with the constexpr specifier.

An immediate-escalating expression shall appear only in an immediate-escalating function.

18 An immediate function is a function or constructor that is
\(18.1\) — declared with the constexpr specifier, or
\(18.2\) — an immediate-escalating function \( F \) whose function body contains an immediate-escalating expression \( E \) such that \( E \)'s innermost enclosing non-block scope is \( F \)'s function parameter scope.

[Example 9]
consteval int id(int i) { return i; }
constexpr char id(char c) { return c; }
template<class T>
cconstexpr int f(T t) {
    return t + id(t);
}

auto a = \&f<char>;       // OK, f<char> is not an immediate function
auto b = \&f<int>;        // error: f<int> is an immediate function

static_assert(f(3) == 6); // OK

template<class T>
cconstexpr int g(T t) {
    // g<int> is not an immediate function
    return t + id(42);     // because id(42) is already a constant
}

template<class T, class F>
cconstexpr bool is_not(T t, F f) {
    return not f(t);
}

consteval bool is_even(int i) { return i % 2 == 0; }

static_assert(is_not(5, is_even)); // OK

int x = 0;
template<class T>
constexpr T h(T t = id(x)) { // h<int> is not an immediate function
    return t;
}

template<class T>
constexpr T hh() { // hh<int> is an immediate function
    return h<T>();
}

int i = hh<int>(); // error: hh<int>() is an immediate-escalating expression
    // outside of an immediate-escalating function

struct A {
    int x;
    int y = id(x);
};

template<class T>
constexpr int k(int) { // k<int> is not an immediate function because k(42) is a
    return A(42).y; // constant expression and thus not immediate-escalating
}

—end example

19 An expression or conversion is **manifestly constant-evaluated** if it is:

(19.1) — a **constant-expression**, or
(19.2) — the condition of a constexpr if statement (8.5.2), or
(19.3) — an immediate invocation, or
(19.4) — the result of substitution into an atomic constraint expression to determine whether it is satisfied (13.5.2.3), or
(19.5) — the initializer of a variable that is usable in constant expressions or has constant initialization (6.9.3.2).

[Example 10:

template<bool> struct X {};
X<std::is_constant_evaluated()> x; // type X<true>
int y;
const int a = std::is_constant_evaluated() ? y : 1; // dynamic initialization to 1
double z[a]; // error: a is not usable
    // in constant expressions
const int b = std::is_constant_evaluated() ? 2 : y; // static initialization to 2
int c = y + (std::is_constant_evaluated() ? 2 : y); // dynamic initialization to y+y

constexpr int f() {
    const int n = std::is_constant_evaluated() ? 13 : 17; // n is 13
    int m = std::is_constant_evaluated() ? 13 : 17; // m can be 13 or 17 (see below)
    char arr[n] = {}; // char[13]
    return m + sizeof(arr);
}

int p = f(); // m is 13; initialized to 26
int q = p + f(); // m is 17 for this call; initialized to 56

—end example]

[Note 10: A manifestly constant-evaluated expression is evaluated even in an unevaluated operand (7.2.3). — end note]

20 An expression or conversion is **potentially constant evaluated** if it is:

(20.1) — a manifestly constant-evaluated expression,
(20.2) — a potentially-evaluated expression (6.3),

74) Testing this condition can involve a trial evaluation of its initializer as described above.
An immediate subexpression of a braced-init-list,\(^75\)

An expression of the form `& cast-expression` that occurs within a templated entity,\(^76\) or

A potentially-evaluated subexpression (6.9.1) of one of the above.

A function or variable is needed for constant evaluation if it is:

- a `constexpr` function that is named by an expression (6.3) that is potentially constant evaluated, or
- a potentially-constant variable named by a potentially constant evaluated expression.

---

\(^75\) In some cases, constant evaluation is needed to determine whether a narrowing conversion is performed (9.4.5).

\(^76\) In some cases, constant evaluation is needed to determine whether such an expression is value-dependent (13.8.3.4).
8 Statements

8.1 Preamble

Except as indicated, statements are executed in sequence.

1

statement:
  labeled-statement
  attribute-specifier-seq_opt expression-statement
  attribute-specifier-seq_opt compound-statement
  attribute-specifier-seq_opt selection-statement
  attribute-specifier-seq_opt iteration-statement
  attribute-specifier-seq_opt jump-statement
  declaration-statement
  attribute-specifier-seq_opt try-block

init-statement:
  expression-statement
  simple-declaration
  alias-declaration

condition:
  expression
  attribute-specifier-seq_opt decl-specifier-seq declarator brace-or-equal-initializer

The optional attribute-specifier-seq appertains to the respective statement.

2

A substatement of a statement is one of the following:

(2.1) — for a labeled-statement, its statement,
(2.2) — for a compound-statement, any statement of its statement-seq,
(2.3) — for a selection-statement, any of its statements or compound-statements (but not its init-statement), or
(2.4) — for an iteration-statement, its statement (but not an init-statement).

[Note 1: The compound-statement of a lambda-expression is not a substatement of the statement (if any) in which the lambda-expression lexically appears. — end note]

3

A statement S1 encloses a statement S2 if

(3.1) — S2 is a substatement of S1,
(3.2) — S1 is a selection-statement or iteration-statement and S2 is the init-statement of S1,
(3.3) — S1 is a try-block and S2 is its compound-statement or any of the compound-statements of its handlers, or
(3.4) — S1 encloses a statement S3 and S3 encloses S2.

A statement S1 is enclosed by a statement S2 if S2 encloses S1.

4

A condition that is not an expression is a declaration (Clause 9). The declarator shall not specify a function or an array. The decl-specifier-seq shall not define a class or enumeration. If the auto type-specifier appears in the decl-specifier-seq, the type of the identifier being declared is deduced from the initializer as described in 9.2.9.6.

5

The value of a condition that is an initialized declaration in a statement other than a switch statement is the value of the declared variable contextually converted to bool (7.3). If that conversion is ill-formed, the program is ill-formed. The value of a condition that is an expression is the value of the expression, contextually converted to bool for statements other than switch; if that conversion is ill-formed, the program is ill-formed. The value of the condition will be referred to as simply “the condition” where the usage is unambiguous.

6

If a condition can be syntactically resolved as either an expression or a declaration, it is interpreted as the latter.

7

In the decl-specifier-seq of a condition, each decl-specifier shall be either a type-specifier or constexpr.
8.2 Label

A label can be added to a statement or used anywhere in a compound-statement.

```c
label:
  attribute-specifier-seq_opt identifier :
  attribute-specifier-seq_opt case constant-expression :
  attribute-specifier-seq_opt default :
```

labeled-statement:
  label statement

The optional attribute-specifier-seq appertains to the label. The only use of a label with an identifier is as the target of a goto. No two labels in a function shall have the same identifier. A label can be used in a goto statement before its introduction.

2 A labeled-statement whose label is a case or default label shall be enclosed by (8.1) a switch statement (8.5.3).

3 A control-flow-limited statement is a statement S for which:

(a)
  — a case or default label appearing within S shall be associated with a switch statement (8.5.3) within S, and

(b)
  — a label declared in S shall only be referred to by a statement (8.7.6) in S.

8.3 Expression statement

Expression statements have the form

```c
expression-statement:
  expression_opt ;
```

The expression is a discarded-value expression (7.2.3). All side effects from an expression statement are completed before the next statement is executed. An expression statement with the expression missing is called a null statement.

[Note 1: Most statements are expression statements — usually assignments or function calls. A null statement is useful to supply a null body to an iteration statement such as a while statement (8.6.2). — end note]

8.4 Compound statement or block

A compound statement (also known as a block) groups a sequence of statements into a single statement.

```c
compound-statement:
  { statement-seq_opt label-seq_opt }
```

```c
statement-seq:
  statement
  statement-seq statement
```

```c
label-seq:
  label
  label-seq label
```

A label at the end of a compound-statement is treated as if it were followed by a null statement.

[Note 1: A compound statement defines a block scope (6.4). A declaration is a statement (8.8). — end note]

8.5 Selection statements

8.5.1 General

Selection statements choose one of several flows of control.

```c
selection-statement:
  if constexpr_opt ( init-statement_opt condition ) statement
  if constexpr_opt ( init-statement_opt condition ) statement else statement
  if !opt constexpr compound-statement
  if !opt constexpr compound-statement else statement
  switch ( init-statement_opt condition ) statement
```

See 9.3.4 for the optional attribute-specifier-seq in a condition.

[Note 1: An init-statement ends with a semicolon. — end note]
[Note 2: Each selection-statement and each substatement of a selection-statement has a block scope (6.4.3). — end note]

8.5.2 The if statement

1 If the condition (8.1) yields true the first substatement is executed. If the else part of the selection statement is present and the condition yields false, the second substatement is executed. If the first substatement is reached via a label, the condition is not evaluated and the second substatement is not executed. In the second form of if statement (the one including else), if the first substatement is also an if statement then that inner if statement shall contain an else part.\(^7\)

2 If the if statement is of the form if constexpr, the value of the condition is contextually converted to bool and the converted expression shall be a constant expression (7.7); this form is called a constexpr if statement. If the value of the converted condition is false, the first substatement is a discarded statement, otherwise the second substatement, if present, is a discarded statement. During the instantiation of an enclosing templated entity (13.1), if the condition is not value-dependent after its instantiation, the discarded substatement (if any) is not instantiated. Each substatement of a constexpr if statement is a control-flow-limited statement (8.2).

[Example 1:]
```c++
if constexpr (sizeof(int[2])) {} // OK, narrowing allowed
— end example]
```

[Note 1: Odr-uses (6.3) in a discarded statement do not require an entity to be defined. — end note]

[Example 2:]
```c++
template<typename T, typename ... Rest> void g(T&& p, Rest&& ...rs) {
    // ... handle p
    if constexpr (sizeof...(rs) > 0)
        g(rs...); // never instantiated with an empty argument list
}
extern int x; // no definition of x required
```

int f() {
    if constexpr (true)
        return 0;
    else if (x)
        return x;
    else
        return -x;
}
— end example]

3 An if statement of the form
```c++
if constexpropt (init-statement condition) statement
```
is equivalent to
```c++
{
    init-statement
    if constexpropt (condition) statement
}
```
and an if statement of the form
```c++
if constexpropt (init-statement condition) statement else statement
```
is equivalent to
```c++
{
    init-statement
    if constexpropt (condition) statement else statement
}
```
except that the init-statement is in the same scope as the condition.

---

\(^7\) In other words, the else is associated with the nearest un-elsed if.
An if statement of the form if constexpr is called a constexpr if statement. The statement, if any, in a constexpr if statement shall be a compound-statement.

[Example 3:
    constexpr void f(bool b) {
      if (true)
        if constexpr {}  // error: not a compound-statement; else not associated with outer if
      }
    — end example]

If a constexpr if statement is evaluated in a context that is manifestly constant-evaluated (7.7), the first substatement is executed.

[Note 2: The first substatement is an immediate function context. — end note]

Otherwise, if the else part of the selection statement is present, then the second substatement is executed. Each substatement of a constexpr if statement is a control-flow-limited statement (8.2).

An if statement of the form

    if ! constexpr compound-statement

is not itself a constexpr if statement, but is equivalent to the constexpr if statement

    if constexpr {} else compound-statement

An if statement of the form

    if ! constexpr compound-statement; else statement_2

is not itself a constexpr if statement, but is equivalent to the constexpr if statement

    if constexpr statement_2 else compound-statement;

8.5.3 The switch statement

The switch statement causes control to be transferred to one of several statements depending on the value of a condition.

The value of a condition that is an initialized declaration is the value of the declared variable, or the value of the expression otherwise. The value of the condition shall be of integral type, enumeration type, or class type.

If of class type, the condition is contextually implicitly converted (7.3) to an integral or enumeration type. If the (possibly converted) type is subject to integral promotions (7.3.7), the condition is converted to the promoted type. Any statement within the switch statement can be labeled with one or more case labels as follows:

    case constant-expression :

where the constant-expression shall be a converted constant expression (7.7) of the adjusted type of the switch condition. No two of the case constants in the same switch shall have the same value after conversion.

There shall be at most one label of the form

    default :

within a switch statement.

Switch statements can be nested; a case or default label is associated with the smallest switch enclosing it.

When the switch statement is executed, its condition is evaluated. If one of the case constants has the same value as the condition, control is passed to the statement following the matched case label. If no case constant matches the condition, and if there is a default label, control passes to the statement labeled by the default label. If no case matches and if there is no default then none of the statements in the switch is executed.

case and default labels in themselves do not alter the flow of control, which continues unimpeded across such labels. To exit from a switch, see break, 8.7.2.

[Note 1: Usually, the substatement that is the subject of a switch is compound and case and default labels appear on the top-level statements contained within the (compound) substatement, but this is not required. Declarations can appear in the substatement of a switch statement. — end note]

A switch statement of the form

    switch ( init-statement condition ) statement

is equivalent to
except that the \textit{init-statement} is in the same scope as the \textit{condition}.

8.6 Iteration statements \[stmt.iter]\n
8.6.1 General \[stmt.iter.general]\n
1 Iteration statements specify looping.

\begin{verbatim}
iteration-statement:
  while ( condition ) statement
do statement while ( expression ) ;
  for ( init-statement condition \textit{opt} ; expression \textit{opt} ) statement
  for ( init-statement \textit{opt} for-range-declaration : for-range-initializer ) statement

for-range-declaration:
  attribute-specifier-seq \textit{opt} decl-specifier-seq declarator
  attribute-specifier-seq \textit{opt} decl-specifier-seq ref-qualifier \textit{opt} [ identifier-list ]

for-range-initializer:
  expr-or-braced-init-list
\end{verbatim}

See 9.3.4 for the optional \textit{attribute-specifier-seq} in a \textit{for-range-declaration}.
[Note 1: An \textit{init-statement} ends with a semicolon. — end note]

2 The substatement in an iteration-statement implicitly defines a block scope (6.4) which is entered and exited each time through the loop. If the substatement in an iteration-statement is a single statement and not a compound-statement, it is as if it was rewritten to be a compound-statement containing the original statement.

[Example 1]:
\begin{verbatim}
while (--x >= 0)
  int i;
\end{verbatim}
can be equivalently rewritten as
\begin{verbatim}
while (--x >= 0) {
  int i;
}
\end{verbatim}
Thus after the \texttt{while} statement, \texttt{i} is no longer in scope. — end example]

8.6.2 The \texttt{while} statement \[stmt.while]\n
1 In the \texttt{while} statement the substatement is executed repeatedly until the value of the condition (8.1) becomes \texttt{false}. The test takes place before each execution of the substatement.

2 A \texttt{while} statement is equivalent to
\begin{verbatim}
label :
  { 
    if ( condition ) { 
      statement 
      goto label ; 
    } 
  }
\end{verbatim}
[Note 1: The variable created in the condition is destroyed and created with each iteration of the loop.

[Example 1]:
\begin{verbatim}
struct A {
  int val;
  A(int i) : val(i) {} 
  ~A() {} 
  operator bool() { return val != 0; }
};
int i = 1;
\end{verbatim}
while (A a = i) {
    // ...
    i = 0;
}

In the while-loop, the constructor and destructor are each called twice, once for the condition that succeeds and once for the condition that fails. — end example]
— end note]

8.6.3 The do statement [stmt.do]
1 The expression is contextually converted to bool (7.3); if that conversion is ill-formed, the program is ill-formed.
2 In the do statement the substatement is executed repeatedly until the value of the expression becomes false. The test takes place after each execution of the statement.

8.6.4 The for statement [stmt.for]
1 The for statement
for ( init-statement condition_opt ; expression_opt ) statement
is equivalent to
{
    init-statement
    while ( condition ) {
        statement
        expression ;
    }
}
except that the init-statement is in the same scope as the condition, and except that a continue in statement (not enclosed in another iteration statement) will execute expression before re-evaluating condition.
[Note 1: Thus the first statement specifies initialization for the loop; the condition (8.1) specifies a test, sequenced before each iteration, such that the loop is exited when the condition becomes false; the expression often specifies incrementing that is sequenced after each iteration. — end note]
2 Either or both of the condition and the expression can be omitted. A missing condition makes the implied while clause equivalent to while(true).

8.6.5 The range-based for statement [stmt.ranged]
1 The range-based for statement
for ( init-statement_opt for-range-declaration : for-range-initializer ) statement
is equivalent to
{
    init-statement_opt
    auto && range = for-range-initializer ;
    auto begin = begin-expr ;
    auto end = end-expr ;
    for ( ; begin != end ; ++begin ) {
        for-range-declaration = * begin ;
        statement
    }
}
where
(1.1) — if the for-range-initializer is an expression, it is regarded as if it were surrounded by parentheses (so that a comma operator cannot be reinterpreted as delimiting two init-declarators);
(1.2) — range, begin, and end are variables defined for exposition only; and
(1.3) — begin-expr and end-expr are determined as follows:
(1.3.1) — if the for-range-initializer is an expression of array type R, begin-expr and end-expr are range and range + N, respectively, where N is the array bound. If R is an array of unknown bound or an array of incomplete type, the program is ill-formed;
(1.3.2) if the for-range-initializer is an expression of class type C, and searches in the scope of C (6.5.2) for the names begin and end each find at least one declaration, begin-expr and end-expr are range.begin() and range.end(), respectively;

(1.3.3) otherwise, begin-expr and end-expr are begin(range) and end(range), respectively, where begin and end undergo argument-dependent lookup (6.5.4).

[Note 1: Ordinary unqualified lookup (6.5.3) is not performed. — end note]

[Example 1:]
```cpp
int array[5] = { 1, 2, 3, 4, 5 };
for (int& x : array)
  x *= 2;
end example]

[Note 2: The lifetime of some temporaries in the for-range-initializer is extended to cover the entire loop (6.7.7). — end note]

[Example 2:]
```cpp
using T = std::list<int>;
const T& f1(const T& t) { return t; }
const T& f2(T t) { return t; }
T g();

void foo() {
  for (auto e : f1(g())) {} // OK, lifetime of return value of g() extended
  for (auto e : f2(g())) {} // undefined behavior
}
```

—end example]

In the decl-specifier-seq of a for-range-declaration, each decl-specifier shall be either a type-specifier or constexpr. The decl-specifier-seq shall not define a class or enumeration.

8.7 Jump statements

8.7.1 General

Jump statements unconditionally transfer control.

jump-statement:
break ;
continue ;
return expr-or-braced-init-list_opt ;
coroutine-return-statement
goto identifier ;

[Note 1: On exit from a scope (however accomplished), objects with automatic storage duration (6.7.5.4) that have been constructed in that scope are destroyed in the reverse order of their construction. For temporaries, see 6.7.7. However, the program can be terminated (by calling std::exit() or std::abort() (17.5), for example) without destroying objects with automatic storage duration. — end note]

[Note 2: A suspension of a coroutine (7.6.2.4) is not considered to be an exit from a scope. — end note]

8.7.2 The break statement

A break statement shall be enclosed by (8.1) an iteration-statement (8.6) or a switch statement (8.5.3). The break statement causes termination of the smallest such enclosing statement; control passes to the statement following the terminated statement, if any.

8.7.3 The continue statement

A continue statement shall be enclosed by (8.1) an iteration-statement (8.6). The continue statement causes control to pass to the loop-continuation portion of the smallest such enclosing statement, that is, to the end of the loop. More precisely, in each of the statements
a `continue` not contained in an enclosed iteration statement is equivalent to `goto continue`.

### 8.7.4 The return statement

1. A function returns to its caller by the `return` statement.
2. The `expr-or-braced-init-list` of a `return` statement is called its operand. A `return` statement with no operand shall be used only in a function whose return type is `cv void`, a constructor (11.4.5), or a destructor (11.4.7). A `return` statement with an operand of type `void` shall be used only in a function that has a `cv void` return type. A `return` statement with any other operand shall be used only in a function that has a return type other than `cv void`; the `return` statement initializes the returned reference or prvalue result object of the (explicit or implicit) function call by copy-initialization (9.4) from the operand.

   

   [Note 1: A constructor or destructor does not have a return type. — end note]

   [Note 2: A `return` statement can involve an invocation of a constructor to perform a copy or move of the operand if it is not a prvalue or if its type differs from the return type of the function. A copy operation associated with a `return` statement can be elided or converted to a move operation if an automatic storage duration variable is returned (11.9.6). — end note]

3. The destructor for the result object is potentially invoked (11.4.7, 14.3).

   [Example 1:]
   ```
   class A {
   ~A() {}  // destructor of A is private (even though it is never invoked)
   };
   A f() { return A(); }  // error: destructor of A is private (even though it is never invoked)
   ```

4. Flowing off the end of a constructor, a destructor, or a non-coroutine function with a `cv void` return type is equivalent to a `return` with no operand. Otherwise, flowing off the end of a function that is neither `main` (6.9.3.1) nor a coroutine (9.5.4) results in undefined behavior.

5. The copy-initialization of the result of the call is sequenced before the destruction of temporaries at the end of the full-expression established by the operand of the `return` statement, which, in turn, is sequenced before the destruction of local variables (8.7) of the block enclosing the `return` statement.

### 8.7.5 The co_return statement

```
coroutine-return-statement:
  co_return expr-or-braced-init-list_opt;
```

1. A coroutine returns to its caller or resumer (9.5.4) by the `co_return` statement or when suspended (7.6.2.4). A coroutine shall not enclose a `return` statement (8.7.4).

   [Note 1: For this determination, it is irrelevant whether the `return` statement is enclosed by a discarded statement (8.5.2). — end note]

2. The `expr-or-braced-init-list` of a `co_return` statement is called its operand. Let `p` be an lvalue naming the coroutine promise object (9.5.4). A `co_return` statement is equivalent to:

   ```
   { S; goto final-suspend; }
   ```

   where `final-suspend` is the exposition-only label defined in 9.5.4 and `S` is defined as follows:

   (2.1) — If the operand is a `braced-init-list` or an expression of non-void type, `S` is `p.return_value(expr-or-braced-init-list)`. The expression `S` shall be a prvalue of type `void`.

   (2.2) — Otherwise, `S` is the `compound-statement { expression_opt ; p.return_void(); }`. The expression `p.return_void()` shall be a prvalue of type `void`.

3. If `p.return_void()` is a valid expression, flowing off the end of a coroutine’s `function-body` is equivalent to a `co_return` with no operand; otherwise flowing off the end of a coroutine’s `function-body` results in undefined behavior.

§ 8.7.5 170
8.7.6 The goto statement

The goto statement unconditionally transfers control to the statement labeled by the identifier. The identifier shall be a label (8.2) located in the current function.

8.8 Declaration statement

A declaration statement introduces one or more new names into a block; it has the form

```
declarations-statement:
  block-declaration
```

[Note 1: If an identifier introduced by a declaration was previously declared in an outer block, the outer declaration is hidden for the remainder of the block (6.5.3), after which it resumes its force. —end note]

A variable with automatic storage duration (6.7.5.4) is active everywhere in the scope to which it belongs after its init-declarator. Upon each transfer of control (including sequential execution of statements) within a function from point P to point Q, all variables with automatic storage duration that are active at P and not at Q are destroyed in the reverse order of their construction. Then, all variables with automatic storage duration that are active at Q but not at P are initialized in declaration order; unless all such variables have vacuous initialization (6.7.3), the transfer of control shall not be a jump. When a declaration-statement is executed, P and Q are the points immediately before and after it; when a function returns, Q is after its body.

[Example 1:]
```
void f() {
  // ...
  goto lx;           // error: jump into scope of a
  // ...
  ly:
  X a = 1;
  // ...
  lx:
  goto ly;           // OK, jump implies destructor call for a followed by
  // construction again immediately following label ly
}
```

[Example 2:]
```
int foo(int i) {
  static int s = foo(2*i);   // undefined behavior: recursive call
  return i+1;
}
```

Dynamic initialization of a block variable with static storage duration (6.7.5.2) or thread storage duration (6.7.5.3) is performed the first time control passes through its declaration; such a variable is considered initialized upon the completion of its initialization. If the initialization exits by throwing an exception, the initialization is not complete, so it will be tried again the next time control enters the declaration. If control enters the declaration concurrently while the variable is being initialized, the concurrent execution shall wait for completion of the initialization.

[Note 2: A conforming implementation cannot introduce any deadlock around execution of the initializer. Deadlocks might still be caused by the program logic; the implementation need only avoid deadlocks due to its own synchronization operations. —end note]

If control re-enters the declaration recursively while the variable is being initialized, the behavior is undefined.

[Note 3: 6.9.3.4 describes the order in which such objects are destroyed. —end note]

78) The transfer from the condition of a switch statement to a case label is considered a jump in this respect.
8.9 Ambiguity resolution

1 There is an ambiguity in the grammar involving expression-statements and declarations: An expression-statement with a function-style explicit type conversion (7.6.1.4) as its leftmost subexpression can be indistinguishable from a declaration where the first declarator starts with a `(`. In those cases the statement is a declaration.

2 [Note 1: If the statement cannot syntactically be a declaration, there is no ambiguity, so this rule does not apply. In some cases, the whole statement needs to be examined to determine whether this is the case. This resolves the meaning of many examples.]

[Example 1: Assuming T is a simple-type-specifier (9.2.9),

T(a)->m = 7; // expression-statement
T(a)++; // expression-statement
T(a,5)<<c; // expression-statement

T(*d)(int); // declaration
T(e)[5]; // declaration
T(f) = { 1, 2 }; // declaration
T(*g)(double(3)); // declaration

In the last example above, g, which is a pointer to T, is initialized to double(3). This is of course ill-formed for semantic reasons, but that does not affect the syntactic analysis. —end example]

The remaining cases are declarations.

[Example 2:

class T {
    // ...
    public:
    T();
    T(int);
    T(int, int);
};
T(a); // declaration
T(*b); // declaration
T(c)=7; // declaration
T(d),e,f=3; // declaration
extern int h;
T(g)(h,2); // declaration
—end example]

The disambiguation is purely syntactic; that is, the meaning of the names occurring in such a statement, beyond whether they are type-names or not, is not generally used in or changed by the disambiguation. Class templates are instantiated as necessary to determine if a qualified name is a type-name. Disambiguation precedes parsing, and a statement disambiguated as a declaration may be an ill-formed declaration. If, during parsing, lookup finds that a name in a template argument is bound to (part of) the declaration being parsed, the program is ill-formed. No diagnostic is required.

[Example 3:

struct T1 {
    T1 operator()(int x) { return T1(x); }
    int operator=(int x) { return x; }
    T1(int) {}
};
struct T2 { T2(int) {} }
int a, (**(b)(T2))(int), c, d;

void f() {
    // disambiguation requires this to be parsed as a declaration:
    T1(a) = 3,
    T2(4),
    (**(b)(T2(c)))(int(d)); // T2 will be declared as a variable of type T1, but this will not
    // allow the last part of the declaration to parse properly,
    // since it depends on T2 being a type-name
}
—end example]
9  Declarations

9.1  Preamble

1 Declarations generally specify how names are to be interpreted. Declarations have the form

\[
\text{declaration-seq}:
\text{declaration}
\text{declaration-seq declaration}
\]

\[
\text{declaration}:
\text{name-declaration}
\text{special-declaration}
\]

\[
\text{name-declaration}:
\text{block-declaration}
\text{nodeclspec-function-declaration}
\text{function-definition}
\text{template-declaration}
\text{deduction-guide}
\text{linkage-specification}
\text{namespace-definition}
\text{empty-declaration}
\text{attribute-declaration}
\text{module-import-declaration}
\]

\[
\text{special-declaration}:
\text{explicit-instantiation}
\text{explicit-specialization}
\text{export-declaration}
\]

\[
\text{block-declaration}:
\text{simple-declaration}
\text{asm-declaration}
\text{namespace-alias-definition}
\text{using-declaration}
\text{using-enum-declaration}
\text{using-directive}
\text{static_assert-declaration}
\text{alias-declaration}
\text{opaque-enum-declaration}
\]

\[
\text{nodeclspec-function-declaration}:
\text{attribute-specifier-seq opt declarator ;}
\]

\[
\text{alias-declaration}:
\text{using identifier attribute-specifier-seq opt = defining-type-id ;}
\]

\[
\text{simple-declaration}:
\text{decl-specifier-seq init-declarator-list opt ;}
\text{attribute-specifier-seq decl-specifier-seq init-declarator-list ;}
\text{attribute-specifier-seq decl-specifier-seq ref-qualifier opt [ identifier-list ] initializer ;}
\]

\[
\text{static_assert-declaration}:
\text{static_assert ( constant-expression ) ;}
\text{static_assert ( constant-expression , string-literal ) ;}
\]

\[
\text{empty-declaration}:
;
\]

\[
\text{attribute-declaration}:
\text{attribute-specifier-seq ;}
\]

[Note 1: \textit{asm-declarations} are described in 9.10, and \textit{linkage-specifications} are described in 9.11; \textit{function-definitions} are described in 9.5 and \textit{template-declarations} and \textit{deduction-guides} are described in 13.7.2.3; \textit{namespace-definitions} are described in 9.8.2, \textit{using-declarations} are described in 9.9 and \textit{using-directives} are described in 9.8.4. — end note]
Certain declarations contain one or more scopes (6.4.1). Unless otherwise stated, utterances in Clause 9 about components in, of, or contained by a declaration or subcomponent thereof refer only to those components of the declaration that are not nested within scopes nested within the declaration.

A simple-declaration or nodeclspec-function-declaration of the form

\[
\text{attribute-specifier-seq}_{\text{opt}} \text{ decl-specifier-seq}_{\text{opt}} \text{ init-declarator-list}_{\text{opt}} ;
\]

is divided into three parts. Attributes are described in 9.12. decl-specifiers, the principal components of a decl-specifier-seq, are described in 9.2. declarators, the components of an init-declarator-list, are described in 9.3. The attribute-specifier-seq appertains to each of the entities declared by the declarators of the init-declarator-list.

[Note 2: In the declaration for an entity, attributes appertaining to that entity can appear at the start of the declaration and after the declarator-id for that declaration. — end note]

[Example 1:

\[
[[\text{noreturn}]] \text{ void f }[[\text{noreturn}]] () ; \quad \text{// OK}
\]

— end example]

4 If a declarator-id is a name, the init-declarator and (hence) the declaration introduce that name.

[Note 3: Otherwise, the declarator-id is a qualified-id or names a destructor or its unqualified-id is a template-id and no name is introduced. — end note]

The defining-type-specifiers (9.2.9) in the decl-specifier-seq and the recursive declarator structure describe a type (9.3.4), which is then associated with the declarator-id.

5 In a simple-declaration, the optional init-declarator-list can be omitted only when declaring a class (11.1) or enumeration (9.7.1), that is, when the decl-specifier-seq contains either a class-specifier, an elaborated-type-specifier with a class-key (11.3), or an enum-specifier. In these cases and whenever a class-specifier or enum-specifier is present in the decl-specifier-seq, the identifiers in these specifiers are also declared (as class-names, enum-names, or enumerators, depending on the syntax). In such cases, the decl-specifier-seq shall (re)introduce one or more names into the program.

[Example 2:

\[
\text{enum } \{ \}; \quad \text{// error}
\text{typedef class } \{ \}; \quad \text{// error}
\]

— end example]

6 A simple-declaration with an identifier-list is called a structured binding declaration (9.6). Each decl-specifier in the decl-specifier-seq shall be static, thread_local, auto (9.2.9.6), or a cv-qualifier.

[Example 3:

\[
\text{template<} \text{T> concept C} = \text{true} ;
\text{C auto } [x, y] = \text{std::pair}(1, 2) ; \quad \text{// error: constrained placeholder-type-specifier}
\text{// not permitted for structured bindings}
\]

— end example]

The initializer shall be of the form “= assignment-expression”, of the form “\{ assignment-expression \}”, or of the form “\{ assignment-expression \}”, where the assignment-expression is of array or non-union class type.

7 If the decl-specifier-seq contains the typedef specifier, the declaration is a typedef declaration and each declarator-id is declared to be a typedef-name, synonymous with its associated type (9.2.4).

[Note 4: Such a declarator-id is an identifier (11.4.8.3). — end note]

Otherwise, if the type associated with a declarator-id is a function type (9.3.4.6), the declaration is a function declaration. Otherwise, if the type associated with a declarator-id is an object or reference type, the declaration is an object declaration. Otherwise, the program is ill-formed.

[Example 4:

\[
\text{int } f() , x ; \quad \text{// OK, function declaration for } f \text{ and object declaration for } x
\text{extern void g() ,} ; \quad \text{// OK, function declaration for } g
\text{y ;} \quad \text{// error: void is not an object type}
\]

— end example]

8 Syntactic components beyond those found in the general form of simple-declaration are added to a function declaration to make a function-definition. An object declaration, however, is also a definition unless it contains
the `extern` specifier and has no initializer (6.2). An object definition causes storage of appropriate size and alignment to be reserved and any appropriate initialization (9.4) to be done.

9 A `nodeclspec-function-declaration` shall declare a constructor, destructor, or conversion function.

[Note 5: Because a member function cannot be subject to a non-defining declaration outside of a class definition (11.4.2), a `nodeclspec-function-declaration` can only be used in a `template-declaration` (13.1), `explicit-instantiation` (13.9.3), or `explicit-specialization` (13.9.4). — end note]

10 In a `static_assert-declaration`, the `constant-expression` is contextually converted to `bool` and the converted expression shall be a constant expression (7.7). If the value of the expression when so converted is `true` or the expression is evaluated in the context of a template definition, the declaration has no effect. Otherwise, the `static_assert-declaration` fails, the program is ill-formed, and the resulting diagnostic message (4.1) should include the text of the `string-literal`, if one is supplied.

[Example 5:

```c
static_assert(sizeof(int) == sizeof(void*), "wrong pointer size");
static_assert(sizeof(int[2]));                // OK, narrowing allowed

template <class T>
void f(T t) {
  if constexpr (sizeof(T) == sizeof(int)) {
    use(t);
  } else {
    static_assert(false, "must be int-sized");
  }
}

void g(char c) {
  f(0);                                         // OK
  f(c);                                         // error on implementations where sizeof(int) > 1: must be int-sized
}
@end example]

11 An `empty-declaration` has no effect.

12 Except where otherwise specified, the meaning of an `attribute-declaration` is implementation-defined.

9.2 Specifiers

9.2.1 General

The specifiers that can be used in a declaration are

```c
  decl-specifier:
    storage-class-specifier
    defining-type-specifier
    function-specifier
    friend
typedef
tconstexpr
tconstexpr
tconstinit
inline
decl-specifier-seq:
  decl-specifier attribute-specifier-seq, opt
decl-specifier decl-specifier-seq
```
If a type-name is encountered while parsing a decl-specifier-seq, it is interpreted as part of the decl-specifier-seq if and only if there is no previous defining-type-specifier other than a cv-qualifier in the decl-specifier-seq. The sequence shall be self-consistent as described below.

[Example 1:

typedef char* Pc;
static Pc; // error: name missing

Here, the declaration static Pc is ill-formed because no name was specified for the static variable of type Pc. To get a variable called Pc, a type-specifier (other than const or volatile) has to be present to indicate that the typedef-name Pc is the name being (re)declared, rather than being part of the decl-specifier sequence. For another example,

void f(const Pc); // void f(char* const) (not const char*)
void g(const int Pc); // void g(const int)

—end example]

[Note 1: Since signed, unsigned, long, and short by default imply int, a type-name appearing after one of those specifiers is treated as the name being (re)declared.

[Example 2:

void h(unsigned Pc); // void h(unsigned int)
void k(unsigned int Pc); // void k(unsigned int)

—end example]

—end note]

9.2.2 Storage class specifiers

The storage class specifiers are

storage-class-specifier:
static
thread_local
extern
mutable

At most one storage-class-specifier shall appear in a given decl-specifier-seq, except that thread_local may appear with static or extern. If thread_local appears in any declaration of a variable it shall be present in all declarations of that entity. If a storage-class-specifier appears in a decl-specifier-seq, there can be no typedef specifier in the same decl-specifier-seq and the init-declarator-list or member-declarator-list of the declaration shall not be empty (except for an anonymous union declared in a namespace scope (11.5.2)). The storage-class-specifier applies to the name declared by each init-declarator in the list and not to any names declared by other specifiers.

[Note 1: See 13.9.4 and 13.9.3 for restrictions in explicit specializations and explicit instantiations, respectively. —end note]

[Note 2: A variable declared without a storage-class-specifier at block scope or declared as a function parameter has automatic storage duration by default (6.7.5.4). —end note]

The thread_local specifier indicates that the named entity has thread storage duration (6.7.5.3). It shall be applied only to the declaration of a variable of namespace or block scope, to a structured binding declaration (9.6), or to the declaration of a static data member. When thread_local is applied to a variable of block scope the storage-class-specifier static is implied if no other storage-class-specifier appears in the decl-specifier-seq.

The static specifier shall be applied only to the declaration of a variable or function, to a structured binding declaration (9.6), or to the declaration of an anonymous union (11.5.2). There can be no static function declarations within a block, nor any static function parameters. A static specifier used in the declaration of a variable declares the variable to have static storage duration (6.7.5.2), unless accompanied by the thread_local specifier, which declares the variable to have thread storage duration (6.7.5.3). A static specifier can be used in declarations of class members; 11.4.9 describes its effect. For the linkage of a name declared with a static specifier, see 6.6.

The extern specifier shall be applied only to the declaration of a variable or function. The extern specifier shall not be used in the declaration of a class member or function parameter. For the linkage of a name declared with an extern specifier, see 6.6.
All declarations for a given entity shall give its name the same linkage.

---

The name of a declared but undefined class can be used in an `extern` declaration. Such a declaration can only be used in ways that do not require a complete class type.

---

The `mutable` specifier shall appear only in the declaration of a non-static data member (11.4) whose type is neither const-qualified nor a reference type.
9.2.3 Function specifiers

A function-specifier can be used only in a function declaration.

function-specifier:
  virtual
  explicit-specifier
explicit-specifier:
  explicit ( constant-expression )
explicit

The virtual specifier shall be used only in the initial declaration of a non-static member function; see 11.7.3.

An explicit-specifier shall be used only in the declaration of a constructor or conversion function within its class definition; see 11.4.8.2 and 11.4.8.3.

In an explicit-specifier, the constant-expression, if supplied, shall be a contextually converted constant expression of type bool (7.7). The explicit-specifier explicit without a constant-expression is equivalent to the explicit-specifier explicit(true). If the constant expression evaluates to true, the function is explicit. Otherwise, the function is not explicit. A ( token that follows explicit is parsed as part of the explicit-specifier.

[Example 1:
  struct S {
    explicit(sizeof(char[2])) S(char); // error: narrowing conversion of value 2 to type bool
    explicit(sizeof(char)) S(bool);  // OK, conversion of value 1 to type bool is non-narrowing
  };
—end example]

9.2.4 The typedef specifier

Declarations containing the decl-specifier typedef declare identifiers that can be used later for naming fundamental (6.8.2) or compound (6.8.4) types. The typedef specifier shall not be combined in a decl-specifier-seq with any other kind of specifier except a defining-type-specifier, and it shall not be used in the decl-specifier-seq of a parameter-declaration (9.3.4.6) nor in the decl-specifier-seq of a function-definition (9.5). If a typedef specifier appears in a declaration without a declarator, the program is ill-formed.

typedef-name:
  identifier
  simple-template-id

A name declared with the typedef specifier becomes a typedef-name. A typedef-name names the type associated with the identifier (9.3) or simple-template-id (13.1); a typedef-name is thus a synonym for another type. A typedef-name does not introduce a new type the way a class declaration (11.3) or enum declaration (9.7.1) does.

[Example 1: After
typedef int MILES, *KLICKSP;
the constructions
  MILES distance;
  extern KLICKSP metricp;
are all correct declarations; the type of distance is int and that of metricp is “pointer to int”. —end example]

A typedef-name can also be introduced by an alias-declaration. The identifier following the using keyword is not looked up; it becomes a typedef-name and the optional attribute-specifier-seq following the identifier appertains to that typedef-name. Such a typedef-name has the same semantics as if it were introduced by the typedef specifier. In particular, it does not define a new type.

[Example 2:
  using handler_t = void (*)(int);
  extern handler_t ignore;
  extern void (*)(ignore)(int); // redeclare ignore

§ 9.2.4
template<class T> struct P { };  
using cell = P<cell*>;          // error: cell not found (6.4.2)
— end example]

The defining-type-specifier-seq of the defining-type-id shall not define a class or enumeration if the alias-declaration is the declaration of a template-declaration.

3 A simple-template-id is only a typedef-name if its template-name names an alias template or a template template-parameter.

[Note 1: A simple-template-id that names a class template specialization is a class-name (11.3). If a typedef-name is used to identify the subject of an elaborated-type-specifier (9.2.9.4), a class definition (Clause 11), a constructor declaration (11.4.5), or a destructor declaration (11.4.7), the program is ill-formed. — end note]

[Example 3:  
struct S {
    S();
    ~S();
};

typedef struct S T;

S a = T();  // OK
struct T * p;  // error
— end example]

4 An unnamed class or enumeration C defined in a typedef declaration has the first typedef-name declared by the declaration to be of type C as its typedef name for linkage purposes (6.6).

[Note 2: A typedef declaration involving a lambda-expression does not itself define the associated closure type, and so the closure type is not given a typedef name for linkage purposes. — end note]

[Example 4:  
typedef struct { } *ps, S;  // S is the typedef name for linkage purposes
typedef decltype({}) C;  // the closure type has no typedef name for linkage purposes
— end example]

5 An unnamed class with a typedef name for linkage purposes shall not

(5.1) — declare any members other than non-static data members, member enumerations, or member classes,
(5.2) — have any base classes or default member initializers, or
(5.3) — contain a lambda-expression,
and all member classes shall also satisfy these requirements (recursively).

[Example 5:  
typedef struct { 
    int f() {}
} X;  // error: struct with typedef name for linkage has member functions
— end example]

9.2.5 The friend specifier [dcl.friend]

1 The friend specifier is used to specify access to class members; see 11.8.4.

9.2.6 The constexpr and consteval specifiers [dcl.constexpr]

1 The constexpr specifier shall be applied only to the definition of a variable or variable template or the declaration of a function or function template. The consteval specifier shall be applied only to the declaration of a function or function template. A function or static data member declared with the constexpr or consteval specifier is implicitly an inline function or variable (9.2.8). If any declaration of a function or function template has a constexpr or consteval specifier, then all its declarations shall contain the same specifier.

[Note 1: An explicit specialization can differ from the template declaration with respect to the constexpr or consteval specifier. — end note]

[Note 2: Function parameters cannot be declared constexpr. — end note]
[Example 1:
constexpr void square(int &x); // OK, declaration
constexpr int bufsz = 1024; // OK, definition
constexpr struct pixel {
    int x;
    int y;
    constexpr pixel(int);
} // OK, declaration
constexpr pixel::pixel(int a) : x(a), y(x) // OK, definition
{ square(x); }
constexpr pixel small(2); // error: square not defined, so small(2) // not constant (7.7) so constexpr not satisfied
constexpr void square(int &x) { // OK, definition
    x *= x;
}
constexpr pixel large(4); // OK, square defined
int next(constexpr int x) { // error: not for parameters
    return x + 1;
}
extern constexpr int memsz; // error: not a definition
—end example]

2 A constexpr or consteval specifier used in the declaration of a function declares that function to be a constexpr function.

[Note 3: A function or constructor declared with the constexpr specifier is an immediate function (7.7). — end note]

A destructor, an allocation function, or a deallocation function shall not be declared with the constexpr specifier.

3 A function is constexpr-suitable if:

— it is not a coroutine (9.5.4), and
— if the function is a constructor or destructor, its class does not have any virtual base classes.

Except for instantiated constexpr functions, non-templated constexpr functions shall be constexpr-suitable.

[Example 2:
constexpr int square(int x) {
    return x * x; }
constexpr long long_max() {
    return 2147483647; }
constexpr int abs(int x) {
    if (x < 0)
        x = -x;
    return x; // OK
}
constexpr int constant_non_42(int n) { // OK
    if (n == 42) {
        static int value = n;
        return value;
    }
    return n;
}
constexpr int uninit() {
    struct { int a; } s;
    return s.a; // error: uninitialized read of s.a
}
constexpr int prev(int x) {
    return --x; }
constexpr int g(int x, int n) { // OK
    int r = 1;
    while (n > 0) r *= x;
}
return r;
}
—end example

4 An invocation of a constexpr function in a given context produces the same result as an invocation of an

equivalent non-constexpr function in the same context in all respects except that

(4.1) — an invocation of a constexpr function can appear in a constant expression (7.7) and

(4.2) — copy elision is not performed in a constant expression (11.9.6).

[Note 4: Declaring a function constexpr can change whether an expression is a constant expression. This can indirectly cause calls to std::is_constant_evaluated within an invocation of the function to produce a different value. — end note]

[Note 5: It is possible to write a constexpr function for which no invocation satisfies the requirements of a core constant expression. — end note]

5 The constexpr and consteval specifiers have no effect on the type of a constexpr function.

[Example 3:
constexpr int bar(int x, int y)
// OK
{ return x + y + x*y; }
// ...
int bar(int x, int y)
// error: redefinition of bar
{ return x * 2 + 3 * y; }
—end example]

6 A constexpr specifier used in an object declaration declares the object as const. Such an object shall have literal type and shall be initialized. In any constexpr variable declaration, the full-expression of the initialization shall be a constant expression (7.7). A constexpr variable that is an object, as well as any temporary to which a constexpr reference is bound, shall have constant destruction.

[Example 4:
struct pixel {
  int x, y;
};
constexpr pixel ur = { 1294, 1024 }; // OK
constexpr pixel origin; // error: initializer missing
—end example]

9.2.7 The constexpr specifier

The constexpr specifier shall be applied only to a declaration of a variable with static or thread storage
duration. If the specifier is applied to any declaration of a variable, it shall be applied to the initializing
declaration. No diagnostic is required if no constexpr declaration is reachable at the point of the initializing
declaration.

If a variable declared with the constexpr specifier has dynamic initialization (6.9.3.3), the program is
ill-formed, even if the implementation would perform that initialization as a static initialization (6.9.3.2).

[Note 1: The constexpr specifier ensures that the variable is initialized during static initialization. — end note]

[Example 1:
const char * g() { return "dynamic initialization"; }
constexpr const char * f(bool p) { return p ? "constant initializer" : g(); }
constexpr const char * c = f(true); // OK
constexpr const char * d = f(false); // error
—end example]

9.2.8 The inline specifier

The inline specifier shall be applied only to the declaration of a variable or function.

A function declaration (9.3.4.6, 11.4.2, 11.8.4) with an inline specifier declares an inline function. The
inline specifier indicates to the implementation that inline substitution of the function body at the point of
call is to be preferred to the usual function call mechanism. An implementation is not required to perform
this inline substitution at the point of call; however, even if this inline substitution is omitted, the other rules
for inline functions specified in this subclause shall still be respected.
[Note 1: The inline keyword has no effect on the linkage of a function. In certain cases, an inline function cannot use names with internal linkage; see 6.6. — end note]

3 A variable declaration with an inline specifier declares an inline variable.

4 The inline specifier shall not appear on a block scope declaration or on the declaration of a function parameter. If the inline specifier is used in a friend function declaration, that declaration shall be a definition or the function shall have previously been declared inline.

5 If a definition of a function or variable is reachable at the point of its first declaration as inline, the program is ill-formed. If a function or variable with external or module linkage is declared inline in one definition domain, an inline declaration of it shall be reachable from the end of every definition domain in which it is declared; no diagnostic is required.

[Note 2: A call to an inline function or a use of an inline variable can be encountered before its definition becomes reachable in a translation unit. — end note]

6 [Note 3: An inline function or variable with external or module linkage can be defined in multiple translation units (6.3), but is one entity with one address. A type or static variable defined in the body of such a function is therefore a single entity. — end note]

7 If an inline function or variable that is attached to a named module is declared in a definition domain, it shall be defined in that domain.

[Note 4: A constexpr function (9.2.6) is implicitly inline. In the global module, a function defined within a class definition is implicitly inline (11.4.2, 11.8.4). — end note]

### 9.2.9 Type specifiers [dcl.type]

#### 9.2.9.1 General [dcl.type.general]

1 The type-specifiers are

```
  type-specifier:
    simple-type-specifier
    elaborated-type-specifier
    typename-specifier
    cv-qualifier

  type-specifier-seq:
    type-specifier attribute-specifier-seq
    type-specifier attribute-specifier-seq

  defining-type-specifier:
    type-specifier
    class-specifier
    enum-specifier

  defining-type-specifier-seq:
    defining-type-specifier attribute-specifier-seq
    defining-type-specifier attribute-specifier-seq
```

The optional attribute-specifier-seq in a type-specifier-seq or a defining-type-specifier-seq appertains to the type denoted by the preceding type-specifiers or defining-type-specifiers (9.3.4). The attribute-specifier-seq affects the type only for the declaration it appears in, not other declarations involving the same type.

2 As a general rule, at most one defining-type-specifier is allowed in the complete decl-specifier-seq of a declaration or in a defining-type-specifier-seq, and at most one type-specifier is allowed in a type-specifier-seq. The only exceptions to this rule are the following:

(2.1) — `const` can be combined with any type specifier except itself.

(2.2) — `volatile` can be combined with any type specifier except itself.

(2.3) — `signed` or `unsigned` can be combined with `char`, `long`, `short`, or `int`.

(2.4) — `short` or `long` can be combined with `int`.

(2.5) — `long` can be combined with `double`.

(2.6) — `long` can be combined with `long`.

§ 9.2.9.1 182
Except in a declaration of a constructor, destructor, or conversion function, at least one defining-type-specifier that is not a cv-qualifier shall appear in a complete type-specifier-seq or a complete decl-specifier-seq.\[79\]

[Note 1: enum-specifiers, class-specifiers, and typename-specifiers are discussed in 9.7.1, Clause 11, and 13.8, respectively. The remaining type-specifiers are discussed in the rest of 9.2.9. — end note]

9.2.9.2 The cv-qualifiers

There are two cv-qualifiers, const and volatile. Each cv-qualifier shall appear at most once in a cv-qualifier-seq. If a cv-qualifier appears in a decl-specifier-seq, the init-declarator-list or member-declarator-list of the declaration shall not be empty.

[Note 1: 6.8.5 and 9.3.4.6 describe how cv-qualifiers affect object and function types. — end note]

Redundant cv-qualifications are ignored.

[Note 2: For example, these could be introduced by typedefs. — end note]

[Note 3: Declaring a variable const can affect its linkage (9.2.2) and its usability in constant expressions (7.7). As described in 9.4, the definition of an object or subobject of const-qualified type must specify an initializer or be subject to default-initialization. — end note]

A pointer or reference to a cv-qualified type need not actually point or refer to a cv-qualified object, but it is treated as if it does; a const-qualified access path cannot be used to modify an object even if the object referenced is a non-const object and can be modified through some other access path.

[Note 4: Cv-qualifiers are supported by the type system so that they cannot be subverted without casting (7.6.1.11). — end note]

Any attempt to modify (7.6.19, 7.6.1.6, 7.6.2.3) a const object (6.8.5) during its lifetime (6.7.3) results in undefined behavior.

[Example 1:

```c
const int ci = 3; // cv-qualified (initialized as required)
    ci = 4; // error: attempt to modify const

int i = 2; // not cv-qualified
const int* cip; // pointer to const int
cip = &i; // OK, cv-qualified access path to unqualified
*cip = 4; // error: attempt to modify through ptr to const

int* ip;
ip = const_cast<int*>(cip); // cast needed to convert const int* to int*
*ip = 4; // defined: *ip points to i, a non-const object

const int* ciq = new const int (3); // initialized as required
int* iq = const_cast<int*>(ciq); // cast required
*iq = 4; // undefined behavior: modifies a const object
```

For another example,

```c
struct X {
    mutable int i;
    int j;
};
struct Y {
    X x;
    Y();
};

const Y y;
y.x.i++; // well-formed: mutable member can be modified
y.x.j++; // error: const-qualified member modified
Y* p = const_cast<Y*>(&y);
p->x.i = 99; // cast away const-ness of y
p->x.j = 99; // well-formed: mutable member can be modified
p->x.j = 99; // undefined behavior: modifies a const subobject
```

— end example]

\[79\] There is no special provision for a decl-specifier-seq that lacks a type-specifier or that has a type-specifier that only specifies cv-qualifiers. The “implicit int” rule of C is no longer supported.
The semantics of an access through a volatile glvalue are implementation-defined. If an attempt is made to access an object defined with a volatile-qualified type through the use of a non-volatile glvalue, the behavior is undefined.

[Note 5: volatile is a hint to the implementation to avoid aggressive optimization involving the object because the value of the object might be changed by means undetectable by an implementation. Furthermore, for some implementations, volatile might indicate that special hardware instructions are required to access the object. See 6.9.1 for detailed semantics. In general, the semantics of volatile are intended to be the same in C++ as they are in C. — end note]

9.2.9.3 Simple type specifiers

The simple type specifiers are

```
simple-type-specifier:
  nested-name-specifier_opt type-name
  nested-name-specifier template simple-template-id
dcltype-specifier
  placeholder-type-specifier
nenamed-name-specifier_opt template-name
class-name
class-name
enum-name
type-name

type-name:
  class-name
  enum-name
typedef-name

char
char8_t
char16_t
char32_t
wchar_t
bool
short
int
long
signed
unsigned
float
double
void
```

The component names of a simple-type-specifier are those of its nested-name-specifier, type-name, simple-template-id, template-name, and/or type-constraint (if it is a placeholder-type-specifier). The component name of a type-name is the first name in it.

A placeholder-type-specifier is a placeholder for a type to be deduced (9.2.9.6). A type-specifier of the form typename_opt nested-name-specifier_opt template-name is a placeholder for a deduced class type (9.2.9.7). The named-name-specifier, if any, shall be non-dependent and the template-name shall name a deducible template. A deducible template is either a class template or is an alias template whose defining-type-id is of the form

```
typename_opt nested-name-specifier_opt template_opt simple-template-id
```

where the nested-name-specifier (if any) is non-dependent and the template-name of the simple-template-id names a deducible template.

[Note 1: An injected-class-name is never interpreted as a template-name in contexts where class template argument deduction would be performed (13.8.2). — end note]

The other simple-type-specifiers specify either a previously-declared type, a type determined from an expression, or one of the fundamental types (6.8.2). Table 17 summarizes the valid combinations of simple-type-specifiers and the types they specify.

When multiple simple-type-specifiers are allowed, they can be freely intermixed with other decl-specifiers in any order.

[Note 2: It is implementation-defined whether objects of char type are represented as signed or unsigned quantities. The signed specifier forces char objects to be signed; it is redundant in other contexts. — end note]

9.2.9.4 Elaborated type specifiers

§ 9.2.9.4

</table>

1. The component names of an *elaborated-type-specifier* are its *identifier* (if any) and those of its *nested-name-specifier* and *simple-template-id* (if any).

2. If an *elaborated-type-specifier* is the sole constituent of a declaration, the declaration is ill-formed unless it is an explicit specialization (13.9.4), an explicit instantiation (13.9.3) or it has one of the following forms:

   - `class-key attribute-specifier-seq_opt nested-name-specifier_opt identifier`
   - `class-key simple-template-id`
   - `class-key nested-name-specifier template_opt simple-template-id enum nested-name-specifier_opt identifier`

§ 9.2.9.4
In the first case, the elaborated-type-specifier declares the identifier as a class-name. The second case shall appear only in an explicit-specialization (13.9.4) or in a template-declaration (where it declares a partial specialization (13.7)). The attribute-specifier-seq, if any, appertains to the class or template being declared.

3 Otherwise, an elaborated-type-specifier E shall not have an attribute-specifier-seq. If E contains an identifier but no nested-name-specifier and (unqualified) lookup for the identifier finds nothing, E shall not be introduced by the enum keyword and declares the identifier as a class-name. The target scope of E is the nearest enclosing namespace or block scope.

4 If an elaborated-type-specifier appears with the friend specifier as an entire member-declaration, the member-declaration shall have one of the following forms:

friend class-key nested-name-specifier,opt identifier;
friend class-key simple-template-id;
friend class-key nested-name-specifier template, opt simple-template-id;

Any unqualified lookup for the identifier (in the first case) does not consider scopes that contain the target scope; no name is bound.

[Note 1: A using-directive in the target scope is ignored if it refers to a namespace not contained by that scope. 6.5.6 describes how name lookup proceeds in an elaborated-type-specifier. — end note]

5 [Note 2: An elaborated-type-specifier can be used to refer to a previously declared class-name or enum-name even if the name has been hidden by a non-type declaration. — end note]

If the identifier or simple-template-id resolves to a class-name or enum-name, the elaborated-type-specifier introduces it into the declaration the same way a simple-type-specifier introduces its type-name (9.2.9.3). If the identifier or simple-template-id resolves to a typedef-name (9.2.4, 13.3), the elaborated-type-specifier is ill-formed.

[Note 3: This implies that, within a class template with a template type-parameter T, the declaration

friend class T;

is ill-formed. However, the similar declaration friend T; is allowed (11.8.4). — end note]

6 The class-key or enum keyword present in the elaborated-type-specifier shall agree in kind with the declaration to which the name in the elaborated-type-specifier refers. This rule also applies to the form of elaborated-type-specifier that declares a class-name or friend class since it can be construed as referring to the definition of the class. Thus, in any elaborated-type-specifier, the enum keyword shall be used to refer to an enumeration (9.7.1), the union class-key shall be used to refer to a union (11.5), and either the class or struct class-key shall be used to refer to a non-union class (11.1).

[Example 1:

enum class E { a, b; 
enum E x = E::a; // OK
struct S { } s;
class S* p = &s; // OK
— end example]

9.2.9.5 Decltype specifiers

dcl.type.decltype

decltype: ( expression )

1 For an expression E, the type denoted by decltype(E) is defined as follows:

(1.1) — if E is an unparenthesized id-expression naming a structured binding (9.6), decltype(E) is the referenced type as given in the specification of the structured binding declaration;

(1.2) — otherwise, if E is an unparenthesized id-expression naming a non-type template-parameter (13.2), decltype(E) is the type of the template-parameter after performing any necessary type deduction (9.2.9.6, 9.2.9.7);

(1.3) — otherwise, if E is an unparenthesized id-expression or an unparenthesized class member access (7.6.1.5), decltype(E) is the type of the entity named by E. If there is no such entity, the program is ill-formed;

(1.4) — otherwise, if E is an xvalue, decltype(E) is T&&, where T is the type of E;

(1.5) — otherwise, if E is an lvalue, decltype(E) is T& where T is the type of E;

(1.6) — otherwise, decltype(E) is the type of E.
The operand of the `decltype` specifier is an unevaluated operand (7.2.3).

[Example 1:

```c
const int&& foo();
int i;
struct A { double x; };  // type is const int&&
dectype(foo()) x1 = 17;  // type is int
dectype(i) x2;           // type is double
struct A* a = new A();  // type is const double&
dectype((a->x)) x3 = x3;  // type is const double&
```
—end example]

[Note 1: The rules for determining types involving `decltype(auto)` are specified in 9.2.9.6. — end note]

If the operand of a `decltype-specifier` is a prvalue and is not a (possibly parenthesized) immediate invocation (7.7), the temporary materialization conversion is not applied (7.3.5) and no result object is provided for the prvalue. The type of the prvalue may be incomplete or an abstract class type.

[Note 2: As a result, storage is not allocated for the prvalue and it is not destroyed. Thus, a class type is not instantiatied as a result of being the type of a function call in this context. In this context, the common purpose of writing the expression is merely to refer to its type. In that sense, a `decltype-specifier` is analogous to a use of a `typedef-name`, so the usual reasons for requiring a complete type do not apply. In particular, it is not necessary to allocate storage for a temporary object or to enforce the semantic constraints associated with invoking the type’s destructor. — end note]

[Note 3: Unlike the preceding rule, parentheses have no special meaning in this context. — end note]

[Example 2:

```c
template<class T> struct A { ~A() = delete; };  // type is const int&&
template<class T> auto h()  // for the temporary introduced by the use of h().  // (A temporary is not introduced as a result of the use of i().)
    -> A<T>;
template<class T> auto i(T)  // identity
    -> T;
template<class T> auto I(T)  // #2
    -> decltype(i(h<T>()));
auto g() -> void {
    f(42);  // OK, calls #2. (#1 is not a viable candidate: type deduction fails (13.10.3) because A<int>::~A() is implicitly used in its
             // decltype-specifier)
}
```

```c
template<class T> auto q(T)  // does not force completion of A<T>; A<T>::~A() is not implicitly
    -> decltype((h<T>()));  // used within the context of this decltype-specifier
```

```c
void r() {
    q(42);  // error: deduction against q succeeds, so overload resolution selects
             // the specialization "q(T) -> decltype((h<T>())" with T=int;
             // the return type is A<int>, so a temporary is introduced and its
defstructor is used, so the program is ill-formed
}
```
—end example]

### 9.2.9.6 Placeholder type specifiers [dcl.spec.auto]

#### 9.2.9.6.1 General [dcl.spec.auto.general]

```c
placeholder-type-specifier:  
    type-constraint_opt auto  
    type-constraint_opt decltype ( auto )
```

1 A `placeholder-type-specifier` designates a placeholder type that will be replaced later by deduction from an initializer.
A placeholder-type-specifier of the form type-constraint_opt auto can be used as a decl-specifier of the decl-specifier-seq of a parameter-declaration of a function declaration or lambda-expression and, if it is not the auto type-specifier introducing a trailing-return-type (see below), is a generic parameter type placeholder of the function declaration or lambda-expression.

[Note 1: Having a generic parameter type placeholder signifies that the function is an abbreviated function template (9.3.4.6) or the lambda is a generic lambda (7.5.5). — end note]

A placeholder type can appear with a function declarator in the decl-specifier-seq, type-specifier-seq, conversion-function-id, or trailing-return-type, in any context where such a declarator is valid. If the function declarator includes a trailing-return-type (9.3.4.6), that trailing-return-type specifies the declared return type of the function. Otherwise, the function declarator shall declare a function. If the declared return type of the function contains a placeholder type, the return type of the function is deduced from non-discarded return statements, if any, in the body of the function (8.5.2).

The type of a variable declared using a placeholder type is deduced from its initializer. This use is allowed in an initializing declaration (9.4) of a variable. The placeholder type shall appear as one of the decl-specifiers in the decl-specifier-seq and the decl-specifier-seq shall be followed by one or more declarators, each of which shall be followed by a non-empty initializer.

[Example 1:

```c
auto x = 5; // OK, x has type int
cost auto *v = &x, u = 6; // OK, v has type const int*, u has type const int
static auto y = 0.0; // OK, y has type double
auto int r; // error: auto is not a storage-class-specifier
auto f() -> int; // OK, f returns int
auto g() { return 0.0; } // OK, g returns double
auto h(); // OK, h’s return type will be deduced when it is defined
```

— end example]

The auto type-specifier can also be used to introduce a structured binding declaration (9.6).

A placeholder type can also be used in the type-specifier-seq in the new-type-id or type-id of a new-expression (7.6.2.8) and as a decl-specifier of the parameter-declaration’s decl-specifier-seq in a template-parameter (13.2). The auto type-specifier can also be used as the simple-type-specifier in an explicit type conversion (functional notation) (7.6.1.4).

A program that uses a placeholder type in a context not explicitly allowed in 9.2.9.6 is ill-formed.

If the init-declarator-list contains more than one init-declarator, they shall all form declarations of variables. The type of each declared variable is determined by placeholder type deduction (9.2.9.6.2), and if the type that replaces the placeholder type is not the same in each deduction, the program is ill-formed.

[Example 2:

```c
auto x = 5, y = &x; // OK, auto is int
auto a = 5, b = { 1, 2 }; // error: different types for auto
```

— end example]

If a function with a declared return type that contains a placeholder type has multiple non-discarded return statements, the return type is deduced for each such return statement. If the type deduced is not the same in each deduction, the program is ill-formed.

If a function with a declared return type that uses a placeholder type has no non-discarded return statements, the return type is deduced as though from a return statement with no operand at the closing brace of the function body.

[Example 3:

```c
auto f() { } // OK, return type is void
auto g() { } // error: cannot deduce auto* from void()
```

— end example]

An exported function with a declared return type that uses a placeholder type shall be defined in the translation unit containing its exported declaration, outside the private-module-fragment (if any).

[Note 2: The deduced return type cannot have a name with internal linkage (6.6). — end note]
If a variable or function with an undeduced placeholder type is named by an expression (6.3), the program is ill-formed. Once a non-discarded return statement has been seen in a function, however, the return type deduced from that statement can be used in the rest of the function, including in other return statements.

[Example 4:]

```cpp
auto n = n; // error: n's initializer refers to n
auto f();
void g() { &f; } // error: f's return type is unknown
auto sum(int i) {
    if (i == 1)
        return i; // sum's return type is int
    else
        return sum(i-1)+i; // OK, sum's return type has been deduced
}
```

—end example]

Return type deduction for a templated function with a placeholder in its declared type occurs when the definition is instantiated even if the function body contains a return statement with a non-type-dependent operand.

[Note 3: Therefore, any use of a specialization of the function template will cause an implicit instantiation. Any errors that arise from this instantiation are not in the immediate context of the function type and can result in the program being ill-formed (13.10.3). — end note]

[Example 5:]

```cpp
template <class T> auto f(T t) { return t; } // return type deduced at instantiation time
typedef decltype(f(1)) fint_t; // instantiates f<int> to deduce return type
template<class T> auto f(T* t) { return *t; } // instantiates both fs to determine return types,
// chooses second
```

—end example]

If a function or function template \( F \) has a declared return type that uses a placeholder type, redeclarations or specializations of \( F \) shall use that placeholder type, not a deduced type; otherwise, they shall not use a placeholder type.

[Example 6:]

```cpp
auto f();
auto f() { return 42; } // return type is int
auto f(); // OK
int f(); // error: auto and int don't match
decltype(auto) f(); // error: auto and decltype(auto) don't match

template <typename T> auto g(T t) { return t; } // #1
template auto g(int); // OK, return type is int
template char g(char); // error: no matching template
template<> auto g(double); // OK, forward declaration with unknown return type

template <class T> T g(T t) { return t; } // OK, not functionally equivalent to #1
template char g(char); // OK, now there is a matching template
template auto g(float); // still matches #1

void h() { return g(42); } // error: ambiguous

template <typename T> struct A {
    friend T frf(T);
};
auto frf(int i) { return i; } // not a friend of A<int>
extern int v;
auto v = 17; // OK, redeclares v
struct S {
    static int i;
};
auto S::i = 23; // OK
```
A function declared with a return type that uses a placeholder type shall not be virtual (11.7.3).

A function declared with a return type that uses a placeholder type shall not be a coroutine (9.5.4).

An explicit instantiation declaration (13.9.3) does not cause the instantiation of an entity declared using a placeholder type, but it also does not prevent that entity from being instantiated as needed to determine its type.

[Example 7:
```cpp
template <typename T> auto f(T t) { return t; }
extern template auto f(int); // does not instantiate f<int>
int (*p)(int) = f; // instantiates f<int> to determine its return type, but an explicit instantiation definition is still required somewhere in the program
```
—end example]

9.2.9.6.2 Placeholder type deduction [dcl.type.auto.deduct]

Placeholder type deduction is the process by which a type containing a placeholder type is replaced by a deduced type.

A type \(T\) containing a placeholder type, and a corresponding initializer-clause \(E\), are determined as follows:

1. For a non-discarded return statement that occurs in a function declared with a return type that contains a placeholder type, \(T\) is the declared return type.
   1.1. If the return statement has no operand, then \(E\) is \(\text{void}()\).
   1.2. If the operand is a braced-init-list (9.4.5), the program is ill-formed.
   1.3. If the operand is an expression \(X\) that is not an assignment-expression, \(E\) is \((X)\).
      [Note 1: A comma expression (7.6.20) is not an assignment-expression. —end note]
   1.4. Otherwise, \(E\) is the operand of the return statement.

   If \(E\) has type \(\text{void}\), \(T\) shall be either \(\text{type-constraint}_{\text{opt}}\ \text{decltype(auto)}\) or \(\text{cv}\ \text{type-constraint}_{\text{opt}}\ \text{auto}\).

2. For a variable declared with a type that contains a placeholder type, \(T\) is the declared type of the variable.
   2.1. If the initializer of the variable is a brace-or-equal-initializer of the form \(=\) initializer-clause, \(E\) is the initializer-clause.
   2.2. If the initializer is a braced-init-list, it shall consist of a single brace-enclosed assignment-expression and \(E\) is the assignment-expression.
   2.3. If the initializer is a parenthesized expression-list, the expression-list shall be a single assignment-expression and \(E\) is the assignment-expression.
   2.4. For an explicit type conversion (7.6.1.4), \(T\) is the specified type, which shall be \text{auto}.

3. For a non-type template parameter declared with a type that contains a placeholder type, \(T\) is the declared type of the non-type template parameter and \(E\) is the corresponding template argument.
   \(T\) shall not be an array type.

3. If the placeholder-type-specifier is of the form \(\text{type-constraint}_{\text{opt}}\ \text{auto}\), the deduced type \(T'\) replacing \(T\) is determined using the rules for template argument deduction. If the initialization is copy-list-initialization, a declaration of \text{std}::\text{initializer_list}\ shall precede (6.5.1) the placeholder-type-specifier. Obtain \(P\) from \(T\) by replacing the occurrences of \(\text{type-constraint}_{\text{opt}}\ \text{auto}\) either with a new invented type template parameter \(U\) or, if the initialization is copy-list-initialization, with \text{std}::\text{initializer_list}<U>. Deduce a value for \(U\) using the rules of template argument deduction from a function call (13.10.3.2), where \(P\) is a function template parameter type and the corresponding argument is \(E\). If the deduction fails, the declaration is ill-formed. Otherwise, \(T'\) is obtained by substituting the deduced \(U\) into \(P\).

[Example 1:
auto x1 = { 1, 2 }; // decltype(x1) is std::initializer_list<int>
auto x2 = { 1, 2.0 }; // error: cannot deduce element type
auto x3 = { 1, 2 }; // error: not a single element
auto x4 = { 3 }; // decltype(x4) is std::initializer_list<int>
auto x5 = 3; // decltype(x5) is int

— end example

Example 2:
const auto &i = expr;
The type of i is the deduced type of the parameter u in the call f(expr) of the following invented function template:
template <class U> void f(const U& u);
— end example

4 If the placeholder-type-specifier is of the form type-constraintopt decltype(auto), T shall be the placeholder alone. The type deduced for T is determined as described in 9.2.9.5, as though E had been the operand of the decltype.

[Example 3:
int i;
int&& f();
auto x2a(i); // decltype(x2a) is int
decletype(auto) x2d(i); // decltype(x2d) is int
auto x3a = i; // decltype(x3a) is int
decletype(auto) x3d = i; // decltype(x3d) is int
auto x4a = (i); // decltype(x4a) is int
decletype(auto) x4d = (i); // decltype(x4d) is int&
auto x5a = f(); // decltype(x5a) is int
decletype(auto) x5d = f(); // decltype(x5d) is int&
auto x6a = { 1, 2 }; // decltype(x6a) is std::initializer_list<int>
decletype(auto) x6d = { 1, 2 }; // error: { 1, 2 } is not an expression
auto *x7a = &i; // decltype(x7a) is int*
decletype(auto)*x7d = &i; // error: declared type is not plain decltype(auto)
auto f1(int x) -> decltype((x)) { return (x); } // return type is int&
auto f2(int x) -> decltype(auto) { return (x); } // return type is int&&

— end example]

5 For a placeholder-type-specifier with a type-constraint, the immediately-declared constraint (13.2) of the type-constraint for the type deduced for the placeholder shall be satisfied.

9.2.9.7 Deduced class template specialization types
[dcl.type.class.deduct]
1 If a placeholder for a deduced class type appears as a decl-specifier in the decl-specifier-seq of an initializing declaration (9.4) of a variable, the declared type of the variable shall be cv T, where T is the placeholder.

[Example 1:
template <class ...T> struct A {
A(T...)
};
A x[29]; // error: no declarator operators allowed
const &x[29]; // error: no declarator operators allowed

— end example]
The placeholder is replaced by the return type of the function selected by overload resolution for class template deduction (12.2.2.9). If the decl-specifier-seq is followed by an init-declarator-list or member-declarator-list containing more than one declarator, the type that replaces the placeholder shall be the same in each deduction.

2 A placeholder for a deduced class type can also be used in the type-specifier-seq in the new-type-id or type-id of a new-expression (7.6.2.8), as the simple-type-specifier in an explicit type conversion (functional notation) (7.6.1.4), or as the type-specifier in the parameter-declaration of a template-parameter (13.2). A placeholder for a deduced class type shall not appear in any other context.

[Example 2:
template<class T> struct container {
    container(T t) {}
    template<class Iter> container(Iter beg, Iter end);
};
template<class Iter>
container(Iter b, Iter e) -> container<typename std::iterator_traits<Iter>::value_type>;
std::vector<double> v = { /* ... */ };
container c(7);
// OK, deduces
auto d = container(v.begin(), v.end()); // OK, deduces double for T
container e{5, 6}; // error: int is not an iterator
— end example]

9.3 Declarators [dcl.decl]
9.3.1 General [dcl.decl.general]
1 A declarator declares a single variable, function, or type, within a declaration. The init-declarator-list appearing in a simple-declaration is a comma-separated sequence of declarators, each of which can have an initializer.

init-declarator-list:
    init-declarator
    init-declarator-list , init-declarator

init-declarator:
    declarator initializer
    declarator requires-clause

2 In all contexts, a declarator is interpreted as given below. Where an abstract-declarator can be used (or omitted) in place of a declarator (9.3.4.6, 14.1), it is as if a unique identifier were included in the appropriate place (9.3.2). The preceding specifiers indicate the type, storage class or other properties of the entity or entities being declared. Each declarator specifies one entity and (optionally) names it and/or modifies the type of the specifiers with operators such as * (pointer to) and () (function returning).

[Note 1: An init-declarator can also specify an initializer (9.4). — end note]
3 Each init-declarator or member-declarator in a declaration is analyzed separately as if it were in a declaration by itself.

[Note 2: A declaration with several declarators is usually equivalent to the corresponding sequence of declarations each with a single declarator. That is, T D1, D2, ... Dn;

is usually equivalent to T D1; T D2; ... T Dn;

where T is a decl-specifier-seq and each Di is an init-declarator or member-declarator. One exception is when a name introduced by one of the declarators hides a type name used by the decl-specifiers, so that when the same decl-specifiers are used in a subsequent declaration, they do not have the same meaning, as in

struct S { /* ... */
S S, T;
// declare two instances of struct S

which is not equivalent to

struct S { /* ... */
S S;
S T;
// error

Another exception is when T is auto (9.2.9.6), for example:

auto i = 1, j = 2.0; // error: deduced types for i and j do not match

as opposed to

auto i = 1; // OK, i deduced to have type int
auto j = 2.0; // OK, j deduced to have type double

— end note]
4 The optional requires-clause (13.1) in an init-declarator or member-declarator shall be present only if the declarator declares a templated function (9.3.4.6). When present after a declarator, the requires-clause is
called the trailing requires-clause. The trailing requires-clause introduces the constraint-expression that results from interpreting its constraint-logical-or-expression as a constraint-expression.

[Example 1:]

```c
void f1(int a) requires true; // error: non-templated function
template<typename T>
    auto f2(T a) -> bool requires true; // OK
template<typename T>
    auto f3(T a) requires true -> bool; // error: requires-clause precedes trailing-return-type
void (*pf)() requires true; // error: constraint on a variable
g(int (*)(char) requires true); // error: constraint on a parameter-declaration
auto* p = new void(*)(char) requires true; // error: not a function declaration
```

—end example—

5 Declarators have the syntax

```plaintext
declarator:
    ptr-declarator
    noptr-declarator parameters-and-qualifiers trailing-return-type
ptr-declarator:
    noptr-declarator
    ptr-operator ptr-declarator
noptr-declarator:
    declarator-id attribute-specifier-seq_opt
    noptr-declarator parameters-and-qualifiers
    noptr-declarator [ constant-expression_opt ] attribute-specifier-seq_opt
    ( ptr-declarator )
parameters-and-qualifiers:
    ( parameter-declaration-clause ) cv-qualifier-seq_opt
    ref-qualifier_opt noexcept-specifier_opt attribute-specifier-seq_opt
trailing-return-type:
    -> type-id
ptr-operator:
    * attribute-specifier-seq_opt cv-qualifier-seq_opt
    & attribute-specifier-seq_opt
    && attribute-specifier-seq_opt
    nested-name-specifier * attribute-specifier-seq_opt cv-qualifier-seq_opt
cv-qualifier-seq:
    cv-qualifier cv-qualifier-seq_opt
cv-qualifier:
    const
    volatile
ref-qualifier:
    &
    &&
declarator-id:
    ....opt id-expression
```

9.3.2 Type names

1 To specify type conversions explicitly, and as an argument of sizeof, alignof, new, or typeid, the name of a type shall be specified. This can be done with a type-id, which is syntactically a declaration for a variable or function of that type that omits the name of the entity.

```plaintext
type-id:
    type-specifier-seq abstract-declarator_opt
defining-type-id:
    defining-type-specifier-seq abstract-declarator_opt
```
It is possible to identify uniquely the location in the *abstract-declarator* where the identifier would appear if the construction were a declarator in a declaration. The named type is then the same as the type of the hypothetical identifier.

*Example 1:*

```c
int // int i
int * // int *pi
int [*][3] // int *p[3]
int (*)(*)[3] // int (*)(p3i)[3]
in *() // int *f()
in (*)(double) // int (*)(double)
```

name respectively the types “*int*”, “pointer to *int*”, “array of 3 pointers to *int*”, “pointer to array of 3 *int*”, “function of (no parameters) returning pointer to *int*”, and “pointer to a function of (*double*) returning *int*”. —end example

A type can also be named (often more easily) by using a *typedef* (9.2.4).

### 9.3.3 Ambiguity resolution

The ambiguity arising from the similarity between a function-style cast and a declaration mentioned in 8.9 can also occur in the context of a declaration. In that context, the choice is between an object declaration with a function-style cast as the initializer and a declaration involving a function declarator with a redundant set of parentheses around a parameter name. Just as for the ambiguities mentioned in 8.9, the resolution is to consider any construct, such as the potential parameter declaration, that could possibly be a declaration to be a declaration.

*Note 1: A declaration can be explicitly disambiguated by adding parentheses around the argument. The ambiguity can be avoided by use of copy-initialization or list-initialization syntax, or by use of a non-function-style cast. —end note*

*Example 1:*

```c
struct S {
    S(int);
};

void foo(double a) {
    S w(int(a)); // function declaration
    S x(int());  // function declaration
    S y((int(a)));// object declaration
    S y((int)a);  // object declaration
    S z = int(a); // object declaration
}
```

—end example

An ambiguity can arise from the similarity between a function-style cast and a *type-id*. The resolution is that any construct that could possibly be a *type-id* in its syntactic context shall be considered a *type-id*.
Example 2:

```c
template <class T> struct X {};
template <int N> struct Y {};
X<int()> a;  // type-id
X<int(1)> b;  // expression (ill-formed)
Y<int()> c;  // type-id (ill-formed)
Y<int(1)> d;  // expression
void foo(signed char a) {
  sizeof(int());  // type-id (ill-formed)
  sizeof(int(a));  // expression
  sizeof(int(unsigned(a)));  // type-id (ill-formed)
  (int())+1;  // type-id (ill-formed)
  (int(a))+1;  // expression
  (int(unsigned(a)))+1;  // type-id (ill-formed)
}
```

—end example]

Another ambiguity arises in a parameter-declaration-clause when a type-name is nested in parentheses. In this case, the choice is between the declaration of a parameter of type pointer to function and the declaration of a parameter with redundant parentheses around the declarator-id. The resolution is to consider the type-name as a simple-type-specifier rather than a declarator-id.

Example 3:

```c
class C { }
void f(int(C)) { }  // void f(int(*fp)(C c)) { }
int g(C);
void foo() {
  f(1);  // error: cannot convert 1 to function pointer
  f(g);  // OK
}
```

For another example,

```c
class C { }
void h(int *(C[10]));  // void h(int *(*_fp)(C _parm[10]));
```

—end example]

9.3.4 Meaning of declarators  [dcl.meaning]

9.3.4.1 General  [dcl.meaning.general]

A declarator contains exactly one declarator-id; it names the entity that is declared. If the unqualified-id occurring in a declarator-id is a template-id, the declarator shall appear in the declaration of a template-declaration (13.7), explicit-specialization (13.9.4), or explicit-instantiation (13.9.3).

[Note 1: An unqualified-id that is not an identifier is used to declare certain functions (11.4.8.3, 11.4.7, 12.4, 12.6). —end note]

The optional attribute-specifier-seq following a declarator-id appertains to the entity that is declared.

If the declaration is a friend declaration:

1. The declarator does not bind a name.
2. If the id-expression E in the declarator-id of the declarator is a qualified-id or a template-id:
   2.1. If the friend declaration is not a template declaration, then in the lookup for the terminal name of E:
      2.1.1. If the unqualified-id in E is a template-id, all function declarations are discarded;
      2.1.2. Otherwise, if the declarator corresponds (6.4.1) to any declaration found of a non-template function, all function template declarations are discarded;
— each remaining function template is replaced with the specialization chosen by deduction from
the friend declaration (13.10.3.7) or discarded if deduction fails.

— The declarator shall correspond to one or more declarations found by the lookup; they shall all
have the same target scope, and the target scope of the declarator is that scope.

— Otherwise, the terminal name of E is not looked up. The declaration’s target scope is the innermost
class scope; if the declaration is contained by a class scope, the declaration shall
 correspond to a reachable (10.7) declaration that inhabits the innermost class scope.

3 Otherwise:

(3.1) — If the id-expression in the declarator-id of the declarator is a qualified-id Q, let S be its lookup context
 (6.5.5); the declaration shall inhabit a namespace scope.

(3.2) — Otherwise, let S be the entity associated with the scope inhabited by the declarator.

(3.3) — If the declarator declares an explicit instantiation or a partial or explicit specialization, the declarator
does not bind a name. If it declares a class member, the terminal name of the declarator-id is not looked
up; otherwise, only those lookup results that are nominable in S are considered when identifying any
function template specialization being declared (13.10.3.7).

[Example 1:

```cpp
namespace N {
  inline namespace O {
    template<class T> void f(T);  // #1
    template<class T> void g(T) {}  // #2, more specialized than #1
  }
  namespace P {
    template<class T> void f(T*);
    template<class> int g;
  }
  using P::f, P::g;
}
template<> void N::f(int*) {}  // OK, #2 is not nominable
template void N::g(int);     // error: lookup is ambiguous
```

— end example]

(3.4) — Otherwise, the terminal name of the declarator-id is not looked up. If it is a qualified name, the
 declarator shall correspond to one or more declarations nominable in S; all the declarations shall have
 the same target scope and the target scope of the declarator is that scope.

[Example 2:

```cpp
namespace Q {
  namespace V {
    void f();
  }
  void V::f() { /* ... */ }  // OK
  void V::g() { /* ... */ }  // error: g() is not yet a member of V
  namespace V {
    void g();
  }
}
namespace R {
  void Q::V::g() { /* ... */ }  // error: R doesn't enclose Q
}
```

— end example]

(3.5) — If the declaration inhabits a block scope S and declares a function (9.3.4.6) or uses the extern specifier,
the declaration shall not be attached to a named module (10.1); its target scope is the innermost
class scope, but the name is bound in S.

[Example 3:

```cpp
namespace X {
  void p() {
    q();  // error: q not yet declared
  }

```
extern void q();  // q is a member of namespace X
extern void r();  // r is a member of namespace X
}

void middle() {
  q();             // error: q not found
}

void q() { /* ... */ }  // definition of X::q
void q() { /* ... */ }  // some other, unrelated q
void X::r() { /* ... */ }  // error: r cannot be declared by qualified-id

Example 4: In the declaration
int unsigned i;
the type specifiers int unsigned determine the type "unsigned int" (9.2.9.3). — end example]

In a declaration attribute-specifier-seq_opt decl-specifier-seq and D is a declarator. Following is a recursive procedure for determining the type specified for the contained declarator-id by such a declaration.

First, the decl-specifier-seq determines a type. In a declaration
T D
where T is of the form attribute-specifier-seq_opt decl-specifier-seq and D is a declarator. Following is a recursive procedure for determining the type specified for the contained declarator-id by such a declaration.

In a declaration T D where D has the form
(D1)
the type of the contained declarator-id is the same as that of the contained declarator-id in the declaration
T D1
Parentheses do not alter the type of the embedded declarator-id, but they can alter the binding of complex declarators.

9.3.4.2 Pointers [dcl.ptr]

In a declaration T D where D has the form
* attribute-specifier-seq_opt cv-qualifier-seq_opt D1
and the type of the contained declarator-id in the declaration T D1 is "derived-declarator-type-list T", the type of the declarator-id in D is "derived-declarator-type-list cv-qualifier-seq pointer to T". The cv-qualifiers apply to the pointer and not to the object pointed to. Similarly, the optional attribute-specifier-seq (9.12.1) appertains to the pointer and not to the object pointed to.

Example 1: The declarations
const int ci = 10, *pc = &ci, *const cpc = pc, **ppc;
int i, *p, *const cp = &i;
declare ci, a constant integer; pc, a pointer to a constant integer; cpc, a constant pointer to a constant integer; ppc, a pointer to a pointer to a constant integer; i, an integer; p, a pointer to integer; and cp, a constant pointer to integer.

The value of ci, cpc, and cp cannot be changed after initialization. The value of pc can be changed, and so can the object pointed to by cp. Examples of some correct operations are
i = ci;
*cp = ci;
pc++;
Examples of ill-formed operations are

```
ci = 1;  // error
.ci++;
.pc = 2;  // error
.cp = &ci; // error
cpc++;  // error
.p = pc;  // error
.ppc = &p; // error
```

Each is unacceptable because it would either change the value of an object declared `const` or allow it to be changed through a cv-unqualified pointer later, for example:

```
*ppc = &ci;  // OK, but would make p point to ci because of previous error
*p = 5;  // clobber ci
```

See also 7.6.19 and 9.4.

[Note 1: Forming a pointer to reference type is ill-formed; see 9.3.4.3. Forming a function pointer type is ill-formed if the function type has cv-qualifiers or a ref-qualifier; see 9.3.4.6. Since the address of a bit-field (11.4.10) cannot be taken, a pointer can never point to a bit-field. — end note]
link* first;

void h(link*& p) { // p is a reference to pointer
    p->next = first;
    first = p;
    p = 0;
}

void k() {
    link* q = new link;
    h(q);
}

declares p to be a reference to a pointer to link so h(q) will leave q with the value zero. See also 9.4.4. —end example]

It is unspecified whether or not a reference requires storage (6.7.5).

There shall be no references to references, no arrays of references, and no pointers to references. The declaration of a reference shall contain an initializer (9.4.4) except when the declaration contains an explicit extern specifier (9.2.2), is a class member (11.4) declaration within a class definition, or is the declaration of a parameter or a return type (9.3.4.6); see 6.2. A reference shall be initialized to refer to a valid object or function.

[Note 2: In particular, a null reference cannot exist in a well-defined program, because the only way to create such a reference would be to bind it to the “object” obtained by indirection through a null pointer, which causes undefined behavior. As described in 11.4.10, a reference cannot be bound directly to a bit-field. —end note]

If a typedef-name (9.2.4, 13.2) or a decltype-specifier (9.2.9.5) denotes a type TR that is a reference to a type T, an attempt to create the type “lvalue reference to cv TR” creates the type “lvalue reference to T”, while an attempt to create the type “value reference to cv TR" creates the type TR.

[Note 3: This rule is known as reference collapsing. —end note]

[Example 3:]

int i;
typedef int& LRI;
typedef int&& RRI;

LRI& r1 = i; // r1 has the type int&
const LRI& r2 = i; // r2 has the type int&
const LRI&& r3 = i; // r3 has the type int&&

RRI& r4 = i; // r4 has the type int&
RRI&& r5 = 5; // r5 has the type int&&
decltype(r2)& r6 = i; // r6 has the type int&
decltype(r2)&& r7 = i; // r7 has the type int&&

—end example]

[Note 4: Forming a reference to function type is ill-formed if the function type has cv-qualifiers or a ref-qualifier; see 9.3.4.6. —end note]

9.3.4.4 Pointers to members [dcl.mptr]

1 The component names of a ptr-operator are those of its nested-name-specifier, if any.

2 In a declaration T D where D has the form

    nested-name-specifier * attribute-specifier-seqopt cv-qualifier-seqopt D1

and the nested-name-specifier denotes a class, and the type of the contained declarator-id in the declaration T D1 is “derived-declarator-type-list T", the type of the declarator-id in D is “derived-declarator-type-list cv-qualifiers seq pointer to member of class nested-name-specifier of type T”. The optional attribute-specifier-seq (9.12.1) appertains to the pointer-to-member.

3 [Example 1:]

struct X {
    void f(int);
int a;
};
struct Y;
int X::* pmi = &X::a;
void (X::* pmf)(int) = &X::f;
double X::* pmd;
char Y::* pmc;
declares pmi, pmf, pmd and pmc to be a pointer to a member of X of type int, a pointer to a member of X of type void(int), a pointer to a member of X of type double and a pointer to a member of Y of type char respectively. The declaration of pmd is well-formed even though X has no members of type double. Similarly, the declaration of pmc is well-formed even though Y is an incomplete type. pmi and pmf can be used like this:

X obj;
// ...  
obj.*pmi = 7;   // assign 7 to an integer member of obj
(obj.*pmf)(7);  // call a function member of obj with the argument 7
— end example

4 A pointer to member shall not point to a static member of a class (11.4.9), a member with reference type, or "cv void".

5 [Note 1: See also 7.6.2 and 7.6.4. The type “pointer to member” is distinct from the type “pointer”, that is, a pointer to member is declared only by the pointer-to-member declarator syntax, and never by the pointer declarator syntax. There is no “reference-to-member” type in C++. — end note]

9.3.4.5 Arrays [dcl.array]

1 In a declaration T D where D has the form

D1 [ constant-expression_opt ] attribute-specifier-seq_opt

and the type of the contained declarator-id in the declaration T D1 is “derived-declarator-type-list T”, the type of the declarator-id in D is “derived-declarator-type-list array of N T”. The constant-expression shall be a converted constant expression of type std::size_t (7.7). Its value N specifies the array bound, i.e., the number of elements in the array; N shall be greater than zero.

2 In a declaration T D where D has the form

D1 [ ] attribute-specifier-seq_opt

and the type of the contained declarator-id in the declaration T D1 is “derived-declarator-type-list T”, the type of the declarator-id in D is “derived-declarator-type-list array of unknown bound of T”, except as specified below.

3 A type of the form “array of N U” or “array of unknown bound of U” is an array type. The optional attribute-specifier-seq appertains to the array type.

4 U is called the array element type; this type shall not be a reference type, a function type, an array of unknown bound, or cv void.

[Note 1: An array can be constructed from one of the fundamental types (except void), from a pointer, from a pointer to member, from a class, from an enumeration type, or from an array of known bound. — end note]

[Example 1:]

float fa[17], *afp[17];
declares an array of float numbers and an array of pointers to float numbers. — end example]

5 Any type of the form “cv-qualifier-seq array of N U” is adjusted to “array of N cv-qualifier-seq U”, and similarly for “array of unknown bound of U”.

[Example 2:]

typedef int A[5], AA[2][3];
typedef const A CA;   // type is “array of 5 const int”
typedef const AA CAA; // type is “array of 2 array of 3 const int”
— end example]

[Note 2: An “array of N cv-qualifier-seq U” has cv-qualified type; see 6.8.5. — end note]
An object of type “array of N U” consists of a contiguously allocated non-empty set of N subobjects of type U, known as the elements of the array, and numbered 0 to N-1.

In addition to declarations in which an incomplete object type is allowed, an array bound may be omitted in some cases in the declaration of a function parameter (9.3.4.6). An array bound may also be omitted when an object (but not a non-static data member) of array type is initialized and the declarator is followed by an initializer (9.4, 11.4, 7.6.1.4, 7.6.2.8). In these cases, the array bound is calculated from the number of initial elements (say, N) supplied (9.4.2), and the type of the array is “array of N U”.

Furthermore, if there is a reachable declaration of the entity that inhabits the same scope in which the bound was specified, an omitted array bound is taken to be the same as in that earlier declaration, and similarly for the definition of a static data member of a class.

[Example 3:
extern int x[10];
struct S {
    static int y[10];
};
int x[];  // OK, bound is 10
int S::y[]; // OK, bound is 10

void f() {
    extern int x[];
    int i = sizeof(x); // error: incomplete object type
}
—end example]

Note 3: When several “array of” specifications are adjacent, a multidimensional array type is created; only the first of the constant expressions that specify the bounds of the arrays can be omitted.

[Example 4:
int x3d[3][5][7];
declares an array of three elements, each of which is an array of five elements, each of which is an array of seven integers. The overall array can be viewed as a three-dimensional array of integers, with rank 3 × 5 × 7. Any of the expressions x3d, x3d[i], x3d[i][j], x3d[i][j][k] can reasonably appear in an expression. The expression x3d[i] is equivalent to *(x3d + i); in that expression, x3d is subject to the array-to-pointer conversion (7.3.3) and is first converted to a pointer to a 2-dimensional array with rank 5 × 7 that points to the first element of x3d. Then i is added, which on typical implementations involves multiplying i by the length of the object to which the pointer points, which is sizeof(int)×5 × 7. The result of the addition and indirection is an lvalue denoting the i\textsuperscript{th} array element of x3d (an array of five arrays of seven integers). If there is another subscript, the same argument applies again, so x3d[i][j] is an lvalue denoting the j\textsuperscript{th} array element of the i\textsuperscript{th} array element of x3d (an array of seven integers), and x3d[i][j][k] is an lvalue denoting the k\textsuperscript{th} array element of the j\textsuperscript{th} array element of the i\textsuperscript{th} array element of x3d (an integer). —end example]

The first subscript in the declaration helps determine the amount of storage consumed by an array but plays no other part in subscript calculations. —end note]

Note 4: Conversions affecting expressions of array type are described in 7.3.3. —end note]

Note 5: The subscript operator can be overloaded for a class (12.4.5). For the operator’s built-in meaning, see 7.6.1.2. —end note]

9.3.4.6 Functions

In a declaration T D where D has the form

\[D1: \text{parameter-declaration-clause} \ cv-qualifier-seq_opt \ ref-qualifier_opt noexcept-specifier_opt attribute-specifier-seq_opt\]

and the type of the contained declarator-id in the declaration T D1 is “derived-declarator-type-list T”, the type of the declarator-id in D is “derived-declarator-type-list noexcept_opt function of parameter-type-list cv-qualifier-seq_opt ref-qualifier_opt returning T”, where

(1.1) — the parameter-type-list is derived from the parameter-declaration-clause as described below and

(1.2) — the optional noexcept is present if and only if the exception specification (14.5) is non-throwing.

The optional attribute-specifier-seq appertains to the function type.
In a declaration \( T \) \( D \) where \( D \) has the form

\[
D1 ( \text{parameter-declaration-clause} ) \text{cv-qualifier-seq}opt \\
\text{ref-qualifier}opt \text{noexcept-specifier}opt \text{attribute-specifier-seq}opt \text{trailing-return-type}
\]

and the type of the contained declarator-id in the declaration \( T \) \( D1 \) is \( \text{"derived-declarator-type-list}\ T\)\text{"}, \( T \) shall be the single type-specifier \( \text{auto} \). The type of the declarator-id in \( D \) is \( \text{"derived-declarator-type-list}\ noexceptopt \text{returning}\ U\)\text{"}, where

1. the parameter-type-list is derived from the parameter-declaration-clause as described below,
2. \( U \) is the type specified by the trailing-return-type, and
3. the optional noexcept is present if and only if the exception specification is non-throwing.

The optional attribute-specifier-seq appertains to the function type.

A type of either form is a function type.\(^{80} \)

\[\text{parameter-declaration-clause:} \]
\[
\text{parameter-declaration-list}opt \ldots opt \\
\text{parameter-declaration-list} \ldots
\]

\[\text{parameter-declaration-list:} \]
\[
\text{parameter-declaration} \\
\text{parameter-declaration-list}, \text{parameter-declaration}
\]

\[\text{parameter-declaration:} \]
\[
\text{attribute-specifier-seq}opt \text{this}opt \text{decl-specifier-seq} \text{declarator} \\
\text{attribute-specifier-seq}opt \text{decl-specifier-seq} \text{declarator} = \text{initializer-clause} \\
\text{attribute-specifier-seq}opt \text{this}opt \text{decl-specifier-seq} \text{abstract-declarator}opt \\
\text{attribute-specifier-seq}opt \text{decl-specifier-seq} \text{abstract-declarator}opt = \text{initializer-clause}
\]

The optional attribute-specifier-seq in a parameter-declaration appertains to the parameter.

The parameter-declaration-clause determines the arguments that can be specified, and their processing, when the function is called.

\[\text{Note 1: The parameter-declaration-clause is used to convert the arguments specified on the function call; see 7.6.1.3. — end note}\]

If the parameter-declaration-clause is empty, the function takes no arguments. A parameter list consisting of a single unnamed parameter of non-dependent type \( \text{void} \) is equivalent to an empty parameter list. Except for this special case, a parameter shall not have type \( \text{cv void} \). A parameter with volatile-qualified type is deprecated; see D.5. If the parameter-declaration-clause terminates with an ellipsis or a function parameter pack (13.7.4), the number of arguments shall be equal to or greater than the number of parameters that do not have a default argument and are not function parameter packs. Where syntactically correct and where “\( \ldots \)” is not part of an abstract-declarator, “, \( \ldots \)” is synonymous with “\( \ldots \)”.

\[\text{Example 1: The declaration} \]
\[
\text{int printf(const char*, \ldots)};
\]

declares a function that can be called with varying numbers and types of arguments.

\[\text{printf("hello world");} \]
\[\text{printf("a=%d b=%d", a, b);} \]

However, the first argument must be of a type that can be converted to a const char*. — end example]

\[\text{Note 2: The standard header <cstdarg> (17.13.2) contains a mechanism for accessing arguments passed using the ellipsis (see 7.6.1.3 and 17.13). — end note}\]

The type of a function is determined using the following rules. The type of each parameter (including function parameter packs) is determined from its own parameter-declaration (9.3). After determining the type of each parameter, any parameter of type “array of \( T \)” or of function type \( T \) is adjusted to be “pointer to \( T \)”. After producing the list of parameter types, any top-level cv-qualifiers modifying a parameter type are deleted when forming the function type. The resulting list of transformed parameter types and the presence or absence of the ellipsis or a function parameter pack is the function’s parameter-type-list.

\[\text{Note 3: This transformation does not affect the types of the parameters. For example, int(*) (const int p, decltype(p)*) and int(*)(int, const int*) are identical types. — end note}\]

\(^{80}\) As indicated by syntax, cv-qualifiers are a significant component in function return types.
An explicit-object-parameter-declaration is a parameter-declaration with a this specifier. An explicit-object-parameter-declaration shall appear only as the first parameter-declaration of a parameter-declaration-list of either:

---

**Example 2:**

```c
void f(char*); // #1
void f(char[]) {} // defines #1
void f(const char*) {} // OK, another overload
void f(char *const) {} // error: redefines #1

void g(char(*)[2]); // #2
void g(char[3][2]) {} // defines #2
void g(char[3][3]) {} // OK, another overload

void h(int x(const int)); // #3
void h(int (*)(int)) {} // defines #3
```

---

### 9.3.4.6

A function parameter declared with an explicit-object-parameter-declaration is an explicit object parameter. An explicit object parameter shall not be a function parameter pack (13.7.4). An explicit object member function is a non-static member function with an explicit object parameter. An implicit object member function is a non-static member function without an explicit object parameter.

The object parameter of a non-static member function is either the explicit object parameter or the implicit object parameter (12.2.2).

A non-object parameter is a function parameter that is not the explicit object parameter. The non-object-parameter-type-list of a member function is the parameter-type-list of that function with the explicit object parameter, if any, omitted.

**Example 4:**
typedef int FIC(int) const;
FIC f;          // error: does not declare a member function
struct S {
    FIC f;          // OK
};
FIC S::*pm = &S::*f; // OK
—end example]

The effect of a `cv-qualifier-seq` in a function declarator is not the same as adding cv-qualification on top of the function type. In the latter case, the cv-qualifiers are ignored.

[Note 5: A function type that has a `cv-qualifier-seq` is not a cv-qualified type; there are no cv-qualified function types. —end note]

[Example 5:
    typedef void F();
    struct S {
        const F f;          // OK, equivalent to: void f();
    };
    —end example]

The return type, the parameter-type-list, the ref-qualifier, the `cv-qualifier-seq`, and the exception specification, but not the default arguments (9.3.4.7) or the trailing requires-clause (9.3), are part of the function type.

[Note 6: Function types are checked during the assignments and initializations of pointers to functions, references to functions, and pointers to member functions. —end note]

[Example 6: The declaration
    int fseek(FILE*, long, int);
declares a function taking three arguments of the specified types, and returning int (9.2.9). —end example]

[Note 7: A single name can be used for several different functions in a single scope; this is function overloading (Clause 12). —end note]

The return type shall be a non-array object type, a reference type, or `cv void`.

[Note 8: An array of placeholder type is considered an array type. —end note]

A volatile-qualified return type is deprecated; see D.5.

Types shall not be defined in return or parameter types.

A typedef of function type may be used to declare a function but shall not be used to define a function (9.5).

[Example 7:
    typedef void F();
    F fv;          // OK, equivalent to void fv();
    F fv {}         // error
    void fv() {}    // OK, definition of fv
    —end example]

An identifier can optionally be provided as a parameter name; if present in a function definition (9.5), it names a parameter.

[Note 9: In particular, parameter names are also optional in function definitions and names used for a parameter in different declarations and the definition of a function need not be the same. —end note]

[Example 8: The declaration
    int i,
    *pi,
    f(),
    *fpi(int),
    (*fpi)(const char*, const char*),
    (*fpi(int))(int);
declares an integer i, a pointer pi to an integer, a function f taking no arguments and returning an integer, a function fpi taking an integer argument and returning a pointer to an integer, a pointer pif to a function which takes two pointers to constant characters and returns an integer, a function fpif taking an integer argument and returning a pointer to a function that takes an integer argument and returns an integer. It is especially useful to compare fpi and pif. The binding of *fpi(int) is *(fpi(int)), so the declaration suggests, and the same construction in an
expression requires, the calling of a function \texttt{fpi}, and then using indirection through the (pointer) result to yield an integer. In the declarator \texttt{(*pif)(const char*, const char*)}, the extra parentheses are necessary to indicate that indirection through a pointer to a function yields a function, which is then called. —end example

[Note 10: typedefs and \texttt{trailing-return-types} are sometimes convenient when the return type of a function is complex. For example, the function \texttt{fpif} above can be declared

\begin{verbatim}
typedef int IFUNC(int);
IFUNC* fpif(int);
\end{verbatim}

or

\begin{verbatim}
auto fpif(int)->int(*)(int);
\end{verbatim}

A \texttt{trailing-return-type} is most useful for a type that would be more complicated to specify before the declarator-id:

\begin{verbatim}
template <class T, class U> auto add(T t, U u) -> decltype(t + u);
\end{verbatim}

rather than

\begin{verbatim}
template <class T, class U> decltype((*(T*)0) + (*(U*)0)) add(T t, U u);
\end{verbatim}

—end note]

21 A \texttt{non-template function} is a function that is not a function template specialization.

[Note 11: A function template is not a function. —end note]

22 An \texttt{abbreviated function template} is a function declaration that has one or more generic parameter type placeholders (9.2.9.6). An abbreviated function template is equivalent to a function template (13.7.7) whose \texttt{template-parameter-list} includes one invented type \texttt{template-parameter} for each generic parameter type placeholder of the function declaration, in order of appearance. For a \texttt{placeholder-type-specifier} of the form \texttt{auto}, the invented parameter is an unconstrained \texttt{type-parameter}. For a \texttt{placeholder-type-specifier} of the form \texttt{type-constraint auto}, the invented parameter is a \texttt{type-parameter} with that \texttt{type-constraint}. The invented type \texttt{template-parameter} is a template parameter pack if the corresponding \texttt{parameter-declaration} declares a function parameter pack. If the placeholder contains \texttt{decltype(auto)}, the program is ill-formed. The adjusted function parameters of an abbreviated function template are derived from the \texttt{parameter-declaration-clause} by replacing each occurrence of a placeholder with the name of the corresponding invented \texttt{template-parameter}.

[Example 9:

\begin{verbatim}
template<typename T> concept C1 = /* ... */;
template<typename T> concept C2 = /* ... */;
template<typename... Ts> concept C3 = /* ... */;
void g1(const C1 auto*, C2 auto&);
void g2(C1 auto&...);
void g3(C3 auto...);
void g4(C3 auto);
\end{verbatim}

The declarations above are functionally equivalent (but not equivalent) to their respective declarations below:

\begin{verbatim}
template<C1 T, C2 U> void g1(const T*, U&);
template<C1... Ts> void g2(Ts&...);
template<C3... Ts> void g3(Ts...);
template<C3 T> void g4(T);
\end{verbatim}

Abbreviated function templates can be specialized like all function templates.

\begin{verbatim}
template<> void g1<int>(const int*, const double&); // OK, specialization of g1<int, const double>
\end{verbatim}

—end example]

23 An \texttt{abbreviated function template} can have a \texttt{template-head}. The invented \texttt{template-parameters} are appended to the \texttt{template-parameter-list} after the explicitly declared \texttt{template-parameters}.

[Example 10:

\begin{verbatim}
template<typename> concept C = /* ... */;
\end{verbatim}

\begin{verbatim}
template <typename T, C U>
void g(T x, U y, C auto z);
\end{verbatim}

This is functionally equivalent to each of the following two declarations.

\begin{verbatim}
template<typename T, C U, C W>
void g(T x, U y, W z);
\end{verbatim}
A function declaration at block scope shall not declare an abbreviated function template.

A declarator-id or abstract-declarator containing an ellipsis shall only be used in a parameter-declaration. When it is part of a parameter-declaration-clause, the parameter-declaration declares a function parameter pack (13.7.4). Otherwise, the parameter-declaration is part of a template-parameter-list and declares a template parameter pack; see 13.2. A function parameter pack is a pack expansion (13.7.4).

Example 11:
```cpp
template< typename T >

void g(T x, U y, W z); // end example
```

Declarator-id or abstract-declarator containing an ellipsis shall only be used in a parameter-declaration.

When it is part of a parameter-declaration-clause, the parameter-declaration declares a function parameter pack (13.7.4). Otherwise, the parameter-declaration is part of a template-parameter-list and declares a template parameter pack; see 13.2. A function parameter pack is a pack expansion (13.7.4).

There is a syntactic ambiguity when an ellipsis occurs at the end of a parameter-declaration-clause without a preceding comma. In this case, the ellipsis is parsed as part of the abstract-declarator if the type of the parameter either names a template parameter pack that has not been expanded or contains auto; otherwise, it is parsed as part of the parameter-declaration-clause.

9.3.4.7 Default arguments

If an initializer-clause is specified in a parameter-declaration this initializer-clause is used as a default argument.

Example 1: The declaration
```cpp
void point(int = 3, int = 4);
```
does not make sense, because the two initializers are unrelated. Instead, choose:
```cpp
void point(int, int);
```

A default argument shall be specified only in the parameter-declaration-clause of a function declaration or lambda-declarator or in a template-parameter (13.2); in the latter case, the initializer-clause shall be an assignment-expression. A default argument shall not be specified for a template parameter pack or a function parameter pack. If it is specified in a parameter-declaration-clause, it shall not occur within a declarator or abstract-declarator of a parameter-declaration.

For non-template functions, default arguments can be added in later declarations of a function that inhabit the same scope. Declarations that inhabit different scopes have completely distinct sets of default arguments. That is, declarations in inner scopes do not acquire default arguments from declarations in outer scopes, and vice versa. In a given function declaration, each parameter subsequent to a parameter with a default argument shall have a default argument supplied in this or a previous declaration, unless the parameter was expanded from a parameter pack, or shall be a function parameter pack.

Example 2:
```cpp
void g(int = 0, ...); // OK, ellipsis is not a parameter so it can follow
// a parameter with a default argument

void f(int, int);
```

81) One can explicitly disambiguate the parse either by introducing a comma (so the ellipsis will be parsed as part of the parameter-declaration-clause) or by introducing a name for the parameter (so the ellipsis will be parsed as part of the declarator-id).

82) This means that default arguments cannot appear, for example, in declarations of pointers to functions, references to functions, or typedef declarations.
For a given inline function defined in different translation units, the accumulated sets of default arguments at the end of the translation units shall be the same; no diagnostic is required. If a friend declaration \( D \) specifies a default argument expression, that declaration shall be a definition and there shall be no other declaration of the function or function template which is reachable from \( D \) or from which \( D \) is reachable.

The default argument has the same semantic constraints as the initializer in a declaration of a variable of the parameter type, using the copy-initialization semantics (9.4). The names in the default argument are looked up, and the semantic constraints are checked, at the point where the default argument appears, except that an immediate invocation (7.7) that is a potentially-evaluated subexpression (6.9.1) of the initializer-clause in a parameter-declaration is neither evaluated nor checked for whether it is a constant expression at that point. Name lookup and checking of semantic constraints for default arguments of templated functions are performed as described in 13.9.2.

\[Example 3:\text{ In the following code, } g \text{ will be called with the value } f(2):\]

\[
\begin{align*}
\text{int } & a = 1; \\
\text{int } & f(\text{int}); \\
\text{int } & g(\text{int } x = f(a)); \\
\text{void } & h() \\
& \{ \\
& \quad \text{a = 2;} \\
& \quad \{ \\
& \quad \quad \text{int } a = 3; \\
& \quad \quad g(); \quad \text{// g(f(::a))} \\
& \quad \} \\
& \}\end{align*}
\]

\[\text{—end example}\]

\[\text{—end example}\]

\[\text{—end note}\]

6 Except for member functions of class templates, the default arguments in a member function definition that appears outside of the class definition are added to the set of default arguments provided by the member function declaration in the class definition; the program is ill-formed if a default constructor (11.4.5.2), copy or move constructor (11.4.5.3), or copy or move assignment operator (11.4.6) is so declared. Default arguments for a member function of a class template shall be specified on the initial declaration of the member function within the class template.

\[Example 4:\]

\[
\begin{align*}
\text{class } & C \{ \\
& \quad \text{void } f(\text{int } i = 3); \\
& \quad \text{void } g(\text{int } i, \text{int } j = 99); \\
& \};
\end{align*}
\]
void C::f(int i = 3) {} // error: default argument already specified in class scope
void C::g(int i = 88, int j) {} // in this translation unit, C::g can be called with no arguments
— end example

7 [Note 4: A local variable cannot be odr-used (6.3) in a default argument. — end note]

[Example 5:
void f() {
  int i;
  extern void g(int x = i); // error
  extern void h(int x = sizeof(i)); // OK
  // ...
}
— end example]

8 [Note 5: The keyword this cannot appear in a default argument of a member function; see 7.5.2.

[Example 6:
class A {
  void f(A* p = this) { } // error
};
— end example]
— end note]

9 A default argument is evaluated each time the function is called with no argument for the corresponding
parameter. A parameter shall not appear as a potentially-evaluated expression in a default argument.

[Note 6: Parameters of a function declared before a default argument are in scope and can hide namespace and class
member names. — end note]

[Example 7:
int a;
int f(int a, int b = a); // error: parameter a used as default argument
typedef int I;
int g(float I, int b = I(2)); // error: parameter I found
int h(int a, int b = sizeof(a)); // OK, unevaluated operand (7.2.3)
— end example]

A non-static member shall not appear in a default argument unless it appears as the id-expression of a class
member access expression (7.6.1.5) or unless it is used to form a pointer to member (7.6.2.2).

[Example 8: The declaration of X::mem1() in the following example is ill-formed because no object is supplied for the
non-static member X::a used as an initializer.

int b;
class X {
  int a;
  int mem1(int i = a); // error: non-static member a used as default argument
  int mem2(int i = b); // OK; use X::b
  static int b;
};
The declaration of X::mem2() is meaningful, however, since no object is needed to access the static member X::b.
Classes, objects, and members are described in Clause 11. — end example]

A default argument is not part of the type of a function.

[Example 9:
int f(int = 0);

void h() {
  int j = f(1);
  int k = f(); // OK, means f(0)
}
int (*p1)(int) = &f;
int (*p2)() = &f; // error: type mismatch

§ 9.3.4.7 208
When an overload set contains a declaration of a function that inhabits a scope $S$, any default argument associated with any reachable declaration that inhabits $S$ is available to the call.

[Note 7: The candidate might have been found through a using-declarator from which the declaration that provides the default argument is not reachable. — end note]

A virtual function call (11.7.3) uses the default arguments in the declaration of the virtual function determined by the static type of the pointer or reference denoting the object. An overriding function in a derived class does not acquire default arguments from the function it overrides.

[Example 10:

```c
struct A {
    virtual void f(int a = 7);
};
struct B : public A {
    void f(int a);
};
void m() {
    B* pb = new B;
    A* pa = pb;
    pa->f();  // OK, calls pa->B::f(7)
    pb->f();  // error: wrong number of arguments for B::f()
}
```
— end example]

## 9.4 Initializers

### 9.4.1 General

The process of initialization described in 9.4 applies to all initializations regardless of syntactic context, including the initialization of a function parameter (7.6.1.3), the initialization of a return value (8.7.4), or when an initializer follows a declarator.

```plaintext
initializer:
    brace-or-equal-initializer
      ( expression-list )
brace-or-equal-initializer:
    = initializer-clause
    braced-init-list
initializer-clause:
    assignment-expression
    braced-init-list
braced-init-list:
    { initializer-list , opt }
    { designated-initializer-list , opt }
    { }
initializer-list:
    initializer-clause ... opt
    initializer-list , initializer-clause ... opt
designated-initializer-list:
    designated-initializer-clause
    designated-initializer-list , designated-initializer-clause
designated-initializer-clause:
    designator brace-or-equal-initializer
designator:
    . identifier
expr-or-braced-init-list:
    expression
    braced-init-list
```

[Note 1: The rules in 9.4 apply even if the grammar permits only the brace-or-equal-initializer form of initializer in a given context. — end note]
Except for objects declared with the `constexpr` specifier, for which see 9.2.6, an initializer in the definition of a variable can consist of arbitrary expressions involving literals and previously declared variables and functions, regardless of the variable’s storage duration.

Example 1:

```c
int f(int);
int a = 2;
int b = f(a);
int c(b);
```

—end example]

[Note 2: Default arguments are more restricted; see 9.3.4.7. — end note]

[Note 3: The order of initialization of variables with static storage duration is described in 6.9.3 and 8.8. — end note]

A declaration $D$ of a variable with linkage shall not have an `initializer` if $D$ inhabits a block scope.

To `zero-initialize` an object or reference of type $T$ means:

- if $T$ is a scalar type (6.8.1), the object is initialized to the value obtained by converting the integer literal $0$ (zero) to $T$;
- if $T$ is a (possibly cv-qualified) non-union class type, its padding bits (6.8.1) are initialized to zero bits and each non-static data member, each non-virtual base class subobject, and, if the object is not a base class subobject, each virtual base class subobject is zero-initialized;
- if $T$ is a (possibly cv-qualified) union type, its padding bits (6.8.1) are initialized to zero bits and the object’s first non-static named data member is zero-initialized;
- if $T$ is an array type, each element is zero-initialized;
- if $T$ is a reference type, no initialization is performed.

To `default-initialize` an object of type $T$ means:

- If $T$ is a (possibly cv-qualified) class type (Clause 11), constructors are considered. The applicable constructors are enumerated (12.2.2.4), and the best one for the `initializer` () is chosen through overload resolution (12.2). The constructor thus selected is called, with an empty argument list, to initialize the object.
- If $T$ is an array type, each element is default-initialized.
- Otherwise, no initialization is performed.

A class type $T$ is `const-default-constructible` if default-initialization of $T$ would invoke a user-provided constructor of $T$ (not inherited from a base class) or if

- each direct non-variant non-static data member $M$ of $T$ has a default member initializer or, if $M$ is of class type $X$ (or array thereof), $X$ is const-default-constructible,
- if $T$ is a union with at least one non-static data member, exactly one variant member has a default member initializer,
- if $T$ is not a union, for each anonymous union member with at least one non-static data member (if any), exactly one non-static data member has a default member initializer, and
- each potentially constructed base class of $T$ is const-default-constructible.

If a program calls for the default-initialization of an object of a const-qualified type $T$, $T$ shall be a const-default-constructible class type or array thereof.

To `value-initialize` an object of type $T$ means:

- if $T$ is a (possibly cv-qualified) class type (Clause 11), then
  - if $T$ has either no default constructor (11.4.5.2) or a default constructor that is user-provided or deleted, then the object is default-initialized;
  - otherwise, the object is zero-initialized and the semantic constraints for default-initialization are checked, and if $T$ has a non-trivial default constructor, the object is default-initialized;
- if $T$ is an array type, then each element is value-initialized;
- otherwise, the object is zero-initialized.

§ 9.4.1

83) As specified in 7.3.12, converting an integer literal whose value is 0 to a pointer type results in a null pointer value.
A program that calls for default-initialization or value-initialization of an entity of reference type is ill-formed.

[Note 4: For every object of static storage duration, static initialization (6.9.3.2) is performed at program startup before any other initialization takes place. In some cases, additional initialization is done later. — end note]

If no initializer is specified for an object, the object is default-initialized.

If the entity being initialized does not have class type, the expression-list in a parenthesized initializer shall be a single expression.

The initialization that occurs in the = form of a brace-or-equal-initializer or condition (8.5), as well as in argument passing, function return, throwing an exception (14.2), handling an exception (14.4), and aggregate member initialization other than by a designated-initializer-clause (9.4.2), is called copy-initialization.

[Note 5: Copy-initialization can invoke a move (11.4.5.3). — end note]

The initialization that occurs

(15.1) — for an initializer that is a parenthesized expression-list or a braced-init-list,
(15.2) — for a new-initializer (7.6.2.8),
(15.3) — in a static_cast expression (7.6.1.9),
(15.4) — in a functional notation type conversion (7.6.1.4), and
(15.5) — in the braced-init-list form of a condition

is called direct-initialization.

The semantics of initializers are as follows. The destination type is the type of the object or reference being initialized and the source type is the type of the initializer expression. If the initializer is not a single (possibly parenthesized) expression, the source type is not defined.

(16.1) — If the initializer is a (non-parenthesized) braced-init-list or is = braced-init-list, the object or reference is list-initialized (9.4.5).
(16.2) — If the destination type is a reference type, see 9.4.4.
(16.3) — If the destination type is an array of characters, an array of char8_t, an array of char16_t, an array of char32_t, or an array of wchar_t, and the initializer is a string-literal, see 9.4.3.
(16.4) — If the initializer is (), the object is value-initialized.

[Note 6: Since () is not permitted by the syntax for initializer,
   X a();
   is not the declaration of an object of class X, but the declaration of a function taking no arguments and returning an X. The form () is permitted in certain other initialization contexts (7.6.2.8, 7.6.1.4, 11.9.3). — end note]

(16.5) — Otherwise, if the destination type is an array, the object is initialized as follows. Let $x_1, \ldots, x_k$ be the elements of the expression-list. If the destination type is an array of unknown bound, it is defined as having $k$ elements. Let $n$ denote the array size after this potential adjustment. If $k$ is greater than $n$, the program is ill-formed. Otherwise, the $i$th array element is copy-initialized with $x_i$ for each $1 \leq i \leq k$, and value-initialized for each $k < i \leq n$. For each $1 \leq i < j \leq n$, every value computation and side effect associated with the initialization of the $i$th element of the array is sequenced before those associated with the initialization of the $j$th element.

(16.6) — Otherwise, if the destination type is a (possibly cv-qualified) class type:

(16.6.1) — If the initializer expression is a prvalue and the cv-unqualified version of the source type is the same class as the class of the destination, the initializer expression is used to initialize the destination object.

[Example 2: T x = T(T());] value-initializes x. — end example]

(16.6.2) — Otherwise, if the initialization is direct-initialization, or if it is copy-initialization where the cv-unqualified version of the source type is the same class as, or a derived class of, the class of the destination, constructors are considered. The applicable constructors are enumerated (12.2.2.4), and the best one is chosen through overload resolution (12.2). Then:

(16.6.2.1) — If overload resolution is successful, the selected constructor is called to initialize the object, with the initialization expression or expression-list as its argument(s).
Otherwise, if no constructor is viable, the destination type is an aggregate class, and the
initializer is a parenthesized expression-list, the object is initialized as follows. Let \( e_1, \ldots, e_n \)
be the elements of the aggregate (9.4.2). Let \( x_1, \ldots, x_k \) be the elements of the expression-list.
If \( k \) is greater than \( n \), the program is ill-formed. The element \( e_i \) is copy-initialized with \( x_i \) for
\( 1 \leq i \leq k \). The remaining elements are initialized with their default member initializers, if
any, and otherwise are value-initialized. For each \( 1 \leq i < j \leq n \), every value computation and
side effect associated with the initialization of \( e_i \) is sequenced before those associated with the
initialization of \( e_j \).

[Note 7: By contrast with direct-list-initialization, narrowing conversions (9.4.5) are permitted,
designators are not permitted, a temporary object bound to a reference does not have its lifetime
extended (6.7.7), and there is no brace elision.]

[Example 3:

```c++
struct A {
    int a;
    int&& r;
};

int f();
int n = 10;

A a1{1, f()};  // OK, lifetime is extended
A a2{1, f()};  // well-formed, but dangling reference
A a3{1.0, 1};  // error: narrowing conversion
A a4{1.0, 1};  // well-formed, but dangling reference
A a5{1.0, std::move(n)};  // OK
```
— end example]
— end note]

— Otherwise, if the source type is a (possibly cv-qualified) class type, conversion functions are considered.
The applicable conversion functions are enumerated (12.2.2.6), and the best one is chosen through
overload resolution (12.2). The user-defined conversion so selected is called to convert the initializer
expression into the object being initialized. If the conversion cannot be done or is ambiguous, the
initialization is ill-formed.

— Otherwise, if the source type is \( \text{std::nullptr_t} \), and the
destination type is \( \text{bool} \), the initial value of the object being initialized is \text{false}.

[Note 8: An expression of type “\text{cv1 T}” can initialize an object of type “\text{cv2 T}” independently of the cv-qualifiers
\text{cv1} and \text{cv2}.

```c++
int a;
const int b = a;
int c = b;
```
— end note]
An immediate invocation (7.7) that is not evaluated where it appears (9.3.4.7, 11.4.1) is evaluated and checked for whether it is a constant expression at the point where the enclosing initializer is used in a function call, a constructor definition, or an aggregate initialization.

An initializer-clause followed by an ellipsis is a pack expansion (13.7.4).

Initialization includes the evaluation of all subexpressions of each initializer-clause of the initializer (possibly nested within braced-init-lists) and the creation of any temporary objects for function arguments or return values (6.7.7).

If the initializer is a parenthesized expression-list, the expressions are evaluated in the order specified for function calls (7.6.1.3).

The same identifier shall not appear in multiple designators of a designated-initializer-list.

An object whose initialization has completed is deemed to be constructed, even if the object is of non-class type or no constructor of the object’s class is invoked for the initialization.

Initialization includes the evaluation of all subexpressions of each initializer-clause of the initializer (possibly nested within braced-init-lists) and the creation of any temporary objects for function arguments or return values (6.7.7).

If the initializer is a parenthesized expression-list, the expressions are evaluated in the order specified for function calls (7.6.1.3).

The same identifier shall not appear in multiple designators of a designated-initializer-list.

A declaration that specifies the initialization of a variable, whether from an explicit initializer or by default-initialization, is called the initializing declaration of that variable.

[Note 9: Such an object might have been value-initialized or initialized by aggregate initialization (9.4.2) or by an inherited constructor (11.9.4). — end note]

Destroying an object of class type invokes the destructor of the class. Destroying a scalar type has no effect other than ending the lifetime of the object (6.7.3). Destroying an array destroys each element in reverse subscript order.

A declaration that specifies the initialization of a variable, whether from an explicit initializer or by default-initialization, is called the initializing declaration of that variable.

[Note 10: In most cases this is the defining declaration (6.2) of the variable, but the initializing declaration of a non-inline static data member (11.4.9.3) can be the declaration within the class definition and not the definition (if any) outside it. — end note]

9.4.2 Aggregates

An aggregate is an array or a class (Clause 11) with

(1.1) no user-declared or inherited constructors (11.4.5),
(1.2) no private or protected direct non-static data members (11.8),
(1.3) no private or protected direct base classes (11.8.3), and
(1.4) no virtual functions (11.7.3) or virtual base classes (11.7.2).

[Note 1: Aggregate initialization does not allow accessing protected and private base class’ members or constructors. — end note]

The elements of an aggregate are:

(2.1) for an array, the array elements in increasing subscript order, or
(2.2) for a class, the direct base classes in declaration order, followed by the direct non-static data members (11.4) that are not members of an anonymous union, in declaration order.

When an aggregate is initialized by an initializer list as specified in 9.4.5, the elements of the initializer list are taken as initializers for the elements of the aggregate. The explicitly initialized elements of the aggregate are determined as follows:

(3.1) If the initializer list is a brace-enclosed designated-initializer-list, the aggregate shall be of class type, the identifier in each designator shall name a direct non-static data member of the class, and the explicitly initialized elements of the aggregate are the elements that are, or contain, those members.
(3.2) If the initializer list is a brace-enclosed initializer-list, the explicitly initialized elements of the aggregate are the first \( n \) elements of the aggregate, where \( n \) is the number of elements in the initializer list.
(3.3) Otherwise, the initializer list must be \( \{ \} \), and there are no explicitly initialized elements.

For each explicitly initialized element:

(4.1) If the element is an anonymous union member and the initializer list is a brace-enclosed designated-initializer-list, the element is initialized by the braced-init-list \( \{ \, D \, \} \), where \( D \) is the designated-initializer-clause naming a member of the anonymous union member. There shall be only one such designated-initializer-clause.

[Example 1:}
struct C {
    union {
        int a;
        const char* p;
    }
    int x;
} c = { .a = 1, .x = 3 };
initializes c.a with 1 and c.x with 3. — end example]

(4.2) — Otherwise, the element is copy-initialized from the corresponding initializer-clause or is initialized with the brace-or-equal-initializer of the corresponding designated-initializer-clause. If that initializer is of the form assignment-expression or = assignment-expression and a narrowing conversion (9.4.5) is required to convert the expression, the program is ill-formed.

[Note 2: If the initialization is by designated-initializer-clause, its form determines whether copy-initialization or direct-initialization is performed. — end note]

[Note 3: If an initializer is itself an initializer list, the element is list-initialized, which will result in a recursive application of the rules in this subclause if the element is an aggregate. — end note]

[Example 2:

    struct A {
        int x;
        struct B {
            int i;
            int j;
        } b;
    } a = { 1, { 2, 3 });
initializes a.x with 1, a.b.i with 2, a.b.j with 3.

    struct base1 { int b1, b2 = 42; };
    struct base2 {
        base2() {
            b3 = 42;
        }
        int b3;
    };
    struct derived : base1, base2 {
        int d;
    };
    derived d1{{1, 2}, {}, 4};
    derived d2{{}, {}, 4};
initializes d1.b1 with 1, d1.b2 with 2, d1.b3 with 42, d1.d with 4, and d2.b1 with 0, d2.b2 with 42, d2.b3 with 42, d2.d with 4. — end example]

5 For a non-union aggregate, each element that is not an explicitly initialized element is initialized as follows:

(5.1) — If the element has a default member initializer (11.4), the element is initialized from that initializer.

(5.2) — Otherwise, if the element is not a reference, the element is copy-initialized from an empty initializer list (9.4.5).

(5.3) — Otherwise, the program is ill-formed.

If the aggregate is a union and the initializer list is empty, then

(5.4) — if any variant member has a default member initializer, that member is initialized from its default member initializer;

(5.5) — otherwise, the first member of the union (if any) is copy-initialized from an empty initializer list.

6 [Example 3:

    struct S { int a; const char* b; int c; int d = b[a]; };
    S ss = { 1, "asdf" };
initializes ss.a with 1, ss.b with "asdf", ss.c with the value of an expression of the form int{} (that is, 0), and ss.d with the value of ss.b[ss.a] (that is, 'a'), and in

    struct X { int i, j, k = 42; };

§ 9.4.2
```cpp
X a[] = { 1, 2, 3, 4, 5, 6 };  
X b[2] = { { 1, 2, 3 }, { 4, 5, 6 } };  

a and b have the same value  

struct A {  
    string a;  
    int b = 42;  
    int c = -1;  
};  
A{.c=21} has the following steps:  
  (6.1) — Initialize a with {}  
  (6.2) — Initialize b with = 42  
  (6.3) — Initialize c with = 21  
—end example]  

7 The initializations of the elements of the aggregate are evaluated in the element order. That is, all value  
computations and side effects associated with a given element are sequenced before those of any element that  
follows it in order.  

8 An aggregate that is a class can also be initialized with a single expression not enclosed in braces, as described  
in 9.4.  

9 The destructor for each element of class type is potentially invoked (11.4.7) from the context where the  
aggregate initialization occurs.  

[Note 4: This provision ensures that destructors can be called for fully-constructed subobjects in case an exception is  
thrown (14.3). — end note]  

10 An array of unknown bound initialized with a brace-enclosed initializer-list containing n initializer-clauses is  
defined as having n elements (9.3.4.5).  

[Example 4]:  
int x[] = { 1, 3, 5 };  
declares and initializes x as a one-dimensional array that has three elements since no size was specified and there are  
three initializers. — end example]  

An array of unknown bound shall not be initialized with an empty braced-init-list {}.  

[Note 5: A default member initializer does not determine the bound for a member array of unknown bound. Since  
the default member initializer is ignored if a suitable mem-initializer is present (11.9.3), the default member initializer  
is not considered to initialize the array of unknown bound.  

[Example 5]:  
struct S {  
    int y[] = { 0 };  // error: non-static data member of incomplete type  
};  
— end example]  
— end note]  

11 [Note 6: Static data members, non-static data members of anonymous union members, and unnamed bit-fields are  
not considered elements of the aggregate.  

[Example 6]:  
struct A {  
    int 1;  
    static int s;  
    int j;  
    int :17;  
    int k;  
} a = { 1, 2, 3 };  
Here, the second initializer 2 initializes a.j and not the static data member A::s, and the third initializer 3 initializes  
a.k and not the unnamed bit-field before it. — end example]  
— end note]  

84) The syntax provides for empty braced-init-lists, but nonetheless C++ does not have zero length arrays.

§ 9.4.2
An initializer-list is ill-formed if the number of initializer-clauses exceeds the number of elements of the aggregate.

[Example 7:]

```c
char cv[4] = {'a', 's', 'd', 'f', 0};  // error
```

is ill-formed. — end example]

If a member has a default member initializer and a potentially-evaluated subexpression thereof is an aggregate initialization that would use that default member initializer, the program is ill-formed.

[Example 8:]

```c
struct A;
extern A a;
struct A {
    const A& a1 { A(a,a) };  // OK
    const A& a2 { A() };  // error
};
A a(a,a);  // OK

struct B {
    int n = B{}.n;  // error
};
```

— end example]

If an aggregate class C contains a subaggregate element e with no elements, the initializer-clause for e shall not be omitted from an initializer-list for an object of type C unless the initializer-clauses for all elements of C following e are also omitted.

[Example 9:]

```c
struct S { } s;
struct A {
    S s1;
    int i1;
    S s2;
    int i2;
    S s3;
    int i3;
} a = {
    { },  // Required initialization
    0,
    s,  // Required initialization
    0
};  // Initialization not required for A::s3 because A::i3 is also not initialized
```

— end example]

When initializing a multi-dimensional array, the initializer-clauses initialize the elements with the last (rightmost) index of the array varying the fastest (9.3.4.5).

[Example 10:]

```c
int x[2][2] = { 3, 1, 4, 2 };
```

initializes x[0][0] to 3, x[0][1] to 1, x[1][0] to 4, and x[1][1] to 2. On the other hand,

```c
float y[4][3] = {
    { 1 }, { 2 }, { 3 }, { 4 }
};
```

initializes the first column of y (regarded as a two-dimensional array) and leaves the rest zero. — end example]

Braces can be elided in an initializer-list as follows. If the initializer-list begins with a left brace, then the succeeding comma-separated list of initializer-clauses initializes the elements of a subaggregate; it is erroneous for there to be more initializer-clauses than elements. If, however, the initializer-list for a subaggregate does not begin with a left brace, then only enough initializer-clauses from the list are taken to initialize the elements of the subaggregate; any remaining initializer-clauses are left to initialize the next element of the aggregate of which the current subaggregate is an element.

[Example 11:]

§ 9.4.2
float y[4][3] = {
    { 1, 3, 5 },
    { 2, 4, 6 },
    { 3, 5, 7 },
};
is a completely-braced initialization: 1, 3, and 5 initialize the first row of the array y[0], namely y[0][0], y[0][1], and y[0][2]. Likewise the next two lines initialize y[1] and y[2]. The initializer ends early and therefore y[3]’s elements are initialized as if explicitly initialized with an expression of the form float(), that is, are initialized with 0.0. In the following example, braces in the initializer-list are elided; however the initializer-list has the same effect as the completely-braced initializer-list of the above example,

float y[4][3] = {
    1, 3, 5, 2, 4, 6, 3, 5, 7
};
The initializer for y begins with a left brace, but the one for y[0] does not, therefore three elements from the list are used. Likewise the next three are taken successively for y[1] and y[2]. — end example

All implicit type conversions (7.3) are considered when initializing the element with an assignment-expression. If the assignment-expression can initialize an element, the element is initialized. Otherwise, if the element is itself a subaggregate, brace elision is assumed and the assignment-expression is considered for the initialization of the first element of the subaggregate.

[Note 7: As specified above, brace elision cannot apply to subaggregates with no elements; an initializer-clause for the entire subobject is required. — end note]

[Example 12:

struct A {
    int i;
    operator int();
};
struct B {
    A a1, a2;
    int z;
};
A a;
B b = { 4, a, a };
Braces are elided around the initializer-clause for b.a1.i. b.a1.i is initialized with 4, b.a2 is initialized with a, b.z is initialized with whatever a.operator int() returns. — end example]

[Note 8: An aggregate array or an aggregate class can contain elements of a class type with a user-declared constructor (11.4.5). Initialization of these aggregate objects is described in 11.9.2. — end note]

[Note 9: Whether the initialization of aggregates with static storage duration is static or dynamic is specified in 6.9.3.2, 6.9.3.3, and 8.8. — end note]

When a union is initialized with an initializer list, there shall not be more than one explicitly initialized element.

[Example 13:

union u { int a; const char* b; }; u a = { 1 }; u b = a; u c = 1; // error u d = { 0, "asdf" }; // error u e = { "asdf" }; // error u f = { .b = "asdf" }; u g = { .a = 1, .b = "asdf" }; // error — end example]

[Note 10: As described above, the braces around the initializer-clause for a union member can be omitted if the union is a member of another aggregate. — end note]

9.4.3 Character arrays

An array of ordinary character type (6.8.2), char8_t array, char16_t array, char32_t array, or wchar_t array may be initialized by an ordinary string literal, UTF-8 string literal, UTF-16 string literal, UTF-32 string literal, or wide string literal, respectively, or by an appropriately-typed string-literal enclosed in braces (5.13.5).
Additionally, an array of `char` or `unsigned char` may be initialized by a UTF-8 string literal, or by such a string literal enclosed in braces. Successive characters of the value of the string-literal initialize the elements of the array, with an integral conversion (7.3.9) if necessary for the source and destination value.

**Example 1:**

```c
char msg[] = "Syntax error on line \%s\n";
```

shows a character array whose members are initialized with a string-literal. Note that because `\n` is a single character and because a trailing `\0` is appended, `sizeof(msg)` is 25. — end example]

2 There shall not be more initializers than there are array elements.

**Example 2:**

```c
char cv[4] = "asdf"; // error
```

is ill-formed since there is no space for the implied trailing `\0`. — end example]

3 If there are fewer initializers than there are array elements, each element not explicitly initialized shall be zero-initialized (9.4).

9.4.4 References [dcl.init.ref]

1 A variable whose declared type is “reference to T” (9.3.4.3) shall be initialized.

**Example 1:**

```c
int g(int) noexcept;
void f() {
    int i;
    int& r = i; // r refers to i
    r = 1; // the value of i becomes 1
    int* p = &r; // p points to i
    int& rr = r; // rr refers to what r refers to, that is, to i
    int (&rg)(int) = g; // rg refers to the function g
    rg(i); // calls function g
    int a[3];
    int (&ra)[3] = a; // ra refers to the array a
    ra[1] = i; // modifies a[1]
}
```

— end example]

2 A reference cannot be changed to refer to another object after initialization.

**[Note 1:** Assignment to a reference assigns to the object referred to by the reference (7.6.19). — end note]

Argument passing (7.6.1.3) and function value return (8.7.4) are initializations.

3 The initializer can be omitted for a reference only in a parameter declaration (9.3.4.6), in the declaration of a function return type, in the declaration of a class member within its class definition (11.4), and where the `extern` specifier is explicitly used.

**Example 2:**

```c
int* r1; // error: initializer missing
extern int* r2; // OK
```

— end example]

4 Given types “`cv1 T1`” and “`cv2 T2`”, “`cv1 T1`” is reference-related to “`cv2 T2`” if T1 is similar (7.3.6) to T2, or T1 is a base class of T2. “`cv1 T1`” is reference-compatible with “`cv2 T2`” if a prvalue of type “pointer to `cv2 T2`” can be converted to the type “pointer to `cv1 T1`” via a standard conversion sequence (7.3). In all cases where the reference-compatible relationship of two types is used to establish the validity of a reference binding and the standard conversion sequence would be ill-formed, a program that necessitates such a binding is ill-formed.

5 A reference to type “`cv1 T1`” is initialized by an expression of type “`cv2 T2`” as follows:

(5.1) — If the reference is an lvalue reference and the initializer expression

(5.1.1) — is an lvalue (but is not a bit-field), and “`cv1 T1`” is reference-compatible with “`cv2 T2`”, or
— has a class type (i.e., \( T_2 \) is a class type), where \( T_1 \) is not reference-related to \( T_2 \), and can be converted to an lvalue of type “\( \texttt{cv} 3 \ T_3 \)”, where “\( \texttt{cv} 1 \ T_1 \)” is reference-compatible with “\( \texttt{cv} 3 \ T_3 \)”, this conversion is selected by enumerating the applicable conversion functions (12.2.2.7) and choosing the best one through overload resolution (12.2),
then the reference binds to the initializer expression lvalue in the first case and to the lvalue result of the conversion in the second case (or, in either case, to the appropriate base class subobject of the object).

[Note 2: The usual lvalue-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) standard conversions are not needed, and therefore are suppressed, when such direct bindings to lvalues are done. — end note]

[Example 3:]

double d = 2.0;
double& rd = d; // rd refers to d
const double& rcd = d; // rcd refers to d

struct A { }
struct B : A { operator int&(); } b;
A& ra = b; // ra refers to A subobject in b
const A& rca = b; // rca refers to A subobject in b
int& ir = B(); // ir refers to the result of B::operator int&
— end example]

— Otherwise, if the reference is an lvalue reference to a type that is not const-qualified or is volatile-qualified, the program is ill-formed.

[Example 4:]
double& rd2 = 2.0; // error: not an lvalue and reference not const
int i = 2;
double& rd3 = i; // error: type mismatch and reference not const
— end example]

— Otherwise, if the initializer expression

— is an rvalue (but not a bit-field) or function lvalue and “\( \texttt{cv} 1 \ T_1 \)” is reference-compatible with “\( \texttt{cv} 2 \ T_2 \)”, or

— has a class type (i.e., \( T_2 \) is a class type), where \( T_1 \) is not reference-related to \( T_2 \), and can be converted to an rvalue or function lvalue of type “\( \texttt{cv} 3 \ T_3 \)”, where “\( \texttt{cv} 1 \ T_1 \)” is reference-compatible with “\( \texttt{cv} 3 \ T_3 \)” (see 12.2.2.7),
then the initializer expression in the first case and the converted expression in the second case is called the converted initializer. If the converted initializer is a prvalue, its type \( T_4 \) is adjusted to type “\( \texttt{cv} 1 \ T_4 \)” (7.3.6) and the temporary materialization conversion (7.3.5) is applied. In any case, the reference binds to the resulting glvalue (or to an appropriate base class subobject).

[Example 5:]

struct A { }
struct B : A { } b;
extern B f();
const A& rca2 = f(); // binds to the A subobject of the B rvalue.
A& rra = f(); // same as above
struct X {
  operator B();
  operator int&();
} x;
const A& r = x; // binds to the A subobject of the result of the conversion
int i2 = 42;
int& rri = static_cast<int&>(i2); // binds directly to i2
B& rrb = x; // binds directly to the result of operator B
— end example]

85) This requires a conversion function (11.4.8.3) returning a reference type.
Otherwise:

(5.4.1) If \(T_1\) or \(T_2\) is a class type and \(T_1\) is not reference-related to \(T_2\), user-defined conversions are considered using the rules for copy-initialization of an object of type \("cv1\ T_1\") by user-defined conversion (9.4, 12.2.2.5, 12.2.2.6); the program is ill-formed if the corresponding non-reference copy-initialization would be ill-formed. The result of the call to the conversion function, as described for the non-reference copy-initialization, is then used to direct-initialize the reference. For this direct-initialization, user-defined conversions are not considered.

(5.4.2) Otherwise, the initializer expression is implicitly converted to a prvalue of type \("T_1\". The temporary materialization conversion is applied, considering the type of the prvalue to be \("cv1\ T_1\", and the reference is bound to the result.

If \(T_1\) is reference-related to \(T_2\):

(5.4.3) \(cv1\) shall be the same cv-qualification as, or greater cv-qualification than, \(cv2\); and

(5.4.4) if the reference is an rvalue reference, the initializer expression shall not be an lvalue.

[Note 3: This can be affected by whether the initializer expression is move-eligible (7.5.4.2). — end note]

Example 6:

```cpp
struct Banana { };  
struct Enigma { operator const Banana(); };  
struct Alaska { operator Banana&(); };  
void enigmatic() {  
    typedef const Banana ConstBanana;  
    Banana &&banana1 = ConstBanana(); // error  
    Banana &&banana2 = Enigma(); // error  
    Banana &&banana3 = Alaska(); // error  
}  
const double& rcd2 = 2; // rcd2 refers to temporary with value 2.0  
double&& rrd = 2; // rrd refers to temporary with value 2.0  
const volatile int cvi = 1;  
const int& r2 = cvi; // error: cv-qualifier dropped  
struct & a { operator volatile int&(); } a;  
const int& r3 = a; // error: cv-qualifier dropped  
// from result of conversion function  
double d2 = 1.0;  
double&& rrd2 = d2; // error: initializer is lvalue of related type  
struct X { operator int&(); } x;  
int&& rri2 = x(); // error: result of conversion function is lvalue of related type  
int i3 = 2;  
double&& rrd3 = i3; // rrd3 refers to temporary with value 2.0  
}  

— end example]
```

In all cases except the last (i.e., implicitly converting the initializer expression to the referenced type), the reference is said to bind directly to the initializer expression.

[Note 4: 6.7.7 describes the lifetime of temporaries bound to references. — end note]

### 9.4.5 List-initialization

List-initialization is initialization of an object or reference from a braced-init-list. Such an initializer is called an initializer list, and the comma-separated initializer-clauses of the initializer-list or designated-initializer-clauses of the designated-initializer-list are called the elements of the initializer list. An initializer list may be empty. List-initialization can occur in direct-initialization or copy-initialization contexts; list-initialization in a direct-initialization context is called direct-list-initialization and list-initialization in a copy-initialization context is called copy-list-initialization.

[Note 1: List-initialization can be used

(1.1) as the initializer in a variable definition (9.4)
(1.2) as the initializer in a new-expression (7.6.2.8)
(1.3) in a return statement (8.7.4)
(1.4) as a for-range-initializer (8.6)
(1.5) — as a function argument (7.6.1.3)
(1.6) — as a subscript (7.6.1.2)
(1.7) — as an argument to a constructor invocation (9.4, 7.6.1.4)
(1.8) — as an initializer for a non-static data member (11.4)
(1.9) — in a mem-initializer (11.9.3)
(1.10) — on the right-hand side of an assignment (7.6.19)

Example 1:

```cpp
int a = {1};
std::complex<double> z{1,2}; // 4 string elements
f( {"Nicholas","Annemarie"} ); // pass list of two elements
return { "Norah" }; // return list of one element
int* e {};
// initialization to zero / null pointer
x = double{1};
// explicitly construct a double
std::map<std::string,int> anim = { {"bear",4}, {"cassowary",2}, {"tiger",7} };
```

—end example

—end note

2 A constructor is an *initializer-list constructor* if its first parameter is of type `std::initializer_list<E>` or reference to `cv std::initializer_list<E>` for some type `E`, and either there are no other parameters or else all other parameters have default arguments (9.3.4.7).

[Note 2: Initializer-list constructors are favored over other constructors in list-initialization (12.2.2.8). Passing an initializer list as the argument to the constructor template `template<class T> C(T)` of a class `C` does not create an initializer-list constructor, because an initializer list argument causes the corresponding parameter to be a non-deduced context (13.10.3.2). —end note]

The template `std::initializer_list` is not predefined; if a standard library declaration (17.10.2, 16.4.2.4) of `std::initializer_list` is not reachable from (10.7) a use of `std::initializer_list` — even an implicit use in which the type is not named (9.2.9.6) — the program is ill-formed.

3 List-initialization of an object or reference of type `T` is defined as follows:

(3.1) — If the braced-init-list contains a designated-initializer-list, `T` shall be an aggregate class. The ordered identifiers in the designators of the designated-initializer-list shall form a subsequence of the ordered identifiers in the direct non-static data members of `T`. Aggregate initialization is performed (9.4.2).

[Example 2:

```cpp
struct A { int x; int y; int z; };
A a{.y = 2, .x = 1}; // error: designator order does not match declaration order
A b{.x = 1, .z = 2}; // OK, b.y initialized to 0
```

—end example]

(3.2) — If `T` is an aggregate class and the initializer list has a single element of type `cv U`, where `U` is `T` or a class derived from `T`, the object is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization).

(3.3) — Otherwise, if `T` is a character array and the initializer list has a single element that is an appropriately-typed string-literal (9.4.3), initialization is performed as described in that subclause.

(3.4) — Otherwise, if `T` is an aggregate, aggregate initialization is performed (9.4.2).

[Example 3:

```cpp
double ad[] = { 1, 2.0 }; // OK
int ai[] = { 1, 2.0 }; // error: narrowing

struct S2 {
  int m1;
  double m2, m3;
};
S2 s21 = { 1, 2, 3.0 }; // OK
S2 s22 { 1.0, 2, 3 }; // error: narrowing
S2 s23 { }; // OK, default to 0,0,0
```

§ 9.4.5
Otherwise, if the initializer list has no elements and \( T \) is a class type with a default constructor, the object is value-initialized.

Otherwise, if \( T \) is a specialization of `std::initializer_list<E>`\(^{a}\), the object is constructed as described below.

Otherwise, if \( T \) is a class type, constructors are considered. The applicable constructors are enumerated and the best one is chosen through overload resolution (12.2, 12.2.2.8). If a narrowing conversion (see below) is required to convert any of the arguments, the program is ill-formed.

\[\text{Example 4:}\]

\[
\begin{align*}
\text{struct S} & \{ \\
& \text{S}((\text{std::initializer_list<double>})); // #1 \\
& \text{S}((\text{std::initializer_list<int>})); // #2 \\
& \text{S}(); // #3 \\
& \text{// ...} \\
& \text{S s1 = \{ 1.0, 2.0, 3.0 \}; // invoke #1} \\
& \text{S s2 = \{ 1, 2, 3 \}; // invoke #2} \\
& \text{S s3 = \{ \}; // invoke #3} \\
\end{align*}
\]

\[\text{— end example}\]

\[\text{Example 5:}\]

\[
\begin{align*}
\text{struct Map} & \{ \\
& \text{Map((\text{std::initializer_list<\text{std::pair<\text{std::string},\text{int}>}}}));} \\
& \text{Map ship = \{\"Sophie\",14\}, \{\"Surprise\",28\};} \\
\end{align*}
\]

\[\text{— end example}\]

\[\text{Example 6:}\]

\[
\begin{align*}
\text{struct S} & \{ \\
& \text{// no initializer-list constructors} \\
& \text{S(int, double, double);} // #1 \\
& \text{S();} // #2 \\
& \text{// ...} \\
& \text{S s1 = \{ 1, 2, 3.0 \}; // OK, invoke #1} \\
& \text{S s2 = \{ 1.0, 2, 3 \}; // error: narrowing} \\
& \text{S s3 = \{ \}; // OK, invoke #2} \\
\end{align*}
\]

\[\text{— end example}\]

Otherwise, if \( T \) is an enumeration with a fixed underlying type (9.7.1) \( U \), the *initializer-list* has a single element \( v \), \( v \) can be implicitly converted to \( U \), and the initialization is direct-list-initialization, the object is initialized with the value \( T(v) \) (7.6.1.4); if a narrowing conversion is required to convert \( v \) to \( U \), the program is ill-formed.

\[\text{Example 7:}\]

\[
\begin{align*}
\text{enum byte : unsigned char} & \{ \}; \\
\text{byte b \{ 42 \};} & // OK \\
\text{byte c \{ 42 \};} & // error \\
\text{byte d = byte\{ 42 \};} & // OK; same value as b \\
\text{byte e \{ -1 \};} & // error \\
\text{struct A \{ byte b; \};} \\
\text{A a1 \{ \{ 42 \} \};} & // error \\
\text{A a2 \{ byte\{ 42 \} \};} & // OK \\
\text{void f(byte);} \\
\text{f\{ 42 \};} & // error \\
\text{enum class Handle : uint32_t} & \{ \text{Invalid} = 0 \}; \\
\text{Handle h \{ 42 \};} & // OK \\
\end{align*}
\]

\[\text{— end example}\]
Otherwise, if the initializer list has a single element of type \( E \) and either \( T \) is not a reference type or its referenced type is reference-related to \( E \), the object or reference is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization); if a narrowing conversion (see below) is required to convert the element to \( T \), the program is ill-formed.

[Example 8:]

\[
\begin{align*}
\text{int } x1 \{2\}; & \quad // \text{OK} \\
\text{int } x2 \{2.0\}; & \quad // \text{error: narrowing} \\
\end{align*}
\]

— end example

(3.10) — Otherwise, if \( T \) is a reference type, a prvalue is generated. The prvalue initializes its result object by copy-list-initialization from the initializer list. The prvalue is then used to direct-initialize the reference. The type of the prvalue is the type referenced by \( T \), unless \( T \) is "reference to array of unknown bound of \( U \)", in which case the type of the prvalue is the type of \( x \) in the declaration \( U \ x[\ ] \ H \), where \( H \) is the initializer list.

[Note 3: As usual, the binding will fail and the program is ill-formed if the reference type is an lvalue reference to a non-const type. — end note]

[Example 9:]

\[
\begin{align*}
\text{struct } S \{ \\
\quad S(\text{std::initializer_list<double>}); & \quad // #1 \\
\quad S(\text{const std::string}&); & \quad // #2 \\
\quad \ldots \\
\}; \\
\text{const } S& \ r1 = \{1, 2, 3.0\}; & \quad // \text{OK, invoke } #1 \\
\text{const } S& \ r2 \{"Spinach"\}; & \quad // \text{OK, invoke } #2 \\
\text{S& } \ r3 = \{1, 2, 3\}; & \quad // \text{error: initializer is not an lvalue} \\
\text{const int& } \ i1 \{\ 1\ \}; & \quad // \text{OK} \\
\text{const int& } \ i2 \{\ 1.1\ \}; & \quad // \text{error: narrowing} \\
\text{const int } (\&iar)[2] \{\ 1, 2\ \}; & \quad // \text{OK, iar is bound to temporary array} \\
\}; \\
\text{struct } A \{\ \}; \\
\text{struct } B \{\ \text{explicit } B(\text{const } A&); \\}; \\
\text{const } S& \ b2[a]; & \quad // \text{error: cannot copy-list-initialize } B \text{ temporary from } A \\
\end{align*}
\]

— end example

(3.11) — Otherwise, if the initializer list has no elements, the object is value-initialized.

[Example 10:]

\[
\begin{align*}
\text{int** } pp \{\ \}; & \quad // \text{initialized to null pointer} \\
\end{align*}
\]

— end example

(3.12) — Otherwise, the program is ill-formed.

[Example 11:]

\[
\begin{align*}
\text{struct } A \{ \text{int } i; \text{int } j; \}; \\
\text{A } a1 \{\ 1, 2\ \}; & \quad // \text{aggregate initialization} \\
\text{A } a2 \{\ 1.2\ \}; & \quad // \text{error: narrowing} \\
\text{struct } B \{ \\
\quad B(\text{std::initializer_list<int>}); & \quad // \text{creates } \text{initializer_list<int>} \text{ and calls constructor} \\
\}; \\
\text{B } b1 \{\ 1, 2\ \}; & \quad // \text{error: narrowing} \\
\text{B } b2 \{\ 1, 2.0\ \}; & \quad // \text{error: narrowing} \\
\text{struct } C \{ \\
\quad C(\text{int } i, \text{double } j); & \quad // \text{calls constructor with arguments } (1, 2.2) \\
\}; \\
\text{C } c1 \{\ 1, 2.2\ \}; & \quad // \text{error: narrowing} \\
\text{C } c2 \{\ 1.1, 2\ \}; & \quad // \text{error: narrowing} \\
\text{int } j \{\ 1\ \}; & \quad // \text{initialize to } 1 \\
\text{int } k \{\ \}; & \quad // \text{initialize to } 0 \\
\end{align*}
\]

— end example

§ 9.4.5 223
Within the *initializer-list* of a *braced-init-list*, the *initializer-clauses*, including any that result from pack expansions (13.7.4), are evaluated in the order in which they appear. That is, every value computation and side effect associated with a given *initializer-clause* is sequenced before every value computation and side effect associated with any *initializer-clause* that follows it in the comma-separated list of the *initializer-list*.

*[Note 4: This evaluation ordering holds regardless of the semantics of the initialization; for example, it applies when the elements of the *initializer-list* are interpreted as arguments of a constructor call, even though ordinarily there are no sequencing constraints on the arguments of a call. — end note]*

An object of type `std::initializer_list<E>` is constructed from an initializer list as if the implementation generated and materialized (7.3.5) a prvalue of type “array of \(N\) const E”, where \(N\) is the number of elements in the initializer list. Each element of that array is copy-initialized with the corresponding element of the initializer list, and the `std::initializer_list<E>` object is constructed to refer to that array.

*[Note 5: A constructor or conversion function selected for the copy is required to be accessible (11.8) in the context of the initializer list. — end note]*

If a narrowing conversion is required to initialize any of the elements, the program is ill-formed.

*Example 12:*

```cpp
struct X {
    X(std::initializer_list<double> v);
};
X x{ 1,2,3 }; // ill-formed, would create a dangling reference
```

The initialization will be implemented in a way roughly equivalent to this:

```cpp
const double __a[3] = {double{1}, double{2}, double{3}};
x(std::initializer_list<double>(__a, __a+3));
```

assuming that the implementation can construct an `initializer_list` object with a pair of pointers. — end example]

A *narrowing conversion* is an implicit conversion:

1. from a floating-point type to an integer type, or
2. from a floating-point type \(T\) to another floating-point type whose floating-point conversion rank is neither greater than nor equal to that of \(T\), except where the source is a constant expression and the actual value after conversion is within the range of values that can be represented (even if it cannot be represented exactly), or
3. from an integer type or unscoped enumeration type to a floating-point type, except where the source is a constant expression and the actual value after conversion will fit into the target type and will produce the original value when converted back to the original type, or

§ 9.4.5 224
from an integer type or unscoped enumeration type to an integer type that cannot represent all the values of the original type, except where

- the source is a bit-field whose width \( w \) is less than that of its type (or, for an enumeration type, its underlying type) and the target type can represent all the values of a hypothetical extended integer type with width \( w \) and with the same signedness as the original type or

- the source is a constant expression whose value after integral promotions will fit into the target type, or

Note 7: As indicated above, such conversions are not allowed at the top level in list-initializations. — end note

Example 14:

```c
int x = 999; // x is not a constant expression
const int y = 999;
const int z = 99;
char c1 = x; // OK, though it potentially narrows (in this case, it does narrow)
char c2(x); // error: potentially narrows
char c3(y); // error: narrows (assuming char is 8 bits)
char c4(z); // OK, no narrowing needed
unsigned char uc1 = {5}; // OK, no narrowing needed
unsigned char uc2 = {-1}; // error: narrows
unsigned int ui1 = {-1}; // error: narrows
signed int s11 =
  { (unsigned int)-1 }; // error: narrows
int ii = (2.0); // error: narrows
float f1 { x }; // error: potentially narrows
float f2 { 7 }; // OK, 7 can be exactly represented as a float
bool b ={"meow"}; // error: narrows
int f(int);
int a[] = { 2, f(2), f(2.0) }; // OK, the double-to-int conversion is not at the top level
— end example
```

9.5 Function definitions

9.5.1 In general

Function definitions have the form

```
function-definition:
  attribute-specifier-seq\_opt decl-specifier-seq\_opt declarator virt-specifier-seq\_opt function-body
  attribute-specifier-seq\_opt decl-specifier-seq\_opt declarator requires-clause function-body

function-body:
  ctor-initializer\_opt compound-statement
  function-try-block
  = default ;
  = delete ;
```

Any informal reference to the body of a function should be interpreted as a reference to the non-terminal `function-body`. The optional `attribute-specifier-seq` in a `function-definition` appertains to the function. A `virt-specifier-seq` can be part of a `function-definition` only if it is a `member-declaration` (11.4).

In a `function-definition`, either `void declarator`; or `declarator`; shall be a well-formed function declaration as described in 9.3.4.6. A function shall be defined only in namespace or class scope. The type of a parameter or the return type for a function declaration shall not be a (possibly cv-qualified) class type that is incomplete or abstract within the function body unless the function is deleted (9.5.3).

[Example 1: A simple example of a complete function definition is

```c
int max(int a, int b, int c) {
  int m = (a > b) ? a : b;
  return (m > c) ? m : c;
}
```

Here `int` is the `decl-specifier-seq: max(int a, int b, int c)` is the `declarator;` `{ /* ... */ }` is the `function-body.` — end example]
ctor-initializer is used only in a constructor; see 11.4.5 and 11.9.

[Note 1: A cv-qualifier-seq affects the type of this in the body of a member function; see 7.5.2. — end note]

[Note 2: Unused parameters need not be named. For example,

```c
void print(int a, int) {
    std::printf("a = %d\n",a);
}
```
—end note]

A function-local predefined variable is a variable with static storage duration that is implicitly defined in a function parameter scope.

The function-local predefined variable __func__ is defined as if a definition of the form

```c
static const char __func__[] = "function-name";
```

had been provided, where function-name is an implementation-defined string. It is unspecified whether such a variable has an address distinct from that of any other object in the program.\(^{86}\)

[Example 2:

```c
struct S {
    S() : s(__func__) { }  // OK
    const char* s;
};
void f(const char* s = __func__);  // error: __func__ is undeclared
```
—end example]

9.5.2 Explicitly-defaulted functions

A function definition whose function-body is of the form = default ; is called an explicitly-defaulted definition. A function that is explicitly defaulted shall

(1.1) be a special member function or a comparison operator function (12.4.3), and
(1.2) not have default arguments.

An explicitly defaulted special member function \(F_1\) is allowed to differ from the corresponding special member function \(F_2\) that would have been implicitly declared, as follows:

(2.1) \(F_1\) and \(F_2\) may have differing ref-qualifiers;
(2.2) if \(F_2\) has an implicit object parameter of type “reference to \(C\)”, \(F_1\) may be an explicit object member function whose explicit object parameter is of type “reference to \(C\)”, in which case the type of \(F_1\) would differ from the type of \(F_2\) in that the type of \(F_1\) has an additional parameter;
(2.3) \(F_1\) and \(F_2\) may have differing exception specifications; and
(2.4) if \(F_2\) has a non-object parameter of type const \(C\&\), the corresponding non-object parameter of \(F_1\) may be of type \(C\&\).

If the type of \(F_1\) differs from the type of \(F_2\) in a way other than as allowed by the preceding rules, then:

(2.5) if \(F_1\) is an assignment operator, and the return type of \(F_1\) differs from the return type of \(F_2\) or \(F_1\)’s non-object parameter type is not a reference, the program is ill-formed;
(2.6) otherwise, if \(F_1\) is explicitly defaulted on its first declaration, it is defined as deleted;
(2.7) otherwise, the program is ill-formed.

A function explicitly defaulted on its first declaration is implicitly inline (9.2.8), and is implicitly constexpr (9.2.6) if it is constexpr-suitable.

[Example 1:

```c
struct S {
    S(int a = 0) = default;  // error: default argument
    void operator=(const S&) = default;  // error: non-matching return type
    ~S() noexcept(false) = default;  // OK, despite mismatched exception specification
private:
    int i;
}
```

\(^{86}\) Implementations are permitted to provide additional predefined variables with names that are reserved to the implementation (5.10). If a predefined variable is not odr-used (6.3), its string value need not be present in the program image.
Explicitly-defaulted functions and implicitly-declared functions are collectively called defaulted functions, and the implementation shall provide implicit definitions for them (11.4.5, 11.4.7, 11.4.5.3, 11.4.6) as described below, including possibly defining them as deleted. A defaulted prospective destructor (11.4.7) that is not a destructor is defined as deleted. A defaulted special member function that is neither a prospective destructor nor an eligible special member function (11.4.4) is defined as deleted. A function is user-provided if it is user-declared and not explicitly defaulted or deleted on its first declaration. A user-provided explicitly-defaulted function (i.e., explicitly defaulted after its first declaration) is implicitly defined at the point where it is explicitly defaulted; if such a function is implicitly defined as deleted, the program is ill-formed. A non-user-provided defaulted function (i.e., implicitly declared or explicitly defaulted in the class) that is not defined as deleted is implicitly defined when it is odr-used (6.3) or needed for constant evaluation (7.7).

Example 2:

```cpp
struct trivial {
    trivial() = default;
    trivial(const trivial&) = default;
    trivial(trivial&&) = default;
    trivial& operator=(const trivial&) = default;
    trivial& operator=(trivial&&) = default;
    ~trivial() = default;
};

struct nontrivial1 {
    nontrivial1();
};
nontrivial1::nontrivial1() = default; // not first declaration
```

9.5.3 Deleted definitions

A deleted definition of a function is a function definition whose function-body is of the form `= delete`; or an explicitly-defaulted definition of the function where the function is defined as deleted. A deleted function is a function with a deleted definition or a function that is implicitly defined as deleted.

A program that refers to a deleted function implicitly or explicitly, other than to declare it, is ill-formed.

Note 1: This includes calling the function implicitly or explicitly and forming a pointer or pointer-to-member to the function. It applies even for references in expressions that are not potentially-evaluated. For an overload set, only the function selected by overload resolution is referenced. The implicit odr-use (6.3) of a virtual function does not, by itself, constitute a reference. — end note]

Example 1: One can prevent default initialization and initialization by non-doubles with

```cpp
struct onlydouble {
    onlydouble() = delete; // OK, but redundant
    template<class T>
    onlydouble(T) = delete;
};
```
Example 2: One can prevent use of a class in certain new-expressions by using deleted definitions of a user-declared operator new for that class.

```cpp
struct sometype {
    void* operator new(std::size_t) = delete;
    void* operator new[](std::size_t) = delete;
};
sometype* p = new sometype; // error: deleted class operator new
sometype* q = new sometype[3]; // error: deleted class operator new[]
```

Example 3: One can make a class uncopyable, i.e., move-only, by using deleted definitions of the copy constructor and copy assignment operator, and then providing defaulted definitions of the move constructor and move assignment operator.

```cpp
struct moveonly {
    moveonly() = default;
    moveonly(const moveonly&) = delete;
    moveonly(moveonly&&) = default;
    moveonly& operator=(const moveonly&) = delete;
    moveonly& operator=(moveonly&&) = default;
    ~moveonly() = default;
};
moveonly* p;
moveonly q(*p); // error: deleted copy constructor
```

4 A deleted function is implicitly an inline function (9.2.8).

[Note 2: The one-definition rule (6.3) applies to deleted definitions. — end note]

A deleted definition of a function shall be the first declaration of the function or, for an explicit specialization of a function template, the first declaration of that specialization. An implicitly declared allocation or deallocation function (6.7.5.5) shall not be defined as deleted.

Example 4:

```cpp
struct sometype {
    sometype();
};
sometype::sometype() = delete; // error: not first declaration
```

9.5.4 Coroutine definitions

A function is a coroutine if its function-body encloses a coroutine-return-statement (8.7.5), an await-expression (7.6.2.4), or a yield-expression (7.6.17). The parameter-declaration-clause of the coroutine shall not terminate with an ellipsis that is not part of a parameter-declaration.

Example 1:

```cpp
task<int> f();

task<void> g1() {
    int i = co_await f();
    std::cout << "f() => " << i << std::endl;
}
template <typename... Args>
task<void> g2(Args&&...) { // OK, ellipsis is a pack expansion
    int i = co_await f();
    std::cout << "f() => " << i << std::endl;
}
```
task<void> g3(int a, ...) {
    // error: variable parameter list not allowed
    int i = co_await f();
    std::cout << "f() => " << i << std::endl;
}

— end example —

3 The promise type of a coroutine is `std::coroutine_traits<R, P_1, ..., P_n>::promise_type`, where \( R \) is the return type of the function, and \( P_1 \ldots P_n \) is the sequence of types of the non-object function parameters, preceded by the type of the object parameter (9.3.4.6) if the coroutine is a non-static member function. The promise type shall be a class type.

4 In the following, \( p_i \) is an lvalue of type \( P_i \), where \( p_1 \) denotes the object parameter and \( p_{i+1} \) denotes the \( i \)th non-object function parameter for a non-static member function, and \( p_i \) denotes the \( i \)th function parameter otherwise. For a non-static member function, \( q_i \) is an lvalue that denotes \(*\text{this}\); any other \( q_i \) is an lvalue that denotes the parameter copy corresponding to \( p_i \), as described below.

5 A coroutine behaves as if its function-body were replaced by:

\[
\begin{align*}
\{ & \text{promise-type} & \text{promise} & \text{promise-constructor-arguments} ; \\
& \text{try} \{ & & \text{co_await} \text{promise}.\text{initial_suspend}() ; \\
& & & \text{function-body} \\
& \} & \text{catch} \ (\ldots) \{ & & \text{if} \ (\text{initial-await-resume-called}) \\
& & & \quad \text{throw} ; \\
& & & \text{promise}.\text{unhandled_exception}() ; \\
& \} & \text{final-suspend} : \\
& & & \text{co_await} \text{promise}.\text{final_suspend}() ; \\
\}
\end{align*}
\]

where

5.1 the await-expression containing the call to initial_suspend is the initial await expression, and
5.2 the await-expression containing the call to final_suspend is the final await expression, and
5.3 initial-await-resume-called is initially false and is set to true immediately before the evaluation of the await-resume expression (7.6.2.4) of the initial await expression, and
5.4 promise-type denotes the promise type, and
5.5 the object denoted by the exposition-only name promise is the promise object of the coroutine, and
5.6 the label denoted by the name final-suspend is defined for exposition only (8.7.5), and
5.7 promise-constructor-arguments is determined as follows: overload resolution is performed on a promise constructor call created by assembling an argument list \( q_1 \ldots q_n \). If a viable constructor is found (12.2.3), then promise-constructor-arguments is \( (q_1, \ldots, q_n) \), otherwise promise-constructor-arguments is empty, and
5.8 a coroutine is suspended at the initial suspend point if it is suspended at the initial await expression, and
5.9 a coroutine is suspended at a final suspend point if it is suspended
5.9.1 at a final await expression or
5.9.2 due to an exception exiting from unhandled_exception().

6 If searches for the names return_void and return_value in the scope of the promise type each find any declarations, the program is ill-formed.

[Note 1: If return_void is found, flowing off the end of a coroutine is equivalent to a co_return with no operand. Otherwise, flowing off the end of a coroutine results in undefined behavior (8.7.5). — end note]

7 The expression promise.get_return_object() is used to initialize the returned reference or prvalue result object of a call to a coroutine. The call to get_return_object is sequenced before the call to initial_suspend and is invoked at most once.

8 A suspended coroutine can be resumed to continue execution by invoking a resumption member function (17.12.4.6) of a coroutine handle (17.12.4) that refers to the coroutine. The evaluation that invoked a
The resumption member function is called the **resumer**. Invoking a resumption member function for a coroutine that is not suspended results in undefined behavior.

9 An implementation may need to allocate additional storage for a coroutine. This storage is known as the **coroutine state** and is obtained by calling a non-array allocation function (6.7.5.5.2). The allocation function's name is looked up by searching for it in the scope of the promise type.

(9.1) — If the search finds any declarations, overload resolution is performed on a function call created by assembling an argument list. The first argument is the amount of space requested, and is a prvalue of type `std::size_t`. The values \( p_1 \ldots p_n \) are the successive arguments. If no viable function is found (12.2.3), overload resolution is performed again on a function call created by passing just the amount of space required as a prvalue of type `std::size_t`.

(9.2) — If the search finds no declarations, a search is performed in the global scope. Overload resolution is performed on a function call created by passing the amount of space required as a prvalue of type `std::size_t`.

10 If a search for the name `get_return_object_on_allocation_failure` in the scope of the promise type (6.5.2) finds any declarations, then the result of a call to an allocation function used to obtain storage for the coroutine state is assumed to return `nullptr` if it fails to obtain storage, and if a global allocation function is selected, the `::operator new(size_t, nothrow_t)` form is used. The allocation function used in this case shall have a non-throwing `noexcept-specifier`. If the allocation function returns `nullptr`, the coroutine returns control to the caller of the coroutine and the return value is obtained by a call to `T::get_return_object_on_allocation_failure()`, where `T` is the promise type.

Example 2:
```
#include <iostream>
#include <coroutine>

// ::operator new(size_t, nothrow_t) will be used if allocation is needed
struct generator {
    struct promise_type {
        int current_value;
        static auto get_return_object_on_allocation_failure() { return generator(nullptr); }
        auto get_return_object() { return generator(handle::from_promise(*this)); }
        auto initial_suspend() { return std::suspend_always{}; }
        auto final_suspend() noexcept { return std::suspend_always{}; }
        void unhandled_exception() { std::terminate(); }
        void return_void() {}
        auto yield_value(int value) {
            current_value = value;
            return std::suspend_always{};
        }
    };  
    bool move_next() { return coro ? (coro.resume(), !coro.done()) : false; }
    int current_value() { return coro.promise().current_value; }
    generator(generator const&) = delete;
    generator(generator && rhs) : coro(rhs.coro) { rhs.coro = nullptr; }
    ~generator() { if (coro) coro.destroy(); }
    private:
    generator(handle h) : coro(h) {}  
    handle coro;
};

generator f() { co_yield 1; co_yield 2; }
int main() {
    auto g = f();
    while (g.move_next()) std::cout << g.current_value() << std::endl;
}
```

—end example]

11 The coroutine state is destroyed when control flows off the end of the coroutine or the **destroy** member function (17.12.4.6) of a coroutine handle (17.12.4) that refers to the coroutine is invoked. In the latter case, control in the coroutine is considered to be transferred out of the function (8.8). The storage for the coroutine
state is released by calling a non-array deallocation function (6.7.5.5.3). If `destroy` is called for a coroutine that is not suspended, the program has undefined behavior.

The deallocation function’s name is looked up by searching for it in the scope of the promise type. If nothing is found, a search is performed in the global scope. If both a usual deallocation function with only a pointer parameter and a usual deallocation function with both a pointer parameter and a size parameter are found, then the selected deallocation function shall be the one with two parameters. Otherwise, the selected deallocation function shall be the function with one parameter. If no usual deallocation function is found, the program is ill-formed. The selected deallocation function shall be called with the address of the block of storage to be reclaimed as its first argument. If a deallocation function with a parameter of type `std::size_t` is used, the size of the block is passed as the corresponding argument.

When a coroutine is invoked, after initializing its parameters (7.6.1.3), a copy is created for each coroutine parameter. For a parameter of type `cv T`, the copy is a variable of type `cv T` with automatic storage duration that is direct-initialized from an xvalue of type `T` referring to the parameter.

The initialization and destruction of each parameter copy occurs in the context of the called coroutine. Initializations of parameter copies are sequenced before the call to the coroutine promise constructor and indeterminately sequenced with respect to each other. The lifetime of parameter copies ends immediately after the lifetime of the coroutine promise object ends.

Otherwise, if the evaluation of the expression `promise.unhandled_exception()` exits via an exception, the coroutine is considered suspended at the final suspend point and the exception propagates to the caller or resumer.

The expression `co_wait promise.final_suspend()` shall not be potentially-throwing (14.5).

9.6 Structured binding declarations

A structured binding declaration introduces the identifiers `v0`, `v1`, `v2`, ... of the `identifier-list` as names of structured bindings. Let `cv` denote the `cv-qualifiers` in the `decl-specifier-seq` and `S` consist of the `storage-class-specifiers` of the `decl-specifier-seq` (if any). A `cv` that includes `volatile` is deprecated; see D.5. First, a variable with a unique name `e` is introduced. If the `assignment-expression` in the `initializer` has array type `cv1 A` and no `ref-qualifier` is present, `e` is defined by

```cpp
attribute-specifier-seq `opt` `S` `cv` `k` `e` `;`
```
and each element is copy-initialized or direct-initialized from the corresponding element of the `assignment-expression` as specified by the form of the `initializer`. Otherwise, `e` is defined as-if by

```cpp
attribute-specifier-seq `opt` `decl-specifier-seq` ref-`qualifier` `opt` `e` `initializer` `;`
```
where the declaration is never interpreted as a function declaration and the parts of the declaration other than the `declarator-id` are taken from the corresponding structured binding declaration. The type of the `id-expression` `e` is called `E`.

If the `initializer` refers to one of the names introduced by the structured binding declaration, the program is ill-formed.

If `E` is an array type with element type `T`, the number of elements in the `identifier-list` shall be equal to the number of elements of `E`. Each `vi` is the name of an lvalue that refers to the element `i` of the array and whose type is `T`; the referenced type is `T`.

If the `top-level cv-qualifiers` of `T` are `cv` — end note

Example 1:

```cpp
auto `f`() -> int(`k`)[2];
auto `[ x, y ] = `f`(); // x and y refer to elements in a copy of the array return value
auto& `[ xr, yr ] = `f`(); // xr and yr refer to elements in the array referred to by `f`’s return value
```

—end example]

Otherwise, if the `qualified-id` `std::tuple_size<E>` names a complete class type with a member named `value`, the expression `std::tuple_size<E>::value` shall be a well-formed integral constant expression and the number of elements in the `identifier-list` shall be equal to the value of that expression. Let `i` be an index prvalue of type `std::size_t` corresponding to `vi`. If a search for the name `get` in the scope of `E (6.5.2)` finds at least
one declaration that is a function template whose first template parameter is a non-type parameter, the
initializer is $e$.get<i>(). Otherwise, the initializer is get<i>(e), where get undergoes argument-dependent
lookup (6.5.4). In either case, get<i> is interpreted as a template-id.

[Note 3: Ordinary unqualified lookup (6.5.3) is not performed. — end note]

In either case, $e$ is an lvalue if the type of the entity $e$ is an lvalue reference and an xvalue otherwise. Given
the type $T_i$, designated by std::tuple_element<i, E>::type and the type $U_i$ designated by either $T_i$& or
$T_i$&&, where $U_i$ is an lvalue reference if the initializer is an lvalue and an rvalue reference otherwise, variables
are introduced with unique names $r_i$ as follows:

$$ S U_i r_i = \text{initializer} ; $$

Each $v_i$ is the name of an lvalue of type $T_i$ that refers to the object bound to $r_i$; the referenced type is $T_i$.

Otherwise, all of $E$’s non-static data members shall be direct members of $E$ or of the same base class of $E$,
well-formed when named as $e$.name in the context of the structured binding, $E$ shall not have an anonymous
union member, and the number of elements in the identifier-list shall be equal to the number of non-static
data members of $E$. Designating the non-static data members of $E$ as $m_0, m_1, m_2, \ldots$ (in declaration order),
each $v_i$ is the name of an lvalue that refers to the member $m_i$ of $e$ and whose type is that of $e.m_i (7.6.1.5)$;
the referenced type is the declared type of $m_i$ if that type is a reference type, or the type of $e.m_i$ otherwise.
The lvalue is a bit-field if that member is a bit-field.

[Example 2:]

```cpp
struct S { mutable int x1 : 2; volatile double y1; };
S f();
const auto [ x, y ] = f();
```

The type of the id-expression $x$ is “int”, the type of the id-expression $y$ is “const volatile double”.
—end example]

9.7 Enumerations

9.7.1 Enumeration declarations

An enumeration is a distinct type (6.8.4) with named constants. Its name becomes an enum-name within its
scope.

```cpp
enum-name:
  identifier
enum-specifier:
  enum-head { enumerator-list_opt }
  enum-head { enumerator-list , }
enum-head:
  enum-key attribute-specifier-seq_opt enum-head-name_opt enum-base_opt
enum-head-name:
  nested-name-specifier_opt identifier
opaque-enum-declaration:
  enum-key attribute-specifier-seq_opt enum-head-name enum-base_opt ;
enum-key:
  enum
  enum class
  enum struct
enum-base:
  : type-specifier-seq
enumerator-list:
  enumerator-definition
  enumerator-list , enumerator-definition
enumerator-definition:
  enumerator
  enumerator = constant-expression
enumerator:
  identifier attribute-specifier-seq_opt
```

The optional attribute-specifier-seq in the enum-head and the opaque-enum-declaration appertains to the enum-
eration; the attributes in that attribute-specifier-seq are thereafter considered attributes of the enumeration

§ 9.7.1
whenever it is named. A following “enum nested-name-specifier opt identifier” within the declspecifier-seq of a member-declaration is parsed as part of an enum-base.

[Note 1: This resolves a potential ambiguity between the declaration of an enumeration with an enum-base and the declaration of an unnamed bit-field of enumeration type.

[Example 1:

```c
struct S {
    enum E : int {}
    ;
    enum E : int {}
    ;
    // error: redeclaration of enumeration
    ;

    // end example]
    // end note]
```

The identifier in an enum-head-name is not looked up and is introduced by the enum-specifier or opaque-enum-declaration. If the enum-head-name of an opaque-enum-declaration contains a nested-name-specifier, the declaration shall be an explicit specialization (13.9.4).

2 The enumeration type declared with an enum-key of only enum is an unscoped enumeration, and its enumerators are unscoped enumerators. The enum-keys enum class and enum struct are semantically equivalent; an enumeration type declared with one of these is a scoped enumeration, and its enumerators are scoped enumerators. The optional enum-head-name shall not be omitted in the declaration of a scoped enumeration. The type-specifier-seq of an enum-base shall name an integral type; any cv-qualification is ignored. An opaque-enum-declaration declaring an unscoped enumeration shall not omit the enum-base. The identifiers in an enumerator-list are declared as constants, and can appear wherever constants are required. The same identifier shall not appear as the name of multiple enumerators in an enumerator-list. An enumerator-definition with = gives the associated enumerator the value indicated by the constant-expression. If the first enumerator has no initializer, the value of the corresponding constant is zero. An enumerator-definition without an initializer gives the enumerator the value obtained by increasing the value of the previous enumerator by one.

[Example 2:

```c
enum { a, b, c=0 }
enum { d, e, f=e+2 }
```

defines a, c, and d to be zero, b and e to be 1, and f to be 3. — end example]

The optional attribute-specifier-seq in an enumerator appertains to that enumerator.

3 An opaque-enum-declaration is either a redeclaration of an enumeration in the current scope or a declaration of a new enumeration.

[Note 2: An enumeration declared by an opaque-enum-declaration has a fixed underlying type and is a complete type. The list of enumerators can be provided in a later redeclaration with an enum-specifier. — end note]

A scoped enumeration shall not be later redeclared as unscoped or with a different underlying type. An unscoped enumeration shall not be later redeclared as scoped and each redeclaration shall include an enum-base specifying the same underlying type as in the original declaration.

4 If an enum-head-name contains a nested-name-specifier, the enclosing enum-specifier or opaque-enum-declaration D shall not inhabit a class scope and shall correspond to one or more declarations nominable in the class, class template, or namespace to which the nested-name-specifier refers (6.4.1). All those declarations shall have the same target scope; the target scope of D is that scope.

Each enumeration defines a type that is different from all other types. Each enumeration also has an underlying type. The underlying type can be explicitly specified using an enum-base. For a scoped enumeration type, the underlying type is int if it is not explicitly specified. In both of these cases, the underlying type is said to be fixed. Following the closing brace of an enum-specifier, each enumerator has the type of its enumeration. If the underlying type is fixed, the type of each enumerator prior to the closing brace is the underlying type and the constant-expression in the enumerator-definition shall be a converted constant expression of the underlying type (7.7). If the underlying type is not fixed, the type of each enumerator prior to the closing brace is determined as follows:

(5.1) — If an initializer is specified for an enumerator, the constant-expression shall be an integral constant expression (7.7). If the expression has unscoped enumeration type, the enumerator has the underlying type of that enumeration type, otherwise it has the same type as the expression.

(5.2) — If no initializer is specified for the first enumerator, its type is an unspecified signed integral type.

§ 9.7.1 233
Otherwise the type of the enumerator is the same as that of the preceding enumerator unless the incremented value is not representable in that type, in which case the type is an unspecified integral type sufficient to contain the incremented value. If no such type exists, the program is ill-formed.

An enumeration whose underlying type is fixed is an incomplete type until immediately after its enum-base (if any), at which point it becomes a complete type. An enumeration whose underlying type is not fixed is an incomplete type until the closing } of its enum-specifier, at which point it becomes a complete type.

For an enumeration whose underlying type is not fixed, the underlying type is an integral type that can represent all the enumerator values defined in the enumeration. If no integral type can represent all the enumerator values, the enumeration is ill-formed. It is implementation-defined which integral type is used as the underlying type except that the underlying type shall not be larger than int unless the value of an enumerator cannot fit in an int or unsigned int. If the enumerator-list is empty, the underlying type is as if the enumeration had a single enumerator with value 0.

For an enumeration whose underlying type is fixed, the values of the enumeration are the values of the underlying type. Otherwise, the values of the enumeration are the values representable by a hypothetical integer type with minimal width M such that all enumerators can be represented. The width of the smallest bit-field large enough to hold all the values of the enumeration type is M. It is possible to define an enumeration that has values not defined by any of its enumerators. If the enumerator-list is empty, the values of the enumeration are as if the enumeration had a single enumerator with value 0.

An enumeration has the same size, value representation, and alignment requirements (6.7.6) as its underlying type. Furthermore, each value of an enumeration has the same representation as the corresponding value of the underlying type.

Two enumeration types are layout-compatible enumerations if they have the same underlying type.

The value of an enumerator or an object of an unscoped enumeration type is converted to an integer by integral promotion (7.3.7).

[Example 3:

```c
enum color { red, yellow, green=20, blue };
color col = red;
color* cp = &col;
if (*cp == blue) // ...
```

makes color a type describing various colors, and then declares col as an object of that type, and cp as a pointer to an object of that type. The possible values of an object of type color are red, yellow, green, blue; these values can be converted to the integral values 0, 1, 20, and 21. Since enumerations are distinct types, objects of type color can be assigned only values of type color.

```c
color c = 1; // error: type mismatch, no conversion from int to color
int i = yellow; // OK, yellow converted to integral value 1, integral promotion
```

Note that this implicit enum to int conversion is not provided for a scoped enumeration:

```c
enum class Col { red, yellow, green };  
int x = Col::red;  // error: no Col to int conversion
Col y = Col::red;  // error: no Col to bool conversion
```

The name of each unscoped enumerator is also bound in the scope that immediately contains the enum-specifier. An unnamed enumeration that does not have a typedef name for linkage purposes (9.2.4) and that has a first enumerator is denoted, for linkage purposes (6.6), by its underlying type and its first enumerator; such an enumeration is said to have an enumerator as a name for linkage purposes.

[Note 3: Each unnamed enumeration with no enumerators is a distinct type. — end note]

[Example 4:

```c
enum direction { left='l', right='r' };

void g() {
    direction d;  // OK
    d = left;  // OK
```
d = direction::right; // OK
}

enum class altitude { high='h', low='l' };

void h() {
    altitude a; // OK
    a = high; // error: high not in scope
    a = altitude::low; // OK
}
—end example]

9.7.2 The using enum declaration [enum.udecl]

using enum-declaration:
    using enum using enum-declarator;

using enum-declarator:
    nested-name-specifier_opt identifier
    nested-name-specifier_opt simple-template-id

1 A using enum-declarator names the set of declarations found by lookup (6.5.3, 6.5.5) for the using enum-declarator. The using enum-declarator shall designate a non-dependent type with a reachable enum-specifier.

2 A using enum-declaration is equivalent to a using declaration for each enumerator.

3 [Note 1: A using enum-declaration in class scope makes the enumerators of the named enumeration available via member lookup.

[Example 1:
    enum class fruit { orange, apple };
    struct S {
        using enum fruit; // OK, introduces orange and apple into S
    };
    void f() {
        S s;
        s.orange; // OK, names fruit::orange
        S::orange; // OK, names fruit::orange
    }
—end example]
—end note]

4 [Note 2: Two using enum-declarations that introduce two enumerators of the same name conflict.

[Example 2:
    enum class fruit { orange, apple };
    enum class color { red, orange };
    void f() {
        using enum fruit; // OK
        using enum color; // error: color::orange and fruit::orange conflict
    }
—end example]
—end note]

9.8 Namespaces [basic.namespace]

9.8.1 General [basic.namespace.general]

1 A namespace is an optionally-named entity whose scope can contain declarations of any kind of entity. The name of a namespace can be used to access entities that belong to that namespace; that is, the members of the namespace. Unlike other entities, the definition of a namespace can be split over several parts of one or more translation units and modules.

2 [Note 1: A namespace definition is exported if it contains any export declarations (10.2). A namespace is never attached to a named module and never has a name with module linkage. — end note]
Example 1:

```c
export module M;
namespace N1 {} // N1 is not exported
export namespace N2 {} // N2 is exported
namespace N3 { export int n; } // N3 is exported
```

--- end example

3 There is a **global namespace** with no declaration; see 6.4.6. The global namespace belongs to the global scope; it is not an unnamed namespace (9.8.2.2).

[Note 2: Lacking a declaration, it cannot be found by name lookup. — end note]

9.8.2 Namespace definition

9.8.2.1 General

```c
namespace-name:
  identifier
namespace-alias

namespace-definition:
  named-name
  namespace-definition
  unnamed-name
  nested-name

named-name:
  inline opt
  namespace
  attribute-specifier-seq opt
  identifier
  { namespace-body }

unnamed-name:
  inline opt
  namespace
  attribute-specifier-seq opt
  { namespace-body }

nested-name:
  namespace
  enclosing-name
  inline opt
  identifier
  { namespace-body }

namespace-body:
  declaration-seq opt
```

1 Every **namespace-definition** shall inhabit a namespace scope (6.4.6).

2 In a **named-name-definition** D, the **identifier** is the name of the namespace. The **identifier** is looked up by searching for it in the scopes of the namespace A in which D appears and of every element of the inline namespace set of A. If the lookup finds a **namespace-definition** for a namespace N, D extends N, and the target scope of D is the scope to which N belongs. If the lookup finds nothing, the **identifier** is introduced as a **namespace-name** into A.

3 Because a **namespace-definition** contains declarations in its **namespace-body** and a **namespace-definition** is itself a declaration, it follows that **namespace-definitions** can be named.

Example 1:

```c
namespace Outer {
  int i;
  namespace Inner {
    void f() { i++; } // Outer::i
    int i;
    void g() { i++; } // Inner::i
  }
}
```

--- end example

4 If the optional initial **inline** keyword appears in a **namespace-definition** for a particular namespace, that namespace is declared to be an **inline namespace**. The **inline** keyword may be used on a **namespace-definition** that extends a namespace only if it was previously used on the **namespace-definition** that initially declared the **namespace-name** for that namespace.

5 The optional **attribute-specifier-seq** in a **named-name-definition** appertains to the namespace being defined or extended.
Members of an inline namespace can be used in most respects as though they were members of the innermost enclosing namespace. Specifically, the inline namespace and its enclosing namespace are both added to the set of associated namespaces used in argument-dependent lookup (6.5.4) whenever one of them is, and a using-directive (9.8.4) that names the inline namespace is implicitly inserted into the enclosing namespace as for an unnamed namespace (9.8.2.2). Furthermore, each member of the inline namespace can subsequently be partially specialized (13.7.6), explicitly instantiated (13.9.3), or explicitly specialized (13.9.4) as though it were a member of the enclosing namespace. Finally, looking up a name in the enclosing namespace via explicit qualification (6.5.5.3) will include members of the inline namespace even if there are declarations of that name in the enclosing namespace.

These properties are transitive: if a namespace \(N\) contains an inline namespace \(M\), which in turn contains an inline namespace \(O\), then the members of \(O\) can be used as though they were members of \(M\) or \(N\). The inline namespace set of \(N\) is the transitive closure of all inline namespaces in \(N\).

A nested-namespace-definition with an enclosing-namespace-specifier \(E\), identifier \(I\) and namespace-body \(B\) is equivalent to

\[
\text{namespace } E \{ \text{inline_opt namespace } I \{ B \} \}
\]

where the optional inline is present if and only if the identifier \(I\) is preceded by inline.

Example 2:

```cpp
namespace A::inline B::C {
    int i;
}
```

The above has the same effect as:

```cpp
namespace A {
    inline namespace B {
        namespace C {
            int i;
        }
    }
}
```

—end example]  

9.8.2.2 Unnamed namespaces

An unnamed-namespace-definition behaves as if it were replaced by

\[
\text{inline_opt namespace unique \{ /* empty body */ \}}
\]

\[
\text{using namespace unique ;}
\]

\[
\text{namespace-body}
\]

where inline appears if and only if it appears in the unnamed-namespace-definition and all occurrences of unique in a translation unit are replaced by the same identifier, and this identifier differs from all other identifiers in the translation unit. The optional attribute-specifier-seq in the unnamed-namespace-definition appertains to unique.

Example 1:

```cpp
namespace { int i; } // unique::i
void f() { i++; } // unique::i++
```

```cpp
namespace A {
    namespace {
        int i; // A::unique::i
        int j; // A::unique::j
    }
    void g() { i++; } // A::unique::i++
}
```

```cpp
using namespace A;
void h() {
    i++; // error: unique::i or A::unique::i
    A::i++; // A::unique::i
    j++; // A::unique::j
}
```
9.8.3 Namespace alias

A namespace-alias-definition declares an alternate name for a namespace according to the following grammar:

namespace-alias:
  identifier

namespace-alias-definition:
  namespace identifier = qualified-name-specifier ;

qualified-name-specifier:
  nested-name-specifier_opt namespace-name

The identifier in a namespace-alias-definition becomes a namespace-alias and denotes the namespace denoted by the qualified-name-specifier.

[Note 1: When looking up a namespace-name in a namespace-alias-definition, only namespace names are considered, see 6.5.7. — end note]

9.8.4 Using namespace directive

using-directive:
  attribute-specifier-seq_opt using namespace nested-name-specifier_opt namespace-name ;

A using-directive shall not appear in class scope, but may appear in namespace scope or in block scope.

[Note 1: When looking up a namespace-name in a using-directive, only namespace names are considered, see 6.5.7. — end note]

The optional attribute-specifier-seq appertains to the using-directive.

[Note 2: A using-directive makes the names in the nominated namespace usable in the scope in which the using-directive appears after the using-directive (6.5.3, 6.5.5.3). During unqualified name lookup, the names appear as if they were declared in the nearest enclosing namespace which contains both the using-directive and the nominated namespace. — end note]

[Note 3: A using-directive does not introduce any names. — end note]

[Example 1:

```cpp
namespace A {
  int i;
  namespace B {
    namespace C {
      int i;
    }
    using namespace A::B::C;
    void f1() {
      i = 5; // OK, C::i visible in B and hides A::i
    }
  }
  namespace D {
    using namespace B;
    using namespace C;
    void f2() {
      i = 5; // ambiguous, B::C::i or A::i?
    }
    void f3() {
      i = 5; // uses A::i
    }
    void f4() {
      i = 5; // error: neither i is visible
    }
  }
}
```

—end example]

[Note 4: A using-directive is transitive: if a scope contains a using-directive that nominates a namespace that itself contains using-directives, the namespaces nominated by those using-directives are also eligible to be considered. — end note]
Example 2:

```cpp
namespace M {
    int i;
}

namespace N {
    int i;
    using namespace M;
}

void f() {
    using namespace N;
    i = 7; // error: both M::i and N::i are visible
}
```

For another example,

```cpp
namespace A {
    int i;
}

namespace B {
    int i;
    int j;
    namespace C {
        namespace D {
            using namespace A;
            int j;
            int k;
            int a = i; // B::i hides A::i
        }
        using namespace D;
        int k = 89; // no problem yet
        int l = k; // ambiguous: C::k or D::k
        int m = i; // B::i hides A::i
        int n = j; // D::j hides B::j
    }
}
```

—end example

5 [Note 5: Declarations in a namespace that appear after a using-directive for that namespace can be found through that using-directive after they appear. —end note]

6 [Note 6: If name lookup finds a declaration for a name in two different namespaces, and the declarations do not declare the same entity and do not declare functions or function templates, the use of the name is ill-formed (6.5). In particular, the name of a variable, function or enumerator does not hide the name of a class or enumeration declared in a different namespace. For example,

```cpp
namespace A {
    class X {
        extern "C" int g();
        extern "C++" int h();
    }

namespace B {
    void X(int);
    extern "C" int g();
    extern "C++" int h(int);
}

using namespace A;
using namespace B;

void f() {
    X(1); // error: name X found in two namespaces
g(); // OK, name g refers to the same entity
h(); // OK, overload resolution selects A::h
}
```

—end note]
Note 7: The order in which namespaces are considered and the relationships among the namespaces implied by the using-directives do not affect overload resolution. Neither is any function excluded because another has the same signature, even if one is in a namespace reachable through using-directives in the namespace of the other.  

Example 3:  
namespace D {  
    int d1;  
    void f(char);  
}  
using namespace D;  
int d1;  // OK, no conflict with D::d1  
namespace E {  
    int e;  
    void f(int);  
}  
namespace D {  // namespace extension  
    int d2;  
    using namespace E;  
    void f(int);  
}  

void f() {  
    d1++;  // error: ambiguous ::d1 or D::d1?  
    ::d1++;  // OK  
    D::d1++;  // OK  
    d2++;  // OK, D::d2  
    e++;  // OK, E::e  
    f(1);  // error: ambiguous: D::f(int) or E::f(int)?  
    f(‘a’);  // OK, D::f(char)  
}  

9.9 The using declaration  
using-declaration:  
    using using-declarator-list ;  
using-declarator-list:  
    using-declarator . . . opt  
    using-declarator-list , using-declarator . . . opt  
using-declarator:  
    typename . . . opt nested-name-specifier unqualified-id  

The component names of a using-declarator are those of its nested-name-specifier and unqualified-id. Each using-declarator in a using-declaration names the set of declarations found by lookup (6.5.5) for the using-declarator, except that class and enumeration declarations that would be discarded are merely ignored when checking for ambiguity (6.5), conversion function templates with a dependent return type are ignored, and certain functions are hidden as described below. If the terminal name of the using-declarator is dependent (13.8.3.2), the using-declarator is considered to name a constructor if and only if the nested-name-specifier has a terminal name that is the same as the unqualified-id. If the lookup in any instantiation finds that a using-declarator that is not considered to name a constructor does do so, or that a using-declarator that is considered to name a constructor does not, the program is ill-formed.

If the using-declarator names a constructor, it declares that the class inherits the named set of constructor declarations from the nominated base class.

88) During name lookup in a class hierarchy, some ambiguities can be resolved by considering whether one member hides the other along some paths (6.5.2). There is no such disambiguation when considering the set of names found as a result of following using-directives.

89) A using-declaration with more than one using-declarator is equivalent to a corresponding sequence of using-declarations with one using-declarator each.
[Note 1: Otherwise, the unqualified-id in the using-declarator is bound to the using-declarator, which is replaced during name lookup with the declarations it names (6.5). If such a declaration is of an enumeration, the names of its enumerators are not bound. For the keyword typename, see 13.8. — end note]

3 In a using-declaration used as a member-declaration, each using-declarator shall either name an enumerator or have a nested-name-specifier naming a base class of the current class (7.5.2).

[Example 1:
enum class button { up, down };
struct S {
  using button::up;
  button b = up; // OK
};
—end example]

If a using-declarator names a constructor, its nested-name-specifier shall name a direct base class of the current class. If the immediate (class) scope is associated with a class template, it shall derive from the specified base class or have at least one dependent base class.

[Example 2:
struct B {
  void f(char);
  enum E { e };
  union { int x; };
};

struct C {
  int f();
};

struct D : B {
  using B::f; // OK, B is a base of D
  using B::e; // OK, e is an enumerator of base B
  using B::x; // OK, x is a union member of base B
  using C::f; // error: C isn't a base of D
  void f(int) { f('c'); } // calls B::f(char)
  void g(int) { g('c'); } // recursively calls D::g(int)
};
template <typename... bases>
struct X : bases... {
  using bases::f...;
};
X<B, C> x; // OK, B::f and C::f named
—end example]

[Note 2: Since destructors do not have names, a using-declaration cannot refer to a destructor for a base class. — end note]

If a constructor or assignment operator brought from a base class into a derived class has the signature of a copy/move constructor or assignment operator for the derived class (11.4.5.3, 11.4.6), the using-declaration does not by itself suppress the implicit declaration of the derived class member; the member from the base class is hidden or overridden by the implicitly-declared copy/move constructor or assignment operator of the derived class, as described below.

5 A using-declaration shall not name a template-id.

[Example 3:
struct A {
  template <class T> void f(T);
  template <class T> struct X { };;
};
struct B : A {
  using A::f<double>; // error
  using A::X<int>; // error
};

§ 9.9 241
A **using-declaration** shall not name a namespace.

A **using-declaration** that names a class member other than an enumerator shall be a **member-declaration**.

```cpp
Example 4:
struct X {
  int i;
  static int s;
};
void f() {
  using X::i; // error: X::i is a class member and this is not a member declaration.
  using X::s; // error: X::s is a class member and this is not a member declaration.
}
```

If a declaration is named by two **using-declarators** that inhabit the same class scope, the program is ill-formed.

**Note 3**: A **using-declarator** whose **nested-name-specifier** names a namespace does not name declarations added to the namespace after it. Thus, additional overloads added after the **using-declaration** are ignored, but default function arguments (9.3.4.7), default template arguments (13.2), and template specializations (13.7.6, 13.9.4) are considered.

```cpp
Example 5:
namespace A {
  void f(int);
}
using A::f; // f is a synonym for A::f; that is, for A::f(int).
namespace A {
  void f(char);
}
void foo() {
  f('a'); // calls f(int), even though f(char) exists.
}
void bar() {
  using A::f; // f is a synonym for A::f; that is, for A::f(int) and A::f(char).
  f('a'); // calls f(char)
}
```

If a declaration named by a **using-declaration** that inhabits the target scope of another declaration potentially conflicts with it (6.4.1), and either is reachable from the other, the program is ill-formed. If two declarations named by **using-declarations** that inhabit the same scope potentially conflict, either is reachable from the other, and they do not both declare functions or function templates, the program is ill-formed.

**Note 4**: Overload resolution possibly cannot distinguish between conflicting function declarations. — end note

```cpp
Example 6:
namespace A {
  int x;
  int f(int);
  int g;
  void h();
}
namespace B {
  int i;
  struct g { };  // declarations barreled into namespace B
  struct x { };  // declarations barreled into namespace B
  void f(int);
  void f(double);
}
```
void g(char);        // OK, hides struct g
}

void func() {
  int i;
  using B::i;       // error: conflicts
  void f(char);
  using A::f;       // OK, each f is a function
  f(i);            // error: ambiguous
  static_cast<int(*)(int)>(f)(1);  // OK, calls A::f
  f(3.5);          // calls B::f(double)
  using B::g;
  g('a');          // calls B::g(char)
  struct g g1;    // g1 has class type B::g
  using A::g;
  void h();
  using A::h;
  using B::x;
  using A::x;      // OK, hides struct B::x
  x = 99;          // assigns to A::x
  struct x x1;    // x1 has class type B::x
}

—end example]  

11 The set of declarations named by a using-declarator that inhabits a class C does not include member functions and member function templates of a base class that correspond to (and thus would conflict with) a declaration of a function or function template in C.

Example 7:

struct B {
    virtual void f(int);
    virtual void f(char);
    void g(int);
    void h(int);
};

struct D : B {
    using B::f;
    void f(int);       // OK, D::f(int) overrides B::f(int);
    using B::g;
    void g(char);      // OK
    using B::h;
    void h(int);       // OK, D::h(int) hides B::h(int)
};

void k(D* p)
{
  p->f(1);            // calls D::f(int)
  p->f('a');          // calls D::f(char)
  p->g(1);            // calls D::g(int)
  p->g('a');          // calls D::g(char)
}

struct B1 {
    B1(int);
};

struct B2 {
    B2(int);
};
struct D1 : B1, B2 {
    using B1::B1;
    using B2::B2;
};
D1 d1(0); // error: ambiguous

struct D2 : B1, B2 {
    using B1::B1;
    using B2::B2;
    D2(int); // OK, D2::D2(int) hides B1::B1(int) and B2::B2(int)
};
D2 d2(0); // calls D2::D2(int)

— end example

[Note 5: For the purpose of forming a set of candidates during overload resolution, the functions named by a using-declaration in a derived class are treated as though they were direct members of the derived class. In particular, the implicit object parameter is treated as if it were a reference to the derived class rather than to the base class (12.2.2). This has no effect on the type of the function, and in all other respects the function remains part of the base class. — end note]

Constructors that are named by a using-declaration are treated as though they were constructors of the derived class when looking up the constructors of the derived class (6.5.5.2) or forming a set of overload candidates (12.2.2.4, 12.2.2.5, 12.2.2.8).

[Note 6: If such a constructor is selected to perform the initialization of an object of class type, all subobjects other than the base class from which the constructor originated are implicitly initialized (11.9.4). A constructor of a derived class is sometimes preferred to a constructor of a base class if they would otherwise be ambiguous (12.2.4). — end note]

In a using-declarator that does not name a constructor, every declaration named shall be accessible. In a using-declarator that names a constructor, no access check is performed.

[Note 7: Because a using-declarator designates a base class member (and not a member subobject or a member function of a base class subobject), a using-declarator cannot be used to resolve inherited member ambiguities.

[Example 8:

```c
struct A { int x(); }; 
struct B : A { }; 
struct C : A {
    using A::x;
    int x(int);
};

struct D : B, C {
    using C::x;
    int x(double);
};
int f(D* d) {
    return d->x(); // error: overload resolution selects A::x, but A is an ambiguous base class
}
— end example
— end note
```

A using-declaration has the usual accessibility for a member-declaration. Base-class constructors considered because of a using-declarator are accessible if they would be accessible when used to construct an object of the base class; the accessibility of the using-declaration is ignored.

[Example 9:

```c
class A {
private:
    void f(char);
public:
    void f(int);
protected:
    void g();
};
```
class B : public A {
    using A::f;    // error: A::f(char) is inaccessible
public:
    using A::g;    // B::g is a public synonym for A::g
};
— end example]

9.10 The \texttt{asm} declaration \[dcl.asm\]

An \texttt{asm} declaration has the form

\begin{verbatim}
asm-declaration:
    attribute-specifier-seq_opt asm (string-literal);
\end{verbatim}

The \texttt{asm} declaration is conditionally-supported; its meaning is implementation-defined. The optional attribute-specifier-seq in an \texttt{asm-declaration} appertains to the \texttt{asm} declaration.

[Note 1: Typically it is used to pass information through the implementation to an assembler. — end note]

9.11 Linkage specifications \[dcl.link\]

All functions and variables whose names have external linkage and all function types have a \textit{language linkage}. \[Note 1: Some of the properties associated with an entity with language linkage are specific to each implementation and are not described here. For example, a particular language linkage might be associated with a particular form of representing names of objects and functions with external linkage, or with a particular calling convention, etc. — end note]

The default language linkage of all function types, functions, and variables is C++ language linkage. Two function types with different language linkages are distinct types even if they are otherwise identical.

2 Linkage (6.6) between C++ and non-C++ code fragments can be achieved using a \textit{linkage-specification}:

\begin{verbatim}
linkage-specification:
    extern string-literal { declaration-seq_opt }
    extern string-literal name-declaration
\end{verbatim}

The \texttt{string-literal} indicates the required language linkage. This document specifies the semantics for the \texttt{string-literals} "C" and "C++". Use of a \texttt{string-literal} other than "C" or "C++" is conditionally-supported, with implementation-defined semantics.

[Note 2: Therefore, a linkage-specification with a \texttt{string-literal} that is unknown to the implementation requires a diagnostic. — end note]

Recommended practice: The spelling of the \texttt{string-literal} should be taken from the document defining that language. For example, \texttt{Ada} (not \texttt{ADA}) and \texttt{Fortran} or \texttt{FORTRAN}, depending on the vintage.

3 Every implementation shall provide for linkage to the C programming language, "C", and C++, "C++".

[Example 1:
complex sqrt(complex);    // C++ language linkage by default
extern "C" {
    double sqrt(double);    // C language linkage
}
— end example]

4 A \texttt{module-import-declaration} appearing in a linkage specification with other than C++ language linkage is conditionally-supported with implementation-defined semantics.

5 Linkage specifications nest. When linkage specifications nest, the innermost one determines the language linkage.

[Note 3: A linkage specification does not establish a scope. — end note]

A \textit{linkage-specification} shall inhabit a namespace scope. In a \textit{linkage-specification}, the specified language linkage applies to the function types of all function declarators and to all functions and variables whose names have external linkage.

[Example 2:
extern "C"        // \texttt{f1} and its function type have C language linkage;
    void f1(void(*pf)(int));    // \texttt{pf} is a pointer to a C function

§ 9.11  245
extern "C" typedef void FUNC();
FUNC f2; // f2 has C++ language linkage and
// its type has C language linkage

extern "C" FUNC f3; // f3 and its type have C language linkage

void (*pf2)(FUNC*); // the variable pf2 has C++ language linkage; its type
// is “pointer to C++ function that takes one parameter of type
// pointer to C function”

extern "C" {
static void f4(); // the name of the function f4 has internal linkage,
// so f4 has no language linkage; its type has C language linkage
}

extern "C" void f5() {
extern void f4(); // OK, name linkage (internal) and function type linkage (C language linkage)
// obtained from previous declaration.
}

extern void f4(); // OK, name linkage (internal) and function type linkage (C language linkage)
// obtained from previous declaration.

void f6() {
extern void f4(); // OK, name linkage (internal) and function type linkage (C language linkage)
// obtained from previous declaration.
}

—end example]

A C language linkage is ignored in determining the language linkage of class members, friend functions with
a trailing requires-clause, and the function type of non-static class member functions.

[Example 3:
extern "C" typedef void FUNC_c();

class C {
    void mf1(FUNC_c*); // the function mf1 and its type have C++ language linkage;
    // the parameter has type “pointer to C function”
    FUNC_c mf2; // the function mf2 and its type have C++ language linkage
    static FUNC_c* q; // the data member q has C++ language linkage;
    // its type is “pointer to C function”
};

extern "C" {
    class X {
        void mf(); // the function mf and its type have C++ language linkage
        void mf2(void(*)()); // the function mf2 has C++ language linkage;
        // the parameter has type “pointer to C function”
    };
} //end example]

6 If two declarations of an entity give it different language linkages, the program is ill-formed; no diagnostic is
required if neither declaration is reachable from the other. A redeclaration of an entity without a linkage
specification inherits the language linkage of the entity and (if applicable) its type.

7 Two declarations declare the same entity if they (re)introduce the same name, one declares a function or
variable with C language linkage, and the other declares such an entity or declares a variable that belongs to
the global scope.

[Example 4:
    int x;
    namespace A {
        extern "C" int f();
    }
extern "C" int g() { return 1; }
extern "C" int h();
extern "C" int x(); // error: same name as global-space object x
}

namespace B {
    extern "C" int f(); // A::f and B::f refer to the same function
    extern "C" int g() { return 1; } // error: the function g with C language linkage has two definitions
}

int A::f() { return 98; } // definition for the function f with C language linkage
extern "C" int h() { return 97; } // definition for the function h with C language linkage
    // A::h and ::h refer to the same function

— end example

A declaration directly contained in a linkage-specification is treated as if it contains the extern specifier (9.2.2) for the purpose of determining the linkage of the declared name and whether it is a definition. Such a declaration shall not specify a storage class.

[Example 5:
extern "C" double f();
static double f(); // error
extern "C" int i; // declaration
extern "C" {
    int i; // definition
}
extern "C" static void g(); // error
— end example]

[Note 4: Because the language linkage is part of a function type, when indirectiong through a pointer to C function, the function to which the resulting lvalue refers is considered a C function. — end note]

Linkage from C++ to objects defined in other languages and to objects defined in C++ from other languages is implementation-defined and language-dependent. Only where the object layout strategies of two language implementations are similar enough can such linkage be achieved.

9.12 Attributes [dcl.attr]

9.12.1 Attribute syntax and semantics [dcl.attr.grammar]

1 Attributes specify additional information for various source constructs such as types, variables, names, blocks, or translation units.
attribute-scoped-token:
  attribute-namespace :: identifier

attribute-namespace:
  identifier

attribute-argument-clause:
  ( balanced-token-seq_opt )

balanced-token-seq:
  balanced-token
  balanced-token-seq balanced-token

balanced-token:
  ( balanced-token-seq_opt )
  [ balanced-token-seq_opt ]
  { balanced-token-seq_opt }

any token other than a parenthesis, a bracket, or a brace

If an attribute-specifier contains an attribute-using-prefix, the attribute-list following that attribute-using-prefix shall not contain an attribute-scoped-token and every attribute-token in that attribute-list is treated as if its identifier were prefixed with N::, where N is the attribute-namespace specified in the attribute-using-prefix.

[Note 1: This rule imposes no constraints on how an attribute-using-prefix affects the tokens in an attribute-argument-clause. — end note]

[Example 1:

[[using CC: opt(1), debug]] // same as [[CC::opt(1), CC::debug]]
  void f() {}
[[using CC: opt(1)]] [[CC::debug]] // same as [[CC::opt(1)]] [[CC::debug]]
  void g() {}
[[using CC::CC::opt(1)]] // error: cannot combine using and scoped attribute token
  void h() {}

— end example]

[Note 2: For each individual attribute, the form of the balanced-token-seq will be specified. — end note]

In an attribute-list, an ellipsis may appear only if that attribute’s specification permits it. An attribute followed by an ellipsis is a pack expansion (13.7.4). An attribute-specifier that contains no attributes has no effect. The order in which the attribute-tokens appear in an attribute-list is not significant. If a keyword (5.11) or an alternative token (5.5) that satisfies the syntactic requirements of an identifier (5.10) is contained in an attribute-token, it is considered an identifier. No name lookup (6.5) is performed on any of the identifiers contained in an attribute-token. The attribute-token determines additional requirements on the attribute-argument-clause (if any).

Each attribute-specifier-seq is said to appertain to some entity or statement, identified by the syntactic context where it appears (Clause 8, Clause 9, 9.3). If an attribute-specifier-seq that appertains to some entity or statement contains an attribute or alignment-specifier that is not allowed to apply to that entity or statement, the program is ill-formed. If an attribute-specifier-seq appertains to a friend declaration (11.8.4), that declaration shall be a definition.

[Note 3: An attribute-specifier-seq cannot appertain to an explicit instantiation (13.9.3). — end note]

For an attribute-token (including an attribute-scoped-token) not specified in this document, the behavior is implementation-defined; any such attribute-token that is not recognized by the implementation is ignored.

[Note 4: A program is ill-formed if it contains an attribute specified in 9.12 that violates the rules specifying to which entity or statement the attribute can apply or the syntax rules for the attribute’s attribute-argument-clause, if any. — end note]

[Note 5: The attributes specified in 9.12 have optional semantics: given a well-formed program, removing all instances of any one of those attributes results in a program whose set of possible executions (4.1.2) for a given input is a subset of those of the original program for the same input, absent implementation-defined guarantees with respect to that attribute. — end note]

An attribute-token is reserved for future standardization if

(6.1) — it is not an attribute-scoped-token and is not specified in this document, or
(6.2) — it is an attribute-scoped-token and its attribute-namespace is std followed by zero or more digits.

Each implementation should choose a distinctive name for the attribute-namespace in an attribute-scoped-token.
Two consecutive left square bracket tokens shall appear only when introducing an attribute-specifier or within the balanced-token-seq of an attribute-argument-clause.

[Note 6: If two consecutive left square brackets appear where an attribute-specifier is not allowed, the program is ill-formed even if the brackets match an alternative grammar production. — end note]

Example 2:

```c
int p[10];
void f() {
    int x = 42, y[5];
    int(p[x] { return x; }()); // error: invalid attribute on a nested declarator-id and
    // not a function-style cast of an element of p.
    y[0] { return 2; }() = 2;  // error even though attributes are not allowed in this context.
    int i [ [vendor::attr([[]])] ]; // well-formed implementation-defined attribute.
}
```

—end example—

### 9.12.2 Alignment specifier

An alignment-specifier may be applied to a variable or to a class data member, but it shall not be applied to a bit-field, a function parameter, or an exception-declaration (14.4). An alignment-specifier may also be applied to the declaration of a class (in an elaborated-type-specifier (9.2.9.4) or class-head (Clause 11), respectively). An alignment-specifier with an ellipsis is a pack expansion (13.7.4).

When the alignment-specifier is of the form `alignas(constant-expression)`:

(2.1) the constant-expression shall be an integral constant expression

(2.2) if the constant expression does not evaluate to an alignment value (6.7.6), or evaluates to an extended alignment and the implementation does not support that alignment in the context of the declaration, the program is ill-formed.

An alignment-specifier of the form `alignas(type-id)` has the same effect as `alignas(alignof(type-id))` (7.6.2.6).

The alignment requirement of an entity is the strictest nonzero alignment specified by its alignment-specifiers, if any; otherwise, the alignment-specifiers have no effect.

The combined effect of all alignment-specifiers in a declaration shall not specify an alignment that is less strict than the alignment that would be required for the entity being declared if all alignment-specifiers appertaining to that entity were omitted.

Example 1:

```c
struct alignas(8) S {};
struct alignas(1) U {
    S s;
}; // error: U specifies an alignment that is less strict than if the alignas(1) were omitted.
```

—end example—

If the defining declaration of an entity has an alignment-specifier, any non-defining declaration of that entity shall either specify equivalent alignment or have no alignment-specifier. Conversely, if any declaration of an entity has an alignment-specifier, every defining declaration of that entity shall specify an equivalent alignment. No diagnostic is required if declarations of an entity have different alignment-specifiers in different translation units.

Example 2:

```c
// Translation unit #1:
struct S { int x; } s, *p = &s;

// Translation unit #2:
struct alignas(16) S; // ill-formed, no diagnostic required: definition of S lacks alignment
extern S* p;
```

—end example—

Example 3: An aligned buffer with an alignment requirement of A and holding N elements of type T can be declared as:

`alignas(T) alignas(A) T buffer[N];`
Specifying `alignas(T)` ensures that the final requested alignment will not be weaker than `alignof(T)`, and therefore the program will not be ill-formed.  

--- end example

8 [Example 4]:

```cpp
alignas(double) void f(); // error: alignment applied to function
alignas(double) unsigned char c[sizeof(double)]; // array of characters, suitably aligned for a double
extern unsigned char c[sizeof(double)]; // no alignas necessary
alignas(float)
    extern unsigned char c[sizeof(double)]; // error: different alignment in declaration
--- end example
```

9.12.3 Assumption attribute  

The attribute-token `assume` may be applied to a null statement; such a statement is an assumption. An attribute-argument-clause shall be present and shall have the form:

```cpp
( conditional-expression )
```

The expression is contextually converted to `bool (7.3.1)`. The expression is not evaluated. If the converted expression would evaluate to `true` at the point where the assumption appears, the assumption has no effect. Otherwise, the behavior is undefined.

[Note 1: The expression is potentially evaluated (6.3). The use of assumptions is intended to allow implementations to analyze the form of the expression and deduce information used to optimize the program. Implementations are not required to deduce any information from any particular assumption. — end note]

[Example 1]:

```cpp
int divide_by_32(int x) {
    [assume(x >= 0)];
    return x/32; // The instructions produced for the division
        // may omit handling of negative values.
}

int f(int y) {
    [assume(++y == 43)]; // y is not incremented
    return y; // statement may be replaced with return 42;
}
--- end example
```

9.12.4 Carries dependency attribute  

The attribute-token `carries_dependency` specifies dependency propagation into and out of functions. No attribute-argument-clause shall be present. The attribute may be applied to a parameter of a function or lambda, in which case it specifies that the initialization of the parameter carries a dependency to (6.9.2) each lvalue-to-rvalue conversion (7.3.2) of that object. The attribute may also be applied to a function or a lambda call operator, in which case it specifies that the return value, if any, carries a dependency to the evaluation of the function call expression.

1 The first declaration of a function shall specify the `carries_dependency` attribute for its declarator-id if any declaration of the function specifies the `carries_dependency` attribute. Furthermore, the first declaration of a function shall specify the `carries_dependency` attribute for a parameter if any declaration of that function specifies the `carries_dependency` attribute for that parameter. If a function or one of its parameters is declared with the `carries_dependency` attribute in its first declaration in one translation unit and the same function or one of its parameters is declared without the `carries_dependency` attribute in its first declaration in another translation unit, the program is ill-formed, no diagnostic required.

3 [Note 1: The `carries_dependency` attribute does not change the meaning of the program, but might result in generation of more efficient code. — end note]

4 [Example 1]:

```cpp
/* Translation unit A. */

struct foo { int* a; int* b; }
std::atomic<struct foo*> foo_head[10];
int foo_array[10][10];
```
[[carries_dependency]] struct foo* f(int i) {
    return foo_head[i].load(memory_order::consume);
}

int g(int* x, int* y [[carries_dependency]]) {
    return kill_dependency(foo_array[*x][*y]);
}

/* Translation unit B. */

[[carries_dependency]] struct foo* f(int i);
int g(int* x, int* y [[carries_dependency]]);
int c = 3;

void h(int i) {
    struct foo* p;
    p = f(i);
    do_something_with(g(&c, p->a));
    do_something_with(g(p->a, &c));
}

The carries_dependency attribute on function f means that the return value carries a dependency out of f, so that
the implementation need not constrain ordering upon return from f. Implementations of f and its caller may choose
to preserve dependencies instead of emitting hardware memory ordering instructions (a.k.a. fences). Function g’s
second parameter has a carries_dependency attribute, but its first parameter does not. Therefore, function h’s first
call to g carries a dependency into g, but its second call does not. The implementation might need to insert a fence
prior to the second call to g. —end example]

9.12.5 Deprecated attribute

The attribute-token deprecated can be used to mark names and entities whose use is still allowed, but is
discouraged for some reason.

[Note 1: In particular, deprecated is appropriate for names and entities that are deemed obsolescent or unsafe.
   —end note]

An attribute-argument-clause may be present and, if present, it shall have the form:

    ( string-literal )

[Note 2: The string-literal in the attribute-argument-clause can be used to explain the rationale for deprecation and/or
to suggest a replacing entity. —end note]

The attribute may be applied to the declaration of a class, a typedef-name, a variable, a non-static data
member, a function, a namespace, an enumeration, an enumerator, a concept, or a template specialization.

An entity declared without the deprecated attribute can later be redeclared with the attribute and vice-versa.

[Note 3: Thus, an entity initially declared without the attribute can be marked as deprecated by a subsequent
redeclaration. However, after an entity is marked as deprecated, later redeclarations do not un-deprecate the entity.
   —end note]

Redeclarations using different forms of the attribute (with or without the attribute-argument-clause or with
different attribute-argument-clauses) are allowed.

Recommended practice: Implementations should use the deprecated attribute to produce a diagnostic message
in case the program refers to a name or entity other than to declare it, after a declaration that specifies the
attribute. The diagnostic message should include the text provided within the attribute-argument-clause of
any deprecated attribute applied to the name or entity.

9.12.6 Fallthrough attribute

The attribute-token fallthrough may be applied to a null statement (8.3); such a statement is a fallthrough
statement. No attribute-argument-clause shall be present. A fallthrough statement may only appear within an
enclosing switch statement (8.5.3). The next statement that would be executed after a fallthrough statement
shall be a labeled statement whose label is a case label or default label for the same switch statement and, if
the fallthrough statement is contained in an iteration statement, the next statement shall be part of the same

§ 9.12.6 251
execution of the substatement of the innermost enclosing iteration statement. The program is ill-formed if there is no such statement.

2 Recommended practice: The use of a fallthrough statement should suppress a warning that an implementation might otherwise issue for a case or default label that is reachable from another case or default label along some path of execution. Implementations should issue a warning if a fallthrough statement is not dynamically reachable.

3 [Example 1:

```c
void f(int n) {
    void g(), h(), i();
    switch (n) {
    case 1:
    case 2:
        g();
        [[fallthrough]];
    case 3:
        { // warning on fallthrough discouraged
            [[fallthrough]];
            // error: next statement is not part of the same substatement execution
            do {
                // error: next statement is not part of the same substatement execution
                [[fallthrough]];
            } while (false);
    case 6:
        { // error: next statement is not part of the same substatement execution
            do {
                [[fallthrough]];
            } while (n--);
    case 7:
        { // error: next statement is not part of the same substatement execution
            while (false) {
                [[fallthrough]];
            }
    case 5:
        h();
    case 4: // implementation may warn on fallthrough
        i();
        [[fallthrough]];
        // error
    }
}
```

—end example]

9.12.7 Likelihood attributes [dcl.attr.likelihood]

1 The attribute-tokens likely and unlikely may be applied to labels or statements. No attribute-argument-clause shall be present. The attribute-token likely shall not appear in an attribute-specifier-seq that contains the attribute-token unlikely.

2 Recommended practice: The use of the likely attribute is intended to allow implementations to optimize for the case where paths of execution including it are arbitrarily more likely than any alternative path of execution that does not include such an attribute on a statement or label. The use of the unlikely attribute is intended to allow implementations to optimize for the case where paths of execution including it are arbitrarily more unlikely than any alternative path of execution that does not include such an attribute on a statement or label. A path of execution includes a label if and only if it contains a jump to that label.

[Note 1: Excessive usage of either of these attributes is liable to result in performance degradation. — end note]

3 [Example 1:

```c
void g(int);
int f(int n) {
    if (n > 5) [[unlikely]] { // n > 5 is considered to be arbitrarily unlikely
        g(0);
        return n * 2 + 1;
    }
}

switch (n) {
    case 1:
        g(1);
        [[fallthrough]];
}
[[likely]] case 2:  // n == 2 is considered to be arbitrarily more
    g(2);      // likely than any other value of n
    break;
  }
  return 3;
}

—end example]

9.12.8 Maybe unused attribute

1 The attribute-token maybe_unused indicates that a name or entity is possibly intentionally unused. No attribute-argument-clause shall be present.

2 The attribute may be applied to the declaration of a class, a typedef-name, a variable (including a structured binding declaration), a non-static data member, a function, an enumeration, or an enumerator.

3 A name or entity declared without the maybe_unused attribute can later be redeclared with the attribute and vice versa. An entity is considered marked after the first declaration that marks it.

4 Recommended practice: For an entity marked maybe_unused, implementations should not emit a warning that the entity or its structured bindings (if any) are used or unused. For a structured binding declaration not marked maybe_unused, implementations should not emit such a warning unless all of its structured bindings are unused.

5 [Example 1:
   
   ```
   [[maybe_unused]] void f([[maybe_unused]] bool thing1,
     [[maybe_unused]] bool thing2) {
       [[maybe_unused]] bool b = thing1 && thing2;
       assert(b);
   }
   ```
   
   Implementations should not warn that b is unused, whether or not NDEBUG is defined. —end example]

9.12.9 Nodiscard attribute

1 The attribute-token nodiscard may be applied to a function or a lambda call operator or to the declaration of a class or enumeration. An attribute-argument-clause may be present and, if present, shall have the form:

   (string-literal)

2 A name or entity declared without the nodiscard attribute can later be redeclared with the attribute and vice-versa.

   [Note 1: Thus, an entity initially declared without the attribute can be marked as nodiscard by a subsequent redeclaration. However, after an entity is marked as nodiscard, later redeclarations do not remove the nodiscard from the entity. — end note]

   Redeclarations using different forms of the attribute (with or without the attribute-argument-clause or with different attribute-argument-clauses) are allowed.

3 A nodiscard type is a (possibly cv-qualified) class or enumeration type marked nodiscard in a reachable declaration. A nodiscard call is either

   (3.1) — a function call expression (7.6.1.3) that calls a function declared nodiscard in a reachable declaration or whose return type is a nodiscard type, or

   (3.2) — an explicit type conversion (7.6.1.4, 7.6.1.9, 7.6.3) that constructs an object through a constructor declared nodiscard in a reachable declaration, or that initializes an object of a nodiscard type.

4 Recommended practice: Appearance of a nodiscard call as a potentially-evaluated discarded-value expression (7.2) is discouraged unless explicitly cast to void. Implementations should issue a warning in such cases.

   [Note 2: This is typically because discarding the return value of a nodiscard call has surprising consequences. — end note]

   The string-literal in a nodiscard attribute-argument-clause should be used in the message of the warning as the rationale for why the result should not be discarded.

5 [Example 1:
   
   ```
   struct [[nodiscard]] my_scopeguard { /* ... */);
   ```

§ 9.12.9  253
struct my_unique {
    my_unique() = default; // does not acquire resource
    [[nodiscard]] my_unique(int fd) { /* ... */ } // acquires resource
    ~my_unique() noexcept { /* ... */ } // releases resource, if any
    /* ... */
};
struct [[nodiscard]] error_info { /* ... */ }; error_info enable_missile_safety_mode(); void launch_missiles();
void test_missiles() {
    my_scopeguard(); // warning encouraged
    (void)my_scopeguard(), // warning not encouraged, cast to void
    launch_missiles(); // warning encouraged
    my_unique(); // warning not encouraged
    enable_missile_safety_mode(); // warning encouraged
    launch_missiles();
}
error_info &foo();
void f() { foo(); } // warning not encouraged: not a nodiscard call, because neither
§ 9.12.11 254

— end example]

9.12.10  Noreturn attribute [dcl.attr.noreturn]
1 The attribute-token noreturn specifies that a function does not return. No attribute-argument-clause shall
be present. The attribute may be applied to a function or a lambda call operator. The first declaration of
a function shall specify the noreturn attribute if any declaration of that function specifies the noreturn
attribute. If a function is declared with the noreturn attribute in one translation unit and the same function
is declared without the noreturn attribute in another translation unit, the program is ill-formed, no diagnostic
required.
2 If a function f is called where f was previously declared with the noreturn attribute and f eventually returns,
the behavior is undefined.
[Note 1: The function may terminate by throwing an exception. — end note]
3 Recommended practice: Implementations should issue a warning if a function marked [[noreturn]] might
return.
4 [Example 1:]

    [[ noreturn ]] void f() {
        throw "error";  // OK
    }

    [[ noreturn ]] void q(int i) { // behavior is undefined if called with an argument <= 0
        if (i > 0)
            throw "positive";
    }
— end example]

9.12.11  No unique address attribute [dcl.attr.nouniqueaddr]
1 The attribute-token no_unique_address specifies that a non-static data member is a potentially-overlapping
subobject (6.7.2). No attribute-argument-clause shall be present. The attribute may appertain to a non-static
data member other than a bit-field.
2 [Note 1: The non-static data member can share the address of another non-static data member or that of a base class,
and any padding that would normally be inserted at the end of the object can be reused as storage for other members.
— end note]
[Example 1:]

    template<typename Key, typename Value,
        typename Hash, typename Pred, typename Allocator>
    class hash_map {
        [[no_unique_address]] Hash hasher;
Here, \texttt{hasher}, \texttt{pred}, and \texttt{alloc} could have the same address as \texttt{buckets} if their respective types are all empty. — end example]
10 Modules

10.1 Module units and purviews

A module unit is a translation unit that contains a module-declaration. A named module is the collection of module units with the same module-name. The identifiers module and import shall not appear as identifiers in a module-name or module-partition. All module-names either beginning with an identifier consisting of std followed by zero or more digits or containing a reserved identifier (5.10) are reserved and shall not be specified in a module-declaration; no diagnostic is required. If any identifier in a reserved module-name is a reserved identifier, the module name is reserved for use by C++ implementations; otherwise it is reserved for future standardization. The optional attribute-specifier-seq appertains to the module-declaration.

A module interface unit is a module unit whose module-declaration starts with export-keyword; any other module unit is a module implementation unit. A named module shall contain exactly one module interface unit with no module-partition, known as the primary module interface unit of the module; no diagnostic is required.

A module partition is a module unit whose module-declaration contains a module-partition. A named module shall not contain multiple module partitions with the same module-partition. All module partitions of a module that are module interface units shall be directly or indirectly exported by the primary module interface unit (10.3). No diagnostic is required for a violation of these rules.

[Note 1: Module partitions can be imported only by other module units in the same module. The division of a module into module units is not visible outside the module. — end note]

[Example 1:
Translation unit #1:
  export module A;
  export import :Foo;
  export int baz();

Translation unit #2:
  export module A:Foo;
  import :Internals;
  export int foo() { return 2 * (bar() + 1); }

Translation unit #3:
  module A:Internals;
  int bar();

Translation unit #4:
  module A;
  import :Internals;
  int bar() { return baz() - 10; }
  int baz() { return 30; }

Module A contains four translation units:
  — a primary module interface unit,
  — a module partition A:Foo, which is a module interface unit forming part of the interface of module A,
  — a module partition A:Internals, which does not contribute to the external interface of module A, and

§ 10.1 256]
(4.4) — a module implementation unit providing a definition of bar and baz, which cannot be imported because it does not have a partition name.

— end example]

5 A module unit purview is the sequence of tokens starting at the module-declaration and extending to the end of the translation unit. The purview of a named module M is the set of module unit purviews of M’s module units.

6 The global module is the collection of all global-module-fragments and all translation units that are not module units. Declarations appearing in such a context are said to be in the purview of the global module.

[Note 2: The global module has no name, no module interface unit, and is not introduced by any module-declaration. — end note]

7 A module is either a named module or the global module. A declaration is attached to a module as follows:

(7.1) — If the declaration is a non-dependent friend declaration that nominates a function with a declarator-id that is a qualified-id or template-id or that nominates a class other than with an elaborated-type-specifier with neither a nested-name-specifier nor a simple-template-id, it is attached to the module to which the friend is attached (6.6).

(7.2) — Otherwise, if the declaration

(7.2.1) — is a namespace-definition with external linkage or

(7.2.2) — appears within a linkage-specification (9.11)

it is attached to the global module.

(7.3) — Otherwise, the declaration is attached to the module in whose purview it appears.

8 A module-declaration that contains neither an export-keyword nor a module-partition implicitly imports the primary module interface unit of the module as if by a module-import-declaration.

[Example 2:

Translation unit #1:
module B:Y;
// does not implicitly import B
int y();

Translation unit #2:
export module B;
import :Y;
// OK, does not create interface dependency cycle
int n = y();

Translation unit #3:
module B:X1;
// does not implicitly import B
int &a = n;
// error: n not visible here

Translation unit #4:
module B:X2;
// does not implicitly import B
import B;
int &b = n;
// OK

Translation unit #5:
module B;
// implicitly imports B
int &c = n;
// OK
— end example]

10.2 Export declaration [module.interface]

export-declaration:
  export name-declaration
  export { declaration-seqopt }
  export-keyword module-import-declaration

An export-declaration shall inhabit a namespace scope and appear in the purview of a module interface unit. An export-declaration shall not appear directly or indirectly within an unnamed namespace or a private-module-fragment. An export-declaration has the declarative effects of its name-declaration, declaration-seq (if any), or module-import-declaration. The name-declaration of an export-declaration shall not declare a partial
specialization (13.7.1). The declaration-seq of an export-declaration shall not contain an export-declaration or module-import-declaration.

[Note 1: An export-declaration does not establish a scope. — end note]

2 A declaration is exported if it is declared within an export-declaration and inhabits a namespace scope or it is

(2.1) — a namespace-definition that contains an exported declaration, or

(2.2) — a declaration within a header unit (10.3) that introduces at least one name.

3 If an exported declaration is not within a header unit, it shall not declare a name with internal linkage.

4 [Example 1:

Source file "a.h":

    export int x;

Translation unit #1:

    module;
    #include "a.h" // error: declaration of x is not in the
    // parview of a module interface unit
    export module M;
    export namespace {} // error: namespace has internal linkage
    namespace {
      export int a2; // error: export of name with internal linkage
    }
    export static int b; // error: b explicitly declared static
    export int f(); // OK
    export namespace N { } // OK
    export using namespace N; // OK

   — end example]

5 If an exported declaration is a using-declaration (9.9) and is not within a header unit, all entities to which all of the using-declarators ultimately refer (if any) shall have been introduced with a name having external linkage.

[Example 2:

Source file "b.h":

    int f();

Importable header "c.h":

    int g();

Translation unit #1:

    export module X;
    export int h();

Translation unit #2:

    module;
    #include "b.h"
    export module M;
    import "c.h";
    import X;
    export using ::f, ::g, ::h; // OK
    struct S;
    export using ::S; // error: S has module linkage
    namespace N {
      export int h();
      static int h(int); // #1
    }
    export using N::h; // error: #1 has internal linkage

   — end example]
[Note 2: These constraints do not apply to type names introduced by \texttt{typedef} declarations and \texttt{alias-declarations}.

[Example 3:

\begin{verbatim}
export module M;
struct S;
export using T = S; // OK, exports name T denoting type S
@end example]
@end note]

6 A redeclaration of an entity $X$ is implicitly exported if $X$ was introduced by an exported declaration; otherwise it shall not be exported.

[Example 4:

\begin{verbatim}
export module M;
struct S { int n; };
typedef S S;
export typedef S S; // OK, does not redeclare an entity
export struct S; // error: exported declaration follows non-exported declaration
@end example]

[Note 3: Names introduced by exported declarations have either external linkage or no linkage; see 6.6. Namespace-scope declarations exported by a module can be found by name lookup in any translation unit importing that module (6.5). Class and enumeration member names can be found by name lookup in any context in which a definition of the type is reachable. — end note]

[Example 5:

Interface unit of $M$:

\begin{verbatim}
export module M;
export struct X {
  static void f();
  struct Y { };
};
namespace {
  struct S { };
}
export void f(S); // OK
struct T { };
export T id(T); // OK
export struct A; // A exported as incomplete
export auto rootFinder(double a) {
  return [=](double x) { return (x + a/x)/2; };}
export const int n = 5; // OK, n has external linkage
\end{verbatim}

Implementation unit of $M$:

\begin{verbatim}
module M;
struct A {
  int value;
};
Main program:

\begin{verbatim}
import M;
int main() {
  X::f(); // OK, X is exported and definition of X is reachable
  X::Y y; // OK, X::Y is exported as a complete type
  auto f = rootFinder(2); // OK
  return A{45}.value; // error: A is incomplete
}
@end example]

§ 10.2 259
[Note 4: Declarations in an exported namespace-definition or in an exported linkage-specification (9.11) are exported and subject to the rules of exported declarations.]

[Example 6:
  
  ```
  export module M;
  export namespace N {
    int x; // OK
    static_assert(1 == 1); // error: does not declare a name
  }
  ```

  —end example]

—end note]

### 10.3 Import declaration

**module-import-declaration:**

- `import-keyword module-name attribute-specifier-seq_opt ;`
- `import-keyword module-partition attribute-specifier-seq_opt ;`
- `import-keyword header-name attribute-specifier-seq_opt ;`

1 A module-import-declaration shall inhabit the global namespace scope. In a module unit, all module-import-declarations and export-declarations exporting module-import-declarations shall appear before all other declarations in the declaration-seq of the translation-unit and of the private-module-fragment (if any). The optional attribute-specifier-seq appertains to the module-import-declaration.

2 A module-import-declaration imports a set of translation units determined as described below.

[Note 1: Namespace-scope declarations exported by the imported translation units can be found by name lookup (6.5) in the importing translation unit and declarations within the imported translation units become reachable (10.7) in the importing translation unit after the import declaration. — end note]

3 A module-import-declaration that specifies a module-name M imports all module interface units of M.

4 A module-import-declaration that specifies a module-partition shall only appear after the module-declaration in a module unit of some module M. Such a declaration imports the so-named module partition of M.

5 A module-import-declaration that specifies a header-name H imports a synthesized header unit, which is a translation unit formed by applying phases 1 to 7 of translation (5.2) to the source file or header nominated by H, which shall not contain a module-declaration.

[Note 2: All declarations within a header unit are implicitly exported (10.2), and are attached to the global module (10.1). — end note]

An importable header is a member of an implementation-defined set of headers that includes all importable C++ library headers (16.4.2.3). H shall identify an importable header. Given two such module-import-declarations:

- (5.1) if their header-names identify different headers or source files (15.3), they import distinct header units;
- (5.2) otherwise, if they appear in the same translation unit, they import the same header unit;
- (5.3) otherwise, it is unspecified whether they import the same header unit.

[Note 3: It is therefore possible that multiple copies exist of entities declared with internal linkage in an importable header. — end note]

[Note 4: A module-import-declaration nominating a header-name is also recognized by the preprocessor, and results in macros defined at the end of phase 4 of translation of the header unit being made visible as described in 15.5. Any other module-import-declaration does not make macros visible. — end note]

6 A declaration of a name with internal linkage is permitted within a header unit despite all declarations being implicitly exported (10.2).

[Note 5: A definition that appears in multiple translation units cannot in general refer to such names (6.3). — end note]

A header unit shall not contain a definition of a non-inline function or variable whose name has external linkage.

[Note 4: A module-import-declaration nominating a header-name is also recognized by the preprocessor, and results in macros defined at the end of phase 4 of translation of the header unit being made visible as described in 15.5. Any other module-import-declaration does not make macros visible. — end note]

7 When a module-import-declaration imports a translation unit T, it also imports all translation units imported by exported module-import-declarations in T; such translation units are said to be exported by T. Additionally, when a module-import-declaration in a module unit of some module M imports another module unit U of M,
it also imports all translation units imported by non-exported module-import-declarations in the module unit purview of $U$.\footnote{90} These rules can in turn lead to the importation of yet more translation units.

[Note 6: Such indirect importation does not make macros available, because a translation unit is a sequence of tokens in translation phase 7 (5.2). Macros can be made available by directly importing header units as described in 15.5. — end note]

A module implementation unit shall not be exported.

[Example 1:

Translation unit #1:

\begin{verbatim}
module M:Part;
\end{verbatim}

Translation unit #2:

\begin{verbatim}
export module M;
export import :Part;  // error: exported partition :Part is an implementation unit
\end{verbatim}

— end example]

A module implementation unit of a module $M$ that is not a module partition shall not contain a module-import-declaration nominating $M$.

[Example 2:

\begin{verbatim}
module M;
import M;
// error: cannot import M in its own unit
\end{verbatim}

— end example]

A translation unit has an interface dependency on a translation unit $U$ if it contains a declaration (possibly a module-declaration) that imports $U$ or if it has an interface dependency on a translation unit that has an interface dependency on $U$. A translation unit shall not have an interface dependency on itself.

[Example 3:

Interface unit of $M_1$:

\begin{verbatim}
export module M1;
import M2;
\end{verbatim}

Interface unit of $M_2$:

\begin{verbatim}
export module M2;
import M3;
\end{verbatim}

Interface unit of $M_3$:

\begin{verbatim}
export module M3;
import M1;  // error: cyclic interface dependency $M_3 \rightarrow M_1 \rightarrow M_2 \rightarrow M_3$
\end{verbatim}

— end example]

10.4 Global module fragment

\begin{verbatim}
module-keyword ; declaration-seq_opt
\end{verbatim}

[module.global.frag]

[Note 1: Prior to phase 4 of translation, only preprocessing directives can appear in the declaration-seq (15.1). — end note]

A global-module-fragment specifies the contents of the global module fragment for a module unit. The global module fragment can be used to provide declarations that are attached to the global module and usable within the module unit.

A declaration $D$ is decl-reachable from a declaration $S$ in the same translation unit if:

1. $D$ does not declare a function or function template and $S$ contains an id-expression, namespace-name, type-name, template-name, or concept-name naming $D$, or
2. $D$ declares a function or function template that is named by an expression (6.3) appearing in $S$, or
3. $S$ contains a dependent call $E$ (13.8.3) and $D$ is found by any name lookup performed for an expression synthesized from $E$ by replacing each type-dependent argument or operand with a value of a placeholder type with no associated namespaces or entities, or

\footnote{90} This is consistent with the lookup rules for imported names (6.5).
[Note 2: This includes the lookup for `operator==` performed when considering rewriting an `!=` expression, the lookup for `operator<=>` performed when considering rewriting a relational comparison, and the lookup for `operator!=` when considering whether an `operator==` is a rewrite target. — end note]

(3.4) S contains an expression that takes the address of an overload set (12.3) that contains D and for which the target type is dependent, or

(3.5) there exists a declaration M that is not a `namespace-definition` for which M is decl-reachable from S and either

(3.5.1) D is decl-reachable from M, or
(3.5.2) D redeclares the entity declared by M or M redeclares the entity declared by D, and D neither is a friend declaration nor inhabits a block scope, or
(3.5.3) D declares a namespace N and M is a member of N, or
(3.5.4) one of M and D declares a class or class template C and the other declares a member or friend of C, or
(3.5.5) one of D and M declares an enumeration E and the other declares an enumerator of E, or
(3.5.6) D declares a function or variable and M is declared in D, or
(3.5.7) one of M and D declares a template and the other declares a partial or explicit specialization or an implicit or explicit instantiation of that template, or
(3.5.8) one of M and D declares a class or enumeration type and the other introduces a typedef name for linkage purposes for that type.

In this determination, it is unspecified

(3.6) whether a reference to an `alias-declaration`, `typedef` declaration, `using-declaration`, or `namespace-alias-definition` is replaced by the declarations they name prior to this determination,
(3.7) whether a `simple-template-id` that does not denote a dependent type and whose `template-name` names an alias template is replaced by its denoted type prior to this determination,
(3.8) whether a `decltype-specifier` that does not denote a dependent type is replaced by its denoted type prior to this determination, and
(3.9) whether a non-value-dependent constant expression is replaced by the result of constant evaluation prior to this determination.

4 A declaration D in a global module fragment of a module unit is discarded if D is not decl-reachable from any declaration in the declaration-seq of the translation-unit.

[Note 3: A discarded declaration is neither reachable nor visible to name lookup outside the module unit, nor in template instantiations whose points of instantiation (13.8.4.1) are outside the module unit, even when the instantiation context (10.6) includes the module unit. — end note]

5 [Example 1:]

```c
const int size = 2;
int ary1[size]; // unspecified whether size is decl-reachable from ary1
constexpr int identity(int x) { return x; } // unspecified whether identity is decl-reachable from ary2

int ary2[identity(2)];

template<typename> struct S;
template<typename, int> struct S2;
constexpr int g(int);
template<typename T, int N> S<T, S2<T, g(N)>> f(); // S, S2, g, and :: are decl-reachable from f

template<int N>
void h() noexcept(g(N) == N); // g and :: are decl-reachable from h
```

6 [Example 2:]

91) A declaration can appear within a lambda-expression in the initializer of a variable.
Source file "foo.h":

```cpp
namespace N {
  struct X {};
  int d();
  int e();
  inline int f(X, int = d()) { return e(); }
  int g(X);
  int h(X);
}
```

Module M interface:

```cpp
module;
#include "foo.h"
export module M;
```

```cpp
template<typename T> int use_f() {
  N::X x; // N::X, N, and :: are decl-reachable from use_f
  return f(x, 123); // N::f is decl-reachable from use_f,
  // N::e is indirectly decl-reachable from use_f
  // because it is decl-reachable from N::f, and
  // N::d is decl-reachable from use_f
  // because it is decl-reachable from N::f
  // even though it is not used in this call
}
```

```cpp
template<typename T> int use_g() {
  N::X x; // N::X, N, and :: are decl-reachable from use_g
  return g((T()), x); // N::g is not decl-reachable from use_g
}
```

```cpp
template<typename T> int use_h() {
  N::X x; // N::X, N, and :: are decl-reachable from use_h
  return h((T()), x); // N::h is not decl-reachable from use_h, but
  // N::h is decl-reachable from use_h<int>
}
```

```cpp
int k = use_h<int>(); // use_h<int> is decl-reachable from k, so
// N::h is decl-reachable from k
```

Module M implementation:

```cpp
module M;
```

```cpp
int a = use_f<int>(); // OK
int b = use_g<int>(); // error: no viable function for call to g;
// g is not decl-reachable from purview of
// module M's interface, so is discarded
int c = use_h<int>(); // OK
```

--- end example] [module.private.frag]

### 10.5 Private module fragment

A **private-module-fragment** shall appear only in a primary module interface unit (10.1). A module unit with a **private-module-fragment** shall be the only module unit of its module; no diagnostic is required.

**[Note 1: A private-module-fragment ends the portion of the module interface unit that can affect the behavior of other translation units. A private-module-fragment allows a module to be represented as a single translation unit without making all of the contents of the module reachable to importers. The presence of a private-module-fragment affects:**

- the point by which the definition of an inline function or variable is required (9.2.8),
- the point by which the definition of an exported function with a placeholder return type is required (9.2.9.6),
- whether a declaration is required not to be an exposure (6.6),
- where definitions for inline functions and templates must appear (6.3, 9.2.8, 13.1),
- the instantiation contexts of templates instantiated before it (10.6), and
- the reachability of declarations within it (10.7).

**end note**
Example 1:

```cpp
export module A;
export inline void fn_e(); // error: exported inline function fn_e not defined
inline void fn_m(); // error: non-exported inline function fn_m not defined
static void fn_s();
export struct X;
export void g(X *x) {
  fn_s();
}
export X *factory(); // OK
module :private;
struct X {};
X *factory() {
  return new X();
}
void fn_e() {}
void fn_m() {}
void fn_s() {}
```

— end example

## 10.6 Instantiation context

The instantiation context is a set of points within the program that determines which declarations are found by argument-dependent name lookup (6.5.4) and which are reachable (10.7) in the context of a particular declaration or template instantiation.

1. During the implicit definition of a defaulted function (11.4.4, 11.10.1), the instantiation context is the union of the instantiation context from the definition of the class and the instantiation context of the program construct that resulted in the implicit definition of the defaulted function.

2. During the implicit instantiation of a template whose point of instantiation is specified as that of an enclosing specialization (13.8.4.1), the instantiation context is the union of the instantiation context of the enclosing specialization and, if the template is defined in a module interface unit of a module \( M \) and the point of instantiation is not in a module interface unit of \( M \), the point at the end of the declaration-seq of the primary module interface unit of \( M \) (prior to the private-module-fragment, if any).

3. During the implicit instantiation of a template that is implicitly instantiated because it is referenced from within the implicit definition of a defaulted function, the instantiation context is the instantiation context of the defaulted function.

4. During the instantiation of any other template specialization, the instantiation context comprises the point of instantiation of the template.

5. In any other case, the instantiation context at a point within the program comprises that point.

Example 1:

Translation unit #1:

```cpp
export module stuff;
export template<typename T, typename U> void foo(T, U u) { auto v = u; }
export template<typename T> void bar(T, U u) { auto v = *u; }
```

Translation unit #2:

```cpp
export module M1;
import "defn.h"; // provides struct X {}
import stuff;
export template<typename T> void f(T t) {
  X x;
  foo(t, x);
}
```

Translation unit #3:

```cpp
export module M2;
import "decl.h"; // provides struct X; (not a definition)
```
import stuff;
export template<typename T> void g(T t) {
    X *x;
    bar(t, x);
}

Translation unit #4:
import M1;
import M2;
void test() {
    f(0);
    g(0);
}

The call to \texttt{f(0)} is valid; the instantiation context of \texttt{foo\textless int, X\textgreater} comprises
\begin{enumerate}
    \item the point at the end of translation unit \#1,
    \item the point at the end of translation unit \#2, and
    \item the point of the call to \texttt{f(0)},
\end{enumerate}
so the definition of \texttt{X} is reachable (10.7).

It is unspecified whether the call to \texttt{g(0)} is valid: the instantiation context of \texttt{bar\textless int, X\textgreater} comprises
\begin{enumerate}
    \item the point at the end of translation unit \#1,
    \item the point at the end of translation unit \#3, and
    \item the point of the call to \texttt{g(0)},
\end{enumerate}
so the definition of \texttt{X} need not be reachable, as described in 10.7. \textit{— end example}

\section{10.7 Reachability [module.reach]}

\begin{enumerate}
\item A translation unit \textit{U} is \textit{necessarily reachable} from a point \textit{P} if \textit{U} is a module interface unit on which the translation unit containing \textit{P} has an interface dependency, or the translation unit containing \textit{P} imports \textit{U}, in either case prior to \textit{P} (10.3).
\[\text{Note 1: While module interface units are reachable even when they are only transitively imported via a non-exported import declaration, namespace-scope names from such module interface units are not found by name lookup (6.5).} \quad \text{— end note}\]

\item All translation units that are necessarily reachable are \textit{reachable}. Additional translation units on which the point within the program has an interface dependency may be considered reachable, but it is unspecified which are and under what circumstances.\footnote{92}{Implementations are therefore not required to prevent the semantic effects of additional translation units involved in the compilation from being observed.}
\[\text{Note 2: It is advisable to avoid depending on the reachability of any additional translation units in programs intending to be portable.} \quad \text{— end note}\]

\item A declaration \textit{D} is \textit{reachable} from a point \textit{P} if
\begin{enumerate}
    \item \textit{D} appears prior to \textit{P} in the same translation unit, or
    \item \textit{D} is not discarded (10.4), appears in a translation unit that is reachable from \textit{P}, and does not appear within a \textit{private-module-fragment}.
\end{enumerate}

An declaration is \textit{reachable} if it is reachable from any point in the instantiation context (10.6).
\[\text{Note 3: Whether a declaration is exported has no bearing on whether it is reachable.} \quad \text{— end note}\]

\item The accumulated properties of all reachable declarations of an entity within a context determine the behavior of the entity within that context.
\[\text{Note 4: These reachable semantic properties include type completeness, type definitions, initializers, default arguments of functions or template declarations, attributes, names bound, etc. Since default arguments are evaluated in the context of the call expression, the reachable semantic properties of the corresponding parameter types apply in that context.} \quad \text{— end note}\]
\end{enumerate}

\begin{example}
Translation unit \#1:

\begin{verbatim}
export module M:A;
\end{verbatim}
\end{example}
export struct B;

Translation unit #2:
module M:B;
struct B {
    operator int();
};

Translation unit #3:
module M:C;
import :A;
B b1;  // error: no reachable definition of struct B

Translation unit #4:
export module M;
export import :A;
import :B;
B b2;
export void f(B b = B());

Translation unit #5:
import M;
B b3;  // error: no reachable definition of struct B
void g() { f(); }  // error: no reachable definition of struct B
— end example
— end note

5 [Note 5: Declarations of an entity can be reachable even where they cannot be found by name lookup. — end note]

Example 2:
Translation unit #1:
export module A;
struct X {};
export using Y = X;

Translation unit #2:
import A;
Y y;  // OK, definition of X is reachable
X x;  // error: X not visible to unqualified lookup
— end example]
11  Classes

11.1  Preamble

1 A class is a type. Its name becomes a class-name (11.3) within its scope.

   class-name:
      identifier
      simple-template-id

A class-specifier or an elaborated-type-specifier (9.2.9.4) is used to make a class-name. An object of a class consists of a (possibly empty) sequence of members and base class objects.

   class-specifier:
      class-head { member-specification\_opt }

   class-head:
      class-key attribute-specifier-seq\_opt class-head-name class-virt-specifier\_opt base-clause\_opt
      class-key attribute-specifier-seq\_opt base-clause\_opt

   class-head-name:
      nested-name-specifier\_opt class-name

   class-virt-specifier:
      final

   class-key:
      class
      struct
      union

A class declaration where the class-name in the class-head-name is a simple-template-id shall be an explicit specialization (13.9.4) or a partial specialization (13.7.6). A class-specifier whose class-head omits the class-head-name defines an unnamed class.

[Note 1: An unnamed class thus can’t be final. — end note]

Otherwise, the class-name is an identifier; it is not looked up, and the class-specifier introduces it.

2 The class-name is also bound in the scope of the class (template) itself; this is known as the injected-class-name. For purposes of access checking, the injected-class-name is treated as if it were a public member name. A class-specifier is commonly referred to as a class definition. A class is considered defined after the closing brace of its class-specifier has been seen even though its member functions are in general not yet defined. The optional attribute-specifier-seq appertains to the class; the attributes in the attribute-specifier-seq are thereafter considered attributes of the class whenever it is named.

3 If a class-head-name contains a nested-name-specifier, the class-specifier shall not inhabit a class scope. If its class-name is an identifier, the class-specifier shall correspond to one or more declarations nominable in the class, class template, or namespace to which the nested-name-specifier refers; they shall all have the same target scope, and the target scope of the class-specifier is that scope.

[Example 1:]

   namespace N {
      template<class>
      struct A {
         struct B;
      };
   }

   using N::A;
   template<class T> struct A<T>::B {};  // OK
   template<> struct A<void> {};        // OK

   — end example]

[Note 2: The class-key determines whether the class is a union (11.5) and whether access is public or private by default (11.8). A union holds the value of at most one data member at a time. — end note]
If a class is marked with the class-virt-specifier `final` and it appears as a class-or-decltype in a base-clause (11.7), the program is ill-formed. Whenever a class-key is followed by a class-head-name, the identifier `final`, and a colon or left brace, `final` is interpreted as a class-virt-specifier.

[Example 2:]
```
struct A;
struct A final {};  // OK, definition of struct A,
                   // not value-initialization of variable final
struct X {
    struct C { constexpr operator int() { return 5; } };  // OK, definition of nested class B,
    struct B final : C{};  // not declaration of a bit-field member final
};  // end example
```

[Note 3: Complete objects of class type have nonzero size. Base class subobjects and members declared with the no_unique_address attribute (9.12.11) are not so constrained. — end note]

[Note 4: Class objects can be assigned (12.4.3.2, 11.4.6), passed as arguments to functions (9.4, 11.4.5.3), and returned by functions (except objects of classes for which copying or moving has been restricted; see 9.5.3 and 11.8). Other plausible operators, such as equality comparison, can be defined by the user; see 12.4. — end note]

### 11.2 Properties of classes [class.prop]

#### 1 A trivially copyable class is a class:

(1.1) — that has at least one eligible copy constructor, move constructor, copy assignment operator, or move assignment operator (11.4.4, 11.4.5.3, 11.4.6),

(1.2) — where each eligible copy constructor, move constructor, copy assignment operator, and move assignment operator is trivial, and

(1.3) — that has a trivial, non-deleted destructor (11.4.7).

#### 2 A trivial class is a class that is trivially copyable and has one or more eligible default constructors (11.4.5.2), all of which are trivial.

[Note 1: In particular, a trivially copyable or trivial class does not have virtual functions or virtual base classes. — end note]

#### 3 A class \( S \) is a standard-layout class if it:

(3.1) — has no non-static data members of type non-standard-layout class (or array of such types) or reference,

(3.2) — has no virtual functions (11.7.3) and no virtual base classes (11.7.2),

(3.3) — has the same access control (11.8) for all non-static data members,

(3.4) — has no non-standard-layout base classes,

(3.5) — has at most one base class subobject of any given type,

(3.6) — has all non-static data members and bit-fields in the class and its base classes first declared in the same class, and

(3.7) — has no element of the set \( M(S) \) of types as a base class, where for any type \( X \), \( M(X) \) is defined as follows:\footnote{93}  

\[ M(X) = \{ \text{the set of types of all non-base-class subobjects that can be at a zero offset in } X \}. \]

[Note 2: \( M(X) \) is the set of the types of all non-base-class subobjects that can be at a zero offset in \( X \). — end note]

(3.7.1) — If \( X \) is a non-union class type with no non-static data members, the set \( M(X) \) is empty.

(3.7.2) — If \( X \) is a non-union class type with a non-static data member of type \( X_0 \) that is either of zero size or is the first non-static data member of \( X \) (where said member may be an anonymous union), the set \( M(X) \) consists of \( X_0 \) and the elements of \( M(X_0) \).

(3.7.3) — If \( X \) is a union type, the set \( M(X) \) is the union of all \( M(U_i) \) and the set containing all \( U_i \), where each \( U_i \) is the type of the \( i^{th} \) non-static data member of \( X \).\footnote{93}
— If \( X \) is an array type with element type \( X_e \), the set \( M(X) \) consists of \( X_e \) and the elements of \( M(X_e) \).

— If \( X \) is a non-class, non-array type, the set \( M(X) \) is empty.

Example 1:

```c
struct B { int i; }; // standard-layout class
struct C : B { }; // standard-layout class
struct D : C { }; // standard-layout class
struct E : D { char : 4; }; // not a standard-layout class
struct Q {};
struct S : Q { };
struct T : Q { };
struct U : S, T { }; // not a standard-layout class
```

Example 2:

```c
struct N { // neither trivial nor standard-layout
    int i;
    int j;
    virtual ~N();
};
struct T { // trivial but not standard-layout
    int i;
    private:
        int j;
};
struct SL { // standard-layout but not trivial
    int i;
    int j;
    ~SL();
};
struct POD { // both trivial and standard-layout
    int i;
    int j;
};
```

Note 3: Standard-layout classes are useful for communicating with code written in other programming languages. Their layout is specified in 11.4. — end note

Note 4: Aggregates of class type are described in 9.4.2. — end note

Class names

A class \( S \) is an implicit-lifetime class if

— it is an aggregate whose destructor is not user-provided or
— it has at least one trivial eligible constructor and a trivial, non-deleted destructor.

1 A class definition introduces a new type.

Example 1:

```c
struct X { int a; };
struct Y { int a; };
X a1;
Y a2;
int a3;
declares three variables of three different types. This implies that
a1 = a2; // error: Y assigned to X
```
a1 = a3; // error: int assigned to X
are type mismatches, and that
int f(x);
int f(y);
declare overloads (Clause 12) named f and not simply a single function f twice. For the same reason,
struct S { int a; };
struct S { int a; }; // error: double definition
is ill-formed because it defines S twice. — end example

2 [Note 1: It can be necessary to use an elaborated-type-specifier to refer to a class that belongs to a scope in which its name is also bound to a variable, function, or enumerator (6.5.6).

Example 2:
struct stat {
  // ...
};

stat gstat; // use plain stat to define variable
int stat(struct stat*); // stat now also names a function

void f() {
  struct stat* ps; // struct prefix needed to name struct stat
  stat(ps); // call stat function
}
— end example]
An elaborated-type-specifier can also be used to declare an identifier as a class-name.

Example 3:
struct s { int a; };

void g() {
  struct s; // hide global struct s with a block-scope declaration
  s* p; // refer to local struct s
  struct s { char* p; }; // define local struct s
  struct s; // redeclaration, has no effect
}
— end example]
Such declarations allow definition of classes that refer to each other.

Example 4:
class Vector;

class Matrix {
  // ...
  friend Vector operator*(const Matrix&, const Vector&);
};

class Vector {
  // ...
  friend Vector operator*(const Matrix&, const Vector&);
};

Declaration of friends is described in 11.8.4, operator functions in 12.4. — end example]
— end note]

3 [Note 2: An elaborated-type-specifier (9.2.9.4) can also be used as a type-specifier as part of a declaration. It differs from a class declaration in that it can refer to an existing class of the given name. — end note]

Example 5:
struct s { int a; };

§ 11.3
void g(int s) {
    struct s* p = new struct s;  // global s
    p->a = s;                     // parameter s
}

—end example

4 [Note 3: The declaration of a class name takes effect immediately after the identifier is seen in the class definition or elaborated-type-specifier. For example,

```cpp
class A * A;
```

first specifies A to be the name of a class and then redefines it as the name of a pointer to an object of that class. This means that the elaborated form class A must be used to refer to the class. Such artistry with names can be confusing and is best avoided. — end note]

5 A simple-template-id is only a class-name if its template-name names a class template.

11.4 Class members

11.4.1 General

The member-specification in a class definition declares the full set of members of the class; no member can be added elsewhere. A direct member of a class X is a member of X that was first declared within the member-specification of X, including anonymous union members (11.5.2) and direct members thereof. Members of a class are data members, member functions (11.4.2), nested types, enumerators, and member templates (13.7.3) and specializations thereof.

[Note 1: A specialization of a static data member template is a static data member. A specialization of a member function template is a member function. A specialization of a member class template is a nested class. — end note]

A member-declaration does not declare new members of the class if it is

1. a friend declaration (11.8.4),
2. a deduction-guide (13.7.2.3),
A `template-declaration` whose declaration is one of the above,

- a `static_assert-declaration`,
- a `using-declaration` (9.9), or
- an `empty-declaration`.

For any other `member-declaration`, each declared entity that is not an unnamed bit-field (11.4.10) is a member of the class, and each such `member-declaration` shall either declare at least one member name of the class or declare at least one unnamed bit-field.

A `data member` is a non-function member introduced by a `member-declarator`. A `member function` is a member that is a function. Nested types are classes (11.3, 11.4.12) and enumerations (9.7.1) declared in the class and arbitrary types declared as members by use of a typedef declaration (9.2.4) or `alias-declaration`. The enumerators of an unscoped enumeration (9.7.1) defined in the class are members of the class.

A data member or member function may be declared `static` in its `member-declaration`, in which case it is a `static member` (see 11.4.9) (a `static data member` (11.4.9.3) or `static member function` (11.4.9.2), respectively) of the class. Any other data member or member function is a `non-static data member` or `non-static member function` (11.4.3), respectively).

[Note 2: A non-static data member of non-reference type is a member subobject of a class object (6.7.2). — end note]

A member shall not be declared twice in the `member-specification`, except that

- a nested class or member class template can be declared and then later defined, and
- an enumeration can be introduced with an `opaque_enum-declaration` and later redeclared with an `enum-specifier`.

[Note 3: A single name can denote several member functions provided their types are sufficiently different (6.4.1). — end note]

A redeclaration of a class member outside its class definition shall be a definition, an explicit specialization, or an explicit instantiation (13.9.4, 13.9.3). The member shall not be a non-static data member.

A `complete-class context` of a class (template) is a

- function body (9.5.1),
- default argument (9.3.4.7),
- default template argument (13.2),
- `noexcept-specifier` (14.5), or
- default member initializer

within the `member-specification` of the class or class template.

[Note 4: A complete-class context of a nested class is also a complete-class context of any enclosing class, if the nested class is defined within the `member-specification` of the enclosing class. — end note]

A class is regarded as complete where its definition is reachable and within its complete-class contexts; otherwise it is regarded as incomplete within its own class `member-specification`.

In a `member-declarator`, an `=` immediately following the `declarator` is interpreted as introducing a `pure-specifier` if the `declarator-id` has function type, otherwise it is interpreted as introducing a `brace-or-equal-initializer`.

[Example 1:
```c
struct S {
    using T = void();
    T * p = 0; // OK, brace-or-equal-initializer
    virtual T f = 0; // OK, pure-specifier
};
```
— end example]

In a `member-declarator` for a bit-field, the `constant-expression` is parsed as the longest sequence of tokens that could syntactically form a `constant-expression`.

[Example 2:
```c
int a;
const int b = 0;
```]
struct S {
    int x1 : 8 = 42;  // OK, "= 42" is brace-or-equal-initializer
    int x2 : 8 { 42 };  // OK, "{ 42 }" is brace-or-equal-initializer
    int y1 : true ? 8 : a = 42;  // OK, brace-or-equal-initializer is absent
    int y2 : true ? 8 : b = 42;  // error: cannot assign to const int
    int y3 : (true ? 8 : b) = 42;  // OK, "= 42" is brace-or-equal-initializer
    int z : 1 || new int { 0 };  // OK, brace-or-equal-initializer is absent
};

—end example

11 A brace-or-equal-initializer shall appear only in the declaration of a data member. (For static data members, see 11.4.9.3; for non-static data members, see 11.9.3 and 9.4.2). A brace-or-equal-initializer for a non-static data member specifies a default member initializer for the member, and shall not directly or indirectly cause the implicit definition of a defaulted default constructor for the enclosing class or the exception specification of that constructor. An immediate invocation (7.7) that is a potentially-evaluated subexpression (6.9.1) of a default member initializer is neither evaluated nor checked for whether it is a constant expression at the point where the subexpression appears.

12 A member shall not be declared with the extern storage-class-specifier. Within a class definition, a member shall not be declared with the thread_local storage-class-specifier unless also declared static.

13 The decl-specifier-seq may be omitted in constructor, destructor, and conversion function declarations only; when declaring another kind of member the decl-specifier-seq shall contain a type-specifier that is not a cv-qualifier. The member-declarator-list can be omitted only after a class-specifier or an enum-specifier or in a friend declaration (11.8.4). A pure-specifier shall be used only in the declaration of a virtual function (11.7.3) that is not a friend declaration.

14 The optional attribute-specifier-seq in a member-declaration appertains to each of the entities declared by the member-declarators; it shall not appear if the optional member-declarator-list is omitted.

15 A virt-specifier-seq shall contain at most one of each virt-specifier. A virt-specifier-seq shall appear only in the first declaration of a virtual member function (11.7.3).

16 The type of a non-static data member shall not be an incomplete type (6.8.1), an abstract class type (11.7.4), or a (possibly multi-dimensional) array thereof.

[Note 5: In particular, a class C cannot contain a non-static member of class C, but it can contain a pointer or reference to an object of class C. — end note]

17 [Note 6: See 7.5.4 for restrictions on the use of non-static data members and non-static member functions. — end note]

18 [Note 7: The type of a non-static member function is an ordinary function type, and the type of a non-static data member is an ordinary object type. There are no special member function types or data member types. — end note]

19 [Example 3: A simple example of a class definition is

struct tnode {
    char tword[20];
    int count;
    tnode* left;
    tnode* right;
};

which contains an array of twenty characters, an integer, and two pointers to objects of the same type. Once this definition has been given, the declaration

tnode s, *sp;

declares s to be a tnode and sp to be a pointer to a tnode. With these declarations, sp->count refers to the count member of the object to which sp points; s.left refers to the left subtree pointer of the object s; and s.right->tword[0] refers to the initial character of the tword member of the right subtree of s. — end example]

20 [Note 8: Non-variant non-static data members of non-zero size (6.7.2) are allocated so that later members have higher addresses within a class object (7.6.9). Implementation alignment requirements can cause two adjacent members not to be allocated immediately after each other; so can requirements for space for managing virtual functions (11.7.3) and virtual base classes (11.7.2). — end note]

21 If T is the name of a class, then each of the following shall have a name different from T:

(21.1) — every static data member of class T;
(21.2) — every member function of class T;

[Note 9: This restriction does not apply to constructors, which do not have names (11.4.5) — end note]

(21.3) — every member of class T that is itself a type;

(21.4) — every member template of class T;

(21.5) — every enumerator of every member of class T that is an unscoped enumeration type; and

(21.6) — every member of every anonymous union that is a member of class T.

22 In addition, if class T has a user-declared constructor (11.4.5), every non-static data member of class T shall have a name different from T.

23 The common initial sequence of two standard-layout struct (11.2) types is the longest sequence of non-static data members and bit-fields in declaration order, starting with the first such entity in each of the structs, such that

(23.1) — corresponding entities have layout-compatible types (6.8),

(23.2) — corresponding entities have the same alignment requirements (6.7.6),

(23.3) — either both entities are declared with the no_unique_address attribute (9.12.11) or neither is, and

(23.4) — either both entities are bit-fields with the same width or neither is a bit-field.

[Example 4:

```c
struct A { int a; char b; }
struct B { const int b1; volatile char b2; }
struct C { int c; unsigned : 0; char b; }
struct D { int d; char b : 4; }
struct E { unsigned int e; char b; }
```

The common initial sequence of A and B comprises all members of either class. The common initial sequence of A and C and of A and D comprises the first member in each case. The common initial sequence of A and E is empty. — end example]

24 Two standard-layout struct (11.2) types are layout-compatible classes if their common initial sequence comprises all members and bit-fields of both classes (6.8).

25 Two standard-layout unions are layout-compatible if they have the same number of non-static data members and corresponding non-static data members (in any order) have layout-compatible types (6.8.1).

26 In a standard-layout union with an active member (11.5) of struct type T1, it is permitted to read a non-static data member m of another union member of struct type T2 provided m is part of the common initial sequence of T1 and T2; the behavior is as if the corresponding member of T1 were nominated.

[Example 5:

```c
struct T1 { int a, b; }
struct T2 { int c; double d; }
union U { T1 t1; T2 t2; }
int f() {
    U u = { { 1, 2 } }; // active member is t1
    return u.t2.c; // OK, as if u.t1.a were nominated
}
```

— end example]

[Note 10: Reading a volatile object through a glvalue of non-volatile type has undefined behavior (9.2.9.2). — end note]

27 If a standard-layout class object has any non-static data members, its address is the same as the address of its first non-static data member if that member is not a bit-field. Its address is also the same as the address of each of its base class subobjects.

[Note 11: There can therefore be unnamed padding within a standard-layout struct object inserted by an implementation, but not at its beginning, as necessary to achieve appropriate alignment. — end note]

[Note 12: The object and its first subobject are pointer-interconvertible (6.8.4, 7.6.1.9). — end note]

11.4.2 Member functions

[class.mfct]

1 If a member function is attached to the global module and is defined (9.5) in its class definition, it is inline (9.2.8).
2 [Example 1:

```cpp
struct X {
    typedef int T;
    static T count;
    void f(T);
};
void X::f(T t = count) { }
```

The definition of the member function \texttt{f} of class \texttt{X} inhabits the global scope; the notation \texttt{X::f} indicates that the function \texttt{f} is a member of class \texttt{X} and in the scope of class \texttt{X}. In the function definition, the parameter type \texttt{T} refers to the typedef member \texttt{T} declared in class \texttt{X} and the default argument \texttt{count} refers to the static data member \texttt{count} declared in class \texttt{X}. — end example]

3 Member functions of a local class shall be defined inline in their class definition, if they are defined at all.

4 [Note 2: A member function can be declared (but not defined) using a typedef for a function type. The resulting member function has exactly the same type as it would have if the function declarator were provided explicitly, see 9.3.4.6. For example,

```cpp
typedef void fv();
typedef void fvc() const;
struct S {
    fv memfunc1;  // equivalent to: void memfunc1();
    void memfunc2();
    fvc memfunc3;  // equivalent to: void memfunc3() const;
};
fv S::* pmfv1 = &S::memfunc1;
fv S::* pmfv2 = &S::memfunc2;
fvc S::* pmfv3 = &S::memfunc3;
```

Also see 13.4. — end note]

11.4.3 Non-static member functions [class.mfct.non.static]

1 A non-static member function may be called for an object of its class type, or for an object of a class derived (11.7) from its class type, using the class member access syntax (7.6.1.5, 12.2.2.2). A non-static member function may also be called directly using the function call syntax (7.6.1.3, 12.2.2.2) from within its class or a class derived from its class, or a member thereof, as described below.

2 When an \textit{id-expression} (7.5.4) that is neither part of a class member access syntax (7.6.1.5) nor the unparenthesized operand of the unary \texttt{&} operator (7.6.2.2) is used where the current class is \texttt{X} (7.5.2), if name lookup (6.5) resolves the name in the \textit{id-expression} to a non-static non-type member of some class \texttt{C}, and if either the \textit{id-expression} is potentially evaluated or \texttt{C} is \texttt{X} or a base class of \texttt{X}, the \textit{id-expression} is transformed into a class member access expression (7.6.1.5) using \texttt{(*this)} as the postfix-expression to the left of the \texttt{.} operator.

[Note 1: If \texttt{C} is not \texttt{X} or a base class of \texttt{X}, the class member access expression is ill-formed. — end note]

This transformation does not apply in the template definition context (13.8.3.2).

[Example 1:

```cpp
struct tnode {
    char tword[20];
    int count;
    tnode* left;
    tnode* right;
    void set(const char*, tnode* l, tnode* r);
};

void tnode::set(const char* w, tnode* l, tnode* r) {
    count = strlen(w)+1;
    if (sizeof(tword)<=count)
        perror("tnode string too long");
    strcpy(tword,w);
    left = l;
    right = r;
}
```
void f(tnode n1, tnode n2) {
    n1.set("abc", &n2, 0);
    n2.set("def", 0, 0);
}

In the body of the member function _tnode::set_, the member names _tword_, _count_, _left_, and _right_ refer to members of the object for which the function is called. Thus, in the call _n1.set("abc", &n2, 0)_ , _tword_ refers to _n1.tword_ , and in the call _n2.set("def", 0, 0)_ , it refers to _n2.tword_. The functions _strlen_, _perror_, and _strcpy_ are not members of the class _tnode_ and should be declared elsewhere.\[94\] — end example

3 [Note 2: An implicit object member function can be declared with cv-qualifiers, which affect the type of the this pointer (7.5.2), and/or a ref-qualifier (9.3.4.6); both affect overload resolution (12.2.2) — end note]

4 An implicit object member function may be declared virtual (11.7.3) or pure virtual (11.7.4).

11.4.4 Special member functions [special]  

1 Default constructors (11.4.5.2), copy constructors, move constructors (11.4.5.3), copy assignment operators, move assignment operators (11.4.6), and prospective destructors (11.4.7) are _special member functions._

[Note 1: The implementation will implicitly declare these member functions for some class types when the program does not explicitly declare them. The implementation will implicitly define them as needed (9.5.2). — end note]

An implicitly-declared special member function is declared at the closing _} of the _class-specifier_. Programs shall not define implicitly-declared special member functions.

2 Programs may explicitly refer to implicitly-declared special member functions.

[Example 1: A program may explicitly call or form a pointer to member to an implicitly-declared special member function.

```c
struct A {
    A &operator=(A &);  // implicitly declared A:: operator=

    B & operator=(const B &);

    B & B::operator=(const B & b) {
        return *this;
        // well-formed
    }

    } — end example
```

[Note 2: The special member functions affect the way objects of class type are created, copied, moved, and destroyed, and how values can be converted to values of other types. Often such special member functions are called implicitly. — end note]

4 Special member functions obey the usual access rules (11.8).

[Example 2: Declaring a constructor protected ensures that only derived classes and friends can create objects using it. — end example]

5 Two special member functions are of the same kind if:

(5.1) — they are both default constructors,
(5.2) — they are both copy or move constructors with the same first parameter type, or
(5.3) — they are both copy or move assignment operators with the same first parameter type and the same cv-qualifiers and ref-qualifier, if any.

6 An _eligible special member function_ is a special member function for which:

(6.1) — the function is not deleted,
(6.2) — the associated constraints (13.5), if any, are satisfied, and
(6.3) — no special member function of the same kind is more constrained (13.5.5).

7 For a class, its non-static data members, its non-virtual direct base classes, and, if the class is not abstract (11.7.4), its virtual base classes are called its _potentially constructed subobjects._

---

94) See, for example, `<cstring>` (23.5.3).
11.4.5 Constructors

11.4.5.1 General

A declarator declares a constructor if it is a function declarator (9.3.4.6) of the form

\[
\text{ptr-declarator ( parameter-declaration-clause ) noexcept-specifier_opt attribute-specifier-seq_opt}
\]

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

1. in a friend declaration (11.8.4), the id-expression is a qualified-id that names a constructor (6.5.5.2);
2. otherwise, in a member-declaration that belongs to the member-specification of a class or class template, the id-expression is the injected-class-name (11.1) of the immediately-enclosing entity;
3. otherwise, the id-expression is a qualified-id whose unqualified-id is the injected-class-name of its lookup context.

Constructors do not have names. In a constructor declaration, each decl-specifier in the optional decl-specifier-seq shall be friend, inline, constexpr, consteval, or an explicit-specifier.

[Example 1:]

```cpp
struct S {
  S(); // declares the constructor
};
S::S() {} // defines the constructor
```

2 A constructor is used to initialize objects of its class type.

[Note 1: Because constructors do not have names, they are never found during unqualified name lookup; however an explicit type conversion using the functional notation (7.6.1.4) will cause a constructor to be called to initialize an object. The syntax looks like an explicit call of the constructor. — end note]

[Example 2:]

```cpp
complex zz = complex(1,2.3);
cprint( complex(7.8,1.2) );
```

[Note 2: For initialization of objects of class type see 11.9. — end note]

3 An object created in this way is unnamed.

[Note 3: 6.7.7 describes the lifetime of temporary objects. — end note]

[Note 4: Explicit constructor calls do not yield lvalues, see 7.2.1. — end note]

4 A constructor can be invoked for a const, volatile or const volatile object. const and volatile semantics (9.2.9.2) are not applied on an object under construction. They come into effect when the constructor for the most derived object (6.7.2) ends.

5 The address of a constructor shall not be taken.

[Note 6: A return statement in the body of a constructor cannot specify a return value (8.7.4). — end note]

A constructor shall not be a coroutine.

6 A constructor shall not have an explicit object parameter (9.3.4.6).

11.4.5.2 Default constructors

A default constructor for a class X is a constructor of class X for which each parameter that is not a function parameter pack has a default argument (including the case of a constructor with no parameters). If there is no user-declared constructor for class X, a non-explicit constructor having no parameters is implicitly declared as defaulted (9.5). An implicitly-declared default constructor is an inline public member of its class.

2 A defaulted default constructor for class X is defined as deleted if:

1. X is a union that has a variant member with a non-trivial default constructor and no variant member of X has a default member initializer,
© ISO/IEC

— X is a non-union class that has a variant member M with a non-trivial default constructor and no variant member of the anonymous union containing M has a default member initializer,

— any non-static data member with no default member initializer (11.4) is of reference type,

— any non-variant non-static data member of const-qualified type (or array thereof) with no brace-or-equal-initializer is not const-default-constructible (9.4),

— X is a union and all of its variant members are of const-qualified type (or array thereof),

— X is a non-union class and all members of any anonymous union member are of const-qualified type (or array thereof),

— any potentially constructed subobject, except for a non-static data member with a brace-or-equal-initializer, has class type M (or array thereof) and either M has no default constructor or overload resolution (12.2) as applied to find M’s corresponding constructor results in an ambiguity or in a function that is deleted or inaccessible from the defaulted default constructor, or

— any potentially constructed subobject has a type with a destructor that is deleted or inaccessible from the defaulted default constructor.

A default constructor is trivial if it is not user-provided and if:

— its class has no virtual functions (11.7.3) and no virtual base classes (11.7.2), and

— no non-static data member of its class has a default member initializer (11.4), and

— all the direct base classes of its class have trivial default constructors, and

— for all the non-static data members of its class that are of class type (or array thereof), each such class has a trivial default constructor.

Otherwise, the default constructor is non-trivial.

An implicitly-defined (9.5.2) default constructor performs the set of initializations of the class that would be performed by a user-written default constructor for that class with no ctor-initializer (11.9.3) and an empty compound-statement. If that user-written default constructor would be ill-formed, the program is ill-formed. If that user-written default constructor would satisfy the requirements of a constexpr function (9.2.6), the implicitly-defined default constructor is constexpr. Before the defaulted default constructor for a class is implicitly defined, all the non-user-provided default constructors for its base classes and its non-static data members are implicitly defined.

[Note 1: An implicitly-declared default constructor has an exception specification (14.5). An explicitly-defaulted definition might have an implicit exception specification, see 9.5. — end note]

[Note 2: A default constructor is implicitly invoked to initialize a class object when no initializer is specified (9.4.1). Such a default constructor is required to be accessible (11.8). — end note]

[Note 3: 11.9.3 describes the order in which constructors for base classes and non-static data members are called and describes how arguments can be specified for the calls to these constructors. — end note]

### 11.4.5.3 Copy/move constructors

A non-template constructor for class X is a copy constructor if its first parameter is of type X&, const X&, volatile X& or const volatile X&, and either there are no other parameters or else all other parameters have default arguments (9.3.4.7).

[Example 1: X::X(const X&) and X::X(X&, int=1) are copy constructors.

```c
struct X {
  X(int);
  X(const X&, int = 1);
};
X a(1);  // calls X(int);
X b(a, 0);  // calls X(const X&, int);
X c = b;  // calls X(const X&, int);
end example]

A non-template constructor for class X is a move constructor if its first parameter is of type X&&, const X&&, volatile X&& or const volatile X&&, and either there are no other parameters or else all other parameters have default arguments (9.3.4.7).

[Example 2: Y::Y(Y&&) is a move constructor.

§ 11.4.5.3 278
struct Y {
    Y(const Y&);
    Y(Y&&);
};
extern Y f(int);
Y d(f(1)); // calls Y(Y&&)
Y e = d;  // calls Y(const Y&)
—end example

[Note 1: All forms of copy/move constructor can be declared for a class.]

[Example 3:
struct X {
    X(const X&);
    X(X&);       // OK
    X(X&&);      // OK, but possibly not sensible
};
—end example]
—end note]

[Note 2: If a class X only has a copy constructor with a parameter of type X&, an initializer of type const X or volatile X cannot initialize an object of type cv X.]

[Example 4:
struct X {
    X();           // default constructor
    X(X&);        // copy constructor with a non-const parameter
};
const X cx;
X x = cx;        // error: X::X(X&) cannot copy cx into x
—end example]
—end note]

A declaration of a constructor for a class X is ill-formed if its first parameter is of type cv X and either there are no other parameters or else all other parameters have default arguments. A member function template is never instantiated to produce such a constructor signature.

[Example 5:
struct S {
    template<typename T> S(T);
    S();
};
S g;

void h() {
    S a(g);  // does not instantiate the member template to produce S::S<T>(g);
    // uses the implicitly declared copy constructor
}
—end example]

If the class definition does not explicitly declare a copy constructor, a non-explicit one is declared implicitly. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy constructor is defined as deleted; otherwise, it is defaulted (9.5). The latter case is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor (D.8).

The implicitly-declared copy constructor for a class X will have the form
X::X(const X&)
if each potentially constructed subobject of a class type M (or array thereof) has a copy constructor whose first parameter is of type const M& or const volatile M&. 95 Otherwise, the implicitly-declared copy constructor

95) This implies that the reference parameter of the implicitly-declared copy constructor cannot bind to a volatile lvalue; see C.6.7.
will have the form
\[ X::X(X&) \]

If the definition of a class \( X \) does not explicitly declare a move constructor, a non-explicit one will be implicitly declared as defaulted if and only if
\[(8.1) \quad \text{X does not have a user-declared copy constructor,}\]
\[(8.2) \quad \text{X does not have a user-declared copy assignment operator,}\]
\[(8.3) \quad \text{X does not have a user-declared move assignment operator, and}\]
\[(8.4) \quad \text{X does not have a user-declared destructor.}\]

[Note 3: When the move constructor is not implicitly declared or explicitly supplied, expressions that otherwise would have invoked the move constructor might instead invoke a copy constructor. — end note]

The implicitly-declared move constructor for class \( X \) will have the form
\[ X::X(X&&) \]

An implicitly-declared copy/move constructor is an inline public member of its class. A defaulted copy/move constructor for a class \( X \) is defined as deleted (9.5.3) if \( X \) has:
\[(10.1) \quad \text{a potentially constructed subobject of type } M \text{ (or array thereof) that cannot be copied/moved because overload resolution (12.2), as applied to find } M \text{'s corresponding constructor, results in an ambiguity or a}\]
\[(10.2) \quad \text{function that is deleted or inaccessible from the defaulted constructor,}\]
\[(10.3) \quad \text{a variant member whose corresponding constructor as selected by overload resolution is non-trivial,}\]
\[(10.4) \quad \text{or, for the copy constructor, a non-static data member of rvalue reference type.}\]

[Note 4: A defaulted move constructor that is defined as deleted is ignored by overload resolution (12.2, 12.3). Such a constructor would otherwise interfere with initialization from an rvalue which can use the copy constructor instead. — end note]

A copy/move constructor for class \( X \) is trivial if it is not user-provided and if:
\[(11.1) \quad \text{class } X \text{ has no virtual functions (11.7.3) and no virtual base classes (11.7.2), and}\]
\[(11.2) \quad \text{the constructor selected to copy/move each direct base class subobject is trivial, and}\]
\[(11.3) \quad \text{for each non-static data member of } X \text{ that is of class type (or array thereof), the constructor selected to}\]
\[(11.4) \quad \text{copy/move that member is trivial; otherwise the copy/move constructor is non-trivial.}\]

[Note 5: The copy/move constructor is implicitly defined even if the implementation elided its odr-use (6.3, 6.7.7). — end note]

If an implicitly-defined (9.5.2) constructor would satisfy the requirements of a constexpr function (9.2.6), the implicitly-defined constructor is constexpr.

Before the defaulted copy/move constructor for a class is implicitly defined, all non-user-provided copy/move constructors for its potentially constructed subobjects are implicitly defined.

[Note 6: An implicitly-declared copy/move constructor has an implied exception specification (14.5). — end note]

The implicitly-defined copy/move constructor for a non-union class \( X \) performs a memberwise copy/move of its bases and members.

[Note 7: Default member initializers of non-static data members are ignored. See also the example in 11.9.3. — end note]

The order of initialization is the same as the order of initialization of bases and members in a user-defined constructor (see 11.9.3). Let \( x \) be either the parameter of the constructor or, for the move constructor, an xvalue referring to the parameter. Each base or non-static data member is copied/moved in the manner appropriate to its type:
\[(14.1) \quad \text{if the member is an array, each element is direct-initialized with the corresponding subobject of } x;\]
\[(14.2) \quad \text{if a member } m \text{ has rvalue reference type } T&&, \text{ it is direct-initialized with static_cast<T&&>(x.m);}\]
\[(14.3) \quad \text{otherwise, the base or member is direct-initialized with the corresponding base or member of } x.\]
Virtual base class subobjects shall be initialized only once by the implicitly-defined copy/move constructor (see 11.9.3).

The implicitly-defined copy/move constructor for a union X copies the object representation (6.8.1) of X. For each object nested within (6.7.2) the object that is the source of the copy, a corresponding object o nested within the destination is identified (if the object is a subobject) or created (otherwise), and the lifetime of o begins before the copy is performed.

11.4.6 Copy/move assignment operator

A user-declared copy assignment operator X::operator= is a non-static non-template member function of class X with exactly one non-object parameter of type X, X&, const X&, volatile X&, or const volatile X&.

[Note 1: An overloaded assignment operator must be declared to have only one parameter; see 12.4.3.2. — end note]

[Note 2: More than one form of copy assignment operator can be declared for a class. — end note]

[Note 3: If a class X only has a copy assignment operator with a parameter of type X&, an expression of type const X cannot be assigned to an object of type X.

[Example 1:]

```cpp
struct X {
  X();
  X& operator=(X&); // error: X::operator=(X&) cannot assign cx into x
};
```

— end example]

— end note]

If the class definition does not explicitly declare a copy assignment operator, one is declared implicitly. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy assignment operator is defined as deleted; otherwise, it is defaulted (9.5). The latter case is deprecated if the class has a user-declared copy constructor or a user-declared destructor (D.8). The implicitly-declared copy assignment operator for a class X will have the form

```
X& X::operator=(const X&)
```

if

1. each direct base class B of X has a copy assignment operator whose parameter is of type const B&, const volatile B&, or B, and

2. for all the non-static data members of X that are of a class type M (or array thereof), each such class type has a copy assignment operator whose parameter is of type const M&, const volatile M&, or M.

Otherwise, the implicitly-declared copy assignment operator will have the form

```
X& X::operator=(X&)
```

A user-declared move assignment operator X::operator= is a non-static non-template member function of class X with exactly one non-object parameter of type X&&, const X&&, volatile X&&, or const volatile X&&.

[Note 4: An overloaded assignment operator must be declared to have only one parameter; see 12.4.3.2. — end note]

[Note 5: More than one form of move assignment operator can be declared for a class. — end note]

---

96) Because a template assignment operator or an assignment operator taking an rvalue reference parameter is never a copy assignment operator, the presence of such an assignment operator does not suppress the implicit declaration of a copy assignment operator. Such assignment operators participate in overload resolution with other assignment operators, including copy assignment operators, and, if selected, will be used to assign an object.

97) This implies that the reference parameter of the implicitly-declared copy assignment operator cannot bind to a volatile lvalue; see C.6.7.
If the definition of a class $X$ does not explicitly declare a move assignment operator, one will be implicitly declared as defaulted if and only if

1. $X$ does not have a user-declared copy constructor,
2. $X$ does not have a user-declared move constructor,
3. $X$ does not have a user-declared copy assignment operator, and
4. $X$ does not have a user-declared destructor.

[Example 2: The class definition

struct S {
  int a;
  S& operator=(const S&) = default;
};

will not have a default move assignment operator implicitly declared because the copy assignment operator has been user-declared. The move assignment operator may be explicitly defaulted.

struct S {
  int a;
  S& operator=(const S&) = default;
  S& operator=(S&&) = default;
};

— end example]

The implicitly-declared move assignment operator for a class $X$ will have the form

$X& X::operator=(X&&)$

The implicitly-declared copy/move assignment operator for class $X$ has the return type $X&$. An implicitly-declared copy/move assignment operator is an inline public member of its class.

A defaulted copy/move assignment operator for class $X$ is defined as deleted if $X$ has:

1. a variant member with a non-trivial corresponding assignment operator and $X$ is a union-like class, or
2. a non-static data member of $\text{const}$ non-class type (or array thereof), or
3. a non-static data member of reference type, or
4. a direct non-static data member of class type $M$ (or array thereof) or a direct base class $M$ that cannot be copied/moved because overload resolution (12.2), as applied to find $M$'s corresponding assignment operator, results in an ambiguity or a function that is deleted or inaccessible from the defaulted assignment operator.

[Note 6: A defaulted move assignment operator that is defined as deleted is ignored by overload resolution (12.2, 12.3). — end note]

Because a copy/move assignment operator is implicitly declared for a class if not declared by the user, a base class copy/move assignment operator is always hidden by the corresponding assignment operator of a derived class (12.4.3.2).

[Note 7: A using-declaration in a derived class $C$ that names an assignment operator from a base class never suppresses the implicit declaration of an assignment operator of $C$, even if the base class assignment operator would be a copy or move assignment operator if declared as a member of $C$. — end note]

A copy/move assignment operator for class $X$ is trivial if it is not user-provided and if:

1. $X$ has no virtual functions (11.7.3) and no virtual base classes (11.7.2), and
2. the assignment operator selected to copy/move each direct base class subobject is trivial, and
3. for each non-static data member of $X$ that is of class type (or array thereof), the assignment operator selected to copy/move that member is trivial;

otherwise the copy/move assignment operator is non-trivial.

An implicitly-defined (9.5.2) copy/move assignment operator is constexpr.

Before the defaulted copy/move assignment operator for a class is implicitly defined, all non-user-provided copy/move assignment operators for its direct base classes and its non-static data members are implicitly defined.
The implicitly-declared copy/move assignment operator for a non-union class X performs memberwise copy/move assignment of its subobjects. The direct base classes of X are assigned first, in the order of their declaration in the base-specifier-list, and then the immediate non-static data members of X are assigned, in the order in which they were declared in the class definition. Let x be either the parameter of the function or, for the move operator, an xvalue referring to the parameter. Each subobject is assigned in the manner appropriate to its type:

12.1 — if the subobject is of class type, as if by a call to operator= with the subobject as the object expression and the corresponding subobject of x as a single function argument (as if by explicit qualification; that is, ignoring any possible virtual overriding functions in more derived classes);

12.2 — if the subobject is an array, each element is assigned, in the manner appropriate to the element type;

12.3 — if the subobject is of scalar type, the built-in assignment operator is used.

It is unspecified whether subobjects representing virtual base classes are assigned more than once by the implicitly-defined copy/move assignment operator.

Example 3:

```c
struct V { }
struct A : virtual V { }
struct B : virtual V { }
struct C : B, A { }
```

It is unspecified whether the virtual base class subobject V is assigned twice by the implicitly-defined copy/move assignment operator for C. —end example

The implicitly-defined copy/move assignment operator for a union X copies the object representation (6.8.1) of X. If the source and destination of the assignment are not the same object, then for each object nested within the object that is the source of the copy, a corresponding object o nested within the destination is created, and the lifetime of o begins before the copy is performed.

The implicitly-defined copy/move assignment operator for a class returns the object for which the assignment operator is invoked, that is, the object assigned to.

11.4.7 Destructors

A declaration whose declarator-id has an unqualified-id that begins with a ~ declares a prospective destructor; its declarator shall be a function declarator (9.3.4.6) of the form

```c
ptr-declarator ( parameter-declaration-clause ) noexcept-specifier_opt attribute-specifier-seq_opt
```

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

1.1 — in a member-declaration that belongs to the member-specification of a class or class template but is not a friend declaration (11.8.4), the id-expression is ~class-name and the class-name is the injected-class-name (11.1) of the immediately-enclosing entity or

1.2 — otherwise, the id-expression is nested-name-specifier ~class-name and the class-name is the injected-class-name of the class nominated by the nested-name-specifier.

A prospective destructor shall take no arguments (9.3.4.6). Each decl-specifier of the decl-specifier-seq of a prospective destructor declaration (if any) shall be friend, inline, virtual, constexpr, or consteval.

If a class has no user-declared prospective destructor, a prospective destructor is implicitly declared as defaulted (9.5). An implicitly-declared prospective destructor is an inline public member of its class.

An implicitly-declared prospective destructor for a class X will have the form

```c
~X()
```

At the end of the definition of a class, overload resolution is performed among the prospective destructors declared in that class with an empty argument list to select the destructor for the class, also known as the selected destructor. The program is ill-formed if overload resolution fails. Destructor selection does not constitute a reference to, or odr-use (6.3) of, the selected destructor, and in particular, the selected destructor may be deleted (9.5.3).

The address of a destructor shall not be taken.
[Note 1: A return statement in the body of a destructor cannot specify a return value (8.7.4). — end note]

A destructor can be invoked for a const, volatile or const volatile object. const and volatile semantics (9.2.9.2) are not applied on an object under destruction. They stop being in effect when the destructor for the most derived object (6.7.2) starts.

[Note 2: A declaration of a destructor that does not have a noexcept-specifier has the same exception specification as if it had been implicitly declared (14.5). — end note]

A defaulted destructor for a class X is defined as deleted if:

(7.1) X is a union-like class that has a variant member with a non-trivial destructor,

(7.2) any potentially constructed subobject has class type M (or array thereof) and M has a deleted destructor or a destructor that is inaccessible from the defaulted destructor,

(7.3) or, for a virtual destructor, lookup of the non-array deallocation function results in an ambiguity or in a function that is deleted or inaccessible from the defaulted destructor.

A destructor is trivial if it is not user-provided and if:

(8.1) the destructor is not virtual,

(8.2) all of the direct base classes of its class have trivial destructors, and

(8.3) for all of the non-static data members of its class that are of class type (or array thereof), each such class has a trivial destructor.

Otherwise, the destructor is non-trivial.

A defaulted destructor is a constexpr destructor if it is constexpr-suitable (9.2.6).

Before a defaulted destructor for a class is implicitly defined, all the non-user-provided destructors for its base classes and its non-static data members are implicitly defined.

A prospective destructor can be declared virtual (11.7.3) and with a pure-specifier (11.7.4). If the destructor of a class is virtual and any objects of that class or any derived class are created in the program, the destructor shall be defined.

[Note 3: Some language constructs have special semantics when used during destruction; see 11.9.5. — end note]

After executing the body of the destructor and destroying any objects with automatic storage duration allocated within the body, a destructor for class X calls the destructors for X’s direct non-variant non-static data members, the destructors for X’s non-virtual direct base classes and, if X is the most derived class (11.9.3), its destructor calls the destructors for X’s virtual base classes. All destructors are called as if they were referenced with a qualified name, that is, ignoring any possible virtual overriding destructors in more derived classes. Bases and members are destroyed in the reverse order of the completion of their constructor (see 11.9.3).

[Note 4: A return statement (8.7.4) in a destructor might not directly return to the caller; before transferring control to the caller, the destructors for the members and bases are called. — end note]

Destructors for elements of an array are called in reverse order of their construction (see 11.9).

A destructor is invoked implicitly

(14.1) for a constructed object with static storage duration (6.7.5.2) at program termination (6.9.3.4),

(14.2) for a constructed object with thread storage duration (6.7.5.3) at thread exit,

(14.3) for a constructed object with automatic storage duration (6.7.5.4) when the block in which an object is created exits (8.8),

(14.4) for a constructed temporary object when its lifetime ends (7.3.5, 6.7.7).

In each case, the context of the invocation is the context of the construction of the object. A destructor may also be invoked implicitly through use of a delete-expression (7.6.2.9) for a constructed object allocated by a new-expression (7.6.2.8); the context of the invocation is the delete-expression.

[Note 5: An array of class type contains several subobjects for each of which the destructor is invoked. — end note]

A destructor can also be invoked explicitly. A destructor is potentially invoked if it is invoked or as specified in 7.6.2.8, 8.7.4, 9.4.2, 11.9.3, and 14.2. A program is ill-formed if a destructor that is potentially invoked is deleted or not accessible from the context of the invocation.

At the point of definition of a virtual destructor (including an implicit definition), the non-array deallocation function is determined as if for the expression delete this appearing in a non-virtual destructor of the...
destructor’s class (see 7.6.2.9). If the lookup fails or if the deallocation function has a deleted definition (9.5), the program is ill-formed.

[Note 6: This assures that a deallocation function corresponding to the dynamic type of an object is available for the \textit{delete-expression} (11.4.11). —end note]

In an explicit destructor call, the destructor is specified by a \texttt{~} followed by a \textit{type-name} or \textit{decltype-specifier} that denotes the destructor’s class type. The invocation of a destructor is subject to the usual rules for member functions (11.4.2); that is, if the object is not of the destructor’s class type and not of a class derived from the destructor’s class type (including when the destructor is invoked via a null pointer value), the program has undefined behavior.

[Note 7: Invoking \texttt{delete} on a null pointer does not call the destructor; see 7.6.2.9. —end note]

\textbf{Example 1:}

```cpp
struct B {
    virtual ~B() { }
};
struct D : B {
    ~D() { }
};

D D_object;
typedef B B_alias;
B* B_ptr = &D_object;

void f() {
    D_object.B::~B();  // calls B’s destructor
    B_ptr->B();        // calls D’s destructor
    B_ptr->B_alias();  // calls B’s destructor
    B_ptr->B_alias::~B_alias();  // calls B’s destructor
}
```

—end example]

[Note 8: An explicit destructor call must always be written using a member access operator (7.6.1.5) or a \textit{qualified-id} (7.5.4.3); in particular, the \textit{unary-expression} \texttt{~X()} in a member function is not an explicit destructor call (7.6.2.2). —end note]

[Note 9: Explicit calls of destructors are rarely needed. One use of such calls is for objects placed at specific addresses using a placement \textit{new-expression}. Such use of explicit placement and destruction of objects can be necessary to cope with dedicated hardware resources and for writing memory management facilities. For example,

```cpp
void* operator new(std::size_t, void* p) { return p; }
struct X {
    X(int);
    ~X();
};

void f(X* p);  

void g() {
    char* buf = new char[ sizeof(X) ];
    X* p = new( buf ) X(222);  // use buf[] and initialize
    f(p);
    p->X::~X();  // cleanup
}
```

—end note]

Once a destructor is invoked for an object, the object’s lifetime ends; the behavior is undefined if the destructor is invoked for an object whose lifetime has ended (6.7.3).

[Example 2: If the destructor for an object with automatic storage duration is explicitly invoked, and the block is subsequently left in a manner that would ordinarily invoke implicit destruction of the object, the behavior is undefined. —end example]

[Note 10: The notation for explicit call of a destructor can be used for any scalar type name (7.5.4.4). Allowing this makes it possible to write code without having to know if a destructor exists for a given type. For example:

```cpp
typedef int I;
```
A destructor shall not be a coroutine.

11.4.8 Conversions

11.4.8.1 General

Type conversions of class objects can be specified by constructors and by conversion functions. These conversions are called user-defined conversions and are used for implicit type conversions (7.3), for initialization (9.4), and for explicit type conversions (7.6.1.4, 7.6.3, 7.6.1.9).

User-defined conversions are applied only where they are unambiguous (6.5.2, 11.4.8.3). Conversions obey the access control rules (11.8). Access control is applied after ambiguity resolution (6.5).

[Note 1: See 12.2 for a discussion of the use of conversions in function calls as well as examples below. — end note]

At most one user-defined conversion (constructor or conversion function) is implicitly applied to a single value.

[Example 1:
```c
struct X {
    operator int();
};

struct Y {
    operator X();
};

Y a;
int b = a;  // error: no viable conversion (a.operator X().operator int() not considered)
int c = X(a); // OK, a.operator X().operator int()
```

—end example]

11.4.8.2 Conversion by constructor

A constructor that is not explicit (9.2.3) specifies a conversion from the types of its parameters (if any) to the type of its class. Such a constructor is called a converting constructor.

[Example 1:
```c
struct X {
    X(int);
    X(const char*, int =0);
    X(int, int);
};

void f(X arg) {
    X a = 1;  // a = X(1)
    X b = "Jessie";  // b = X("Jessie",0)
    a = 2;  // a = X(2)
    f(3);  // f(X(3))
    f({1, 2});  // f(X(1,2))
}
```

—end example]

[Note 1: An explicit constructor constructs objects just like non-explicit constructors, but does so only where the direct-initialization syntax (9.4) or where casts (7.6.1.9, 7.6.3) are explicitly used; see also 12.2.2.5. A default constructor can be an explicit constructor; such a constructor will be used to perform default-initialization or value-initialization (9.4).

[Example 2:
```c
struct Z {
    explicit Z();
    explicit Z(int);
    explicit Z(int, int);
};
```
A non-explicit copy/move constructor (11.4.5.3) is a converting constructor.

[Note 2: An implicitly-declared copy/move constructor is not an explicit constructor; it can be called for implicit type conversions. — end note]

### 11.4.8.3 Conversion functions

A declaration whose declarator-id has an unqualified-id that is a conversion-function-id declares a conversion function; its declarator shall be a function declarator (9.3.4.6) of the form

```c
ptr-declarator ( parameter-declaration-clause ) cv-qualifier-seq opt
ref-qualifier-seq opt noexcept-specifier opt attribute-specifier-seq opt
```

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

1. In a member-declaration that belongs to the member-specification of a class or class template but is not a friend declaration (11.8.4), the id-expression is a conversion-function-id;
2. Otherwise, the id-expression is a qualified-id whose unqualified-id is a conversion-function-id.

A conversion function shall have no non-object parameters and shall be a non-static member function of a class or class template X; it specifies a conversion from X to the type specified by the conversion-type-id, interpreted as a type-id (9.3.2). A decl-specifier in the decl-specifier-seq of a conversion function (if any) shall not be a defining-type-specifier.

The type of the conversion function is “`noexcept opt` function taking no parameter cv-qualifier-seq opt ref-qualifier opt returning conversion-type-id”.

A conversion function is never used to convert a (possibly cv-qualified) object to the (possibly cv-qualified) same object type (or a reference to it), to a (possibly cv-qualified) base class of that type (or a reference to it), or to `cv void`.

[Example 1]

```c
struct X {
    operator int();
    operator auto() -> short; // error: trailing return type
};

void f(X a) {
    int i = int(a);
    i = (int)a;
    i = a;
}
```

98 These conversions are considered as standard conversions for the purposes of overload resolution (12.2.4.2, 12.2.4.2.5) and therefore initialization (9.4) and explicit casts (7.6.1.9). A conversion to `void` does not invoke any conversion function (7.6.1.9). Even though never directly called to perform a conversion, such conversion functions can be declared and can potentially be reached through a call to a virtual conversion function in a base class.
In all three cases the value assigned will be converted by `X::operator int()`. — end example]

5 A conversion function may be explicit (9.2.3), in which case it is only considered as a user-defined conversion for direct-initialization (9.4). Otherwise, user-defined conversions are not restricted to use in assignments and initializations.

[Example 2:

```cpp
class Y { },
struct Z {
    explicit operator Y() const;
};

void h(Z z) {
    Y y1(z); // OK, direct-initialization
    Y y2 = z; // error: no conversion function candidate for copy-initialization
    Y y3 = (Y)z; // OK, cast notation
}
```]

6 The conversion-type-id shall not represent a function type nor an array type. The conversion-type-id in a conversion-function-id is the longest sequence of tokens that could possibly form a conversion-type-id.

[Note 1: This prevents ambiguities between the declarator operator `*` and its expression counterparts.

[Example 3:

```cpp
& ac.operator int* i; // syntax error:
    // parsed as: & (ac.operator int *) i
    // not as: & (ac.operator int)* i
```]

The `*` is the pointer declarator and not the multiplication operator. — end example]

This rule also prevents ambiguities for attributes.

[Example 4:

```cpp
operator int [[noreturn]] (); // error: noreturn attribute applied to a type
``` — end example]

— end note]

7 [Note 2: A conversion function in a derived class hides only conversion functions in base classes that convert to the same type. A conversion function template with a dependent return type hides only templates in base classes that correspond to it (6.5.2); otherwise, it hides and is hidden as a non-template function. Function overload resolution (12.2.4) selects the best conversion function to perform the conversion.

[Example 5:

```cpp
struct X {
    operator int();
};

struct Y : X {
    operator char();
};

void f(Y& a) {
    if (a) { // error: ambiguous between X::operator int() and Y::operator char()
    }
}
``` — end example]

— end note]
Conversion functions can be virtual.

A conversion function template shall not have a deduced return type (9.2.9.6).

[Example 6:

```cpp
struct S {
    operator auto() const { return 10; }  // OK
    template<class T>
    operator auto() const { return 1.2; }  // error: conversion function template
};
```

—end example]

11.4.9 Static members

11.4.9.1 General

A static member `s` of class `X` may be referred to using the qualified-id expression `X::s`; it is not necessary to use the class member access syntax (7.6.1.5) to refer to a static member. A static member may be referred to using the class member access syntax, in which case the object expression is evaluated.

[Example 1:

```cpp
struct process {
    static void reschedule();
};

process& g();

void f() {
    process::reschedule();  // OK, no object necessary
    g().reschedule();  // g() is called
}
```

—end example]

Static members obey the usual class member access rules (11.8). When used in the declaration of a class member, the static specifier shall only be used in the member declarations that appear within the member-specification of the class definition.

[Note 1: It cannot be specified in member declarations that appear in namespace scope. — end note]

11.4.9.2 Static member functions

[Note 1: The rules described in 11.4.2 apply to static member functions. — end note]

[Note 2: A static member function does not have a this pointer (7.5.2). A static member function cannot be qualified with `const`, `volatile`, or virtual (9.3.4.6). — end note]

11.4.9.3 Static data members

A static data member is not part of the subobjects of a class. If a static data member is declared `thread_local` there is one copy of the member per thread. If a static data member is not declared `thread_local` there is one copy of the data member that is shared by all the objects of the class.

A static data member shall not be mutable (9.2.2). A static data member shall not be a direct member (11.4) of an unnamed (11.1) or local (11.6) class or of a (possibly indirectly) nested class (11.4.12) thereof.

The declaration of a non-inline static data member in its class definition is not a definition and may be of an incomplete type other than `cv void`.

[Note 1: The initializer in the definition of a static data member is in the scope of its class (6.4.7). — end note]

[Example 1:

```cpp
class process {
    static process* run_chain;
    static process* running;
};

process* process::running = get_main();
process* process::run_chain = running;
```

The definition of the static data member `run_chain` of class `process` inhabits the global scope; the notation `process::run_chain` indicates that the member `run_chain` is a member of class `process` and in the scope of class...
process. In the static data member definition, the initializer expression refers to the static data member running of class process. — end example

[Note 2: Once the static data member has been defined, it exists even if no objects of its class have been created. Example 2: In the example above, run_chain and running exist even if no objects of class process are created by the program. — end example]

The initialization and destruction of static data members is described in 6.9.3.2, 6.9.3.3, and 6.9.3.4. — end note

4 If a non-volatile non-inline const static data member is of integral or enumeration type, its declaration in the class definition can specify a brace-or-equal-initializer in which every initializer-clause that is an assignment-expression is a constant expression (7.7). The member shall still be defined in a namespace scope if it is odr-used (6.3) in the program and the namespace scope definition shall not contain an initializer. The declaration of an inline static data member (which is a definition) may specify a brace-or-equal-initializer. If the member is declared with the constexpr specifier, it may be redeclared in namespace scope with no initializer (this usage is deprecated; see D.6). Declarations of other static data members shall not specify a brace-or-equal-initializer.

5 [Note 3: There is exactly one definition of a static data member that is odr-used (6.3) in a valid program. — end note]

6 [Note 4: Static data members of a class in namespace scope have the linkage of the name of the class (6.6). — end note]

11.4.10 Bit-fields

1 A member-declarator of the form

identifier_opt attribute-specifier-seq_opt : constant-expression brace-or-equal-initializer_opt

specifies a bit-field. The optional attribute-specifier-seq appertains to the entity being declared. A bit-field shall not be a static member. A bit-field shall have integral or (possibly cv-qualified) enumeration type; the bit-field semantic property is not part of the type of the class member. The constant-expression shall be an integral constant expression with a value greater than or equal to zero and is called the width of the bit-field. If the width of a bit-field is larger than the width of the bit-field’s type (or, in case of an enumeration type, of its underlying type), the extra bits are padding bits (6.8.1). Allocation of bit-fields within a class object is implementation-defined. Alignment of bit-fields is implementation-defined. Bit-fields are packed into some addressable allocation unit.

[Note 1: Bit-fields straddle allocation units on some machines and not on others. Bit-fields are assigned right-to-left on some machines, left-to-right on others. — end note]

2 A declaration for a bit-field that omits the identifier declares an unnamed bit-field. Unnamed bit-fields are not members and cannot be initialized. An unnamed bit-field shall not be declared with a cv-qualified type.

[Note 2: An unnamed bit-field is useful for padding to conform to externally-imposed layouts. — end note]

As a special case, an unnamed bit-field with a width of zero specifies alignment of the next bit-field at an allocation unit boundary. Only when declaring an unnamed bit-field may the width be zero.

3 The address-of operator & shall not be applied to a bit-field, so there are no pointers to bit-fields. A non-const reference shall not bind to a bit-field (9.4.4).

[Note 3: If the initializer for a reference of type const T& is an lvalue that refers to a bit-field, the reference is bound to a temporary initialized to hold the value of the bit-field; the reference is not bound to the bit-field directly. See 9.4.4. — end note]

4 If a value of integral type (other than bool) is stored into a bit-field of width N and the value would be representable in a hypothetical signed or unsigned integer type with width N and the same signedness as the bit-field’s type, the original value and the value of the bit-field compare equal. If the value true or false is stored into a bit-field of type bool of any size (including a one bit bit-field), the original bool value and the value of the bit-field compare equal. If a value of an enumeration type is stored into a bit-field of the same type and the width is large enough to hold all the values of that enumeration type (9.7.1), the original value and the value of the bit-field compare equal.

[Example 1:

enum BOOL { FALSE=0, TRUE=1 };  
struct A {
    BOOL b:1;
};

]
A a;
void f() {
    a.b = TRUE;
    if (a.b == TRUE) // yields true
        /* ... */
}
—end example]  

11.4.11 Allocation and deallocation functions [class.free]

1 Any allocation function for a class T is a static member (even if not explicitly declared static).

2 [Example 1:
   class Arena;
   struct B {
       void* operator new(std::size_t, Arena*);
   };
   struct D1 : B {
   };
   Arena* ap;
   void foo(int i) {
       new (ap) D1; // calls B::operator new(std::size_t, Arena*)
       new D1[i]; // calls ::operator new[](std::size_t)
       new D1; // error: ::operator new(std::size_t) hidden
   }
   —end example]

3 Any deallocation function for a class X is a static member (even if not explicitly declared static).

3 [Example 2:
   class X {
       void operator delete(void*);
       void operator delete[](void*, std::size_t);
   };
   class Y {
       void operator delete(void*, std::size_t);
       void operator delete[](void*);
   };
   —end example]

4 Since member allocation and deallocation functions are static they cannot be virtual.

[Note 1: However, when the cast-expression of a delete-expression refers to an object of class type with a virtual destructor, because the deallocation function is chosen by the destructor of the dynamic type of the object, the effect is the same in that case. For example,

   struct B {
       virtual ~B();
       void operator delete(void*, std::size_t);
   };
   struct D : B {
       void operator delete(void*);
   };
   struct E : B {
       void_log_deletion();
       void operator delete(E *p, std::destroying_delete_t) {
           p->log_deletion();
           p->~E();
           ::operator delete(p);
       }
   };

§ 11.4.11 291
void f() {
  B* bp = new D;
  delete bp;    // 1: uses D::operator delete(void*)
  bp = new E;
  delete bp;    // 2: uses E::operator delete(E*, std::destroying_delete_t)
}

Here, storage for the object of class D is deallocated by D::operator delete(), and the object of class E is destroyed and its storage is deallocated by E::operator delete(), due to the virtual destructor. — end note

[Note 2: Virtual destructors have no effect on the deallocation function actually called when the cast-expression of a delete-expression refers to an array of objects of class type. For example,

```c
struct B {
  virtual ~B();
  void operator delete[](void*, std::size_t);
};

struct D : B {
  void operator delete[](void*, std::size_t);
};
```

void f(int i) {
  D* dp = new D[i];
  delete [] dp;    // uses D::operator delete[](void*, std::size_t)
  B* bp = new D[i];
  delete[] bp;     // undefined behavior
}
— end note]

5 Access to the deallocation function is checked statically, even if a different one is actually executed.

[Example 3: For the call on line “// 1” above, if B::operator delete() had been private, the delete expression would have been ill-formed. — end example]

6 [Note 3: If a deallocation function has no explicit noexcept-specifier, it has a non-throwing exception specification (14.5). — end note]

11.4.12 Nested class declarations [class.nest]

A class can be declared within another class. A class declared within another is called a nested class.

[Note 1: See 7.5.4 for restrictions on the use of non-static data members and non-static member functions. — end note]

[Example 1:

```c
int x;
int y;

struct enclose {
  int x;
  static int s;

  struct inner {
    void f(int i) {
      int a = sizeof(x);    // OK, operand of sizeof is an unevaluated operand
      x = i;             // error: assign to enclose::x
      s = i;            // OK, assign to enclose::s
      ::x = i;          // OK, assign to global x
      y = i;            // OK, assign to global y
    }
    void g(enclose* p, int i) {
      p->x = i;          // OK, assign to enclose::x
    }
  }

  inner* p = 0;       // error: inner not found

  void g(enclose* p, int i) {
    p->x = i;          // OK, assign to enclose::x
  }
}

void g(enclose* p, int i) {
  p->x = i;          // OK, assign to enclose::x
}
```
Note 2: Nested classes can be defined either in the enclosing class or in an enclosing namespace; member functions and static data members of a nested class can be defined either in the nested class or in an enclosing namespace scope.

Example 2:
```cpp
struct enclose {
    struct inner {
        static int x;
        void f(int i);
    };
};
int enclose::inner::x = 1;
void enclose::inner::f(int i) { /* ... */ }
```

class E {
    class I1; // forward declaration of nested class
    class I2;
    class I1 {}; // definition of nested class
    class E::I2 {}; // definition of nested class
} — end example

A friend function (11.8.4) defined within a nested class has no special access rights to members of an enclosing class.

11.5 Unions [class.union]
11.5.1 General [class.union.general]

A union is a class defined with the `union` class-key.

In a union, a non-static data member is active if its name refers to an object whose lifetime has begun and has not ended (6.7.3). At most one of the non-static data members of an object of union type can be active at any time, that is, the value of at most one of the non-static data members can be stored in a union at any time.

Note 1: One special guarantee is made in order to simplify the use of unions: If a standard-layout union contains several standard-layout structs that share a common initial sequence (11.4), and if a non-static data member of an object of this standard-layout union type is active and is one of the standard-layout structs, it is permitted to inspect the common initial sequence of any of the standard-layout struct members; see 11.4. — end note

The size of a union is sufficient to contain the largest of its non-static data members. Each non-static data member is allocated as if it were the sole member of a non-union class.

Note 2: A union object and its non-static data members are pointer-interconvertible (6.8.4, 7.6.1.9). As a consequence, all non-static data members of a union object have the same address. — end note

A union can have member functions (including constructors and destructors), but it shall not have virtual (11.7.3) functions. A union shall not have base classes. A union shall not be used as a base class. If a union contains a non-static data member of reference type the program is ill-formed.

Note 3: Absent default member initializers (11.4), if any non-static data member of a union has a non-trivial default constructor (11.4.5.2), copy constructor, move constructor (11.4.5.3), copy assignment operator, move assignment operator (11.4.6), or destructor (11.4.7), the corresponding member function of the union must be user-provided or it will be implicitly deleted (9.5.3) for the union.

Example 1: Consider the following union:
```cpp
union U {
    int i;
    float f;
    std::string s;
};
```
Since `std::string` (23.4) declares non-trivial versions of all of the special member functions, `U` will have an implicitly deleted default constructor, copy/move constructor, copy/move assignment operator, and destructor. To use `U`, some or all of these member functions must be user-provided. — end example

When the left operand of an assignment operator involves a member access expression (7.6.1.5) that nominates a union member, it may begin the lifetime of that union member, as described below. For an expression `E`, define the set `S(E)` of subexpressions of `E` as follows:

- If `E` is of the form `A.B`, `S(E)` contains the elements of `S(A)`, and also contains `A.B` if `B` names a union member of a non-class, non-array type, or of a class type with a trivial default constructor that is not deleted, or an array of such types.
- If `E` is of the form `A[B]` and is interpreted as a built-in array subscripting operator, `S(E)` is `S(A)` if `A` is of array type, `S(B)` if `B` is of array type, and empty otherwise.
- Otherwise, `S(E)` is empty.

In an assignment expression of the form `E1 = E2` that uses either the built-in assignment operator (7.6.19) or a trivial assignment operator (11.4.6), for each element `X` of `S(E1)`, if modification of `X` would have undefined behavior under 6.7.3, an object of the type of `X` is implicitly created in the nominated storage; no initialization is performed and the beginning of its lifetime is sequenced after the value computation of the left and right operands and before the assignment.

[Note 4: This ends the lifetime of the previously-active member of the union, if any (6.7.3). — end note]

[Example 2]:
```cpp
union A { int x; int y[4]; };
struct B { A a; };
union C { B b; int k; };
int f() {
    C c;  // does not start lifetime of any union member
    c.b.a.y[3] = 4;  // OK, S(c.b.a.y[3]) contains c.b and c.b.a.y;
    // creates objects to hold union members c.b and c.b.a.y
    return c.b.a.y[3];  // OK, c.b.a.y refers to newly created object (see 6.7.3)
}

struct X { const int a; int b; };
union Y { X x; int k; };
void g() {
    Y y = { { 1, 2 } };  // OK, y.x is active union member (11.4)
    int n = y.x.a;
    y.k = 4;  // OK, ends lifetime of y.x, y.k is active member of union
    y.x.b = n;  // undefined behavior: y.x.b modified outside its lifetime,
    // S(y.x.b) is empty because X's default constructor is deleted,
    // so union member y.x's lifetime does not implicitly start
}
```

—end example]

[Note 5: In cases where the above rule does not apply, the active member of a union can only be changed by the use of a placement new-expression. — end note]

[Example 3]: Consider an object `u` of a union type `U` having non-static data members `m` of type `M` and `n` of type `N`. If `M` has a non-trivial destructor and `N` has a non-trivial constructor (for instance, if they declare or inherit virtual functions), the active member of `u` can be safely switched from `m` to `n` using the destructor and placement new-expression as follows:
```cpp
u.m.~M();
new (&u.n) N;
```
—end example]

### 11.5.2 Anonymous unions

[class.union.anon]

A union of the form
```cpp
union { member-specification };
```
is called an anonymous union; it defines an unnamed type and an unnamed object of that type called an anonymous union member if it is a non-static data member or an anonymous union variable otherwise. Each

§ 11.5.2 294
member-declaration in the member-specification of an anonymous union shall either define one or more public non-static data members or be a static_assert-declaration. Nested types, anonymous unions, and functions shall not be declared within an anonymous union. The names of the members of an anonymous union are bound in the scope inhabited by the union declaration.

[Example 1:

```c
void f() {
    union { int a; const char* p; }; 
    a = 1; 
    p = "Jennifer"; 
}
```

Here a and p are used like ordinary (non-member) variables, but since they are union members they have the same address. — end example]

2 Anonymous unions declared in the scope of a namespace with external linkage shall be declared static. Anonymous unions declared at block scope shall be declared with any storage class allowed for a block variable, or with no storage class. A storage class is not allowed in a declaration of an anonymous union in a class scope.

[Note 1: A union for which objects, pointers, or references are declared is not an anonymous union.

[Example 2:

```c
void f() {
    union { int aa; char* p; } obj, *ptr = &obj;
    aa = 1; // error
    ptr->aa = 1; // OK
}
```

The assignment to plain aa is ill-formed since the member name is not visible outside the union, and even if it were visible, it is not associated with any particular object. — end example]

— end note]

[Note 2: Initialization of unions with no user-declared constructors is described in 9.4.2. — end note]

4 A union-like class is a union or a class that has an anonymous union as a direct member. A union-like class X has a set of variant members. If X is a union, a non-static data member of X that is not an anonymous union is a variant member of X. In addition, a non-static data member of an anonymous union that is a member of X is also a variant member of X. At most one variant member of a union may have a default member initializer.

[Example 3:

```c
union U {
    int x = 0;
    union {
        int k;
    };
    union {
        int z;
        int y = 1; // error: initialization for second variant member of U
    };
};
```

— end example]

11.6 Local class declarations [class.local]

1 A class can be declared within a function definition; such a class is called a local class.

[Note 1: A declaration in a local class cannot odr-use (6.3) a local entity from an enclosing scope. — end note]

[Example 1:

```c
int x;
void f() {
    static int s;
    int x;
    const int N = 5;
    extern int q();
    int arr[2];
```
auto [y, z] = arr;

struct local {
    int g() { return x; } // error: odr-use of non-odr-usable variable x
    int h() { return s; } // OK
    int k() { return ::x; } // OK
    int l() { return q(); } // OK
    int m() { return N; } // OK, not an odr-use
    int* n() { return &N; } // error: odr-use of non-odr-usable variable N
    int p() { return y; } // error: odr-use of non-odr-usable structured binding y
};

local* p = 0; // error: local not found

—end example—

2 An enclosing function has no special access to members of the local class; it obeys the usual access rules (11.8). Member functions of a local class shall be defined within their class definition, if they are defined at all.

3 If class X is a local class a nested class Y may be declared in class X and later defined in the definition of class X or be later defined in the same scope as the definition of class X. A class nested within a local class is a local class.

4 [Note 2: A local class cannot have static data members (11.4.9.3). — end note]

11.7 Derived classes [class.derived]

11.7.1 General [class.derived.general]

1 A list of base classes can be specified in a class definition using the notation:

\[
\text{base-clause:}
\begin{align*}
&\text{base-specifier-list} \\
&\quad:\text{base-specifier-list} \\
&\quad\text{base-specifier} \quad\text{base-specifier-list} \quad\text{opt} \\
&\quad\text{base-specifier-list} \\
&\quad\text{opt}
\end{align*}
\]

\[
\begin{align*}
\text{base-specifier:} & \quad\text{attribute-specifier-seqopt class-or-decltype} \\
& \quad\text{attribute-specifier-seqopt virtual access-specifieropt class-or-decltype} \\
& \quad\text{attribute-specifier-seqopt access-specifier virtual opt class-or-decltype}
\end{align*}
\]

\[
\begin{align*}
\text{class-or-decltype:} & \quad\text{nested-name-specifieropt type-name} \\
& \quad\text{nested-name-specifier template simple-template-id} \\
& \quad\text{decltype-specifier}
\end{align*}
\]

\[
\begin{align*}
\text{access-specifier:} & \quad\text{private} \\
& \quad\text{protected} \\
& \quad\text{public}
\end{align*}
\]

The optional attribute-specifier-seq appertains to the base-specifier.

2 The component names of a class-or-decltype are those of its nested-name-specifier, type-name, and/or simple-template-id. A class-or-decltype shall denote a (possibly cv-qualified) class type that is not an incompletely defined class (11.4); any cv-qualifiers are ignored. The class denoted by the class-or-decltype of a base-specifier is called a direct base class for the class being defined. The lookup for the component name of the type-name or simple-template-id is type-only (6.5). A class B is a base class of a class D if it is a direct base class of D or a direct base class of one of D’s base classes. A class is an indirect base class of another if it is a base class but not a direct base class. A class is said to be (directly or indirectly) derived from its (direct or indirect) base classes.

[Note 1: See 11.8 for the meaning of access-specifier. — end note]

Members of a base class are also members of the derived class.

[Note 2: Constructors of a base class can be explicitly inherited (9.9). Base class members can be referred to in expressions in the same manner as other members of the derived class, unless their names are hidden or ambiguous (6.5.2). The scope resolution operator :: (7.5.4.3) can be used to refer to a direct or indirect base member

§ 11.7.1
explicitly, even if it is hidden in the derived class. A derived class can itself serve as a base class subject to access control; see 11.8.3. A pointer to a derived class can be implicitly converted to a pointer to an accessible unambiguous base class (7.3.12). An lvalue of a derived class type can be bound to a reference to an accessible unambiguous base class (9.4.4). — end note

The base-specifier-list specifies the type of the base class subobjects contained in an object of the derived class type.

Example 1:
```cpp
struct Base {
    int a, b, c;
};
struct Derived : Base {
    int b;
};
struct Derived2 : Derived {
    int c;
};
```
Here, an object of class Derived2 will have a subobject of class Derived which in turn will have a subobject of class Base. — end example]

A base-specifier followed by an ellipsis is a pack expansion (13.7.4).

The order in which the base class subobjects are allocated in the most derived object (6.7.2) is unspecified.

Note 3: A derived class and its base class subobjects can be represented by a directed acyclic graph (DAG) where an arrow means “directly derived from” (see Figure 3). An arrow need not have a physical representation in memory. A DAG of subobjects is often referred to as a “subobject lattice”. — end note]

A class can be derived from any number of base classes.

Example 1:
```cpp
class A { /* ... */ };
class B { /* ... */ };
class C { /* ... */ };
class D : public A, public B, public C { /* ... */ };
```
— end example]

A class shall not be specified as a direct base class of a derived class more than once.

Note 3: A class can be an indirect base class more than once and can be a direct and an indirect base class. There are limited things that can be done with such a class; lookup that finds its non-static data members and member
functions in the scope of the derived class will be ambiguous. However, the static members, enumerations and types can be unambiguously referred to. —end note]

[Example 2:

```cpp
    class X { /* ... */ };
    class Y : public X, public X { /* ... */ };
    // error
    class L { public: int next; /* ... */ };
    class A : public L { /* ... */ };
    class B : public L { /* ... */ };
    class C : public A, public B { void f(); /* ... */ };
    // well-formed
    class D : public A, public L { void f(); /* ... */ };
    // well-formed
```

—end example]

4 A base class specifier that does not contain the keyword virtual specifies a non-virtual base class. A base class specifier that contains the keyword virtual specifies a virtual base class. For each distinct occurrence of a non-virtual base class in the class lattice of the most derived class, the most derived object (6.7.2) shall contain a corresponding distinct base class subobject of that type. For each distinct base class that is specified virtual, the most derived object shall contain a single base class subobject of that type.

5 [Note 4: For an object of class type C, each distinct occurrence of a (non-virtual) base class L in the class lattice of C corresponds one-to-one with a distinct L subobject within the object of type C. Given the class C defined above, an object of class C will have two subobjects of class L as shown in Figure 4.

![Figure 4: Non-virtual base](fig:4:nonvirt)

In such lattices, explicit qualification can be used to specify which subobject is meant. The body of function C::f can refer to the member next of each L subobject:

```cpp
    void C::f() { A::next = B::next; }  // well-formed
```

Without the A:: or B:: qualifiers, the definition of C::f above would be ill-formed because of ambiguity (6.5.2). —end note]

6 [Note 5: In contrast, consider the case with a virtual base class:

```cpp
    class V { /* ... */ };
    class A : virtual public V { /* ... */ };
    class B : virtual public V { /* ... */ };
    class C : public A, public B { /* ... */ };
```

![Figure 5: Virtual base](fig:5:virt)

For an object c of class type C, a single subobject of type V is shared by every base class subobject of c that has a virtual base class of type V. Given the class C defined above, an object of class C will have one subobject of class V, as shown in Figure 5. —end note]
[Note 6: A class can have both virtual and non-virtual base classes of a given type.]

```cpp
class B { /* ... */ };  
class X : virtual public B { /* ... */ };  
class Y : virtual public B { /* ... */ };  
class Z : public B { /* ... */ };  
class AA : public X, public Y, public Z { /* ... */ };  
```

For an object of class AA, all **virtual** occurrences of base class B in the class lattice of AA correspond to a single B subobject within the object of type AA, and every other occurrence of a (non-virtual) base class B in the class lattice of AA corresponds one-to-one with a distinct B subobject within the object of type AA. Given the class AA defined above, class AA has two subobjects of class B: Z's B and the virtual B shared by X and Y, as shown in Figure 6.

![Figure 6: Virtual and non-virtual base](fig:virtnonvirt)

--- end note

### 11.7.3 Virtual functions

A non-static member function is a **virtual function** if it is first declared with the keyword `virtual` or if it overrides a virtual member function declared in a base class (see below).

[Note 1: Virtual functions support dynamic binding and object-oriented programming. — end note]

A class with a virtual member function is called a **polymorphic class**.

If a virtual member function F is declared in a class B, and, in a class D derived (directly or indirectly) from B, a declaration of a member function G corresponds (6.4.1) to a declaration of F, ignoring trailing `requires-clauses`, then G overrides F. For convenience we say that any virtual function overrides itself.

A virtual member function V of a class object S is a **final overrider** unless the most derived class (6.7.2) of which S is a base class subobject (if any) has another member function that overrides V. In a derived class, if a virtual member function of a base class subobject has more than one final overrider the program is ill-formed.

[Example 1:]

```cpp
struct A {  
    virtual void f();  
};  
struct B : virtual A {  
    virtual void f();  
};  
struct C : B, virtual A {  
    using A::f;  
};  

void foo() {  
    C c;  
    c.f();  // calls B::f, the final overrider  
    c.C::f();  // calls A::f because of the using-declaration  
}
```

--- end example

99) The use of the `virtual` specifier in the declaration of an overriding function is valid but redundant (has empty semantics).

100) If all virtual functions are immediate functions, the class is still polymorphic even if its internal representation does not otherwise require any additions for that polymorphic behavior.

101) A function with the same name but a different parameter list (Clause 12) as a virtual function is not necessarily virtual and does not override. Access control (11.8) is not considered in determining overriding.
Example 2:

```cpp
struct A { virtual void f(); }
struct B : A {};
struct C : A { void f(); }
struct D : B, C { }
    // OK, A::f and C::f are the final overriders
    // for the B and C subobjects, respectively
```

— end example

Note 2: A virtual member function does not have to be visible to be overridden, for example,

```cpp
struct B {
    virtual void f();
};
struct D : B {
    void f(int);
};
struct D2 : D {
    void f();
};
```

the function `f(int)` in class `D` hides the virtual function `f()` in its base class `B`; `D::f(int)` is not a virtual function. However, `f()` declared in class `D2` has the same name and the same parameter list as `B::f()`, and therefore is a virtual function that overrides the function `B::f()` even though `B::f()` is not visible in class `D2`. — end note

If a virtual function `f` in some class `B` is marked with the `virt-specifier final` and in a class `D` derived from `B` a function `D::f` overrides `B::f`, the program is ill-formed.

Example 3:

```cpp
struct B {
    virtual void f() const final;
};
struct D : B {
    void f() const; // error: D::f attempts to override final B::f
};
```

— end example

If a virtual function is marked with the `virt-specifier override` and does not override a member function of a base class, the program is ill-formed.

Example 4:

```cpp
struct B {
    virtual void f(int);
};
struct D : B {
    virtual void f(long) override; // error: wrong signature overriding B::f
    virtual void f(int) override; // OK
};
```

— end example

A virtual function shall not have a trailing `requires-clause` (9.3).

Example 5:

```cpp
template<typename T>
struct A {
    virtual void f() requires true; // error: virtual function cannot be constrained (13.5.3)
};
```

— end example

The `ref-qualifier`, or lack thereof, of an overriding function shall be the same as that of the overridden function.

The return type of an overriding function shall be either identical to the return type of the overridden function or `covariant` with the classes of the functions. If a function `D::f` overrides a function `B::f`, the return types of the functions are covariant if they satisfy the following criteria:
— both are pointers to classes, both are lvalue references to classes, or both are rvalue references to classes.

— the class in the return type of $B::f$ is the same class as the class in the return type of $D::f$, or is an unambiguous and accessible direct or indirect base class of the class in the return type of $D::f$

— both pointers or references have the same cv-qualification and the class type in the return type of $D::f$ has the same cv-qualification as or less cv-qualification than the class type in the return type of $B::f$.

If the class type in the covariant return type of $D::f$ differs from that of $B::f$, the class type in the return type of $D::f$ shall be complete at the locus (6.4.2) of the overriding declaration or shall be the class type $D$.

When the overriding function is called as the final overrider of the overridden function, its result is converted to the type returned by the (statically chosen) overridden function (7.6.1.3).

[Example 6:]

```cpp
class B { }

class D : private B { friend class Derived; }

struct Base {
    virtual void vf1();
    virtual void vf2();
    virtual void vf3();
    virtual B* vf4();
    virtual B* vf5();
    void f();
};

struct No_good : public Base {
    D* vf4();     // error: B (base class of D) inaccessible
};

class A;

struct Derived : public Base {
    void vf1();     // virtual and overrides Base::vf1
    void vf2(int);  // not virtual, hides Base::vf2
    char vf3();     // error: invalid difference in return type only
    D* vf4();      // OK, returns pointer to derived class
    A* vf5();      // error: returns pointer to incomplete class
    void f();
};

void g() {
    Derived d;
    Base* bp = &d;           // standard conversion:
    Derived* dp = &d;        // Derived* to Base*
    bp->vf1();               // calls Derived::vf1()
    bp->vf2();               // calls Base::vf2()
    bp->f();                 // calls Base::f() (not virtual)
    B* p = bp->vf4();        // calls Derived::vf4() and converts the
                             // result to B*
    Derived* dp = &d;
    D* q = dp->vf4();        // calls Derived::vf4() and does not
                             // convert the result to B*
    dp->vf2();               // error: argument mismatch
}
```

[Note 3: The interpretation of the call of a virtual function depends on the type of the object for which it is called (the dynamic type), whereas the interpretation of a call of a non-virtual member function depends only on the type of the pointer or reference denoting that object (the static type) (7.6.1.3). — end note]

[Note 4: The virtual specifier implies membership, so a virtual function cannot be a non-member (9.2.3) function. Nor can a virtual function be a static member, since a virtual function call relies on a specific object for determining which function to invoke. A virtual function declared in one class can be declared a friend (11.8.4) in another class. — end note]

[102] Multi-level pointers to classes or references to multi-level pointers to classes are not allowed.
A virtual function declared in a class shall be defined, or declared pure (11.7.4) in that class, or both; no diagnostic is required (6.3).

[Example 7: Here are some uses of virtual functions with multiple base classes:

```c
struct A {
  virtual void f();
};

struct B1 : A {
  // note non-virtual derivation
  void f();
};

struct B2 : A {
  void f();
};

struct D : B1, B2 {
  // D has two separate A subobjects
};
```

```c
void foo() {
  D d;
  // A* ap = &d; // would be ill-formed: ambiguous
  B1* b1p = &d;
  A* ap = b1p;
  D* dp = &d;
  ap->f(); // calls D::B1::f
  dp->f(); // error: ambiguous
}
```

In class `D` above there are two occurrences of class `A` and hence two occurrences of the virtual member function `A::f`. The final overrider of `B1::A::f` is `B1::f` and the final overrider of `B2::A::f` is `B2::f`. — end example]

[Example 8: The following example shows a function that does not have a unique final overrider:

```c
struct A {
  virtual void f();
};

struct VB1 : virtual A {
  // note virtual derivation
  void f();
};

struct VB2 : virtual A {
  void f();
};

struct Error : VB1, VB2 {
  // error
};

struct Okay : VB1, VB2 {
  void f();
};
```

Both `VB1::f` and `VB2::f` override `A::f` but there is no overrider of both of them in class `Error`. This example is therefore ill-formed. Class `Okay` is well-formed, however, because `Okay::f` is a final overrider. — end example]

[Example 9: The following example uses the well-formed classes from above:

```c
struct VB1a : virtual A {
  // does not declare f
};

struct Da : VB1a, VB2 {
};
```

```c
void foe() {
  VB1a* vblap = new Da;
  vblap->f(); /* calls VB2::f */
}
```

§ 11.7.3
Explicit qualification with the scope operator (7.5.4.3) suppresses the virtual call mechanism.

[Example 10:

```cpp
class B { public: virtual void f(); }
class D : public B { public: void f(); };

void D::f() { /* ... */ B::f(); }
```

Here, the function call in D::f really does call B::f and not D::f. — end example]

A deleted function (9.5) shall not override a function that is not deleted. Likewise, a function that is not deleted shall not override a deleted function.

A constexpr virtual function shall not override a virtual function that is not constexpr. A constexpr virtual function shall not be overridden by a virtual function that is not constexpr.

### 11.7.4 Abstract classes

1. [Note 1: The abstract class mechanism supports the notion of a general concept, such as a shape, of which only more concrete variants, such as circle and square, can actually be used. An abstract class can also be used to define an interface for which derived classes provide a variety of implementations. — end note]

2. A virtual function is specified as a pure virtual function by using a pure-specifier (11.4) in the function declaration in the class definition.

   [Note 2: Such a function might be inherited: see below. — end note]

3. A class is an abstract class if it has at least one pure virtual function.

   [Note 3: An abstract class can be used only as a base class of some other class; no objects of an abstract class can be created except as subobjects of a class derived from it (6.2, 11.4). — end note]

   A pure virtual function need be defined only if called with, or as if with (11.4.7), the qualified-id syntax (7.5.4.3).

   [Example 1:

   ```cpp
class point { /* ... */ };
class shape {
  // abstract class
  point center;
  public:
  point where() { return center; }
  void move(point p) { center=p; draw(); }
  virtual void rotate(int) = 0; // pure virtual
  virtual void draw() = 0; // pure virtual
};
```

   [Note 4: A function declaration cannot provide both a pure-specifier and a definition. — end note]

   [Example 2:

   ```cpp
   struct C {
     virtual void f() = 0 ;
   };
   ```

   [Note 5: An abstract class type cannot be used as a parameter or return type of a function being defined (9.3.4.6) or called (7.6.1.3), except as specified in 9.2.9.3. Further, an abstract class type cannot be used as the type of an explicit type conversion (7.6.1.9, 7.6.1.10, 7.6.1.11), because the resulting prvalue would be of abstract class type (7.2.1). However, pointers and references to abstract class types can appear in such contexts. — end note]

   A class is abstract if it has at least one pure virtual function for which the final overrider is pure virtual.

   [Example 3:

   ```cpp
class ab_circle : public shape {
  int radius;
  public:
  void rotate(int) {} //ab_circle::draw() is a pure virtual
};
```
Since `shape::draw()` is a pure virtual function, `ab_circle::draw()` is a pure virtual by default. The alternative declaration,

```cpp
class circle : public shape {
  int radius;
  public:
    void rotate(int) { }  // a definition is required somewhere
    void draw();
};
```

would make class `circle` non-abstract and a definition of `circle::draw()` must be provided. — end example

[Note 6: An abstract class can be derived from a class that is not abstract, and a pure virtual function can override a virtual function which is not pure. — end note]

Member functions can be called from a constructor (or destructor) of an abstract class; the effect of making a virtual call (11.7.3) to a pure virtual function directly or indirectly for the object being created (or destroyed) from such a constructor (or destructor) is undefined.

### 11.8 Member access control

#### 11.8.1 General

A member of a class can be

1. private, that is, it can be named only by members and friends of the class in which it is declared;
2. protected, that is, it can be named only by members and friends of the class in which it is declared, by classes derived from that class, and by their friends (see 11.8.5); or
3. public, that is, it can be named anywhere without access restriction.

[Note 1: A constructor or destructor can be named by an expression (6.3) even though it has no name. — end note]

A member of a class can also access all the members to which the class has access. A local class of a member function may access the same members that the member function itself may access.

Members of a class defined with the keyword `class` are private by default. Members of a class defined with the keywords `struct` or `union` are public by default.

[Example 1:

```cpp
class X {
  int a;  // X::a is private by default
};

struct S {
  int a;  // S::a is public by default
};

— end example]
```

Access control is applied uniformly to declarations and expressions.

[Note 2: Access control applies to members nominated by friend declarations (11.8.4) and using-declarations (9.9). — end note]

When a using-declarator is named, access control is applied to it, not to the declarations that replace it. For an overload set, access control is applied only to the function selected by overload resolution.

[Example 2:

```cpp
struct S {
  void f(int);
  private:
    void f(double);
};

void g(S* sp) {
  sp->f(2);  // OK, access control applied after overload resolution
}

— end example]
```

103 Access permissions are thus transitive and cumulative to nested and local classes.
[Note 3: Because access control applies to the declarations named, if access control is applied to a typedef-name, only the accessibility of the typedef or alias declaration itself is considered. The accessibility of the entity referred to by the typedef-name is not considered. For example,

```c++
class A {
    class B { };
    public:
        typedef B BB;
};

void f() {
    A::BB x; // OK, typedef is public
    A::B y;  // access error, typedef is private
}
```
—end note

5 [Note 4: Access control does not prevent members from being found by name lookup or implicit conversions to base classes from being considered. —end note]

The interpretation of a given construct is established without regard to access control. If the interpretation established makes use of inaccessible members or base classes, the construct is ill-formed.

6 All access controls in 11.8 affect the ability to name a class member from the declaration of a particular entity, including parts of the declaration preceding the name of the entity being declared and, if the entity is a class, the definitions of members of the class appearing outside the class's member-specification.

[Note 5: This access also applies to implicit references to constructors, conversion functions, and destructors. —end note]

7 [Example 3:

```c++
class A {
    typedef int I;    // private member
    I f();
    friend I g(I);
    static I x;
    template<int> struct Q;
    template<int> friend struct R;
    protected:
        struct B { };
};

A::I A::f() { return 0; }
A::I g(A::I p = A::x);
A::I g(A::I p) { return 0; }
A::I A::x = 0;
template<A::I> struct A::Q { };
template<A::I> struct R { };

struct D: A::B, A { };
```
Here, all the uses of A::I are well-formed because A::f, A::x, and A::Q are members of class A and g and R are friends of class A. This implies, for example, that access checking on the first use of A::I must be deferred until it is determined that this use of A::I is as the return type of a member of class A. Similarly, the use of A::B as a base-specifier is well-formed because D is derived from A, so checking of base-specifiers must be deferred until the entire base-specifier-list has been seen. —end example]

8 Access is checked for a default argument (9.3.4.7) at the point of declaration, rather than at any points of use of the default argument. Access checking for default arguments in function templates and in member functions of class templates is performed as described in 13.9.2.

9 Access for a default template-argument (13.2) is checked in the context in which it appears rather than at any points of use of it.

[Example 4:

```c++
class B { };
template <class T> class C {
    protected:
        typedef T TT;
```
template <class U, class V = typename U::TT>
class D : public U { };

D <C<B> >* d;  // access error, C::TT is protected
— end example]

11.8.2 Access specifiers

Member declarations can be labeled by an access-specifier (11.7):

access-specifier : member-specification_opt

An access-specifier specifies the access rules for members following it until the end of the class or until another access-specifier is encountered.

[Example 1:

class X {
    int a;  // X::a is private by default: class used
    public:
        int b;  // X::b is public
        int c;  // X::c is public
};
— end example]

Any number of access specifiers is allowed and no particular order is required.

[Example 2:

struct S {
    int a;  // S::a is public by default: struct used
    protected:
        int b;  // S::b is protected
    private:
        int c;  // S::c is private
    public:
        int d;  // S::d is public
};
— end example]

When a member is redeclared within its class definition, the access specified at its redeclaration shall be the same as at its initial declaration.

[Example 3:

struct S {
    class A;
    enum E : int;
    private:
        class A {};  // error: cannot change access
        enum E: int { e0 };  // error: cannot change access
};
— end example]

[Note 1: In a derived class, the lookup of a base class name will find the injected-class-name instead of the name of the base class in the scope in which it was declared. The injected-class-name might be less accessible than the name of the base class in the scope in which it was declared. — end note]

[Example 4:

class A { };
class B : private A { };
class C : public B {
    A* p;  // error: injected-class-name A is inaccessible
    ::A* q;  // OK
};
— end example]
11.8.3 Accessibility of base classes and base class members

If a class is declared to be a base class (11.7) for another class using the `public` access specifier, the public members of the base class are accessible as public members of the derived class and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the `protected` access specifier, the public and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the `private` access specifier, the public and protected members of the base class are accessible as private members of the derived class.

In the absence of an access-specifier for a base class, `public` is assumed when the derived class is defined with the class-key `struct` and `private` is assumed when the class is defined with the class-key `class`.

**Example 1:**

```cpp
class B { /* ... */ };  // B public by default
class D1 : private B { /* ... */ };  // B private by default
class D2 : public B { /* ... */ };  // B public by default
class D3 : B { /* ... */ };  // B private by default
struct D4 : public B { /* ... */ };  // B public by default
struct D5 : private B { /* ... */ };  // B private by default
class D6 : B { /* ... */ };  // B private by default
struct D7 : protected B { /* ... */ };  // B protected by default
struct D8 : protected B { /* ... */ };  // B protected by default
```

Here `B` is a public base of `D2`, `D4`, and `D6`, a private base of `D1`, `D3`, and `D5`, and a protected base of `D7` and `D8`. **— end example**

[A member of a private base class can be inaccessible as inherited, but accessible directly. Because of the rules on pointer conversions (7.3.12) and explicit casts (7.6.1.4, 7.6.1.9, 7.6.3), a conversion from a pointer to a derived class to a pointer to an inaccessible base class can be ill-formed if an implicit conversion is used, but well-formed if an explicit cast is used. For example,

```cpp
class B {
public:
    int mi;  // non-static member
    static int si;  // static member
};
class D : private B {
};
class DD : public D {
    void f();
};

void DD::f() {
    mi = 3;  // error: mi is private in D
    si = 3;  // error: si is private in D
    ::B b;
    b.mi = 3;  // OK (b.mi is different from this->mi)
    b.si = 3;  // OK (b.si is different from this->si)
    ::B::si = 3;  // OK
    ::B* bp1 = this;
    ::B* bp2 = (::B*)this;  // OK with cast
    bp2->mi = 3;  // OK, access through a pointer to B.
}
**— end note**
```

A base class `B` of `N` is accessible at `R`, if:

1. an invented public member of `B` would be a public member of `N`, or
2. `R` occurs in a direct member or friend of class `N`, and an invented public member of `B` would be a private or protected member of `N`, or
3. `R` occurs in a direct member or friend of a class `P` derived from `N`, and an invented public member of `B` would be a private or protected member of `P`, or

---

194) As specified previously in 11.8, private members of a base class remain inaccessible even to derived classes unless friend declarations within the base class definition are used to grant access explicitly.
there exists a class S such that B is a base class of S accessible at R and S is a base class of N accessible at R.

[Example 2:]
class B {  
public:  
    int m;  
};

class S: private B {  
    friend class N;  
};

class N: private S {  
    void f() {  
        B* p = this;  
        // OK because class S satisfies the fourth condition above: B is a base class of N  
        // accessible in f() because B is an accessible base class of S and S is an accessible  
        // base class of N.  
    }  
};

—end example]

If a base class is accessible, one can implicitly convert a pointer to a derived class to a pointer to that base class (7.3.12, 7.3.13).

[Note 2: It follows that members and friends of a class X can implicitly convert an X* to a pointer to a private or protected immediate base class of X. —end note]

The access to a member is affected by the class in which the member is named. This naming class is the class in whose scope name lookup performed a search that found the member.

[Note 3: This class can be explicit, e.g., when a qualified-id is used, or implicit, e.g., when a class member access operator (7.6.1.5) is used (including cases where an implicit “this->” is added). If both a class member access operator and a qualified-id are used to name the member (as in p->T::m), the class naming the member is the class denoted by the nested-name-specifier of the qualified-id (that is, T). —end note]

A member m is accessible at the point R when named in class N if

— m as a member of N is public, or
— m as a member of N is private, and R occurs in a direct member or friend of class N, or
— m as a member of N is protected, and R occurs in a direct member or friend of class N, or in a member of a class P derived from N, where m as a member of P is public, private, or protected, or
— there exists a base class B of N that is accessible at R, and m is accessible at R when named in class B.

[Example 3:]
class B;  
class A {  
    private:  
        int i;  
        friend void f(B*);  
    };  
class B: public A {  
};  
void f(B* p) {  
    p->i = 1;  
    // OK, B* can be implicitly converted to A*, and f has access to i in A  
}

—end example]

If a class member access operator, including an implicit “this->”, is used to access a non-static data member or non-static member function, the reference is ill-formed if the left operand (considered as a pointer in the “.” operator case) cannot be implicitly converted to a pointer to the naming class of the right operand.

[Note 4: This requirement is in addition to the requirement that the member be accessible as named. —end note]
11.8.4  Friends

A friend of a class is a function or class that is given permission to name the private and protected members of the class. A class specifies its friends, if any, by way of friend declarations. Such declarations give special access rights to the friends, but they do not make the nominated friends members of the befriending class.

[Example 1: The following example illustrates the differences between members and friends:

```cpp
class X {
   int a;
   friend void friend_set(X*, int);
public:
   void member_set(int);
};

void friend_set(X* p, int i) { p->a = i; }
void X::member_set(int i) { a = i; }

void f() {
   X obj;
   friend_set(&obj,10);
   obj.member_set(10);
}
```
—end example]

Declaring a class to be a friend implies that private and protected members of the class granting friendship can be named in the `base-specifiers` and member declarations of the befriended class.

[Example 2:

```cpp
class A {
   class B { };
   friend class X;
};

struct X : A::B {
   A::B mx;
   class Y {
      A::B my;
   };
};
```
—end example]

[Example 3:

```cpp
class X {
   enum { a=100 };
   friend class Y;
};

class Y {
   int v[X::a];
};

class Z {
   int v[X::a];
};
```
—end example]

A friend declaration that does not declare a function shall have one of the following forms:

```cpp
friend elaborated-type-specifier ;
friend simple-type-specifier ;
friend typename-specifier ;
```

[Note 1: A friend declaration can be the `declaration` in a `template-declaration` (13.1, 13.7.5). — end note]

If the type specifier in a friend declaration designates a (possibly cv-qualified) class type, that class is declared as a friend; otherwise, the friend declaration is ignored.

§ 11.8.4
Example 4:

class C;
typedef C Ct;

class X1 {
    friend C; // OK, class C is a friend
};

class X2 {
    friend Ct; // OK, class C is a friend
    friend D; // error: D not found
    friend class D; // OK, elaborated-type-specifier declares new class
};

template <typename T> class R {
    friend T;
};

R<C> rc; // class C is a friend of R<C>
R<int> R1; // OK, "friend int;" is ignored

—end example

4 A function first declared in a friend declaration has the linkage of the namespace of which it is a member (6.6). Otherwise, the function retains its previous linkage (9.2.2).

5 [Note 2: A friend declaration refers to an entity, not (all overloads of) a name. A member function of a class X can be a friend of a class Y.

Example 5:

class Y {
    friend char* X::foo(int);
    friend X::X(char); // constructors can be friends
    friend X::~X(); // destructors can be friends
};

—end example

—end note

6 A function may be defined in a friend declaration of a class if and only if the class is a non-local class (11.6) and the function name is unqualified.

Example 6:

class M {
    friend void f() {} // definition of global f, a friend of M,
    // not the definition of a member function
};

—end example

7 Such a function is implicitly an inline (9.2.8) function if it is attached to the global module.

[Note 3: If a friend function is defined outside a class, it is not in the scope of the class. — end note]

8 No storage-class-specifier shall appear in the decl-specifier-seq of a friend declaration.

9 A member nominated by a friend declaration shall be accessible in the class containing the friend declaration. The meaning of the friend declaration is the same whether the friend declaration appears in the private, protected, or public (11.4) portion of the class member-specification.

10 Friendship is neither inherited nor transitive.

Example 7:

class A {
    friend class B;
    int a;
};
class B {
    friend class C;
};

class C {
    void f(A* p) {
        p->a++;
        // error: C is not a friend of A despite being a friend of a friend
    }
};

class D : public B {
    void f(A* p) {
        p->a++;
        // error: D is not a friend of A despite being derived from a friend
    }
};
—end example

[Note 4: A friend declaration never binds any names (9.3.4, 9.2.9.4). — end note]

Example 8:

// Assume f and g have not yet been declared.
void h(int);
template <class T> void f2(T);
namespace A {
    class X {
        friend void f(X);
        // A::f(X) is a friend
class Y {
        friend void g();
        // A::g is a friend
        friend void h(int);
        // A::h is a friend
        // :h not considered
        friend void f2<(int) ;
        // ::f2<(int) is a friend
    };,
    // A::f, A::g and A::h are not visible here
    X x;
    void g() { f(x); }    // definition of A::g
    void f(X) { /* ... */ }    // definition of A::f
    void h(int) { /* ... */ }    // definition of A::h
    // A::f, A::g and A::h are visible here and known to be friends
    }
}

using A::x;

void h() {
    A::f(x);
    A::X::f(x);            // error: f is not a member of A::X
    A::X::Y::g();            // error: g is not a member of A::X::Y
}
—end example

Example 9:

class X;
void a();
void f() {
    class Y;
    extern void b();
    class A {
        friend class X;    // OK, but X is a local class, not ::X
        friend class Y;    // OK
        friend class Z;    // OK, introduces local class Z
        friend void a();    // error, ::a is not considered
        friend void b();    // OK
        friend void c();    // error
    }
11.8.5 Protected member access [class.protected]

An additional access check beyond those described earlier in 11.8 is applied when a non-static data member or non-static member function is a protected member of its naming class (11.8.3). As described earlier, access to a protected member is granted because the reference occurs in a friend or direct member of some class C. If the access is to form a pointer to member (7.6.2.2), the nested-name-specifier shall denote C or a class derived from C. All other accesses involve a (possibly implicit) object expression (7.6.1.5). In this case, the class of the object expression shall be C or a class derived from C.

[Example 1:

class B {
    protected:
        int i;
        static int j;
    };

class D1 : public B {
};

class D2 : public B {
    friend void fr(B*, D1*, D2*);
    void mem(B*, D1*);
};

void fr(B* pb, D1* p1, D2* p2) {
    pb->i = 1;  // error
    p1->i = 2;  // error
    p2->i = 3;  // OK (access through a D2)
    p2->B::i = 4; // OK (access through a D2, even though naming class is B)
    int B::* pmi_B = &B::i;
    int B::* pmi_B2 = &D2::i; // OK (type of &D2::i is int B::*)
    B::j = 5; // error: not a friend of naming class B
    D2::j = 6; // OK (because refers to static member)
}

void D2::mem(B* pb, D1* p1) {
    pb->i = 1;  // error
    p1->i = 2;  // error
    i = 3;  // OK (access through this)
    B::i = 4; // OK (access through this, qualification ignored)
    int B::* pmi_B = &B::i;
    int B::* pmi_B2 = &D2::i; // OK
    j = 5; // OK (because j refers to static member)
    B::j = 6; // OK (because B::j refers to static member)
}

void g(B* pb, D1* p1, D2* p2) {
    pb->i = 1;  // error
    p1->i = 2;  // error
    p2->i = 3;  // error
}
—end example]

105) This additional check does not apply to other members, e.g., static data members or enumerator member constants.
11.8.6 Access to virtual functions

The access rules (11.8) for a virtual function are determined by its declaration and are not affected by the rules for a function that later overrides it.

1

Example 1:

```cpp
class B {
public:
  virtual int f();
};

class D : public B {
private:
  int f();
};

void f() {
  D d;
  B* pb = &d;
  D* pd = &d;

  pb->f(); // OK, B::f() is public, D::f() is invoked
  pd->f(); // error: D::f() is private
}
```

—end example

2

Access is checked at the call point using the type of the expression used to denote the object for which the member function is called (B* in the example above). The access of the member function in the class in which it was defined (D in the example above) is in general not known.

11.8.7 Multiple access

If a declaration can be reached by several paths through a multiple inheritance graph, the access is that of the path that gives most access.

1

Example 1:

```cpp
class W { public: void f(); }; 
class A : private virtual W { }; 
class B : public virtual W { }; 
class C : public A, public B {
  void f() { W::f(); } // OK
};
```

Since W::f() is available to C::f() along the public path through B, access is allowed. —end example

11.8.8 Nested classes

A nested class is a member and as such has the same access rights as any other member. The members of an enclosing class have no special access to members of a nested class; the usual access rules (11.8) shall be obeyed.

1

Example 1:

```cpp
class E {
  int x;
  class B {
  
};

  class I {
    B b; // OK, E::I can access E::B
    int y;
    void f(E* p, int i) {
      p->x = i; // OK, E::I can access E::x
    }
  
};

  int g(I* p) {
    return p->y; // error: I::y is private
  }
```
11.9 Initialization

11.9.1 General

1. When no initializer is specified for an object of (possibly cv-qualified) class type (or array thereof), or the initializer has the form (), the object is initialized as specified in 9.4.

2. An object of class type (or array thereof) can be explicitly initialized; see 11.9.2 and 11.9.3.

3. When an array of class objects is initialized (either explicitly or implicitly) and the elements are initialized by constructor, the constructor shall be called for each element of the array, following the subscript order; see 9.3.4.5.

   [Note 1: Destructors for the array elements are called in reverse order of their construction.  — end note]

11.9.2 Explicit initialization

1. An object of class type can be initialized with a parenthesized expression-list, where the expression-list is construed as an argument list for a constructor that is called to initialize the object. Alternatively, a single assignment-expression can be specified as an initializer using the = form of initialization. Either direct-initialization semantics or copy-initialization semantics apply; see 9.4.

   [Example 1:
   
   struct complex {
       complex();
       complex(double);
       complex(double,double);
   };

   complex sqrt(complex,complex);

   complex a(1);      // initialized by calling complex(double) with argument 1
   complex b = a;     // initialized as a copy of a
   complex c = complex(1,2); // initialized by calling complex(double,double) with arguments 1 and 2
   complex d = sqrt(b,c); // initialized by calling sqrt(complex,complex) with d as its result object
   complex e;
   complex f = 3;      // initialized by calling complex(double) with argument 3
   complex g = { 1, 2 }; // initialized by calling complex(double, double) with arguments 1 and 2
   —end example]

   [Note 1: Overloading of the assignment operator (12.4.3.2) has no effect on initialization.  — end note]

2. An object of class type can also be initialized by a braced-init-list. List-initialization semantics apply; see 9.4 and 9.4.5.

   [Example 2:
   
   complex v[6] = { 1, complex(1,2), complex(), 2 }; 

   Here, complex::complex(double) is called for the initialization of v[0] and v[3], complex::complex(double, double) is called for the initialization of v[1], complex::complex() is called for the initialization of v[2], v[4], and v[5]. For another example,

   struct X {
       int i;
       float f;
       complex c;
   } x = { 99, 88.8, 77.7 }; 

   Here, x.i is initialized with 99, x.f is initialized with 88.8, and complex::complex(double) is called for the initialization of x.c.  — end example]

   [Note 2: Braces can be elided in the initializer-list for any aggregate, even if the aggregate has members of a class type with user-defined type conversions; see 9.4.2.  — end note]

3. [Note 3: If T is a class type with no default constructor, any declaration of an object of type T (or array thereof) is ill-formed if no initializer is explicitly specified (see 11.9 and 9.4).  — end note]
Note 4: The order in which objects with static or thread storage duration are initialized is described in 6.9.3.3 and 8.8. — end note

11.9.3 Initializing bases and members

In the definition of a constructor for a class, initializers for direct and virtual base class subobjects and non-static data members can be specified by a ctor-initializer, which has the form

```
cTOR-initializer:
  : mem-initializer-list
mem-initializer-list:
  mem-initializer . . . opt
  mem-initializer-list , mem-initializer . . . opt
mem-initializer:
  mem-initializer-id ( expression-list_opt )
  mem-initializer-id braced-init-list
mem-initializer-id:
  class-or-decltype identifier
```

1 Look up for an unqualified name in a mem-initializer-id ignores the constructor’s function parameter scope.

Note 1: If the constructor’s class contains a member with the same name as a direct or virtual base class of the class, a mem-initializer-id naming the member or base class and composed of a single identifier refers to the class member. A mem-initializer-id for the hidden base class can be specified using a qualified name. — end note

Unless the mem-initializer-id names the constructor’s class, a non-static data member of the constructor’s class, or a direct or virtual base of that class, the mem-initializer is ill-formed.

3 A mem-initializer-list can initialize a base class using any class-or-decltype that denotes that base class type.

Example 1:
```c
struct A { A(); };
typedef A global_A;
struct B { };
struct C: public A, public B { C(); };
C::C(): global_A() { } // mem-initializer for base A
```
— end example

4 If a mem-initializer-id is ambiguous because it designates both a direct non-virtual base class and an indirect virtual base class, the mem-initializer is ill-formed.

Example 2:
```c
struct A { A(); };
struct B: public virtual A { };
struct C: public A, public B { C(); };
C::C(): A() { } // error: which A?
```
— end example

5 A ctor-initializer may initialize a variant member of the constructor’s class. If a ctor-initializer specifies more than one mem-initializer for the same member or for the same base class, the ctor-initializer is ill-formed.

6 A mem-initializer-list can delegate to another constructor of the constructor’s class using any class-or-decltype that denotes the constructor’s class itself. If a mem-initializer-id designates the constructor’s class, it shall be the only mem-initializer; the constructor is a delegating constructor, and the constructor selected by the mem-initializer is the target constructor. The target constructor is selected by overload resolution. Once the target constructor returns, the body of the delegating constructor is executed. If a constructor delegates to itself directly or indirectly, the program is ill-formed, no diagnostic required.

Example 3:
```c
struct C {
  C( int ) { } // #1: non-delegating constructor
  C(): C(42) { } // #2: delegates to #1
  C( char c ) : C(42.0) { } // #3: ill-formed due to recursion with #4
  C( double d ) : C(‘a’) { } // #4: ill-formed due to recursion with #3
};
```
The expression-list or braced-init-list in a mem-initializer is used to initialize the designated subobject (or, in the case of a delegating constructor, the complete class object) according to the initialization rules of 9.4 for direct-initialization.

[Example 4:]

```c
struct B1 { B1(int); /* ... */
struct B2 { B2(int); /* ... */
struct D : B1, B2 {
    D(int);
    B1 b;
    const int c;
};
D::D(int a) : B2(a+1), B1(a+2), c(a+3), b(a+4) { /* ... */ }
D d(10);
```

—end example]

[Note 2: The initialization performed by each mem-initializer constitutes a full-expression (6.9.1). Any expression in a mem-initializer is evaluated as part of the full-expression that performs the initialization. — end note]

A mem-initializer where the mem-initializer-id denotes a virtual base class is ignored during execution of a constructor of any class that is not the most derived class.

8 A temporary expression bound to a reference member in a mem-initializer is ill-formed.

[Example 5:]

```c
struct A {
    A() : v(42) { } // error
    const int& v;
};
```

—end example]

In a non-delegating constructor other than an implicitly-defined copy/move constructor (11.4.5.3), if a given potentially constructed subobject is not designated by a mem-initializer-id (including the case where there is no mem-initializer-list because the constructor has no ctor-initializer), then

9 (9.1) — if the entity is a non-static data member that has a default member initializer (11.4) and either

(9.1.1) — the constructor’s class is a union (11.5), and no other variant member of that union is designated by a mem-initializer-id or

(9.1.2) — the constructor’s class is not a union, and, if the entity is a member of an anonymous union, no other member of that union is designated by a mem-initializer-id,

the entity is initialized from its default member initializer as specified in 9.4;

(9.2) — otherwise, if the entity is an anonymous union or a variant member (11.5.2), no initialization is performed;

(9.3) — otherwise, the entity is default-initialized (9.4).

[Note 3: An abstract class (11.7.4) is never a most derived class, thus its constructors never initialize virtual base classes, therefore the corresponding mem-initializers can be omitted. — end note]

An attempt to initialize more than one non-static data member of a union renders the program ill-formed.

[Note 4: After the call to a constructor for class X for an object with automatic or dynamic storage duration has completed, if the constructor was not invoked as part of value-initialization and a member of X is neither initialized nor given a value during execution of the compound-statement of the body of the constructor, the member has an indeterminate value. — end note]

[Example 6:]

```c
struct A {
    A();
};
```
struct B {
    B(int);
};

struct C {
    C() { } // initializes members as follows:
    A a; // OK, calls A::A()
    const B b; // error: B has no default constructor
    int i; // OK, i has indeterminate value
    int j = 5; // OK, j has the value 5
};

—end example]

10 If a given non-static data member has both a default member initializer and a mem-initializer, the initialization specified by the mem-initializer is performed, and the non-static data member’s default member initializer is ignored.

[Example 7: Given

struct A {
    int i = /* some integer expression with side effects */;
    A(int arg) : i(arg) { }
    // ...
};

the A(int) constructor will simply initialize i to the value of arg, and the side effects in i’s default member initializer will not take place. —end example]

11 A temporary expression bound to a reference member from a default member initializer is ill-formed.

[Example 8:

struct A {
    A() = default; // OK
    A(int v) : v(v) { } // OK
    const int& v = 42; // OK
};

A a1; // error: ill-formed binding of temporary to reference
A a2(1); // OK, unfortunately

—end example]

12 In a non-delegating constructor, the destructor for each potentially constructed subobject of class type is potentially invoked (11.4.7).

[Note 5: This provision ensures that destructors can be called for fully-constructed subobjects in case an exception is thrown (14.3). —end note]

13 In a non-delegating constructor, initialization proceeds in the following order:

(13.1) — First, and only for the constructor of the most derived class (6.7.2), virtual base classes are initialized in the order they appear on a depth-first left-to-right traversal of the directed acyclic graph of base classes, where “left-to-right” is the order of appearance of the base classes in the derived class base-specifier-list.

(13.2) — Then, direct base classes are initialized in declaration order as they appear in the base-specifier-list (regardless of the order of the mem-initializers).

(13.3) — Then, non-static data members are initialized in the order they were declared in the class definition (again regardless of the order of the mem-initializers).

(13.4) — Finally, the compound-statement of the constructor body is executed.

[Note 6: The declaration order is mandated to ensure that base and member subobjects are destroyed in the reverse order of initialization. —end note]

14 [Example 9:

struct V {
    V();
    V(int);
};

§ 11.9.3 317
struct A : virtual V {
    A();
    A(int);
};

struct B : virtual V {
    B();
    B(int);
};

struct C : A, B, virtual V {
    C();
    C(int);
};

A::A(int i) : V(i) { /* ... */ }
B::B(int i) { /* ... */ }
C::C(int i) { /* ... */ }

V v(1);        // use V(int)
A a(2);        // use V(int)
B b(3);        // use V()
C c(4);        // use V()

—end example]

[Note 7: The expression-list or braced-init-list of a mem-initializer is in the function parameter scope of the constructor and can use this to refer to the object being initialized. —end note]

[Example 10:]
class X {
    int a;
    int b;
    int i;
    int j;
public:
    const int& r;
    X(int i): r(a), b(i), i(i), j(this->i) { } 
};

initializes X::r to refer to X::a, initializes X::b with the value of the constructor parameter i, initializes X::i with the value of the constructor parameter i, and initializes X::j with the value of X::i; this takes place each time an object of class X is created. —end example]

16 Member functions (including virtual member functions, 11.7.3) can be called for an object under construction. Similarly, an object under construction can be the operand of the typeid operator (7.6.1.8) or of a dynamic_cast (7.6.1.7). However, if these operations are performed in a ctor-initializer (or in a function called directly or indirectly from a ctor-initializer) before all the mem-initializers for base classes have completed, the program has undefined behavior.

[Example 11:]
class A {
public:
    A(int);
};

class B : public A {
    int j;
public:
    int f();
    B() : A(f()), // undefined behavior: calls member function but base A not yet initialized
        j(f()) { } // well-defined: bases are all initialized
};
class C {
public:
    C(int);
};

class D : public B, C {
    int i;
public:
    D() : C(f()), // undefined behavior: calls member function but base C not yet initialized
        i(f()) { } // well-defined: bases are all initialized
};

—end example

17 [Note 8: 11.9.5 describes the results of virtual function calls, typeid and dynamic_casts during construction for the well-defined cases; that is, describes the polymorphic behavior of an object under construction. —end note]

18 A mem-initializer followed by an ellipsis is a pack expansion (13.7.4) that initializes the base classes specified by a pack expansion in the base-specifier-list for the class.

[Example 12:
   template<class... Mixins>
   class X : public Mixins... {
   public:
       X(const Mixins&... mixins) : Mixins(mixins)... { }
   }

   —end example]

11.9.4  Initialization by inherited constructor

[class.inhctor.init]

1 When a constructor for type B is invoked to initialize an object of a different type D (that is, when the constructor was inherited (9.9)), initialization proceeds as if a defaulted default constructor were used to initialize the D object and each base class subobject from which the constructor was inherited, except that the B subobject is initialized by the invocation of the inherited constructor. The complete initialization is considered to be a single function call; in particular, the initialization of the inherited constructor’s parameters is sequenced before the initialization of any part of the D object.

[Example 1:
   struct B1 {
       B1(int, ...) { }
   };

   struct B2 {
       B2(double) { }
   };

   int get();

   struct D1 : B1 {
       using B1::B1; // inherits B1(int, ...)
       int x;
       int y = get();
   };

   void test() {
       D1 d(2, 3, 4); // OK, B1 is initialized by calling B1(2, 3, 4),
                     // then d.x is default-initialized (no initialization is performed),
                     // then d.y is initialized by calling get()
       D1 e; // error: D1 has no default constructor
   }

   struct D2 : B2 {
       using B2::B2;
       B1 b;
   };

§ 11.9.4 319
D2 f(1.0);    // error: B1 has no default constructor

struct W { W(int); };  
struct X : virtual W { using W::W; X() = delete; };  
struct Y : X { using X::X; };  
struct Z : Y, virtual W { using Y::Y; };  
Z z(0);  // OK, initialization of Y does not invoke default constructor of X

template<class T> struct Log : T {  
    using T::T;  // inherits all constructors from class T
    ~Log() { std::clog << "Destroying wrapper" << std::endl; }
};

Class template Log wraps any class and forwards all of its constructors, while writing a message to the standard log whenever an object of class Log is destroyed. —end example

2 If the constructor was inherited from multiple base class subobjects of type B, the program is ill-formed.

[Example 2:
 struct A { A(int); };  
struct B : A { using A::A; };  

struct C1 : B { using B::B; };  
struct C2 : B { using B::B; };  

struct D1 : C1, C2 {  
    using C1::C1;  
    using C2::C2;
};  

struct V1 : virtual B { using B::B; };  
struct V2 : virtual B { using B::B; };  

struct D2 : V1, V2 {  
    using V1::V1;  
    using V2::V2;
};  

D1 d1(0);    // error: ambiguous  
D2 d2(0);    // OK, initializes virtual B base class, which initializes the A base class
    // then initializes the V1 and V2 base classes as if by a defaulted default constructor

struct M { M(); M(int); };  
struct N : M { using M::M; };  
struct O : M {};  
struct P : N, O { using N::N; using O::O; };  
P p(0);  // OK, use M() to initialize N’s base class,  
        // use M() to initialize O’s base class
—end example]

3 When an object is initialized by an inherited constructor, initialization of the object is complete when the initialization of all subobjects is complete.

11.9.5 Construction and destruction [class.cdtor]

1 For an object with a non-trivial constructor, referring to any non-static member or base class of the object before the constructor begins execution results in undefined behavior. For an object with a non-trivial destructor, referring to any non-static member or base class of the object after the destructor finishes execution results in undefined behavior.

[Example 1:
 struct X { int i; };  
struct Y : X { Y(); };  // non-trivial  
struct A { int a; };  
struct B : public A { int j; Y y; };  // non-trivial

§ 11.9.5 320
extern B bobj;
B* pb = &bobj; // OK

int* p1 = &bobj.a; // undefined behavior: refers to base class member
int* p2 = &bobj.y.i; // undefined behavior: refers to member's member

A* pa = &bobj; // undefined behavior: upcast to a base class type
B bobj; // definition of bobj

extern X xobj;
int* p3 = &xobj.i; // OK, X is a trivial class
X xobj;

For another example,

struct W { int j;};
struct X : public virtual W { };
struct Y {
    int* p;
    X x;
    Y() : p(&x.j) { // undefined, x is not yet constructed
    }
};

—end example]

2 During the construction of an object, if the value of the object or any of its subobjects is accessed through a glvalue that is not obtained, directly or indirectly, from the constructor’s this pointer, the value of the object or subobject thus obtained is unspecified.

[Example 2]:

struct C;
void no_opt(C*);

struct C {
    int c;
    C() : c(0) { no_opt(this); }
};

const C cobj;

void no_opt(C* cptr) {
    int i = cobj.c * 100; // value of cobj.c is unspecified
    cptr->c = 1;
    cout << cobj.c * 100 // value of cobj.c is unspecified
          << '\n';
}

extern struct D d;
struct D {
    D(int a) : a(a), b(d.a) {}
    int a, b;
};
D d = D(1); // value of d.b is unspecified
—end example]

3 To explicitly or implicitly convert a pointer (a glvalue) referring to an object of class X to a pointer (reference) to a direct or indirect base class B of X, the construction of X and the construction of all of its direct or indirect bases that directly or indirectly derive from B shall have started and the destruction of these classes shall not have completed, otherwise the conversion results in undefined behavior. To form a pointer to (or access the value of) a direct non-static member of an object obj, the construction of obj shall have started and its destruction shall not have completed, otherwise the computation of the pointer value (or accessing the member value) results in undefined behavior.

[Example 3:

struct A { }
struct B : virtual A { };
struct C : B { };  
struct D : virtual A { D(A*); };  
struct X { X(A*); };  

struct E : C, D, X {
    E() : D(this),  
    // undefined behavior: upcast from E* to A* might use path E* → D* → A*  
    // but D is not constructed  
    // “D((C*)this)” would be defined: E* → C* is defined because E() has started,  
    // and C* → A* is defined because C is fully constructed  
    X(this) {}  
    // defined: upon construction of X, C/B/D/A sublattice is fully constructed  
};  

—end example

Member functions, including virtual functions (11.7.3), can be called during construction or destruction (11.9.3). When a virtual function is called directly or indirectly from a constructor or from a destructor, including during the construction or destruction of the class’s non-static data members, and the object to which the call applies is the object (call it \(x\)) under construction or destruction, the function called is the final overrider in the constructor’s or destructor’s class and not one overriding it in a more-derived class. If the virtual function call uses an explicit class member access (7.6.1.5) and the object expression refers to the complete object of \(x\) or one of that object’s base class subobjects but not \(x\) or one of its base class subobjects, the behavior is undefined.

[Example 4:]

```c
struct V {
    virtual void f();  
    virtual void g();  
};

struct A : virtual V {
    virtual void f();  
};

struct B : virtual V {
    virtual void g();  
    B(V*, A*);  
};

struct D : A, B {
    virtual void f();  
    virtual void g();  
    D() : B((A*)this, this) { }  
};

B::B(V* v, A* a) {  
    f();  
    // calls V::f, not A::f  
    g();  
    // calls B::g, not D::g  
    v->g();  
    // v is base of B, the call is well-defined, calls B::g  
    a->f();  
    // undefined behavior: a’s type not a base of B  
}
```

—end example

The `typeid` operator (7.6.1.8) can be used during construction or destruction (11.9.3). When `typeid` is used in a constructor (including the `mem-initializer` or default member initializer (11.4) for a non-static data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of `typeid` refers to the object under construction or destruction, `typeid` yields the `std::type_info` object representing the constructor or destructor’s class. If the operand of `typeid` refers to the object under construction or destruction and the static type of the operand is neither the constructor or destructor’s class nor one of its bases, the behavior is undefined.

`dynamic_cast` (7.6.1.7) can be used during construction or destruction (11.9.3). When a `dynamic_cast` is used in a constructor (including the `mem-initializer` or default member initializer for a non-static data member)
or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the
operand of the \texttt{dynamic
cast} refers to the object under construction or destruction, this object is considered
to be a most derived object that has the type of the constructor or destructor’s class. If the operand of the
\texttt{dynamic
cast} refers to the object under construction or destruction and the static type of the operand is
not a pointer to or object of the constructor or destructor’s own class or one of its bases, the \texttt{dynamic
cast} results in undefined behavior.

\textbf{Example 5:}

\begin{verbatim}
struct V {
    virtual void f();
};

struct A : virtual V {};

struct B : virtual V {
    B(V*, A*);
};

struct D : A, B {
    D() : B((A*)this, this) { }
};

B::B(V* v, A* a) {
    typeid(*this);
    // type_info for B
    typeid(*v);
    // well-defined: *v has type V, a base of B yields type_info for B
    typeid(*a);
    // undefined behavior: type A not a base of B
    dynamic_cast<B*>(v);
    // well-defined: v of type V*, V base of B results in B*
    dynamic_cast<B*>(a);
    // undefined behavior: a has type A*, A not a base of B
}
\end{verbatim}

\textit{— end example}
unchanged except for the execution of constructors and destructors for the object declared by the exception-declaration.

[Note 1: There cannot be a move from the exception object because it is always an lvalue. — end note]

Copy elision is not permitted where an expression is evaluated in a context requiring a constant expression (7.7) and in constant initialization (6.9.3.2).

[Note 2: It is possible that copy elision is performed if the same expression is evaluated in another context. — end note]

2 [Example 1:

```cpp
class Thing {
public:
    Thing();
    ~Thing();
    Thing(const Thing&);
};

Thing t() {
    Thing t;
    return t;
}

Thing t2 = t();

struct A {
    void *p;
    constexpr A(): p(this) {} // well-formed, a.p points to a
};

constexpr A a; // well-formed, a.p points to a
constexpr A b = g(); // error: b.p would be dangling (7.7)

void h() {
    A c = g(); // well-formed, c.p can point to c or be dangling
}
```

Here the criteria for elision can eliminate the copying of the object `t` with automatic storage duration into the result object for the function call `f()`, which is the non-local object `t2`. Effectively, the construction of `t` can be viewed as directly initializing `t2`, and that object’s destruction will occur at program exit. Adding a move constructor to `Thing` has the same effect, but it is the move construction from the object with automatic storage duration to `t2` that is elided. — end example]

3 [Example 2:

```cpp
class Thing {
public:
    Thing();
    ~Thing();
    Thing(Thing&&); // well-formed, a.p points to a
private:
    Thing(const Thing&);
};

Thing t(bool b) {
    Thing t;
    if (b)
        throw t; // OK, Thing(Thing&&) used (or elided) to throw t
    return t; // OK, Thing(Thing&&) used (or elided) to return t
}
Thing t2 = f(false); // OK, no extra copy/move performed, t2 constructed by call to f

struct Weird {
    Weird();
    Weird(Weird&);
};

Weird g(bool b) {
    static Weird w1;
    Weird w2;
    if (b)
        return w1; // OK, uses Weird(Weird&)
    else
        return w2; // error: w2 in this context is an xvalue
}

int& h(bool b, int i) {
    static int s;
    if (b)
        return s; // OK
    else
        return i; // error: i is an xvalue
}

decltype(auto) h2(Thing t) {
    return t; // OK, t is an xvalue and h2's return type is Thing
}

decltype(auto) h3(Thing t) {
    return (t); // OK, (t) is an xvalue and h3's return type is Thing&&
} — end example

[Example 3:

```cpp
template<class T> void g(const T&);

template<class T> void f() {
    T x;
    try {
        T y;
        try { g(x); }
        catch (...) {
            if (/*...*/)
                throw x; // does not move
            throw y; // moves
        }
        g(y);
    } catch(...) {
        g(x);
        g(y); // error: y is not in scope
    }
} — end example
```

11.10 Comparisons [class.compare]

11.10.1 Defaulted comparison operator functions [class.compare.default]

A defaulted comparison operator function (12.4.3) for some class C shall be a non-template function that is

1. a non-static member or friend of C and
2. either has two parameters of type `const C&` or two parameters of type C, where the implicit object parameter (if any) is considered to be the first parameter.
Name lookups in the implicit definition (9.5.2) of a comparison operator function are performed from a context equivalent to its function-body. A definition of a comparison operator as defaulted that appears in a class shall be the first declaration of that function.

2 A defaulted $\llcorner\llcorner$ or $\llcorner\llcorner$ operator function for class $C$ is defined as deleted if any non-static data member of $C$ is of reference type or $C$ has variant members (11.5.2).

3 A binary operator expression $a \oplus b$ is usable if either

\begin{itemize}
  \item $a$ or $b$ is of class or enumeration type and overload resolution (12.2) as applied to $a \oplus b$ results in a usable candidate, or
  \item neither $a$ nor $b$ is of class or enumeration type and $a \oplus b$ is a valid expression.
\end{itemize}

4 If the member-specification does not explicitly declare any member or friend named operator$==$, an $==$ operator function is declared implicitly for each three-way comparison operator function defined as defaulted in the member-specification, with the same access and function-definition and in the same class scope as the respective three-way comparison operator function, except that the return type is replaced with bool and the declarator-id is replaced with operator$==$.

[Note 1: Such an implicitly-declared $==$ operator for a class $X$ is defined as defaulted in the definition of $X$ and has the same parameter-declaration-clause and trailing requires-clause as the respective three-way comparison operator. It is declared with friend, virtual, constexpr, or consteval if the three-way comparison operator function is so declared. If the three-way comparison operator function has no noexcept-specifier, the implicitly-declared $==$ operator function has an implicit exception specification (14.5) that can differ from the implicit exception specification of the three-way comparison operator function. —end note]

[Example 1:

```cpp
template<
  typename T>
struct X {
  friend constexpr bool operator==(const X&) const = default;
  // implicitly declares: friend constexpr bool operator==(X, X) const = default;

  [[nodiscard]] virtual std::strong_ordering operator<=>(const X&) const = default;
  // implicitly declares: [[nodiscard]] virtual std::strong_ordering operator<=>(const X&, const X&) = default;
};

// OK, returns x.i == y.i
```]

[Note 2: The $==$ operator function is declared implicitly even if the defaulted three-way comparison operator function is defined as deleted. —end note]

5 The direct base class subobjects of $C$, in the order of their declaration in the base-specifier-list of $C$, followed by the non-static data members of $C$, in the order of their declaration in the member-specification of $C$, form a list of subobjects. In that list, any subobject of array type is recursively expanded to the sequence of its elements, in the order of increasing subscript. Let $x_i$ be an lvalue denoting the $i^{th}$ element in the expanded list of subobjects for an object $x$ (of length $n$), where $x_i$ is formed by a sequence of derived-to-base conversions (12.2.4.2), class member access expressions (7.6.1.5), and array subscript expressions (7.6.1.2) applied to $x$.

### 11.10.2 Equality operator

[class.eq]

1 A defaulted equality operator function (12.4.3) shall have a declared return type bool.

2 A defaulted $==$ operator function for a class $C$ is defined as deleted unless, for each $x_i$ in the expanded list of subobjects for an object $x$ of type $C$, $x_i == x_i$ is usable (11.10.1).

3 The return value $V$ of a defaulted $==$ operator function with parameters $x$ and $y$ is determined by comparing corresponding elements $x_i$ and $y_i$ in the expanded lists of subobjects for $x$ and $y$ (in increasing index order) until the first index $i$ where $x_i == y_i$ yields a result value which, when contextually converted to bool, yields false. If no such index exists, $V$ is true. Otherwise, $V$ is false.

[Example 1:

```cpp
struct D {
  int i;
  friend bool operator==(const D& x, const D& y) = default;
  // OK, returns x.i == y.i
};
```]
11.10.3 Three-way comparison

The synthesized three-way comparison of type \( R \) (17.11.2) of glvalues \( a \) and \( b \) of the same type is defined as follows:

(1.1) If \( a \leftrightarrow b \) is usable (11.10.1) and can be explicitly converted to \( R \) using `static_cast`, `static_cast<R>(a \leftrightarrow b)`.

(1.2) Otherwise, if overload resolution for \( a \leftrightarrow b \) is performed and finds at least one viable candidate, the synthesized three-way comparison is not defined.

(1.3) Otherwise, if \( R \) is not a comparison category type, or either the expression \( a == b \) or the expression \( a < b \) is not usable, the synthesized three-way comparison is not defined.

(1.4) Otherwise, if \( R \) is `strong_ordering`, then

\[
\begin{align*}
& a == b \ ? \ `strong_ordering::equal` : \\
& a < b \ ? \ `strong_ordering::less` : \\
& \quad \ `strong_ordering::greater`
\end{align*}
\]

(1.5) Otherwise, if \( R \) is `weak_ordering`, then

\[
\begin{align*}
& a == b \ ? \ `weak_ordering::equivalent` : \\
& a < b \ ? \ `weak_ordering::less` : \\
& \quad \ `weak_ordering::greater`
\end{align*}
\]

(1.6) Otherwise (when \( R \) is `partial_ordering`),

\[
\begin{align*}
& a == b \ ? \ `partial_ordering::equivalent` : \\
& a < b \ ? \ `partial_ordering::less` : \\
& b < a \ ? \ `partial_ordering::greater` : \\
& \quad \ `partial_ordering::unordered`
\end{align*}
\]

[Note 1: A synthesized three-way comparison is ill-formed if overload resolution finds usable candidates that do not otherwise meet the requirements implied by the defined expression. —end note]

2 Let \( R \) be the declared return type of a defaulted three-way comparison operator function, and let \( x_i \) be the elements of the expanded list of subobjects for an object \( x \) of type \( C \).

(2.1) If \( R \) is `auto`, then let \( cv_i \), \( R_i \) be the type of the expression \( x_i \leftrightarrow x_j \). The operator function is defined as deleted if that expression is not usable or if \( R_i \) is not a comparison category type (17.11.2.1) for any \( i \). The return type is deduced as the common comparison type (see below) of \( R_0, R_1, \ldots, R_{n-1} \).

(2.2) Otherwise, \( R \) shall not contain a placeholder type. If the synthesized three-way comparison of type \( R \) between any objects \( x_i \) and \( x_j \) is not defined, the operator function is defined as deleted.

3 The return value \( V \) of type \( R \) of the defaulted three-way comparison operator function with parameters \( x \) and \( y \) of the same type is determined by comparing corresponding elements \( x_i \) and \( y_i \) in the expanded lists of subobjects for \( x \) and \( y \) (in increasing index order) until the first index \( i \) where the synthesized three-way comparison of type \( R \) between \( x_i \) and \( y_i \) yields a result value \( v_i \) where \( v_i \neq 0 \), contextually converted to `bool`, yields `true`; \( V \) is a copy of \( v_i \). If no such index exists, \( V \) is `static_cast<R>(std::strong_ordering::equal)`.

4 The common comparison type `U` of a possibly-empty list of \( n \) comparison category types `T_0`, `T_1`, \ldots, `T_{n-1}` is defined as follows:

(4.1) If at least one `T_i` is `std::partial_ordering`, `U` is `std::partial_ordering` (17.11.2.2).

(4.2) Otherwise, if at least one `T_i` is `std::weak_ordering`, `U` is `std::weak_ordering` (17.11.2.3).

(4.3) Otherwise, `U` is `std::strong_ordering` (17.11.2.4).

[Note 2: In particular, this is the result when \( n = 0 \). —end note]

11.10.4 Secondary comparison operators

A secondary comparison operator is a relational operator (7.6.9) or the `!=` operator. A defaulted operator function (12.4.3) for a secondary comparison operator `@` shall have a declared return type `bool`.

2 The operator function with parameters \( x \) and \( y \) is defined as deleted if

(2.1) overload resolution (12.2), as applied to \( x \@ y \), does not result in a usable candidate, or

(2.2) the candidate selected by overload resolution is not a rewritten candidate.

Otherwise, the operator function yields \( x \@ y \). The defaulted operator function is not considered as a candidate in the overload resolution for the `@` operator.
Example 1:

```cpp
struct HasNoLessThan {};

struct C {
    friend HasNoLessThan operator<=>(const C&, const C&);
    bool operator<(const C&) const = default;       // OK, function is deleted
};
```

— end example]
12 Overloading

12.1 Preamble

[Note 1: Each of two or more entities with the same name in the same scope, which must be functions or function templates, is commonly called an “overload”. — end note]

When a function is named in a call, which function declaration is being referenced and the validity of the call are determined by comparing the types of the arguments at the point of use with the types of the parameters in the declarations in the overload set. This function selection process is called overload resolution and is defined in 12.2.

Example 1:

```cpp
double abs(double);
int abs(int);
abs(1); // calls abs(int);
abs(1.0); // calls abs(double);
```

— end example

12.2 Overload resolution

12.2.1 General

Overload resolution is a mechanism for selecting the best function to call given a list of expressions that are to be the arguments of the call and a set of candidate functions that can be called based on the context of the call. The selection criteria for the best function are the number of arguments, how well the arguments match the parameter-type-list of the candidate function, how well (for non-static member functions) the object matches the object parameter, and certain other properties of the candidate function.

[Note 1: The function selected by overload resolution is not guaranteed to be appropriate for the context. Other restrictions, such as the accessibility of the function, can make its use in the calling context ill-formed. — end note]

Overload resolution selects the function to call in seven distinct contexts within the language:

1. invocation of a function named in the function call syntax (12.2.2.2);
2. invocation of a function call operator, a pointer-to-function conversion function, a reference-to-pointer-to-function conversion function, or a reference-to-function conversion function on a class object named in the function call syntax (12.2.2.3);
3. invocation of the operator referenced in an expression (12.2.2.3);
4. invocation of a constructor for default- or direct-initialization (9.4) of a class object (12.2.2.4);
5. invocation of a user-defined conversion for copy-initialization (9.4) of a class object (12.2.2.5);
6. invocation of a conversion function for initialization of an object of a non-class type from an expression of class type (12.2.2.6); and
7. invocation of a conversion function for conversion in which a reference (9.4.4) will be directly bound (12.2.2.7).

Each of these contexts defines the set of candidate functions and the list of arguments in its own unique way. But, once the candidate functions and argument lists have been identified, the selection of the best function is the same in all cases:

1. First, a subset of the candidate functions (those that have the proper number of arguments and meet certain other conditions) is selected to form a set of viable functions (12.2.3).
2. Then the best viable function is selected based on the implicit conversion sequences (12.2.4.2) needed to match each argument to the corresponding parameter of each viable function.

If a best viable function exists and is unique, overload resolution succeeds and produces it as the result. Otherwise overload resolution fails and the invocation is ill-formed. When overload resolution succeeds, and the best viable function is not accessible (11.8) in the context in which it is used, the program is ill-formed.
Overload resolution results in a *usable candidate* if overload resolution succeeds and the selected candidate is either not a function (12.5), or is a function that is not deleted and is accessible from the context in which overload resolution was performed.

### 12.2.2 Candidate functions and argument lists

#### 12.2.2.1 General

The subclauses of 12.2.2 describe the set of candidate functions and the argument list submitted to overload resolution in each context in which overload resolution is used. The source transformations and constructions defined in these subclauses are only for the purpose of describing the overload resolution process. An implementation is not required to use such transformations and constructions.

The set of candidate functions can contain both member and non-member functions to be resolved against the same argument list. If a member function is

1. an implicit object member function that is not a constructor, or
2. a static member function and the argument list includes an implied object argument,

it is considered to have an extra first parameter, called the *implicit object parameter*, which represents the object for which the member function has been called.

Similarly, when appropriate, the context can construct an argument list that contains an *implied object argument* as the first argument in the list to denote the object to be operated on.

For implicit object member functions, the type of the implicit object parameter is

1. “lvalue reference to `cv X`” for functions declared without a *ref-qualifier* or with the `&` *ref-qualifier*
2. “rvalue reference to `cv X`” for functions declared with the `&&` *ref-qualifier*

where X is the class of which the function is a member and cv is the cv-qualification on the member function declaration.

[Example 1: For a const member function of class X, the extra parameter is assumed to have type “lvalue reference to const X”. — end example]

For conversion functions that are implicit object member functions, the function is considered to be a member of the class of the implied object argument for the purpose of defining the type of the implicit object parameter. For non-conversion functions that are implicit object member functions nominated by a *using-declaration* in a derived class, the function is considered to be a member of the derived class for the purpose of defining the type of the implicit object parameter. For static member functions, the implicit object parameter is considered to match any object (since if the function is selected, the object is discarded).

[Note 1: No actual type is established for the implicit object parameter of a static member function, and no attempt will be made to determine a conversion sequence for that parameter (12.2.4). — end note]

During overload resolution, the implied object argument is indistinguishable from other arguments. The implicit object parameter, however, retains its identity since no user-defined conversions can be applied to achieve a type match with it. For implicit object member functions declared without a *ref-qualifier*, even if the implicit object parameter is not const-qualified, an rvalue can be bound to the parameter as long as in all other respects the argument can be converted to the type of the implicit object parameter.

[Note 2: The fact that such an argument is an rvalue does not affect the ranking of implicit conversion sequences (12.2.4.3). — end note]

Because other than in list-initialization only one user-defined conversion is allowed in an implicit conversion sequence, special rules apply when selecting the best user-defined conversion (12.2.4, 12.2.4.2).
In each case where conversion functions of a class \( S \) are considered for initializing an object or reference of type \( T \), the candidate functions include the result of a search for the conversion-function-id operator \( T \) in \( S \).

[Note 3: This search can find a specialization of a conversion function template (6.5). — end note]

Each such case also defines sets of permissible types for explicit and non-explicit conversion functions; each (non-template) conversion function that

(7.1) — is a non-hidden member of \( S \),

(7.2) — yields a permissible type, and,

(7.3) — for the former set, is non-explicit

is also a candidate function. If initializing an object, for any permissible type \( cv\ U \), any \( cv2\ U \), \( cv2\ U\& \), or \( cv2\ U&& \) is also a permissible type. If the set of permissible types for explicit conversion functions is empty, any candidates that are explicit are discarded.

In each case where a candidate is a function template, candidate function template specializations are generated using template argument deduction (13.10.4, 13.10.3). If a constructor template or conversion function template has an explicit-specifier whose constant-expression is value-dependent (13.8.3), template argument deduction is performed first and then, if the context admits only candidates that are not explicit and the generated specialization is explicit (9.2.3), it will be removed from the candidate set. Those candidates are then handled as candidate functions in the usual way.\(^{107}\) A given name can refer to, or a conversion can consider, one or more function templates as well as a set of non-template functions. In such a case, the candidate functions generated from each function template are combined with the set of non-template candidate functions.

A defaulted move special member function (11.4.5.3, 11.4.6) that is defined as deleted is excluded from the set of candidate functions in all contexts. A constructor inherited from class type \( C \) (11.9.4) that has a first parameter of type “reference to \( cv1\ P \)” (including such a constructor instantiated from a template) is excluded from the set of candidate functions when constructing an object of type \( cv2\ D \) if the argument list has exactly one argument and \( C \) is reference-related to \( P \) and \( P \) is reference-related to \( D \).

[Example 3:

```cpp
struct A {
    A(); // #1
    A(A&&); // #2
    template<typename T> A(T&&); // #3
};
struct B : A {
    using A::A;
    B(const B&); // #4
    B(B&&) = default; // #5, implicitly deleted
};
struct X { X(X&&) = delete; } x;
extern B b1;
B b2 = static_cast<B&&>(b1); // calls #4: #1 is not viable, #2, #3, and #5 are not candidates
struct C { operator B&&(); }; // calls #4
— end example]
```

12.2.2.2 Function call syntax

12.2.2.2.1 General

In a function call (7.6.1.3)

```
postfix-expression ( expression-list_opt )
```

\(^{107}\) The process of argument deduction fully determines the parameter types of the function template specializations, i.e., the parameters of function template specializations contain no template parameter types. Therefore, except where specified otherwise, function template specializations and non-template functions (9.3.4.6) are treated equivalently for the remainder of overload resolution.
if the *postfix-expression* names at least one function or function template, overload resolution is applied as specified in 12.2.2.2. If the *postfix-expression* denotes an object of class type, overload resolution is applied as specified in 12.2.2.3.

2 If the *postfix-expression* is the address of an overload set, overload resolution is applied using that set as described above.

[Note 1: No implied object argument is added in this case. — end note]

If the function selected by overload resolution is an implicit object member function, the program is ill-formed.

[Note 2: The resolution of the address of an overload set in other contexts is described in 12.3. — end note]

### 12.2.2.2.2 Call to named function

Of interest in 12.2.2.2.2 are only those function calls in which the *postfix-expression* ultimately contains an *id-expression* that denotes one or more functions. Such a *postfix-expression*, perhaps nested arbitrarily deep in parentheses, has one of the following forms:

- `postfix-expression:`
  - `postfix-expression . id-expression`
  - `postfix-expression -> id-expression`
  - `primary-expression`

These represent two syntactic subcategories of function calls: qualified function calls and unqualified function calls.

2 In qualified function calls, the function is named by an *id-expression* preceded by an `->` or `.` operator. Since the construct `A->B` is generally equivalent to `(A).B`, the rest of Clause 12 assumes, without loss of generality, that all member function calls have been normalized to the form that uses an object and the `.` operator. Furthermore, Clause 12 assumes that the *postfix-expression* that is the left operand of the `.` operator has type “cv T” where T denotes a class.\(^{108}\) The function declarations found by name lookup (6.5.2) constitute the set of candidate functions. The argument list is the *expression-list* in the call augmented by the addition of the left operand of the `.` operator in the normalized member function call as the implied object argument (12.2.2).

3 In unqualified function calls, the function is named by a *primary-expression*. The function declarations found by name lookup (6.5) constitute the set of candidate functions. Because of the rules for name lookup, the set of candidate functions consists either entirely of non-member functions or entirely of member functions of some class T. In the former case or if the *primary-expression* is the address of an overload set, the argument list is the same as the *expression-list* in the call. Otherwise, the argument list is the *expression-list* in the call augmented by the addition of an implied object argument as in a qualified function call. If the current class is, or is derived from, T, and the keyword **this** (7.5.2) refers to it, then the implied object argument is (**this**). Otherwise, a contrived object of type T becomes the implied object argument;\(^{109}\) if overload resolution selects a non-static member function, the call is ill-formed.

[Example 1:]

```cpp
struct C {
    void a();
    void b() {
        a(); // OK, (**this).a()
    }

    void c(this const C&); // #1
    void c&; // #2
    static void c(int = 0); // #3

    void d() {
        c(); // error: ambiguous between #2 and #3
        (C::c)(); // error: as above
        (&(C::c))(); // error: cannot resolve address of overloaded this->C::c (12.3)
        (&C::c)(C{}); // selects #1
        (&C::c)(**this); // error: selects #2, and is ill-formed (12.2.2.2.1)
    }
```

\(^{108}\) Note that cv-qualifiers on the type of objects are significant in overload resolution for both glvalue and class prvalue objects.

\(^{109}\) An implied object argument is contrived to correspond to the implicit object parameter attributed to member functions during overload resolution. It is not used in the call to the selected function. Since the member functions all have the same implicit object parameter, the contrived object will not be the cause to select or reject a function.
© ISO/IEC

12.2.2.2.3 Call to object of class type

If the postfix-expression \( E \) in the function call syntax evaluates to a class object of type “\( cv\ T \)”, then the set of candidate functions includes at least the function call operators of \( T \). The function call operators of \( T \) are the results of a search for the name `operator()` in the scope of \( T \).

In addition, for each non-explicit conversion function declared in \( T \) of the form

\[
\text{operator conversion-type-id () cv-qualifier-seq_opt ref-qualifier_opt noexcept-specifier_opt attribute-specifier-seq_opt} ;
\]

where the optional `cv-qualifier-seq` is the same `cv`-qualification as, or a greater `cv`-qualification than, `cv`, and where `conversion-type-id` denotes the type “pointer to function of \((P_1, \ldots, P_n)\) returning \( R \)”, or the type “reference to pointer to function of \((P_1, \ldots, P_n)\) returning \( R \)”, or the type “reference to function of \((P_1, \ldots, P_n)\) returning \( R \)”, a surrogate call function with the unique name `call-function` and having the form

\[
R \text{ call-function ( conversion-type-id F, P_1 a_1, \ldots, P_n a_n) { return F (a_1, \ldots, a_n); } }
\]

is also considered as a candidate function. Similarly, surrogate call functions are added to the set of candidate functions for each non-explicit conversion function declared in a base class of \( T \) provided the function is not hidden within \( T \) by another intervening declaration.

The argument list submitted to overload resolution consists of the argument expressions present in the function call syntax preceded by the implied object argument \((E)\).

[Note 1: When comparing the call against the function call operators, the implied object argument is compared against the object parameter of the function call operator. When comparing the call against a surrogate call function, the implied object argument is compared against the first parameter of the surrogate call function. — end note]

[Example 1:

```cpp
(int f1(int);
int f2(float);
typedef int (*fp1)(int);
typedef int (*fp2)(float);
struct A {
  operator fp1() { return f1; }
  operator fp2() { return f2; }
} a;
int i = a(1); // calls f1 via pointer returned from conversion function
```

— end example]

110) Note that this construction can yield candidate call functions that cannot be differentiated one from the other by overload resolution because they have identical declarations or differ only in their return type. The call will be ambiguous if overload resolution cannot select a match to the call that is uniquely better than such undifferentiable functions.
12.2.2.3 Operators in expressions

If no operand of an operator in an expression has a type that is a class or an enumeration, the operator is assumed to be a built-in operator and interpreted according to 7.6.

[Note 1: Because .. .*, and :: cannot be overloaded, these operators are always built-in operators interpreted according to 7.6. ?: cannot be overloaded, but the rules in this subclause are used to determine the conversions to be applied to the second and third operands when they have class or enumeration type (7.6.16). — end note]

[Example 1:

```cpp
struct String {
    String (const String&);
    String (const char*);
    operator const char* (){
    };
    String operator + (const String&, const String&);
}

void f() {
    const char* p = "one" + "two";  // error: cannot add two pointers; overloaded operator+ not considered
    int I = 1 + 1;  // always evaluates to 2 even if class or enumeration types exist
}
```
— end example]

If either operand has a type that is a class or an enumeration, a user-defined operator function can be declared that implements this operator or a user-defined conversion can be necessary to convert the operand to a type that is appropriate for a built-in operator. In this case, overload resolution is used to determine which operator function or built-in operator is to be invoked to implement the operator. Therefore, the operator notation is first transformed to the equivalent function-call notation as summarized in Table 18 (where @ denotes one of the operators covered in the specified subclause). However, the operands are sequenced in the order prescribed for the built-in operator (7.6).

3 For a unary operator @ with an operand of type cv1 T1, and for a binary operator @ with a left operand of type cv1 T1 and a right operand of type cv2 T2, four sets of candidate functions, designated member candidates, non-member candidates, built-in candidates, and rewritten candidates, are constructed as follows:

(3.1) — If T1 is a complete class type or a class currently being defined, the set of member candidates is the result of a search for operator@ in the scope of T1; otherwise, the set of member candidates is empty.

(3.2) — For the operators =, [], or ->, the set of non-member candidates is empty; otherwise, it includes the result of unqualified lookup for operator@ in the rewritten function call (6.5.3, 6.5.4), ignoring all member functions. However, if no operand has a class type, only those non-member functions in the lookup set that have a first parameter of type T1 or “reference to cv T1”, when T1 is an enumeration type, or (if there is a right operand) a second parameter of type T2 or “reference to cv T2”, when T2 is an enumeration type, are candidate functions.

(3.3) — For the operator , the unary operator & or the operator ->, the built-in candidates set is empty. For all other operators, the built-in candidates include all of the candidate operator functions defined in 12.5 that, compared to the given operator,

(3.3.1) — have the same operator name, and

(3.3.2) — accept the same number of operands, and
— accept operand types to which the given operand or operands can be converted according to 12.2.4.2, and

— do not have the same parameter-type-list as any non-member candidate or rewritten non-member candidate that is not a function template specialization.

— The rewritten candidate set is determined as follows:

— For the relational (7.6.9) operators, the rewritten candidates include all non-rewritten candidates for the expression \( x \ll y \).

— For the relational (7.6.9) and three-way comparison (7.6.8) operators, the rewritten candidates also include a synthesized candidate, with the order of the two parameters reversed, for each non-rewritten candidate for the expression \( y \ll x \).

— For the \(!=\) operator (7.6.10), the rewritten candidates include all non-rewritten candidates for the expression \( x == y \) that are rewrite targets with first operand \( x \) (see below).

— For the equality operators, the rewritten candidates also include a synthesized candidate, with the order of the two parameters reversed, for each non-rewritten candidate for the expression \( y == x \) that is a rewrite target with first operand \( y \).

— For all other operators, the rewritten candidate set is empty.

[Note 2: A candidate synthesized from a member candidate has its object parameter as the second parameter, thus implicit conversions are considered for the first, but not for the second, parameter. — end note]

4 A non-template function or function template \( F \) named \( \text{operator==} \) is a rewrite target with first operand \( o \) unless a search for the name \( \text{operator!=} \) in the scope \( S \) from the instantiation context of the operator expression finds a function or function template that would correspond (6.4.1) to \( F \) if its name were \( \text{operator==} \), where \( S \) is the scope of the class type of \( o \) if \( F \) is a class member, and the namespace scope of which \( F \) is a member otherwise. A function template specialization named \( \text{operator==} \) is a rewrite target if its function template is a rewrite target.

[Example 2:]

```cpp
struct A {}

// #1
bool a1 = 0 == A();
// OK, calls reversed #1

// #2
struct B {}

// #3
struct C : B {}

// #4
struct D {}

// #5
inline namespace N {

// #6
bool d1 = 0 == D();
// OK, calls reversed #4; #5 does not forbid #4 as a rewrite target
}
```

5 For the built-in assignment operators, conversions of the left operand are restricted as follows:

— no temporaries are introduced to hold the left operand, and

— no user-defined conversions are applied to the left operand to achieve a type match with the left-most parameter of a built-in candidate.
For all other operators, no such restrictions apply.

The set of candidate functions for overload resolution for some operator \( \oplus \) is the union of the member candidates, the non-member candidates, the built-in candidates, and the rewritten candidates for that operator \( \oplus \).

The argument list contains all of the operands of the operator. The best function from the set of candidate functions is selected according to 12.2.3 and 12.2.4.\(^{111} \)

Example 3:

```c
struct A {
    operator int();
};
A operator+(const A&, const A&);
void m() {
    A a, b;
    a + b; // operator+(a, b) chosen over int(a) + int(b)
}
```

Example 4:

```c
struct X {
    operator double();
};

struct Y {
    operator int*();
};

int *a = Y(); + 100.0; // error: pointer arithmetic requires integral operand
int *b = Y(); + X(); // error: pointer arithmetic requires integral operand
```

The second operand of operator \(-\rightarrow\) is ignored in selecting an \(\rightarrow\) function, and is not an argument when the \(\rightarrow\) function is called. When \(\rightarrow\) returns, the operator \(-\rightarrow\) is applied to the value returned, with the original second operand.\(^{112} \)

If the operator is the operator \(\&\), the unary operator \&, or the operator \(-\rightarrow\), and there are no viable functions, then the operator is assumed to be the built-in operator and interpreted according to 7.6.

Note 3: The lookup rules for operators in expressions are different than the lookup rules for operator function names in a function call, as shown in the following example:

```c
struct A { }
```

---

111) If the set of candidate functions is empty, overload resolution is unsuccessful.

112) If the value returned by the \(\rightarrow\) function has class type, this can result in selecting and calling another \(\rightarrow\) function. The process repeats until an \(\rightarrow\) function returns a value of non-class type.
void operator + (A, A);

struct B {
    void operator + (B);
    void f ();
};

A a;

void B::f() {
    operator+ (a,a);          // error: global operator hidden by member
    a + a;                    // OK, calls global operator+
}

—end note

12.2.2.4 Initialization by constructor [over.match.ctor]

1 When objects of class type are direct-initialized (9.4), copy-initialized from an expression of the same or a derived class type (9.4), or default-initialized (9.4), overload resolution selects the constructor. For direct-initialization or default-initialization that is not in the context of copy-initialization, the candidate functions are all the constructors of the class of the object being initialized. For copy-initialization (including default initialization in the context of copy-initialization), the candidate functions are all the converting constructors (11.4.8.2) of that class. The argument list is the expression-list or assignment-expression of the initializer.

12.2.2.5 Copy-initialization of class by user-defined conversion [over.match.copy]

1 Under the conditions specified in 9.4, as part of a copy-initialization of an object of class type, a user-defined conversion can be invoked to convert an initializer expression to the type of the object being initialized. Overload resolution is used to select the user-defined conversion to be invoked.

[Note 1: The conversion performed for indirect binding to a reference to a possibly cv-qualified class type is determined in terms of a corresponding non-reference copy-initialization. — end note]

Assuming that “cv1 T” is the type of the object being initialized, with T a class type, the candidate functions are selected as follows:

(1.1) — The converting constructors (11.4.8.2) of T are candidate functions.

(1.2) — When the type of the initializer expression is a class type “cv S”, conversion functions are considered. The permissible types for non-explicit conversion functions are T and any class derived from T. When initializing a temporary object (11.4) to be bound to the first parameter of a constructor where the parameter is of type “reference to cv2 T” and the constructor is called with a single argument in the context of direct-initialization of an object of type “cv3 T”, the permissible types for explicit conversion functions are the same; otherwise there are none.

2 In both cases, the argument list has one argument, which is the initializer expression.

[Note 2: This argument will be compared against the first parameter of the constructors and against the object parameter of the conversion functions. — end note]

12.2.2.6 Initialization by conversion function [over.match.conv]

1 Under the conditions specified in 9.4, as part of an initialization of an object of non-class type, a conversion function can be invoked to convert an initializer expression of class type to the type of the object being initialized. Overload resolution is used to select the conversion function to be invoked. Assuming that “cv T” is the type of the object being initialized, the candidate functions are selected as follows:

(1.1) — The permissible types for non-explicit conversion functions are those that can be converted to type T via a standard conversion sequence (12.2.4.2.2). For direct-initialization, the permissible types for explicit conversion functions are those that can be converted to type T with a (possibly trivial) qualification conversion (7.3.6); otherwise there are none.

2 The argument list has one argument, which is the initializer expression.

[Note 1: This argument will be compared against the object parameter of the conversion functions. — end note]
12.2.2.7 Initialization by conversion function for direct reference binding

Under the conditions specified in 9.4.4, a reference can be bound directly to the result of applying a conversion function to an initializer expression. Overload resolution is used to select the conversion function to be invoked. Assuming that “reference to cv1 T” is the type of the reference being initialized, the candidate functions are selected as follows:

1. Let \( R \) be a set of types including:
   - “lvalue reference to cv2 T2” (when initializing an lvalue reference or an rvalue reference to function)
   - “cv2 T2” and “rvalue reference to cv2 T2” (when initializing an rvalue reference or an lvalue reference to function)

for any T2. The permissible types for non-explicit conversion functions are the members of \( R \) where “cv1 T” is reference-compatible (9.4.4) with “cv2 T2”. For direct-initialization, the permissible types for explicit conversion functions are the members of \( R \) where T2 can be converted to type T with a (possibly trivial) qualification conversion (7.3.6); otherwise there are none.

The argument list has one argument, which is the initializer expression.

[Note 1: This argument will be compared against the object parameter of the conversion functions. — end note]

12.2.2.8 Initialization by list-initialization

When objects of non-aggregate class type T are list-initialized such that 9.4.5 specifies that overload resolution is performed according to the rules in this subclause or when forming a list-initialization sequence according to 12.2.4.2.6, overload resolution selects the constructor in two phases:

1. If the initializer list is not empty or T has no default constructor, overload resolution is first performed where the candidate functions are the initializer-list constructors (9.4.5) of the class T and the argument list consists of the initializer list as a single argument.

2. Otherwise, or if no viable initializer-list constructor is found, overload resolution is performed again, where the candidate functions are all the constructors of the class T and the argument list consists of the elements of the initializer list.

In copy-list-initialization, if an explicit constructor is chosen, the initialization is ill-formed.

[Note 1: This differs from other situations (12.2.2.4, 12.2.2.5), where only converting constructors are considered for copy-initialization. This restriction only applies if this initialization is part of the final result of overload resolution. — end note]

12.2.2.9 Class template argument deduction

When resolving a placeholder for a deduced class type (9.2.9.7) where the template-name names a primary class template C, a set of functions and function templates, called the guides of C, is formed comprising:

1. If C is defined, for each constructor of C, a function template with the following properties:
   - The template parameters are the template parameters of C followed by the template parameters (including default template arguments) of the constructor, if any.
   - The types of the function parameters are those of the constructor.
   - The return type is the class template specialization designated by C and template arguments corresponding to the template parameters of C.

2. If C is not defined or does not declare any constructors, an additional function template derived as above from a hypothetical constructor C().

3. An additional function template derived as above from a hypothetical constructor C(C), called the copy deduction candidate.

4. For each deduction-guide, a function or function template with the following properties:
   - The template parameters, if any, and function parameters are those of the deduction-guide.
   - The return type is the simple-template-id of the deduction-guide.

In addition, if C is defined and its definition satisfies the conditions for an aggregate class (9.4.2) with the assumption that any dependent base class has no virtual functions and no virtual base classes, and the initializer is a non-empty braced-init-list or parenthesized expression-list, and there are no deduction-guides.
for C, the set contains an additional function template, called the aggregate deduction candidate, defined as follows. Let \( x_1, \ldots, x_n \) be the elements of the initializer-list or designated-initializer-list of the braced-init-list, or of the expression-list. For each \( x_i \), let \( e_i \) be the corresponding aggregate element of C or of one of its (possibly recursive) subaggregates that would be initialized by \( x_i \) (9.4.2) if

1. brace elision is not considered for any aggregate element that has
   - a dependent non-array type,
   - an array type with a value-dependent bound, or
   - an array type with a dependent array element type and \( x_i \) is a string literal; and
2. each non-trailing aggregate element that is a pack expansion is assumed to correspond to no elements of the initializer list, and
3. a trailing aggregate element that is a pack expansion is assumed to correspond to all remaining elements of the initializer list (if any).

If there is no such aggregate element \( e_i \) for any \( x_i \), the aggregate deduction candidate is not added to the set.

The aggregate deduction candidate is derived as above from a hypothetical constructor \( C(T_1, \ldots, T_n) \), where

1. if \( e_i \) is of array type and \( x_i \) is a braced-init-list, \( T_i \) is an rvalue reference to the declared type of \( e_i \), and
2. if \( e_i \) is of array type and \( x_i \) is a string-literal, \( T_i \) is an lvalue reference to the const-qualified declared type of \( e_i \), and
3. otherwise, \( T_i \) is the declared type of \( e_i \),

except that additional parameter packs of the form \( P_j \ldots \) are inserted into the parameter list in their original aggregate element position corresponding to each non-trailing aggregate element of type \( P_j \) that was skipped because it was a parameter pack, and the trailing sequence of parameters corresponding to a trailing aggregate element that is a pack expansion (if any) is replaced by a single parameter of the form \( T_n, \ldots \). In addition, if C is defined and inherits constructors (9.9) from a direct base class denoted in the base-specifier-list by a class-or-decltype B, let A be an alias template whose template parameter list is that of C and whose defining-type-id is B. If A is a deducible template (9.2.9.3), the set contains the guides of A with the return type \( R \) of each guide replaced with \( \text{typename CC}<R>::\text{type} \) given a class template

\[
\text{template<typename T> class CC;}
\]

whose primary template is not defined and with a single partial specialization whose template parameter list is that of A and whose template argument list is a specialization of A with the template argument list of A (13.8.3.2) having a member typedef type designating a template specialization with the template argument list of A but with C as the template.

[Note 1: Equivalently, the template parameter list of the specialization is that of C, the template argument list of the specialization is B, and the member typedef names C with the template argument list of C. — end note]

Example 1:

```cpp
template<typename T> struct B {
  B(T);
};
template<typename T> struct C : public B<T> {
  using B<T>::B;
};
template<typename T> struct D : public B<T> {
};
C c(42); // OK, deduces C<int>
D d(42); // error: deduction failed, no inherited deduction guides
B<int> -> B<char>;
C c2(42); // OK, deduces C<char>
template<typename T> struct E : public B<int> {
  using B<int>::B;
};
E e(42); // error: deduction failed, arguments of E cannot be deduced from introduced guides
```
template <typename T, typename U, typename V> struct F {
    F(T, U, V);
};
template <typename T, typename U> struct G : F<U, T, int> {
    using G::F::F;
}
G g(true, 'a', 1);  // OK, deduces G<char, bool>

template<class T, std::size_t N> 
struct H {
    T array[N];
};
template<class T, std::size_t N> 
struct I {
    volatile T array[N];
};
template<std::size_t N> 
struct J {
    unsigned char array[N];
};
H h = { "abc" };  // OK, deduces H<char, 4> (not T = const char)
I i = { "def" };  // OK, deduces I<char, 4>
J j = { "ghi" };  // error: cannot bind reference to array of unsigned char to array of char in deduction

3 When resolving a placeholder for a deduced class type (9.2.9.3) where the template-name names an alias template A, the defining-type-id of A must be of the form
typename_opt nested-name-specifier_opt template_opt simple-template-id
as specified in 9.2.9.3. The guides of A are the set of functions or function templates formed as follows. For each function or function template f in the guides of the template named by the simple-template-id of the defining-type-id, the template arguments of the return type of f are deduced from the defining-type-id of A according to the process in 13.10.3.6 with the exception that deduction does not fail if not all template arguments are deduced. If deduction fails for another reason, proceed with an empty set of deduced template arguments. Let g denote the result of substituting these deductions into f. If substitution succeeds, form a function or function template f' with the following properties and add it to the set of guides of A:

(3.1) — The function type of f' is the function type of g.
(3.2) — If f is a function template, f' is a function template whose template parameter list consists of all the template parameters of A (including their default template arguments) that appear in the above deductions or (recursively) in their default template arguments, followed by the template parameters of f that were not deduced (including their default template arguments), otherwise f' is not a function template.
(3.3) — The associated constraints (13.5.3) are the conjunction of the associated constraints of g and a constraint that is satisfied if and only if the arguments of A are deducible (see below) from the return type.
(3.4) — If f is a copy deduction candidate, then f' is considered to be so as well.
(3.5) — If f was generated from a deduction-guide (13.7.2.3), then f' is considered to be so as well.
(3.6) — The explicit-specifier of f' is the explicit-specifier of g (if any).

4 The arguments of a template A are said to be deducible from a type T if, given a class template
template <typename T> class AA;
with a single partial specialization whose template parameter list is that of A and whose template argument list is a specialization of A with the template argument list of A (13.8.3.2), AA<T> matches the partial specialization.

5 Initialization and overload resolution are performed as described in 9.4 and 12.2.2.4, 12.2.2.5, or 12.2.2.8 (as appropriate for the type of initialization performed) for an object of a hypothetical class type, where the guides of the template named by the placeholder are considered to be the constructors of that class type for
the purpose of forming an overload set, and the initializer is provided by the context in which class template argument deduction was performed. The following exceptions apply:

(5.1) — The first phase in 12.2.2.8 (considering initializer-list constructors) is omitted if the initializer list consists of a single expression of type \( cv U \), where \( U \) is, or is derived from, a specialization of the class template directly or indirectly named by the placeholder.

(5.2) — During template argument deduction for the aggregate deduction candidate, the number of elements in a trailing parameter pack is only deduced from the number of remaining function arguments if it is not otherwise deduced.

If the function or function template was generated from a constructor or deduction-guide that had an explicit-specifier, each such notional constructor is considered to have that same explicit-specifier. All such notional constructors are considered to be public members of the hypothetical class type.

6 [Example 2:]

```cpp
template <class T> struct A {
    explicit A(const T&, ...) noexcept; // #1
    A(T&&, ...); // #2
};

int i;
A a1 = { i, i }; // error: explicit constructor #1 selected in copy-list-initialization during deduction,
                // cannot deduce from non-forwarding rvalue reference in #2

A a2(i, i); // OK, #1 deduces to A<int> and also initializes
A a3(0, i); // OK, #2 deduces to A<int> and also initializes
A a4 = {0, i}; // OK, #2 deduces to A<int> and also initializes

template <class T> A(T&&, T&&) -> A<T>; // #3

template <class T> explicit A(T&&, const T&) -> A<T>; // #4
```

```cpp
int i;
A a5 = {0, 1}; // error: explicit deduction guide #4 selected in copy-list-initialization during deduction
A a6(0,1); // OK, #4 deduces to A<int> and #2 initializes
A a7 = {0, i}; // error: #3 deduces to A<int&>, #1 and #2 declare same constructor
A a8(0,i); // error: #3 deduces to A<int&>, #1 and #2 declare same constructor
```

```cpp
template <class T> struct B {
    template <class U> using TA = T;
    template <class U> B(U, TA<U>);
};

B b{(int*)0, (char*)0}; // OK, deduces B<char*>
D d1 = {1, 2};  // error: deduction failed
D d2 = {1, 2, 3};  // OK, braces elided, deduces D<int>

template <typename T>
struct E {
    T t;
    decltype(t) t2;
};

E e1 = {1, 2};  // OK, deduces E<int>

template <typename... T>
struct Types {};

template <typename... T>
struct F : Types<T...>, T... {};

struct X {};
struct Y {};
struct Z {};
struct W { operator Y(); }

F f1 = {Types<X, Y, Z>{}, {}, {}};  // OK, F<X, Y, Z> deduced
F f2 = {Types<X, Y, Z>{}, X{}, Y{}};  // OK, F<X, Y, Z> deduced
F f3 = {Types<X, Y, Z>{}, X{}, W{}};  // error: conflicting types deduced; operator Y not considered

—end example

Example 3:
template <class T, class U> struct C {
    C(T, U);  // #1
};
template<class T, class U>
C(T, U) -> C<T, std::type_identity_t<U>>;  // #2

template<class V> using A = C<V *, V *>

int i{}
double d{}
A a1(&i, &i);  // deduces A<int>
A a2(i, i);  // error: cannot deduce V * from i
A a3(&i, &d);  // error: #1: cannot deduce (V*, V*) from (int *, double *)  
                // #2: cannot deduce A<W> from C<int *, double *>
B b1(&i, &i);  // deduces B<int>
B b2(&d, &d);  // error: cannot deduce B<W> from C<double *, double *>

Possible exposition-only implementation of the above procedure:

// The following concept ensures a specialization of A is deduced.
template <class> class AA;
template <class V> class AA<A<V>> { };
template <class T> concept deduces_A = requires { sizeof(AA<T>); };

// f1 is formed from the constructor #1 of C, generating the following function template
template<class T, class U>
auto f1(T, U) -> C<T, U>;

// Deducing arguments for C<T, U> from C<V *, V *> deduces T as V * and U as V *;
// f1' is obtained by transforming f1 as described by the above procedure.
template<class V>
requires deduces_A<C<V *, V *>>
auto f1_prime(V *, V *) -> C<V *, V *>;

// f2 is formed from the deduction-guide #2 of C
template<class T, class U>
auto f2(T, U) -> C<T, std::type_identity_t<U>>;
// Deducing arguments for C<T, std::type_identity_t<U>> from C<V *, V*> deduces T as V *;
// f2' is obtained by transforming f2 as described by the above procedure.

template<class V, class U>
requires deduces_A<C<V *, std::type_identity_t<U>>>
auto f2_prime(V *, U) -> C<V *, std::type_identity_t<U>>;

// The following concept ensures a specialization of B is deduced.

template <class>
class BB;

template <class V> class BB<B<V>> { };  

template <class T> concept deduces_B = requires { sizeof(BB<T>); };  

// The guides for B derived from the above f1' and f2' for A are as follows:

template<std::integral W>
requires deduces_A<C<W *, W *>> && deduces_B<C<W *, W *>>
auto f1_prime_for_B(W *, W *) -> C<W *, W *>;  

template<std::integral W, class U>
requires deduces_A<C<W *, std::type_identity_t<U>>> &&
deduces_B<C<W *, std::type_identity_t<U>>>  
auto f2_prime_for_B(W *, U) -> C<W *, std::type_identity_t<U>>;  

— end example

12.2.3 Viable functions

From the set of candidate functions constructed for a given context (12.2.2), a set of viable functions is chosen, from which the best function will be selected by comparing argument conversion sequences and associated constraints (13.5.3) for the best fit (12.2.4). The selection of viable functions considers associated constraints, if any, and relationships between arguments and function parameters other than the ranking of conversion sequences.

First, to be a viable function, a candidate function shall have enough parameters to agree in number with the arguments in the list.

(2.1) — If there are m arguments in the list, all candidate functions having exactly m parameters are viable.

(2.2) — A candidate function having fewer than m parameters is viable only if it has an ellipsis in its parameter list (9.3.4.6). For the purposes of overload resolution, any argument for which there is no corresponding parameter is considered to “match the ellipsis” (12.2.4.2.4).

(2.3) — A candidate function having more than m parameters is viable only if all parameters following the mth have default arguments (9.3.4.7). For the purposes of overload resolution, the parameter list is truncated on the right, so that there are exactly m parameters.

Second, for a function to be viable, if it has associated constraints (13.5.3), those constraints shall be satisfied (13.5.2).

Third, for F to be a viable function, there shall exist for each argument an implicit conversion sequence (12.2.4.2) that converts that argument to the corresponding parameter of F. If the parameter has reference type, the implicit conversion sequence includes the operation of binding the reference, and the fact that an lvalue reference to non-const cannot bind to an rvalue and that an rvalue reference cannot bind to an lvalue can affect the viability of the function (see 12.2.4.2.5).

12.2.4 Best viable function

12.2.4.1 General

Define ICS(F) as the implicit conversion sequence that converts the ith argument in the list to the type of the ith parameter of viable function F. 12.2.4.2 defines the implicit conversion sequences and 12.2.4.3 defines what it means for one implicit conversion sequence to be a better conversion sequence or worse conversion sequence than another.

Given these definitions, a viable function F1 is defined to be a better function than another viable function F2 if for all arguments i, ICS(F1) is not a worse conversion sequence than ICS(F2), and then

(2.1) — for some argument j, ICS(F1) is a better conversion sequence than ICS(F2), or, if not that,

(2.2) — the context is an initialization by user-defined conversion (see 9.4, 12.2.2.6, and 12.2.2.7) and the standard conversion sequence from the return type of F1 to the destination type (i.e., the type of the...
entity being initialized) is a better conversion sequence than the standard conversion sequence from the return type of \( F_2 \) to the destination type.

**Example 1:**

```cpp
struct A {
    A();
    operator int();
    operator double();
} a;
int i = a; // a.operator int() followed by no conversion is better than
// a.operator double() followed by a conversion to int
float x = a; // ambiguous: both possibilities require conversions,
// and neither is better than the other
```

— end example]

or, if not that,

(2.3) — the context is an initialization by conversion function for direct reference binding (12.2.2.7) of a reference to function type, the return type of \( F_1 \) is the same kind of reference (lvalue or rvalue) as the reference being initialized, and the return type of \( F_2 \) is not.

**Example 2:**

```cpp
template <class T> struct A {
    operator T&(); // #1
    operator T&&(); // #2
};
typeid Fn();
A<Fn> a;
Fn& lf = a; // calls #1
Fn&& rf = a; // calls #2
— end example]
```

or, if not that,

(2.4) — \( F_1 \) is not a function template specialization and \( F_2 \) is a function template specialization, or, if not that,

(2.5) — \( F_1 \) and \( F_2 \) are function template specializations, and the function template for \( F_1 \) is more specialized than the template for \( F_2 \) according to the partial ordering rules described in 13.7.7.3, or, if not that,

(2.6) — \( F_1 \) and \( F_2 \) are non-template functions with the same parameter-type-lists, and \( F_1 \) is more constrained than \( F_2 \) according to the partial ordering of constraints described in 13.5.5, or if not that,

(2.7) — \( F_1 \) is a constructor for a class \( D \), \( F_2 \) is a constructor for a base class \( B \) of \( D \), and for all arguments the corresponding parameters of \( F_1 \) and \( F_2 \) have the same type.

**Example 3:**

```cpp
struct A {
    A(int = 0);
};

struct B: A {
    using A::A;
    B();
};
int main() {
    B b; // OK, B::B()
} — end example]
```

or, if not that,

(2.8) — \( F_2 \) is a rewritten candidate (12.2.2.3) and \( F_1 \) is not.

**Example 4:**

```cpp
struct S {
    friend auto operator<=>(const S&, const S&) = default; // #1
```
friend bool operator<(const S&, const S&); // #2

bool b = S() < S(); // calls #2

— end example]

or, if not that,

— F1 and F2 are rewritten candidates, and F2 is a synthesized candidate with reversed order of parameters and F1 is not

[Example 5:

struct S {
    friend std::weak_ordering operator<=>(const S&, int); // #1
    friend std::weak_ordering operator<=>(int, const S&); // #2

};

bool b = 1 < S(); // calls #2

— end example]

or, if not that

— F1 and F2 are generated from class template argument deduction (12.2.2.9) for a class D, and F2 is generated from inheriting constructors from a base class of D while F1 is not, and for each explicit function argument, the corresponding parameters of F1 and F2 are either both ellipses or have the same type, or, if not that,

— F1 is generated from a deduction-guide (12.2.2.9) and F2 is not, or, if not that,

— F1 is the copy deduction candidate (12.2.2.9) and F2 is not, or, if not that,

— F1 is generated from a non-template constructor and F2 is generated from a constructor template.

[Example 6:

template <class T> struct A {
    using value_type = T;
    A(value_type); // #1
    A(const A&); // #2
    A(T, T, int); // #3
    template<
        class U>
    A(int, T, U); // #4
    // #5 is the copy deduction candidate, A(A)
};

A x(1, 2, 3); // uses #3, generated from a non-template constructor

template <class T>
A(T) -> A<T>; // #6, less specialized than #5

A a(42); // uses #6 to deduce A<int> and #1 to initialize
A b = a; // uses #5 to deduce A<int> and #2 to initialize

template <class T>
A(A<T>) -> A<A<T>>; // #7, as specialized as #5

A b2 = a; // uses #7 to deduce A<A<int>> and #1 to initialize

— end example]

3 If there is exactly one viable function that is a better function than all other viable functions, then it is the one selected by overload resolution; otherwise the call is ill-formed.113

[Example 7:

void Fcn(const int*, short);
void Fcn(int*, int);

113) The algorithm for selecting the best viable function is linear in the number of viable functions. Run a simple tournament to find a function W that is not worse than any opponent it faced. Although it is possible that another function F that W did not face is at least as good as W, F cannot be the best function because at some point in the tournament F encountered another function G such that F was not better than G. Hence, either W is the best function or there is no best function. So, make a second pass over the viable functions to verify that W is better than all other functions.

§ 12.2.4.1
int i;
short s = 0;

void f() {
    Fcn(&i, s); // is ambiguous because &i \rightarrow int* is better than &i \rightarrow const int*
    // but s \rightarrow short is also better than s \rightarrow int
    Fcn(&i, 1L); // calls Fcn(int*, int), because &i \rightarrow int* is better than &i \rightarrow const int*
    // and 1L \rightarrow short and 1L \rightarrow int are indistinguishable
    Fcn(&i, 'c'); // calls Fcn(int*, int), because &i \rightarrow int* is better than &i \rightarrow const int*
    // and 'c' \rightarrow int is better than 'c' \rightarrow short
}

—end example

4 If the best viable function resolves to a function for which multiple declarations were found, and if any two of
these declarations inhabit different scopes and specify a default argument that made the function viable, the
program is ill-formed.

[Example 8:
namespace A {
    extern "C" void f(int = 5);
}
namespace B {
    extern "C" void f(int = 5);
}
using A::f;
using B::f;

void use() {
    f(3);  // OK, default argument was not used for viability
    f();   // error: found default argument twice
}
—end example]

12.2.4.2 Implicit conversion sequences [over.best.ics]
12.2.4.2.1 General [over.best.ics.general]

1 An implicit conversion sequence is a sequence of conversions used to convert an argument in a function call
to the type of the corresponding parameter of the function being called. The sequence of conversions is an
implicit conversion as defined in 7.3, which means it is governed by the rules for initialization of an object or
reference by a single expression (9.4, 9.4.4).

2 Implicit conversion sequences are concerned only with the type, cv-qualification, and value category of the
argument and how these are converted to match the corresponding properties of the parameter.
[Note 1: Other properties, such as the lifetime, storage class, alignment, accessibility of the argument, whether the
argument is a bit-field, and whether a function is deleted (9.5.3), are ignored. So, although an implicit conversion
sequence can be defined for a given argument-parameter pair, the conversion from the argument to the parameter
might still be ill-formed in the final analysis. — end note]

3 A well-formed implicit conversion sequence is one of the following forms:

(3.1) — a standard conversion sequence (12.2.4.2.2),
(3.2) — a user-defined conversion sequence (12.2.4.2.3), or
(3.3) — an ellipsis conversion sequence (12.2.4.2.4).

4 However, if the target is

(4.1) — the first parameter of a constructor or
(4.2) — the object parameter of a user-defined conversion function
and the constructor or user-defined conversion function is a candidate by

(4.3) — 12.2.2.4, when the argument is the temporary in the second step of a class copy-initialization,
user-defined conversion sequences are not considered.

[Note 2: These rules prevent more than one user-defined conversion from being applied during overload resolution, thereby avoiding infinite recursion. — end note]

[Example 1:

```
struct Y { Y(int); };
struct A { operator int(); };
Y y1 = A(); // error: A::operator int() is not a candidate

struct X { X(); };
struct B { operator X(); };
B b;
X x{{b}}; // error: B::operator X() is not a candidate
```
— end example]

5 For the case where the parameter type is a reference, see 12.2.4.2.5.

6 When the parameter type is not a reference, the implicit conversion sequence models a copy-initialization of the parameter from the argument expression. The implicit conversion sequence is the one required to convert the argument expression to a prvalue of the type of the parameter.

[Note 3: When the parameter has a class type, this is a conceptual conversion defined for the purposes of Clause 12; the actual initialization is defined in terms of constructors and is not a conversion. — end note]

Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion.

[Example 2: A parameter of type A can be initialized from an argument of type const A. The implicit conversion sequence for that case is the identity sequence; it contains no “conversion” from const A to A. — end example]

7 When the parameter has a class type and the argument expression has the same type, the implicit conversion sequence is an identity conversion. When the parameter has a class type and the argument expression has a derived class type, the implicit conversion sequence is a derived-to-base conversion from the derived class to the base class. A derived-to-base conversion has Conversion rank (12.2.4.2.2).

[Note 4: There is no such standard conversion; this derived-to-base conversion exists only in the description of implicit conversion sequences. — end note]

8 When the parameter is the implicit object parameter of a static member function, the implicit conversion sequence is a standard conversion sequence that is neither better nor worse than any other standard conversion sequence.

9 In all contexts, when converting to the implicit object parameter or when converting to the left operand of an assignment operation only standard conversion sequences are allowed.

[Note 5: When converting to the explicit object parameter, if any, user-defined conversion sequences are allowed. — end note]

10 If no conversions are required to match an argument to a parameter type, the implicit conversion sequence is the standard conversion sequence consisting of the identity conversion (12.2.4.2.2).

11 If no sequence of conversions can be found to convert an argument to a parameter type, an implicit conversion sequence cannot be formed.

12 If there are multiple well-formed implicit conversion sequences converting the argument to the parameter type, the implicit conversion sequence associated with the parameter is defined to be the unique conversion sequence designated the ambiguous conversion sequence. For the purpose of ranking implicit conversion sequences as described in 12.2.4.3, the ambiguous conversion sequence is treated as a user-defined conversion sequence that is indistinguishable from any other user-defined conversion sequence.

[Note 6: This rule prevents a function from becoming non-viable because of an ambiguous conversion sequence for one of its parameters.

[Example 3:

```
class B;
```
class A { A (B&); };
class B { operator A () ; };
class C { C (B&); };
void f(A) { }
void f(C) { }
B b;
f(b); // error: ambiguous because there is a conversion b → C (via constructor)
// and an (ambiguous) conversion b → A (via constructor or conversion function)
void f(B) { }
f(b); // OK, unambiguous
— end example]
— end note]

If a function that uses the ambiguous conversion sequence is selected as the best viable function, the call will
be ill-formed because the conversion of one of the arguments in the call is ambiguous.

13 The three forms of implicit conversion sequences mentioned above are defined in the following subclauses.

12.2.4.2.2 Standard conversion sequences

Table 19 summarizes the conversions defined in 7.3 and partitions them into four disjoint categories: Lvalue Transformation, Qualification Adjustment, Promotion, and Conversion.

[Note 1: These categories are orthogonal with respect to value category, cv-qualification, and data representation: the Lvalue Transformations do not change the cv-qualification or data representation of the type; the Qualification Adjustments do not change the value category or data representation of the type; and the Promotions and Conversions do not change the value category or cv-qualification of the type. — end note]

2 [Note 2: As described in 7.3, a standard conversion sequence either is the Identity conversion by itself (that is, no conversion) or consists of one to three conversions from the other four categories. If there are two or more conversions in the sequence, the conversions are applied in the canonical order: Lvalue Transformation, Promotion or Conversion, Qualification Adjustment. — end note]

3 Each conversion in Table 19 also has an associated rank (Exact Match, Promotion, or Conversion). These are used to rank standard conversion sequences (12.2.4.3). The rank of a conversion sequence is determined by considering the rank of each conversion in the sequence and the rank of any reference binding (12.2.4.2.5). If any of those has Conversion rank, the sequence has Conversion rank; otherwise, if any of those has Promotion rank, the sequence has Promotion rank; otherwise, the sequence has Exact Match rank.

12.2.4.2.3 User-defined conversion sequences

A user-defined conversion sequence consists of an initial standard conversion sequence followed by a user-defined conversion (11.4.8) followed by a second standard conversion sequence. If the user-defined conversion is specified by a constructor (11.4.8.2), the initial standard conversion sequence converts the source type to the type of the first parameter of that constructor. If the user-defined conversion is specified by a conversion
function (11.4.8.3), the initial standard conversion sequence converts the source type to the type of the object parameter of that conversion function.

The second standard conversion sequence converts the result of the user-defined conversion to the target type for the sequence; any reference binding is included in the second standard conversion sequence. Since an implicit conversion sequence is an initialization, the special rules for initialization by user-defined conversion apply when selecting the best user-defined conversion for a user-defined conversion sequence (see 12.2.4 and 12.2.4.2).

If the user-defined conversion is specified by a specialization of a conversion function template, the second standard conversion sequence shall have exact match rank.

A conversion of an expression of class type to the same class type is given Exact Match rank, and a conversion of an expression of class type to a base class of that type is given Conversion rank, in spite of the fact that a constructor (i.e., a user-defined conversion function) is called for those cases.

12.2.4.2.4 Ellipsis conversion sequences

An ellipsis conversion sequence occurs when an argument in a function call is matched with the ellipsis parameter specification of the function called (see 7.6.1.3).

12.2.4.2.5 Reference binding

When a parameter of reference type binds directly (9.4.4) to an argument expression, the implicit conversion sequence is the identity conversion, unless the argument expression has a type that is a derived class of the parameter type, in which case the implicit conversion sequence is a derived-to-base conversion (12.2.4.2).

[Example 1:]

```cpp
struct A {}
struct B : public A {} b;
int f(A&);
int f(B&);
int i = f(b); // calls f(B&), an exact match, rather than f(A&), a conversion
```

If the parameter binds directly to the result of applying a conversion function to the argument expression, the implicit conversion sequence is a user-defined conversion sequence (12.2.4.2.3) whose second standard conversion sequence is either an identity conversion or, if the conversion function returns an entity of a type that is a derived class of the parameter type, a derived-to-base conversion.

When a parameter of reference type is not bound directly to an argument expression, the conversion sequence is the one required to convert the argument expression to the referenced type according to 12.2.4.2. Conceptually, this conversion sequence corresponds to copy-initializing a temporary of the referenced type with the argument expression. Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion.

Except for an implicit object parameter, for which see 12.2.2, an implicit conversion sequence cannot be formed if it requires binding an lvalue reference other than a reference to a non-volatile `const` type to an rvalue or binding an rvalue reference to an lvalue other than a function lvalue.

[Note 1: This means, for example, that a candidate function cannot be a viable function if it has a non-`const` lvalue reference parameter (other than the implicit object parameter) and the corresponding argument would require a temporary to be created to initialize the lvalue reference (see 9.4.4). — end note]

Other restrictions on binding a reference to a particular argument that are not based on the types of the reference and the argument do not affect the formation of an implicit conversion sequence, however.

[Example 2: A function with an “lvalue reference to int” parameter can be a viable candidate even if the corresponding argument is an int bit-field. The formation of implicit conversion sequences treats the int bit-field as an int lvalue and finds an exact match with the parameter. If the function is selected by overload resolution, the call will nonetheless be ill-formed because of the prohibition on binding a non-`const` lvalue reference to a bit-field (9.4.4). — end example]

12.2.4.2.6 List-initialization sequence

When an argument is an initializer list (9.4.5), it is not an expression and special rules apply for converting it to a parameter type.

If the initializer list is a designated-initializer-list, a conversion is only possible if the parameter has an aggregate type that can be initialized from the initializer list according to the rules for aggregate initialization (9.4.2),
in which case the implicit conversion sequence is a user-defined conversion sequence whose second standard
conversion sequence is an identity conversion.

[Note 1: Aggregate initialization does not require that the members are declared in designation order. If, after
overload resolution, the order does not match for the selected overload, the initialization of the parameter will be
ill-formed (9.4.5).

[Example 1:

```cpp
struct A { int x, y; };
struct B { int y, x; };
void f(A a, int);        // #1
void f(B b, ...);        // #2
void g(A a);             // #3
void g(B b);             // #4
void h() {
  f({.x = 1, .y = 2}, 0); // OK; calls #1
  f({.y = 2, .x = 1}, 0); // error: selects #1, initialization of a fails
                          // due to non-matching member order (9.4.5)
  g({.x = 1, .y = 2});    // error: ambiguous between #3 and #4
}
```

—end example]
—end note]

3 Otherwise, if the parameter type is an aggregate class X and the initializer list has a single element of type
cv_U, where U is X or a class derived from X, the implicit conversion sequence is the one required to convert
the element to the parameter type.

4 Otherwise, if the parameter type is a character array and the initializer list has a single element that is an
appropriately-typed string-literal (9.4.3), the implicit conversion sequence is the identity conversion.

5 Otherwise, if the parameter type is std::initializer_list<X> and all the elements of the initializer list
can be implicitly converted to X, the implicit conversion sequence is the worst conversion necessary to convert
an element of the list to X, or if the initializer list has no elements, the identity conversion. This conversion
can be a user-defined conversion even in the context of a call to an initializer-list constructor.

[Example 2:

```cpp
void f(std::initializer_list<int>);
f( {} );                        // OK, f(initializer_list<int>) identity conversion
f( {1,2,3} );                   // OK, f(initializer_list<int>) identity conversion
f( {'a','b'} );                 // OK, f(initializer_list<int>) integral promotion
f( {1.0} );                     // error: narrowing

struct A {
  A(std::initializer_list<double>);       // #1
  A(std::initializer_list<complex<double>>); // #2
  A(std::initializer_list<std::string>);   // #3
};
A a{ 1.0,2.0 };                  // OK, uses #1

void g(A);
g( {"foo", "bar" } );           // OK, uses #3

typedef int IA[3];
void h(const IA&);
h( { 1, 2, 3 } );                // OK, identity conversion
```

—end example]

6 Otherwise, if the parameter type is “array of N X” or “array of unknown bound of X”, if there exists an
implicit conversion sequence from each element of the initializer list (and from {} in the former case if N
exceeds the number of elements in the initializer list) to X, the implicit conversion sequence is the worst such
implicit conversion sequence.

7 Otherwise, if the parameter is a non-aggregate class X and overload resolution per 12.2.2.8 chooses a single
best constructor C of X to perform the initialization of an object of type X from the argument initializer list:

114) Since there are no parameters of array type, this will only occur as the referenced type of a reference parameter.
If \( C \) is not an initializer-list constructor and the initializer list has a single element of type \( cv\ U \), where \( U \) is \( X \) or a class derived from \( X \), the implicit conversion sequence has Exact Match rank if \( U \) is \( X \), or Conversion rank if \( U \) is derived from \( X \).

Otherwise, the implicit conversion sequence is a user-defined conversion sequence whose second standard conversion sequence is an identity conversion.

If multiple constructors are viable but none is better than the others, the implicit conversion sequence is the ambiguous conversion sequence. User-defined conversions are allowed for conversion of the initializer list elements to the constructor parameter types except as noted in 12.2.4.2.

[Example 3:

```cpp
struct A {
    A(std::initializer_list<int>);
};
void f(A);
f( {a, b} ); // OK, f(A(std::initializer_list<int>)) user-defined conversion

struct B {
    B(int, double);
};
void g(B);
g( {a, b} ); // OK, g(B(int, double)) user-defined conversion
g( {1.0, 1.0} ); // error: narrowing

void f(B);
f( {a, b} ); // error: ambiguous f(A) or f(B)

struct C {
    C(std::string);
};
void h(C);
h( {"foo"} ); // OK, h(C(std::string("foo")))

struct D {
    D(A, C);
};
void i(D);
i( {1,2}, {"bar"} ); // OK, i(D(A(std::initializer_list<int>{1,2}), C(std::string("bar"))))
```

—end example]

8 Otherwise, if the parameter has an aggregate type which can be initialized from the initializer list according to the rules for aggregate initialization (9.4.2), the implicit conversion sequence is a user-defined conversion sequence whose second standard conversion sequence is an identity conversion.

[Example 4:

```cpp
struct A {
    int m1;
    double m2;
};

void f(A);
f( {a, b} ); // OK, f(A(int,double)) user-defined conversion
f( {1.0} ); // error: narrowing
```

—end example]

9 Otherwise, if the parameter is a reference, see 12.2.4.2.5.

[Note 2: The rules in this subclause will apply for initializing the underlying temporary for the reference. — end note]

[Example 5:

```cpp
struct A {
    int m1;
    double m2;
};

```
**10** Otherwise, if the parameter type is not a class:

1. If the initializer list has one element that is not itself an initializer list, the implicit conversion sequence is the one required to convert the element to the parameter type;

   [Example 6:
   ```cpp
   void f(int);
   f( {'a'} ); // OK, same conversion as char to int
   f( {1.0} ); // error: narrowing
   ```
   — end example]

2. If the initializer list has no elements, the implicit conversion sequence is the identity conversion.

   [Example 7:
   ```cpp
   void f(int);
   f( {} ); // OK, identity conversion
   ```
   — end example]

**11** In all cases other than those enumerated above, no conversion is possible.

### 12.2.4.3 Ranking implicit conversion sequences [over.ics.rank]

This subclause defines a partial ordering of implicit conversion sequences based on the relationships *better conversion sequence* and *better conversion*. If an implicit conversion sequence S1 is defined by these rules to be a better conversion sequence than S2, then it is also the case that S2 is a *worse conversion sequence* than S1. If conversion sequence S1 is neither better than nor worse than conversion sequence S2, S1 and S2 are said to be *indistinguishable conversion sequences*.

1. When comparing the basic forms of implicit conversion sequences (as defined in 12.2.4.2):

   - a standard conversion sequence (12.2.4.2.2) is a better conversion sequence than a user-defined conversion sequence or an ellipsis conversion sequence, and
   - a user-defined conversion sequence (12.2.4.2.3) is a better conversion sequence than an ellipsis conversion sequence (12.2.4.2.4).

2. Two implicit conversion sequences of the same form are indistinguishable conversion sequences unless one of the following rules applies:

   - List-initialization sequence L1 is a better conversion sequence than list-initialization sequence L2 if
     1. L1 converts to `std::initializer_list<X>` for some X and L2 does not, or, if not that,
   2. L1 and L2 convert to arrays of the same element type, and either the number of elements \( n_1 \) initialized by L1 is less than the number of elements \( n_2 \) initialized by L2, or \( n_1 = n_2 \) and L2 converts to an array of unknown bound and L1 does not,

   even if one of the other rules in this paragraph would otherwise apply.

   [Example 1:
   ```cpp
   void f1(int); // #1
   void f1(std::initializer_list<long>); // #2
   void g1() { f1({42}); } // chooses #2
   ```
   ```cpp
   void f2(std::pair<const char*, const char*>); // #3
   void f2(std::initializer_list<std::string>); // #4
   void g2() { f2({"foo","bar"}); } // chooses #4
   ```
   — end example]

3. [Example 2:
   ```cpp
   void f(int (&)[]); // #1
   ```
   ```cpp
   § 12.2.4.3 352
   ```
void f(double (&&)[] ); // #2
void f(int (&&)[2]); // #3

f( {1} );  // Calls #1: Better than #2 due to conversion, better than #3 due to bounds
f( {1.0} ); // Calls #2: Identity conversion is better than floating-integral conversion
f( {1.0, 2.0} ); // Calls #2: Identity conversion is better than floating-integral conversion
f( {1, 2} ); // Calls #3: Converting to array of known bound is better than to unknown bound,
              // and an identity conversion is better than floating-integral conversion

—end example—

(3.2) Standard conversion sequence S1 is a better conversion sequence than standard conversion sequence S2 if

(3.2.1) S1 is a proper subsequence of S2 (comparing the conversion sequences in the canonical form defined by 12.2.4.2.2, excluding any Lvalue Transformation; the identity conversion sequence is considered to be a subsequence of any non-identity conversion sequence) or, if not that,

(3.2.2) the rank of S1 is better than the rank of S2, or S1 and S2 have the same rank and are distinguishable by the rules in the paragraph below, or, if not that,

(3.2.3) S1 and S2 include reference bindings (9.4.4) and neither refers to an implicit object parameter of a non-static member function declared without a ref-qualifier, and S1 binds an rvalue reference to an rvalue and S2 binds an lvalue reference

[Example 3:

```c
int i;
int f1();
int&& f2();
int g(const int&);
int g(const int&&);
int j = g(i); // calls g(const int&)
int k = g(f1()); // calls g(const int&&)
int l = g(f2()); // calls g(const int&&)

struct A {
    &A operator<<(int);
    void p() &;
    void p() &&;
};
A() << 1; // calls A::operator<<(int)
A() << 'c'; // calls operator<<(A&&, char)
A a;
a << 1; // calls A::operator<<(int)
a << 'c'; // calls A::operator<<(int)
A().p(); // calls A::p()&
a.p(); // calls A::p()&&
—end example]
```

or, if not that,

(3.2.4) S1 and S2 include reference bindings (9.4.4) and S1 binds an lvalue reference to a function lvalue and S2 binds an rvalue reference to a function lvalue

[Example 4:

```c
int f(void&()); // #1
int f(void&&()); // #2
void g();
int i1 = f(g); // calls #1
—end example]
```

or, if not that,

(3.2.5) S1 and S2 differ only in their qualification conversion (7.3.6) and yield similar types T1 and T2, respectively, where T1 can be converted to T2 by a qualification conversion.

[Example 5:
int f(const volatile int *);
int f(const int *);

int i;
int j = f(&i); // calls f(const int*)
— end example]
or, if not that,

(3.2.6) — S1 and S2 include reference bindings (9.4.4), and the types to which the references refer are the same type except for top-level cv-qualifiers, and the type to which the reference initialized by S2 refers is more cv-qualified than the type to which the reference initialized by S1 refers.

[Example 6:
int f(const int &);
int f(int &);
int g(const int &);
ing(int);

int i;
int j = f(i); // calls f(int &)
int k = g(i); // ambiguous

struct X {
    void f() const;
    void f();
};
void g(const X& a, X b) {
    a.f(); // calls X::f() const
    b.f(); // calls X::f()
}
— end example]

(3.3) — User-defined conversion sequence U1 is a better conversion sequence than another user-defined conversion sequence U2 if they contain the same user-defined conversion function or constructor or they initialize the same class in an aggregate initialization and in either case the second standard conversion sequence of U1 is better than the second standard conversion sequence of U2.

[Example 7:
struct A {
    operator short();
} a;
ing(float);
ing(int);
int i = f(a); // calls f(int), because short → int is
            // better than short → float.
— end example]

4 Standard conversion sequences are ordered by their ranks: an Exact Match is a better conversion than a Promotion, which is a better conversion than a Conversion. Two conversion sequences with the same rank are indistinguishable unless one of the following rules applies:

(4.1) — A conversion that does not convert a pointer or a pointer to member to bool is better than one that does.

(4.2) — A conversion that promotes an enumeration whose underlying type is fixed to its underlying type is better than one that promotes to the promoted underlying type, if the two are different.

(4.3) — A conversion in either direction between floating-point type FP1 and floating-point type FP2 is better than a conversion in the same direction between FP1 and arithmetic type T3 if

(4.3.1) — the floating-point conversion rank (6.8.6) of FP1 is equal to the rank of FP2, and

(4.3.2) — T3 is not a floating-point type, or T3 is a floating-point type whose rank is not equal to the rank of FP1, or the floating-point conversion subrank (6.8.6) of FP2 is greater than the subrank of T3.

[Example 8:
int f(std::float32_t);
int f(std::float64_t);
int f(long long);
float x;
std::float16_t y;
int i = f(x); // calls f(std::float32_t) on implementations where
// float and std::float32_t have equal conversion ranks
int j = f(y); // error: ambiguous, no equal conversion rank

—end example

— (4.4) If class B is derived directly or indirectly from class A, conversion of B* to A* is better than conversion of B* to void*, and conversion of A* to void* is better than conversion of B* to void*.
(4.5) If class B is derived directly or indirectly from class A and class C is derived directly or indirectly from B,
(4.5.1) — conversion of C* to B* is better than conversion of C* to A*,
[Example 9:
struct A {};
struct B : public A {};
struct C : public B {};
C* pc;
int f(A*);
int f(B*);
int i = f(pc); // calls f(B*)
— end example]
(4.5.2) — binding of an expression of type C to a reference to type B is better than binding an expression of type C to a reference to type A,
(4.5.3) — conversion of A::* to B::* is better than conversion of A::* to C::*,
(4.5.4) — conversion of C to B is better than conversion of C to A,
(4.5.5) — conversion of B* to A* is better than conversion of C* to A*,
(4.5.6) — binding of an expression of type B to a reference to type A is better than binding an expression of type C to a reference to type A,
(4.5.7) — conversion of B::* to C::* is better than conversion of A::* to C::*; and
(4.5.8) — conversion of B to A is better than conversion of C to A.
[Note 1: Compared conversion sequences will have different source types only in the context of comparing the second standard conversion sequence of an initialization by user-defined conversion (see 12.2.4); in all other contexts, the source types will be the same and the target types will be different. — end note]

12.3 Address of an overload set [over.over]

An id-expression whose terminal name refers to an overload set S and that appears without arguments is resolved to a function, a pointer to function, or a pointer to member function for a specific function that is chosen from a set of functions selected from S determined based on the target type required in the context (if any), as described below. The target can be

(1.1) — an object or reference being initialized (9.4, 9.4.4, 9.4.5),
(1.2) — the left side of an assignment (7.6.19),
(1.3) — a parameter of a function (7.6.1.3),
(1.4) — a parameter of a user-defined operator (12.4),
(1.5) — the return value of a function, operator function, or conversion (8.7.4),
(1.6) — an explicit type conversion (7.6.1.4, 7.6.1.9, 7.6.3), or
(1.7) — a non-type template-parameter (13.4.3).

The id-expression can be preceded by the & operator.
[Note 1: Any redundant set of parentheses surrounding the function name is ignored (7.5.3). — end note]

2 If there is no target, all non-template functions named are selected. Otherwise, a non-template function with type F is selected for the function type FT of the target type if F (after possibly applying the function pointer conversion (7.3.14)) is identical to FT.
The specialization, if any, generated by template argument deduction (13.10.4, 13.10.3.3, 13.10.2) for each function template named is added to the set of selected functions considered.

Non-member functions, static member functions, and explicit object member functions match targets of function pointer type or reference to function type. Implicit object member functions match targets of pointer-to-member-function type.

All functions with associated constraints that are not satisfied (13.5.3) are eliminated from the set of selected functions. If more than one function in the set remains, all function template specializations in the set are eliminated if the set also contains a function that is not a function template specialization. Any given non-template function F0 is eliminated if the set contains a second non-template function that is more constrained than F0 according to the partial ordering rules of 13.5.5. Any given function template specialization F1 is eliminated if the set contains a second function template specialization whose function template is more specialized than the function template of F1 according to the partial ordering rules of 13.7.7.3. After such eliminations, if any, there shall remain exactly one selected function.

The initialization of pfe is ill-formed because no f() with type int(...) has been declared, and not because of any ambiguity. For another example,

```c
struct X {
  int f(int);
  static int f(long);
};
```

```c
int (X::*p1)(int) = &X::f; // OK
int (X::*p2)(int) = &X::f; // error: mismatch
int (X::*p3)(long) = &X::f; // OK
int (X::*p4)(long) = &X::f; // error: mismatch
int (X::*p5)(int) = &X::f; // error: wrong syntax for
  // pointer to member
int (*p6)(long) = &X::f; // OK
```

—end example

[Note 5: Even if B is a public base of D, we have

```c
D* f();
B* (*p1)() = &f; // error
void g(D*);
void (*p2)(B*) = &g; // error
```

—end note]

12.4 Overloaded operators

12.4.1 General

A declaration whose declarator-id is an operator-function-id shall declare a function or function template or an explicit instantiation or specialization of a function template. A function so declared is an operator function.
A function template so declared is an operator function template. A specialization of an operator function template is also an operator function. An operator function is said to implement the operator named in its operator-function-id.

operator-function-id:
  operator operator

operator: one of
  new  delete  new[]  delete[]  co_await  ()  []  ->  ->*
  ~  !  +  -  *  /  %  ^  &
  |=  ==  !=  <  >  <=  >=  <=>  &&
  ||=  +=  -=  *=  /=  %=  ^=  &=
  ||=  ==  !=  <  >  <=  >=  <=>  &&

[Note 1: The operators new[], delete[], (), and [] are formed from more than one token. The latter two operators are function call (7.6.1.3) and subscripting (7.6.1.2). — end note]

2 Both the unary and binary forms of
  
  +  -  *  &

  can be overloaded.

3 [Note 2: The following operators cannot be overloaded:

  .  .*  ::  ?:

  nor can the preprocessing symbols # (15.6.3) and ## (15.6.4). — end note]

4 Operator functions are usually not called directly; instead they are invoked to evaluate the operators they implement (12.4.2 – 12.4.7). They can be explicitly called, however, using the operator-function-id as the name of the function in the function call syntax (7.6.1.3).

[Example 1:]
  complex z = a.operator+(b);  // complex z = a+b;
  void* p = operator new(sizeof(int)*n);

  — end example]

5 The allocation and deallocation functions, operator new, operator new[], operator delete, and operator delete[], are described completely in 6.7.5.5. The attributes and restrictions found in the rest of 12.4 do not apply to them unless explicitly stated in 6.7.5.5.

6 The co_await operator is described completely in 7.6.2.4. The attributes and restrictions found in the rest of 12.4 do not apply to it unless explicitly stated in 7.6.2.4.

7 An operator function shall either

(7.1) — be a member function or

(7.2) — be a non-member function that has at least one non-object parameter whose type is a class, a reference to a class, an enumeration, or a reference to an enumeration.

It is not possible to change the precedence, grouping, or number of operands of operators. The meaning of the operators =, (unary) &, and , (comma), predefined for each type, can be changed for specific class types by defining operator functions that implement these operators. Likewise, the meaning of the operators (unary) & and , (comma) can be changed for specific enumeration types. Operator functions are inherited in the same manner as other base class functions.

8 An operator function shall be a prefix unary, binary, function call, subscripting, class member access, increment, or decrement operator function.

9 [Note 3: The identities among certain predefined operators applied to basic types (for example, ++a ≡ a+=1) need not hold for operator functions. Some predefined operators, such as +=, require an operand to be an lvalue when applied to basic types; this is not required by operator functions. — end note]

10 An operator function cannot have default arguments (9.3.4.7), except where explicitly stated below. Operator functions cannot have more or fewer parameters than the number required for the corresponding operator, as described in the rest of 12.4.

11 Operators not mentioned explicitly in subclauses 12.4.3.2 through 12.4.7 act as ordinary unary and binary operators obeying the rules of 12.4.2 or 12.4.3.
12.4.2 Unary operators

A prefix unary operator function is a function named `operator()` for a prefix unary-operator `@` (7.6.2.2) that is either a non-static member function (11.4.2) with no non-object parameters or a non-member function with one parameter. For a unary-expression of the form `@ cast-expression`, the operator function is selected by overload resolution (12.2.2.3). If a member function is selected, the expression is interpreted as

```cpp
cast-expression . operator ()
```

Otherwise, if a non-member function is selected, the expression is interpreted as

```cpp
operator () ( cast-expression )
```

[Note 1: The operators ++ and -- (7.6.2.3) are described in 12.4.7. —end note]

2 [Note 2: The unary and binary forms of the same operator have the same name. Consequently, a unary operator can hide a binary operator from an enclosing scope, and vice versa. —end note]

12.4.3 Binary operators

12.4.3.1 General

A binary operator function is a function named `operator()` for a binary operator `@` that is either a non-static member function (11.4.2) with one non-object parameter or a non-member function with two parameters. For an expression `x @ y` with subexpressions `x` and `y`, the operator function is selected by overload resolution (12.2.2.3). If a member function is selected, the expression is interpreted as

```cpp
x . operator () ( y )
```

Otherwise, if a non-member function is selected, the expression is interpreted as

```cpp
operator () ( x , y )
```

2 An equality operator function is an operator function for an equality operator (7.6.10). A relational operator function is an operator function for a relational operator (7.6.9). A three-way comparison operator function is an operator function for the three-way comparison operator (7.6.8). A comparison operator function is an equality operator function, a relational operator function, or a three-way comparison operator function.

12.4.3.2 Simple assignment

A simple assignment operator function is a binary operator function named `operator=`. A simple assignment operator function shall be a non-static member function.

[Note 1: Because only standard conversion sequences are considered when converting to the left operand of an assignment operation (12.2.4.2), an expression `x = y` with a subexpression `x` of class type is always interpreted as `x . operator= (y)`. —end note]

2 [Note 2: Since a copy assignment operator is implicitly declared for a class if not declared by the user (11.4.6), a base class assignment operator function is always hidden by the copy assignment operator function of the derived class. —end note]

3 [Note 3: Any assignment operator function, even the copy and move assignment operators, can be virtual. For a derived class `D` with a base class `B` for which a virtual copy/move assignment has been declared, the copy/move assignment operator in `D` does not override `B`'s virtual copy/move assignment operator.

[Example 1:]

```cpp
struct B {
  virtual int operator= (int);
  virtual B& operator= (const B&);
};
struct D : B {
  virtual int operator= (int);
  virtual D& operator= (const B&);
};

D dobj1;
D dobj2;
B* bptr = &dobj1;
void f() {
  bptr->operator=(99); // calls D::operator=(int)
  *bptr = 99; // ditto
  bptr->operator=(dobj2); // calls D::operator=(const B&)
  *bptr = dobj2; // ditto
}
```
dobj1 = dobj2;  // calls implicitly-declared D::operator=(const D&)
}

—end example]
—end note]

12.4.4 Function call [over.call]
1 A function call operator function is a function named operator() that is a member function with an arbitrary number of parameters. It may have default arguments. For an expression of the form

```
postfix-expression ( expression-list_opt )
```

where the postfix-expression is of class type, the operator function is selected by overload resolution (12.2.2.3).

If a surrogate call function is selected, let e be the result of invoking the corresponding conversion operator function on the postfix-expression;

the expression is interpreted as

```
e ( expression-list_opt )
```

Otherwise, the expression is interpreted as

```
postfix-expression . operator () ( expression-list_opt )
```

12.4.5 Subscripting [over.sub]
1 A subscripting operator function is a member function named operator[] with an arbitrary number of parameters. It may have default arguments. For an expression of the form

```
postfix-expression [ expression-list_opt ]
```

the operator function is selected by overload resolution (12.2.2.3). If a member function is selected, the expression is interpreted as

```
postfix-expression . operator [] ( expression-list_opt )
```

2 [Example 1]:

```
struct X {
    Z operator[](std::initializer_list<int>);
    Z operator[](auto...);
};
X x;
x[1,2,3] = 7;    // OK, meaning x.operator[](1,2,3)
x[1,2,3] = 7;    // OK, meaning x.operator[](1,2,3)
int a[10];
a[1,2,3] = 7;    // error: built-in subscript operator
a[1,2,3] = 7;    // error: built-in subscript operator
—end example]
```

12.4.6 Class member access [over.ref]
1 A class member access operator function is a function named operator-> that is a non-static member function taking no non-object parameters. For an expression of the form

```
postfix-expression -> template_opt id-expression
```

the operator function is selected by overload resolution (12.2.2.3), and the expression is interpreted as

```
( postfix-expression . operator -> () ) -> template_opt id-expression
```

12.4.7 Increment and decrement [over.inc]
1 An increment operator function is a function named operator++. If this function is a non-static member function with no non-object parameters, or a non-member function with one parameter, it defines the prefix increment operator ++ for objects of that type. If the function is a non-static member function with one non-object parameter (which shall be of type int) or a non-member function with two parameters (the second of which shall be of type int), it defines the postfix increment operator ++ for objects of that type. When the postfix increment is called as a result of using the ++ operator, the int argument will have value zero.\footnote{Calling operator++ explicitly, as in expressions like a.operator++(2), has no special properties: The argument to operator++ is 2.}

[Example 1:}
struct X {
    X& operator++();  // prefix ++a
    X operator++(int);  // postfix a++
};

struct Y {
};

Y& operator++(Y&);  // prefix ++b
Y operator++(Y&, int);  // postfix b++

void f(X a, Y b) {
    ++a;  // a.operator++();
    a++;  // a.operator++(0);
    ++b;  // operator++(b);
    b++;  // operator++(b, 0);

    a.operator++();  // explicit call: like ++a;
    a.operator++(0);  // explicit call: like a++;
    operator++(b);  // explicit call: like ++b;
    operator++(b, 0);  // explicit call: like b++;
}

—end example

2 A decrement operator function is a function named operator-- and is handled analogously to an increment operator function.

12.5 Built-in operators [over.built]

The candidate operator functions that represent the built-in operators defined in 7.6 are specified in this subclause. These candidate functions participate in the operator overload resolution process as described in 12.2.2.3 and are used for no other purpose.

[Note 1: Because built-in operators take only operands with non-class type, and operator overload resolution occurs only when an operand expression originally has class or enumeration type, operator overload resolution can resolve to a built-in operator only when an operand has a class type that has a user-defined conversion to a non-class type appropriate for the operator, or when an operand has an enumeration type that can be converted to a type appropriate for the operator. Also note that some of the candidate operator functions given in this subclause are more permissive than the built-in operators themselves. As described in 12.2.2.3, after a built-in operator is selected by overload resolution the expression is subject to the requirements for the built-in operator given in 7.6, and therefore to any additional semantic constraints given there. In some cases, user-written candidates with the same name and parameter types as a built-in candidate operator function cause the built-in operator function to not be included in the set of candidate functions. —end note]

2 In this subclause, the term promoted integral type is used to refer to those cv-unqualified integral types which are preserved by integral promotion (7.3.7) (including e.g. int and long but excluding e.g. char).

[Note 2: In all cases where a promoted integral type is required, an operand of unscoped enumeration type will be acceptable by way of the integral promotions. — end note]

3 In the remainder of this subclause, vq represents either volatile or no cv-qualifier.

4 For every pair (T, vq), where T is a cv-unqualified arithmetic type other than bool or a cv-unqualified pointer to (possibly cv-qualified) object type, there exist candidate operator functions of the form

    vq T& operator++(vq T&);
    T operator++(vq T&, int);
    vq T& operator--(vq T&);
    T operator--(vq T&, int);

5 For every (possibly cv-qualified) object type T and for every function type T that has neither cv-qualifiers nor a ref-qualifier, there exist candidate operator functions of the form

    T&  operator*(T*);

6 For every type T there exist candidate operator functions of the form

    T*  operator*(T*);

7 For every cv-unqualified floating-point or promoted integral type T, there exist candidate operator functions of the form

    T  operator+(T);
T operator-(T);

8 For every promoted integral type T, there exist candidate operator functions of the form
   T operator-(T);

9 For every quintuple (C1, C2, T, cv1, cv2), where C2 is a class type, C1 is the same type as C2 or is a derived
   class of C2, and T is an object type or a function type, there exist candidate operator functions of the form
   cv12 T& operator->*(cv1 C1*, cv2 T C2::*);
   where cv12 is the union of cv1 and cv2. The return type is shown for exposition only; see 7.6.4 for the
   determination of the operator’s result type.

10 For each pair of types L and R, where each of L and R is a floating-point or promoted integral type, there
    exist candidate operator functions of the form
    LR operator*(L, R);
    LR operator/(L, R);
    LR operator-(L, R);
    bool operator==(L, R);
    bool operator!=(L, R);
    bool operator<(L, R);
    bool operator>(L, R);
    bool operator<=(L, R);
    bool operator>=(L, R);
    R operator<=>(L, R);

   where LR is the result of the usual arithmetic conversions (7.4) between types L and R.

11 For every integral type T there exists a candidate operator function of the form
   std::strong_ordering operator<=>(T, T);

12 For every pair of floating-point types L and R, there exists a candidate operator function of the form
   std::partial_ordering operator<=>(L, R);

13 For every cv-qualified or cv-unqualified object type T there exist candidate operator functions of the form
   T* operator+(T*, std::ptrdiff_t);
   T& operator[](T*, std::ptrdiff_t);
   T* operator-(T*, std::ptrdiff_t);
   T* operator+(std::ptrdiff_t, T*);
   T& operator[](std::ptrdiff_t, T*);

14 For every T, where T is a pointer to object type, there exist candidate operator functions of the form
   std::ptrdiff_t operator-(T, T);

15 For every T, where T is an enumeration type or a pointer type, there exist candidate operator functions of the
   form
   bool operator==(T, T);
   bool operator!=(T, T);
   bool operator<(T, T);
   bool operator>(T, T);
   bool operator<=(T, T);
   bool operator>=(T, T);
   R operator<=>(T, T);

   where R is the result type specified in 7.6.8.

16 For every T, where T is a pointer-to-member type or std::nullptr_t, there exist candidate operator
   functions of the form
   bool operator==(T, T);
   bool operator!=(T, T);

17 For every pair of promoted integral types L and R, there exist candidate operator functions of the form
   LR operator%(L, R);
   LR operator&(L, R);
   LR operator~(L, R);
   LR operator|(L, R);
   L operator<<=(L, R);
18 For every triple \((L, vq, R)\), where \(L\) is an arithmetic type, and \(R\) is a floating-point or promoted integral type, there exist candidate operator functions of the form

\[
\begin{align*}
vq Lk & \text{ operator}=(vq Lk, R); \\
vq Lk & \text{ operator}== (vq Lk, R); \\
vq Lk & \text{ operator} /= (vq Lk, R); \\
vq Lk & \text{ operator} %= (vq Lk, R); \\
vq Lk & \text{ operator} >>= (vq Lk, R); \\
vq Lk & \text{ operator} <<= (vq Lk, R); \\
vq Lk & \text{ operator} &= (vq Lk, R); \\
vq Lk & \text{ operator} ^= (vq Lk, R); \\
vq Lk & \text{ operator} |= (vq Lk, R);
\end{align*}
\]

19 For every pair \((T, vq)\), where \(T\) is any type, there exist candidate operator functions of the form

\[
\begin{align*}
& T\text{*}vq k \text{ operator}=(T\text{*}vq k, T); \\
& vq Tk \text{ operator}=(vq Tk, T);
\end{align*}
\]

20 For every pair \((T, vq)\), where \(T\) is an enumeration or pointer-to-member type, there exist candidate operator functions of the form

\[
\begin{align*}
& T\text{*}vq k \text{ operator}=+(T\text{*}vq k, std::ptrdiff_t); \\
& T\text{*}vq k \text{ operator}=- (T\text{*}vq k, std::ptrdiff_t);
\end{align*}
\]

21 For every triple \((L, vq, R)\), where \(L\) is an integral type, and \(R\) is a promoted integral type, there exist candidate operator functions of the form

\[
\begin{align*}
vq Lk & \text{ operator}%= (vq Lk, R); \\
vq Lk & \text{ operator}<<(= (vq Lk, R); \\
vq Lk & \text{ operator}>>=(vq Lk, R); \\
vq Lk & \text{ operator}&=(vq Lk, R); \\
vq Lk & \text{ operator}^=(vq Lk, R); \\
vq Lk & \text{ operator}|=(vq Lk, R);
\end{align*}
\]

22 For every pair of types \(L\) and \(R\), where each of \(L\) and \(R\) is a floating-point or promoted integral type, there exist candidate operator functions of the form

\[
\begin{align*}
& bool \text{ operator}!(bool); \\
& bool \text{ operator}&& (bool, bool); \\
& bool \text{ operator}||(bool, bool);
\end{align*}
\]

23 There also exist candidate operator functions of the form

\[
\begin{align*}
& bool \text{ operator}?: (bool, L, R);
\end{align*}
\]

24 For every pair of types \(L\) and \(R\), where each of \(L\) and \(R\) is a floating-point or promoted integral type, there exist candidate operator functions of the form

\[
\begin{align*}
& LR \text{ operator}?:(bool, L, R);
\end{align*}
\]

where \(LR\) is the result of the usual arithmetic conversions (7.4) between types \(L\) and \(R\).

[Note 3: As with all these descriptions of candidate functions, this declaration serves only to describe the built-in operator for purposes of overload resolution. The operator \("?:\"\) cannot be overloaded. —end note]

25 For every type \(T\), where \(T\) is a pointer, pointer-to-member, or scoped enumeration type, there exist candidate operator functions of the form

\[
\begin{align*}
& T \text{ operator}?:(bool, T, T);
\end{align*}
\]

12.6 User-defined literals

\[
\begin{align*}
literal-operator-id: & \text{ operator} \text{ string-literal identifier} \\
& \text{ operator} \text{ user-defined-string-literal}
\end{align*}
\]

1 The string-literal or user-defined-string-literal in a literal-operator-id shall have no encoding-prefix and shall contain no characters other than the implicit terminating ‘\'\0’. The ud-suffix of the user-defined-string-literal or the identifier in a literal-operator-id is called a literal suffix identifier. The first form of literal-operator-id is deprecated. Some literal suffix identifiers are reserved for future standardization; see 16.4.5.3.6. A declaration whose literal-operator-id uses such a literal suffix identifier is ill-formed, no diagnostic required.

2 A declaration whose declarator-id is a literal-operator-id shall declare a function or function template that belongs to a namespace (it could be a friend function (11.8.4)) or an explicit instantiation or specialization of a function template. A function declared with a literal-operator-id is a literal operator. A function template declared with a literal-operator-id is a literal operator template.
The declaration of a literal operator shall have a parameter-declaration-clause equivalent to one of the following:

```plaintext
const char*
unsigned long long int
long double
wchar_t
char
char8_t
char16_t
char32_t
const char*, std::size_t
const wchar_t*, std::size_t
const char8_t*, std::size_t
const char16_t*, std::size_t
const char32_t*, std::size_t
```

If a parameter has a default argument (9.3.4.7), the program is ill-formed.

A **raw literal operator** is a literal operator with a single parameter whose type is `const char*`.

A **numeric literal operator template** is a literal operator template whose template-parameter-list has a single template-parameter that is a non-type template parameter pack (13.7.4) with element type `char`. A **string literal operator template** is a literal operator template whose template-parameter-list comprises a single non-type template-parameter of class type. The declaration of a literal operator template shall have an empty parameter-declaration-clause and shall declare either a numeric literal operator template or a string literal operator template.

Literal operators and literal operator templates shall not have C language linkage.

[Note 1: Literal operators and literal operator templates are usually invoked implicitly through user-defined literals (5.13.8). However, except for the constraints described above, they are ordinary namespace-scope functions and function templates. In particular, they are looked up like ordinary functions and function templates and they follow the same overload resolution rules. Also, they can be declared `inline` or `constexpr`, they can have internal, module, or external linkage, they can be called explicitly, their addresses can be taken, etc. — end note]

[Example 1:

```plaintext
void operator "_km(long double);       // OK
string operator " _i18n(const char*, std::size_t); // OK, deprecated
template <char...> double operator "\u03c0();   // OK, UCN for lowercase pi
float operator "_e(const char*);      // OK
float operator "E(const char*);       // ill-formed, no diagnostic required:
                                    // reserved literal suffix (16.4.5.3.6, 5.13.8)
double operator"_Bq(long double);    // OK, does not use the reserved identifier _Bq (5.10)
double operator" _Bq(long double);   // ill-formed, no diagnostic required:
                                    // uses the reserved identifier _Bq (5.10)
float operator " B(const char*);      // error: non-empty string-literal
string operator "S\x(const char*, std::size_t); // error: invalid literal suffix identifier
double operator "_miles(double);      // error: invalid parameter-declaration-clause
template <char...> int operator "_j(const char*); // error: invalid parameter-declaration-clause
extern "C" void operator "_m(long double); // error: C language linkage
```

— end example]
13 Templates

13.1 Preamble

1 A template defines a family of classes, functions, or variables, an alias for a family of types, or a concept.

```
template-declaration:
  template-head declaration
  template-head concept-definition

template-head:
  template < template-parameter-list > requires-clause, opt

template-parameter-list:
  template-parameter
  template-parameter-list , template-parameter

requires-clause:
  requires constraint-logical-or-expression

constraint-logical-or-expression:
  constraint-logical-and-expression
  constraint-logical-or-expression || constraint-logical-and-expression

constraint-logical-and-expression:
  primary-expression
  constraint-logical-and-expression && primary-expression
```

[Note 1: The > token following the template-parameter-list of a template-declaration can be the product of replacing a >> token by two consecutive > tokens (13.3). — end note]

2 The declaration in a template-declaration (if any) shall

(2.1) — declare or define a function, a class, or a variable, or

(2.2) — define a member function, a member class, a member enumeration, or a static data member of a class
template or of a class nested within a class template, or

(2.3) — define a member template of a class or class template, or

(2.4) — be a deduction-guide, or

(2.5) — be an alias-declaration.

3 A template-declaration is a declaration. A declaration introduced by a template declaration of a variable is a variable template. A variable template at class scope is a static data member template.

[Example 1:
```
template<class T>
  constexpr T pi = T(3.1415926535897932385L);

template<class T>
  T circular_area(T r) {
    return pi<T> * r * r;
  }

struct matrix_constants {
  template<class T>
    using pauli = hermitian_matrix<T, 2>;

  template<class T>
    constexpr static pauli<T> sigma1 = { { 0, 1 }, { 1, 0 } };

  template<class T>
    constexpr static pauli<T> sigma2 = { { 0, -1i }, { 1i, 0 } };

  template<class T>
    constexpr static pauli<T> sigma3 = { { 1, 0 }, { 0, -1 } };

};
```
— end example]

4 [Note 2: A template-declaration can appear only as a namespace scope or class scope declaration. — end note]
Its *declaration* shall not be an *export-declaration*. In a function template declaration, the *unqualified-id* of the *declarator-id* shall be a name.

[Note 3: A class or variable template declaration of a *simple-template-id* declares a partial specialization (13.7.6). — end note]

5 In a *template-declaration*, explicit specialization, or explicit instantiation the *init-declarator-list* in the declaration shall contain at most one declarator. When such a declaration is used to declare a class template, no declarator is permitted.

6 A specialization (explicit or implicit) of one template is distinct from all specializations of any other template. A template, an explicit specialization (13.9.4), and a partial specialization shall not have C language linkage.

[Note 4: Default arguments for function templates and for member functions of class templates are considered definitions for the purpose of template instantiation (13.7) and must obey the one-definition rule (6.3). — end note]

7 [Note 5: A template cannot have the same name as any other name bound in the same scope (6.4.1), except that a function template can share a name with non-template functions (9.3.4.6) and/or function templates (13.10.4). Specializations, including partial specializations (13.7.6), do not reintroduce or bind names. Their target scope is the target scope of the primary template, so all specializations of a template belong to the same scope as it does. — end note]

8 An entity is *templated* if it is

(8.1) — a template,
(8.2) — an entity defined (6.2) or created (6.7.7) in a templated entity,
(8.3) — a member of a templated entity,
(8.4) — an enumerator for an enumeration that is a templated entity, or
(8.5) — the closure type of a *lambda-expression* (7.5.5.2) appearing in the declaration of a templated entity.

[Note 6: A local class, a local or block variable, or a friend function defined in a templated entity is a templated entity. — end note]

A *templated function* is a function template or a function that is templated. A *templated class* is a class template or a class that is templated. A *templated variable* is a variable template or a variable that is templated.

9 A *template-declaration* is written in terms of its template parameters. The optional *requires-clause* following a *template-parameter-list* allows the specification of constraints (13.5.3) on template arguments (13.4). The *requires-clause* introduces the *constraint-expression* that results from interpreting the *constraint-logical-or-expression* as a *constraint-expression*. The *constraint-logical-or-expression* of a *requires-clause* is an unevaluated operand (7.2.3).

[Note 7: The expression in a *requires-clause* uses a restricted grammar to avoid ambiguities. Parentheses can be used to specify arbitrary expressions in a *requires-clause*.]

Example 2:
```c
template<int N> requires N == sizeof new unsigned short
int f();  // error: parentheses required around == expression
```

— end example]

— end note]

10 A definition of a function template, member function of a class template, variable template, or static data member of a class template shall be reachable from the end of every definition domain (6.3) in which it is implicitly instantiated (13.9.2) unless the corresponding specialization is explicitly instantiated (13.9.3) in some translation unit; no diagnostic is required.

### 13.2 Template parameters

1 The syntax for *template-parameters* is:

```
template-parameter:
  type-parameter
  parameter-declaration
```
type-parameter:
  type-parameter-key ...opt identifier ...opt
type-parameter-key identifier = type-id
type-constraint ...opt identifier ...opt
type-constraint identifier = type-id
template-head type-parameter-key ...opt identifier ...opt
template-head type-parameter-key identifier ...opt = id-expression

The component names of a type-constraint are its concept-name and those of its nested-name-specifier (if any).

[Note 1: The > token following the template-parameter-list of a type-parameter can be the product of replacing a >> token by two consecutive > tokens (13.3). — end note]

There is no semantic difference between class and typename in a type-parameter-key. typename followed by an unqualified-id names a template type parameter. typename followed by a qualified-id denotes the type in a non-type parameter-declaration. A template-parameter of the form class identifier is a type-parameter.

[Example 1:

```cpp
class T { /* ... */ };  
int i;

template<class T, T i> void f(T t) {
    T t1 = i;        // template-parameters T and i
    ::T t2 = ::i;    // global namespace members T and i
}
```

Here, the template `f` has a type-parameter called `T`, rather than an unnamed non-type template-parameter of class `T`. — end example]

A storage class shall not be specified in a template-parameter declaration. Types shall not be defined in a template-parameter declaration.

The identifier in a type-parameter is not looked up. A type-parameter whose identifier does not follow an ellipsis defines its identifier to be a typedef-name (if declared without template) or template-name (if declared with template) in the scope of the template declaration.

[Note 2: A template argument can be a class template or alias template. For example,

```cpp
template<class K, class V, template<class T> class C = myarray>
class Map {
    C<K> key;
    C<V> value;
};
```

— end note]

A type-constraint Q that designates a concept C can be used to constrain a contextually-determined type or template type parameter pack T with a constraint-expression E defined as follows. If Q is of the form C<A₁, · · · , Aₙ>, then let E' be C<T, A₁, · · · , Aₙ>. Otherwise, let E' be C<T>. If T is not a pack, then E is E', otherwise E is (E' && ...). This constraint-expression E is called the immediately-declared constraint of Q for T. The concept designated by a type-constraint shall be a type concept (13.7.9).

A type-parameter that starts with a type-constraint introduces the immediately-declared constraint of the type-constraint for the parameter.

[Example 2:

```cpp
template<typename T> concept C1 = true;
template<typename... Ts> concept C2 = true;
```

116) Since template template-parameters and template template-arguments are treated as types for descriptive purposes, the terms non-type parameter and non-type argument are used to refer to non-type, non-template parameters and arguments.
template<
    typename T, typename U>
concept C3 = true;

template<C1 T> struct s1;  // associates C1<T>
template<C1... T> struct s2;  // associates (C1<T> && ...)
template<C2... T> struct s3;  // associates C2<T> && ...
template<C3<int> T> struct s4;  // associates C3<T, int>
template<C3<int>... T> struct s5;  // associates (C3<T, int> && ...)

— end example

A non-type template-parameter shall have one of the following (possibly cv-qualified) types:

(6.1) — a structural type (see below),
(6.2) — a type that contains a placeholder type (9.2.9.6), or
(6.3) — a placeholder for a deduced class type (9.2.9.7).

The top-level cv-qualifiers on the template-parameter are ignored when determining its type.

A structural type is one of the following:

(7.1) — a scalar type, or
(7.2) — an lvalue reference type, or
(7.3) — a literal class type with the following properties:

(7.3.1) — all base classes and non-static data members are public and non-mutable and
(7.3.2) — the types of all bases classes and non-static data members are structural types or (possibly multi-dimensional) array thereof.

An id-expression naming a non-type template-parameter of class type T denotes a static storage duration object of type const T, known as a template parameter object, whose value is that of the corresponding template argument after it has been converted to the type of the template-parameter. All such template parameters in the program of the same type with the same value denote the same template parameter object. A template parameter object shall have constant destruction (7.7).

[Note 3: If an id-expression names a non-type non-reference template-parameter, then it is a prvalue if it has non-class type. Otherwise, if it is of class type T, it is an lvalue and has type const T (7.5.4.2). —end note]

[Example 3:

using X = int;
struct A {};

template<const X& x, int i, A a> void f() {
    i++;
    // error: change of template-parameter value
    &x;  // error: address of non-reference template-parameter
    &i;  // error: address of non-reference template-parameter
    &a;  // OK
    int& ri = i;  // error: attempt to bind non-const reference to temporary
    const int& cri = i;  // OK, const reference binds to temporary
    const A& ra = a;  // OK, const reference binds to a template parameter object
}
— end example]

[Note 4: A non-type template-parameter cannot be declared to have type cv void.

[Example 4:

template<
    void v>
class X;  // error
template<
    void* pv>
class Y;  // OK
— end example]
— end note]

A non-type template-parameter of type “array of T” or of function type T is adjusted to be of type “pointer to T”.

[Example 5:

template<int* a> struct R { /* ... */ };
template<int b[5]> struct S { /* ... */ };

§ 13.2 367
A non-type template parameter declared with a type that contains a placeholder type with a type-constraint introduces the immediately-declared constraint of the type-constraint for the invented type corresponding to the placeholder (9.3.4.6).

A default template-argument is a template-argument (13.4) specified after = in a template-parameter. A default template-argument may be specified for any kind of template-parameter (type, non-type, template) that is not a template parameter pack (13.7.4). A default template-argument may be specified in the template-parameter-lists of the definition of a member of a class template that appears outside of the member’s class. A default template-argument shall not be specified in a friend class template declaration. If a friend function template declaration D specifies a default template-argument, that declaration shall be a definition and there shall be no other declaration of the function template which is reachable from D or from which D is reachable.

The set of default template-arguments available for use is obtained by merging the default arguments from all prior declarations of the template in the same way default function arguments are (9.3.4.7).

Example 6:

```cpp
template<class T1, class T2 = int> class A;
template<class T1 = int, class T2> class A;
```

is equivalent to

```cpp
template<class T1 = int, class T2 = int> class A;
```

—end example

If a template-parameter of a class template, variable template, or alias template has a default template-argument, each subsequent template-parameter shall either have a default template-argument supplied or be a template parameter pack. If a template-parameter of a primary class template, primary variable template, or alias template is a template parameter pack, it shall be the last template-parameter. A template parameter pack of a function template shall not be followed by another template parameter unless that template parameter can be deduced from the parameter-type-list (9.3.4.6) of the function template or has a default argument (13.10.3). A template parameter of a deduction guide template (13.7.2.3) that does not have a default argument shall be deducible from the parameter-type-list of the deduction guide template.

Example 7:

```cpp
template<class T1 = int, class T2> class B; // error
```

U can be neither deduced from the parameter-type-list nor specified

```cpp
template<class... T, class... U> void f() {} // error
template<class... T, class U> void g() {} // error
```

—end example

When parsing a default template-argument for a non-type template-parameter, the first non-nested > is taken as the end of the template-parameter-list rather than a greater-than operator.

Example 8:

```cpp
template<int i = 3 > 4 > // syntax error
class X { /* ... */ };
```

```cpp
template<int i = (3 > 4) > // OK
class Y { /* ... */ };
```

—end example

A template-parameter of a template template-parameter is permitted to have a default template-argument. When such default arguments are specified, they apply to the template template-parameter in the scope of the template template-parameter.

Example 9:
template <template <class TT = float> class T> struct A {
inline void f();
inline void g();
};
template <template <class TT> class T> void A<T>::f() {
T<> t;  // error: TT has no default template argument
}
template <template <class TT = char> class T> void A<T>::g() {
T<> t;  // OK, T<char>
}
—end example

17 If a template-parameter is a type-parameter with an ellipsis prior to its optional identifier or is a parameter-declaration that declares a pack (9.3.4.6), then the template-parameter is a template parameter pack (13.7.4). A template parameter pack that is a parameter-declaration whose type contains one or more unexpanded packs is a pack expansion. Similarly, a template parameter pack that is a type-parameter with a template-parameter-list containing one or more unexpanded packs is a pack expansion. A type parameter pack with a type-constraint that contains an unexpanded parameter pack is a pack expansion. A template parameter pack that is a pack expansion shall not expand a template parameter pack declared in the same template-parameter-list.

[Example 10:

template <class... Types>
    class Tuple;  // Types is a template type parameter pack

    template <class T, int... Dims>
        struct multi_array;  // Dims is a non-type template parameter pack

    template <class... T>
        struct value_holder {
            template <T... Values> struct apply { };  // Values is a non-type template parameter pack
        };

    template <class... T, T... Values>
        struct static_array;  // error: Values expands template type parameter

—end example]

13.3 Names of template specializations [temp.names]  

1 A template specialization (13.9) can be referred to by a template-id:

    simple-template-id:
        template-name < template-argument-list_opt >

    template-id:
        simple-template-id
        operator-function-id < template-argument-list_opt >
        literal-operator-id < template-argument-list_opt >

    template-name:
        identifier

    template-argument-list:
        template-argument ... opt
        template-argument-list , template-argument ... opt

    template-argument:
        constant-expression
        type-id
        id-expression

2 The component name of a simple-template-id, template-id, or template-name is the first name in it.

3 A < is interpreted as the delimiter of a template-argument-list if it follows a name that is not a conversion-function-id and

(3.1) — that follows the keyword template or a - after a nested-name-specifier or in a class member access expression, or

§ 13.3 369
— for which name lookup finds the injected-class-name of a class template or finds any declaration of a template, or
— that is an unqualified name for which name lookup either finds one or more functions or finds nothing, or
— that is a terminal name in a using-declarator (9.9), in a declarator-id (9.3.4), or in a type-only context other than a nested-name-specifier (13.8).

[Note 1: If the name is an identifier, it is then interpreted as a template-name. The keyword template is used to indicate that a dependent qualified name (13.8.3.2) denotes a template where an expression might appear. — end note]

[Example 1:

```cpp
struct X {
    template<std::size_t> X* alloc();
    template<std::size_t> static X* adjust();
};

template<class T> void f(T* p) {
    T* p1 = p->alloc<200>(); // error: < means less than
    T* p2 = p->template alloc<200>(); // OK, < starts template argument list
    T::adjust<100>(); // error: < means less than
    T::template adjust<100>(); // OK, < starts template argument list
}
```
—end example]

4 When parsing a template-argument-list, the first non-nested \(^\text{117}^\) is taken as the ending delimiter rather than a greater-than operator. Similarly, the first non-nested \(\gg\) is treated as two consecutive but distinct \(\rangle\) tokens, the first of which is taken as the end of the template-argument-list and completes the template-id.

[Note 2: The second \(\rangle\) token produced by this replacement rule can terminate an enclosing template-id construct or it can be part of a different construct (e.g., a cast). — end note]

[Example 2:

```cpp
template<int i> class X { /* ... */ ;

X< 1>2 > x1; // syntax error
X<(1>2)> x2; // OK

template<class T> class Y { /* ... */ ;
Y<X<1>> x3; // OK, same as Y<X<1> > x3;
Y<X<6>1>> x4; // syntax error
Y<X<(6>>1)>> x5; // OK
```
—end example]

5 The keyword template shall not appear immediately after a declarative nested-name-specifier (7.5.4.3).

6 A name prefixed by the keyword template shall be followed by a template argument list or refer to a class template or an alias template. The latter case is deprecated (D.10). The keyword template shall not appear immediately before a \(\sim\) token (as to name a destructor).

[Note 3: The keyword template cannot be applied to non-template members of class templates. — end note]

[Note 4: As is the case with the typename prefix, the template prefix is allowed even when lookup for the name would already find a template. — end note]

[Example 3:

```cpp
template<class T> struct A {
    void f(int);
    template <class U> void f(U);
};

template <class T> void f(T t) {
    A<T> a;
    a.template f<>((t); // OK, calls template
```

\(^{117}\) A \(\rangle\) that encloses the type-id of a dynamic_cast, static_cast, reinterpret_cast or const_cast, or which encloses the template-arguments of a subsequent template-id, is considered nested for the purpose of this description.
7 A template-id is valid if

(7.1) there are at most as many arguments as there are parameters or a parameter is a template parameter

(7.2) there is an argument for each non-deducible non-pack parameter that does not have a default template-argument

(7.3) each template-argument matches the corresponding template-parameter (13.4).

(7.4) substitution of each template argument into the following template parameters (if any) succeeds, and

(7.5) if the template-id is non-dependent, the associated constraints are satisfied as specified in the next paragraph.

A simple-template-id shall be valid unless it names a function template specialization (13.10.3).

[Example 4:]

template<class T, T::type n = 0> class X;  
struct S {  
    using type = int;  
};  
using T1 = X<S, int, int>; // error: too many arguments  
using T2 = X<>; // error: no default argument for first template parameter  
using T3 = X<int>;; // error: value 1 does not match type-parameter  
using T4 = X<int>; // error: substitution failure for second template parameter  
using T5 = X<S>; // OK

—end example]

8 When the template-name of a simple-template-id names a constrained non-function template or a constrained template template-parameter, and all template-arguments in the simple-template-id are non-dependent (13.8.3.5), the associated constraints (13.5.3) of the constrained template shall be satisfied (13.5.2).

[Example 5:]

template< typename T> concept C1 = sizeof(T) != sizeof(int);  

template< C1 T> struct S1 { };  
template< C1 T> using Ptr = T*;

S1<int>* p; // error: constraints not satisfied  
Ptr<int> p; // error: constraints not satisfied

template< typename T>  
struct S2 { Ptr<int> x; }; // ill-formed, no diagnostic required

template< typename T>  
struct S3 { Ptr<T> x; }; // OK, satisfaction is not required

S3<int> x; // error: constraints not satisfied

template<template< C1 T> class X>  
struct S4 {  
    X<int> x; // ill-formed, no diagnostic required
};
template<typename T> concept C2 = sizeof(T) == 1;

template<C2 T> struct S {};

template struct S<char[2]>; // error: constraints not satisfied
template<> struct S<char[2]> { };// error: constraints not satisfied

— end example

9 A concept-id is a simple-template-id where the template-name is a concept-name. A concept-id is a prvalue of type bool, and does not name a template specialization. A concept-id evaluates to true if the concept’s normalized constraint-expression (13.5.3) is satisfied (13.5.2) by the specified template arguments and false otherwise.

[Note 5: Since a constraint-expression is an unevaluated operand, a concept-id appearing in a constraint-expression is not evaluated except as necessary to determine whether the normalized constraints are satisfied. — end note]

[Example 6]:

```cpp
template<typename T> concept C = true;
static_assert(C<int>); // OK
```

— end example

13.4 Template arguments

13.4.1 General

There are three forms of template-argument, corresponding to the three forms of template-parameter: type, non-type and template. The type and form of each template-argument specified in a template-id shall match the type and form specified for the corresponding parameter declared by the template in its template-parameter-list. When the parameter declared by the template is a template parameter pack (13.7.4), it will correspond to zero or more template-arguments.

[Example 1]:

```cpp
template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int);
    T& elem(int i) { return v[i]; }
};

Array<int> v1(20);
typedef std::complex<double> dcomplex; // std::complex is a standard library template
Array<dcomplex> v2(30);
Array<dcomplex> v3(40);

void bar() {
    v1[3] = 7;
    v2[3] = v3.elem(4) = dcomplex(7,8);
}
```

— end example

2 The template argument list of a template-head is a template argument list in which the nth template argument has the value of the nth template parameter of the template-head. If the nth template parameter is a template parameter pack (13.7.4), the nth template argument is a pack expansion whose pattern is the name of the template parameter pack.

3 In a template-argument, an ambiguity between a type-id and an expression is resolved to a type-id, regardless of the form of the corresponding template-parameter.118

[Example 2]:

```cpp
template<class T> void f();
template<int I> void f();
```

118) There is no such ambiguity in a default template-argument because the form of the template-parameter determines the allowable forms of the template-argument.

§ 13.4.1 372
void g() {
    f<int>()();    // int() is a type-id: call the first f()
}

—end example[4]

[Note 1: Names used in a template-argument are subject to access control where they appear. Because a template-parameter is not a class member, no access control applies. —end note]

[Example 3:]

template<class T> class X {
    static T t;
};

class Y {
private:
    struct S { /* ... */ };  // OK, S is accessible
    X<S> x;                // X<Y::S> has a static member of type Y::S
    // OK, even though Y::S is private
};

X<Y::S> y;        // error: S not accessible
—end example]

For a template-argument that is a class type or a class template, the template definition has no special access rights to the members of the template-argument.

[Example 4:]

template <template <class TT> class T> class A {
    typename T<int>::S s;
};

template <class U> class B {
private:
    struct S { /* ... */ };  // OK, S is accessible
};

A<B> b;        // error: B has no access to B::S
—end example]

When template argument packs or default template-arguments are used, a template-argument list can be empty. In that case the empty <> brackets shall still be used as the template-argument-list.

[Example 5:]

template<class T = char> class String;
String<> p;            // OK, String<char>
String* q;            // syntax error

template<class ... Elements> class Tuple;
Tuple<> t;           // OK, Elements is empty
Tuple* u;           // syntax error
—end example]

An explicit destructor call (11.4.7) for an object that has a type that is a class template specialization may explicitly specify the template-arguments.

[Example 6:]

template<class T> struct A {
    ~A();
};

void f(A<int>* p, A<int>* q) {
    p->A<int>::~A();        // OK, destructor call
    q->A<int>::~A<int>();   // OK, destructor call
}
—end example]
If the use of a template-argument gives rise to an ill-formed construct in the instantiation of a template specialization, the program is ill-formed.

When name lookup for the component name of a template-id finds an overload set, both non-template functions in the overload set and function templates in the overload set for which the template-arguments do not match the template-parameters are ignored.

[Note 2: If none of the function templates have matching template-parameters, the program is ill-formed. — end note]

When a simple-template-id does not name a function, a default template-argument is implicitly instantiated (13.9.2) when the value of that default argument is needed.

[Example 7:
```
template<typename T, typename U = int> struct S { };  
S<bool> * p;  // the type of p is S<bool, int>*
```

The default argument for U is instantiated to form the type S<bool, int>*. — end example]

A template-argument followed by an ellipsis is a pack expansion (13.7.4).

### 13.4.2 Template type arguments [temp.arg.type]

1. A template-argument for a template-parameter which is a type shall be a type-id.

2. [Example 1:
```
template <class T> class X { };  
template <class T> void f(T t) { }
struct { } unnamed_obj;

void f() {
  struct A { };  
  enum { e1 };  
  typedef struct { } B;  
  B b;  
  X<A> x1; // OK  
  X<A*> x2; // OK  
  X<B> x3; // OK  
  f(e1); // OK  
  f(unnamed_obj); // OK  
  f(b); // OK
}
```

— end example]

[Note 1: A template type argument can be an incomplete type (6.8.1). — end note]

### 13.4.3 Template non-type arguments [temp.arg.nontype]

1. If the type T of a template-parameter (13.2) contains a placeholder type (9.2.9.6) or a placeholder for a deduced class type (9.2.9.7), the type of the parameter is the type deduced for the variable x in the invented declaration

   \[ T \, x = \text{template-argument} \;

   \]

   If a deduced parameter type is not permitted for a template-parameter declaration (13.2), the program is ill-formed.

2. A template-argument for a non-type template-parameter shall be a converted constant expression (7.7) of the type of the template-parameter.

   [Note 1: If the template-argument is an overload set (or the address of such, including forming a pointer-to-member), the matching function is selected from the set (12.3). — end note]

3. For a non-type template-parameter of reference or pointer type, or for each non-static data member of reference or pointer type in a non-type template-parameter of class type or subobject thereof, the reference or pointer value shall not refer to or be the address of (respectively):

   - a temporary object (6.7.7),
   - a string literal object (5.13.5),
   - the result of a typeid expression (7.6.1.8),
— a predefined `__func__` variable (9.5.1), or
— a subobject (6.7.2) of one of the above.

4 [Example 1:

```cpp
template<const int* pci> struct X { /* ... */ }; int ai[10];
X<ai> x1; // array to pointer and qualification conversions

struct Y { /* ... */ }; template<const Y& b> struct Z { /* ... */ }; Y y;
Z<y> z; // no conversion, but note extra cv-qualification

template<int (&pa)[5]> struct W { /* ... */ }; int b[5];
W<b> w; // no conversion

void f(char);
void f(int);

template<void (*pf)(int)> struct A { /* ... */ }; A<&f> a;
// selects f(int)

template<auto n> struct B { /* ... */ }; B<5> b1; // OK, template parameter type is int
B<'a'> b2; // OK, template parameter type is char
B<2.5> b3; // OK, template parameter type is double
B<void(0)> b4; // error: template parameter type cannot be void
— end example]
```

5 [Note 2: A string-literal (5.13.5) is not an acceptable template-argument for a template-parameter of non-class type.

[Example 2:

```cpp
template<class T, T p> class X { /* ... */ };

X<const char*, "Studebaker"> x; // error: string literal object as template-argument
X<const char*, "Knope" + 1> x2; // error: subobject of string literal object as template-argument

const char p[] = "Vivisectionist";
X<const char*, p> y; // OK

struct A {
    constexpr A(const char*) {}
};

X<A, "Pyrophoricity"> z; // OK, string-literal is a constructor argument to A
— end example]
— end note]

6 [Note 3: A temporary object is not an acceptable template-argument when the corresponding template-parameter has reference type.

[Example 3:

```cpp
template<const int& CRI> struct B { /* ... */ };
B<1> b1; // error: temporary would be required for template argument

int c = 1;
B<c> b2; // OK

struct X { int n; }
```

§ 13.4.3 375
struct Y { const int &r; }

 template<Y y> struct C { /* ... */ };
 C<X(Y{1}.n)> c;  
 // error: subobject of temporary object used to initialize
 // reference member of template parameter

—end example]
—end note]

13.4.4 Template template arguments

A template-argument for a template template-parameter shall be the name of a class template or an alias template, expressed as id-expression. Only primary templates are considered when matching the template template argument with the corresponding parameter; partial specializations are not considered even if their parameter lists match that of the template template parameter.

Any partial specializations (13.7.6) associated with the primary template are considered when a specialization based on the template template-parameter is instantiated. If a specialization is not reachable from the point of instantiation, and it would have been selected had it been reachable, the program is ill-formed, no diagnostic required.

[Example 1:

template<class T> class A {  // primary template
    int x;
};
template<class T> class A<T*> {  // partial specialization
    long x;
};
template<template<class U> class V> class C {
    V<int> y;
    V<int*> z;
};
C<A> c;  
// V<int> within C<A> uses the primary template, so c.y.x has type int
// V<int*> within C<A> uses the partial specialization, so c.z.x has type long

—end example]

A template-argument matches a template template-parameter P when P is at least as specialized as the template-argument A. In this comparison, if P is unconstrained, the constraints on A are not considered. If P contains a template parameter pack, then A also matches if P if each of A’s template parameters matches the corresponding template parameter in the template-head of P. Two template parameters match if they are of the same kind (type, non-type, template), for non-type template-parameters, their types are equivalent (13.7.7.2), and for template template-parameters, each of their corresponding template template parameters matches, recursively. When P’s template-head contains a template parameter pack (13.7.4), the template parameter pack will match zero or more template parameters or template parameter packs in the template-head of A with the same type and form as the template parameter pack in P (ignoring whether those template parameters are template parameter packs).

[Example 2:

template<class T> class A { /* ... */ };

X<A> xa;  // OK
X<B> xb;  // OK
X<C> xc;  // OK
Y<A> ya;  // OK
Y<B> yb;  // OK
Y<C> yc;  // OK
Z<D> zd;  // OK

—end example]
Example 3:

```cpp
template <class T> struct eval;

template <template <class, class...> class TT, class T1, class... Rest>
struct eval<TT<T1, Rest...>> { };

template <class T1> struct A;
template <class T1, class T2> struct B;
template <int N> struct C;
template <class T1, int N> struct D;
template <class T1, class T2, int N = 17> struct E;

eval<A<int>> eA; // OK, matches partial specialization of eval

eval<B<int, float>> eB; // OK, matches partial specialization of eval

eval<C<int>> eC; // error: C does not match TT in partial specialization

eval<D<int, 17>> eD; // error: D does not match TT in partial specialization

eval<E<int, float>> eE; // error: E does not match TT in partial specialization
```

— end example ]

Example 4:

```cpp
template<typename T> concept C = requires (T t) { t.f(); };
template<typename T> concept D = C<T> && requires (T t) { t.g(); };
template<template<C> class P> struct S { };
template<C> struct X { };
template<D> struct Y { };
template<typename T> struct Z { };

S<X> s1; // OK, X and P have equivalent constraints
S<Y> s2; // error: P is not at least as specialized as Y
S<Z> s3; // OK, P is at least as specialized as Z
```

— end example]

A template template-parameter P is at least as specialized as a template template-argument A if, given the following rewrite to two function templates, the function template corresponding to P is at least as specialized as the function template corresponding to A according to the partial ordering rules for function templates (13.7.7.3). Given an invented class template X with the template-head of A (including default arguments and requires-clause, if any):

(4.1) — Each of the two function templates has the same template parameters and requires-clause (if any), respectively, as P or A.

(4.2) — Each function template has a single function parameter whose type is a specialization of X with template arguments corresponding to the template parameters from the respective function template where, for each template parameter PP in the template-head of the function template, a corresponding template argument AA is formed. If PP declares a template parameter pack, then AA is the pack expansion PP... (13.7.4); otherwise, AA is the id-expression PP.

If the rewrite produces an invalid type, then P is not at least as specialized as A.

13.5 Template constraints [temp.constr]

13.5.1 General [temp.constr.general]

[Note 1: Subclause 13.5 defines the meaning of constraints on template arguments. The abstract syntax and satisfaction rules are defined in 13.5.2. Constraints are associated with declarations in 13.5.3. Declarations are partially ordered by their associated constraints (13.5.5). — end note]

13.5.2 Constraints [temp.constr.constr]

13.5.2.1 General [temp.constr.constr.general]

A constraint is a sequence of logical operations and operands that specifies requirements on template arguments. The operands of a logical operation are constraints. There are three different kinds of constraints:

(1.1) — conjunctions (13.5.2.2),
In order for a constrained template to be instantiated (13.9), its associated constraints (13.5.3) shall be satisfied as described in the following subclauses.

[Note 1: Forming the name of a specialization of a class template, a variable template, or an alias template (13.3) requires the satisfaction of its constraints. Overload resolution (12.2.3) requires the satisfaction of constraints on functions and function templates. — end note]

13.5.2.2 Logical operations [temp.constr.op]

There are two binary logical operations on constraints: conjunction and disjunction.

[Note 1: These logical operations have no corresponding C++ syntax. For the purpose of exposition, conjunction is spelled using the symbol $\land$ and disjunction is spelled using the symbol $\lor$. The operands of these operations are called the left and right operands. In the constraint $A \land B$, $A$ is the left operand, and $B$ is the right operand. — end note]

A conjunction is a constraint taking two operands. To determine if a conjunction is satisfied, the satisfaction of the first operand is checked. If that is not satisfied, the conjunction is not satisfied. Otherwise, the conjunction is satisfied if and only if the second operand is satisfied.

A disjunction is a constraint taking two operands. To determine if a disjunction is satisfied, the satisfaction of the first operand is checked. If that is not satisfied, the conjunction is not satisfied. Otherwise, the disjunction is satisfied if and only if the second operand is satisfied.

[Example 1:

```cpp
template<typename T>
constexpr bool get_value() { return T::value; }

template<typename T>
requires (sizeof(T) > 1) && (get_value<T>())
void f(T);

void f('a'); // OK, calls f(int)
```

In the satisfaction of the associated constraints (13.5.3) of f, the constraint `sizeof(char) > 1` is not satisfied; the second operand is not checked for satisfaction.

[Note 2: A logical negation expression (7.6.2.2) is an atomic constraint; the negation operator is not treated as a logical operation on constraints. As a result, distinct negation constraint-expressions that are equivalent under 13.7.7.2 do not subsume one another under 13.5.5. Furthermore, if substitution to determine whether an atomic constraint is satisfied (13.5.2.3) encounters a substitution failure, the constraint is not satisfied, regardless of the presence of a negation operator.

[Example 2:

```cpp
template <class T> concept sad = false;

template <class T> int f1(T) requires (!sad<T>);

template <class T> int f1(T) requires (!sad<T>) && true;

int i1 = f1(42); // ambiguous, !sad<T> atomic constraint expressions (13.5.2.3)
// are not formed from the same expression

int i2 = f2(42); // OK, !sad<T> atomic constraint expressions both come from not_sad

// error: associated constraints not satisfied due to substitution failure
```

Here, requires (!sad<typename T::type>) requires that there is a nested type that is not sad, whereas requires (!sad_nested_type<T>) requires that there is no sad nested type. — end example]

§ 13.5.2.2 378
13.5.2.3 Atomic constraints

An atomic constraint is formed from an expression \( E \) and a mapping from the template parameters that appear within \( E \) to template arguments that are formed via substitution during constraint normalization in the declaration of a constrained entity (and, therefore, can involve the unsubstituted template parameters of the constrained entity), called the parameter mapping (13.5.3).

[Note 1: Atomic constraints are formed by constraint normalization (13.5.4). \( E \) is never a logical AND expression (7.6.14) nor a logical OR expression (7.6.15). — end note]

2 Two atomic constraints, \( e_1 \) and \( e_2 \), are identical if they are formed from the same appearance of the same expression and if, given a hypothetical template \( A \) whose template-parameter-list consists of template-parameters corresponding and equivalent (13.7.7.2) to those mapped by the parameter mappings of the expression, a template-id naming \( A \) whose template-arguments are the targets of the parameter mapping of \( e_1 \) is the same (13.6) as a template-id naming \( A \) whose template-arguments are the targets of the parameter mapping of \( e_2 \).

[Note 2: The comparison of parameter mappings of atomic constraints operates in a manner similar to that of declaration matching with alias template substitution (13.7.8).]

[Example 1:

```cpp
template <unsigned N> constexpr bool Atomic = true;
template <unsigned N> concept C = Atomic<N>;
template <unsigned N> concept Add1 = C<N + 1>;
template <unsigned N> concept AddOne = C<N + 1>;
template <unsigned N> void f()
    requires Add1<2 * M>;
template <unsigned N> void f()
    requires AddOne<2 * M> & & true;

int x = f<0>(); // OK, the atomic constraints from concept C in both fs are Atomic<N> with mapping similar to N → 2 * M + 1

template <unsigned N> struct WrapN;
template <unsigned N> using Add1Ty = WrapN<N + 1>;
template <unsigned N> using AddOneTy = WrapN<N + 1>;
template <unsigned N> void g(Add1Ty<2 * M> *);
template <unsigned N> void g(AddOneTy<2 * M> *);

void h() {
    g<0>(nullptr); // OK, there is only one g
}
```

— end example]

As specified in 13.7.7.2, if the validity or meaning of the program depends on whether two constructs are equivalent, and they are functionally equivalent but not equivalent, the program is ill-formed, no diagnostic required.

[Example 2:

```cpp
 template <unsigned N> void f2()
    requires Add1<2 * N>;
template <unsigned N> int f2()
    requires Add1<N * 2> & & true;
void h2() {
    f2<0>(); // ill-formed, no diagnostic required:
    // requires determination of subsumption between atomic constraints that are functionally equivalent but not equivalent
}
```

— end example]

3 To determine if an atomic constraint is satisfied, the parameter mapping and template arguments are first substituted into its expression. If substitution results in an invalid type or expression, the constraint is not satisfied. Otherwise, the lvalue-to-rvalue conversion (7.3.2) is performed if necessary, and \( E \) shall be a constant expression of type bool. The constraint is satisfied if and only if evaluation of \( E \) results in true.
If, at different points in the program, the satisfaction result is different for identical atomic constraints and template arguments, the program is ill-formed, no diagnostic required.

[Example 3:]
```cpp
template<typename T> concept C = sizeof(T) == 4 && !true; // requires atomic constraints sizeof(T) == 4 and !true
template<typename T> struct S {
    constexpr operator bool() const { return true; }
};
template<typename T> requires (S<T>{})
void f(T); // #1
void f(int); // #2

void g() {
    f(0);   // error: expression S<int>{} does not have type bool
    // while checking satisfaction of deduced arguments of #1;
    // call is ill-formed even though #2 is a better match
}
```

— end example

13.5.3 Constrained declarations [temp.constr.decl]

1 A template declaration (13.1) or templated function declaration (9.3.4.6) can be constrained by the use of a `requires-clause`. This allows the specification of constraints for that declaration as an expression:

```
constraint-expression:
    logical-or-expression
```

2 Constraints can also be associated with a declaration through the use of `type-constraints` in a `template-parameter-list` or parameter-type-list. Each of these forms introduces additional `constraint-expressions` that are used to constrain the declaration.

3 A declaration’s associated constraints are defined as follows:

   (3.1) If there are no introduced `constraint-expressions`, the declaration has no associated constraints.

   (3.2) Otherwise, if there is a single introduced `constraint-expression`, the associated constraints are the normal form (13.5.4) of that expression.

   (3.3) Otherwise, the associated constraints are the normal form of a logical AND expression (7.6.14) whose operands are in the following order:

      (3.3.1) the `constraint-expression` introduced by each `type-constraint` (13.2) in the declaration’s `template-parameter-list`, in order of appearance, and

      (3.3.2) the `constraint-expression` introduced by a `requires-clause` following a `template-parameter-list` (13.1), and

      (3.3.3) the `constraint-expression` introduced by each `type-constraint` in the parameter-type-list of a function declaration, and

      (3.3.4) the `constraint-expression` introduced by a trailing `requires-clause` (9.3) of a function declaration (9.3.4.6).

The formation of the associated constraints establishes the order in which constraints are instantiated when checking for satisfaction (13.5.2).

[Example 1:]
```cpp
template<typename T> concept C = true;

template<C T> void f1(T);
template<typename T> requires C<T> void f2(T);
template<typename T> void f3(T) requires C<T>;
```

The functions `f1`, `f2`, and `f3` have the associated constraint `C<T>`.

```cpp
template<typename T> concept C1 = true;
template<typename T> concept C2 = sizeof(T) > 0;
```
template<C1 T> void f4(T) requires C2<T>;
template< typename T> requires C1<T> && C2<T> void f5(T);
The associated constraints of f4 and f5 are C1<T> ∧ C2<T>.
template<C1 T> requires C2<T> void f6();
template<C2 T> requires C1<T> void f7();
The associated constraints of f6 are C1<T> ∧ C2<T>, and those of f7 are C2<T> ∧ C1<T>. — end example

When determining whether a given introduced constraint-expression \( C_1 \) of a declaration in an instantiated specialization of a templated class is equivalent (13.7.7.2) to the corresponding constraint-expression \( C_2 \) of a declaration outside the class body, \( C_1 \) is instantiated. If the instantiation results in an invalid expression, the constraint-expressions are not equivalent.

[Note 1: This can happen when determining which member template is specialized by an explicit specialization declaration. — end note]

[Example 2:

```cpp
template <class T> concept C = true;
template <class T> struct A {
    template <class U> U f(U) requires C<typename T::type>; // #1
    template <class U> U f(U) requires C<T>; // #2
};

template <> template <class U> U A<int>::f(U u) requires C<int> { return u; } // OK, specializes #2
```
Substituting int for T in C<typename T::type> produces an invalid expression, so the specialization does not match #1. Substituting int for T in C<T> produces C<int>, which is equivalent to the constraint-expression for the specialization, so it does match #2. — end example]

### 13.5.4 Constraint normalization [temp.constr.normal]

The normal form of an expression \( E \) is a constraint (13.5.2) that is defined as follows:

1. The normal form of an expression \( E \) is the normal form of \( E \).
2. The normal form of an expression \( E_1 || E_2 \) is the disjunction (13.5.2.2) of the normal forms of \( E_1 \) and \( E_2 \).
3. The normal form of an expression \( E_1 && E_2 \) is the conjunction of the normal forms of \( E_1 \) and \( E_2 \).
4. The normal form of a concept-id \( C<A_1, A_2, ..., A_n> \) is the normal form of the constraint-expression of \( C \), after substituting \( A_1, A_2, ..., A_n \) for \( C \)'s respective template parameters in the parameter mappings in each atomic constraint. If any such substitution results in an invalid type or expression, the program is ill-formed; no diagnostic is required.

[Example 1:

```cpp
template<typename T> concept A = T::value || true;
template<typename U> concept B = A<U*>;
template<typename V> concept C = B<V&>;
```
Normalization of B's constraint-expression is valid and results in T::value (with the mapping T↦U*) ∨ true (with an empty mapping), despite the expression T::value being ill-formed for a pointer type T. Normalization of C's constraint-expression results in the program being ill-formed, because it would form the invalid type V&* in the parameter mapping. — end example]

5. The normal form of any other expression \( E \) is the atomic constraint whose expression is \( E \) and whose parameter mapping is the identity mapping.

The process of obtaining the normal form of a constraint-expression is called normalization.

[Note 1: Normalization of constraint-expressions is performed when determining the associated constraints (13.5.2) of a declaration and when evaluating the value of an id-expression that names a concept specialization (7.5.4). — end note]

[Example 2:

```cpp
template<typename T> concept C1 = sizeof(T) == 1;
template<typename U> concept C2 = C1<T> && 1 == 2;
template<typename T> concept C3 = requires { typename T::type; };
template<typename T> concept C4 = requires (T x) { ++x; };
```
13.5.5 Partial ordering by constraints

A constraint is in conjunctive normal form when it is a conjunction of clauses where each clause is a disjunction of atomic constraints. For atomic constraints $A$, $B$, and $C$, the disjunctive normal form of the constraint $A \land (B \lor C)$ is $(A \land B) \lor (A \land C)$. Its disjunctive clauses are $(A \land B)$ and $(A \land C)$.

A constraint is in disjunctive normal form when it is a disjunction of clauses where each clause is a conjunction of atomic constraints. For atomic constraints $A$, $B$, and $C$, the constraint $A \lor (B \land C)$ is in conjunctive normal form. Its conjunctive clauses are $A$ and $(B \land C)$.

13.6 Type equivalence

Two template-ids are the same if

1. their template-names, operator-function-ids, or literal-operator-ids refer to the same template, and
2. their corresponding type template-arguments are the same type, and
— their corresponding non-type template-arguments are template-argument-equivalent (see below) after conversion to the type of the template-parameter, and

— their corresponding template template-arguments refer to the same template.

Two template-ids that are the same refer to the same class, function, or variable.

2 Two values are template-argument-equivalent if they are of the same type and

— they are of integral type and their values are the same, or

— they are of floating-point type and their values are identical, or

— they are of type std::nullptr_t, or

— they are of enumeration type and their values are the same, or

— they are of pointer type and they have the same pointer value, or

— they are of pointer-to-member type and they refer to the same class member or are both the null member pointer value, or

— they are of reference type and they refer to the same object or function, or

— they are of array type and their corresponding elements are template-argument-equivalent, or

— they are of union type and either they both have no active member or they have the same active member and their active members are template-argument-equivalent, or

— they are of class type and their corresponding direct subobjects and reference members are template-argument-equivalent.

[Example 1:]

```c
template<class E, int size> class buffer { /* ... */
buffer<char,2*512> x;
buffer<char,1024> y;
```
declares x and y to be of the same type, and

```c
template<class T, void(*err_fct)()> class list { /* ... */
list<int,&error_handler1> x1;
list<int,&error_handler2> x2;
list<int,&error_handler2> x3;
list<char,&error_handler2> x4;
```
declares x2 and x3 to be of the same type. Their type differs from the types of x1 and x4.

```c
template<class T> struct X { }
template<class> struct Y { }
template<class T> using Z = Y<T>
X<Y<int> > y;
X<Z<int> > z;
```
declares y and z to be of the same type. — end example]

4 If an expression $e$ is type-dependent (13.8.3.3), decltype($e$) denotes a unique dependent type. Two such decltype-specifiers refer to the same type only if their expressions are equivalent (13.7.7.2).

[Note 1: However, such a type might be aliased, e.g., by a typedef-name. — end note]

### 13.7 Template declarations

#### 13.7.1 General

1 The template parameters of a template are specified in the angle bracket enclosed list that immediately follows the keyword `template`.

2 A primary template declaration is one in which the name of the template is not followed by a template-argument-list. The template argument list of a primary template is the template argument list of its template-head (13.4). A template declaration in which the name of the template is followed by a template-argument-list is a partial specialization (13.7.6) of the template named in the declaration, which shall be a class or variable template.

3 For purposes of name lookup and instantiation, default arguments, type-constraints, requires-clauses (13.1), and noexcept-specifiers of function templates and of member functions of class templates are considered
definitions; each default argument, type-constraint, requires-clause, or noexcept-specifier is a separate definition which is unrelated to the templated function definition or to any other default arguments, type-constraints, requires-clauses, or noexcept-specifiers. For the purpose of instantiation, the substatements of a constexpr if statement (8.5.2) are considered definitions.

4 Because an alias-declaration cannot declare a template-id, it is not possible to partially or explicitly specialize an alias template.

13.7.2 Class templates

13.7.2.1 General

A class template defines the layout and operations for an unbounded set of related types.

[Example 1: It is possible for a single class template List to provide an unbounded set of class definitions: one class List<T> for every type T, each describing a linked list of elements of type T. Similarly, a class template Array describing a contiguous, dynamic array can be defined like this:

```
template<class T> class Array {
  T* v;
  int sz;
  public:
    explicit Array(int);
    T& operator[](int);
    T& elem(int i) { return v[i]; }
};
```

The prefix template<class T> specifies that a template is being declared and that a type-name T can be used in the declaration. In other words, Array is a parameterized type with T as its parameter. — end example]

3 [Note 1: When a member of a class template is defined outside of the class template definition, the member definition is defined as a template definition with the template-head equivalent to that of the class template. The names of the template parameters used in the definition of the member can differ from the template parameter names used in the class template definition. The class template name in the member definition is followed by the template argument list of the template-head (13.4).

[Example 2:

```
template<class T1, class T2> struct A {
  void f1();
  void f2();
};
```

```
template<class T2, class T1> void A<T2,T1>::f1() { } // OK
template<class T2, class T1> void A<T1,T2>::f2() { } // error
```

```
template<class ... Types> struct B {
  void f3();
  void f4();
};
```

```
template<class ... Types> void B<Types ...>::f3() { } // OK
template<class ... Types> void B<Types>::f4() { } // error
```

```
template<typename T> concept C = true;
template<typename T> concept D = true;
```

```
template<typename T> requires C<T> // ill-formed, no diagnostic required: template-heads are
void S<T>::h() { } // functionally equivalent but not equivalent
```
template<C X> template<D Y>
struct S<X>::Inner { }; // OK
— end example]
— end note]

In a partial specialization, explicit specialization or explicit instantiation of a class template, the class-key shall agree in kind with the original class template declaration (9.2.9.4).

13.7.2.2 Member functions of class templates [temp.mem.func]

A member function of a class template may be defined outside of the class template definition in which it is declared.

[Example 1:

```cpp
template<class T> class Array {
T* v;
int sz;
pubilc:
explicit Array(int);
T& operator[](int);
T& elem(int i) { return v[i]; }
};
declares three member functions of a class template. The subscript function can be defined like this:
```}
template<class T> T& Array<T>::operator[](int i) {
    if (i<0 || sz<=i) error("Array: range error");
    return v[i];
}
A constrained member function can be defined out of line:
```cpp
template<typename T> concept C = requires {
    typename T::type;
};
template<typename T> struct S {
    void f() requires C<T>;
    void g() requires C<T>;
};
template<typename T>
void S<T>::f() requires C<T> { } // OK
```}
template<typename T>
void S<T>::g() { } // error: no matching function in S<T>
— end example]

2 The template-arguments for a member function of a class template are determined by the template-arguments of the type of the object for which the member function is called.

[Example 2: The template-argument for Array<T>::operator[] will be determined by the Array to which the subscripting operation is applied.
```cpp
Array<int> v1(20);
Array<dcomplex> v2(30);
v1[3] = 7; // Array<int>::operator[]
v2[3] = dcomplex(7,8); // Array<dcomplex>::operator[]
— end example]

13.7.2.3 Deduction guides [temp.deduct.guide]

Deduction guides are used when a template-name appears as a type specifier for a deduced class type (9.2.9.7). Deduction guides are not found by name lookup. Instead, when performing class template argument deduction (12.2.2.9), all reachable deduction guides declared for the class template are considered.

deduction-guide:
    explicit-specifier_opt template-name ( parameter-declaration-clause ) -> simple-template-id ;
Example 1:

```cpp
template<class T, class D = int>
struct S {
    T data;
};
template<class U>
S(U) -> S<typename U::type>;

struct A {
    using type = short;
    operator type();
};
S x(A());  // x is of type S<short, int>
```

— end example]

The same restrictions apply to the parameter-declaration-clause of a deduction guide as in a function declaration (9.3.4.6). The simple-template-id shall name a class template specialization. The template-name shall be the same identifier as the template-name of the simple-template-id. A deduction-guide shall inhabit the scope to which the corresponding class template belongs and, for a member class template, have the same access. Two deduction guide declarations for the same class template shall not have equivalent parameter-declaration-clauses if either is reachable from the other.

13.7.2.4 Member classes of class templates

A member class of a class template may be defined outside the class template definition in which it is declared.

[Note 1: The member class must be defined before its first use that requires an instantiation (13.9.2). For example,
```
template<class T> struct A {
    class B;
};
A<int>::B* b1;
// OK, requires A to be defined but not A::B
template<class T> class A<T>::B { };
A<int>::B b2;
// OK, requires A::B to be defined
```
— end note]

13.7.2.5 Static data members of class templates

A definition for a static data member or static data member template may be provided in a namespace scope enclosing the definition of the static member’s class template.

[Example 1:
```
template<class T> class X {
    static T s;
};
template<class T> T X<T>::s = 0;

struct limits {
    template<class T>
    static const T min;  // declaration
};

template<class T>
const T limits::min = { };  // definition
```
— end example]

An explicit specialization of a static data member declared as an array of unknown bound can have a different bound from its definition, if any.

[Example 2:
```
template <class T> struct A {
    static int i[];
};
template <class T> int A<T>::i[4];  // 4 elements
template <> int A<int>::i[] = { 1 };  // OK, 1 element
```

§ 13.7.2.5
13.7.2.6 Enumeration members of class templates

An enumeration member of a class template may be defined outside the class template definition.

Example 1:
```cpp
template<class T> struct A {
    enum E : T;
};
A<int> a;
template<class T> enum A<T>::E : T { e1, e2 };
A<int>::E e = A<int>::e1;
```

13.7.3 Member templates

A template can be declared within a class or class template; such a template is called a member template. A member template can be defined within or outside its class definition or class template definition. A member template of a class template that is defined outside of its class template definition shall be specified with a template-head equivalent to that of the class template followed by a template-head equivalent to that of the member template (13.7.7.2).

Example 1:
```cpp
template<class T> struct string {
    template<class T2> int compare(const T2&);
    template<class T2> string(const string<T2>& s) { /* ... */ }
};
template<class T> template<class T2> int string<T>::compare(const T2& s) {
    // ...
}
```

Example 2:
```cpp
template<typename T> concept C1 = true;
template<typename T> concept C2 = sizeof(T) <= 4;
template<C1 T> struct S {
    template<C2 U> void f(U);
    template<C2 U> void g(U);
};
template<C1 T> template<C2 U>
void S<T>::f(U) { } // OK
template<C1 T> template<typename U>
void S<T>::g(U) { } // error: no matching function in S<T>
```

A local class of non-closure type shall not have member templates. Access control rules (11.8) apply to member template names. A destructor shall not be a member template. A non-template member function (9.3.4.6) with a given name and type and a member function template of the same name, which could be used to generate a specialization of the same type, can both be declared in a class. When both exist, a use of that name and type refers to the non-template member unless an explicit template argument list is supplied.

Example 3:
```cpp
template <class T> struct A {
    void f(int);
    template <class T2> void f(T2);
};
template <> void A<int>::f(int) { } // non-template member function
template <> template <> void A<int>::f<>(int) { } // member function template specialization
```
```
int main() {
    A<char> ac;
    ac.f(1);  // non-template
    ac.f('c');  // template
    ac.f<>((1);  // template
}
—end example]
3 A member function template shall not be declared virtual.

[Example 4:
```template <class T> struct AA {
    template <class C> virtual void g(C);  // error
    virtual void f();  // OK
};
—end example]
4 A specialization of a member function template does not override a virtual function from a base class.

[Example 5:
class B {
    virtual void f(int);
};
class D : public B {
    template <class T> void f(T);  // does not override B::f(int)
    void f(int i) { f<>((i); }  // overriding function that calls the function template specialization
};
—end example]
5 [Note 1: A specialization of a conversion function template is referenced in the same way as a non-template conversion function that converts to the same type (11.4.8.3).

[Example 6:
```struct A {
    template <class T> operator T*();
};
template <class T> A::operator T*() { return 0; }
template <> A::operator char*() { return 0; }  // specialization
template A::operator void*();  // explicit instantiation

int main() {
    A a;
    int* ip;
    ip = a.operator int*();  // explicit call to template operator A::operator int*()
}
—end example]
There is no syntax to form a template-id (13.3) by providing an explicit template argument list (13.10.2) for a conversion function template. —end note]

13.7.4 Variadic templates [temp.variadic]

1 A template parameter pack is a template parameter that accepts zero or more template arguments.

[Example 1:
```template<class ... Types> struct Tuple { };
Tuple<> t0;  // Types contains no arguments
Tuple<int> t1;  // Types contains one argument: int
Tuple<int, float> t2;  // Types contains two arguments: int and float
Tuple<> error;  // error: 0 is not a type
—end example]
2 A function parameter pack is a function parameter that accepts zero or more function arguments.

[Example 2:
template<class ... Types> void f(Types ... args);

f();                       // args contains no arguments
f(1);                     // args contains one argument: int
f(2, 1.0);                 // args contains two arguments: int and double
— end example]

3 An init-capture pack is a lambda capture that introduces an init-capture for each of the elements in the pack expansion of its initializer.

[Example 3:

```cpp
template <typename... Args>
void foo(Args... args) {
    [...xs=args]{
        bar(xs...);          // xs is an init-capture pack
    }
}
foo();                     // xs contains zero init-captures
foo(1);                    // xs contains one init-capture
— end example]
```

4 A pack is a template parameter pack, a function parameter pack, or an init-capture pack. The number of elements of a template parameter pack or a function parameter pack is the number of arguments provided for the parameter pack. The number of elements of an init-capture pack is the number of elements in the pack expansion of its initializer.

5 A pack expansion consists of a pattern and an ellipsis, the instantiation of which produces zero or more instantiations of the pattern in a list (described below). The form of the pattern depends on the context in which the expansion occurs. Pack expansions can occur in the following contexts:

(5.1) — In a function parameter pack (9.3.4.6); the pattern is the parameter-declaration without the ellipsis.
(5.2) — In a using-declaration (9.9); the pattern is a using-declarator.
(5.3) — In a template parameter pack that is a pack expansion (13.2):
    (5.3.1) — if the template parameter pack is a parameter-declaration; the pattern is the parameter-declaration without the ellipsis;
    (5.3.2) — if the template parameter pack is a type-parameter; the pattern is the corresponding type-parameter without the ellipsis.
(5.4) — In an initializer-list (9.4); the pattern is an initializer-clause.
(5.5) — In a base-specifier-list (11.7); the pattern is a base-specifier.
(5.6) — In a mem-initializer-list (11.9.3) for a mem-initializer whose mem-initializer-id denotes a base class; the pattern is the mem-initializer.
(5.7) — In a template-argument-list (13.4); the pattern is a template-argument.
(5.8) — In an attribute-list (9.12.1); the pattern is an attribute.
(5.9) — In an alignment-specifier (9.12.2); the pattern is the alignment-specifier without the ellipsis.
(5.10) — In a capture-list (7.5.5.3); the pattern is the capture without the ellipsis.
(5.11) — In a sizeof... expression (7.6.2.5); the pattern is an identifier.
(5.12) — In a fold-expression (7.5.6); the pattern is the cast-expression that contains an unexpanded pack.

[Example 4:

```cpp
template<class ... Types> void f(Types ... rest);
template<class ... Types> void g(Types ... rest) {
    f(&rest ...);            // "&rest ..." is a pack expansion; "&rest" is its pattern
}
— end example]
```

6 For the purpose of determining whether a pack satisfies a rule regarding entities other than packs, the pack is considered to be the entity that would result from an instantiation of the pattern in which it appears.
A pack whose name appears within the pattern of a pack expansion is expanded by that pack expansion. An appearance of the name of a pack is only expanded by the innermost enclosing pack expansion. The pattern of a pack expansion shall name one or more packs that are not expanded by a nested pack expansion; such packs are called unexpanded packs in the pattern. All of the packs expanded by a pack expansion shall have the same number of arguments specified. An appearance of a name of a pack that is not expanded is ill-formed.

[Example 5:]
```cpp
template<typename...> struct Tuple {};  
template<typename T1, typename T2> struct Pair {};  
template<class ... Args1> struct zip {  
  template<class ... Args2> struct with {  
    typedef Tuple<Pair<Args1, Args2> ... > type;  
  };  
};  
```
```cpp
typedef zip<short, int>::with<unsigned short, unsigned>::type T1;  
// T1 is Tuple<Pair<short, unsigned short>, Pair<int, unsigned>>  
typedef zip<short>::with<unsigned short, unsigned>::type T2;  
// error: different number of arguments specified for Args1 and Args2

```cpp
```cpp
template<class ... Args>  
void f(Args ... args) {  
  // OK, Args is expanded by the function parameter pack args
  f(const_cast<const Args*>(&args)...);  
  // OK, “Args” and “args” are expanded
  f(S ...);  
  // error: pattern does not contain any packs
  f(args);  
  // error: pack “args” is not expanded
  f(h(args ...) + args ...);  
  // OK, first “args” expanded within h,
  // second “args” expanded within i
}
```— end example]

The instantiation of a pack expansion considers items \( E_1, E_2, \ldots, E_N \), where \( N \) is the number of elements in the pack expansion parameters. Each \( E_i \) is generated by instantiating the pattern and replacing each pack expansion parameter with its \( i \)th element. Such an element, in the context of the instantiation, is interpreted as follows:

1. if the pack is a template parameter pack, the element is an \textit{id-expression} (for a non-type template parameter pack), a \textit{typedef-name} (for a type template parameter pack declared without \texttt{template}), or a \textit{template-name} (for a type template parameter pack declared with \texttt{template}), designating the \( i \)th corresponding type or value template argument;
2. if the pack is a function parameter pack, the element is an \textit{id-expression} designating the \( i \)th function parameter that resulted from instantiation of the function parameter pack declaration; otherwise
3. if the pack is an \textit{init-capture} pack, the element is an \textit{id-expression} designating the variable introduced by the \( i \)th \textit{init-capture} that resulted from instantiation of the \textit{init-capture} pack.

When \( N \) is zero, the instantiation of a pack expansion does not alter the syntactic interpretation of the enclosing construct, even in cases where omitting the pack expansion entirely would otherwise be ill-formed or would result in an ambiguity in the grammar.

The instantiation of a \texttt{sizeof...} expression (7.6.2.5) produces an integral constant with value \( N \).

The instantiation of a \texttt{fold-expression} (7.5.6) produces:

1. \(( (E_1 \ op \ E_2) \ op \cdots \ op \ E_N ) \) for a unary left fold,
2. \(( E_1 \ op \ (\cdots \ op \ (E_{N-1} \ op \ E_N) ) ) \) for a unary right fold,
3. \(( (E \ op \ E_1) \ op \ E_2 \ op \cdots \ op \ E_N ) \) for a binary left fold, and
4. \(( E_1 \ op \ (\cdots \ op \ (E_{N-1} \ op \ (E_N \ op \ E) ) ) ) \) for a binary right fold.

In each case, \( \texttt{op} \) is the \textit{fold-operator}. For a binary fold, \( E \) is generated by instantiating the \texttt{cast-expression} that did not contain an unexpanded pack.

[Example 6:]

\section{§ 13.7.4}
template<typename ...Args>
    bool all(Args ...args) { return (... && args); }

    bool b = all(true, true, true, false);
Within the instantiation of all, the returned expression expands to 
((true && true) && true) && false, which evaluates to false. — end example]

If \( N \) is zero for a unary fold, the value of the expression is shown in Table 20; if the operator is not listed in
Table 20, the instantiation is ill-formed.

Table 20: Value of folding empty sequences  [tab:temp.fold.empty]

<table>
<thead>
<tr>
<th>Operator</th>
<th>Value when pack is empty</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;&amp;</td>
<td>true</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>,</td>
<td>void()</td>
</tr>
</tbody>
</table>

The instantiation of any other pack expansion produces a list of elements \( E_1, E_2, \ldots, E_N \).

[Note 1: The variety of list varies with the context: expression-list, base-specifier-list, template-argument-list, etc. — end note]

When \( N \) is zero, the instantiation of the expansion produces an empty list.

[Example 7:]

```cpp
template<class... T> struct X : T... { };
template<class... T> void f(T... values) {
    X<T...> x(values...);
}
template void f<>(); // OK, X< > has no base classes
// x is a variable of type X< > that is value-initialized
```

—end example]

13.7.5  Friends  [temp.friend]

A friend of a class or class template can be a function template or class template, a specialization of a
function template or class template, or a non-template function or class.

[Example 1:]

```cpp
template<class T> class task;
template<class T> task<T>* preempt(task<T>**);

template<class T> class task {
    friend void next_time();
    friend void process(task<T>**);
    friend task<T>** preempt<T>(task<T>**);
    template<class C> friend int func(C);

    friend class task<int>;
    template<class F> friend class frd;
};
```

Here, each specialization of the task class template has the function next_time as a friend; because process does not
have explicit template-arguments, each specialization of the task class template has an appropriately typed function
process as a friend, and this function is not a function template specialization; because the friend preempt has an
explicit template-argument T, each specialization of the task class template has the appropriate specialization of the
function template preempt as a friend; and each specialization of the task class template has all specializations of the
function template func as friends. Similarly, each specialization of the task class template has the class template specialization task<int> as a friend, and has all specializations of the class template frd as friends. — end example]

Friend classes, class templates, functions, or function templates can be declared within a class template.
When a template is instantiated, its friend declarations are found by name lookup as if the specialization had
been explicitly declared at its point of instantiation.

§ 13.7.5  391
A friend template may be declared within a class or class template. A friend function template may be defined within a class or class template, but a friend class template may not be defined in a class or class template. In these cases, all specializations of the friend class or friend function template are friends of the class or class template granting friendship.

Example 2:

```cpp
class A {
    template<class T> friend class B;  // OK
    template<class T> friend void f(T) { /* ... */ } // OK
};
@end example
```

A template friend declaration specifies that all specializations of that template, whether they are implicitly instantiated (13.9.2), partially specialized (13.7.6) or explicitly specialized (13.9.4), are friends of the class containing the template friend declaration.

Example 3:

```cpp
class X {
    template<class T> friend struct A;
class Y { };  // OK
};
template<class T> struct A { X::Y ab; };  // OK
template<class T> struct A<T*> { X::Y ab; };  // OK
@end example
```

A template friend declaration may declare a member of a dependent type to be a friend. The friend declaration shall declare a function or specify a type with an elaborated-type-specifier, in either case with a nested-name-specifier ending with a simple-template-id, C, whose template-name names a class template. The template parameters of the template friend declaration shall be deducible from C (13.10.3.6). In this case, a member of a specialization S of the class template is a friend of the class granting friendship if deduction of the template parameters of C from S succeeds, and substituting the deduced template arguments into the friend declaration produces a declaration that corresponds to the member of the specialization.

Example 4:

```cpp
template<class T> struct A {
    struct B { };   // OK
    struct D {
        void g();
    };  // OK
    T h();
    template<T U> T i();
};
template<class T> struct A<int> {
    struct B { };   // OK
    int f();
    struct D {
        void g();
    };  // OK
    template<int U> int i();
};
template<class T> struct A<float*> {
    int *h();
};

class C {
    template<class T> friend struct A<T>::B;  // grants friendship to A<int>::B even though
    // it is not a specialization of A<T>::B
    template<class T> friend void A<T>::f();  // does not grant friendship to A<int>::f()
```
A friend template shall not be declared in a local class.

Friend declarations shall not declare partial specializations.

When a friend declaration refers to a specialization of a function template, the function parameter declarations shall not include default arguments, nor shall the \texttt{inline}, \texttt{constexpr}, or \texttt{consteval} specifiers be used in such a declaration.

A non-template friend declaration with a \texttt{requires-clause} shall be a definition. A friend function template with a constraint that depends on a template parameter from an enclosing template shall be a definition. Such a constrained friend function or function template declaration does not declare the same function or function template as a declaration in any other scope.

\section*{13.7.6 Partial specialization \[\text{temp.spec.partial}\]}

\subsection*{13.7.6.1 General \[\text{temp.spec.partial.general}\]}

A partial specialization of a template provides an alternative definition of the template that is used instead of the primary definition when the arguments in a specialization match those given in the partial specialization (13.7.6.2). A declaration of the primary template shall precede any partial specialization of that template. A partial specialization shall be reachable from any use of a template specialization that would make use of the partial specialization as the result of an implicit or explicit instantiation; no diagnostic is required.

Two partial specialization declarations declare the same entity if they are partial specializations of the same template and have equivalent template-heads and template argument lists (13.7.7.2). Each partial specialization is a distinct template.

A partial specialization may be constrained (13.5).

The first declaration declares the primary (unspecified) class template. The second and subsequent declarations declare partial specializations of the primary template. —\textit{end example}

A partial specialization is a distict template.

The first declaration declares the primary (unspecified) class template. The second and subsequent declarations declare partial specializations of the primary template. —\textit{end example}

Both partial specializations are more specialized than the primary template. \texttt{#1} is more specialized because the deduction of its template arguments from the template argument list of the class template specialization succeeds, while the reverse does not. \texttt{#2} is more specialized because the template arguments are equivalent, but the partial specialization is more constrained (13.5.5). —\textit{end example}

The template argument list of a partial specialization is the \texttt{template-argument-list} following the name of the template.
A partial specialization may be declared in any scope in which the corresponding primary template may be defined (9.3.4, 11.4, 13.7.3).

[Example 3:]
```
template<class T> struct A {
    struct C {
        template<class T2> struct B { };  // partial specialization #1
    };
};

// partial specialization of A<T>::C::B<T2>
template<class T> template<class T2>
    struct A<T>::C::B<T2*> { };  // #2

A<short>::C::B<int*> absip;  // uses partial specialization #2
```
—end example—

Partial specialization declarations do not introduce a name. Instead, when the primary template name is used, any reachable partial specializations of the primary template are also considered.

[Note 1: One consequence is that a using-declaration which refers to a class template does not restrict the set of partial specializations that are found through the using-declaration. — end note]

[Example 4:]
```
namespace N {
    template<class T1, class T2> class A { };  // primary template
}

using N::A;  // refers to the primary template

namespace N {
    template<class T> class A<T, T*> { };  // partial specialization
}

A<int,int*> a;  // uses the partial specialization, which is found through the using-declaration
    // which refers to the primary template
—end example—
```

A non-type argument is non-specialized if it is the name of a non-type parameter. All other non-type arguments are specialized.

Within the argument list of a partial specialization, the following restrictions apply:

(9.1) — The type of a template parameter corresponding to a specialized non-type argument shall not be dependent on a parameter of the partial specialization.

[Example 5:]
```
template <class T, T t> struct C {};  // error

template <class T> struct C<T, 1>;  // error

template< int X, int (*array_ptr)[X] > class A {};  // error
int array[5];
template< int X > class A<X,array> { };  // error
```
—end example—

(9.2) — The partial specialization shall be more specialized than the primary template (13.7.6.3).

(9.3) — The template parameter list of a partial specialization shall not contain default template argument values.\(^\text{123}\)

(9.4) — An argument shall not contain an unexpanded pack. If an argument is a pack expansion (13.7.4), it shall be the last argument in the template argument list.

The usual access checking rules do not apply to non-dependent names used to specify template arguments of the simple-template-id of the partial specialization.

\(^{123}\) There is no context in which they would be used.
[Note 2: The template arguments can be private types or objects that would normally not be accessible. Dependent names cannot be checked when declaring the partial specialization, but will be checked when substituting into the partial specialization. — end note]

### 13.7.6.2 Matching of partial specializations

When a template is used in a context that requires an instantiation of the template, it is necessary to determine whether the instantiation is to be generated using the primary template or one of the partial specializations. This is done by matching the template arguments of the template specialization with the template argument lists of the partial specializations.

1. If exactly one matching partial specialization is found, the instantiation is generated from that partial specialization.
2. If more than one matching partial specialization is found, the partial order rules (13.7.6.3) are used to determine whether one of the partial specializations is more specialized than the others. If such a partial specialization exists, the instantiation is generated from that partial specialization; otherwise, the use of the template is ambiguous and the program is ill-formed.
3. If no matches are found, the instantiation is generated from the primary template.

A partial specialization matches a given actual template argument list if the template arguments of the partial specialization can be deduced from the actual template argument list (13.10.3), and the deduced template arguments satisfy the associated constraints of the partial specialization, if any (13.5.3).

#### Example 1

```cpp
template<class T1, class T2, int I> class A { }; // #1
template<class T, int I> class A<T, T*, I> { }; // #2
template<class T1, class T2, int I> class A<T1*, T2, I> { }; // #3
template<class T> class A<int, T*, 5> { }; // #4
template<class T1, class T2, int I> class A<T1, T2*, I> { }; // #5

A<int, int, 1> a1; // uses #1
A<int, int*, 1> a2; // uses #2, T is int, I is 1
A<int, char*, 5> a3; // uses #4, T is char
A<int, char*, 1> a4; // uses #5, T1 is int, T2 is char, I is 1
A<int*, int*, 2> a5; // ambiguous: matches #3 and #5
```

#### Example 2

```cpp
template<typename T> concept C = requires (T t) { t.f(); };

template<typename T> struct S { }; // #1
template<C T> struct S<T> { }; // #2

struct Arg { void f(); }; // #3

S<int> s1; // uses #1; the constraints of #2 are not satisfied
S<Arg> s2; // uses #2; both constraints are satisfied but #2 is more specialized
```

If the template arguments of a partial specialization cannot be deduced because of the structure of its `template-parameter-list` and the `template-id`, the program is ill-formed.

#### Example 3

```cpp
template <int I, int J> struct A {}; // error

template <int I> struct A<I+5, I*2> {}; // OK

template <int I> struct A<I, I> {}; // OK
```

§ 13.7.6.2
In a name that refers to a specialization of a class or variable template (e.g., \(A<\text{int}, \text{int}, 1>\)), the argument list shall match the template parameter list of the primary template. The template arguments of a partial specialization are deduced from the arguments of the primary template.

### 13.7.6.3 Partial ordering of partial specializations

For two partial specializations, the first is more specialized than the second if, given the following rewrite to two function templates, the first function template is more specialized than the second according to the ordering rules for function templates (13.7.7.3):

1. Each of the two function templates has the same template parameters and associated constraints (13.5.3) as the corresponding partial specialization.
2. Each function template has a single function parameter whose type is a class template specialization where the template arguments are the corresponding template parameters from the function template for each template argument in the `template-argument-list` of the `simple-template-id` of the partial specialization.

**Example 1:**

```cpp
template<int I, int J, class T> class X { };
template<int I, int J> class X<I, J, int> { };  // #1

template<int I> class X<I, I, int> { };  // #2

template<int I0, int J0> void f(X<I0, J0, int>);  // A

template<int I0> void f(X<I0, I0, int>);  // B

template <auto v> class Y { };
template <auto* p> class Y<p> { };  // #3

template <auto** pp> class Y<pp> { };  // #4

template <auto* p0> void g(Y<p0>);  // C

template <auto** pp0> void g(Y<pp0>);  // D
```

According to the ordering rules for function templates, the function template `B` is more specialized than the function template `A` and the function template `D` is more specialized than the function template `C`. Therefore, the partial specialization #2 is more specialized than the partial specialization #1 and the partial specialization #4 is more specialized than the partial specialization #3. — end example

**Example 2:**

```cpp
template<typename T> concept C = requires (T t) { t.f(); };
template<typename T> concept D = C<T> && requires (T t) { t.f(); };

template<typename T> class S { };
template<C T> class S<T> { };  // #1

template<D T> class S<T> { };  // #2

template<C T> void f(S<T>);  // A

template<D T> void f(S<T>);  // B
```

The partial specialization #2 is more specialized than #1 because B is more specialized than A. — end example

### 13.7.6.4 Members of class template partial specializations

The members of the class template partial specialization are unrelated to the members of the primary template. Class template partial specialization members that are used in a way that requires a definition shall be defined; the definitions of members of the primary template are never used as definitions for members of a class template partial specialization. An explicit specialization of a member of a class template partial specialization is declared in the same way as an explicit specialization of a member of the primary template.

**Example 1:**

```cpp
// primary class template
template<class T, int I> struct A {
    void f();
};

// member of primary class template
template<class T, int I> void A<T,I>::f() { }
```
// class template partial specialization
template<class T> struct A<T,2> {
    void f();
    void g();
    void h();
};

// member of class template partial specialization
template<class T> void A<T,2>::g() { }

// explicit specialization
template<> void A<char,2>::h() { }

int main() {
    A<char,0> a0;
    A<char,2> a2;
    a0.f();   // OK, uses definition of primary template’s member
    a2.g();   // OK, uses definition of partial specialization’s member
    a2.h();   // OK, uses definition of explicit specialization’s member
    a2.f();   // error: no definition of f for A<T,2>; the primary template is not used here
}

—end example

If a member template of a class template is partially specialized, the member template partial specializations are member templates of the enclosing class template; if the enclosing class template is instantiated (13.9.2, 13.9.3), a declaration for every member template partial specialization is also instantiated as part of creating the members of the class template specialization. If the primary member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the partial specializations of the member template are ignored for this specialization of the enclosing class template. If a partial specialization of the member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the primary member template and its other partial specializations are still considered for this specialization of the enclosing class template.

[Example 2:

template<class T> struct A {
    template<class T2> struct B {}; // #1
    template<class T2> struct B<T2*> {}; // #2
};

template<> template<class T2> struct A<short>::B {}; // #3
A<char>::B<int*> abcip; // uses #2
A<short>::B<int*> absip; // uses #3
A<char>::B<int> abci; // uses #1
—end example]

13.7.7 Function templates [temp.fct]
13.7.7.1 General [temp.fct.general]

A function template defines an unbounded set of related functions.

[Example 1: A family of sort functions can be declared like this:

template<class T> class Array { };
template<class T> void sort(Array&);  // #1
—end example]

[Note 1: A function template can have the same name as other function templates and non-template functions (9.3.4.6) in the same scope. —end note]

A non-template function is not related to a function template (i.e., it is never considered to be a specialization), even if it has the same name and type as a potentially generated function template specialization.124

124 That is, declarations of non-template functions do not merely guide overload resolution of function template specializations with the same name. If such a non-template function is odr-used (6.3) in a program, it must be defined; it will not be implicitly instantiated using the function template definition.
13.7.7.2 Function template overloading

It is possible to overload function templates so that two different function template specializations have the same type.

[Example 1:

```
// translation unit 1:
template<class T>
void f(T*);
void g(int* p) {
    f(p); // calls f<int>(int*)
}

// translation unit 2:
template<class T>
void f(T);
void h(int* p) {
    f(p); // calls f<int*>(int*)
}
```

—end example]

Such specializations are distinct functions and do not violate the one-definition rule (6.3).

The signature of a function template is defined in Clause 3. The names of the template parameters are significant only for establishing the relationship between the template parameters and the rest of the signature.

[Note 1: Two distinct function templates can have identical function return types and function parameter lists, even if overload resolution alone cannot distinguish them.

```
template<class T> void f();
template<int I> void f(); // OK, overloads the first template
```

—end note]

When an expression that references a template parameter is used in the function parameter list or the return type in the declaration of a function template, the expression that references the template parameter is part of the signature of the function template. This is necessary to permit a declaration of a function template in one translation unit to be linked with another declaration of the function template in another translation unit and, conversely, to ensure that function templates that are intended to be distinct are not linked with one another.

[Example 2:

```
template <int I, int J> A<I+J> f(A<I>, A<J>); // #1
template <int K, int L> A<K+L> f(A<K>, A<L>); // same as #1
template <int I, int J> A<I-J> f(A<I>, A<J>); // different from #1
```

—end example]

[Note 2: Most expressions that use template parameters use non-type template parameters, but it is possible for an expression to reference a type parameter. For example, a template type parameter can be used in the `sizeof` operator. — end note]

Two expressions involving template parameters are considered equivalent if two function definitions containing the expressions would satisfy the one-definition rule (6.3), except that the tokens used to name the template parameters may differ as long as a token used to name a template parameter in one expression is replaced by another token that names the same template parameter in the other expression. Two unevaluated operands that do not involve template parameters are considered equivalent if two function definitions containing the expressions would satisfy the one-definition rule, except that the tokens used to name types and declarations may differ as long as they name the same entities, and the tokens used to form concept-ids (13.3) may differ as long as the two template-ids are the same (13.6).

[Note 3: For instance, `A<42>` and `A<40+2>` name the same type. — end note]

Two lambda-expressions are never considered equivalent.

[Note 4: The intent is to avoid lambda-expressions appearing in the signature of a function template with external linkage. — end note]

For determining whether two dependent names (13.8.3) are equivalent, only the name itself is considered, not the result of name lookup.

[Note 5: If such a dependent name is unqualified, it is looked up from the first declaration of the function template (13.8.4.2). — end note]

[Example 3:

```
template <int I, int J> void f(A<I+J>); // #1
template <int K, int L> void f(A<K+L>); // same as #1
```

§ 13.7.7.2 398
template <class T> decltype(g(T())) h();
int g(int);

template <class T> decltype(g(T())) h() // redeclaration of h() uses the earlier lookup...
  { return g(T()); } // ... although the lookup here does find g(int)
int i = h<int>(); // template argument substitution fails; g(int)
  // not considered at the first declaration of h()

// ill-formed, no diagnostic required: the two expressions are functionally equivalent but not equivalent
template <int N> void foo(const char (*s)[(][{}, N)]);
template <int N> void foo(const char (*s)[(][{}, N)]);

// two different declarations because the non-dependent portions are not considered equivalent

template <class T> void spam(decltype(()[{]} (*s)[sizeof(T)]));
template <class T> void spam(decltype(()[{]} (*s)[sizeof(T)]));

—end example—

Two potentially-evaluated expressions involving template parameters that are not equivalent are functionally equivalent if, for any given set of template arguments, the evaluation of the expression results in the same value. Two unevaluated operands that are not equivalent are functionally equivalent if, for any given set of template arguments, the expressions perform the same operations in the same order with the same entities.

[Note 6: For instance, one could have redundant parentheses. —end note]

[Example 4:]

```c++
template<int I> concept C = true;
template<typename T> struct A {
  void f() requires C<42>; // #1
  void f() requires true; // OK, different functions
};
—end example—
```

Two template-heads are equivalent if their template-parameter-lists have the same length, corresponding template-parameters are equivalent and are both declared with type-constraints that are equivalent if either template-parameter is declared with a type-constraint, and if either template-head has a requires-clause, they both have requires-clauses and the corresponding constraint-expressions are equivalent. Two template-parameters are equivalent under the following conditions:

- (6.1) they declare template parameters of the same kind,
- (6.2) if either declares a template parameter pack, they both do,
- (6.3) if they declare non-type template parameters, they have equivalent types ignoring the use of type-constraints for placeholder types, and
- (6.4) if they declare template template parameters, their template parameters are equivalent.

When determining whether types or type-constraints are equivalent, the rules above are used to compare expressions involving template parameters. Two template-heads are functionally equivalent if they accept and are satisfied by (13.5.2) the same set of template argument lists.

7 If the validity or meaning of the program depends on whether two constructs are equivalent, and they are functionally equivalent but not equivalent, the program is ill-formed, no diagnostic required. Furthermore, if two function templates that do not correspond

- (7.1) have the same name,
- (7.2) have corresponding signatures (6.4.1),
- (7.3) would declare the same entity (6.6) considering them to correspond, and
- (7.4) accept and are satisfied by the same set of template argument lists,
the program is ill-formed, no diagnostic required.

8 [Note 7: This rule guarantees that equivalent declarations will be linked with one another, while not requiring implementations to use heroic efforts to guarantee that functionally equivalent declarations will be treated as distinct. For example, the last two declarations are functionally equivalent and would cause a program to be ill-formed:

```c++
// guaranteed to be the same
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+10>);
```
Partial ordering of function templates

If multiple function templates share a name, the use of that name can be ambiguous because template argument deduction (13.10.3) may identify a specialization for more than one function template. Partial ordering of overloaded function template declarations is used in the following contexts to select the function template to which a function template specialization refers:

1. During overload resolution for a call to a function template specialization (12.2.4);
2. When the address of a function template specialization is taken;
3. When a placement operator delete that is a function template specialization is selected to match a placement operator new (6.7.5.5.3, 7.6.2.8);
4. When a friend function declaration (13.7.5), an explicit instantiation (13.9.3) or an explicit specialization (13.9.4) refers to a function template specialization.

Partial ordering selects which of two function templates is more specialized than the other by transforming each template in turn and performing template argument deduction using the function type. The deduction process determines whether one of the templates is more specialized than the other. If so, the more specialized template is the one chosen by the partial ordering process. If both deductions succeed, the partial ordering selects the more constrained template (if one exists) as determined below.

To produce the transformed template, for each type, non-type, or template template parameter (including template parameter packs (13.7.4) thereof) synthesize a unique type, value, or class template respectively and substitute it for each occurrence of that parameter in the function type of the template.

Each function template \( M \) that is a member function is considered to have a new first parameter of type \( X(M) \), described below, inserted in its function parameter list. If exactly one of the function templates was considered by overload resolution via a rewritten candidate (12.2.2.3) with a reversed order of parameters, then the order of the function parameters in its transformed template is reversed. For a function template \( M \) with cv-qualifiers \( cv \) that is a member of a class \( A \):

1. The type \( X(M) \) is “rvalue reference to \( cv A \)” if the optional ref-qualifier of \( M \) is && or if \( M \) has no ref-qualifier and the positionally-corresponding parameter of the other transformed template has rvalue reference type; if this determination depends recursively upon whether \( X(M) \) is an rvalue reference type, it is not considered to have rvalue reference type.
2. Otherwise, \( X(M) \) is “lvalue reference to \( cv A \)”.

Example 1:

```cpp
struct A { };

struct B {
    template<class T> struct B {
        template<class R> int operator*(R&);
    };

    template<class T, class R> int operator*(T&, R&);
};
```

int main() {
    A a;
    B<A> b;
}

Example 1:

```cpp
template<int I> void f(A<I>, A<I+10>);
```

// ill-formed, no diagnostic required

```cpp
template<int I> void f(A<I>, A<I+11>);
```

// guaranteed to be different

```cpp
template<int I> void f(A<I>, A<I+10>);
```

```cpp
template<int I> void f(A<I>, A<I+1+2+3+4>);
```

— end note
Using the transformed function template’s function type, perform type deduction against the other template as described in 13.10.3.5.

[Example 2:

```cpp
template<class T> struct A { A(); }

template<class T> void f(T);
template<class T> void f(T*);
template<class T> void f(const T*);

template<class T> void g(T);
template<class T> void g(T&);

template<class T> void h(const T&);
template<class T> void h(A<T>&);

void m() {
    const int* p;
    f(p); // f(const T*) is more specialized than f(T) or f(T*)
    float x;
    g(x); // ambiguous: g(T) or g(T&)
    A<int> z;
    h(z); // overload resolution selects h(A<T>&)
    const A<int> z2;
    h(z2); // h(const T&) is called because h(A<T>&) is not callable
}
```

— end example]

[Note 3: Since, in a call context, such type deduction considers only parameters for which there are explicit call arguments, some parameters are ignored (namely, function parameter packs, parameters with default arguments, and ellipsis parameters).

[Example 3:

```cpp
template<class T> void f(T);
// #1
template<class T> void f(T*, int=1);
// #2
template<class T> void g(T);
// #3
template<class T> void g(T*, ...);
// #4

int main() {
    int* ip;
    f(ip); // calls #2
    g(ip); // calls #4
}
```

— end example]

[Example 4:

```cpp
template<class T, class U> struct A { }

template<class T, class U> void f(U, A<U, T>* p = 0); // #1
template<class T, class U> void f(U, A<U, U>* p = 0); // #2
template<class T> void g(T, T = T()); // #3
template<class T, class... U> void g(T, U ...); // #4

void h() {
    f<int>(42, (A<int, int>*)(0)); // calls #2
    f<int>(42); // error: ambiguous
    g(42); // error: ambiguous
}
```

— end example]
If deduction against the other template succeeds for both transformed templates, constraints can be considered as follows:

(6.1) If their template-parameter-lists (possibly including template-parameters invented for an abbreviated function template (9.3.4.6)) or function parameter lists differ in length, neither template is more specialized than the other.

(6.2) Otherwise:

(6.2.1) If exactly one of the templates was considered by overload resolution via a rewritten candidate with reversed order of parameters:

(6.2.1.1) If, for either template, some of the template parameters are not deducible from their function parameters, neither template is more specialized than the other.

(6.2.1.2) If there is either no reordering or more than one reordering of the associated template-parameter-list such that

— the corresponding template-parameters of the template-parameter-lists are equivalent and
— the function parameters that positionally correspond between the two templates are of the same type,

neither template is more specialized than the other.

(6.2.2) Otherwise, if the corresponding template-parameters of the template-parameter-lists are not equivalent (13.7.7.2) or if the function parameters that positionally correspond between the two templates are not of the same type, neither template is more specialized than the other.

(6.3) Otherwise, if the context in which the partial ordering is done is that of a call to a conversion function and the return types of the templates are not the same, then neither template is more specialized than the other.

(6.4) Otherwise, if one template is more constrained than the other (13.5.5), the more constrained template is more specialized than the other.

(6.5) Otherwise, neither template is more specialized than the other.

Example 6:

```cpp
template <typename T, typename U> constexpr bool True = true;
template <typename T> concept C = True<T>;

void f(C auto &, auto &); // delete;
template <C Q> void f(Q &, C auto &);

void g(struct A *ap, struct B *bp) {
  f(*ap, *bp); // OK, can use different methods to produce template parameters
}

template <typename T, typename U> struct X {};

template <typename T, C U, typename V> bool operator==(X<T, U>, V) = delete;
template <C T, C U, C V> bool operator==(T, X<U, V>);
```
void h() {
    X<void *, int>{} == 0; // OK, correspondence of [T, U, V] and [U, V, T]
}
—end example]

13.7.8 Alias templates

A template-declaration in which the declaration is an alias-declaration (9.1) declares the identifier to be an alias template. An alias template is a name for a family of types. The name of the alias template is a template-name.

2 When a template-id refers to the specialization of an alias template, it is equivalent to the associated type obtained by substitution of its template-arguments for the template-parameters in the defining-type-id of the alias template.

[Note 1: An alias template name is never deduced. — end note]

[Example 1]:

```cpp
template<class T> struct Alloc { /* ... */ };
template<class T> using Vec = vector<T, Alloc<T>>;
Vec<int> v; // same as vector<int, Alloc<int>> v;

template<class T>
    void process(Vec<T>& v)
    { /* ... */ }

template<class T>
    void process(vector<T, Alloc<T>>& w)
    { /* ... */ } // error: redefinition

template<template<class> class TT>
    void f(TT<int>);
f<v>; // error: Vec not deduced

template<template<class, class> class TT>
    void g(TT<int, Alloc<int>>);
g<v>; // OK, TT = vector
—end example]
```

3 However, if the template-id is dependent, subsequent template argument substitution still applies to the template-id.

[Example 2]:

```cpp
template<typename...> using void_t = void;
template<typename T> void_t<typename T::foo> f();
f<int>(); // error: int does not have a nested type foo
—end example]
```

4 The defining-type-id in an alias template declaration shall not refer to the alias template being declared. The type produced by an alias template specialization shall not directly or indirectly make use of that specialization.

[Example 3]:

```cpp
template <class T> struct A;
template <class T> using B = typename A<T>::U;
template <class T> struct A {
    typedef B<T> U;
};
B<short> b; // error: instantiation of B<short> uses own type via A<short>::U
—end example]
```

5 The type of a lambda-expression appearing in an alias template declaration is different between instantiations of that template, even when the lambda-expression is not dependent.

[Example 4]:

§ 13.7.8 403
13.7.9 Concept definitions

A concept is a template that defines constraints on its template arguments.

```
concept-definition:
  concept concept-name attribute-specifier-seq = constraint-expression ;
```

A concept-definition declares a concept. Its identifier becomes a concept-name referring to that concept within its scope. The optional attribute-specifier-seq appertains to the concept.

```
Example 1:

```template<typename T>
concept C = requires(T x) {
  { x == x } -> std::convertible_to<bool>;
};
```

```template<typename T>
requires C<T> // C constrains f1(T) in constraint-expression
T f1(T x) { return x; }
```

```template<C T>
// C, as a type-constraint, constrains f2(T)
T f2(T x) { return x; }
```

—end example

1 A concept-definition shall inhabit a namespace scope (6.4.6).
2 A concept shall not have associated constraints (13.5.3).
3 A concept is not instantiated (13.9).

[Note 1: A concept-id (13.3) is evaluated as an expression. A concept cannot be explicitly instantiated (13.9.3), explicitly specialized (13.9.4), or partially specialized (13.7.6). —end note]

The constraint-expression of a concept-definition is an unevaluated operand (7.2.3).

The first declared template parameter of a concept definition is its prototype parameter. A type concept is a concept whose prototype parameter is a type template-parameter.

13.8 Name resolution

1 A name that appears in a declaration $D$ of a template $T$ is looked up from where it appears in an unspecified declaration of $T$ that either is $D$ itself or is reachable from $D$ and from which no other declaration of $T$ that contains the usage of the name is reachable. If the name is dependent (as specified in 13.8.3), it is looked up for each specialization (after substitution) because the lookup depends on a template parameter.

[Note 1: Some dependent names are also looked up during parsing to determine that they are dependent or to interpret following < tokens. Uses of other names might be type-dependent or value-dependent (13.8.3.3, 13.8.3.4). A using-declarator is never dependent in a specialization and is therefore replaced during lookup for that specialization (6.5). —end note]

```
Example 1:

```struct A { operator int(); };
```

```template<class B, class T>
struct D : B {
  T get() { return operator T(); } // conversion-function-id is dependent
};
```

```int f(D<A, int> d) { return d.get(); } // OK, lookup finds A::operator int
```

—end example

Example 2:

```
void f(char);
```
template<class T> void g(T t) {
    f(1);  // f(char)
    f(T(1));  // dependent
    f(t);  // dependent
    dd++;  // not dependent; error: declaration for dd not found
}

eenum E { e };
void f(E);

double dd;
void h() {
    g(e);  // will cause one call of f(char) followed by two calls of f(E)
    g('a');  // will cause three calls of f(char)
}

—end example]

Example 3:
struct A {
    struct B { /* ... */ };
    int a;
    int Y;
};

int a;

template<class T> struct Y : T {
    struct B { /* ... */ };
    B b;  // The B defined in Y
    void f(int i) { a = i; }  // ::a
    Y* p;  // Y<T>
};

Y<A> ya;
The members A::B, A::a, and A::Y of the template argument A do not affect the binding of names in Y<A>. —end example]

If the validity or meaning of the program would be changed by considering a default argument or default template argument introduced in a declaration that is reachable from the point of instantiation of a specialization (13.8.4.1) but is not found by lookup for the specialization, the program is ill-formed, no diagnostic required.

typedef-name-specifier:
    typename nested-name-specifier identifier
    typename nested-name-specifier template_opt simple-template-id

The component names of a typename-specifier are its identifier (if any) and those of its nested-name-specifier and simple-template-id (if any). A typename-specifier denotes the type or class template denoted by the simple-type-specifier (9.2.9.3) formed by omitting the keyword typename.

[Note 2: The usual qualified name lookup (6.5.5) applies even in the presence of typename. —end note]

Example 4:
struct A {
    struct X { };  // X
    int X;
};
struct B {
    struct X { };  // X
};
template<class T> void f(T t) {
    typename T::X x;
}
void foo() {
    A a;
A qualified or unqualified name is said to be in a *type-only context* if it is the terminal name of

(4.1)  — a *typename-specifier*, *nested-name-specifier*, *elaborated-type-specifier*, *class-or-decltype*, or

(4.2)  — a *type-specifier* of a

(4.2.1)  — *new-type-id*,
(4.2.2)  — *defining-type-id*,
(4.2.3)  — *conversion-type-id*,
(4.2.4)  — *trailing-return-type*,
(4.2.5)  — default argument of a *type-parameter*, or
(4.2.6)  — *type-id* of a *static_cast*, *const_cast*, *reinterpret_cast*, or *dynamic_cast*, or

(4.3)  — a *decl-specifier* of the *decl-specifier-seq* of a

(4.3.1)  — simple-declaration or a function-definition in namespace scope,
(4.3.2)  — member-declaration,
(4.3.3)  — parameter-declaration in a member-declaration, unless that parameter-declaration appears in a default argument,
(4.3.4)  — parameter-declaration in a declarator of a function or function template declaration whose declarator-id is qualified, unless that parameter-declaration appears in a default argument,
(4.3.5)  — parameter-declaration in a lambda-declarator or requirement-parameter-list, unless that parameter-declaration appears in a default argument, or
(4.3.6)  — parameter-declaration of a (non-type) *template-parameter*.

[Example 5:]

```cpp
template<class T> T::R f();  // OK, return type of a function declaration at global scope
template<class T> void f(T::R);  // ill-formed, no diagnostic required: attempt to declare
// a void variable template
template<class T> struct S {
  using Ptr = PtrTraits<T>::Ptr;  // OK, in a defining-type-id
  T::R f(T::P p) {  // OK, class scope
    return static_cast<T::R>(p);  // OK, type-id of a static_cast
  }
  auto g() -> S<T*>::Ptr;  // OK, trailing-return-type
};
template<typename T> void f() {  // variable pf of type void* initialized with T::X
  void (*pf)(T::X);
  void g(T::X);  // error: T::X at block scope does not denote a type
  // (attempt to declare a void variable)
}
```

—end example]  

A qualified-id whose terminal name is dependent and that is in a type-only context is considered to denote a type. A name that refers to a *using-declarator* whose terminal name is dependent is interpreted as a *typedef-name* if the *using-declarator* uses the keyword *typename*.

[Example 6:]

```cpp
template <class T> void f(int i) {
  T::x * i;  // expression, not the declaration of a variable i
}
```

125) This includes friend function declarations.
The validity of a template may be checked prior to any instantiation.

[Note 3: Knowing which names are type names allows the syntax of every template to be checked in this way. — end note]

The program is ill-formed, no diagnostic required, if:

1. no valid specialization, ignoring `static_assert-declarations` that fail, can be generated for a template or a substatement of a `constexpr` if statement (8.5.2) within a template and the template is not instantiated, or
2. any `constraint-expression` in the program, introduced or otherwise, has (in its normal form) an atomic constraint \( A \) where no satisfaction check of \( A \) could be well-formed and no satisfaction check of \( A \) is performed, or
3. every valid specialization of a variadic template requires an empty template parameter pack, or
4. a hypothetical instantiation of a template immediately following its definition would be ill-formed due to a construct that does not depend on a template parameter, or
5. the interpretation of such a construct in the hypothetical instantiation is different from the interpretation of the corresponding construct in any actual instantiation of the template.

[Note 4: This can happen in situations including the following:

1. a type used in a non-dependent name is incomplete at the point at which a template is defined but is complete at the point at which an instantiation is performed, or
2. lookup for a name in the template definition found a `using-declaration`, but the lookup in the corresponding scope in the instantiation does not find any declarations because the `using-declaration` was a pack expansion and the corresponding pack is empty, or
3. an instantiation uses a default argument or default template argument that had not been defined at the point at which the template was defined, or
4. constant expression evaluation (7.7) within the template instantiation uses
   1. the value of a `const` object of integral or unscoped enumeration type or
   2. the value of a `constexpr` object or
   3. the value of a reference or
   4. the definition of a `constexpr` function,
   and that entity was not defined when the template was defined, or
5. a class template specialization or variable template specialization that is specified by a non-dependent `simple-template-id` is used by the template, and either it is instantiated from a partial specialization that was not defined when the template was defined or it names an explicit specialization that was not declared when the template was defined.

— end note]

Otherwise, no diagnostic shall be issued for a template for which a valid specialization can be generated.

[Note 5: If a template is instantiated, errors will be diagnosed according to the other rules in this document. Exactly when these errors are diagnosed is a quality of implementation issue. — end note]

[Example 7:

```c
int j;
```
template<class T> class X {
  void f(T t, int i, char* p) {
    t = i;  // diagnosed if X::f is instantiated, and the assignment to t is an error
    p = i;  // may be diagnosed even if X::f is not instantiated
    p = j;  // may be diagnosed even if X::f is not instantiated
    X<T>::g(t);  // OK
    X<T>::h();  // may be diagnosed even if X::f is not instantiated
  }
  void g(T t) {
    ++t;  // may be diagnosed even if X::g is not instantiated
  }
};

template<class... T> struct A {
  void operator++(int, T... t);  // error: too many parameters
};

template<class... T> union X : T... { };  // error: union with base class

template<class... T> struct A : T..., T... { };  // error: duplicate base class

—end example

7 [Note 6: For purposes of name lookup, default arguments and noexcept-specifiers of function templates and default arguments and noexcept-specifiers of member functions of class templates are considered definitions (13.7). — end note]

13.8.2 Locally declared names [temp.local]

1 Like normal (non-template) classes, class templates have an injected-class-name (11.1). The injected-class-name can be used as a template-name or a type-name. When it is used with a template-argument-list, as a template-argument for a template template-parameter, or as the final identifier in the elaborated-type-specifier of a friend class template declaration, it is a template-name that refers to the class template itself. Otherwise, it is a type-name equivalent to the template-name followed by the template argument list (13.7.1, 13.4.1) of the class template enclosed in <>.

2 When the injected-class-name of a class template specialization or partial specialization is used as a type-name, it is equivalent to the template-name followed by the template-arguments of the class template specialization or partial specialization enclosed in <>.

[Example 1:

```cpp
template<template<class> class T> class A { }
template<class T> class Y;
template<class T> class Y<int> {  
  Y* p;  // meaning Y<int>
  Y<char>* q;  // meaning Y<char>
  A<Y>* a;  // meaning A<Y>
  class B {
    template<class> friend class Y;  // meaning ::Y
  }
};
—end example]
```

3 The injected-class-name of a class template or class template specialization can be used as either a template-name or a type-name wherever it is named.

[Example 2:

```cpp
template <class T> struct Base {
  Base* p;
};

template <class T> struct Derived: public Base<T> {
  typename Derived::Base* p;  // meaning Derived::Base<T>
};

template<class T, template<class> class U = T::Base> struct Third { }
Third<Derived<int> > t;  // OK, default argument uses injected-class-name as a template
—end example]

§ 13.8.2
A lookup that finds an injected-class-name (6.5.2) can result in an ambiguity in certain cases (for example, if it is found in more than one base class). If all of the injected-class-names that are found refer to specializations of the same class template, and if the name is used as a template-name, the reference refers to the class template itself and not a specialization thereof, and is not ambiguous.

[Example 3:

```cpp
template <class T> struct Base { }
template <class T> struct Derived: Base<int>, Base<char> {
    typename Derived::Base b; // error: ambiguous
    typename Derived::Base<double> d; // OK
};
@end example]

When the normal name of the template (i.e., the name from the enclosing scope, not the injected-class-name) is used, it always refers to the class template itself and not a specialization of the template.

[Example 4:

```cpp
template<class T> class X {
    X* p;
    // meaning X<T>
    X<T>* p2;
    X<int>* p3;
    ::X* p4; // error: missing template argument list
    // ::X does not refer to the injected-class-name
};
@end example]

The name of a template-parameter shall not be bound to any following declaration whose locus is contained by the scope to which the template-parameter belongs.

[Example 5:

```cpp
template<class T, int i> class Y {
    int T;
    void f() {
        char T;
        // error: template-parameter hidden
    }
    friend void T(); // OK, no name bound
};

template<class X> class X; // error: hidden by template-parameter
@end example]

Unqualified name lookup considers the template parameter scope of a template-declaration immediately after the outermost scope associated with the template declared (even if its parent scope does not contain the template-parameter-list).

[Note 1: The scope of a class template, including its non-dependent base classes (13.8.3.2, 6.5.2), is searched before its template parameter scope. —end note]

[Example 6:

```cpp
struct B { }
namespace N {
    typedef void V;
    template<class T> struct A : B {
        typedef void C;
        void f();
        template<class U> void g(U);
    };
}

template<class V> void N::A<V>::f() { // N::V not considered here
    V v; // V is still the template parameter, not N::V
}

template<class B> template<class C> void N::A<B>::g(C) {
    B b; // B is the base class, not the template parameter
}
```
13.8.3 Dependent names

13.8.3.1 General

Inside a template, some constructs have semantics which may differ from one instantiation to another. Such a construct depends on the template parameters. In particular, types and expressions may depend on the type and/or value of template parameters (as determined by the template arguments) and this determines the context for name lookup for certain names. An expression may be type-dependent (that is, its type may depend on a template parameter) or value-dependent (that is, its value when evaluated as a constant expression (7.7) may depend on a template parameter) as described below.

A dependent call is an expression, possibly formed as a non-member candidate for an operator (12.2.2.3), of the form:

\[
\text{postfix-expression ( expression-list_opt )}
\]

where the postfix-expression is an unqualified-id and

(2.1) — any of the expressions in the expression-list is a pack expansion (13.7.4), or
(2.2) — any of the expressions or braced-init-lists in the expression-list is type-dependent (13.8.3.3), or
(2.3) — the unqualified-id is a template-id in which any of the template arguments depends on a template parameter.

The component name of an unqualified-id (7.5.4.2) is dependent if

(2.4) — it is a conversion-function-id whose conversion-type-id is dependent, or
(2.5) — it is operator= and the current class is a templated entity, or
(2.6) — the unqualified-id is the postfix-expression in a dependent call.

[Example 1: Such names are looked up only at the point of the template instantiation (13.8.4.1) in both the context of the template definition and the context of the point of instantiation (13.8.4.2). — end note]

13.8.3.2 Dependent types

A name or template-id refers to the current instantiation if it is

(1.1) — in the definition of a class template, a nested class of a class template, a member of a class template, or a member of a nested class of a class template, the injected-class-name (11.1) of the class template or nested class,
(1.2) — in the definition of a primary class template or a member of a primary class template, the name of the class template followed by the template argument list of its template-head (13.4) enclosed in <> (or an equivalent template alias specialization),
(1.3) — in the definition of a nested class of a class template, the name of the nested class referenced as a member of the current instantiation, or
(1.4) — in the definition of a class template partial specialization or a member of a class template partial specialization, the name of the class template followed by a template argument list equivalent to that of the partial specialization (13.7.6) enclosed in <> (or an equivalent template alias specialization).

[Example 1: ]

```
template<class T> struct X : B<T> {    
  typename T::A* pa;    
  void f(B<T>* pb) {     
    static int i = B<T>::i;    
    pb->j++;            
  }                    
};                       
```

The base class name B<T>, the type name T::A, the names B<T>::i and pb->j explicitly depend on the template-parameter. — end example]
is equivalent to a template parameter if it denotes the same type. For a non-type template parameter, a template argument is equivalent to a template parameter if it is an identifier that names a variable that is equivalent to the template parameter. A variable is equivalent to a template parameter if

\[ (2.1) \]

— it has the same type as the template parameter (ignoring cv-qualification) and

\[ (2.2) \]

— its initializer consists of a single identifier that names the template parameter or, recursively, such a variable.

[Note 1: Using a parenthesized variable name breaks the equivalence. — end note]

[Example 1:
\[
\begin{aligned}
template <\text{class } T> \text{ class } \text{A} \{ \\
A^* \ p1; & // \text{A is the current instantiation} \\
A<T^*^*> \ p2; & // \text{A<T^*> is the current instantiation} \\
A<T^*> \ p3; & // \text{A<T^*> is not the current instantiation} \\
::A<T^*> \ p4; & // ::A<T^*> is the current instantiation \\
\}; \\
\text{class B \{} \\
B^* \ p1; & // B is the current instantiation \\
A<T^*>::B^* \ p2; & // A<T^*>::B is the current instantiation \\
typename A<T^*>::B \ p3; & // A<T^*>::B is not the current instantiation \\
\}; \\
\}; \}
\end{aligned}
\]

\[
\begin{aligned}
template <\text{class } T> \text{ class } \text{A}<T^*> \{ \\
A<T^*>^* \ p1; & // \text{A<T^*> is the current instantiation} \\
A<T^*> \ p2; & // \text{A<T^*> is not the current instantiation} \\
\}; \\
template <\text{class } T1, \text{class } T2, \text{int } I> \text{ struct } \text{B} \{ \\
B<T1, T2, I^* \ b1; & // \text{refers to the current instantiation} \\
B<T2, T1, I^* \ b2; & // \text{not the current instantiation} \\
\text{typedef } T1 \text{ my}_T1; \\
\text{static const int my}_I = I; \\
\text{static const int my}_I^2 = I^*^0; \\
\text{static const int my}_I^3 = my_I; \\
\text{static const long my}_I^4 = I; \\
\text{static const int my}_I^5 = (I); \\
B<my_T1, T2, my_I^* \ b3; & // \text{refers to the current instantiation} \\
B<my_T1, T2, my_I^2^* \ b4; & // \text{not the current instantiation} \\
B<my_T1, T2, my_I^3^* \ b5; & // \text{refers to the current instantiation} \\
B<my_T1, T2, my_I^4^* \ b6; & // \text{not the current instantiation} \\
B<my_T1, T2, my_I^5^* \ b7; & // \text{not the current instantiation} \\
\}; \}
\end{aligned}
\]

— end example]

\[
3\text{ A dependent base class is a base class that is a dependent type and is not the current instantiation.} \\
[Note 2: A base class can be the current instantiation in the case of a nested class naming an enclosing class as a base.} \\
[Example 2:
\[
\begin{aligned}
\text{template<\text{class } T> \text{ struct } \text{A} \{} \\
\text{typedef int } M; \\
\text{struct B \{} \\
\text{ typedef void } M; \\
\text{ struct C;} \\
\}; \\
\}; \\
\text{template<\text{class } T> \text{ struct } \text{A}<T^*>::B::C : A<T^*> \{} \\
\text{ M m; \ // OK, A<T^*>::M} \\
\}; \\
\end{aligned}
\]

— end example]

— end note]
A qualified (6.5.5) or unqualified name is a member of the current instantiation if

— its lookup context, if it is a qualified name, is the current instantiation, and

— lookup for it finds any member of a class that is the current instantiation

[Example 3:

```cpp
template <class T> class A {
    static const int i = 5;
    int n1[i]; // i refers to a member of the current instantiation
    int n2[A::i]; // A::i refers to a member of the current instantiation
    int n3[A<T>::i]; // A<T>::i refers to a member of the current instantiation
    int f();
};

template <class T> int A<T>::f() {
    return i; // i refers to a member of the current instantiation
}
```
—end example]

A qualified or unqualified name names a dependent member of the current instantiation if it is a member of the current instantiation that, when looked up, refers to at least one member declaration (including a using-declarator whose terminal name is dependent) of a class that is the current instantiation.

A qualified name (6.5.5) is dependent if

— it is a conversion-function-id whose conversion-type-id is dependent, or

— its lookup context is dependent and is not the current instantiation, or

— its lookup context is the current instantiation and it is operator=, or

— its lookup context is the current instantiation and has at least one dependent base class, and qualified name lookup for the name finds nothing (6.5.5).

[Example 4:

```cpp
struct A {
    using B = int;
    A f();
};
struct C : A {};
template<class T>
void g(T t) {
    decltype(t.A::f())::B i;  // error: typename needed to interpret B as a type
}
template void g(C);       // ... even though A is ::A here
—end example]

Every instantiation of a class template declares a different set of assignment operators.
```cpp
int g() { return m; } // finds A::m in the template definition context

template int C<B>::f(); // error: finds both A::m and B::m
template int C<B>::g(); // OK, transformation to class member access syntax
// does not occur in the template definition context; see 11.4.3

— end example]

7 A type is dependent if it is
   (7.1) — a template parameter,
   (7.2) — denoted by a dependent (qualified) name,
   (7.3) — a nested class or enumeration that is a direct member of a class that is the current instantiation,
   (7.4) — a cv-qualified type where the cv-unqualified type is dependent,
   (7.5) — a compound type constructed from any dependent type,
   (7.6) — an array type whose element type is dependent or whose bound (if any) is value-dependent,
   (7.7) — a function type whose parameters include one or more function parameter packs,
   (7.8) — a function type whose exception specification is value-dependent,
   (7.9) — denoted by a simple-template-id in which either the template name is a template parameter or any of
         the template arguments is a dependent type or an expression that is type-dependent or value-dependent or
         is a pack expansion,127 or
   (7.10) — denoted by decltype(expression), where expression is type-dependent (13.8.3.3).

8 [Note 3: Because typedefs do not introduce new types, but instead simply refer to other types, a name that refers to
a typedef that is a member of the current instantiation is dependent only if the type referred to is dependent. — end
note]

13.8.3.3 Type-dependent expressions
   [temp.dep.expr]

1 Except as described below, an expression is type-dependent if any subexpression is type-dependent.

2 this is type-dependent if the current class (7.5.2) is dependent (13.8.3.2).

3 An id-expression is type-dependent if it is a template-id that is not a concept-id and is dependent; or if its
   terminal name is
       (3.1) — associated by name lookup with one or more declarations declared with a dependent type,
       (3.2) — associated by name lookup with a non-type template-parameter declared with a type that contains a
             placeholder type (9.2.9.6),
       (3.3) — associated by name lookup with a variable declared with a type that contains a placeholder type (9.2.9.6)
             where the initializer is type-dependent,
       (3.4) — associated by name lookup with one or more declarations of member functions of a class that is the
             current instantiation declared with a return type that contains a placeholder type,
       (3.5) — associated by name lookup with a structured binding declaration (9.6) whose brace-or-equal-initializer is
             type-dependent,
       (3.6) — associated by name lookup with an entity captured by copy (7.5.5.3) in a lambda-expression that has an
             explicit object parameter whose type is dependent (9.3.4.6),
       (3.7) — the identifier __func__ (9.5.1), where any enclosing function is a template, a member of a class template,
             or a generic lambda,
       (3.8) — a conversion-function-id that specifies a dependent type, or
       (3.9) — dependent

or if it names a dependent member of the current instantiation that is a static data member of type “array of
unknown bound of T” for some T (13.7.2.5). Expressions of the following forms are type-dependent only if
the type specified by the type-id, simple-type-specifier, typename-specifier, or new-type-id is dependent, even if
any subexpression is type-dependent:

127) This includes an injected-class-name (11.1) of a class template used without a template-argument-list.

§ 13.8.3.3

413
Expressions of the following forms are never type-dependent (because the type of the expression cannot be
dependent):

- literal
- sizeof unary-expression
- sizeof ( type-id )
- sizeof ... ( identifier )
- alignof ( type-id )
- typeid ( expression )
- typeid ( type-id )

   ::opt delete cast-expression
   ::opt delete [ ] cast-expression
   throw assignment-expressionopt
   noexcept ( expression )

[Note 1: For the standard library macro offsetof, see 17.2. — end note]

A class member access expression (7.6.1.5) is type-dependent if the terminal name of its id-expression, if any,
is dependent or the expression refers to a member of the current instantiation and the type of the referenced
member is dependent.

[Note 2: In an expression of the form x.y or xp->y the type of the expression is usually the type of the member y of
the class of x (or the class pointed to by xp). However, if x or xp refers to a dependent type that is not the current
instantiation, the type of y is always dependent. — end note]

A braced-init-list is type-dependent if any element is type-dependent or is a pack expansion.

A fold-expression is type-dependent.

13.8.3.4 Value-dependent expressions [temp.dep.constexpr]

Except as described below, an expression used in a context where a constant expression is required is
value-dependent if any subexpression is value-dependent.

An id-expression is value-dependent if:

1. it is a concept-id and any of its arguments are dependent,
2. it is type-dependent,
3. it is the name of a non-type template parameter,
4. it names a static data member that is a dependent member of the current instantiation and is not
   initialized in a member-declarator,
5. it names a static member function that is a dependent member of the current instantiation, or
6. it names a potentially-constant variable (7.7) that is initialized with an expression that is value-
dependent.

Expressions of the following form are value-dependent if the unary-expression or expression is type-dependent
or the type-id is dependent:

- sizeof unary-expression
- sizeof ( type-id )
- typeid ( expression )
- typeid ( type-id )
- alignof ( type-id )
- noexcept ( expression )

[Note 1: For the standard library macro offsetof, see 17.2. — end note]
Expressions of the following form are value-dependent if either the \textit{type-id} or \textit{simple-type-specifier} is dependent or the \textit{expression} or \textit{cast-expression} is value-dependent:

\begin{itemize}
  \item \texttt{simple-type-specifier ( expression-list \texttt{opt} )}
  \item \texttt{static\_cast < type-id > ( expression )}
  \item \texttt{const\_cast < type-id > ( expression )}
  \item \texttt{reinterpret\_cast < type-id > ( expression )}
  \item \texttt{( type-id ) cast-expression}
\end{itemize}

Expressions of the following form are value-dependent:

\texttt{sizeof ... ( identifier )}

An expression of the form \texttt{&\ qualified-id} where the \texttt{qualified-id} names a dependent member of the current instantiation is value-dependent. An expression of the form \texttt{&\ cast-expression} is also value-dependent if evaluating \texttt{cast-expression} as a core constant expression (7.7) succeeds and the result of the evaluation refers to a templated entity that is an object with static or thread storage duration or a member function.

13.8.3.5 Dependent template arguments

A type \textit{template-argument} is dependent if the type it specifies is dependent.

A non-type \textit{template-argument} is dependent if its type is dependent or the constant expression it specifies is value-dependent.

Furthermore, a non-type \textit{template-argument} is dependent if the corresponding non-type \textit{template-parameter} is of reference or pointer type and the \textit{template-argument} designates or points to a member of the current instantiation or a member of a dependent type.

A template \textit{template-parameter} is dependent if it names a \textit{template-parameter} or its terminal name is dependent.

13.8.4 Dependent name resolution

13.8.4.1 Point of instantiation

For a function template specialization, a member function template specialization, or a specialization for a member function or static data member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization and the context from which it is referenced depends on a template parameter, the point of instantiation of the specialization is the point of instantiation of the enclosing specialization. Otherwise, the point of instantiation for such a specialization immediately follows the namespace scope declaration or definition that refers to the specialization.

If a function template or member function of a class template is called in a way which uses the definition of a default argument of that function template or member function, the point of instantiation of the default argument is the point of instantiation of the function template or member function specialization.

For a \texttt{nothrow-specifier} of a function template specialization or specialization of a member function of a class template, if the \texttt{nothrow-specifier} is implicitly instantiated because it is needed by another template specialization and the context that requires it depends on a template parameter, the point of instantiation of the specialization is the point of instantiation of the specialization that requires it. Otherwise, the point of instantiation for such a \texttt{nothrow-specifier} immediately follows the namespace scope declaration or definition that requires the \texttt{nothrow-specifier}.

For a class template specialization, a class member template specialization, or a specialization for a class member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization, if the context from which the specialization is referenced depends on a template parameter, and if the specialization is not instantiated previous to the instantiation of the enclosing template, the point of instantiation is immediately before the point of instantiation of the enclosing template. Otherwise, the point of instantiation for such a specialization immediately precedes the namespace scope declaration or definition that refers to the specialization.

If a virtual function is implicitly instantiated, its point of instantiation is immediately following the point of instantiation of its enclosing class template specialization.

An explicit instantiation definition is an instantiation point for the specialization or specializations specified by the explicit instantiation.
A specialization for a function template, a member function template, or of a member function or static data member of a class template may have multiple points of instantiations within a translation unit, and in addition to the points of instantiation described above,

(7.1) for any such specialization that has a point of instantiation within the declaration-seq of the translation-unit, prior to the private-module-fragment (if any), the point after the declaration-seq is also considered a point of instantiation, and

(7.2) for any such specialization that has a point of instantiation within the private-module-fragment, the end of the translation unit is also considered a point of instantiation.

A specialization for a class template has at most one point of instantiation within a translation unit. A specialization for any template may have points of instantiation in multiple translation units. If two different points of instantiation give a template specialization different meanings according to the one-definition rule (6.3), the program is ill-formed, no diagnostic required.

13.8.4.2 Candidate functions

If a dependent call (13.8.3) would be ill-formed or would find a better match had the lookup for its dependent name considered all the function declarations with external linkage introduced in the associated namespaces in all translation units, not just considering those declarations found in the template definition and template instantiation contexts (6.5.4), then the program is ill-formed, no diagnostic required.

1 [Example 1:

Source file "X.h":

```cpp
namespace Q {
    struct X { }
};
```

Source file "G.h":

```cpp
namespace Q {
    void g_impl(X, X);
}
```

Module interface unit of M1:

```cpp
module;
#include "X.h"
#include "G.h"
export module M1;
export template<typename T>
void g(T t) {
    g_impl(t, Q::X{ }); // ADL in definition context finds Q::g_impl, g_impl not discarded
}
```

Module interface unit of M2:

```cpp
module;
#include "X.h"
export module M2;
import M1;
void h(Q::X x) {
    g(x); // OK
}
```

—end example]

2 [Example 2:

Module interface unit of Std:

```cpp
export module Std;
export template<typename Iter>
void indirect_swap(Iter lhs, Iter rhs)
{
    swap(*lhs, *rhs); // swap not found by unqualified lookup, can be found only via ADL
}
```
Module interface unit of M:

```c
export module M;
import Std;

struct S { /* ... */ };  // #1

void f(S* p, S* q)
{  // finds #1 via ADL in instantiation context
    indirect_swap(p, q);
}
```

—end example]

[Example 3:

Source file "X.h":

```c
struct X { /* ... */ ];
X operator+(X, X);
```

Module interface unit of F:

```c
export module F;
export template<typename T>
void f(T t) {  // OK, instantiates t from F,
    t + t;  // operator+ is visible in instantiation context
}
```

Module interface unit of M:

```c
module;  // OK, instantiates t from F,
#include "X.h"
export module M;
import F;
void g(X x) {
    f(x);
}
```

—end example]

[Example 4:

Module interface unit of A:

```c
export module A;
export template<typename T>
void f(T t) {
    cat(t, t);  // #1
    dog(t, t);  // #2
}
```

Module interface unit of B:

```c
export module B;
import A;
export template<typename T, typename U>
void g(T t, U u) {
    f(t);
}
```

Source file "foo.h", not an importable header:

```c
struct foo {
    friend int cat(foo, foo);
};
int dog(foo, foo);
```

Module interface unit of C1:

```c
module;
```
Template instantiation and specialization

13.9 Template instantiation and specialization [temp.spec]

13.9.1 General [temp.spec.general]

1. The act of instantiating a function, a variable, a class, a member of a class template, or a member template is referred to as template instantiation.

2. A function instantiated from a function template is called an instantiated function. A class instantiated from a class template is called an instantiated class. A member function, a member class, a member enumeration, or a static data member of a class template instantiated from the member definition of the class template is called, respectively, an instantiated member function, member class, member enumeration, or static data member. A member function instantiated from a function template is called an instantiated member function. A member class instantiated from a member class template is called an instantiated member class. A variable instantiated from a variable template is called an instantiated variable. A static data member instantiated from a static data member template is called an instantiated static data member.

3. An explicit specialization may be declared for a function template, a variable template, a class template, a member of a class template, or a member template. An explicit specialization declaration is introduced by `template<>`. In an explicit specialization declaration for a variable template, a class template, a member of a class template, or a class member template, the variable or class that is explicitly specialized shall be specified with a `simple-template-id`. In the explicit specialization declaration for a function template or a member function template, the function or member function explicitly specialized may be specified using a `template-id`.

[Example 1:]

```
#include "foo.h" // dog not referenced, discarded
export module C1;
import B;
export template<
typename T>
void h(T t) {
    g(foo{ }, t);
}
Translation unit:
import C1;
void i() {
    h(0); // error: dog not found at #2
}
Importable header "bar.h":
struct bar {
    friend int cat(bar, bar);
};
int dog(bar, bar);
Module interface unit of C2:
module;
#include "bar.h" // imports header unit "bar.h"
export module C2;
import B;
export template<
typename T>
void j(T t) {
    g(bar{ }, t);
}
Translation unit:
import C2;
void k() {
    j(0); // OK, dog found in instantiation context:
        // visible at end of module interface unit of C2
}
—end example]
An instantiated template specialization can be either implicitly instantiated (13.9.2) for a given argument list or be explicitly instantiated (13.9.3). A specialization is a class, variable, function, or class member that is either instantiated (13.9.2) from a templated entity or is an explicit specialization (13.9.4) of a templated entity.

For a given template and a given set of template-arguments,

1. an explicit instantiation definition shall appear at most once in a program,
2. an explicit specialization shall be defined at most once in a program, as specified in 6.3, and
3. both an explicit instantiation and a declaration of an explicit specialization shall not appear in a program unless the explicit specialization is reachable from the explicit instantiation.

An implementation is not required to diagnose a violation of this rule if neither declaration is reachable from the other.

The usual access checking rules do not apply to names in a declaration of an explicit instantiation or explicit specialization, with the exception of names appearing in a function body, default argument, base-clause, member-specification, enumerator-list, or static data member or variable template initializer.

[Note 1: In particular, the template arguments and names used in the function declarator (including parameter types, return types and exception specifications) can be private types or objects that would normally not be accessible. —end note]

Each class template specialization instantiated from a template has its own copy of any static members.

[Example 2:]

```cpp
template<class T> struct X {
  static T s;
};
template<class T> T X<T>::s = 0;
X<int> aa;
X<char*> bb;
X<int> has a static member s of type int and X<char*> has a static member s of type char*. —end example]
```

If a function declaration acquired its function type through a dependent type (13.8.3.2) without using the syntactic form of a function declarator, the program is ill-formed.

[Example 3:]

```cpp
template<class T> struct A {
  static T t;
};
typedef int function();
A<function> a;     // error: would declare A<function>::t as a static member function
—end example]
```
13.9.2 Implicit instantiation [temp.inst]

A template specialization $E$ is a declared specialization if there is a reachable explicit instantiation definition (13.9.3) or explicit specialization declaration (13.9.4) for $E$, or if there is a reachable explicit instantiation declaration for $E$ and $E$ is not

1. an inline function,
2. declared with a type deduced from its initializer or return value (9.2.9.6),
3. a potentially-constant variable (7.7), or
4. a specialization of a templated class.

[Note 1: An implicit instantiation in an importing translation unit cannot use names with internal linkage from an imported translation unit (6.6). — end note]

Unless a class template specialization is a declared specialization, the class template specialization is implicitly instantiated when the specialization is referenced in a context that requires a completely-defined object type or when the completeness of the class type affects the semantics of the program.

[Note 2: In particular, if the semantics of an expression depend on the member or base class lists of a class template specialization, the class template specialization is implicitly generated. For instance, deleting a pointer to class type depends on whether or not the class declares a destructor, and a conversion between pointers to class type depends on the inheritance relationship between the two classes involved. — end note]

[Example 1:
```
template<class T> class B { /* ... */ };  
template<class T> class D : public B<T> { /* ... */ };  

void f(void*);
void f(B<int>*);

void g(D<int>* p, D<char>* pp, D<double>* ppp) {
    f(p);  // instantiation of D<int> required: call f(B<int>*)
    B<char>* q = pp;  // instantiation of D<char> required: convert D<char>* to B<char>*
    delete ppp;  // instantiation of D<double> required
}
```
— end example]

If the template selected for the specialization (13.7.6.2) has been declared, but not defined, at the point of instantiation (13.8.4.1), the instantiation yields an incomplete class type (6.8.1).

[Example 2:
```
template<class T> class X;
X<char> ch;  // error: incomplete type X<char>
```
— end example]

[Note 3: Within a template declaration, a local class (11.6) or enumeration and the members of a local class are never considered to be entities that can be separately instantiated (this includes their default arguments, noexcept-specifiers, and non-static data member initializers, if any, but not their type-constraints or requires-clauses). As a result, the dependent names are looked up, the semantic constraints are checked, and any templates used are instantiated as part of the instantiation of the entity within which the local class or enumeration is declared. — end note]

3 The implicit instantiation of a class template specialization causes

1. the implicit instantiation of the declarations, but not of the definitions, of the non-deleted class member functions, member classes, scoped member enumerations, static data members, member templates, and friends; and
2. the implicit instantiation of the definitions of deleted member functions, unscoped member enumerations, and member anonymous unions.

The implicit instantiation of a class template specialization does not cause the implicit instantiation of default arguments or noexcept-specifiers of the class member functions.

[Example 3:
```
template<class T>
struct C {
    void f() { T x; }
```
— end example]
However, for the purpose of determining whether an instantiated redeclaration is valid according to 6.3 and 11.4, an instantiated declaration that corresponds to a definition in the template is considered to be a definition.

Example 4:

```cpp
template<class T, class U>
struct Outer {
    template<class X, class Y> struct Inner;
    template<class Y> struct Inner<T, Y>;  // #1a
    template<class Y> struct Inner<T, Y> { };  // #1b; OK, valid redeclaration of #1a
    template<class Y> struct Inner<U, Y> { };  // #2
};

Outer<int, int> outer;  // error at #2
Outer<int, int>::Inner<int, Y> is redeclared at #1b. (It is not defined but noted as being associated with a definition in Outer<T, U>.) #2 is also a redeclaration of #1a. It is noted as associated with a definition, so it is an invalid redeclaration of the same partial specialization.
```

4 Unless a member of a templated class is a declared specialization, the specialization of the member is implicitly instantiated when the specialization is referenced in a context that requires the member definition to exist or if the existence of the definition of the member affects the semantics of the program; in particular, the initialization (and any associated side effects) of a static data member does not occur unless the static data member is itself used in a way that requires the definition of the static data member to exist.

5 Unless a function template specialization is a declared specialization, the function template specialization is implicitly instantiated when the specialization is referenced in a context that requires a function definition to exist or if the existence of the definition affects the semantics of the program. A function whose declaration was instantiated from a friend function definition is implicitly instantiated when it is referenced in a context that requires a function definition to exist or if the existence of the definition affects the semantics of the program. Unless a call is to a function template explicit specialization or to a member function of an explicitly specialized class template, a default argument for a function template or a member function of a class template is implicitly instantiated when the function is called in a context that requires the value of the default argument.

[Note 4: An inline function that is the subject of an explicit instantiation declaration is not a declared specialization; the intent is that it still be implicitly instantiated when odr-used (6.3) so that the body can be considered for inlining, but that no out-of-line copy of it be generated in the translation unit. — end note]

Example 5:

```cpp
template<class T> struct Z {
    void f();
    void g();
};

void h() {
    Z<int>a;  // instantiation of class Z<int> required
    Z<char>* p;  // instantiation of class Z<char> not required
    Z<double>* q;  // instantiation of class Z<double> not required

    a.f();  // instantiation of Z<int>::f() required
    p->g();  // instantiation of class Z<char> required, and
```
Nothing in this example requires `class Z<double>`, `Z<int>::g()`, or `Z<char>::f()` to be implicitly instantiated.

— end example

7 Unless a variable template specialization is a declared specialization, the variable template specialization is implicitly instantiated when it is referenced in a context that requires a variable definition to exist or if the existence of the definition affects the semantics of the program. A default template argument for a variable template is implicitly instantiated when the variable template is referenced in a context that requires the value of the default argument.

8 The existence of a definition of a variable or function is considered to affect the semantics of the program if the variable or function is needed for constant evaluation by an expression (7.7), even if constant evaluation of the expression is not required or if constant expression evaluation does not use the definition.

[Example 6]:

```cpp
template<typename T> constexpr int f() { return T::value; }
template<bool B, typename T> void g(decltype(B ? f<T>() : 0));
template<bool B, typename T> void g(...);
template<bool B, typename T> void h(decltype(int{B ? f<T>() : 0}));
template<bool B, typename T> void h(...);

void x() {
  g<false, int>(0); // OK, B ? f<T>() : 0 is not potentially constant evaluated
  h<false, int>(0); // error, instantiates f<int> even though B evaluates to false and
                  // list-initialization of int from int cannot be narrowing
}
— end example
```

9 If the function selected by overload resolution (12.2) can be determined without instantiating a class template definition, it is unspecified whether that instantiation actually takes place.

[Example 7]:

```cpp
template <class T> struct S {
  operator int();
};

void f(int);
void f(S<int>&);
void f(S<float>);

void g(S<int>& sr) {
  f(sr); // instantiation of S<int> allowed but not required
  h<false, int>(0); // instantiation of S<float> allowed but not required
}
— end example
```

10 If a function template or a member function template specialization is used in a way that involves overload resolution, a declaration of the specialization is implicitly instantiated (13.10.4).

11 An implementation shall not implicitly instantiate a function template, a variable template, a member template, a non-virtual member function, a member class or static data member of a templated class, or a substatement of a constexpr if statement (8.5.2), unless such instantiation is required.

[Note 5]: The instantiation of a generic lambda does not require instantiation of substatements of a constexpr if statement within its compound-statement unless the call operator template is instantiated. — end note]

It is unspecified whether or not an implementation implicitly instantiates a virtual member function of a class template if the virtual member function would not otherwise be instantiated. The use of a template specialization in a default argument or default member initializer shall not cause the template to be implicitly instantiated except where needed to determine the correctness of the default argument or default member initializer. The use of a default argument in a function call causes specializations in the default argument to be implicitly instantiated. Similarly, the use of a default member initializer in a constructor definition or an aggregate initialization causes specializations in the default member initializer to be instantiated.

12 If a templated function `f` is called in a way that requires a default argument to be used, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the default
argument is done as if the default argument had been an initializer used in a function template specialization with the same scope, the same template parameters and the same access as that of the function template f used at that point, except that the scope in which a closure type is declared (7.5.5.2) — and therefore its associated namespaces — remain as determined from the context of the definition for the default argument. This analysis is called default argument instantiation. The instantiated default argument is then used as the argument of f.

13 Each default argument is instantiated independently.

[Example 8:
  template<class T> void f(T x, T y = ydef(T()), T z = zdef(T()));

  class A { };
  A zdef(A);

  void g(A a, A b, A c) {
      f(a, b, c); // no default argument instantiation
      f(a, b); // default argument z = zdef(T()) instantiated
      f(a); // error: ydef is not declared
  }
  —end example]

14 The noexcept-specifier of a function template specialization is not instantiated along with the function declaration; it is instantiated when needed (14.5). If such an noexcept-specifier is needed but has not yet been instantiated, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the noexcept-specifier is done as if it were being done as part of instantiating the declaration of the specialization at that point.

[Note 6: 13.8.4.1 defines the point of instantiation of a template specialization. —end note]

15 There is an implementation-defined quantity that specifies the limit on the total depth of recursive instantiations (Annex B), which could involve more than one template. The result of an infinite recursion in instantiation is undefined.

[Example 9:
  template<class T> class X {
    X<T>* p; // OK
    X<T*> a; // implicit generation of X<T*> requires
            // the implicit instantiation of X<T**> which . . .
  };
  —end example]

16 The type-constraints and requires-clause of a template specialization or member function are not instantiated along with the specialization or function itself, even for a member function of a local class; substitution into the atomic constraints formed from them is instead performed as specified in 13.5.3 and 13.5.2.3 when determining whether the constraints are satisfied or as specified in 13.5.3 when comparing declarations.

[Note 7: The satisfaction of constraints is determined during template argument deduction (13.10.3) and overload resolution (12.2). —end note]

[Example 10:
  template<typename T> concept C = sizeof(T) > 2;
  template<typename T> concept D = C<T> && sizeof(T) > 4;

  template<typename T> struct S {
    S() requires C<T> { } // #1
    S() requires D<T> { } // #2
  };

  S<char> s1; // error: no matching constructor
  S<char[8]> s2; // OK, calls #2

§ 13.9.2 423
When S<char> is instantiated, both constructors are part of the specialization. Their constraints are not satisfied, and they suppress the implicit declaration of a default constructor for S<char> (11.4.5.2), so there is no viable constructor for s1. —end example

Example 11:

```cpp
template<typename T> struct S1 {
    template<typename U>
    requires false
    struct Inner1; // ill-formed, no diagnostic required
};

template<typename T> struct S2 {
    template<typename U>
    requires (sizeof(T[-(int)sizeof(T)]) > 1)
    struct Inner2; // ill-formed, no diagnostic required
};
```

The class S1<T>::Inner1 is ill-formed, no diagnostic required, because it has no valid specializations. S2 is ill-formed, no diagnostic required, since no substitution into the constraints of its Inner2 template would result in a valid expression. —end example

13.9.3 Explicit instantiation [temp.explicit]

1 A class, function, variable, or member template specialization can be explicitly instantiated from its template. A member function, member class or static data member of a class template can be explicitly instantiated from the member definition associated with its class template.

2 The syntax for explicit instantiation is:

```cpp
explicit-instantiation:
    externopt template declaration
```

There are two forms of explicit instantiation: an explicit instantiation definition and an explicit instantiation declaration. An explicit instantiation declaration begins with the `extern` keyword.

3 An explicit instantiation shall not use a `storage-class-specifier` (9.2.2) other than `thread_local`. An explicit instantiation of a function template, member function of a class template, or variable template shall not use the `inline`, `constexpr`, or `consteval` specifiers. No `attribute-specifier-seq` (9.12.1) shall appertain to an explicit instantiation.

4 If the explicit instantiation is for a class or member class, the `elaborated-type-specifier` in the `declaration` shall include a `simple-template-id`; otherwise, the `declaration` shall be a `simple-declaration` whose `init-declarator-list` comprises a single `init-declarator` that does not have an `initializer`. If the explicit instantiation is for a variable template specialization, the `unqualified-id` in the `declarator` shall be a `simple-template-id`.

[Example 1:]

```cpp
template<class T> class Array { void mf(); };
template class Array<char>;
template void Array<int>::mf();

template<class T> void sort(Array<T>& v) { /* ... */ }
template void sort(Array<char>&); // argument is deduced here

namespace N {
    template<class T> void f(T&); 
} 
template void N::f<int>(int&);
—end example]
```

5 An explicit instantiation does not introduce a name (6.4.1). A declaration of a function template, a variable template, a member function or static data member of a class template, or a member function template of a class or class template shall be reachable from any explicit instantiation of that entity. A definition of a class template, a member class of a class template, or a member class template of a class or class template shall be reachable from any explicit instantiation of that entity unless an explicit specialization of the entity with the same template arguments is reachable therefrom. If the declaration of the explicit instantiation names an implicitly-declared special member function (11.4.4), the program is ill-formed.

§ 13.9.3  424
The declaration in an explicit-instantiation and the declaration produced by the corresponding substitution into the templated function, variable, or class are two declarations of the same entity.

[Note 1: These declarations are required to have matching types as specified in 6.6, except as specified in 14.5.]

[Example 2:

```cpp
// Example 2:
template<typename T> T var = {};
template float var<float>{}; // OK, instantiated variable has type float
template int var<int[16]>[]; // OK, absence of major array bound is permitted
template int *var<int>*; // error: instantiated variable has type int

template<typename T> auto av = T();
template int av<int>{}; // OK, variable with type int can be redeclared with type auto

template<typename T> auto f() {} // error: function with deduced return type
// redeclared with non-deduced return type (9.2.9.6)
```

—end example]

—end note]

Despite its syntactic form, the declaration in an explicit-instantiation for a variable is not itself a definition and does not conflict with the definition instantiated by an explicit instantiation definition for that variable.

For a given set of template arguments, if an explicit instantiation of a template appears after a declaration of an explicit specialization for that template, the explicit instantiation has no effect. Otherwise, for an explicit instantiation definition, the definition of a function template, a variable template, a member function template, or a member function or static data member of a class template shall be present in every translation unit in which it is explicitly instantiated.

A trailing template-argument can be left unspecified in an explicit instantiation of a function template specialization or of a member function template specialization provided it can be deduced (13.10.3.7). If all template arguments can be deduced, the empty template argument list <> may be omitted.

[Example 3:

```cpp
// Example 3:
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

// instantiate sort(Array<int>&) – template-argument deduced
template void sort<>(Array<int>&);
```

—end example]

[Note 2: An explicit instantiation of a constrained template is required to satisfy that template’s associated constraints (13.5.3). The satisfaction of constraints is determined when forming the template name of an explicit instantiation in which all template arguments are specified (13.3), or, for explicit instantiations of function templates, during template argument deduction (13.10.3.7) when one or more trailing template arguments are left unspecified.

—end note]

An explicit instantiation that names a class template specialization is also an explicit instantiation of the same kind (declaration or definition) of each of its direct non-template members that has not been previously explicitly specialized in the translation unit containing the explicit instantiation, provided that the associated constraints, if any, of that member are satisfied by the template arguments of the explicit instantiation (13.5.3, 13.5.2), except as described below.

[Note 3: In addition, it will typically be an explicit instantiation of certain implementation-dependent data about the class. —end note]

An explicit instantiation definition that names a class template specialization explicitly instantiates the class template specialization and is an explicit instantiation definition of only those members that have been defined at the point of instantiation.

An explicit instantiation of a prospective destructor (11.4.7) shall correspond to the selected destructor of the class.

If an entity is the subject of both an explicit instantiation declaration and an explicit instantiation definition in the same translation unit, the definition shall follow the declaration. An entity that is the subject of an explicit instantiation declaration and that is also used in a way that would otherwise cause an implicit...
instantiation (13.9.2) in the translation unit shall be the subject of an explicit instantiation definition somewhere in the program; otherwise the program is ill-formed, no diagnostic required.

[Note 4: This rule does apply to inline functions even though an explicit instantiation declaration of such an entity has no other normative effect. This is needed to ensure that if the address of an inline function is taken in a translation unit in which the implementation chose to suppress the out-of-line body, another translation unit will supply the body. — end note]

An explicit instantiation declaration shall not name a specialization of a template with internal linkage.

14 An explicit instantiation does not constitute a use of a default argument, so default argument instantiation is not done.

[Example 4:

```c
char* p = 0;
template<class T> T g(T x = &p) { return x; }
template int g<int>(int);   // OK even though &p isn't an int.
```

— end example]

13.9.4 Explicit specialization

An explicit specialization of any of the following:

1. function template
2. class template
3. variable template
4. member function of a class template
5. static data member of a class template
6. member class of a class template
7. member enumeration of a class template
8. member class template of a class or class template
9. member function template of a class or class template

can be declared by a declaration introduced by `template<>`; that is:

```
explicit-specialization:
    template <> declaration
```

[Example 1:

```c
template<class T> class stream;

template<> class stream<char> { /* ... */ };

template<class T> class Array { /* ... */ };  
template<class T> void sort(Array<T>& v) { /* ... */ }

template<> void sort<char*>(Array<char*>&);
```

Given these declarations, `stream<char>` will be used as the definition of streams of `chars`; other streams will be handled by class template specializations instantiated from the class template. Similarly, `sort<char*>` will be used as the sort function for arguments of type `Array<char*>`; other `Array` types will be sorted by functions generated from the template. — end example]

The declaration in an explicit-specialization shall not be an export-declaration. An explicit specialization shall not use a storage-class-specifier (9.2.2) other than thread_local.

An explicit specialization may be declared in any scope in which the corresponding primary template may be defined (9.3.4, 11.4, 13.7.3).

An explicit specialization does not introduce a name (6.4.1). A declaration of a function template, class template, or variable template being explicitly specialized shall be reachable from the declaration of the explicit specialization.

[Note 1: A declaration, but not a definition of the template is required. — end note]
The definition of a class or class template shall be reachable from the declaration of an explicit specialization for a member template of the class or class template.

[Example 2:

```cpp
template<> class X<int> { /* ... */ }; // error: X not a template

template<class T> class X;

template<> class X<char*> { /* ... */ }; // OK, X is a template
```
—end example]

A member function, a member function template, a member class, a member enumeration, a member class template, a static data member, or a static data member template of a class template may be explicitly specialized for a class specialization that is implicitly instantiated; in this case, the definition of the class template shall be reachable from the explicit specialization for the member of the class template. If such an explicit specialization for the member of a class template names an implicitly-declared special member function (11.4.4), the program is ill-formed.

A member of an explicitly specialized class is not implicitly instantiated from the member declaration of the class template; instead, the member of the class template specialization shall itself be explicitly defined if its definition is required. The definition of the class template explicit specialization shall be reachable from the definition of any member of it. The definition of an explicitly specialized class is unrelated to the definition of a generated specialization. That is, its members need not have the same names, types, etc. as the members of a generated specialization. Members of an explicitly specialized class template are defined in the same manner as members of normal classes, and not using the `template<>` syntax. The same is true when defining a member of an explicitly specialized member class. However, `template<>` is used in defining a member of an explicitly specialized member class template that is specialized as a class template.

[Example 3:

```cpp
template<class T> struct A {
    struct B {};  // not used for a member of an explicitly specialized class template
    struct U > struct C {};  
};

template<> struct A<int> {
    void f(int);
};

void h() {
    A<int> a;
    a.f(16);  // A<int>::f must be defined somewhere
}

// template<> not used for a member of an explicitly specialized class template
void A<int>::f(int) { /* ... */ }

template<> struct A<char>::B {  // also not used when defining a member of an explicitly specialized member class
    void f();
};

// template<> also not used when defining a member of an explicitly specialized member class
void A<char>::B::f() { /* ... */ }

template<> template<class U> struct A<char>::C {  // specialized as a class template
    void f();
};

// template<> is used when defining a member of an explicitly specialized member class template
// specialized as a class template

template<> template<class U> void A<char>::C<U>::f() { /* ... */ }

template<> struct A<short>::B {  // not permitted
    void f();
};

template<> void A<short>::B::f() { /* ... */ }  // error: template<> not permitted
```
7 If a template, a member template or a member of a class template is explicitly specialized, a declaration of that specialization shall be reachable from every use of that specialization that would cause an implicit instantiation to take place, in every translation unit in which such a use occurs; no diagnostic is required. If the program does not provide a definition for an explicit specialization and either the specialization is used in a way that would cause an implicit instantiation to take place or the member is a virtual member function, the program is ill-formed, no diagnostic required. An implicit instantiation is never generated for an explicit specialization that is declared but not defined.

[Example 4:

```cpp
class String { }

template<class T> class Array { /* ... */ };

template<class T> void sort(Array<T>& v) { /* ... */ }

void f(Array<String>& v) {
    sort(v); // use primary template sort(Array<T>&), T is String
}

template<> void sort<String>(Array<String>& v); // error: specialization after use of primary template
template<> void sort<Array<char>*>(Array<char*>& v); // OK, sort<char*> not yet used

template<class T> struct A {
    enum E : T;
    enum class S : T;
};

template<> enum A<int>::E : int { eint }; // OK
template<> enum class A<int>::S : int { sint }; // OK

template<class T> enum A<T>::E : T { eT }; // error: A<T>::E was instantiated when A<T> was instantiated

template<class T> enum A<char>::E : char { echar }; // OK
```

—end example]

8 The placement of explicit specialization declarations for function templates, class templates, variable templates, member functions of class templates, static data members of class templates, member classes of class templates, member enumerations of class templates, member class templates of class templates, member function templates of class templates, static data member templates of class templates, member functions of member templates of class templates, member functions of member templates of non-template classes, static data member templates of non-template classes, member function templates of member classes of class templates, etc., and the placement of partial specialization declarations of class templates, variable templates, member class templates of non-template classes, static data member templates of non-template classes, member class templates of class templates, etc., can affect whether a program is well-formed according to the relative positioning of the explicit specialization declarations and their points of instantiation in the translation unit as specified above and below. When writing a specialization, be careful about its location; or to make it compile will be such a trial as to kindle its self-immolation.

9 A simple-template-id that names a class template explicit specialization that has been declared but not defined can be used exactly like the names of other incompletely-defined classes (6.8).

[Example 5:

```cpp
template<class T> class X; // X is a class template
template<class T> class X<int>;

X<int>** p; // OK, pointer to declared class X<int>
X<int> x; // error: object of incomplete class X<int>
```

—end example]
A trailing template-argument can be left unspecified in the template-id naming an explicit function template specialization provided it can be deduced (13.10.3.7).

[Example 6:

```cpp
template<class T> class Array { /* ... */ };  
template<class T> void sort(Array<T>& v);

// explicit specialization for sort(Array<int>&)
// with deduced template-argument of type int
template<> void sort(Array<int>&);
```

—end example]

[Note 2: An explicit specialization of a constrained template is required to satisfy that template’s associated constraints (13.5.3). The satisfaction of constraints is determined when forming the template name of an explicit specialization in which all template arguments are specified (13.3), or, for explicit specializations of function templates, during template argument deduction (13.10.3.7) when one or more trailing template arguments are left unspecified. —end note]

A function with the same name as a template and a type that exactly matches that of a template specialization is not an explicit specialization (13.7.7).

Whether an explicit specialization of a function or variable template is inline, constexpr, constinit, or consteval is determined by the explicit specialization and is independent of those properties of the template. Similarly, attributes appearing in the declaration of a template have no effect on an explicit specialization of that template.

[Example 7:

```cpp
template<class T> void f(T) { /* ... */ }  
template<class T> inline T g(T) { /* ... */ }

template<> inline void f<>(int) { /* ... */ } // OK, inline
template<> int g<>(int) { /* ... */ } // OK, not inline

template<typename> [[noreturn]] void h(
[[maybe_unused]] int i);
```

```cpp
template<> void h<int>(int i) {
    // Implementations are expected not to warn that the function returns
    // but can warn about the unused parameter.
}
```

—end example]

An explicit specialization of a static data member of a template or an explicit specialization of a static data member template is a definition if the declaration includes an initializer; otherwise, it is a declaration.

[Note 3: The definition of a static data member of a template for which default-initialization is desired can use functional cast notation (7.6.1.4):

```cpp
template<> X Q<int>::x; // declaration
```

```cpp

template<> X Q<int>::x (); // error: declares a function
template<> X Q<int>::x = X(); // definition
—end note]

A member or a member template of a class template may be explicitly specialized for a given implicit instantiation of the class template, even if the member or member template is defined in the class template definition. An explicit specialization of a member or member template is specified using the syntax for explicit specialization.

[Example 8:

```cpp
template<class T> struct A {
    void f(T);
    template<class X1> void g1(T, X1);
    template<class X2> void g2(T, X2);
    void h(T) { }
};
```

```cpp
籴 // specialization
template<> void A<int>::f(int);
```
// out of class member template definition
template<class T> template<class X1> void A<T>::g1(T, X1) { }

// member template specialization
template<> template<class X1> void A<int>::g1(int, X1);

// member template specialization
template<> template<class X1> void A<int>::g1(int, char);   // X1 deduced as char
void A<int>::g2(char)(int, char);                           // X2 specified as char

// member specialization even if defined in class definition
template<> void A<int>::h(int) { }

—end example] 16

A member or a member template may be nested within many enclosing class templates. In an explicit specialization for such a member, the member declaration shall be preceded by a template<> for each enclosing class template that is explicitly specialized.

[Example 9:]
template<class T1> class A {
    template<class T2> class B {
        void mf();
    }
};
template<> template<> class A<int>::B<double>;
template<> template<> void A<char>::B<char>::mf();
—end example]

17 In an explicit specialization declaration for a member of a class template or a member template that appears in namespace scope, the member template and some of its enclosing class templates may remain unspecialized, except that the declaration shall not explicitly specialize a class member template if its enclosing class templates are not explicitly specialized as well. In such an explicit specialization declaration, the keyword template followed by a template-parameter-list shall be provided instead of the template<> preceding the explicit specialization declaration of the member. The types of the template-parameters in the template-parameter-list shall be the same as those specified in the primary template definition.

[Example 10:]
template <class T1> class A {
    template<class T2> class B {
        template<class T3> void mf1(T3);
        void mf2();
    }
};
template <> template <class X>
    class A<int>::B {
        template <class T> void mf1(T);
    }
.template <> template <> template<class T>
    void A<int>::B<double>::mf1(T t) { } // error: B<double> is specialized but its enclosing class template A is not

—end example]

18 A specialization of a member function template, member class template, or static data member template of a non-specialized class template is itself a template.

19 An explicit specialization declaration shall not be a friend declaration.

20 Default function arguments shall not be specified in a declaration or a definition for one of the following explicit specializations:

(20.1) — the explicit specialization of a function template;
the explicit specialization of a member function template;

the explicit specialization of a member function of a class template where the class template specialization to which the member function specialization belongs is implicitly instantiated.

[Note 4: Default function arguments can be specified in the declaration or definition of a member function of a class template specialization that is explicitly specialized. — end note]

13.10 Function template specializations

13.10.1 General

A function instantiated from a function template is called a function template specialization; so is an explicit specialization of a function template. Template arguments can be explicitly specified when naming the function template specialization, deduced from the context (e.g., deduced from the function arguments in a call to the function template specialization, see 13.10.3), or obtained from default template arguments.

Each function template specialization instantiated from a template has its own copy of any static variable.

Example 1:

```cpp
template<class T> void f(T* p) {
    static T s;
}
void g(int a, char* b) {
    f(&a); // calls f<int>(int*)
    f(&b); // calls f<char*>(char**)  
}
```

Here `f<int>(int*)` has a static variable `s` of type `int` and `f<char*>(char**)` has a static variable `s` of type `char*`.

13.10.2 Explicit template argument specification

Template arguments can be specified when referring to a function template specialization that is not a specialization of a constructor template by qualifying the function template name with the list of template-arguments in the same way as template-arguments are specified in uses of a class template specialization.

Example 1:

```cpp
template<class T> void sort(Array<T>& v);
void f(Array<dcomplex>& cv, Array<int>& ci) {
    sort<dcomplex>(cv); // sort<Array<dcomplex>&)
    sort<int>(ci);     // sort<Array<int>&)
}
```

and

```cpp
template<class U, class V> U convert(V v);
```

```cpp
void g(double d) {
    int i = convert<int,double>(d); // int convert(double)
    char c = convert<char<double>>(d); // char convert(double)
}
```

Template arguments shall not be specified when referring to a specialization of a constructor template (11.4.5, 6.5.5.2).

A template argument list may be specified when referring to a specialization of a function template

1. when a function is called,
2. when the address of a function is taken, when a function initializes a reference to function, or when a pointer to member function is formed,
3. in an explicit specialization,
4. in an explicit instantiation, or
5. in a friend declaration.
Trailing template arguments that can be deduced (13.10.3) or obtained from default template-arguments may be omitted from the list of explicit template-arguments.

[Note 1: A trailing template parameter pack (13.7.4) not otherwise deduced will be deduced as an empty sequence of template arguments. — end note]

If all of the template arguments can be deduced or obtained from default template-arguments, they may all be omitted; in this case, the empty template argument list <> itself may also be omitted.

[Example 2:

template<class X, class Y> X f(Y);
template<class X, class Y, class ... Z> X g(Y);
void h() {
    int i = f<int>(5.6);  // Y deduced as double
    int j = f(5.6);       // error: X cannot be deduced
    f<void>(f<int, bool>);  // Y for outer f deduced as int (*)(bool)
    f<void>(f<int>);       // error: f<int> does not denote a single function template specialization
    int k = g<int>(5.6);  // Y deduced as double; Z deduced as an empty sequence
    f<void>(g<int, bool>);  // Y for outer f deduced as int (*)(bool),
                           // Z deduced as an empty sequence
}
—end example]

[Note 2: An empty template argument list can be used to indicate that a given use refers to a specialization of a function template even when a non-template function (9.3.4.6) is visible that would otherwise be used. For example:

    template <class T> int f(T);   // #1
    int f(int);                      // #2
    int k = f(1);                    // uses #2
    int l = f<>(1);                  // uses #1

—end note]

Template arguments that are present shall be specified in the declaration order of their corresponding template-parameters. The template argument list shall not specify more template-arguments than there are corresponding template-parameters unless one of the template-parameters is a template parameter pack.

[Example 3:

template<class X, class Y, class Z> X f(Y, Z);
template<class ... Args> void f2();
void g() {
    f<int,const char*,double>("aa",3.0);        // error: Y cannot be deduced
    f<int>("aa",3.0);                           // Z deduced as double
    f("aa",3.0);                               // Y deduced as const char*; Z deduced as double
    f("aa",3.0);                               // error: X cannot be deduced
    f2<char, short, int, long>();              // OK
}
—end example]

Implicit conversions (7.3) will be performed on a function argument to convert it to the type of the corresponding function parameter if the parameter type contains no template-parameters that participate in template argument deduction.

[Note 3: Template parameters do not participate in template argument deduction if they are explicitly specified. For example,

template<class T> void f(T);

class Complex {
    Complex(double);
};

void g() {
    f<Complex>(1);      // OK, means f<Complex>(Complex(1))
}  
—end note]
Note 4: Because the explicit template argument list follows the function template name, and because constructor templates (11.4.5) are named without using a function name (6.5.5.2), there is no way to provide an explicit template argument list for these function templates. — end note

Template argument deduction can extend the sequence of template arguments corresponding to a template parameter pack, even when the sequence contains explicitly specified template arguments.

Example 4:

    template<class ... Types> void f(Types ... values);
    void g() {
        f<int*, float*>(0, 0, 0); // Types deduced as the sequence int*, float*, int
    }

—end example

13.10.3 Template argument deduction

13.10.3.1 General

When a function template specialization is referenced, all of the template arguments shall have values. The values can be explicitly specified or, in some cases, be deduced from the use or obtained from default template-arguments.

Example 1:

    void f(Array<dcomplex>& cv, Array<int>& ci) {
        sort(cv); // calls sort(Array<dcomplex>&)
        sort(ci); // calls sort(Array<int>&)
    }

and

    void g(double d) {
        int i = convert<int>(d); // calls convert<int,double>(double)
        int c = convert<char>(d); // calls convert<char,double>(double)
    }

—end example

When an explicit template argument list is specified, if the given template-id is not valid (13.3), type deduction fails. Otherwise, the specified template argument values are substituted for the corresponding template parameters as specified below.

Example 2: A parameter type of “void (const int, int[5])” becomes “void(*)(int,int*)”. — end example

[Note 1: A top-level qualifier in a function parameter declaration does not affect the function type but still affects the type of the function parameter variable within the function. — end note]

Example 3:

    template <class T> void f(T t);
    template <class X> void g(const X x);
    template <class Z> void h(Z, Z*);

    int main() {
        // #1: function type is f(int), t is non const
        f<int>(1);

        // #2: function type is f(int), t is const
        f<const int>(1);

        // #3: function type is g(int), x is const
        g<int>(1);

        // #4: function type is g(int), x is const
        g<const int>(1);
    }
// #5: function type is h(int, const int*)
    h<const int>(1,0);

—end example]

4 [Note 2: f<int>(1) and f<const int>(1) call distinct functions even though both of the functions called have the same function type. — end note]

5 The resulting substituted and adjusted function type is used as the type of the function template for template argument deduction. If a template argument has not been deduced and its corresponding template parameter has a default argument, the template argument is determined by substituting the template arguments determined for preceding template parameters into the default argument. If the substitution results in an invalid type, as described above, type deduction fails.

[Example 4:
    template <class T, class U = double>
    void f(T t = 0, U u = 0);
    
    void g() {
    f(1, 'c'); // f<int,char>(1,'c')
    f(1);     // f<int,double>(1,0)
    f();      // error: T cannot be deduced
    f<int>(); // f<int,double>(0,0)
    f<int,char>();// f<int,char>(0,0)
    }
—end example]

When all template arguments have been deduced or obtained from default template arguments, all uses of template parameters in the template parameter list of the template are replaced with the corresponding deduced or default argument values. If the substitution results in an invalid type, as described above, type deduction fails. If the function template has associated constraints (13.5.3), those constraints are checked for satisfaction (13.5.2). If the constraints are not satisfied, type deduction fails. In the context of a function call, if type deduction has not yet failed, then for those function parameters for which the function call has arguments, each function parameter with a type that was non-dependent before substitution of any explicitly-specified template arguments is checked against its corresponding argument; if the corresponding argument cannot be implicitly converted to the parameter type, type deduction fails.

[Note 3: Overload resolution will check the other parameters, including parameters with dependent types in which no template parameters participate in template argument deduction and parameters that became non-dependent due to substitution of explicitly-specified template arguments. — end note]

If type deduction has not yet failed, then all uses of template parameters in the function type are replaced with the corresponding deduced or default argument values. If the substitution results in an invalid type, as described above, type deduction fails.

[Example 5:
    template <class T> struct Z {
    typedef typename T::x xx;
    };
    template <class T> concept C = requires { typename T::A; };  
    template <C T> typename Z<T>::xx f(void *, T);
    // #1
    template <class T> void f(int, T);
    // #2
    struct A {} a;
    struct ZZ {
    template <class T, class = typename Z<T>::xx> operator T *();
    operator int();
    };  
    int main() {
    ZZ zz;
    f(1, a);   // OK, deduction fails for #1 because there is no conversion from int to void*
    f(zz, 42); // OK, deduction fails for #1 because C<int> is not satisfied
    }
—end example]
At certain points in the template argument deduction process it is necessary to take a function type that makes use of template parameters and replace those template parameters with the corresponding template arguments. This is done at the beginning of template argument deduction when any explicitly specified template arguments are substituted into the function type, and again at the end of template argument deduction when any template arguments that were deduced or obtained from default arguments are substituted.

The **deduction substitution loci** are

1. the function type outside of the `noexcept-specifier`,
2. the `explicit-specifier`, and
3. the template parameter declarations.

The substitution occurs in all types and expressions that are used in the deduction substitution loci. The expressions include not only constant expressions such as those that appear in array bounds or as nontype template arguments but also general expressions (i.e., non-constant expressions) inside `sizeof`, `decltype`, and other contexts that allow non-constant expressions. The substitution proceeds in lexical order and stops when a condition that causes deduction to fail is encountered. If substitution into different declarations of the same function template would cause template instantiations to occur in a different order or not at all, the program is ill-formed; no diagnostic required.

**Note 4:** The equivalent substitution in exception specifications is done only when the `noexcept-specifier` is instantiated, at which point a program is ill-formed if the substitution results in an invalid type or expression. —end note

**Example 6:**

```cpp
template <class T> struct A { using X = typename T::X; };
template <class T> typename T::X f(typename A<T>::X);
template <class T> void f(...) { }
template <class T> auto g(typename A<T>::X) -> typename T::X;
template <class T> void g(...) { }
template <class T> typename T::X h(typename A<T>::X);
template <class T> auto h(typename A<T>::X) -> typename T::X; // redeclaration
template <class T> void h(...) { }

void x() {
f<int>(0); // OK, substituting return type causes deduction to fail
g<int>(0); // error, substituting parameter type instantiates A<int>
h<int>(0); // ill-formed, no diagnostic required
}
```

—end example]

If a substitution results in an invalid type or expression, type deduction fails. An invalid type or expression is one that would be ill-formed, with a diagnostic required, if written in the same context using the substituted arguments.

**Note 5:** If no diagnostic is required, the program is still ill-formed. Access checking is done as part of the substitution process. —end note

Invalid types and expressions can result in a deduction failure only in the immediate context of the deduction substitution loci.

**Note 6:** The substitution into types and expressions can result in effects such as the instantiation of class template specializations and/or function template specializations, the generation of implicitly-defined functions, etc. Such effects are not in the “immediate context” and can result in the program being ill-formed. —end note

A **lambda-expression** appearing in a function type or a template parameter is not considered part of the immediate context for the purposes of template argument deduction.

**Note 7:** The intent is to avoid requiring implementations to deal with substitution failure involving arbitrary statements.

**Example 7:**

```cpp
template <class T>
auto f(T) -> decltype([]() { T::invalid; }())
void f(...);
f(0); // error: invalid expression not part of the immediate context
```
template <class T, std::size_t = sizeof([]() { T::invalid; })>
void g(T);
void g(...);
g(0); // error: invalid expression not part of the immediate context

template <class T>
auto h(T) -> decltype([x = T::invalid]() { });
void h(...);
h(0); // error: invalid expression not part of the immediate context

template <class T>
auto i(T) -> decltype([]() -> typename T::invalid { });
void i(...);
i(0); // error: invalid expression not part of the immediate context

template <class T>
auto j(T t) -> decltype([](auto x) -> decltype(x.invalid) { } (t)); // #1
void j(...); // #2
j(0); // deduction fails on #1, calls #2
— end example]
— end note

[Example 8:
struct X {
};
struct Y {
    Y(X) {}
};

template <class T> auto f(T t1, T t2) -> decltype(t1 + t2); // #1
X f(Y, Y); // #2
X x1, x2;
X x3 = f(x1, x2); // deduction fails on #1 (cannot add X+X), calls #2
— end example]

[Note 8: Type deduction can fail for the following reasons:
(11.1) — Attempting to instantiate a pack expansion containing multiple packs of differing lengths.
(11.2) — Attempting to create an array with an element type that is void, a function type, or a reference type, or attempting to create an array with a size that is zero or negative.
(11.3) — Attempting to use a type that is not a class or enumeration type in a qualified name.
(11.4) — Attempting to use a type in a nested-name-specifier of a qualified-id when that type does not contain the specified member, or

(11.4.1) — the specified member is not a type where a type is required, or
(11.4.2) — the specified member is not a template where a template is required, or
(11.4.3) — the specified member is not a non-type where a non-type is required.

[Example 10:
 template <class T> int f(typename T::B*);
 int i = f<int>(0);
 int j = f<void>(0); // invalid array
— end example]

[Example 11:
 template <int I> struct X {
};
 template <template <class T> class> struct Z {
};
 template <class T> void f(typename T::Y*) {}
template <class T> void g(X<T::N>*) {}
template <class T> void h(Z<T::TT>*) {}

struct A {};
struct B { int Y; };
struct C {
    typedef int N;
};
struct D {
    typedef int TT;
};

int main() {
    // Deduction fails in each of these cases:
f<A>(0); // k does not contain a member Y
f<B>(0); // The Y member of B is not a type
g<C>(0); // The N member of C is not a non-type
h<D>(0); // The TT member of D is not a template
}

— end example]

— Attempting to create a pointer to reference type.
— Attempting to create a reference to void.
— Attempting to create “pointer to member of T” when T is not a class type.

[Example 12:
    template <class T> int f(int T::*);
    int i = f<int>(0);
— end example]

— Attempting to give an invalid type to a non-type template parameter.

[Example 13:
    template <class T, T> struct S {};
    template <class T> int f(S<T, T()>*); // #1
class X {
    int m;
};
    int i0 = f<X>(0); // #1 uses a value of non-structural type X as a non-type template argument
— end example]

— Attempting to perform an invalid conversion in either a template argument expression, or an expression used in the function declaration.

[Example 14:
    template <class T, T*> int f(int);
    int i2 = f<int,1>(0); // can’t convert 1 to int*
— end example]

— Attempting to create a function type in which a parameter has a type of void, or in which the return type is a function type or array type.

— end note]

12 [Example 15: In the following example, assuming a signed char cannot represent the value 1000, a narrowing conversion (9.4.5) would be required to convert the template-argument of type int to signed char, therefore substitution fails for the second template (13.4.3).

    template <int> int f(int);
    template <signed char> int f(int);
    int i1 = f<1000>(0); // OK
    int i2 = f<1>(0); // ambiguous; not narrowing
— end example]

13.10.3.2 Deducing template arguments from a function call [temp.deduct.call]
corresponding argument of the call (call it \( A \)) as described below. If removing references and cv-qualifiers from \( P \) gives std::initializer_list<\( P' \)> or \( P'[N] \) for some \( P' \) and \( N \) and the argument is a non-empty initializer list (9.4.5), then deduction is performed instead for each element of the initializer list independently, taking \( P' \) as separate function template parameter types \( P'_i \) and the \( i \)th initializer element as the corresponding argument. In the \( P'[N] \) case, if \( N \) is a non-type template parameter, \( N \) is deduced from the length of the initializer list. Otherwise, an initializer list argument causes the parameter to be considered a non-deduced context (13.10.3.6).

**Example 1:**

```cpp
template<class T> void f(std::initializer_list<T>); f({1,2,3}); // T deduced as int f({"asdf"}); // error: T deduced as both int and const char*
```

```cpp
template<class T> void g(T); g({1,2,3}); // error: no argument deduced for T
```

```cpp
template<class T, int N> void h(T const(&)[N]); h({1,2,3}); // T deduced as int; N deduced as 3
```

```cpp
template<class T> void j(T const(&)[3]); j({42}); // T deduced as int; array bound not considered
```

```cpp
struct Aggr { int i; int j; }; template<int N> void k(Aggr const(&)[N]); k({1,2,3}); // error: deduction fails, no conversion from int to Aggr k({1,2,3,4}); // OK, N deduced as 3
```

```cpp
template<int N, int M> void m(int const(&)[M][N]) { }
```

```cpp
template<class T, int N> void n(T const(&)[N], T); n({1,2,3}, Aggr()); // OK, T is Aggr, N is 3
```

```cpp
template<typename T, int N> void o(T (*const(&)[N])(T));
```

```cpp
int f1(int); int f4(int); char f4(char);
o({ &f1, &f4 }); // OK, T deduced as int from first element, nothing
do({ &f1, static_cast<char(*)<char>*>(&f4) }); // error: conflicting deductions for T
```

--- end example

For a function parameter pack that occurs at the end of the parameter-declaration-list, deduction is performed for each remaining argument of the call, taking the type \( P \) of the declarator-id of the function parameter pack as the corresponding function template parameter type. Each deduction deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. When a function parameter pack appears in a non-deduced context (13.10.3.6), the type of that pack is never deduced.

**Example 2:**

```cpp
template<class ... Types> void f(Types& ...);
template<class T1, class ... Types> void g(T1, Types ...);
template<class T1, class ... Types> void g1(Types ..., T1);
```

```cpp
void h(int x, float& y) {
    const int z = x;
    f(x, y, z); // Types deduced as int, float, const int
g(x, y, z); // T1 deduced as int; Types deduced as float, int
gl(x, y, z); // error: Types is not deduced
gl<int, int, int>(x, y, z); // OK, no deduction occurs
}
```

--- end example

2 If \( P \) is not a reference type:
If $A$ is an array type, the pointer type produced by the array-to-pointer standard conversion (7.3.3) is used in place of $A$ for type deduction; otherwise,

If $A$ is a function type, the pointer type produced by the function-to-pointer standard conversion (7.3.4) is used in place of $A$ for type deduction; otherwise,

If $A$ is a cv-qualified type, the top-level cv-qualifiers of $A$’s type are ignored for type deduction.

If $P$ is a cv-qualified type, the top-level cv-qualifiers of $P$’s type are ignored for type deduction. If $P$ is a reference type, the type referred to by $P$ is used for type deduction.

A forwarding reference is an rvalue reference to a cv-unqualified template parameter that does not represent a template parameter of a class template (during class template argument deduction (12.2.2.9)). If $P$ is a forwarding reference and the argument is an lvalue, the type “lvalue reference to $A$” is used in place of $A$ for type deduction.

4 In general, the deduction process attempts to find template argument values that will make the deduced $A$ identical to $A$ (after the type $A$ is transformed as described above). However, there are three cases that allow a difference:

If the original $P$ is a reference type, the deduced $A$ (i.e., the type referred to by the reference) can be more cv-qualified than the transformed $A$.

The transformed $A$ can be another pointer or pointer-to-member type that can be converted to the deduced $A$ via a function pointer conversion (7.3.14) and/or qualification conversion (7.3.6).

If $P$ is a class and $P$ has the form simple-template-id, then the transformed $A$ can be a derived class $D$ of the deduced $A$. Likewise, if $P$ is a pointer to a class of the form simple-template-id, the transformed $A$ can be a pointer to a derived class $D$ pointed to by the deduced $A$. However, if there is a class $C$ that is a (direct or indirect) base class of $D$ and derived (directly or indirectly) from a class $B$ and that would be a valid deduced $A$, the deduced $A$ cannot be $B$ or pointer to $B$, respectively.

[Example 5:

```c
template <typename... T> struct X;
```
template <> struct X<> {};  
template <typename T, typename... Ts>  
struct X<T, Ts...> : X<Ts...> {};  
struct D : X<int> {};  
struct E : X<>, X<int> {};  

// Example

template <typename... T>  
int f(const X<T...>&);  
int x = f(D());  // calls f<int>, not f<>  
// B is X<> C is X<int>  
int z = f(E());  // calls f<int>, not f<>  

— end example

5  
These alternatives are considered only if type deduction would otherwise fail. If they yield more than one  
possible deduced A, the type deduction fails.  

[Note 1: If a template-parameter is not used in any of the function parameters of a function template, or is used  
only in a non-deduced context, its corresponding template-argument cannot be deduced from a function call and the  
template-argument must be explicitly specified. — end note]  

6  
When P is a function type, function pointer type, or pointer-to-member-function type:

(6.1)  
— If the argument is an overload set containing one or more function templates, the parameter is treated  
as a non-deduced context.  

(6.2)  
— If the argument is an overload set (not containing function templates), trial argument deduction is  
attempted using each of the members of the set. If deduction succeeds for only one of the overload set  
members, that member is used as the argument value for the deduction. If deduction succeeds for more  
than one member of the overload set the parameter is treated as a non-deduced context.

7  
[Example 6:  
// Only one function of an overload set matches the call so the function parameter is a deduced context.  
template <class T> int f(T (*p)(T));  
int g(int);  
int g(char);  
int i = f(g);  // calls f(int (*)(int))  
— end example]

8  
[Example 7:  
// Ambiguous deduction causes the second function parameter to be a non-deduced context.  
template <class T> int f(T, T (*p)(T));  
int g(int);  
char g(char);  
int i = f(1, g);  // calls f(int, int (*)(int))  
— end example]

9  
[Example 8:  
// The overload set contains a template, causing the second function parameter to be a non-deduced context.  
template <class T> int f(T, T (*p)(T));  
char g(char);  
template <class T> T g(T);  
int i = f(1, g);  // calls f(int, int (*)(int))  
— end example]

13.10.3.3 Deducing template arguments taking the address of a function template  
[temp.deduct.funcaddr]

Template arguments can be deduced from the type specified when taking the address of an overload set (12.3).  
If there is a target, the function template's function type and the target type are used as the types of P and  
A, and the deduction is done as described in 13.10.3.6. Otherwise, deduction is performed with empty sets of  
types P and A.

A placeholder type (9.2.9.6) in the return type of a function template is a non-deduced context. If template  
argument deduction succeeds for such a function, the return type is determined from instantiation of the  
function body.
13.10.3.4 Deducing conversion function template arguments

1 Template argument deduction is done by comparing the return type of the conversion function template (call it \( P \)) with the type specified by the conversion-type-id of the conversion-function-id being looked up (call it \( A \)) as described in 13.10.3.6. If the conversion-function-id is constructed during overload resolution (12.2.2), the rules in the remainder of this subclause apply.

2 If \( P \) is a reference type, the type referred to by \( P \) is used in place of \( P \) for type deduction and for any further references to or transformations of \( P \) in the remainder of this subclause.

3 If \( A \) is not a reference type:
   - (3.1) If \( P \) is an array type, the pointer type produced by the array-to-pointer standard conversion (7.3.3) is used in place of \( P \) for type deduction; otherwise,
   - (3.2) If \( P \) is a function type, the pointer type produced by the function-to-pointer standard conversion (7.3.4) is used in place of \( P \) for type deduction; otherwise,
   - (3.3) If \( P \) is a cv-qualified type, the top-level cv-qualifiers of \( P \)'s type are ignored for type deduction.

4 If \( A \) is a cv-qualified type, the top-level cv-qualifiers of \( A \)'s type are ignored for type deduction. If \( A \) is a reference type, the type referred to by \( A \) is used for type deduction.

5 In general, the deduction process attempts to find template argument values that will make the deduced \( A \) identical to \( A \). However, certain attributes of \( A \) may be ignored:
   - (5.1) If the original \( A \) is a reference type, any cv-qualifiers of \( A \) (i.e., the type referred to by the reference).
   - (5.2) If the original \( A \) is a function pointer or pointer-to-member-function type with a potentially-throwing exception specification (14.5), the exception specification.
   - (5.3) Any cv-qualifiers in \( A \) that can be restored by a qualification conversion.

These attributes are ignored only if type deduction would otherwise fail. If ignoring them allows more than one possible deduced \( A \), the type deduction fails.

13.10.3.5 Deducing template arguments during partial ordering

1 Template argument deduction is done by comparing certain types associated with the two function templates being compared.

2 Two sets of types are used to determine the partial ordering. For each of the templates involved there is the original function type and the transformed function type.

[Note 1: The creation of the transformed type is described in 13.7.7.3. — end note]

The deduction process uses the transformed type as the argument template and the original type of the other template as the parameter template. This process is done twice for each type involved in the partial ordering comparison: once using the transformed template-1 as the argument template and template-2 as the parameter template and again using the transformed template-2 as the argument template and template-1 as the parameter template.

3 The types used to determine the ordering depend on the context in which the partial ordering is done:
   - (3.1) In the context of a function call, the types used are those function parameter types for which the function call has arguments.\(^{128}\)
   - (3.2) In the context of a call to a conversion function, the return types of the conversion function templates are used.
   - (3.3) In other contexts (13.7.7.3) the function template’s function type is used.

4 Each type nominated above from the parameter template and the corresponding type from the argument template are used as the types of \( P \) and \( A \).

5 Before the partial ordering is done, certain transformations are performed on the types used for partial ordering:
   - (5.1) If \( P \) is a reference type, \( P \) is replaced by the type referred to.
   - (5.2) If \( A \) is a reference type, \( A \) is replaced by the type referred to.

\(^{128}\) Default arguments are not considered to be arguments in this context; they only become arguments after a function has been selected.
If both \( P \) and \( A \) were reference types (before being replaced with the type referred to above), determine which of the two types (if any) is more cv-qualified than the other; otherwise the types are considered to be equally cv-qualified for partial ordering purposes. The result of this determination will be used below.

Remove any top-level cv-qualifiers:

- (7.1) If \( P \) is a cv-qualified type, \( P \) is replaced by the cv-unqualified version of \( P \).
- (7.2) If \( A \) is a cv-qualified type, \( A \) is replaced by the cv-unqualified version of \( A \).

Using the resulting types \( P \) and \( A \), the deduction is then done as described in 13.10.3.6. If \( P \) is a function parameter pack, the type \( A \) of each remaining parameter type of the argument template is compared with the type \( P \) of the declarator-id of the function parameter pack. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. Similarly, if \( A \) was transformed from a function parameter pack, it is compared with each remaining parameter type of the parameter template. If deduction succeeds for a given type, the type from the argument template is considered to be at least as specialized as the type from the parameter template.

**Example 1:**

```cpp
template<class... Args> void f(Args... args);  // #1
template<class T1, class... Args> void f(T1 a1, Args... args);  // #2

template<class T1, class T2> void f(T1 a1, T2 a2);  // #3
```

f();  // calls #1
f(1, 2, 3);  // calls #2
f(1, 2);  // calls #3; non-variadic template #3 is more specialized
          // than the variadic templates #1 and #2

9 If, for a given type, the types are identical after the transformations above and both \( P \) and \( A \) were reference types (before being replaced with the type referred to above):

- (9.1) if the type from the argument template was an lvalue reference and the type from the parameter template was not, the parameter type is not considered to be at least as specialized as the argument type; otherwise,
- (9.2) if the type from the argument template is more cv-qualified than the type from the parameter template (as described above), the parameter type is not considered to be at least as specialized as the argument type.

10 Function template \( F \) is at least as specialized as function template \( G \) if, for each pair of types used to determine the ordering, the type from \( F \) is at least as specialized as the type from \( G \). \( F \) is more specialized than \( G \) if \( F \) is at least as specialized as \( G \) and \( G \) is not at least as specialized as \( F \).

11 If, after considering the above, function template \( F \) is at least as specialized as function template \( G \) and vice-versa, and if \( G \) has a trailing function parameter pack for which \( F \) does not have a corresponding parameter, and if \( F \) does not have a trailing function parameter pack, then \( F \) is more specialized than \( G \).

In most cases, deduction fails if not all template parameters have values, but for partial ordering purposes a template parameter may remain without a value provided it is not used in the types being used for partial ordering.

**Note 2:** A template parameter used in a non-deducted context is considered used. — end note}

**Example 2:**

```cpp
template <class T> T f(int);  // #1
template <class T, class U> T f(U);  // #2

void g() {
    f<int>(1);  // calls #1
}
```

**Note 3:** Partial ordering of function templates containing template parameter packs is independent of the number of deduced arguments for those template parameter packs. — end note}

**Example 3:**

```cpp
template<class ...> struct Tuple { }

template<class ... Types> void g(Tuple<Types ...>);  // #1
```
template<class T1, class ... Types> void g(Tuple<T1, Types ...>); // #2

template<class T1, class ... Types> void g(Tuple<T1, Types& ...>); // #3

g(Tuple<>()); // calls #1
g(Tuple<int, float>()); // calls #2
g(Tuple<int, float&>()); // calls #3
g(Tuple<int>()); // calls #3

— end example

13.10.3.6 Deducing template arguments from a type

Template arguments can be deduced in several different contexts, but in each case a type that is specified
in terms of template parameters (call it P) is compared with an actual type (call it A), and an attempt
is made to find template argument values (a type for a type parameter, a value for a non-type parameter, or a
template for a template parameter) that will make P, after substitution of the deduced values (call it the
deduced A), compatible with A.

In some cases, the deduction is done using a single set of types P and A, in other cases, there will be a set
of corresponding types P and A. Type deduction is done independently for each P/A pair, and the deduced
template argument values are then combined. If type deduction cannot be done for any P/A pair, or if for any
pair the deduction leads to more than one possible set of deduced values, or if different pairs yield different
deduced values, or if any template argument remains neither deduced nor explicitly specified, template
argument deduction fails. The type of a type parameter is only deduced from an array bound if it is not
otherwise deduced.

A given type P can be composed from a number of other types, templates, and non-type values:

1. A function type includes the types of each of the function parameters, the return type, and its exception
   specification.
2. A pointer-to-member type includes the type of the class object pointed to and the type of the member
   pointed to.
3. A type that is a specialization of a class template (e.g., A<int>) includes the types, templates, and
   non-type values referenced by the template argument list of the specialization.
4. An array type includes the array element type and the value of the array bound.

In most cases, the types, templates, and non-type values that are used to compose P participate in template
argument deduction. That is, they may be used to determine the value of a template argument, and template
argument deduction fails if the value so determined is not consistent with the values determined elsewhere.
In certain contexts, however, the value does not participate in type deduction, but instead uses the values of
template arguments that were either deduced elsewhere or explicitly specified. If a template parameter is
used only in non-deduced contexts and is not explicitly specified, template argument deduction fails.

[Note 1: Under 13.10.3.2, if P contains no template-parameters that appear in deduced contexts, no deduction is done,
so P and A need not have the same form. — end note]

The non-deduced contexts are:
1. The nested-name-specifier of a type that was specified using a qualified-id.
2. The expression of a decltype-specifier.
3. A non-type template argument or an array bound in which a subexpression references a template
   parameter.
4. A template parameter used in the parameter type of a function parameter that has a default argument
   that is being used in the call for which argument deduction is being done.
5. A function parameter for which the associated argument is an overload set (12.3), and one or more of
   the following apply:
   1. more than one function matches the function parameter type (resulting in an ambiguous deduction),
   or
   2. no function matches the function parameter type, or
   3. the overload set supplied as an argument contains one or more function templates.
(5.6) A function parameter for which the associated argument is an initializer list (9.4.5) but the parameter does not have a type for which deduction from an initializer list is specified (13.10.3.2).

[Example 1:]
```cpp
template<class T> void g(T);
g({1,2,3});  // error: no argument deduced for T
```
—end example]

(5.7) A function parameter pack that does not occur at the end of the parameter-declaration-list.

When a type name is specified in a way that includes a non-deduced context, all of the types that comprise that type name are also non-deduced. However, a compound type can include both deduced and non-deduced types.

[Example 2: If a type is specified as A<T>::B<T2>, both T and T2 are non-deduced. Likewise, if a type is specified as A<I+J>::X<T>, I, J, and T are non-deduced. If a type is specified as void f(typename A<T>::B, A<T>), the T in A<T>::B is non-deduced but the T in A<T> is deduced. — end example]

7 [Example 3: Here is an example in which different parameter/argument pairs produce inconsistent template argument deductions:

```cpp
template<class T> void f(T x, T y) { /* ... */ }
struct A { /* ... */ };       
struct B : A { /* ... */ };   
void g(A a, B b) {             
    f(a,b);  // error: T deduced as both A and B
    f(b,a);  // error: T deduced as both A and B
    f(a,a);  // OK, T is A
    f(b,b);  // OK, T is B
}
```

Here is an example where two template arguments are deduced from a single function parameter/argument pair. This can lead to conflicts that cause type deduction to fail:

```cpp
template <class T, class U> void f( T (*)( T, U, U ) );
int g1( int, float, float);
char g2( int, float, float);
int g3( int, char, float);
void r() {
    f(g1);  // OK, E is false
    f(g2);  // error: T deduced as both char and int
    f(g3);  // error: U deduced as both char and float
}
```

Here is an example where the exception specification of a function type is deduced:

```cpp
template<bool E> void f1(void (*)() noexcept(E));
template<bool> struct A { };       
template<bool B> void f2(void (*)(A<B>) noexcept(B));
void g1();
void g2() noexcept;
void g3(A<true>);
void h() {
    f1(g1);  // OK, E is false
    f1(g2);  // OK, E is true
    f2(g3);  // error: B deduced as both true and false
}
```

Here is an example where a qualification conversion applies between the argument type on the function call and the deduced template argument type:

```cpp
template<class T> void f(const T*) { }
int* p;
void s() {
    f(p);        // f(const int*)
}
```
Here is an example where the template argument is used to instantiate a derived class type of the corresponding function parameter type:

```cpp
template <class T> struct B { };

template <class T> struct D : public B<T> {};  
struct D2 : public B<int> {};  

template <class T> void f(B<T>&) {}  
void t() {  
D<int> d;  
D2 d2;  
f(d);    // calls f(B<int>&)  
f(d2);   // calls f(B<int>&)  
}
```

—end example—

A template type argument T, a template template argument TT, or a template non-type argument i can be deduced if P and A have one of the following forms:

- cv opt T
- T*
- T&
- T&&
- T opt
- T opt [i opt]
- T opt(T opt) noexcept(i opt)
- T opt::*
- TT opt<T>
- TT opt<i>
- TT opt<TT>
- TT opt<>

where

- (8.1) T opt represents a type or parameter-type-list that either satisfies these rules recursively, is a non-deduced context in P or A, or is the same non-dependent type in P and A,
- (8.2) TT opt represents either a class template or a template template parameter,
- (8.3) i opt represents an expression that either is an i, is value-dependent in P or A, or has the same constant value in P and A, and
- (8.4) noexcept(i opt) represents an exception specification (14.5) in which the (possibly-implicit, see 9.3.4.6) noexcept-specifier’s operand satisfies the rules for an i opt above.

[Note 2: If a type matches such a form but contains no Ts, Is, or TTs, deduction is not possible. —end note—]

Similarly, <T> represents template argument lists where at least one argument contains a T, <i> represents template argument lists where at least one argument contains an i and <> represents template argument lists where no argument contains a T or an i.

If P has a form that contains <T> or <i>, then each argument P i of the respective template argument list of P is compared with the corresponding argument A i of the corresponding template argument list of A. If the template argument list of P contains a pack expansion that is not the last template argument, the entire template argument list is a non-deduced context. If P i is a pack expansion, then the pattern of P i is compared with each remaining argument in the template argument list of A. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by P i. During partial ordering (13.10.3.5), if A i was originally a pack expansion:

- (9.1) if P does not contain a template argument corresponding to A i then A i is ignored;
- (9.2) otherwise, if P i is not a pack expansion, template argument deduction fails.

[Example 4:]

```cpp
template<class T1, class... Z> class S;  // #1  
template<class T1, class... Z> class S<T1, const Z&...> { };  // #2  
template<class T1, class T2> class S<T1, T2> { };  // #3  
S<int, const int&> s;  // both #2 and #3 match; #3 is more specialized

template<class T, class... U> struct A { };  // #1  
template<class T1, class T2, class... U> struct A<T1, T2*, U...> { };  // #2  
template<class T1, class T2> struct A<T1, T2> { };  // #3
```
template struct A<int, int*>; // selects #2

—end example

Similarly, if \( P \) has a form that contains \((T)\), then each parameter type \( P_i \) of the respective parameter-type-list (9.3.4.6) of \( P \) is compared with the corresponding parameter type \( A_i \) of the corresponding parameter-type-list of \( A \). If \( P \) and \( A \) are function types that originated from deduction when taking the address of a function template (13.10.3.3) or when deducing template arguments from a function declaration (13.10.3.7) and \( P_i \) and \( A_i \) are parameters of the top-level parameter-type-list of \( P \) and \( A \), respectively, \( P_i \) is adjusted if it is a forwarding reference (13.10.3.2) and \( A_i \) is an lvalue reference, in which case the type of \( P_i \) is changed to be the template parameter type (i.e., \( T&& \) is changed to simply \( T \)).

[Note 3: As a result, when \( P_i \) is \( T&& \) and \( A_i \) is \( X& \), the adjusted \( P_i \) will be \( T \), causing \( T \) to be deduced as \( X& \). —end note]

[Example 5]:

```cpp
template <class T> void f(T&&);
template <> void f(int&) { } // #1
template <> void f(int&&) { } // #2
void g(int i) {
    f(i); // calls f<int&>(int&), i.e., #1
    f(0); // calls f<int>(int&&), i.e., #2
}
—end example
```

If the parameter-declaration corresponding to \( P_i \) is a function parameter pack, then the type of its declarator-id is compared with each remaining parameter type in the parameter-type-list of \( A \). Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. During partial ordering (13.10.3.5), if \( A_i \) was originally a function parameter pack:

(10.1) — if \( P \) does not contain a function parameter type corresponding to \( A_i \) then \( A_i \) is ignored;

(10.2) — otherwise, if \( P_i \) is not a function parameter pack, template argument deduction fails.

[Example 6]:

```cpp
template<class T, class... U> void f(T*, U...) { } // #1
template<class T> void f(T) { } // #2
template void f(int*); // selects #1
—end example
```

These forms can be used in the same way as \( T \) is for further composition of types.

[Example 7]:

\[ X\langle int \rangle (\ast)(\text{char}[6]) \]

is of the form

\[ \text{template-name<}\ T\ (\ast)(\text{type}[i]) \]

which is a variant of

\[ \text{type} (\ast)(\text{T}) \]

where type is \( X\langle int \rangle \) and \( T \) is \( \text{char}[6] \). —end example]

When the value of the argument corresponding to a non-type template parameter \( P \) that is declared with a dependent type is deduced from an expression, the template parameters in the type of \( P \) are deduced from the type of the value.

[Example 8]:

```cpp
template<long n> struct A { };
template<typename T> struct C;
template<typename T, T n> struct C<A<n>> { 
    using Q = T;
};
```

§ 13.10.3.6
The type of \( N \) in the type \( T[N] \) is `std::size_t`.

**Example 9:**

```cpp
template<typename T> struct S;  
template<typename T, T n> struct S<int[n]> {   
using Q = T; 
};  
using V = decltype(sizeof 0);  
using V = S<int[42]>::Q; // OK; T was deduced as std::size_t from the type int[42]  
```

**Example 10:**

```cpp
template<bool> struct A { };  
template<auto> struct B;  
template<auto X, void (*F)() noexcept(X)> struct B<F> {   
A<X> ax; 
};  
void f_nothrow() noexcept;  
B<f_nothrow> bn; // OK, type of X deduced as bool  
```

**Example 11:**

```cpp
template<class T, T i> void f(int (&a)[i]);  
int v[10];  
void g() {   
f(v); // OK, T is std::size_t  
}  
```

**Note 4:** Except for reference and pointer types, a major array bound is not part of a function parameter type and cannot be deduced from an argument:

```cpp
template<int i> void f1(int a[10][i]);  
template<int i> void f2(int a[i][20]);  
template<int i> void f3(int (&a)[i][20]);  
void g() {   
int v[10][20];   
f1(v); // OK, i deduced as 20   
f2<20>(v); // OK   
f2<10>(v); // error: cannot deduce template-argument i   
f3(v); // OK, i deduced as 10   
}  
```

**Note 5:** If, in the declaration of a function template with a non-type template parameter, the non-type template parameter is used in a subexpression in the function parameter list, the expression is a non-deduced context as specified above.

**Example 12:**

```cpp
template <int i> class A { /* ... */ };  
template <int i> void g(A<i+1>);  
template <int i> void f(A<i>, A<i+1>);  
void k() {   
A<i> a1;   
A<i+1> a2;   
g(a1); // error: deduction fails for expression i+1  
}  
```

§ 13.10.3.6
Note 6: Template parameters do not participate in template argument deduction if they are used only in non-deduced contexts. For example,

```cpp
template<int i, typename T>
T deduce(typename A<T>::X x, // T is not deduced here
          T t, // but T is deduced here
typename B<i>::Y y); // i is not deduced here
A<int> a;
B<77> b;

int x = deduce<77>(a.xm, 62, b.ym); // T deduced as int; a.xm must be convertible to A<int>::X
// i is explicitly specified to be 77; b.ym must be convertible to B<77>::Y
```

—end note

If P has a form that contains <i>, and if the type of i differs from the type of the corresponding template parameter of the template named by the enclosing simple-template-id, deduction fails. If P has a form that contains [i], and if the type of i is not an integral type, deduction fails.\(^\text{[29]}\) If P has a form that includes noexcept(i) and the type of i is not bool, deduction fails.

[Example 13:]

```cpp
template<int i> class A { /* ... */ };  // P has a form that contains <i>, and type of i differs from template parameter
template<class T> void f(void(*)(T,int));  // P has a form that contains [i], and type of i is not an integral type

void g(int,int);  // error: ambiguous
void g(char,int);  // error: type deduction fails because foo is a template
```

—end example

A template-argument can be deduced from a function, pointer to function, or pointer-to-member-function type.

[Example 14:]

```cpp
template<class T> void f(void(*)(T,int));  // P has a form that contains <i>, and type of i differs from template parameter
```

\(^{[29]}\) Although the template-argument corresponding to a template-parameter of type bool can be deduced from an array bound, the resulting value will always be true because the array bound will be nonzero.
A template type-parameter cannot be deduced from the type of a function default argument.

[Example 15:

```cpp
template <class T> void f(T = 5, T = 7);
void g() {
    f(1); // OK, calls f<int>(1,7)
    f(); // error: cannot deduce T
    f<int>(); // OK, calls f<int>(5,7)
}
```
—end example]

The template-argument corresponding to a template template-parameter is deduced from the type of the template-argument of a class template specialization used in the argument list of a function call.

[Example 16:

```cpp
template <template <class T> class X> struct A { };  
template <template <class T> class X> void f(A<X>) { }  
template<class T> struct B { }; 
A<B> ab;  
f(ab);   // calls f(A<B>)
```
—end example]

[Note 7: Template argument deduction involving parameter packs (13.7.4) can deduce zero or more arguments for each parameter pack. — end note]

[Example 17:

```cpp
template<class> struct X { };  
template<class R, class ... ArgTypes> struct X<R(int, ArgTypes ...)> { };  
template<class ... Types> struct Y { };  
template<class T, class ... Types> struct Y<T, Types& ...> { };  

template<class ... Types> int f(void (*)(Types ...));  
void g(int, float);  
X<int> x1;  
X<int(float, double)> x2;  // uses partial specialization; ArgTypes contains float, double  
X<int(float, int)> x3;  // uses primary template  
Y<int> y1;  // uses primary template; Types is empty  
Y<int, float, double> y2;  // uses partial specialization; T is int, Types contains float, double  
Y<int, float, double> y3;  // uses primary template; Types contains int, float, double  
int fv = f(g);  // OK; Types contains int, float
```
—end example]

13.10.3.7 Deducing template arguments from a function declaration  
[temp.deduct.decl]

In a declaration whose declarator-id refers to a specialization of a function template, template argument deduction is performed to identify the specialization to which the declaration refers. Specifically, this is done for explicit instantiations (13.9.3), explicit specializations (13.9.4), and certain friend declarations (13.7.5). This is also done to determine whether a deallocation function template specialization matches a placement operator new (6.7.5.3, 7.6.2.8). In all these cases, P is the type of the function template being considered as a potential match and A is either the function type from the declaration or the type of the deallocation function that would match the placement operator new as described in 7.6.2.8. The deduction is done as described in 13.10.3.6.

If, for the set of function templates so considered, there is either no match or more than one match after partial ordering has been considered (13.7.7.3), deduction fails and, in the declaration cases, the program is ill-formed.

13.10.4 Overload resolution  
[temp.over]

When a call of a function or function template is written (explicitly, or implicitly using the operator notation), template argument deduction (13.10.3) and checking of any explicit template arguments (13.4) are performed for each function template to find the template argument values (if any) that can be used with that function template to instantiate a function template specialization that can be invoked with the call arguments or, for conversion function templates, that can convert to the required type. For each function template, if
the argument deduction and checking succeeds, the template-arguments (deduced and/or explicit) are used to synthesize the declaration of a single function template specialization which is added to the candidate functions set to be used in overload resolution. If, for a given function template, argument deduction fails or the synthesized function template specialization would be ill-formed, no such function is added to the set of candidate functions for that template. The complete set of candidate functions includes all the synthesized declarations and all of the non-template functions found by name lookup. The synthesized declarations are treated like any other functions in the remainder of overload resolution, except as explicitly noted in 12.2.4.

Example 1:

```cpp
template<class T> T max(T a, T b) { return a>b?a:b; }
void f(int a, int b, char c, char d) {
  int m1 = max(a,b); // max(int a, int b)
  char m2 = max(c,d); // max(char a, char b)
  int m3 = max(a,c);  // error: cannot generate max(int, char)
}
```

Adding the non-template function

```cpp
int max(int,int);
```

to the example above would resolve the third call, by providing a function that can be called for `max(a,c)` after using the standard conversion of `char` to `int` for `c`. — end example]

Example 2: Here is an example involving conversions on a function argument involved in template-argument deduction:

```cpp
template<class T> struct B { /* ... */ }
template<class T> struct D : public B<T> { /* ... */ }
template<class T> void f(B<T>&);
void g(B<int>& bi, D<int>& di) {
  f(bi);  // f(bi)
  f(di);  // f((B<int>&)di)
}
— end example]
```

Example 3: Here is an example involving conversions on a function argument not involved in template-parameter deduction:

```cpp
template<class T> void f(T*,int);  // #1
template<class T> void f(T,char);  // #2
void h(int* pi, int i, char c) {
  f(pi,i);  // #1: f<int>(pi,i)
  f(pi,c);  // #2: f<int*>(pi,c)
  f(i,c);  // #2: f<int>(i,c)
  f(i,i);  // #2: f<int>(i,char(i))
}
— end example]
```

Only the signature of a function template specialization is needed to enter the specialization in a set of candidate functions. Therefore only the function template declaration is needed to resolve a call for which a template specialization is a candidate.

Example 4:

```cpp
template<class T> void f(T);  // declaration
void g() {
  f("Annemarie");  // calls f<const char>*
}
```

130) The parameters of function template specializations contain no template parameter types. The set of conversions allowed on deduced arguments is limited, because the argument deduction process produces function templates with parameters that either match the call arguments exactly or differ only in ways that can be bridged by the allowed limited conversions. Non-deduced arguments allow the full range of conversions. Note also that 12.2.4 specifies that a non-template function will be given preference over a template specialization if the two functions are otherwise equally good candidates for an overload match.
The call to \texttt{f} is well-formed even if the template \texttt{f} is only declared and not defined at the point of the call. The program will be ill-formed unless a specialization for \texttt{f<\texttt{const char*}>} is explicitly instantiated in some translation unit (13.1). — end example]
14 Exception handling

14.1 Preamble

Exception handling provides a way of transferring control and information from a point in the execution of a thread to an exception handler associated with a point previously passed by the execution. A handler will be invoked only by throwing an exception in code executed in the handler’s try block or in functions called from the handler’s try block.

```plaintext
try-block:
  try compound-statement handler-seq
function-try-block:
  try ctor-initializer_opt compound-statement handler-seq
handler-seq:
  handler handler-seq_opt
handler:
  catch (exception-declaration) compound-statement
exception-declaration:
  attribute-specifier-seq_opt type-specifier-seq declarator
  attribute-specifier-seq_opt type-specifier-seq abstract-declarator_opt
...
```

The optional `attribute-specifier-seq` in an `exception-declaration` appertains to the parameter of the catch clause (14.4).

2 A `try-block` is a statement (8.1).

[Note 1: Within this Clause “try block” is taken to mean both `try-block` and `function-try-block`. — end note]

3 The `compound-statement` of a try block or of a handler is a control-flow-limited statement (8.2).

[Example 1:
```plaintext
void f() {
  goto l1;  // error
  goto l2;  // error
  try {
    goto l1;  // OK
    goto l2;  // error
    l1: ;
  } catch (...) {
    l2: ;
    goto l1;  // error
    goto l2;  // OK
  }
}
— end example]
```

A `goto`, `break`, `return`, or `continue` statement can be used to transfer control out of a try block or handler. When this happens, each variable declared in the try block will be destroyed in the context that directly contains its declaration.

[Example 2:
```plaintext
lab: try {
  T1 t1;
  try {
    T2 t2;
    if (condition)
      goto lab;
  } catch(...) {/*! handler 2 */}
} catch(...) {/*! handler 1 */}
```
Here, executing `goto lab;` will destroy first `t2`, then `t1`, assuming the condition does not declare a variable. Any exception thrown while destroying `t2` will result in executing handler 2; any exception thrown while destroying `t1` will result in executing handler 1. — end example]

4 A function-try-block associates a handler-seq with the ctor-initializer, if present, and the compound-statement. An exception thrown during the execution of the compound-statement or, for constructors and destructors, during the initialization or destruction, respectively, of the class’s subobjects, transfers control to a handler in a function-try-block in the same way as an exception thrown during the execution of a try-block transfers control to other handlers.

[Example 3:

```cpp
int f(int);
class C {
    int i;
    double d;
public:
    C(int, double);
};
C::C(int ii, double id)
try : i(f(ii)), d(id) {
    // constructor statements
} catch (...) {
    // handles exceptions thrown from the ctor-initializer and from the constructor statements
}
— end example]

In this Clause, “before” and “after” refer to the “sequenced before” relation (6.9.1).

14.2 Throwing an exception

Throwing an exception transfers control to a handler.

[Note 1: An exception can be thrown from one of the following contexts: throw-expressions (7.6.18), allocation functions (6.7.5.5.2), dynamic_cast (7.6.1.7), typeid (7.6.1.8), new-expressions (7.6.2.8), and standard library functions (16.3.2.4). — end note]

An object is passed and the type of that object determines which handlers can catch it.

[Example 1:

```cpp
throw "Help!";
```

can be caught by a handler of const char* type:

```cpp
try {
    // ...
    catch(const char* p) {
        // handle character string exceptions here
    }
}
```

and

```cpp
class Overflow {
public:
    Overflow(char, double, double);
};
```

```cpp
void f(double x) {
    throw Overflow('+', x, 3.45e107);
}
```

can be caught by a handler for exceptions of type Overflow:

```cpp
try {
    f(1.2);
    } catch(Overflow& oo) {
        // handle exceptions of type Overflow here
    }
— end example]

§ 14.2
When an exception is thrown, control is transferred to the nearest handler with a matching type (14.4); “nearest” means the handler for which the compound-statement or ctor-initializer following the try keyword was most recently entered by the thread of control and not yet exited.

Throwing an exception copy-initializes (9.4, 11.4.5.3) a temporary object, called the exception object. If the type of the exception object would be an incomplete type, an abstract class type (11.7.4), or a pointer to an incomplete type other than cv void the program is ill-formed.

The memory for the exception object is allocated in an unspecified way, except as noted in 6.7.5.5.2. If a handler exits by rethrowing, control is passed to another handler for the same exception object. The points of potential destruction for the exception object are:

1. When an active handler for the exception exits by any means other than rethrowing, immediately after the destruction of the object (if any) declared in the exception-declaration in the handler;
2. When an object of type std::exception_ptr (17.9.7) that refers to the exception object is destroyed, before the destructor of std::exception_ptr returns.

Among all points of potential destruction for the exception object, there is an unspecified last one where the exception object is destroyed. All other points happen before that last one (6.9.2.2).

The implementation may then deallocate the memory for the exception object; any such deallocation is done in an unspecified way.

When the thrown object is a class object, the constructor selected for the copy-initialization as well as the constructor selected for a copy-initialization considering the thrown object as an lvalue shall be non-deleted and accessible, even if the copy/move operation is elided (11.9.6). The destructor is potentially invoked (11.4.7).

An exception is considered caught when a handler for that exception becomes active (14.4).

If the exception handling mechanism handling an uncaught exception (14.6.3) directly invokes a function that exits via an exception, the function std::terminate is invoked (14.6.2).

[Example 2:]
```cpp
struct C {
    C() { }
    C(const C&) {
        if (std::uncaught_exceptions()) {
            throw 0; // throw during copy to handler’s exception-declaration object (14.4)
        }
    }
};

int main() {
    try {
        throw C(); // calls std::terminate if construction of the handler’s
                    // exception-declaration object is not elided (11.9.6)
    } catch(C) { }
}
```

14.3 Constructors and destructors

As control passes from the point where an exception is thrown to a handler, objects are destroyed by a process, specified in this subclause, called stack unwinding.

Each object with automatic storage duration is destroyed if it has been constructed, but not yet destroyed, since the try block was entered. If an exception is thrown during the destruction of temporaries or local...
variables for a return statement (8.7.4), the destructor for the returned object (if any) is also invoked. The objects are destroyed in the reverse order of the completion of their construction.

[Example 1:]

```cpp
struct A { };
struct Y { ~Y() noexcept(false) { throw 0; } };

A f() {
    try {
        A a;
        Y y;
        A b;
        return {};              // #1
    } catch (...) {
    }
    return {};             // #2
}
```

At #1, the returned object of type A is constructed. Then, the local variable b is destroyed (8.7). Next, the local variable y is destroyed, causing stack unwinding, resulting in the destruction of the returned object, followed by the destruction of the local variable a. Finally, the returned object is constructed again at #2. — end example]

If the initialization of an object other than by delegating constructor is terminated by an exception, the destructor is invoked for each of the object’s subobjects that were known to be initialized by the object’s initialization and whose initialization has completed (9.4).

[Note 1: If such an object has a reference member that extends the lifetime of a temporary object, this ends the lifetime of the reference member, so the lifetime of the temporary object is effectively not extended. — end note]

A subobject is known to be initialized if its initialization is specified

1. in 11.9.3 for initialization by constructor,
2. in 11.4.5.3 for initialization by defaulted copy/move constructor,
3. in 11.9.4 for initialization by inherited constructor,
4. in 9.4.2 for aggregate initialization,
5. in 7.5.5.3 for the initialization of the closure object when evaluating a lambda-expression,
6. in 9.4.1 for default-initialization, value-initialization, or direct-initialization of an array.

[Note 2: This includes virtual base class subobjects if the initialization is for a complete object, and can include variant members that were nominated explicitly by a mem-initializer or designated-initializer-clause or that have a default member initializer. — end note]

If the destructor of an object is terminated by an exception, each destructor invocation that would be performed after executing the body of the destructor (11.4.7) and that has not yet begun execution is performed.

[Note 3: This includes virtual base class subobjects if the destructor was invoked for a complete object. — end note]

The subobjects are destroyed in the reverse order of the completion of their construction. Such destruction is sequenced before entering a handler of the function-try-block of the constructor or destructor, if any.

If the compound-statement of the function-body of a delegating constructor for an object exits via an exception, the object’s destructor is invoked. Such destruction is sequenced before entering a handler of the function-try-block of a delegating constructor for that object, if any.

[Note 4: If the object was allocated by a new-expression (7.6.2.8), the matching deallocation function (6.7.5.5.3), if any, is called to free the storage occupied by the object. — end note]

### 14.4 Handling an exception

The exception-declaration in a handler describes the type(s) of exceptions that can cause that handler to be entered. The exception-declaration shall not denote an incomplete type, an abstract class type, or an rvalue reference type. The exception-declaration shall not denote a pointer or reference to an incomplete type, other than “pointer to cv void”.

A handler of type “array of T” or function type T is adjusted to be of type “pointer to T”.

§ 14.4 455
A handler is a match for an exception object of type \( E \) if

1. The handler is of type \( cv\ T \) or \( cv\ T\& \) and \( E \) and \( T \) are the same type (ignoring the top-level \( cv\)-qualifiers), or
2. the handler is of type \( cv\ T \) or \( cv\ T\& \) and \( T \) is an unambiguous public base class of \( E \), or
3. the handler is of type \( cv\ T \) or \( const\ T\& \) where \( T \) is a pointer or pointer-to-member type and \( E \) is a pointer or pointer-to-member type that can be converted to \( T \) by one or more of
   1. a standard pointer conversion (7.3.12) not involving conversions to pointers to private or protected or ambiguous classes
   2. a function pointer conversion (7.3.14)
   3. a qualification conversion (7.3.6), or
4. the handler is of type \( cv\ T \) or \( const\ T\& \) where \( T \) is a pointer or pointer-to-member type and \( E \) is \( \text{std::nullptr_t} \).

[Note 1: A throw-expression whose operand is an integer literal with value zero does not match a handler of pointer or pointer-to-member type. A handler of reference to array or function type is never a match for any exception object (7.6.18). — end note]

[Example 1:

```cpp
class Matherr { /* ... */ virtual void vf(); };  
class Overflow: public Matherr { /* ... */ };  
class Underflow: public Matherr { /* ... */ };  
class Zerodivide: public Matherr { /* ... */ };  

void f() {
  try {
    g();
  } catch (Overflow oo) {
    // ...
  } catch (Matherr mm) {
    // ...
  }
}
```

Here, the Overflow handler will catch exceptions of type Overflow and the Matherr handler will catch exceptions of type Matherr and of all types publicly derived from Matherr including exceptions of type Underflow and Zerodivide. — end example]

4. The handlers for a try block are tried in order of appearance.

[Note 2: This makes it possible to write handlers that can never be executed, for example by placing a handler for a final derived class after a handler for a corresponding unambiguous public base class. — end note]

5. A ... in a handler’s exception-declaration functions similarly to ... in a function parameter declaration; it specifies a match for any exception. If present, a ... handler shall be the last handler for its try block.

6. If no match is found among the handlers for a try block, the search for a matching handler continues in a dynamically surrounding try block of the same thread.

7. A handler is considered active when initialization is complete for the parameter (if any) of the catch clause.

[Note 3: The stack will have been unwound at that point. — end note]

Also, an implicit handler is considered active when the function \( \text{std::terminate} \) is entered due to a throw. A handler is no longer considered active when the catch clause exits.

8. The exception with the most recently activated handler that is still active is called the currently handled exception.

9. If no matching handler is found, the function \( \text{std::terminate} \) is invoked; whether or not the stack is unwound before this invocation of \( \text{std::terminate} \) is implementation-defined (14.6.2).

10. Referring to any non-static member or base class of an object in the handler for a function-try-block of a constructor or destructor for that object results in undefined behavior.

11. Exceptions thrown in destructors of objects with static storage duration or in constructors of objects associated with non-block variables with static storage duration are not caught by a function-try-block on the \texttt{main} function (6.9.3.1). Exceptions thrown in destructors of objects with thread storage duration or in

\section*{14.4}
constructors of objects associated with non-block variables with thread storage duration are not caught by a function-try-block on the initial function of the thread.

If a return statement (8.7.4) appears in a handler of the function-try-block of a constructor, the program is ill-formed.

The currently handled exception is rethrown if control reaches the end of a handler of the function-try-block of a constructor or destructor. Otherwise, flowing off the end of the compound-statement of a handler of a function-try-block is equivalent to flowing off the end of the compound-statement of that function (see 8.7.4).

The variable declared by the exception-declaration, of type cv T or cv T&, is initialized from the exception object, of type E, as follows:

1. If T is a base class of E, the variable is copy-initialized (9.4) from an lvalue of type T designating the corresponding base class subobject of the exception object;
2. Otherwise, the variable is copy-initialized (9.4) from an lvalue of type E designating the exception object.

The lifetime of the variable ends when the handler exits, after the destruction of any objects with automatic storage duration initialized within the handler.

When the handler declares an object, any changes to that object will not affect the exception object. When the handler declares a reference to an object, any changes to the referenced object are changes to the exception object and will have effect should that object be rethrown.

### 14.5 Exception specifications

The predicate indicating whether a function cannot exit via an exception is called the exception specification of the function. If the predicate is false, the function has a potentially-throwing exception specification, otherwise it has a non-throwing exception specification. The exception specification is either defined implicitly, or defined explicitly by using a noexcept-specifier as a suffix of a function declarator (9.3.4.6).

```cpp
noexcept-specifier:
  noexcept ( constant-expression )
  noexcept
```

In a noexcept-specifier, the constant-expression, if supplied, shall be a contextually converted constant expression of type bool (7.7); that constant expression is the exception specification of the function type in which the noexcept-specifier appears. A ( token that follows noexcept is part of the noexcept-specifier and does not commence an initializer (9.4). The noexcept-specifier noexcept without a constant-expression is equivalent to the noexcept-specifier noexcept(true).

[Example 1:
```cpp
void f() noexcept(sizeof(char[2])); // error: narrowing conversion of value 2 to type bool
void g() noexcept(sizeof(char));    // OK, conversion of value 1 to type bool is non-narrowing
```

Example 2:
```cpp
struct B {
  virtual void f() noexcept;
  virtual void g();
  virtual void h() noexcept = delete;
};
```

If a virtual function has a non-throwing exception specification, all declarations, including the definition, of any function that overrides that virtual function in any derived class shall have a non-throwing exception specification, unless the overriding function is defined as deleted.

§ 14.5
struct D: B {
    void f();  // error
    void g() noexcept; // OK
    void h() = delete; // OK
};

The declaration of D::f is ill-formed because it has a potentially-throwing exception specification, whereas B::f has a non-throwing exception specification. — end example]

5 Whenever an exception is thrown and the search for a handler (14.4) encounters the outermost block of a function with a non-throwing exception specification, the function std::terminate is invoked (14.6.2).
[Note 1: An implementation is not permitted to reject an expression merely because, when executed, it throws or might throw an exception from a function with a non-throwing exception specification. — end note]

[Example 3:
    extern void f(); // potentially-throwing

    void g() noexcept {
        f();  // valid, even if f throws
        throw 42; // valid, effectively a call to std::terminate
    }
]
The call to f is well-formed despite the possibility for it to throw an exception. — end example]

6 An expression E is potentially-throwing if

(6.1) — E is a function call (7.6.1.3) whose postfix-expression has a function type, or a pointer-to-function type, with a potentially-throwing exception specification, or
(6.2) — E implicitly invokes a function (such as an overloaded operator, an allocation function in a new-expression, a constructor for a function argument, or a destructor if E is a full-expression (6.9.1)) that has a potentially-throwing exception specification, or
(6.3) — E is a throw-expression (7.6.18), or
(6.4) — E is a dynamic_cast expression that casts to a reference type and requires a runtime check (7.6.1.7), or
(6.5) — E is a typeid expression applied to a (possibly parenthesized) built-in unary * operator applied to a pointer to a polymorphic class type (7.6.1.8), or
(6.6) — any of the immediate subexpressions (6.9.1) of E is potentially-throwing.

7 An implicitly-declared constructor for a class X, or a constructor without a noexcept-specifier that is defaulted on its first declaration, has a potentially-throwing exception specification if and only if any of the following constructs is potentially-throwing:

(7.1) — the invocation of a constructor selected by overload resolution in the implicit definition of the constructor for class X to initialize a potentially constructed subobject, or
(7.2) — a subexpression of such an initialization, such as a default argument expression, or,
(7.3) — for a default constructor, a default member initializer.

[Note 2: Even though destructors for fully-constructed subobjects are invoked when an exception is thrown during the execution of a constructor (14.3), their exception specifications do not contribute to the exception specification of the constructor, because an exception thrown from such a destructor would call the function std::terminate rather than escape the constructor (14.2, 14.6.2). — end note]

8 The exception specification for an implicitly-declared destructor, or a destructor without a noexcept-specifier, is potentially-throwing if and only if any of the destructors for any of its potentially constructed subobjects has a potentially-throwing exception specification or the destructor is virtual and the destructor of any virtual base class has a potentially-throwing exception specification.

9 The exception specification for an implicitly-declared assignment operator, or an assignment-operator without a noexcept-specifier that is defaulted on its first declaration, is potentially-throwing if and only if the invocation of any assignment operator in the implicit definition is potentially-throwing.

10 A deallocation function (6.7.5.5.3) with no explicit noexcept-specifier has a non-throwing exception specification.
The exception specification for a comparison operator function (12.4.3) without a `noexcept-specifier` that is defaulted on its first declaration is potentially-throwing if and only if any expression in the implicit definition is potentially-throwing.

[Example 4:

```cpp
struct A {
    A(int = (A(5), 0)) noexcept;
    A(const A&) noexcept;
    A(A&&) noexcept;
    ~A();
};
struct B {
    B() noexcept;
    B(const B&) = default;  // implicit exception specification is noexcept(true)
    B(B&&, int = (throw 42, 0)) noexcept;
    ~B() noexcept(false);
};
int n = 7;
struct D : public A, public B {
    int * p = new int[n];
    //D::D() potentially-throwing, as the new operator may throw bad_alloc or bad_array_new_length
    //D::D(const D&) non-throwing
    //D::D(D&&) potentially-throwing, as the default argument for B's constructor may throw
    //D::~D() potentially-throwing
};
```

Furthermore, if `A::~A()` were virtual, the program would be ill-formed since a function that overrides a virtual function from a base class shall not have a potentially-throwing exception specification if the base class function has a non-throwing exception specification. — end example]

An exception specification is considered to be needed when:

- in an expression, the function is selected by overload resolution (12.2, 12.3);
- the function is odr-used (6.3) or, if it appears in an unevaluated operand, would be odr-used if the expression were potentially-evaluated;
- the exception specification is compared to that of another declaration (e.g., an explicit specialization or an overriding virtual function);
- the function is defined; or
- the exception specification is needed for a defaulted function that calls the function.

[Note 3: A defaulted declaration does not require the exception specification of a base member function to be evaluated until the implicit exception specification of the derived function is needed, but an explicit `noexcept-specifier` needs the implicit exception specification to compare against. — end note]

The exception specification of a defaulted function is evaluated as described above only when needed; similarly, the `noexcept-specifier` of a specialization of a function template or member function of a class template is instantiated only when needed.

### 14.6 Special functions

#### 14.6.1 General

The function `std::terminate` (14.6.2) is used by the exception handling mechanism for coping with errors related to the exception handling mechanism itself. The function `std::current_exception()` (17.9.7) and the class `std::nested_exception` (17.9.8) can be used by a program to capture the currently handled exception.

#### 14.6.2 The std::terminate function

In some situations exception handling is abandoned for less subtle error handling techniques.

[Note 1: These situations are:

- when the exception handling mechanism, after completing the initialization of the exception object but before activation of a handler for the exception (14.2), calls a function that exits via an exception, or
- when the exception handling mechanism cannot find a handler for a thrown exception (14.4), or

§ 14.6.2 459
— when the search for a handler (14.4) encounters the outermost block of a function with a non-throwing exception specification (14.5), or

— when the destruction of an object during stack unwinding (14.3) terminates by throwing an exception, or

— when initialization of a non-block variable with static or thread storage duration (6.9.3.3) exits via an exception, or

— when destruction of an object with static or thread storage duration exits via an exception (6.9.3.4), or

— when execution of a function registered with std::atexit or std::at_quick_exit exits via an exception (17.5), or

— when a throw-expression (7.6.18) with no operand attempts to rethrow an exception and no exception is being handled (14.2), or

— when the function std::nested_exception::rethrow_nested is called for an object that has captured no exception (17.9.8), or

— when execution of the initial function of a thread exits via an exception (33.4.3.3), or

— for a parallel algorithm whose ExecutionPolicy specifies such behavior (22.12.4, 22.12.5, 22.12.6), when execution of an element access function (27.3.1) of the parallel algorithm exits via an exception (27.3.4), or

— when the destructor or the move assignment operator is invoked on an object of type std::thread that refers to a joinable thread (33.4.3.4, 33.4.3.5), or

— when a call to a wait(), wait_until(), or wait_for() function on a condition variable (33.7.4, 33.7.5) fails to meet a postcondition.

— end note]

2 In such cases, the function std::terminate is invoked (17.9.5). In the situation where no matching handler is found, it is implementation-defined whether or not the stack is unwound before std::terminate is invoked. In the situation where the search for a handler (14.4) encounters the outermost block of a function with a non-throwing exception specification (14.5), it is implementation-defined whether the stack is unwound, unwound partially, or not unwound at all before the function std::terminate is invoked. In all other situations, the stack shall not be unwound before the function std::terminate is invoked. An implementation is not permitted to finish stack unwinding prematurely based on a determination that the unwind process will eventually cause an invocation of the function std::terminate.

14.6.3 The std::uncaught_exceptions function

An exception is considered uncaught after completing the initialization of the exception object (14.2) until completing the activation of a handler for the exception (14.4).

[Note 1: As a consequence, an exception is considered uncaught during any stack unwinding resulting from it being thrown. — end note]

If an exception is rethrown (7.6.18, 17.9.7), it is considered uncaught from the point of rethrow until the rethrown exception is caught. The function std::uncaught_exceptions (17.9.6) returns the number of uncaught exceptions in the current thread.

text-line:
pp-tokens_opt new-line

conditionally-supported-directive:
pp-tokens new-line
A **preprocessing directive** consists of a sequence of preprocessing tokens that satisfies the following constraints: At the start of translation phase 4, the first token in the sequence, referred to as a **directive-introducing token**, begins with the first character in the source file (optionally after whitespace containing no new-line characters) or follows whitespace containing at least one new-line character, and is

1. **A # preprocessing token**, or
2. **an import preprocessing token immediately followed on the same logical line by a header-name, <, identifier, string-literal, or : preprocessing token**, or
3. **a module preprocessing token immediately followed on the same logical line by an identifier, :, or ; preprocessing token**, or
4. **an export preprocessing token immediately followed on the same logical line by one of the two preceding forms.**

The last token in the sequence is the first token within the sequence that is immediately followed by whitespace containing a new-line character.\(^\text{131}\)

\[\text{Note 1: A new-line character ends the preprocessing directive even if it occurs within what would otherwise be an invocation of a function-like macro. — end note}\]

\[\text{Example 1}:\]

```plaintext
#!/usr/bin/env \text{preprocessing directive}
module ; // preprocessing directive
export module leftpad; // preprocessing directive
import <string>; // preprocessing directive
export import "squee"; // preprocessing directive
import rightpad; // preprocessing directive
import :part; // preprocessing directive
module // not a preprocessing directive
; // not a preprocessing directive
export // not a preprocessing directive
import // not a preprocessing directive
foo; // not a preprocessing directive
export // not a preprocessing directive
import foo; // preprocessing directive (ill-formed at phase 7)
import :: // not a preprocessing directive
import -> // not a preprocessing directive
@end example\]

2 A sequence of preprocessing tokens is only a **text-line** if it does not begin with a directive-introducing token. A sequence of preprocessing tokens is only a **conditionally-supported-directive** if it does not begin with any of the directive names appearing after a # in the syntax. A **conditionally-supported-directive** is conditionally-supported with implementation-defined semantics.

---

\(^{131}\) Thus, preprocessing directives are commonly called “lines”. These “lines” have no other syntactic significance, as all whitespace is equivalent except in certain situations during preprocessing (see the # character string literal creation operator in 15.6.3, for example).
At the start of phase 4 of translation, the group of a pp-global-module-fragment shall contain neither a text-line nor a pp-import.

When in a group that is skipped (15.2), the directive syntax is relaxed to allow any sequence of preprocessing tokens to occur between the directive name and the following new-line character.

The only whitespace characters that shall appear between preprocessing tokens within a preprocessing directive (from just after the directive-introducing token through just before the terminating new-line character) are space and horizontal-tab (including spaces that have replaced comments or possibly other whitespace characters in translation phase 3).

The implementation can process and skip sections of source files conditionally, include other source files, import macros from header units, and replace macros. These capabilities are called preprocessing, because conceptually they occur before translation of the resulting translation unit.

The preprocessing tokens within a preprocessing directive are not subject to macro expansion unless otherwise stated.

[Example 2: In:
  
  #define EMPTY
  EMPTY  #  include <file.h>

  the sequence of preprocessing tokens on the second line is not a preprocessing directive, because it does not begin with a # at the start of translation phase 4, even though it will do so after the macro EMPTY has been replaced. — end example]

15.2 Conditional inclusion

`defined-macro-expression`:
  defined identifier
  defined ( identifier )

`h-preprocessing-token`:
  any preprocessing-token other than >

`h-pp-tokens`:
  h-preprocessing-token
  h-pp-tokens h-preprocessing-token

`header-name-tokens`:
  string-literal
  < h-pp-tokens >

`has-include-expression`:
  __has_include ( header-name )
  __has_include ( header-name-tokens )

`has-attribute-expression`:
  __has_cpp_attribute ( pp-tokens )

The expression that controls conditional inclusion shall be an integral constant expression except that identifiers (including those lexically identical to keywords) are interpreted as described below and it may contain zero or more defined-macro-expressions and/or has-include-expressions and/or has-attribute-expressions as unary operator expressions.

A `defined-macro-expression` evaluates to 1 if the identifier is currently defined as a macro name (that is, if it is predefined or if it has one or more active macro definitions (15.5), for example because it has been the subject of a `#define` preprocessing directive without an intervening `#undef` directive with the same subject identifier), 0 if it is not.

The second form of `has-include-expression` is considered only if the first form does not match, in which case the preprocessing tokens are processed just as in normal text.

The header or source file identified by the parenthesized preprocessing token sequence in each contained has-include-expression is searched for as if that preprocessing token sequence were the pp-tokens in a `#include` directive, except that no further macro expansion is performed. If such a directive would not satisfy the syntactic requirements of a `#include` directive, the program is ill-formed. The has-include-expression evaluates to 1 if the search for the source file succeeds, and to 0 if the search fails.

---

132) Because the controlling constant expression is evaluated during translation phase 4, all identifiers either are or are not macro names — there simply are no keywords, enumeration constants, etc.
Each *has-attribute-expression* is replaced by a non-zero *pp-number* matching the form of an *integer-literal* if the implementation supports an attribute with the name specified by interpreting the *pp-tokens*, after macro expansion, as an *attribute-token*, and by 0 otherwise. The program is ill-formed if the *pp-tokens* do not match the form of an *attribute-token*.

For an attribute specified in this document, the value of the *has-attribute-expression* is given by Table 21. For other attributes recognized by the implementation, the value is implementation-defined.

[Note 1: It is expected that the availability of an attribute can be detected by any non-zero result. — end note]

Table 21: __has_cpp_attribute values [tab:cpp.cond.ha]

<table>
<thead>

</tbody>
</table>

The #ifdef, #ifndef, #elifdef, and #elifndef directives, and the defined conditional inclusion operator, shall treat __has_include and __has_cpp_attribute as if they were the names of defined macros. The identifiers __has_include and __has_cpp_attribute shall not appear in any context not mentioned in this subclause.

Each preprocessing token that remains (in the list of preprocessing tokens that will become the controlling expression) after all macro replacements have occurred shall be in the lexical form of a token (5.6).

Preprocessing directives of the forms

```cpp
#if constant-expression new-line group_opt
#elif constant-expression new-line group_opt
```

check whether the controlling constant expression evaluates to nonzero.

Prior to evaluation, macro invocations in the list of preprocessing tokens that will become the controlling constant expression are replaced (except for those macro names modified by the defined unary operator), just as in normal text. If the token defined is generated as a result of this replacement process or use of the defined unary operator does not match one of the two specified forms prior to macro replacement, the behavior is undefined.

After all replacements due to macro expansion and evaluations of defined-macro-expressions, has-include-expressions, and has-attribute-expressions have been performed, all remaining identifiers and keywords, except for true and false, are replaced with the *pp-number* 0, and then each preprocessing token is converted into a token.

[Note 2: An alternative token (5.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not subject to this replacement. — end note]

The resulting tokens comprise the controlling constant expression which is evaluated according to the rules of 7.7 using arithmetic that has at least the ranges specified in 17.3. For the purposes of this token conversion and evaluation all signed and unsigned integer types act as if they have the same representation as, respectively, intmax_t or uintmax_t (17.4.1).

[Note 3: Thus on an implementation where std::numeric_limits<int>::max() is 0x7FFF and std::numeric_limits<unsigned int>::max() is 0xFFFF, the integer literal 0x8000 is signed and positive within a #if expression even though it is unsigned in translation phase 7 (5.2). — end note]

This includes interpreting character-literals according to the rules in 5.13.3.

[Note 4: The associated character encodings of literals are the same in #if and #elif directives and in any expression. — end note]
Each subexpression with type `bool` is subjected to integral promotion before processing continues.

Preprocessing directives of the forms

```
  # ifdef  identifier new-line group_opt
  # ifndef identifier new-line group_opt
  # elifdef identifier new-line group_opt
  # elifndef identifier new-line group_opt
```

check whether the identifier is or is not currently defined as a macro name. Their conditions are equivalent to `#if defined identifier`, `#if !defined identifier`, `#elif defined identifier`, and `#elif !defined identifier`, respectively.

Each directive's condition is checked in order. If it evaluates to false (zero), the group that it controls is skipped: directives are processed only through the name that determines the directive in order to keep track of the level of nested conditionals; the rest of the directives’ preprocessing tokens are ignored, as are the other preprocessing tokens in the group. Only the first group whose control condition evaluates to true (nonzero) is processed; any following groups are skipped and their controlling directives are processed as if they were in a group that is skipped. If none of the conditions evaluates to true, and there is a `#else` directive, the group controlled by the `#else` is processed; lacking a `#else` directive, all the groups until the `#endif` are skipped.

---

**Example 1**: This demonstrates a way to include a library `optional` facility only if it is available:

```c
#include <optional>
#if __cpp_lib_optional >= 201603
#define have_optional 1
#endif
#elif __has_include(<experimental/optional>)
#include <optional>
#if __cpp_lib_experimental_optional >= 201411
#define have_optional 1
#define experimental_optional 1
#endif
#endif
#ifndef have_optional
#define have_optional 0
#endif
```

---

**Example 2**: This demonstrates a way to use the attribute `[[acme::deprecated]]` only if it is available.

```c
#include <optional>
#if __has_cpp_attribute(acme::deprecated)
#define ATTR_DEPRECATED(msg) [[acme::deprecated(msg)]]
#else
#define ATTR_DEPRECATED(msg) [[deprecated(msg)]]
#endif
ATTR_DEPRECATED("This function is deprecated") void anvil();
```

---

### 15.3 Source file inclusion

A `#include` directive shall identify a header or source file that can be processed by the implementation.

A preprocessing directive of the form

```
# include < h-char-sequence > new-line
```

searches a sequence of implementation-defined places for a header identified uniquely by the specified sequence between the `<` and `>` delimiters, and causes the replacement of that directive by the entire contents of the header. How the places are specified or the header identified is implementation-defined.

A preprocessing directive of the form

```
# include " q-char-sequence " new-line
```

---

133) As indicated by the syntax, a preprocessing token cannot follow a `#else` or `#endif` directive before the terminating new-line character. However, comments can appear anywhere in a source file, including within a preprocessing directive.
causes the replacement of that directive by the entire contents of the source file identified by the specified sequence between the " delimiters. The named source file is searched for in an implementation-defined manner. If this search is not supported, or if the search fails, the directive is reprocessed as if it read

```
#include <h-char-sequence> new-line
```

with the identical contained sequence (including > characters, if any) from the original directive.

4 A preprocessing directive of the form

```
#include pp-tokens new-line
```

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after include in the directive are processed just as in normal text (i.e., each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined. The method by which a sequence of preprocessing tokens between a < and a > preprocessing token pair or a pair of " characters is combined into a single header name preprocessing token is implementation-defined.

5 The implementation shall provide unique mappings for sequences consisting of one or more nondigits or digits (5.10) followed by a period (.) and a single nondigit. The first character shall not be a digit. The implementation may ignore distinctions of alphabetical case.

6 A #include preprocessing directive may appear in a source file that has been read because of a #include directive in another file, up to an implementation-defined nesting limit.

7 If the header identified by the header-name denotes an importable header (10.3), it is implementation-defined whether the #include preprocessing directive is instead replaced by an import directive (15.5) of the form

```
#include "header-name" ; new-line
```

8 [Note 1: An implementation can provide a mechanism for making arbitrary source files available to the < > search. However, using the < > form for headers provided with the implementation and the " " form for sources outside the control of the implementation achieves wider portability. For instance:

```c
#include <stdio.h>
#include <unistd.h>
#include "usefullib.h"
#include "myprog.h"
```

—end note]

9 [Example 1: This illustrates macro-replaced #include directives:

```c
#if VERSION == 1
#define INCFILE "vers1.h"
#elif VERSION == 2
#define INCFILE "vers2.h" // and so on
#else
#define INCFILE "versN.h"
#endif
#include INCFILE
```

—end example]

15.4 Module directive

```
module: [cpp.module]

export_opt module pp-tokens ; new-line
```

1 A pp-module shall not appear in a context where module or (if it is the first token of the pp-module) export is an identifier defined as an object-like macro.

2 Any preprocessing tokens after the module preprocessing token in the module directive are processed just as in normal text.

[Note 1: Each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens.

—end note]

134) Note that adjacent string-literals are not concatenated into a single string-literal (see the translation phases in 5.2); thus, an expansion that results in two string-literals is an invalid directive.
The module and export (if it exists) preprocessing tokens are replaced by the module-keyword and export-keyword preprocessing tokens respectively.

[Note 2: This makes the line no longer a directive so it is not removed at the end of phase 4. — end note]

### 15.5  Header unit importation

**pp-import:**

```cpp
export_opt import header-name pp-tokens_opt ; new-line
export_opt import header-name-tokens pp-tokens_opt ; new-line
export_opt import pp-tokens ; new-line
```

1. A pp-import shall not appear in a context where import or (if it is the first token of the pp-import) export is an identifier defined as an object-like macro.

2. The preprocessing tokens after the import preprocessing token in the import control-line are processed just as in normal text (i.e., each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens).

    [Note 1: An import directive matching the first two forms of a pp-import instructs the preprocessor to import macros from the header unit (10.3) denoted by the header-name, as described below. — end note]

The point of macro import for the first two forms of pp-import is immediately after the new-line terminating the pp-import. The last form of pp-import is only considered if the first two forms did not match, and does not have a point of macro import.

3. If a pp-import is produced by source file inclusion (including by the rewrite produced when a `#include` directive names an importable header) while processing the group of a module-file, the program is ill-formed.

4. In all three forms of pp-import, the import and export (if it exists) preprocessing tokens are replaced by the import-keyword and export-keyword preprocessing tokens respectively.

    [Note 2: This makes the line no longer a directive so it is not removed at the end of phase 4. — end note]

Additionally, in the second form of pp-import, a header-name token is formed as if the header-name-tokens were the pp-tokens of a `#include` directive. The header-name-tokens are replaced by the header-name token.

    [Note 3: This ensures that imports are treated consistently by the preprocessor and later phases of translation. — end note]

5. Each `#define` directive encountered when preprocessing each translation unit in a program results in a distinct macro definition.

    [Note 4: A predefined macro name (15.11) is not introduced by a `#define` directive. Implementations providing mechanisms to redefine additional macros are encouraged to not treat them as being introduced by a `#define` directive. — end note]

Each macro definition has at most one point of definition in each translation unit and at most one point of undefinition, as follows:

1. The point of definition of a macro definition within a translation unit $T$ is

    1.1. If the `#define` directive of the macro definition occurs within $T$, the point at which that directive occurs, or otherwise,

    1.2. If the macro name is not lexically identical to a keyword (5.11) or to the identifiers module or import, the first point of macro import in $T$ of a header unit containing a point of definition for the macro definition, if any.

In the latter case, the macro is said to be imported from the header unit.

2. The point of undefined of a macro definition within a translation unit is the first point at which a `#undef` directive naming the macro occurs after its point of definition, or the first point of macro import of a header unit containing a point of undefined for the macro definition, whichever (if any) occurs first.

6. A macro directive is active at a source location if it has a point of definition in that translation unit preceding the location, and does not have a point of undefined in that translation unit preceding the location.

7. If a macro would be replaced or redefined, and multiple macro definitions are active for that macro name, the active macro definitions shall all be valid redefinitions of the same macro (15.6).

    [Note 5: The relative order of pp-imports has no bearing on whether a particular macro definition is active. — end note]
15.6 Macro replacement

15.6.1 General

Two replacement lists are identical if and only if the preprocessing tokens in both have the same number, ordering, spelling, and whitespace separation, where all whitespace separations are considered identical.

An identifier currently defined as an object-like macro (see below) may be redefined by another \#define preprocessing directive provided that the second definition is an object-like macro definition and the two replacement lists are identical, otherwise the program is ill-formed. Likewise, an identifier currently defined as a function-like macro (see below) may be redefined by another \#define preprocessing directive provided that the second definition is a function-like macro definition that has the same number and spelling of parameters, and the two replacement lists are identical, otherwise the program is ill-formed.

[Example 1: The following sequence is valid:

\#define OBJ_LIKE (1 - 1)
\#define OBJ_LIKE /* whitespace */ (1 - 1) /* other */
\#define FUNC_LIKE(a) ( a )
\#define FUNC_LIKE(a) ( /* note the whitespace */ 
   a /* other stuff on this line */ )

But the following redefinitions are invalid:

\#define OBJ_LIKE (0) // different token sequence
\#define OBJ_LIKE (1 - 1) // different whitespace
\#define FUNC_LIKE(b) ( a ) // different parameter usage
\#define FUNC_LIKE(b) ( b ) // different parameter spelling

— end example]
There shall be whitespace between the identifier and the replacement list in the definition of an object-like macro.

If the identifier-list in the macro definition does not end with an ellipsis, the number of arguments (including those arguments consisting of no preprocessing tokens) in an invocation of a function-like macro shall equal the number of parameters in the macro definition. Otherwise, there shall be at least as many arguments in the invocation as there are parameters in the macro definition (excluding the . . .). There shall exist a ) preprocessing token that terminates the invocation.

The identifiers __VA_ARGS__ and __VA_OPT__ shall occur only in the replacement-list of a function-like macro that uses the ellipsis notation in the parameters.

A parameter identifier in a function-like macro shall be uniquely declared within its scope.

The identifier immediately following the define is called the macro name. There is one name space for macro names. Any whitespace characters preceding or following the replacement list of preprocessing tokens are not considered part of the replacement list for either form of macro.

If a # preprocessing token, followed by an identifier, occurs lexically at the point at which a preprocessing directive can begin, the identifier is not subject to macro replacement.

A preprocessing directive of the form

```
#define identifier replacement-list new-line
```

defines an object-like macro that causes each subsequent instance of the macro name to be replaced by the replacement list of preprocessing tokens that constitute the remainder of the directive. The replacement list is then rescanned for more macro names as specified below.

Example 2: The simplest use of this facility is to define a “manifest constant”, as in

```c
#define TABSIZE 100
int table[TABSIZE];
```

A preprocessing directive of the form

```
#define identifier lparen identifier-list opt ) replacement-list new-line
#define identifier lparen . . . ) replacement-list new-line
#define identifier lparen identifier-list , . . . ) replacement-list new-line
```

defines a function-like macro with parameters, whose use is similar syntactically to a function call. The parameters are specified by the optional list of identifiers. Each subsequent instance of the function-like macro name followed by a ( as the next preprocessing token introduces the sequence of preprocessing tokens that is replaced by the replacement list in the definition (an invocation of the macro). The replaced sequence of preprocessing tokens is terminated by the matching ) preprocessing token, skipping intervening matched pairs of left and right parenthesis preprocessing tokens. Within the sequence of preprocessing tokens making up an invocation of a function-like macro, new-line is considered a normal whitespace character.

The sequence of preprocessing tokens bounded by the outside-most matching parentheses forms the list of arguments for the function-like macro. The individual arguments within the list are separated by comma preprocessing tokens, but comma preprocessing tokens between matching inner parentheses do not separate arguments. If there are sequences of preprocessing tokens within the list of arguments that would otherwise act as preprocessing directives, the behavior is undefined.

Example 3: The following defines a function-like macro whose value is the maximum of its arguments. It has the disadvantages of evaluating one or the other of its arguments a second time (including side effects) and generating more code than a function if invoked several times. It also cannot have its address taken, as it has none.

```c
#define max(a, b) ((a) > (b) ? (a) : (b))
```

The parentheses ensure that the arguments and the resulting expression are bound properly.

If there is a . . . immediately preceding the ) in the function-like macro definition, then the trailing arguments (if any), including any separating comma preprocessing tokens, are merged to form a single item: the variable

---

135) Since, by macro-replacement time, all character-literals and string-literals are preprocessing tokens, not sequences possibly containing identifier-like subsequences (see 5.2, translation phases), they are never scanned for macro names or parameters.

136) An alternative token (5.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not possible to define a macro whose name is the same as that of an alternative token.

137) A conditionally-supported-directive is a preprocessing directive regardless of whether the implementation supports it.
arguments. The number of arguments so combined is such that, following merger, the number of arguments is either equal to or one more than the number of parameters in the macro definition (excluding the .).

15.6.2 Argument substitution

va-opt-replacement:

__VA_OPT__ ( pp-tokensopt )

1 After the arguments for the invocation of a function-like macro have been identified, argument substitution takes place. For each parameter in the replacement list that is neither preceded by a # or ## preprocessing token nor followed by a ## preprocessing token, the preprocessing tokens naming the parameter are replaced by a token sequence determined as follows:

(1.1) — If the parameter is of the form va-opt-replacement, the replacement preprocessing tokens are the preprocessing token sequence for the corresponding argument, as specified below.

(1.2) — Otherwise, the replacement preprocessing tokens are the preprocessing tokens of corresponding argument after all macros contained therein have been expanded. The argument’s preprocessing tokens are completely macro replaced before being substituted as if they formed the rest of the preprocessing file with no other preprocessing tokens being available.

[Example 1]:

```cpp
#define LPAREN() (  #define G(Q) 42
#define F(R, X, ...) __VA_OPT__(G R X) )
int x = F(LPAREN(), 0, <:->);  // replaced by int x = 42;
```

2 An identifier __VA_ARGS__ that occurs in the replacement list shall be treated as if it were a parameter, and the variable arguments shall form the preprocessing tokens used to replace it.

[Example 2]:

```cpp
#define debug(...) fprintf(stderr, __VA_ARGS__)
#define showlist(...) puts(#__VA_ARGS__)
#define report(test, ...) ((test) ? puts(#test) : printf(__VA_ARGS__))

d Debug("Flag");
d Debug("X = \%d\n", x);
ds Showlist(The first, second, and third items.);
report(x>y, "x is \%d but y is \%d", x, y);
```

results in

```cpp
fprintf(stderr, "Flag");
fprintf(stderr, "X = \%d\n", x);
puts("The first, second, and third items.");
((x>y) ? puts("x>y") : printf("x is \%d but y is \%d", x, y));
```

[Example 3]:

```cpp
#define F(...) f(0 __VA_OPT__(,) __VA_ARGS__)
#define G(X, ...) f(0, X __VA_OPT__(,) __VA_ARGS__)
#define SDEF(sname, ...) S sname __VA_OPT__(= { __VA_ARGS__ })
#define EMP
```

4 The identifier __VA_OPT__ shall always occur as part of the preprocessing token sequence va-opt-replacement; its closing ) is determined by skipping intervening pairs of matching left and right parentheses in its pp-tokens. The pp-tokens of a va-opt-replacement shall not contain __VA_OPT__. If the pp-tokens would be ill-formed as the replacement list of the current function-like macro, the program is ill-formed. A va-opt-replacement is treated as if it were a parameter, and the preprocessing token sequence for the corresponding argument is defined as follows. If the substitution of __VA_ARGS__ as neither an operand of # nor ## consists of no preprocessing tokens, the argument consists of a single placemarker preprocessing token (15.6.4, 15.6.5). Otherwise, the argument consists of the results of the expansion of the contained pp-tokens as the replacement list of the current function-like macro before removal of placemarker tokens, rescanning, and further replacement.

[Note 1: The placemarker tokens are removed before stringization (15.6.3), and can be removed by rescanning and further replacement (15.6.5). — end note]

[Example 3]:

```cpp
#define F(...) f(0 __VA_OPT__(,) __VA_ARGS__)  
#define G(X, ...) f(0, X __VA_OPT__(,) __VA_ARGS__)  
#define SDEF(sname, ...) S sname __VA_OPT__(= { __VA_ARGS__ })  
#define EMP
```
F(a, b, c)  // replaced by F(0, a, b, c)
F()      // replaced by F(0)
F(EMP)   // replaced by F(0)

G(a, b, c)  // replaced by G(0, a, b, c)
G(a)       // replaced by G(0, a)
G(a, )     // replaced by G(0, a)

SDEF(foo);  // replaced by S foo;
SDEF(bar, 1, 2);  // replaced by S bar = { 1, 2 };

#define H1(X, ...) X __VA_OPT__(##) __VA_ARGS__  // error: ## may not appear at
// the beginning of a replacement list (15.6.4)
#define H2(X, Y, ...) __VA_OPT__(X ## Y,) __VA_ARGS__
H2(a, b, c, d)  // replaced by ab, c, d
#define H3(X, ...) #__VA_OPT__(X##X X##X)
H3(, 0)  // replaced by ""
#define H4(X, ...) __VA_OPT__(a X ## X) ## b
H4(, 1)  // replaced by a b
#define H5A(...) __VA_OPT__()/**/__VA_OPT__()
#define H5B(X) a ## X ## b
#define H5C(X) H5B(X)
H5C(H5A())  // replaced by ab

—end example

15.6.3 The # operator

1 Each # preprocessing token in the replacement list for a function-like macro shall be followed by a parameter
as the next preprocessing token in the replacement list.

2 A character string literal is a string-literal with no prefix. If, in the replacement list, a parameter is immediately
preceded by a # preprocessing token, both are replaced by a single character string literal preprocessing token
that contains the spelling of the preprocessing token sequence for the corresponding argument (excluding
placemarker tokens). Let the stringizing argument be the preprocessing token sequence for the corresponding
argument with placemarker tokens removed. Each occurrence of whitespace between the stringizing argument’s
preprocessing tokens becomes a single space character in the character string literal. Whitespace before
the first preprocessing token and after the last preprocessing token comprising the stringizing argument is
deleted. Otherwise, the original spelling of each preprocessing token in the stringizing argument is retained
in the character string literal, except for special handling for producing the spelling of string-literals and
character-literals: a \ character is inserted before each " and \ character of a character-literal or string-literal
(including the delimiting " characters). If the replacement that results is not a valid character string literal,
the behavior is undefined. The character string literal corresponding to an empty stringizing argument is "".
The order of evaluation of # and ## operators is unspecified.

15.6.4 The ## operator

1 A ## preprocessing token shall not occur at the beginning or at the end of a replacement list for either form
of macro definition.

2 If, in the replacement list of a function-like macro, a parameter is immediately preceded or followed by a ##
preprocessing token, the parameter is replaced by the corresponding argument’s preprocessing token sequence;
however, if an argument consists of no preprocessing tokens, the parameter is replaced by a placemarker
preprocessing token instead.\footnote{Placemarker preprocessing tokens do not appear in the syntax because they are temporary entities that exist only within translation phase 4.}

3 For both object-like and function-like macro invocations, before the replacement list is reexamined for more
macro names to replace, each instance of a ## preprocessing token in the replacement list (not from an
argument) is deleted and the preceding preprocessing token is concatenated with the following preprocessing
token. Placemarker preprocessing tokens are handled specially: concatenation of two placemarkers results

\footnote{Placemarker preprocessing tokens do not appear in the syntax because they are temporary entities that exist only within translation phase 4.}
in a single placemarker preprocessing token, and concatenation of a placemarker with a non-placemarker preprocessing token results in the non-placemarker preprocessing token. If the result begins with a sequence matching the syntax of universal-character-name, the behavior is undefined.

[Note 1: This determination does not consider the replacement of universal-character-names in translation phase 3 (5.2). — end note]

If the result is not a valid preprocessing token, the behavior is undefined. The resulting token is available for further macro replacement. The order of evaluation of ## operators is unspecified.

4 [Example 1: The sequence]

```c
#define str(s) # s
#define xstr(s) str(s)
#define debug(s, t) printf("x" # s "= %d, x" # t "= %s", \ 
 x ## s, x ## t)
#define INCFILE(n) vers ## n
#define glue(a, b) a ## b
#define xglue(a, b) glue(a, b)
#define HIGHLOW "hello"
#define LOW LOW ", world"

debug(1, 2);
fputs(str(strncmp("abc\0d", "abc", '\4') == 0) str(: @
), s);
#include xstr(INCFILE(2).h)
```

results in

```
printf("x" "1" "= %d, x" "2" "= %s", x1, x2);
```

or, after concatenation of the character string literals,

```
printf("x1= %d, x2= %s", x1, x2);
```

5 [Example 2: In the following fragment:

```c
#define hash_hash # ## #
#define mkstr(a) # a
#define in_between(a) mkstr(a)
#define join(c, d) in_between(c hash_hash d)
char p[] = join(x, y);
```

The expansion produces, at various stages:

```
join(x, y)
```

```
in_between(x hash_hash y)
```

```
in_between(x ## y)
```

```
"x ## y"
```

In other words, expanding hash_hash produces a new token, consisting of two adjacent sharp signs, but this new token is not the ## operator. — end example]

6 [Example 3: To illustrate the rules for placemarker preprocessing tokens, the sequence]

```c
#define t(x,y,z) x ## y ## z
```

```
int j[] = { t(1,2,3), t(,4,5), t(6,7), t(8,9),
 t(10,), t(,11), t(,,12), t(,,) };
```

results in
15.6.5 Rescanning and further replacement

After all parameters in the replacement list have been substituted and # and ## processing has taken place, all placemerker preprocessing tokens are removed. Then the resulting preprocessing token sequence is rescanned, along with all subsequent preprocessing tokens of the source file, for more macro names to replace.

Example 1: The sequence

```c
#define x 3
#define f(a) f(x * (a))
#undef x
#define x 2
#define g f
#define h g(~
#define m(a) a(w)
#define w 0,1
#define t(a) a
#define p() int
#define q(x) x
#define r(x,y) x ## y
#define str(x) # x

f(y+1) + f(f(x)) % t(t(g)(0) + t)(1);
g(x*(3,4)-w) | h 5) & m
(f)^m(m);
p() i[q()] = { q(1), r(2,3), r(4,), r(,5), r(,) );
char c[2][6] = { str(hello), str() };
```

results in

```c
f(2 * (y+1)) + f(2 * (f(2 * (z[0]))))) % f(2 * (0)) + t(1);
f(2 * (2*(3,4)-0,1)) | f(2 * (~ 5)) & f(2 * (0,1))"m(0,1);
int i[1] = { 1, 23, 4, 5, };
char c[2][6] = { "hello", "" };
```

15.6.6 Scope of macro definitions

A macro definition lasts (independent of block structure) until a corresponding `#undef` directive is encountered or (if none is encountered) until the end of the translation unit. Macro definitions have no significance after translation phase 4.

A preprocessing directive of the form

```c
#define identifier new-line
```

causes the specified identifier no longer to be defined as a macro name. It is ignored if the specified identifier is not currently defined as a macro name.

15.7 Line control

The `string-literal` of a `#line` directive, if present, shall be a character string literal.

The `line number` of the current source line is one greater than the number of new-line characters read or introduced in translation phase 1 (5.2) while processing the source file to the current token.
3 A preprocessing directive of the form
   # line digit-sequence new-line
causes the implementation to behave as if the following sequence of source lines begins with a source line that
has a line number as specified by the digit sequence (interpreted as a decimal integer). If the digit sequence
specifies zero or a number greater than 2147483647, the behavior is undefined.

4 A preprocessing directive of the form
   # line digit-sequence " s-char-sequence,opt " new-line
sets the presumed line number similarly and changes the presumed name of the source file to be the contents
of the character string literal.

5 A preprocessing directive of the form
   # line pp-tokens new-line
(that does not match one of the two previous forms) is permitted. The preprocessing tokens after line on the
directive are processed just as in normal text (each identifier currently defined as a macro name is replaced by
its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match
one of the two previous forms, the behavior is undefined; otherwise, the result is processed as appropriate.

15.8 Diagnostic directives
1 A preprocessing directive of either of the following forms
   # error pp-tokens,opt new-line
   # warning pp-tokens,opt new-line
causes the implementation to produce a diagnostic message that should include the specified sequence of
preprocessing tokens; the # error directive renders the program ill-formed.

15.9 Pragma directive
1 A preprocessing directive of the form
   # pragma pp-tokens,opt new-line
causes the implementation to behave in an implementation-defined manner. The behavior may cause
translation to fail or cause the translator or the resulting program to behave in a non-conforming manner.
Any pragma that is not recognized by the implementation is ignored.

15.10 Null directive
1 A preprocessing directive of the form
   # new-line
has no effect.

15.11 Predefined macro names
1 The following macro names shall be defined by the implementation:

   __cplusplus
   The integer literal 202002L.

   [Note 1: Future revisions of C++ will replace the value of this macro with a greater value. — end note]

The names listed in Table 22.
   The macros defined in Table 22 shall be defined to the corresponding integer literal.
   [Note 2: Future revisions of C++ might replace the values of these macros with greater values. — end note]

   __DATE__
   The date of translation of the source file: a character string literal of the form "Mmm dd yyyy", where
the names of the months are the same as those generated by the asctime function, and the first
character of dd is a space character if the value is less than 10. If the date of translation is not available,
an implementation-defined valid date shall be supplied.

   __FILE__
   The presumed name of the current source file (a character string literal).

   [139] The presumed source file name can be changed by the #line directive.
__LINE__
The presumed line number (within the current source file) of the current source line (an integer literal).\textsuperscript{140}

__STDC_HOSTED__
The integer literal 1 if the implementation is a hosted implementation or the integer literal 0 if it is a freestanding implementation (4.1).

__STDCPP_DEFAULT_NEW_ALIGNMENT__
An integer literal of type \texttt{std::size\_t} whose value is the alignment guaranteed by a call to \texttt{operator new(std::size\_t)} or \texttt{operator new[](std::size\_t)}.

\textit{[Note 3: Larger alignments will be passed to \texttt{operator new(std::size\_t, std::align\_val\_t)}, etc. (7.6.2.8). – end note]}

__STDCPP_FLOAT16\_T__
Defined as the integer literal 1 if and only if the implementation supports the ISO/IEC/IEEE 60559 floating-point interchange format binary16 as an extended floating-point type (6.8.3).

__STDCPP_FLOAT32\_T__
Defined as the integer literal 1 if and only if the implementation supports the ISO/IEC/IEEE 60559 floating-point interchange format binary32 as an extended floating-point type.

__STDCPP_FLOAT64\_T__
Defined as the integer literal 1 if and only if the implementation supports the ISO/IEC/IEEE 60559 floating-point interchange format binary64 as an extended floating-point type.

__STDCPP_FLOAT128\_T__
Defined as the integer literal 1 if and only if the implementation supports the ISO/IEC/IEEE 60559 floating-point interchange format binary128 as an extended floating-point type.

__STDCPP_BFLOAT16\_T__
Defined as the integer literal 1 if and only if the implementation supports an extended floating-point type with the properties of the typedef-name \texttt{std::bfloat16\_t} as described in 6.8.3.

__TIME__
The time of translation of the source file: a character string literal of the form "\texttt{hh:mm:ss}" as in the time generated by the \texttt{asctime} function. If the time of translation is not available, an implementation-defined valid time shall be supplied.

2 The following macro names are conditionally defined by the implementation:

`__STDC__`

Whether `__STDC__` is predefined and if so, what its value is, are implementation-defined.
The integer literal 1, intended to indicate that, in the encoding for `wchar_t`, a member of the basic character set need not have a code value equal to its value when used as the lone character in an ordinary character literal.

Whether `__STDC__` is predefined and if so, what its value is, are implementation-defined.

An integer literal of the form `yyyymmL` (for example, `199712L`). Whether `__STDC_ISO_10646__` is predefined and if so, what its value is, are implementation-defined.

Defined, and has the value integer literal 1, if and only if a program can have more than one thread of execution (6.9.2).

The values of the predefined macros (except for `__FILE__` and `__LINE__`) remain constant throughout the translation unit.

If any of the pre-defined macro names in this subclause, or the identifier `defined`, is the subject of a `#define` or a `#undef` preprocessing directive, the behavior is undefined. Any other predefined macro names shall begin with a leading underscore followed by an uppercase letter or a second underscore.

### 15.12 Pragma operator

A unary operator expression of the form:

```
Pragma ( string-literal )
```

is processed as follows: The `string-literal` is *destringized* by deleting the L prefix, if present, deleting the leading and trailing double-quotes, replacing each escape sequence `\"` by a double-quote, and replacing each escape sequence `\` by a single backslash. The resulting sequence of characters is processed through translation phase 3 to produce preprocessing tokens that are executed as if they were the *pp-tokens* in a pragma directive. The original four preprocessing tokens in the unary operator expression are removed.

**Example 1:**

```
#pragma listing on "..\listing.dir"
```

can also be expressed as:

```
Pragma ( "listing on \"..\listing.dir\"" )
```

The latter form is processed in the same way whether it appears literally as shown, or results from macro replacement, as in:

```
#define LISTING(x) PRAGMA(listing on #x)
#define PRAGMA(x) _Pragma(#x)

LISTING( ..\listing.dir )
```

—end example]
16 Library introduction

16.1 General

1 This Clause describes the contents of the C++ standard library, how a well-formed C++ program makes use of the library, and how a conforming implementation may provide the entities in the library.

2 The following subclauses describe the method of description (16.3) and organization (16.4.2) of the library. 16.4, Clause 17 through Clause 33, and Annex D specify the contents of the library, as well as library requirements and constraints on both well-formed C++ programs and conforming implementations.

3 Detailed specifications for each of the components in the library are in Clause 17–Clause 33, as shown in Table 23.

</tbody>
</table>

4 The language support library (Clause 17) provides components that are required by certain parts of the C++ language, such as memory allocation (7.6.2.8, 7.6.2.9) and exception processing (Clause 14).

5 The concepts library (Clause 18) describes library components that C++ programs may use to perform compile-time validation of template arguments and perform function dispatch based on properties of types.

6 The diagnostics library (Clause 19) provides a consistent framework for reporting errors in a C++ program, including predefined exception classes.

7 The memory management library (Clause 20) provides components for memory management, including smart pointers and scoped allocators.

8 The metaprogramming library (Clause 21) describes facilities for use in templates and during constant evaluation, including type traits, integer sequences, and rational arithmetic.

9 The general utilities library (Clause 22) includes components used by other library elements, such as a predefined storage allocator for dynamic storage management (6.7.5.5), and components used as infrastructure in C++ programs, such as tuples and function wrappers.

10 The strings library (Clause 23) provides support for manipulating text represented as sequences of type char, sequences of type char8_t, sequences of type char16_t, sequences of type char32_t, sequences of type wchar_t, and sequences of any other character-like type.

11 The containers (Clause 24), iterators (Clause 25), ranges (Clause 26), and algorithms (Clause 27) libraries provide a C++ program with access to a subset of the most widely used algorithms and data structures.
The numerics library (Clause 28) provides numeric algorithms and complex number components that extend support for numeric processing. The `valarray` component provides support for n-at-a-time processing, potentially implemented as parallel operations on platforms that support such processing. The random number component provides facilities for generating pseudo-random numbers.

The time library (Clause 29) provides generally useful time utilities.

The input/output library (Clause 31) provides the `iostream` components that are the primary mechanism for C++ program input and output. They can be used with other elements of the library, particularly strings, locales, and iterators.

The regular expressions library (Clause 32) provides regular expression matching and searching.

The concurrency support library (Clause 33) provides components to create and manage threads, including atomic operations, mutual exclusion, and interthread communication.

### 16.2 The C standard library [library.c]

The C++ standard library also makes available the facilities of the C standard library, suitably adjusted to ensure static type safety.

The descriptions of many library functions rely on the C standard library for the semantics of those functions. In some cases, the signatures specified in this document may be different from the signatures in the C standard library, and additional overloads may be declared in this document, but the behavior and the preconditions (including any preconditions implied by the use of an ISO C `restrict` qualifier) are the same unless otherwise stated.

A call to a C standard library function is a non-constant library call (3.35) if it raises a floating-point exception other than `FE_INEXACT`. The semantics of a call to a C standard library function evaluated as a core constant expression are those specified in Annex F of the C standard to the extent applicable to the floating-point types (6.8.2) that are parameter types of the called function.

[Note 1: Annex F specifies the conditions under which floating-point exceptions are raised and the behavior when NaNs and/or infinities are passed as arguments. — end note]

[Note 2: Equivalently, a call to a C standard library function is a non-constant library call if `errno` is set when `math_errhandling & MATH_ERRNO` is true. — end note]

### 16.3 Method of description [description]

#### 16.3.1 General [description.general]

Subclause 16.3 describes the conventions used to specify the C++ standard library. 16.3.2 describes the structure of Clause 17 through Clause 33 and Annex D. 16.3.3 describes other editorial conventions.

#### 16.3.2 Structure of each clause [structure]

##### 16.3.2.1 Elements [structure.elements]

Each library clause contains the following elements, as applicable:

1. Summary
2. Requirements
3. Detailed specifications
4. References to the C standard library

##### 16.3.2.2 Summary [structure.summary]

The Summary provides a synopsis of the category, and introduces the first-level subclauses. Each subclause also provides a summary, listing the headers specified in the subclause and the library entities provided in each header.

The contents of the summary and the detailed specifications include:

1. Macros

---

141) See also ISO/IEC 9899:2018 section 7.6.
142) To save space, items that do not apply to a Clause are omitted. For example, if a Clause does not specify any requirements, there will be no “Requirements” subclause.
16.3.2.3 Requirements

Requirements describe constraints that shall be met by a C++ program that extends the standard library. Such extensions are generally one of the following:

1. Template arguments
2. Derived classes
3. Containers, iterators, and algorithms that meet an interface convention or model a concept

The string and iostream components use an explicit representation of operations required of template arguments. They use a class template `char_traits` to define these constraints.

Interface convention requirements are stated as generally as possible. Instead of stating “class \( X \) has to define a member function \( \text{operator}++() \)”, the interface requires “for any object \( x \) of class \( X \), \( \text{operator}++(x) \) is defined”. That is, whether the operator is a member is unspecified.

Requirements are stated in terms of well-defined expressions that define valid terms of the types that meet the requirements. For every set of well-defined expression requirements there is either a named concept or a table that specifies an initial set of the valid expressions and their semantics. Any generic algorithm (Clause 27) that uses the well-defined expression requirements is described in terms of the valid expressions for its template type parameters.

The library specification uses a typographical convention for naming requirements. Names in italic type that begin with the prefix `Cpp17` refer to sets of well-defined expression requirements typically presented in tabular form, possibly with additional prose semantic requirements. For example, `Cpp17Destructible` (Table 35) is such a named requirement. Names in constant width type refer to library concepts which are presented as a concept definition (Clause 13), possibly with additional prose semantic requirements. For example, `destructible` (18.4.10) is such a named requirement.

Template argument requirements are sometimes referenced by name. See 16.3.3.3.

In some cases the semantic requirements are presented as C++ code. Such code is intended as a specification of equivalence of a construct to another construct, not necessarily as the way the construct must be implemented.

Required operations of any concept defined in this document need not be total functions; that is, some arguments to a required operation may result in the required semantics failing to be met.

[Example 1: The required \( < \) operator of the `totally_ordered` concept (18.5.5) does not meet the semantic requirements of that concept when operating on NaNs. —end example]

This does not affect whether a type models the concept.

A declaration may explicitly impose requirements through its associated constraints (13.5.3). When the associated constraints refer to a concept (13.7.9), the semantic constraints specified for that concept are additionally imposed on the use of the declaration.

16.3.2.4 Detailed specifications

The detailed specifications each contain the following elements:

1. Name and brief description
2. Synopsis (class definition or function declaration, as appropriate)
3. Restrictions on template arguments, if any
4. Description of class invariants
5. Description of function semantics

---

143) Although in some cases the code given is unambiguously the optimum implementation.
2 Descriptions of class member functions follow the order (as appropriate):\textsuperscript{144}

- \textit{constructor(s)} and \textit{destructor}
- \textit{copying, moving & assignment functions}
- \textit{comparison operator functions}
- \textit{modifier functions}
- \textit{observer functions}
- \textit{operators and other non-member functions}

3 Descriptions of function semantics contain the following elements (as appropriate):\textsuperscript{145}

- \textit{Constraints}: the conditions for the function’s participation in overload resolution (12.2).
  
  \textit{[Note 1: Failure to meet such a condition results in the function’s silent non-viability. — end note]}

  \textit{[Example 1: An implementation can express such a condition via a constraint-expression (13.5.3). — end example]}

- \textit{Mandates}: the conditions that, if not met, render the program ill-formed.

  \textit{[Example 2: An implementation can express such a condition via the constant-expression in a static_assert-declaration (9.1). If the diagnostic is to be emitted only after the function has been selected by overload resolution, an implementation can express such a condition via a constraint-expression (13.5.3) and also define the function as deleted. — end example]}

- \textit{Preconditions}: the conditions that the function assumes to hold whenever it is called; violation of any preconditions results in undefined behavior.

- \textit{Effects}: the actions performed by the function.

- \textit{Synchronization}: the synchronization operations (6.9.2) applicable to the function.

- \textit{Postconditions}: the conditions (sometimes termed observable results) established by the function.

- \textit{Result}: for a \textit{typename-specifier}, a description of the named type; for an \textit{expression}, a description of the type of the expression; the expression is an lvalue if the type is an lvalue reference type, an xvalue if the type is an rvalue reference type, and a prvalue otherwise.

- \textit{Returns}: a description of the value(s) returned by the function.

- \textit{Throws}: any exceptions thrown by the function, and the conditions that would cause the exception.

- \textit{Complexity}: the time and/or space complexity of the function.

- \textit{Remarks}: additional semantic constraints on the function.

- \textit{Error conditions}: the error conditions for error codes reported by the function.

4 Whenever the \textit{Effects} element specifies that the semantics of some function \( F \) are \textit{Equivalent to} some code sequence, then the various elements are interpreted as follows. If \( F \)'s semantics specifies any \textit{Constraints} or \textit{Mandates} elements, then those requirements are logically imposed prior to the \textit{equivalent-to} semantics. Next, the semantics of the code sequence are determined by the \textit{Constraints}, \textit{Mandates}, \textit{Preconditions}, \textit{Effects}, \textit{Synchronization}, \textit{Postconditions}, \textit{Returns}, \textit{Throws}, \textit{Complexity}, \textit{Remarks}, and \textit{Error conditions} specified for the function invocations contained in the code sequence. The value returned from \( F \) is specified by \( F \)'s \textit{Returns} element, or if \( F \) has no \textit{Returns} element, a non-\textit{void} return from \( F \) is specified by the \textit{return} statements (8.7.4) in the code sequence. If \( F \)'s semantics contains a \textit{Throws}, \textit{Postconditions}, or \textit{Complexity} element, then that supersedes any occurrences of that element in the code sequence.

5 For non-reserved replacement and handler functions, Clause 17 specifies two behaviors for the functions in question: their required and default behavior. The \textit{default behavior} describes a function definition provided by the implementation. The \textit{required behavior} describes the semantics of a function definition provided by either the implementation or a C++ program. Where no distinction is explicitly made in the description, the behavior described is the required behavior.

\textsuperscript{144} To save space, items that do not apply to a class are omitted. For example, if a class does not specify any comparison operator functions, there will be no “Comparison operator functions” subclause.

\textsuperscript{145} To save space, elements that do not apply to a function are omitted. For example, if a function specifies no preconditions, there will be no \textit{Preconditions}: element.
If the formulation of a complexity requirement calls for a negative number of operations, the actual requirement
is zero operations.\textsuperscript{146}

Complexity requirements specified in the library clauses are upper bounds, and implementations that provide
better complexity guarantees meet the requirements.

Error conditions specify conditions where a function may fail. The conditions are listed, together with a
suitable explanation, as the \texttt{enum class errc} constants (19.5).

16.3.2.5 C library

Paraphrase labeled “SEE ALSO” contain cross-references to the relevant portions of other standards (Clause
2).

16.3.3 Other conventions

16.3.3.1 General

Subclause 16.3.3 describes several editorial conventions used to describe the contents of the C\textsuperscript{++}
standard library. These conventions are for describing implementation-defined types (16.3.3.3), and member functions
(16.3.3.4).

16.3.3.2 Exposition-only entities, etc.

Several entities and \texttt{typedef-names} defined in Clause 17 through Clause 33 and Annex D are only defined
for the purpose of exposition. The declaration of such an entity or \texttt{typedef-name} is followed by a comment
ending in \texttt{exposition only}.

The following are defined for exposition only to aid in the specification of the library:

\begin{verbatim}
namespace std {
    template<class T>
    requires convertible_to<T, decay_t<T>>
    constexpr decay_t<T> decay_copy(T&& v)
    noexcept(is_nothrow_convertible_v<T, decay_t<T>>) // exposition only
    { return std::forward<T>(v); }

    constexpr auto synth-three-way =
        [](<class T, class U>(const T& t, const U& u)
        requires requires {
            { t < u } -> boolean-testable;
            { u < t } -> boolean-testable;
        }
        { if constexpr (three_way_comparable_with<T, U>) {
            return t <=> u;
        } else {
            if (t < u) return weak_ordering.less;
            if (u < t) return weak_ordering.greater;
            return weak_ordering.equivalent;
        }}
    ;

    template<class T, class U=T>
    using synth-three-way-result = decltype(synth-three-way(declval<T&>(), declval<U&>()));
}
\end{verbatim}

16.3.3.3 Type descriptions

16.3.3.3.1 General

The Requirements subclauses may describe names that are used to specify constraints on template argu-
ments.\textsuperscript{147} These names are used in library Clauses to describe the types that may be supplied as arguments
by a C\textsuperscript{++} program when instantiating template components from the library.

Certain types defined in Clause 31 are used to describe implementation-defined types. They are based on
other types, but with added constraints.

\textsuperscript{146} This simplifies the presentation of complexity requirements in some cases.

\textsuperscript{147} Examples from 16.4.4 include: \texttt{Cpp17EqualityComparable}, \texttt{Cpp17LessThanComparable}, \texttt{Cpp17CopyConstructible}. Examples
from 25.3 include: \texttt{Cpp17InputIterator}, \texttt{Cpp17ForwardIterator}.
16.3.3.3.2 Enumerated types

Several types defined in Clause 31 are enumerated types. Each enumerated type may be implemented as an enumeration or as a synonym for an enumeration.\[^{148}\]

The enumerated type `enumerated` can be written:

```c
enum enumerated { V_0, V_1, V_2, V_3, ... }
```

```c
inline const enumerated C_0(V_0);
inline const enumerated C_1(V_1);
inline const enumerated C_2(V_2);
inline const enumerated C_3(V_3);
...
```

Here, the names `C_0`, `C_1`, etc. represent enumerated elements for this particular enumerated type. All such elements have distinct values.

16.3.3.3.3 Bitmask types

Several types defined in Clause 17 through Clause 33 and Annex D are bitmask types. Each bitmask type can be implemented as an enumerated type that overloads certain operators, as an integer type, or as a `bitset` (22.9.2).

The bitmask type `bitmask` can be written:

```c
// For exposition only.
// int_type is an integral type capable of representing all values of the bitmask type.
enum bitmask : int_type {
  V_0 = 1 << 0, V_1 = 1 << 1, V_2 = 1 << 2, V_3 = 1 << 3, ...
};
```

```c
inline constexpr bitmask C_0(V_0);
inline constexpr bitmask C_1(V_1);
inline constexpr bitmask C_2(V_2);
inline constexpr bitmask C_3(V_3);
...
```

```c
constexpr bitmask operator& (bitmask X, bitmask Y) {
  return static_cast<bitmask>(
    static_cast<int_type>(X) & static_cast<int_type>(Y));
}
```

```c
constexpr bitmask operator| (bitmask X, bitmask Y) {
  return static_cast<bitmask>(
    static_cast<int_type>(X) | static_cast<int_type>(Y));
}
```

```c
constexpr bitmask operator^ (bitmask X, bitmask Y) {
  return static_cast<bitmask>(
    static_cast<int_type>(X) ^ static_cast<int_type>(Y));
}
```

```c
constexpr bitmask operator~ (bitmask X) {
  return static_cast<bitmask>(
    ~static_cast<int_type>(X));
}
```

```c
bitmask& operator&=(bitmask& X, bitmask Y) { X = X & Y; return X;
}
```

```c
bitmask& operator|=(bitmask& X, bitmask Y) { X = X | Y; return X;
}
```

```c
bitmask& operator^=(bitmask& X, bitmask Y) { X = X ^ Y; return X;
}
```

\[^{148}\] Such as an integer type, with constant integer values (6.8.2).
The value 0 is used to represent an empty bitmask, in which no bitmask elements are set.

The following terms apply to objects and values of bitmask types:

(4.1) To set a value \(Y\) in an object \(X\) is to evaluate the expression \(X \|= Y\).

(4.2) To clear a value \(Y\) in an object \(X\) is to evaluate the expression \(X \&= ~Y\).

(4.3) The value \(Y\) is set in the object \(X\) if the expression \(X \& Y\) is nonzero.

16.3.3.3.4 Character sequences

16.3.3.3.4.1 General

The C standard library makes widespread use of characters and character sequences that follow a few uniform conventions:

(1.1) Properties specified as locale-specific may change during program execution by a call to \texttt{setlocale(int, const char*)} (30.5.1), or by a change to a locale object, as described in 30.3 and Clause 31.

(1.2) The execution character set and the execution wide-character set are supersets of the basic literal character set (5.3). The encodings of the execution character sets and the sets of additional elements (if any) are locale-specific. Each element of the execution wide-character set is encoded as a single code unit representable by a value of type \texttt{wchar_t}.

[Note 1: The encodings of the execution character sets can be unrelated to any literal encoding. —end note]

(1.3) A letter is any of the 26 lowercase or 26 uppercase letters in the basic character set.

(1.4) The decimal-point character is the locale-specific (single-byte) character used by functions that convert between a (single-byte) character sequence and a value of one of the floating-point types. It is used in the character sequence to denote the beginning of a fractional part. It is represented in Clause 17 through Clause 33 and Annex D by a period, ' . ' , which is also its value in the "C" locale.

(1.5) A character sequence is an array object (9.3.4.5) \(A\) that can be declared as \(T\{A[N]\}\), where \(T\) is any of the types \texttt{char}, \texttt{wchar_t}, or \texttt{signed char} (6.8.2), optionally qualified by any combination of \texttt{const} or \texttt{volatile}. The initial elements of the array have defined contents up to and including an element determined by some predicate. A character sequence can be designated by a pointer value \(S\) that points to its first element.

16.3.3.3.4.2 Byte strings

A null-terminated byte string, or NTBS, is a character sequence whose highest-addressed element with defined content has the value zero (the terminating null character); no other element in the sequence has the value zero.\(^{149}\)

The length of an NTBS is the number of elements that precede the terminating null character. An empty NTBS has a length of zero.

The value of an NTBS is the sequence of values of the elements up to and including the terminating null character.

A static NTBS is an NTBS with static storage duration.\(^{150}\)

16.3.3.3.4.3 Multibyte strings

A multibyte character is a sequence of one or more bytes representing the code unit sequence for an encoded character of the execution character set.

A null-terminated multibyte string, or NTMBS, is an NTBS that constitutes a sequence of valid multibyte characters, beginning and ending in the initial shift state.\(^{151}\)

A static NTMBS is an NTMBS with static storage duration.

---

\(^{149}\) Many of the objects manipulated by function signatures declared in \texttt{<cstring> (23.5.3)} are character sequences or NTBSs. The size of some of these character sequences is limited by a length value, maintained separately from the character sequence.

\(^{150}\) A string literal, such as "abc", is a static NTBS.

\(^{151}\) An NTBS that contains characters only from the basic literal character set is also an NTMBS. Each multibyte character then consists of a single byte.
16.3.3.3.5 Customization Point Object types

A customization point object is a function object (22.10) with a literal class type that interacts with program-defined types while enforcing semantic requirements on that interaction.

The type of a customization point object, ignoring cv-qualifiers, shall model semiregular (18.6).

All instances of a specific customization point object type shall be equal (18.2). The effects of invoking different instances of a specific customization point object type on the same arguments are equivalent.

The type T of a customization point object, ignoring cv-qualifiers, shall model invocable<T&, Args...>, invocable<const T&, Args...>, invocable<T, Args...>, and invocable<const T, Args...> (18.7.2) when the types in Args... meet the requirements specified in that customization point object’s definition. When the types of Args... do not meet the customization point object’s requirements, T shall not have a function call operator that participates in overload resolution.

For a given customization point object o, let p be a variable initialized as if by auto p = o; Then for any sequence of arguments args..., the following expressions have effects equivalent to o(args...):

(5.1)    p(args...)
(5.2)    as_const(p)(args...)
(5.3)    std::move(p)(args...)
(5.4)    std::move(as_const(p))(args...)

Each customization point object type constrains its return type to model a particular concept.

16.3.3.4 Functions within classes

For the sake of exposition, Clause 17 through Clause 33 and Annex D do not describe copy/move constructors, assignment operators, or (non-virtual) destructors with the same apparent semantics as those that can be generated by default (11.4.5.3, 11.4.6, 11.4.7). It is unspecified whether the implementation provides explicit definitions for such member function signatures, or for virtual destructors that can be generated by default.

16.3.3.5 Private members

Clause 17 through Clause 33 and Annex D do not specify the representation of classes, and intentionally omit specification of class members (11.4). An implementation may define static or non-static class members, or both, as needed to implement the semantics of the member functions specified in Clause 17 through Clause 33 and Annex D.

For the sake of exposition, some subclauses provide representative declarations, and semantic requirements, for private members of classes that meet the external specifications of the classes. The declarations for such members are followed by a comment that ends with exposition only, as in:

```cpp
streambuf* sb; // exposition only
```

An implementation may use any technique that provides equivalent observable behavior.

16.3.3.6 Freestanding items

A freestanding item is a declaration, entity, typedef-name, or macro that is required to be present in a freestanding implementation and a hosted implementation.

Unless otherwise specified, the requirements on freestanding items for a freestanding implementation are the same as the corresponding requirements for a hosted implementation, except that not all of the members of the namespaces are required to be present.

[Note 1: This implies that freestanding item enumerations have the same enumerators on freestanding implementations and hosted implementations. Furthermore, class types have the same members and class templates have the same deduction guides on freestanding implementations and hosted implementations. — end note]

A declaration in a header synopsis is a freestanding item if

(3.1)    it is followed by a comment that includes freestanding, or
(3.2)    the header synopsis begins with a comment that includes all freestanding.

An entity or typedef-name is a freestanding item if it is:

(4.1)    introduced by a declaration that is a freestanding item,
(4.2)    an enclosing namespace of a freestanding item,

§ 16.3.3.6 485
(4.3) — a friend of a freestanding item,
(4.4) — denoted by a typedef-name that is a freestanding item, or
(4.5) — denoted by an alias template that is a freestanding item.

5 A macro is a freestanding item if it is defined in a header synopsis and

— the definition is followed by a comment that includes freestanding, or

— the header synopsis begins with a comment that includes all freestanding.

6 [Example 1:
   #define NULL see below // freestanding
   — end example]

[Example 2:
   // all freestanding
   namespace std {
   — end example]

16.4 Library-wide requirements [requirements]

16.4.1 General [requirements.general]

1 Subclause 16.4 specifies requirements that apply to the entire C++ standard library. Clause 33 and Annex D specify the requirements of individual entities within the library.

2 Requirements specified in terms of interactions between threads do not apply to programs having only a single thread of execution.

3 16.4.2 describes the library’s contents and organization, 16.4.3 describes how well-formed C++ programs gain access to library entities, 16.4.4 describes constraints on types and functions used with the C++ standard library, 16.4.5 describes constraints on well-formed C++ programs, and 16.4.6 describes constraints on conforming implementations.

16.4.2 Library contents and organization [organization]

16.4.2.1 General [organization.general]

1 16.4.2.2 describes the entities and macros defined in the C++ standard library. 16.4.2.3 lists the standard library headers and some constraints on those headers. 16.4.2.5 lists requirements for a freestanding implementation of the C++ standard library.

16.4.2.2 Library contents [contents]

1 The C++ standard library provides definitions for the entities and macros described in the synopses of the C++ standard library headers (16.4.2.3), unless otherwise specified.

2 All library entities except operator new and operator delete are defined within the namespace std or namespaces nested within namespace std. It is unspecified whether names declared in a specific namespace are declared directly in that namespace or in an inline namespace inside that namespace.

3 Whenever an unqualified name other than swap, make_error_code, or make_error_condition is used in the specification of a declaration D in Clause 17 through Clause 33 or Annex D, its meaning is established as-if by performing unqualified name lookup (6.5.3) in the context of D.

[Note 1: Argument-dependent lookup is not performed. — end note]

Similarly, the meaning of a qualified-id is established as-if by performing qualified name lookup (6.5.5) in the context of D.

[Example 1: The reference to is_array_v in the specification of std::to_array (24.3.7.6) refers to ::std::is_array_v.
— end example]

[Note 2: Operators in expressions (12.2.2.3) are not so constrained; see 16.4.6.4. — end note]

The meaning of the unqualified name swap is established in an overload resolution context for swappable values (16.4.4.3). The meanings of the unqualified names make_error_code and make_error_condition are established as-if by performing argument-dependent lookup (6.5.4).

152) The C standard library headers (17.14) also define names within the global namespace, while the C++ headers for C library facilities (16.4.2.3) can also define names within the global namespace.

153) This gives implementers freedom to use inline namespaces to support multiple configurations of the library.
16.4.2.3 Headers

1 Each element of the C++ standard library is declared or defined (as appropriate) in a header.\(^{154}\)

2 The C++ standard library provides the C++ library headers, shown in Table 24.

### Table 24: C++ library headers [tab:headers.cpp]

<table>
<thead>

</tr>
<tr>
<td>&lt;cwctype&gt;</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

4 The headers listed in Table 24, or, for a freestanding implementation, the subset of such headers that are provided by the implementation, are collectively known as the importable C++ library headers.

[Note 1: Importable C++ library headers can be imported (10.3). — end note]

[Example 1:]

```cpp
import <vector>;  // imports the <vector> header unit
std::vector<int> vi;  // OK
```

[Example 2:]

```cpp
import <vector>;
std::vector<int> vi;  // OK
```

5 Except as noted in Clause 16 through Clause 33 and Annex D, the contents of each header `c_name` is the same as that of the corresponding header `name.h` as specified in the C standard library (Clause 2). In the C++ standard library, however, the declarations (except for names which are defined as macros in C) are within namespace scope (6.4.6) of the namespace `std`. It is unspecified whether these names (including any overloads added in Clause 17 through Clause 33 and Annex D) are first declared within the global namespace scope and are then injected into namespace `std` by explicit using-declarations (9.9).

6 Names which are defined as macros in C shall be defined as macros in the C++ standard library, even if C grants license for implementation as functions.

---

\(^{154}\) A header is not necessarily a source file, nor are the sequences delimited by `<` and `>` in header names necessarily valid source file names (15.3).

\(^{155}\) It is intentional that there is no C++ header for any of these C headers: `<stdnoreturn.h>`, `<threads.h>`. 

§ 16.4.2.3 487
7 Names that are defined as functions in C shall be defined as functions in the C++ standard library.\textsuperscript{156}

8 Identifiers that are keywords or operators in C++ shall not be defined as macros in C++ standard library headers.\textsuperscript{157}

9 \textbf{17.14, C standard library headers}, describes the effects of using the \texttt{name.h} (C header) form in a C++ program.\textsuperscript{158}

10 Annex K of the C standard describes a large number of functions, with associated types and macros, which “promote safer, more secure programming” than many of the traditional C library functions. The names of the functions have a suffix of \_s: most of them provide the same service as the C library function with the unsuffixed name, but generally take an additional argument whose value is the size of the result array. If any C++ header is included, it is implementation-defined whether any of these names is declared in the global namespace. (None of them is declared in namespace std.)

11 Table 26 lists the Annex K names that may be declared in some header. These names are also subject to the restrictions of 16.4.5.3.3.

</tbody>
</table>

16.4.2.4 Modules

1 The C++ standard library provides the following \textit{C++ library modules}.

2 The named module \texttt{std} exports declarations in namespace \texttt{std} that are provided by the importable C++ library headers (Table 24 or the subset provided by a freestanding implementation) and the C++ headers for C library facilities (Table 25). It additionally exports declarations in the global namespace for the storage allocation and deallocation functions that are provided by \texttt{<new> (17.6.2)}.

3 The named module \texttt{std.compat} exports the same declarations as the named module \texttt{std}, and additionally exports declarations in the global namespace corresponding to the declarations in namespace \texttt{std} that are provided by the C++ headers for C library facilities (Table 25), except the explicitly excluded declarations described in 17.14.7.

4 It is unspecified to which module a declaration in the standard library is attached.

\textsuperscript{156} This disallows the practice, allowed in C, of providing a masking macro in addition to the function prototype. The only way to achieve equivalent inline behavior in C++ is to provide a definition as an \texttt{extern inline} function.

\textsuperscript{157} In particular, including the standard header \texttt{<iso646.h>} has no effect.

\textsuperscript{158} The *.h* headers dump all their names into the global namespace, whereas the newer forms keep their names in namespace std. Therefore, the newer forms are the preferred forms for all uses except for C++ programs which are intended to be strictly compatible with C.
Recommended practice: Implementations should ensure such attachments do not preclude further evolution or decomposition of the standard library modules.

Note 1: Implementations are required to ensure that mixing `#include` and `import` does not result in conflicting attachments (6.6). — end note

Recommended practice: Implementations should ensure such attachments do not preclude further evolution or decomposition of the standard library modules.

A declaration in the standard library denotes the same entity regardless of whether it was made reachable through including a header, importing a header unit, or importing a C++ library module.

Recommended practice: Implementations should avoid exporting any other declarations from the C++ library modules.

Note 2: Like all named modules, the C++ library modules do not make macros visible (10.3), such as `assert` (19.3.2), `errno` (19.4.2), `offsetof` (17.2.1), and `va_arg` (17.13.2). — end note

16.4.2.5 Freestanding implementations

Two kinds of implementations are defined: hosted and freestanding (4.1); the kind of the implementation is implementation-defined. For a hosted implementation, this document describes the set of available headers.

A freestanding implementation has an implementation-defined set of headers. This set shall include at least the headers shown in Table 27.

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>17.2</td>
<td><code>&lt;cstddef&gt;</code></td>
</tr>
<tr>
<td>17.3</td>
<td><code>&lt;cfloat&gt;, &lt;climits&gt;, &lt;limits&gt;, &lt;version&gt;</code></td>
</tr>
<tr>
<td>17.4.1</td>
<td><code>&lt;cstdint&gt;</code></td>
</tr>
<tr>
<td>17.5</td>
<td><code>&lt;cstdlib&gt;</code></td>
</tr>
<tr>
<td>17.6</td>
<td><code>&lt;new&gt;</code></td>
</tr>
<tr>
<td>17.7</td>
<td><code>&lt;typeinfo&gt;</code></td>
</tr>
<tr>
<td>17.8</td>
<td><code>&lt;source_location&gt;</code></td>
</tr>
<tr>
<td>17.9</td>
<td><code>&lt;exception&gt;</code></td>
</tr>
<tr>
<td>17.10</td>
<td><code>&lt;initializer_list&gt;</code></td>
</tr>
<tr>
<td>17.11</td>
<td><code>&lt;compare&gt;</code></td>
</tr>
<tr>
<td>17.12</td>
<td><code>&lt;coroutine&gt;</code></td>
</tr>
<tr>
<td>17.13</td>
<td><code>&lt;cassert&gt;</code></td>
</tr>
<tr>
<td>Clause 18</td>
<td><code>&lt;concepts&gt;</code></td>
</tr>
<tr>
<td>21.3</td>
<td><code>&lt;type_traits&gt;</code></td>
</tr>
<tr>
<td>22.15</td>
<td><code>&lt;bit&gt;</code></td>
</tr>
<tr>
<td>33.5</td>
<td><code>&lt;atomic&gt;</code></td>
</tr>
<tr>
<td>22.2</td>
<td><code>&lt;utility&gt;</code></td>
</tr>
<tr>
<td>22.4</td>
<td><code>&lt;tuple&gt;</code></td>
</tr>
<tr>
<td>20.2</td>
<td><code>&lt;memory&gt;</code></td>
</tr>
<tr>
<td>22.10</td>
<td><code>&lt;functional&gt;</code></td>
</tr>
<tr>
<td>21.4</td>
<td><code>&lt;ratio&gt;</code></td>
</tr>
<tr>
<td>Clause 25</td>
<td><code>&lt;iterator&gt;</code></td>
</tr>
<tr>
<td>Clause 26</td>
<td><code>&lt;ranges&gt;</code></td>
</tr>
</tbody>
</table>

For each of the headers listed in Table 27, a freestanding implementation provides at least the freestanding items (16.3.3.6) declared in the header.

16.4.3 Using the library

16.4.3.1 Overview

Subclause 16.4.3 describes how a C++ program gains access to the facilities of the C++ standard library. 16.4.3.2 describes effects during translation phase 4, while 16.4.3.3 describes effects during phase 8 (5.2).

16.4.3.2 Headers

The entities in the C++ standard library are defined in headers, whose contents are made available to a translation unit when it contains the appropriate `#include` preprocessing directive (15.3) or the appropriate `import` declaration (10.3).
A translation unit may include library headers in any order (5.1). Each may be included more than once, with no effect different from being included exactly once, except that the effect of including either `<cassert>` (19.3.2) or `<assert.h>` (17.14) depends each time on the lexically current definition of \texttt{NDEBUG}.

A translation unit shall include a header only outside of any declaration or definition and, in the case of a module unit, only in its \texttt{global-module-fragment}, and shall include the header or import the corresponding header unit lexically before the first reference in that translation unit to any of the entities declared in that header. No diagnostic is required.

### 16.4.3.3 Linkage

Entities in the C++ standard library have external linkage (6.6). Unless otherwise specified, objects and functions have the default \texttt{extern "C++"} linkage (9.11).

Whether a name from the C standard library declared with external linkage has \texttt{extern "C"} or \texttt{extern "C++"} linkage is implementation-defined. It is recommended that an implementation use \texttt{extern "C++"} linkage for this purpose.

Objects and functions defined in the library and required by a C++ program are included in the program prior to program startup.

See also replacement functions (16.4.5.6), runtime changes (16.4.5.7).

### 16.4.4 Requirements on types and expressions

#### 16.4.4.1 General

16.4.4.2 describes requirements on types and expressions used to instantiate templates defined in the C++ standard library. 16.4.4.3 describes the requirements on swappable types and swappable expressions. 16.4.4.4 describes the requirements on pointer-like types that support null values. 16.4.4.5 describes the requirements on hash function objects. 16.4.4.6 describes the requirements on storage allocators.

#### 16.4.4.2 Template argument requirements

The template definitions in the C++ standard library refer to various named requirements whose details are set out in Tables 28–35. In these tables,

- \( T \) denotes an object or reference type to be supplied by a C++ program instantiating a template,
- \( a, b, \) and \( c \) denote values of type (possibly const) \( T \),
- \( s \) and \( t \) denote modifiable lvalues of type \( T \),
- \( u \) denotes an identifier,
- \( rv \) denotes an rvalue of type \( T \), and
- \( v \) denotes an lvalue of type (possibly const) \( T \) or an rvalue of type \texttt{const} \( T \).

In general, a default constructor is not required. Certain container class member function signatures specify \( T() \) as a default argument. \( T() \) shall be a well-defined expression (9.4) if one of those signatures is called using the default argument (9.3.4.7).

#### Table 28: Cpp17EqualityComparable requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Requirement</th>
</tr>
</thead>
</table>
| \( a == b \) | \texttt{decltype(a == b)} | \( == \) is an equivalence relation, that is, it has the following properties:
|             |             | - For all \( a, a == a \). |
|             |             | - If \( a == b \), then \( b == a \). |
|             |             | - If \( a == b \) and \( b == c \), then \( a == c \). |

---

159) This is the same as the C standard library.
160) The only reliable way to declare an object or function signature from the C standard library is by including the header that declares it, notwithstanding the latitude granted in 7.1.4 of the C Standard.
Table 29: \texttt{Cpp17LessThanComparable} requirements

<tr>
<td>\texttt{t = v}</td>
<td>\texttt{T&amp;}</td>
<td>\texttt{t}</td>
<td>\texttt{t} is equivalent to \texttt{v}, the value of \texttt{v} is unchanged</td>
</tr>
</tbody>
</table>
### Swappable requirements

1. This subclause provides definitions for swappable types and expressions. In these definitions, let \( t \) denote an expression of type \( T \), and let \( u \) denote an expression of type \( U \).

2. An object \( t \) is **swappable with** an object \( u \) if and only if:

   - the expressions \( \text{swap}(t, u) \) and \( \text{swap}(u, t) \) are valid when evaluated in the context described below, and

   - these expressions have the following effects:

      - the object referred to by \( t \) has the value originally held by \( u \) and

      - the object referred to by \( u \) has the value originally held by \( t \).

3. The context in which \( \text{swap}(t, u) \) and \( \text{swap}(u, t) \) are evaluated shall ensure that a binary non-member function named “swap” is selected via overload resolution (12.2) on a candidate set that includes:

   - the two `swap` function templates defined in `<utility>` (22.2.1) and

   - the lookup set produced by argument-dependent lookup (6.5.4).

   **Note 1:** If \( T \) and \( U \) are both fundamental types or arrays of fundamental types and the declarations from the header `<utility>` are in scope, the overall lookup set described above is equivalent to that of the qualified name lookup applied to the expression `std::swap(t, u)` or `std::swap(u, t)` as appropriate. — end note

   **Note 2:** It is unspecified whether a library component that has a swappable requirement includes the header `<utility>` to ensure an appropriate evaluation context. — end note

4. An rvalue or lvalue \( t \) is **swappable** if and only if \( t \) is swappable with any rvalue or lvalue, respectively, of type \( T \).

5. A type \( X \) meets the **Cpp17Swappable** requirements if lvalues of type \( X \) are swappable.

6. A type \( X \) meeting any of the iterator requirements (25.3) meets the **Cpp17ValueSwappable** requirements if, for any dereferenceable object \( x \) of type \( X \), \( *x \) is swappable.

7. **Example 1:** User code can ensure that the evaluation of `swap` calls is performed in an appropriate context under the various conditions as follows:

   ```cpp
   #include <cassert>
   #include <utility>

   template<class T, class U>
   void value_swap(T&& t, U&& u) {
      using std::swap;
      swap(std::forward<T>(t), std::forward<U>(u)); // OK, uses “swappable with” conditions
      // for rvalues and lvalues
   }

   template<class T>
   void lv_swap(T& t1, T& t2) {
      using std::swap;
      swap(t1, t2); // OK, uses swappable conditions for lvalues of type T
   }

   namespace N {
      struct A { int m; };
      struct Proxy { A* a; };  
      Proxy proxy(A& a) { return Proxy{ &a }; }
   }
   ```

---

**Example 2:**

```cpp
// Preconditions: std::forward<T>(t) is swappable with std::forward<U>(u).
template<class T, class U>
void value_swap(T&& t, U&& u) {
   using std::swap;
   swap(std::forward<T>(t), std::forward<U>(u)); // OK, uses “swappable with” conditions
   // for rvalues and lvalues
}

// Preconditions: T meets the Cpp17Swappable requirements.
template<class T>
void lv_swap(T& t1, T& t2) {
   using std::swap;
   swap(t1, t2); // OK, uses swappable conditions for lvalues of type T
}
```

---
void swap(A& x, Proxy p) {
    std::swap(x.m, p.a->m);
    // OK, uses context equivalent to swappable
    // conditions for fundamental types
}

void swap(Proxy p, &x) { swap(x, p); }
// satisfy symmetry constraint

int main() {
    int i = 1, j = 2;
    lv_swap(i, j);
    assert(i == 2 && j == 1);

    N::A a1 = { 5 }, a2 = { -5 };
    value_swap(a1, proxy(a2));
    assert(a1.m == -5 && a2.m == 5);
}

— end example

16.4.4.4 Cpp17NullablePointer requirements [nullpointer.requirements]

1 A Cpp17NullablePointer type is a pointer-like type that supports null values. A type $P$ meets the Cpp17NullablePointer requirements if:

1.1 — $P$ meets the Cpp17EqualityComparable, Cpp17DefaultConstructible, Cpp17CopyConstructible, Cpp17CopyAssignable, Cpp17Swappable, and Cpp17Destructible requirements,

1.2 — the expressions shown in Table 36 are valid and have the indicated semantics, and

1.3 — $P$ meets all the other requirements of this subclause.

2 A value-initialized object of type $P$ produces the null value of the type. The null value shall be equivalent only to itself. A default-initialized object of type $P$ may have an indeterminate value.

[Note 1: Operations involving indeterminate values can cause undefined behavior. — end note]

3 An object $p$ of type $P$ can be contextually converted to bool (7.3). The effect shall be as if $p != \text{nullptr}$ had been evaluated in place of $p$.

4 No operation which is part of the Cpp17NullablePointer requirements shall exit via an exception.

5 In Table 36, $u$ denotes an identifier, $t$ denotes a non-const lvalue of type $P$, $a$ and $b$ denote values of type (possibly const) $P$, and $np$ denotes a value of type (possibly const) std::nullptr_t.

Table 36: Cpp17NullablePointer requirements [tab:cpp17.nullablepointer]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>$P\ u(np);$</td>
<td>Postconditions: $u == \text{nullptr}$</td>
<td></td>
</tr>
<tr>
<td>$P\ u = np;$</td>
<td>Postconditions: $P(np) == \text{nullptr}$</td>
<td></td>
</tr>
<tr>
<td>$t = np$</td>
<td>Postconditions: $t == \text{nullptr}$</td>
<td></td>
</tr>
<tr>
<td>$a != b$</td>
<td>decltype($a != b$) models $!(a == b)$</td>
<td>boolean-testable</td>
</tr>
<tr>
<td>$a == np$</td>
<td>decltype($a == np$) and $a == P()$</td>
<td>each model boolean-testable</td>
</tr>
<tr>
<td>$np == a$</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$a != np$</td>
<td>decltype($a != np$) and $!(a == np)$</td>
<td>boolean-testable</td>
</tr>
<tr>
<td>$np != a$</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

16.4.4.5 Cpp17Hash requirements [hash.requirements]

1 A type $H$ meets the Cpp17Hash requirements if:

1.1 — it is a function object type (22.10),

§ 16.4.4.5 493
— it meets the `Cpp17CopyConstructible` (Table 32) and `Cpp17Destructible` (Table 35) requirements, and
— the expressions shown in Table 37 are valid and have the indicated semantics.

2 Given `Key` is an argument type for function objects of type `H`, in Table 37 `h` is a value of type (possibly const) `H`, `u` is an lvalue of type `Key`, and `k` is a value of a type convertible to (possibly const) `Key`.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>h(k)</code></td>
<td><code>size_t</code></td>
<td>The value returned shall depend only on the argument <code>k</code> for the duration of the program. [Note 1: Thus all evaluations of the expression <code>h(k)</code> with the same value for <code>k</code> yield the same result for a given execution of the program. — end note] For two different values <code>t1</code> and <code>t2</code>, the probability that <code>h(t1)</code> and <code>h(t2)</code> compare equal should be very small, approaching <code>1.0 / numeric_limits&lt;size_t&gt;::max()</code>.</td>
</tr>
<tr>
<td><code>h(u)</code></td>
<td><code>size_t</code></td>
<td>Shall not modify <code>u</code>.</td>
</tr>
</tbody>
</table>

16.4.4.6 `Cpp17Allocator` requirements [allocator.requirements]

16.4.4.6.1 General [allocator.requirements.general]

The library describes a standard set of requirements for ` allocators`, which are class-type objects that encapsulate the information about an allocation model. This information includes the knowledge of pointer types, the type of their difference, the type of the size of objects in this allocation model, as well as the memory allocation and deallocation primitives for it. All of the string types (Clause 23), containers (Clause 24) (except `array`), string buffers and string streams (Clause 31), and `match_results` (Clause 32) are parameterized in terms of allocators.

2 In subclause 16.4.4.6,

— `T`, `U`, `C` denote any cv-unqualified object type (6.8.1),
— `X` denotes an allocator class for type `T`,
— `Y` denotes the corresponding allocator class for type `U`,
— `XX` denotes the type `allocator_traits<X>`,
— `YY` denotes the type `allocator_traits<Y>`,
— `a`, `a1`, `a2` denote lvalues of type `X`,
— `u` denotes the name of a variable being declared,
— `b` denotes a value of type `Y`,
— `c` denotes a pointer of type `C*` through which indirection is valid,
— `p` denotes a value of type `XX::pointer` obtained by calling `a1.allocate`, where `a1 == a`,
— `q` denotes a value of type `XX::const_pointer` obtained by conversion from a value `p`,
— `r` denotes a value of type `T&` obtained by the expression `*p`,
— `w` denotes a value of type `XX::void_pointer` obtained by conversion from a value `p`,
— `x` denotes a value of type `XX::const_void_pointer` obtained by conversion from a value `q` or a value `w`,
— `y` denotes a value of type `XX::const_void_pointer` obtained by conversion from a result value of `YY::allocate`, or else a value of type (possibly const) `std::nullptr_t`,
— `n` denotes a value of type `XX::size_type`,
— `Args` denotes a template parameter pack, and
— `args` denotes a function parameter pack with the pattern `Args&&`.  

3 The class template `allocator_traits` (20.2.9) supplies a uniform interface to all allocator types. This subclause describes the requirements on allocator types and thus on types used to instantiate `allocator_traits`. A requirement is optional if a default for a given type or expression is specified. Within the standard
library allocator_traits template, an optional requirement that is not supplied by an allocator is replaced by the specified default type or expression.

[Note 1: There are no program-defined specializations of allocator_traits. — end note]

typename X::pointer

  Remarks: Default: T*

typename X::const_pointer

  Mandates: X::pointer is convertible to X::const_pointer.

  Remarks: Default: pointer_traits<X::pointer>::rebind<const T>

typename X::void_pointer

typename Y::void_pointer

  Mandates: X::pointer is convertible to X::void_pointer. X::void_pointer and Y::void_pointer are the same type.

  Remarks: Default: pointer_traits<X::pointer>::rebind<void>

typename X::const_void_pointer

typename Y::const_void_pointer

  Mandates: X::pointer, X::const_pointer, and X::void_pointer are convertible to X::const_void_pointer. X::const_void_pointer and Y::const_void_pointer are the same type.

  Remarks: Default: pointer_traits<X::pointer>::rebind<const void>

typename X::value_type

  Result: Identical to T.

typename X::size_type

  Result: An unsigned integer type that can represent the size of the largest object in the allocation model.

  Remarks: Default: make_unsigned_t<X::difference_type>

typename X::difference_type

  Result: A signed integer type that can represent the difference between any two pointers in the allocation model.

  Remarks: Default: pointer_traits<X::pointer>::difference_type

typename X::template rebind<U>::other

  Result: Y

  Postconditions: For all U (including T), Y::rebind_alloc<T> is X.

  Remarks: If Allocator is a class template instantiation of the form SomeAllocator<T, Args>, where Args is zero or more type arguments, and Allocator does not supply a rebind member template, the standard allocator_traits template uses SomeAllocator<U, Args> in place of Allocator::rebind<U>::other by default. For allocator types that are not template instantiations of the above form, no default is provided.

  [Note 2: The member class template rebind of X is effectively a typedef template. In general, if the name Allocator is bound to SomeAllocator<T>, then Allocator::rebind<U>::other is the same type as SomeAllocator<U>, where SomeAllocator<T>::value_type is T and SomeAllocator<U>::value_type is U. — end note]

*p

  Result: T&

*q

  Result: const T&

  Postconditions: *q refers to the same object as *p.
p->m
   Result: Type of T::m.
   Preconditions: (*p).m is well-defined.
   Effects: Equivalent to (*p).m.

q->m
   Result: Type of T::m.
   Preconditions: (*q).m is well-defined.
   Effects: Equivalent to (*q).m.

static_cast<XX::pointer>(w)
   Result: XX::pointer
   Postconditions: static_cast<XX::pointer>(w) == p.

static_cast<XX::const_pointer>(x)
   Result: XX::const_pointer
   Postconditions: static_cast<XX::const_pointer>(x) == q.

pointer_traits<XX::pointer>::pointer_to(r)
   Result: XX::pointer
   Postconditions: Same as p.

a.allocate(n)
   Result: XX::pointer
   Effects: Memory is allocated for an array of n T and such an object is created but array elements are not constructed.

[Example 1: When reusing storage denoted by some pointer value p, launder(reinterpret_cast<T*>(new (p) byte[n * sizeof(T)])) can be used to implicitly create a suitable array object and obtain a pointer to it. —end example]

   Throws: allocate may throw an appropriate exception.

   [Note 3: It is intended that a.allocate be an efficient means of allocating a single object of type T, even when sizeof(T) is small. That is, there is no need for a container to maintain its own free list. —end note]

   Remarks: If n == 0, the return value is unspecified.

a.allocate(n, y)
   Result: XX::pointer
   Effects: Same as a.allocate(n). The use of y is unspecified, but it is intended as an aid to locality.
   Remarks: Default: a.allocate(n)

a.allocate_at_least(n)
   Result: allocation_result<XX::pointer, XX::size_type>
   Returns: allocation_result<XX::pointer, XX::size_type>{ptr, count} where ptr is memory allocated for an array of count T and such an object is created but array elements are not constructed, such that count ≥ n. If n == 0, the return value is unspecified.
   Throws: allocate_at_least may throw an appropriate exception.
   Remarks: Default: {a.allocate(n), n}.

a.deallocate(p, n)
   Result: (not used)
   Preconditions:
If \( p \) is memory that was obtained by a call to `a.allocate_at_least`, let `ret` be the value returned and `req` be the value passed as the first argument of that call. \( p \) is equal to `ret.ptr` and \( n \) is a value such that \( req \leq n \leq ret.count \).

Otherwise, \( p \) is a pointer value obtained from `allocate`. \( n \) equals the value passed as the first argument to the invocation of `allocate` which returned \( p \).

\( p \) has not been invalidated by an intervening call to `deallocate`.

`a.max_size()`

**Throws:** Nothing.

`a1 == a2`

**Result:** bool

**Returns:** true only if storage allocated from each can be deallocated via the other.

**Throws:** Nothing.

**Remarks:** `operator==` shall be reflexive, symmetric, and transitive.

`a1 != a2`

**Result:** bool

**Returns:** !(a1 == a2).

`a == b`

**Result:** bool

**Returns:** a == YY::rebind_alloc<T>(b).

`a != b`

**Result:** bool

**Returns:** !(a == b).

\[ X \ u(a); \]
\[ X \ u = a; \]

**Postconditions:** \( u == a \)

**Throws:** Nothing.

\[ X \ u(b); \]

**Postconditions:** \( Y(u) == b \) and \( u == X(b) \).

**Throws:** Nothing.

\[ X \ u(std::move(a)); \]
\[ X \ u = std::move(a); \]

**Postconditions:** The value of \( a \) is unchanged and is equal to \( u \).

**Throws:** Nothing.

\[ X \ u(std::move(b)); \]

**Postconditions:** \( u \) is equal to the prior value of \( X(b) \).

**Throws:** Nothing.

`a.construct(c, args)`

**Result:** (not used)

**Effects:** Constructs an object of type \( C \) at \( c \).

**Remarks:** Default: `construct_at(c, std::forward<Args>(args)...)`
a.destroy(c)

Result: (not used)

Effects: Destroys the object at c.

Remarks: Default: destroy_at(c)

a.select_on_container_copy_construction()

Result: X

Returns: Typically returns either a or X().

Remarks: Default: return a;

typename X::propagate_on_container_copy_assignment

Result: Identical to or derived from true_type or false_type.

Returns: true_type only if an allocator of type X should be copied when the client container is
copy-assigned; if so, X shall meet the Cpp17CopyAssignable requirements (Table 34) and the copy
operation shall not throw exceptions.

Remarks: Default: false_type

typename X::propagate_on_container_move_assignment

Result: Identical to or derived from true_type or false_type.

Returns: true_type only if an allocator of type X should be moved when the client container is
move-assigned; if so, X shall meet the Cpp17MoveAssignable requirements (Table 33) and the move
operation shall not throw exceptions.

Remarks: Default: false_type

typename X::propagate_on_container_swap

Result: Identical to or derived from true_type or false_type.

Returns: true_type only if an allocator of type X should be swapped when the client container is
swapped; if so, X shall meet the Cpp17Swappable requirements (16.4.4.3) and the swap
operation shall not throw exceptions.

Remarks: Default: false_type

typename X::is_always_equal

Result: Identical to or derived from true_type or false_type.

Returns: true_type only if the expression a1 == a2 is guaranteed to be true for any two (possibly
const) values a1, a2 of type X.

Remarks: Default: is_empty<X>::type

An allocator type X shall meet the Cpp17CopyConstructible requirements (Table 32). The XX::pointer,
XX::const_pointer, XX::void_pointer, and XX::const_void_pointer types shall meet the Cpp17Nullable-
Pointer requirements (Table 36). No constructor, comparison operator function, copy operation, move
operation, or swap operation on these pointer types shall exit via an exception. XX::pointer and XX::const-
pointer shall also meet the requirements for a Cpp17RandomAccessIterator (25.3.5.7) and the additional
requirement that, when p and (p + n) are dereferenceable pointer values for some integral value n,

```
addressof(*(p + n)) == addressof(*p) + n
```

is true.

Let x1 and x2 denote objects of (possibly different) types XX::void_pointer, XX::const_void_pointer,
XX::pointer, or XX::const_pointer. Then, x1 and x2 are equivalently-valued pointer values, if and only if
both x1 and x2 can be explicitly converted to the two corresponding objects px1 and px2 of type XX::const-
pointer, using a sequence of static_casts using only these four types, and the expression px1 == px2
evaluates to true.

Let w1 and w2 denote objects of type XX::void_pointer. Then for the expressions

```
w1 == w2
w1 != w2
```
either or both objects may be replaced by an equivalently-valued object of type `XX::const_void_pointer` with no change in semantics.

Let `p1` and `p2` denote objects of type `XX::pointer`. Then for the expressions

```plaintext
p1 == p2
p1 != p2
p1 <= p2
p1 >= p2
p1 > p2
p1 - p2
```
either or both objects may be replaced by an equivalently-valued object of type `XX::const_pointer` with no change in semantics.

An allocator may constrain the types on which it can be instantiated and the arguments for which its `construct` or `destroy` members may be called. If a type cannot be used with a particular allocator, the allocator class or the call to `construct` or `destroy` may fail to instantiate.

If the alignment associated with a specific over-aligned type is not supported by an allocator, instantiation of the allocator for that type may fail. The allocator also may silently ignore the requested alignment.

[Note 4: Additionally, the member function `allocate` for that type can fail by throwing an object of type `bad_alloc`. — end note]

[Example 2: The following is an allocator class template supporting the minimal interface that meets the requirements of 16.4.4.6.1:

```cpp
template<class T>
struct SimpleAllocator {
    using value_type = T;
    using allocator_traits = std::allocator_traits<T>;

    SimpleAllocator() {
        std::allocator_traits::ctor args;
    }

    template<class U> SimpleAllocator(const SimpleAllocator<U>& other);  

    T* allocate(std::size_t n);  
    void deallocate(T* p, std::size_t n);
    
    template<class U> bool operator==(const SimpleAllocator<U>& rhs) const;
};
```
]

16.4.4.6.2 Allocator completeness requirements

If `X` is an allocator class for type `T`, `X` additionally meets the allocator completeness requirements if, whether or not `T` is a complete type:

1. `X` is a complete type, and
2. all the member types of `allocator_traits<X>` (20.2.9) other than `value_type` are complete types.

16.4.5 Constraints on programs

16.4.5.1 Overview

Subclause 16.4.5 describes restrictions on C++ programs that use the facilities of the C++ standard library. The following subclauses specify constraints on the program’s use of namespaces (16.4.5.2.1), its use of various reserved names (16.4.5.3), its use of headers (16.4.5.4), its use of standard library classes as base classes (16.4.5.5), its definitions of replacement functions (16.4.5.6), and its installation of handler functions during execution (16.4.5.7).

16.4.5.2 Namespace use

Unless otherwise specified, the behavior of a C++ program is undefined if it adds declarations or definitions to namespace `std` or to a namespace within namespace `std`. 

§ 16.4.5.2.1
Unless explicitly prohibited, a program may add a template specialization for any standard library class template to namespace `std` provided that (a) the added declaration depends on at least one program-defined type and (b) the specialization meets the standard library requirements for the original template.\[161\]

The behavior of a C++ program is undefined if it declares an explicit or partial specialization of any standard library variable template, except where explicitly permitted by the specification of that variable template. [Note 1: The requirements on an explicit or partial specialization are stated by each variable template that grants such permission. — end note]

The behavior of a C++ program is undefined if it declares

(4.1) — an explicit specialization of any member function of a standard library class template, or

(4.2) — an explicit specialization of any member function template of a standard library class or class template, or

(4.3) — an explicit or partial specialization of any member class template of a standard library class or class template, or

(4.4) — a deduction guide for any standard library class template.

A program may explicitly instantiate a class template defined in the standard library only if the declaration (a) depends on the name of at least one program-defined type and (b) the instantiation meets the standard library requirements for the original template.

Let `F` denote a standard library function (16.4.6.4), a standard library static member function, or an instantiation of a standard library function template. Unless `F` is designated an `addressable function`, the behavior of a C++ program is unspecified (possibly ill-formed) if it explicitly or implicitly attempts to form a pointer to `F`.

[Note 2: Possible means of forming such pointers include application of the unary `k` operator (7.6.2.2), `addressof` (20.2.11), or a function-to-pointer standard conversion (7.3.4). — end note]

Moreover, the behavior of a C++ program is unspecified (possibly ill-formed) if it attempts to form a reference to `F` or if it attempts to form a pointer-to-member designating either a standard library non-static member function (16.4.6.5) or an instantiation of a standard library member function template.

A translation unit shall not declare namespace `std` to be an inline namespace (9.8.2).

### 16.4.5.2.2 Namespace `posix` [namespace.posix]

The behavior of a C++ program is undefined if it adds declarations or definitions to namespace `posix` or to a namespace within namespace `posix` unless otherwise specified. The namespace `posix` is reserved for use by ISO/IEC/IEEE 9945 and other POSIX standards.

### 16.4.5.2.3 Namespaces for future standardization [namespace.future]

Top-level namespaces whose `namespace-name` consists of `std` followed by one or more digits (5.10) are reserved for future standardization. The behavior of a C++ program is undefined if it adds declarations or definitions to such a namespace.

[Example 1: The top-level namespace `std2` is reserved for use by future revisions of this International Standard. — end example]

### 16.4.5.3 Reserved names [reserved.names]

#### 16.4.5.3.1 General [reserved.names.general]

The C++ standard library reserves the following kinds of names:

(1.1) — macros

(1.2) — global names

(1.3) — names with external linkage

If a program declares or defines a name in a context where it is reserved, other than as explicitly allowed by Clause 16, its behavior is undefined.

---

\[161\) Any library code that instantiates other library templates must be prepared to work adequately with any user-supplied specialization that meets the minimum requirements of this document.
16.4.5.3.2 Zombie names

In namespace std, the following names are reserved for previous standardization:

1. auto_ptr,
2. auto_ptr_ref,
3. binary_function,
4. binary_negate,
5. bind1st,
6. bind2nd,
7. binder1st,
8. binder2nd,
9. const_mem_fun1_ref_t,
10. const_mem_fun1_t,
11. const_mem_fun_ref_t,
12. const_mem_fun_t,
13. declare_no_pointers,
14. declare_reachable,
15. get_pointer_safety,
16. get_temporary_buffer,
17. get_unexpected,
18. gets,
19. is_literal_type,
20. is_literal_type_v,
21. mem_fun1_ref_t,
22. mem_fun1_t,
23. mem_fun_ref_t,
24. mem_fun_ref,
25. mem_fun_t,
26. mem_fun,
27. not1,
28. not2,
29. pointer_safety,
30. pointer_to_binary_function,
31. pointer_to_unary_function,
32. ptr_fun,
33. random_shuffle,
34. raw_storage_iterator,
35. result_of,
36. result_of_t,
37. return_temporary_buffer,
38. set_unexpected,
39. unary_function,
40. unary_negate,
41. uncaught_exception,
undeclare_no_pointers,
undeclare_reachable, and
unexpected_handler.

2 The following names are reserved as members for previous standardization, and may not be used as a name for object-like macros in portable code:

— argument_type,
— first_argument_type,
— io_state,
— open_mode,
— preferred,
— second_argument_type,
— seek_dir, and.
— strict.

3 The name stossc is reserved as a member function for previous standardization, and may not be used as a name for function-like macros in portable code.

4 The header names <ccomplex>, <ciso646>, <cstdalign>, <cstdbool>, and <ctgmath> are reserved for previous standardization.

16.4.5.3.3 Macro names

A translation unit that includes a standard library header shall not #define or #undef names declared in any standard library header.

A translation unit shall not #define or #undef names lexically identical to keywords, to the identifiers listed in Table 4, or to the attribute-tokens described in 9.12, except that the names likely and unlikely may be defined as function-like macros (15.6).

16.4.5.3.4 External linkage

Each name declared as an object with external linkage in a header is reserved to the implementation to designate that library object with external linkage, both in namespace std and in the global namespace.

Each global function signature declared with external linkage in a header is reserved to the implementation to designate that function signature with external linkage.

Each name from the C standard library declared with external linkage is reserved to the implementation for use as a name with extern "C" linkage, both in namespace std and in the global namespace.

Each function signature from the C standard library declared with external linkage is reserved to the implementation for use as a function signature with both extern "C" and extern "C++" linkage, or as a name of namespace scope in the global namespace.

16.4.5.3.5 Types

For each type T from the C standard library, the types ::T and std::T are reserved to the implementation and, when defined, ::T shall be identical to std::T.

16.4.5.3.6 User-defined literal suffixes

Literal suffix identifiers (12.6) that do not start with an underscore are reserved for future standardization. Literal suffix identifiers that contain a double underscore __ are reserved for use by C++ implementations.

16.4.5.4 Headers

If a file with a name equivalent to the derived file name for one of the C++ standard library headers is not provided as part of the implementation, and a file with that name is placed in any of the standard places for a source file to be included (15.3), the behavior is undefined.

162) The list of such reserved names includes errno, declared or defined in <cerrno> (19.4.2).
163) The list of such reserved function signatures with external linkage includes setjmp(jmp_buf), declared or defined in <setjmp> (17.13.3), and va_end(va_list), declared or defined in <stdarg> (17.13.2).
164) The function signatures declared in <cuchar> (23.5.5), <cwchar> (23.5.4), and <cwctype> (23.5.2) are always reserved, notwithstanding the restrictions imposed in subclause 4.5.1 of Amendment 1 to the C Standard for these headers.
16.4.5.5 Derived classes

Virtual member function signatures defined for a base class in the C++ standard library may be overridden in a derived class defined in the program (11.7.3).

16.4.5.6 Replacement functions

Clause 17 through Clause 33 and Annex D describe the behavior of numerous functions defined by the C++ standard library. Under some circumstances, however, certain of these function descriptions also apply to replacement functions defined in the program.

A C++ program may provide the definition for any of the following dynamic memory allocation function signatures declared in header `<new>` (6.7.5.5, 17.6.2):

- `operator new(std::size_t)`
- `operator new(std::size_t, std::align_val_t)`
- `operator new(std::size_t, const std::nothrow_t&)`
- `operator new(std::size_t, std::align_val_t, const std::nothrow_t&)`
- `operator delete(void*)`
- `operator delete(void*, std::size_t)`
- `operator delete(void*, std::align_val_t)`
- `operator delete(void*, std::size_t, std::align_val_t)`
- `operator delete(void*, const std::nothrow_t&)`
- `operator delete(void*, std::align_val_t, const std::nothrow_t&)`
- `operator new[](std::size_t)`
- `operator new[](std::size_t, std::align_val_t)`
- `operator new[](std::size_t, const std::nothrow_t&)`
- `operator new[](std::size_t, std::align_val_t, const std::nothrow_t&)`
- `operator delete[](void*)`
- `operator delete[](void*, std::size_t)`
- `operator delete[](void*, std::align_val_t)`
- `operator delete[](void*, std::size_t, std::align_val_t)`
- `operator delete[](void*, const std::nothrow_t&)`
- `operator delete[](void*, std::align_val_t, const std::nothrow_t&)`

The program’s definitions are used instead of the default versions supplied by the implementation (17.6.3). Such replacement occurs prior to program startup (6.3, 6.9.3). The program’s declarations shall not be specified as inline. No diagnostic is required.

16.4.5.7 Handler functions

The C++ standard library provides a default version of the following handler function (Clause 17):

1. `terminate_handler`

A C++ program may install different handler functions during execution, by supplying a pointer to a function defined in the program or the library as an argument to (respectively):

2. `set_new_handler`
3. `set_terminate`

See also subclauses 17.6.4, Storage allocation errors, and 17.9, Exception handling.

A C++ program can get a pointer to the current handler function by calling the following functions:

4. `get_new_handler`
5. `get_terminate`

Calling the `set_*` and `get_*` functions shall not incur a data race. A call to any of the `set_*` functions shall synchronize with subsequent calls to the same `set_*` function and to the corresponding `get_*` function.

16.4.5.8 Other functions

In certain cases (replacement functions, handler functions, operations on types used to instantiate standard library template components), the C++ standard library depends on components supplied by a C++ program. If these components do not meet their requirements, this document places no requirements on the implementation.

In particular, the behavior is undefined in the following cases:
For replacement functions (17.6.3), if the installed replacement function does not implement the semantics of the applicable Required behavior: paragraph.

For handler functions (17.6.4.3, 17.9.5.1), if the installed handler function does not implement the semantics of the applicable Required behavior: paragraph.

For types used as template arguments when instantiating a template component, if the operations on the type do not implement the semantics of the applicable Requirements subclause (16.4.4.6, 24.2, 25.3, 27.2, 28.2). Operations on such types can report a failure by throwing an exception unless otherwise specified.

If any replacement function or handler function or destructor operation exits via an exception, unless specifically allowed in the applicable Required behavior: paragraph.

If an incomplete type (6.8.1) is used as a template argument when instantiating a template component or evaluating a concept, unless specifically allowed for that component.

16.4.5.9 Function arguments

Each of the following applies to all arguments to functions defined in the C++ standard library, unless explicitly stated otherwise.

If an argument to a function has an invalid value (such as a value outside the domain of the function or a pointer invalid for its intended use), the behavior is undefined.

If a function argument is described as being an array, the pointer actually passed to the function shall have a value such that all address computations and accesses to objects (that would be valid if the pointer did point to the first element of such an array) are in fact valid.

If a function argument is bound to an rvalue reference parameter, the implementation may assume that this parameter is a unique reference to this argument, except that the argument passed to a move-assignment operator may be a reference to *this (16.4.6.15).

Note 1: If the type of a parameter is a forwarding reference (13.10.3.2) that is deduced to an lvalue reference type, then the argument is not bound to an rvalue reference. —end note

Note 2: If a program casts an lvalue to an xvalue while passing that lvalue to a library function (e.g., by calling the function with the argument std::move(x)), the program is effectively asking that function to treat that lvalue as a temporary object. The implementation is free to optimize away aliasing checks which would possibly be needed if the argument was an lvalue. —end note

16.4.5.10 Library object access

The behavior of a program is undefined if calls to standard library functions from different threads may introduce a data race. The conditions under which this may occur are specified in 16.4.6.10.

Note 1: Modifying an object of a standard library type that is shared between threads risks undefined behavior unless objects of that type are explicitly specified as being shareable without data races or the user supplies a locking mechanism. —end note

If an object of a standard library type is accessed, and the beginning of the object’s lifetime (6.7.3) does not happen before the access, or the access does not happen before the end of the object’s lifetime, the behavior is undefined unless otherwise specified.

Note 2: This applies even to objects such as mutexes intended for thread synchronization. —end note

16.4.5.11 Semantic requirements

A sequence Args of template arguments is said to model a concept C if Args satisfies C (13.5.3) and meets all semantic requirements (if any) given in the specification of C.

If the validity or meaning of a program depends on whether a sequence of template arguments models a concept, and the concept is satisfied but not modeled, the program is ill-formed, no diagnostic required.

If the semantic requirements of a declaration’s constraints (16.3.2.3) are not modeled at the point of use, the program is ill-formed, no diagnostic required.

16.4.6 Conforming implementations

16.4.6.1 Overview

Subclause 16.4.6 describes the constraints upon, and latitude of, implementations of the C++ standard library.
An implementation’s use of headers is discussed in 16.4.6.2, its use of macros in 16.4.6.3, non-member functions in 16.4.6.4, member functions in 16.4.6.5, data race avoidance in 16.4.6.10, access specifiers in 16.4.6.11, class derivation in 16.4.6.12, and exceptions in 16.4.6.13.

16.4.6.2 Headers

A C++ header may include other C++ headers. A C++ header shall provide the declarations and definitions that appear in its synopsis. A C++ header shown in its synopsis as including other C++ headers shall provide the declarations and definitions that appear in the synopses of those other headers.

Certain types and macros are defined in more than one header. Every such entity shall be defined such that any header that defines it may be included after any other header that also defines it (6.3).

The C standard library headers (17.14) shall include only their corresponding C++ standard library header, as described in 16.4.2.3.

16.4.6.3 Restrictions on macro definitions

The names and global function signatures described in 16.4.2.2 are reserved to the implementation.

All object-like macros defined by the C standard library and described in this Clause as expanding to integral constant expressions are also suitable for use in #if preprocessing directives, unless explicitly stated otherwise.

16.4.6.4 Non-member functions

It is unspecified whether any non-member functions in the C++ standard library are defined as inline (9.2.8).

A call to a non-member function signature described in Clause 17 through Clause 33 and Annex D shall behave as if the implementation declared no additional non-member function signatures.

An implementation shall not declare a non-member function signature with additional default arguments.

Unless otherwise specified, calls made by functions in the standard library to non-operator, non-member functions do not use functions from another namespace which are found through argument-dependent name lookup (6.5.4).

[Note 1: The phrase “unless otherwise specified” applies to cases such as the swappable with requirements (16.4.4.3). The exception for overloaded operators allows argument-dependent lookup in cases like that of ostream_iterator::operator= (25.6.3.3):

Effects:

*out_stream << value;
if (delim != 0)
   *out_stream << delim;
return *this;
—end note]

16.4.6.5 Member functions

It is unspecified whether any member functions in the C++ standard library are defined as inline (9.2.8).

For a non-virtual member function described in the C++ standard library, an implementation may declare a different set of member function signatures, provided that any call to the member function that would select an overload from the set of declarations described in this document behaves as if that overload were selected.

[Note 1: For instance, an implementation can add parameters with default values, or replace a member function with default arguments with two or more member functions with equivalent behavior, or add additional signatures for a member function name. —end note]

16.4.6.6 Friend functions

Whenever this document specifies a friend declaration of a function or function template within a class or class template definition, that declaration shall be the only declaration of that function or function template provided by an implementation.

[Note 1: In particular, an implementation is not allowed to provide an additional declaration of that function or function template at namespace scope. —end note]

[Note 2: Such a friend function or function template declaration is known as a hidden friend, as it is visible neither to ordinary unqualified lookup (6.5.3) nor to qualified lookup (6.5.5). —end note]

165) A valid C++ program always calls the expected library non-member function. An implementation can also define additional non-member functions that would otherwise not be called by a valid C++ program.
16.4.6.7 Constexpr functions and constructors

This document explicitly requires that certain standard library functions are constexpr (9.2.6). An implementation shall not declare any standard library function signature as constexpr except for those where it is explicitly required. Within any header that provides any non-defining declarations of constexpr functions or constructors an implementation shall provide corresponding definitions.

16.4.6.8 Requirements for stable algorithms

When the requirements for an algorithm state that it is “stable” without further elaboration, it means:

1. For the sort algorithms the relative order of equivalent elements is preserved.
2. For the remove and copy algorithms the relative order of the elements that are not removed is preserved.
3. For the merge algorithms, for equivalent elements in the original two ranges, the elements from the first range (preserving their original order) precede the elements from the second range (preserving their original order).

16.4.6.9 Reentrancy

Except where explicitly specified in this document, it is implementation-defined which functions in the C++ standard library may be recursively reentered.

16.4.6.10 Data race avoidance

This subclause specifies requirements that implementations shall meet to prevent data races (6.9.2). Every standard library function shall meet each requirement unless otherwise specified. Implementations may prevent data races in cases other than those specified below.

2. A C++ standard library function shall not directly or indirectly access objects (6.9.2) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s arguments, including this.
3. A C++ standard library function shall not directly or indirectly modify objects (6.9.2) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s non-const arguments, including this.
4. [Note 1: This means, for example, that implementations can’t use an object with static storage duration for internal purposes without synchronization because doing so can cause a data race even in programs that do not explicitly share objects between threads. — end note]
5. A C++ standard library function shall not access objects indirectly accessible via its arguments or via elements of its container arguments except by invoking functions required by its specification on those container elements.
6. Operations on iterators obtained by calling a standard library container or string member function may access the underlying container, but shall not modify it.
7. [Note 2: In particular, container operations that invalidate iterators conflict with operations on iterators associated with that container. — end note]
8. Unless otherwise specified, C++ standard library functions shall perform all operations solely within the current thread if those operations have effects that are visible (6.9.2) to users.
9. [Note 3: This allows implementations to parallelize operations if there are no visible side effects. — end note]

16.4.6.11 Protection within classes

It is unspecified whether any function signature or class described in Clause 17 through Clause 33 and Annex D is a friend of another class in the C++ standard library.

16.4.6.12 Derived classes

An implementation may derive any class in the C++ standard library from a class with a name reserved to the implementation.

2. Certain classes defined in the C++ standard library are required to be derived from other classes in the C++ standard library. An implementation may derive such a class directly from the required base or indirectly through a hierarchy of base classes with names reserved to the implementation.
In any case:

(3.1) Every base class described as `virtual` shall be virtual;

(3.2) Every base class not specified as `virtual` shall not be virtual;

(3.3) Unless explicitly stated otherwise, types with distinct names shall be distinct types.

[Note 1: There is an implicit exception to this rule for types that are described as synonyms (9.2.4, 9.9), such as `size_t` (17.2) and `streamoff` (31.2.2). — end note]

All types specified in the C++ standard library shall be non-`final` types unless otherwise specified.

16.4.6.13 Restrictions on exception handling

Any of the functions defined in the C++ standard library can report a failure by throwing an exception of a type described in its `Throws` paragraph, or of a type derived from a type named in the `Throws` paragraph that would be caught by an exception handler for the base type.

Functions from the C standard library shall not throw exceptions except when such a function calls a program-supplied function that throws an exception.

Destructor operations defined in the C++ standard library shall not throw exceptions. Every destructor in the C++ standard library shall behave as if it had a non-throwing exception specification.

Functions defined in the C++ standard library that do not have a `Throws` paragraph do have a potentially-throwing exception specification may throw implementation-defined exceptions. Implementations should report errors by throwing exceptions of or derived from the standard exception classes (17.6.4.1, 17.9, 19.2).

An implementation may strengthen the exception specification for a non-virtual function by adding a non-throwing exception specification.

16.4.6.14 Value of error codes

Certain functions in the C++ standard library report errors via a `std::error_code` (19.5.4.1) object. That object’s `category()` member shall return `std::system_category()` for errors originating from the operating system, or a reference to an implementation-defined `error_category` object for errors originating elsewhere. The implementation shall define the possible values of `value()` for each of these error categories.

[Example 1: For operating systems that are based on POSIX, implementations should define the `std::system_category()` values as identical to the POSIX `errno` values, with additional values as defined by the operating system’s documentation. Implementations for operating systems that are not based on POSIX should define values identical to the operating system’s values. For errors that do not originate from the operating system, the implementation may provide enums for the associated values. — end example]

16.4.6.15 Moved-from state of library types

Objects of types defined in the C++ standard library may be moved from (11.4.5.3). Move operations may be explicitly specified or implicitly generated. Unless otherwise specified, such moved-from objects shall be placed in a valid but unspecified state.

An object of a type defined in the C++ standard library may be move-assigned (11.4.6) to itself. Unless otherwise specified, such an assignment places the object in a valid but unspecified state.

166) That is, the C library functions can all be treated as if they are marked `noexcept`. This allows implementations to make performance optimizations based on the absence of exceptions at runtime.

167) The functions `qsort()` and `bsearch()` (27.12) meet this condition.

168) In particular, they can report a failure to allocate storage by throwing an exception of type `bad_alloc`, or a class derived from `bad_alloc` (17.6.4.1).
17 Language support library

17.1 General

1 This Clause describes the function signatures that are called implicitly, and the types of objects generated implicitly, during the execution of some C++ programs. It also describes the headers that declare these function signatures and define any related types.

2 The following subclauses describe common type definitions used throughout the library, characteristics of the predefined types, functions supporting start and termination of a C++ program, support for dynamic memory management, support for dynamic type identification, support for exception processing, support for initializer lists, and other runtime support, as summarized in Table 38.

```

§ 17.2.1
template<class IntType>
    constexpr IntType to_integer(byte b) noexcept;
}

#define NULL see below
#define offsetof(P, D) see below

1 The contents and meaning of the header <cassert> are the same as the C standard library header <cassert.h>, except that it does not declare the type wchar_t, that it also declares the type byte and its associated operations (17.2.5), and as noted in 17.2.3 and 17.2.4.

See also: ISO C 7.19

### 17.2.2 Header <cstdlib> synopsis

```
namespace std {
    using size_t = see below; // freestanding
    using div_t = see below;
    using ldiv_t = see below;
    using lldiv_t = see below;
}
```

```
#define NULL see below // freestanding
#define EXIT_FAILURE see below
#define EXIT_SUCCESS see below
#define RAND_MAX see below
#define MB_CUR_MAX see below
```

```
namespace std {
    // Exposition-only function type aliases
    extern "C" using c_atexit_handler = void(); // exposition only
    extern "C++" using atexit_handler = void(); // exposition only
    extern "C" using c_compare_pred = int(const void*, const void*); // exposition only
    extern "C++" using compare_pred = int(const void*, const void*); // exposition only

    // 17.5, start and termination
    [[noreturn]] void abort() noexcept; // freestanding

constexpr ldiv_t ldiv(long int numer, long int denom);
constexpr lldiv_t lldiv(long long int numer, long long int denom);

1 The contents and meaning of the header <cstdlib> are the same as the C standard library header <stdlib.h>, except that it does not declare the type wchar_t, and except as noted in 17.2.3, 17.2.4, 17.5, 20.2.12, 23.5.6, 27.12, 28.5.10, and 28.7.2.

[Note 1: Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (16.2). — end note]

See also: ISO C 7.22

17.2.3 Null pointers [support.types.nullptr]

1 The type nullptr_t is a synonym for the type of a nullptr expression, and it has the characteristics described in 6.8.2 and 7.3.12.

[Note 1: Although nullptr’s address cannot be taken, the address of another nullptr_t object that is an lvalue can be taken. — end note]

2 The macro NULL is an implementation-defined null pointer constant.¹⁶⁹

See also: ISO C 7.19

17.2.4 Sizes, alignments, and offsets [support.types.layout]

1 The macro offsetof(type, member-designator) has the same semantics as the corresponding macro in the C standard library header <stddef.h>, but accepts a restricted set of type arguments in this document. Use of the offsetof macro with a type other than a standard-layout class (11.2) is conditionally-supported.¹⁷⁰

The expression offsetof(type, member-designator) is never type-dependent (13.8.3.3) and it is value-dependent (13.8.3.4) if and only if type is dependent. The result of applying the offsetof macro to a static

¹⁶⁹) Possible definitions include 0 and 0L, but not (void*)0.
¹⁷⁰) Note that offsetof is required to work as specified even if unary operator& is overloaded for any of the types involved.
data member or a function member is undefined. No operation invoked by the offsetof macro shall throw an exception and noexcept(offsetof(type, member-designator)) shall be true.

The type ptrdiff_t is an implementation-defined signed integer type that can hold the difference of two subscripts in an array object, as described in 7.6.6.

The type size_t is an implementation-defined unsigned integer type that is large enough to contain the size in bytes of any object (7.6.2.5).

Recommended practice: An implementation should choose types for ptrdiff_t and size_t whose integer conversion ranks (6.8.6) are no greater than that of signed long int unless a larger size is necessary to contain all the possible values.

The type max_align_t is a trivial standard-layout type whose alignment requirement is at least as great as that of every scalar type, and whose alignment requirement is supported in every context (6.7.6).

See also: ISO C 7.19

17.2.5 byte type operations [support.types.byteops]

template<class IntType>
constexpr byte& operator<<=(byte& b, IntType shift) noexcept;

Constraints: is_integral_v<IntType> is true.

Effects: Equivalent to: return b = b << shift;

template<class IntType>
constexpr byte operator<<(byte b, IntType shift) noexcept;

Constraints: is_integral_v<IntType> is true.

Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(b) << shift);

template<class IntType>
constexpr byte& operator>>=(byte& b, IntType shift) noexcept;

Constraints: is_integral_v<IntType> is true.

Effects: Equivalent to: return b = b >> shift;

template<class IntType>
constexpr byte operator>>(byte b, IntType shift) noexcept;

Constraints: is_integral_v<IntType> is true.

Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(b) >> shift);

cconstexpr byte& operator|=(byte& l, byte r) noexcept;

Effects: Equivalent to: return l = l | r;

cconstexpr byte operator|(byte l, byte r) noexcept;

Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(l) | static_cast<unsigned int>(r));

cconstexpr byte& operator&=(byte& l, byte r) noexcept;

Effects: Equivalent to: return l = l & r;

cconstexpr byte operator&(byte l, byte r) noexcept;

Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(l) & static_cast<unsigned int>(r));

cconstexpr byte& operator^=(byte& l, byte r) noexcept;

Effects: Equivalent to: return l = l ^ r;

cconstexpr byte operator^ (byte l, byte r) noexcept;

Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(l) ^ static_cast<unsigned int>(r));

§ 17.2.5
constexpr byte operator^(byte l, byte r) noexcept;

Effects: Equivalent to:
return static_cast<byte>(static_cast<unsigned int>(l) ^ static_cast<unsigned int>(r));

constexpr byte operator~(byte b) noexcept;

Effects: Equivalent to:
return static_cast<byte>(~static_cast<unsigned int>(b));

template<class IntType>
constexpr IntType to_integer(byte b) noexcept;

Constraints: is_integral_v<IntType> is true.

Effects: Equivalent to:
return static_cast<IntType>(b);

17.3 Implementation properties [support.limits]

17.3.1 General [support.limits.general]

The headers `<limits>` (17.3.3), `<climits>` (17.3.6), and `<cfloat>` (17.3.7) supply characteristics of implementation-dependent arithmetic types (6.8.2).

17.3.2 Header `<version>` synopsis [version.syn]

Each of the macros defined in `<version>` supplies implementation-dependent information about the C++ standard library (e.g., version number and release date).

Note: Future revisions of C++ might replace the values of these macros with greater values. — end note

17.3.4 Ενάρξη float_round_style

namespace std {
    enum float_round_style {
        round_indeterminate = -1,
        round_toward_zero = 0,
        round_to_nearest = 1,
        round_toward_infinity = 2,
        round_toward_neg_infinity = 3
    };
}

1 The rounding mode for floating-point arithmetic is characterized by the values:

(1.1) — round_indeterminate if the rounding style is indeterminable
(1.2) — round_toward_zero if the rounding style is toward zero
(1.3) — round_to_nearest if the rounding style is to the nearest representable value
(1.4) — round_toward_infinity if the rounding style is toward infinity
(1.5) — round_toward_neg_infinity if the rounding style is toward negative infinity

17.3.5 Κλάση καλύμματος numeric_limits

17.3.5.1 Γενικά

1 The numeric_limits class template provides a C++ program with information about various properties of the implementation’s representation of the arithmetic types.

namespace std {
    template<class T> class numeric_limits {
        public:
            static constexpr bool is_specialized = false;
            static constexpr T min() noexcept { return T(); }
            static constexpr T max() noexcept { return T(); }
            static constexpr int digits = 0;
            static constexpr int digits10 = 0;
            static constexpr int max_digits10 = 0;
            static constexpr bool is_signed = false;
            static constexpr bool is_integer = false;
            static constexpr bool is_exact = false;
            static constexpr int radix = 0;
            static constexpr T epsilon() noexcept { return T(); }
            static constexpr T round_error() noexcept { return T(); }
            static constexpr int min_exponent = 0;
            static constexpr int min_exponent10 = 0;
            static constexpr int max_exponent = 0;
            static constexpr int max_exponent10 = 0;
            static constexpr T epsilon() noexcept { return T(); }
            static constexpr T round_error() noexcept { return T(); }

            static constexpr int min_exponent = 0;
            static constexpr int min_exponent10 = 0;
            static constexpr int max_exponent = 0;
            static constexpr int max_exponent10 = 0;

§ 17.3.5.1 516
static constexpr bool has_infinity = false;
static constexpr bool has_quiet_NaN = false;
static constexpr bool has_signaling_NaN = false;
static constexpr T infinity() noexcept { return T(); }
static constexpr T quiet_NaN() noexcept { return T(); }
static constexpr T signaling_NaN() noexcept { return T(); }
static constexpr T denorm_min() noexcept { return T(); }
static constexpr bool is_iec559 = false;
static constexpr bool is_bounded = false;
static constexpr bool is_modulo = false;
static constexpr bool traps = false;
static constexpr bool tinyness_before = false;
static constexpr float_round_style round_style = round_toward_zero;
};

For all members declared **static constexpr** in the **numeric_limits** template, specializations shall define these values in such a way that they are usable as constant expressions.

For the **numeric_limits** primary template, all data members are value-initialized and all member functions return a value-initialized object.

[Note 1: This means all members have zero or **false** values unless **numeric_limits** is specialized for a type. — end note]

Specializations shall be provided for each arithmetic type, both floating-point and integer, including **bool**. The member **is_specialized** shall be **true** for all such specializations of **numeric_limits**.

The value of each member of a specialization of **numeric_limits** on a cv-qualified type **cv T** shall be equal to the value of the corresponding member of the specialization on the unqualified type **T**.

Non-arithmetic standard types, such as **complex<T>** (28.4.3), shall not have specializations.

### 17.3.5.2 **numeric_limits** members

1. Each member function defined in this subclause is signal-safe (17.13.5).

   - **static constexpr T min() noexcept;**
     Minimum finite value.\(^{171}\)
     \[\text{For floating-point types with subnormal numbers, returns the minimum positive normalized value.}\]
     \[\text{Meaningful for all specializations in which **is_bounded** != **false**, or **is_bounded** == **false** && **is_}
     \text{-signed** == **false.}\]

   - **static constexpr T max() noexcept;**
     Maximum finite value.\(^{172}\)
     \[\text{Meaningful for all specializations in which **is_bounded** != **false.}\]

   - **static constexpr T lowest() noexcept;**
     A finite value \(x\) such that there is no other finite value \(y\) where \(y < x\).\(^{173}\)
     \[\text{Meaningful for all specializations in which **is_bounded** != **false.}\]

   - **static constexpr int digits;**
     Number of **radix** digits that can be represented without change.
     \[\text{For integer types, the number of non-sign bits in the representation.}\]
     \[\text{For floating-point types, the number of **radix** digits in the mantissa.}\] \(^{174}\)

---

\(^{171}\) Equivalent to **CHAR_MIN**, **SHRT_MIN**, **FLT_MIN**, **DBL_MIN**, etc.

\(^{172}\) Equivalent to **CHAR_MAX**, **SHRT_MAX**, **FLT_MAX**, **DBL_MAX**, etc.

\(^{173}\) **lowest()** is necessary because not all floating-point representations have a smallest (most negative) value that is the negative of the largest (most positive) finite value.

\(^{174}\) Equivalent to **FLT_MANT_DIG**, **DBL_MANT_DIG**, **LDBL_MANT_DIG**.
static constexpr int digits10;
    Number of base 10 digits that can be represented without change.\textsuperscript{175}
    Meaningful for all specializations in which \texttt{is\_bounded} != \texttt{false}.

static constexpr int max_digits10;
    Number of base 10 digits required to ensure that values which differ are always differentiated.
    Meaningful for all floating-point types.

static constexpr bool is_signed;
    \texttt{true} if the type is signed.
    Meaningful for all specializations.

static constexpr bool is_integer;
    \texttt{true} if the type is integer.
    Meaningful for all specializations.

static constexpr bool is_exact;
    \texttt{true} if the type uses an exact representation. All integer types are exact, but not all exact types are
    integer. For example, rational and fixed-exponent representations are exact but not integer.
    Meaningful for all specializations.

static constexpr int radix;
    For floating-point types, specifies the base or radix of the exponent representation (often 2).\textsuperscript{176}
    For integer types, specifies the base of the representation.\textsuperscript{177}
    Meaningful for all specializations.

static constexpr T epsilon() noexcept;
    Machine epsilon: the difference between 1 and the least value greater than 1 that is representable.\textsuperscript{178}
    Meaningful for all floating-point types.

static constexpr T round_error() noexcept;
    Measure of the maximum rounding error.\textsuperscript{179}

static constexpr int min_exponent;
    Minimum negative integer such that \texttt{radix} raised to the power of one less than that integer is a
    normalized floating-point number.\textsuperscript{180}
    Meaningful for all floating-point types.

static constexpr int min_exponent10;
    Minimum negative integer such that 10 raised to that power is in the range of normalized floating-point
    numbers.\textsuperscript{181}
    Meaningful for all floating-point types.

static constexpr int max_exponent;
    Maximum positive integer such that \texttt{radix} raised to the power one less than that integer is a representable
    finite floating-point number.\textsuperscript{182}

\textsuperscript{175} Equivalent to \texttt{FLT\_DIG}, \texttt{DBL\_DIG}, \texttt{LDBL\_DIG}.
\textsuperscript{176} Equivalent to \texttt{FLT\_RADIX}.
\textsuperscript{177} Distinguishes types with bases other than 2 (e.g., BCD).
\textsuperscript{178} Equivalent to \texttt{FLT\_EPSILON}, \texttt{DBL\_EPSILON}, \texttt{LDBL\_EPSILON}.
\textsuperscript{179} Rounding error is described in LIA-1 Section 5.2.4 and Annex C Rationale Section C.5.2.4 — Rounding and rounding
    constants.
\textsuperscript{180} Equivalent to \texttt{FLT\_MIN\_EXP}, \texttt{DBL\_MIN\_EXP}, \texttt{LDBL\_MIN\_EXP}.
\textsuperscript{181} Equivalent to \texttt{FLT\_MIN\_10\_EXP}, \texttt{DBL\_MIN\_10\_EXP}, \texttt{LDBL\_MIN\_10\_EXP}.
\textsuperscript{182} Equivalent to \texttt{FLT\_MAX\_EXP}, \texttt{DBL\_MAX\_EXP}, \texttt{LDBL\_MAX\_EXP}.
Meaningful for all floating-point types.

```cpp
static constexpr int max_exponent10;
```

Maximum positive integer such that 10 raised to that power is in the range of representable finite floating-point numbers.\(^{183}\)

Meaningful for all floating-point types.

```cpp
static constexpr bool has_infinity;
```

true if the type has a representation for positive infinity.

Meaningful for all floating-point types.

```cpp
static constexpr bool has_quiet_NaN;
```

true if the type has a representation for a quiet (non-signaling) “Not a Number”.\(^{184}\)

Meaningful for all floating-point types.

```cpp
static constexpr bool has_signaling_NaN;
```

true if the type has a representation for a signaling “Not a Number”.\(^{185}\)

Meaningful for all floating-point types.

```cpp
static constexpr T infinity() noexcept;
```

Representation of positive infinity, if available.\(^{186}\)

Meaningful for all specializations for which has_infinity != false. Required in specializations for which is_iec559 != false.

```cpp
static constexpr T quiet_NaN() noexcept;
```

Representation of a quiet “Not a Number”, if available.\(^{187}\)

Meaningful for all specializations for which has_quiet_NaN != false. Required in specializations for which is_iec559 != false.

```cpp
static constexpr T signaling_NaN() noexcept;
```

Representation of a signaling “Not a Number”, if available.\(^{188}\)

Meaningful for all specializations for which has_signaling_NaN != false. Required in specializations for which is_iec559 != false.

```cpp
static constexpr T denorm_min() noexcept;
```

Minimum positive subnormal value, if available.\(^{189}\) Otherwise, minimum positive normalized value.

Meaningful for all floating-point types.

```cpp
static constexpr bool is_iec559;
```

true if and only if the type adheres to ISO/IEC/IEEE 60559.\(^{190}\)

[Note 1: The value is true for any of the types float16_t, float32_t, float64_t, or float128_t, if present (6.8.3). — end note]

Meaningful for all floating-point types.

---

\(^{183}\) Equivalent to FLT_MAX_10_EXP, DBL_MAX_10_EXP, LDBL_MAX_10_EXP.

\(^{184}\) Required by LIA-1.

\(^{185}\) Required by LIA-1.

\(^{186}\) Required by LIA-1.

\(^{187}\) Required by LIA-1.

\(^{188}\) Required by LIA-1.

\(^{189}\) Required by LIA-1.

static constexpr bool is_bounded;
true if the set of values representable by the type is finite.\[191\]

[Note 2: All fundamental types (6.8.2) are bounded. This member would be false for arbitrary precision types. — end note]

Meaningful for all specializations.

static constexpr bool is_modulo;
true if the type is modulo.\[192\] A type is modulo if, for any operation involving +, -, or * on values of that type whose result would fall outside the range [min(), max()], the value returned differs from the true value by an integer multiple of max() - min() + 1.

[Example 1: is_modulo is false for signed integer types (6.8.2) unless an implementation, as an extension to this document, defines signed integer overflow to wrap. — end example]

Meaningful for all specializations.

static constexpr bool traps;
true if, at the start of the program, there exists a value of the type that would cause an arithmetic operation using that value to trap.\[193\]

Meaningful for all specializations.

static constexpr bool tinyness_before;
true if tinyness is detected before rounding.\[194\]

Meaningful for all floating-point types.

static constexpr float_round_style round_style;
The rounding style for the type.\[195\]

Meaningful for all floating-point types. Specializations for integer types shall return round_toward_-zero.

17.3.5.3 numeric_limits specializations [numeric.special]

All members shall be provided for all specializations. However, many values are only required to be meaningful under certain conditions (for example, epsilon() is only meaningful if is_integer is false). Any value that is not “meaningful” shall be set to 0 or false.

[Example 1:]

```cpp
namespace std {
    template<> class numeric_limits<float> {
        public:
            static constexpr bool is_specialized = true;

            static constexpr float min() noexcept { return 1.17549435E-38F; }
            static constexpr float max() noexcept { return 3.40282347E+38F; }
            static constexpr float lowest() noexcept { return -3.40282347E+38F; }

            static constexpr int digits = 24;
            static constexpr int digits10 = 6;
            static constexpr int max_digits10 = 9;

            static constexpr bool is_signed = true;
            static constexpr bool is_integer = false;
            static constexpr bool is_exact = false;

            static constexpr int radix = 2;
            static constexpr float epsilon() noexcept { return 1.19209290E-07F; }
        }
    }
}
```

\[191\] Required by LIA-1.
\[192\] Required by LIA-1.
\[193\] Required by LIA-1.
\[194\] Refer to ISO/IEC/IEEE 60559. Required by LIA-1.
\[195\] Equivalent to FLT_ROUNDS. Required by LIA-1.
static constexpr float round_error() noexcept { return 0.5F; }

static constexpr int min_exponent = -125;
static constexpr int min_exponent10 = -37;
static constexpr int max_exponent = +128;
static constexpr int max_exponent10 = +38;

static constexpr bool has_infinity = true;
static constexpr bool has_quiet_NaN = true;
static constexpr bool has_signaling_NaN = true;

static constexpr float infinity() noexcept { return \texttt{value}; }
static constexpr float quiet_NaN() noexcept { return \texttt{value}; }
static constexpr float signaling_NaN() noexcept { return \texttt{value}; }
static constexpr float denorm_min() noexcept { return min(); }

static constexpr bool is_iec559 = true;
static constexpr bool is_bounded = true;
static constexpr bool is_modulo = false;
static constexpr bool tinyness_before = true;

static constexpr float_round_style round_style = round_to_nearest;

—end example]}

3 The specialization for \texttt{bool} shall be provided as follows:

namespace std {
    template<> class numeric_limits<bool> {
        public:
            static constexpr bool is_specialized = true;
            static constexpr bool min() noexcept { return false; }
            static constexpr bool max() noexcept { return true; }
            static constexpr bool lowest() noexcept { return false; }
            static constexpr int digits = 1;
            static constexpr int digits10 = 0;
            static constexpr int max_digits10 = 0;
            static constexpr bool is_signed = false;
            static constexpr bool is_integer = true;
            static constexpr bool is_exact = true;
            static constexpr int radix = 2;
            static constexpr bool epsilon() noexcept { return 0; }
            static constexpr bool round_error() noexcept { return 0; }
            static constexpr int min_exponent = 0;
            static constexpr int min_exponent10 = 0;
            static constexpr int max_exponent = 0;
            static constexpr int max_exponent10 = 0;
            static constexpr bool has_infinity = false;
            static constexpr bool has_quiet_NaN = false;
            static constexpr bool has_signaling_NaN = false;
            static constexpr bool infinity() noexcept { return 0; }
            static constexpr bool quiet_NaN() noexcept { return 0; }
            static constexpr bool signaling_NaN() noexcept { return 0; }
            static constexpr bool denorm_min() noexcept { return 0; }
            static constexpr bool is_iec559 = false;
            static constexpr bool is_bounded = true;
            static constexpr bool is_modulo = false;

§ 17.3.5.3
static constexpr bool traps = false;
static constexpr bool tinyness_before = false;
static constexpr float_round_style round_style = round_toward_zero;
};
}

17.3.6 Header <climits> synopsis

All freestanding
#define CHAR_BIT see below

17.4 Arithmetic types [support.arith.types]

17.4.1 Header `<cstdint>` synopsis [cstdint.syn]

1 The header `<cstdint>` supplies integer types having specified widths, and macros that specify limits of integer types.

```c
// all freestanding
namespace std {
  using int8_t = signed integer type; // optional
  using int16_t = signed integer type; // optional
  using int32_t = signed integer type; // optional
  using int64_t = signed integer type; // optional
  using int_least8_t = signed integer type;
  using int_least16_t = signed integer type;
  using int_least32_t = signed integer type;
  using int_least64_t = signed integer type;
  using intmax_t = signed integer type;
  using intptr_t = signed integer type; // optional
  using uint8_t = unsigned integer type; // optional
  using uint16_t = unsigned integer type; // optional
  using uint32_t = unsigned integer type; // optional
  using uint64_t = unsigned integer type; // optional
  using uint_least8_t = unsigned integer type;
  using uint_least16_t = unsigned integer type;
  using uint_least32_t = unsigned integer type;
  using uint_least64_t = unsigned integer type;
  using uintmax_t = unsigned integer type;
  using uintptr_t = unsigned integer type; // optional
}
```
using uintmax_t = unsigned integer type;
using uintptr_t = unsigned integer type; // optional

#define INT_N_MIN see below
#define INT_N_MAX see below
#define UINT_N_MAX see below
#define INT_FAST_N_MIN see below
#define INT_FAST_N_MAX see below
#define UINT_FAST_N_MAX see below

#define INTMAX_MAX see below
#define UINTMAX_MAX see below
#define INTPTR_MIN see below
#define INTPTR_MAX see below
#define UINTPTR_MAX see below
#define PTRDIFF_MIN see below
#define PTRDIFF_MAX see below
#define SIZE_MAX see below
#define SIG_ATOMIC_MIN see below
#define SIG_ATOMIC_MAX see below
#define WCHAR_MIN see below
#define WCHAR_MAX see below
#define WINT_MIN see below
#define WINT_MAX see below
#define INT_N_C(value) see below
#define UINT_N_C(value) see below
#define INTMAX_C(value) see below
#define UINTMAX_C(value) see below

The header defines all types and macros the same as the C standard library header <stdint.h>.

See also: ISO C 7.20

All types that use the placeholder \( N \) are optional when \( N \) is not 8, 16, 32, or 64. The exact-width types int\( N \)_t and uint\( N \)_t for \( N = 8, 16, 32, \) and 64 are also optional; however, if an implementation defines integer types with the corresponding width and no padding bits, it defines the corresponding typedef-names. Each of the macros listed in this subclause is defined if and only if the implementation defines the corresponding typedef-name.

\[ \text{Note 1: The macros INT}_N\text{C and UINT}_N\text{C correspond to the typedef-names int_least}_N\_t and uint_least}_N\_t, respectively. — end note} \]

### 17.4.2 Header <stdfloat> synopsis [stdfloat.syn]

The header <stdfloat> defines type aliases for the optional extended floating-point types that are specified in 6.8.3.

```cpp
namespace std {
  #if defined(__STDCPP_FLOAT16_T__)
    using float16_t = implementation-defined; // see 6.8.3
  #endif
  #if defined(__STDCPP_FLOAT32_T__)
    using float32_t = implementation-defined; // see 6.8.3
  #endif
}
```
#endif
#if defined(__STDCPP_FLOAT64_T__)
  using float64_t = implementation-defined; // see 6.8.3
#endif
#if defined(__STDCPP_FLOAT128_T__)
  using float128_t = implementation-defined;
  // see 6.8.3
#endif
#if defined(__STDCPP_BFLOAT16_T__)
  using bfloat16_t = implementation-defined;
  // see 6.8.3
#endif
}

17.5 Startup and termination

[Note 1: The header <cstdlib> (17.2.2) declares the functions described in this subclause. — end note]

[[noreturn]] void _Exit(int status) noexcept;

Effects: This function has the semantics specified in the C standard library.

Remarks: The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to atexit() (6.9.3.4). The function _Exit is signal-safe (17.13.5).

[[noreturn]] void abort() noexcept;

Effects: This function has the semantics specified in the C standard library.

Remarks: The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to atexit() (6.9.3.4). The function abort is signal-safe (17.13.5).

int atexit(atexit-handler* f) noexcept;
int atexit(c-atexit-handler* f) noexcept;

Effects: The atexit() functions register the function pointed to by f to be called without arguments at normal program termination. It is unspecified whether a call to atexit() that does not happen before (6.9.2) a call to exit() will succeed.

[Note 2: The atexit() functions do not introduce a data race (16.4.6.10). — end note]

Implementation limits: The implementation shall support the registration of at least 32 functions.

Returns: The atexit() function returns zero if the registration succeeds, nonzero if it fails.

[[noreturn]] void exit(int status);

Effects:

— First, objects with thread storage duration and associated with the current thread are destroyed. Next, objects with static storage duration are destroyed and functions registered by calling atexit are called. See 6.9.3.4 for the order of destructions and calls. (Objects with automatic storage duration are not destroyed as a result of calling exit().) If a registered function invoked by exit exits via an exception, the function std::terminate is invoked (14.6.2).

— Next, all open C streams (as mediated by the function signatures declared in <cstdio> (31.13.1)) with unwritten buffered data are flushed, all open C streams are closed, and all files created by calling tmpfile() are removed.

— Finally, control is returned to the host environment. If status is zero or EXIT_SUCCESS, an implementation-defined form of the status successful termination is returned. If status is EXIT_FAILURE, an implementation-defined form of the status unsuccessful termination is returned. Otherwise the status returned is implementation-defined.

196) A function is called for every time it is registered.
197) Objects with automatic storage duration are all destroyed in a program whose main function (6.9.3.1) contains no objects with automatic storage duration and executes the call to exit(). Control can be transferred directly to such a main function by throwing an exception that is caught in main.
198) The macros EXIT_FAILURE and EXIT_SUCCESS are defined in <cstdlib> (17.2.2).
int at_quick_exit(c-atexit-handler f) noexcept;
int at_quick_exit(atexit-handler f) noexcept;

Effects: The at_quick_exit() functions register the function pointed to by f to be called without arguments when quick_exit is called. It is unspecified whether a call to at_quick_exit() that does not happen before (6.9.2) all calls to quick_exit will succeed.

[Note 3: The at_quick_exit() functions do not introduce a data race (16.4.6.10). — end note]

[Note 4: The order of registration could be indeterminate if at_quick_exit was called from more than one thread. — end note]

[Note 5: The at_quick_exit registrations are distinct from the atexit registrations, and applications might need to call both registration functions with the same argument. — end note]

Implementation limits: The implementation shall support the registration of at least 32 functions.

Returns: Zero if the registration succeeds, nonzero if it fails.

[[noreturn]] void quick_exit(int status) noexcept;

Effects: Functions registered by calls to at_quick_exit are called in the reverse order of their registration, except that a function shall be called after any previously registered functions that had already been called at the time it was registered. Objects shall not be destroyed as a result of calling quick_exit. If a registered function invoked by quick_exit exits via an exception, the function std::terminate is invoked (14.6.2).

[Note 6: A function registered via at_quick_exit is invoked by the thread that calls quick_exit, which can be a different thread than the one that registered it, so registered functions cannot rely on the identity of objects with thread storage duration. — end note]

After calling registered functions, quick_exit shall call _Exit(status).

Remarks: The function quick_exit is signal-safe (17.13.5) when the functions registered with at-_quick_exit are.

See also: ISO C 7.22.4

17.6 Dynamic memory management

17.6.1 General

The header <new> defines several functions that manage the allocation of dynamic storage in a program. It also defines components for reporting storage management errors.

17.6.2 Header <new> synopsis

namespace std {
    // 17.6.4, storage allocation errors
    class bad_alloc;
    class bad_array_new_length;

    struct destroying_delete_t {
        explicit destroying_delete_t() = default;
    };
    inline constexpr destroying_delete_t destroying_delete{};

    // global operator new control
    enum class align_val_t : size_t {
    };

    struct nothrow_t { explicit nothrow_t() = default; };
    extern const nothrow_t noexcept;
    using new_handler = void (*)();
    new_handler get_new_handler() noexcept;
    new_handler set_new_handler(new_handler new_p) noexcept;

    // 17.6.5, pointer optimization barrier
    template<class T> [[nodiscard]] constexpr T* launder(T* p) noexcept;
}
// 17.6.6, hardware interference size
inline constexpr size_t hardware_destructive_interference_size = implementation-defined;
inline constexpr size_t hardware_constructive_interference_size = implementation-defined;
}

// 17.6.3, storage allocation and deallocation
[[nodiscard]] void* operator new(std::size_t size);
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment);
[[nodiscard]] void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;

void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, const std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

// 17.6.3.1 General

1 Except where otherwise specified, the provisions of 6.7.5.5 apply to the library versions of operator new and operator delete. If the value of an alignment argument passed to any of these functions is not a valid alignment value, the behavior is undefined.

17.6.3.2 Single-object forms

[[nodiscard]] void* operator new[](std::size_t size);
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment);
[[nodiscard]] void* operator new[](std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;

void operator delete[](void* ptr) noexcept;
void operator delete[](void* ptr, std::size_t size) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment) noexcept;
void operator delete[](void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
void operator delete[](void* ptr, const std::nothrow_t&) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

17.6.3 Storage allocation and deallocation

17.6.3.1 General

[[nodiscard]] void* operator new(std::size_t size);
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment);

Effects: The allocation functions (6.7.5.5.2) called by a new-expression (7.6.2.8) to allocate size bytes of storage. The second form is called for a type with new-extended alignment, and the first form is called otherwise.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Required behavior: Return a non-null pointer to suitably aligned storage (6.7.5.5), or else throw a bad_alloc exception. This requirement is binding on any replacement versions of these functions.

Default behavior:

(4.1) — Executes a loop: Within the loop, the function first attempts to allocate the requested storage. Whether the attempt involves a call to the C standard library functions malloc or aligned_alloc is unspecified.

(4.2) — Returns a pointer to the allocated storage if the attempt is successful. Otherwise, if the current new_handler (17.6.4.5) is a null pointer value, throws bad_alloc.
Otherwise, the function calls the current `new_handler` function (17.6.4.3). If the called function returns, the loop repeats.

The loop terminates when an attempt to allocate the requested storage is successful or when a called `new_handler` function does not return.

```cpp
[[nodiscard]] void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

**Effects:** Same as above, except that these are called by a placement version of a `new-expression` when a C++ program prefers a null pointer result as an error indication, instead of a `bad_alloc` exception.

**Replaceable:** A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

**Required behavior:** Return a non-null pointer to suitably aligned storage (6.7.5.5), or else return a null pointer. Each of these nothrow versions of `operator new` returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

**Default behavior:** Calls `operator new(size)`, or `operator new(size, alignment)`, respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

```cpp
T* p1 = new T; // throws bad_alloc if it fails
T* p2 = new(nothrow) T; // returns nullptr if it fails
```

**Effects:** The deallocation functions (6.7.5.5.3) called by a `delete-expression` (7.6.2.9) to render the value of `ptr` invalid.

**Replaceable:** A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a `size` parameter is defined, the program should also define the corresponding function with a `size` parameter. If a function with a `size` parameter is defined, the program shall also define the corresponding version without the `size` parameter.

**Default behavior:** The functions that have a `size` parameter forward their other parameters to the corresponding function without a `size` parameter.

**Preconditions:** `ptr` is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new(std::size_t)` or `operator new(std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete`.

If the `alignment` parameter is not present, `ptr` was returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument is equal to the `alignment` argument passed to the allocation function that returned `ptr`. If present, the `size` argument is equal to the `size` argument passed to the allocation function that returned `ptr`.

**Effects:** The deallocation functions called by a `delete-expression` (7.6.2.9) to render the value of `ptr` invalid.

**Replaceable:** A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a `size` parameter is defined, the program should also define the corresponding function with a `size` parameter. If a function with a `size` parameter is defined, the program shall also define the corresponding version without the `size` parameter.

**Required behavior:** A call to an `operator delete` with a `size` parameter may be changed to a call to the corresponding `operator delete` without a `size` parameter, without affecting memory allocation.

**Note 2:** A conforming implementation is for `operator delete(void* ptr, std::size_t size)` to simply call `operator delete(ptr)`. — end note

**Default behavior:** The functions that have a `size` parameter forward their other parameters to the corresponding function without a `size` parameter.

**Note 3:** See the note in the above `Replaceable:` paragraph. — end note

**Default behavior:** If `ptr` is null, does nothing. Otherwise, reclaims the storage allocated by the earlier call to `operator new`.

§ 17.6.3.2 528
Remarks: It is unspecified under what conditions part or all of such reclaimed storage will be allocated by subsequent calls to `operator new` or any of `aligned_alloc`, `calloc`, `malloc`, or `realloc`, declared in `<cstdlib>` (17.2.2).

```
void operator delete(void* ptr, const std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

Preconditions: `ptr` is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new(std::size_t)` or `operator new(std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete`.

If the `alignment` parameter is not present, `ptr` was returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument is equal to the `alignment` argument passed to the allocation function that returned `ptr`.

Effects: The deallocation functions (6.7.5.5.3) called by the implementation to render the value of `ptr` invalid when the constructor invoked from a nothrow placement version of the `new-expression` throws an exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Default behavior: Calls `operator delete(ptr)`, or `operator delete(ptr, alignment)`, respectively.

17.6.3.3 Array forms

```
[[nodiscard]] void* operator new[](std::size_t size);
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment);
```

Effects: The allocation functions (6.7.5.5.2) called by the array form of a `new-expression` (7.6.2.8) to allocate `size` bytes of storage. The second form is called for a type with new-extended alignment, and the first form is called otherwise.\(^{199}\)

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Required behavior: Same as for the corresponding single-object forms. This requirement is binding on any replacement versions of these functions.

Default behavior: Returns `operator new(size)`, or `operator new(size, alignment)`, respectively.

```
[[nodiscard]] void* operator new[](std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

Effects: Same as above, except that these are called by a placement version of a `new-expression` when a C++ program prefers a null pointer result as an error indication, instead of a `bad_alloc` exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Required behavior: Return a non-null pointer to suitably aligned storage (6.7.5.5), or else return a null pointer. Each of these nothrow versions of `operator new[]` returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

Default behavior: Calls `operator new[](size)`, or `operator new[](size, alignment)`, respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

```
void operator delete[](void* ptr) noexcept;
void operator delete[](void* ptr, std::size_t size) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment) noexcept;
void operator delete[](void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
```

Preconditions: `ptr` is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new[](std::size_t)` or `operator

\(^{199}\) It is not the direct responsibility of `operator new[]` or `operator delete[]` to note the repetition count or element size of the array. Those operations are performed elsewhere in the array `new` and `delete` expressions. The array `new` expression, can, however, increase the `size` argument to `operator new[]` to obtain space to store supplemental information.
new[](std::size_t, std::align_val_t) which has not been invalidated by an intervening call to operator delete[].

If the alignment parameter is not present, ptr was returned by an allocation function without an alignment parameter. If present, the alignment argument is equal to the alignment argument passed to the allocation function that returned ptr. If present, the size argument is equal to the size argument passed to the allocation function that returned ptr.

Effects: The deallocation functions (6.7.5.5.3) called by the array form of a delete-expression to render the value of ptr invalid.

Replaceable: A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a size parameter is defined, the program should also define the corresponding function with a size parameter. If a function with a size parameter is defined, the program shall also define the corresponding version without the size parameter.

[Note 1: The default behavior below might change in the future, which will require replacing both deallocation functions when replacing the allocation function. — end note]

Required behavior: A call to an operator delete[] with a size parameter may be changed to a call to the corresponding operator delete[] without a size parameter, without affecting memory allocation.

[Note 2: A conforming implementation is for operator delete[](void* ptr, std::size_t size) to simply call operator delete[](ptr). — end note]

Default behavior: The functions that have a size parameter forward their other parameters to the corresponding function without a size parameter. The functions that do not have a size parameter forward their parameters to the corresponding operator delete (single-object) function.

void operator delete[](void* ptr, const std::nothrow_t&) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

Preconditions: ptr is a null pointer or its value represents the address of a block of memory allocated by an earlier call to a (possibly replaced) operator new[](std::size_t) or operator new[](std::size_t, std::align_val_t) which has not been invalidated by an intervening call to operator delete[].

If the alignment parameter is not present, ptr was returned by an allocation function without an alignment parameter. If present, the alignment argument is equal to the alignment argument passed to the allocation function that returned ptr.

Effects: The deallocation functions (6.7.5.5.3) called by the implementation to render the value of ptr invalid when the constructor invoked from a nothrow placement version of the array new-expression throws an exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Default behavior: Calls operator delete[](ptr), or operator delete[](ptr, alignment), respectively.

17.6.3.4 Non-allocating forms

These functions are reserved; a C++ program may not define functions that displace the versions in the C++ standard library (16.4.5). The provisions of 6.7.5.5 do not apply to these reserved placement forms of operator new and operator delete.

[[nodiscard]] void* operator new(std::size_t size, void* ptr) noexcept;

Returns: ptr.

Remarks: Intentionally performs no other action.

[Example 1: This can be useful for constructing an object at a known address:

    void* place = operator new(sizeof(Something));
    Something* p = new (place) Something();

    — end example]

§ 17.6.3.4 530
[[nodiscard]] void* operator new[](std::size_t size, void* ptr) noexcept;

Returns: `ptr`.

Remarks: Intentionally performs no other action.

void operator delete(void* ptr, void*) noexcept;

Effects: Intentionally performs no action.

Remarks: Default function called when any part of the initialization in a placement `new-expression` that invokes the library’s non-array placement operator new terminates by throwing an exception (7.6.2.8).

void operator delete[](void* ptr, void*) noexcept;

Effects: Intentionally performs no action.

Remarks: Default function called when any part of the initialization in a placement `new-expression` that invokes the library’s array placement operator new terminates by throwing an exception (7.6.2.8).

17.6.3.5 Data races

For purposes of determining the existence of data races, the library versions of `operator new`, user replacement versions of global `operator new`, the C standard library functions `aligned_alloc`, `calloc`, and `malloc`, the library versions of `operator delete`, user replacement versions of `operator delete`, the C standard library function `free`, and the C standard library function `realloc` shall not introduce a data race (16.4.6.10). Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before (6.9.2) the next allocation (if any) in this order.

17.6.4 Storage allocation errors

17.6.4.1 Class `bad_alloc`

```cpp
namespace std {
    class bad_alloc : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}
```

1 The class `bad_alloc` defines the type of objects thrown as exceptions by the implementation to report a failure to allocate storage.

```cpp
const char* what() const noexcept override;
```

Returns: An implementation-defined nDTS.

17.6.4.2 Class `bad_array_new_length`

```cpp
namespace std {
    class bad_array_new_length : public bad_alloc {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}
```

1 The class `bad_array_new_length` defines the type of objects thrown as exceptions by the implementation to report an attempt to allocate an array of size less than zero or greater than an implementation-defined limit (7.6.2.8).

```cpp
const char* what() const noexcept override;
```

Returns: An implementation-defined nDTS.

17.6.4.3 Type `new_handler`

```cpp
using new_handler = void (*)();
```

1 The type of a `handler function` to be called by `operator new()` or `operator new[]( )` (17.6.3) when they cannot satisfy a request for additional storage.
2 Required behavior: A new_handler shall perform one of the following:

(2.1) — make more storage available for allocation and then return;
(2.2) — throw an exception of type bad_alloc or a class derived from bad_alloc;
(2.3) — terminate execution of the program without returning to the caller.

17.6.4.4 set_new_handler

new_handler set_new_handler(new_handler new_p) noexcept;

1 Effects: Establishes the function designated by new_p as the current new_handler.
2 Returns: The previous new_handler.
3 Remarks: The initial new_handler is a null pointer.

17.6.4.5 get_new_handler

new_handler get_new_handler() noexcept;

1 Returns: The current new_handler.
2 [Note 1: This can be a null pointer value. — end note]

17.6.5 Pointer optimization barrier

(template<class T> [[nodiscard]] constexpr T* launder(T* p) noexcept;

1 Mandates: !is_function_v<T> && !is_void_v<T> is true.
2 Preconditions: p represents the address A of a byte in memory. An object X that is within its lifetime (6.7.3) and whose type is similar (7.3.6) to T is located at the address A. All bytes of storage that would be reachable through (6.8.4) the result are reachable through p.
3 Returns: A value of type T* that points to X.
4 Remarks: An invocation of this function may be used in a core constant expression if and only if the (converted) value of its argument may be used in place of the function invocation.
5 [Note 1: If a new object is created in storage occupied by an existing object of the same type, a pointer to the original object can be used to refer to the new object unless its complete object is a const object or it is a base class subobject; in the latter cases, this function can be used to obtain a usable pointer to the new object. See 6.7.3. — end note]
6 [Example 1:
   struct X { int n; };
   const X *p = new const X{3};
   const int a = p->n;
   new (const_cast<X*>(p)) const X{5}; // p does not point to new object (6.7.3) because its type is const
   const int b = p->n; // undefined behavior
   const int c = std::launder(p)->n; // OK
   — end example]

17.6.6 Hardware interference size

inline constexpr size_t hardware_destructive_interference_size = implementation-defined;

This number is the minimum recommended offset between two concurrently-accessed objects to avoid additional performance degradation due to contention introduced by the implementation. It shall be at least alignof(max_align_t).

[Example 1:
   struct keep_apart {
      alignas(hardware_destructive_interference_size) atomic<int> cat;
      alignas(hardware_destructive_interference_size) atomic<int> dog;
   };
   — end example]
inline constexpr size_t hardware_constructive_interference_size = implementation-defined;

This number is the maximum recommended size of contiguous memory occupied by two objects accessed with temporal locality by concurrent threads. It shall be at least alignof(max_align_t).

[Example 2:

```
struct together {
  atomic<int> dog;
  int puppy;
};
struct kennel {
  // Other data members...
  alignas(sizeof(together)) together pack;
  // Other data members...
};
static_assert(sizeof(together) <= hardware_constructive_interference_size);
```
—end example]

17.7 Type identification [support.rtti]

17.7.1 General [support.rtti.general]

The header `<typeinfo>` defines a type associated with type information generated by the implementation. It also defines two types for reporting dynamic type identification errors.

17.7.2 Header `<typeinfo>` synopsis [typeinfo.syn]

```
// all freestanding
namespace std {
  class type_info;
  class bad_cast;
  class bad_typeid;
}
```

17.7.3 Class `type_info` [type.info]

```
namespace std {
  class type_info {
    public:
      virtual ~type_info();
      constexpr bool operator==(const type_info& rhs) const noexcept;
      bool before(const type_info& rhs) const noexcept;
      size_t hash_code() const noexcept;
      const char* name() const noexcept;
      type_info(const type_info&) = delete;
      // cannot be copied
      type_info& operator=(const type_info&) = delete;
      // cannot be copied
  };
}
```

The class `type_info` describes type information generated by the implementation (7.6.1.8). Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoding rule, and collating sequence for types are all unspecified and may differ between programs.

```
constexpr bool operator==(const type_info& rhs) const noexcept;

Effects: Compares the current object with `rhs`.

Returns: `true` if the two values describe the same type.
```

```
bool before(const type_info& rhs) const noexcept;

Effects: Compares the current object with `rhs`.

Returns: `true` if `*this` precedes `rhs` in the implementation’s collation order.
```
size_t hash_code() const noexcept;

Returns: An unspecified value, except that within a single execution of the program, it shall return the same value for any two \texttt{type\_info} objects which compare equal.

Remarks: An implementation should return different values for two \texttt{type\_info} objects which do not compare equal.

const char* name() const noexcept;

Returns: An implementation-defined ntbs.

Remarks: The message may be a null-terminated multibyte string (16.3.3.4.3), suitable for conversion and display as a \texttt{wstring} (23.4, 30.4.2.5).

17.7.4 Class \texttt{bad\_cast} \[bad.cast\]

namespace std {
    class bad_cast : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}

The class \texttt{bad\_cast} defines the type of objects thrown as exceptions by the implementation to report the execution of an invalid \texttt{dynamic\_cast} expression (7.6.1.7).

const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

17.7.5 Class \texttt{bad\_typeid} \[bad.typeid\]

namespace std {
    class bad_typeid : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}

The class \texttt{bad\_typeid} defines the type of objects thrown as exceptions by the implementation to report a null pointer in a \texttt{typeid} expression (7.6.1.8).

const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

17.8 Source location \[support.srcloc\]

17.8.1 Header \texttt{<source\_location>} synopsis \[source.location.syn\]

The header \texttt{<source\_location>} defines the class \texttt{source\_location} that provides a means to obtain source location information.

// all freestanding
namespace std {
    struct source_location;
}

17.8.2 Class \texttt{source\_location} \[support.srcloc.class\]

17.8.2.1 General \[support.srcloc.class.general\]

namespace std {
    struct source_location {
        // source location construction
        static constexpr source_location current() noexcept;
        constexpr source_location() noexcept;
    };
}
The type `source_location` meets the `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, `Cpp17CopyAssignable`, `Cpp17Swappable`, and `Cpp17Destructible` requirements (16.4.4.2, 16.4.4.3). All of the following conditions are true:

1. (1.1) — `is_nothrow_move_constructible_v<source_location>`
2. (1.2) — `is_nothrow_move_assignable_v<source_location>`
3. (1.3) — `is_nothrow_swappable_v<source_location>`

[Note 1: The intent of `source_location` is to have a small size and efficient copying. It is unspecified whether the copy/move constructors and the copy/move assignment operators are trivial and/or constexpr. — end note]

The data members `file_name_` and `function_name_` always each refer to an NTBS.

The copy/move constructors and the copy/move assignment operators of `source_location` meet the following postconditions: Given two objects `lhs` and `rhs` of type `source_location`, where `lhs` is a copy/move result of `rhs`, and where `rhs_p` is a value denoting the state of `rhs` before the corresponding copy/move operation, then each of the following conditions is true:

1. (3.1) — `strcmp(lhs.file_name(), rhs_p.file_name()) == 0`
2. (3.2) — `strcmp(lhs.function_name(), rhs_p.function_name()) == 0`
3. (3.3) — `lhs.line() == rhs_p.line()`
4. (3.4) — `lhs.column() == rhs_p.column()`

### 17.8.2.2 Creation

```cpp
static constexpr source_location current() noexcept;
```

1. **Returns:**
   1. (1.1) — When invoked by a function call whose `postfix-expression` is a (possibly parenthesized) `id-expression` naming `current`, returns a `source_location` with an implementation-defined value. The value should be affected by `#line` (15.7) in the same manner as for `__LINE__` and `__FILE__`. The values of the exposition-only data members of the returned `source_location` object are indicated in Table 39.
   2. (1.2) — Otherwise, when invoked in some other way, returns a `source_location` whose data members are initialized with valid but unspecified values.

2. **Remarks:** Any call to `current` that appears as a default member initializer (11.4), or as a subexpression thereof, should correspond to the location of the constructor definition or aggregate initialization that uses the default member initializer. Any call to `current` that appears as a default argument (9.3.4.7), or as a subexpression thereof, should correspond to the location of the invocation of the function that uses the default argument (7.6.1.3).

3. **[Example 1]:**

```cpp
struct s {
    source_location member = source_location::current();
    int other_member;
    s(source_location loc = source_location::current())
        : member(loc) // values of member refer to the location of the calling function (9.3.4.7)
    {}
}
```
### Table 39: Value of object returned by `current`

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>line_</code></td>
<td>A presumed line number (15.11). Line numbers are presumed to be 1-indexed; however, an implementation is encouraged to use 0 when the line number is unknown.</td>
</tr>
<tr>
<td><code>column_</code></td>
<td>An implementation-defined value denoting some offset from the start of the line denoted by <code>line_</code>. Column numbers are presumed to be 1-indexed; however, an implementation is encouraged to use 0 when the column number is unknown.</td>
</tr>
<tr>
<td><code>file_name_</code></td>
<td>A presumed name of the current source file (15.11) as an Numbs.</td>
</tr>
<tr>
<td><code>function_name_</code></td>
<td>A name of the current function such as in <code>__func_</code> (9.5.1) if any, an empty string otherwise.</td>
</tr>
</tbody>
</table>

```c
s(int blather) : // values of member refer to this location
tother_member(blather) {} // values of member refer to this location
s(double) {} // values of member refer to this location
};
void f(source_location a = source_location::current()) {
    source_location b = source_location::current(); // values in b refer to this line
}
void g() {
    f(); // f’s first argument corresponds to this line of code
    source_location c = source_location::current();
    f(c); // f’s first argument gets the same values as c, above
}
— end example |
constexpr source_location() noexcept;
```

### Effects: The data members are initialized with valid but unspecified values.

#### 17.8.2.3 Observers

```c
constexpr uint_least32_t line() const noexcept;
Returns: `line_`.
```

```c
constexpr uint_least32_t column() const noexcept;
Returns: `column_`.
```

```c
constexpr const char* file_name() const noexcept;
Returns: `file_name_`.
```

```c
constexpr const char* function_name() const noexcept;
Returns: `function_name_`.
```

### 17.9 Exception handling

#### 17.9.1 General

The header `<exception>` defines several types and functions related to the handling of exceptions in a C++ program.
17.9.2 Header <exception> synopsis
[exception.syn]

```cpp
// all freestanding
namespace std {
    class exception;
    class bad_exception;
    class nested_exception;

    using terminate_handler = void (*)(void);
    terminate_handler get_terminate() noexcept;
    terminate_handler set_terminate(terminate_handler f) noexcept;
    [[noreturn]] void terminate() noexcept;

    int uncaught_exceptions() noexcept;

    using exception_ptr = unspecified;
    exception_ptr current_exception() noexcept;
    [[noreturn]] void rethrow_exception(exception_ptr p);
    template<class E> exception_ptr make_exception_ptr(E e) noexcept;
    template<class T> [[noreturn]] void throw_with_nested(T&& t);
    template<class E> void rethrow_if_nested(const E& e);
}
```

17.9.3 Class exception
[exception]

```cpp
namespace std {
    class exception {
        public:
            exception() noexcept;
            exception(const exception&) noexcept;
            exception& operator=(const exception&) noexcept;
            virtual ~exception();
            virtual const char* what() const noexcept;
    };
}
```

1 The class `exception` defines the base class for the types of objects thrown as exceptions by C++ standard library components, and certain expressions, to report errors detected during program execution.

2 Each standard library class `T` that derives from class `exception` has the following publicly accessible member functions, each of them having a non-throwing exception specification (14.5):

   (2.1) — default constructor (unless the class synopsis shows other constructors)
   (2.2) — copy constructor
   (2.3) — copy assignment operator

   The copy constructor and the copy assignment operator meet the following postcondition: If two objects `lhs` and `rhs` both have dynamic type `T` and `lhs` is a copy of `rhs`, then `strcmp(lhs.what(), rhs.what())` is equal to 0. The `what()` member function of each such `T` satisfies the constraints specified for `exception::what()` (see below).

```cpp
exception(const exception& rhs) noexcept;
exception& operator=(const exception& rhs) noexcept;
```

3 `Postconditions`: If `*this` and `rhs` both have dynamic type `exception` then the value of the expression `strcmp(what(), rhs.what())` shall equal 0.

```cpp
virtual ~exception();
```

4 `Effects`: Destroys an object of class `exception`.

```cpp
virtual const char* what() const noexcept;
```

5 `Returns`: An implementation-defined NTBS.
Remarks: The message may be a null-terminated multibyte string (16.3.3.4.3), suitable for conversion and display as a wstring (23.4, 30.4.2.5). The return value remains valid until the exception object from which it is obtained is destroyed or a non-const member function of the exception object is called.

17.9.4 Class bad_exception

namespace std {
    class bad_exception : public exception {
        public:
            // see 17.9.3 for the specification of the special member functions
            const char* what() const noexcept override;
    };
}

The class bad_exception defines the type of the object referenced by the exception_ptr returned from a call to current_exception (17.9.7) when the currently active exception object fails to copy.

const char* what() const noexcept override;

Returns: An implementation-defined NTBS.

17.9.5 Abnormal termination

17.9.5.1 Type terminate_handler

using terminate_handler = void (*)();

The type of a handler function to be invoked by terminate when terminating exception processing.

Required behavior: A terminate_handler shall terminate execution of the program without returning to the caller.

Default behavior: The implementation’s default terminate_handler calls abort().

17.9.5.2 set_terminate

terminate_handler set_terminate(terminate_handler f) noexcept;

Effects: Establishes the function designated by f as the current handler function for terminating exception processing.

Returns: The previous terminate_handler.

Remarks: It is unspecified whether a null pointer value designates the default terminate_handler.

17.9.5.3 get_terminate

terminate_handler get_terminate() noexcept;

Returns: The current terminate_handler.

[Note 1: This can be a null pointer value. — end note]

17.9.5.4 terminate

[[noreturn]] void terminate() noexcept;

Effects: Calls a terminate_handler function. It is unspecified which terminate_handler function will be called if an exception is active during a call to set_terminate. Otherwise calls the current terminate_handler function.

[Note 1: A default terminate_handler is always considered a callable handler in this context. — end note]

Remarks: Called by the implementation when exception handling must be abandoned for any of several reasons (14.6.2). May also be called directly by the program.

17.9.6 uncaught_exceptions

int uncaught_exceptions() noexcept;

Returns: The number of uncaught exceptions (14.6.3).

Remarks: When uncaught_exceptions() > 0, throwing an exception can result in a call of the function std::terminate (14.6.2).
17.9.7 Exception propagation

The type exception_ptr can be used to refer to an exception object.

**exception_ptr** meets the requirements of Cpp17NullablePointer (Table 36).

Two non-null values of type exception_ptr are equivalent and compare equal if and only if they refer to the same exception.

The default constructor of exception_ptr produces the null value of the type.

**exception_ptr** shall not be implicitly convertible to any arithmetic, enumeration, or pointer type.

[Note 1: An implementation can use a reference-counted smart pointer as exception_ptr. — end note]

For purposes of determining the presence of a data race, operations on exception_ptr objects shall access and modify only the exception_ptr objects themselves and not the exceptions they refer to. Use of rethrow_exception on exception_ptr objects that refer to the same exception object shall not introduce a data race.

[Note 2: If rethrow_exception rethrows the same exception object (rather than a copy), concurrent access to that rethrown exception object can introduce a data race. Changes in the number of exception_ptr objects that refer to a particular exception do not introduce a data race. — end note]

**exception_ptr current_exception() noexcept;**

**Returns:** An exception_ptr object that refers to the currently handled exception (14.4) or a copy of the currently handled exception, or a null exception_ptr object if no exception is being handled. The referenced object shall remain valid at least as long as there is an exception_ptr object that refers to it. If the function needs to allocate memory and the attempt fails, it returns an exception_ptr object that refers to an instance of bad_alloc. It is unspecified whether the return values of two successive calls to current_exception refer to the same exception object.

[Note 3: That is, it is unspecified whether current_exception creates a new copy each time it is called. — end note]

If the attempt to copy the current exception object throws an exception, the function returns an exception_ptr object that refers to the thrown exception object or, if this is not possible, to an instance of bad_exception.

[Note 4: The copy constructor of the thrown exception can also fail, so the implementation is allowed to substitute a bad_exception object to avoid infinite recursion. — end note]

**[[noretum]] void rethrow_exception(exception_ptr p);**

**Preconditions:** p is not a null pointer.

**Effects:** Let u be the exception object to which p refers, or a copy of that exception object. It is unspecified whether a copy is made, and memory for the copy is allocated in an unspecified way.

1. If allocating memory to form u fails, throws an instance of bad_alloc;
2. otherwise, if copying the exception to which p refers to form u throws an exception, throws that exception;
3. otherwise, throws u.

**template<class E> exception_ptr make_exception_ptr(E e) noexcept;**

**Effects:** Creates an exception_ptr object that refers to a copy of e, as if:

```
try {
    throw e;
} catch(...) {
    return current_exception();
}
```

[Note 5: This function is provided for convenience and efficiency reasons. — end note]

17.9.8 nested_exception

**namespace std {**

**class nested_exception {**

§ 17.9.8
The class `nested_exception` is designed for use as a mixin through multiple inheritance. It captures the currently handled exception and stores it for later use.

**Note 1:** `nested_exception` has a virtual destructor to make it a polymorphic class. Its presence can be tested for with `dynamic_cast`. — end note

```cpp
nested_exception() noexcept;
```

**Effects:** The constructor calls `current_exception()` and stores the returned value.

```cpp
[[noreturn]] void rethrow_nested() const;
```

**Effects:** If `nested_ptr()` returns a null pointer, the function calls the function `std::terminate`. Otherwise, it throws the stored exception captured by `*this`.

```cpp
exception_ptr nested_ptr() const noexcept;
```

**Returns:** The stored exception captured by this `nested_exception` object.

```cpp
template<class T> [[noreturn]] void throw_with_nested(T&& t);
```

**Let** `U` be `decay_t<T>`.

**Preconditions:** `U` meets the `Cpp17CopyConstructible` requirements.

**Throws:** If `is_class_v<U> && !is_final_v<U> && !is_base_of_v<nested_exception, U>` is true, an exception of unspecified type that is publicly derived from both `U` and `nested_exception` and constructed from `std::forward<T>(t)`, otherwise `std::forward<T>(t)`.

```cpp
template<class E> void rethrow_if_nested(const E& e);
```

**Effects:** If `E` is not a polymorphic class type, or if `nested_exception` is an inaccessible or ambiguous base class of `E`, there is no effect. Otherwise, performs:

```cpp
if (auto p = dynamic_cast<const nested_exception*>(addressof(e)))
    p->rethrow_nested();
```

### 17.10 Initializer lists

#### 17.10.1 General

The header `<initializer_list>` defines a class template and several support functions related to list-initialization (see 9.4.5). All functions specified in 17.10 are signal-safe (17.13.5).

#### 17.10.2 Header `<initializer_list>` synopsis

```cpp
// all freestanding
namespace std {
    template<class E> class initializer_list {
        public:
            using value_type = E;
            using reference = const E&;
            using const_reference = const E&;
            using size_type = size_t;

            using iterator = const E*;
            using const_iterator = const E*;
    }
}
```
constexpr initializer_list() noexcept;
constexpr size_t size() const noexcept;  // number of elements
constexpr const E* begin() const noexcept;  // first element
constexpr const E* end() const noexcept;    // one past the last element

// 17.10.5, initializer list range access
template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;
template<class E> constexpr const E* end(initializer_list<E> il) noexcept;
}

An object of type initializer_list<E> provides access to an array of objects of type const E.

[Note 1: A pair of pointers or a pointer plus a length would be obvious representations for initializer_list. initializer_list is used to implement initializer lists as specified in 9.4.3. Copying an initializer list does not copy the underlying elements. — end note]

If an explicit specialization or partial specialization of initializer_list is declared, the program is ill-formed.

17.10.3 Initializer list constructors
constexpr initializer_list() noexcept;

Postconditions: size() == 0.

17.10.4 Initializer list access
constexpr const E* begin() const noexcept;

Returns: A pointer to the beginning of the array. If size() == 0 the values of begin() and end() are unspecified but they shall be identical.

constexpr const E* end() const noexcept;

Returns: begin() + size().

constexpr size_t size() const noexcept;

Returns: The number of elements in the array.

Complexity: Constant time.

17.10.5 Initializer list range access
template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;

Returns: il.begin().

template<class E> constexpr const E* end(initializer_list<E> il) noexcept;

Returns: il.end().

17.11 Comparisons

17.11.1 Header <compare> synopsis

The header <compare> specifies types, objects, and functions for use primarily in connection with the three-way comparison operator (7.6.8).

// all freestanding
namespace std {

    // 17.11.2, comparison category types
    class partial_ordering;
    class weak_ordering;
    class strong_ordering;

    // named comparison functions
    constexpr bool is_eq (partial_ordering cmp) noexcept { return cmp == 0; }
    constexpr bool is_neq (partial_ordering cmp) noexcept { return cmp != 0; }
    constexpr bool is_lt (partial_ordering cmp) noexcept { return cmp < 0; }

§ 17.11.1
constexpr bool is_lteq(partial_ordering cmp) noexcept { return cmp <= 0; }
constexpr bool is_gt (partial_ordering cmp) noexcept { return cmp > 0; }
constexpr bool is_gteq(partial_ordering cmp) noexcept { return cmp >= 0; }

// 17.11.3, common comparison category type
template<class... Ts>
struct common_comparison_category {
    using type = see below;
};
template<class... Ts>
using common_comparison_category_t = typename common_comparison_category<Ts...>::type;

// 17.11.4, concept three_way_comparable
template<class T, class Cat = partial_ordering>
concept three_way_comparable = see below;
template<class T, class U, class Cat = partial_ordering>
concept three_way_comparable_with = see below;

// 17.11.5, result of three-way comparison
template<class T, class U = T> struct compare_three_way_result;
template<class T, class U = T>
using compare_three_way_result_t = typename compare_three_way_result<T, U>::type;

// 22.10.8.8, class compare_three_way
struct compare_three_way;

// 17.11.6, comparison algorithms
inline namespace unspecified {
    inline constexpr unspecified strong_order = unspecified;
    inline constexpr unspecified weak_order = unspecified;
    inline constexpr unspecified partial_order = unspecified;
    inline constexpr unspecified compare_strong_order_fallback = unspecified;
    inline constexpr unspecified compare_weak_order_fallback = unspecified;
    inline constexpr unspecified compare_partial_order_fallback = unspecified;
}

17.11.2 Comparison category types

17.11.2.1 Preamble

The types partial_ordering, weak_ordering, and strong_ordering are collectively termed the comparison category types. Each is specified in terms of an exposition-only data member named value whose value typically corresponds to that of an enumerator from one of the following exposition-only enumerations:

```cpp
enum class ord { equal = 0, equivalent = equal, less = -1, greater = 1 }; // exposition only
enum class ncmp { unordered = -127 }; // exposition only
```

[Note 1: The type strong_ordering corresponds to the term total ordering in mathematics. — end note]

The relational and equality operators for the comparison category types are specified with an anonymous parameter of unspecified type. This type shall be selected by the implementation such that these parameters can accept literal 0 as a corresponding argument.

[Example 1: nullptr_t meets this requirement. — end example]

In this context, the behavior of a program that supplies an argument other than a literal 0 is undefined.

For the purposes of subclause 17.11.2, substitutability is the property that f(a) == f(b) is true whenever a == b is true, where f denotes a function that reads only comparison-salient state that is accessible via the argument’s public const members.

17.11.2.2 Class partial_ordering

The partial_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) for a type that admits all of the six two-way comparison operators (7.6.9, 7.6.10), for which equality need not
imply substitutability, and that permits two values to be incomparable.\footnote{That is, $a < b$, $a = b$, and $a > b$ might all be false.}

namespace std {

  // exposition only constructors
  constexpr explicit partial_ordering(ord v) noexcept : value(int(v)), is_ordered(true) {} // exposition only
  constexpr explicit partial_ordering(ncmp v) noexcept : value(int(v)), is_ordered(false) {} // exposition only

  // valid values
  static const partial_ordering less;
  static const partial_ordering equivalent;
  static const partial_ordering greater;
  static const partial_ordering unordered;

  // comparisons
  friend constexpr bool operator==(partial_ordering v, unspecified) noexcept;
  friend constexpr bool operator==(partial_ordering v, partial_ordering w) noexcept = default;
  friend constexpr bool operator<(partial_ordering v, unspecified) noexcept;
  friend constexpr bool operator<(partial_ordering v, partial_ordering w) noexcept;
  friend constexpr bool operator<=(partial_ordering v, unspecified) noexcept;
  friend constexpr bool operator<=(partial_ordering v, partial_ordering w) noexcept;
  friend constexpr bool operator>(unspecified, partial_ordering v) noexcept;
  friend constexpr bool operator>(partial_ordering v, unspecified) noexcept;
  friend constexpr bool operator>=(unspecified, partial_ordering v) noexcept;
  friend constexpr bool operator>=(partial_ordering v, unspecified) noexcept;
  friend constexpr partial_ordering operator<=>(partial_ordering v, unspecified) noexcept;
  friend constexpr partial_ordering operator<=>(unspecified, partial_ordering v) noexcept;

  // valid values' definitions
  inline constexpr partial_ordering partial_ordering::less(ord::less);
  inline constexpr partial_ordering partial_ordering::equivalent(ord::equivalent);
  inline constexpr partial_ordering partial_ordering::greater(ord::greater);
  inline constexpr partial_ordering partial_ordering::unordered(ncmp::unordered);
}

2 Returns: For operator\@\@, $v$.is_ordered && v.value \@ 0.

3 Returns: For operator\@\@, $v$.is_ordered && 0 \@ v.value.

4 Returns: v.

5 Returns: $v < 0 \ ? \ partial_ordering::greater : v > 0 \ ? \ partial_ordering::less : v.$

\footnote{That is, $a < b$, $a = b$, and $a > b$ might all be false.}
17.11.2.3 Class weak_ordering

The weak_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) for a type that admits all of the six two-way comparison operators (7.6.9, 7.6.10) and for which equality need not imply substitutability.

namespace std {
    class weak_ordering {
        int value; // exposition only

        // exposition-only constructors
        constexpr explicit weak_ordering(ord v) noexcept : value(int(v)) {} // exposition only

    public:
        // valid values
        static const weak_ordering less;
        static const weak_ordering equivalent;
        static const weak_ordering greater;

        // conversions
        constexpr operator partial_ordering() const noexcept;

        // comparisons
        friend constexpr bool operator==(weak_ordering v, unspecified) noexcept;
        friend constexpr bool operator<(weak_ordering v, unspecified) noexcept;
        friend constexpr bool operator>(weak_ordering v, unspecified) noexcept;
        friend constexpr bool operator<=(weak_ordering v, unspecified) noexcept;
        friend constexpr bool operator>=(weak_ordering v, unspecified) noexcept;
        friend constexpr bool operator<(unspecified, weak_ordering v) noexcept;
        friend constexpr bool operator>(unspecified, weak_ordering v) noexcept;
        friend constexpr bool operator<=(unspecified, weak_ordering v) noexcept;
        friend constexpr bool operator>=(unspecified, weak_ordering v) noexcept;
        friend constexpr weak_ordering operator<=>(weak_ordering v, unspecified) noexcept;
        friend constexpr weak_ordering operator<=>(unspecified, weak_ordering v) noexcept;
    }

    // valid values' definitions
    inline constexpr weak_ordering weak_ordering::less(ord::less);
    inline constexpr weak_ordering weak_ordering::equivalent(ord::equivalent);
    inline constexpr weak_ordering weak_ordering::greater(ord::greater);
}

constexpr operator partial_ordering() const noexcept;

Returns:
value == 0 ? partial_ordering::equivalent :
value < 0 ? partial_ordering::less :
partial_ordering::greater

constexpr bool operator==(weak_ordering v, unspecified) noexcept;
constexpr bool operator<(weak_ordering v, unspecified) noexcept;
constexpr bool operator>(weak_ordering v, unspecified) noexcept;
constexpr bool operator<=(weak_ordering v, unspecified) noexcept;
constexpr bool operator>=(weak_ordering v, unspecified) noexcept;
constexpr bool operator<(unspecified, weak_ordering v) noexcept;
constexpr bool operator>(unspecified, weak_ordering v) noexcept;
constexpr bool operator<=(unspecified, weak_ordering v) noexcept;
constexpr bool operator>=(unspecified, weak_ordering v) noexcept;

Returns: v.value @ 0 for operator@.

constexpr bool operator<(unspecified, weak_ordering v) noexcept;
constexpr bool operator>(unspecified, weak_ordering v) noexcept;
constexpr bool operator<=(unspecified, weak_ordering v) noexcept;
constexpr bool operator>=(unspecified, weak_ordering v) noexcept;

Returns: 0 @ v.value for operator@.
constexpr weak_ordering operator<=>(weak_ordering v, unspecified) noexcept;

Returns: v.

constexpr weak_ordering operator<=>(unspecified, weak_ordering v) noexcept;

Returns: v < 0 ? weak_ordering::greater : v > 0 ? weak_ordering::less : v.

17.11.2.4 Class strong_ordering

The `strong_ordering` type is typically used as the result type of a three-way comparison operator (7.6.8) for a type that admits all of the six two-way comparison operators (7.6.9, 7.6.10) and for which equality does imply substitutability.

```cpp
namespace std {
    class strong_ordering {
        int value; // exposition only

        // exposition-only constructors
        constexpr explicit strong_ordering(ord v) noexcept : value(int(v)) {} // exposition only

    public:
        // valid values
        static const strong_ordering less;
        static const strong_ordering equal;
        static const strong_ordering equivalent;
        static const strong_ordering greater;

        // conversions
        constexpr operator partial_ordering() const noexcept;
        constexpr operator weak_ordering() const noexcept;

        // comparisons
        friend constexpr bool operator==(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator==(strong_ordering v, strong_ordering w) noexcept = default;
        friend constexpr bool operator< (strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator< (strong_ordering v, unspecified) noexcept = default;
        friend constexpr bool operator> (strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator> (strong_ordering v, unspecified) noexcept = default;
        friend constexpr bool operator<= (unspecified, strong_ordering v) noexcept;
        friend constexpr bool operator>= (unspecified, strong_ordering v) noexcept;
        friend constexpr strong_ordering operator<=>(strong_ordering v, unspecified) noexcept;
        friend constexpr strong_ordering operator<=>(unspecified, strong_ordering v) noexcept;
    }

    // valid values' definitions
    inline constexpr strong_ordering strong_ordering::less(ord::less);
    inline constexpr strong_ordering strong_ordering::equal(ord::equal);
    inline constexpr strong_ordering strong_ordering::equivalent(ord::equivalent);
    inline constexpr strong_ordering strong_ordering::greater(ord::greater);
}
```

constexpr operator partial_ordering() const noexcept;

Returns:
value == 0 ? partial_ordering::equivalent :
value < 0 ? partial_ordering::less :
partial_ordering::greater

constexpr operator weak_ordering() const noexcept;

Returns:
value == 0 ? weak_ordering::equivalent :
value < 0 ? weak_ordering::less :
weak_ordering::greater

§ 17.11.2.4
constexpr bool operator==(strong_ordering v, unspecified) noexcept;
constexpr bool operator< (strong_ordering v, unspecified) noexcept;
constexpr bool operator> (strong_ordering v, unspecified) noexcept;
constexpr bool operator<=(strong_ordering v, unspecified) noexcept;
constexpr bool operator>=(strong_ordering v, unspecified) noexcept;

4 Returns: v.value @ 0 for operator@.
constexpr bool operator< (unspecified, strong_ordering v) noexcept;
constexpr bool operator> (unspecified, strong_ordering v) noexcept;
constexpr bool operator<= (unspecified, strong_ordering v) noexcept;
constexpr bool operator>= (unspecified, strong_ordering v) noexcept;

5 Returns: 0 @ v.value for operator@.
constexpr strong_ordering operator<= (strong_ordering v, unspecified) noexcept;
constexpr strong_ordering operator>=(unspecified, strong_ordering v) noexcept;

6 Returns: v.
constexpr strong_ordering operator<=> (strong_ordering v, unspecified) noexcept;
constexpr strong_ordering operator<=> (unspecified, strong_ordering v) noexcept;

7 Returns: v < 0 ? strong_ordering::greater : v > 0 ? strong_ordering::less : v.

17.11.3 Class template common_comparison_category

The type common_comparison_category provides an alias for the strongest comparison category to which all of the template arguments can be converted.

[Note 1: A comparison category type is stronger than another if they are distinct types and an instance of the former can be converted to an instance of the latter. —end note]

template<class... Ts>
struct common_comparison_category {
    using type = see below;
};

2 Remarks: The member typedef-name type denotes the common comparison type (11.10.3) of Ts..., the expanded parameter pack, or void if any element of Ts is not a comparison category type.

[Note 2: This is std::strong_ordering if the expansion is empty. —end note]

17.11.4 Concept three_way_comparable

template<class T, class Cat>
concept compares-as = // exposition only
    same_as<common_comparison_category_t<T, Cat>, Cat>;

template<class T, class U>
concept partially-ordered-with = // exposition only
    requires(const remove_reference_t<T>& t, const remove_reference_t<U>& u) {
        { t < u } -> boolean-testable;
        { t > u } -> boolean-testable;
        { t <= u } -> boolean-testable;
        { t == u } -> boolean-testable;
        { u < t } -> boolean-testable;
        { u <= t } -> boolean-testable;
        { u > t } -> boolean-testable;
        { u >= t } -> boolean-testable;
    };

1 Let t and u be values of types const remove_reference_t<T> and const remove_reference_t<U>, respectively. T and U model partially-ordered-with<T, U> only if:

1.1 t < u, t <= u, t > u, t >= u, u < t, u <= t, u > t, and u >= t have the same domain.
1.2 bool(t < u) == bool(u > t) is true,
1.3 bool(u < t) == bool(t > u) is true,
1.4 bool(t <= u) == bool(u >= t) is true, and
1.5 bool(u <= t) == bool(t >= u) is true.
template<class T, class Cat = partial_ordering>
concept three_way_comparable =
  weakly-equality-comparable-with<T, T> &&
  partially-ordered-with<T, T> &&
requires(const remove_reference_t<T>& a, const remove_reference_t<T>& b) {
  { a <=> b } -> compares-as<Cat>;
};

Let a and b be lvalues of type const remove_reference_t<T>. T and Cat model three_way_comparable<T, Cat> only if:

(2.1) — (a <=> b == 0) == bool(a == b) is true,
(2.2) — (a <=> b != 0) == bool(a != b) is true,
(2.3) — ((a <=> b) <=> 0) and (0 <=> (b <=> a)) are equal,
(2.4) — (a <=> b < 0) == bool(a < b) is true,
(2.5) — (a <=> b > 0) == bool(a > b) is true,
(2.6) — (a <=> b <= 0) == bool(a <= b) is true,
(2.7) — (a <=> b >= 0) == bool(a >= b) is true,
(2.8) — if Cat is convertible to strong_ordering, T models totally_ordered (18.5.5).

template<class T, class U, class Cat = partial_ordering>
concept three_way_comparable_with =
  three_way_comparable<T, Cat> &&
  three_way_comparable<U, Cat> &&
  comparison-common-type-with<T, U> &&
  three_way_comparable<
    common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>, Cat> &&
  weakly-equality-comparable-with<T, U> &&
  partially-ordered-with<T, U> &&
requires(const remove_reference_t<T>& t, const remove_reference_t<U>& u) {
  { t <=> u } -> compares-as<Cat>;
  { u <=> t } -> compares-as<Cat>;
};

Let t and t2 be lvalues denoting distinct equal objects of types const remove_reference_t<T> and remove_cvref_t<T>, respectively, and let u and u2 be lvalues denoting distinct equal objects of types const remove_reference_t<U> and remove_cvref_t<U>, respectively. Let C be common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>. Let CONVERT_TO_LVALUE<C>(E) be defined as in 18.5.1. T, U, and Cat model three_way_comparable_with<T, U, Cat> only if:

(3.1) — t <=> u and u <=> t have the same domain,
(3.2) — ((t <=> u) <=> 0) and (0 <=> (u <=> t)) are equal,
(3.3) — (t <=> u == 0) == bool(t == u) is true,
(3.4) — (t <=> u != 0) == bool(t != u) is true,
(3.5) — Cat(t <=> u) == Cat(CONVERT_TO_LVALUE<C>(t2) <=> CONVERT_TO_LVALUE<C>(u2)) is true,
(3.6) — (t <=> u < 0) == bool(t < u) is true,
(3.7) — (t <=> u > 0) == bool(t > u) is true,
(3.8) — (t <=> u <= 0) == bool(t <= u) is true,
(3.9) — (t <=> u >= 0) == bool(t >= u) is true,
(3.10) — if Cat is convertible to strong_ordering, T and U model totally_ordered_with<T, U> (18.5.5).

17.11.5 Result of three-way comparison  [cmp.result]

1 The behavior of a program that adds specializations for the compare_three_way_result template defined in this subclause is undefined.

2 For the compare_three_way_result type trait applied to the types T and U, let t and u denote lvalues of types const remove_reference_t<T> and const remove_reference_t<U>, respectively. If the expression
t <=> u is well-formed when treated as an unevaluated operand (7.2.3), the member typedef-name type denotes the type decltype(t <=> u). Otherwise, there is no member type.

17.11.6 Comparison algorithms

1 The name `strong_order` denotes a customization point object (16.3.3.3.5). Given subexpressions E and F, the expression strong_order(E, F) is expression-equivalent (3.21) to the following:

1.1 — If the decayed types of E and F differ, strong_order(E, F) is ill-formed.

1.2 — Otherwise, strong_ordering(strong_order(E, F)) if it is a well-formed expression where the meaning of strong_order is established as-if by performing argument-dependent lookup only (6.5.4).

1.3 — Otherwise, if the decayed type T of E is a floating-point type, yields a value of type strong_ordering that is consistent with the ordering observed by T’s comparison operators, and if numeric_limits<T>::is_iec559 is true, is additionally consistent with the totalOrder operation as specified in ISO/IEC/IEEE 60559.

1.4 — Otherwise, strong_ordering(compare_three_way()(E, F)) if it is a well-formed expression.

1.5 — Otherwise, strong_order(E, F) is ill-formed.

[Note 1: Ill-formed cases above result in substitution failure when strong_order(E, F) appears in the immediate context of a template instantiation. — end note]

2 The name `weak_order` denies a customization point object (16.3.3.3.5). Given subexpressions E and F, the expression weak_order(E, F) is expression-equivalent (3.21) to the following:

2.1 — If the decayed types of E and F differ, weak_order(E, F) is ill-formed.

2.2 — Otherwise, weak_ordering(weak_order(E, F)) if it is a well-formed expression where the meaning of weak_order is established as-if by performing argument-dependent lookup only (6.5.4).

2.3 — Otherwise, if the decayed type T of E is a floating-point type, yields a value of type weak_ordering that is consistent with the ordering observed by T’s comparison operators and strong_order, and if numeric_limits<T>::is_iec559 is true, is additionally consistent with the following equivalence classes, ordered from lesser to greater:

2.3.1 — together, all negative NaN values;

2.3.2 — negative infinity;

2.3.3 — each normal negative value;

2.3.4 — each subnormal negative value;

2.3.5 — together, both zero values;

2.3.6 — each subnormal positive value;

2.3.7 — each normal positive value;

2.3.8 — positive infinity;

2.3.9 — together, all positive NaN values.

2.4 — Otherwise, weak_ordering(compare_three_way()(E, F)) if it is a well-formed expression.

2.5 — Otherwise, weak_ordering(strong_order(E, F)) if it is a well-formed expression.

2.6 — Otherwise, weak_order(E, F) is ill-formed.

[Note 2: Ill-formed cases above result in substitution failure when weak_order(E, F) appears in the immediate context of a template instantiation. — end note]

3 The name `partial_order` denotes a customization point object (16.3.3.3.5). Given subexpressions E and F, the expression partial_order(E, F) is expression-equivalent (3.21) to the following:

3.1 — If the decayed types of E and F differ, partial_order(E, F) is ill-formed.

3.2 — Otherwise, partial_ordering(partial_order(E, F)) if it is a well-formed expression where the meaning of partial_order is established as-if by performing argument-dependent lookup only (6.5.4).

3.3 — Otherwise, partial_ordering(compare_three_way()(E, F)) if it is a well-formed expression.

3.4 — Otherwise, partial_ordering(weak_order(E, F)) if it is a well-formed expression.

3.5 — Otherwise, partial_order(E, F) is ill-formed.

§ 17.11.6
The name `compare_strong_order_fallback` denotes a customization point object (16.3.3.3.5). Given subexpressions `E` and `F`, the expression `compare_strong_order_fallback(E, F)` is expression-equivalent (3.21) to:

1. If the decayed types of `E` and `F` differ, `compare_strong_order_fallback(E, F)` is ill-formed.
2. Otherwise, `strong_order(E, F)` if it is a well-formed expression.
3. Otherwise, if the expressions `E == F` and `E < F` are both well-formed and each of `decltype(E == F)` and `decltype(E < F)` models `boolean-testable`,
   
   ```cpp
   E == F ? strong_ordering::equal :
   E < F  ? strong_ordering::less :
           strong_ordering::greater
   ```

   except that `E` and `F` are evaluated only once.
4. Otherwise, `compare_strong_order_fallback(E, F)` is ill-formed.

The name `compare_weak_order_fallback` denotes a customization point object (16.3.3.3.5). Given subexpressions `E` and `F`, the expression `compare_weak_order_fallback(E, F)` is expression-equivalent (3.21) to:

1. If the decayed types of `E` and `F` differ, `compare_weak_order_fallback(E, F)` is ill-formed.
2. Otherwise, `weak_order(E, F)` if it is a well-formed expression.
3. Otherwise, if the expressions `E == F` and `E < F` are both well-formed and each of `decltype(E == F)` and `decltype(E < F)` models `boolean-testable`,
   
   ```cpp
   E == F ? weak_ordering::equivalent :
   E < F  ? weak_ordering::less :
           weak_ordering::greater
   ```

   except that `E` and `F` are evaluated only once.
4. Otherwise, `compare_weak_order_fallback(E, F)` is ill-formed.

The name `compare_partial_order_fallback` denotes a customization point object (16.3.3.3.5). Given subexpressions `E` and `F`, the expression `compare_partial_order_fallback(E, F)` is expression-equivalent (3.21) to:

1. If the decayed types of `E` and `F` differ, `compare_partial_order_fallback(E, F)` is ill-formed.
2. Otherwise, `partial_order(E, F)` if it is a well-formed expression.
3. Otherwise, if the expressions `E == F`, `E < F`, and `F < E` are all well-formed and each of `decltype(E == F)` and `decltype(E < F)` models `boolean-testable`,
   
   ```cpp
   E == F ? partial_ordering::equivalent :
   E < F  ? partial_ordering::less :
   F < E  ? partial_ordering::greater :
           partial_ordering::unordered
   ```

   except that `E` and `F` are evaluated only once.
4. Otherwise, `compare_partial_order_fallback(E, F)` is ill-formed.

17.12 Coroutines

17.12.1 General

The header `<coroutine>` defines several types providing compile and run-time support for coroutines in a C++ program.
17.12.2 Header <coroutine> synopsis

// all freestanding
#include <compare> // see 17.11.1

namespace std {
    // 17.12.3, coroutine traits
    template<class R, class... ArgTypes>
        struct coroutine_traits;

    // 17.12.4, coroutine handle
    template<class Promise = void>
        struct coroutine_handle;

    // 17.12.4.8, comparison operators
    constexpr bool operator==(coroutine_handle<> x, coroutine_handle<> y) noexcept;
    constexpr strong_ordering operator<=>(coroutine_handle<> x, coroutine_handle<> y) noexcept;

    // 17.12.4.9, hash support
    template<class T> struct hash;
    template<class P> struct hash<coroutine_handle<P>>;

    // 17.12.5, no-op coroutines
    struct noop_coroutine_promise;
    template<> struct coroutine_handle<noop_coroutine_promise>;
    using noop_coroutine_handle = coroutine_handle<noop_coroutine_promise>;
    noop_coroutine_handle noop_coroutine() noexcept;

    // 17.12.6, trivial awaitables
    struct suspend_never;
    struct suspend_always;
}

17.12.3 Coroutine traits

17.12.3.1 General

Subclause 17.12.3 defines requirements on classes representing coroutine traits, and defines the class template coroutine_traits that meets those requirements.

17.12.3.2 Class template coroutine_traits

The header <coroutine> defines the primary template coroutine_traits such that if ArgTypes is a parameter pack of types and if the qualified-id R::promise_type is valid and denotes a type (13.10.3), then coroutine_traits<R, ArgTypes...> has the following publicly accessible member:

using promise_type = typename R::promise_type;

Otherwise, coroutine_traits<R, ArgTypes...> has no members.

17.12.4 Class template coroutine_handle

17.12.4.1 General

namespace std {
    template<class>
        struct coroutine_handle<void> {
    
    // 17.12.4.2, construct/reset
    constexpr coroutine_handle() noexcept;
    constexpr coroutine_handle(nullptr_t) noexcept;
    coroutine_handle& operator=(nullptr_t) noexcept;

§ 17.12.4.1 550
// 17.12.4.4, export/import
constexpr void* address() const noexcept;
static constexpr coroutine_handle from_address(void* addr);

// 17.12.4.5, observers
constexpr explicit operator bool() const noexcept;
bool done() const;

// 17.12.4.6, resumption
void operator()() const;
void resume() const;
void destroy() const;

private:
    void* ptr; // exposition only
};

template<class Promise>
struct coroutine_handle
{
    // 17.12.4.2, construct/reset
    constexpr coroutine_handle() noexcept;
    constexpr coroutine_handle(nullptr_t) noexcept;
    static coroutine_handle from_promise(Promise&);
    coroutine_handle& operator=(nullptr_t) noexcept;

    // 17.12.4.4, export/import
    constexpr void* address() const noexcept;
    static constexpr coroutine_handle from_address(void* addr);

    // 17.12.4.3, conversion
    constexpr operator coroutine_handle<>() const noexcept;

    // 17.12.4.5, observers
    constexpr explicit operator bool() const noexcept;
    bool done() const;

    // 17.12.4.6, resumption
    void operator()() const;
    void resume() const;
    void destroy() const;

    // 17.12.4.7, promise access
    Promise& promise() const;

private:
    void* ptr; // exposition only
};

1 An object of type coroutine_handle<T> is called a coroutine handle and can be used to refer to a suspended or executing coroutine. A coroutine_handle object whose member address() returns a null pointer value does not refer to any coroutine. Two coroutine_handle objects refer to the same coroutine if and only if their member address() returns the same non-null value.

2 If a program declares an explicit or partial specialization of coroutine_handle, the behavior is undefined.

17.12.4.2 Construct/reset

constexpr coroutine_handle() noexcept;
constexpr coroutine_handle(nullptr_t) noexcept;

¹ Postconditions: address() == nullptr.
static coroutine_handle from_promise(Promise& p);

Preconditions: p is a reference to a promise object of a coroutine.

Postconditions: addressof(h.promise()) == addressof(p).

Returns: A coroutine handle h referring to the coroutine.

coroutine_handle& operator=(nullptr_t) noexcept;

Postconditions: address() == nullptr.

Returns: *this.

17.12.4.3 Conversion

constexpr operator coroutine_handle<>() const noexcept;

Effects: Equivalent to: return coroutine_handle<>::from_address(address());

17.12.4.4 Export/import

constexpr void* address() const noexcept;

Returns: ptr.

static constexpr coroutine_handle<> coroutine_handle<>::from_address(void* addr);

Preconditions: addr was obtained via a prior call to address on an object whose type is a specialization of coroutine_handle.

Postconditions: from_address(address()) == *this.

static constexpr coroutine_handle<Promise> coroutine_handle<Promise>::from_address(void* addr);

Preconditions: addr was obtained via a prior call to address on an object of type cv coroutine_handle<Promise>.

Postconditions: from_address(address()) == *this.

17.12.4.5 Observers

constexpr explicit operator bool() const noexcept;

Returns: address() != nullptr.

bool done() const;

Preconditions: *this refers to a suspended coroutine.

Returns: true if the coroutine is suspended at its final suspend point, otherwise false.

17.12.4.6 Resumption

Resuming a coroutine via resume, operator() , or destroy on an execution agent other than the one on which it was suspended has implementation-defined behavior unless each execution agent either is an instance of std::thread or std::jthread, or is the thread that executes main.

[Note 1: A coroutine that is resumed on a different execution agent should avoid relying on consistent thread identity throughout, such as holding a mutex object across a suspend point. — end note]

[Note 2: A concurrent resumption of the coroutine can result in a data race. — end note]

void operator()() const;
void resume() const;

Preconditions: *this refers to a suspended coroutine. The coroutine is not suspended at its final suspend point.

Effects: Resumes the execution of the coroutine.

void destroy() const;

Preconditions: *this refers to a suspended coroutine.

Effects: Destroys the coroutine (9.5.4).
17.12.4.7 Promise access

`Promise& promise() const;`

**Preconditions:** `*this` refers to a coroutine.

**Returns:** A reference to the promise of the coroutine.

17.12.4.8 Comparison operators

```cpp
constexpr bool operator==(coroutine_handle<> x, coroutine_handle<> y) noexcept;
```

**Returns:** `x.address() == y.address()`.

```cpp
constexpr strong_ordering operator<=>(coroutine_handle<> x, coroutine_handle<> y) noexcept;
```

**Returns:** `compare_three_way()(x.address(), y.address())`.

17.12.4.9 Hash support

```cpp
template<class P> struct hash<coroutine_handle<P>>;
```

The specialization is enabled (22.10.19).

17.12.5 No-op coroutines

17.12.5.1 Class `noop_coroutine_promise`

```cpp
struct noop_coroutine_promise {};
```

The class `noop_coroutine_promise` defines the promise type for the coroutine referred to by `noop_coroutine_handle` (17.12.2).

17.12.5.2 Class `coroutine_handle<noop_coroutine_promise>`

```cpp
namespace std {
    template<>
    struct coroutine_handle<noop_coroutine_promise> {
        // 17.12.5.2.1, conversion
        constexpr operator coroutine_handle<>() const noexcept;
        // 17.12.5.2.2, observers
        constexpr explicit operator bool() const noexcept;
        constexpr bool done() const noexcept;
        // 17.12.5.2.3, resumption
        constexpr void operator()() const noexcept;
        constexpr void resume() const noexcept;
        constexpr void destroy() const noexcept;
        // 17.12.5.2.4, promise access
        noop_coroutine_promise& promise() const noexcept;
        // 17.12.5.2.5, address
        constexpr void* address() const noexcept;
        private:
            coroutine_handle<unspecified>;
            void* ptr; // exposition only
    };
}
```

17.12.5.2.1 Conversion

```cpp
constexpr operator coroutine_handle<>() const noexcept;
```

**Effects:** Equivalent to: `return coroutine_handle<>::from_address(address());`
17.12.5.2.2 Observers

constexpr explicit operator bool() const noexcept;

Returns: true.

constexpr bool done() const noexcept;

Returns: false.

17.12.5.2.3 Resumption

constexpr void operator()() const noexcept;
constexpr void resume() const noexcept;
constexpr void destroy() const noexcept;

Effects: None.

Remarks: If noop_coroutine_handle is converted to coroutine_handle<> calls to operator(), resume and destroy on that handle will also have no observable effects.

17.12.5.2.4 Promise access

noop_coroutine_promise& promise() const noexcept;

Returns: A reference to the promise object associated with this coroutine handle.

17.12.5.2.5 Address

constexpr void* address() const noexcept;

Returns: A non-null pointer value.

Remarks: A noop_coroutine_handle’s ptr is always a non-null pointer value.

17.12.5.3 Function noop_coroutine

noop_coroutine_handle noop_coroutine() noexcept;

Returns: A handle to a coroutine that has no observable effects when resumed or destroyed.

Remarks: A handle returned from noop_coroutine may or may not compare equal to a handle returned from another invocation of noop_coroutine.

17.12.6 Trivial awaitables

namespace std {

    struct suspend_never {
        constexpr bool await_ready() const noexcept { return true; }
        constexpr void await_suspend(coroutine_handle<>) const noexcept {}
        constexpr void await_resume() const noexcept {}
    };

    struct suspend_always {
        constexpr bool await_ready() const noexcept { return false; }
        constexpr void await_suspend(coroutine_handle<>) const noexcept {}
        constexpr void await_resume() const noexcept {}
    };
}

[Note 1: The types suspend_never and suspend_always can be used to indicate that an await-expression either never suspends or always suspends, and in either case does not produce a value. — end note]

17.13 Other runtime support

17.13.1 General

Headers <csetjmp> (nonlocal jumps), <csignal> (signal handling), <cstdarg> (variable arguments), and <cstdlib> (runtime environment getenv, system), provide further compatibility with C code.

Calls to the function getenv (17.2.2) shall not introduce a data race (16.4.6.10) provided that nothing modifies the environment.

[Note 1: Calls to the POSIX functions setenv and putenv modify the environment. — end note]
3 A call to the setlocale function (30.5) may introduce a data race with other calls to the setlocale function or with calls to functions that are affected by the current C locale. The implementation shall behave as if no library function other than locale::global calls the setlocale function.

17.13.2 Header <cstdarg> synopsis

```
// all freestanding
namespace std {
    using va_list = see below;
}

#define va_arg(V, P) see below
#define va_copy(VDST, VSRC) see below
#define va_end(V) see below
#define va_start(V, P) see below
```

1 The contents of the header <cstdarg> are the same as the C standard library header <stdarg.h>, with the following changes:

1.1 In lieu of the default argument promotions specified in ISO C 6.5.2.2, the definition in 7.6.1.3 applies.

1.2 The restrictions that ISO C places on the second parameter to the va_start macro in header <stdarg.h> are different in this document. The parameter parmN is the rightmost parameter in the variable parameter list of the function definition (the one just before the ...).201 If the parameter parmN is a pack expansion (13.7.4) or an entity resulting from a lambda capture (7.5.5), the program is ill-formed, no diagnostic required. If the parameter parmN is of a reference type, or of a type that is not compatible with the type that results when passing an argument for which there is no parameter, the behavior is undefined.

See also: ISO C 7.16.1.1

17.13.3 Header <csetjmp> synopsis

```
namespace std {
    using jmp_buf = see below;
    // [noreturn] void longjmp(jmp_buf env, int val);
}

#define setjmp(env) see below
```

1 The contents of the header <csetjmp> are the same as the C standard library header <setjmp.h>.

2 The function signature longjmp(jmp_buf jbuf, int val) has more restricted behavior in this document. A setjmp/longjmp call pair has undefined behavior if replacing the set jmp and long jmp by catch and throw would invoke any non-trivial destructors for any objects with automatic storage duration. A call to set jmp or long jmp has undefined behavior if invoked in a suspension context of a coroutine (7.6.2.4).

See also: ISO C 7.13

17.13.4 Header <csignal> synopsis

```
namespace std {
    using sig_atomic_t = see below;
    // 17.13.5, signal handlers
    extern "C" using signal-handler = void(int); // exposition only
    signal-handler* signal(int sig, signal-handler* func);
    int raise(int sig);
}
```

201) Note that va_start is required to work as specified even if unary operator& is overloaded for the type of parmN.
The contents of the header `<csignal>` are the same as the C standard library header `<signal.h>`.

17.13.5 Signal handlers

A call to the function `signal` synchronizes with any resulting invocation of the signal handler so installed.

A plain lock-free atomic operation is an invocation of a function `f` from 33.5, such that:

1. `f` is the function `atomic_is_lock_free()`, or
2. `f` is the member function `is_lock_free()`, or
3. `f` is a non-static member function of class `atomic_flag`, or
4. `f` is a non-member function, and the first parameter of `f` has type `cv atomic_flag*`, or
5. `f` is a non-static member function invoked on an object `A`, such that `A.is_lock_free()` yields `true`, or
6. `f` is a non-member function, and for every pointer-to-atomic argument `A` passed to `f`, `atomic_is_lock_free(A)` yields `true`.

An evaluation is signal-safe unless it includes one of the following:

1. A call to any standard library function, except for plain lock-free atomic operations and functions explicitly identified as signal-safe;
   
   [Note 1: This implicitly excludes the use of `new` and `delete` expressions that rely on a library-provided memory allocator. — end note]

2. An access to an object with thread storage duration;
3. A `dynamic_cast` expression;
4. Throwing of an exception;
5. Control entering a try-block or function-try-block;
6. Initialization of a variable with static storage duration requiring dynamic initialization (6.9.3.3, 8.8) or
   
   [202] Waiting for the completion of the initialization of a variable with static storage duration (8.8).

A signal handler invocation has undefined behavior if it includes an evaluation that is not signal-safe.

The function `signal` is signal-safe if it is invoked with the first argument equal to the signal number corresponding to the signal that caused the invocation of the handler.

See also: ISO C 7.14

17.14 C headers

17.14.1 General

For compatibility with the C standard library, the C++ standard library provides the C headers shown in Table 40. The intended use of these headers is for interoperability only. It is possible that C++ source files need to include one of these headers in order to be valid ISO C. Source files that are not intended to also be valid ISO C should not use any of the C headers.

[Note 1: The C headers either have no effect, such as `<stdbool.h>` (17.14.5) and `<stdalign.h>` (17.14.4), or otherwise the corresponding header of the form `<cname>` provides the same facilities and assuredly defines them in namespace `std`. — end note]
**Example 1:** The following source file is both valid C++ and valid ISO C. Viewed as C++, it declares a function with C language linkage; viewed as C it simply declares a function (and provides a prototype).

```c
#include <stdbool.h>  // for bool in C, no effect in C++
#include <stddef.h>   // for size_t

#ifdef __cplusplus
extern "C"
#endif

void f(bool b[], size_t n);
```

--- end example

#### 17.14.2 Header `<complex.h>` synopsis

1. The header `<complex.h>` behaves as if it simply includes the header `<complex>` (28.4.2).

   [Note 1: Names introduced by `<complex>` in namespace `std` are not placed into the global namespace scope by `<complex.h>`.
   — end note]

#### 17.14.3 Header `<iso646.h>` synopsis

1. The C++ header `<iso646.h>` is empty.

   [Note 1: and, and_eq, bitand, bitor, compl, not_eq, not, or, or_eq, xor, and xor_eq are keywords in C++ (5.11).
   — end note]

#### 17.14.4 Header `<stdbool.h>` synopsis

1. The contents of the C++ header `<stdbool.h>` are the same as the C standard library header `<stdbool.h>`, with the following changes: The header `<stdbool.h>` does not define a macro named `alignas`.

   See also: ISO C 7.15

#### 17.14.5 Header `<stdalign.h>` synopsis

1. The contents of the C++ header `<stdalign.h>` are the same as the C standard library header `<stdalign.h>`, with the following changes: The header `<stdalign.h>` does not define macros named `bool`, `true`, or `false`.

   See also: ISO C 7.18

#### 17.14.6 Header `<tgmath.h>` synopsis

1. The header `<tgmath.h>` behaves as if it simply includes the headers `<cmath>` (28.7.1) and `<complex>` (28.4.2).

   [Note 1: The overloads provided in C by type-generic macros are already provided in `<complex>` and `<cmath>` by “sufficient” additional overloads.
   — end note]

2. [Note 2: Names introduced by `<cmath>` or `<complex>` in namespace `std` are not placed into the global namespace scope by `<tgmath.h>`.
   — end note]

#### 17.14.7 Other C headers

1. Every C header other than `<complex.h>` (17.14.2), `<iso646.h>` (17.14.3), `<stdalign.h>` (17.14.4), `<stdatomic.h>` (33.5.12), `<stdbool.h>` (17.14.5), and `<tgmath.h>` (17.14.6), each of which has a name of the form `<cname.h>`, behaves as if each name placed in the standard library namespace by the corresponding `<cname>` header is placed within the global namespace scope, except for the functions described in 28.7.6.
the `std::lerp` function overloads (28.7.4), the declaration of `std::byte` (17.2.1), and the functions and function templates described in 17.2.5. It is unspecified whether these names are first declared or defined within namespace scope (6.4.6) of the namespace `std` and are then injected into the global namespace scope by explicit `using-declarations` (9.9).

2 [Example 1: The header `<cstdlib>` assuredly provides its declarations and definitions within the namespace `std`. It may also provide these names within the global namespace. The header `<stdlib.h>` assuredly provides the same declarations and definitions within the global namespace, much as in the C Standard. It may also provide these names within the namespace `std`. — end example]
18 Concepts library

18.1 General

This Clause describes library components that C++ programs may use to perform compile-time validation of template arguments and perform function dispatch based on properties of types. The purpose of these concepts is to establish a foundation for equational reasoning in programs.

The following subclauses describe language-related concepts, comparison concepts, object concepts, and callable concepts as summarized in Table 41.

Table 41: Fundamental concepts library summary

<table>

18.2 Equality preservation

An expression is equality-preserving if, given equal inputs, the expression results in equal outputs. The inputs to an expression are the set of the expression’s operands. The output of an expression is the expression’s result and all operands modified by the expression. For the purposes of this subclause, the operands of an expression are the largest subexpressions that include only:

1. an id-expression (7.5.4), and
2. invocations of the library function templates std::move, std::forward, and std::declval (22.2.4, 22.2.6).

[Example 1: The operands of the expression a = std::move(b) are a and std::move(b). —end example]

Not all input values need be valid for a given expression.

[Example 2: For integers a and b, the expression a / b is not well-defined when b is 0. This does not preclude the expression a / b being equality-preserving. —end example]

The domain of an expression is the set of input values for which the expression is required to be well-defined.

Expressions required to be equality-preserving are further required to be stable: two evaluations of such an expression with the same input objects are required to have equal outputs absent any explicit intervening modification of those input objects.

[Note 1: This requirement allows generic code to reason about the current values of objects based on knowledge of the prior values as observed via equality-preserving expressions. It effectively forbids spontaneous changes to an object, changes to an object from another thread of execution, changes to an object as side effects of non-modifying expressions, and changes to an object as side effects of modifying a distinct object if those changes could be observable to a library function via an equality-preserving expression that is required to be valid for that object. — end note]

Expressions declared in a requires-expression in the library clauses are required to be equality-preserving, except for those annotated with the comment “not required to be equality-preserving.” An expression so annotated may be equality-preserving, but is not required to be so.

An expression that may alter the value of one or more of its inputs in a manner observable to equality-preserving expressions is said to modify those inputs. The library clauses use a notational convention to specify which expressions declared in a requires-expression modify which inputs: except where otherwise specified, an expression operand that is a non-constant lvalue or rvalue may be modified. Operands that are constant lvalues or rvalues are required to not be modified. For the purposes of this subclause, the cv-qualification and value category of each operand are determined by assuming that each template type parameter denotes a cv-unqualified complete non-array object type.
Where a requires-expression declares an expression that is non-modifying for some constant lvalue operand, additional variations of that expression that accept a non-constant lvalue or (possibly constant) rvalue for the given operand are also required except where such an expression variation is explicitly required with differing semantics. These implicit expression variations are required to meet the semantic requirements of the declared expression. The extent to which an implementation validates the syntax of the variations is unspecified.

[Example 3:

```cpp
template<class T> concept C = requires(T a, T b, const T c, const T d) {
  c == d; // #1
  a = std::move(b); // #2
  a = c; // #3
};
```

For the above example:

(7.1) — Expression #1 does not modify either of its operands, #2 modifies both of its operands, and #3 modifies only its first operand a.

(7.2) — Expression #1 implicitly requires additional expression variations that meet the requirements for c == d (including non-modification), as if the expressions

```
c == b;
c == std::move(b);
std::move(c) == d;
std::move(c) == std::move(b);
```

had been declared as well.

(7.3) — Expression #3 implicitly requires additional expression variations that meet the requirements for a = c (including non-modification of the second operand), as if the expressions

```
a = b;
a = std::move(b);
```

had been declared. Expression #3 does not implicitly require an expression variation with a non-constant rvalue second operand, since expression #2 already specifies exactly such an expression explicitly.

— end example

[Example 4: The following type T meets the explicitly stated syntactic requirements of concept C above but does not meet the additional implicit requirements:

```cpp
struct T {
  bool operator==(const T&) const { return true; }
  bool operator==(T&) = delete;
};
```

T fails to meet the implicit requirements of C, so T satisfies but does not model C. Since implementations are not required to validate the syntax of implicit requirements, it is unspecified whether an implementation diagnoses as ill-formed a program that requires C<T>. — end example

18.3 Header <concepts> synopsis

```cpp

template<class R, class T, class U>
concept strict_weak_order = see below;

18.4 Language-related concepts

18.4.1 General

Subclause 18.4 contains the definition of concepts corresponding to language features. These concepts express relationships between types, type classifications, and fundamental type properties.

18.4.2 Concept same_as

template<class T, class U>
concept same_as_impl = is_same_v<T, U>; // exposition only

template<class T, class U>
concept same_as = same_as_impl<T, U> && same_as_impl<U, T>;

[Note 1: same_as<T, U> subsumes same_as<U, T> and vice versa. — end note]

18.4.3 Concept derived_from

template<class Derived, class Base>
concept derived_from = is_base_of_v<Base, Derived> &&
is_convertible_v<Derived*, const volatile Base*>

[Note 1: derived_from<Derived, Base> is satisfied if and only if Derived is publicly and unambiguously derived from Base, or Derived and Base are the same class type ignoring cv-qualifiers. — end note]
18.4.4 Concept convertible_to [concept.convertible]

Given types From and To and an expression E whose type and value category are the same as those of declval<From>() convertibles_to<From, To> requires E to be both implicitly and explicitly convertible to type To. The implicit and explicit conversions are required to produce equal results.

```cpp
template<class From, class To>
concept convertible_to =
    is_convertible_v<From, To> &&
    requires {
        static_cast<To>(declval<From>());
    };
```

Let FromR be add_rvalue_reference_t<From> and test be the invented function:

```cpp
To test(FromR (&f)()) {
    return f();
}
```

and let f be a function with no arguments and return type FromR such that f() is equality-preserving. Types From and To model convertible_to<From, To> only if:

1. To is not an object or reference-to-object type, or static_cast<To>(f()) is equal to test(f).
2. FromR is not a reference-to-object type, or
   1. If FromR is an rvalue reference to a non const-qualified type, the resulting state of the object referenced by f() after either above expression is valid but unspecified (16.4.6.15).
   2. Otherwise, the object referred to by f() is not modified by either above expression.

18.4.5 Concept common_reference_with [concept.commonref]

For two types T and U, if common_reference_t<T, U> is well-formed and denotes a type C such that both convertible_to<T, C> and convertible_to<U, C> are modeled, then T and U share a common reference type, C.

[Note 1: C can be the same as T or U, or can be a different type. C can be a reference type. — end note]

```cpp
template<class T, class U>
concept common_reference_with =
    same_as<common_reference_t<T, U>, common_reference_t<U, T>> &&
    convertible_to<T, common_reference_t<T, U>> &&
    convertible_to<U, common_reference_t<T, U>>;
```

Let C be common_reference_t<T, U>. Let t1 and t2 be equality-preserving expressions (18.2) such that decltype((t1)) and decltype((t2)) are each T, and let u1 and u2 be equality-preserving expressions such that decltype((u1)) and decltype((u2)) are each U. T and U model common_reference_with<T, U> only if:

1. C(t1) equals C(t2) if and only if t1 equals t2, and
2. C(u1) equals C(u2) if and only if u1 equals u2.

[Note 2: Users can customize the behavior of common_reference_with by specializing the basic_common_reference class template (21.3.8.7). — end note]

18.4.6 Concept common_with [concept.common]

If T and U can both be explicitly converted to some third type, C, then T and U share a common type, C.

[Note 1: C can be the same as T or U, or can be a different type. C is not necessarily unique. — end note]

```cpp
template<class T, class U>
concept common_with =
    same_as<common_type_t<T, U>, common_type_t<U, T>> &&
    requires {
        static_cast<common_type_t<T, U>>(declval<T>());
        static_cast<common_type_t<T, U>>(declval<U>());
    };
```
common_reference_with<
    add_lvalue_reference_t<const T>,
    add_lvalue_reference_t<const U>> &&
common_reference_with<
    add_lvalue_reference_t<common_type_t<T, U>>,
    common_reference_t<
        add_lvalue_reference_t<const T>,
        add_lvalue_reference_t<const U>>>;

2 Let $C$ be common_type_t<T, U>. Let $t_1$ and $t_2$ be equality-preserving expressions (18.2) such that
decltype((t1)) and decltype((t2)) are each T, and let $u_1$ and $u_2$ be equality-preserving expressions such that decltype((u1)) and decltype((u2)) are each U. T and U model common_with<T, U> only if:

(2.1) $C(t_1)$ equals $C(t_2)$ if and only if $t_1$ equals $t_2$, and
(2.2) $C(u_1)$ equals $C(u_2)$ if and only if $u_1$ equals $u_2$.

[Note 2: Users can customize the behavior of common_with by specializing the common_type class template (21.3.8.7). —end note]

18.4.7 Arithmetic concepts [concepts.arithmetic]

template<class T>
    concept integral = is_integral_v<T>;

template<class T>
    concept signed_integral = integral<T> && is_signed_v<T>;

template<class T>
    concept unsigned_integral = integral<T> && !signed_integral<T>;

template<class T>
    concept floating_point = is_floating_point_v<T>;  

[Note 1: signed_integral can be modeled even by types that are not signed integer types (6.8.2); for example, char. —end note]

2 [Note 2: unsigned_integral can be modeled even by types that are not unsigned integer types (6.8.2); for example, bool. —end note]

18.4.8 Concept assignable_from [concept.assignable]

template<class LHS, class RHS>
    concept assignable_from =
        is_lvalue_reference_v<LHS> &&
        common_reference_with<
            const remove_reference_t<LHS>&,
            const remove_reference_t<RHS>&> &&
        requires(LHS lhs, RHS&& rhs) {
            ( lhs = std::forward<RHS>(rhs) ) -> same_as<LHS>;
        };

Let:

(1.1) $lhs$ be an lvalue that refers to an object $lcopy$ such that decltype((lhs)) is LHS,
(1.2) $rhs$ be an expression such that decltype((rhs)) is RHS, and
(1.3) $rcopy$ be a distinct object that is equal to $rhs$.

LHS and RHS model assignable_from<LHS, RHS> only if

(1.4) $addressof(lhs = rhs) == addressof(lcopy)$.
(1.5) After evaluating $lhs = rhs$:

(1.5.1) $lhs$ is equal to $rcopy$, unless $rhs$ is a non-const xvalue that refers to $lcopy$.
(1.5.2) If $rhs$ is a non-const xvalue, the resulting state of the object to which it refers is valid but unspecified (16.4.6.15).
(1.5.3) Otherwise, if $rhs$ is a glvalue, the object to which it refers is not modified.

[Note 1: Assignment need not be a total function (16.3.2.3); in particular, if assignment to an object $x$ can result in a modification of some other object $y$, then $x = y$ is likely not in the domain of =. —end note]
18.4.9 Concept swappable

Let \( t_1 \) and \( t_2 \) be equality-preserving expressions that denote distinct equal objects of type \( T \), and let \( u_1 \) and \( u_2 \) similarly denote distinct equal objects of type \( U \).

[Note 1: \( t_1 \) and \( u_1 \) can denote distinct objects, or the same object. — end note]

An operation exchanges the values denoted by \( t_1 \) and \( u_1 \) if and only if the operation modifies neither \( t_2 \) nor \( u_2 \) and:

\[
\begin{align*}
(1.1) & \quad \text{If } T \text{ and } U \text{ are the same type, the result of the operation is that } t_1 \text{ equals } u_2 \text{ and } u_1 \text{ equals } t_2. \\
(1.2) & \quad \text{If } T \text{ and } U \text{ are different types and } \text{common_reference_with\langle decltype((t_1)), decltype((u_1))\rangle} \text{ is modeled, the result of the operation is that } C(t_1) \text{ equals } C(u_2) \text{ and } C(u_1) \text{ equals } C(t_2) \text{ where } C \text{ is } \text{common_reference_t\langle decltype((t_1)), decltype((u_1))\rangle}. 
\end{align*}
\]

The name `ranges::swap` denotes a customization point object (16.3.3.3.5). The expression `ranges::swap(E_1, E_2)` for subexpressions \( E_1 \) and \( E_2 \) is expression-equivalent to an expression \( S \) determined as follows:

\[
\begin{align*}
(2.1) & \quad S \text{ is } (\text{void})\text{swap}(E_1, E_2) \text{ if } E_1 \text{ or } E_2 \text{ has class or enumeration type (6.8.4) and that expression is valid, with overload resolution performed in a context that includes the declaration} \\
& \quad \text{template<class } T > \\
& \quad \quad \quad \text{void } \text{swap}(T&, T&) = \text{delete}; \\
& \quad \text{and does not include a declaration of } \text{ranges::swap}. \text{ If the function selected by overload resolution does not exchange the values denoted by } E_1 \text{ and } E_2, \text{ the program is ill-formed, no diagnostic required.} \\
& \quad [\text{Note 2: This precludes calling unconstrained program-defined overloads of } \text{swap}. \text{ When the deleted overload is viable, program-defined overloads need to be more specialized (13.7.7.3) to be selected. — end note}]
\end{align*}
\]

\[
\begin{align*}
(2.2) & \quad \text{Otherwise, if } E_1 \text{ and } E_2 \text{ are lvalues of array types (6.8.4) with equal extent and } \text{ranges::swap}(\text{std::move}(E_1), \text{std::move}(E_2)) \text{ is a valid expression, } S \text{ is } (\text{void})\text{ranges::swap_ranges}(E_1, E_2), \text{ except that } \text{noexcept}(S) \text{ is equal to } \text{noexcept(ranges::swap}(\text{std::move}(E_1), \text{std::move}(E_2))). \\
(2.3) & \quad \text{Otherwise, if } E_1 \text{ and } E_2 \text{ are lvalues of the same type } T \text{ that models } \text{move_constructible\langle T \rangle} \text{ and } \text{assignable_from\langle T&, T \rangle}, \text{ } S \text{ is an expression that exchanges the denoted values. } S \text{ is a constant expression if} \\
& \quad \quad \quad \text{if } \text{(2.3.1) } \text{T is a literal type (6.8.1),} \\
& \quad \quad \quad \text{(2.3.2) both } E_1 = \text{std::move}(E_2) \text{ and } E_2 = \text{std::move}(E_1) \text{ are constant subexpressions (3.14), and} \\
& \quad \quad \quad \text{(2.3.3) the full-expressions of the initializers in the declarations} \\
& \quad \quad \quad \text{T t_1(\text{std::move}(E_1));} \\
& \quad \quad \quad \text{T t_2(\text{std::move}(E_2));} \\
& \quad \quad \quad \text{are constant subexpressions.} \\
& \quad \text{noexcept}(S) \text{ is equal to } \text{is_nothrow_move_constructible_v\langle T \rangle } \&\& \text{is_nothrow_move_assignable_v\langle T \rangle}. \\
(2.4) & \quad \text{Otherwise, } \text{ranges::swap}(E_1, E_2) \text{ is ill-formed.} \\
& \quad [\text{Note 3: This case can result in substitution failure when } \text{ranges::swap}(E_1, E_2) \text{ appears in the immediate context of a template instantiation. — end note}]
\end{align*}
\]

\[
\begin{align*}
(2.4) & \quad \text{Otherwise, } \text{ranges::swap}(E_1, E_2) \text{ is ill-formed.} \\
& \quad & \text{[Note 4: Whenever } \text{ranges::swap}(E_1, E_2) \text{ is a valid expression, it exchanges the values denoted by } E_1 \text{ and } E_2 \text{ and has type void. — end note]}
\end{align*}
\]

\[
\begin{align*}
\text{template<class } T > \\
& \quad \text{concept swappable } = \text{requires}(T& a, T& b) \{ \text{ranges::swap}(a, b); \};
\end{align*}
\]

\[
\begin{align*}
\text{template<class } T, \text{ class } U > \\
& \quad \text{concept swappable_with } = \\
& \quad \text{common_reference_with\langle } T, U \text{ \rangle } \&\& \\
& \quad \text{requires}(T& t, U& u) \{ \\
& \quad \quad \text{ranges::swap(\text{std::forward}\langle T\rangle(t), \text{std::forward}\langle T\rangle(t));} \\
& \quad \quad \text{ranges::swap(\text{std::forward}\langle U\rangle(u), \text{std::forward}\langle U\rangle(u));} \\
& \quad \quad \text{ranges::swap(\text{std::forward}\langle U\rangle(u), \text{std::forward}\langle T\rangle(t));}
\end{align*}
\]

203) The name `swap` is used here unqualified.
Note 5: The semantics of the `swappable` and `swappable_with` concepts are fully defined by the `ranges::swap` customization point object. — end note

Example 1: User code can ensure that the evaluation of `swap` calls is performed in an appropriate context under the various conditions as follows:

```cpp
#include <cassert>
#include <concepts>
#include <utility>
namespace ranges = std::ranges;

template<class T, std::swappable_with<T> U>
void value_swap(T&& t, U&& u) {
    ranges::swap(std::forward<T>(t), std::forward<U>(u));
}

template<std::swappable T>
void lv_swap(T& t1, T& t2) {
    ranges::swap(t1, t2);
}

namespace N {
    struct A { int m; }; 
    struct Proxy {
        A* a;
        Proxy(A& a) : a(&a) {} 
        friend void swap(Proxy x, Proxy y) {
            ranges::swap(*x.a, *y.a);
        }
    };
    Proxy proxy(A& a) { return Proxy{ a }; }
}

int main() {
    int i = 1, j = 2;
    lv_swap(i, j);
    assert(i == 2 && j == 1);
    N::A a1 = { 5 }, a2 = { -5 };
    value_swap(a1, proxy(a2));
    assert(a1.m == -5 && a2.m == 5);
}
— end example]

18.4.10 Concept destructible

The `destructible` concept specifies properties of all types, instances of which can be destroyed at the end of their lifetime, or reference types.

```

18.4.11 Concept constructible_from

The `constructible_from` concept constrains the initialization of a variable of a given type with a particular set of argument types.

```
18.4.12 Concept default_initializable

```
template<class T>
constexpr bool is-default-initializable = see below; // exposition only
```

For a type \( T \), \texttt{is-default-initializable}\(<T>\) is \texttt{true} if and only if the variable definition
\[ T t; \]
is well-formed for some invented variable \( t \); otherwise it is \texttt{false}. Access checking is performed as if in
a context unrelated to \( T \). Only the validity of the immediate context of the variable initialization is
considered.

18.4.13 Concept move_constructible

```
template<class T>
concept move_constructible = constructible_from<T, T> && convertible_to<T, T>;
```

If \( T \) is an object type, then let \( rv \) be an rvalue of type \( T \) and \( u_2 \) a distinct object of type \( T \) equal to \( rv \).
\( T \) models \texttt{move_constructible} only if
\begin{enumerate}
\item After the definition \( T u = rv; \), \( u \) is equal to \( u_2 \).
\item \( T(rv) \) is equal to \( u_2 \).
\item If \( T \) is not \texttt{const}, \( rv \)'s resulting state is valid but unspecified (16.4.6.15); otherwise, it is unchanged.
\end{enumerate}

18.4.14 Concept copy_constructible

```
template<class T>
concept copy_constructible = move_constructible<T> && constructible_from<T, T&> && convertible_to<T&, T> &&
 constructible_from<T, const T&> && convertible_to<const T&, T> &&
 constructible_from<T, const T> && convertible_to<const T, T>;
```

If \( T \) is an object type, then let \( v \) be an lvalue of type \( T \) or \texttt{const} \( T \) or an rvalue of type \texttt{const} \( T \). \( T \) models \texttt{copy_constructible} only if
\begin{enumerate}
\item After the definition \( T u = v; \), \( u \) is equal to \( v \) (18.2) and \( v \) is not modified.
\item \( T(v) \) is equal to \( v \) and does not modify \( v \).
\end{enumerate}

18.5 Comparison concepts

18.5.1 General

Given an expression \( E \) and a type \( C \), let \texttt{CONVERT_TO_LVALUE}<\( C >(E) \) be:
\begin{enumerate}
\item \texttt{static_cast<const C&>(as_const(E))} if that is a valid expression, and
\item \texttt{static_cast<const C&>(std::move(E))} otherwise.
\end{enumerate}

18.5.2 Boolean testability

The exposition-only \texttt{boolean-testable} concept specifies the requirements on expressions that are convertible
to \texttt{bool} and for which the logical operators (7.6.14, 7.6.15, 7.6.2.2) have the conventional semantics.

```
template<class T>
concept boolean-testable-impl = convertible_to<T, bool>; // exposition only
```

Let \( e \) be an expression such that \texttt{dec_type}(\( e \)) is \( T \). \( T \) models \texttt{boolean-testable-impl} only if:
\begin{enumerate}
\item \texttt{either remove_cvref_t<T>(\( e \))} is not a class type, or a search for the names \texttt{operator\&\&} and \texttt{operator\|\|}
in the scope of \texttt{remove_cvref_t<T>} finds nothing; and
\end{enumerate}
— argument-dependent lookup (6.5.4) for the names `operator&&` and `operator||` with `T` as the only argument type finds no disqualifying declaration (defined below).

A **disqualifying parameter** is a function parameter whose declared type `P`

— is not dependent on a template parameter, and there exists an implicit conversion sequence (12.2.4.2) from `e` to `P`; or

— is dependent on one or more template parameters, and either

  — `P` contains no template parameter that participates in template argument deduction (13.10.3.6), or

  — template argument deduction using the rules for deducing template arguments in a function call (13.10.3.2) and `e` as the key parameter succeeds.

A **key parameter** of a function template `D` is a function parameter of type `cv X` or reference thereto, where `X` names a specialization of a class template that has the same innermost enclosing non-inline namespace as `D`, and `X` contains at least one template parameter that participates in template argument deduction.

[Example 1: In

```cpp
namespace Z {
    template<class> struct C {}; 
    template<class T>
    void operator&&(C<T> x, T y); 
    template<class T>
    void operator||(C<type_identity_t<T>> x, T y); 
}
```

the declaration of `Z::operator&&` contains one key parameter, `C<T> x`, and the declaration of `Z::operator||` contains no key parameters. — end example]

A **disqualifying declaration** is

— a (non-template) function declaration that contains at least one disqualifying parameter; or

— a function template declaration that contains at least one disqualifying parameter, where

  — at least one disqualifying parameter is a key parameter; or

  — the declaration contains no key parameters; or

  — the declaration declares a function template to which no name is bound (9.3.4).

[Note 1: The intention is to ensure that given two types `T1` and `T2` that each model `boolean-testable-impl`, the `&&` and `||` operators within the expressions `declval<T1>() && declval<T2>()` and `declval<T1>() || declval<T2>()` resolve to the corresponding built-in operators. — end note]

```cpp
template<class T> 
concept boolean-testable = // exposition only 
    boolean-testable-impl<T> && requires(T&& t) { 
    { !std::forward<T>(t) } -> boolean-testable-impl; 
    };
```

Let `e` be an expression such that `decltype((e))` is `T`. `T` models `boolean-testable` only if `bool(e) == !bool(!e)`.

[Example 2: The types `bool, true_type` (21.3.3), `int*`, and `bitset<N>::reference` (22.9.2) model `boolean-testable`. — end example]

### 18.5.3 Comparison common types

```cpp
template<class T, class U, class C = common_reference_t<const T&, const U&>>
concept comparison-common-type-with-impl = // exposition only 
    same_as<common_reference_t<const T&, const U&>>, 
    common_reference_t<const U&, const T&>> &&
    requires {
    requires convertible_to<const T&, const C&> || convertible_to<T, const C&>; 
    requires convertible_to<const U&, const C&> || convertible_to<U, const C&>; 
    };
```
18.5.4  Concept equality_comparable

```cpp
template<class T, class U>
class equality_comparable = // exposition only
concept equality_comparable = weakly-equality-comparable-with<T, U> &&
comparison-common-type-with<T, U> &&
equality_comparable<
    common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>,
    remove_cvref_t<T>, remove_cvref_t<U>;;
```

1 Let C be `common_reference_t<const T&, const U&>`. Let `t1` and `t2` be equality-preserving expressions that are lvalues of type `remove_cvref_t<T>`, and let `u1` and `u2` be equality-preserving expressions that are lvalues of type `remove_cvref_t<U>`. T and U model `comparison-common-type-with<T, U>` only if:

1.1) `CONVERT_TO_LVALUE<C>(t1)` equals `CONVERT_TO_LVALUE<C>(t2)` if and only if `t1` equals `t2`, and

1.2) `CONVERT_TO_LVALUE<C>(u1)` equals `CONVERT_TO_LVALUE<C>(u2)` if and only if `u1` equals `u2`.

18.5.5  Concept totally_ordered

```cpp
template<class T>
class totally_ordered = // exposition only
concept totally_ordered = equality_comparable<T> &&
comparison-common-type-with<T, U> &&
equality_comparable<
    common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>,
    remove_cvref_t<T>, remove_cvref_t<U>;;
```

Given types T and U, let `t` and `t2` be lvalues denoting distinct equal objects of types `const remove_reference_t<T>` and `remove_cvref_t<T>`, respectively, let `u` and `u2` be lvalues denoting distinct equal objects of types `const remove_reference_t<U>` and `remove_cvref_t<U>`, respectively, and let C be:

```cpp
common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>
```

T and U model `equality_comparable_with<T, U>` only if:

```cpp
equality_comparable<
    common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>,
    remove_cvref_t<T>, remove_cvref_t<U>;;
```

Given types T and U, let `t` and `t2` be lvalues denoting distinct equal objects of types `const remove_reference_t<T>` and `remove_cvref_t<T>`, respectively, let `u` and `u2` be lvalues denoting distinct equal objects of types `const remove_reference_t<T>` and `remove_cvref_t<T>`, respectively, and let C be:

```cpp
common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>
```

T and U model `equality_comparable_with<T, U>` only if:

```cpp
equality_comparable<
    common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>,
    remove_cvref_t<T>, remove_cvref_t<U>;;
```

Given types T and U, let `t` and `t2` be lvalues denoting distinct equal objects of types `const remove_reference_t<T>` and `remove_cvref_t<T>`, respectively, let `u` and `u2` be lvalues denoting distinct equal objects of types `const remove_reference_t<T>` and `remove_cvref_t<T>`, respectively, and let C be:

```cpp
common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>
```

T and U model `equality_comparable_with<T, U>` only if:
equality_comparable<T> && partially_ordered_with<T, T>;

Given a type T, let a, b, and c be lvalues of type const remove_reference_t<T>. T models totally_ordered only if

1.1 Exactly one of bool(a < b), bool(a > b), or bool(a == b) is true.
1.2 If bool(a < b) and bool(b < c), then bool(a < c).
1.3 bool(a <= b) == !bool(b < a).
1.4 bool(a >= b) == !bool(a < b).

template<class T, class U>
concept totally_ordered_with =
totally_ordered<T> && totally_ordered<U> &&
equality_comparable_with<T, U> &&
totally_ordered<
  common_reference_t<
    const remove_reference_t<T>&,
    const remove_reference_t<U>&>
  && partially_ordered_with<T, U>;

Given types T and U, let t and t2 be lvalues denoting distinct equal objects of types const remove_reference_t<T> and remove_cvref_t<T>, respectively, let u and u2 be lvalues denoting distinct equal objects of types const remove_reference_t<U> and remove_cvref_t<U>, respectively, and let C be:

common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&> T and U model totally_ordered_with<T, U> only if

2.1 bool(t < u) == bool(CONVERT_TO_LVALUE<C>(t2) < CONVERT_TO_LVALUE<C>(u2)).
2.2 bool(t > u) == bool(CONVERT_TO_LVALUE<C>(t2) > CONVERT_TO_LVALUE<C>(u2)).
2.3 bool(t <= u) == bool(CONVERT_TO_LVALUE<C>(t2) <= CONVERT_TO_LVALUE<C>(u2)).
2.4 bool(t >= u) == bool(CONVERT_TO_LVALUE<C>(t2) >= CONVERT_TO_LVALUE<C>(u2)).
2.5 bool(u < t) == bool(CONVERT_TO_LVALUE<C>(u2) < CONVERT_TO_LVALUE<C>(t2)).
2.6 bool(u > t) == bool(CONVERT_TO_LVALUE<C>(u2) > CONVERT_TO_LVALUE<C>(t2)).
2.7 bool(u <= t) == bool(CONVERT_TO_LVALUE<C>(u2) <= CONVERT_TO_LVALUE<C>(t2)).
2.8 bool(u >= t) == bool(CONVERT_TO_LVALUE<C>(u2) >= CONVERT_TO_LVALUE<C>(t2)).

18.6 Object concepts [concepts.object]

This subclause describes concepts that specify the basis of the value-oriented programming style on which the library is based.

template<class T>
concept movable = is_object_v<T> && move_constructible<T> &&
  assignable_from<T&, T> && swappable<T>;

template<class T>
concept copyable = copy_constructible<T> && movable<T> && assignable_from<T&, T> &&
  assignable_from<T&, const T&> && assignable_from<T&, const T>;

template<class T>
concept semiregular = copyable<T> && default_initializable<T>;

template<class T>
concept regular = semiregular<T> && equality_comparable<T>;

[Note 1: The semiregular concept is modeled by types that behave similarly to fundamental types like int, except that they need not be comparable with ==. — end note]

[Note 2: The regular concept is modeled by types that behave similarly to fundamental types like int and that are comparable with ==. — end note]

18.7 Callable concepts [concepts.callable]

18.7.1 General [concepts.callable.general]

The concepts in subclause 18.7 describe the requirements on function objects (22.10) and their arguments.
18.7.2 Concept invocable

The invocable concept specifies a relationship between a callable type \( F \) and a set of argument types \( \text{Args...} \) which can be evaluated by the library function \( \text{invoke} \).

```cpp
template<class F, class... Args>
concept invocable = requires(F&& f, Args&&... args) {
  invoke(std::forward<F>(f), std::forward<Args>(args)...); // not required to be equality-preserving
};
```

[Example 1: A function that generates random numbers can model invocable, since the \( \text{invoke} \) function call expression is not required to be equality-preserving (18.2). — end example]

18.7.3 Concept regular_invocable

```cpp
template<class F, class... Args>
concept regular_invocable = invocable<F, Args...>;
```

The \( \text{invoke} \) function call expression shall be equality-preserving (18.2) and shall not modify the function object or the arguments.

[Note 1: This requirement supersedes the annotation in the definition of invocable. — end note]

[Example 1: A random number generator does not model regular_invocable. — end example]

[Note 2: The distinction between invocable and regular_invocable is purely semantic. — end note]

18.7.4 Concept predicate

```cpp
template<class F, class... Args>
concept predicate =
  regular_invocable<F, Args...> && boolean-testable<invoke_result_t<F, Args...>>;
```

18.7.5 Concept relation

```cpp
template<class R, class T, class U>
concept relation =
  predicate<R, T, T> && predicate<R, U, U> &&
  predicate<R, T, U> && predicate<R, U, T>;
```

18.7.6 Concept equivalence_relation

```cpp
template<class R, class T, class U>
concept equivalence_relation = relation<R, T, U>;
```

A relation models equivalence_relation only if it imposes an equivalence relation on its arguments.

18.7.7 Concept strict_weak_order

```cpp
template<class R, class T, class U>
concept strict_weak_order = relation<R, T, U>;
```

A relation models strict_weak_order only if it imposes a strict weak ordering on its arguments.

The term strict refers to the requirement of an irreflexive relation (\( \neg \text{comp}(x, x) \) for all \( x \)), and the term weak to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define \( \text{equiv}(a, b) \) as \( \neg \text{comp}(a, b) \land \neg \text{comp}(b, a) \), then the requirements are that \( \text{comp} \) and \( \text{equiv} \) both be transitive relations:

1. \( \text{comp}(a, b) \land \text{comp}(b, c) \) implies \( \text{comp}(a, c) \)
2. \( \text{equiv}(a, b) \land \text{equiv}(b, c) \) implies \( \text{equiv}(a, c) \)

[Note 1: Under these conditions, it can be shown that]

1. \( \text{equiv} \) is an equivalence relation,
2. \( \text{comp} \) induces a well-defined relation on the equivalence classes determined by \( \text{equiv} \), and
3. the induced relation is a strict total ordering. — end note]
19 Diagnostics library

19.1 General

This Clause describes components that C++ programs may use to detect and report error conditions.

The following subclauses describe components for reporting several kinds of exceptional conditions, documenting program assertions, obtaining stacktraces, and a global variable for error number codes, as summarized in Table 42.

Table 42: Diagnostics library summary

19.2 Exception classes

19.2.1 General

The C++ standard library provides classes to be used to report certain errors (16.4.6.13) in C++ programs. In the error model reflected in these classes, errors are divided into two broad categories: logic errors and runtime errors.

By contrast, runtime errors are due to events beyond the scope of the program. They cannot be easily predicted in advance. The header <stdexcept> defines several types of predefined exceptions for reporting errors in a C++ program. These exceptions are related by inheritance.

19.2.2 Header <stdexcept> synopsis

namespace std {
    class logic_error;
    class domain_error;
    class invalid_argument;
    class length_error;
    class out_of_range;
    class runtime_error;
    class range_error;
    class overflow_error;
    class underflow_error;
}

19.2.3 Class logic_error

namespace std {
    class logic_error : public exception {
        public:
            explicit logic_error(const string& what_arg);
            explicit logic_error(const char* what_arg);
    };
}

The class logic_error defines the type of objects thrown as exceptions to report errors presumably detectable before the program executes, such as violations of logical preconditions or class invariants.
19.2.4 Class domain_error

namespace std {
    class domain_error : public logic_error {
        public:
            explicit domain_error(const string& what_arg);
            explicit domain_error(const char* what_arg);
    }
}

The class domain_error defines the type of objects thrown as exceptions by the implementation to report domain errors.

domain_error(const string& what_arg);
        
        Postconditions: strcmp(what(), what_arg.c_str()) == 0.

domain_error(const char* what_arg);
        
        Postconditions: strcmp(what(), what_arg) == 0.

19.2.5 Class invalid_argument

namespace std {
    class invalid_argument : public logic_error {
        public:
            explicit invalid_argument(const string& what_arg);
            explicit invalid_argument(const char* what_arg);
    }
}

The class invalid_argument defines the type of objects thrown as exceptions to report an invalid argument.

invalid_argument(const string& what_arg);
        
        Postconditions: strcmp(what(), what_arg.c_str()) == 0.

invalid_argument(const char* what_arg);
        
        Postconditions: strcmp(what(), what_arg) == 0.

19.2.6 Class length_error

namespace std {
    class length_error : public logic_error {
        public:
            explicit length_error(const string& what_arg);
            explicit length_error(const char* what_arg);
    }
}

The class length_error defines the type of objects thrown as exceptions to report an attempt to produce an object whose length exceeds its maximum allowable size.

length_error(const string& what_arg);
        
        Postconditions: strcmp(what(), what_arg.c_str()) == 0.

length_error(const char* what_arg);
        
        Postconditions: strcmp(what(), what_arg) == 0.

§ 19.2.6 573
19.2.7 Class `out_of_range`  

```cpp
namespace std {
  class out_of_range : public logic_error {
    public:
      explicit out_of_range(const string& what_arg);
      explicit out_of_range(const char* what_arg);
    }
}
```

The class `out_of_range` defines the type of objects thrown as exceptions to report an argument value not in its expected range.

```cpp
out_of_range(const string& what_arg);
Postconditions: strcmp(what(), what_arg.c_str()) == 0.
```

```cpp
out_of_range(const char* what_arg);
Postconditions: strcmp(what(), what_arg) == 0.
```

19.2.8 Class `runtime_error`  

```cpp
namespace std {
  class runtime_error : public exception {
    public:
      explicit runtime_error(const string& what_arg);
      explicit runtime_error(const char* what_arg);
    }
}
```

The class `runtime_error` defines the type of objects thrown as exceptions to report errors presumably detectable only when the program executes.

```cpp
runtime_error(const string& what_arg);
Postconditions: strcmp(what(), what_arg.c_str()) == 0.
```

```cpp
runtime_error(const char* what_arg);
Postconditions: strcmp(what(), what_arg) == 0.
```

19.2.9 Class `range_error`  

```cpp
namespace std {
  class range_error : public runtime_error {
    public:
      explicit range_error(const string& what_arg);
      explicit range_error(const char* what_arg);
    }
}
```

The class `range_error` defines the type of objects thrown as exceptions to report range errors in internal computations.

```cpp
range_error(const string& what_arg);
Postconditions: strcmp(what(), what_arg.c_str()) == 0.
```

```cpp
range_error(const char* what_arg);
Postconditions: strcmp(what(), what_arg) == 0.
```

19.2.10 Class `overflow_error`  

```cpp
namespace std {
  class overflow_error : public runtime_error {
    public:
      explicit overflow_error(const string& what_arg);
      explicit overflow_error(const char* what_arg);
    }
}
```
The class `overflow_error` defines the type of objects thrown as exceptions to report an arithmetic overflow error.

`overflow_error(const string& what_arg);`

**Postconditions:** `strcmp(what(), what_arg.c_str()) == 0`.

`overflow_error(const char* what_arg);`

**Postconditions:** `strcmp(what(), what_arg) == 0`.

19.2.11 Class `underflow_error` [underflow.error]

namespace std {
  class underflow_error : public runtime_error {
    public:
      explicit underflow_error(const string& what_arg);
      explicit underflow_error(const char* what_arg);
  };
}

The class `underflow_error` defines the type of objects thrown as exceptions to report an arithmetic underflow error.

`underflow_error(const string& what_arg);`

**Postconditions:** `strcmp(what(), what_arg.c_str()) == 0`.

`underflow_error(const char* what_arg);`

**Postconditions:** `strcmp(what(), what_arg) == 0`.

19.3 Assertions [assertions]

19.3.1 General [assertions.general]

The header `<cassert>` provides a macro for documenting C++ program assertions and a mechanism for disabling the assertion checks.

19.3.2 Header `<cassert>` synopsis [cassert.syn]

#define assert(E) see below

The contents are the same as the C standard library header `<assert.h>`, except that a macro named `static_assert` is not defined.

See also: ISO C 7.2

19.3.3 The `assert` macro [assertions.assert]

An expression `assert(E)` is a constant subexpression (3.14), if

(1.1) — `NDEBUG` is defined at the point where `assert` is last defined or redefined, or

(1.2) — `E` contextually converted to `bool` (7.3) is a constant subexpression that evaluates to the value `true`.

19.4 Error numbers [errno]

19.4.1 General [errno.general]

The contents of the header `<cerrno>` are the same as the POSIX header `<errno.h>`, except that `errno` shall be defined as a macro.

[Note 1: The intent is to remain in close alignment with the POSIX standard. — end note]

A separate `errno` value is provided for each thread.

19.4.2 Header `<cerrno>` synopsis [cerrno.syn]

#define errno see below

19.5 System error support

19.5.1 General

1 Subclause 19.5 describes components that the standard library and C++ programs may use to report error conditions originating from the operating system or other low-level application program interfaces.

2 Components described in 19.5 do not change the value of errno (19.4).

Recommended practice: Implementations should leave the error states provided by other libraries unchanged.

19.5.2 Header <system_error> synopsis

namespace std {
    class error_category;
    const error_category& generic_category() noexcept;
    const error_category& system_category() noexcept;
    class error_code;
    class error_condition;
    class system_error;

    template<class T>
    struct is_error_code_enum : public false_type {};

    template<class T>
    struct is_error_condition_enum : public false_type {};

19.5.6, comparison operator functions
bool operator==(const error_code& lhs, const error_code& rhs) noexcept;
bool operator==(const error_code& lhs, const error_condition& rhs) noexcept;
bool operator==(const error_condition& lhs, const error_code& rhs) noexcept;
strong_ordering operator<=>(const error_code& lhs, const error_code& rhs) noexcept;
strong_ordering operator<=>(const error_condition& lhs, const error_condition& rhs) noexcept;

19.5.7, hash support
template<class T> struct hash;
template<> struct hash<error_code>;
template<> struct hash<error_condition>;

19.5, system error support
template<class T>
constexpr bool is_error_code_enum_v = is_error_code_enum<T>::value;
template<class T>
constexpr bool is_error_condition_enum_v = is_error_condition_enum<T>::value;

1 The value of each enum errc enumerator is the same as the value of the <cerrno> macro shown in the above synopsis. Whether or not the <system_error> implementation exposes the <cerrno> macros is unspecified.

2 The is_error_code_enum and is_error_condition_enum templates may be specialized for program-defined types to indicate that such types are eligible for class error_code and class error_condition implicit conversions, respectively.

19.5.3 Class error_category

19.5.3.1 Overview

The class error_category serves as a base class for types used to identify the source and encoding of a particular category of error code. Classes may be derived from error_category to support categories of errors in addition to those defined in this document. Such classes shall behave as specified in subclause 19.5.3.

[Note 1: error_category objects are passed by reference, and two such objects are equal if they have the same address. If there is more than a single object of a custom error_category type, such equality comparisons can evaluate to false even for objects holding the same value. —end note]

namespace std {
class error_category {
public:
constexpr error_category() noexcept;
virtual ~error_category();
error_category(const error_category&) = delete;
error_category& operator=(const error_category&) = delete;
virtual const char* name() const noexcept = 0;
virtual error_condition default_error_condition(int ev) const noexcept;
virtual bool equivalent(int code, const error_condition& condition) const noexcept;
virtual bool equivalent(const error_code& code, int condition) const noexcept;
virtual string message(int ev) const = 0;

bool operator==(const error_category& rhs) const noexcept;
strong_ordering operator<=>(const error_category& rhs) const noexcept;
};

const error_category& generic_category() noexcept;
const error_category& system_category() noexcept;
}

19.5.3.2 Virtual members

virtual const char* name() const noexcept = 0;

1 Returns: A string naming the error category.
virtual error_condition default_error_condition(int ev) const noexcept;

Returns: error_condition(ev, *this).

virtual bool equivalent(int code, const error_condition& condition) const noexcept;

Returns: default_error_condition(code) == condition.

virtual bool equivalent(const error_code& code, int condition) const noexcept;

Returns: *this == code.category() && code.value() == condition.

virtual string message(int ev) const = 0;

Returns: A string that describes the error condition denoted by ev.

19.5.3.3 Non-virtual members

bool operator==(const error_category& rhs) const noexcept;

Returns: this == &rhs.

strong_ordering operator<=>(const error_category& rhs) const noexcept;

Returns: compare_three_way()(this, &rhs).

[Note 1: compare_three_way (22.10.8.8) provides a total ordering for pointers. — end note]

19.5.3.4 Program-defined classes derived from error_category

virtual const char* name() const noexcept = 0;

Returns: A string naming the error category.

virtual error_condition default_error_condition(int ev) const noexcept;

Returns: An object of type error_condition that corresponds to ev.

virtual bool equivalent(int code, const error_condition& condition) const noexcept;

Returns: true if, for the category of error represented by *this, code is considered equivalent to condition; otherwise, false.

virtual bool equivalent(const error_code& code, int condition) const noexcept;

Returns: true if, for the category of error represented by *this, code is considered equivalent to condition; otherwise, false.

19.5.3.5 Error category objects

const error_category& generic_category() noexcept;

Returns: A reference to an object of a type derived from class error_category. All calls to this function shall return references to the same object.

Remarks: The object’s default_error_condition and equivalent virtual functions shall behave as specified for the class error_category. The object’s name virtual function shall return a pointer to the string "generic".

const error_category& system_category() noexcept;

Returns: A reference to an object of a type derived from class error_category. All calls to this function shall return references to the same object.

Remarks: The object’s equivalent virtual functions shall behave as specified for class error_category. The object’s name virtual function shall return a pointer to the string "system". The object’s default_error_condition virtual function shall behave as follows:

If the argument ev is equal to 0, the function returns error_condition(0, generic_category()). Otherwise, if ev corresponds to a POSIX errno value pxv, the function returns error_condition(pxv, generic_category()). Otherwise, the function returns error_condition(ev, system_category()). What constitutes correspondence for any given operating system is unspecified.

[Note 1: The number of potential system error codes is large and unbounded, and some might not correspond to any POSIX errno value. Thus implementations are given latitude in determining correspondence. — end note]
19.5.4 Class error_code

19.5.4.1 Overview

The class error_code describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces.

[Note 1: Class error_code is an adjunct to error reporting by exception. — end note]

namespace std {
    class error_code {
        public:
            // 19.5.4.2, constructors
            error_code() noexcept;
            error_code(int val, const error_category& cat) noexcept;
            template<class ErrorCodeEnum>
                error_code(ErrorCodeEnum e) noexcept;
            // 19.5.4.3, modifiers
            void assign(int val, const error_category& cat) noexcept;
            template<class ErrorCodeEnum>
                error_code& operator=(ErrorCodeEnum e) noexcept;
            void clear() noexcept;
            // 19.5.4.4, observers
            int value() const noexcept;
            const error_category& category() const noexcept;
            error_condition default_error_condition() const noexcept;
            string message() const;
            explicit operator bool() const noexcept;
        private:
            int val_; // exposition only
            const error_category* cat_; // exposition only
    };
    // 19.5.4.5, non-member functions
    error_code make_error_code(errc e) noexcept;
    template<class charT, class traits>
        basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>&, const error_code& ec);
}

19.5.4.2 Constructors

error_code() noexcept;

Effects: Initializes val_ with 0 and cat_ with &system_category().

error_code(int val, const error_category& cat) noexcept;

Effects: Initializes val_ with val and cat_ with &cat.

template<class ErrorCodeEnum>
    error_code(ErrorCodeEnum e) noexcept;

Constraints: is_error_code_enum_v<ErrorCodeEnum> is true.

Effects: Equivalent to:
        error_code ec = make_error_code(e);
        assign(ec.value(), ec.category());

19.5.4.3 Modifiers

void assign(int val, const error_category& cat) noexcept;

Postconditions: val_ == val and cat_ == &cat.
template<class ErrorCodeEnum>
    error_code& operator=(ErrorCodeEnum e) noexcept;

Constraints: is_error_code_enum_v<ErrorCodeEnum> is true.

Effects: Equivalent to:
    error_code ec = make_error_code(e);
    assign(ec.value(), ec.category());

Returns: *this.

void clear() noexcept;

Postconditions: value() == 0 and category() == system_category().

19.5.4.4 Observers

int value() const noexcept;

Returns: val_.

const error_category& category() const noexcept;

Returns: *cat_.

error_condition default_error_condition() const noexcept;

Returns: category().default_error_condition(value()).

string message() const;

Returns: category().message(value()).

explicit operator bool() const noexcept;

Returns: value() != 0.

19.5.4.5 Non-member functions

error_code make_error_code(errc e) noexcept;

Returns: error_code(static_cast<int>(e), generic_category()).

template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const error_code& ec);

Effects: Equivalent to: return os << ec.category().name() << ':' << ec.value();

19.5.5 Class error_condition

19.5.5.1 Overview

The class error_condition describes an object used to hold values identifying error conditions.

[Note 1: error_condition values are portable abstractions, while error_code values (19.5.4) are implementation specific. — end note]

namespace std {
    class error_condition {
        public:
            // 19.5.5.2, constructors
            error_condition() noexcept;
            error_condition(int val, const error_category& cat) noexcept;
            template<class ErrorConditionEnum>
                error_condition(ErrorConditionEnum e) noexcept;

            // 19.5.5.3, modifiers
            void assign(int val, const error_category& cat) noexcept;
            template<class ErrorConditionEnum>
                error_condition& operator=(ErrorConditionEnum e) noexcept;
            void clear() noexcept;
        }
// 19.5.5.4, observers
int value() const noexcept;
const error_category& category() const noexcept;
string message() const;
explicit operator bool() const noexcept;

private:
int val_;          // exposition only
const error_category* cat_; // exposition only
};

19.5.5.2 Constructors

error_condition() noexcept;

Effects: Initializes val_ with 0 and cat_ with &generic_category().

error_condition(int val, const error_category& cat) noexcept;

Effects: Initializes val_ with val and cat_ with &cat.

template<class ErrorConditionEnum>
error_condition(ErrorConditionEnum e) noexcept;

Constraints: is_error_condition_enum_v<ErrorConditionEnum> is true.

Effects: Equivalent to:
error_condition ec = make_error_condition(e);
assign(ec.value(), ec.category());

19.5.5.3 Modifiers

void assign(int val, const error_category& cat) noexcept;

Postconditions: val_ == val and cat_ == &cat.

template<class ErrorConditionEnum>
error_condition& operator=(ErrorConditionEnum e) noexcept;

Constraints: is_error_condition_enum_v<ErrorConditionEnum> is true.

Effects: Equivalent to:
error_condition ec = make_error_condition(e);
assign(ec.value(), ec.category());

Returns: *this.

void clear() noexcept;

Postconditions: value() == 0 and category() == generic_category().

19.5.5.4 Observers

int value() const noexcept;

Returns: val_.

const error_category& category() const noexcept;

Returns: *cat_.

string message() const;

Returns: category().message(value()).

explicit operator bool() const noexcept;

Returns: value() != 0.
19.5.5.5 Non-member functions

error_condition make_error_condition(errc e) noexcept;

1

Returns:
error_condition(static_cast<int>(e), generic_category()).

19.5.6 Comparison operator functions

bool operator==(const error_code& lhs, const error_code& rhs) noexcept;

1

Returns:
lhs.category() == rhs.category() && lhs.value() == rhs.value()

bool operator==(const error_condition& lhs, const error_code& rhs) noexcept;

2

Returns:
lhs.category().equivalent(lhs.value(), rhs) || rhs.category().equivalent(lhs, rhs.value())

bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;

3

Returns:
lhs.category() == rhs.category() && lhs.value() == rhs.value()

strong_ordering operator<=>(const error_code& lhs, const error_code& rhs) noexcept;

4

Effects: Equivalent to:
if (auto c = lhs.category() <=> rhs.category(); c != 0) return c;
return lhs.value() <=> rhs.value();

strong_ordering operator<=>(const error_condition& lhs, const error_condition& rhs) noexcept;

5

Returns:
if (auto c = lhs.category() <=> rhs.category(); c != 0) return c;
return lhs.value() <=> rhs.value();

19.5.7 System error hash support

template<> struct hash<error_code>;

template<> struct hash<error_condition>;

1

The specializations are enabled (22.10.19).

19.5.8 Class system_error

19.5.8.1 Overview

The class system_error describes an exception object used to report error conditions that have an associated error code. Such error conditions typically originate from the operating system or other low-level application program interfaces.

2 [Note 1: If an error represents an out-of-memory condition, implementations are encouraged to throw an exception object of type bad_alloc (17.6.4.1) rather than system_error. — end note]

namespace std {

    class system_error : public runtime_error {
        public:
            system_error(error_code ec, const string& what_arg);
            system_error(error_code ec, const char* what_arg);
            system_error(error_code ec);
            system_error(int ev, const error_category& ecat, const string& what_arg);
            system_error(int ev, const error_category& ecat, const char* what_arg);
            system_error(int ev, const error_category& ecat);
            system_error() const noexcept;
            const error_code& code() const noexcept override;
            const char* what() const noexcept override;
    };

}
19.5.8.2 Members

system_error(error_code ec, const string& what_arg);

Postconditions: code() == ec and
string_view(what()).find(what_arg.c_str()) != string_view::npos.

system_error(error_code ec, const char* what_arg);

Postconditions: code() == ec and string_view(what()).find(what_arg) != string_view::npos.

system_error(error_code ec);

Postconditions: code() == ec.

system_error(int ev, const error_category& ecat, const string& what_arg);

Postconditions: code() == error_code(ev, ecat) and
string_view(what()).find(what_arg.c_str()) != string_view::npos.

system_error(int ev, const error_category& ecat, const char* what_arg);

Postconditions: code() == error_code(ev, ecat) and
string_view(what()).find(what_arg) != string_view::npos.

system_error(int ev, const error_category& ecat);

Postconditions: code() == error_code(ev, ecat).

cast_error_code& code() const noexcept;

Returns: ec or error_code(ev, ecat), from the constructor, as appropriate.

cast_char* what() const noexcept override;

Returns: An NTBS incorporating the arguments supplied in the constructor.

[Note 1: The returned NTBS might be the contents of what_arg + " : " + code.message(). — end note]

19.6 Stacktrace

19.6.1 General

Subclause 19.6 describes components that C++ programs may use to store the stacktrace of the current thread of execution and query information about the stored stacktrace at runtime.

The invocation sequence of the current evaluation \( x_0 \) in the current thread of execution is a sequence \((x_0, \ldots, x_n)\) of evaluations such that, for \( i \geq 0 \), \( x_i \) is within the function invocation \( x_{i+1} \) (6.9.1).

A stacktrace is an approximate representation of an invocation sequence and consists of stacktrace entries. A stacktrace entry represents an evaluation in a stacktrace.

19.6.2 Header <stacktrace> synopsis

```cpp
#include <compare>  // see 17.11.1

namespace std {
    // 19.6.3, class stacktrace_entry
    class stacktrace_entry;

    // 19.6.4, class template basic_stacktrace
    template<class Allocator>
    class basic_stacktrace;

    // basic_stacktrace typedef-names
    using stacktrace = basic_stacktrace<allocator<stacktrace_entry>>;

    // 19.6.4.6, non-member functions
    template<class Allocator>
    void swap(basic_stacktrace<Allocator>& a, basic_stacktrace<Allocator>& b) noexcept(noexcept(a.swap(b)));

    string to_string(const stacktrace_entry& f);
}
```

§ 19.6.2 585
template<class Allocator>
string to_string(const basic_stacktrace<Allocator>& st);

ostream& operator<<(ostream& os, const stacktrace_entry& f);

template<class Allocator>
ostream& operator<<(ostream& os, const basic_stacktrace<Allocator>& st);

// 19.6.4.7, formatting support
namespace{ struct formatter<stacktrace_entry>;
  template<class Allocator> struct formatter<basic_stacktrace<Allocator>>;
}

namespace pmr {
  using stacktrace = basic_stacktrace<polymorphic_allocator<stacktrace_entry>>;
}

// 19.6.4.8, hash support
namespace { struct hash<stacktrace_entry>;
  template<class Allocator> struct hash<basic_stacktrace<Allocator>>;
}

19.6.3 Class stacktrace_entry

19.6.3.1 Overview

namespace std {
  class stacktrace_entry {
    public:
      using native_handle_type = implementation-defined;
      // 19.6.3.2, constructors
      constexpr stacktrace_entry() noexcept;
      constexpr stacktrace_entry(const stacktrace_entry& other) noexcept;
      constexpr stacktrace_entry& operator=(const stacktrace_entry& other) noexcept;
      ~stacktrace_entry();
      // 19.6.3.3, observers
      constexpr native_handle_type native_handle() const noexcept;
      constexpr explicit operator bool() const noexcept;
      // 19.6.3.4, query
      string description() const;
      string source_file() const;
      uint_least32_t source_line() const;
      // 19.6.3.5, comparison
      friend constexpr bool operator==(const stacktrace_entry& x,
                                      const stacktrace_entry& y) noexcept;
      friend constexpr strong_ordering operator<=>(const stacktrace_entry& x,
                                                    const stacktrace_entry& y) noexcept;
    };
  }
}

An object of type stacktrace_entry is either empty, or represents a stacktrace entry and provides operations for querying information about it. The class stacktrace_entry models regular (18.6) and three_way_comparable,strong_ordering (17.11.4).

19.6.3.2 Constructors

constexpr stacktrace_entry() noexcept;

Postconditions: *this is empty.

§ 19.6.3.2
19.6.3.3 Observers

constexpr native_handle_type native_handle() const noexcept;

1 The semantics of this function are implementation-defined.

Remarks: Successive invocations of the native_handle function for an unchanged stacktrace_entry object return identical values.

constexpr explicit operator bool() const noexcept;

2 Returns: false if and only if *this is empty.

19.6.3.4 Query

string description() const;

1 Returns: A description of the evaluation represented by *this, or an empty string.

4 Slowly allocates if memory for the internal data structures or the resulting string cannot be allocated.

string source_file() const;

3 Returns: The presumed or actual name of the source file (15.11) that lexically contains the expression or statement whose evaluation is represented by *this, or an empty string.

5 Throws: bad_alloc if memory for the internal data structures or the resulting string cannot be allocated.

uint_least32_t source_line() const;

6 Returns: 0, or a 1-based line number that lexically relates to the evaluation represented by *this. If source_file returns the presumed name of the source file, returns the presumed line number; if source_file returns the actual name of the source file, returns the actual line number.

7 Throws: bad_alloc if memory for the internal data structures cannot be allocated.

19.6.3.5 Comparison

friend constexpr bool operator==(const stacktrace_entry& x, const stacktrace_entry& y) noexcept;

1 Returns: true if and only if x and y represent the same stacktrace entry or both x and y are empty.

19.6.4 Class template basic_stacktrace

namespace std {
    template<class Allocator>
    class basic_stacktrace {

        public:
            using value_type = stacktrace_entry;
            using const_reference = const value_type&;
            using reference = value_type&;
            using const_iterator = implementation-defined; // see 19.6.4.3
            using iterator = const_iterator;
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::reverse_iterator<const_iterator>;
            using difference_type = implementation-defined;
            using size_type = implementation-defined;
            using allocator_type = Allocator;

            // 19.6.4.2, creation and assignment
            static basic_stacktrace current(const Allocator& alloc = Allocator()) noexcept;
            static basic_stacktrace current(size_type skip,
                const Allocator& alloc = Allocator()) noexcept;
            static basic_stacktrace current(size_type skip, size_type max_depth,
                const Allocator& alloc = Allocator()) noexcept;

§ 19.6.4.1 587
The class template `basic_stacktrace` satisfies the requirements of a reversible container (24.2.2.3), of an allocator-aware container (24.2.2.5), and of a sequence container (24.2.4), except that

(1.1) — only move, assignment, swap, and operations defined for const-qualified sequence containers are supported and,

(1.2) — the semantics of comparison functions are different from those required for a container.

### 19.6.4.2 Creation and assignment

static basic_stacktrace current(const allocator_type& alloc = allocator_type()) noexcept;

Returns: A `basic_stacktrace` object with `frames_` storing the stacktrace of the current evaluation in the current thread of execution, or an empty `basic_stacktrace` object if the initialization of
frames_ failed. alloc is passed to the constructor of the frames_ object.

[Note 1: If the stacktrace was successfully obtained, then frames_.front() is the stacktrace_entry representing approximately the current evaluation, and frames_.back() is the stacktrace_entry representing approximately the initial function of the current thread of execution. —end note]

static basic_stacktrace current(size_type skip,
    const allocator_type& alloc = allocator_type()) noexcept;

Let t be a stacktrace as-if obtained via basic_stacktrace::current(alloc). Let n be t.size().

Returns: A basic_stacktrace object where frames_ is direct-non-list-initialized from arguments t.begin() + min(n, skip), t.end(), and alloc, or an empty basic_stacktrace object if the initialization of frames_ failed.

static basic_stacktrace current(size_type skip, size_type max_depth,
    const allocator_type& alloc = allocator_type()) noexcept;

Let t be a stacktrace as-if obtained via basic_stacktrace::current(alloc). Let n be t.size().

Preconditions: skip <= skip + max_depth is true.

Returns: A basic_stacktrace object where frames_ is direct-non-list-initialized from arguments t.begin() + min(n, skip), t.begin() + min(n, skip + max_depth), and alloc, or an empty basic_stacktrace object if the initialization of frames_ failed.

basic_stacktrace() noexcept(is_nothrow_default_constructible_v<allocator_type>);

Postconditions: empty() is true.

explicit basic_stacktrace(const allocator_type& alloc) noexcept;

Effects: alloc is passed to the frames_ constructor.

Postconditions: empty() is true.

basic_stacktrace(const basic_stacktrace& other);

basic_stacktrace(const basic_stacktrace& other, const allocator_type& alloc);

basic_stacktrace(basic_stacktrace&& other, const allocator_type& alloc);

basic_stacktrace& operator=(const basic_stacktrace& other);

basic_stacktrace& operator=(basic_stacktrace&& other)
    noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
    allocator_traits<Allocator>::is_always_equal::value);

Remarks: Implementations may strengthen the exception specification for these functions (16.4.6.13) by ensuring that empty() is true on failed allocation.

19.6.4.3 Observers

using const_iterator = implementation-defined;

The type models random_access_iterator (25.3.4.13) and meets the Cpp17RandomAccessIterator requirements (25.3.5.7).

allocator_type get_allocator() const noexcept;

Returns: frames_.get_allocator().

const_iterator begin() const noexcept;

const_iterator cbegin() const noexcept;

Returns: An iterator referring to the first element in frames_. If empty() is true, then it returns the same value as end().

const_iterator end() const noexcept;

const_iterator cend() const noexcept;

Returns: The end iterator.

const_reverse_iterator rbegin() const noexcept;

const_reverse_iterator crbegin() const noexcept;

Returns: reverse_iterator(cend()).
const_reverse_iterator rend() const noexcept;
const_reverse_iterator crend() const noexcept;

Returns: reverse_iterator(cbegin()).

[[nodiscard]] bool empty() const noexcept;

Returns: frames_.empty().

size_type size() const noexcept;

Returns: frames_.size().

size_type max_size() const noexcept;

Returns: frames_.max_size().

const_reference operator[](size_type frame_no) const;

Preconditions: frame_no < size() is true.

Returns: frames_[frame_no].

Throws: Nothing.

const_reference at(size_type frame_no) const;

Returns: frames_[frame_no].

Throws: out_of_range if frame_no >= size().

19.6.4.4 Comparisons [stacktrace.basic.cmp]

template<class Allocator2>
friend bool operator==(const basic_stacktrace& x, const basic_stacktrace<Allocator2>& y) noexcept;

Returns: equal(x.begin(), x.end(), y.begin(), y.end()).

template<class Allocator2>
friend strong_ordering
operator<=>(const basic_stacktrace& x, const basic_stacktrace<Allocator2>& y) noexcept;

Returns: x.size() <=> y.size() if x.size() != y.size(); lexicographical_compare_three_way(x.begin(), x.end(), y.begin(), y.end()) otherwise.

19.6.4.5 Modifiers [stacktrace.basic.mod]

void swap(basic_stacktrace& other)

noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
allocator_traits<Allocator>::is_always_equal::value);

Effects: Exchanges the contents of *this and other.

19.6.4.6 Non-member functions [stacktrace.basic.nonmem]

template<class Allocator>
void swap(basic_stacktrace<Allocator>& a, basic_stacktrace<Allocator>& b)

noexcept(noexcept(a.swap(b)));

Effects: Equivalent to a.swap(b).

string to_string(const stacktrace_entry& f);

Returns: A string with a description of f.

Recommended practice: The description should provide information about the contained evaluation, including information from f.source_file() and f.source_line().

template<class Allocator>
string to_string(const basic_stacktrace<Allocator>& st);

Returns: A string with a description of st.

[Note 1: The number of lines is not guaranteed to be equal to st.size(). — end note]
ostream& operator<<(ostream& os, const stacktrace_entry& f);

Effects: Equivalent to: return os << to_string(f);

template<class Allocator>
ostream& operator<<(ostream& os, const basic_stacktrace<Allocator>& st);

Effects: Equivalent to: return os << to_string(st);

19.6.4.7 Formatting support

template<> struct formatter<stacktrace_entry>;

formatter<stacktrace_entry> interprets format-spec as a stacktrace-entry-format-spec. The syntax of format specifications is as follows:

stacktrace-entry-format-spec:
  fill-and-align_opt width_opt

[Note 1: The productions fill-and-align and width are described in 22.14.2.2. — end note]

A stacktrace_entry object se is formatted as if by copying to_string(se) through the output iterator of the context with additional padding and adjustments as specified by the format specifiers.

template<class Allocator> struct formatter<basic_stacktrace<Allocator>>;

For formatter<basic_stacktrace<Allocator>>, format-spec is empty.

A basic_stacktrace object s is formatted as if by copying to_string(s) through the output iterator of the context.

19.6.4.8 Hash support

template<> struct hash<stacktrace_entry>;

template<class Allocator> struct hash<basic_stacktrace<Allocator>>;

The specializations are enabled (22.10.19).
20 Memory management library [mem]

20.1 General [mem.general]

This Clause describes components for memory management.

The following subclauses describe general memory management facilities, smart pointers, memory resources, and scoped allocators, as summarized in Table 43.

Table 43: Memory management library summary [tab:mem.summary]

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>20.2 Memory</td>
<td><code>&lt;cstdlib&gt;</code>, <code>&lt;memory&gt;</code></td>
</tr>
<tr>
<td>20.3 Smart pointers</td>
<td><code>&lt;memory&gt;</code></td>
</tr>
<tr>
<td>20.4 Memory resources</td>
<td><code>&lt;memory_resource&gt;</code></td>
</tr>
<tr>
<td>20.5 Scoped allocators</td>
<td><code>&lt;scoped_allocator&gt;</code></td>
</tr>
</tbody>
</table>

20.2 Memory [memory]

20.2.1 In general [memory.general]

Subclause 20.2 describes the contents of the header `<memory>` (20.2.2) and some of the contents of the header `<cstdlib>` (17.2.2).

20.2.2 Header `<memory>` synopsis [memory.syn]

The header `<memory>` defines several types and function templates that describe properties of pointers and pointer-like types, manage memory for containers and other template types, destroy objects, and construct objects in uninitialized memory buffers (20.2.3–20.2.11 and 27.11). The header also defines the templates `unique_ptr`, `shared_ptr`, `weak_ptr`, `out_ptr_t`, `inout_ptr_t`, and various function templates that operate on objects of these types (20.3).

Let `POINTER_OF(T)` denote a type that is

1. `T::pointer` if the qualified-id `T::pointer` is valid and denotes a type,
2. `T::element_type*` if the qualified-id `T::element_type` is valid and denotes a type,
3. otherwise, `pointer_traits<T>::element_type*`.

Let `POINTER_OF_OR(T, U)` denote a type that is:

1. `POINTER_OF(T)` if `POINTER_OF(T)` is valid and denotes a type,
2. otherwise, `U`.

```cpp
#include <compare> // see 17.11.1
namespace std {
    namespace { // 20.2.3, pointer traits
        template<class Ptr> struct pointer_traits;
        template<class T> struct pointer_traits<T*>;
    }

    // 20.2.4, pointer conversion
    template<class T>
        constexpr T* to_address(T* p) noexcept;
    template<class Ptr>
        constexpr auto to_address(const Ptr& p) noexcept;

    // 20.2.5, pointer alignment
    void* align(size_t alignment, size_t size, void*& ptr, size_t& space);
    template<size_t N, class T>
        [[nodiscard]] constexpr T* assume_aligned(T* ptr);
}
```

§ 20.2.2
20.2.6, explicit lifetime management

```cpp
// freestanding
template<class T>
T* start_lifetime_as(void* p) noexcept;
// freestanding
template<class T>
const T* start_lifetime_as(const void* p) noexcept;
// freestanding
template<class T>
volatile T* start_lifetime_as(volatile void* p) noexcept;
// freestanding
template<class T>
const volatile T* start_lifetime_as(const volatile void* p) noexcept;
// freestanding
template<class T>
T* start_lifetime_as_array(void* p, size_t n) noexcept;
// freestanding
template<class T>
const T* start_lifetime_as_array(const void* p, size_t n) noexcept;
// freestanding
template<class T>
volatile T* start_lifetime_as_array(volatile void* p, size_t n) noexcept;
// freestanding
template<class T>
const volatile T* start_lifetime_as_array(const volatile void* p, size_t n) noexcept;
```

20.2.7, allocator argument tag

```cpp
struct allocator_arg_t {
    explicit allocator_arg_t() = default;
};
inline constexpr allocator_arg_t allocator_arg{};
```

20.2.8, uses_allocator

```cpp
// freestanding
template<class T, class Alloc> struct uses_allocator;
// freestanding
```

20.2.8.1, uses_allocator

```cpp
// freestanding
template<class T, class Alloc>
constexpr bool uses_allocator_v = uses_allocator<T, Alloc>::value;
```

20.2.8.2, uses-allocator construction

```cpp
template<class T, class Alloc, class... Args>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                              Args&&... args) noexcept;
// freestanding
template<class T, class Alloc, class Tuple1, class Tuple2>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                              piecewise_construct_t,
                                              Tuple1&& x, Tuple2&& y) noexcept;
// freestanding
template<class T, class Alloc, class U, class V>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                              pair<U, V>& pr) noexcept;
// freestanding
template<class T, class Alloc, class U, class V>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                              const pair<U, V>& pr) noexcept;
// freestanding
template<class T, class Alloc, pair-like P>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
                                              P&& p) noexcept;
```

§ 20.2.2

593
template<class T, class Alloc, class... Args>
constexpr T make_obj_using_allocator(const Alloc& alloc, Args&&... args); // freestanding

template<class T, class Alloc, class... Args>
constexpr T* uninitialized_construct_using_allocator(T* p, // freestanding

    Pointer ptr;
    SizeType count;
};

// 20.2.10, the default allocator
template<class T> class allocator;

template<class T, class U>
constexpr bool operator==(const allocator<T>&, const allocator<U>&) noexcept;

// 20.2.11, addressof
template<class T>
constexpr T* addressof(T& r) noexcept; // freestanding

template<class T>
const T* addressof(const T&&) = delete; // freestanding

// 27.11, specialized algorithms
// 27.11.2, special memory concepts
template<class I>
concept nothrow-input-iterator = see below; // exposition only

template<class I>
concept nothrow-forward-iterator = see below; // exposition only

template<class S, class I>
concept nothrow-sentinel-for = see below; // exposition only

template<class R>
concept nothrow-input-range = see below; // exposition only

template<class R>
concept nothrow-forward-range = see below; // exposition only

template<class NoThrowForwardIterator>
void uninitialized_default_construct(NoThrowForwardIterator first, // freestanding
NoThrowForwardIterator last);

template<class ExecutionPolicy, class NoThrowForwardIterator>
void uninitialized_default_construct(ExecutionPolicy&& exec, // see 27.3.5
NoThrowForwardIterator first, NoThrowForwardIterator last);

template<class NoThrowForwardIterator, class Size>
NoThrowForwardIterator
uninitialized_default_construct_n(NoThrowForwardIterator first, Size n); // freestanding

template<class ExecutionPolicy, class NoThrowForwardIterator, class Size>
NoThrowForwardIterator
uninitialized_default_construct_n(ExecutionPolicy&& exec, // see 27.3.5
NoThrowForwardIterator first, Size n);

namespace ranges {
    template<nothrow-forward-iterator I, nothrow-sentinel-for<I> S>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_default_construct(I first, S last); // freestanding

    template<nothrow-forward-range R>
    requires default_initializable<range_value_t<R>>
    borrowed_iterator_t<R> uninitialized_default_construct(R&& r); // freestanding
}
# std::uninitialized_value_construct

The `std::uninitialized_value_construct` template function is used to uninitialized elements in ranges.

```
template<nothrow-forward-iterator I>
    requires default_initializable<iter_value_t<I>>
    I uninitialized_default_construct_n(I first, iter_difference_t<I> n); // freestanding

template<class NoThrowForwardIterator>
    void uninitialized_value_construct(NoThrowForwardIterator first, NoThrowForwardIterator last);

template<class ExecutionPolicy, class NoThrowForwardIterator>
    void uninitialized_value_construct(ExecutionPolicy&& exec, NoThrowForwardIterator first, NoThrowForwardIterator last);

template<class NoThrowForwardIterator, class Size>
    NoThrowForwardIterator uninitialized_value_construct_n(NoThrowForwardIterator first, Size n); // freestanding

namespace ranges {
    template<nothrow-forward-iterator I, nothrow-sentinel-for<I> S>
        requires default_initializable<iter_value_t<I>>
        I uninitialized_value_construct(I first, S last); // freestanding
    template<nothrow-forward-range R>
        requires default_initializable<range_value_t<R>>
        borrowed_iterator_t<R> uninitialized_value_construct(R&& r); // freestanding

    template<nothrow-forward-iterator I>
        requires default_initializable<iter_value_t<I>>
        I uninitialized_value_construct_n(I first, iter_difference_t<I> n); // freestanding
}
```

## std::uninitialized_copy

The `std::uninitialized_copy` template function is used to copy uninitialized elements from one range to another.

```
template<class InputIterator, class NoThrowForwardIterator>
    NoThrowForwardIterator uninitialized_copy(InputIterator first, InputIterator last, NoThrowForwardIterator result);

template<class ExecutionPolicy, class ForwardIterator, class NoThrowForwardIterator>
    NoThrowForwardIterator uninitialized_copy(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, NoThrowForwardIterator result);

namespace ranges {
    template<input_iterator I, sentinel_for<I> S1, nothrow-forward-iterator O, nothrow-sentinel-for<O> S2>
        requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
        uninitialized_copy_result<I, O> uninitialized_copy(I ifirst, S1 ilast, O ofirst, S2 olast);

    template<input_range IR, nothrow-forward-range OR>
        requires constructible_from<range_value_t<OR>, range_reference_t<IR>>
        uninitialized_copy_result<borrowed_iterator_t<IR>, borrowed_iterator_t<OR>>
        uninitialized_copy(IR&& in_range, OR&& out_range); // freestanding
}
```
template<class I, class O>
using uninitialized_copy_n_result = in_out_result<I, O>; // freestanding

template<input_iterator I, nothrow-forward_iterator O, nothrow-sentinel-for<O> S>
requires constructible_from<iter_value_t<O>, iter_reference_t<I>>
uninitialized_copy_n_result<I, O>
uninitialized_copy_n(I ifirst, iter_difference_t<I> n, O ofirst, S olast); // freestanding

}

template<class InputIterator, class NoThrowForwardIterator>
NoThrowForwardIterator uninitialized_move(InputIterator first, InputIterator last, NoThrowForwardIterator result);

class inout_ptr_t;

// 20.3.4.4, function template inout_ptr  
template<class Pointer = void, class Smart, class... Args>  
auto inout_ptr(Smart& s, Args&&... args);

}

```cpp
template<class T> struct pointer_traits<T*> {
  using pointer = T*;
  using element_type = T;
  using difference_type = ptrdiff_t;
  template<class U> using rebind = U*;
  static constexpr pointer pointer_to(r) noexcept;
};
```

### 20.2.3.2 Member types

The definitions in this subclause make use of the following exposition-only class template and concept:

```cpp
template<class T> struct ptr-traits-elem { };  // exposition only
```

```cpp
template<class T> requires requires { typename T::element_type; }
  struct ptr-traits-elem<T> { using type = typename T::element_type; };  // exposition only
```

```cpp
template<template<class...> class SomePointer, class T, class... Args>
  requires (!requires { typename SomePointer<T, Args...>::element_type; })
  struct ptr-traits-elem<SomePointer<T, Args...>> { using type = T; };  // exposition only
```

```cpp
template<class Ptr>
  concept has-elem-type = // exposition only
    requires { typename ptr-traits-elem<Ptr>::type; }
```

If `Ptr` satisfies `has-elem-type`, a specialization `pointer_traits<Ptr>` generated from the `pointer_traits` primary template has the following members as well as those described in 20.2.3.3; otherwise, such a specialization has no members by any of those names.

```cpp
using pointer = see below;
```

**Type:** `Ptr`.

```cpp
using element_type = see below;
```

**Type:** `typename ptr-traits-elem<Ptr>::type`.

```cpp
using difference_type = see below;
```

**Type:** `Ptr::difference_type` if the qualified-id `Ptr::difference_type` is valid and denotes a type (13.10.3); otherwise, `ptrdiff_t`.

```cpp
template<class U> using rebind = see below;
```

**Alias template:** `Ptr::rebind<U>` if the qualified-id `Ptr::rebind<U>` is valid and denotes a type (13.10.3); otherwise, `SomePointer<U, Args>` if `Ptr` is a class template instantiation of the form `SomePointer<T, Args>`, where `Args` is zero or more type arguments; otherwise, the instantiation of `rebind` is ill-formed.

### 20.2.3.3 Member functions

```cpp
static pointer pointer_traits::pointer_to(see below r);
static constexpr pointer pointer_traits<T*>::pointer_to(see below r) noexcept;
```

**Mandates:** For the first member function, `Ptr::pointer_to(r)` is well-formed.

**Preconditions:** For the first member function, `Ptr::pointer_to(r)` returns a pointer to `r` through which indirection is valid.

**Returns:** The first member function returns `Ptr::pointer_to(r)`. The second member function returns `addressof(r)`.

**Remarks:** If `element_type` is `cv void`, the type of `r` is unspecified; otherwise, it is `element_type`.

---

§ 20.2.3.3
20.2.3.4 Optional members

Specializations of `pointer_traits` may define the member declared in this subclause to customize the behavior of the standard library. A specialization generated from the `pointer_traits` primary template has no member by this name.

```cpp
static element_type* to_address(pointer p) noexcept;
```

1. **Returns:** A pointer of type `element_type*` that references the same location as the argument `p`.

2. `[Note 1: This function is intended to be the inverse of `pointer_to`. If defined, it customizes the behavior of the non-member function `to_address` (20.2.4). — end note]

20.2.4 Pointer conversion

```cpp
template<class T> constexpr T* to_address(T* p) noexcept;
```

1. **Mandates:** `T` is not a function type.

2. **Returns:** `p`.

```cpp
template<class Ptr> constexpr auto to_address(const Ptr& p) noexcept;
```

3. **Returns:** `pointer_traits<Ptr>::to_address(p)` if that expression is well-formed (see 20.2.3.4), otherwise `to_address(p.operator->())`.

20.2.5 Pointer alignment

```cpp
void* align(size_t alignment, size_t size, void*& ptr, size_t& space);
```

1. **Preconditions:**
   - [(1.1)] `alignment` is a power of two
   - [(1.2)] `ptr` represents the address of contiguous storage of at least `space` bytes

2. **Effects:** If it is possible to fit `size` bytes of storage aligned by `alignment` into the buffer pointed to by `ptr` with length `space`, the function updates `ptr` to represent the first possible address of such storage and decreases `space` by the number of bytes used for alignment. Otherwise, the function does nothing.

3. **Returns:** A null pointer if the requested aligned buffer would not fit into the available space, otherwise the adjusted value of `ptr`.

4. `[Note 1: The function updates its `ptr` and `space` arguments so that it can be called repeatedly with possibly different `alignment` and `size` arguments for the same buffer. — end note]

```cpp
template<size_t N, class T> [[nodiscard]] constexpr T* assume_aligned(T* ptr);
```

5. **Mandates:** `N` is a power of two.

6. **Preconditions:** `ptr` points to an object `X` of a type similar (7.3.6) to `T`, where `X` has alignment `N` (6.7.6).

7. **Returns:** `ptr`.

8. **Throws:** Nothing.

9. `[Note 2: The alignment assumption on an object `X` expressed by a call to `assume_aligned` might result in generation of more efficient code. It is up to the program to ensure that the assumption actually holds. The call does not cause the implementation to verify or enforce this. An implementation might only make the assumption for those operations on `X` that access `X` through the pointer returned by `assume_aligned`. — end note]

20.2.6 Explicit lifetime management

```cpp
template<class T>
T* start_lifetime_as(void* p) noexcept;
```

1. **Mandates:** `T` is an implicit-lifetime type (6.8.1) and not an incomplete type (6.8.1).
Preconditions: \((p, (\text{char}*)p + \text{sizeof}(T))\) denotes a region of allocated storage that is a subset of the region of storage reachable through (6.8.4) \(p\) and suitably aligned for the type \(T\).

Effects: Implicitly creates objects (6.7.2) within the denoted region consisting of an object \(a\) of type \(T\) whose address is \(p\), and objects nested within \(a\), as follows: The object representation of \(a\) is the contents of the storage prior to the call to `start_lifetime_as`. The value of each created object \(o\) of trivially-copyable type \(U\) is determined in the same manner as for a call to `bit_cast<U>(E)` (22.15.3), where \(E\) is an lvalue of type \(U\) denoting \(o\), except that the storage is not accessed. The value of any other created object is unspecified.

[Note 1: The unspecified value can be indeterminate. — end note]

Returns: A pointer to the \(a\) defined in the Effects paragraph.

```cpp
template<class T>
T* start_lifetime_as_array(void* p, size_t n) noexcept;
template<class T>
const T* start_lifetime_as_array(const void* p, size_t n) noexcept;
template<class T>
volatile T* start_lifetime_as_array(volatile void* p, size_t n) noexcept;
template<class T>
const volatile T* start_lifetime_as_array(const volatile void* p, size_t n) noexcept;
```

Mandates: \(T\) is a complete type.

Preconditions: \(p\) is suitably aligned for an array of \(T\) or is null. \(n \leq \text{size}_t(-1) / \text{sizeof}(T)\) is true. If \(n > 0\) is true, \(((\text{char}*)p, (\text{char}*)p + (n * \text{sizeof}(T)))\) denotes a region of allocated storage that is a subset of the region of storage reachable through (6.8.4) \(p\).

Effects: If \(n > 0\) is true, equivalent to `start_lifetime_as<U>(p)` where \(U\) is the type “array of \(n\) \(T\)”. Otherwise, there are no effects.

Returns: A pointer to the first element of the created array, if any; otherwise, a pointer that compares equal to \(p\) (7.6.10).

## 20.2.7 Allocator argument tag

```cpp
namespace std {
    struct allocator_arg_t { explicit allocator_arg_t() = default; }
    inline constexpr allocator_arg_t allocator_arg{};
}
```

The `allocator_arg_t` struct is an empty class type used as a unique type to disambiguate constructor and function overloading. Specifically, several types (see `tuple` 22.4) have constructors with `allocator_arg_t` as the first argument, immediately followed by an argument of a type that meets the `Cpp17Allocator` requirements (16.4.4.6.1).

## 20.2.8 uses_allocator

### 20.2.8.1 uses_allocator trait

```cpp
template<class T, class Alloc> struct uses_allocator;
```

Remarks: Automatically detects whether \(T\) has a nested `allocator_type` that is convertible from `Alloc`. Meets the `Cpp17BinaryTypeTrait` requirements (21.3.2). The implementation shall provide a definition that is derived from `true_type` if the `qualified-id T::allocator_type` is valid and denotes a type (13.10.3) and `is_convertible_v<Alloc, T::allocator_type> != false`, otherwise it shall be derived from `false_type`. A program may specialize this template to derive from `true_type` for a program-defined type \(T\) that does not have a nested `allocator_type` but nonetheless can be constructed with an allocator where either:

1. the first argument of a constructor has type `allocator_arg_t` and the second argument has type `Alloc` or
2. the last argument of a constructor has type `Alloc`.

### 20.2.8.2 Uses-allocator construction

`Uses-allocator construction` with allocator `alloc` and constructor arguments `args...` refers to the construction of an object of type \(T\) such that `alloc` is passed to the constructor of \(T\) if \(T\) uses an allocator type compatible
The following utility functions support three conventions for passing alloc to a constructor:

1. If T does not use an allocator compatible with alloc, then alloc is ignored.
2. Otherwise, if T has a constructor invocable as T(allocation_arg, alloc, args...) (leading-allocator convention), then uses-allocator construction chooses this constructor form.
3. Otherwise, if T has a constructor invocable as T(args..., alloc) (trailing-allocator convention), then uses-allocator construction chooses this constructor form.

The uses_allocator_construction_args function template takes an allocator and argument list and produces (as a tuple) a new argument list matching one of the above conventions. Additionally, overloads are provided that treat specializations of pair such that uses-allocator construction is applied individually to the first and second data members. The make_obj_using_allocator and uninitialized_construct_using_allocator function templates apply the modified constructor arguments to construct an object of type T as a return value or in-place, respectively.

[Note 1: For uses_allocator_construction_args and make_obj_using_allocator, type T is not deduced and must therefore be specified explicitly by the caller. — end note]

template<class T, class Alloc, class... Args>
constexpr auto uses_allocator_construction_args(const Alloc& alloc, Args&&... args) noexcept;

Constraints: remove_cv_t<T> is not a specialization of pair.

Returns: A tuple value determined as follows:

1. If uses_allocator_v<remove_cv_t<T>, Alloc> is false and is_constructible_v<T, Args...> is true, return forward_as_tuple(std::forward<Args>(args)...).
2. Otherwise, if uses_allocator_v<remove_cv_t<T>, Alloc> is true and is_constructible_v<T, allocator_arg_t, const Alloc&, Args...> is true, return tuple<allocator_arg_t, const Alloc&, Args&&...>(allocator_arg, alloc, std::forward<Args>(args)...) .
3. Otherwise, if uses_allocator_v<remove_cv_t<T>, Alloc> is true and is_constructible_v<T, Args..., const Alloc&> is true, return forward_as_tuple(std::forward<Args>(args)..., alloc).
4. Otherwise, the program is ill-formed.

[Note 2: This definition prevents a silent failure to pass the allocator to a constructor of a type for which uses_allocator_v<T, Alloc> is true. — end note]

template<class T, class Alloc, class Tuple1, class Tuple2>
constexpr auto uses_allocator_construction_args(const Alloc& alloc, piecewise_construct_t, Tuple1&& x, Tuple2&& y) noexcept;

Let T1 be T::first_type. Let T2 be T::second_type.

Constraints: remove_cv_t<T> is a specialization of pair.

Effects: Equivalent to:

return make_tuple(
piecewise_construct,
apply([&alloc](auto&... args1) { return uses_allocator_construction_args<T1>(alloc, std::forward<decimaltype(args1)>(args1)...); }, std::forward<Tuple1>(x)),
apply([&alloc](auto&... args2) { return uses_allocator_construction_args<T2>(alloc, std::forward<decimaltype(args2)>(args2)...); }, std::forward<Tuple2>(y)));

template<class T, class Alloc>
constexpr auto uses_allocator_construction_args(const Alloc& alloc) noexcept;

Constraints: remove_cv_t<T> is a specialization of pair.
Effects: Equivalent to:

```cpp
template<class T, class Alloc, class U, class V>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
    U&& u, V&& v) noexcept;
```

Constraints: `remove_cv_t<T>` is a specialization of `pair`.

Effects: Equivalent to:

```cpp
template<class T, class Alloc, class U, class V>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
    pair<U, V>& pr) noexcept;
```

Constraints: `remove_cv_t<T>` is a specialization of `pair`.

Effects: Equivalent to:

```cpp
template<class T, class Alloc, class U, class V>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
    pair<U, V>&& pr) noexcept;
```

Constraints: `remove_cv_t<T>` is a specialization of `pair`.

Effects: Equivalent to:

```cpp
template<class T, class Alloc, class U>
constexpr auto uses_allocator_construction_args(const Alloc& alloc,
    U&& u) noexcept;
```

Let `FUN` be the function template:

```cpp
template<class A, class B>
void FUN(const pair<A, B>&);
```

Constraints: `remove_cv_t<T>` is a specialization of `pair`, and either:

- `remove_cvref_t<T>` is a specialization of `ranges::subrange`, or
- `U` does not satisfy `pair-like` and the expression `FUN(u)` is not well-formed when considered as an unevaluated operand.

§ 20.2.8.2
Let `pair-constructor` be an exposition-only class defined as follows:

```cpp
class pair-constructor {
    using pair_type = remove_cv_t<T>; // exposition only

    constexpr auto do-construct(const pair_type& p) const {
        // exposition only
        return make_obj_using_allocator<pair_type>(alloc_, p);
    }

    constexpr auto do-construct(pair_type&& p) const {
        // exposition only
        return make_obj_using_allocator<pair_type>(alloc_, std::move(p));
    }

    const Alloc& alloc_; // exposition only
    U& u_; // exposition only

public:
    constexpr operator pair_type() const {
        return do-construct(std::forward<U>(u_));
    }
};
```

Returns: `make_tuple(pc)`, where `pc` is a `pair-constructor` object whose `alloc_` member is initialized with `alloc` and whose `u_` member is initialized with `u`.

```cpp
template<class T, class Alloc, class... Args>
constexpr T make_obj_using_allocator(const Alloc& alloc, Args&&... args);
```

Effects: Equivalent to:

```cpp
return make_from_tuple<T>(uses_allocator_construction_args<T>(
    alloc, std::forward<Args>(args)....));
```

```cpp
template<class T, class Alloc, class... Args>
constexpr T* uninitialized_construct_using_allocator(T* p, const Alloc& alloc, Args&&... args);
```

Effects: Equivalent to:

```cpp
return apply([&]<class... U>(U&&... xs) {
    return construct_at(p, std::forward<U>(xs)....);
}, uses_allocator_construction_args<T>(alloc, std::forward<Args>(args)....));
```

20.2.9 Allocator traits

20.2.9.1 General

The class template `allocator_traits` supplies a uniform interface to all allocator types. An allocator cannot be a non-class type, however, even if `allocator_traits` supplies the entire required interface.

[Note 1: Thus, it is always possible to create a derived class from an allocator. — end note]

If a program declares an explicit or partial specialization of `allocator_traits`, the program is ill-formed, no diagnostic required.

```cpp
namespace std {
    template<class Alloc> struct allocator_traits {
        using allocator_type = Alloc;

        using value_type = typename Alloc::value_type;

        using pointer = see below;
        using const_pointer = see below;
        using void_pointer = see below;
        using const_void_pointer = see below;

        using difference_type = see below;
        using size_type = see below;

        using propagate_on_container_copy_assignment = see below;
        using propagate_on_container_move_assignment = see below;
        using propagate_on_container_swap = see below;
    }
}
```
using is_always_equal = see below;

template<class T> using rebind_alloc = see below;
template<class T> using rebind_traits = allocator_traits<rebind_alloc<T>>;

[[nodiscard]] static constexpr pointer allocate(Alloc& a, size_type n);
[[nodiscard]] static constexpr pointer allocate(Alloc& a, size_type n,
               const void_pointer hint);
[[nodiscard]] static constexpr allocation_result<pointer, size_type>
               allocate_at_least(Alloc& a, size_type n);

static constexpr void deallocate(Alloc& a, pointer p, size_type n);
template<class T, class... Args>
static constexpr void construct(Alloc& a, T* p, Args&&... args);
template<class T>
static constexpr void destroy(Alloc& a, T* p);

static constexpr size_type max_size(const Alloc& a) noexcept;
static constexpr Alloc select_on_container_copy_construction(const Alloc& rhs);
}

§ 20.2.9.2 Member types

using pointer = see below;

1 Type: Alloc::pointer if the qualified-id Alloc::pointer is valid and denotes a type (13.10.3); otherwise, value_type*.

using const_pointer = see below;

2 Type: Alloc::const_pointer if the qualified-id Alloc::const_pointer is valid and denotes a type (13.10.3); otherwise, pointer_traits<pointer>::rebind<const value_type>.

using void_pointer = see below;

3 Type: Alloc::void_pointer if the qualified-id Alloc::void_pointer is valid and denotes a type (13.10.3); otherwise, pointer_traits<pointer>::rebind<void>.

using const_void_pointer = see below;

4 Type: Alloc::const_void_pointer if the qualified-id Alloc::const_void_pointer is valid and denotes a type (13.10.3); otherwise, pointer_traits<pointer>::rebind<const void>.

using difference_type = see below;

5 Type: Alloc::difference_type if the qualified-id Alloc::difference_type is valid and denotes a type (13.10.3); otherwise, pointer_traits<pointer>::difference_type.

using size_type = see below;

6 Type: Alloc::size_type if the qualified-id Alloc::size_type is valid and denotes a type (13.10.3); otherwise, make_unsigned_t<difference_type>.

using propagate_on_container_copy_assignment = see below;

7 Type: Alloc::propagate_on_container_copy_assignment if the qualified-id Alloc::propagate_on_container_copy_assignment is valid and denotes a type (13.10.3); otherwise false_type.

using propagate_on_container_move_assignment = see below;

8 Type: Alloc::propagate_on_container_move_assignment if the qualified-id Alloc::propagate_on_container_move_assignment is valid and denotes a type (13.10.3); otherwise false_type.
using propagate_on_container_swap = see below;

Type: Alloc::propagate_on_container_swap if the qualified-id Alloc::propagate_on_container_swap is valid and denotes a type (13.10.3); otherwise false_type.

using is_always_equal = see below;

Type: Alloc::is_always_equal if the qualified-id Alloc::is_always_equal is valid and denotes a type (13.10.3); otherwise is_empty<Alloc>::type.

template<class T> using rebind_alloc = see below;

Alias template: Alloc::rebind<T>::other if the qualified-id Alloc::rebind<T>::other is valid and denotes a type (13.10.3); otherwise, Alloc<T, Args> if Alloc is a class template instantiation of the form Alloc<U, Args>, where Args is zero or more type arguments; otherwise, the instantiation of rebind_alloc is ill-formed.

20.2.9.3 Static member functions

[[nodiscard]] static constexpr pointer allocate(Alloc& a, size_type n);

Returns: a.allocate(n).

[[nodiscard]] static constexpr pointer allocate(Alloc& a, size_type n, const_void_pointer hint);

Returns: a.allocate(n, hint) if that expression is well-formed; otherwise, a.allocate(n).

[[nodiscard]] static constexpr allocation_result<pointer, size_type> allocate_at_least(Alloc& a, size_type n);

Returns: a.allocate_at_least(n) if that expression is well-formed; otherwise, {a.allocate(n), n}.

static constexpr void deallocate(Alloc& a, pointer p, size_type n);

Effects: Calls a.deallocate(p, n).

Throws: Nothing.

template<class T, class... Args>
static constexpr void construct(Alloc& a, T* p, Args&&... args);

Effects: Calls a.construct(p, std::forward<Args>(args)...) if that call is well-formed; otherwise, invokes construct_at(p, std::forward<Args>(args)...).

template<class T>
static constexpr void destroy(Alloc& a, T* p);

Effects: Calls a.destroy(p) if that call is well-formed; otherwise, invokes destroy_at(p).

static constexpr size_type max_size(const Alloc& a) noexcept;

Returns: a.max_size() if that expression is well-formed; otherwise, numeric_limits<size_type>::max()/sizeof(value_type).

static constexpr Alloc select_on_container_copy_construction(const Alloc& rhs);

Returns: rhs.select_on_container_copy_construction() if that expression is well-formed; otherwise, rhs.

20.2.9.4 Other

The class template allocation_result has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

20.2.10 The default allocator

20.2.10.1 General

All specializations of the default allocator meet the allocator completeness requirements (16.4.4.6.2).
using size_type = size_t;
using difference_type = ptrdiff_t;
using propagate_on_container_move_assignment = true_type;

constexpr allocator() noexcept;
constexpr allocator(const allocator&) noexcept;
constexpr allocator(const allocator<U>&) noexcept;
constexpr allocator() noexcept;

[[nodiscard]] constexpr T* allocate(size_t n);
[[nodiscard]] constexpr allocation_result<T*> allocate_at_least(size_t n);
constexpr void deallocate(T* p, size_t n);

[[nodiscard]] constexpr T* allocate(size_t n);
[[nodiscard]] constexpr allocation_result<T*> allocate_at_least(size_t n);
constexpr void deallocate(T* p, size_t n);

allocator_traits<allocator<T>>::is_always_equal::value
is true for any T.

20.2.10.2 Members

Except for the destructor, member functions of the default allocator shall not introduce data races (6.9.2) as a result of concurrent calls to those member functions from different threads. Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before the next allocation (if any) in this order.

[[nodiscard]] constexpr T* allocate(size_t n);

Mandates: T is not an incomplete type (6.8.1).

Returns: A pointer to the initial element of an array of n T.

Throws: bad_array_new_length if numeric_limits<size_t>::max() / sizeof(T) < n, or bad_alloc if the storage cannot be obtained.

Remarks: The storage for the array is obtained by calling ::operator new (17.6.3), but it is unspecified when or how often this function is called. This function starts the lifetime of the array object, but not that of any of the array elements.

[[nodiscard]] constexpr allocation_result<T*> allocate_at_least(size_t n);

Mandates: T is not an incomplete type (6.8.1).

Returns: allocation_result<T*>{ptr, count}, where ptr is a pointer to the initial element of an array of count T and count ≥ n.

Throws: bad_array_new_length if numeric_limits<size_t>::max() / sizeof(T) < n, or bad_alloc if the storage cannot be obtained.

Remarks: The storage for the array is obtained by calling ::operator new, but it is unspecified when or how often this function is called. This function starts the lifetime of the array object, but not that of any of the array elements.

constexpr void deallocate(T* p, size_t n);

Preconditions:
(10.1) If p is memory that was obtained by a call to allocate_at_least, let ret be the value returned and req be the value passed as the first argument to that call. p is equal to ret.ptr and n is a value such that req ≤ n ≤ ret.count.
(10.2) Otherwise, p is a pointer value obtained from allocate. n equals the value passed as the first argument to the invocation of allocate which returned p.

Effects: Deallocates the storage referenced by p.

Remarks: Uses ::operator delete (17.6.3), but it is unspecified when this function is called.

20.2.10.3 Operators

template<class T, class U>
constexpr bool operator==(const allocator<T> &, const allocator<U> &) noexcept;

Returns: true.

20.2.11 addressof

Returns: The actual address of the object or function referenced by r, even in the presence of an overloaded operator&.

Remarks: An expression addressof(E) is a constant subexpression (3.14) if E is an lvalue constant subexpression.

20.2.12 C library memory allocation

[Note 1: The header <cstdlib> (17.2.2) declares the functions described in this subclause. — end note]

void* aligned_alloc(size_t alignment, size_t size);
void* calloc(size_t nmemb, size_t size);
void* malloc(size_t size);
void* realloc(void* ptr, size_t size);

Effects: These functions have the semantics specified in the C standard library.

Remarks: These functions do not attempt to allocate storage by calling ::operator new() (17.6.3).

These functions implicitly create objects (6.7.2) in the returned region of storage and return a pointer to a suitable created object. In the case of calloc and realloc, the objects are created before the storage is zeroed or copied, respectively.

void free(void* ptr);

Effects: This function has the semantics specified in the C standard library.

Remarks: This function does not attempt to deallocate storage by calling ::operator delete().

See also: ISO C 7.22.3

20.3 Smart pointers

20.3.1 Unique-ownership pointers

20.3.1.1 General

A unique pointer is an object that owns another object and manages that other object through a pointer. More precisely, a unique pointer is an object u that stores a pointer to a second object p and will dispose of p when u is itself destroyed (e.g., when leaving block scope (8.8)). In this context, u is said to own p.

The mechanism by which u disposes of p is known as p's associated deleter, a function object whose correct invocation results in p's appropriate disposition (typically its deletion).

Let the notation u.p denote the pointer stored by u, and let u.d denote the associated deleter. Upon request, u can reset (replace) u.p and u.d with another pointer and deleter, but properly disposes of its owned object via the associated deleter before such replacement is considered completed.

Each object of a type U instantiated from the unique_ptr template specified in 20.3.1 has the strict ownership semantics, specified above, of a unique pointer. In partial satisfaction of these semantics, each such U is Cpp17MoveConstructible and Cpp17MoveAssignable, but is not Cpp17CopyConstructible nor Cpp17CopyAssignable. The template parameter T of unique_ptr may be an incomplete type.

[Note 1: The uses of unique_ptr include providing exception safety for dynamically allocated memory, passing ownership of dynamically allocated memory to a function, and returning dynamically allocated memory from a function. — end note]

20.3.1.2 Default deleters

20.3.1.2.1 In general

The class template default_delete serves as the default deleter (destruction policy) for the class template unique_ptr.

The template parameter T of default_delete may be an incomplete type.
20.3.1.2.2 default_delete

```cpp
namespace std {
    template<class T> struct default_delete {
        constexpr default_delete() noexcept = default;
        template<class U> constexpr default_delete(const default_delete<U>&) noexcept;
        constexpr void operator()(T*) const;
    };
}
```

1 Constraints: U* is implicitly convertible to T*.
2 Effects: Constructs a default_delete object from another default_delete<U> object.

```cpp
template<class U> constexpr default_delete(const default_delete<U>& other) noexcept;
```

3 Mandates: T is a complete type.
4 Effects: Calls delete on ptr.

20.3.1.2.3 default_delete<T[]>

```cpp
namespace std {
    template<class T> struct default_delete<T[]> {
        constexpr default_delete() noexcept = default;
        template<class U> constexpr default_delete(const default_delete<U[]>& other) noexcept;
        template<class U> constexpr void operator()(U* ptr) const;
    };
}
```

1 Constraints: U(*)[] is convertible to T(*)[].
2 Effects: Constructs a default_delete object from another default_delete<U[]> object.

```cpp
template<class U> constexpr default_delete(const default_delete<U[]>& other) noexcept;
```

3 Constraints: U(*)[] is convertible to T(*)[].
4 Mandates: U is a complete type.
5 Effects: Calls delete[] on ptr.

20.3.1.3 unique_ptr for single objects

20.3.1.3.1 General

```cpp
namespace std {
    template<class T, class D = default_delete<T>> class unique_ptr {
        public:
            using pointer = see below;
            using element_type = T;
            using deleter_type = D;

            // 20.3.1.3.2, constructors
            constexpr unique_ptr() noexcept;
            constexpr explicit unique_ptr(type_identity_t<pointer> p) noexcept;
            constexpr unique_ptr(type_identity_t<pointer> p, see below d1) noexcept;
            constexpr unique_ptr(type_identity_t<pointer> p, see below d2) noexcept;
            constexpr unique_ptr(unique_ptr&& u) noexcept;
            constexpr unique_ptr(nullptr_t) noexcept;
            template<class U, class E>
                constexpr unique_ptr(unique_ptr<unique_ptr<U, E>>, u) noexcept;

            // 20.3.1.3.3, destructor
            constexpr ~unique_ptr();

            // 20.3.1.3.4, assignment
            constexpr unique_ptr& operator=(unique_ptr&& u) noexcept;
    };
```

§ 20.3.1.3.1
template<class U, class E>
    constexpr unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
constexpr unique_ptr& operator=(nullptr_t) noexcept;

// 20.3.1.3.5, observers
constexpr add_lvalue_reference_t<T> operator*() const noexcept;
constexpr pointer operator->() const noexcept;
constexpr pointer get() const noexcept;
constexpr deleter_type& get_deleter() noexcept;
constexpr const deleter_type& get_deleter() const noexcept;
constexpr explicit operator bool() const noexcept;

// 20.3.1.3.6, modifiers
constexpr pointer release() noexcept;
constexpr void reset(pointer p = pointer()) noexcept;
constexpr void swap(unique_ptr& u) noexcept;

// disable copy from lvalue
unique_ptr(const unique_ptr&) = delete;
unique_ptr& operator=(const unique_ptr&) = delete;

1. The default type for the template parameter D is default_delete. A client-supplied template argument D shall be a function object type (22.10), lvalue reference to function, or lvalue reference to function object type for which, given a value d of type D and a value ptr of type unique_ptr<T, D>::pointer, the expression d(ptr) is valid and has the effect of disposing of the pointer as appropriate for that deleter.

2. If the deleter’s type D is not a reference type, D shall meet the Cpp17Destructible requirements (Table 35).

3. If the qualified-id remove_reference_t<D>::pointer is valid and denotes a type (13.10.3), then unique_ptr<T, D>::pointer shall be a synonym for remove_reference_t<D>::pointer. Otherwise unique_ptr<T, D>::pointer shall be a synonym for element_type*. The type unique_ptr<T, D>::pointer shall meet the Cpp17NullablePointer requirements (Table 36).

4. [Example 1: Given an allocator type X (16.4.4.6.1) and letting A be a synonym for allocator_traits<X>, the types A::pointer, A::const_pointer, A::void_pointer, and A::const_void_pointer may be used as unique_ptr<T, D>::pointer. —end example]

20.3.1.3.2 Constructors

constexpr unique_ptr() noexcept;
constexpr unique_ptr(nullptr_t) noexcept;

1. Constraints: is_pointer_v<deleter_type> is false and is_default_constructible_v<deleter_type> is true.
2. Preconditions: D meets the Cpp17DefaultConstructible requirements (Table 30), and that construction does not throw an exception.
3. Effects: Constructs a unique_ptr object that owns nothing, value-initializing the stored pointer and the stored deleter.
4. Postconditions: get() == nullptr. get_deleter() returns a reference to the stored deleter.

constexpr explicit unique_ptr(type_identity_t<pointer> p) noexcept;

5. Constraints: is_pointer_v<deleter_type> is false and is_default_constructible_v<deleter_type> is true.
6. Preconditions: D meets the Cpp17DefaultConstructible requirements (Table 30), and that construction does not throw an exception.
7. Effects: Constructs a unique_ptr which owns p, initializing the stored pointer with p and value-initializing the stored deleter.
8. Postconditions: get() == p. get_deleter() returns a reference to the stored deleter.
constexpr unique_ptr(type_identity_t<pointer> p, remove_reference_t<D>&& d) noexcept;

Constraints: is_constructible_v<D, decltype(d)> is true.

Preconditions: For the first constructor, if D is not a reference type, D meets the Cpp17CopyConstructible requirements and such construction does not exit via an exception. For the second constructor, if D is not a reference type, D meets the Cpp17MoveConstructible requirements and such construction does not exit via an exception.

Effects: Constructs a unique_ptr object which owns p, initializing the stored pointer with p and initializing the deleter from std::forward<decltype(d)>(d).

Postconditions: get() == p. get_deleter() returns a reference to the stored deleter. If D is a reference type then get_deleter() returns a reference to the lvalue d.

Remarks: If D is a reference type, the second constructor is defined as deleted.

[Example 1:
D d;
unique_ptr<int, D> p1(new int, D()); // D must be Cpp17MoveConstructible
unique_ptr<int, D> p2(new int, d);  // D must be Cpp17CopyConstructible
unique_ptr<int, D> p3(new int, d);  // p3 holds a reference to d
unique_ptr<int, const D&> p4(new int, D()); // error: rvalue deleter object combined with reference deleter type
—end example]

constexpr unique_ptr(unique_ptr&& u) noexcept;

Constraints: is_move_constructible_v<D> is true.

Preconditions: If D is not a reference type, D meets the Cpp17MoveConstructible requirements (Table 31). Construction of the deleter from an rvalue of type D does not throw an exception.

Effects: Constructs a unique_ptr from u. If D is a reference type, this deleter is copy constructed from u’s deleter; otherwise, this deleter is move constructed from u’s deleter.

[Note 1: The construction of the deleter can be implemented with std::forward<D>. —end note]

Postconditions: get() yields the value u.get() yielded before the construction. u.get() == nullptr. get_deleter() returns a reference to the stored deleter that was constructed from u.get_deleter(). If D is a reference type then get_deleter() and u.get_deleter() both reference the same lvalue deleter.

[Note 2: The deleter constructor can be implemented with std::forward<E>. —end note]

template<class U, class E> constexpr unique_ptr(unique_ptr<U, E>&& u) noexcept;

Constraints:
(19.1) unique_ptr<U, E>::pointer is implicitly convertible to pointer,
(19.2) U is not an array type, and
(19.3) either D is a reference type and E is the same type as D, or D is not a reference type and E is implicitly convertible to D.

Preconditions: If E is not a reference type, construction of the deleter from an rvalue of type E is well-formed and does not throw an exception. Otherwise, E is a reference type and construction of the deleter from an lvalue of type E is well-formed and does not throw an exception.

Effects: Constructs a unique_ptr from u. If E is a reference type, this deleter is copy constructed from u’s deleter; otherwise, this deleter is move constructed from u’s deleter.

[Note 2: The deleter constructor can be implemented with std::forward<E>. —end note]

Postconditions: get() yields the value u.get() yielded before the construction. u.get() == nullptr. get_deleter() returns a reference to the stored deleter that was constructed from u.get_deleter().

20.3.1.3.3 Destructor

constexpr unique_ptr();

Effects: Equivalent to: if (get()) get_deleter()(get());

[Note 1: The use of default_delete requires T to be a complete type. —end note]
Remarks: The behavior is undefined if the evaluation of \( \text{get}\_\text{deleter}() \)\( \text{get}() \) throws an exception.

20.3.1.3.4 Assignment

```cpp
constexpr unique_ptr& operator=(unique_ptr&& u) noexcept;
```

1 Constraints: \( \text{is\_move\_assignable} \_v<D> \) is true.
2 Preconditions: If \( D \) is not a reference type, \( D \) meets the \( \text{Cpp17MoveAssignatable} \) requirements (Table 33) and assignment of the deleter from an rvalue of type \( D \) does not throw an exception. Otherwise, \( D \) is a reference type; \( \text{remove\_reference\_t}<\!D\!> \) meets the \( \text{Cpp17CopyAssignatable} \) requirements and assignment of the deleter from an lvalue of type \( D \) does not throw an exception.
3 Effects: Calls \( \text{reset}(u.\text{release()} ) \) followed by \( \text{get}\_\text{deleter}() = \text{std::forward}<\!D\!>(u.\text{get}\_\text{deleter}()) \).
4 Postconditions: If \( \text{this} \neq \text{addressof}(u) \), u.get() == nullptr, otherwise u.get() is unchanged.
5 Returns: *this.

```cpp
template<class U, class E> constexpr unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
```

6 Constraints:
   (6.1) \( \text{unique\_ptr<U, E>::pointer} \) is implicitly convertible to \( \text{pointer} \), and
   (6.2) \( U \) is not an array type, and
   (6.3) \( \text{is\_assignable} \_v<D&, E&&> \) is true.
7 Preconditions: If \( E \) is not a reference type, assignment of the deleter from an rvalue of type \( E \) is well-formed and does not throw an exception. Otherwise, \( E \) is a reference type and assignment of the deleter from an lvalue of type \( E \) is well-formed and does not throw an exception.
8 Effects: Calls \( \text{reset}(u.\text{release()} ) \) followed by \( \text{get}\_\text{deleter}() = \text{std::forward}<\!E\!>(u.\text{get}\_\text{deleter}()) \).
9 Postconditions: u.get() == nullptr.
10 Returns: *this.

```cpp
constexpr unique_ptr& operator=(nullptr_t) noexcept;
```

11 Effects: As if by \( \text{reset}() \).
12 Postconditions: get() == nullptr.
13 Returns: *this.

20.3.1.3.5 Observers

```cpp
constexpr add\_lvalue\_reference\_t<T> operator*() const noexcept(noexcept(*declval<pointer>()));
```

1 Preconditions: get() != nullptr.
2 Returns: *get().

```cpp
constexpr pointer operator->() const noexcept;
```

3 Preconditions: get() != nullptr.
4 Returns: get().
5 [Note 1: The use of this function typically requires that \( T \) be a complete type. — end note]
6

```cpp
constexpr pointer get() const noexcept;
```

6 Returns: The stored pointer.

```cpp
constexpr deleter\_type& get\_deleter() noexcept;
```

7 Returns: A reference to the stored deleter.

```cpp
constexpr explicit operator bool() const noexcept;
```

8 Returns: get() != nullptr.
20.3.1.3.6 Modifiers

```cpp
constexpr pointer release() noexcept;
```

1. **Postconditions:** get() == nullptr.
2. **Returns:** The value get() had at the start of the call to release.

```cpp
constexpr void reset(pointer p = pointer()) noexcept;
```

3. **Effects:** Assigns p to the stored pointer, and then, with the old value of the stored pointer, old_p, evaluates if (old_p) get_deleter()(old_p);
4. **Postconditions:** get() == p.
5. **Remarks:** The behavior is undefined if the evaluation of get_deleter()(old_p) throws an exception.

```cpp
constexpr void swap(unique_ptr& u) noexcept;
```

6. **Preconditions:** get_deleter() is swappable (16.4.4.3) and does not throw an exception under swap.
7. **Effects:** Invokes swap on the stored pointers and on the stored deleters of *this and u.

20.3.1.4 unique_ptr for array objects with a runtime length

20.3.1.4.1 General

```cpp
namespace std {
    template<class T, class D> class unique_ptr<T[], D> {
        public:
            using pointer = see below;
            using element_type = T;
            using deleter_type = D;

            // 20.3.1.4.2, constructors
            constexpr unique_ptr() noexcept;
            template<class U> constexpr explicit unique_ptr(U p) noexcept;
            template<class U> constexpr unique_ptr(U p, see below d) noexcept;
            constexpr unique_ptr(unique_ptr&& u) noexcept;
            template<class U, class E>
                constexpr unique_ptr(unique_ptr<U, E>&& u) noexcept;
            constexpr unique_ptr(nullptr_t) noexcept;

            // destructor
            constexpr ~unique_ptr();

            // assignment
            constexpr unique_ptr& operator=(unique_ptr&& u) noexcept;
            template<class U, class E>
                constexpr unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
            constexpr unique_ptr& operator=(nullptr_t) noexcept;

            // 20.3.1.4.4, observers
            constexpr T& operator[](size_t i) const;
            constexpr pointer get() const noexcept;
            constexpr deleter_type& get_deleter() noexcept;
            constexpr const deleter_type& get_deleter() const noexcept;
            constexpr explicit operator bool() const noexcept;

            // 20.3.1.4.5, modifiers
            constexpr pointer release() noexcept;
            template<class U> constexpr void reset(U p) noexcept;
            constexpr void reset(nullptr_t = nullptr) noexcept;
            constexpr void swap(unique_ptr& u) noexcept;
    }
}
```
A specialization for array types is provided with a slightly altered interface.

1 A specialization for array types is provided with a slightly altered interface.

(1.1) — Conversions between different types of unique_ptr<T[], D> that would be disallowed for the corresponding pointer-to-array types, and conversions to or from the non-array forms of unique_ptr, produce an ill-formed program.

(1.2) — Pointers to types derived from T are rejected by the constructors, and by reset.

(1.3) — The observers operator* and operator-> are not provided.

(1.4) — The indexing observer operator[] is provided.

(1.5) — The default deleter will call delete[].

2 Descriptions are provided below only for members that differ from the primary template.

3 The template argument T shall be a complete type.

20.3.1.4.2 Constructors

template<class U> constexpr explicit unique_ptr(U p) noexcept;

1 This constructor behaves the same as the constructor in the primary template that takes a single parameter of type pointer.

2 Constraints: (2.1) — U is the same type as pointer, or

(2.2) — pointer is the same type as element_type*, U is a pointer type V*, and V(*)[] is convertible to element_type(*)[].

20.3.1.4.3 Assignment

template<class U, class E> constexpr unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;

1 This operator behaves the same as in the primary template.

2 Constraints: Where UP is unique_ptr<U, E>:

(6.1) — U is an array type, and

(6.2) — pointer is the same type as element_type*, and

(6.3) — UP::pointer is the same type as UP::element_type*, and

(6.4) — UP::element_type(*)[] is convertible to element_type(*)[]. and

(6.5) — either D is a reference type and E is the same type as D, or D is not a reference type and E is implicitly convertible to D.

[Note 1: This replaces the Constraints: specification of the primary template. — end note]
ISO/IEC N4944

— \( U \) is an array type, and
— \texttt{pointer} is the same type as \texttt{element_type*}, and
— \texttt{UP::pointer} is the same type as \texttt{UP::element_type*}, and
— \texttt{UP::element_type(*)[]} is convertible to \texttt{element_type(*)[]} , and
— \texttt{is_assignable_v<D&, E&&>} is true.

[Note 1: This replaces the Constraints: specification of the primary template. — end note]

### 20.3.1.4.4 Observers

```cpp
constexpr T& operator[](size_t i) const;
```

1. **Preconditions:** \( i < \) the number of elements in the array to which the stored pointer points.
2. **Returns:** \texttt{get()[i]}.

### 20.3.1.4.5 Modifiers

```cpp
constexpr void reset(nullptr_t p = nullptr) noexcept;
```

1. **Effects:** Equivalent to \texttt{reset(pointer())}.
2. **This function behaves the same as the \texttt{reset} member of the primary template.
3. **Constraints:**
   - \( U \) is the same type as \texttt{pointer}, or
   - \texttt{pointer} is the same type as \texttt{element_type*}, \( U \) is a pointer type \( V* \), and \( V(*)[] \) is convertible to \texttt{element_type(*)[]}.

### 20.3.1.5 Creation

```cpp
template<class T, class... Args> constexpr unique_ptr<T> make_unique(Args&&... args);
```

1. **Constraints:** \( T \) is not an array type.
2. **Returns:** \texttt{unique_ptr<T>(new T(std::forward<Args>(args)...))}.

```cpp
template<class T> constexpr unique_ptr<T> make_unique(size_t n);
```

3. **Constraints:** \( T \) is an array of unknown bound.
4. **Returns:** \texttt{unique_ptr<T>(new remove_extent_t<T>[n]()})

```cpp
template<class T, class... Args> unspecified make_unique(Args&&...) = delete;
```

5. **Constraints:** \( T \) is an array of known bound.

```cpp
template<class T> constexpr unique_ptr<T> make_unique_for_overwrite();
```

6. **Constraints:** \( T \) is not an array type.
7. **Returns:** \texttt{unique_ptr<T>(new T)}.

```cpp
template<class T> constexpr unique_ptr<T> make_unique_for_overwrite(size_t n);
```

8. **Constraints:** \( T \) is an array of unknown bound.
9. **Returns:** \texttt{unique_ptr<T>(new remove_extent_t<T>[n])}.

```cpp
template<class T, class... Args> unspecified make_unique_for_overwrite(Args&&...) = delete;
```

10. **Constraints:** \( T \) is an array of known bound.

### 20.3.1.6 Specialized algorithms

```cpp
template<class T, class D> constexpr void swap(unique_ptr<T, D>& x, unique_ptr<T, D>& y) noexcept;
```

1. **Constraints:** \texttt{is_swappable_v<D>} is true.
2. **Effects:** Calls \texttt{x.swap(y)}.
template<class T1, class D1, class T2, class D2>
constexpr bool operator==(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: x.get() == y.get().

template<class T1, class D1, class T2, class D2>
bool operator<(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Let CT denote

common_type_t<typename unique_ptr<T1, D1>::pointer,
        typename unique_ptr<T2, D2>::pointer>

Mandates:
(5.1) — unique_ptr<T1, D1>::pointer is implicitly convertible to CT and
(5.2) — unique_ptr<T2, D2>::pointer is implicitly convertible to CT.

Preconditions: The specialization less<CT> is a function object type (22.10) that induces a strict weak
ordering (27.8) on the pointer values.

Returns: less<CT>()(x.get(), y.get()).

template<class T1, class D1, class T2, class D2>
bool operator>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: y < x.

template<class T1, class D1, class T2, class D2>
bool operator<=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: !(y < x).

template<class T1, class D1, class T2, class D2>
bool operator>=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: !(x < y).

requires three_way_comparable_with<typename unique_ptr<T1, D1>::pointer,
        typename unique_ptr<T2, D2>::pointer>

compare_three_way_result_t<typename unique_ptr<T1, D1>::pointer,
        typename unique_ptr<T2, D2>::pointer>

operator<=>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: compare_three_way()(x.get(), y.get()).

template<class T, class D>
constexpr bool operator==(const unique_ptr<T, D>& x, nullptr_t) noexcept;

Returns: !x.

template<class T, class D>
constexpr bool operator<(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
constexpr bool operator<(nullptr_t, const unique_ptr<T, D>& x);

Preconditions: The specialization less<unique_ptr<T, D>::pointer> is a function object type (22.10)
that induces a strict weak ordering (27.8) on the pointer values.

Returns: The first function template returns
less<unique_ptr<T, D>::pointer>()(x.get(), nullptr)
The second function template returns
less<unique_ptr<T, D>::pointer>()(nullptr, x.get())

template<class T, class D>
constexpr bool operator>(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
constexpr bool operator>(nullptr_t, const unique_ptr<T, D>& x);

Returns: The first function template returns nullptr < x. The second function template returns x < nullptr.

template<class T, class D>
constexpr bool operator<(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
constexpr bool operator<=(nullptr_t, const unique_ptr<T, D>& x);

Returns: The first function template returns !(nullptr < x). The second function template returns !(x < nullptr).

template<class T, class D>
constexpr bool operator<=(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
constexpr bool operator>=(nullptr_t, const unique_ptr<T, D>& x);

Returns: The first function template returns !(nullptr < x). The second function template returns !(x < nullptr).

template<class T, class D>
requires three_way_comparable<typename unique_ptr<T, D>::pointer>
constexpr compare_three_way_result_t<typename unique_ptr<T, D>::pointer>
operator<=>(const unique_ptr<T, D>& x, nullptr_t);

Returns:
compare_three_way(x.get(), static_cast<typename unique_ptr<T, D>::pointer>(nullptr)).

20.3.1.7 I/O [unique.ptr.io]

template<class E, class T, class Y, class D>
basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const unique_ptr<Y, D>& p);

Constraints: os << p.get() is a valid expression.

Effects: Equivalent to: os << p.get();

Returns: os.

20.3.2 Shared-ownership pointers [util.sharedptr]

20.3.2.1 Class bad_weak_ptr [util.smartptr.weak.bad]

namespace std {
    class bad_weak_ptr : public exception {
    public:
        // see 17.9.3 for the specification of the special member functions
        const char* what() const noexcept override;
    };  // see 17.9.3 for the specification of the special member functions
}

An exception of type bad_weak_ptr is thrown by the shared_ptr constructor taking a weak_ptr.

const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

20.3.2.2 Class template shared_ptr [util.smartptr.shared]

20.3.2.2.1 General [util.smartptr.shared.general]

The shared_ptr class template stores a pointer, usually obtained via new. shared_ptr implements semantics of shared ownership; the last remaining owner of the pointer is responsible for destroying the object, or otherwise releasing the resources associated with the stored pointer. A shared_ptr is said to be empty if it does not own a pointer.

namespace std {
    template<class T> class shared_ptr {
    public:
        using element_type = remove_extent_t<T>;
        using weak_type = weak_ptr<T>;
    }
// 20.3.2.2.1, constructors
constexpr shared_ptr() noexcept;
constexpr shared_ptr(nullptr_t) noexcept : shared_ptr() { }
template<class Y>
    explicit shared_ptr(Y* p);
template<class Y, class D>
    shared_ptr(Y* p, D d);
template<class Y, class D, class A>
    shared_ptr(Y* p, D d, A a);
template<class D>
    shared_ptr(nullptr_t p, D d);
template<class D, class A>
    shared_ptr(nullptr_t p, D d, A a);
template<class Y>
    shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
template<class Y, class D>
    shared_ptr(const shared_ptr<Y>&& r, element_type* p) noexcept;
template<class Y>
    shared_ptr(const shared_ptr<Y>& r) noexcept;
template<class Y, class D>
    shared_ptr(const shared_ptr<Y>& r) noexcept;
template<class Y>
    shared_ptr(shared_ptr<Y>&& r);
template<class Y, class D>
    shared_ptr(unique_ptr<Y, D>&& r);

// 20.3.2.2.2, constructors

// 20.3.2.2.3, destructor
-shared_ptr();

// 20.3.2.2.4, assignment
shared_ptr& operator=(const shared_ptr& r) noexcept;
template<class Y>
    shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;
template<class Y>
    shared_ptr& operator=(shared_ptr&& r) noexcept;
template<class Y>
    shared_ptr& operator=(const shared_ptr<Y>&& r) noexcept;
template<class Y, class D>
    shared_ptr& operator=(unique_ptr<Y, D>&& r);

// 20.3.2.2.5, modifiers
void swap(shared_ptr& r) noexcept;
void reset() noexcept;
template<class Y>
    void reset(Y* p);
template<class Y, class D>
    void reset(Y* p, D d);
template<class Y, class D, class A>
    void reset(Y* p, D d, A a);

// 20.3.2.2.6, observers
element_type* get() const noexcept;
T& operator*() const noexcept;
T* operator->() const noexcept;
element_type& operator[](ptrdiff_t i) const;
lazy_use_count() const noexcept;
explicit operator bool() const noexcept;
template<class U>
    bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U>
    bool owner_before(const weak_ptr<U>& b) const noexcept;
};

§ 20.3.2.2.1
2 Specializations of `shared_ptr` shall be `Cpp17CopyConstructible`, `Cpp17CopyAssignable`, and `Cpp17LessThanComparable`, allowing their use in standard containers. Specializations of `shared_ptr` shall be contextually convertible to `bool`, allowing their use in boolean expressions and declarations in conditions.

3 The template parameter `T` of `shared_ptr` may be an incomplete type.

[Note 1: `T` can be a function type. — end note]

4 [Example 1:
   
   ```
   if (shared_ptr<X> px = dynamic_pointer_cast<X>(py)) {
     // do something with px
   }
   ```
   
   —end example]

5 For purposes of determining the presence of a data race, member functions shall access and modify only the `shared_ptr` and `weak_ptr` objects themselves and not objects they refer to. Changes in `use_count()` do not reflect modifications that can introduce data races.

6 For the purposes of subclause 20.3, a pointer type `Y*` is said to be compatible with a pointer type `T*` when either `Y*` is convertible to `T*` or `Y` is `U[N]` and `T` is `cv U[]`.

20.3.2.2.2 Constructors

1 In the constructor definitions below, enables `shared_from_this` with `p`, for a pointer `p` of type `Y*`, means that if `Y` has an unambiguous and accessible base class that is a specialization of `enable_shared_from_this` (20.3.2.5), then `remove_cv_t<Y>*` shall be implicitly convertible to `T*` and the constructor evaluates the statement:

```
if (p != nullptr && p->weak_this.expired())
  p->weak_this = shared_ptr<remove_cv_t<Y>>(*this, const_cast<remove_cv_t<Y>*>(p));
```

The assignment to the `weak_this` member is not atomic and conflicts with any potentially concurrent access to the same object (6.9.2).

```
constexpr shared_ptr() noexcept;
```

2 Postconditions: `use_count() == 0 && get() == nullptr`.

```
template<class Y> explicit shared_ptr(Y* p);
```

3 `Constraints`: When `T` is an array type, the expression `delete[] p` is well-formed and either `T` is `U[N]` and `Y(*)[N]` is convertible to `T*`, or `T` is `U[]` and `Y(*)[]` is convertible to `T*`. When `T` is not an array type, the expression `delete p` is well-formed and `Y*` is convertible to `T*`.

`Mandates`: `Y` is a complete type.

4 `Preconditions`: The expression `delete[] p`, when `T` is an array type, or `delete p`, when `T` is not an array type, has well-defined behavior, and does not throw exceptions.

5 `Effects`: When `T` is not an array type, constructs a `shared_ptr` object that owns the pointer `p`. Otherwise, constructs a `shared_ptr` that owns `p` and a deleter of an unspecified type that calls `delete[] p`. When `T` is not an array type, enables `shared_from_this` with `p`. If an exception is thrown, `delete p` is called when `T` is not an array type, `delete[] p` otherwise.

6 `Postconditions`: `use_count() == 1 && get() == p`.

7 `Throws`: `bad_alloc`, or an implementation-defined exception when a resource other than memory cannot be obtained.

8

```
template<class Y, class D> shared_ptr(Y* p, D d);
template<class Y, class D, class A> shared_ptr(Y* p, D d, A a);
```
template<class D, class A> shared_ptr(nullptr_t p, D d, A a);

Constraints: is_move_constructible_v<D> is true, and d(p) is a well-formed expression. For the first two overloads:

(9.1) If T is an array type, then either T is U[N] and Y(*)[N] is convertible to T*, or T is U[] and Y(*)[] is convertible to T*.
(9.2) If T is not an array type, then Y* is convertible to T*.

Preconditions: Construction of d and a deleter of type D initialized with std::move(d) do not throw exceptions. The expression d(p) has well-defined behavior and does not throw exceptions. A meets the Cpp17Allocator requirements (16.4.4.6.1).

Effects: Constructs a shared_ptr object that owns the object p and the deleter d. When T is not an array type, the first and second constructors enable shared_from_this with p. The second and fourth constructors shall use a copy of a to allocate memory for internal use. If an exception is thrown, d(p) is called.

Postconditions: use_count() == 1 && get() == p.

Throws: bad_alloc, or an implementation-defined exception when a resource other than memory cannot be obtained.

template<class Y> shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
template<class Y> shared_ptr(shared_ptr<Y>&& r, element_type* p) noexcept;

Effects: Constructs a shared_ptr instance that stores p and shares ownership with the initial value of r.

Postconditions: get() == p. For the second overload, r is empty and r.get() == nullptr.

[Note 1: Use of this constructor leads to a dangling pointer unless p remains valid at least until the ownership group of r is destroyed. —end note]

[Note 2: This constructor allows creation of an empty shared_ptr instance with a non-null stored pointer. —end note]
shared_ptr(r.release(), ref(r.get_deleter())). If an exception is thrown, the constructor has no effect.

20.3.2.2.3 Destructor

\[\text{~shared\_ptr();}\]

1 Effects:
   
   (1.1) If *this is empty or shares ownership with another shared_ptr instance (use_count() > 1),
         there are no side effects.
   
   (1.2) Otherwise, if *this owns an object p and a deleter d, d(p) is called.
   
   (1.3) Otherwise, *this owns a pointer p, and delete p is called.

2 [Note 1: Since the destruction of *this decreases the number of instances that share ownership with *this by one,
       after *this has been destroyed all shared_ptr instances that shared ownership with *this will report a use_count()
       that is one less than its previous value. —end note]

20.3.2.2.4 Assignment

\[\text{shared\_ptr\& operator=(const shared\_ptr\& r) noexcept;}\]
\[\text{template<class Y> shared\_ptr\& operator=(const shared\_ptr\<Y\>& r) noexcept;}\]

1 Effects: Equivalent to shared_ptr(r).swap(*this).

2 Returns: *this.

3 [Note 1: The use count updates caused by the temporary object construction and destruction are not observable
      side effects, so the implementation can meet the effects (and the implied guarantees) via different means, without
      creating a temporary. In particular, in the example:
      
      shared_ptr<int> p(new int);
      shared_ptr<void> q(p);
      p = p;
      q = p;
      
      both assignments can be no-ops. —end note]

\[\text{shared\_ptr\& operator=(shared\_ptr&& r) noexcept;}\]
\[\text{template<class Y> shared\_ptr\& operator=(shared\_ptr\<Y\>&& r) noexcept;}\]

4 Effects: Equivalent to shared_ptr(std::move(r)).swap(*this).

5 Returns: *this.

6 template<class Y, class D> shared_ptr\& operator=(unique_ptr\<Y, D\>&& r);

7 Effects: Equivalent to shared_ptr(std::move(r)).swap(*this).

20.3.2.2.5 Modifiers

\[\text{void swap(shared\_ptr\& r) noexcept;}\]

1 Effects: Exchanges the contents of *this and r.

\[\text{void reset() noexcept;}\]

2 Effects: Equivalent to shared_ptr().swap(*this).

\[\text{template<class Y> void reset(Y* p);}\]

3 Effects: Equivalent to shared_ptr(p).swap(*this).

\[\text{template<class Y, class D> void reset(Y* p, D d);}\]

4 Effects: Equivalent to shared_ptr(p, d).swap(*this).

\[\text{template<class Y, class D, class A> void reset(Y* p, D d, A a);}\]

5 Effects: Equivalent to shared_ptr(p, d, a).swap(*this).
20.3.2.2.6 Observers

`element_type* get() const noexcept;`

- **Returns**: The stored pointer.

`T& operator*() const noexcept;`

- **Preconditions**: `get() != nullptr`.
- **Remarks**: When `T` is an array type or `cv void`, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

`T* operator->() const noexcept;`

- **Preconditions**: `get() != nullptr`.
- **Remarks**: When `T` is an array type, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

`element_type& operator[](ptrdiff_t i) const;`

- **Preconditions**: `get() != nullptr && i >= 0`. If `T` is `U[N]`, `i < N`.
- **Returns**: `get()[i]`.
- **Remarks**: When `T` is not an array type, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

`long use_count() const noexcept;`

- **Synchronization**: None.
- **Returns**: The number of `shared_ptr` objects, `*this` included, that share ownership with `*this`, or 0 when `*this` is empty.

- **Note 1**: `get() == nullptr` does not imply a specific return value of `use_count()`. — end note
- **Note 2**: `weak_ptr<T>::lock()` can affect the return value of `use_count()`. — end note
- **Note 3**: When multiple threads might affect the return value of `use_count()`, the result is approximate. In particular, `use_count() == 1` does not imply that accesses through a previously destroyed `shared_ptr` have in any sense completed. — end note

`explicit operator bool() const noexcept;`

- **Returns**: `get() != nullptr`.

20.3.2.2.7 Creation

The common requirements that apply to all `make_shared`, `allocate_shared`, `make_shared_for_overwrite`, and `allocate_shared_for_overwrite` overloads, unless specified otherwise, are described below.

```cpp
template<class T, ...>
shared_ptr<T> make_shared(args);
```
template<class T, class A, ...>
  shared_ptr<T> allocate_shared(const A& a, args);

template<class T, ...>
  shared_ptr<T> make_shared_for_overwrite(args);

template<class T, class A, ...>
  shared_ptr<T> allocate_shared_for_overwrite(const A& a, args);

Preconditions: A meets the Cpp17Allocator requirements (16.4.4.6.1).

Effects: Allocates memory for an object of type T (or U[N] when T is U[], where N is determined from args as specified by the concrete overload). The object is initialized from args as specified by the concrete overload. The allocate_shared and allocate_shared_for_overwrite templates use a copy of a (rebound for an unspecified value_type) to allocate memory. If an exception is thrown, the functions have no effect.

Postconditions: r.get() != nullptr & r.use_count() == 1, where r is the return value.

Returns: A shared_ptr instance that stores and owns the address of the newly constructed object.

Throws: bad_alloc, or an exception thrown from allocate or from the initialization of the object.

Remarks:

— Implementations should perform no more than one memory allocation.
  [Note 1: This provides efficiency equivalent to an intrusive smart pointer. — end note]

— When an object of an array type U is specified to have an initial value of u (of the same type), this shall be interpreted to mean that each array element of the object has as its initial value the corresponding element from u.

— When an object of an array type is specified to have a default initial value, this shall be interpreted to mean that each array element of the object has a default initial value.

— When a (sub)object of a non-array type U is specified to have an initial value of v, or U(1...), where 1... is a list of constructor arguments, make_shared shall initialize this (sub)object via the expression ::new(pv) U(v) or ::new(pv) U(1...) respectively, where pv has type void* and points to storage suitable to hold an object of type U.

— When a (sub)object of a non-array type U is specified to have an initial value of v, or U(1...), where 1... is a list of constructor arguments, allocate_shared shall initialize this (sub)object via the expression

  allocator_traits<A2>::construct(a2, pv, v) or

  allocator_traits<A2>::construct(a2, pv, 1...)

respectively, where pv points to storage suitable to hold an object of type U and a2 of type A2 is a rebound copy of the allocator a passed to allocate_shared such that its value_type is remove_cv_t<U>.

— When a (sub)object of non-array type U is specified to have a default initial value, make_shared shall initialize this (sub)object via the expression ::new(pv) U(), where pv has type void* and points to storage suitable to hold an object of type U.

— When a (sub)object of non-array type U is specified to have a default initial value, allocate_shared shall initialize this (sub)object via the expression allocator_traits<A2>::construct(a2, pv), where pv points to storage suitable to hold an object of type U and a2 of type A2 is a rebound copy of the allocator a passed to allocate_shared such that its value_type is remove_cv_t<U>.

— When a (sub)object of non-array type U is initialized by make_shared_for_overwrite or allocate_shared_for_overwrite, it is initialized via the expression ::new(pv) U, where pv has type void* and points to storage suitable to hold an object of type U.

— Array elements are initialized in ascending order of their addresses.

— When the lifetime of the object managed by the return value ends, or when the initialization of an array element throws an exception, the initialized elements are destroyed in the reverse order of their original construction.

— When a (sub)object of non-array type U that was initialized by make_shared is to be destroyed, it is destroyed via the expression pv->U() where pv points to that object of type U.
When a (sub)object of non-array type \( U \) that was initialized by `allocate_shared` is to be destroyed, it is destroyed via the expression `allocator_traits<A2>::destroy(a2, pv)` where `pv` points to that object of type `remove_cv_t\<U>` and `a2` of type `A2` is a rebound copy of the allocator `a` passed to `allocate_shared` such that its `value_type` is `remove_cv_t\<U>`.

[Note 2: These functions will typically allocate more memory than `sizeof(T)` to allow for internal bookkeeping structures such as reference counts. —end note]

```cpp
template<class T, class... Args>
shared_ptr<T> make_shared(Args&&... args); // T is not array

template<class T, class A, class... Args>
shared_ptr<T> allocate_shared(const A& a, Args&&... args); // T is not array
```

### Constraints:
- `T` is not an array type.

### Returns:
- A `shared_ptr` to an object of type `T` with an initial value `T(std::forward<Args>(args)...).`

### Remarks:
The `shared_ptr` constructors called by these functions enable `shared_from_this` with the address of the newly constructed object of type `T`.

#### Example 1:
```cpp
shared_ptr<int> p = make_shared<int>(); // shared_ptr to int()
shared_ptr<vector<int>> q = make_shared<vector<int>>(16, 1); // shared_ptr to vector of 16 elements with value 1
```

#### Example 2:
```cpp
shared_ptr<double[]> p = make_shared<double[]>(1024); // shared_ptr to a value-initialized double[1024]
shared_ptr<double[2][2]> q = make_shared<double[2][2]>(6); // shared_ptr to a value-initialized double[6][2][2]
```

#### Example 3:
```cpp
shared_ptr<double[1024]> p = make_shared<double[1024]>();
shared_ptr<double[6][2][2]> q = make_shared<double[6][2][2]>();
```

### Example 4:
```cpp
shared_ptr<double[]> p = make_shared<double[]>(1024); // shared_ptr to a value-initialized double[1024]
shared_ptr<double[6][2][2]> q = make_shared<double[6][2][2]>();
```

#### Example 5:
```cpp
shared_ptr<double[]> p = make_shared<double[]>(1024); // shared_ptr to a value-initialized double[1024]
shared_ptr<double[6][2][2]> q = make_shared<double[6][2][2]>();
```

### Constraints:
- `T` is of the form `U[]`.
Returns: A `shared_ptr` to an object of type `U[N]`, where `U` is `remove_extent_t<T>` and each array element has an initial value of `u`.

Example 4:

```cpp
    shared_ptr<double[]> p = make_shared<double[]>(1024, 1.0);
    // shared_ptr to a double[1024], where each element is 1.0
    shared_ptr<double[2][]> q = make_shared<double[2]>(6, {1.0, 0.0});
    // shared_ptr to a double[6][2], where each double[2] element is {1.0, 0.0}
    shared_ptr<vector<int>[]> r = make_shared<vector<int>[]>(4, {1, 2});
    // shared_ptr to a vector<int>[4], where each vector has contents {1, 2}
```

--- end example

```
template<class T>
    shared_ptr<T> make_shared(const remove_extent_t<T>& u);
// T is U[N]

template<class T, class A>
    shared_ptr<T> allocate_shared(const A& a,
        const remove_extent_t<T>& u);  // T is U[N]
```

Constraints: `T` is of the form `U[N]`.

Returns: A `shared_ptr` to an object of type `T`, where each array element of type `remove_extent_t<T>` has an initial value of `u`.

Example 5:

```cpp
    shared_ptr<double[1024]> p = make_shared<double[1024]>(1.0);
    // shared_ptr to a double[1024], where each element is 1.0
    shared_ptr<double[6][2]> q = make_shared<double[6][2]>({1.0, 0.0});
    // shared_ptr to a double[6][2], where each double[2] element is {1.0, 0.0}
    // shared_ptr to a vector<int>[4], where each vector has contents {1, 2}
```

--- end example

```
template<class T>
    shared_ptr<T> make_shared_for_overwrite();

template<class T, class A>
    shared_ptr<T> allocate_shared_for_overwrite(const A& a);
```

Constraints: `T` is not an array of unknown bound.

Returns: A `shared_ptr` to an object of type `T`.

Example 6:

```cpp
    struct X { double data[1024];; }
    shared_ptr<X> p = make_shared_for_overwrite<X>();
    // shared_ptr to a default-initialized X, where each element in X::data has an indeterminate value
    shared_ptr<double[1024]> q = make_shared_for_overwrite<double[1024]>();
    // shared_ptr to a default-initialized double[1024], where each element has an indeterminate value
```

--- end example

```
template<class T>
    shared_ptr<T> make_shared_for_overwrite(size_t N);

template<class T, class A>
    shared_ptr<T> allocate_shared_for_overwrite(const A& a, size_t N);
```

Constraints: `T` is an array of unknown bound.

Returns: A `shared_ptr` to an object of type `U[N]`, where `U` is `remove_extent_t<T>`.

Example 7:

```cpp
    shared_ptr<double[]> p = make_shared_for_overwrite<double[]>(1024);
    // shared_ptr to a default-initialized double[1024], where each element has an indeterminate value
```

--- end example

20.3.2.2.8 Comparison

```
template<class T, class U>
```

§ 20.3.2.2.8
bool operator==(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;

Returns: a.get() == b.get.

template<class T>
bool operator==(const shared_ptr<T>& a, nullptr_t) noexcept;

Returns: !a.

template<class T, class U>
strong_ordering operator<=>(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;

Returns: compare_three_way(a.get(), b.get()).

[Note 1: Defining a comparison operator function allows shared_ptr objects to be used as keys in associative containers. —end note]

template<class T>
strong_ordering operator<=>(const shared_ptr<T>& a, nullptr_t) noexcept;

Returns: compare_three_way(a.get(), static_cast<typename shared_ptr<T>::element_type*>(nullptr)).

20.3.2.2.9 Specialized algorithms

template<class T>
void swap(shared_ptr<T>& a, shared_ptr<T>& b) noexcept;

Effects: Equivalent to a.swap(b).

20.3.2.2.10 Casts

template<class T, class U>
shared_ptr<T> static_pointer_cast(const shared_ptr<U>& r) noexcept;

template<class T, class U>
shared_ptr<T> static_pointer_cast(shared_ptr<U>&& r) noexcept;

Mandates: The expression static_cast<T*>(U*)nullptr is well-formed.

Returns: shared_ptr<T>(R, static_cast<typename shared_ptr<T>::element_type*>(r.get()))

where R is r for the first overload, and std::move(r) for the second.

[Note 1: The seemingly equivalent expression shared_ptr<T>=(static_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. —end note]

template<class T, class U>
shared_ptr<T> dynamic_pointer_cast(const shared_ptr<U>& r) noexcept;

template<class T, class U>
shared_ptr<T> dynamic_pointer_cast(shared_ptr<U>&& r) noexcept;

Mandates: The expression dynamic_cast<T*>(U*)nullptr is well-formed. The expression dynamic_cast<typename shared_ptr<T>::element_type*>(r.get()) is well-formed.

 Preconditions: The expression dynamic_cast<typename shared_ptr<T>::element_type*>(r.get()) has well-defined behavior.

Returns:

(6.1) — When dynamic_cast<typename shared_ptr<T>::element_type*>(r.get()) returns a non-null value p, shared_ptr<T>(R, p), where R is r for the first overload, and std::move(r) for the second.

(6.2) — Otherwise, shared_ptr<T>().

[Note 2: The seemingly equivalent expression shared_ptr<T>(dynamic_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. —end note]

template<class T, class U>
shared_ptr<T> const_pointer_cast(const shared_ptr<U>&& r) noexcept;
template<class T, class U>
shared_ptr<T> const_pointer_cast(shared_ptr<U>&& r) noexcept;

Mandates: The expression const_cast<T*>(U*nullptr) is well-formed.

Returns:
shared_ptr<T>(R, const_cast<typename shared_ptr<T>::element_type*>(r.get()))
where R is r for the first overload, and std::move(r) for the second.

[Note 3: The seemingly equivalent expression shared_ptr<T>(const_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

template<class T, class U>
shared_ptr<T> reinterpret_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
shared_ptr<T> reinterpret_pointer_cast(shared_ptr<U>&& r) noexcept;

Mandates: The expression reinterpret_cast<T*>(U*nullptr) is well-formed.

Returns:
shared_ptr<T>(R, reinterpret_cast<typename shared_ptr<T>::element_type*>(r.get()))
where R is r for the first overload, and std::move(r) for the second.

[Note 4: The seemingly equivalent expression shared_ptr<T>(reinterpret_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

20.3.2.2.11 get_deleter

template<class D, class T>
D* get_deleter(const shared_ptr<T>& p) noexcept;

Returns: If p owns a deleter d of type cv-unqualified D, returns addressof(d); otherwise returns nullptr. The returned pointer remains valid as long as there exists a shared_ptr instance that owns d.

[Note 1: It is unspecified whether the pointer remains valid longer than that. This can happen if the implementation doesn’t destroy the deleter until all weak_ptr instances that share ownership with p have been destroyed. — end note]

20.3.2.2.12 I/O

template<class E, class T, class Y>
basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const shared_ptr<Y>& p);

Effects: As if by: os << p.get();

Returns: os.

20.3.2.3 Class template weak_ptr

20.3.2.3.1 General

The weak_ptr class template stores a weak reference to an object that is already managed by a shared_ptr. To access the object, a weak_ptr can be converted to a shared_ptr using the member function lock.

namespace std {
    template<class T>
    class weak_ptr {
    public:
        using element_type = remove_extent_t<T>;

        // 20.3.2.3.2, constructors
        constexpr weak_ptr() noexcept;
        template<class Y>
        weak_ptr(const shared_ptr<Y>& r) noexcept;
        weak_ptr(const weak_ptr<Y>& r) noexcept;
        template<class Y>
        weak_ptr(const weak_ptr<Y>&& r) noexcept;
        weak_ptr(weak_ptr<Y>&& r) noexcept;
        template<class Y>
        weak_ptr(weak_ptr<Y>&& r) noexcept;
    }
2 Specializations of `weak_ptr` shall be `Cpp17CopyConstructible` and `Cpp17CopyAssignable`, allowing their use in standard containers. The template parameter `T` of `weak_ptr` may be an incomplete type.

### 20.3.2.3.2 Constructors

`constexpr weak_ptr() noexcept;`

**Effects:** Constructs an empty `weak_ptr` object that stores a null pointer value.

**Postconditions:** `use_count() == 0`.

`weak_ptr(const weak_ptr& r) noexcept;`

**Constraints:** For the second and third constructors, `Y*` is compatible with `T*`.

**Effects:** If `r` is empty, constructs an empty `weak_ptr` object that stores a null pointer value; otherwise, constructs a `weak_ptr` object that shares ownership with `r` and stores a copy of the pointer stored in `r`.

**Postconditions:** `use_count() == r.use_count()`.

`weak_ptr(weak_ptr&& r) noexcept;`

**Constraints:** For the second constructor, `Y*` is compatible with `T*`.

**Effects:** Move constructs a `weak_ptr` instance from `r`.

**Postconditions:** `*this` contains the old value of `r`. `r` is empty, stores a null pointer value, and `r.use_count() == 0`.

### 20.3.2.3.3 Destructor

`~weak_ptr();`

**Effects:** Destroys this `weak_ptr` object but has no effect on the object its stored pointer points to.
20.3.2.3.4 Assignment

weak_ptr& operator=(const weak_ptr& r) noexcept;

Effects: Equivalent to weak_ptr(r).swap(*this).

Returns: *this.

Remarks: The implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary object.

weak_ptr& operator=(weak_ptr&& r) noexcept;

Effects: Equivalent to weak_ptr(std::move(r)).swap(*this).

Returns: *this.

20.3.2.3.5 Modifiers

void swap(weak_ptr& r) noexcept;

Effects: Exchanges the contents of *this and r.

void reset() noexcept;

Effects: Equivalent to weak_ptr().swap(*this).

20.3.2.3.6 Observers

long use_count() const noexcept;

Returns: 0 if *this is empty; otherwise, the number of shared_ptr instances that share ownership with *this.

bool expired() const noexcept;

Returns: use_count() == 0.

shared_ptr<T> lock() const noexcept;

Returns: expired() ? shared_ptr<T>(): shared_ptr<T>(*this), executed atomically.

template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;

Returns: An unspecified value such that

— x.owner_before(y) defines a strict weak ordering as defined in 27.8;
— under the equivalence relation defined by owner_before, !a.owner_before(b) && !b.owner_before(a), two shared_ptr or weak_ptr instances are equivalent if and only if they share ownership or are both empty.

20.3.2.3.7 Specialized algorithms

template<class T>
void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;

Effects: Equivalent to a.swap(b).

20.3.2.4 Class template owner_less

The class template owner_less allows ownership-based mixed comparisons of shared and weak pointers.

namespace std {
    template<class T = void> struct owner_less;

    template<class T> struct owner_less<shared_ptr<T>> {
        bool operator()(const shared_ptr<T>&, const shared_ptr<T>&) const noexcept;
        bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
        bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
    };
}
template<class T> struct owner_less<weak_ptr<T>> {
    bool operator()(const weak_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
};

template<> struct owner_less<void> {
    template<class T, class U>
    bool operator()(const shared_ptr<T>&, const shared_ptr<U>&) const noexcept;
    template<class T, class U>
    bool operator()(const shared_ptr<T>&, const weak_ptr<U>&) const noexcept;
    template<class T, class U>
    bool operator()(const weak_ptr<T>&, const shared_ptr<U>&) const noexcept;
    template<class T, class U>
    bool operator()(const weak_ptr<T>&, const weak_ptr<U>&) const noexcept;

    using is_transparent = unspecified;
};

2 operator()(x, y) returns x.owner_before(y).

[Note 1: Note that

— (2.1) operator() defines a strict weak ordering as defined in 27.8;
— (2.2) two shared_ptr or weak_ptr instances are equivalent under the equivalence relation defined by operator(), !operator()(a, b) && !operator()(b, a), if and only if they share ownership or are both empty.

— end note]

20.3.2.5 Class template enable_shared_from_this [util.smartptr.enab]

A class T can inherit from enable_shared_from_this<T> to inherit the shared_from_this member functions that obtain a shared_ptr instance pointing to *this.

2 [Example 1]:
struct X: public enable_shared_from_this<X> { }

int main() {
    shared_ptr<X> p(new X);
    shared_ptr<X> q = p->shared_from_this();
    assert(p == q);
    assert(!p.owner_before(q) && !q.owner_before(p)); // p and q share ownership
}

— end example]

namespace std {
    template<class T> class enable_shared_from_this {
        // exposition only
    protected:
        constexpr enable_shared_from_this() noexcept;
        enable_shared_from_this(const enable_shared_from_this&) noexcept;
        enable_shared_from_this& operator=(const enable_shared_from_this&) noexcept;
        ~enable_shared_from_this();

        public:
            shared_ptr<T> shared_from_this();
            shared_ptr<T const> shared_from_this() const;
            weak_ptr<T> weak_from_this() noexcept;
            weak_ptr<T const> weak_from_this() const noexcept;

        private:
            mutable weak_ptr<T> weak_this; // exposition only
    };

3 The template parameter T of enable_shared_from_this may be an incomplete type.

costexpr enable_shared_from_this() noexcept;
enable_shared_from_this(const enable_shared_from_this<T>&) noexcept;

Effects: Value-initializes weak_this.

enable_shared_from_this<T>& operator=(const enable_shared_from_this<T>&) noexcept;

Returns: *this.

[Note 1: weak_this is not changed. — end note]

shared_ptr<T> shared_from_this();
shared_ptr<T const> shared_from_this() const;

Returns: shared_ptr<T>(weak_this).

weak_ptr<T> weak_from_this() noexcept;
weak_ptr<T const> weak_from_this() const noexcept;

Returns: weak_this.

20.3.3 Smart pointer hash support

template<class T, class D> struct hash<unique_ptr<T, D>>;

Letting UP be unique_ptr<T, D>, the specialization hash<UP> is enabled (22.10.19) if and only if hash<typename UP::pointer> is enabled. When enabled, for an object p of type UP, hash<UP>()(p) evaluates to the same value as hash<typename UP::pointer>()(p.get()). The member functions are not guaranteed to be noexcept.

template<class T> struct hash<shared_ptr<T>>;

For an object p of type shared_ptr<T>, hash<shared_ptr<T>>()(p) evaluates to the same value as hash<typename shared_ptr<T>::element_type*>()(p.get()).

20.3.4 Smart pointer adaptors

20.3.4.1 Class template out_ptr_t

out_ptr_t is a class template used to adapt types such as smart pointers (20.3) for functions that use output pointer parameters.

[Example 1:
#include <memory>
#include <cstdio>

int fopen_s(std::FILE** f, const char* name, const char* mode);

struct fclose_deleter {
    void operator()(std::FILE* f) const noexcept {
        std::fclose(f);
    }
};

int main(int, char*[]) {
    constexpr const char* file_name = "ow.o";
    std::unique_ptr<std::FILE, fclose_deleter> file_ptr;
    int err = fopen_s(std::out_ptr<std::FILE*>(file_ptr), file_name, "r+b");
    if (err != 0) {
        return 1;
        // *file_ptr is valid
        return 0;
    }
}

unique_ptr can be used with out_ptr to be passed into an output pointer-style function, without needing to hold onto an intermediate pointer value and manually delete it on error or failure. — end example]

namespace std {
    template<class Smart, class Pointer, class... Args>
    class out_ptr_t {
    public:
        explicit out_ptr_t(Smart&, Args...);
out_ptr_t(const out_ptr_t&) = delete;

~out_ptr_t();

operator Pointer*() const noexcept;
operator void**() const noexcept;

private:
  Smart& s;     // exposition only
  tuple<Args...> a;  // exposition only
  Pointer p;     // exposition only
};

3 Pointer shall meet the Cpp17NullablePointer requirements. If Smart is a specialization of shared_ptr and sizeof...(Args) == 0, the program is ill-formed.

[Note 1: It is typically a user error to reset a shared_ptr without specifying a deleter, as shared_ptr will replace a custom deleter upon usage of reset, as specified in 20.3.2.2.5. — end note]

4 Program-defined specializations of out_ptr_t that depend on at least one program-defined type need not meet the requirements for the primary template.

5 Evaluations of the conversion functions on the same object may conflict (6.9.2.2).

explicit out_ptr_t(Smart& smart, Args... args);

6 Effects: Initializes s with smart, a with std::forward<Args>(args)..., and value-initializes p. Then, equivalent to:

   — s.reset();
     if the expression s.reset() is well-formed;

   — otherwise,
     s = Smart();

   — otherwise, the program is ill-formed.

7 [Note 2: The constructor is not noexcept to allow for a variety of non-terminating and safe implementation strategies. For example, an implementation can allocate a shared_ptr’s internal node in the constructor and let implementation-defined exceptions escape safely. The destructor can then move the allocated control block in directly and avoid any other exceptions. — end note]

8 Let SP be POINTER_OF_OR(Smart, Pointer) (20.2.1).

9 Effects: Equivalent to:

   — if (p) {
     apply([&](auto&&... args) {
       s.reset(static_cast<SP>(p), std::forward<Args>(args)...); }, std::move(a));
   }
   if the expression s.reset(static_cast<SP>(p), std::forward<Args>(args)...) is well-formed;

   — otherwise,
     if (p) {
       apply([&](auto&&... args) {
         s = Smart(static_cast<SP>(p), std::forward<Args>(args)...); }, std::move(a));
     }
   if is_constructible_v<Smart, SP, Args...> is true;

   — otherwise, the program is ill-formed.

10 Preconditions: operator void**() has not been called on *this.
Returns: `addressof(const_cast<Pointer&>(p))`.

operator void**() const noexcept;

Constraints: `is_same_v<Pointer, void*>` is false.

Mandates: `is_pointer_v<Pointer>` is true.

Preconditions: `operator Pointer*()` has not been called on `*this`.

Returns: A pointer value `v` such that:

1. the initial value `*v` is equivalent to `static_cast<void*>(p)` and
2. any modification of `*v` that is not followed by a subsequent modification of `*this` affects the value of `p` during the destruction of `*this`, such that `static_cast<void*>(p) == *v`.

Remarks: Accessing `*v` outside the lifetime of `*this` has undefined behavior.

[Note 3: `reinterpret_cast<void**>(static_cast<Pointer*>(*this))` can be a viable implementation strategy for some implementations. —end note]

20.3.4.2 Function template `out_ptr` [out.ptr]

```
1  template<class Pointer = void, class Smart, class... Args>
2    auto out_ptr(Smart& s, Args&&... args);
```

1. Let `P` be `Pointer` if `is_void_v<Pointer>` is false, otherwise `POINTER_OF(Smart)`.
2. `Returns: out_ptr_t<Smart, P, Args&&...>(s, std::forward<Args>(args)...)`

20.3.4.3 Class template `inout_ptr_t` [inout.ptr.t]

`inout_ptr_t` is a class template used to adapt types such as smart pointers (20.3) for functions that use output pointer parameters whose dereferenced values may first be deleted before being set to another allocated value.

[Example 1:

```cpp
#include <memory>

struct star_fish* star_fish_alloc();
int star_fish_populate(struct star_fish** ps, const char* description);
struct star_fish_deleter {
    void operator() (struct star_fish* c) const noexcept;
};
using star_fish_ptr = std::unique_ptr<star_fish, star_fish_deleter>;

int main(int, char*[]) {
    star_fish_ptr peach(star_fish_alloc());
    // ...
    // used, need to re-make
    int err = star_fish_populate(std::inout_ptr(peach), "caring clown-fish liker");
    return err;
}
```

A `unique_ptr` can be used with `inout_ptr` to be passed into an output pointer-style function. The original value will be properly deleted according to the function it is used with and a new value reset in its place. —end example]
private:
  Smart& s;  // exposition only
  tuple<Args...> a;  // exposition only
  Pointer p;  // exposition only
};

3 Pointer shall meet the Cpp17NullablePointer requirements. If Smart is a specialization of shared_ptr, the program is ill-formed.

[Note 1: It is impossible to properly acquire unique ownership of the managed resource from a shared_ptr given its shared ownership model. — end note]

4 Program-defined specializations of inout_ptr_t that depend on at least one program-defined type need not meet the requirements for the primary template.

5 Evaluations of the conversion functions on the same object may conflict (6.9.2.2).

    explicit inout_ptr_t(Smart& smart, Args... args);

    Effects: Initializes s with smart, a with std::forward<Args>(args)..., and p to either
    (6.1) — smart if is_pointer_v<Smart> is true,
    (6.2) — otherwise, smart.get().

    Remarks: An implementation can call s.release().

    —[Note 2: The constructor is not noexcept to allow for a variety of non-terminating and safe implementation strategies. For example, an intrusive pointer implementation with a control block can allocate in the constructor and safely fail with an exception. — end note]

    ~inout_ptr_t();

    Let SP be POINTER_OF_OR(Smart, Pointer) (20.2.1).

    Let release-statement be s.release(); if an implementation does not call s.release() in the constructor. Otherwise, it is empty.

    Effects: Equivalent to:
    (11.1) — if (p) {
      apply([&](auto&&... args) {
        s = Smart( static_cast<SP>(p), std::forward<Args>(args)...); }, std::move(a));
      }
      if is_pointer_v<Smart> is true;
    (11.2) — otherwise,
      release-statement;
      if (p) {
        apply([&](auto&&... args) {
          s.reset(static_cast<SP>(p), std::forward<Args>(args)...); }, std::move(a));
        }
      if the expression s.reset(static_cast<SP>(p), std::forward<Args>(args)...) is well-formed;
    (11.3) — otherwise,
      release-statement;
      if (p) {
        apply([&](auto&&... args) {
          s = Smart(static_cast<SP>(p), std::forward<Args>(args)...); }, std::move(a));
        }
      if is_constructible_v<Smart, SP, Args...> is true;
    (11.4) — otherwise, the program is ill-formed.

    operator Pointer*() const noexcept;

    Preconditions: operator void**() has not been called on *this.

    Returns: addressof(const_cast<Pointer&>(p)).
operator void**() const noexcept;

Constraints: is_same_v<Pointer, void*> is false.

Mandates: is_pointer_v<Pointer> is true.

Preconditions: operator Pointer*() has not been called on *this.

Returns: A pointer value v such that:

(17.1) the initial value *v is equivalent to static_cast<void*>(p) and

(17.2) any modification of *v that is not followed by subsequent modification of *this affects the value of p during the destruction of *this, such that static_cast<void*>(p) == *v.

Remarks: Accessing *v outside the lifetime of *this has undefined behavior.

[Note 3: reinterpret_cast<void**>(static_cast<Pointer*>(*this)) can be a viable implementation strategy for some implementations. — end note]

20.3.4.4 Function template inout_ptr

20.4 Memory resources

20.4.1 Header <memory_resource> synopsis

namespace std::pmr {
    // 20.4.2, class memory_resource
    class memory_resource;

    bool operator==(const memory_resource& a, const memory_resource& b) noexcept;

    // 20.4.3, class template polymorphic_allocator
    template<class Tp = byte> class polymorphic_allocator;

    template<class T1, class T2>
    bool operator==(const polymorphic_allocator<T1>& a, const polymorphic_allocator<T2>& b) noexcept;

    // 20.4.4, global memory resources
    memory_resource* new_delete_resource() noexcept;
    memory_resource* null_memory_resource() noexcept;
    memory_resource* set_default_resource(memory_resource* r) noexcept;
    memory_resource* get_default_resource() noexcept;

    // 20.4.5, pool resource classes
    struct pool_options;
    class synchronized_pool_resource;
    class unsynchronized_pool_resource;
    class monotonic_buffer_resource;
}

20.4.2 Class memory_resource

The memory_resource class is an abstract interface to an unbounded set of classes encapsulating memory resources.

namespace std::pmr {
    class memory_resource {
        static constexpr size_t max_align = alignof(max_align_t);  // exposition only

        ...
public:
    memory_resource() = default;
    memory_resource(const memory_resource&) = default;
    virtual ~memory_resource();

    memory_resource& operator=(const memory_resource&) = default;

    [[nodiscard]] void* allocate(size_t bytes, size_t alignment = max_align);
    void deallocate(void* p, size_t bytes, size_t alignment = max_align);
    bool is_equal(const memory_resource& other) const noexcept;

private:
    virtual void* do_allocate(size_t bytes, size_t alignment) = 0;
    virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;
    virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;
};

20.4.2.2 Public member functions

~memory_resource();
1 Effects: Destroys this memory_resource.

[[nodiscard]] void* allocate(size_t bytes, size_t alignment = max_align);
2 Effects: Allocates storage by calling do_allocate(bytes, alignment) and implicitly creates objects
within the allocated region of storage.
3 Returns: A pointer to a suitable created object (6.7.2) in the allocated region of storage.
4 Throws: What and when the call to do_allocate throws.

void deallocate(void* p, size_t bytes, size_t alignment = max_align);
5 Effects: Equivalent to do_deallocate(p, bytes, alignment).

bool is_equal(const memory_resource& other) const noexcept;
6 Effects: Equivalent to: return do_is_equal(other);

20.4.2.3 Private virtual member functions

virtual void* do_allocate(size_t bytes, size_t alignment) = 0;
1 Preconditions: alignment is a power of two.
2 Returns: A derived class shall implement this function to return a pointer to allocated storage (6.7.5.5.2)
with a size of at least bytes, aligned to the specified alignment.
3 Throws: A derived class implementation shall throw an appropriate exception if it is unable to allocate
memory with the requested size and alignment.

virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;
4 Preconditions: p was returned from a prior call to allocate(bytes, alignment) on a memory resource
equal to *this, and the storage at p has not yet been deallocated.
5 Effects: A derived class shall implement this function to dispose of allocated storage.
6 Throws: Nothing.

virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;
7 Returns: A derived class shall implement this function to return true if memory allocated from this
can be deallocated from other and vice-versa, otherwise false.
[Note 1: It is possible that the most-derived type of other does not match the type of this. For a derived
class D, an implementation of this function can immediately return false if dynamic_cast<const D*>(other)
== nullptr. — end note]
20.4.2.4 Equality

```
bool operator==(const memory_resource& a, const memory_resource& b) noexcept;
```

1 Returns: \&a == \&b || a.is_equal(b).

20.4.3 Class template polymorphic_allocator

20.4.3.1 General

1 A specialization of class template `pmr::polymorphic_allocator` meets the `Cpp17Allocator` requirements (16.4.4.6.1) if its template argument is a `cv`-unqualified object type. Constructed with different memory resources, different instances of the same specialization of `pmr::polymorphic_allocator` can exhibit entirely different allocation behavior. This runtime polymorphism allows objects that use `polymorphic_allocator` to behave as if they used different allocator types at run time even though they use the same static allocator type.

2 A specialization of class template `pmr::polymorphic_allocator` meets the allocator completeness requirements (16.4.4.6.2) if its template argument is a `cv`-unqualified object type.

```cpp
namespace std::pmr {
  template<class Tp = byte> class polymorphic_allocator {

      return *a.resource() == *b.resource();
    }
  };
}
### 20.4.3.2 Constructors

**polymorphic_allocator()** noexcept;

**Effects**: Sets `memory_rsrg` to `get_default_resource()`.

**polymorphic_allocator(memory_resource* r);**

**Preconditions**: `r` is non-null.

**Effects**: Sets `memory_rsrg` to `r`.

**Throws**: Nothing.

[Note 1: This constructor provides an implicit conversion from `memory_resource*`. — end note]

**template<class U> polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;**

**Effects**: Sets `memory_rsrg` to `other.resource()`.

### 20.4.3.3 Member functions

**[[nodiscard]] Tp* allocate(size_t n);**

**Effects**: If `numeric_limits<size_t>::max() / sizeof(Tp) < n`, throws `bad_array_new_length`. Otherwise equivalent to:

```
return static_cast<Tp*>(memory_rsrg->allocate(n * sizeof(Tp), alignof(Tp)));
```

**void deallocate(Tp* p, size_t n);**

**Preconditions**: `p` was allocated from a memory resource `x`, equal to `*memory_rsrg`, using `x.allocate(n * sizeof(Tp), alignof(Tp))`.

**Effects**: Equivalent to `memory_rsrg->deallocate(p, n * sizeof(Tp), alignof(Tp))`.

**Throws**: Nothing.

[Note 1: The return type is `void*` (rather than, e.g., `byte*`) to support conversion to an arbitrary pointer type `U*` by `static_cast<U*>(...)`, thus facilitating construction of a `U` object in the allocated memory. — end note]

**void deallocate_bytes(void* p, size_t nbytes, size_t alignment = alignof(max_align_t));**

**Effects**: Equivalent to `memory_rsrg->deallocate(p, nbytes, alignment)`.

**template<class U> polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;**

**Effects**: Sets `memory_rsrg` to `other.resource()`.

**[[nodiscard]] T* allocate_object(size_t n = 1);**

**Effects**: Allocates memory suitable for holding an array of `n` objects of type `T`, as follows:

- (8.1) if `numeric_limits<size_t>::max() / sizeof(T) < n`, throws `bad_array_new_length`,
- (8.2) otherwise equivalent to:

```
return static_cast<T*>(allocate_bytes(n*sizeof(T), alignof(T)));
```

[Note 2: `T` is not deduced and must therefore be provided as a template argument. — end note]

**template<class T>**

**void deallocate_object(T* p, size_t n = 1);**

**Effects**: Equivalent to `deallocate_bytes(p, n*sizeof(T), alignof(T))`.

**template<class T, class... CtorArgs>**

**[[nodiscard]] T* new_object(CtorArgs&&... ctor_args);**

**Effects**: Allocates and constructs an object of type `T`, as follows. Equivalent to:

```
T* p = allocate_object<T>();
try {
  construct(p, std::forward<CtorArgs>(ctor_args)...);
} catch (...) {
  deallocate_object(p);
```
throw;
} return p;

[Note 3: T is not deduced and must therefore be provided as a template argument. — end note]

template<class T>
void delete_object(T* p);

Effects: Equivalent to:
allocator_traits<polymorphic_allocator>::destroy(*this, p);
deallocate_object(p);

template<class T, class... Args>
void construct(T* p, Args&&... args);

Mandates: Uses-allocator construction of T with allocator *this (see 20.2.8.2) and constructor arguments
std::forward<Args>(args)... is well-formed.

Effects: Construct a T object in the storage whose address is represented by p by uses-allocator
construction with allocator *this and constructor arguments std::forward<Args>(args)...

Throws: Nothing unless the constructor for T throws.

polymorphic_allocator select_on_container_copy_construction() const;

Returns: polymorphic_allocator().

[Note 4: The memory resource is not propagated. — end note]

memory_resource* resource() const;

Returns: memory_rsrc.

20.4.3.4 Equality

template<class T1, class T2>
bool operator==(const polymorphic_allocator<T1>& a, const polymorphic_allocator<T2>& b) noexcept;

Returns: *a.resource() == *b.resource().

20.4.4 Access to program-wide memory_resource objects

memory_resource* new_delete_resource() noexcept;

Returns: A pointer to a static-duration object of a type derived from memory_resource that can
serve as a resource for allocating memory using ::operator new and ::operator delete. The same
value is returned every time this function is called. For a return value p and a memory resource r, p->is_equal(r) returns &r == p.

memory_resource* null_memory_resource() noexcept;

Returns: A pointer to a static-duration object of a type derived from memory_resource for which
allocate() always throws bad_alloc and for which deallocate() has no effect. The same value is
returned every time this function is called. For a return value p and a memory resource r, p->is_equal(r) returns &r == p.

The default memory resource pointer is a pointer to a memory resource that is used by certain facilities when
an explicit memory resource is not supplied through the interface. Its initial value is the return value of
new_delete_resource().

memory_resource* set_default_resource(memory_resource* r) noexcept;

Effects: If r is non-null, sets the value of the default memory resource pointer to r, otherwise sets the
default memory resource pointer to new_delete_resource().

Returns: The previous value of the default memory resource pointer.

Remarks: Calling the set_default_resource and get_default_resource functions shall not incur a
data race. A call to the set_default_resource function shall synchronize with subsequent calls to
the set_default_resource and get_default_resource functions.
Returns: The current value of the default memory resource pointer.

20.4.5 Pool resource classes

20.4.5.1 Classes synchronized_pool_resource and unsynchronized_pool_resource

The synchronized_pool_resource and unsynchronized_pool_resource classes (collectively called pool resource classes) are general-purpose memory resources having the following qualities:

(1.1) Each resource frees its allocated memory on destruction, even if deallocate has not been called for some of the allocated blocks.

(1.2) A pool resource consists of a collection of pools, serving requests for different block sizes. Each individual pool manages a collection of chunks that are in turn divided into blocks of uniform size, returned via calls to do_allocate. Each call to do_allocate(size, alignment) is dispatched to the pool serving the smallest blocks accommodating at least size bytes.

(1.3) When a particular pool is exhausted, allocating a block from that pool results in the allocation of an additional chunk of memory from the upstream allocator (supplied at construction), thus replenishing the pool. With each successive replenishment, the chunk size obtained increases geometrically.

[Note 1: By allocating memory in chunks, the pooling strategy increases the chance that consecutive allocations will be close together in memory. — end note]

(1.4) Allocation requests that exceed the largest block size of any pool are fulfilled directly from the upstream allocator.

(1.5) A pool_options struct may be passed to the pool resource constructors to tune the largest block size and the maximum chunk size.

A synchronized_pool_resource may be accessed from multiple threads without external synchronization and may have thread-specific pools to reduce synchronization costs. An unsynchronized_pool_resource class may not be accessed from multiple threads simultaneously and thus avoids the cost of synchronization entirely in single-threaded applications.

namespace std::pmr {
    struct pool_options {
        size_t max_blocks_per_chunk = 0;
        size_t largest_required_pool_block = 0;
    };

class synchronized_pool_resource : public memory_resource {
    public:
    synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

    synchronized_pool_resource() :
        synchronized_pool_resource(pool_options(), get_default_resource()) {} 
    explicit synchronized_pool_resource(memory_resource* upstream) :
        synchronized_pool_resource(pool_options(), upstream) {} 
    explicit synchronized_pool_resource(const pool_options& opts) :
        synchronized_pool_resource(opts, get_default_resource()) {} 

    synchronized_pool_resource(const synchronized_pool_resource&) = delete;
    virtual ~synchronized_pool_resource();

    synchronized_pool_resource& operator=(const synchronized_pool_resource&) = delete;

    void release();
    memory_resource* upstream_resource() const;
    pool_options options() const;

    protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;
};
bool do_is_equal(const memory_resource& other) const noexcept override;
};

class unsynchronized_pool_resource : public memory_resource {
public:
    unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);
    unsynchronized_pool_resource() : unsynchronized_pool_resource(pool_options(), get_default_resource()) {}
    explicit unsynchronized_pool_resource(memory_resource* upstream) {
        unsynchronized_pool_resource(pool_options(), upstream) {}  
    }
    explicit unsynchronized_pool_resource(const pool_options& opts) :
        unsynchronized_pool_resource(opts, get_default_resource()) {}  
virtual ~unsynchronized_pool_resource();
    unsynchronized_pool_resource& operator=(const unsynchronized_pool_resource&) = delete;
    memory_resource* upstream_resource() const;
    pool_options options() const;
}protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;
    bool do_is_equal(const memory_resource& other) const noexcept override;
};

20.4.5.2 pool_options data members

The members of pool_options comprise a set of constructor options for pool resources. The effect of each option on the pool resource behavior is described below:

size_t max_blocks_per_chunk;

The maximum number of blocks that will be allocated at once from the upstream memory resource (20.4.6) to replenish a pool. If the value of max_blocks_per_chunk is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose to use a smaller value than is specified in this field and may use different values for different pools.

size_t largest_required_pool_block;

The largest allocation size that is required to be fulfilled using the pooling mechanism. Attempts to allocate a single block larger than this threshold will be allocated directly from the upstream memory resource. If largest_required_pool_block is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose a pass-through threshold larger than specified in this field.

20.4.5.3 Constructors and destructors

synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);
unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

1 Preconditions: upstream is the address of a valid memory resource.

2 Effects: Constructs a pool resource object that will obtain memory from upstream whenever the pool resource is unable to satisfy a memory request from its own internal data structures. The resulting object will hold a copy of upstream, but will not own the resource to which upstream points.

[Note 1: The intention is that calls to upstream->allocate() will be substantially fewer than calls to this->allocate() in most cases. – end note]

The behavior of the pooling mechanism is tuned according to the value of the opts argument.
Throws: Nothing unless `upstream->allocate()` throws. It is unspecified if, or under what conditions, this constructor calls `upstream->allocate()`.

```
virtual ~synchronized_pool_resource();
virtual ~unsynchronized_pool_resource();
```

Effects: Calls `release()`.

**20.4.5.4 Members**

```
void release();
```

Effects: Calls `upstream_resource()->deallocate()` as necessary to release all allocated memory.

[Note 1: The memory is released back to `upstream_resource()` even if `deallocate` has not been called for some of the allocated blocks. — end note]

```
memory_resource* upstream_resource() const;
```

Returns: The value of the `upstream` argument provided to the constructor of this object.

```
pool_options options() const;
```

Returns: The options that control the pooling behavior of this resource. The values in the returned struct may differ from those supplied to the pool resource constructor in that values of zero will be replaced with implementation-defined defaults, and sizes may be rounded to unspecified granularity.

```
void* do_allocate(size_t bytes, size_t alignment) override;
```

Effects: If the pool selected for a block of size `bytes` is unable to satisfy the memory request from its own internal data structures, it will call `upstream_resource()->allocate()` to obtain more memory. If `bytes` is larger than that which the largest pool can handle, then memory will be allocated using `upstream_resource()->allocate()`.

Returns: A pointer to allocated storage (6.7.5.5.2) with a size of at least `bytes`. The size and alignment of the allocated memory shall meet the requirements for a class derived from `memory_resource` (20.4.2).

Throws: Nothing unless `upstream_resource()->allocate()` throws.

```
void do_deallocate(void* p, size_t bytes, size_t alignment) override;
```

Effects: Returns the memory at `p` to the pool. It is unspecified if, or under what circumstances, this operation will result in a call to `upstream_resource()->deallocate()`.

Throws: Nothing.

```
bool do_is_equal(const memory_resource& other) const noexcept override;
```

Returns: `this == &other`.

**20.4.6 Class monotonic_buffer_resource**

```
namespace std::pmr {
    class monotonic_buffer_resource : public memory_resource {
        memory_resource* upstream_rsrc; // exposition only
        void* current_buffer; // exposition only
        size_t next_buffer_size; // exposition only

        public:
            explicit monotonic_buffer_resource(memory_resource* upstream);
            monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);
            monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);
            monotonic_buffer_resource();
            : monotonic_buffer_resource(get_default_resource()) {}
    }
}
```

§ 20.4.6.1 644
explicit monotonic_buffer_resource(size_t initial_size)
  : monotonic_buffer_resource(initial_size, get_default_resource()) {}
monotonic_buffer_resource(void* buffer, size_t buffer_size)
  : monotonic_buffer_resource(buffer, buffer_size, get_default_resource()) {}
monotonic_buffer_resource(const monotonic_buffer_resource&) = delete;
virtual ~monotonic_buffer_resource();
monotonic_buffer_resource& operator=(const monotonic_buffer_resource&) = delete;
void release();
memory_resource* upstream_resource() const;
protected:
  void* do_allocate(size_t bytes, size_t alignment) override;
  void do_deallocate(void* p, size_t bytes, size_t alignment) override;
  bool do_is_equal(const memory_resource& other) const noexcept override;
};

20.4.6.2 Constructors and destructor

explicit monotonic_buffer_resource(memory_resource* upstream);
monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);

  Preconditions: upstream is the address of a valid memory resource. initial_size, if specified, is
greater than zero.

  Effects: Sets upstream_rsrc to upstream and current_buffer to nullptr. If initial_size is
specified, sets next_buffer_size to at least initial_size; otherwise sets next_buffer_size to an
implementation-defined size.

monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);

  Preconditions: upstream is the address of a valid memory resource. buffer_size is no larger than the
number of bytes in buffer.

  Effects: Sets upstream_rsrc to upstream, current_buffer to buffer, and next_buffer_size to
buffer_size (but not less than 1), then increases next_buffer_size by an implementation-defined
growth factor (which need not be integral).

~monotonic_buffer_resource();

  Effects: Calls release().

20.4.6.3 Members

void release();

  Effects: Calls upstream_rsrc->deallocate() as necessary to release all allocated memory. Resets
current_buffer and next_buffer_size to their initial values at construction.

  [Note 1: The memory is released back to upstream_rsrc even if some blocks that were allocated from this
have not been deallocated from this. —end note]

memory_resource* upstream_resource() const;

  Returns: The value of upstream_rsrc.

void* do_allocate(size_t bytes, size_t alignment) override;

  Effects: If the unused space in current_buffer can fit a block with the specified bytes and alignment,
then allocate the return block from current_buffer; otherwise set current_buffer to upstream_rsrc->allocate(n, m), where n is not less than max(bytes, next_buffer_size) and m is not less
than alignment, and increase next_buffer_size by an implementation-defined growth factor (which
need not be integral), then allocate the return block from the newly-allocated current_buffer.
Returns: A pointer to allocated storage (6.7.5.5.2) with a size of at least bytes. The size and alignment of the allocated memory shall meet the requirements for a class derived from memory_resource (20.4.2).

Throws: Nothing unless upstream_rsrc->allocate() throws.

void do_deallocate(void* p, size_t bytes, size_t alignment) override;

Effects: None.

Throws: Nothing.

Remarks: Memory used by this resource increases monotonically until its destruction.

bool do_is_equal(const memory_resource& other) const noexcept override;

Returns: this == &other.

20.5 Class template scoped_allocator_adaptor

20.5.1 Header <scoped_allocator> synopsis

namespace std {

// class template scoped_allocator_adaptor
template<class OuterAlloc, class... InnerAllocs>
class scoped_allocator_adaptor;

// 20.5.5, scoped allocator operators
template<class OuterA1, class OuterA2, class... InnerAllocs>
bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;

} // namespace std

The class template scoped_allocator_adaptor is an allocator template that specifies an allocator resource (the outer allocator) to be used by a container (as any other allocator does) and also specifies an inner allocator resource to be passed to the constructor of every element within the container. This adaptor is instantiated with one outer and zero or more inner allocator types. If instantiated with only one allocator type, the inner allocator becomes the scoped_allocator_adaptor itself, thus using the same allocator resource for the container and every element within the container and, if the elements themselves are containers, each of their elements recursively. If instantiated with more than one allocator, the first allocator is the outer allocator for use by the container, the second allocator is passed to the constructors of the container’s elements, and, if the elements themselves are containers, the third allocator is passed to the elements’ elements, and so on. If containers are nested to a depth greater than the number of allocators, the last allocator is used repeatedly, as in the single-allocator case, for any remaining recursions.

[Note 1: The scoped_allocator_adaptor is derived from the outer allocator type so it can be substituted for the outer allocator type in most expressions. —end note]

namespace std {

template<class OuterAlloc, class... InnerAllocs>
class scoped_allocator_adaptor : public OuterAlloc {

private:
using OuterTraits = allocator_traits<OuterAlloc>;   // exposition only
scoped_allocator_adaptor<InnerAllocs...> inner;    // exposition only

        OuterAlloc, InnerAllocs...>;

20.5.2 Member types

using inner_allocator_type = see below;

1 Type: scoped_allocator_adaptor<OuterAlloc> if sizeof...(InnerAllocs) is zero; otherwise,

    scoped_allocator_adaptor<InnerAllocs...>.

using propagate_on_container_copy_assignment = see below;

2 Type: true_type if allocator_traits<A>::propagate_on_container_copy_assignment::value is
ture for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.
using propagate_on_container_move_assignment = see below;

Type: true_type if allocator_traits<A>::propagate_on_container_move_assignment::value is true for any A in the set of OuterAlloc and InnerAlloks...; otherwise, false_type.

using propagate_on_container_swap = see below;

Type: true_type if allocator_traits<A>::propagate_on_container_swap::value is true for any A in the set of OuterAlloc and InnerAlloks...; otherwise, false_type.

using is_always_equal = see below;

Type: true_type if allocator_traits<A>::is_always_equal::value is true for every A in the set of OuterAlloc and InnerAlloks...; otherwise, false_type.

20.5.3 Constructors

scoped_allocator_adaptor();

Effects: Value-initializes the OuterAlloc base class and the inner allocator object.

template<class OuterA2>
scoped_allocator_adaptor(OuterA2& outerAlloc, const InnerAlloks&... innerAlloks) noexcept;

Constraints: is_constructible_v<OuterAlloc, OuterA2> is true.

Effects: Initializes the OuterAlloc base class with std::forward<OuterA2>(outerAlloc) and inner with innerAlloks... (hence recursively initializing each allocator within the adaptor with the corresponding allocator from the argument list).

scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;

Effects: Initializes each allocator within the adaptor with the corresponding allocator from other.

scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;

Effects: Move constructs each allocator within the adaptor with the corresponding allocator from other.

template<class OuterA2>
scoped_allocator_adaptor(scoped_allocator_adaptor<OuterA2, InnerAlloks...>&& other) noexcept;

Constraints: is_constructible_v<OuterAlloc, OuterA2> is true.

Effects: Initializes each allocator within the adaptor with the corresponding allocator rvalue from other.

20.5.4 Members

inner_allocator_type& inner_allocator() noexcept;

Returns: *this if sizeof...(InnerAlloks) is zero; otherwise, inner.

outer_allocator_type& outer_allocator() noexcept;

Returns: static_cast<OuterAlloc*>(*this).
const outer_allocator_type& outer_allocator() const noexcept;

Returns: static_cast<const OuterAlloc&>(*this).

[[nodiscard]] pointer allocate(size_type n);

Returns: allocator_traits<OuterAlloc>::allocate(outer_allocator(), n).

[[nodiscard]] pointer allocate(size_type n, const_void_pointer hint);

Returns: allocator_traits<OuterAlloc>::allocate(outer_allocator(), n, hint).

void deallocate(pointer p, size_type n) noexcept;

Effects: As if by: allocator_traits<OuterAlloc>::deallocate(outer_allocator(), p, n);

size_type max_size() const;

Returns: allocator_traits<OuterAlloc>::max_size(outer_allocator()).

template<class T, class... Args>
void construct(T* p, Args&&... args);

Effects: Equivalent to:

apply([p, this](auto&&... newargs) {
    OUTERMOST_ALLOC_TRAITS(*this)::construct(
        OUTERMOST(*this), p,
        std::forward<decltype(newargs)>(newargs)...);
},
    uses_allocator_construction_args<T>(inner_allocator(),
        std::forward<Args>(args)...));

template<class T>
void destroy(T* p);

Effects: Calls OUTERMOST_ALLOC_TRAITS(*this)::destroy(OUTERMOST(*this), p).

scoped_allocator_adaptor select_on_container_copy_construction() const;

Returns: A new scoped_allocator_adaptor object where each allocator a1 within the adaptor is initialized with allocator_traits<A1>::select_on_container_copy_construction(a2), where A1 is the type of a1 and a2 is the corresponding allocator in *this.

20.5.5 Operators

template<class OuterA1, class OuterA2, class... InnerAllocs>
bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
    const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;

Returns: If sizeof... (InnerAllocs) is zero,
    a.outer_allocator() == b.outer_allocator()
otherwise
    a.outer_allocator() == b.outer_allocator() && a.inner_allocator() == b.inner_allocator()
21 Metaprogramming library [meta]

21.1 General [meta.general]

This Clause describes metaprogramming facilities. These facilities are summarized in Table 44.

Table 44: Metaprogramming library summary [tab:meta.summary]

21.2 Compile-time integer sequences [intseq]

21.2.1 In general [intseq.general]

The library provides a class template that can represent an integer sequence. When used as an argument to a function template the template parameter pack defining the sequence can be deduced and used in a pack expansion.

[Note 1: The index_sequence alias template is provided for the common case of an integer sequence of type size_t; see also 22.4.6. — end note]

21.2.2 Class template integer_sequence [intseq.intseq]

namespace std {
    template<class T, T... I> struct integer_sequence {
        using value_type = T;
        static constexpr size_t size() noexcept { return sizeof...(I); }
    };
}

Mandates: T is an integer type.

21.2.3 Alias template make_integer_sequence [intseq.make]

template<class T, T N>
    using make_integer_sequence = integer_sequence<T, see below>;

Mandates: N ≥ 0.

The alias template make_integer_sequence denotes a specialization of integer_sequence with N non-type template arguments. The type make_integer_sequence<T, N> is an alias for the type integer_sequence<T, 0, 1, ..., N-1>.

[Note 1: make_integer_sequence<int, 0> is an alias for the type integer_sequence<int>. — end note]

21.3 Metaprogramming and type traits [type.traits]

21.3.1 General [type.traits.general]

Subclause 21.3 describes components used by C++ programs, particularly in templates, to support the widest possible range of types, optimize template code usage, detect type related user errors, and perform type inference and transformation at compile time. It includes type classification traits, type property inspection traits, and type transformations. The type classification traits describe a complete taxonomy of all possible C++ types, and state where in that taxonomy a given type belongs. The type property inspection traits allow important characteristics of types or of combinations of types to be inspected. The type transformations allow certain properties of types to be manipulated.

All functions specified in 21.3 are signal-safe (17.13.5).
21.3.2 Requirements

1 A `Cpp17UnaryTypeTrait` describes a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the property being described. It shall be `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, and publicly and unambiguously derived, directly or indirectly, from its base characteristic, which is a specialization of the template `integral_constant` (21.3.4), with the arguments to the template `integral_constant` determined by the requirements for the particular property being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the `Cpp17UnaryTypeTrait`.

2 A `Cpp17BinaryTypeTrait` describes a relationship between two types. It shall be a class template that takes two template type arguments and, optionally, additional arguments that help define the relationship being described. It shall be `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, and publicly and unambiguously derived, directly or indirectly, from its base characteristic, which is a specialization of the template `integral_constant` (21.3.4), with the arguments to the template `integral_constant` determined by the requirements for the particular relationship being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the `Cpp17BinaryTypeTrait`.

3 A `Cpp17TransformationTrait` modifies a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the modification. It shall define a publicly accessible nested type named `type`, which shall be a synonym for the modified type.

4 Unless otherwise specified, the behavior of a program that adds specializations for any of the templates specified in 21.3 is undefined.

5 Unless otherwise specified, an incomplete type may be used to instantiate a template specified in 21.3. The behavior of a program is undefined if:

   (5.1) — an instantiation of a template specified in 21.3 directly or indirectly depends on an incompletely-defined object type `T`, and

   (5.2) — that instantiation could yield a different result were `T` hypothetically completed.

21.3.3 Header `<type_traits>` synopsis

```cpp
// all freestanding
namespace std {
    // 21.3.4, helper class
    template<class T, T v> struct integral_constant;
    template<bool B>
        using bool_constant = integral_constant<bool, B>;
    using true_type = bool_constant<true>;
    using false_type = bool_constant<false>;

    // 21.3.5.2, primary type categories

template<class B>
constexpr bool negation_v = negation<B>::value;

// 21.3.10, member relationships
template<class S, class M>
constexpr bool is_pointer_interconvertible_with_class(M S::*m) noexcept;

template<class S1, class S2, class M1, class M2>
constexpr bool is_corresponding_member(M1 S1::*m1, M2 S2::*m2) noexcept;

// 21.3.11, constant evaluation context
constexpr bool is_constant_evaluated() noexcept;

21.3.4 Helper classes

namespace std {
    template<class T, T v>
    struct integral_constant {
        static constexpr T value = v;

        using value_type = T;
        using type = integral_constant<T, v>;

        constexpr operator value_type() const noexcept { return value; }
        constexpr value_type operator()() const noexcept { return value; }
    };
}

The class template integral_constant, alias template bool_constant, and its associated typedef-names true_type and false_type are used as base classes to define the interface for various type traits.

21.3.5 Unary type traits

21.3.5.1 General

Subclause 21.3.5 contains templates that may be used to query the properties of a type at compile time.

Each of these templates shall be a Cpp17UnaryTypeTrait (21.3.2) with a base characteristic of true_type if the corresponding condition is true, otherwise false_type.

21.3.5.2 Primary type categories

The primary type categories correspond to the descriptions given in subclause 6.8 of the C++ standard.

For any given type T, the result of applying one of these templates to T and to cv T shall yield the same result.

[Note 1: For any given type T, exactly one of the primary type categories has a value member that evaluates to true. —end note]

<td></td>
</tr>
</tbody>
</table>

21.3.5.3 Composite type traits [meta.unary.comp]

1 These templates provide convenient compositions of the primary type categories, corresponding to the descriptions given in subclause 6.8.

2 For any given type T, the result of applying one of these templates to T and to cv T shall yield the same result.

</tr>
</tbody>
</table>

21.3.5.4 Type properties [meta.unary.prop]

1 These templates provide access to some of the more important properties of types.

2 It is unspecified whether the library defines any full or partial specializations of any of these templates.

3 For all of the class templates X declared in this subclause, instantiating that template with a template-argument that is a class template specialization may result in the implicit instantiation of the template argument if and only if the semantics of X require that the argument is a complete type.
For the purpose of defining the templates in this subclause, a function call expression `declval<T>()` for any type `T` is considered to be a trivial (6.8.1, 11.4.4) function call that is not an odr-use (6.3) of `declval` in the context of the corresponding definition notwithstanding the restrictions of 22.2.6.

For the purpose of defining the templates in this subclause, let `VAL<T>` for some type `T` be an expression defined as follows:

- If `T` is a reference or function type, `VAL<T>` is an expression with the same type and value category as `declval<T>()`.
- Otherwise, `VAL<T>` is a prvalue that initially has type `T`.

[Note 1: If `T` is cv-qualified, the cv-qualification is subject to adjustment (7.2.2). — end note]

| template<class T, class U> struct reference_constructs_from_temporary; | T is a reference type, and the initialization T t(VAL<U>); is well-formed and binds t to a temporary object whose lifetime is extended (6.7.7). Access checking is performed as if in a context unrelated to T and U. Only the validity of the immediate context of the variable initialization is considered.  

[Note 5: The initialization can result in effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such effects are not in the “immediate context” and can result in the program being ill-formed. —end note] | T and U shall be complete types, cv void, or arrays of unknown bound. |

| template<class T, class U> struct reference_converts_from_temporary; | T is a reference type, and the initialization T t = VAL<U>; is well-formed and binds t to a temporary object whose lifetime is extended (6.7.7). Access checking is performed as if in a context unrelated to T and U. Only the validity of the immediate context of the variable initialization is considered.  

[Note 6: The initialization can result in effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such effects are not in the “immediate context” and can result in the program being ill-formed. —end note] | T and U shall be complete types, cv void, or arrays of unknown bound. |

6 [Example 1:  
is_const_v<const volatile int>  // true  
is_const_v<const int*>      // false  
is_const_v<const int&>      // false]
Example 1:

- `is_const_v<int[3]>` // false
- `is_const_v<const int[3]>` // true

— end example

Example 2:

- `remove_const_t<const volatile int>` // volatile int
- `remove_const_t<const int* const>` // const int*
- `remove_const_t<const int&>` // const int&

— end example

Example 3:

// Given:
struct P final { };
union U1 { };
union U2 final { };

// the following assertions hold:
static_assert(!is_final_v<int>);
static_assert(is_final_v<P>);
static_assert(!is_final_v<U1>);
static_assert(is_final_v<U2>);

— end example

The predicate condition for a template specialization `is_constructible<T, Args...>` shall be satisfied if and only if the following variable definition would be well-formed for some invented variable `t`:

```cpp
T t(declval<Args>()...);
```

[Note 7: These tokens are never interpreted as a function declaration. — end note]

Access checking is performed as if in a context unrelated to `T` and any of the `Args`. Only the validity of the immediate context of the variable initialization is considered.

[Note 8: The evaluation of the initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

The predicate condition for a template specialization `has_unique_object_representations<T>` shall be satisfied if and only if:

(10.1) — `T` is trivially copyable, and

(10.2) — any two objects of type `T` with the same value have the same object representation, where two objects of array or non-union class type are considered to have the same value if their respective sequences of direct subobjects have the same values, and two objects of union type are considered to have the same value if they have the same active member and the corresponding members have the same value.

The set of scalar types for which this condition holds is implementation-defined.

[Note 9: If a type has padding bits, the condition does not hold; otherwise, the condition holds true for integral types. — end note]

### 21.3.6 Type property queries [meta.unary.prop.query]

This subclause contains templates that may be used to query properties of types at compile time.

<table>
<thead>
<tr>
<th>Template</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template&lt;class T&gt;</code></td>
<td><code>alignof(T).</code></td>
</tr>
<tr>
<td>struct <code>alignment_of;</code></td>
<td><code>Mandates: alignof(T) is a valid expression (7.6.2.6)</code></td>
</tr>
<tr>
<td><code>template&lt;class T&gt;</code></td>
<td><code>If T is an array type, an integer value representing the number of dimensions of T; otherwise, 0.</code></td>
</tr>
<tr>
<td>struct <code>rank;</code></td>
<td><code>If T is not an array type, or if it has rank less than or equal to I, or if I is 0 and T has type “array of unknown bound of U”, then 0; otherwise, the bound (9.3.4.5) of the I\textsuperscript{th} dimension of T, where indexing of I is zero-based.</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Template</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template&lt;class T, unsigned I = 0&gt;</code></td>
<td><code>If T is an array type, or if it has rank less than or equal to I, or if I is 0 and T has type “array of unknown bound of U”, then 0; otherwise, the bound (9.3.4.5) of the I\textsuperscript{th} dimension of T, where indexing of I is zero-based.</code></td>
</tr>
</tbody>
</table>

§ 21.3.6
Each of these templates shall be a `Cpp17UnaryTypeTrait (21.3.2)` with a base characteristic of `integral_constant<size_t, Value>`.

Example 1:

```cpp
// the following assertions hold:
assert(rank_v<int> == 0);
assert(rank_v<int[2]> == 1);
assert(rank_v<int[][4]> == 2);
@end example
```

Example 2:

```cpp
// the following assertions hold:
assert(extent_v<int> == 0);
assert(extent_v<int[2]> == 2);
assert(extent_v<int[2][4]> == 2);
assert(extent_v<int[], 1> == 0);
assert((extent_v<int[2], 1>) == 4);
assert((extent_v<int[], 1>) == 4);
@end example
```

21.3.7 Relationships between types

This subclause contains templates that may be used to query relationships between types at compile time.

Each of these templates shall be a `Cpp17BinaryTypeTrait (21.3.2)` with a base characteristic of `true_type` if the corresponding condition is true, otherwise `false_type`.

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template&lt;class T, class U&gt; struct is_same;</code></td>
<td>T and U name the same type with the same cv-qualifications</td>
<td></td>
</tr>
<tr>
<td><code>template&lt;class Base, class Derived&gt; struct is_base_of;</code></td>
<td>Base is a base class of Derived (11.7) without regard to cv-qualifiers or Base and Derived are not unions and name the same class type without regard to cv-qualifiers</td>
<td>If Base and Derived are non-union class types and are not (possibly cv-qualified versions of) the same type, Derived shall be a complete type. [Note 1: Base classes that are private, protected, or ambiguous are, nonetheless, base classes. —end note]</td>
</tr>
<tr>
<td><code>template&lt;class From, class To&gt; struct is_convertible;</code></td>
<td>see below</td>
<td>From and To shall be complete types, cv void, or arrays of unknown bound.</td>

</thead>
<tbody>
<tr>
<td>template&lt;class Base, class Derived&gt; struct is_pointer_interconvertible_base_of;</td>
<td>Derived is unambiguously derived from Base without regard to cv-qualifiers, and each object of type Derived is pointer-interconvertible (6.8.4) with its Base subobject, or Base and Derived are not unions and name the same class type without regard to cv-qualifiers.</td>
<td>If Base and Derived are non-union class types and are not (possibly cv-qualified versions of) the same type, Derived shall be a complete type.</td>
</tr>
<tr>
<td>template&lt;class Fn, class... ArgTypes&gt; struct is_invocable;</td>
<td>The expression ( \text{INVOKE}(\text{declval}&lt;\text{Fn}&gt;(), \text{declval}&lt;\text{ArgTypes}&gt;()...) ) (22.10.4) is well-formed when treated as an unevaluated operand (7.2.3)</td>
<td>Fn and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>template&lt;class R, class Fn, class... ArgTypes&gt; struct is_invocable_r;</td>
<td>The expression ( \text{INVOKE}&lt;\text{R}&gt;(\text{declval}&lt;\text{Fn}&gt;(), \text{declval}&lt;\text{ArgTypes}&gt;()...) ) is well-formed when treated as an unevaluated operand</td>
<td>Fn, R, and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>template&lt;class Fn, class... ArgTypes&gt; struct is_nothrow_invocable;</td>
<td>is_invocable_v&lt; Fn, ArgTypes...&gt; is true and the expression ( \text{INVOKE}(\text{declval}&lt;\text{Fn}&gt;(), \text{declval}&lt;\text{ArgTypes}&gt;()...) ) is known not to throw any exceptions (7.6.2.7)</td>
<td>Fn and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>template&lt;class R, class Fn, class... ArgTypes&gt; struct is_nothrow_invocable_r;</td>
<td>is_invocable_r_v&lt; R, Fn, ArgTypes...&gt; is true and the expression ( \text{INVOKE}&lt;\text{R}&gt;(\text{declval}&lt;\text{Fn}&gt;(), \text{declval}&lt;\text{ArgTypes}&gt;()...) ) is known not to throw any exceptions (7.6.2.7)</td>
<td>Fn, R, and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
</tbody>
</table>

---

3 For the purpose of defining the templates in this subclause, a function call expression \( \text{declval}<\text{T}>() \) for any type \( \text{T} \) is considered to be a trivial (6.8.1, 11.4.4) function call that is not an odr-use (6.3) of \( \text{declval} \) in the context of the corresponding definition notwithstanding the restrictions of 22.2.6.

4 [Example 1]:

```cpp
struct B {};
struct B1 : B {};
struct B2 : B {};
struct D : private B1, private B2 {};

is_base_of_v<B, D> // true
is_base_of_v<const B, D> // true
is_base_of_v<B, const D> // true
is_base_of_v<B, const B> // true
is_base_of_v<D, B> // false
is_base_of_v<B& , D&> // false
is_base_of_v<B[3], D[3]> // false
is_base_of_v<int, int> // false

-- end example
```
The predicate condition for a template specialization `is_convertible<From, To>` shall be satisfied if and only if the return expression in the following code would be well-formed, including any implicit conversions to the return type of the function:

```cpp
To test() {
    return declval<From>();
}
```

[Note 2: This requirement gives well-defined results for reference types, array types, function types, and `cv` void. — end note]

Access checking is performed in a context unrelated to `To` and `From`. Only the validity of the immediate context of the expression of the `return` statement (8.7.4) (including initialization of the returned object or reference) is considered.

[Note 3: The initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

### 21.3.8 Transformations between types [meta.trans]

#### 21.3.8.1 General [meta.trans.general]

1. Subclause 21.3.8 contains templates that may be used to transform one type to another following some predefined rule.
2. Each of the templates in 21.3.8 shall be a `Cpp17TransformationTrait` (21.3.2).

### 21.3.8.2 Const-volatile modifications [meta.trans.cv]

#### Template Comments

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| `template<class T>
struct remove_const;` | The member typedef `type` denotes the type formed by removing any top-level const-qualifier from `T`. [Example 1: `remove_const_t<const volatile int>` evaluates to `volatile int`, whereas `remove_const_t<const int*>` evaluates to `const int*`. — end example] |
| `template<class T>
struct remove_volatile;` | The member typedef `type` denotes the type formed by removing any top-level volatile-qualifier from `T`. [Example 2: `remove_volatile_t<const volatile int>` evaluates to `const int`, whereas `remove_volatile_t<volatile int*>` evaluates to `volatile int*`. — end example] |
| `template<class T>
struct remove_cv;` | The member typedef `type` denotes the type formed by removing any top-level cv-qualifiers from `T`. [Example 3: `remove_cv_t<const volatile int>` evaluates to `int`, whereas `remove_cv_t<const volatile int*>` evaluates to `const volatile int*`. — end example] |
| `template<class T>
struct add_const;` | If `T` is a reference, function, or top-level const-qualified type, then `type` denotes `T`, otherwise `T` const. |
| `template<class T>
struct add_volatile;` | If `T` is a reference, function, or top-level volatile-qualified type, then `type` denotes `T`, otherwise `T` volatile. |
| `template<class T>
struct add_cv;` | The member typedef `type` denotes `add_const_t<add_volatile_t<T>>`. |

### 21.3.8.3 Reference modifications [meta.trans.ref]

```cpp
<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| `template<class T>
struct remove_reference;` | If `T` has type “reference to `T1`” then the member typedef `type` denotes `T1`; otherwise, `type` denotes `T`. |

§ 21.3.8.3 669
Table 51: Reference modifications (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| `template<class T>`<br>```c++
struct add_lvalue_reference;
```<br>[Note 1: This rule reflects the semantics of reference collapsing (9.3.4.3). —end note]
| If `T` is a referenceable type (3.45) then the member typedef `type` denotes `T&`; otherwise, `type` denotes `T`. |

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| `template<class T>`<br>```c++
struct add_rvalue_reference;
```<br>[Note 2: This rule reflects the semantics of reference collapsing (9.3.4.3).]
| If `T` is a referenceable type then the member typedef `type` denotes `T&&`; otherwise, `type` denotes `T`. |

21.3.8.4 Sign modifications

Table 52: Sign modifications

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| `template<class T>`<br>```c++
struct make_signed;
```<br><br>[Note 1: For multidimensional arrays, only the first array dimension is removed. For a type “array of const U”, the resulting type is `const U`.
| If `T` is a (possibly cv-qualified) signed integer type (6.8.2) then the member typedef `type` denotes `T`; otherwise, if `T` is a (possibly cv-qualified) unsigned integer type then `type` denotes the corresponding signed integer type, with the same cv-qualifiers as `T`; otherwise, `type` denotes the signed integer type with smallest rank (6.8.6) for which `sizeof(T) == sizeof(type)`, with the same cv-qualifiers as `T`. |

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| `template<class T>`<br>```c++
struct make_unsigned;
```<br><br>[Note 1: For multidimensional arrays, only the first array dimension is removed. For a type “array of const U”, the resulting type is `const U`.
| If `T` is a (possibly cv-qualified) unsigned integer type (6.8.2) then the member typedef `type` denotes `T`; otherwise, if `T` is a (possibly cv-qualified) signed integer type then `type` denotes the corresponding unsigned integer type, with the same cv-qualifiers as `T`; otherwise, `type` denotes the unsigned integer type with smallest rank (6.8.6) for which `sizeof(T) == sizeof(type)`, with the same cv-qualifiers as `T`. |

21.3.8.5 Array modifications

Table 53: Array modifications

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| `template<class T>`<br>```c++
struct remove_extent;
```<br><br>[Note 1: For multidimensional arrays, only the first array dimension is removed. For a type “array of const U”, the resulting type is `const U`. —end note]
| If `T` is a type “array of U”, the member typedef `type` denotes `U`, otherwise `T`. |

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| `template<class T>`<br>```c++
struct remove_all_extents;
```<br><br>[Note 1: For multidimensional arrays, only the first array dimension is removed. For a type “array of const U”, the resulting type is `const U`. —end note]
| If `T` is “multi-dimensional array of U”, the resulting member typedef `type` denotes `U`, otherwise `T`. |

1

[Example 1:]
```
// the following assertions hold:
assert((is_same_v<remove_extent_t<int>, int>));
assert((is_same_v<remove_extent_t<int[2], int>>));
assert((is_same_v<remove_extent_t<int[2][3], int[3]>));
assert((is_same_v<remove_extent_t<int[1][3], int[3]>));
-- end example]
```
Example 2:

// the following assertions hold:
assert((is_same_v<remove_all_extents_t<int>, int>));
assert((is_same_v<remove_all_extents_t<int[2]>, int>));
assert((is_same_v<remove_all_extents_t<int[2][3]>, int>));
assert((is_same_v<remove_all_extents_t<int[1][3]>, int>));

—end example

21.3.8.6 Pointer modifications

Table 54: Pointer modifications

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class T>
| struct remove_pointer; | If T has type “(possibly cv-qualified) pointer to T1” then the member typedef type denotes T1; otherwise, it denotes T. |
| template<class T>
| struct add_pointer; | If T is a referenceable type (3.45) or a cv void type then the member typedef type denotes remove_reference_t<T>*; otherwise, type denotes T. |

21.3.8.7 Other transformations

Table 55: Other transformations

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class T>
| struct type_identity; | The member typedef type denotes T. |
| template<class T>
| struct remove_cvref; | The member typedef type denotes remove_cv_t<remove_reference_t<T>>. |
| template<class T>
| struct decay; | Let U be remove_reference_t<T>. If is_array_v<U> is true, the member typedef type denotes remove_extent_t<U>*. If is_function_v<U> is true, the member typedef type denotes add_pointer_t<U>. Otherwise the member typedef type denotes remove_cv_t<U>. |

[Note 1: This behavior is similar to the value-to-rvalue (7.3.2), array-to-pointer (7.3.3), and function-to-pointer (7.3.4) conversions applied when an lvalue is used as an rvalue, but also strips cv-qualifiers from class types in order to more closely model by-value argument passing. — end note]

| template<bool B, class T = void>
| struct enable_if; | If B is true, the member typedef type denotes T; otherwise, there shall be no member type. |
| template<bool B, class T, class F>
| struct conditional; | If B is true, the member typedef type denotes T. If B is false, the member typedef type denotes F. |
| template<class... T>
| struct common_type; | Unless this trait is specialized (as specified in Note B, below), the member type is defined or omitted as specified in Note A, below. If it is omitted, there shall be no member type. Each type in the template parameter pack T shall be complete, cv void, or an array of unknown bound. |
| template<class, class, template<class> class, template<class> class>
| struct basic_common_reference; | Unless this trait is specialized (as specified in Note D, below), there shall be no member type. |
| template<class... T>
| struct common_reference; | The member typedef-name type is defined or omitted as specified in Note C, below. Each type in the parameter pack T shall be complete or cv void. |
| template<class T>
| struct underlying_type; | If T is an enumeration type, the member typedef type denotes the underlying type of T (9.7.1); otherwise, there is no member type. Mandates: T is not an incomplete enumeration type. |
Table 55: Other transformations (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class Fn, class... ArgTypes> struct invoke_result; | If the expression \textit{INVOKE}(\texttt{declval<Fn>()}) , \texttt{declval<ArgTypes>()...} \textit{(22.10.4)} is well-formed when treated as an unevaluated operand \textit{(7.2.3)}, the member typedef \texttt{type} denotes the type \texttt{decltype(INVOKE(declval<Fn>(), declval<ArgTypes>()...))}; otherwise, there shall be no member \texttt{type}. Access checking is performed as if in a context unrelated to \texttt{Fn} and \texttt{ArgTypes}. Only the validity of the immediate context of the expression is considered. \textit{[Note 2: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. —end note]}
| Preconditions: \texttt{Fn} and all types in the template parameter pack \texttt{ArgTypes} are complete types, cv void, or arrays of unknown bound. |
| template<class T> struct unwrap_reference; | If \texttt{T} is a specialization \texttt{reference_wrapper<X>} for some type \texttt{X}, the member typedef \texttt{type} of \texttt{unwrap_reference<T>} denotes \texttt{X}, otherwise \texttt{type} denotes \texttt{T}. |
| template<class T> unwrap_ref_decay; | The member typedef \texttt{type} of \texttt{unwrap_ref_decay<T>} denotes the type \texttt{unwrap_reference_t<decay_t<T>>}. |

1 In addition to being available via inclusion of the \texttt{<type_traits>} header, the templates \texttt{unwrap_reference}, \texttt{unwrap_ref_decay}, \texttt{unwrap_reference_t}, and \texttt{unwrap_ref_decay_t} are available when the header \texttt{<functional>} \textit{(22.10.2)} is included.

2 Let:

\begin{align*}
\text{(2.1) } & \quad \text{\texttt{CREF(A)}} \text{ be } \text{\texttt{add_lvalue_reference_t<}} \text{\texttt{const remove_reference_t}} \text{\texttt{<A>}}, \\
\text{(2.2) } & \quad \text{\texttt{XREF(A)}} \text{ denote a unary alias template } \texttt{T} \text{ such that } \texttt{T<}} \text{\texttt{U}>} \text{ denotes the same type as } \texttt{U} \text{ with the addition of } \texttt{A} \text{'s cv and reference qualifiers, for a non-reference cv-unqualified type } \texttt{U}, \\
\text{(2.3) } & \quad \text{\texttt{COPYCV(FROM, TO)}} \text{ be an alias for type } \texttt{TO} \text{ with the addition of } \texttt{FROM}'s \text{ top-level cv-qualifiers,} \\
\text{(2.4) } & \quad \text{\texttt{COND-RES(X, Y)}} \text{ be } \text{\texttt{decltype(false ? declval<}} \text{\texttt{X(}} \text{\texttt{&)}>\text{() : declval<}} \text{\texttt{Y(}} \text{\texttt{&)}>\text{()}}. \\
\end{align*}

Given types \texttt{A} and \texttt{B}, let \texttt{X} be \texttt{remove_reference_t<}} \texttt{A>, let \texttt{Y} be \texttt{remove_reference_t<}} \texttt{B>, and let \texttt{COMMON-REF(A, B)} be:

\begin{align*}
\text{(2.5) } & \quad \text{\texttt{If } A \text{ and } B \text{ are both lvalue reference types, } \texttt{COMMON-REF(A, B)}} \text{ is } \texttt{COND-RES(COPYCV(X, Y, &), COPYCV(} \texttt{Y, X, &)} \text{ } \text{if that type exists and is a reference type.} \\
\text{(2.6) } & \quad \text{\texttt{Otherwise, let } C \text{ be } \texttt{remove_reference_t<COMMON-REF(Xk, Yk>>k}. \text{ If } A \text{ and } B \text{ are both rvalue reference types, } C \text{ is well-formed, and } \texttt{is_convertible_v<}} \texttt{A, C> & k is_convertible_v<}} \texttt{B, C> is true, then } \texttt{COMMON-REF(A, B)} \text{ is } C. \\
\text{(2.7) } & \quad \text{\texttt{Otherwise, let } D \text{ be } \texttt{COMMON-REF(const Xk, Yk)}. \text{ If } A \text{ is an rvalue reference and } B \text{ is an lvalue reference and } D \text{ is well-formed and } \texttt{is_convertible_v<}} \texttt{A, D> is true, then } \texttt{COMMON-REF(A, B)} \text{ is } D. \\
\text{(2.8) } & \quad \text{\texttt{Otherwise, if } A \text{ is an lvalue reference and } B \text{ is an rvalue reference, then } \texttt{COMMON-REF(A, B)} \text{ is } \texttt{COMMON-REF(B, A)}. \\
\text{(2.9) } & \quad \text{\texttt{Otherwise, COMMON-REF(A, B)} is ill-formed.} \\
\end{align*}

If any of the types computed above is ill-formed, then \texttt{COMMON-REF(A, B)} is ill-formed.

3 Note A: For the \texttt{common_type} trait applied to a template parameter pack \texttt{T} of types, the member \texttt{type} shall be either defined or not present as follows:

\begin{align*}
\text{(3.1) } & \quad \text{\texttt{If sizeof...}(T) is zero, there shall be no member \texttt{type}.} \\
\text{(3.2) } & \quad \text{\texttt{If sizeof...}(T) is one, let } TO \text{ denote the sole type constituting the pack } T. \text{ The member } \texttt{typedef-name type} \text{ shall denote the same type, if any, as } \texttt{common_type_t<}} \texttt{TO, TO>}; \text{ otherwise there shall be no member \texttt{type}.} \\
\end{align*}
Otherwise, if is_same_v<T1, D1> is false or is_same_v<T2, D2> is false, let C denote the same type, if any, as common_type_t<D1, D2>.

[Note 3: None of the following will apply if there is a specialization common_type<D1, D2>. — end note]

Otherwise, if
\[
\text{decay_t<decltype(false ? declval<D1>() : declval<D2>())>
\]
denotes a valid type, let C denote that type.

Otherwise, if COND-RES(CREF(D1), CREF(D2)) denotes a type, let C denote the type decay_t<COND-RES(CREF(D1), CREF(D2))>.

In either case, the member typedef-name type shall denote the same type, if any, as C. Otherwise, there shall be no member type.

If sizeof...(T) is greater than two, let T1, T2, and R, respectively, denote the first, second, and (pack of) remaining types constituting T. Let C denote the same type, if any, as common_type_t<T1, T2>. If there is such a type C, the member typedef-name type shall denote the same type, if any, as common_type_t<C, R...>. Otherwise, there shall be no member type.

Note B: Notwithstanding the provisions of 21.3.3, and pursuant to 16.4.5.2.1, a program may specialize common_type<T1, T2> for types T1 and T2 such that is_same_v<T1, decay_t<T1>> and is_same_v<T2, decay_t<T2>> are each true.

[Note 4: Such specializations are needed when only explicit conversions are desired between the template arguments. — end note]

Such a specialization need not have a member named type, but if it does, the qualified-id common_type<T1, T2>::type shall denote a cv-unqualified non-reference type to which each of the types T1 and T2 is explicitly convertible. Moreover, common_type_t<T1, T2> shall denote the same type, if any, as does common_type_t<T1, T2, T1>. No diagnostic is required for a violation of this Note’s rules.

Note C: For the common_reference trait applied to a parameter pack T of types, the member type shall be either defined or not present as follows:

If sizeof...(T) is zero, there shall be no member type.

Otherwise, if sizeof...(T) is one, let T0 denote the sole type in the pack T. The member typedef type shall denote the same type as T0.

Otherwise, if sizeof...(T) is two, let T1 and T2 denote the two types in the pack T. Then

Let R be COMMON-REF(T1, T2). If T1 and T2 are reference types, R is well-formed, and is_convertible_v<cadd_pointer_t<T1>, cadd_pointer_t<R>> && is_convertible_v<cadd_pointer_t<T2>, cadd_pointer_t<R>> is true, then the member typedef type denotes R.

Otherwise, if basic_common_reference<remove_cvref_t<T1>, remove_cvref_t<T2>, XREF(T1), XREF(T2)>::type is well-formed, then the member typedef type denotes that type.

Otherwise, if COND-RES(T1, T2) is well-formed, then the member typedef type denotes that type.

Otherwise, if common_type_t<T1, T2> is well-formed, then the member typedef type denotes that type.

Otherwise, there shall be no member type.

Otherwise, if sizeof...(T) is greater than two, let T1, T2, and Rest, respectively, denote the first, second, and (pack of) remaining types comprising T. Let C be the type common_reference_t<T1, T2>. Then:

If there is such a type C, the member typedef type shall denote the same type, if any, as common_reference_t<C, Rest...>.

Otherwise, there shall be no member type.

Note D: Notwithstanding the provisions of 21.3.3, and pursuant to 16.4.5.2.1, a program may partially specialize basic_common_reference<T, U, TQual, UQual> for types T and U such that is_same_v<T, decay_t<T>> and is_same_v<U, decay_t<U>> are each true.
Note 5: Such specializations can be used to influence the result of `common_reference`, and are needed when only explicit conversions are desired between the template arguments. — end note]

Such a specialization need not have a member named `type`, but if it does, the `qualified-id basic_common_reference<T, U, TQual, UQual>::type` shall denote a type to which each of the types `TQual<T>` and `UQual<U>` is convertible. Moreover, `basic_common_reference<T, U, TQual, UQual>::type` shall denote the same type, if any, as does `basic_common_reference<U, T, UQual, TQual>::type`. No diagnostic is required for a violation of these rules.

Example 2: Given these definitions:

```cpp
using PF1 = bool (*)(());
using PF2 = short (*)(long);
struct S {
    operator PF2() const;
    double operator()(char, int&);
    void fn(long) const;
    char data;
};
using PMF = void (S::*)(long) const;
using PMD = char S::*;
```

the following assertions will hold:

```cpp
static_assert(is_same_v<invoke_result_t<S, int>, short>);
static_assert(is_same_v<invoke_result_t<S&, unsigned char, int&>, double>);
static_assert(is_same_v<invoke_result_t<PF1>, bool>);
static_assert(is_same_v<invoke_result_t<PMF, unique_ptr<S>, int, void>});
static_assert(is_same_v<invoke_result_t<PMF, S, char&>});
static_assert(is_same_v<invoke_result_t<PMD, const S*, const char&>});
— end example
```

21.3.9 Logical operator traits [meta.logical]

This subclause describes type traits for applying logical operators to other type traits.

```cpp
template<class... B> struct conjunction : see below { }; 
```

The class template `conjunction` forms the logical conjunction of its template type arguments.

For a specialization `conjunction<B_1, ..., B_N>`, if there is a template type argument `B_i` for which `bool(B_i::value)` is false, then instantiating `conjunction<B_1, ..., B_N>::value` does not require the instantiation of `B_j::value` for `j > i`.

[Note 1: This is analogous to the short-circuiting behavior of the built-in operator `&&`. — end note]

Every template type argument for which `B_i::value` is instantiated shall be usable as a base class and shall have a member `value` which is convertible to `bool`, is not hidden, and is unambiguously available in the type.

The specialization `conjunction<B_1, ..., B_N>` has a public and unambiguous base that is either

(5.1) — the first type `B_i` in the list `true_type, B_1, ..., B_N` for which `bool(B_i::value)` is false, or

(5.2) — if there is no such `B_i`, the last type in the list.

[Note 2: This means a specialization of `conjunction` does not necessarily inherit from either `true_type` or `false_type`. — end note]

The member names of the base class, other than `conjunction` and `operator=`, shall not be hidden and shall be unambiguously available in `conjunction`.

```cpp
template<class... B> struct disjunction : see below { }; 
```

The class template `disjunction` forms the logical disjunction of its template type arguments.

For a specialization `disjunction<B_1, ..., B_N>`, if there is a template type argument `B_i` for which `bool(B_i::value)` is true, then instantiating `disjunction<B_1, ..., B_N>::value` does not require the instantiation of `B_j::value` for `j > i`.

[Note 3: This is analogous to the short-circuiting behavior of the built-in operator `||`. — end note]
Every template type argument for which \( B_i::\text{value} \) is instantiated shall be usable as a base class and shall have a member \texttt{value} which is convertible to \texttt{bool}, is not hidden, and is unambiguously available in the type.

The specialization \texttt{disjunction<\( B_1, \ldots, B_N \)>} has a public and unambiguous base that is either

1. the first type \( B_i \) in the list \texttt{false_type}, \( B_1, \ldots, B_N \) for which \texttt{bool(\( B_i::\text{value} \))} is \texttt{true}, or
2. if there is no such \( B_i \), the last type in the list.

\[ \text{Note 4: This means a specialization of disjunction does not necessarily inherit from either true_type or false_type. — end note} \]

The member names of the base class, other than \texttt{disjunction} and \texttt{operator=}, shall not be hidden and shall be unambiguously available in \texttt{disjunction}.

\begin{verbatim}
template<class B> struct negation : see below {};
\end{verbatim}

The class template \texttt{negation} forms the logical negation of its template type argument. The type \texttt{negation<B>} is a \texttt{Cpp17UnaryTypeTrait} with a base characteristic of \texttt{bool_constant<!bool(B::value)>}

\textbf{21.3.10 Member relationships} [meta.member]

\begin{verbatim}
template<class S, class M>
constexpr bool is_pointer_interconvertible_with_class(M S::*m) noexcept;
\end{verbatim}

\texttt{Mandates}: \( S \) is a complete type.

\texttt{Returns}: \texttt{true} if and only if \( S \) is a standard-layout type, \( M \) is an object type, \( m \) is not null, and each object \( s \) of type \( S \) is pointer-interconvertible (6.8.4) with its subobject \( s.*m \).

\begin{verbatim}
template<class S1, class S2, class M1, class M2>
constexpr bool is_corresponding_member(M1 S1::*m1, M2 S2::*m2) noexcept;
\end{verbatim}

\texttt{Mandates}: \( S1 \) and \( S2 \) are complete types.

\texttt{Returns}: \texttt{true} if and only if \( S1 \) and \( S2 \) are standard-layout struct (11.2) types, \( M1 \) and \( M2 \) are object types, \( m1 \) and \( m2 \) are not null, and \( m1 \) and \( m2 \) point to corresponding members of the common initial sequence (11.4) of \( S1 \) and \( S2 \).

\[ \text{Note 1: The type of a pointer-to-member expression \&\( C::b \) is not always a pointer to member of \( C \), leading to potentially surprising results when using these functions in conjunction with inheritance.} \]

\[ \text{Example 1:} \]
\begin{verbatim}
struct A { int a; }; // a standard-layout class
struct B { int b; }; // a standard-layout class
struct C: public A, public B { }; // not a standard-layout class
static_assert( is_pointer_interconvertible_with_class( &C::b ) ); // Succeeds because, despite its appearance, \&C::b has type
// “pointer to member of B of type int”.
static_assert( is_pointer_interconvertible_with_class<C>( &C::b ) ); // Forc...'
\end{verbatim}

\begin{verbatim}
static_assert( is_corresponding_member( &C::a, &C::b ) ); // Succeeds because, despite its appearance, &C::a and &C::b have types
// “pointer to member of A of type int” and
// “pointer to member of B of type int”, respectively.
static_assert( is_corresponding_member<C, C>( &C::a, &C::b ) ); // Forc...
\end{verbatim}

\texttt{— end example}]

\texttt{— end note}\n
\textbf{21.3.11 Constant evaluation context} [meta.const.eval]

\begin{verbatim}
constexpr bool is_constant_evaluated() noexcept;
\end{verbatim}

\texttt{Effects}: Equivalent to:
```cpp
if constexpr {
    return true;
} else {
    return false;
}
```

**Example 1:**
```cpp
cconstexpr void f(unsigned char *p, int n) {
    if (std::is_constant_evaluated()) {  // should not be a constexpr if statement
        for (int k = 0; k<n; ++k) p[k] = 0;
    } else {
        memset(p, 0, n);  // not a core constant expression
    }
}
```

---

### 21.4 Compile-time rational arithmetic

#### 21.4.1 In general

Subclause 21.4 describes the ratio library. It provides a class template `ratio` which exactly represents any finite rational number with a numerator and denominator representable by compile-time constants of type `intmax_t`.

Throughout subclause 21.4, the names of template parameters are used to express type requirements. If a template parameter is named `R1` or `R2`, and the template argument is not a specialization of the `ratio` template, the program is ill-formed.

#### 21.4.2 Header `<ratio>` synopsis

```cpp
namespace std {
   // 21.4.3, class template ratio
   template<intmax_t N, intmax_t D = 1> class ratio;

   // 21.4.4, ratio arithmetic
   template<class R1, class R2> using ratio_add = see below;
   template<class R1, class R2> using ratio_subtract = see below;
   template<class R1, class R2> using ratio_multiply = see below;
   template<class R1, class R2> using ratio_divide = see below;

   // 21.4.5, ratio comparison
   template<class R1, class R2> struct ratio_equal;
   template<class R1, class R2> struct ratio_not_equal;
   template<class R1, class R2> struct ratio_less;
   template<class R1, class R2> struct ratio_less_equal;
   template<class R1, class R2> struct ratio_greater;
   template<class R1, class R2> struct ratio_greater_equal;

   template<class R1, class R2>
   constexpr bool ratio_equal_v = ratio_equal<R1, R2>::value;
   template<class R1, class R2>
   constexpr bool ratio_not_equal_v = ratio_not_equal<R1, R2>::value;
   template<class R1, class R2>
   constexpr bool ratio_less_v = ratio_less<R1, R2>::value;
   template<class R1, class R2>
   constexpr bool ratio_less_equal_v = ratio_less_equal<R1, R2>::value;
   template<class R1, class R2>
   constexpr bool ratio_greater_v = ratio_greater<R1, R2>::value;
   template<class R1, class R2>
   constexpr bool ratio_greater_equal_v = ratio_greater_equal<R1, R2>::value;

   // 21.4.6, convenience SI typedefs
   using yocto = ratio<1, intmax_t '000' '000' '000' '000' '000' '000' '000' '000'>;  // see below
   using zepto = ratio<1, intmax_t '000' '000' '000' '000' '000' '000' '000' '000'>;  // see below
   using atto = ratio<1, 1'000' '000' '000' '000' '000' '000' '000' '000'>;  // see below
```

§ 21.4.2
21.4.3 Class template ratio

```cpp
namespace std {
    template<intmax_t N, intmax_t D = 1> class ratio {
        public:
            static constexpr intmax_t num;
            static constexpr intmax_t den;
            using type = ratio<num, den>;
    };
}
```

1 If the template argument D is zero or the absolute values of either of the template arguments N and D is not representable by type intmax_t, the program is ill-formed.

[Note 1: These rules ensure that infinite ratios are avoided and that for any negative input, there exists a representable value of its absolute value which is positive. This excludes the most negative value. — end note]

2 The static data members num and den shall have the following values, where gcd represents the greatest common divisor of the absolute values of N and D:

(2.1) num shall have the value sgn(N) * sgn(D) * abs(N) / gcd.

(2.2) den shall have the value abs(D) / gcd.

21.4.4 Arithmetic on ratios

1 Each of the alias templates ratio_add, ratio_subtract, ratio_multiply, and ratio_divide denotes the result of an arithmetic computation on two ratios R1 and R2. With X and Y computed (in the absence of arithmetic overflow) as specified by Table 56, each alias denotes a ratio<U, V> such that U is the same as ratio<X, Y>::num and V is the same as ratio<X, Y>::den.

2 If it is not possible to represent U or V with intmax_t, the program is ill-formed. Otherwise, an implementation should yield correct values of U and V. If it is not possible to represent X or Y with intmax_t, the program is ill-formed unless the implementation yields correct values of U and V.

Table 56: Expressions used to perform ratio arithmetic

<table>
<thead>
<tr>
<th>Type</th>
<th>Value of X</th>
<th>Value of Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>ratio_add&lt;R1, R2&gt;</td>
<td>R1::num * R2::den + R1::den * R2::den</td>
<td></td>
</tr>
<tr>
<td></td>
<td>R2::num * R1::den</td>
<td></td>
</tr>
<tr>
<td>ratio_subtract&lt;R1, R2&gt;</td>
<td>R1::num * R2::den - R1::den * R2::den</td>
<td></td>
</tr>
<tr>
<td></td>
<td>R2::num * R1::den</td>
<td></td>
</tr>
<tr>
<td>ratio_multiply&lt;R1, R2&gt;</td>
<td>R1::num * R2::num</td>
<td></td>
</tr>
<tr>
<td></td>
<td>R1::den * R2::den</td>
<td></td>
</tr>
<tr>
<td>ratio_divide&lt;R1, R2&gt;</td>
<td>R1::num * R2::den</td>
<td></td>
</tr>
<tr>
<td></td>
<td>R1::den * R2::den</td>
<td></td>
</tr>
</tbody>
</table>

3 Example 1:

```cpp
static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::num == 1, "1/3+1/6 == 1/2");
```
static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::den == 2, "1/3+1/6 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::num == 1, "1/3*3/2 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::den == 2, "1/3*3/2 == 1/2");

// The following cases may cause the program to be ill-formed under some implementations
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::num == 2,
"1/MAX+1/MAX == 2/MAX");
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::den == INT_MAX,
"1/MAX+1/MAX == 2/MAX");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::num == 1,
"1/MAX * MAX/2 == 1/2");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::den == 2,
"1/MAX * MAX/2 == 1/2");

—end example

21.4.5 Comparison of ratios

template<class R1, class R2>
struct ratio_equal : bool_constant<R1::num == R2::num && R1::den == R2::den> { };  

template<class R1, class R2>
struct ratio_not_equal : bool_constant<!ratio_equal_v<R1, R2>> { };  

template<class R1, class R2>
struct ratio_less : bool_constant<see below> { };  

If R1::num × R2::den is less than R2::num × R1::den, ratio_less<R1, R2> shall be derived from bool_constant<true>; otherwise it shall be derived from bool_constant<false>. Implementations may use other algorithms to compute this relationship to avoid overflow. If overflow occurs, the program is ill-formed.

template<class R1, class R2>
struct ratio_less_equal : bool_constant<!ratio_less_v<R2, R1>> { };  

template<class R1, class R2>
struct ratio_greater : bool_constant<ratio_less_v<R2, R1>> { };  

template<class R1, class R2>
struct ratio_greater_equal : bool_constant<!ratio_less_v<R1, R2>> { };  

21.4.6 SI types for ratio

For each of the typedef-names yocto, zepto, zetta, and yotta, if both of the constants used in its specification are representable by intmax_t, the typedef is defined; if either of the constants is not representable by intmax_t, the typedef is not defined.
22 General utilities library

22.1 General

This Clause describes utilities that are generally useful in C++ programs; some of these utilities are used by other elements of the C++ standard library. These utilities are summarized in Table 57.

22.2 Utility components

22.2.1 Header <utility> synopsis

The header <utility> contains some basic function and class templates that are used throughout the rest of the library.

```cpp
#include <compare>  // see 17.11.1
#include <initializer_list>  // see 17.10.2

namespace std {

   // 22.2.2, swap
   template<class T>
   constexpr void swap(T& a, T& b) noexcept((see below));
   template<class T, size_t N>
   constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);

   // 22.2.3, exchange
   template<class T, class U = T>
   constexpr T exchange(T& obj, U& new_val) noexcept((see below));

   // 22.2.4, forward/move
   template<class T>
   constexpr T& forward(remove_reference_t<T>& t) noexcept;
   template<class T>
   constexpr T& forward(remove_reference_t<T>&& t) noexcept;
   template<class T, class U>
   [[nodiscard]] constexpr auto forward_like(U&& x) noexcept -> see below;
   template<class T>
   constexpr remove_reference_t<T>&& move(T&&) noexcept;
```

§ 22.2.1
```
```
struct basic_common_reference<pair<T1, T2>, pair<U1, U2>, TQual, UQual> {
    using type = pair<common_reference_t<TQual<T1>, UQual<U1>>,
    common_reference_t<TQual<T2>, UQual<U2>>>;
};

template<class T1, class T2, class U1, class U2>
requires requires { typename pair<common_type_t<T1, U1>, common_type_t<T2, U2>>; } 
struct common_type<pair<T1, T2>, pair<U1, U2>> {
    using type = pair<common_type_t<T1, U1>, common_type_t<T2, U2>>;
};

#endif

// 22.3.3, pair specialized algorithms

template<class T1, class T2, class U1, class U2>
constexpr bool operator==(const pair<T1, T2>&, const pair<U1, U2>&);

template<class T1, class T2, class U1, class U2>
constexpr common_comparison_category_t<
    synth-three-way-result<T1, U1>,
    synth-three-way-result<T2, U2>>
operator<=>(const pair<T1, T2>&, const pair<U1, U2>&);

template<class T1, class T2>
constexpr void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));

template<class T1, class T2>
constexpr void swap(const pair<T1, T2>& x, const pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));

// 22.3.4, tuple-like access to pair

template<class T> struct tuple_size;

template<size_t I, class T> struct tuple_element;

template<class T1, class T2> struct tuple_size<pair<T1, T2>>;

template<size_t I, class T1, class T2> struct tuple_element<I, pair<T1, T2>>;

template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>&) noexcept;

template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>&& get(pair<T1, T2>&&) noexcept;

template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>&) noexcept;

template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>&& get(const pair<T1, T2>&&) noexcept;

template<class T1, class T2>
constexpr T1& get(pair<T1, T2>& p) noexcept;

template<class T1, class T2>
constexpr const T1& get(const pair<T1, T2>& p) noexcept;

template<class T1, class T2>
constexpr T1&& get(pair<T1, T2>&& p) noexcept;

template<class T1, class T2>
constexpr const T1&& get(const pair<T1, T2>&& p) noexcept;

template<class T2, class T1>
constexpr T2& get(pair<T1, T2>& p) noexcept;

template<class T2, class T1>
constexpr const T2& get(const pair<T1, T2>& p) noexcept;

template<class T2, class T1>
constexpr T2&& get(pair<T1, T2>&& p) noexcept;

template<class T2, class T1>
constexpr const T2&& get(const pair<T1, T2>&& p) noexcept;

// 22.3.5, pair piecewise construction

struct piecewise_construct_t {
    explicit piecewise_construct_t() = default;
};

N4944

```cpp
inline constexpr piecewise_construct_t piecewise_construct{};
```

// defined in <tuple> (22.4.2)

```cpp
template<class... Types> class tuple;
```

```
// in-place construction
struct in_place_t {
  explicit in_place_t() = default;
};
inline constexpr in_place_t in_place{};
```

```cpp
template<class T>
struct in_place_type_t {
  explicit in_place_type_t() = default;
};
```

```cpp
template<class T> constexpr in_place_type_t<T> in_place_type{};
```

```cpp
template<size_t I>
struct in_place_index_t {
  explicit in_place_index_t() = default;
};
```

```cpp
template<size_t I> constexpr in_place_index_t<I> in_place_index{};
```

22.2.2 swap [utility.swap]

```cpp
template<class T>
constexpr void swap(T& a, T& b) noexcept(see below);
```

1 **Constraints**: is_move_constructible_v<T> is true and is_move_assignable_v<T> is true.

2 **Preconditions**: Type T meets the Cpp17MoveConstructible (Table 31) and Cpp17MoveAssignable (Table 33) requirements.

3 **Effects**: Exchanges values stored in two locations.

4 **Remarks**: The exception specification is equivalent to:

```cpp
is_nothrow_move_constructible_v<T> && is_nothrow_move_assignable_v<T>
```

```cpp
template<class T, size_t N>
constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);
```

5 **Constraints**: is_swappable_v<T> is true.

6 **Preconditions**: a[i] is swappable with (16.4.4.3) b[i] for all i in the range [0, N).

7 **Effects**: As if by swap_ranges(a, a + N, b).

22.2.3 exchange [utility.exchange]

```cpp
template<class T, class U = T>
constexpr T exchange(T& obj, U&& new_val) noexcept(see below);
```

1 **Effects**: Equivalent to:

```cpp
T old_val = std::move(obj);
obj = std::forward<U>(new_val);
return old_val;
```

2 **Remarks**: The exception specification is equivalent to:

```cpp
is_nothrow_move_constructible_v<T> && is_nothrow_assignable_v<T&, U>
```

22.2.4 Forward/move helpers [forward]

1 The library provides templated helper functions to simplify applying move semantics to an lvalue and to simplify the implementation of forwarding functions. All functions specified in this subclause are signal-safe (17.13.5).

```cpp
template<class T> constexpr T&& forward(remove_reference_t<T>& t) noexcept;
```

2 **Mandates**: For the second overload, is_lvalue_reference_v<T> is false.

§ 22.2.4 682
3 Returns: static_cast<T&>(t).

4 [Example 1:

template<class T, class A1, class A2>
shared_ptr<T> factory(A1&& a1, A2&& a2) {
    return shared_ptr<T>(new T(std::forward<A1>(a1), std::forward<A2>(a2)));
}

struct A {
    A(int&, const double&);
};

void g() {
    shared_ptr<A> sp1 = factory<A>(2, 1.414); // error: 2 will not bind to int&
    int i = 2;
    shared_ptr<A> sp2 = factory<A>(i, 1.414); // OK
}

In the first call to factory, A1 is deduced as int, so 2 is forwarded to A’s constructor as an rvalue. In the
second call to factory, A1 is deduced as int&, so i is forwarded to A’s constructor as an lvalue. In both cases,
A2 is deduced as double, so 1.414 is forwarded to A’s constructor as an rvalue. —end example]

template<class T, class U>
[[nodiscard]] constexpr auto forward_like(U&& x) noexcept ->

5 see below;

Mandates: T is a referenceable type (3.45).

(5.1) Let COPY_CONST(A, B) be const B if A is a const type, otherwise B.
(5.2) Let OVERRIDE_REF(A, B) be remove_reference_t<B>&& if A is an rvalue reference type, otherwise B&.
(5.3) Let V be

OVERRIDE_REF(T&&, COPY_CONST(remove_reference_t<T>, remove_reference_t<U>))

Returns: static_cast<V>(x).

Remarks: The return type is V.

[Example 2:

struct accessor {
    vector<string>* container;
    decltype(auto) operator[](this auto&& self, size_t i) {
        return std::forward_like<decltype(self)>((*container)[i]);
    }
};

void g() {
    vector v{"a", "b"};
    accessor a{&v};
    string& x = a[0]; // OK, binds to lvalue reference
    string&& y = std::move(a)[0]; // OK, is rvalue reference
    string const&& z = std::move(as_const(a))[1]; // OK, is const&&
    string& w = as_const(a)[1]; // error: will not bind to non-const
}

—end example]

template<class T> constexpr remove_reference_t<T>&& move(T&& t) noexcept;

9 Returns: static_cast<remove_reference_t<T>&&>(t).

[Example 3:

template<class T, class A1>
shared_ptr<T> factory(A1&& a1) {
    return shared_ptr<T>(new T(std::forward<A1>(a1)));
}

struct A {
    A();

§ 22.2.4
A(const A&);  // copies from lvalues
A(A&&);  // moves from rvalues

void g() {
  A a;
  shared_ptr<A> sp1 = factory<A>(a);  // "a" binds to A(const A&)
  shared_ptr<A> sp2 = factory<A>(std::move(a));  // "a" binds to A(A&&)
}

In the first call to factory, A1 is deduced as A&, so a is forwarded as a non-const lvalue. This binds to the constructor A(const A&), which copies the value from a. In the second call to factory, because of the call std::move(a), A1 is deduced as A, so a is forwarded as an rvalue. This binds to the constructor A(A&&), which moves the value from a. — end example]

template<class T> constexpr conditional_t<!is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>

move_if_noexcept(T& x) noexcept;

Returns: std::move(x).

22.2.5 Function template as_const

template<class T> constexpr add_const_t<T>& as_const(T& t) noexcept;

1 Returns: t.

22.2.6 Function template declval

The library provides the function template declval to simplify the definition of expressions which occur as unevaluated operands (7.2.3).

template<class T> add_rvalue_reference_t<T> declval() noexcept;  // as unevaluated operand

1 Mandates: This function is not odr-used (6.3).
2 Remarks: The template parameter T of declval may be an incomplete type.
3 [Example 1:
   template<class To, class From> decltype(static_cast<To>(declval<From>())) convert(From&&);
   declares a function template convert which only participates in overload resolution if the type From can be explicitly converted to type To. For another example see class template common_type (21.3.8.7). — end example]

22.2.7 Integer comparison functions

template<class T, class U>
constexpr bool cmp_equal(T t, U u) noexcept;

1 Mandates: Both T and U are standard integer types or extended integer types (6.8.2).
2 Effects: Equivalent to:
    using UT = make_unsigned_t<T>;
    using UU = make_unsigned_t<U>;
    if constexpr (is_signed_v<T> == is_signed_v<U>)
       return t == u;
    else if constexpr (is_signed_v<T>)
       return t < 0 ? false : UT(t) == u;
    else
       return u < 0 ? false : t == UU(u);

template<class T, class U>
constexpr bool cmp_not_equal(T t, U u) noexcept;

3 Effects: Equivalent to: return !cmp_equal(t, u);

template<class T, class U>
constexpr bool cmp_less(T t, U u) noexcept;

4 Mandates: Both T and U are standard integer types or extended integer types (6.8.2).
5 Effects: Equivalent to:
using UT = make_unsigned_t<T>;
using UU = make_unsigned_t<U>;
if constexpr (is_signed_v<T> == is_signed_v<U>)
  return t < u;
else if constexpr (is_signed_v<T>)
  return t < 0 ? true : UT(t) < u;
else
  return u < 0 ? false : t < UU(u);

template<class T, class U>
constexpr bool cmp_greater(T t, U u) noexcept;

Effects: Equivalent to: return cmp_less(u, t);

template<class T, class U>
constexpr bool cmp_less_equal(T t, U u) noexcept;

Effects: Equivalent to: return !cmp_greater(t, u);

template<class T, class U>
constexpr bool cmp_greater_equal(T t, U u) noexcept;

Effects: Equivalent to: return !cmp_less(t, u);

template<class R, class T>
constexpr bool in_range(T t) noexcept;

Mandates: Both T and R are standard integer types or extended integer types (6.8.2).

Effects: Equivalent to:

return cmp_greater_equal(t, numeric_limits<R>::min()) &&
cmp_less_equal(t, numeric_limits<R>::max());

[Note 1: These function templates cannot be used to compare byte, char, char8_t, char16_t, char32_t, wchar_t, and bool. — end note]

22.2.8 Function template to_underlying

[utility.underlying]

template<class T>
constexpr underlying_type_t<T> to_underlying(T value) noexcept;

Returns: static_cast<underlying_type_t<T>>(value).

22.2.9 Function unreachable

[utility.unreachable]

[[noreturn]] void unreachable();

Preconditions: false is true.

[Note 1: This precondition cannot be satisfied, thus the behavior of calling unreachable is undefined. — end note]

[Example 1:

int f(int x) {
  switch (x) {
    case 0:
    case 1:
      return x;
    default:
      std::unreachable();
  }
}

int a = f(1);  // OK, a has value 1
int b = f(3);  // undefined behavior

— end example]
22.3 Pairs

22.3.1 In general

The library provides a template for heterogeneous pairs of values. The library also provides a matching function template to simplify their construction and several templates that provide access to pair objects as if they were tuple objects (see 22.4.7 and 22.4.8).

22.3.2 Class template pair

```cpp
namespace std {
    template<class T1, class T2>
    struct pair {
        using first_type = T1;
        using second_type = T2;

        T1 first;
        T2 second;

        pair(const pair&) = default;
        pair(pair&&) = default;
        constexpr explicit(pair(const T1& x, const T2& y));
        template<class U1 = T1, class U2 = T2>
        constexpr explicit(pair(U1&& x, U2&& y));
        template<class U1, class U2>
        constexpr explicit(pair(U1&& x, U2&& y));
        template<class U1, class U2>
        constexpr explicit(pair<U1, U2>& p);
        template<class U1, class U2>
        constexpr explicit(pair<U1, U2>&& p);
        template<class U1, class U2>
        constexpr explicit(pair(pair<U1, U2>& p));
        template<class U1, class U2>
        constexpr explicit(pair(pair<U1, U2>&& p));
        template<class U1, class U2>
        constexpr explicit(pair(pair_like P));
        template<class T1, class T2>
        pair(T1, T2) -> pair<T1, T2>;

        constexpr pair& operator=(const pair& p);
        constexpr const pair& operator=(const pair& p) const;
        template<class U1, class U2>
        constexpr pair& operator=(const pair<U1, U2>& p);
        template<class U1, class U2>
        constexpr pair& operator=(const pair<U1, U2>&& p);
        constexpr void swap(pair& p) noexcept;
        constexpr void swap(const pair& p) const noexcept;
    };
}
```

Constructors and member functions of pair do not throw exceptions unless one of the element-wise operations specified to be called for that operation throws an exception.
The defaulted move and copy constructor, respectively, of `pair` is a constexpr function if and only if all required element-wise initializations for move and copy, respectively, would satisfy the requirements for a constexpr function.

If `(is_trivially_destructible_v<T1> && is_trivially_destructible_v<T2>)` is true, then the destructor of `pair` is trivial.

`pair<T, U>` is a structural type (13.2) if `T` and `U` are both structural types. Two values `p1` and `p2` of type `pair<T, U>` are template-argument-equivalent (13.6) if and only if `p1.first` and `p2.first` are template-argument-equivalent and `p1.second` and `p2.second` are template-argument-equivalent.

```
constexpr explicit(see below) pair();

Constraints:
(5.1) — is_default_constructible_v<T1> is true and
(5.2) — is_default_constructible_v<T2> is true.
```

```
Effects: Value-initializes first and second.
```

```
Remarks: The expression inside explicit evaluates to true if and only if either `T1` or `T2` is not implicitly default-constructible.

[Note 1: This behavior can be implemented with a trait that checks whether a `const T1&` or a `const T2&` can be initialized with `{}`. — end note]
```

```
constexpr explicit(see below) pair(const T1& x, const T2& y);

Constraints:
(8.1) — is_copy_constructible_v<T1> is true and
(8.2) — is_copy_constructible_v<T2> is true.
```

```
Effects: Initializes first with `x` and second with `y`.
```

```
Remarks: The expression inside explicit is equivalent to:
!is_convertible_v<const T1&, T1> || !is_convertible_v<const T2&, T2>
```

```
template<class U1 = T1, class U2 = T2> constexpr explicit(see below) pair(U1&& x, U2&& y);
```

Constraints:
(11.1) — is_constructible_v<T1, U1> is true and
(11.2) — is_constructible_v<T2, U2> is true.

Effects: Initializes first with `std::forward<U1>(x)` and second with `std::forward<U2>(y)`.

```
Remarks: The expression inside explicit is equivalent to:
!is_convertible_v<U1, T1> || !is_convertible_v<U2, T2>
```

This constructor is defined as deleted if `reference_constructs_from_temporary_v<first_type, U1&&>` is true or `reference_constructs_from_temporary_v<second_type, U2&&>` is true.

```
template<class U1, class U2> constexpr explicit(see below) pair(pair<U1, U2>& p);
```

Constraints:
(15.1) — For the last overload, `remove_cvref_t<P>` is not a specialization of `ranges::subrange`,
(15.2) — is_constructible_v<T1, decltype(get<0>(FWD(p)))> is true, and
(15.3) — is_constructible_v<T2, decltype(get<1>(FWD(p)))> is true.

Effects: Initializes first with `get<0>(FWD(p))` and second with `get<1>(FWD(p))`.

Remarks: The expression inside explicit is equivalent to:

§ 22.3.2 687
The constructor is defined as deleted if
\[
reference_{\text{convertible}}_{\text{from}}_{\text{temporary}}_{\text{v}}<\text{first}\_\text{type}, \text{decltype}(<0>(\text{FWD}(p)))> \quad \text{||}
\]
\[
reference_{\text{convertible}}_{\text{from}}_{\text{temporary}}_{\text{v}}<\text{second}\_\text{type}, \text{decltype}(<1>(\text{FWD}(p)))>
\]
is true.

```cpp
template<class... Args1, class... Args2>
constexpr pair(piecewise_construct_t,
    tuple<Args1...> first_args, tuple<Args2...> second_args);
```

**Mandates:**

- (18.1) `is_constructible_v<T1, Args1...>` is true and
- (18.2) `is_constructible_v<T2, Args2...>` is true.

**Effects:** Initializes `first` with arguments of types `Args1...` obtained by forwarding the elements of `first_args` and initializes `second` with arguments of types `Args2...` obtained by forwarding the elements of `second_args`. (Here, forwarding an element `x` of type `U` within a `tuple` object means calling `std::forward<U>(x)`.) This form of construction, whereby constructor arguments for `first` and `second` are each provided in a separate `tuple` object, is called **piecewise construction**.

**Note 2:** If a data member of `pair` is of reference type and its initialization binds it to a temporary object, the program is ill-formed (11.9.3). —end note

```cpp
constexpr pair& operator=(const pair& p);
```

**Effects:** Assigns `p.first` to `first` and `p.second` to `second`.

**Returns:** `*this`.

**Remarks:** This operator is defined as deleted unless `is_copy_assignable_v<T1>` is true and `is_copy_assignable_v<T2>` is true.

```cpp
constexpr const pair& operator=(const pair& p) const;
```

**Constraints:**

- (23.1) `is_copy_assignable_v<const T1>` is true and
- (23.2) `is_copy_assignable_v<const T2>` is true.

**Effects:** Assigns `p.first` to `first` and `p.second` to `second`.

**Returns:** `*this`.

```cpp
template<class U1, class U2> constexpr pair& operator=(const pair<U1, U2>& p);
```

**Constraints:**

- (26.1) `is_assignable_v<T1&, const U1&>` is true and
- (26.2) `is_assignable_v<T2&, const U2&>` is true.

**Effects:** Assigns `p.first` to `first` and `p.second` to `second`.

**Returns:** `*this`.

```cpp
template<class U1, class U2> constexpr const pair& operator=(const pair<U1, U2>& p) const;
```

**Constraints:**

- (29.1) `is_assignable_v<const T1&, const U1&>` is true, and
- (29.2) `is_assignable_v<const T2&, const U2&>` is true.

**Effects:** Assigns `p.first` to `first` and `p.second` to `second`.

**Returns:** `*this`.

```cpp
constexpr pair& operator=(pair&& p) noexcept(see below);
```

**Constraints:**

- (32.1) `is_move_assignable_v<T1>` is true and
is_move_assignable_v<T2> is true.

**Effects**: Assigns to first with std::forward<T1>(p.first) and to second with std::forward<T2>(p.second).

**Returns**: *this.

**Remarks**: The exception specification is equivalent to:

\[
\text{is_nothrow_move_assignable_v<T1> && is_nothrow_move_assignable_v<T2>}
\]

```cpp
cconstexpr const pair& operator=(pair&& p) const;
```

**Constraints**: 

- is_assignable_v<const T1&, T1> is true and 
- is_assignable_v<const T2&, T2> is true.

**Effects**: Assigns std::forward<T1>(p.first) to first and std::forward<T2>(p.second) to second.

**Returns**: *this.

```cpp
template<class U1, class U2> constexpr pair& operator=(pair<U1, U2>&& p);
```

**Constraints**: 

- different-from<P, pair> (26.5.2) is true, 
- remove_cvref_t<P> is not a specialization of ranges::subrange, 
- is_assignable_v<T1&, decltype(get<0>(std::forward<P>(p)))> is true, and
- is_assignable_v<T2&, decltype(get<1>(std::forward<P>(p)))> is true.

**Effects**: Assigns get<0>(std::forward<P>(p)) to first and get<1>(std::forward<P>(p)) to second.

**Returns**: *this.

```cpp
template<pair-like P> constexpr const pair& operator=(P&& p) const;
```

**Constraints**: 

- different-from<P, pair> (26.5.2) is true, 
- remove_cvref_t<P> is not a specialization of ranges::subrange, 
- is_assignable_v<T1&, decltype(get<0>(std::forward<P>(p)))> is true, and
- is_assignable_v<T2&, decltype(get<1>(std::forward<P>(p)))> is true.

**Effects**: Assigns get<0>(std::forward<P>(p)) to first and get<1>(std::forward<P>(p)) to second.

**Returns**: *this.

```cpp
template<class U1, class U2> constexpr const pair& operator=(pair<U1, U2>&& p) const;
```

**Constraints**: 

- is_assignable_v<const T1&, U1> is true, and 
- is_assignable_v<const T2&, U2> is true.

**Effects**: Assigns std::forward<U1>(p.first) to first and std::forward<U2>(p.second) to second.

**Returns**: *this.
constexpr void swap(pair& p) noexcept;
constexpr void swap(const pair& p) const noexcept;

Mandates:
- For the first overload, is_swappable_v<T1> is true and is_swappable_v<T2> is true.
- For the second overload, is_swappable_v<const T1> is true and is_swappable_v<const T2> is true.

Preconditions: first is swappable with (16.4.4.3) p.first and second is swappable with p.second.
Effects: Swaps first with p.first and second with p.second.
Remarks: The exception specification is equivalent to:
- is_nothrow_swappable_v<T1> && is_nothrow_swappable_v<T2> for the first overload, and
- is_nothrow_swappable_v<const T1> && is_nothrow_swappable_v<const T2> for the second overload.

22.3.3 Specialized algorithms [pairs.spec]
template<class T1, class T2, class U1, class U2>
constexpr bool operator==(const pair<T1, T2>& x, const pair<U1, U2>& y);

1 Preconditions: Each of decltype(x.first == y.first) and decltype(x.second == y.second) models boolean-testable.
Returns: x.first == y.first && x.second == y.second.

template<class T1, class T2, class U1, class U2>
constexpr common_comparison_category_t<
  synth-three-way-result<T1, U1>,
  synth-three-way-result<T2, U2>>
operator<=>(const pair<T1, T2>& x, const pair<U1, U2>& y);

2 Effects: Equivalent to:
if (auto c = synth-three-way(x.first, y.first); c != 0) return c;
return synth-three-way(x.second, y.second);

template<class T1, class T2>
constexpr void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));

template<class T1, class T2>
constexpr void swap(const pair<T1, T2>& x, const pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));

4 Constraints:
- For the first overload, is_swappable_v<T1> is true and is_swappable_v<T2> is true.
- For the second overload, is_swappable_v<const T1> is true and is_swappable_v<const T2> is true.

5 Effects: Equivalent to x.swap(y).

template<class T1, class T2>
constexpr pair<unwrap_ref_decay_t<T1>, unwrap_ref_decay_t<T2>> make_pair(T1&& x, T2&& y);

6 Returns:
pair<unwrap_ref_decay_t<T1>,
  unwrap_ref_decay_t<T2>>(std::forward<T1>(x), std::forward<T2>(y))

7 [Example 1: In place of:
return pair<int, double>(5, 3.1415926); // explicit types
a C++ program may contain:
return make_pair(5, 3.1415926); // types are deduced
—end example]

22.3.4 Tuple-like access to pair [pair.astuple]
template<class T1, class T2>
struct tuple_size<pair<T1, T2>> : integral_constant<size_t, 2> { };
template<size_t I, class T1, class T2>
struct tuple_element<I, pair<T1, T2>> {
    using type = see below;
};

Mandates: I < 2.

Type: The type T1 if I is 0, otherwise the type T2.

template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>& p) noexcept;
template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>& p) noexcept;
template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>&& get(pair<T1, T2>&& p) noexcept;
template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>&& get(const pair<T1, T2>&& p) noexcept;

Mandates: I < 2.

Returns:

(4.1) — If I is 0, returns a reference to p.first.
(4.2) — If I is 1, returns a reference to p.second.

template<class T1, class T2>
constexpr T1& get(pair<T1, T2>& p) noexcept;
template<class T1, class T2>
constexpr const T1& get(const pair<T1, T2>& p) noexcept;
template<class T1, class T2>
constexpr T1&& get(pair<T1, T2>&& p) noexcept;
template<class T1, class T2>
constexpr const T1&& get(const pair<T1, T2>&& p) noexcept;

Mandates: T1 and T2 are distinct types.

Returns: A reference to p.first.

template<class T2, class T1>
constexpr T2& get(pair<T1, T2>& p) noexcept;
template<class T2, class T1>
constexpr const T2& get(const pair<T1, T2>& p) noexcept;
template<class T2, class T1>
constexpr T2&& get(pair<T1, T2>&& p) noexcept;
template<class T2, class T1>
constexpr const T2&& get(const pair<T1, T2>&& p) noexcept;

Mandates: T1 and T2 are distinct types.

Returns: A reference to p.second.

### 22.3.5 Piecewise construction [pair.piecewise]

struct piecewise_construct_t {
    explicit piecewise_construct_t() = default;
};
inline constexpr piecewise_construct_t piecewise_construct{};

The struct `piecewise_construct_t` is an empty class type used as a unique type to disambiguate constructor and function overloading. Specifically, `pair` has a constructor with `piecewise_construct_t` as the first argument, immediately followed by two `tuple` (22.4) arguments used for piecewise construction of the elements of the `pair` object.

### 22.4 Tuples [tuple]

#### 22.4.1 In general [tuple.general]

Subclause 22.4 describes the tuple library that provides a tuple type as the class template `tuple` that can be instantiated with any number of arguments. Each template argument specifies the type of an element in the
tuple. Consequently, tuples are heterogeneous, fixed-size collections of values. An instantiation of tuple
with two arguments is similar to an instantiation of pair with the same two arguments. See 22.3.

### 22.4.2 Header <tuple> synopsis

```
// all freestanding
#include <compare>
// see 17.11.1
namespace std {
    // 22.4.4, class template tuple
    template<class... Types>
    class tuple;
    // 22.4.3, concept tuple-like
    template<class T>
    concept tuple-like = see below; // exposition only
    template<class T>
    concept pair-like =
        tuple-like<T> && tuple_size_v<remove_cvref_t<T>> == 2;

    // 22.4.10, common_reference related specializations
    template<tuple-like TTuple, tuple-like UTuple,
             template<class> class TQual, template<class> class UQual>
    struct basic_common_reference<TTuple, UTuple, TQual, UQual>;
    template<tuple-like TTuple, tuple-like UTuple>
    struct common_type<TTuple, UTuple>;

    // 22.4.5, tuple creation functions
    inline constexpr unspecified ignore;
    template<class... TTypes>
    constexpr tuple<unwrap_ref_decay_t<TTypes>...> make_tuple(TTypes&&...);
    template<class... TTypes>
    constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&...) noexcept;
    template<class... TTypes>
    constexpr tuple<TTypes&...> tie(TTypes&...) noexcept;
    template<tuple-like... Tuples>
    constexpr tuple<CTypes...> tuple_cat(Tuples&&...);

    // 22.4.6, calling a function with a tuple of arguments
    template<class F, tuple-like Tuple>
    constexpr decltype(auto) apply(F&& f, Tuple&& t);
    template<class T, tuple-like Tuple>
    constexpr T make_from_tuple(Tuple&& t);

    // 22.4.7, tuple helper classes
    template<class T> struct tuple_size; // not defined
    template<class T> struct tuple_size<const T>;
    template<class... Types> struct tuple_size<tuple<Types...>>;
    template<size_t I, class T> struct tuple_element; // not defined
    template<size_t I, class T> struct tuple_element<1, const T>;
    template<size_t I, class... Types>
    struct tuple_element<1, tuple<Types...>>;
    template<size_t I, class T>
    using tuple_element_t = typename tuple_element<I, T>::type;
```
// 22.4.8, element access
template<
  size_t I,
  class... Types>
constexpr tuple_element_t<I, tuple<Types...>>& get(tuple<Types...>&) noexcept;

// 22.4.8, element access
template<
  size_t I,
  class... Types>
constexpr tuple_element_t<I, tuple<Types...>>& get(const tuple<Types...>&) noexcept;

// 22.4.8, element access
template<
  size_t I,
  class... Types>
constexpr tuple_element_t<I, tuple<Types...>>& get(tuple<Types...>&&) noexcept;

// 22.4.8, element access
template<
  size_t I,
  class... Types>
constexpr tuple_element_t<I, tuple<Types...>>& get(const tuple<Types...>&&) noexcept;

// 22.4.9, relational operators
template<class... TTypes, class... UTypes>
constexpr bool operator==(const tuple<TTypes...>&, const tuple<UTypes...>&);

// 22.4.9, relational operators
template<class... TTypes, tuple-like UTuple>
constexpr bool operator==(const tuple<TTypes...>&, const UTuple&);

// 22.4.9, relational operators
template<class... TTypes, class... UTypes>
constexpr common_comparison_category_t<
  synth-three-way-result<TTypes, UTypes>...>
operator<=>(const tuple<TTypes...>&, const tuple<UTypes...>&);

// 22.4.9, relational operators
template<class... TTypes, tuple-like UTuple>
constexpr common_comparison_category_t<
  synth-three-way-result<TTypes, UTypes>...>
operator<=>(const tuple<TTypes...>&, const UTuple&);

// 22.4.11, allocator-related traits
template<class... Types, class Alloc>
struct uses_allocator<
tuple<Types...>, Alloc>;

// 22.4.12, specialized algorithms
template<class... Types>
constexpr void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept;

// 22.4.12, specialized algorithms
template<class... Types>
constexpr void swap(const tuple<Types...>& x, const tuple<Types...>& y) noexcept;

// 22.4.7, tuple helper classes
template<class T>
constexpr size_t tuple_size_v = tuple_size<T>::value;

22.4.3 Concept tuple-like

```cpp
// exposition only
concept tuple-like = see below;
```

A type `T` models and satisfies the exposition-only concept `tuple-like` if `remove_cvref_t<T>` is a specialization of `array, pair, tuple, or ranges::subrange`.

22.4.4 Class template tuple

```cpp
namespace std {
  template<class... Types>
  class tuple {
    public:
      // 22.4.4.1, tuple construction
      constexpr explicit(see below) tuple();
      constexpr explicit(see below) tuple(const Types&...);
      constexpr explicit(see below) tuple(UTypes&&...);
      // only if sizeof...(Types) >= 1
      template<class... UTypes>
      constexpr explicit(see below) tuple(UTypes&&...);
      // only if sizeof...(Types) >= 1
  }
}
```
tuple(const tuple&) = default;

tuple(tuple&&) = default;

template<class... UTypes>
constexpr explicit(see below) tuple(tuple<UTypes...>&);

template<class... UTypes>
constexpr explicit(see below) tuple(const tuple<UTypes...>&);

template<class... UTypes>
constexpr explicit(see below) tuple(tuple<UTypes...>&&);

template<class... UTypes>
constexpr explicit(see below) tuple(const tuple<UTypes...>&&);

template<class U1, class U2>
constexpr explicit(see below) tuple(pair<U1, U2>&);  // only if sizeof...(Types) == 2

template<class U1, class U2>
constexpr explicit(see below) tuple(const pair<U1, U2>&);  // only if sizeof...(Types) == 2

template<class U1, class U2>
constexpr explicit(see below) tuple(pair<U1, U2>&&);  // only if sizeof...(Types) == 2

template<class U1, class U2>
constexpr explicit(see below) tuple(const pair<U1, U2>&&);  // only if sizeof...(Types) == 2

template<tuple-like UTuple>
constexpr explicit(see below) tuple(UTuple&&);

// allocator-extended constructors

template<class Alloc>
constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a);

template<class Alloc>
constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, const Types&...);

template<class Alloc, class... UTypes>
constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&);

template<class Alloc, class... UTypes>
constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&);

template<class Alloc, class... UTypes>
constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&&);

template<class Alloc, class... UTypes>
constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&&);

template<class Alloc, class U1, class U2>
constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&);

template<class Alloc, class U1, class U2>
constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&);

template<class Alloc, class U1, class U2>
constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&&);

template<class Alloc, class U1, class U2>
constexpr explicit(see below) tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&&);
template<class Alloc, tuple-like UTuple>
    constexpr explicit(see below) tuple(allocation_arg_t, const Alloc& a, UTuple&&);

// 22.4.4.2 tuple assignment
constexpr tuple& operator=(const tuple&);
constexpr const tuple& operator=(const tuple&) const;
constexpr tuple& operator=(tuple&&) noexcept(see below);
constexpr const tuple& operator=(tuple&&) const;

template<class... UTypes>
    constexpr tuple& operator=(const tuple<UTypes...>&);
template<class... UTypes>
    constexpr const tuple& operator=(const tuple<UTypes...>&) const;
template<class... UTypes>
    constexpr tuple& operator=(tuple<UTypes...>&&);
template<class... UTypes>
    constexpr const tuple& operator=(tuple<UTypes...>&&) const;

// 22.4.4.3 tuple swap
constexpr void swap(tuple&) noexcept(see below);
constexpr void swap(const tuple&) const noexcept(see below);

};

template<class... UTypes>
    tuple<UTypes...> -> tuple<UTypes...>;
template<class T1, class T2>
    tuple<pair<T1, T2>> -> tuple<T1, T2>;
template<class Alloc, class... UTypes>
    tuple(allocation_arg_t, Alloc, UTypes...) -> tuple<UTypes...>;
template<class Alloc, class T1, class T2>
    tuple(allocation_arg_t, Alloc, pair<T1, T2>) -> tuple<T1, T2>;
template<class Alloc, class... UTypes>
    tuple(allocation_arg_t, Alloc, tuple<UTypes...>) -> tuple<UTypes...>;

22.4.4.1 Construction [tuple.cnstr]

1 In the descriptions that follow, let \( i \) be in the range \([0, \text{sizeof}(\ldots\text{Types}))\) in order, \( T_i \) be the \( i \)th type in \( \text{Types} \), and \( U_i \) be the \( i \)th type in a template parameter pack named \( \text{UTypes} \), where indexing is zero-based.

2 For each tuple constructor, an exception is thrown only if the construction of one of the types in \( \text{Types} \) throws an exception.

3 The defaulted move and copy constructor, respectively, of tuple is a constexpr function if and only if all required element-wise initializations for move and copy, respectively, would satisfy the requirements for a constexpr function. The defaulted move and copy constructor of tuple<> are constexpr functions.

4 If is_trivially_destructible_v<T_i> is true for all \( T_i \), then the destructor of tuple is trivial.

5 The default constructor of tuple<> is trivial.
constexpr explicit(see below) tuple();

Constraints: is_default_constructible_v<T_i> is true for all i.

Effects: Value-initializes each element.

Remarks: The expression inside explicit evaluates to true if and only if T_i is not copy-list-initializable from an empty list for at least one i.

[Note 1: This behavior can be implemented with a trait that checks whether a const T_i& can be initialized with {}. — end note]

constexpr explicit(see below) tuple(const Types&...);

Constraints: sizeof...(Types) ≥ 1 and is_copy_constructible_v<T_i> is true for all i.

Effects: Initializes each element with the value of the corresponding parameter.

Remarks: The expression inside explicit is equivalent to:

!conjunction_v<is_convertible<const Types&, Types>...>

template<class... UTypes> constexpr explicit(see below) tuple(UTypes&&... u);

Let disambiguating-constraint be:

(12.1) negation<is_same<remove_cvref_t<U_0>, tuple>> if sizeof...(Types) is 1;
(12.2) otherwise, bool_constant<!is_same_v<remove_cvref_t<U_0>, allocator_arg_t> || is_same_v<remove_cvref_t<T_0>, allocator_arg_t>> if sizeof...(Types) is 2 or 3;
(12.3) otherwise, true_type.

Constraints:

(13.1) sizeof...(Types) equals sizeof...(UTypes),
(13.2) sizeof...(Types) ≥ 1, and
(13.3) conjunction_v<disambiguating-constraint, is_constructible<Types, UTypes>...> is true.

Effects: Initializes the elements in the tuple with the corresponding value in std::forward<UTypes>(u).

Remarks: The expression inside explicit is equivalent to:

!conjunction_v<is_convertible<UTypes, Types>...>

This constructor is defined as deleted if

(reference_constructs_from_temporary_v<Types, UTypes&&> || ...)

is true.

tuple(const tuple& u) = default;

Mandates: is_copy_constructible_v<T_i> is true for all i.

Effects: Initializes each element of *this with the corresponding element of u.

tuple(tuple&& u) = default;

Constraints: is_move_constructible_v<T_i> is true for all i.

Effects: For all i, initializes the i-th element of *this with std::forward<T_i>(get<i>(u)).

Let I be the pack 0, 1, ..., (sizeof...(Types) - 1).
Let FWD(u) be static_cast<decltype(u)>(u).

template<class... UTypes> constexpr explicit(see below) tuple(tupletuple<UTypes...>& u);
template<class... UTypes> constexpr explicit(see below) tuple(tupletuple<UTypes...>&& u);
template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>&& u);
template<class... UTypes> constexpr explicit(see below) tuple(const tuple<UTypes...>& u);

Let I be the pack 0, 1, ..., (sizeof...(Types) - 1).
Let FWD(u) be static_cast<decltype(u)>(u).

Constraints:

(21.1) sizeof...(Types) equals sizeof...(UTypes), and
(21.2) (is_constructible_v<Types, decltype(get<I>(FWD(u)))> && ...) is true, and
— either `sizeof...(Types)` is not 1, or (when `Types...` expands to `T` and `UTypes...` expands to `U`) `is_convertible_v<decltype(u), T>`, `is_constructible_v<T, decltype(u)>`, and `is_same_v<T, U>` are all false.

**Effects:** For all `i`, initializes the `i`th element of `*this` with `get<i>(FWD(u))`.

**Remarks:** The expression inside `explicit` is equivalent to:

```cpp
!(is_convertible_v<decltype(get<0>(FWD(u))), T0> || ...) ||
!(is_convertible_v<decltype(get<1>(FWD(u))), T1> || ...)
```

The constructor is defined as deleted if

```cpp
(reference_constructs_from_temporary_v<Types, decltype(get<0>(FWD(u))))> || ...
```

is true.

```cpp
template<class U1, class U2> constexpr explicit(see below) tuple(pair<U1, U2>& u);
template<class U1, class U2> constexpr explicit(see below) tuple(const pair<U1, U2>& u);
```

Let `FWD(u)` be `static_cast<decltype(u)>(u)`.

**Constraints:**

- `sizeof...(Types)` is 2,
- `is_convertible_v<decltype(get<0>(FWD(u))), T0>` is true, and
- `is_convertible_v<decltype(get<1>(FWD(u))), T1>` is true.

**Effects:** Initializes the first element with `get<0>(FWD(u))` and the second element with `get<1>(FWD(u))`.

**Remarks:** The expression inside `explicit` is equivalent to:

```cpp
!(is_convertible_v<decltype(get<0>(FWD(u))), T0> || !is_convertible_v<decltype(get<1>(FWD(u))), T1>)
```

The constructor is defined as deleted if

```cpp
reference_constructs_from_temporary_v<Types, decltype(get<0>(FWD(u))))> || reference_constructs_from_temporary_v<Types, decltype(get<1>(FWD(u))))>
```

is true.

```cpp
template<tuple-like UTuple>
constexpr explicit(see below) tuple(UTuple&& u);
```

Let `I` be the pack `0, 1, ..., (sizeof...(Types) - 1)`.

**Constraints:**

- `different_from<UTuple, tuple>(26.5.2) is true,`
- `remove_cvref_t<UTuple>` is not a specialization of `ranges::subrange`,
- `sizeof...(Types)` equals `tuple_size_v<remove_cvref_t<UTuple>>`,
- `(is_constructible_v<decltype(get<I>(std::forward<UTuple>(u))))> && ...)` is true, and
- either `sizeof...(Types)` is not 1, or (when `Types...` expands to `T`) `is_convertible_v<UTuple, T>` and `is_constructible_v<T, U>` are both false.

**Effects:** For all `i`, initializes the `i`th element of `*this` with `get<i>(std::forward<UTuple>(u))`.

**Remarks:** The expression inside `explicit` is equivalent to:

```cpp
!(is_convertible_v<decltype(get<I>(std::forward<UTuple>(u)))), Types> && ...)
```
template<class Alloc, class... UTypes>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc a, UTypes&&...);

template<class Alloc>
constexpr tuple(allocator_arg_t, const Alloc a, const tuple&);

template<class Alloc>
constexpr tuple(allocator_arg_t, const Alloc a, const tuple&&);

template<class Alloc, class... UTypes>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc a, tuple<UTypes...>&);

template<class Alloc, class... UTypes>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc a, const tuple<UTypes...>&);

template<class Alloc, class... UTypes>
constexpr explicit(see below)
    tuple(allocator_arg_t, const Alloc a, tuple<UTypes...>&&);

32 Preconditions: Alloc meets the Cpp17Allocator requirements (16.4.4.6.1).
33 Effects: Equivalent to the preceding constructors except that each element is constructed with uses-
allocator construction (20.2.8.2).

22.4.4.2 Assignment [tuple.assign]
For each tuple assignment operator, an exception is thrown only if the assignment of one of the types in Types
throws an exception. In the function descriptions that follow, let i be in the range [0, sizeof...(Types))
in order, T_i be the i-th type in Types, and U_i be the i-th type in a template parameter pack named UTypes,
where indexing is zero-based.

constexpr tuple& operator=(const tuple& u);
1 Effects: Assigns each element of u to the corresponding element of *this.
2 Returns: *this.
3 Remarks: This operator is defined as deleted unless is_copy_assignable_v<T_i> is true for all i.

constexpr tuple& operator=(tuple&& u) noexcept(see below);
4 Constraints: is_move_assignable_v<T_i> is true for all i.
5 Effects: For all i, assigns std::forward<T_i>(get<i>(u)) to get<i>(*this).
6 Returns: *this.

§ 22.4.4.2
Remarks: The exception specification is equivalent to the logical AND of the following expressions:

\[
is_{\text{nothrow-move-assignable-v}}<T_i>\]

where \(T_i\) is the \(i\)th type in \(\text{Types}\).

```cpp
constexpr const tuple& operator=(tuple&& u) const;
```

Constraints:

- \((\text{is_assignable-v<const Types&, Types> && ...})\) is true.

Effects: For all \(i\), assigns \(\text{std::forward}<T_i,>(\text{get}<i>(u))\) to \(\text{get}<i>(*\text{this})\).

Returns: \(*\text{this}\).

```cpp
template<class... UTypes> constexpr tuple& operator=(const tuple<UTypes...>& u);
```

Constraints:

- \(\text{sizeof...(Types)}\) equals \(\text{sizeof...(UTypes)}\) and
- \(\text{is_assignable-v<T_i&, const U_i&> is true for all } i\).

Effects: Assigns each element of \(u\) to the corresponding element of \(*\text{this}\).

Returns: \(*\text{this}\).

```cpp
template<class... UTypes> constexpr const tuple& operator=(const tuple<UTypes...>& u) const;
```

Constraints:

- \(\text{sizeof...(Types)}\) equals \(\text{sizeof...(UTypes)}\) and
- \((\text{is_assignable-v<const Types&, const UTypes&> && ...})\) is true.

Effects: Assigns each element of \(u\) to the corresponding element of \(*\text{this}\).

Returns: \(*\text{this}\).

```cpp
template<class... UTypes> constexpr tuple& operator=(tuple<UTypes...>&& u);
```

Constraints:

- \(\text{sizeof...(Types)}\) equals \(\text{sizeof...(UTypes)}\) and
- \(\text{is_assignable-v<T_i&, U_i> is true for all } i\).

Effects: For all \(i\), assigns \(\text{std::forward}<U_i,>(\text{get}<i>(u))\) to \(\text{get}<i>(*\text{this})\).

Returns: \(*\text{this}\).

```cpp
template<class... UTypes> constexpr const tuple& operator=(tuple<UTypes...>&& u) const;
```

Constraints:

- \(\text{sizeof...(Types)}\) equals \(\text{sizeof...(UTypes)}\) and
- \((\text{is_assignable-v<const Types&, UTypes> && ...})\) is true.

Effects: For all \(i\), assigns \(\text{std::forward}<U_i,>(\text{get}<i>(u))\) to \(\text{get}<i>(*\text{this})\).

Returns: \(*\text{this}\).

```cpp
template<class U1, class U2> constexpr tuple& operator=(const pair<U1, U2>& u);
```

Constraints:

- \(\text{sizeof...(Types)}\) is 2 and
- \(\text{is_assignable-v<T_0&, const U1&> is true, and}\)
- \(\text{is_assignable-v<T_1&, const U2&> is true.}\)

Effects: Assigns \(u\text{.first}\) to the first element of \(*\text{this}\) and \(u\text{.second}\) to the second element of \(*\text{this}\).

Returns: \(*\text{this}\).

```cpp
template<class U1, class U2> constexpr const tuple& operator=(const pair<U1, U2>& u) const;
```

Constraints:

- \(\text{sizeof...(Types)}\) is 2,
- \(\text{is_assignable-v<const T_0&, const U1&> is true, and}\)
is_assignable_v<const T_1&, const U_2&> is true.

**Effects:** Assigns u.first to the first element and u.second to the second element.

**Returns:** *this.

template<class U1, class U2> constexpr tuple& operator=(pair<U1, U2>&& u);

**Constraints:**
- sizeof...(Types) is 2 and
- is_assignable_v<const T_0&, U_1> is true, and
- is_assignable_v<const T_1&, U_2> is true.

**Effects:** Assigns std::forward<U_1>(u.first) to the first element and std::forward<U_2>(u.second) to the second element of *this.

**Returns:** *this.

template<class U1, class U2> constexpr const tuple& operator=(pair<U1, U2>&& u) const;

**Constraints:**
- sizeof...(Types) is 2,
- is_assignable_v<const T_0&, U_1> is true, and
- is_assignable_v<const T_1&, U_2> is true.

**Effects:** Assigns std::forward<U_1>(u.first) to the first element and std::forward<U_2>(u.second) to the second element.

**Returns:** *this.

template<tuple-like UTuple>
constexpr tuple& operator=(UTuple&& u);

**Constraints:**
- different-from<UTuple, tuple> (26.5.2) is true,
- remove_cvref_t<UTuple> is not a specialization of ranges::subrange,
- sizeof...(Types) equals tuple_size_v<remove_cvref_t<UTuple>>, and,
- is_assignable_v<T_i&, decltype(get<i>(std::forward<UTuple>(u)))> is true for all i.

**Effects:** For all i, assigns get<i>(std::forward<UTuple>(u)) to get<i>(*this).

**Returns:** *this.

template<tuple-like UTuple>
constexpr const tuple& operator=(UTuple&& u) const;

**Constraints:**
- different-from<UTuple, tuple> (26.5.2) is true,
- remove_cvref_t<UTuple> is not a specialization of ranges::subrange,
- sizeof...(Types) equals tuple_size_v<remove_cvref_t<UTuple>>, and,
- is_assignable_v<const T_i&, decltype(get<i>(std::forward<UTuple>(u)))> is true for all i.

**Effects:** For all i, assigns get<i>(std::forward<UTuple>(u)) to get<i>(*this).

**Returns:** *this.

### 22.4.4.3 swap

```cpp
constexpr void swap(tuple& rhs) noexcept(see below);
constexpr void swap(const tuple& rhs) const noexcept(see below);
```

**Mandates:**

1. Let i be in the range [0, sizeof...(Types)) in order.

2. For the first overload, (is_swappable_v<Types> && ...) is true.
22.4.5 Tuple creation functions

template<class... TTypes>
constexpr tuple<unwrap_ref_decay_t<TTypes>...> make_tuple(TTypes&&... t);

Returns: tuple<unwrap_ref_decay_t<TTypes>...>(std::forward<TTypes>(t)...).

[Example 1:]
int i; float j;
make_tuple(1, ref(i), cref(j));
creates a tuple of type tuple<int, int&, const float&>. —end example]

template<class... TTypes>
constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&... t) noexcept;

Effects: Constructs a tuple of references to the arguments in t suitable for forwarding as arguments to
a function. Because the result may contain references to temporary objects, a program shall ensure
that the return value of this function does not outlive any of its arguments (e.g., the program should
typically not store the result in a named variable).

Returns: tuple<TTypes&&...>(std::forward<TTypes>(t)...).

template<class... TTypes>
constexpr tuple<TTypes&...> tie(TTypes&... t) noexcept;

Returns: tuple<TTypes&...>(t...). When an argument in t is ignore, assigning any value to the
corresponding tuple element has no effect.
